Lampadem tradere

mipro - path to knowledge and innovation

mipro proceedings

My profession.
My organization.
My IEEE.

Discover the benefits of IEEE membership.

Join a community of more than 365,000 innovators in over 150 countries. IEEE is the world's largest technical society, providing members with access to the latest technical information and research, global networking and career opportunities, and exclusive discounts on education and insurance products.

MIPRO 2014

37th International Convention

May 26 - 30, 2014
Opatija, Croatia

Proceedings

Conferences:

Microelectronics, Electronics and Electronic Technology /MEET

Distributed Computing, Visualization and Biomedical Engineering /DC VIS

Telecommunications & Information /CTI

Computers in Education /CE

Computers in Technical Systems /CTS

Intelligent Systems /CIS

Information Systems Security /ISS

Business Intelligence Systems /miproBIS

Digital Economy and Government, Local Government, Public Services / DE-GLGPS

MIPRO Junior - Student Papers /SP

Edited by:
Petar Biljanović

CONTENTS

LIST OF PAPER REVIEWERS

AUTHOR INDEX

FOREWORD

MICROELECTRONICS, ELECTRONICS AND ELECTRONIC TECHNOLOGY

INVITED PAPER 3

Nanotechnology, from the Recent History to (un) Predictable Future 5
J. Turković

PAPERS 11

Spectroscopic Evidence of Coexistence of Clusters Based on Low (α) and High Temperature (β) GeS_2 Crystalline Phases in Glassy Germanium Disulfide Matrix 13
V. Mitsa, R. Holomb, G. Lovas, M. Veres , M. Ivanda, T. Kovach

Synthesis and Characterization of Silver Colloidal Nanoparticles and Their Application in Surface Enhanced Raman Spectroscopy 17
L. Mikac, M. Ivanda, M. Gotić, T. Mihelj

Raman Spectroscopy of Tellurite Glasses 21
H. Gebavi, D. Ristić, V. Đerek, L. Mikec, M. Ivanda, D. Milanese

Coated Spherical Microresonators for Cutting-Edge Photonics Application 24
D. Ristić, M. Mazzola, A. Chiappini, C. Armellini, A. Rasoloniaina, P. Féron, R. Ramponi, G.N. Conti, S. Pelli, G.C. Righini, G. Cibiel, M. Ivanda, M. Ferrari

Examination of Silicon Material Properties Using THz Time-Domain Spectroscopy 28
B. Pejčinović

Impact of Microstrip Width and Annealing Time on the Characteristics of Micro-Scale Graphene FETs 33
M. Poljak , M. Wang, S. Žonja, V. Đerek, M. Ivanda, K.L. Wang, T. Suligoj

Graphene Base Transistors with Optimized Emitter and Dielectrics 39
S. Venica, F. Driussi, P. Palestri, L. Selmi

Phonon-Limited Hole Mobility in Sub-20 nm-Thick Double-Gate Germanium MOSFETs 45
V. Ivanić, M. Poljak, T. Suligoj

Comparison of RF Performance between 20 nm-Gate Bulk and SOI FinFET 51
S. Krivec, H. Prgić, M. Poljak, T. Suligoj

Simulation Study of Aging in CMOS Binary Adders 57
T. An, C. Hao, L. Alves de Barros Naviner

Analytical Method for Reliability Assessment of Concurrent Checking Circuits Under Multiple Faults 62
T. An, K. Liu, L. Alves de Barros Naviner

Synthesis of CMOS Multiplier Structures Using Multifunctional Circuits 66
C. Popa

Improved Accuracy Current-Mode Analog Function Synthesizer 70
C. Popa

Analysis and Optimization of a SAR ADC with Attenuation Capacitor 74
S. Brenna, A. Bonfanti, A. Abba, F. Caponio, A.L. Lacaita

A Simulation and Modeling Environment for the Analysis and Design of Charge Redistribution DACs Used in SAR ADCs 80
S. Brenna, A. Bonetti, A. Bonfanti, A.L. Lacaita

High-Speed Energy-Efficient 5:2 Compressor 86
A. Najafi, S. Timarchi, A. Najafi

An Electrochemical Sensor ASIC for Agriculture Applications 91
T.K. Yew, Y.Yusoff, L.K. Sieng, H.C. Lah, H. Majid, N. Shelida

Application of Charge Amplifiers with Polyvinylidene Fluoride Materials 97
A.S. Marinov, O.P. Stanchev, E.B. Bekov

Design of Transdermal Drug Delivery System with PZT Actuated Micropump 102
T. Dolžan, D. Vrtačnik, D. Resnik, U. Aljančič, M. Možek, B. Pečar, S. Amon

Modern Monitoring System for Water Pollution by Petrochemical Products Based on Optical Fibre Refractometer 106
J. Turán, Ľ. Ovseník

Broadband Characterization of SMA Connectors by Measurements 110
M. Magerl, T. Mandić, A. Barić

Application of TEM Cell in Measurement of Electromagnetic Fields of Electronic Modules 116
K. Ivanuš, A. Barić

Model of Low-Noise, Small-Current-Measurement System Using MATLAB/Simulink Tools 121
D. Nagradić, K. Pardon, D. Jurišić

Algorithm for Fast Determination of LiFePO4 Battery Nominal Current 127
I. Sirotić, V. Šunde, Ž. Ban

100 nA Power Management Circuit for Energy Harvesting Devices 131
D. Vinko, G. Horvat

Evaluation of the Operation of Depletion-Mode SiC Power JFET in DC-DC Converter Applications 136
J. Bačmaga, K. Bene, B. Pejčinović, A. Barić

Photocopier PID Controller with Iterative Error Compensation 142
K. Fukuda, V. Čeperić, A. Barić

Introduction of Some Design Aspects for Improved Performance of the DC/AC Induction Motor Converter 147
J. Podržaj, G. Babić, M. Podhraski, J. Trontelj

Microcontroller Implementation of Dynamically Adaptable Control of Stepper Motor with Continuous Second Derivative of Speed Curve 152
J. Divić, J. Đurić, K. Vrančić

Optimized Coupled Band-Pass Filters 156
N. Mijat, D. Jurišić

Development and Testing of Complex PLL Algorithm Using Hardware in the Loop System 162
T. Čihak, M. Puškarić, Ž. Jakopović

Software Simulation of LDPC Codes and Performance Analysis 168
C. Sandu, I. Florescu, C. Rotaru

Smart Home Automation System for Energy Efficient Housing 172
N. Skeledžija, J. Ćesić, E. Kočo, V. Bachler, H.N. Vučemilo, H. Džapo

Remote Laboratory for Testing Processor Cores in FPGA Device 178
K. Saksida, A. Trošt

Towards an Energy Efficient SoC Computing Cluster 184
Z. Krpić, G. Horvat, D. Žagar, G. Martinović

Electronic Interpretation of Selected Lessons in Fuzzy Mathematics 189
L. Perković, D. Kovačević, T. Karađole, M. Jović

Fuzzy Gates Interchangeability 195
D. Kovačević, T. Karađole, J. Vrsalović

Solving Mathematic Problems in Electronic Environment, Finding Global and Local Minimum and Maximum Function Values 201
I. Madunić, D. Kovačević, L. Perković, T. Karađole

DISTRIBUTED COMPUTING, VISUALIZATION AND BIOMEDICAL ENGINEERING

PAPERS 209

BIOMEDICAL ENGINEERING

Twenty-Nine-Year Stimulation of the Common Peroneal Nerve in a Hemiplegic Patient 213
P. Pečlin, J. Krajnik, R. Aćimović-Janežič, U. Stanič, J. Rozman

A Method for Time-Domain Analysis of Respiratory Sinus Arrhythmia 217
R. Trobec, V. Avbelj

Review of Regularization Techniques in Electrocardiographic Imaging 221
M. Milanič, V. Jazbinšek, R. Hren

Single-Dipole and Dual-Dipole Inverse Solutions in Electrocardiography 227
V. Jazbinšek, R. Hren

Automatic Knot Fastener Cor-Knot and United States Pharmacopeial Convention Class I Knot Pull-Apart Force Safety Regulations 233
B. Geršak, J. Sauer

Control and Optimization of Complex Biological Systems 235
D. Tomić, B. Pernarić

Classification of Benign and Malignant Massesin Breast Mammograms 241
A. Šerifović-Trbalić, A. Trbalić, D. Demirović, N. Prljača, P.C. Cattin

CHO Cell Viability in CO_2 Saturated Media 247
A. Štefanič, J. Jelenc, A. Osterman, M. Dular, D. Miklavčič, A. Maček Lebar

Automatic Cell Counter for Cell Viability Estimation 252
J. Lojk, L. Šajn, U. Čibej, M. Pavlin

Morphological Changes of Pressure Pulses in Oscillometric Non-Invasive Blood Pressure Measurements 258
V. Avbelj

Personalized Guiding Templates for Pedicle Screw Placement 262
U. Tominc, M. Vesel, S. Al Mawed, M. Dobravec, M. Jug, S. Herman, D. Kreuh

iHELP Emergency Care Network 265
A. Ogorevc, B. Lončarevič

Graph-Based Diagnosis and Treatment of Neuronal Communication Disorders 269
M. Veletić

Use of 3D Preoperative Planning Program in Understanding of Articular Fracture Treatment **275**
M. Tomaževič, A. Fischinger, A. Kristan, D. Kreuh, M. Cimerman

Education of Cosmetic Device Users in Slovenia **279**
Š.E. Soklič, J. Jelenc

Telehealth Using ECG Sensor and Accelerometer **283**
H. Gjoreski, A. Rashkovska, S. Kozina, M. Luštrek, M. Gams

Children Obesity Treatment Support with Telemedicine **288**
M. Kozlovszky, K. Karóczkai, B. Jókai, B. Ruda, D. Kacsuk, Z. Meixner

Analysis of sEMG Signals Associated with Isometric Contraction of Triceps Brachii Muscles Using Multifractals **292**
K. Marri, R. Swaminathan

DISTRIBUTED COMPUTING

Improving Data-Parallel Construction of δ_N-Nets with Maximum Dispersion **299**
P. Zinterhof

High Productivity Data Processing Analytics Methods with Applications **304**
M. Riedel, A.S. Memon, M.S. Memon

Optimal Block Size for Matrix Multiplication Using Blocking **310**
S. Ristov, M. Gusev, G. Velkoski

Extensible Framework for Execution of Distributed Genetic Algorithms on Grid Clusters **316**
D. Georgiev, E. Atanassov

The Performance Impact Analysis of Loop Unrolling **322**
G. Velkoski, M. Gusev, S. Ristov

Developing a Ticket Management SaaS Solution **328**
M. Gusev, S. Ristov, P. Gushev

Alert Notification as a Service **334**
M. Gusev, S. Ristov, G. Velkoski, P. Gushev

Crowd Computing to Support EGI Scientists **340**
J. Kovács, R. Lovas

Obtaining Massive Data Sets for Contextual Experiments in Quantum Information . **347**
M. Pavičić

Parallel Implicit Time Integration for Particle-Based Models on Graphics Clusters ... **351**
A. Sabou, D. Gorgan

Frequency Table Computation on Dataflow Architecture **357**
P. Škoda, V. Sruk, B. Medved Rogina

Virtue - a Different Approach to Human/Computer Interaction **362**
Z. Šojat, T. Ćosić, K. Skala

Dynamic Workflow Support in gUSE **369**
E. Kail, A. Bánáti, K. Karóczkai, P. Kacsuk, M. Kozlovszky

Formal Checking of WS-BPEL Orchestrations **375**
J. Matković, K. Fertalj

Hybrid MPI-OpenMP Parallel Optimization for Thermo-Fluid Problems **382**
M. Depolli

Delivering Bioinformatics MapReduce Applications in the Cloud **388**
L. Forer, T. Lipić, S. Schönherr, H. Weißensteiner, D. Davidović, F. Kronenberg, E. Afgan

Microspheres as Sensors to Measure Instant Refractive Index Variation During Phase Transition of Low Melting Substances **393**
H.-B. Fu, Y.-X. Huang

Multilingual Cloudlet-Based Dictionary **395**
A. Bahtovski, M. Gusev

Mjolnirr: Private PaaS as Distributed Computing Evolution **401**
D. Savchenko, G. Radchenko

VISUALIZATION

Visualization Support for Code Development in EUROfusion Integrated Modelling .. **409**
L. Kos

Fast Motion Estimation Algorithm Using Dual Bit-Plane Matching Criteria **415**
C. Choi, J. Jeong

Edge Detection in Segmented Non-Convex Space Polygon **419**
I. Kožar, D. Lozzi-Kožar, Ž. Jeričević

Visualization of Meteorological Data **423**
I. Hakštok, Ž. Mihajlović

3D Volume Localization Using Miniatures **428**
L. Šajn, M. Radojević , T. Dobravec

Evaluation of Image Processing Algorithms on ARM Powered Mobile Devices **434**
D. Demirović, A. Šerifović-Trbalić, N. Prljača, P.C. Cattin

Natural Eye Gaze Computer Interaction for Medical Oculography Diagnosis: Current Status and Future Prospects **438**
I. Grubišić, I. Grbeša, T. Lipić, K. Skala, O. Zrinšćak, R. Iveković, Z. Vatavuk

TELECOMMUNICATIONS AND INFORMATION

INVITED PAPER **445**

Green ICT for Sustainability: A Holistic Approach **447**
S. Aleksic

PAPERS **453**

TELECOM MARKET REGULATIONS

4G Mobile Internet, Services, Regulation and Mobile Operators in Bosnia and Herzegovina **457**
D. Šerval, Č. Marković, S. Kovačević

Creating Regulatory Environment for Cloud Services **461**
S. Hadžović, R. Šeremet

Emergency Communication in IMS Network: Challenges in Implementation **465**
I. Krevatin, I. Visković

Međupovezivanje i regulacija u telekomunikacijama s osvrtom na međupovezivanje i regulaciju u telekomunikacijama Bosne i Hercegovine **469**
J. Gabela, F. Gabela, A. Gabela

BUSINESS MODELLING

Connecting Clouds **477**
I. Vrbovčan, T. Pavić, M. Šoša Anić

Competence Transfer through Enterprise Mobile Application Development **481**
S. Vojvodić, M. Zović, V. Režić, H. Maračić, M. Kušek

An Empirical Study of Factors Affecting the Adoption of Self-Service Checkout Terminals in Slovenia **486**
B. Šumak, M. Pušnik, M. Heričko

Cash Register Lines Optimization System Using RFID Technology **492**
D. Budić, Ž. Martinović, D. Šimunić

Pozicija BH Telecoma d.d. Sarajevo prema Adižesovoj teoriji životnih ciklusa preduzeća 496
A. Gabela, L. Pamuk, J. Gabela

Unaprjeđenje upravljanja resursima uz pomoć sustava za podršku 500
D. Markulin, K. Musa

Predprodajna reklamna aplikacija telekomunikacijskih usluga..... 504
J. Mulabegović, H. Šabanović, A. Arslanagić

INTERNET & WEB APPLICATIONS

Multi-User Web Application for Content Management on Multi-Touch Devices..... 513
M. Cvijanović, P. Kirin, D. Pleša, J. Soko, S. Stamenov, A. Cikojević, S. Kelemen, A. Karin

Front End Optimization Methods and Their Effect 517
I. Iliev, G. Petrov Dimitrov

Comparative Analysis of Google and Bing SEO on leading Croatian News portals 526
I. Britvić, J. Đurić, D. Bužić

CHALLENGING ICTs

State of the Art in IPTV..... 531
B. Veselinovska, M. Gusev, T. Janevski

Kinect-based Presenter Tracking Prototype for Videoconferencing 537
D. Gadanac, M. Dujak, D. Tomić , D. Jerčić

Iterative Receiver for Qc-LDPC Coded Underwater Acoustic Communication Systems 543
L. Zhao

Software Platform for Wireless Indoor Localization Planning Based on the Strength of Received Radio Signal 547
I. Vitas, B. Lukovac, D. Šimunić

Management in M2M Networks 553
V. Čačković, Ž. Popović

Next-Generation Utilities Based on M2M Communications..... 559
M. Dujak, Z. Kljaić, M. Šerbec, H. Jelačić

Applications Methods of the Objects, and Suitability for Universal Applications in Computer Graphics Context 566
N. Zeqiri

On-line Rapid Diagnostics of the Human Immune Status 571
T.A. Hryhorova, L.V. Vorobiov

INFORMATION SYSTEMS

Information System Infrastructure Planning - Threshold Setting Based on Risk Analysis 579
I. Golub, B. Radojević

Interactive Application in Service of Popularizing Architectural Heritage 584
M. Jozić, T. Oštarčević, M. Šalković, D. Šimunić

Adresiranje i usmjeravanje e-dokumenata u sustavu informacijskog posrednika za uslugu e-Računa 587
D. Matić, A. Čičak, B. Vrdoljak

Informacijske pretpostavke za izgradnju infrastrukture za širokopojasni pristup 593
D. Mesarić, M. Štimac, F. Ambroš

Upotreba naprednih informacijskih sustava u kontekstu ubrzanja izrade studija izvodljivosti za potrebe izgradnje širokopojasne infrastrukture u RH 599
D. Medved, S. Vojvodić, S. Drezgić

QUALITY MANAGEMENT

Real Time Assuring QoE in the Lowest OSI/ISO Layers During Delivering of IPTV Services 607
N. Goran, M. Hadžialić, A. Begović

Measuring XML Schema Standard Quality Change through Versioning 611
M. Pušnik, M. Heričko, B. Šumak

N-BEB: New Backoff Algorithm for IEEE 802.11 MAC Protocol 615
M. Shurman, B. Al-Shua'b, M. Alsaedeen, M.F. Al-Mistarihi, K. Darabkh

Multi-Objective Parameter Optimization of S-MAC Protocol 620
E. Kaljić, S. Konjicija

Primjena FMEA metode u upravljanju kvalitetom telekomunikacijskih usluga 626
N. Karahmetović

SOFTWARE ENGINEERING & TOOLS

Experiences from Building a EUD Business Portal 635
N. Tanković, T. Galinac Grbac, M. Žagar

Modeling of Software Failure Cost in ERP Systems 641
F. Urem, K. Fertalj, I. Livaja

Automatizirano projektiranje telekomunikacijske infrastrukture softverskim alatom baziranim na geografskom informacijskom sustavu (GIS) 646
T. Pavičić, D. Medved, S. Vojvodić, N. Severinac, V. Roland

Upotreba alata za mjerenja na radijskom sučelju u nastavi mobilnih komunikacija... 652
L. Novosel

NETWORKS & ENVIRONMENT

Reselection of Base Station in TETRA Network 659
S. Punčikar

Inventory Management System for Water Supply Network 664
O. Jukić, I. Heđi

Procjena vrijednosti parametra SAR u blizini GSM/UMTS baznih stanica..... 668
D.S. Šuka, P.S. Međedović, M.I. Simić

Utjecaj LTE tehnologije na razine elektromagnetskih polja u mobilnim mrežama Hrvatskog Telekoma 674
R. Gajić, K. Janaček

NETWORKS PERFORMANCE

Incremental-Relaying Cooperative-Networks Using Dual Transmit Diversity and Decode and Forward Relaying Scheme with Best Relay Selection..... 681
A.M. Hayajneh, M. Khodeir, M.F. Al-Mistarihi

Closed-form Expression for Outage Probability in Relay-Based Cooperative Diversity Systems over Nakagami Fading Channels with Interference 687
R. Mohaisen, M.F. Al-Mistarihi, A. Sharaqa

On Practical Solutions of AQM Queues with Large Buffers 692
P. Mrozowski, A. Chydzinski

COMPUTERS IN EDUCATION

INVITED PAPERS 701

Children as Co-Creators of Video Stories: Mobile Videos for Learning..... 703
J. Multisilta, H. Niemi

Children's Safety on the Internet-Development of the School Curriculum 708
L. Kralj

PAPERS **713**

Introducing E-CRM into Academic Libraries: Exploration of Needs and Possibilities **715**
A. Papić, M. Primorac

Virtual Machines in Education **721**
V. Mateljan, V. Juričić, M. Moguljak

Open^n **726**
H. Jaakkola, T. Mäkinen, J. Henno, J. Mäkelä

From Learning to E-learning to M-learning to C-learning to ... ? **734**
J. Henno, H. Jaakkola, J. Mäkelä

The Evocation of Creativity and Critical Thinking: Analysis of Information Competencies and Behaviour Among Students of Electrical Engineering and Computing **741**
D. Vrkić, M. Pavlovski

Application of Modern Teaching Techniques in the Educational Process **746**
M. Filipović Tretinjak, A. Bednjanec, M. Tretinjak

Open Access Initiative and Its Impact on Use of Digital Information Resources for Research and Teaching in Higher Education Institutions in Croatia **751**
R. Vrana

The Organization of Classes and Assessment System Using Moodle **757**
T. Alajbeg, T. Horvat, T. Novak

Perceived Quality of Verificator in Teaching Programming **761**
T. Orehovački, D. Radošević, M. Konecki

E-learning Materials to Study Properties of Liquid Crystals at University Level and in Schools **767**
R. Repnik, A. Šabeder, M. Krašna

Distance Learning: Challenges, New Solution **771**
P. Panahi, F. Borna

Online vs. Paper-Based Testing: A Comparison of Test Results **775**
S. Čandrlić, M. Ašenbrener Katić, M. Holenko Dlab

Comparing Classification Models in the Final Exam Performance Prediction **781**
J. Gamulin, O. Gamulin, D. Kermek

The Role of Management in Career Development **787**
M. Lamza-Maronić, J. Glavaš, I. Uroda

E-learning Next Step – Learning Materials for Students **792**
M. Krašna, M. Duh, T. Bratina

Configurable Image-Processing System for Education in Automotive Applications 800
C. Madritsch, T. Klinger

Using Hybrid Mobile Applications for Adaptive Multimedia Content Delivery 804
A. Karadimce, D. Capeska Bogatinoska

A Model of Adaptive Learning with Interactive Images - ADELE 810
M. Gusev, S. Ristov, P. Gushev, G. Velkoski

User Satisfaction Evaluation of the Electronic Student Services System – iKnow 816
A. Guseva, M. Gusev, S. Ristov

Sign Language Tutor - Rebuilding and Optimizing 822
N. Ackovska, M. Kostoska

Interoperability Challenges Among University Electronic Services Systems 828
M. Kostoska, M. Gusev, S. Ristov

Cloud Based Laboratory for Distance Education 834
S. Ristov, M. Gusev, A. Donevski

Mediated Heritage Learning in Formal and Informal Contexts: Antiquity CyberEd.. 840
G. Zlodi, Ž. Miklošević

Development of an Online Multimedia Course 845
M. Trošelj, M. Matetić, M. Tkalčić, M. Brkić, P. Pahljina

Are they a Perfect Match?
Analysis of Usage of Author Suggested Keywords, IEEE Terms and Social Tags 850
D. Vrkić

Lab Assessments in Undergraduate Course in Compilers for Students with No Prior Knowledge in Assembly 856
V. Kirandziska, M. Jovanov, M. Mihova, M. Gusev

Analysis of Elective Courses Selection in Post - Bologna Programmes 862
I. Rožanc, B. Slivnik

Data Mining of Computer Game Assisted e/m-learning Systems in Higher Education..868
P. Jurić, M. Matetić, M. Brkić

E-education 2.0: Students' Digital Identity and Online Learning Activities..... 874
S. Babić, M. Krešić, K. Kućel

Usefulness of Prezi and PowerPoint Presentation..... 880
A. Špernjak

An On-line Solution Verification System for Programming Competitions..... 883
A.S. Dorofeev

Implementation of Information Competencies as Key Employment Skills at the Faculty of Humanities and Social Sciences **886**
S. Špiranec, T. Ivanjko, Đ. Pečarić

Learning Management Systems: Trends and Alternatives **891**
L. Abazi-Bexheti, M. Apostolova-Trpkovska, A. Kadriu

Information Competences - Students' Perspective **896**
K. Pavlina, S. Špiranec, A. Pongrac Pavlina

Development and Analyses of "ProSysEngine" M-Learning Course Management System **900**
J. Saveski, M. Fetaji, B. Fetaji, M. Ebibi, L. Abazi

Investigation of Natural User Interfaces and Their Application in Gesture-Driven Human-Computer Interaction **906**
A. Petrovski, B. Fetaji, M. Fetaji, M. Ebibi

ICT Supported Laboratory Testing of Installation Circuit Breaker **913**

FOREWORD

The *37th International ICT Convention MIPRO 2014* was held from 26th until 30th of May 2014 in Opatija, the Adriatic Coast, Croatia. The Convention consisted of nine conferences under the titles: *Microelectronics, Electronics and Electronic Technology (MEET), Distributed Computing, Visualization and Biomedical Engineering (DC VIS), Telecommunications & Information (CTI), Computers in Education (CE), Computers in Technical Systems (CTS), Intelligent Systems (CIS), Information Systems Security (ISS), Business Intelligence Systems (miproBIS), Digital Economy and Government, Local Government, Public Services (DE/GLGPS)*. A special conference was dedicated to works of the students: *MIPRO Junior-Student Papers (SP)*.

The papers presented on these conferences are contained in this comprehensive Book of Proceedings. All the papers were reviewed by an international review board. The list of reviewers is contained in the Book of Proceedings. All the positively reviewed papers are included in the Book of Proceedings. These papers were written by authors from the industry, scientific institutions, educational institutions, state and local administration.

The convention was organized by the Croatian ICT Society MIPRO with the help of numerous patrons and sponsors to whom we owe our sincere thanks. We specially single out our gold sponsors Ericsson Nikola Tesla, T-Croatian Telecom and Končar-Electrical Industries and the silver sponsor InfoDom. Our bronze sponsors are HEP–Croatian Electricity Company, VIPNet, Transmitters and Communications Company and Storm Computers.

To all who helped organize the 37th International ICT Convention *MIPRO 2014* as well as editing of this Book of Proceedings we extend our heartfelt thanks.

Prof. Petar Biljanović, PhD
International Program Committee
General Chair

MEET

International Conference on

MICROELECTRONICS, ELECTRONICS AND ELECTRONIC TECHNOLOGY

Steering Committee

Chairs: Željko Butković, University of Zagreb, Croatia
Petar Biljanović, University of Zagreb, Croatia

Members: Slavko Amon, University of Ljubljana, Slovenia
Dubravko Babić, University of Zagreb, Croatia
Maurizio Ferrari, CNR-IFN, Povo-Trento, Italy
Mile Ivanda, Ruđer Bošković Institute, Zagreb, Croatia
Branimir Pejčinović, Portland State University, USA
Aleksandar Szabo, IEEE Croatia Section
Baldomir Zajc, University of Ljubljana, Slovenia

INVITED PAPER

Nanotechnology, from the recent history to (un)predictable future

Josip Turković B.Sc.Physics
CEI Mikroelektronika d.o.o. , Zagreb, Croatia
josip.turkovic@hi.t-com.hr

Abstract - The diversity of nano-themes (nano science, nanoelectronics, nano materials, and other nano-something), did not result in sharper focus on the substantial processes behind the all of it. The author suggests that nanotechnology originated from the methods of microelectronics from the late1980's: ever growing complexity of mixed CMOS and bipolar planar silicon technology, and concept of MEMS devices as a way of integrating functions (and thinking) from former mutually exclusive area of electronics, machine engineering, biology, chemistry etc. The fully developed diagnostic methods enabled deep and accurate insights into the structure of material, and the methods of producing thin layered structures produce new complex entities with exotic physical and/or chemical properties. What is the impact of nanotechnology on the world outside the usual scientific community, from something like small business to corporative imperial giants? The author presents two examples of nano structured products: substrates for TEM and new type of MOS cell based on graphene and silicon as very appropriate cases for the business environment. Nanotechnology without any doubt can give complex structures with enlarged computing and processing power in very near future. But, what is it all about? Do we really need a smart toilet bowl, wich processes Tbyte information to make our stay in such a place more meaningful? In other words, do we need such an intense development just to produce new gadgets? From commercial point of view, the answer is a big YES. From the point of view of global human society progress, the answer is no. The rest of the paper presents the concept of the anisotropic boundaries as a product of already reached state of the nanotechnology, what boundaries can change the global civilizational paradigm, turning the meaning of the nano-something from the gadgetry to a new chapter in the evolution of human society.

I. Introduction

Most of the people involved in the microelectronic litography process, either in laboratory or production facility, know what the descumming of photoresist is. In autumn 1979, a group of technologists from RIZ Semiconductor Factory published a paper at a Munich conference about the method of preparation of the photoresist to get increased quality of edge definition in planar silicon technology, naming it descumming. The members of this group were Branka Šmalcelj, Antonia Delač, Rudi Ročak and myself. It has been one month after I joined the RIZ Semiconductor Factory.

In 1983, one of my colleagues Radja Jakiša and me solved the problem of eutectic bonding of silicon chips on nickel plated headers for high reliability hermetic components. The technology passed on out to western companies through a well known Dutch corporation, and to eastern counterparts through a Polish company. Mr Radja Jakiša is today a leader of litography team in Texas Instrument, Huston.

It was really an honor to join the people who produced a second ever made chip in Europe. That chip was produced in 1968 using improvised laboratory equipment at the RIZ Institute, and as a kind of particularity, that chip was in a triangular form.

Moreover, I have to mention a chip design group originated from RIZ Semiconductor Factory and leaded by Srebrenka Ursić and Damir Vuk which are still designing very sophisticated IC's, at the real edge of the modern microelectronic technology.

Because of the limitation of time and number of pages of this paper, it is impossible to mention all of the people we had been in contact with, from all over the world, and who participated in the crucial development of microelectronic technology during the 1980, and I apologize to them. They will probably be a part of some other story-telling circumstances.

II. Big bang in nanotech, mystery or what?

In the close communication with the people deeply involved in the development of nano-science in the last 15 years, nobody between them has noticed anything spectacular about the fact that new knowledge is produced in an accelerated rate. The effect can be seen clearly when comparing today's processes with the situation after the conceptual definition of Quantum Mechanics (QM). The prediction possibility of QM did not result in the development of the specific proper

technology. The nuclear reactor and bomb, usually considered the most important achievement of QM, in fact, were not realized with essentially new technology, but by the conventional methods of chemistry, physics, machine engineering, etc. In the last 10 years the first pure QM effect of photon entanglement, gave hope of serious QM-based technology in the field of quantum computing. The time interval of virtual "latency" of QM was about 90 years.

On the other hand, the experimental data from nanoscience were not predicted by QM , but all of them were explained by the QM. A good example of the excellent knowledge, and at the same time the impotence in the sense of technology breakthroughs, and engineering power.

Where does differences between QM and nanoscience come from? The answer is a very simple one. The development of microelectronics in the 1980, left as a legacy a few things:

1. highly developed diagnostic tools, not improvised and specific to a given laboratory, but standardized in scientific and high tech community.
2. standardized methods to manipulate micro objects in reproducible way, so you can get what you want by design.
3. MEMS (Micro electromechanical systems) as a concept of the intermixing functions of the systems based on electronics, biology, physics, machine engineering, etc. on the same chip.

The first two items represent the real tools, and the last item represent the change in the way of thinking.

Till the expansion of MEMS components, one of the dogma accepted in microelectronics was that on the silicon chip you can have electrical components and nothing but electrical. After breaking up any dogma someone expects a kind of progress. And that is just what happened in nano area: an almost explosive growth of knowledge, technology and engineering.

Such a sudden growth is not something the responsible researchers usually dream of. The clear example are protective coatings filled with various types of nanoparticles. Due to the excellent properties of self cleaning and resistivity to weathering, such coatings are pushed in mass production and commercial use, without full understanding of the mechanisms behind it and their environmental impact. The pressure to push new concepts from science to final products was sometimes illicitly high.

III. Nanotech in small and corporate business

The scientific community is a little bit confused by t very fast development of nanotechnology. What to say about the politicians, who are definitely incompetent to understand the subject, and its impact on the social and financial state of the given environment. There are all together 5 essentially distinct business environments: USA, Europe, Russia, China and Japan. As the length of this paper is limited, we will discuss only two of them.

A. USA - small and medium enterprises (SMEs)

In the USA, SMEs are virtually free to make trials in high tech domain, and by some subtle regulations, they are even pushed into the direction of new advanced technologies. If you obey some simple regulations, there are no restrictions on purchasing raw materials. It is expected, and the reality confirms it, that after proof of concept, more or less successful start up and recognized market for the future product, the small company has to be sold to the (probably serious) investor, like some corporations or specialized state agencies. In the last 5 years when I met some young people who just started as operators in small business in the USA, all of them declared that their ultimate business goal is to sell company to somebody who has real money. None of them wanted to make extra effort to make their companies grow and mature in the direction of the increased volume of money, goods, employees and organization. The maturing of the small companies is rather complicated process in USA.

B. Europe - SMEs

Except in the case of some special circumstances, small business in Europe is in the domain of high tech practically impossible. To start up company you need special licensees, and the process of evaluation lasts from 3 to 5 years. And if you get all papers needed (and it includes the data like what your great-grandma ate for breakfast), you are faced with the problem of purchasing the equipment and raw materials.

You can start the company in a normal way if you have a supervisor like a well known science institute or some special state agencies. That increases the overall costs, but who cares? Free lancers in high tech small business are not allowed in Europe. In spite of that, there are a lot of subjects in small and medium high tech business in Europe, but they were all created by original European corporations which are part of the global European establishment. Therefore if you want to make some serious small business in high tech in Europe, think either about founding a secret (I mean really secret) society, or make a deal with some of the corporations, which is the simplest solution.

C. USA - corporate business

Corporations in the USA have all the attributes of imperial system. They have their own long range development plan, market share contracts and well defined area of influence. Their power is based on whichever high technologies they own today, and the one they will own in the near future, accompanied by all necessary human resources. Corporate task force

teams are in some cases at the level of police forces of some small countries, with the goal of assuring the domination of the corporation in the forseeable future. But what is the most important, these corporations are not a part of the establishment. Nevertheless, these corporations are under the tight control of the state in every sense.

D. Europe - corporate business

Corporations in Europe have attributes of feudal system with lords behind the stage. Their power is based primarily on political power, and high techs are of secondary character. All corporations are a part of the European establishment, and are rarely leaders in the field of global R&D. In the last 10 years German corporations started to copy US model, which was not welcomed in the rest of (old) Europe, and will probably become a seed of the future tensions between European feudal lords. The newcomers in Europe are without any importance regarding existing corporate structures, which has to be expected as obvious: otherwise, they will never become newcomers.

E. Example 1: very simple product from nanotech domain

Figure 1 shows the SEM photo of the silicon nitride membarane with etched holes in it. Thikness of the membrane and diameter of the holes are both 10^{-7}m. Such peices of membrane are produced on 0.2 m diameter silicon wafer. Each piece is of square shape $3 \cdot 10^{-3}$m by $3 \cdot 10^{-3}$m, mounted on ceramic frame 10^{-3}m thick. Such small membranes are carriers for the samples for transmission electron microscopy (TEM). But such carriers can be used for the few more purposes like:

- Cell biology: attached cells can be grown in their environment on the support film and subsequently analyzed
- Analysis of colloids, aerosols, nanoparticles
- Self-assembled mono-layers
- Polymer research
- Thin film research (directly deposited on the Silicon Nitride Support Film)
- Materials science
- Properties of nano-structures for semiconductor devices
- Semiconductor: characterization of thin films
- Catalyst development

If we focus only to the application of the membrane in TEM, let us estimate what is financial effect of producing (and selling) such membranes. The membranes are packaged as a set of 10 units, with purchase price of $400. Because of the simple structure, 0.2m diameter silicon wafer has yield of at least 80%. Purchase price

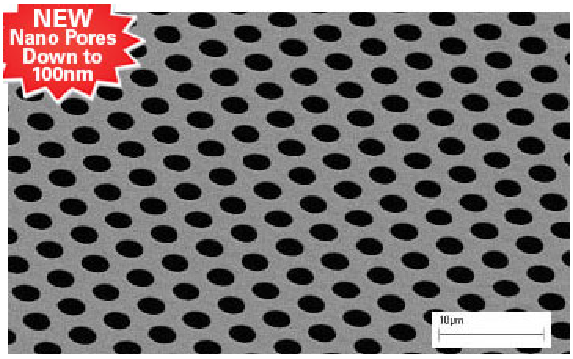

Figure 1: Thin silicon nitride membrane with 100 nm holes

of silicon wafer (which is processed in microelectronic laboratory or production facility, not in small business company) is app. $\$5,000.00$. Cutting the wafer into separate pieces is done in small company, and it requires clean room, diamond saw, and not more then 50 m^2 space and no more then 2 workers. With two silicon wafers per month, including all fixed expenses and taxes, it is a job of more then 2 million $ per year. Not so bad for such a simple product.

Last month I had a meeting with some young people from the "Faculty of Electrical Engineering and Computing" in Zagreb. They asked me if I can suggest a few types of products which can be produced in small nano laboratory. After about one week, I found about 120 examples of simple products like the just described silicon membrane for the TEM. Not a single case is from Europe, in spite of the fact that Europe has good enough laboratories for processing similar products, and that Europe is one of the biggest consumers of such products.

I would like now to say something about the nanotechnology in my homeland Croatia. We all know that politicians have a life full of stress.They are starting every day by checking wheather their pockets are deep enough, so that in every moment they can be ready to steal some more money from the people. The politicians in Croatia are even pushed to specialize themselves in those activities in an accelerated way, so they don't have time to analyze what could be the significance of the nanotechnology in such a small country like my homeland. So let us no disturb them in their everyday struggle for their better life. So much about nanotechnology in Croatia.

F. Example 2: graphen double layer photo detector

As a second example I choose a case which was announced as a note in the official magazine of AIOP (American Institute of Physics) for publishing the news from science and technology [1]. Before I explain why I made such a choice, let me quote the reporter Tushna C. of physicsworld.com : "*Graphene is a layer of carbon just one atom thick and since it was first isolated in 2004 its remarkable electronic and mechanical properties have been studied by physicists worldwide....*", and

"*....and colleagues from the University of Michigan have been developing photodetectors that can take advantage of graphene's unique material properties, including its ultra-broadband light-absorption capability. As graphene is a semimetal, it is capable of absorbing light across a wide spectrum – from ultraviolet to far infrared. This is unlike conventional photodetectors, which are made from semiconductors that can only absorb light at specific wavelengths.*".

The authors of the innovation are Chang-Hua Liu, You- Chia Chang, Theodore B. Norris & Zhaohui Zhong [2]. From the journalist's report and abstract of the paper [2], it looks like the team from the University of Michigen has done some everyday's routine job. But let us analyze few details from the Figure 2.

1. Two layers of the graphene are clearly sketched, and they represent the whole active part of circuitry. The first layer accumulate positive electric charge and electrostatically influences electric current in the layer beneath. The active layer is only two atoms thick.

2. Silicon dioxide and silicon thin layers are noth ing more than carriers for the graphen's active structure and electric contacts. From the whole legacy of microelectronics, a new type of active device use planar silicon technology "only" as a way to support the new structure. But without this support, there is no way to realize such a device. That is the true meaning of the valuable legacy, after all.

3. The graphen is recognized as an exotic material in 2004. In less than 10 years we are faced with a very sophisticated new concepts on the basis of the knowladge of about totally new and unusual phenomena.

4. By the authors of the innovation, the device is compared with MOSFET structure, but that is essentially wrong. The device is a new type of active device which can be called GCG (graphen-channel-graphen) device, or anything else, but not the MOS structure. Sensitivity, power consumption, fast switching and noise tolerance when designing circuits with such devices, must be reconsidered from the beginning.

5. Small power dissipation, and very thin active structure, give the possibility to stack the circuitry in the third dimension. By my modest opinion, that is the best promise of not so distant future.

6. Promoting the concept of the new device, from laboratory work to industrial product with reasonable application, that job cannot be done by the small and medium business subjects. That is typycal object case for corporative business, where financial power altogether with human resources can change the world as we know it.

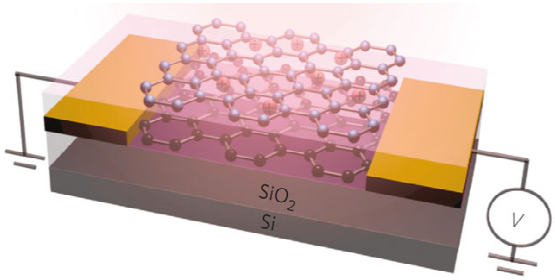

Figure 2: The graphen double-layer photo detector

IV. Ever growing circuit complexity, what is all about ?

The measure of the complexity of the electric circuits on microelectronic (or nanoelectronic) chips, is accepted as a measure of the state of the art of the technology achieved, or as the grade of excellency of some laboratory or facility. The question is, do I really need an intelligent toilet bowl whith controled temperature, humidity, light, and which connects me to the social networks on the internet and read me a status of my credit card, all presented in pretty way as a projection on my eye-glasses? Complexity of electronic circuits built into microcontrollers, with appropriate software behind, allows such solutions, and without any doubt such products have their market and satisfied customers.

In recent communication with some people from big corporations, I got an information that more then 80 % of their production based on microelectronic components, are in fact gadgetry. So, it seems that the main mission of microelectronic technology is to find new type of play-toys. Maybe it is good for business, but I find myself a little bit humiliated. The role of the science and the development of the technology are the means by which human species is getting better chance to survive, with additional responsibility for the rest of the planetary life-forms. It seems that people forgot that threats around are very real. One piece of the stone 10 km in diameter can end the history of civilization. Besides, we already have silent kiler(s) present in a form of new ugly diseases, and apparently slow climate changes. The role of the science has not to be the creation of the new computer games with multiple virtual realities.

What we really need is a kind of mission defined on a global level. The mission means a coherence in understanding what is the goal in front of us and how to move closer to them. Many years before, one american politician said in his famous speech, I quote:

"*No nation which expects to be the leader of other nations can expect to stay behind in this race for space. ...We choose to go to the Moon in this decade and do the other things, not because they are easy, but because they are hard.*"

By this words the whole nation (and great part of the rest of the world) recognized what the mission is.

The Europeans are very suspicious to any idea of coherency and mission. The reason is of historical nature. When somebody says "one homeland, one people, one state and one leader", and if you translate this words into German language, everything becoms much clearer.

I don't no either who is able to define the mission on the global level or what that mission would be, but I can try to show you how to open small window with a sight into not so distant future. Let us look!

V. Concept of the anysotropic boundaries

Suppose we have a plate (vertically positioned) in air as shown by the sketch in Figure 3. Having in mind the elementary collision processes from kinetic theory of gases, simple boundary on each side of plate is place where the molecules of air are reflected from the surface, either elastically or plastically. If one of these boundary does not reflect the molecules, but leaves them pass through the plate, we have a case of anysotropic boundary. In Figure 2, the boundary closer to viewer is standard boundary, and boundary on the other side of plate is anysotropic boundary.

What are the physical consequencies of the presence of the anysotropic boundary?

1. On the side where the boundary is anysotropic, there is no effect of the air pressure. The air pressure is created by the change in momentum of the molecules in the process of reflection from the body's surface. If the boundary does not reflect molecules, there is no pressure on the body.

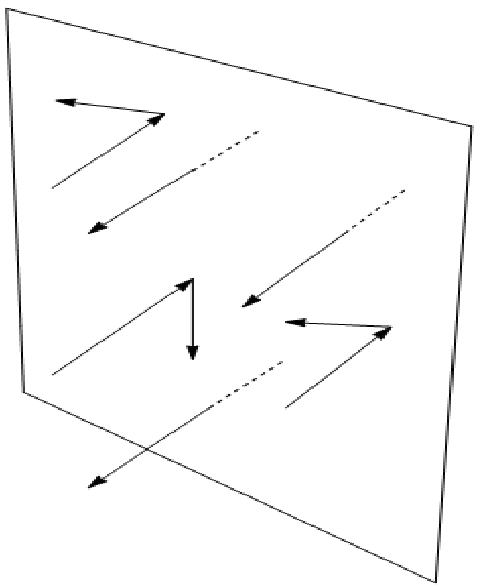

Figure 3: Anysotropic boundary is behind of the plate

2. On the side where the boundary is "normal" and reflects the molecules of the air, pressure is acting on the surface of the body.
3. Unbalanced pressure on oposite surfaces of the plate, results in the force in direction from "normal" boundary" to anysotropic boundary, and that is what we actually call the thrust.
4. If the body is moving in the direction so that anysotropic boundary is the attacked surface, there is no resistance to the flow of fluid, and there is no formation of the density discontinuities in the fluid. In other words, moving bodies with velocities greater than the speed of sound in the fluid do not produce so called bow shock and wake shock.

Modern airfighters usually have two jet engines, whith overall thrust of 75, 000 N per engine as an short time allowable maximum. Depending on the greatest inner diameter of the expansion chamber, I will make a rough estimation of specific thrust to about 60,000 (N/m^2). If we relize the anysotropic boundary with efficiency of **only 1 %**, our specific thrust on plate with anysotropic boundary would be 1,000 (N/m^2).

Now we must take into account the fact that jet engine is not shorter than 4 m, and that we can stack plates with anysotropic boundary in a sandwich system, satisfying the condition that distance between two plates must be greater than 100 times the mean free path of the air molecules. Let stack them at the distance of 5 mm between plates. Such a combination would give a specific thrust of 800,000 (N/m^2) what is almost 14 times greater of what modern airfighters can achieve.

And, yes...I forgot to emphasize: sandwich system of the plates with one anysotropic boundary does not need fuel! Knowing that *perpetum mobile* is not possible, where all this energy for such a trust is coming from? The answer is: from the kinetic energy of air molecules, or in other words from internal energy of the fluid. The air on the side of the anysotropic surface is in the state of the adiabatic expansion, which results in cooling, and the air on opposite side is in the state of adiabatic compression, which results in heating. The difference between heating and cooling is converted into usefull work delivered to the plate.

In the early days of the thermodynamics, analysis of the engines which use internal energy of the surrounding fluid, has been violently disregarded, almost prohibited. Only circular processes like Carnot and similar, were accepted and fully analyzed, probably because by the technology they had only such termodynymic engines could have been realized.

There are three different ways to realize anysotropic boundaries, and all three by the nanotechnology processes. We have some extras regarding the application of anysotropic boundaries outside the conventional fluids like gases and liquids. The vacuum state is by the QM theory a foam of boiling

short-living particles which oscillate between virtual states and real states in our space. This concept is approved by the experiment with so called Casimir's force in the vacuum.

There are two ways to realize anysotropic boundaries for the applications in vacuum environment. And of course, you guess : by the method of nanotechnology. What are the consequencies of such possibilities?

First, let us analyse how the conventional rocket technology has been used in space travel till today. After reaching the Earth low orbite, space module engages rocket engines and after a few minutes when the required velocity is obtained, the state of the module becomes passive. The module follows the so called ballistic trajectory. With ballistic trajectories you need several days to reach the Moon, 6 to 14 months to reach the Mars (depending on relative position of Mars and Earth), and more than 30,000 years to reach a nearby star.

If you have engines based on anysotropic boundaries, you can afford a kind of active trajectory. The reason is the enormous thrust possibility and no need for fuel. The fuel is right there in the space. If we decide to use active trajectory with acceleration of 1 g to the halfway, and deceleration of 1 g to the destination, the typical times to reach some space destinations are: 3,5 hours to the Moon, 49 hours ours to the Mars, 8 Earth years or 1,5 month of space module time to the nearby star. In this last case you have to account for the relativistic effect of time dilatation for space module. The calculation is very simple, and you can chack it by yourself.

Let us now close that window with our sight set on the near future. Maybe the drought from the future is not so harmless as we expected.

Because of the physical limitation of this paper, one question will be left unanswered: are you sure that you are ready to face the new space challenge?

We can reshape the question in a more familiar form: are you ready "*...boldly to go where nobody has gone before?*"

VI. Conclusions

A breif review of the fast rate of development in the domain of new technologies (nanotechnology), clearly shows that the achivement of the microelectronics during the 1980 is a legacy which boosts overall processes in science and technology progress. There can be no science progress without technology progress. Science and technology are the two faces of the same coin.

The lack of the coherent vision of the future on the global level, as a rule, results in pushing the huge potential of the nano science into the banality, which eventually results in the flurishing of gadgetry. It is necessary to remember what is the more profound mission of science and technology.

The lack of vision is probably the cause of the fear of the future in the human mind. It looks like humanity is punished to stay inside the borders of the Earth's habitat. Already for many years the humanity has been treating our planet as a jail. The environmental care is replaced by hate.

As a part of the possible vision of the future, the author announce an original concept of anysotropic boundary. A small number of possible repercussions are discussed, showing that humanity's habitat is much more spacious than we thought. It is certain that the hopes oriented in that direction will definitely change the existing civilizational paradigm. But, that is a story for some other paper.

Thanks

Before the daedline for submitting the paper, I did not received the permission to use a picture of double layer graphen photodetector, published in [1]. I hope that there is no reason to refuse such a permission, because papers submitted to MIPRO are not of the commercial character. Whatever, after all, I express my gratitude to the editors of IOP magazine for using the published drawing.

I would thank all the readers of this paper for having understood that it was imposible to cite all the authors whose papers are read to get the informative database about the fact of extraordinary fast progress in domain of the nanotechnology (more than 200 authors). But the abstracts of their papers can be found in IOP magazine collections for the year 2005-2014, avaliable online at physicsworld.com.

Abstract – Technologically modified g-$GeS_2(T_iV_j)$ glasses prepared by melt quenching from different temperatures (T_i) and with different cooling rates (V_j) were studied using Raman spectroscopy and model calculations. Differential Raman spectra {$I_RGeS_2(T_iV_1)$-$I_RGeS_2(T_2V_1)$} showed the splitting of the main, most intensive wide-band, centered at 340 cm^{-1}. The position of the peaks found in the differential Raman spectra near 340 and 360 cm^{-1} and position of the main vibrational modes in the ordinary Raman spectra of low- and high-temperature crystalline phases (α-, β-GeS_2) were found to be in good agreement. Vibrational spectra of 4- and 6-member ring fragments selected from crystalline structure of β-GeS_2 were also determined using model calculations. Based on rings composed of GeS_4 tetrahedrons connected by corners and edges the structural interpretation of the vibrational bands of g-$GeS_2(T_iV_j)$ at 360, 370 and 433 cm^{-1} in their Raman spectra was performed. The existence of homopolar Ge-Ge and S-S "defect" bonds in the structure of germanium disulfide glasses was proved by formation of 5-member rings. Formation of fragments of both low- and high-temperature α-, β-GeS_2 crystalline phases in the structure of g-$GeS_2(T_iV_j)$ glasses indicates the existence of mixed medium-range ordering in g-GeS_2.

I. INTRODUCTION

Glassy germanium disulfide is among chalcogenide glasses attracting much attention and widely studied for many years. Thanks to the large infrared optical transmission window it found usage as material for night vision, acusto-optical modulators, chemical sensors, mid-infrared light delivery, thermal imaging, environmental monitoring, integrated optics and also in the area of fast ion conducting glasses for battery applications [1-6]. One of the promising new ways of its mid-IR application is to prepare glass-ceramics with controlled crystallization [7]. Due to their specific optical properties transparent glassy ceramics are considered as perspective materials for photonics [7]. A number of structural studies were performed on this material and it was concluded that the medium-range order existing in g-GeS_2 is connected with clustering of GeS_4 tetrahedral units by edges or corners and the two kinds of linkages produce both six- and four-member rings in a 2:1 ratio, like in layered β-GeS_2 crystalline structure [8-13]. In the low temperature α-GeS_2 crystalline phase the corner-sharing $GeS_{4/2}$ tetrahedra form a three-dimensional (3D) structure [14,15]. The density of α-GeS_2 is only about 0.055 g/cm^3 higher than that of β-GeS_2 [14]. The structure of α-GeS_2 crystal was used as starting configuration in a Reverse Monte Carlo (RMC) calculations [16]. In contrast to the common conclusions [8-13] about layered structure of g-GeS_2, the RMC simulation revealed that the structure of g-GeS_2 is somewhere between the structure of α-GeS_2 and β-GeS_2 crystals [16]. This conclusion was also confirmed by studies of g-GeS_2 performed at high pressures [17], where short-range structures of densified g-GeS_2 transformed from a mixed α-GeS_2 and β-GeS_2 type arrangement into an α-GeS_2-like structure [17]. Comparison of the Raman spectra of g-GeS_2 and α- and β-GeS_2 crystals in [18] showed that the middle-range structural order of g-GeS_2 is controlled by a corner-shared three-dimensional network which is topologically similar to that in the α-GeS_2 crystal. Similarity of medium-range ordering of g-GeS_2 and α-GeS_2 was also confirmed by the study of GeS_2 microcrystals grown in g-GeS_2 during annealing at 497 °C, below the glass transition temperature [18]. Linear crystal growth kinetics of both α-GeS_2 and β-GeS_2 polymorphs has also been observed in g-$Ge_{42}S_{58}$ over a relatively broad range of temperatures, *i.e.* 420 < T < 494 °C that correspond to viscosity of supercooled melt: $3 \times 10^9 > \eta > 8 \times 10^5$ Pa s [19].

In spite of the findings described above, the structural information about medium-range ordering in g-GeS_2 is controversial. It is still debated whether the structure of g-GeS_2-type glass is a continuous or a broken network of Ge–$(S_{1/2})_4$ tetrahedra [20]. The new potential applications, however, compel a need for thorough structural characterization of these glasses prepared in different technological regimes, including the utilization

of both experimental techniques and atomic scale modeling.

II. Materials and Methods

The g-GeS_2 samples were synthesized by melt quenching from different temperatures: 1173 K (T_1), 1273 K (T_2), 1373 K (T_3) and 1473 K (T_4) and cooling rates of 100 K/s (V_1) and 150 K/s (V_2). The four different g-GeS_2 samples will hereafter be denoted as (T_1V_1), (T_2V_2), (T_3V_2) and (T_4V_2). DFT calculations were performed on Ge_nS_m (n=2,3,5,6,12; m=6–9,14,16,30) units that represent the local structure of g-GeS_2 and some 'defect' Ge_nS_m clusters (Fig.1). The local short-range order structural units representing the beta form of GeS_2 crystal are corner- and edge-sharing tetrahedra (models I and II). Further extension of the length scale to the larger coordination spheres leads to an increase in the degree of freedom in the formation of amorphous structures. In this case, the structure formation may be studied in detail by *ab initio* method using a gas-phase cluster approach. The largest cluster which can be found in the crystal structure of GeS_2 is a six-member ring consisting of three $GeSe_4$ tetrahedra connected by their corners (III). It should be noted here that two edge-sharing tetrahedra can also be classified as a four-member ring. Models IV and V represent two six-member rings selected from two directions of 2D of β-GeS_2 crystal. In the first case the rings are connected by common Ge atom while in the other model rings are connected via the edge-sharing block. The largest cluster obtained from the crystal structure of GeS_2 monolayer (VI) consists of a big 16-member ring. Here, we represent few possible models with homopolar Ge–Ge (VII–VIII) and S–S (IX–XI) bonds. The simplest model of Ge–Ge bond being present in the hypothetical cluster is the so-called ethane-like geometry (VII). There is also possibility of S–S bond formation on the edge of the so-called 'outrigger raft' structure (model XI represents a part of this structure) [8]. In α-GeS_2 the $GeS_{4/2}$ tetrahedra pack to form a dense three-dimensional network with large hollows surrounded by twenty four-member rings together with six-member rings (Fig. 2).

Raman spectra of g-GeS_2 and β-GeS_2 were measured using Dilor–Labram and Renishaw system 1000 Raman spectrometers equipped with CCD detectors. Excitation was performed with lasers operating at 1064 and 785 nm.

III. Results and Discussion

Fig. 3 shows the Raman spectra of g-GeS_2 glasses measured using excitation photon energy of 1.17 eV (1064 nm), being less than the Tauc optical gap of GeS_2 glasses (E_g=3.2 eV) [21]. All these spectra are very similar to those measured with shorter excitation wavelengths (632.8 and 785 nm) and they can be treated as non-resonant Raman spectra. All spectra are normalized to their 340 cm^{-1} peak. A pronounced difference between the samples is that both the (T_1V_1) and the (T_3V_2) samples show similar small increases in the intensity of 370 and 433 cm^{-1} vibrational modes, as compared to (T_2V_2). For the (T_4V_2) sample these peaks broadened and merge with the main peak at 340 cm^{-1}. A very weak c-GeS-like Raman mode at ~200 cm^{-1} is observed for all samples while a weak S-S mode at 490 cm^{-1} is detected only for (T_2V_2) showing evidence of c-GeS type clusters (Fig.4) and S-rich clusters (IX–XI) respectively (Fig.1).

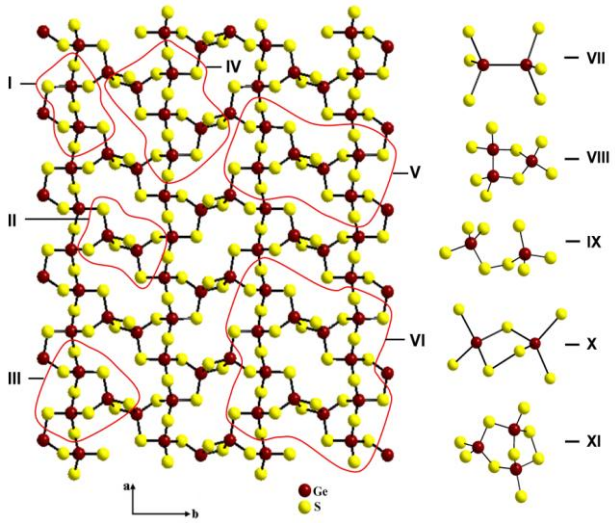

Figure 1. The crystal structure of high- temperature (β) GeS_2 monolayer [15] with the selected Ge_nS_m cluster models (I–VI) (left) and the 'defect' Ge_nS_m cluster geometries with homopolar Ge–Ge (VII–VIII) and S–S (IX–XI) bonds (right). Saturating hydrogen atoms and corresponding bonds are not shown for clarity.

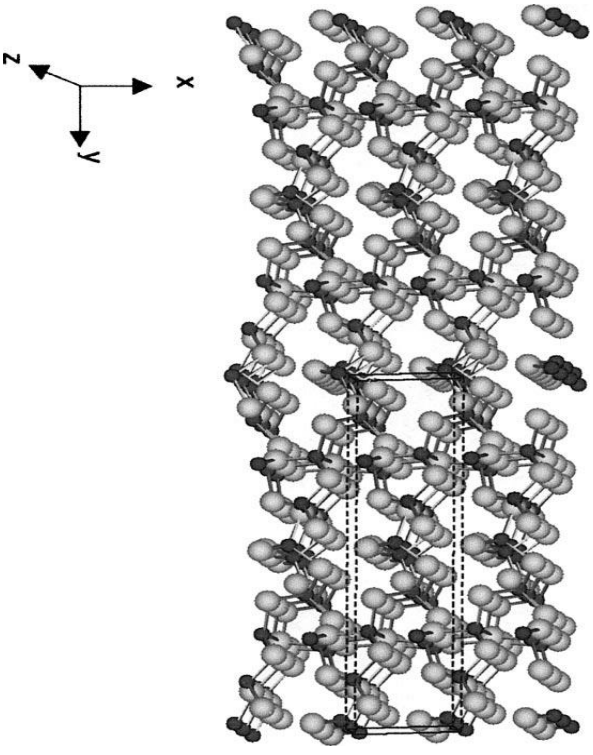

Figure 2. Crystal structure of α-GeS_2 (low-temperature modification) [14].

The Raman spectrum of g-$GeS_2(T_2V_2)$ didn't show band near 255 cm^{-1} being characteristic for Ge–Ge bonds in (VII–VIII) type of clusters (Fig.1). The Raman spectrum of this (T_2V_2) technological regime contains only minority of 'defect' clusters and was chosen as reference spectrum for the extraction of other differential Raman spectra of g-$GeS_2(T_iV_j)$ samples. The Raman modes at 360 and 370 cm^{-1} are related to the Ge-S stretching vibrations in so called corner- and edge-sharing tetrahedra, respectively [21]. However, the former modes can also be characteristic for an 'outrigger raft' cluster [8]. Our recent theoretical study on formation energy, stability and electronic properties of different Ge_nS_m clusters indicates that the formation of single ethane-like cluster, single corner sharing GeS_4 tetrahedra and cluster based on two GeS_4 tetrahedra connected by an S-S bridge are energetically not favorable structural motifs [22]. On the other hand, we have found that the ring-like structures were most favorable within our Ge_nS_m cluster models. One of our previous studies [21] showed that the vibrational mode at ~250 cm^{-1} observed in the Raman spectra of GeS_2 glass can be interpreted as the existence of GeS microphase rather than ethane-like Ge_nS_m cluster with Ge-Ge bond.

The differential Raman spectra {$I^RGeS_2(T_iV_2)$-$I^RGeS_2(T_2V_2)$}, (i=1, 3 and 4) clearly show two bands centered at 339 and 360 cm^{-1} (Fig.5) which are typical for Raman spectra of α-GeS_2 and β-GeS_2, respectively [23,24]. These two bands are more distinct in the differential Raman spectra {$I^RGeS_2(T_iV_1)$-I^Rβ-GeS_2} (Fig.6). Differential Raman spectrum {$I^RGeS_2(T_1V_1)$-I^Rβ-$GeS_2(T_2V_1)$} is mainly β-GeS_2 like (Fig.5). For this (T_1V_1) technological regime the fraction of edge-sharing tetrahedra in the glassy structure increases. By increasing temperature from T_2 to T_3 and T_4 the concentration of 5-member rings with Ge-Ge bonds and GeS-like clusters

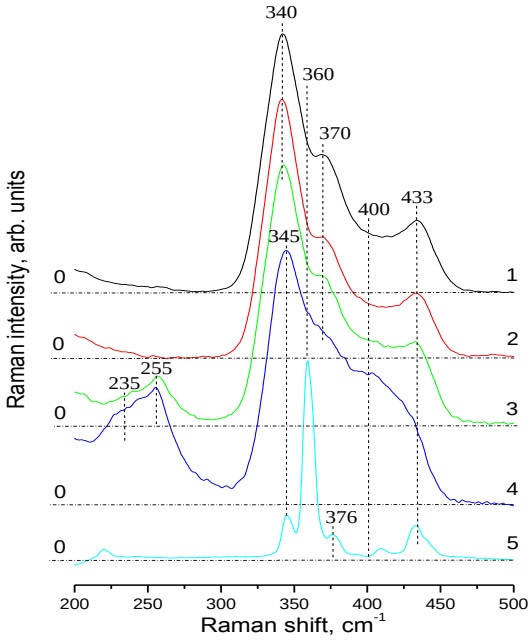

Figure 3. Raman spectra of GeS_2 glasses: 1- T_1V_1; 2- T_2V_2; 3- T_3V_2; 4- T_4V_2; 5- Raman spectrum of β-GeS_2.

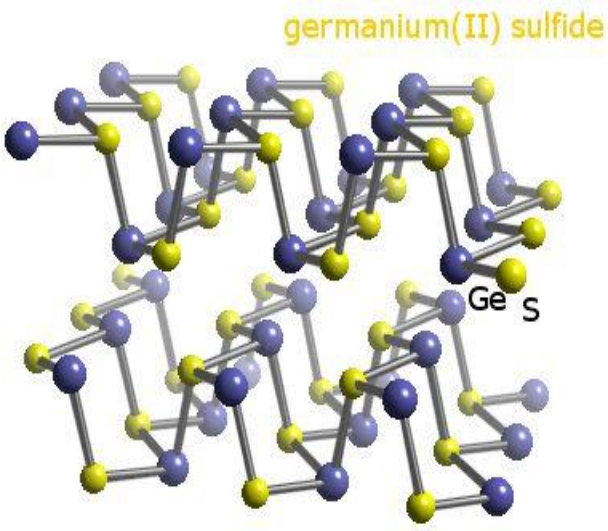

Figure 4. Crystal structure of c-GeS [14]

increases and concentration of 4-member rings with edge-sharing tetrahedra in the structure decreases. Therefore, in structural aspect, nucleates with medium-range ordering based on α-GeS_2 and β-GeS_2 crystal type clusters coexist in the structure of g-$GeS_2(T_iV_1)$ during nucleation of the melt by quenching from different temperatures.

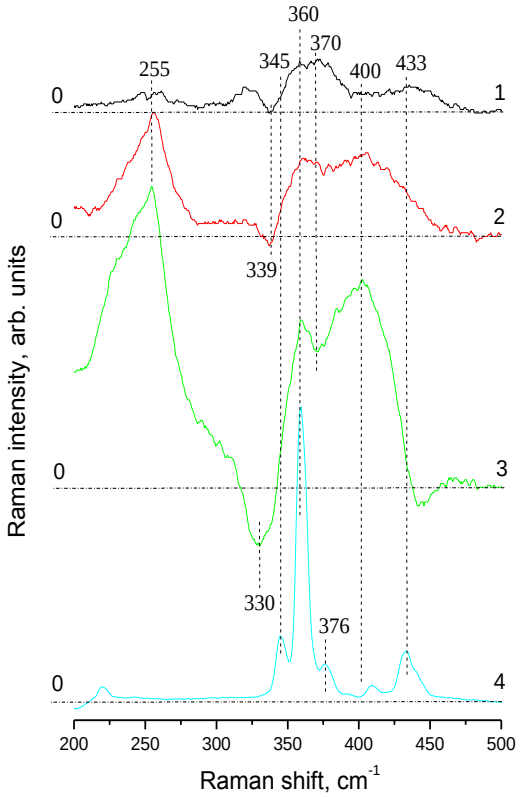

Figure 5. Differential Raman spectra {$I^RGeS_2(T_iV_1)$-$I^RGeS_2(T_2V_2)$}: 1- T_1V_1; 2- T_3V_2; 3- T_4V_2; 4 - Raman spectrum of β-GeS_2.

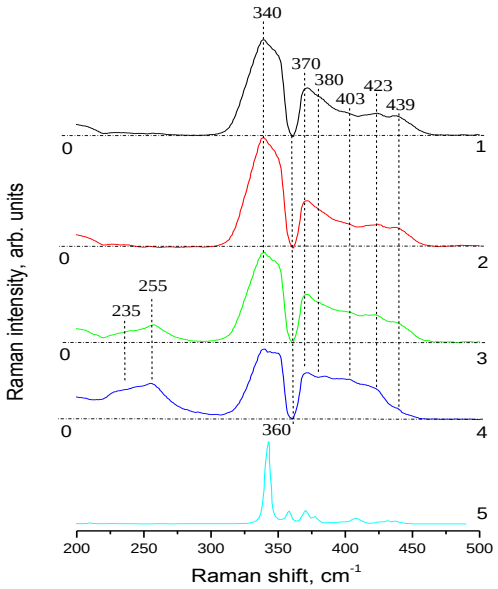

Figure 6. Differential Raman spectra {$I^RGeS_2(T_iV_1)$- $I^R\beta$-GeS_2}: 1 - T_1V_1; 2 - T_2V_2; 3 - T_3V_2, 4 - T_4V_2; 5 - Raman spectrum of α-GeS_2 [18].

IV. Conlusion

Two bands, centered at 339 and 360 cm^{-1} were observed in the differential Raman spectra {$I^RGeS_2(T_iV_1)$-$I^RGeS_2(T_2V_2)$, (i=1,3,4), which are typical for most intense bands in Raman spectrum of α-GeS_2 and β-GeS_2 crystals, respectively. These two peaks appear more clearly in the differential spectra {$I^RGeS_2(T_iV_1)$-$I^R\beta$-GeS_2), i=1-4. In structural aspect, during the melt clustering by quenching a middle-range structural ordering is created in g-GeS_2 as mixture of corner-shared three-dimensional clusters being topologically similar to those in α-GeS_2 crystal and middle range order which is topological similar to the two-dimensional β-GeS_2 crystal type.

Abstract. – Silver colloids were produced by chemical reduction of silver salt (silver nitrate, $AgNO_3$) solution. As a reducing agents trisodium citrate, sodium borohydride, ascorbic acid, PVP (Polyvinylpyrrolidone) and glucose were used. The characters of silver nanoparticles were investigated using UV-Vis spectrophotometer, dynamic light scattering (DLS), zeta (ζ) potential measurements and scanning electron microscopy. The as prepared silver nanoparticles were used in SERS measurements of pyridine. The best enhancement of the signal was achieved using sample reduced and stabilized with citrate, with the particle size of approximately 40 nm and non-uniform distribution. As aggregating agents $NaNO_3$, KCl and KBr in different concentrations were tested. The Raman signal for pyridine was enhanced even more with the addition of sodium borohydride instead of other aggregating agents. Addition of borohydride had the largest impact to sample stabilized with DEAE-dextran which consists of large (0.5 μm) as well as very small silver nanoparticles. The mixture colloid-borohydride-pyridine was stable for hours.

I. INTRODUCTION

During the past decades metal nanostructures received great interest in many fields due to their interesting optical and electric properties. They have been used in electronics [(1)], catalysis [2], biomedicine [3] and surface-enhanced Raman scattering (SERS) [4],[5]. There is particular interest in silver nanostructures due to their outstanding plasmonic properties which lead to a great enhancement of the Raman signal. SERS is an advanced Raman technique that enhances the vibrational spectrum of molecules adsorbed on or in the vicinity of metal particles.

It is currently accepted that two mechanisms, electromagnetic and chemical, contribute to the SERS enhancement [6]. In the electromagnetic mechanism, the laser light excites collective oscillations of the surface electrons in a metal which results in the enhancement of the local electromagnetic field. The molecule which is near the metal surface or adsorbed to it, experiences this enhancement and as a result the intensity of the Raman scattered light is enhanced. In the chemical mechanism the polarizability of the molecule adsorbed on the metal surface increases. The total Raman signal enhancement is the product of both processes. In recent times a significant enhancement of the Raman signal has also been obtained from surfaces of oxide nanosensors (α-Fe_2O_3 thin films) [7] which indicates the importance of the chemical enhancement. Because of its readiness, sensitivity, and minimum sample preparation requirements, SERS is being considered as a powerful technique for detection of wide variety of analytes at very low concentrations, even down to the single molecule level [8].

The main issue today is the synthesis of metal (Ag, Au, Cu) nanoparticles with tunable size, shape and morphology [9]. Silver colloids are usually synthesized by in-situ reduction methods, such as chemical reduction, photo reduction [10], electrochemical reduction [11], or thermal decomposition [12]. Chemical reduction involves the reduction of a silver salt with a reducing agent in the presence of stabilizer. The most used methods for the preparation of silver nanoparticles in aqueous solution are reduction of silver nitrate, $AgNO_3$, using reducing agents such as citrate [13],[14], ascorbic acid [15], or borohydride [16]. The purity of water and reagents, cleanliness of the glassware and solution temperature are critical parameters in the synthesis process. In addition, the nanoparticles prepared by chemical reduction are usually mixtures of spherical and rod-like silver particles due to the poor balance of nucleation and growth processes [17]. Nevertheless, due to simplicity of preparation and the fact that they offer fairly good SERS enhancement (up to 10^6) under acceptably reproducible experimental conditions, silver colloids with stabilizing agents have been widely used. The stabilizing agents are chemicals used in the synthesis of nanoparticles that prevent their aggregation through electrostatic or steric repulsion (or both). In the case of silver colloids most commonly used stabilizing agents are citrate, sodium borohydride, polyvinylpyrrolidone (PVP) and CTAB (cetyltrimethylammonium bromide). According to the type of stabilizing agent particles of varying size, shape and stability are obtained.

II. MATERIALS AND METHODS

Sample AGC was prepared using chemical reduction method according to the slightly modified method of Lee and Meisel. Sample AGA was synthesized using ascorbic acid as reducing agent and citrate as stabilizer. Sample AGBH was synthesized using ice-cold sodium borohydride according to Creighton method. Sample AGD was synthesized using sodium borohydride as reducing agent in the presence of dextran as stabilizer. Sample AGP was prepared with PVP as reducing and stabilizing agent. Sample AGG was prepared by reducing the silver nitrate with glucose in PVP aqueous solution with sodium hydroxide which accelerates the reaction.

The absorption optical spectra of silver samples were recorded using UV–Vis–NIR spectrophotometer (UV-3600, Shimadzu). All the spectra were recorded at room temperature.

The morphology of silver nanoparticles in silver samples was investigated with Jeol JSM 7000F field emission scanning electron microscope (FE SEM) coupled with Energy-dispersive spectroscopy (EDS). 10 µL of colloid solution was pipetted on silicon wafer and allowed to dry in ambient conditions. Dynamic light scattering (DLS) measurements were performed by a Zetasizer Nano ZS (Malvern Instruments, UK) equipped with a 532 nm "green" laser.

The Raman spectra were recorded by Horiba Jobin Yvon T64000 triple Raman spectrometer in the subtractive mode. The 514.5 nm argon ion laser and 532 diode laser were used.

III. RESULTS AND DISCUSSION

A. Colloid characterization

Figure 1 shows UV-Vis spectra of the synthesized silver nanoparticles in the range from 200 to 800 nm. The absorption band in visible light region from 350 to 550 nm is typical for silver nanoparticles and the samples AGC, AGA, AGBH and AGD have the absorption maximum at 407, 402, 390 and 410 nm respectively. AGC sample has the broadest band indicating non-uniform distribution of silver nanoparticles. Samples AGA, AGBH and AGD have smaller values of absorption peak FWHM indicative of a narrow size distribution. FE-SEM measurements were carried out to observe the size and morphology of the silver nanoparticles prepared with different reducing and stabilizing agents. Figure 2 shows SEM image of synthesized nanoparticle. The sample AGC prepared with citrate consists of quasi-regular spherical nanoparticles with small amount of rod-like nanoparticles.

TABLE 1. CHARACTERIZATION OF THE PREPARED SILVER SAMPLES.

Sample	Reducing/ Stabilizing Agent	SEM (nm)	Zeta (mV)	Hydrodynamic diameter (nm)	UV-Vis-NIR (nm)	pH
AGC	citrate/citrate	35.8+/- 6.3	-33.4	14.6; 69.8	407	7.7
AGA	ascorbic acid /citrate	16.7 +/- 4.4	-46.8	5.4	402	7.9
AGBH	$NaBH_4/BH^{4-}$	10.9 +/- 2.9	-10.1	2.87	390	7.5
AGD	$NaBH_4$/DEAE-dextran	518 +/- 114	39.5	473	410	8.2
AGP	PVP/PVP	11.6 +/- 4.1	-0.867	4.62	420	5.6
AGG	glucose/PVP	12.6 +/- 4.2	-11.2	14.28	283	7.9

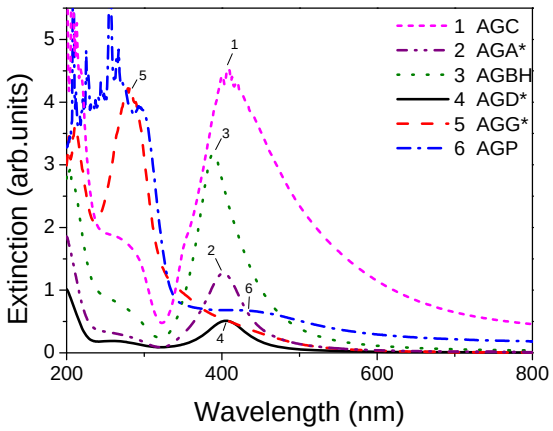

Figure 1. UV–Vis spectra of the silver nanoparticles synthesized. The samples marked with asterisk were diluted with water (sample AGA 10 times; samples AGD and AGG 300 times).

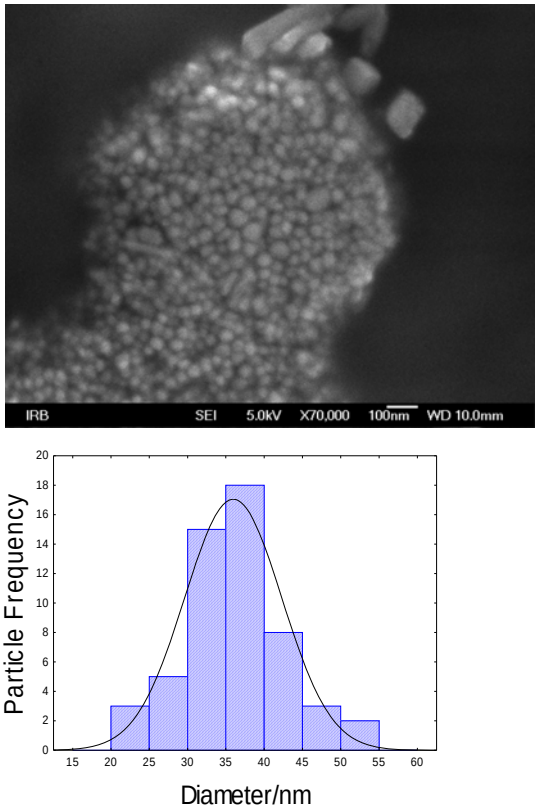

Figure 2. SEM image and particle diameter for AGC sample.

The particle size distribution was calculated from the corresponding SEM images using ImageJ computer program. The calculated mean particle sizes and their standard deviation are given in Table 1. Also, the hydrodynamic diameters and zeta potential results of DLS measurements are given in Table 1. Typically, nanoparticles with zeta potentials greater than 20 mV or less than -20 mV have sufficient electrostatic repulsion to remain stable in solution. The silver nanoparticles in AGC and AGA samples are stabilized with adsorbed negative citrate ions that cause repulsive force along particles and prevent aggregation while AGD, AGP and AGG samples are stabilized sterically.

The hydrodynamic diameter values in most cases are slightly lower than the diameter calculated from SEM images. Air dried colloids for SEM measurements are probably not a good representative of the same colloids in aqueous suspension.

B. SERS measurements.

The performances of the colloids were evaluated by their SERS activity using pyridine. To determine the suitable volume of colloid for further analysis, different volumes of AGC, AGA, AGD and AGBH samples were tested. The other samples show very low SERS enhancement. The SERS spectra of pyridine were also detected using KBr, KCl, $NaNO_3$ and $NaBH_4$ in different concentrations to find the optimal aggregating agent as well as optimum concentration for SERS enhancement. The differences of the SERS spectra of pyridine when adding different types and concentrations of ions to the colloids may be attributed to the both effects of degree of aggregation of the colloid and the change on the surface of silver structures.

Figure 3 shows enhanced Raman intensities as a function of concentration for two pyridine bands at 532 nm excitation wavelength.

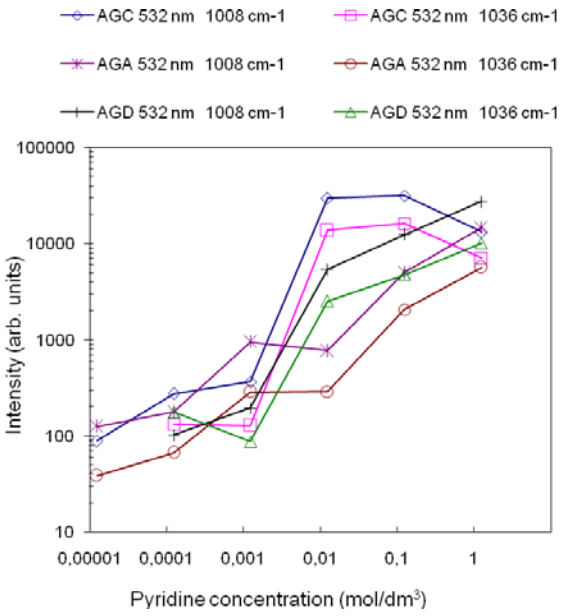

Figure 3. Pyridine SERS intensities at 1008 and 1036 cm^{-1} as a function of pyridine concentration in log-log scale in AGC, AGA and AGD samples.

The SERS enhancement factor values were calculated by comparing the intensity of the appropriate pyridine peak (~1008 cm^{-1}) measured in the SERS experiments to the corresponding peak measured from an aqueous solution of pyridine.

The SERS enhancement factor is defined as

$$EF = (I_{SERS}/I_{NR}) \times (c_{NR}/c_{SERS}) \quad (1)$$

where I_{SERS} and I_{NR} are intensities of the band of pyridine in the SERS spectrum and in the normal Raman spectrum, respectively (in this case 1008 cm^{-1}) and c is the pyridine concentration in the aqueous solution (c_{NR}) or in the colloid (c_{SERS}).

IV. CONCLUSION

A range of silver colloids, prepared by different methods, were investigated with respect to nanoparticle morphology and SERS activity. The results from UV-Vis, zeta potential, DLS and SEM confirm that stable silver nanoparticles of a certain size and charge are formed. The silver particles with 10–40 nm size and spherical shape were prepared by reducing silver nitrate with citrate, ascorbic acid, $NaBH_4$, PVP and glucose in the presence of stabilizing agents. Thus obtained silver nanoparticles were used as reproducible SERS substrate with pyridine as analyte. The volume of AGC, AGA, AGD and AGBH samples required for obtaining the best surface enhancement of the Raman signal was studied. Furthermore, the addition of various aggregating agents in terms of concentration was investigated. The surface-enhanced Raman spectroscopy of pyridine varied clearly when different kinds and concentration of aggregating agents were used. The best enhancement of the Raman signal was achieved for 1M salt solutions. The addition of sodium borohydride further amplified the Raman signal of pyridine. The best Raman enhancement for pyridine was achieved for AGC sample with the addition of 0.1M borohydride. The SERS enhancement factors for pyridine were calculated taking into account the number of molecules on the silver nanoparticles in laser activation volume and for the best results was estimated to be of the order 10^6.

Abstract - Tellurite glasses are known as a promising material for optical fiber fabrication thanks to the specific optical and thermo-mechanical features. This paper shows tellurite glasses doped with different concentrations of various rare earth ions characterized by Raman spectroscopy. Especial attention was paid to the low frequency 'Boson peak' and the modes of vibration which correspond to TeO_4 and TeO_3 structural units. The results show interesting correlation between structural order and rare earth ions concentration.

I. INTRODUCTION

Tellurite glasses are considered as the promising material for active and passive optical fibers due to their specific characteristics. The most important and valuable features are: a) low phonon energy (among oxide glasses, tellurite glasses feature the lowest phonon energy of ~ 750 cm-1), b) high refractive index (at 633 nm ~2), c) wide transmission range (0.4 – 5 μm), d) thermo - mechanical stability and corrosion resistance (assuring sufficient stability towards crystallization), e) rheological properties (it is accepted that tellurite glasses exhibit Newtonian behavior which offers easy fibre drawing performance), f) high concentration solubility (tellurite glasses can accept up to 22 10^{20} cm^{-3} rare earth ions) [1, 2].

The infrared emission in active tellurite glasses can be obtained by utilizing particular energy level transitions of rare earths (RE) such as Yb^{3+} and Tm^{3+}. Up to now, the significant attention was dedicated to ~1 μm Yb^{3+} and ~ 2 μm Tm^{3+} emissions. Apart from the huge research efforts regarding RE fluorescence characteristics, the structural features should not be neglected since they are directly related with thermo-mechanical features linked with the fiber drawing process. The already published research papers consider mostly glasses doped with the low RE concentrations while the high dopant concentrations are still not well investigated. The incorporation of high RE concentrations in the glass host material can as the consequence cause glass crystallization or the phonon energy change.

Pure TeO_2 glasses are built of TeO_4 trigonal bi-pyramid (tbp) polyhedral [3]. In this paper we considered a ternary host glass (TeO2:ZnO:Na2O – 'TZN') codoped with Yb^{3+} and Tm^{3+}. The glass modifiers, ZnO and Na_2O as well as RE dopants, change glass structure which as the consequence influence thermal, mechanical and optical properties of the glass.

Identify applicable sponsor/s here. If no sponsors, delete this text box.

In TZN host several characteristic bands and corresponding structural units can be observed. Namely, at ~ 764 cm^{-1} (TeO_3 trigonal pyramid structural unit) and ~ 670 cm^{-1} (TeO_4 trigonal bi-pyramid structural unit) corresponds to stretching vibrations, while ~ 433 cm^{-1} ($Te_{eq} – O_{ax} – Te$) belongs to banding vibrations. The low frequency so called 'boson peak' at around 40 cm^{-1} [1] is assumed to be combination of acoustic phonons and rotational molecular modes [4]. Furthermore, the chemical glass composition can change the position or increase the intensity of the boson peak which is correlated with the medium range order decreases [5]. The structural order increase indicates the structural transformation trend from $TeO_4 \rightarrow TeO_3$ polyhedra [1].

II. EXPERIMENTAL

Raman spectroscopy features of tellurite glasses were monitored by Jobin Yvon T64000 instrument in micro – Raman configuration. The excitation source was Coherent Innova 100 argon ion laser operating at 514.5 nm and power of 20 mW.

The first glass group was doped with Yb^{3+} ions while the second group was codoped with Tm^{3+} ions. Dopant concentrations were in the range from 0.5 to 5 mol% and therefore the samples were labeled with letters 'Y' for Yb^{3+} and 'T' for Tm^{3+} followed with the concentration value. In order to determine dopant ion concentration in the unit volume it is necessary to determine glass density. Density measurements were obtained by precise mass measurements in air and water environment on selected specimens following the Archimedes's principle and using water as immersion liquid. Detailed dopant concentration are listed in Tables 1 and 2.

Table 1. Dopant concentration and density for Yb^{3+}-doped $75TeO_2$-$20ZnO$-$5Na_2O$ glasses.

Sample name	*Yb^{3+} (ppm)*	*$Yb^{3+}x10^{20}(cm^{-3})$*	*$\rho(g/cm^3)$*

III. RESULTS

A. Group I (TZN – Yb3+)

Raman spectroscopy spectra of TZN glasses doped with 0.5 and 5 %mol of Yb3+ are shown in Fig. 1.

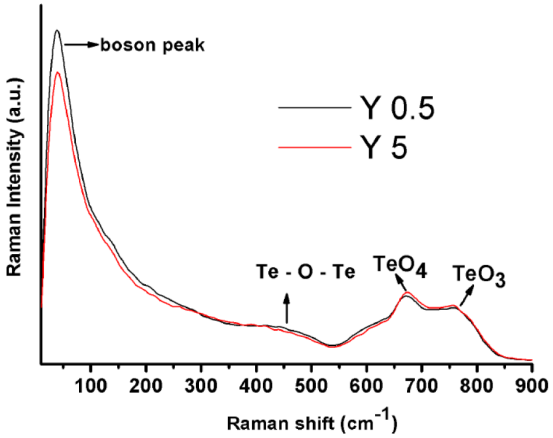

Figure 1. Raman spectra of TZN glass doped with Yb^{3+} with 514.5 nm laser excitation.

In the case of TZN doping with Yb^{3+}, boson peak position remained the same, at 40 cm^{-1} while the intensity decreased with dopant concentration increase. That showed that Yb^{3+} ion in TZN matrix has the same effect as Tm^{3+} ion [1, 2]. The mode of vibration which belongs to TeO_4 structural unit showed slightly wider width for larger dopant concentration.

B. Group II (TZN – Tm^{3+}, Yb^{3+})

In Fig. 2 Raman spectra of Tm - Yb doped TZN glass with 514.5 nm excitation line are displayed. As in the case of doping with only Yb^{3+}, characteristic boson peak and tellurite structural units can be observed.

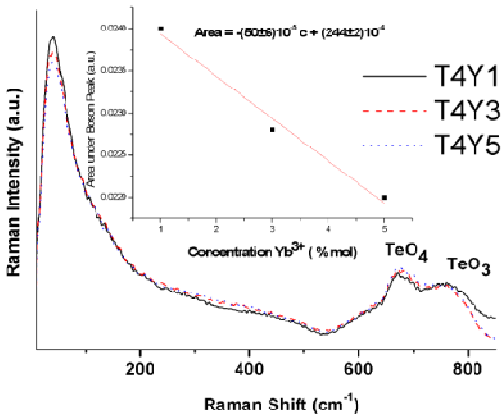

Figure 2. Raman spectra of TZN glass doped with Tm^{3+} - Yb^{3+} under excitation wavelength of 514.5 nm. The inset shows linear decrease of the area under boson peak with the increase of Yb^{3+} content.

In this case, the mode of vibration which corresponds to TeO_3 structural unit shows narrower shape. The highest frequency vibrational bend determinates phonon energy of the glass which influences numerous photonics features such as fluorescence quenching and cross relaxation in the case of thulium ions [1,2]. Therefore, the phonon energy is very important factor for the host material selection. This result shows indication of the phonon energy decrease although for the negligible value which would hardly influence the potential fiber laser. Another explanation for the TeO_3 band change could be clustering which probably occurs for higher dopant concentrations as in the case of the T4Y3 and T4Y5 samples. Boson peak linearly decreased with increasing dopant concentration as in [1]. Similar behavior is noticed for the TxY1 group (Fig. 3).

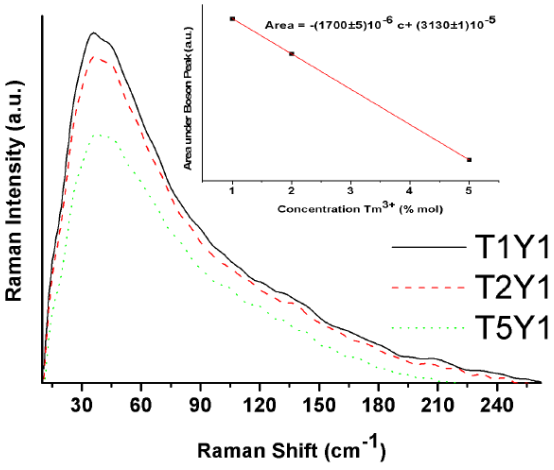

Figure 3. Raman spectra of group II (TZN - Tm^{3+}, Yb^{3+}) with 514.5 nm laser excitation..

From Fig. 2 it is obvious that TeO_4 structural unit changed its spectral line shape when Yb^{3+} concentration increased: the peak became narrower and its intensity slightly increased in comparison with TeO_3 band. Tm^{3+} and Yb^{3+} atomic and covalent radii are almost identical so the question is which property causes different band spectral shape?

One of the reasons can be that TeO_4 structural unit is more isolated from the amorphous network than in the case with Tm doping of TZN host which makes it narrower.

In Zhao paper [6] excitation wavelength for Tm/Yb doped tellurite glass was the same, 514.5 nm, but the change in TeO_4 band shape was not observed. Similar behavior of tellurite glass doped with Yb^{3+} at 514.5 nm laser excitation is not observed in literature to the best of author knowledge.

IV. CONLUSION

This paper reports structural changes of tellurite glasses observed by using Raman spectroscopy.

Raman spectroscopy showed that doping with Yb^{3+} influenced the TeO_3 structural unit and its role in glass matrix when the high concentration of thulium ions is present. A more precise definition and explanation would require additional measurements. As in the case of Tm^{3+}, position of TeO_4 and TeO_3 bands remained unchanged as well as the mutual ratio under 514.5 nm excitation.

All glass groups were characterized by the boson peak positioned at around 40 cm^{-1} and related to acoustic phonons. Boson peak linearly decreased with increasing dopant concentration indicating the increase of the middle range order.

We present some results regarding the coating of spherical microresonators and their different applications in photonics. The spherical microresonators high Q-factor and low mode volume make them perfect for a number of photonics applications. A thin film coating on the surface of the resonator using an optically active or passive layer can be used to modify signifactly the optical properties of the resonator. We have succesfully coated the microresonators with a sol-gel derived coating and have studied the effect of the coating on different optical and spectroscopical properties of the microresonator.

IV. INTRODUCTION

Microresonators are small resonators of dimensions that can range from 30 μm to 1mm [1]. Generally they can be produced in different shape, of different materials and by different methods. The simplest microresonator is a silica microsphere which can be made by simply melting the tip of a standard telecom optical fibre by a oxy-gas torch or by an electrical spark. After the fibre melts, the surface tension will form it into a perfect sphere. This kind of silica microresonator can exhibit very high Q-factors (10^7 up to 10^9), Q-factor defined as the average number of round trips a photon can take inside a resonator before being absorbed or scattered inside the microresonators the light is confined by total internal reflection, so that the light is travelling along the circumference of the resonator. The modes of such resonators are called whispering gallery modes (WGM). In addition to the high quality factors the WGM also have a very low mode volume which means that we can confine light in a very small volume for a long period of time. This makes them very useful for different applications such as sensing [2], lasers and amplifiers[3], optoelectronic oscillators or non-linear optics[4].

V. THEORY

To calculate the eigenfrequencies of the whispering gallery modes of a coated sphere the Aden-Kerker generalization of the Mie scattering theory can be used [5,6]. The radial dependence of the electric field of the WGMs is given by the Bessel function in the core, a linear combination of the Bessel and Neumann functions in the coating and by the Neumann function outside of the sphere. The continuity of the tangential components of the electric and magnetic fields at the core-coating (r_1) and coating-air (r_2) interfaces leads to the following system of equations:

$$\begin{aligned}
&\psi_l(kn_s r_1) = \alpha\,\psi_l(kn_c r_1) + \beta\,\chi_l(kn_c r_1)\\
&P_s\,\psi_l'(kn_s r_1) = \alpha\,P_c\,\psi_l'(kn_c r_1) + \beta\,P_c\,\chi_l'(kn_c r_1)\\
&\alpha\,\psi_l(kn_c r_2) + \beta\,\chi_l(kn_c r_2) = \gamma\,\chi_l(kn_0 r_2)\\
&\alpha\,P_c\psi_l'(kn_c r_2) + \beta\,P_c\,\chi_l'(kn_c r_2) = \gamma\,P_0\,\chi_l'(kn_0 r_2)
\end{aligned} \qquad (1)$$

where $k=2\pi/\lambda$, n_s, n_c ,n_0 are the refractive indices of the sphere core, coating and surrounding medium respectively, $\psi_l(x)=xj_l(x)$ and $\chi_l(x)=xn_l(x)$ where j_l and n_l are the spherical Bessel and Neumann functions respectively, $P_s=n_s$, $P_c=n_c$, $P_0=n_0$ for the transversal electric (TE) and $P_s=1/n_s$, $P_c=1/n_c$, $P_0=1/n_0$ for the transversal magnetic (TM) modes. This system of equations can be solved numerically to obtain the eigenfrequencies of the WGMs. Each mode will be characterized by three integer number p, l and m, where p, $l-|m|$ and m correspond to the number of nodes of the wave function in the radial, azimuthal and polar directions respectively. Usually, the mode which can be coupled to the most efficiently is the $p=0$ fundamental mode because it is the mode which is confined closest to the surface and therefore will have the largest part of its electric filed extending outside of the sphere. This is

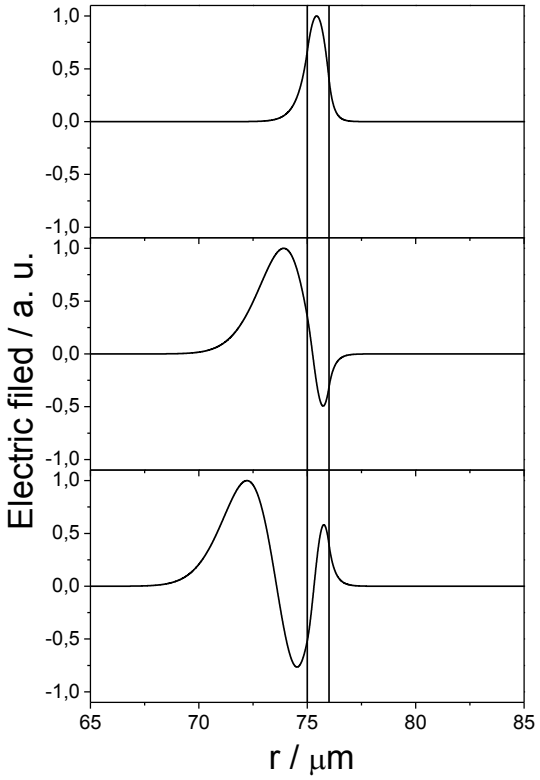

Figure 1. The electric field distribution of the fundamental (p=0) and first two internal (p=1,2) WGMs of a coated microsphere

demonstrated in Figure 1 which shown the WGM field profiles for a coated microsphere for the fundamental (p=0) and first two internal modes (p>1,2) for a 150 μm silica (n=1.44) microsphere coated with a $70SiO_2$-$30HfO_2$ coating(n=1.6) at the wavelength of 1550 nm.

VI. EXPERIMENT

The microspheres were produced by melting the tip of a standard optical telecommunications fiber. The diameter of the microspheres was found to be 130-160 μm using a standard optical microscope. The microsphere was coated with a film of composition $70SiO_2$-$30HfO_2$ activated with 0.3% mol Er^{3+}. The films were coated using the dip coating technique. The sol was prepared by mixing a solution of $Si(OC_2H_5)_4$ (TEOS), HCl, H_2O, CH_3CH_2OH (ethanol) and $HfOCl_2$. The molar ratio between TEOS, water and the catalyst (HCl) was $n(H_2O) : n(Si(OC_2H_5)_4) : n(HCl) = 200:100:1$. The molar ratio between the TEOS and $HfOCl_2$ was chosen to be $n(Si(OC_2H_5)_4) : n(HfOCl_2) = 70:30$ on the basis of previous experiments [18]. The overall amount of Si and Hf in the sol was controlled so that $c(Si(OC_2H_5)_4) + c(HfOCl_2) = 4.48\ 10^{-4}$ mol/mL in order to have a sol viscosity which makes the dipping rate 30 nm/dip. $Er(NO_3)_3$ x $5H_2O$ was added to activate the film so that the molar concentration of Er^{3+} in the sol is 0.3 % mol. The mixture of TEOS, HCl and H_2O was prehydrolised at 65 ^oC for 1 hour before adding the $HfOCl_2$ and the Er $(NO_3)_3$ x $5H_2O$. The entire mixture was then stirred for 16 h until the sol became transparent. Each microsphere was dipped 30 times into the sol. The dipping speed was 40 mm/min and the dipping time 20 s. After each dip the microspheres were densified at 900 ^oC for 50s and after every 10 dips an additional densification was made for 2 min. At the end of the deposition a final densification for 5 min at 900 ^oC was made.

The measurement of the whispering gallery modes was done using a microsphere-taper coupling setup. A 1480 nm fiber diode laser was used for the pumping. The coupling of light inside the sphere was achieved using a tapered fiber. The pump laser inside the microsphere is absorbed by Er^{3+} ions inside the coating which in turn emit in the C-band wavelength region around 1550 nm. The emission will be greatly enhanced at wavelengths which correspond to the WGMs of the microsphere. This emitted light is then coupled out of the sphere and into the taper and detected by an Anritsu MS9710B optical spectrum analyzer. The Q-factor of the spheres was measured by sweeping a tunable laser over a single resonance and monitoring the transmission, all in the C-band range. The Q factor is then the ration of the laser frequency to the width of the resonance dip.

VII. RESULTS

The spheres were produce by melting the tip of a standard SMF28 optical fiber. The Q-factor of the spheres was measured before the coating and a typical Q-factor measurement is presented in Figure 2. There is a dip in transmission clearly visible which corresponds to a single WGM. The 35 MHz width of the dip corresponds to a Q-factor of about $7x10^6$. This is a typical value of the Q-factor of our spheres before the coating. For most of our spheres the Q-factor before the coating falls in the range between $5x10^6$-$2x10^7$. After the coating the Q-factor is usually reduced by an order of magnitude ($5x10^5$-10^6) which is because of the erbium absorption. In fact the Q-factor of a coated sphere is lowest at about 1530 where there is the maximum of erbium absorption and then increases when going towards higher wavelengths (1550-1560 nm). A picture of the microsphere and the taper used

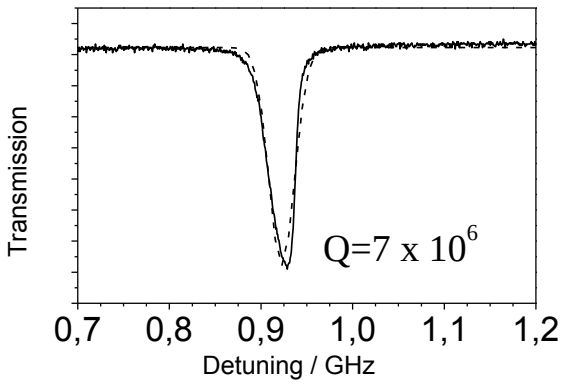

Figure 2. A typical Q-factor measurements of a silica microsphere. The dotted lines are the Lorenzian fit to the experimental data

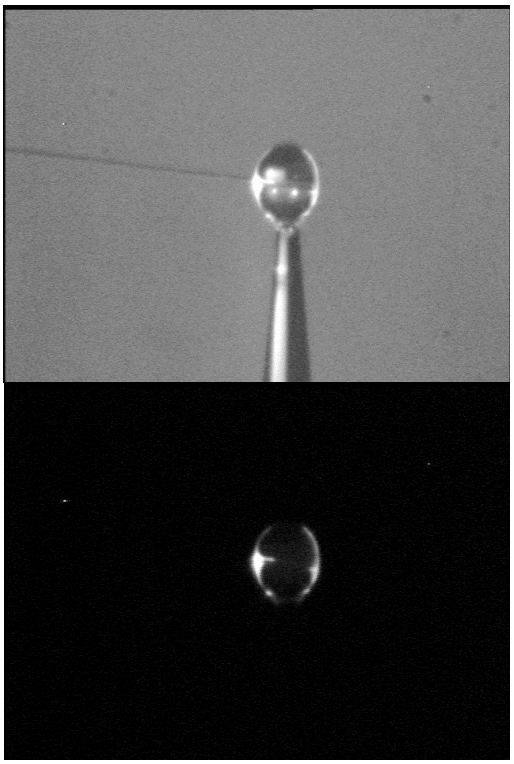

Figure 3. Optical microscopy images of the microsphere and the taper. The lower image shows the Er^{3+} green upconversion

for the pumping and signal recovery is shown in Figure 3. In the bottom part of Figure 3 can be seen the green Er^{3+} up-conversion from the WGMs of the microsphere. This up-conversion is the proof that we are efficiently coupling light inside the resonator.

A typical WGM luminescence spectrum is shown in Figure 4. The sharp peaks seen in the Figure are to be attributed to the WGMs with a different value of the *l* number. The modes with different values of the *m* number are frequency degenerate so that they cannot be observed unless the sphere is slightly elliptical. The modes presented in Figure 4 can be attributed to the fundamental (p=0) mode since the internal (p>0) modes are more difficult to couple light in and/or out of and therefore are less likely to be visible. In Figure 5 is shown a lasing spectrum of a coated microsphere. If the coating is thick enough so that the number of erbium ions interacting with

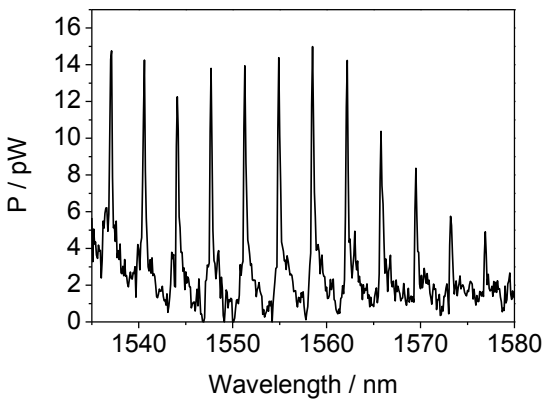

Figure 4. The WGM luminescence of a coated microsphere

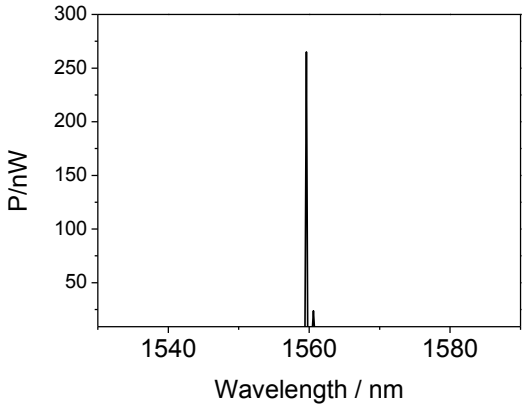

Figure 5. Lasing spectrum of a coated microsphere

the electric field of the WGMs is high enough, the stimulated emission gain can become greater than the cavity round trip loss and the sphere will start to lase. In Figure 5 we can see the lasing spectrum of a WGM with the peak power of 280 nW. To calculate the mode volume of the WGMs in Figures 4 and 5 we first need to consider the *m* values of the modes. For the studied system we can calculate the effective refractive index of the fundamental (l=m) mode around 1560 μm (l=430) which is around 1.53. Since the effective index of a body of a 3 μm taper is about 1.4 we can conclude that the taper is phase matched to the WGM with m=l*1.4/1.53=394. Thus we can conclude that the azimuthal mode distension is about $R\pi(l-m)/l$=18 μm. Since the radial distension for the p=0 mode is about 1μm and the polar distension is just the circumference of the sphere we conclude that the mode volume is around 8000 μm^3.

V. CONCLUSION

We have produced spherical microresonators and coated them with an optically active layer. We observed both the WGM luminescence and lasing. The maximum lasing peak power was found to be 280 nW

Examination of silicon material properties using THz Time-Domain Spectroscopy

pejcinb@pdx.edu

Abstract - High-resistivity silicon is a very popular choice for substrate material when examining e.g. various thin films, biological samples etc. using THz radiation. This paper provides an overview of research on its THz properties, examines various practical issues appearing when determining its properties and reports results on complex index of refraction, permittivity and conductivity, obtained using modern instrumentation. Potential problems related to water absorption are highlighted. Various Drude models and parameters are also presented and discussed.

I. INTRODUCTION

THz Time-Domain Spectroscopy (TDS) is fast becoming a standard tool for examination of material properties of both electronic and optical materials, as well as detection of various biological and chemical compounds. Due to its relative transparency at THz frequencies and availability, many researchers use high-resistivity silicon wafers as the most convenient substrate to hold their samples. Therefore, it is imperative to understand hi-res silicon properties in detail and as accurately as possible.

A. History

Advantages of hi-res Si for THz use were recognized early, which prompted more detailed studies. THz TDS studies of silicon date back to early 1990-s and there have been a few follow-on studies [1-9]. Many other semiconductor materials were subject to TDS studies, which filled a gap between the electronic properties measured at DC to mm-wave frequencies, and optical characterization from far-IR to visible and beyond. Some exciting new materials, such as GaN, have been studied in some detail, see e.g. [16].

In the earlier days TDS systems were constructed from separate components, which allowed greater flexibility in, for example, choice of sources and detectors. Nowadays, several commercial systems exist, e.g. Advanced Photonix [11] and Teraview [12], each with is own specific advantages. One major advance has been in the speed of processing data. In the earlier literature it is rare to find use of averaging, which is either not mentioned or very few averages are reported. With T-Ray 4000 system used at Portland State University we can easily accumulate 5000 to 10000 responses in a matter of minutes. This brings the noise floor down which improves signal-to-noise ratio and increases the measurement bandwidth.

Theoretical foundation for most of the early experimental studies was provided by Drude theory, which showed reasonable accuracy and could fit most of the data across 0.2 – 2 THz or more. In cases where optical phonons contributed to THz response, such as ZnS, additional models had to be included [15]. More recently, detailed simulation and theoretical studies have been published which enable detailed and more first-principles-based comparison between theory and experiments [6] and modeling is moving beyond simple fitting of parameters to experimental data.

II. TDS MEASUREMENT SYSTEM

THz radiation can be generated and detected using differnt operating principles but current systems are predominantly based on photoconductive switching where ps-long pulses are generated by discharging a capacitor/antenna and a similar antenna/switch is used on output for detection [14]. Key advantage of TDS systems is coherent detection so that both amplitude and phase can be measured after FFT to frequency domain.

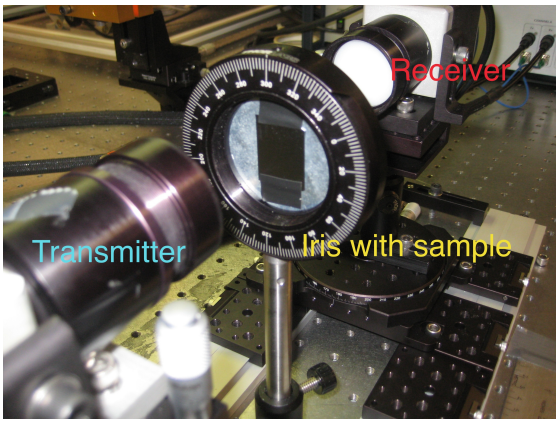

Figure 1 TDS measurement system in transmission mode with metal iris holding a sample. Iris prevents collimated THz beam from reaching the receiver without passing through the sample.

Experiments can be set up in reflection or transmission mode. The former is preferred for highly absorptive materials where very thin samples would be required for transmission measurements. Whenever possible, experimentalists prefer transmission measurement due to its simple setup and easyly obtained reference waveform.

When samples are big enough to cover the entier THz beam then all that is required is a simple holder with adjustments of hight and rotation to make sure that sample is normal to the beam. If samples are smaller than the beam, then some metal iris is used to restrict the beam and to hold the sample, see Figure 1. Of course, this leads to reduced signal strength. Alternatively, a focusing mirror or lens can be used to focus the beam on the

sample. Focusing should provide larger signal strength but its alignment is more involved.

In this report we use collimated beams with iris. Figure 1 shows a typical setup in transmission mode with a rotating iris. Focusing setup would look exactly the same but would use different lenses inside the transmitter and receiver heads.

Because of susceptability of THz radiation to absorption by water vapor, best results are obtained in enclosed environments filled with dry air or nitrogen. In this set of measurements our samples were in regular lab environment with relative humidity of around 30-35%.

A. Time-domain results

There are two modes in which TDS system can be used: transmission and reflection. Below, in Figure 2, are two examples of measurements on two silicon wafers: one is nominally high-resistivity (ρ > 10 kOhm-cm) and another has measured resistivity of 1.5 Ohm-cm. Interpretation of transmission measurements is fairly straightforward since we can easily observe two main effects: reduction of peak amplitude and delay. In addition, in hi-res sample we can observe multiple "echoes" of the signal as it is reflected within the sample multiple times. This is also called Fabry-Perot effect. The 1.5 Ohm-cm sample is more absorptive and it is difficult to distinguish secondary echoes.

Note that we could potentially utilize up to 320 ps of waveform, which is limited by the system, but internal reflections, e.g. reflections back-and-forth between the lenses, may appear and adversely affect parameter extraction. With around 125 ps included we can get 8 GHz resolution in frequency, which is more than sufficient for this study.

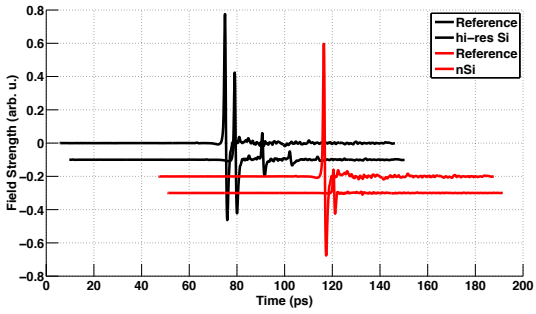

Figure 2 Time-domain waveforms from transmission TDS measurement of hi-res Si and 1.5 Ohm-cm n-Si wafers. They include multiple reflections within Si samples (Fabry-Perot) which have to be accounted for. Reference is obtained by removing the sample from the THz beam path.

Reflection mode results for the same samples are shown in Figure 2. Signal strength is reduced due to use of beam splitter but the advantage is that both incident and reflected beam are normal and there is no need to align transmit and receive heads, as is done in, e.g. elipsometry type of measurements. Reference waveform is provided by a "perfect" mirror, which in practice means metalic surface. In our case we used self-adhesive copper tape to cover the surface of another silicon wafer of similar thickness.

Interpretation is not as simple but we could get a first-order estimate of index of refraction by using the ratio between reference and sample waveform peaks in Fresnel coefficient equation. Reference waveform may have to be mathematically "shifted" in phase so that its front (reflection) surface lines up with sample one [17].

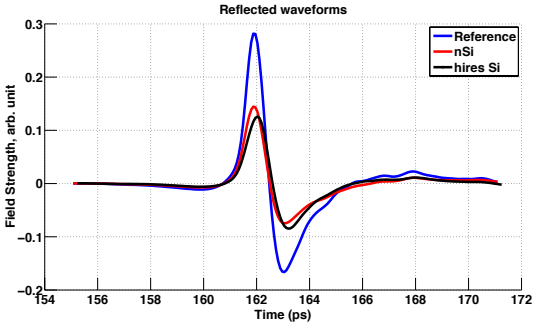

Figure 3 Time-domain waveforms from reflection TDS measurement of hi-res Si and 1.5 Ohm-cm n-Si wafers. Typically, only the first reflection is used and the rest of the waveform is windowed out. Reference waveform is from a perfect reflector (mirror).

Note that the waveforms have been windowed and only the first reflected pulse is retained. There is only around 15 ps of waveform which gives frequency resolution of around 65 GHz which would be sufficient for this study. The rest of this paper will deal exclusively with transmission mode measurements of silicon samples.

III. THEORY OF TEM WAVE PROPAGATION

Fundamental equation for transfer function of EM signal through sample is given in eq. (1) [13]. The summation part includes Fabry-Perot (FP) effects and is neglected when time-domain waveform is windowed to contain only the main (first) pulse. If more than 5 pulses (echoes) are included then a limit of infinite FP reflections can be applied resulting in eq. (2).

$$H(f) = t_{12}(f)t_{21}(f)exp\left(-\frac{i2\pi fd(\tilde{n}(f)-n_{air})}{c}\right) \cdot \sum_{l=0}^{m}\left[r^2(f)exp\left(-\frac{i4\pi fd\tilde{n}(f)}{c}\right)\right]^l \quad (1)$$

$$H_2(f) = \frac{t_{12}(f)t_{21}(f)exp\left(-\frac{i2\pi fd(\tilde{n}(f)-n_{air})}{c}\right)}{1 - r^2(f)exp\left(-\frac{i4\pi fd\tilde{n}(f)}{c}\right)} \quad (2)$$

$$r(f) = \frac{\tilde{n}(f)-n_{air}}{\tilde{n}(f)+n_{air}},$$

$$t_{12}(f) = \frac{2n_{air}}{\tilde{n}(f)+n_{air}}, \quad t_{21}(f) = \frac{2\tilde{n}(f)}{\tilde{n}(f)+n_{air}}$$

The transfer function given above is equated with ratio of measured response with sample and without it. The resulting set of nonlinear equations is solved for complex index of refraction $\tilde{n} = n_1 - i\,n_2$ using MATLAB function fsolve. Note that this derivation implies an EM

wave of the form $E(t) = E_0 \exp[i(\omega t - kx)]$ which has a $+\omega t$ term. Many authors use different definition which is complex conjugate of this one. As a result, our definitions of index of refraction, permittivity, and conductivity would have negative sign for their imaginary parts: $\tilde{\epsilon} = \epsilon_1 - i\,\epsilon_2$ and $\tilde{\sigma} = \sigma_1 - i\,\sigma_2$. If we take the complex conjugate of $\tilde{n}$ and use that to calculate permittivity and conductivity then we can keep the + sign in their definitions. In our definition n_2 is a positive number (also called extinction coefficient), as required to have attenuation in the sample.

Permittivity is calculated using $\tilde{\varepsilon} = \tilde{n}^2$ and to calculate conductivity we use this definition:

$$\tilde{\epsilon} = \epsilon_\infty + \frac{i\tilde{\sigma}}{\omega\varepsilon_0} \qquad (3)$$

where ϵ_∞ is permitivity in the limit of very high frequency where there is only dielectric response and no contribution from conduction. Unlike $\tilde{n}$ and $\tilde{\varepsilon}$, complex conductivity $\tilde{\sigma}$ has units and is typically reported as [1/(Ohm-cm)] or [S/cm].

Next, we need to model the frequency behavior of permittivity and conductivity, which is often done using Drude model and its variants. The simplest Drude model states

$$\epsilon = \epsilon_\infty + \frac{i\sigma}{\omega\varepsilon_0} = \epsilon_\infty - \frac{\omega_p^2}{\omega(\omega + i\Gamma)} \qquad (4)$$

$$\tilde{\sigma} = \frac{i\varepsilon_0\omega_p^2}{(\omega + i\Gamma)} \qquad (5)$$

where ω_p is plasma frequency and Γ is scattering or damping rate. These two parameters are optimized to fit the measured results and can be used to calculate carrier concentration and mobility [9]. In certain situations Cole-Davidson or Drude-Smith variants may provide a better fit [9], and a generalized form of conductivity was proposed in [6].

IV. Results

In this section we will present extracted values of index of refraction $\tilde{n}$, permittivity $\tilde{\varepsilon}$ and conductivity $\tilde{\sigma}$ vs. frequency for hi-res and 1.5 Ohm-cm silicon samples. These are just different representations of the same data so no new information is gained by switching from one to the other. However, modeling of the frequency response is almost never done for n; instead, Drude, Lorentz, Debye etc. models are applied to permittivity and/or conductivity. Representation in permittivity allows comparison with, or utilisation of, high frequency limit where we usually know optically measured value. Similarly, representation in conductivity allows comparison with measured DC values and calculation of carrier conecntration and mobility.

A. Index of refraction

Real part of index of refraction is shown in Figure 4 and imaginary part in Figure 5. When multiple reflections are included there is some residual oscillatory behavior despite optimization of sample thickness, as explained in [10]. Nonetheless, the results are the virtually the same independent of data processing method used. Extracted real values are very close to those reported for hi-res silicon and 1.5 Ohm-cm shows qualitative behavior observed by others [1-3]. Imaginary part of n is infrequently reported but, as will be shown later, other derived parameters are in good agreement with published results.

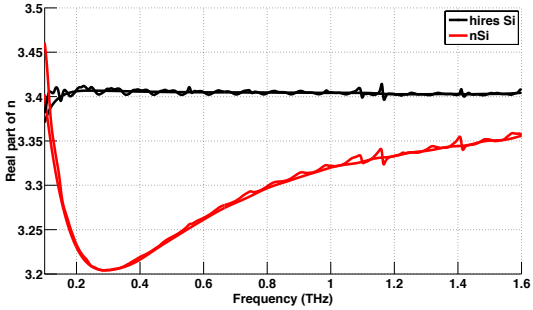

Figure 4 Real part of index of refraction for hi-res Si and 1.5 Ohm-cm n-Si wafers. Results for multiple-reflections and single pulse are included.

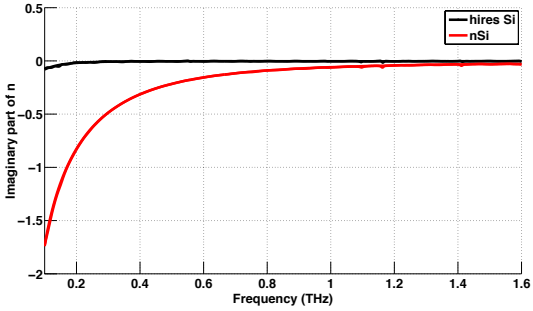

Figure 5 Imaginary part of index of refraction (= -n_2) for hi-res Si and 1.5 Ohm-cm n-Si wafers. Results for multiple-reflections and single pulse are included.

B. Permittivity

Given the simple square relationship between $\tilde{n}$ and $\tilde{\varepsilon}$, Figure 6 has no surprises. Real part for both samples converges to high frequency value of around 11.6. Imaginary part is related to conductive losses and it falls of with frequency but this is more easily interpreted by looking directly at conductivity.

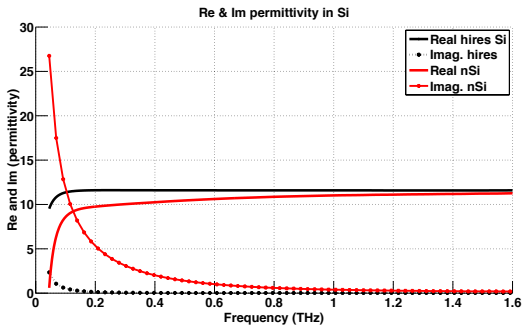

Figure 6 Real and imaginary permittivity (ϵ_1& ϵ_2) of hi-res Si and 1.5 Ohm-cm n-Si wafers. Only the first transmitted pulse is included.

C. Conductivity

Real and imaginary conductivity is shown in Figure 7. By extrapolating real part to DC we can extract resistivities of around 1.5 Ohm-cm which agrees well with four-point probe measurement results. The hi-res sample, however, shows an upswing at lower frequencies which would extrapolate to resistivity of around 20 Ohm-cm. We belive that this is due to a loss of precision at frequencies below 0.2 THz and that we should extrapolate from higher frequencies, in which case we obtain ≈100 Ohm-cm, which is closer to the nominal value. We will also do a four-point probe measurement to verify the nominal value.

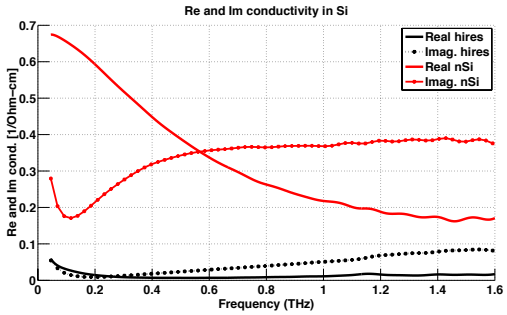

Figure 7 Real and imaginary parts of conductivity (σ_1 & σ_2) in hi-res Si and 1.5 Ohm-cm n-Si wafers. Only the first transmitted pulse is included.

Another interesting feature is frequency behavior of imaginary component. In both cases it plateaus at certain value. Others [1-3] have reported that it shows a maximum but it becomes less pronounced at lower resistivities. Reported data, however, is farily noisy which makes peak determination difficult. One possible reason for this behavior is the measurement environment and we will repeat these measurements in dry air and compare the results.

D. Extraction of Drude parameters

Despite some observed qualitative differences relative to earlier results for imaginary part of conductivity we attempted to extract parameters for simple Drude model. Fitting was done in MATLAB using lnsqnonlin and lsqcurvefit functions. Frequency range was limited to 0.31 to 1.1 THz . As observed by others, it can be difficult to fit Drude model if the peak in imaginary component is not well defined. As shown in Figure 8, fit for the real part is reasonably good but there is some divergence above 1 THz. Also shown are results from [3] which used samples with resistivity of 1.31 Ohm-cm.

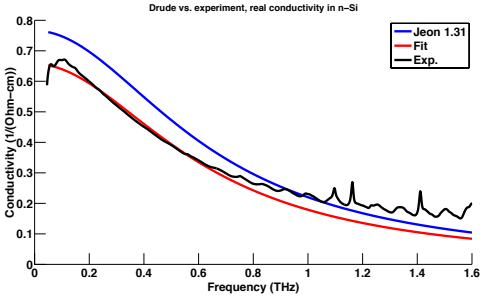

Figure 8 Real part of conductivity from [3] (blue), our measured results (black), and fitted Drude response (red). Multi-reflections.

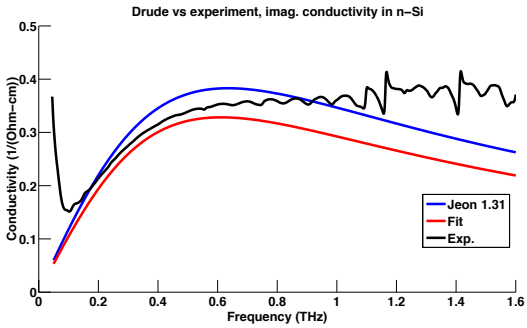

Figure 9 Imaginary part of conductivity from [3] (blue), our measured results (black), and fitted Drude response (red). Multiple reflections are included.

A summary of parameters from the literature and in this work is shown in Table 1. Imaginary component, shown in Figure 9, is not fitted as well, especially above 1 THz.

Table 1 Drude model parameters for silicon as reported in the literature. DC resistivity is from four-point probe measurements.

0.17	4.49	1.985	[2]

E. Thickness determination

Accurate material parameter extraction is critically dependent on determination of sample thickness. When possible, it can be measured directly using a micrometer but it has been shown that it can also be determined by optimization procedure that minimizes oscillations in transfer function. Additional geometry parameter that can also be used is angle of incidence which is usually assumed to be 0 degrees.

We have applied procedure given in [10] and obtained reasonable agreement with micrometer measurements. One problem is that in our case some “oscillations“ (or resonances) are real water vapor absorption lines and not due to Fabry-Perot effect. This makes thickness optimization less effective since it tends to weigh more heavily areas of rapid change, i.e. resonances. This problem was circuimvented by restricting the optimization

bandwidth but in the future we will perform the measurements in dry-air environment.

Figure 10 illustrates effects of 2 μm and 4 μm change in assumed thickness on real part of index of refraction. Relative changes are small, on the order of 1%, which is acceptable in many situations.

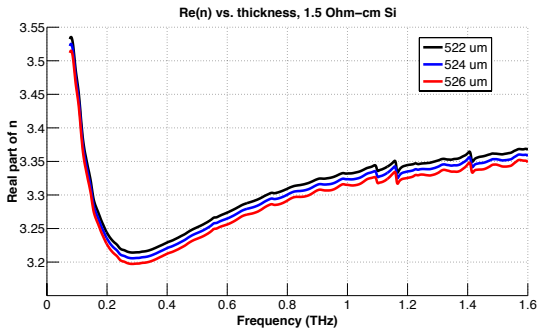

Figure 10 Variation of real part of index of refraction with assumed sample thickness. Silicon wafer has 1.5 Ohm-cm resistivity. Multiple reflections are included.

On the other hand, Figure 11 illustrates changes in real and imaginary part of conductivity. Real part is practically unaffected but imaginary part exhibits large changes and even shows a slightly different trend: 522 μm is starting to fall off with frequency while 526 μm increases.

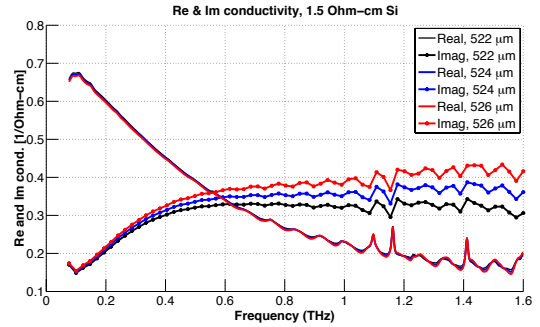

Figure 11 Variation of real and imaginary parts of conductivity with assumed sample thickness. Silicon wafer has 1.5 Ohm-cm resistivity. Multiple reflections are included.

Therefore, extracting material paramters with the best possible precision requires attention to details, from utilizing the best environemnt (dry air or nitrogen, if possible) to measuring thickness through independent means. Some parameters are more susceptible than others and we have to determine how much precision is needed for a specific problem. Some estimates, with 1% or 2% accuracy, can be obtained fairly quickly and that may be all that we need.

V. CONCLUSIONS

A brief review of various THz TDS techniques was given and pros and cons discussed, followed by a discussion of theory behind EM wave propagation in dielectric samples. Measurements and extracted parameters – index of refraction, permittivity and conductivity - were presented for two silicon samples. Real parts behaved as expected but imaginary part of conductivity did not show a distinct peak. Parameters of Drude model were extracted but only approximately due to lack of distinct peaks. Table of Drude models was compiled for comparison with presented results. Finally, influce of sample thickness and environement on extracted material parameters was discussed.

***Abstract* – Graphene field-effect transistors are fabricated using CVD-grown graphene and a wet transfer technique. Devices are characterized in terms of carrier mobility, contact resistance, output and transfer characteristics. We found that the mobility decreases and contact resistance increases with the decreasing graphene microstrip width. In addition, we found that graphene FET characteristics strongly depend on annealing time. The behavior of device characteristics is explained by discussing carrier scattering on defects and impurities, and the formation of *pn*-junctions in graphene.**

I. INTRODUCTION

Due to its high carrier mobility and two-dimensional structure, graphene-based field-effect transistors (FETs) have become promising alternatives to silicon MOSFETs for future devices [1]. Graphene exhibits a linear dispersion relation, which results in massless carriers and low density of states (DOS) [2]. The former is responsible for the high carrier velocity and mobility in graphene (in excess of 200.000 cm^2/Vs in suspended samples [3], ~10.000 cm^2/Vs in graphene on SiO_2 [4]), whereas the latter results in low carrier injection into graphene. Therefore, despite the high carrier mobility in the channel of the graphene FET, the ON-state performance is limited by the contact resistance that is governed by injection of carriers from the metal.

The feasibility of graphene FETs depends on the OFF-state current and ON-OFF current ratio, which is crucial for digital/logic applications, and on the ON-state performance, which is crucial for high-speed applications. Most of the papers reported so far have focused on reducing I_{OFF} through bandgap engineering, e.g. using graphene nanoribbons [5], [6], [7]. However, the number of reports on examining and improving the ON-state performance is limited [8], [9]. Hence, both the experimental study and theoretical analyses of carrier transport and contact resistance are necessary. Although the mechanically exfoliated graphene exhibits the highest mobilities at room temperature, the method is not viable for larger scale production. The growth of graphene by chemical vapor deposition (CVD) on certain metal foils has become a promising method [10], [11]. Nevertheless, a wet transfer technique is necessary to transfer the graphene layer onto substrate, which results in defects and may result in doping of graphene. In this paper, we study the feasibility of CVD-grown graphene FETs for micro-scale applications by examining the properties of carrier mobility, contact resistance and *I-V* characteristics. We focus on the analysis of size effects, i.e. the impact of graphene microstrip width, and annealing time (used with the initial aim of reducing the unwanted doping) on device figures of merit.

II. DEVICE FABRICATION

Chemical vapor deposition (CVD) of carbon on thin copper foils was used for the fabrication of mono-layer graphene. The process was performed in a tube furnace at 1000 °C and low pressure, using a mixture of a high purity methane (CH_4) and hydrogen (H_2). The details of the graphene growth process can be found elsewhere [10].

The substrate was a heavily doped *n*-type silicon with a 300 nm thick layer of SiO_2, where silicon is the gate electrode, while SiO_2 serves as the gate dielectric. The substrate was cut into several pieces (dies) each approx. 1.5 cm × 1.5 cm in size, after which the dies were cleaned (acetone rinse, isopropanol (IPA) cleaning, and O_2 plasma ashing). Graphene was transferred to the substrate using the wet transfer technique [12], which is briefly described here. The copper foil with graphene was fixed to an auxiliary wafer and a thick layer of polymethyl methacrylate (PMMA) was coated onto the foil with a spin coater (1000 rpm, 45 s), followed by bake-out at 180 °C for 2 – 3 min on a hot plate. The copper foil with graphene and PMMA on top of it was cut into smaller pieces, each with approx. dimensions of 1 cm × 1 cm. The copper-foil-graphene pieces were put onto the surface of the copper etchant ($FeCl_3$) for 10 min, keeping PMMA on the top side. A transparent layer of PMMA was floating on the surface with graphene attached to the bottom of the PMMA layer after the copper was etched out. After copper etching, the PMMA-graphene sample was cleaned in deionized (DI) water in two steps (10 min two times in two separate beakers). After DI cleaning, the floating PMMA-graphene sample was transferred to substrate using the previously prepared Si-SiO_2 dies. In this final step of the transfer process, we obtained the Si-SiO_2-graphene-PMMA layered structure. In order to allow the following fabrication steps, the PMMA was removed by acetone (30 min) and the dies were cleaned by IPA rinsing (5 min) and N_2 blow drying.

The next step was device fabrication using the obtained Si-SiO_2-graphene samples. The fabrication of graphene FETs consisted of three main steps: first lithography, metal deposition, and second lithography. During the first lithography, contacts and wires were defined. The die was coated with AZ5214 photoresist with

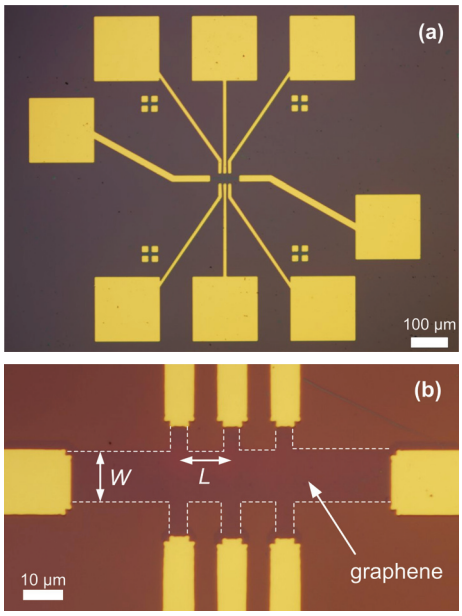

Fig. 1. Device layout showing (a) arrangement of contact pads and wires, and (b) magnified central part with the graphene layer.

a spin coater (4000 rpm, 40 s), followed by baking at 100 °C for 1 min. Next, the sample was exposed to UV light (365 nm) in the lithography system (hard exposure for 5 s, bake-out at 120 °C for 1 min, flood exposure 120 s). Photoresist was developed in 1 : 5 AZ400K : H_2O solution for 40 s, after which the dies were rinsed with DI water and N_2 blow-dried. Metal deposition (10 nm/100 nm Ti/Au) was performed using the e-beam metal deposition system. Metal lift-off and photoresist removal was done in acetone for 2 h, which was followed by additional acetone rinsing, cleaning by IPA and N_2 blow drying. The layout of the graphene layer was defined in the second lithography. In the lithography system, the exposure lasted 10 s in the hard-contact mode, and the photoresist was developed in 1 : 4 AZ400K : H_2O solution (1 min). After photoresist development, the die was cleaned with DI water and N_2 blow drying. The excess graphene was etched away by O_2 plasma (in plasma asher system for 10 min). Finally, the photoresist was removed by acetone (the samples were left in it for 2 hrs). The last step was cleaning with IPA and N_2 blow drying.

Figure 1(a) shows the final arrangement of contact pads (200 µm × 200 µm) and wires (10 or 20 µm in width), while the magnified central part in Fig. 1(b) shows the graphene area obtained after the second lithography. The width of the graphene microstrip in Fig. 2(b) is ~15 µm. The layout shown in Fig. 1 is standard for transport characterization using the four-probe setup [13]. We have fabricated devices with different graphene microstrip widths (5, 8, 10 and 15 µm) and different separations of inner electrodes (8 and 10 µm).

III. Characterization of Graphene FETs

A. *Raman Spectroscopy*

The number of layers and quality of graphene samples can be examined by Raman spectroscopy [14], [15].

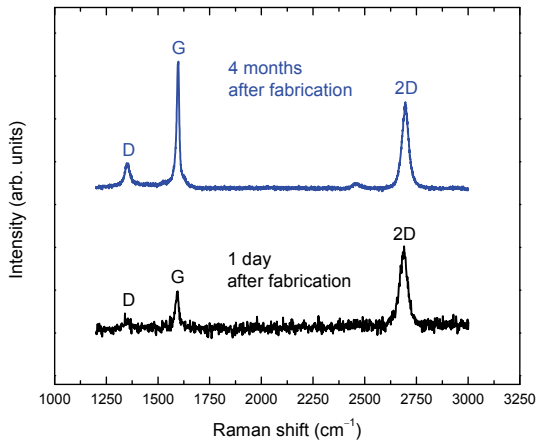

Fig. 2. Typical Raman spectra of graphene measured ~1 day and ~4 months after fabrication. The apparent noise in the spectrum of the fresh graphene sample is due to shorter integration time.

Typically, a fresh single-layer graphene (SLG) exhibits a Raman spectrum that contains two main peaks: G (graphite) peak centered at ~1580 cm^{-1} and 2D (double resonant defect) peak centered at ~2700 cm^{-1}. The G peak comes from phonon modes at the zone center (in the vicinity of Γ point). The fresh undoped SLG exhibits the intensity ratio I(G)/I(2D) of ~0.3. Furthermore, the 2D band can be approximated by a single Lorentzian curve in the case of SLG, which indicates a single Raman frequency. Yet another feature of SLG is that the FWHM of the 2D band equals ~30 cm^{-1}. The D (defect) peak centered at ~1350 cm^{-1} can be also observed, which depends on defect density in graphene. The D peak is a consequence of any kind of symmetry breaking; it can be induced by edge defects or defects at domain borders. In comparison to SLG, multi-layer graphene has a different 2D band shape and different values of I(G)/I(2D). For example, in bilayer graphene 2D band is approximated by four Lorentzian curves, with FWHM and I(G)/I(2D) ratio significantly higher than for SLG.

Raman spectroscopy was performed on all samples and a rather uniform response was obtained. Figure 2 presents a typical Raman spectrum of graphene devices, taken ~1 day after fabrication and ~4 months after fabrication. In the Raman spectrum obtained for fresh graphene devices, we observe a clear SLG signature; the G peak is centered at ~1590 cm^{-1} and 2D band is centered at ~2690 cm^{-1} with FWHM of ~35 cm^{-1}. In addition, the ratio I(G)/I(2D) equals ~0.4. Surprisingly, the spectrum taken ~4 months after fabrication exhibits I(G)/I(2D) ratio of ~1.46, while the G peak remains centered at ~1590 cm^{-1} and 2D band centered at ~2690 cm^{-1} with FWHM of ~35 cm^{-1}. The shape of the 2D band corresponds to that of SLG, however the values of I(G)/I(2D) is something we would expect from multi-layer graphene. Since the devices were kept at room temperature and in atmospheric conditions, we assume that a strong doping of graphene has occurred. Ni *et al.* [16] report that Raman spectrum of graphene can be modified by doping, i.e. that the G peak can increase compared to the 2D peak. Therefore, it seems that Raman spectroscopy can be used to analyze the doping and aging of SLG by monitoring the change in I(G)/I(2D).

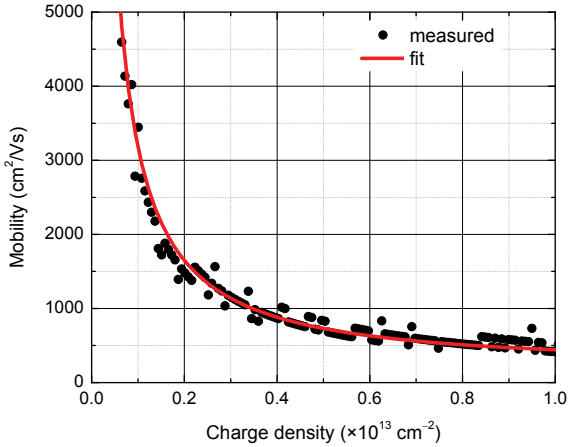

Fig. 3. Measured mobility of a typical graphene device with $W = 15$ µm and $L = 10$ µm at room temperature and in atmospheric conditions.

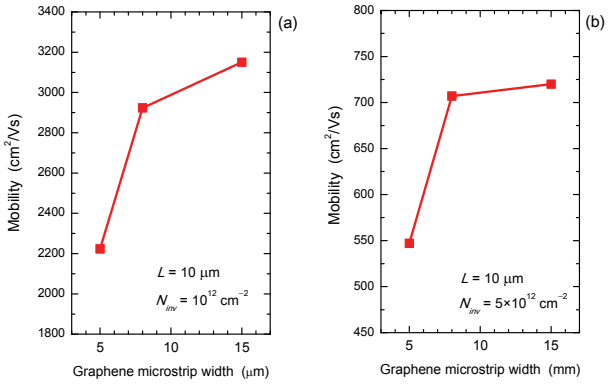

Fig. 4. Impact of downscaling of the graphene microstrip width on carrier mobility for N_{inv} of (a) 10^{12} cm^{-2} and (b) 5×10^{12} cm^{-2}.

B. *Mobility*

The mobility is measured by the four-probe method [13], [17] at room temperature and in atmospheric conditions. The measurement was performed on a probe station using HP 4145B Semiconductor Parameter Analyzer (HP-SPA). First, the low-field conductivity which is modulated by the back-gate voltage is extracted using the following equation:

$$\sigma = \frac{L}{W}\frac{I_{14}}{V_{23}}, \tag{1}$$

where W is the width of the graphene sample, L is the separation between inner electrodes 2 and 3, I_{14} is the current set between the outer electrodes 1 and 4, and V_{23} is the voltage drop measured between the inner electrodes. The mobility is calculated using:

$$\mu = \frac{\sigma}{qN_{inv}}, \tag{2}$$

where N_{inv} is the carrier density induced by the gate voltage calculated by the following expression:

$$N_{inv} = \frac{C_{ox}}{q}\left(V_G - V_D\right), \tag{3}$$

where C_{ox} is the oxide capacitance per unit area and $V_G - V_D$ is the gate voltage over-drive compared to the Dirac voltage. For $V_G - V_D > 0$, electrons are induced in graphene because the Fermi level is effectively shifted into the conduction band. In contrast, for $V_G - V_D < 0$ the Fermi level is in the valence band. For $V_G = V_D$ the Fermi level is precisely set at the crossing point of the valence and conduction bands, i.e. at the point of minimum DOS. This results in minimum conductivity at the Dirac point because carrier concentration is negligible for $V_G = V_D$.

The measured mobility of a typical graphene device with $W = 15$ µm and $L = 10$ µm at room temperature is shown in Fig. 3. Due to deviation of the measured mobility, which is a consequence of the low voltage resolution of the HP-SPA (1 mV), a fitted curve is also indicated. A rather high Dirac voltage is obtained from the measured conductivity, i.e. V_D is approx. 100 V, which means that graphene is heavily doped with *p*-type impurities. Consequently, the measured mobility shown in Fig. 3 is obtained for $V_G - V_D < 0$, i.e. it shows hole mobility. In order to measure the electron mobility $V_G > 100$ V is needed, which is beyond the range reachable by the HP-SPA. We report the mobility of 3180 cm^2/Vs at $N_{inv} = 10^{12}$ cm^{-2} (moderate inversion) and 450 cm^2/Vs at $N_{inv} = 10^{13}$ cm^{-2} (strong inversion). These values are comparable to other reported mobilities in CVD-grown and transferred graphene [17] and considerably lower than in exfoliated or suspended graphene samples [3], [4]. For the latter, the reasons are (i) the impact of remote phonon scattering that originates in the dielectric substrate, (ii) scattering on grain/domain boundaries that form during the CVD growth, (iii) scattering on lattice defects either on the edges of the graphene microstrip or on defects induced by the transfer process. Nevertheless, the fabricated graphene FETs exhibit greater mobility (3180 cm^2/Vs for holes) than bulk Si MOSFETs for either carrier type (~400 cm^2/Vs for holes, ~1500 cm^2/Vs for electrons). Hence, CVD-grown and transferred graphene is a feasible channel material as it exhibits a superior carrier mobility.

Devices with different microstrip widths were fabricated, which allows the investigation of the influence of edge-defect scattering on carrier mobility. Figure 4 presents the dependence of mobility on microstrip width for devices with L =10 µm, for two N_{inv} values. Both in weak and moderate inversion the mobility decreases with decreasing W. At $N_{inv} = 10^{12}$ cm^{-2}, the averaged mobility decreases from 3150 cm^2/Vs at $W = 15$ µm, over 2920 cm^2/Vs at $W = 8$ µm, to 2220 cm^2/Vs at $W = 8$ µm, i.e. mobility deteriorates by 29% when W is downscaled from 15 to 5 µm. In moderately strong inversion, i.e. for $N_{inv} = 5\times10^{12}$ cm^{-2} shown in Fig. 4(b), the decrease is approx. 24%. Mobility decrease reported in Fig. 4 indicates stronger carrier scattering in narrower microstrips. As shown in [7], [18], the contributions of all relevant scattering mechanisms increase when W decreases, and scattering induced by line-edge roughness exhibits an especially strong W-dependence. In the fabricated devices the relative ratio $\Delta W/W$ increases in narrower microstrips due to lithography resolution, which leads to stronger mobility degradation caused by the increased line-edge roughness scattering. In comparison to graphene nanoribbons ($W < 100$ nm) in which the strong W-dependence is naturally expected due to strong quantum confinement effects, mobility features reported

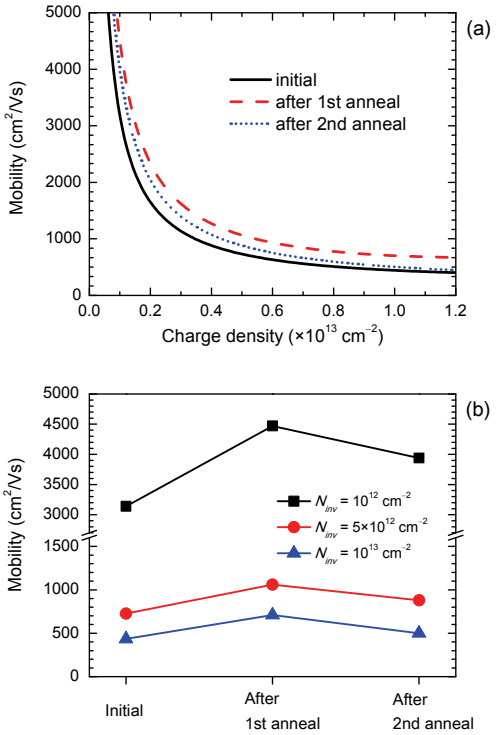

Fig. 5. Influence of annealing duration on carrier mobility in graphene with an emphasis on (a) N_{inv} and (b) annealing-step dependence.

in Fig. 4 exemplify the importance of device width engineering even at the micro scale.

The extracted high Dirac voltage indicates a heavy doping of graphene with *p*-type impurities. In addition to shifting the V_D, the doping also decreases the mobility due to increased carrier scattering on either neutral or charged impurities. In this work, we ask whether annealing can reduce doping, and hence we study the effects of hot-plate annealing at 300 °C performed in two steps, first lasting 30 min, the second 90 min. Figure 5 presents the initial mobility and two mobility curves obtained after each annealing step. The annealing and measurement were performed in atmospheric conditions and at room temperature for the same device as in Fig. 3 ($W = 15$ µm and $L = 10$ µm). After the first annealing (30 min at 300 °C), the mobility increases. We attribute this increase to evaporation of the adsorbed impurities from graphene. Surprisingly, the additional 90 min annealing decreases the mobility in comparison to the previous step, while keeping it above the initial mobility curve. The effects of annealing are quantified in Fig. 5(b) for three different N_{inv} values. The impact of annealing steps is qualitatively the same in weak, moderate and strong inversion, i.e. the first 30 min anneal increases the mobility, while the second 90 min step decreases the mobility. For example at $N_{inv} = 10^{12}$ cm^{-2}, the first anneal causes an increase of approx. 41% in comparison to the initial graphene sample, whereas the second annealing decreases the mobility by approx. 12%. Despite the decrease, after the second anneal the mobility is by 24% higher than in the initial sample. Therefore, annealing proved to be a viable method of reducing impurity density and increasing carrier mobility. However, the duration is a limiting factor due to defect generation, which is discussed in Subsect. III-C.

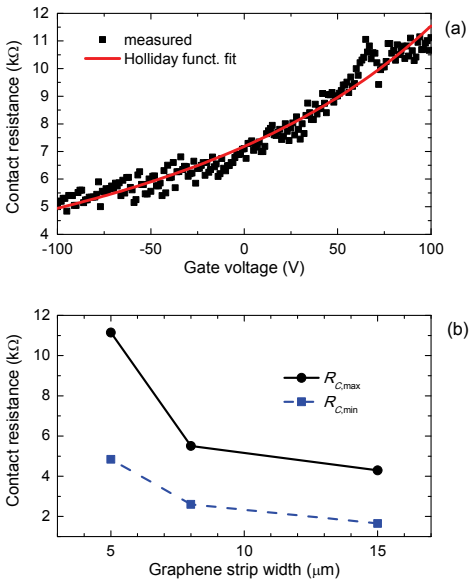

Fig. 6. (a) Contact resistance versus gate voltage for a device with $W = 5$ µm and $L = 10$ µm. (b) Dependence of $R_{C,\min}$ and $R_{C,\max}$ on the width of the graphene microstrip.

C. *Contact Resistance*

The contact resistance of the Ti/Au-graphene contacts is extracted by subtracting the resistance between the inner electrodes (R_{23}) from the resistance between the outer electrodes (R_{14}) and taking into account device dimensions. The following equation was used:

$$R_C = \frac{1}{2}\left(R_{14} - R_{23}\frac{L_{14}}{L_{23}} \right), \qquad (4)$$

where L_{14} and L_{23} are the separations of the respective electrodes [8], [13]. For all devices, the L_{14} equals 90 µm.

Dependence of the extracted contact resistance of the device with $W = 5$ µm and $L = 10$ µm on gate voltage is shown in Fig. 6(a). We observe that R_C depends on the gate voltage and ranges from ~5 kΩ (away from the Dirac point) to ~11 kΩ (close to the Dirac point). When the electrode width is taken into account, we find that $R_C W$ ranges from ~25 kΩ µm up to ~55 kΩ µm, which is comparable to the previously reported results for the contact resistance of Ti/Au-graphene samples [8], but is also much higher that those reported for Ni contacts (~1 kΩ µm [8]) and Pd/Au contacts (~200 Ω µm [9]).

The behavior of the contact resistance can be understood by examining the band structure of the metal-graphene interface, which is illustrated in Fig. 7. We model graphene as metal since it exhibits a zero bandgap, and we take into account the difference between work-functions for Ti and graphene (4.3 and 4.5 eV, respectively). Due to low DOS in graphene, the screening length is considerably larger in graphene than in metal [19], which leads to a finite spatial change of the vacuum level as illustrated in Fig. 7(a). Due to work-function difference, an electron charge transfer region is formed in graphene near the junction even without the applied gate voltage [Fig. 7(b)]. The situation in Fig. 7(b) corresponds to $V_G = V_D$ since E_F is in the neutrality point away from

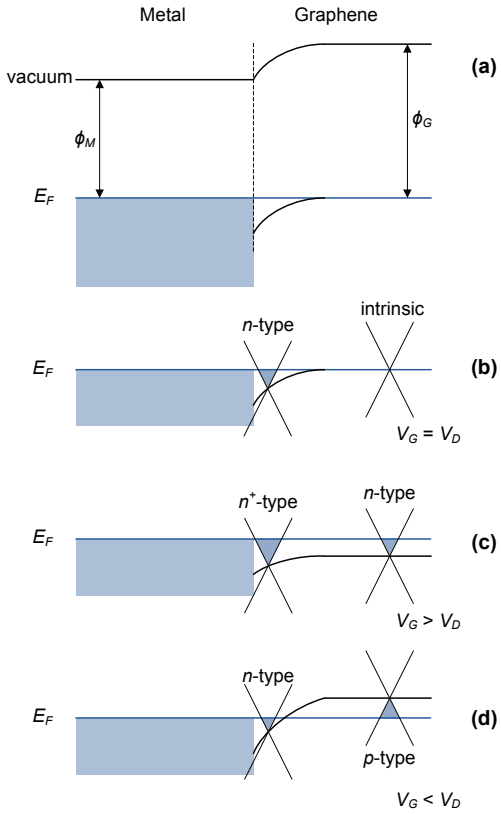

Fig. 7. Band diagram of the metal-graphene junction illustrating (a) band alignment, and specific cases when (b) $V_G = V_D$, (c) $V_G > V_D$ and (d) $V_G < V_D$.

the interfaces. In this case, an *n-i* junction is formed which results in the lowest possible conduction since the DOS in the intrinsic part equals zero. When V_G higher than V_D is applied, the neutrality level moves down and the Fermi level effectively shifts up, which results in high conduction since an n^+-*n* junction is formed [shown in Fig. 7(c)]. Finally, for $V_G < V_D$, the Fermi level effectively shifts down, which results in low conductance because a *p-n* junction is formed [see Fig. 7(d)]. Therefore, the experimental results in Fig. 6(a) can be explained using metal-graphene junction examples from Fig. 7(d) and (b). Namely, our graphene is heavily *p*-doped, which means that the cause of R_C increase with V_G in Fig. 6(a) is the evolution from *n-p* towards *n-i* junction type.

The influence of microstrip width downscaling on $R_{C,\min}$ and $R_{C,\max}$, extracted at V_G of −100 V and 100 V, respectively, is reported in Fig. 6(b). We observe that R_C increases with the decrease of the microstrip width. In turn, this means that the carriers are injected from the metal into graphene on the contact edges, which agrees with conclusions reported in [8].

Figure 8. shows the consequences of annealing on R_C in the device with $W = 15$ µm and $L = 10$ µm. After the first annealing (30 min at 300 °C), a decrease of both $R_{C,\min}$ and $R_{C,\max}$ is observed. The decrease equals ~7% and ~17% in the case of $R_{C,\min}$ and $R_{C,\max}$, respectively. The reduction of R_C indicates a change of the metal-graphene junction type from *n-p* to either *n-p*$^+$, *n-n* or *n-n*$^+$, since *n-p*$^+$, *n-n* and *n-n*$^+$ junctions are more conductive than the *n-p* junction, according to theoretical/numerical

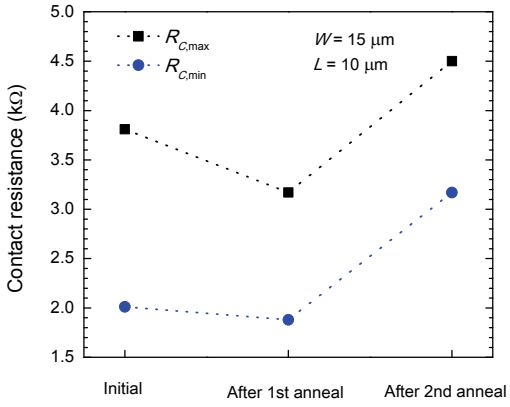

Fig. 8. Impact of annealing duration on contact resistances, $R_{C,\min}$ and $R_{C,\max}$, in a device with $W = 5$ µm and $L = 10$ µm. Annealing temperature is 300 °C (hot plate).

studies reported in [20], [21]. The most feasible assumption is the change from *n-p* to *n-n*$^-$ junction type because it seems unreasonable that a high doping, either of p^+ or n^+ type, would occur in graphene after the first annealing. The change of doping that is inferred from the R_C behavior agrees with the previously discussed mobility increase after the first annealing step, which was attributed to impurity evaporation. After the second annealing step (90 min at 300 °C), contact resistance increases considerably (~69% and ~42% for $R_{C,\min}$ and $R_{C,\max}$, respectively). We attribute this increase mainly to defect generation in graphene caused by evaporation of impurities and residual PMMA.

D. Output I-V Characteristics

Figure 9 shows the output characteristics of the graphene FET with $W = 15$ µm and $L = 10$ µm. The initial measurements are presented in Fig. 9(a), while (b) and (c) show the *I-V* curves obtained after the first and second annealing step, respectively. The curves are obtained for −100 V to 100 V range of V_G, and V_D from −5 V to 5 V, and the current is normalized by the microstrip width. Our devices do not exhibit current saturation, i.e. output conductance does not decrease as in semiconductor FETs. We observe similar behavior up to V_D of ±50 V, above which the high current densities destroy the devices. The absence of saturation is partly attributed to high V_D, so the pinch-off at the drain side cannot occur even for $V_D < 50$ V, and is partly caused by the absence of a high-κ dielectric that would be a source of remote (soft) phonon scattering [22]. The maximum current that is extracted at $V_D = 5$ V slightly increases from 55 µA/µm to 57 µA/µm after the first anneal (30 min), which is a consequence of increased carrier mobility and decreased R_C (see previous subsections). In contrast, the second annealing step (90 min) results in $I_{D,\max}$ of 42 µA/µm, which is lower than the current in the initial sample. We attribute this strong deterioration of $I_{D,\max}$ (~24%) to the increase of contact resistance as reported in Fig. 8.

IV. Conclusion

Graphene field-effect transistors are fabricated using CVD-grown graphene and a wet transfer technique. Devices are characterized in terms of carrier mobility,

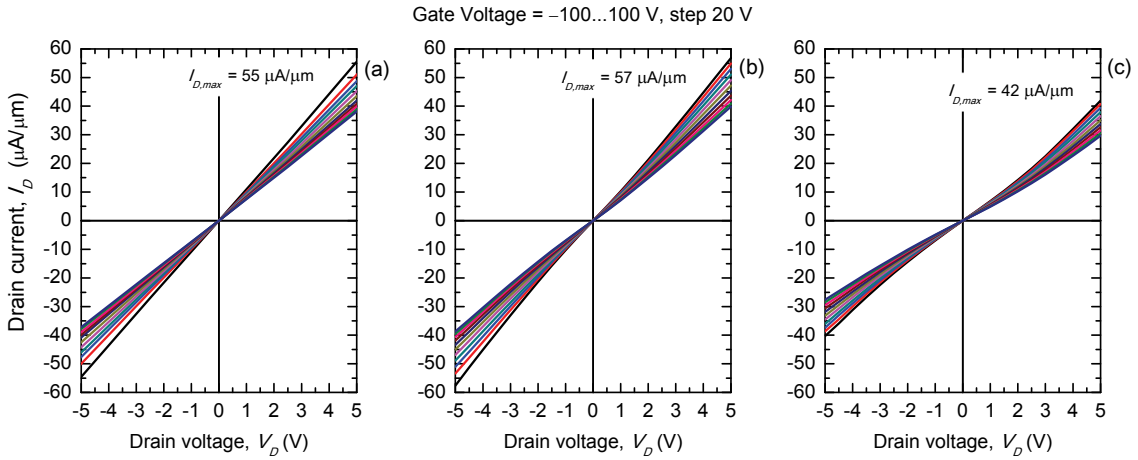

Fig. 9. Output characteristics of graphene FETs obtained for V_G range from −100 V to 100 V, and V_D range from −5 V to 5 V. The current is normalized by the microstrip width. Figures show (a) initial measurement, and measurement after the (b) first and (c) second annealing step.

contact resistance, output and transfer characteristics. Before annealing, typical device exhibits mobility of ~3200 cm^2/Vs at inversion charge density of 10^{12} cm^{-2}, with contact resistance of up to ~11 kΩ (~55 kΩ μm when microstrip width is taken into account). When graphene microstrip width is downscaled, the mobility decreases and contact resistance increases. Furthermore, device characteristics strongly depend on annealing time. For shorter anneal (30 min), mobility increases (+41%) and contact resistance decreases, while the additional longer anneal (90 min) has the opposite results. The impact of microstrip width and annealing on carrier mobility and contact resistance is explained by discussing the contributions from impurity and defect scattering and the consequences of *pn*-junction formation in graphene.

***Abstract*—The Graphene Base Transistor (GBT) is a very promising device concept for analog applications. The device operates similar to the hot electron transistor and exploits the high carrier mobility of graphene to reduce the base resistance that limits the unity power gain frequency (f_{max}) and the noise figure (NF) of RF devices. Although the DC functionality of the GBT has been experimentally demonstrated, at present RF performance can be investigated by simulations only. In this paper, we predict the DC current and the cutoff frequency of different GBT designs (including dimensions and various materials), with the aim to optimize the GBT structure and to achieve THz operation. In particular, optimized emitter/dielectrics combinations are proposed to maximize RF figures of merit.**

I. Introduction

The very large mobility of graphene makes this material very interesting, especially for analog and RF devices [1], [2]. Indeed, the graphene field effect transitor (GFET), obtained by integrating a graphene layer as channel material in a conventional FET structure, has been already largely investigated and it has shown intrinsic cutoff frequency of about 400GHz [3]. Potentially, the GFET can reach THz operation [4], however it suffers of a high output conductance and too large off currents [5]. This is a significant limitation mainly for digital applications and it is related to the zero band gap of graphene.

Recently, a new device concept, the Graphene Base Transistor (GBT), has been proposed and demonstrated [6], [7]. The first experimental results have been reported in [7], [8] and demostrate the basic DC functionality pf the GBT. The RF performance, instead, has been preliminary investigated by simulations [9], [10] and cutoff frequencies in the THz range for the intrinsic device have been predicted. The output resistance and intrinsic gain are expected to be larger than for GFETs [9], thus GBT may overcome one of the main limitations of GFETs.

In this work, we have extensively explored by simulations the design space of the GBT, in order to investigate the dependence of the GBT performance on the structure and material parameters. To this purpose, we made use of a refined version of the GBT model presented in [9], that has been extended by adding further physical mechanism relevant for the GBT operation. After this preliminary exploration, criteria for device optimization have been proposed and a few designs have been extensively analyzed in terms of cutoff frequency, intrinsic gain and output conductance.

II. GBT structure and operation

The Graphene Base Transistor has a structure very different from the GFET [6]. In the GBT, two insulators separate the three terminals of the device. The emitter, the graphene base and the collector are arranged vertically as in Fig. 1.

The device operates similarly to the hot electron transistor [11]. In particular, the electrons are injected by tunneling from the emitter towards the collector, thus crossing the emitter–base insulator (EBI), the graphene base and the base–collector insulator (BCI) [6]. Hence the charge travels perpendicular to the graphene sheet [12], [13]. Although the base is atomically thin, it is expected that the high mobility of the graphene reduces the base resistance.

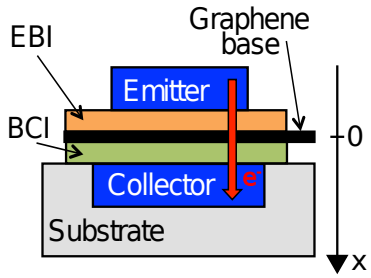

Fig. 1. Sketch of the GBT structure. Electrons leave the emitter by tunneling through the emitter–base insulator (EBI), cross the graphene base and then travel inside the conduction band of the base–collector insulator (BCI).

III. Simulation of the GBT

The model we used to simulate the GBT I–V characteristics is one–dimentional (in the x direction of the GBT structure in Fig. 1) and calculates the the potential profile self–consistently with the charge stored in the graphene base and that traveling inside the GBT.

Concerning the GBT current, we considered only electron's tunneling from the emitter and neglect any hole transport. Furthermore, since the physical origin of the base current is still unclear and debated [8], we assume a priori a negligible base current. The collector current density (J_C) is due to the electrons injected from the emitter.

The unity short circuit current gain frequency f_T is then estimated with the quasi–static expression [9]

$$f_T = \frac{1}{2\pi \frac{dQ_B}{dJ_C}}, \tag{1}$$

where Q_B is the charge density in the graphene base.

The basic equations describing the modeling approach can be found in [9]. However, the model has been extended in order

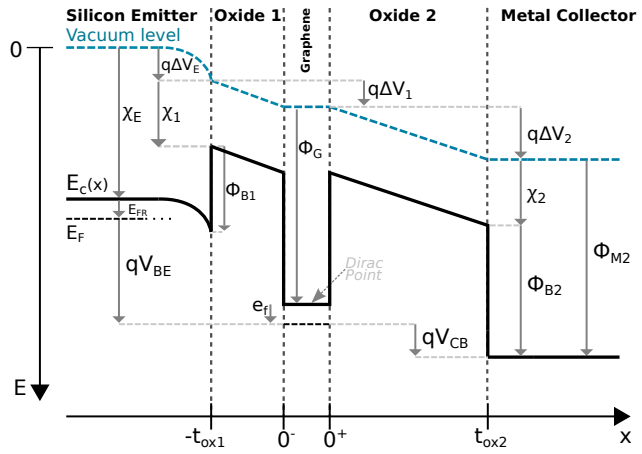

Fig. 2. Conduction band diagram of a GBT with Si–emitter. The band bending in the Si–emitter is calculated by the model self–consistently with the potential along the GBT structure. χ_E, χ_1 and χ_2 are the affinities of Si, the EBI and the BCI, respectively.

to consider GBTs with different emitter materials, including Si–emitters[14]. This allowed us also to verify the model against available experiments [7].

Furthermore, the impact of the charge traveling in the GBT structure is now accounted for when computing the electrostatics. As a result, space charge effects at high current (that usually reduce the maximum f_T value in bipolar transistors) are included in the model.

A. GBT with Si–emitter

Figure 2 reports the Conduction Band (CB) diagram of a GBT with an *n*–doped Si–emitter. As it can be seen, the applied base–emitter voltage (V_{BE}) is distributed among the voltage drops on the Si–emitter (ΔV_E), on the EBI (ΔV_1) and on the graphene. In particular, during normal operation of the GBT, due to the limited density of states in the graphene, the Fermi level (e_f) shifts below to the Dirac Point to induce holes in the base. The applied collector–base voltage (V_{CB}), instead, induces a voltage drop across the BCI (ΔV_2)[1] and, again, on the graphene.

Once ΔV_1, ΔV_2, ΔV_E and e_f are determined, the electrostatic of the GBT is obtained. The complete derivation of the the model is discussed in an upcoming paper [14]. Here we just underline that the graphene charge $Q_B(e_F)$ is computed according to a Fermi–Dirac distribution. Furthermore, by using an approach similar to what done in [15], we expressed the electric field (E_S) at the emitter side of the Si/EBI interface as a function of the potential drop ΔV_E. Now, with the $E_S(\Delta V_E)$ relationship and by resorting to the continuity of the electric displacement field at the Si/EBI interface we can write ΔV_1 as a function of ΔV_E

$$\frac{\Delta V_1}{t_{ox1}} k\varepsilon_0 = \varepsilon_E E_S(\Delta V_E), \qquad (2)$$

[1]Henceforth, to keep the notation as light as possible, we indicate the quantities related to the emitter section and collector section with the subscripts 1 and 2, respectively.

where ε_E is the electric permittivity of the emitter material (ε_E=ε_{Si} in our case), k and t_{ox1} are the relative permittivity and thickness of the EBI.

Equation 2 has been added to the model of [9] to link the electrostatic of the GBT to the Si band bending. The resulting system of non linear equations is solved self–consistently in MATLAB until the potentials inside the GBT structure are obtained. The GBT current is calculated following [9].

B. Impact of the electrons traveling inside the GBT

The high current effects (h.c.e.) impacting the maximum f_T of a HBT are due to the electrostatic feedback generated by the charge traveling inside the device itself [16]. We included this physical mechanism in our model, in order to investigate if GBTs are prone to similar effects and if THz operation is feasible.

In particular, the electron charge injected by the emitter and traveling inside the dielectrics induces holes inside the graphene base, thus reducing the electric field across the insulators and, consequently, the emitter injection current. To estimate this reduction, first we assume that the electrons in the CB of EBI and BCI are moving with constant drift velocity (v_d) and set v_d to a realistic value of 10^7 cm/s [17]. Second, we assume a uniform electron concentration n inside the insulators, hence n=$J_C/(qv_d)$. The impact of n on the GBT electrostatics becomes larger as J_C increases.

The calculated potential profile along the GBT now depends on n and, thus, on the current level. On the other hand, J_C can be calculated once the GBT electrostatic is solved and is known [9]. Therefore, the electrostatic calculation requires a coupled solution of the potentials and of the GBT current. We solved this problem by implementing an iterative procedure that obtains J_C from the potential profile (initial guess by considering n=0), which then becomes an input for the electrostatic solution. The model iterates until convergence is reached.

Figure 3(a) shows the calculated ΔV_1 versus the applied V_{BE}. The symbols are the reference curve calculated with the model of [9]. In the new model (lines), when the energy barrier height between the emitter and the EBI (Φ_{B1}) is relatively large, the tunneling current is low and, thus, the charge in the oxides is small. Since n is negligible, the new simulations agree with [9]. By reducing Φ_{B1}, instead, the tunneling of emitter electrons (thus J_C) increases. This raises the n value inside the oxides and, hence, changes the potential profile. In fact, Fig. 3(a) shows that by reducing Φ_{B1}, ΔV_1 degrades with respect to [9] (symbols).

Figure 3(b) shows how the k value affects the h.c.e. For low k values, the difference between the new model and that of [9] is relatively large, while for large k values, it is reduced. This means that GBTs with high–k dielectrics are less prone to h.c.e. and this is due to the fact that a larger permittivity of the dielectric reduces the impact of the space charge on the GBT electrostatics.

C. Impact of design and materials on GBT performance

We explored in detail the design space of the GBT, thus extending the work in [9]. In particular, we compared GBTs

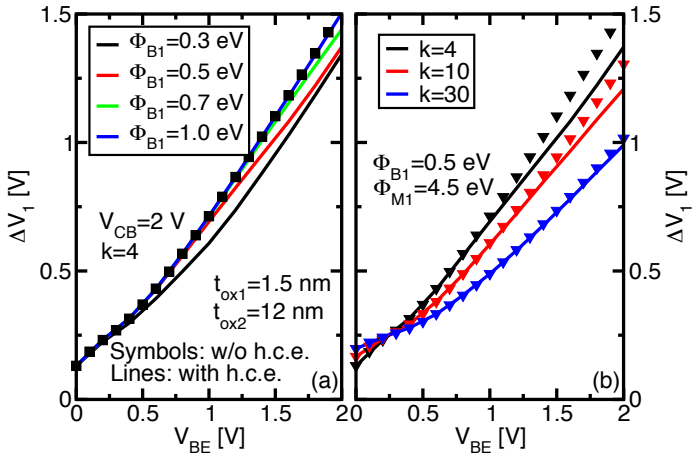

Fig. 3. Potential drop ΔV_1 on the EBI as a function of the applied V_{BE} for different EBI barrier heights Φ_{B1} (a) and for different dielectric constants (b) of metal emitter GBT designs. (a) The electrostatics visibly changes when relatively low Φ_{B1} are considered due to the J_C impact on the electrostatics. (b) The k value mediates the h.c.e.

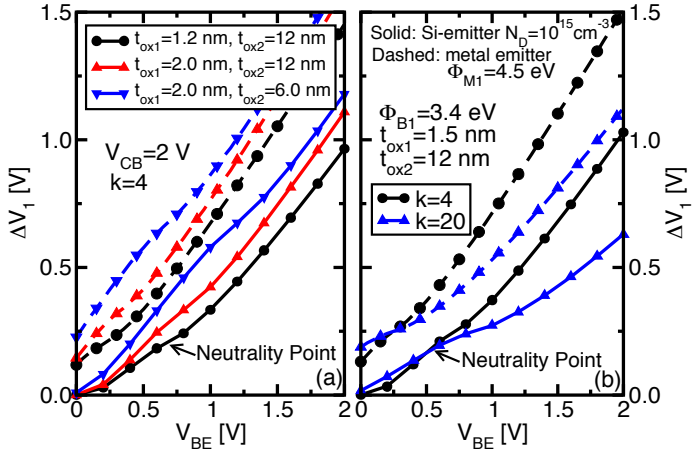

Fig. 4. Potential drop ΔV_1 as a function of V_{BE} for a few combinations of t_{ox1} and t_{ox2} (a) and for different k (b) for GBTs with metal (dashed lines) or Si–emitter (solid lines). The Si band bending reduces ΔV_1 and induces a shift of the neutrality point to higher V_{BE} with respect to metal emitter case.

with metal and Si emitter and investigated their performance as a function of the structure and material parameters. Fig. 4 shows ΔV_1 calculated for different EBI (t_{ox1}) and BCI (t_{ox2}) thicknesses and two k values. The inflection point in the ΔV_1 vs. V_{BE} curves indicates the Neutrality Point (NP), hence the zero base charge condition (Q_B=0) [9]. In normal GBT operation, the base is charged with holes, thus NP corresponds to the minimum V_{BE} that ensures the normal operation of the device. We see that for Si–emitter GBT, NP is moved towards higher V_{BE} and this is due to the additional voltage drop in the Si emitter (ΔV_E). This translates in larger threshold voltages to switch on the device. While t_{ox1} and t_{ox2} contribute to set the NP bias (Fig. 4(a)), this latter is not impacted by k (b).

Figure 5 reports the calculated J_C vs. V_{BE} for the metal (a) and the Si–emitter (b) GBT. It is worth noting the opposite trend of the current on the k value in the two cases. In the metal emitter device, for V_{BE}<1.5 V, the larger the k is, the lower the current is. For V_{BE}>1.5 V, instead, h.c.e. becomes

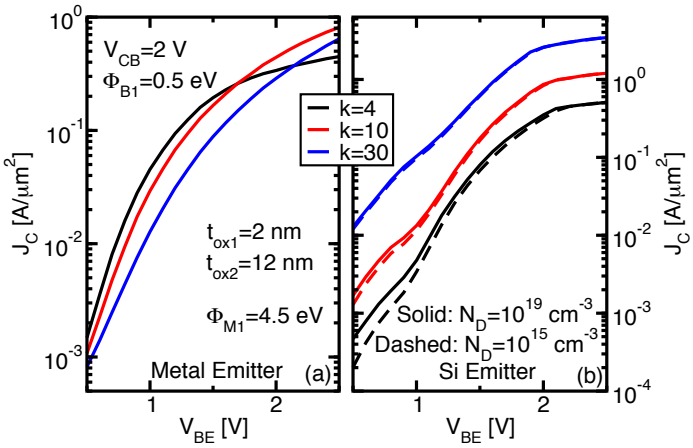

Fig. 5. Collector current density as a function of V_{BE} for a few values of k for GBTs with metal emitter (a) and Si–emitter (b). The Si doping is N_D=$10^{15}cm^{-3}$ (dashed lines) and N_D=$10^{19}cm^{-3}$ (solid lines).

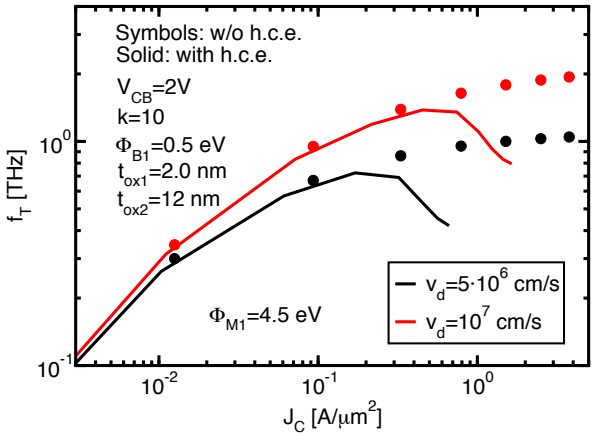

Fig. 6. Cutoff frequency f_T vs. J_C of a metal emitter GBT calculated with different models and for a few v_d values. H.c.e induce f_T drop at large J_C.

relevant and, since GBTs with low k oxides are more prone to h.c.e., a low k value results in a lower J_C. In fact, in Fig. 5(a), we see the black line crossing the other curves.

For the Si–emitter device (Fig. 5(b)), instead, the larger the k is, the higher the J_C is. This is due to Eq. 2, where larger k values result in larger E_S and, hence, larger ΔV_E. ΔV_E lowers the EBI energy barrier with respect to the Si Fermi level (E_F, see Fig. 2) and thus increases J_C. This trend is maintained also at high V_{BE}, where h.c.e. limit the current. Fig. 5(b) shows also that the J_C dependence on the Si doping (N_D) is limited, especially at large V_{BE}, where the Si emitter is driven in strong accumulation and comparable ΔV_E values are obtained, regardless of N_D.

Figure 6 shows f_T versus J_C estimated assuming different v_d values. The simulations that account for the h.c.e. (lines) show the drop off at large J_C typically seen also in HBTs. This effect is not visible in the simulations with the model of [9] (symbols), that are reported as a reference. When v_d is reduced, the maximum f_T of the device is lower. Note that with a realistic value of v_d=10^7 cm/s, the THz operation of the intrinsic device is maintained also when accounting for h.c.e.

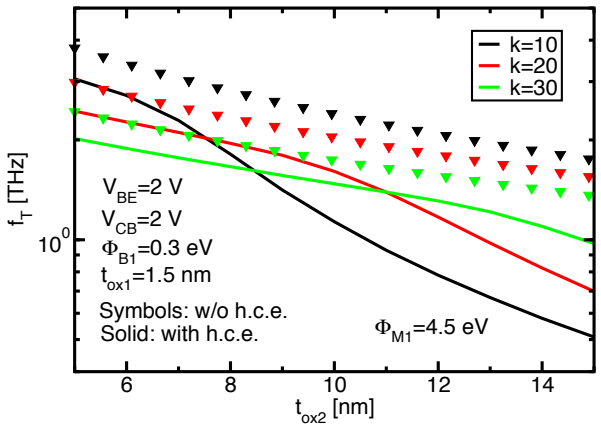

Fig. 7. Cutoff frequency f_T as a function of t_{ox2} for metal emitter GBTs, calculated using different models: thick BCI layers cause a serious decay in the GBT performance.

The cutoff frequency of the GBT is limited by the electrostatic impact of the charge inside the BCI layer, as demonstrated by Fig. 7, that shows f_T as a function of t_{ox2}. The BCI is typically much larger than the EBI, hence it contains a larger amount of charge that, via the electrostatics feedback, impacts the base hole density, thus reducing f_T (see Eq. 1). Indeed the model predicts that, by increasing t_{ox2}, f_T decreases below the values obtained with the model in [9]. Again, the k value is effective in mediating the impact of h.c.e. on f_T: the larger the k is, the smaller the f_T reduction is.

IV. Design and Optimization of the GBT

The above study of the GBT performance as a function of structure and material parameters allowed us to design and analyze optimized GBT structures. In particular, we simulated GBTs with Si or metal emitter, comparing them in terms of relevant RF figures of merit.

A. DEV.1: Silicon emitter GBT

Figure 5(b) shows that dielectrics with large k values ensure large J_C for Si–emitters devices. Therefore, to design the Si–emitter GBT structure, we selected Ta_2O_5 as EBI and BCI, because of its large k value (≈25) and the small CB offset with respect to silicon [21]. Furthermore we assume a Si emitter doping of N_D=10^{19} cm^{-3} and a BCI thickness of t_{ox2}=12 nm, that ensures that the NP is positioned at relatively low V_{BE} (Fig. 4).

Figure 8 shows the calculated J_C and transconductance (g_m) of the above GBT design (hereafter denoted as DEV.1). The model parameters used to simulate DEV.1 are listed in Tab. I. By assuming $t_{ox1} \leq$ 2 nm [9], J_C and g_m reach very large values (Fig. 8(a)). For $V_{BE} \geq$ 1.5 V, J_C is rather independent of t_{ox1} since it is limited by the h.c.e. induced by the charge in the BCI.

B. DEV.2: Metal emitter GBT

Figure 5(a) shows that GBTs with metal emitter are expected to have better performance if low–k dielectrics are selected for the EBI and BCI layers (at least until h.c.e. do not start to degrade the GBT operation). Hence, to design the metal

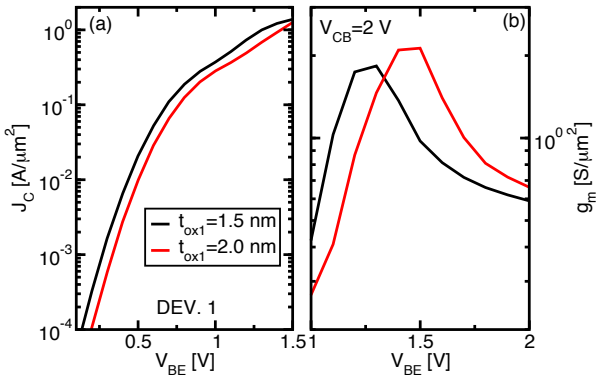

Fig. 8. J_C (a) and g_m (b) as functions of V_{BE} for a few t_{ox1} in DEV.1.

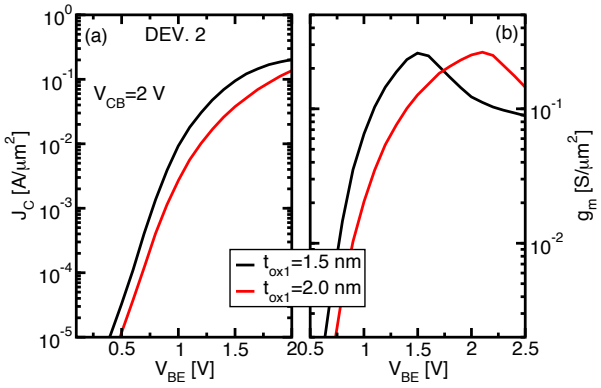

Fig. 9. J_C (a) and g_m (b) of DEV.2 as functions of V_{BE} for a few t_{ox1}.

emitter GBT (hereafter referred as DEV.2), we select a low–k material for the insulators (i. e. SiCOH, [22]). Furthermore, we assumed Ti emitter and collector terminals.

Figure 9 shows J_C and g_m for DEV.2, simulated by using the model parameters in Tab. I. We note that, if the two devices have similar EBI and BCI thickness, J_C and g_m of DEV.2 are lower than in DEV.1. This is due: firstly, to the smaller tunneling barrier between Si and Ta_2O_5 (0.36 eV) than between Ti and SiCOH (0.5 eV); secondly, to the band bending in the Si emitter, which lowers the energy barrier height for electrons tunneling at the emitter Fermi energy (see Fig. 2), thus increasing J_C.

TABLE I. Parameters used to simulate the optimized GBTs. m_I is the tunneling mass inside EBI and BCI to calculate the tunneling current [9]. Collector metal is Ti.

	DEV.1	**DEV.2**	**DEV. 3**
Emitter	Si N_D [cm^{-3}] 10^{19}	Ti Φ_{M1} [eV] 4.33	Si N_D [cm^{-3}] 10^{19}
EBI	Ta_2O_5	SiCOH	Ta_2O_5
BCI	Ta_2O_5	SiCOH	SiCOH
m_I [m_0]	0.5 Ref. [18], [19]	0.5	0.5
k [ε]	25 Ref. [20]	2.5 Ref. [22]	25 / 2.5
Φ_{B1} [eV]	0.36 Ref. [21]	0.53 Ref. [22]	0.36
Φ_{M2} [eV]	4.33	4.33	4.33
t_{ox2} [nm]	12	12	12

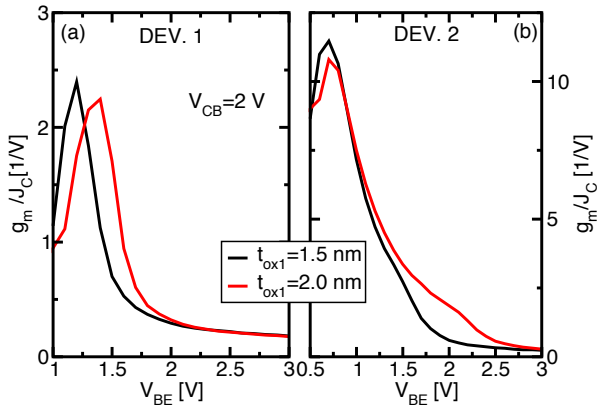

Fig. 11. g_m/J_C ratio as a function of V_{BE} for a few values of EBI thickness, for DEV.1 (a) and DEV.2 (b) GBTs. Mind the different y–axis scale in the two plots.

C. RF performance of GBTs with Si and metal emitters

Figure 10 reports the simulated f_T for DEV.1 and DEV.2. As it can be seen, f_T for DEV.1 (solid lines) is larger than for DEV.2 (dashed) at similar EBI and BCI thicknesses, as expected based on the larger current of DEV.1. This latter transistor shows maximum f_T values up to ≈10 THz, but also for DEV.2 THz operation is reachable by the intrinsic device.

Concerning other figures of merit for analog applications, Fig. 11 reports the transconductance efficiency (g_m/J_C) for the two devices. We note that DEV.2 has a large g_m/J_C ratio, that is comparable to those of scaled CMOS technologies [23]. Furthermore, Fig. 12 compares the instrinsic voltage gains (g_m/g_d) and, again, DEV.2 shows a better behavior. In particular, the metal emitter GBT can reach a g_m/g_d of 20, while for the Si emitter case, the gain is rather low (≈4).

The low intrinsic gain for DEV.1 is due to the high output conductance g_d, in spite of a large g_m compared to that of DEV.2, as demonstrated by Fig. 13. Indeed, the use of a high–k BCI induces a large capacitance coupling between the collector and the base. The base potential can be appreciably modulated by the collector bias, thus increasing the output conductance of the device. This problem can be alleviated by integrating in the Si–emitter GBT structure a BCI with a lower k value, as

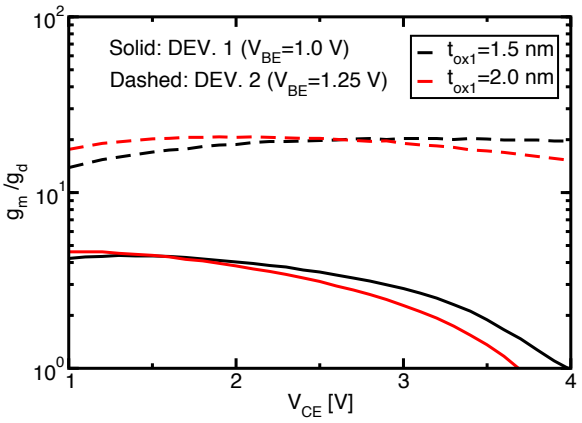

Fig. 12. Intrinsic gain g_m/g_d as a function of V_{CE} for a few values of the EBI thickness, for DEV.1 (a) and DEV.2 (b) GBTs.

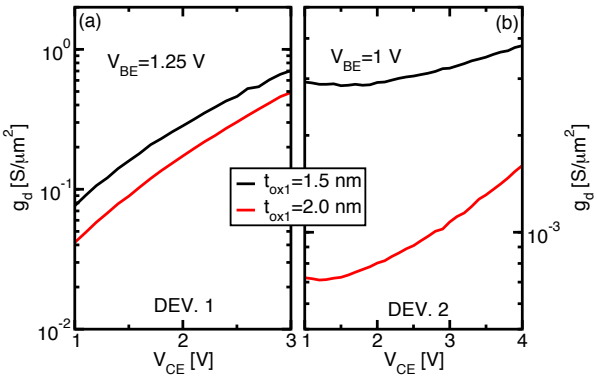

Fig. 13. Output conductance g_d versus V_{CE} for DEV.1 (a) and DEV.2 (b).

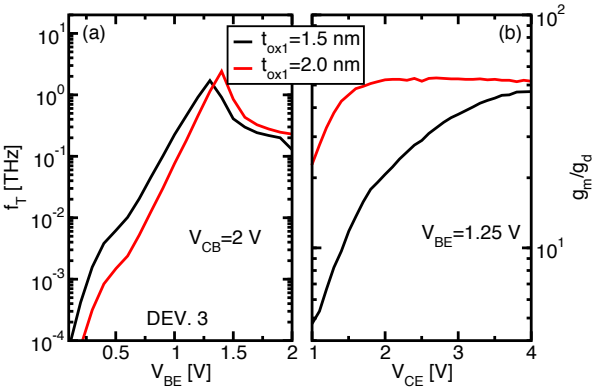

Fig. 14. Cutoff frequency (a) and intrinsic gain (b) for DEV.3.

demonstrated by Fig. 14(b), where we simulated a Si emitter GBT with Ta_2O_5 EBI and SiCOH BCI (named DEV.3). The use of a low–k BCI reduces the base–collector capacitance and increases g_d and, consequently, the gain. In fact g_m/g_d for DEV.3 is around 50 in the best case (Fig. 14, red curve), that is one order of magnitude larger than for DEV.1 (Fig. 12, solid lines). DEV.3 also achieves a maximum f_T above 1 THz (Fig. 14(a)).

V. Conclusion

We explored the design space of the GBT with an improved model for metal or Si emitter devices. The model accounts also for the electrostatic feedback of the charge traveling in the EBI and BCI regions during conduction. We showed that this charge limits the GBT performance at high currents, but the THz operation is still feasible for the GBT.

The model suggests that GBTs with Si/Ta_2O_5 emitters can ensure the largest J_C and f_T values, while GBTs with Ti/SiCOH barriers have better transconductance efficiency and intrinsic gain. Indeed, these figures of merit are strongly related to the permittivity of the EBI and BCI. In particular, a high–k EBI can reduce the tunneling barrier for the electrons in case of Si emitters, while a low–k BCI is the best option to achieve high intrinsic gain and low output conductance.

***Abstract*—Physics-based modeling of hole mobilities in ultra-thin germanium layers is calculated with self-consistent Schödinger-Poisson solver and Kubo-Greenwood formula. Quantum confinement is taken into account for heavy, light and split-off hole band in a double-gate germanium MOSFET structure. Acoustic and optical phonon scattering is taken into consideration in the calculation of hole momentum relaxation time. The observed reduction of mobility in thinner layers is explained by examining the influence of field-induced and geometry-induced confinement. Contributions from different hole bands are investigated by calculating band population and respective band mobilities.**

I. Introduction

Metal-oxide-semiconductor field-effect transistor or MOSFET is the basic element in modern semiconductor electronics. In order to increase transistor performance new materials and device architectures are explored [1]. For example, ultrathin-body (UTB) semiconductor on insulator (SOI) MOSFET in combination with strain in crystal lattice in order to suppress short channel effects (SCE) and improve drive current [2], [3]. Among advanced multi gate structures, FinFET is the most promising device due to high scalability, improved immunity to SCEs and compatibility with CMOS [4], [5]. In order to meet ITRS requirements for future CMOS technology nodes [6], germanium is considered to be a promising material for next generation pMOS devices due to its high hole mobility [7], [8]. The UTB Ge MOSFETs are often coupled with III-V MOSFETs, e.g. InGaAs, in a dual-channel CMOS [9].

In this work, we study hole mobility behavior with the downscaling of body thickness in UTB double gate (DG) germanium MOSFETs using semiclassical numerical modeling. Physics-based modeling of the hole mobility is indispensable for the performance prediction of UTB Ge transistors. Since ultra-thin bodies are needed to suppress the SCEs in the extremely scaled MOSFETs [1], we investigate the effects of germanium layer thickness (T_{Ge}) on the mobility. Schrödinger's and Poisson's equation is solved self-consistently, which takes quantum confinement of holes into account. Scattering rates (on acoustic and optical phonons), form factor and hole distribution in the channel are calculated and used to find the mobility for different hole bands (heavy, light and split-off). Some of the mobility features are explained by examining the field-induced and geometry-induced confinement.

II. Theory and Numerical Modeling

A. Schrödinger's and Poisson's Equation

The DG germanium MOSFET is a multi-layered structure, with a potential energy profile that has a shape of a quantum well with the assumed barrier heights of 3 eV. As a consequence, holes in the inversion channel experience quantum confinement. Inside the quantum well holes have discrete energy levels with accompanying wavefunctions [10], [11]. The z-axis is perpendicular to the oxide-semiconductor interface, at which end the voltage bias is applied to create the inversion layer. Density of states is represented with 2D Fermi gas because holes are confined in xy-plane. An effective mass model is used with a simplification of spherical equipotential energy surface in the **K** space. Each hole band is described by three different masses: effective quantization or confinement mass (m_q) for calculating discrete energy levels, effective mass used for calculating density of states (DOS) (m_d) and effective conductivity mass (m_c) [12]. We assume $m_q = m_d = m_c$ for each hole band due to assumption of spherical bands, which, in turn, is made because of lack of effective mass data in the literature.

Schrödinger's equation in z-direction for DG MOS structure is

$$\left(-\frac{\hbar^2}{2m_{q,\nu}}\frac{\partial^2}{\partial z^2}+U(z)\right)\phi_{\nu,n}(z)=\varepsilon_{\nu,n}\phi_{\nu,n}(z). \quad (1)$$

First term describes kinetic energy of a hole, $U(z)$ potential energy of a hole. $\phi_{\nu,n}$ and $\varepsilon_{\nu,n}$ are resulting eigen energy levels and eigen wavefunctions. ν determines hole band and n determines state inside quantum well. Equation is solved numerically using finite differences approach on a uniform grid [13], i.e.

$$\frac{\partial^2\phi(z_k)}{\partial z^2}\approx\frac{\phi_{k+1}+\phi_{k-1}-2\phi_k}{a^2}. \quad (2)$$

The result from (1) and (2) are $\varepsilon_{\nu,n}$ and $\phi_{\nu,n}(z_k)$. $|\phi_{\nu,n}(z_k)|^2$ is probability of finding a hole in band ν and subband n at node z_k. Energy levels and wavefunctions are used for calculation of hole density per unit volume and inversion charge density per unit area which is perpendicular to inversion channel. Hole density per unit volume

is

$$p_{\nu,n}(z_k) = |\phi_{\nu,n}(z_k)|^2 \int_{-\infty}^{+\infty} g_{\nu,n}(E) f_{FD}(E) dE, \quad (3)$$

where $g_{\nu,n}$ is density of states for 2D Fermi gas, and $f_{FD}(E)$ is Fermi-Dirac distribution function. Total hole density per unit volume, $p(z_k)$, is calculated by summation over all available indices ν, n. Inversion density per unit area for is calculated from

$$P_{\nu,n}^{inv} = \int_0^{T_{Ge}} p_{\nu,n}(z) dz, \quad (4)$$

where T_{Ge} is thickness of Ge layer. For studying band occupancy for separate hole type

$$P_{\nu}^{\%} = \sum_n \frac{P_{\nu,n}^{inv}}{P_{inv}} \quad (5)$$

is used.

If we apply external voltage bias the $U(z)$ term in Schrödinger's equation becomes

$$U(z) = -eV(z) - \chi(z), \quad (6)$$

$V(z)$ describes external voltage and $\chi(z)$ is position-dependent carrier affinity which is determined by height of barriers in DG MOS structure. Spatial distribution of holes changes electrostatic potential $V(z)$ via Poisson's equation:

$$-\frac{d}{dz}\left[\varepsilon_r(z)\frac{V(z)}{dz}\right] = \frac{e}{\varepsilon_0}\left[p(z) + N_I(z)\right], \quad (7)$$

where $p(z)$ is volume charge density and $\varepsilon_r(z)$ is the spatially variable dielectric constant. $N_I(z)$ is volume density of ionized dopants which is here assumed to be zero as the Ge body is undoped. The Poisson's equation also contains a second derivation and it is solved similarly to (1), the result being the electrostatic potential $V(z)$. The iterative solving of the Schrödinger's and Poisson's equation is done numerically until convergence is achieved, i.e. until a desired error is obtained which in this work equals $\varepsilon_{error} = 10^{-3}$ [12], [10].

B. Scattering Rates in Inversion Layer

When passing through Ge, or any other semiconductor, holes are scattered by crystal lattice vibrations (phonons), impurities or defects in lattice [14]. Using time dependent perturbation theory, transition from initial to final state is calculated with Fermi's golden rule [11]. Scattering rates for various scattering mechanisms are calculated [15] by linearizing the scattering term in the Boltzmann's transport equation. In this paper, only intra-band scattering for holes is considered, nevertheless, both intra- and inter-subband transitions are taken into account. The band designates hole type (HH, LH, SO), while the subband designates the eigenstate inside the quantum well. Important quantity for scattering is wavefunction form factor (FF)

$$F_{\nu;i,j} = \int_0^{T_{Ge}} |\phi_{\nu,i}(z)|^2 |\phi_{\nu,j}(z)|^2 dz \quad (8)$$

TABLE I
PARAMETERS USED FOR MOBILITY CALCULATIONS

m_{HH}	$0.33m_0$
m_{LH}	$0.043m_0$
m_{SO}	$0.084m_0$
D_{AP}	11 [eV]
D_{OP}	$6 \cdot 10^8$ [eV/cm]
E_{OP}	38 [meV]
v_s	$5 \cdot 10^5$ [cm/s]
ρ	5.32 [g/cm^3]

which describes overlap of probability functions of initial state i and final state j for band ν. In this work, the mobility simulation is based on calculating momentum relaxation time (MRT). The MRT for acoustic phonons (AP) is calculated from:

$$\frac{1}{\tau_{\nu,i}^{AP}(E)} = \sum_j \frac{n_\nu m_{d,\nu} k_B T D_{AP,\nu}^2}{\hbar^3 \rho v_s^2} \times F_{\nu;i,j} H(E - \varepsilon_{\nu,j}), \quad (9)$$

[15], [16]. Same index ν on both sides shows that this is intra-band scattering, i and j designates initial and final state inside quantum well, n_ν is band multiplicity for band ν, $m_{d,\nu}$ is effective density of states mass for band ν, k_B is Boltzmann constant, T is temperature, $D_{AP,\nu}$ is the acoustic deformation potential for band ν, $\hbar$ is reduced Planck constant, ρ is density of Ge, v_s is speed of sound in Ge and H is Heaviside step function.

Similar expression is given for MRT for optical phonons (OP):

$$\frac{1}{\tau_{\nu,i}^{OP}(E)} = \sum_j \frac{n_\nu m_{d,\nu} D_{OP}^2}{2\hbar\rho E_{OP}} \times \left(f_{BE}(E_{OP}) + \frac{1}{2} \pm \frac{1}{2}\right) \frac{1 - f_{FD}(E \pm E_{OP})}{1 - f_{FD}(E)} \times F_{\nu;i,j} H(E - (\varepsilon_{\nu,j} \mp E_{OP})), \quad (10)$$

but in this case scattering is inelastic [15], [16]. D_{OP} is optical phonon deformation strength, $E_{OP}(E)$ is energy of optical phonon. Numbers of states of phonons, which are bosons, is given with Bose–Einstein distribution f_{BE}. Holes, which are fermions, are represented with Fermi-Dirac distribution f_{FD}. Sign $\pm$ represent two possibilities of absorption or emission of optical phonon. Spin multiplicity factor, n_{sp}=1, is omitted because holes are scattered on phonons. Holes which are fermions and have half-integer spin do not change their spin while interacting with phonons which are bosons and have integer spin. Parameters need for calculation are taken from [17], [3] and are listed in Table I.

There can be many different sources of scattering present at the same time: AP, OP, polar OP, surface roughness, Coulomb scattering, alloy disorder. In this preliminary work, only AP and OP scattering is taken into account in order to assess the properties of the intrinsic mobility in ultra-thin DG UTB Ge MOSFETs. For comparison with experiments and other work more scattering mechanisms should be taken in consideration and this will be done in future work.

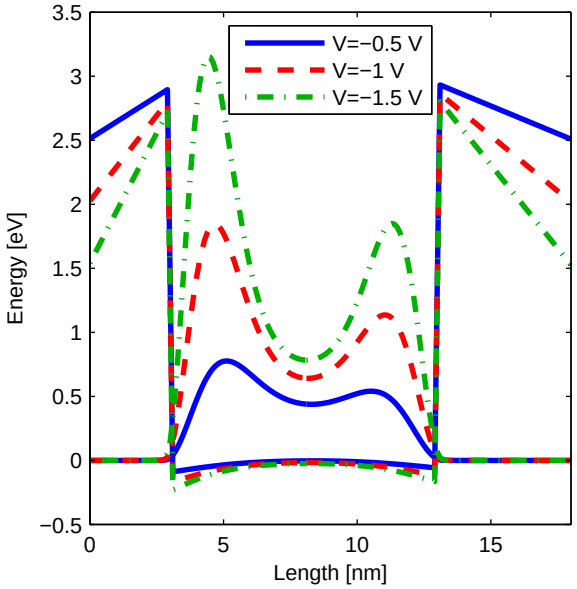

Fig. 1. Energy diagram and hole density per unit volume for UTB GOI MOSFET with gate voltage as parameter. Straight lines shows modified potential well. Curved lines shows hole density per unit volume. Greater localization of holes can be seen near thinner oxide for greater voltages.

Generally, combining MRT for more scattering mechanisms when they are mutually independent is done by Matthiessen's rule:

$$\frac{1}{\tau_{\nu,n}(E)} = \sum_{mech} \frac{1}{\tau^{mech}_{\nu,n}(E)}. \tag{11}$$

From total MRT mobility for n-th subband in band ν is calculated with Kubo-Greenwood formula [15]

$$\mu_{\nu,n} = \frac{e}{m_{c,\nu}} \frac{\int_{\varepsilon_{\nu,n}}^{+\infty} (E-\varepsilon_{\nu,n})\tau_{\nu,n}(E) \left|\frac{\partial f_{FD}(E)}{\partial E}\right| dE}{\int_{\varepsilon_{\nu,n}}^{+\infty} (E-\varepsilon_{\nu,n}) \left|\frac{\partial f_{FD}(E)}{\partial E}\right| dE}. \tag{12}$$

Total mobility is calculated from combining subband and band mobilities weighted by subband and band hole inversion densities in total hole inversion densities:

$$\mu = \sum_{\nu,n} \frac{P^{inv}_{\nu,n}}{P_{inv}} \mu_{\nu,n}. \tag{13}$$

III. Results and Discussions

A. Self-Consistent Schrödinger-Poisson Solver and Momentum Relaxation Time

Results of self-consistent Schrödinger-Poisson solver are shown on Fig. 1. Main results are eigen energies and eigen wavefunctions. Thickness of oxide layer is deliberately chosen to be asymmetrical, 3 and 5 nm, to illustrate the consequences of quantum confinement. From Fig. 1 it is seen that there is greater concentration of holes in inversion channel at side with thinner oxide layer due to stronger field-induced inversion. Greater concentration of holes is achieved for greater voltages. For three voltages deformation of rectangle quantum well is shown with greater deformation for greater voltages. Small penetration of wavefunction inside oxide layer is due to finite barrier height.

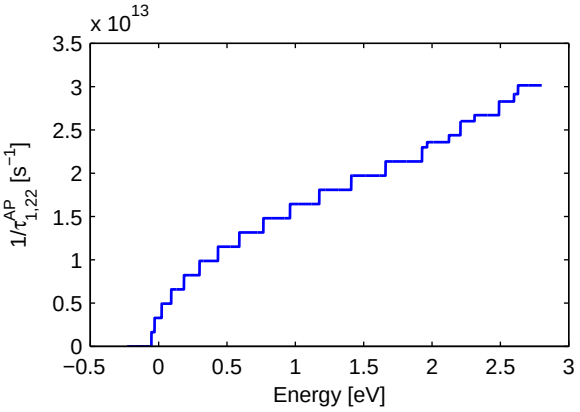

Fig. 2. Inverse MRT for AP. Indices (1,22) labels heavy hole, 22 state in subband of quantum well. Dimensions of oxide-semiconductor-oxide are 3, 10, 5 nm respectably and voltage bias on DG is -1V.

Eigen energies and eigen wavefunction from self-consistent Schrödinger-Poisson solver are used for calculation of MRT according to (9) and (10). The MRT for the twenty second state in the HH band is shown on Fig. 2, each step is determined by step function from (9), which stems from DOS of 2D Fermi gas. Heavier holes will have shorter MRT and increase of FF will also lead to shorter MRT. Greater voltages accelerates holes to greater speeds and consequently to greater energies which leads to shorter MRT. Therefore, holes under greater voltages will scatter more often than holes under smaller bias.

B. Effects of Body-Thickness Downscaling

For the following results, the thickness of oxide layers is constant (3 nm), while the thickness of the germanium layer is varied. Instead of plotting various data vs. voltage bias, data can be plotted vs. inversion charge, P_{inv}, which is more suitable for comparison with different materials and structures. In Fig. 3 dependence of hole mobility on inversion charge is shown for several body thicknesses that range from 2 to 20 nm, and it is clear that the mobility decreases with the downscaling of T_{Ge}. Thicker layers, $T_{Ge} > 10$ nm, exhibit inversion modulation of the mobility that is induced by external field. For $T_{Ge} = 20$ nm mobility drops by 38% from $P_{inv} = 3 \times 10^{12}$ cm^{-2} to $P_{inv} = 10^{13}$ cm^{-2}. Mobility in thinner layers, $T_{Ge} < 10$ nm, is constant and determined only by T_{Ge}, i.e. geometry of Ge layer. Two important effects have to be considered, field-induced confinement and geometry-induced confinement.

If we examine Fig. 1, greater spatial confinement dominates for higher voltages, and consequently higher P_{inv}. For explanation, more detailed discussion about the wavefunction form factor is needed. Higher voltage on gates, which also induces greater P_{inv}, confides holes in smaller space near the oxide layer and their wavefunctions will overlap more leading to higher FF. Equation (8) shows how much probabilities of different hole states overlap.

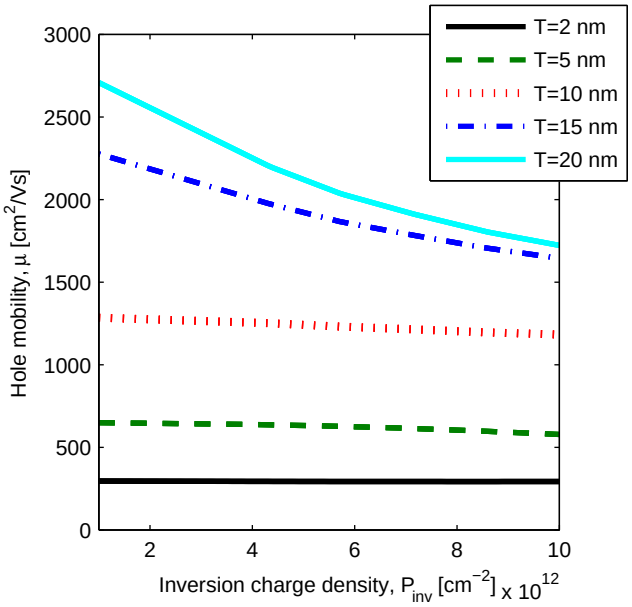

Fig. 3. Inversion charge density, P_{inv}, vs. hole mobilities, μ, with body-thickness, T_{Ge}, ranging from 2 to 20 nm as parameter.

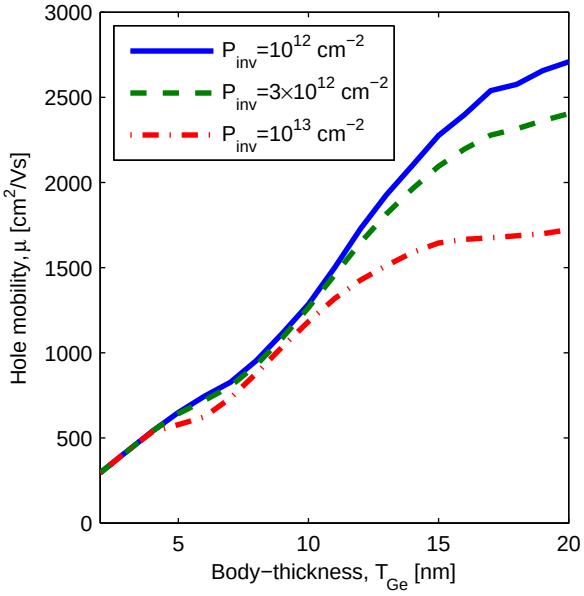

Fig. 5. Body-thickness vs. hole mobility with inversion charge as parameter.

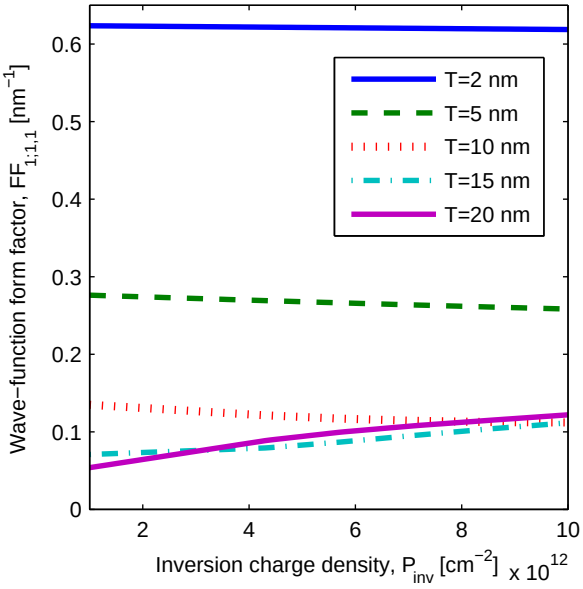

Fig. 4. Inversion charge density, P_{inv}, vs. wavefunction form factor, $FF_{1;1,1}$, with body-thickness, T_{Ge}, ranging from 2 to 20 nm as parameter. Indices (1;1,1) labels heavy hole band scattering from first energy subband to first energy subband.

Correlation between P_{inv} and $FF_{1;1,1}$ is shown on the Fig. 4. Scaling down T_{Ge} rises FF. External field induces inversion charge modulation of FF in thicker layers. For $T_{Ge} = 20$ nm FF drops by 39% from $P_{inv} = 10^{13}$ cm^{-2} to $P_{inv} = 3 \times 10^{12}$ cm^{-2}. Also for large inversion density around $P_{inv} = 10^{13}$ cm^{-2} FF is almost the same for T_{Ge} ranging from 10 to 20 nm. This is evidence of field-induced confinement in thicker layers, during which localization of holes near oxide-semiconductor interface increases with voltage bias. For thinner layers FF is constant for different P_{inv} and it is evidence of geometry-induced confinement. Higher FF in (9) and (10) lowers MRT in (12) and μ. In the same way lower FF raises μ.

Effect of body-thickness on hole mobility is shown on Fig. 5. It shows that scaling down T_{Ge} from 20 to 2 nm lowers mobilities by 88% for $P_{inv} = 3 \times 10^{12}$ cm^{-2} and 83% for $P_{inv} = 10^{13}$ cm^{-2}. Geometry-induced confinement is again seen for thinner layers because there is no modulation with P_{inv}. Field-induced confinement becomes dominant for layers above 12 nm. At $P_{inv} = 10^{13}$ cm^{-2} mobility starts falling more rapidly for $T_{Ge} < 12$ nm. From 12 nm to 4 nm mobility drops from 1400 cm^2/Vs to 500 cm^2/Vs. It is interesting to compare this results with other works for hole mobilities in silicon. Donetti L., et al. [18], also taking into account only AP and OP reports hole mobilities at $P_{inv} = 3 \times 10^{12}$ cm^{-2}: $\mu_\nu = 200$ cm^2/Vs for $T_{Si} = 10$ nm, $\mu_\nu = 150$ cm^2/Vs for $T_{Si} = 5$ nm, $\mu_\nu = 120$ cm^2/Vs for $T_{Si} = 3$ nm. If we compare it with our results from Fig. 3 and Fig. 5 reported hole mobilities for silicon are 70 to 80 % smaller than for our results for germanium. This has to be taken with caution because our model is uncalibrated and results in [18] are from calibrated simulation.

More details for smaller mobility in thinner layers are found inspecting FF, but this time its dependence on Ge layer thickness shown on Fig. 6. FF increases when scaling down T_{Ge} from 20 to 2 nm. Drop of 88% for $P_{inv} = 3 \times 10^{12}$ cm^{-2} and 81% for $P_{inv} = 10^{13}$ cm^{-2} is obtained. Similarity with figures for mobilities when downscaling T_{Ge} shows that rise in FF is one of dominating effect of lowering mobility for thinner layers. Geometry induced confinement is dominant for thinner layers because wavefunction will be forced to overlap more. From Fig. 1 we can picture what happens

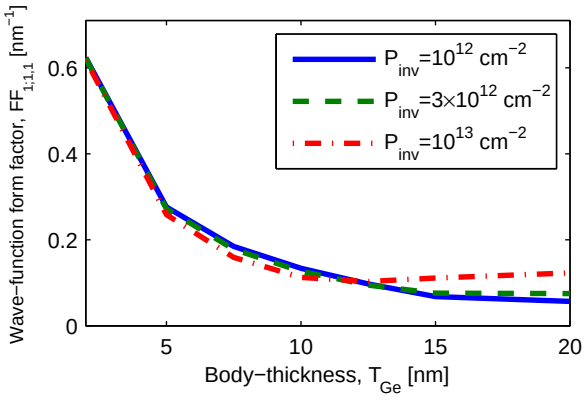

Fig. 6. Body-thickness vs. wavefunction form factor, $FF_{1;1,1}$ with inversion charge as parameter. Indices (1;1,1) labels HH band scattering from first energy subband to first energy subband.

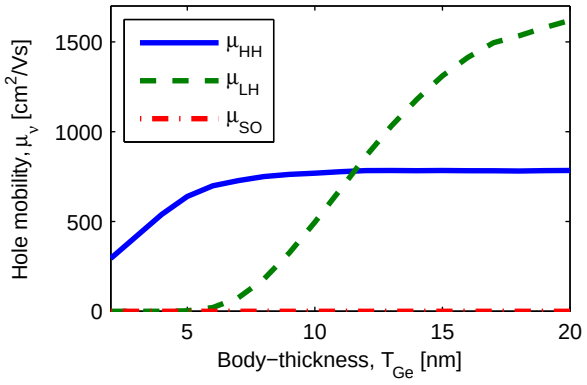

Fig. 7. Effect of body thickness on different hole mobility for $P_{inv} = 3 \times 10^{12}$ cm^{-2}

to wavefunctions with downscaling of T_{Ge}. Maximum of wavefunction will be shifted closer to center and they will overlap more with wavefunction of holes confined at other oxide layer. For thicker layers, wavefunctions are shifted apart and overlap is smaller. At $T_{Ge} = 20$ nm FF is the largest for $P_{inv} = 10^{13}$ cm^{-2} because higher voltages forces wavefunction to smaller space near the oxide-semiconductor interface and will overlap more. As said before, larger FF leads to smaller μ so this explains smaller mobility in thicker layers for high inversion in Fig. 3 and Fig. 5.

Contributions of different hole bands to the total mobility is reported in Fig. 7 for T_{Ge} ranging from 2 to 20 nm at $P_{inv} = 3 \times 10^{12}$ cm^{-2}. Picture is qualitative the same for different inversion densities which means that this is geometry related effect. For thicker layers mobility of light holes is greater than mobility of heavy holes. At $T_{Ge} = 20$ nm μ_{HH} is 52% lower than $\mu_{LH} = 1600$ cm^2/Vs. Around $T_{Ge} = 12$ nm mobilities are the same for both bands. Light holes exhibit a steep descend in mobility from $\mu_{LH} = 1400$ cm^2/Vs for 16 nm to $\mu_{LH} = 20$ cm^2/Vs for 6 nm. We can conclude that μ_{LH} has strong geometry dependence. Mobility of heavy holes is almost constant for thickness above 6 nm, while the geometry dependence

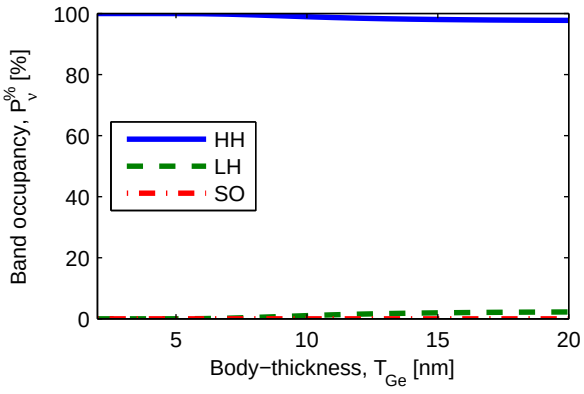

Fig. 8. Band occupancy of heavy, light and split-off holes for various body thickness at $P_{inv} = 3 \times 10^{12}$ cm^{-2}.

becomes noticeable below $T_{Ge} = 6$ nm. Mobility of heavy holes drops by 58% for $T_{Ge} = 6$ nm from 700 cm^2/Vs to 300 cm^2/Vs for $T_{Ge} = 2$ nm. Mobility of split-off holes is $\mu_{SO} = 0.002$ cm^2/Vs at best and can be assumed to be zero for all practical purpose. To explain greatly varying μ_{LH}, separate P_{inv} for every hole has to be studied, as different hole mobilities are weighted by their P_{inv} in total mobility as in (5).

Band occupancy for separate hole bands is shown in Fig. 8. For every $T_{Ge} = 2 - 20$ nm population of heavy holes dominates, with $P^{\%}_{HH}$ over 99.99% for $T_{Ge} = 2$ nm and slowly declining to $P^{\%}_{HH} = 97.75\%$ for $T_{Ge} = 20$ nm. Population of LH is $P^{\%}_{LH} \approx 0\%$ for $T_{Ge} = 2$ nm. If we look at Fig. 7 again, interesting thickness are $T_{Ge} = 6$ nm with $P^{\%}_{LH} = 0.07\%$ where μ_{LH} begins to contribute to total μ, $T_{Ge} = 12$ nm with $P^{\%}_{LH} = 1.54\%$ where $\mu_{HH} = \mu_{LH}$ and maximal thickness $T_{Ge} = 20$ nm with $P^{\%}_{LH} = 2.25\%$. Question arises how can LH with such small populations contribute so much to total mobility. We see in (12) and (9) or (10) that

$$\mu_\nu = \frac{1}{m_{c,\nu}} < \tau > \sim \frac{1}{m_{c,\nu}} \frac{1}{m_{d,\nu}}. \qquad (14)$$

Great difference in masses between LH and HH, $m^2_{HH}/m^2_{LH} \approx 60$ is responsible for μ_{LH} of the same order as μ_{HH} even for small population as $P^{\%}_{LH} \approx 1-2\%$.

IV. Conclusion

In this work mobility of holes in UTB DG MOSFET was assessed numerically. Self-consistent Schrödinger-Poisson solver was used for physics-based modeling of energy levels and distribution of holes inside UTB GOI MOSFET. Heavy, light and split-off hole band was taken in consideration with effect of quantum confinement in Ge layer between two oxides. Simple effective mass model is used were effective confinement, density of state and conductivity masses are the same. Mobility of holes is calculated from scattering rates of holes on AP and OP for Ge layers from 2 to 20 nm. It is clearly shown that mobility of holes decreases for thinner layers of Ge. When scaling down germanium layer from 20 to 2 nm mobility drops by 88% for lower inversion ($P_{inv} = 3 \times 10^2$ cm^{-2}) and 83%

for higher inversion ($P_{inv} = 10^3$ cm^{-2}). For layers below 12 nm decrease in mobility is independent of voltage on gate. Main limiting factor for hole mobility is geometry-induced confinement. Thickness of Ge changes overlap of hole wavefunctions shown through form-factor. In layers above 12 nm field-induced confinement is dominant and voltage bias is main modulating quantity. Greater mobility of light holes than of heavy holes for low light hole band occupancy, $P_{LH}^{\%} \approx 1-2\%$, is explained by great difference of hole masses $m_{HH}^2/m_{LH}^2 \approx 60$. When compared with silicon, germanium is more promising when downscaling because of greater hole mobilities. Only acoustic and optical phonon limited results show 70-80% lower hole mobilities for silicon.

Abstract – **Due to their 3D architecture, FinFETs exhibit a strong dependence of RF figures-of-merit on device geometry due to large extrinsic resistances and capacitances. We analyze the RF performance of 20-nm gate length FinFETs implemented on either bulk or SOI substrate by using 3D numerical device simulation. SOI and bulk FinFET are compared in terms of cut-off and maximum oscillation frequency, gate capacitance and trans-conductance. We have proposed and investigated the influence of different doping methods that aim at improving the RF figures-of-merit of 20 nm bulk FinFETs while maintaining acceptable DC performance.**

I. Introduction

The successful scaling of the CMOS technology for digital/logic applications has also demonstrated its potential for high frequency applications [1]. Namely, smaller channel length intrinsically results in higher drive currents and higher level of integration. Regardless of these advantages, the continuous scaling results in a group of problems known as short-channel-effects (SCEs) which are caused by the decreased control of gate over the channel. The SCEs involve subthreshold swing (SS) degradation, increase of the drain-induced barrier lowering (DIBL), device variability and increased leakage currents. In order to suppress the SCEs, new device architectures have been introduced. Multiple-gate MOSFETs have shown excellent down-scaling characteristics and high-performance when compared to the conventional single-gate device structures, due to better gate controllability of the channel [2].

The most feasible implementation of the multiple-gate architecture is the FinFET structure [3], [4], [5] which has been implemented in microprocessors of the latest generation. FinFETs are classified into two types, bulk FinFET and SOI FinFET [6]. Structurally, bulk FinFETs and SOI FinFETs are similar except that in SOI FinFETs the gate electrode and fin are isolated from the bulk silicon substrate. Although SOI devices have shown excellent short channel characteristics, they exhibit certain disadvantages over bulk devices such as higher wafer cost, heat transfer problems and may suffer from the floating body problem. Bulk FinFET structure draws attention mainly due its ability to be integrated with the conventional bulk planar CMOS technology. Although FinFETs alleviate electrostatic limitations in further scaling, their 3D structure plays a significant role in forming a large parasitics thus degrading radio frequency (RF) performance [7], [8], [9]. Therefore, it is necessary to optimize FinFET device geometry, materials and doping profiles for each technology generation in order to meet DC and RF performance metrics as given by the ITRS [10].

In this paper, we analyze the RF performance of 20 nm gate length FinFETs implemented on either bulk or SOI substrate. Analysis is performed on structures with identical geometrical dimensions, in order to assess the suitability and compare bulk and SOI FinFET technologies. Devices are compared both in terms of their DC performance and RF figures of merit.

II. Numerical Simulations

Bulk FinFET and SOI FinFET structures are analyzed and compared by using 3D numerical device simulator [11]. Figure 1(a) and (b) show 3D illustrations of both structures while the cross-sectional views are shown in Fig. 1(c). We assumed *p*-type body doping of 10^{15} cm^{-3}, source and drain doping of 10^{20} cm^{-3}, gate oxide thickness of 2 nm and top-gate nitride thickness of 10 nm. The top gate nitride layer cancels the influence of the gate electrode on the top of the fin which makes the devices effectively double-gate. Source and drain junctions are extended 2 nm below the gate. Fin height is set to 30 nm and gate length is set to 20 nm, while the fin width is set to 8 nm. In order to set the threshold voltage to positive values of around 0.2 V we used metal gate with a workfunction of 4.5 eV. In case of SOI FinFET, the thickness of the buried oxide (BOX) layer is set to 50 nm.

Electrostatic analysis is performed with Sentaurus SDevice [11]. The transport model used in simulations is based on the drift-diffusion formalism with band to band tunneling included in the Shockley-Read-Hall recombination. We used the concentration-dependent mobility model which includes the effect of impurity scattering and the mobility model which includes degradation of mobility due high electric field. Since the structures analyzed in this work have sub-20 nm dimensions in the active area, one can expect a strong influence of quantum effects such as carrier energy quantization or mobility dependence on fin width [12]. These effects are ignored in this study since we focus on qualitative comparison of the performance of SOI and bulk FinFET structures. Nevertheless, we acknowledge

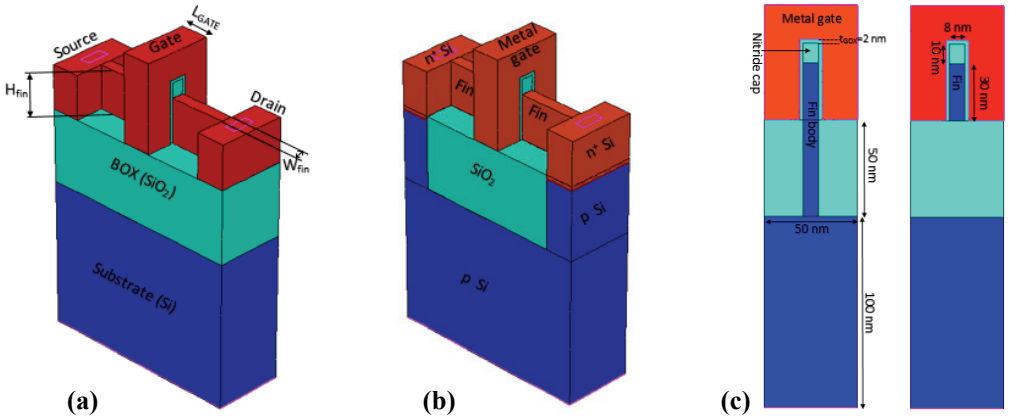

Fig. 1. 3D illustration of (a) SOI FinFET and (b) bulk FinFET . (c) 2D cross-section along transistor gate of bulk and SOI FinFET

the importance of the aforementioned effects and they will be accounted for in future work.

III. Results And Discussion

A. DC Analysis

Transfer functions for SOI and undoped bulk FinFET, obtained for V_{DS} of 0.05 V and 0.9 V are shown in Fig. 2. We use the attribute "undoped" to emphasize the initial bulk FinFET structure that has uniform doping in the whole fin (active part of the fin and the body-tied region). In this case, SOI FinFET has DIBL of 139 mV/V and SS of 91 mV/dec, whereas the undoped bulk FinFET has DIBL of 211 mV/V and SS of 186 mV/dec. The higher SS and DIBL of undoped bulk FinFET can be attributed to higher dielectric constant of depleted silicon compared to silicon oxide, which guides the drain electric field towards the source under gate. Figure 2 shows that the leakage current in OFF state (at V_{DS}= 0.9 V, V_{GS}= 0 V) is greater in the undoped bulk FinFET in comparison with SOI FinFET. This can be explained by examining the 2D cross-sectional current density plot reported in Figure 3, where we clearly see that current flow exists in the body-tied region, i.e. in the lower part of the fin that is out of reach of the gate electrode. Due to decreased control of the fin, both the DIBL and SS increase for the undoped bulk FinFET.

In order to make the undoped bulk FinFET comparable with SOI FinFET in terms of DC performance, the leakage current in bulk FinFET must be suppressed, which will, in turn, improve its sub-threshold performance. One approach to suppress leakage current in the body-tied (inactive part of the fin) region is to increase the body doping in that region. This reduces the punch-through effect because drain and source depletion regions become smaller, which prevents the generation of the parasitic current path [13]. This type of doping is also called Punch Trough Stopper (PTS) [14]. The doping profile in the body-tied region is a Gaussian function, with the maximum concentration of 5.2×10^{18} cm^{-3} set at 8 nm depth below the bottom of the gate where maximum

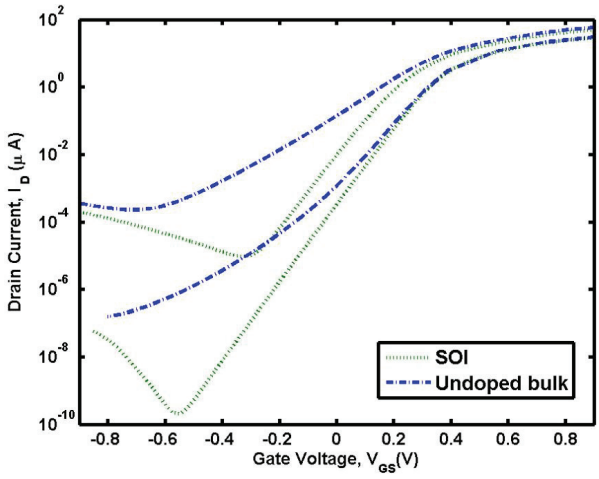

Fig. 2. Transfer characteristics for SOI and undoped bulk FinFET (at V_{DS}=0.9 V and V_{DS}=0.05 V). Increased leakage deteriorates subthreshold performance of bulk FinFET.

current leakage was determined. From that point, the PTS region spreads 20 nm toward substrate and also 20 nm toward upper fin. Two PTS-doping approaches are examined in this work; in plane-doped bulk FinFETs the PTS extends under the active fin and source/drain regions, which can be implanted before the gate fabrication whereas in the fin-doped bulk FinFET the PTS is implanted only under the active part of the fin, which can be implemented in gate-last process flow.

The results of DC analysis for all the examined structures are listed in Table I, and Fig. 4 shows the transfer characteristics for all the examined structures. With the PTS region, the bulk FinFET exhibits a subthreshold slope of 94 mV/dec, DIBL of 132 mV/V and OFF state current is 8 nA which is approximately 20 times smaller than the OFF state current of the undoped bulk FinFET. This improvement is partially attributed to increase in threshold voltage for doped bulk structures. Also, the DIBL has improved by 38 % and SS by 50 % in comparison with undoped bulk FinFET.

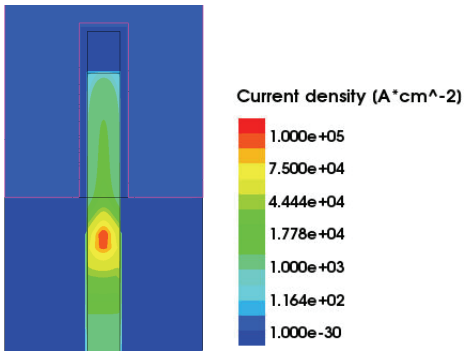

Fig. 3. 2D cross-sectional current density plots in OFF state for undoped bulk FinFET (at V_{DS}= 0.9 V, V_{GS}= 0 V). Current flow exists in the body-tied region, i.e. in the lower part of the fin that is out of reach of the gate electrode.

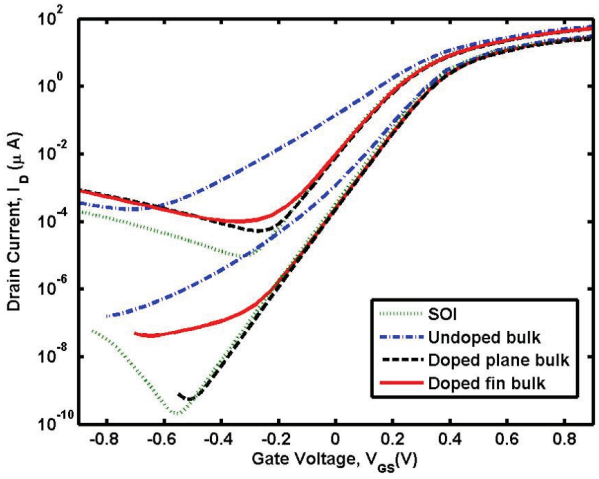

Fig. 4. Transfer characteristics for all examined structures (at V_{DS} = 0.9 V and V_{DS} = 0.05 V). Better subthreshold performance for doped bulk structures is observed.

It is shown that doped bulk structures have better subthreshold performance and lower leakage current than the initial undoped bulk FinFET. Doped-plane and doped-fin bulk FinFET, have approximately 4 % and 10 % higher SS than SOI FinFET, respectively. As expected, DIBL is the highest for undoped bulk, while in both cases of bulk FinFET with PTS, the achieved DIBL is lowered by about 40 % in regard to initial bulk FinFET. In the end that is 6 % lower than SOI for doped plane bulk and 3 % higher than SOI for doped fin bulk FinFET. For all examined structures, the ON state currents (at V_{DS} = 0.9 V, V_{GS} = 0.9 V) are around 50 µA for the fin height of 30 nm. The ON state current per channel width is approximately between 0.8 mA/µm and 1 mA/µm, where channel width is $W = 2 \times H_{fin}$, which is still significantly above the requirements for High Performance Logic Technology stated in ITRS [10]. Therefore, both approaches for suppressing leakage in bulk FinFETs give satisfying results. Slightly better results, especially in terms of current in OFF state and DIBL are achieved in the case of doped plane bulk FinFET. It is shown that doped plane bulk and doped fin bulk structures have about 3 and 2 times smaller OFF current than SOI FinFET, respectively. Since PTS in both bulk doped structures slightly penetrates in upper fin making the fin more doped compared to undoped bulk or SOI FinFET, both bulk doped FinFETs have higher linear subthreshold voltage ($V_{TH,LIN}$), about 65 % higher than undoped bulk and 15 % higher than SOI FinFET.

Figure 5 shows comparison of output characteristics for all structures obtained for V_{GS} = 0.9 V. Output characteristics of undoped bulk FinFET show higher drain currents than in the case of SOI FinFET. For

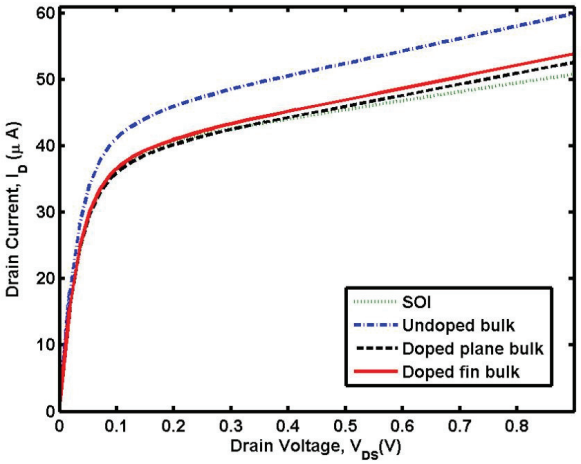

Fig. 5. Output characteristics for all examined structures (at V_{GS}= 0.9 V). Drain current and output conductance are higher for bulk FinFET structures.

V_{GS} = 0.9 V the channel is effectively wider than in the case of SOI FinFET due the inversion of the fin below the gate. Additionally, higher drain currents can be attributed to increased overdrive voltage due to lower threshold voltage. For that reason also, drain current and output conductance are higher for doped bulk FinFET structures. For the doped bulk structures the output conductance is approx. 16 µS, while for the undoped bulk it equals 19 µS and for SOI FinFET equals 13 µS.

Table I. Results of electrostatic analysis for all examined structures at V_{DS} = 0.9 V

Structure	SOI FinFET	Undoped Bulk FinFET	Doped Plane Bulk FinFET	Doped Fin Bulk FinFET
$V_{TH,LIN}$ [V]	0.191	0.135	0.226	0.219
I_{ON} [µA]	48.0	59.8	51.4	52.3
I_{OFF} [nA]	24.4	184.9	8.0	10.4
SS [mV/dec]	91	186	94	100
DIBL [mV/V]	139	211	132	143

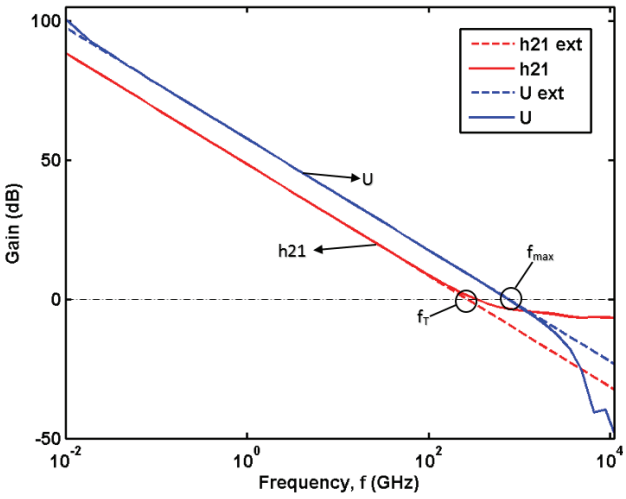

Fig. 6. Unilateral gain (U) and current gain (h_{21}) for SOI FinFET (V_{GS}= V_{DS}= 0.9 V). The f_{max} and f_T are extrapolated as frequencies where U and h_{21}, respectively, are equal 1 assuming a 20 dB/dec slope.

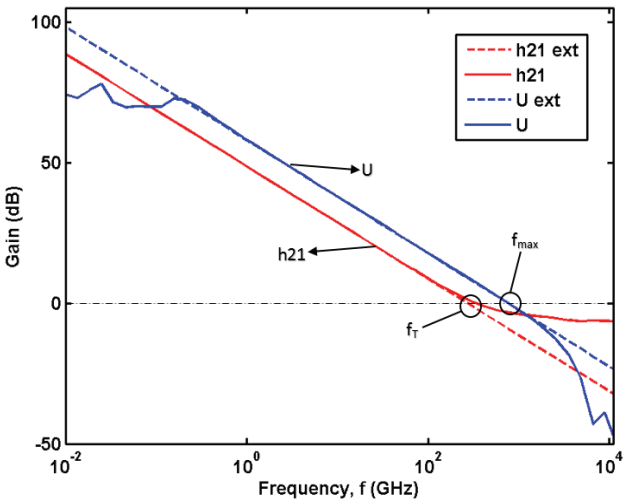

Fig. 7. Unilateral gain (U) and current gain (h_{21}) for plane-doped bulk FinFET (V_{GS}= V_{DS}= 0.9 V).

Table II. The cut-off and maximum oscillation frequency at V_{GS}= V_{DS}= 0.9 V for all examined structures

Structure	SOI FinFET	Undoped Bulk FinFET	Plane-doped Bulk FinFET	Fin-doped Bulk FinFET
f_T [GHz]	269.8	276.1	269.3	272.5
f_{max} [GHz]	776.5	713	744.4	760

B. RF Performance Analysis

In this section, the previously described SOI and bulk FinFETs are compared in terms of the cut-off (f_T) and maximum oscillation frequency (f_{max}). These two frequencies present the most relevant figures of merit for high frequency capabilities of MOS transistor [15]. The cut-off frequency can be determined by finding the frequency where the current gain equals 1, i.e. 0 dB. The current gain is defined by admittance parameters:

$$|h_{21}| = \frac{|y_{21}|}{|y_{11}|}, \qquad (1)$$

where y_{21} is the forward transfer admittance and y_{11} is the input admittance when output is short-circuited. The admittance parameters were extracted using small signal analysis in Sentaurus Sdevice. Using the definition of unilateral power gain (U), maximum oscillation frequency can be determined by finding the frequency where U equals 1, i.e. 0 dB. The unilateral power gain (U) is also defined using admittance parameters:

$$U = \frac{|y_{21} - y_{12}|^2}{4\left[\mathrm{Re}(y_{11})\mathrm{Re}(y_{22}) - \mathrm{Re}(y_{12})\mathrm{Re}(y_{21})\right]}, \qquad (2)$$

where y_{12} is the reverse transfer admittance and y_{22} is the output admittance when input is short-circuited. Figures 6 and 7 show unilateral power and current gains versus frequency for SOI and plane-doped bulk FinFET, respectively. Although U and h_{21} often drop at a rate much faster than 20 dB/decade at high frequencies, it is common to extrapolate f_{max} and f_T as frequencies where U and h_{21}, respectively, are equal 1 assuming a 20 dB/dec slope [15].

Extrapolated frequencies for all examined structures are listed in Table II. Cut-off frequencies are approx. the same, 270 GHz, for all the examined structures, whereas f_{max} differs significantly depending on the structure. Since the cut-off frequency is proportional to transconductance g_m and inversely proportional to gate capacitance C_g, we investigate the influence of these parameters on cut-off frequency.

Figure 8 shows transconductance versus gate voltage. The transconductance was extracted from transfer characteristic where drain voltage was fixed at 0.9 V and gate voltage was changed from 0 V to 0.9 V. It can be seen that the transconductance is the highest for the initial bulk FinFET which is a consequence of increased overdrive voltage due to lower threshold voltage for this structure. For higher gate voltages (V_{GS}> 0.5 V) in both doped bulk FinFETs channel is also formed in smaller part of fin below the gate influence, so the channel width is effectively wider compared with SOI FinFET which results with higher transconductance for both doped bulk FinFETs. Since PTS in both bulk doped structures slightly penetrates in the active fin, at lower voltages (V_{GS} < 0.5 V) channel width for both doped bulk FinFETs

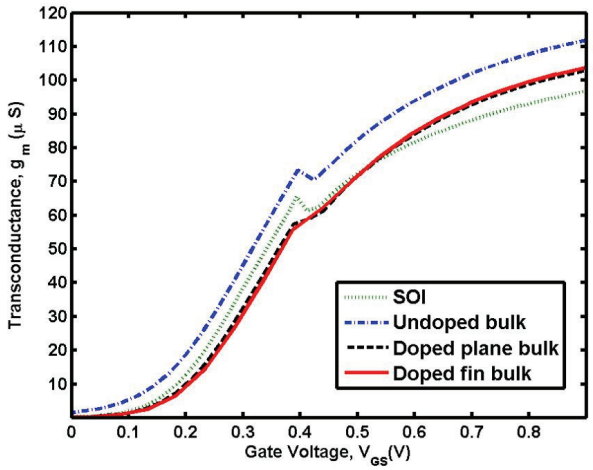

Fig. 8. Transconductance g_m versus gate voltage for all examined structures (V_{DS} = 0.9 V). As g_m is proportional to channel width, with smaller width we get smaller transconductance.

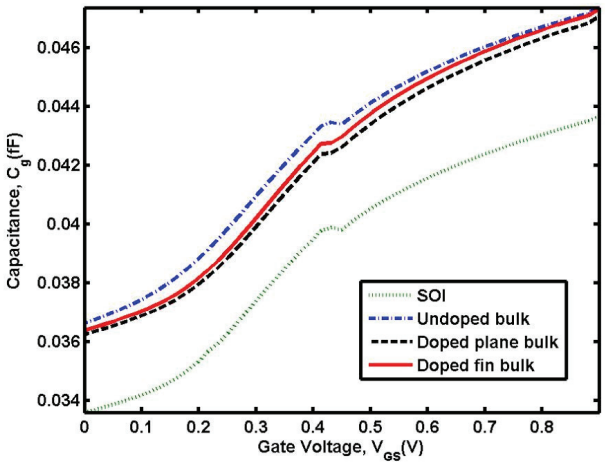

Fig. 9. Capacitance C_g versus gate voltage for all examined structures at 500 GHz (V_{DS} = 0.9 V). It is shown that capacitance is the lowest for SOI FinFET.

is narrower compared with SOI FinFET where fin is uniformly doped. As g_m is proportional to channel width, smaller width results in smaller transconductance. Figure 9 shows gate capacitance dependency of V_{GS} at 500 GHz. Capacitance was extracted using small signal analysis in Sentaurus Sdevice at the same bias as transconductance. It is shown that capacitance is the highest for undoped bulk FinFET. If we assume that at V_{GS}= 0.9 V the gate capacitance is mostly determined by gate oxide capacitance, then this capacitance has higher influence on total difference of C_g between bulk and SOI structures than capacitance toward substrate. Since the channel is effectively wider in case of bulk FinFETs, that determines their higher total gate capacitance. Also, if we compare capacitance towards substrate of SOI and bulk structures, we can conclude that bulk structures will have higher capacitance due higher dielectric constant of silicon than silicon oxide. In g_m-V_{GS} and C_{GS}-V_{GS} characteristics, kink effect was observed which is consequence of corner effect. Due to low body doping corner effect is not noticeable in the transfer characteristic [16].

Figures 10 and 11 show the dependence of f_T and f_{max} for different structures as a function of gate voltage, respectively. As expected, considering the values of C_g and g_m at V_{GS}= 0.9 V, the highest cut-off frequency is obtained for undoped bulk FinFET, and the lowest for SOI. With both bulk structures with implemented PTS in body region, satisfying results were achieved. Cut-off frequencies for both of them are almost equal to f_T of their SOI counterpart. Maximum oscillation frequency dependence on f_T and g_{ds} is approximated by

$$f_{\max} \sim \frac{f_T}{\sqrt{g_{ds}}}, \qquad (3)$$

where g_{ds} is the output conductance. Since the cut-off frequencies are approximately the same for all the examined structures, f_{max} is determined by the difference

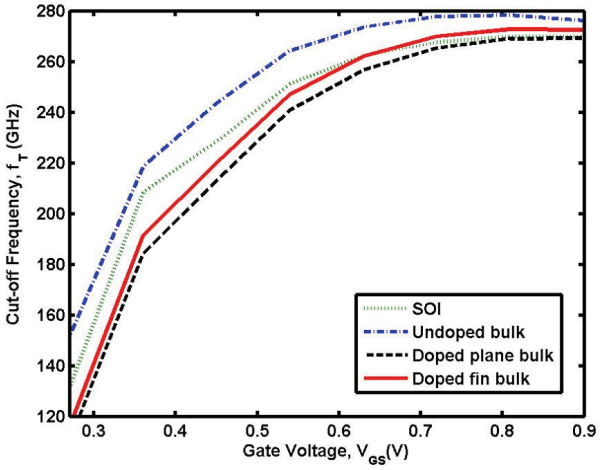

Fig. 10. Dependence of f_T on the gate voltage for all examined structures (V_{DS} = 0.9 V). For V_{GS} = 0.9 V, the highest cut-off frequency is obtained for undoped bulk FinFET, and the lowest for plane-doped bulk FinFET.

in g_{ds} for different structures. Therefore, due to the highest g_{ds}, undoped bulk FinFET exhibits the lowest f_{max} (713 GHz), while the SOI FinFET has the lowest g_{ds} and therefore highest f_{max} (776.5 GHz). The maximum oscillation frequency of plane-doped bulk FinFET is 744.4 GHz which is 4.5 % lower than SOI and 4.5 % higher than the initial bulk FinFET. On the other hand, fin-doped bulk FinFET shows slightly better results, with only 3 % lower f_{max} than SOI FinFET and 6.5 % higher f_{max} than the initial bulk structure. This slightly higher f_{max} in case of fin-doped bulk FinFET is good argument for using this type of bulk FinFET to achieve RF performance comparable to that of the SOI FinFET. However, the fin-doped type of FinFET is a more challenging solution from the fabrication point-of-view than plane-doped bulk FinFET. According to [1], [4], [7],

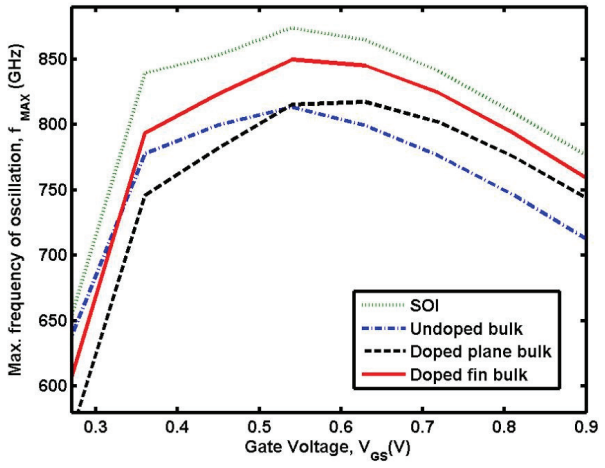

Fig. 11. Dependence of f_{max} on the gate voltage for all examined structures (V_{DS}= 0.9 V). For V_{GS}= 0.9 V, the highest f_{max} is obtained for SOI and the lowest for undoped bulk FinFET.

[17] with gate length downscaling the peak value of FOMs like f_T and f_{max} is increasing. In aforementioned literature, results of RF-FOMs for 12 nm-FinFETs are around 300 GHz which is approximately two times lower than results presented in this paper. Therefore, our results over-estimate the RF FOMs at the 20 nm gate length, most likely because high doping of source/drain extensions is assumed, resulting in significantly underestimated series resistances. In addition, since quantum effects were neglected, carrier mobility in our simulations is most likely significantly larger than expected in extremely-scaled structures. Finally, discrepancy with the measured data is partially attributed to omission of gate resistance since metal gates were used. Nevertheless, this study serves as a comparative analysis that indicates possible methods of improvement of RF performance in extremely-scaled bulk FinFETs.

IV. Conclusion

FinFETs with 20-nm gate length implemented on either bulk or SOI substrate were analyzed in terms of DC and RF performance by using 3D numerical device simulation. The initial undoped bulk FinFET has significantly higher current in the OFF state than its SOI counterpart, which demands a PTS doping in the inactive fin region in order to make bulk FinFET comparable with SOI in terms of DC performance. Bulk structures with two types of PTS doping were examined. For both bulk structures with PTS, approximately 20 times smaller current in the OFF state was achieved. Also, both doped bulk structures have shown similar RF performance as their SOI counterpart. Cut-off frequencies are roughly the same about 270 GHz, but bigger difference is seen in the f_{max}. The SOI FinFET has the highest f_{max} of 776.5 GHz, which is only 4.5 % and 3 % higher than in the plane-doped and fin-doped bulk FinFET, respectively. Therefore, considering the f_{max}, we can conclude that bulk structures with PTS exhibit significantly improved RF performance compared to undoped FinFETs, and are comparable with SOI FinFETs. The reported results for doped bulk FinFETs make a good argument for using them as future RF devices, even though the PTS doping is challenging from the fabrication point of view.

***Abstract*—Hot carrier injection (HCI) and negative bias temperature instability (NBTI) become dominant reliability issues in nanometer CMOS technology. These aging effects can induce additional delay which will be accumulated through logic gates and thus degrade the performance of the circuits. This paper discusses performance degradations induced by aging mechanisms in digital integrated circuits. We propose an aging-aware synthesis flow taking into account NBTI and HCI. This flow is demonstrated through the implementation of several architectures of adders using CMOS technology. The simulation results show that Kogge-Stone Adder (KSA) and SKlansky Adder (SKA) are the best solutions whether in terms of the complexity or the resistance to aging effects with induced delay degradation below 0.35%.**

I. Introduction

As essential arithmetic elements, adders are wildly used in digital integrated circuits (ICs), such as CORDIC and Finite Impulse Response (FIR) processors. They are also applied to build more complicated arithmetic elements in digital signal processors. Various binary addition architectures have been proposed over the last decades, in order to meet principal design specifications: speed, power and area [1].

The scaling down of CMOS technology causes reliability problems in ICs and systems [2]. NBTI and HCI are treated as main aging effects in sub-micron CMOS circuits [3]. These effects induce additional delay through many logic gates and thus degrade circuit performance. Aging effects have been intensively studied on logic gates (inverter, NAND, NOR) [4] [5]. Nevertheless, a few of researches focus on arithmetic operators. Siddiqua *et al.* reported NBTI-aware analysis on the adder, whereas only Kogge-Stone adder is studied [6].

Traditional digital IC's design tasks includes behavioral description (VHDL/Verilog), functional simulation, RTL (register transfer level) synthesis and post-layout simulation. In order to consider performance degradation due to scaling down, reliability should be included in this design flow. Since a non-critical path can become a critical path with the time progress due to NBTI effect [7], we particularly concentrate on the aging effects on critical path and near critical path of circuits [8].

In this paper, we propose a design flow that includes aging estimation taking into account both NBTI and HCI mechanisms. With the help of this flow, it is possible to aging-aware simulate the circuit netlist generated from RTL synthesis. Binary adders with 65 nm CMOS in different architectures are studied in order to demonstrate this flow. We show a comprehensive simulation study of aging effects in binary adders with 65 nm CMOS.

The paper is organized as follows. Section II reviews aging mechanisms in MOS transistors and introduces the adders architectures studied in this work. Section III presents the proposed synthesis flow considering aging effects. Section IV applies this flow to adders in different architectures. Section V outlines some conclusions and future work.

II. Preliminaries

A. Aging effects

NBTI and HCI are two major aging degradation effects in nanometer CMOS technology [9] [10]. Figure 1(a) and 1(b) show NBTI and HCI mechanisms in PMOS/NMOS type transistors. NBTI refers to the generation of positive oxide charge and interface traps at the Si-SiO_2 interface under negative gate bias to PMOS transistor, in particular at elevated temperature. HCI happens in NMOS type transistor, when hot electrons overcome the potential barrier and inject into gate oxide due to high lateral electric field near the drain.

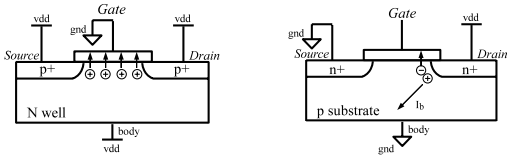

Fig. 1. HCI and NBTI mechanisms at CMOS device level: a. NBTI causes positive oxide charge and interface traps in PMOS type transistors, b. Hot carriers inject into the dielectric at the drain end of NMOS type transistors

As shown in Figure 2(a), HCI can influence sub-threshold swing coefficient (n_{fac}), intrinsic threshold voltage (v_{th0}), intrinsic mobility (μ_0), saturation velocity (v_{sat}), drain source resistance per width (r_{dsw}), subthreshold region DIBL coefficient (eta_0) and threshold voltage offset (v_{off}). Besides, the only BSIM4 [11] parameter affected by NBTI is v_{th0} of PMOS transistor (see Figure 2(b)). More severe v_{th0} degradation is observed when PMOS transistor work at high temperature ($150°C$) [12]. These physical parameter degradations can lead to circuit level degradation. In particular, this work focuses on delay degradation.

B. Digital adders

According to design requirements, different adder architectures can be applied to digital ICs design [16]. Five architectures are taken into account in this work. Ripple Carry Adder

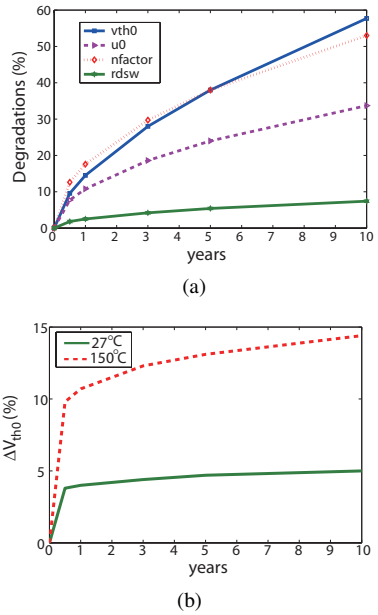

Fig. 2. HCI and NBTI induced physical parameters degradation in: a. NMOS and b. PMOS transistor

(RCA) is the simplest carry propagation adder leading to a low operation speed. Carry Select Adder (CSA) [13] accelerates the speed thanks to redundancy. Carry Lookahead Adder (CLA), also referred as Parallel-Prefix Adders (PPAs) is another fast adder suitable for high-speed application. We also explore some advanced PPAs like Kogge-Stone Adder (KSA) [14] and SKlansky Adder (SKA) [15]. Table I summarizes the characteristics of each architecture, according to area, delay, regularity (synthesis).

TABLE I. COMPARISONS OF DIFFERENT ADDER ARCHITECTURE [1]

Adder architecture	Area	Delay	Regularity
RCA	$O(N)$	$O(N)$	highest
CSA	$O(N)$	$O(N^{\frac{1}{2}})$	high
CLA	$O(N)$	$O(logN)$	medium
KSA	$O(NlogN)$	$O(logN)$	medium
SKA	$O(NlogN)$	$O(logN)$	medium

III. AGING-AWARE DESIGN FLOW

SPICE simulators are widely used to evaluate timing performance at gate level. Nevertheless, they are not suitable to directly simulate aging induced timing degradations in complex circuits due to low computation efficiency [17]. The proposed aging-aware design flow is based on the gate-level netlist generation of traditional synthesis, as illustrated in Figure 3. Traditional RTL synthesizers can produce a structural (i.e. logic or transistor level) description based on a HDL description for a given digital block.

According to design specifications, the *Behavioral modeling language* for digital circuits (e.g., VHDL, Verilog) is used to describe the functions of logic circuits. Their function correctness is verified by the *Functional simulation*. The *Library statement* includes necessary technology files. A gate-level netlist is generated by *RTL synthesis* and re-simulated by the *Aging simulator*.

In this work, we considered NBTI and HCI aging models available on Eldo simulator from Mentor Graphics [18]. With an initialization of aging setup (e.g., aging model selection, aging stress duration), a transient simulation is performed to evaluate the stress on each transistor [19]. Then, aged netlist which contains degraded information is generated and can be further applied to post-layout simulations. Finally, both ideal and aged synthesis report can be investigated by designers.

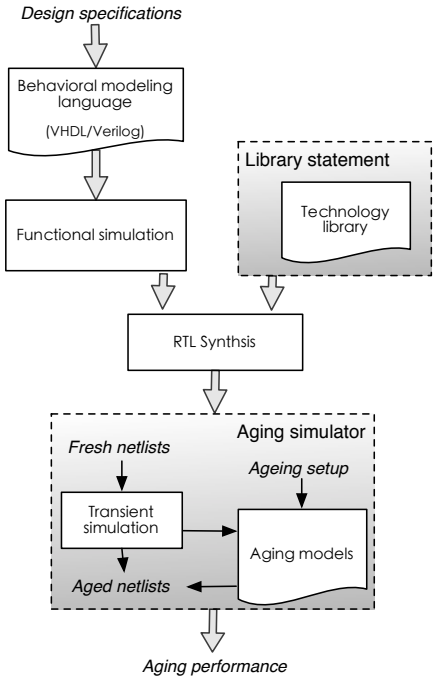

Fig. 3. Aging-aware design flow

IV. CASE STUDY: 65 NM ADDERS

This section presents the ASIC implementation results as well as the aging effect performance of different adders as mentioned in Section II-B. We used the 65 nm CMOS technology to demonstrate the proposed flow. Even the 65 nm technology is not highly susceptible to aging effects, our flow allows to explore how they affect adder circuits anyway. The simulation environment is characterized with room temperature of 27°C and 1.2 V supply voltage. The input duty cycle is set to 50%. Notice that the experimental results are obtained without the consideration of input probability. We conservatively assume that all the PMOS and NMOS transistors in the adders are affected equally by NBTI and HCI respectively.

A. Synthesis results

Table II shows the performance comparison, where ADP and PDP indicate relative area delay product and power delay product, respectively. Different word length adders are reported (4 bits, 8 bits and 16 bits). From this table, KSA and SKA

TABLE II. PERFORMANCE COMPARISON OF ADDERS

Adder Architecture	Area (μm^2)			Delay (ps)			Power			ADP (Normalized)			PDP (Normalized)			Dominant effect
	4	8	16	4	8	16	4	8	16	4	8	16	4	8	16	
RCA	49.9	99.8	199.7	524.8	992.4	1926.6	2.71	5.42	11.08	1.17	1.36	1.59	1.05	1.22	1.62	NBTI
CSA	96.7	193.4	386.9	372.7	600.7	1056.7	7.24	14.48	28.96	1.61	1.60	1.69	1.80	1.97	2.25	NBTI
CLA	64.5	130,0	257.9	348.2	651.4	1257.8	4.71	9.41	18.82	1.00	1.16	1.34	1.21	1.39	1.79	NBTI

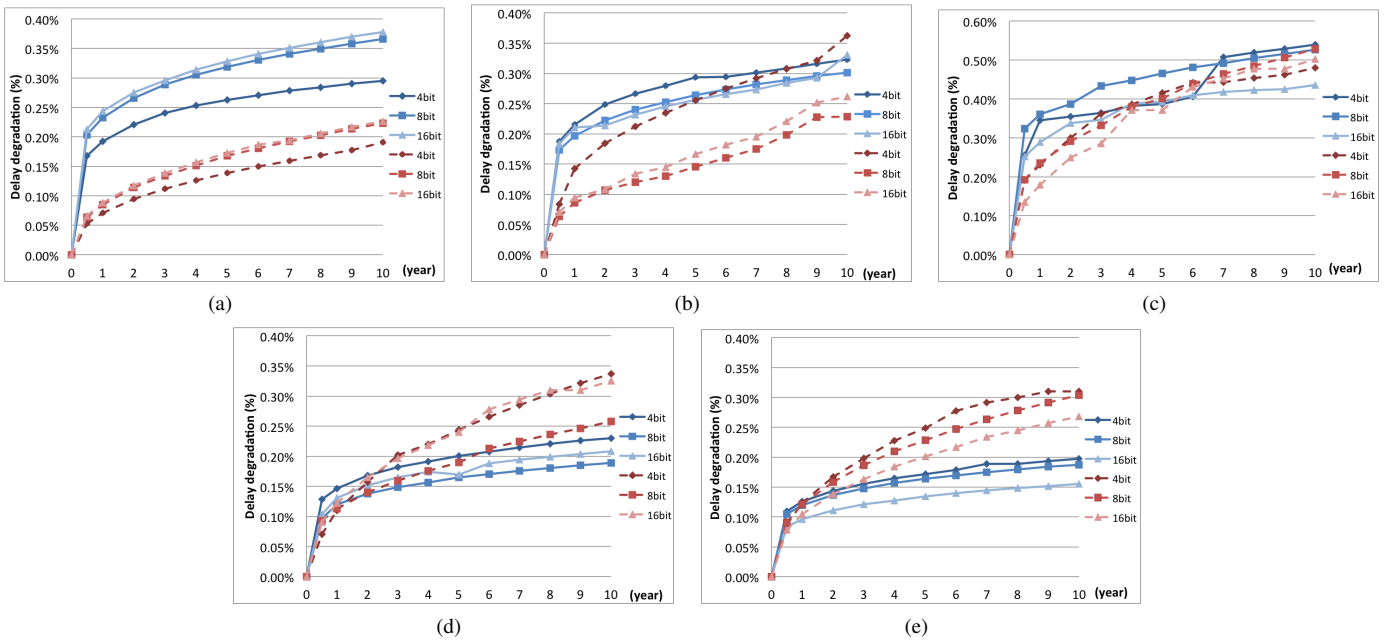

Fig. 5. NBTI and HCI Delay degradation over time of different adders, T=300K: (a) RCA (b) CSA (c) CLA (d) KSA (e) SKA ; (d)An example (8 bits-length KSA) to demonstrate the critical path changing with time under the HCI effect

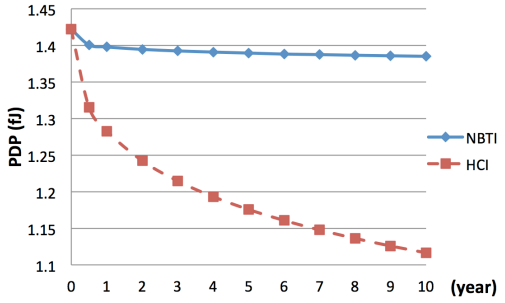

Fig. 4. Power delay product versus year of 4 bits-length RCA

are the best tradeoffs considering area, delay and power. It is noteworthy both adders have an interesting delay performance, especially in the case of long word length. Thus, they are referred to fast adders in this work.

As it can be seen from Table II, the impacts of NBTI and HCI exhibit different features according to adder architectures. Aging effects can lead to delay degradation and decrease the ADP product. Instead, they have positive influences on power and thus increase the PDP. This particularly true for HCI (see Fig. 4). We therefore concentrate on delay degradation. More details are shown in Figure 5, where blue lines stand for the delay degradation induced by NBTI and red lines for HCI. The impacts of NBTI and HCI on adders will be further discussed in the next subsection.

B. *Ageing consideration*

As shown in Figure 5, both NBTI and HCI induced additional delay are time-dependent and monotonic increasing. The dominant aging effect changes with adder architecture and depends on PMOS and NMOS partitions. The fast adders are more sensitive to HCI, while no significant difference between two effects is observed for CSA. NBTI is the dominant aging effect for RCA and CLA. Particularly, CLA's delay is severely degraded by NBTI (higher than 0.5% after 10 years stress). Remind that the experiments are performed at room temperature. NBTI degradation will get worse with temperature increasing [9], whereas HCI can not be intensified at high temperature [10].

Besides, we observe that the dominant aging effect varies with time in the case of faster adders. They become more sensible to HCI than NBTI after 2 years stress. The degradation speed caused by HCI is always faster than NBTI which makes the HCI as dominant effect in the later period, as expected according to Fig. 2.

Another interesting aspect is that the maximum delay

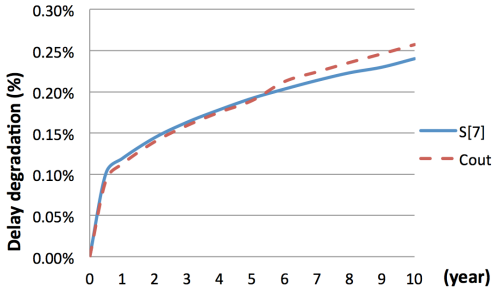

Fig. 6. An example (8 bits-length KSA) to demonstrate the critical path changing with time under the HCI effect

degradation is not always appearing at critical path. Taking CLA as example, the most significant degradation occurs on "carry out" bit which is near the critical path (MSB of the sum). As aforementioned, NBTI can lead to the possible critical path changing. Our experimental results prove that HCI may also result in this changing (see Figure 6). Let take a 8 bits KSA for instance, we notice the fresh circuit has bit "S[7]" as the critical path. However, the bit "Cout" is more sensible to HCI with the time progress, and will surpass the critical path after several years. Furthermore, the arise of delay do not always enhance the impact of aging effects. On the contrary, the impact could be reduced with increasing of delay. The 16 bits SKA suffers less degradation than the 4 bits SKA. This suggests that the aging effect is not a linear function of the impact on the individual logic gate.

Figure 7 depicts the performance comparison of different adders under aging effects. The observations are summarized as follows:

- Either NBTI or HCI, CLA is the most aging-sensitive adder among all architectures. For instance, a 8 bits-length CLA is thrice sensible to HCI than a 8 bits-length SKA. Moreover, CLA is much more vulnerable to HCI than others.
- SKA is the least NBTI-sensitive adder architectures (delay degradation$< 0.2\%$), while RCA is the most efficient architecture to resist HCI.
- Compared with the other adders, the fast adders can be the best trade-off considering both NBTI and HCI.
- The aging induced delay degradation in 65 nm CMOS adders is low compared with that related to other reliability effects (e.g., process variation). In other words, this observation demonstrates that 65 nm CMOS adders are reliable with respect to aging effects.

V. Conclusions

In this paper, we proposed an aging-aware design flow taking into account two major aging effects: NBTI and HCI. Five adder architectures were studied to demonstrate this flow using 65 nm CMOS technology. Adders were compared with respect to area, delay and timing performance under aging effect. The experimental results showed that the fast adders overcome both in hardware complexity and resistance to aging effects.The aging consideration enables to point out that the dominant effect strongly depends on architecture. The fast adders are more vulnerable to HCI than NBTI and while the opposite is true for low-speed adders. The difference delay degradation among studied adder architectures can be up to three times according to the circuit size and time stress. In addition, it is possible that the increasing of critical path reduce the impact of aging effect, an shown for SKA. Future work will focus on the experimental verification of obtained results as well as other reliability effects in digital circuits.

***Abstract*—Reliability issues due to transient faults have increased with CMOS scaling and become an important concern for deep submicron technologies. Concurrent Error Detection (CED) scheme has been widely used against transient faults under the assumption of single fault and/or fault-free checking parts. In this work, we propose an analytical method in order to assess CED circuit reliability under more realistic hypothesis. In other words, we take into account the occurrence of multiple faults and fault-prone checking parts. This method allows to demonstrate the efficiency of CED schemes. The computational requirements for such an assessment are reduced by progressive analysis of the overall circuit through conditional probabilities. The proposed solution has been demonstrated on classical CED schemes.**

I. INTRODUCTION

With the shrinking of CMOS technology, electronic Integrated Circuits (ICs) are expected to suffer low reliability due to permanent and transient faults [1]. Permanent faults arise from the parametric variability in materials and fabrication processes. Transient faults mainly arise from the sensibility to external environment (radiation-related effects, low voltage, etc) and are important sources of soft errors.

Among existing fault-tolerant techniques, *Concurrent Error Detection* (CED) techniques are widely applied to detect errors occurring during normal circuit operation. This technique is particularly effective for the detection of soft errors which cannot be predicted in advance by test. Various CED schemes have been presented in last decades [2]–[5].

Traditionally, CED schemes are characterized under the hypothesis of single fault [6], [7]. However, the influence of multiple faults is no more negligible as circuits scale down to nanometer dimensions [8]. Multiple faults analysis of CED schemes have been only reported in few literature and most of them assume that faults do not affect fault-check parts [9]. Vasconcelos *et al.* proposed an analysis method based on fault injection and functional simulation approach [10]. The method assume that faults can occur independently on all components in CED circuits. Nevertheless, the time complexity of this approach is exponential with the number of binary inputs and the number of gates in circuit.

In this paper, we present an analytical solution for accurate reliability assessment of CED circuits. The solution deals with multiple faults, wherever they occur on, including fault-check parts.

The paper is organized as follows: Section II recalls basics on reliability analysis with probability matrices and CED schemes. Section III describes the proposed method. Section IV analyses the performance of the proposed solution. Finally, conclusions of this work are outlined in Section V.

II. BACKGROUND

A. Basics on PTM

The *Probabilistic Transfer Matrices* (PTMs) approach for reliability assessment is based on matrix representation of error probabilities [11].

Consider a logic block b with input x and output y, where $x \in \{x_0, x_1, \cdots, x_i, \cdots, x_{2^n-1}\}$ and $y \in \{y_0, y_1, \cdots, y_j, \cdots, y_{2^m-1}\}$, and both of them have binary representations. For example, x_{15} is noted as "1111" when n is "4". The PTM of block b, denoted PTM_b, has $2^n \times 2^m$ elements and each (i, j) element is the probability of getting output $y = y_j$ given the occurrence of input $x = x_i$, noted $p(j|i)$. In the case of an ideal (i.e. fault free) block, the PTM contains only zeros and ones and is referred as ITM (Ideal Transfer Matrix).

Fig. 1 shows the PTM of an OR logic gate with error probability equals to $1 - q$, where q represents the probability of getting a correct output. We can note that ITM is defined for $q = 1$. To calculate PTM of a whole circuit C, we combine PTMs of its basic blocks using matrix products and tensor products [11]. The reliability of a block or a circuit is directly

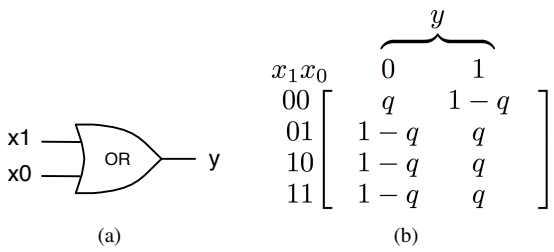

Fig. 1. (a) Logic gate OR and (b) its corresponding PTM.

extracted from the respective PTM and ITM, according to (1), where $p(i)$ denotes the probability that input x is x_i.

$$R = \sum_{ITM(i,j)=1} p(j|i) \cdot p(i) \tag{1}$$

The expression above gives the sum of probabilities corresponding to correct outputs. That is, the element in position (i, j) of PTM matrix will contribute to the sum only if the respective (i, j) element of the ITM has a value 1. Since the PTM gives the exact probabilities of getting correct outputs, this expression provides accurate reliability assessment.

B. Basics on CED

The general scheme of a CED structure is depicted in Fig. 2. It considers a main (target) *Function* F. A *Function Predictor* F_p predicts some special characteristics z of F's output y and a *Function Checker* F_c checks whether these characteristics are satisfied by y. This checking results in an one-bit output e. In the remainder of this paper, it is assumed that $e = 0$ when no error is detected and $e = 1$ otherwise. This is solely a convention that does not restrict the scope of the analysis. The output w of a such CED circuit is the concatenation of the outputs e and y: $w = [e, y]$.

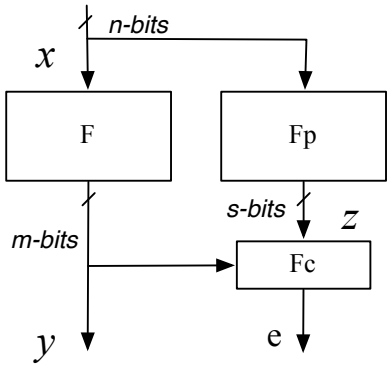

Fig. 2. Concurrent Error Detection circuit

C. Functional reliability of a CED circuit

Functional reliability can be defined as the ability of a system or component to perform its required functions under stated conditions for a specified period of time, even in presence of faults [12]. Actually, we can state that the functional reliability of a CED circuit shown in Fig. 2 is related to the probability of producing only the events E_1 or E_2 defined as follows:

Definition 1: The event E_1 is the occurrence of a correct output y combined with an output e indicating no error detected.

Definition 2: The event E_2 is the occurrence of an incorrect output y combined with an output e indicating error detected.

Indeed, the events E_1 and E_2 are mutually exclusive. Therefore, the functional reliability can be expressed as:

$$R = p(E_1) + p(E_2) \tag{2}$$

III. CED RELIABILITY ASSESSMENT

A. CED reliability assessment with PTM

In this section we show that R_{CED} can be obtained by using PTM principle.

First, consider rewriting the expression (2) to show the probability of occurrence of inputs and outputs as defined in section II-A. The expression (3) is produced by doing this, where $p(i)$ stands for the probability of $x = x_i$ and $p(j \in E_1|i) + p(j \in E_2|i)$ is related to a proper functioning of the CED for $x = x_i$. In other words, it represents the probability of having a proper $[e, y]_j$ given that the input is x_i.

$$\begin{aligned} R &= \sum_j \sum_i p(i)\left[p(j \in E_1|i)) + p(j \in E_2|i)\right] \\ &= \sum_j \sum_i p(i) \cdot PTM_{CED}(i,j) \cdot ITM_{CED}(i,j) \end{aligned} \tag{3}$$

In order to illustrate this idea, let's take an OR gate as Function F. The corresponding ITM_{CED} is presented in Fig. 3. We remark that left half of matrix ITM_{CED} (columns for $e = 0$) is the ITM_{OR}, while the right half (columns for $e = 1$) is the logic complement of ITM_{OR}.

$$\begin{array}{c} \\ 00 \\ 01 \\ 10 \\ 11 \end{array} \begin{array}{c} \overbrace{}^{e=0}\ \overbrace{}^{e=1} \\ \begin{bmatrix} 1 & 0 & 0 & 1 \\ 0 & 1 & 1 & 0 \\ 0 & 1 & 1 & 0 \\ 0 & 1 & 1 & 0 \end{bmatrix} \end{array} \begin{array}{c} \\ 00\ 01\ 10\ 11 \\ \\ \\ \\ \end{array} = [ITM_{OR}, \overline{ITM_{OR}}]$$

Fig. 3. ITM_{CED} for an OR gate as function circuit F.

This can be generalized in a straightforward way for any CED circuit. Therefore, assuming F with n-bits input and m-bits output, the functional reliability can be expressed as:

$$\begin{aligned} R = &\sum_{j=0}^{(2^m-1)} \sum_{i=0}^{(2^n-1)} p(i) \cdot PTM_{CED}(i,j) \cdot ITM_F(i,j) \\ &+ \sum_{j=2^n}^{(2^{m+1}-1)} \sum_{i=0}^{(2^n-1)} p(i) \cdot PTM_{CED}(i,j) \cdot \overline{ITM_F(i,j)} \end{aligned} \tag{4}$$

B. CED reliability assessment: alternative approach

The following paragraphs present an alternative approach for estimating R. The objective is to reduce the computational complexity. For this, we define the events A and B:

Definition 3: The event A is the occurrence of a correct circuit output y.

Definition 4: The event B is the occurrence of a checker output e indicating no error.

Let $p(y_j^c)$ be as the probability of $y_j \in A$. According to the joint probability theory, the probability of E_1 is represented in (5), where $\coprod$ depicts the disjoint union.

$$\begin{aligned} p(A \cap B) &= p\Big(\coprod_j y_j^c \cap B\Big) \\ &= \sum_j \big(p(y_j^c) \cap B\big) \\ &= \sum_j p(y_j^c) \cdot p\big(B|y_j^c\big) \end{aligned} \tag{5}$$

We can notice the following equalities, where $p(z_k)$ is the probability that $z = z_k$.

$$p(y_j^c) \cdot p\big(B|y_j^c\big) = \sum_k p(y_j^c) \cdot p(B|y_j^c \cap z_k) \cdot p(z_k|y_j^c) \quad (6)$$

We now analyze the dependency of z with respect to y_j^c. Based on the law of conditional probability and the law of total probability, we get (7) and (8), respectively.

$$p(z|y_j^c) = \frac{p(z \cap y_j^c)}{p(y_j^c)} \quad (7)$$

$$p(y_j^c) = \sum_i p(x_i) \cdot p(y_j^c|x_i) \quad (8)$$

Since faults are considered to occur independently on F or F_p, y and z are independent for a given x_i:

$$\begin{aligned} & p(z \cap y|x_i) = p(z|x_i) \cdot p(y|x_i) \\ & \Rightarrow p(z \cap y) = \sum_i p(x_i) \cdot p(z|x_i) \cdot p(y|x_i) \end{aligned} \quad (9)$$

Applying (9) into (7) we have :

$$\begin{aligned} p(z|y_j^c) &= \frac{\sum_i p(x_i) \cdot p(y_j^c|x_i) \cdot p(z|x_i)}{p(y_j^c)} \\ &= \sum_i p(y_j^c|x_i) \cdot \frac{p(x_i)}{p(y_j^c)} \cdot p(z|x_i) \end{aligned} \quad (10)$$

We rewrite (5) by replacing $p(z_k|y_j^c)$ in (6) with that given in (10), and thus express the probability of E_1 as shown in equation (11).

$$\begin{aligned} p(A \cap B) = \sum_j \Big(& \sum_k p\left(B|y_j^c \cap z_k\right) \\ & \cdot \sum_i \big(p(y_j^c|x_i) \cdot p(z_k|x_i) \cdot p(x_i)\big) \Big) \end{aligned} \quad (11)$$

The probabilities in the equation (11) can be obtained from PTMs of F, F_p and F_c as the following:

$$p\left(B|y_j^c \cap z_k\right) = PTM_{F_c}((m \times j + k), 0) \quad (12)$$

$$p(y_j^c|x_i) = PTM_F(i,j) \cdot ITM_F(i,j) \quad (13)$$

$$p(z_k|x_i) = PTM_{F_p}(i,k) \quad (14)$$

Applying these equalities to (11) allows us to rewrite E_1 in (15). In an equivalent manner, we can get E_2 as given in (16). We notice that only PTMs of sub-circuits are required instead of that of the overall CED circuit.

IV. Performance analysis

A. Complexity evaluation

This section focuses on the computational complexity of methods proposed in previous section. Suppose PTMs and ITMs of sub-circuits F, F_p and F_c are already available. Meanwhile, denote $\oplus$ as the computational complexity for adding two numbers and $\otimes$ as the computational complexity for multiplying two numbers.

In the case of method described in III-A, the complexity is that of obtaining the global matrix PTM_{CED} and adding the appropriate elements in accordance with the equation (4).

On the basis of PTMs approach, the PTM of two blocks b_1 and b_2 in cascade results from the inner product of PTM_{b_1} and PTM_{b_2}. In the case of parallel structure, the resulting PTM comes from the tensor product of PTM_{b_1} and PTM_{b_2}.

Figure 4 shows the partitioning of the CED circuit in order to calculate the overall PTM_{CED}. Utilizing the rules above on the blocks in a level u leads to the values T_u in Table I. Similarly, the complexities related to the cascade involving different levels are shown in Table II.

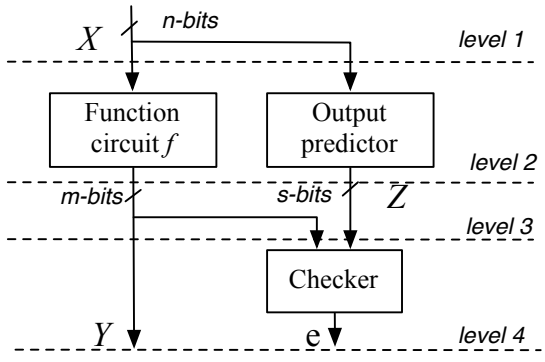

Fig. 4. Level partition of CED circuit

TABLE I. Computational complexity to obtain PTM for a given level.

T_1	$(2 \times 2^2)^n \times \otimes = 2^{3n} \times \otimes$
T_2	$2^{n+m} \times 2^{n+s} \times \otimes = 2^{2n+m+s} \times \otimes$
T_3	$(2 \times 2^2)^m \times (2^2)^s \times \otimes = 2^{3m+2s} \times \otimes$
T_4	$(2^2)^m \times (2^{m+s} \times 2) \times \otimes = 2^{3m+s+1} \times \otimes$

$$p(E_1) = \sum_{j=0}^{2^m-1} \Big(\sum_{k=0}^{2^s-1} PTM_{F_c}((m \times j + k), 0) \cdot \sum_{i=0}^{2^n-1} \big(PTM_F(i,j) \cdot PTM_{F_p}(i,k) \cdot ITM_F(i,j) \cdot p(i)\big) \Big) \quad (15)$$

$$p(E_2) = \sum_{j=0}^{2^m-1} \Big(\sum_{k=0}^{2^s-1} PTM_{F_c}((m \times j + k), 1) \cdot \sum_{i=0}^{2^n-1} \big(PTM_F(i,j) \cdot PTM_{F_p}(i,k) \cdot \overline{ITM_F}(i,j) \cdot p(i)\big) \Big) \quad (16)$$

TABLE II. COMPUTATIONAL COMPLEXITY TO OBTAIN PTM FOR A CASCADE OF LEVELS

$T_{1\to 2}$	$2^{n+2n+(m+s)}(\oplus+\otimes)$ $= 2^{3n+m+s}(\oplus+\otimes)$
$T_{1\to 3}$	$2^{2n+(m+s)+(2m+s)}(\oplus+\otimes)$ $= 2^{2n+3m+2s}(\oplus+\otimes)$
$T_{1\to 4}$	$2^{(m+s)+(2m+s)+(m+1)}(\oplus+\otimes)$ $= 2^{4m+2s+1}(\oplus+\otimes)$

The total complexity T_a thus is:

$$T_a = 2^{n+m+1}(2\times\otimes+\oplus)-\oplus+\sum_u T_u+\sum_v T_{1\to v} \quad (18)$$

In the case of method described in III-B, the total complexity comes straight from the computation of (15) and (16):

$$T_b = 2^{m+n+s+1}(2^2\times\otimes+\oplus)-\oplus \quad (19)$$

We can easily conclude that $T_b \ll T_a$, which confirms a significant gain in computation efficiency.

B. Experimental results

The proposed methodologies have been implemented with Matlab [13], while Modelsim [14] has been used as the simulation platform for a fault injection approach [10]. Experimental results were performed on a Linux workstation with a 2GHz AMD Athlon microprocessor and 2GB RAM.

Remind that in fault injection approach, the result accuracy can be improved by increasing the maximum number of considered simultaneous faults, but the computational complexity would be dramatically increased as well. In order to optimize the procedure of simulations, we assume the maximum number of simultaneous faults to be 3 in the fault injection approach

We consider three different CED schemes adopted in a ripple carry adder (RCA) operator: an identical duplication adder (noted as RCA_Dup), a diverse duplication adder (noted as RCA_Div_Dup) and a parity checking adder (noted as RCA_Parity).

Table III shows the run-time comparison. It is noteworthy that conventional PTMs based method is impracticable for RCA_Dup and RCA_Div_Dup due to excessive memory requirements. The obtained results verifies the remarkable performance of the solution described in III-B, particularly for identical duplication circuit.

TABLE III. TIME CONSUMPTIONS (S)

Circuit type	Evaluation method			Gate
	Fault injection [10]	Basic PTM	Alternative	Nb.
RCA_Dup	7398.1	NA	18.6	86
RCA_Div_Dup	6345.7	NA	19.3	78
RCA_Parity	367.2	50.3	4.7	32

V. CONCLUSION

This work dealt with the reliability assessment of CED circuits under multiple faults. We proposed an accurate analytical solution based on PTMs approach. We firstly presented how to apply PTMs to assess the functional reliability. Afterwords, we proposed an alternative approach to reduces the analysis computational complexity.

The computational efficiency of the alternative solution has been mathematically demonstrated. Arithmetic operators were considered as case studies. The experimental results confirmed that the proposed alternative solution outperforms the basic PTMs based method as well as the fault injection approach.

Future work will concentrate on exploring different CED schemes through the proposed method.

VI. ACKNOWLEDGMENT

Synthesis of CMOS Multiplier Structures Using Multifunctional Circuits

C. Popa
Faculty of Electronics, Telecommunications and Information Technology, Bucharest, Romania
cosmin_popa@yahoo.com

Abstract - The paper will present new high accuracy multiplier circuits, focused on the implementation of original techniques for improving the linearity of the proposed structures. The new approach of designing high precision multipliers using multifunctional cores presents the important advantage of allowing a facile reconfiguration of the designed circuits, the multiplier core being able to implement a multitude of additional circuit functions: amplifying, squaring and square-rooting or simulating a positive and negative equivalent resistance. The multiplier structures are designed for low-voltage low-power operation (the supply voltage is $\pm 1.8V$ for implementing in $0.18\mu m$ CMOS technology and the current consumption is smaller than $50\mu A$ for any proposed multiplier).

Keywords - Analog signal processing, multiplier circuits, linearity error, multifunctional cores, translinear circuits

I. INTRODUCTION

Computational circuits and particularly multipliers are important building blocks for telecommunication applications, medical equipments, hearing devices and disk drives [1]-[4]. Different mathematical principles represent the functional cores for designing multiplier structures with increased linearity and either currents or voltages as input variables [5]-[7].

II. THEORETICAL ANALYSIS

In order to extend the possibility of generation of a multitude of additional circuit functions, the proposed multiplier circuits are designed using two original implementations of multifunctional cores - MFC (computational blocks with output variables containing a linear combination of elementary circuit functions). This new original approach of designing computational circuits using multifunctional cores presents the important advantage of generating large number of circuit functions using the same core (amplifying, multiplying or simulating a positive or negative equivalent resistance). Thus, the possibility of reconfiguration of these structures is strongly increased. This original design method facilitates the implementation of field programmable analog arrays (FPAAs) with improved performances and reduced design costs.

It will be presented a group of original implementations of multiplier circuits, the main goal being the improvement of their linearity for an extended range of the input voltage amplitudes. The operation of the proposed circuits is based on an original principle of operation and on two original implementations of multifunctional cores. In order to improve the circuits' frequency response, only MOS transistors biased in saturation will be used.

A. Principle of operation

The principle of operation for the proposed multiplier circuits is based on the compensation of the nonlieairities introduced by two complementary mathematical functions. As in CMOS technology it is very simple to implement the squaring function using MOS transistors biased in saturation region, the complementary functions are chosen to be squaring and square-rooting functions. The squaring dependencies are generated using a classical MOS differential amplifier, while the square-rooting functions are obtained considering the difference between two gate-source voltages of MOS transistors biased at different drain currents.
The mathematical relations that model the squaring dependencies are:

$$I_{O1} = \frac{K}{2}\left(V_{GS1} - V_T\right)^2 \tag{1}$$

$$I_{O2} = \frac{K}{2}\left(V_{GS2} - V_T\right)^2 \tag{2}$$

and:

$$V_{GS1} - V_{GS2} = V_3 - V_4 \tag{3}$$

resulting:

$$\sqrt{I_{O1}} - \sqrt{I_{O2}} = \sqrt{\frac{K}{2}}\left(V_3 - V_4\right) \tag{4}$$

The implementation of a square-root dependence of two output currents, I_{OUT1} and I_{OUT2}, on two biasing currents, I_{O1} and I_{O2}, respectively, exploits a translinear loop containing two gate-source voltages of MOS transistors biased at different drain currents. The difference of these gate-source voltages is forced to be equal with a multiple of a $V_1 - V_2$ differential input voltage:

$$V_{GS}\left(I_{OUT1}\right) - V_{GS}\left(I_{O1}\right) = a\left(V_1 - V_2\right) \tag{5}$$

a representing a constant that depends on the particular implementation of the circuit that uses this principle of operation. Imposing a biasing in saturation of all MOS transistors from the circuit, it results the following relation:

$$\sqrt{I_{OUT1}} = \sqrt{I_{O1}} + a\sqrt{\frac{K}{2}}(V_1 - V_2) \quad (6)$$

So, I_{OUT1} current will be expressed as:

$$I_{OUT1} = I_{O1} + a\sqrt{2KI_{O1}}(V_1 - V_2) + \frac{a^2K}{2}(V_1 - V_2)^2 \quad (7)$$

Similarly, another I_{OUT2} current will have a square-root dependence on I_{O2} biasing current:

$$I_{OUT2} = I_{O2} + a\sqrt{2KI_{O2}}(V_1 - V_2) + \frac{a^2K}{2}(V_1 - V_2)^2 \quad (8)$$

In order to obtain the multiplying function between two differential input voltages, the output current must have a particular linear dependence on the previous currents:

$$I_{OUT} = (I_{OUT1} + I_{O2}) - (I_{OUT2} + I_{O1}) \quad (9)$$

resulting:

$$I_{OUT} = a\sqrt{2K}\left(\sqrt{I_{O1}} - \sqrt{I_{O2}}\right)(V_1 - V_2) \quad (10)$$

Replacing (4) in (10), it results that I_{OUT} current will have the following expression:

$$I_{OUT} = aK(V_1 - V_2)(V_3 - V_4) \quad (11)$$

B. Multiplier architectures using the new principle of operation

The proposed multiplier circuits are based on multifunctional cores that are able to implement the required mathematical relations for obtaining the multiplying function. Additionally, these multifunctional cores allow the generation of a multitude of circuit functions: amplifying, squaring or simulating an active resistance. The proposed multifunctional core (MFC I) is presented in Figure 1. The M1-M2 differential input stage is biased using M3 transistor, the drain current of M2 transistor being forced to be equal to I_{O1} current.

The functional relation implemented by the circuit is:

$$V_{GS}(I_{OUT1}) - V_{GS}(I_{O1}) = V_1 - V_2 \quad (12)$$

So, the I_{OUT1} output current will be expressed by (7), for $a = 1$. The first proposed implementation of a multiplier circuit (Figure 2) uses two multifunctional cores from Figure 1.

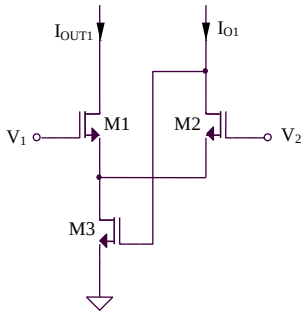

Figure1. The multifunctional core (MFC I)

The first multifunctional core, M1-M3, is biased at I_{O1} current and generates the I_{OUT1} output current. In order to extract I_{O1} current, M4 transistor is used. The expressions of I_{OUT1} and I_{OUT2} output currents are:

$$I_{OUT1,2} = I_{O1,2} + \sqrt{2KI_{O1,2}}(V_1 - V_2) + \frac{K}{2}(V_1 - V_2)^2 \quad (13)$$

As a result of two cross-connections, the output current of the multiplier circuit can be expressed using (9), resulting:

$$I_{OUT} = \sqrt{2K}\left(\sqrt{I_{O1}} - \sqrt{I_{O2}}\right)(V_1 - V_2) \quad (14)$$

The I_{O1} and I_{O2} currents are generated by the M9-M10 differential stage, the relation between them being given by (4). So, the output current of the multiplier circuit presented in Figure 2 will be proportional with the product of two differential input voltages:

$$I_{OUT} = K(V_1 - V_2)(V_3 - V_4) \quad (15)$$

The aspect ratios of MOS transistors are shown in Table 1.

TABLE 1. THE ASPECT RATIOS OF MOST RANSISTORS

M	M1	M2	M3	M4	M5	M6
W/L	4.5/0.9	4.5/0.9	9/0.9	4.5/0.9	4.5/0.9	4.5/0.9

M	M7	M8	M9	M10	M11	M12
W/L	4.5/0.9	9/0.9	9/0.9	9/0.9	4.5/0.9	4.5/0.9

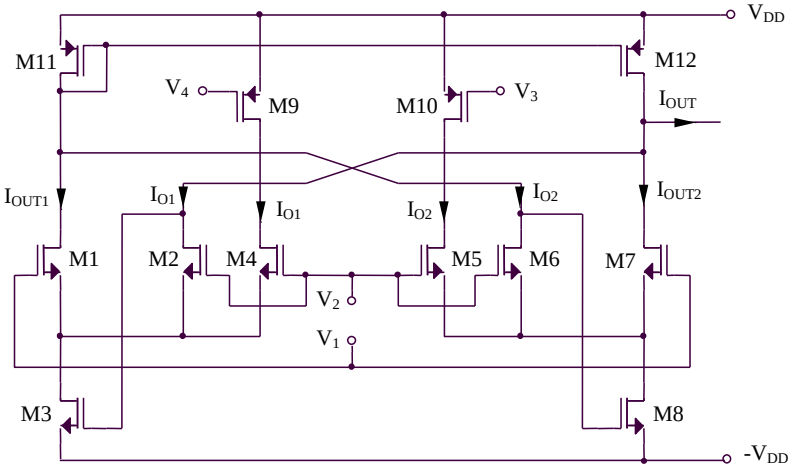

Figure 2. Multiplier circuit (I) using MFC I

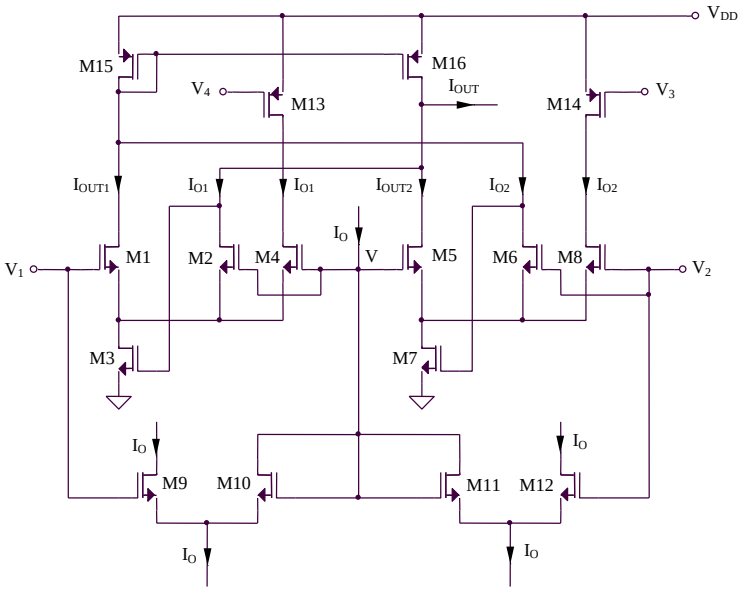

Figure 3. Multiplier circuit (II) using MFC I

The same multifunctional core from Figure 1 can be re-used for implementing another original multiplier circuit (Figure 3). Similar multifunctional cores M1-M3 and M5-M7 are used for realizing the required dependencies (7) and (8) of I_{OUT1} and I_{OUT2} output currents on I_{O1} and I_{O2} currents, respectively. The M4 and M8 transistors are used for connecting these cores with the M13-M14 differential amplifier that allows to obtain relation (4). The M9-M12 group computes the arithmetical mean of V_1 and V_2 input potentials, $V=(V_1+V_2)/2$. For the M1-M3 multifunctional core, the relation between the gate-source voltages can be expressed as follows:

$$V_{GS}(I_{OUT1})-V_{GS}(I_{O1})=V_1-V=\frac{V_1-V_2}{2} \qquad (16)$$

So, comparing with (5), it results that $a=1/2$, so the expression of the output current is obtained from (11):

$$I_{OUT}=\frac{K}{2}(V_1-V_2)(V_3-V_4) \qquad (17)$$

The aspect ratios of MOS transistors are shown in Table 2.

TABLE 2. THE ASPECT RATIOS OF MOS TRANSISTORS

M	M1	M2	M3	M4	M5	M6
W/L	4.5/0.9	4.5/0.9	9/0.9	4.5/0.9	4.5/0.9	4.5/0.9

M	M7	M8	M9	M10	M11	M12
W/L	9/0.9	4.5/0.9	4.5/0.9	4.5/0.9	4.5/0.9	4.5/0.9

M	M13	M14	M15	M16
W/L	9/0.9	9/0.9	9/0.9	9/0.9

The second proposed multifunctional core (MFC II) is presented in Figure 4.

The M1 and M3 transistors are biased at I_{O1} current, while M2 and M4 transistors have the same drain current, equal with I_{OUT1}.

The relation between their gate-source voltages is:

$$2V_{GS}(I_{OUT1})-2V_{GS}(I_{O1})=V_1-V_2 \qquad (18)$$

Relation (18) is similar with (5), so I_{OUT1} output current will be expressed by (7) (for $a=1/2$).

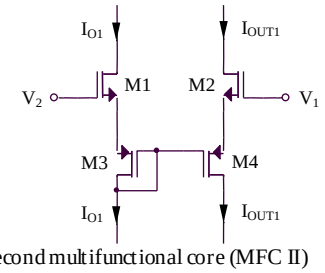

Figure 4. The second multifunctional core (MFC II)

The original proposed implementation of a multiplier circuit (Figure 5) uses two multifunctional cores from Figure 4 (M1-M4 and M5-M8 groups in Figure 5). Using (7) and (8), the expressions of I_{OUT1} and I_{OUT2} output currents will be:

$$I_{OUT1}=I_{O1}+\sqrt{\frac{KI_{O1}}{2}}(V_1-V_2)+\frac{K}{8}(V_1-V_2)^2 \qquad (19)$$

and:

$$I_{OUT2}=I_{O2}+\sqrt{\frac{KI_{O2}}{2}}(V_1-V_2)+\frac{K}{8}(V_1-V_2)^2 \qquad (20)$$

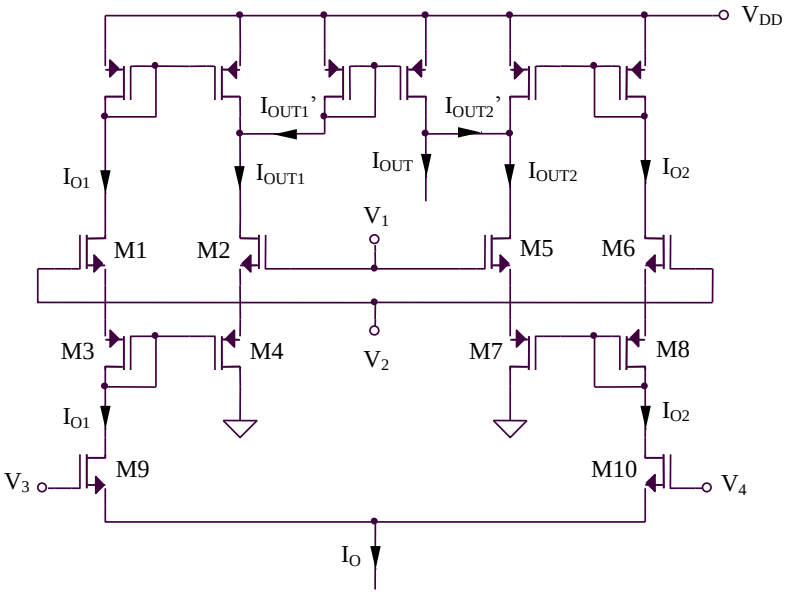

Figure 5. Multiplier circuit (III) using MFC II

As a result of the circuit connections, the output current of the multiplier can be expressed using (9), resulting:

$$I_{OUT} = \sqrt{\frac{K}{2}}\left(\sqrt{I_{O1}} - \sqrt{I_{O2}}\right)(V_1 - V_2) \qquad (21)$$

The I_{O1} and I_{O2} currents are generated by the M9-M10 differential stage, the relation between them being given by (4). So, the output current of the multiplier circuit presented in Figure 5 will be proportional with the product of two differential input voltages:

$$I_{OUT} = \frac{K}{2}(V_1 - V_2)(V_3 - V_4) \qquad (22)$$

III. CONCLUSIONS

There were presented original implementations of multiplier circuits, the main goal of designing these structures being represented by the increasing of their linearity. The new proposed method for obtaining high accuracy multiplier circuits was based on the utilization of two functional cores that are able to generate a multitude of circuit functions. This original approach of designing computational structures has the very important advantage of multifunctionality, the proposed multiplier circuits, implemented using multifunctional cores, allowing a facile reconfiguration. As the design and implementation costs were mainly related to the improving of the circuit core performances, the costs associated with the implementation of one circuit function can be strongly reduced using this new approach. Comparing with similar designs that describe CMOS implementations of voltage multipliers, the proposed circuits present the advantage of a relatively simple implementation, correlated with a very good linearity.

Improved Accuracy Current-Mode Analog Function Synthesizer

C. Popa
Faculty of Electronics, Telecommunications and Information Technology, Bucharest, Romania
cosmin_popa@yahoo.com

Abstract - An original analog function synthesizer circuit with increased accuracy will be presented, allowing to implement a multitude of important continuous mathematical functions. The accuracy of the proposed structure is excellent and the range of the input variable is strongly extended as a result of the third-order approximation of the implemented functions. The circuit performance is expected to be stable against process corners as all functions exclusively depend on current ratios. The great advantages of the increased modularity and controllability and of the associated reduced design costs per function represent an immediate consequence of the multiple functions realized by the proposed structure. The function synthesizer circuit is designed for implementing in $0.18\mu m$ CMOS technology and it is supplied at $1.8V$. The SPICE simulations confirm the estimated theoretical results, showing an approximating error smaller than 0.01% for the composing squaring block and smaller than 0.013% for the composing multiplier/divider block.

Keywords - analog signal processing, approximation function, computational circuits, multiplier/divider

I. INTRODUCTION

An original implementation of a current-mode analog function synthesizer circuit will be presented. The proposed structure is based on a particular approximation function, being able to generate any continuous mathematical function. It presents the important advantages of an improved accuracy and of excellent reconfiguration properties.

It exists in literature a relatively limited number of analog function synthesizers implemented in CMOS technology [1] - [6], most applications being dedicated exclusively to the design of exponential [7] - [9], squaring, square-rooting or Euclidean distance functions. In [1], the approximation of the implemented function can be implemented by adding the weighted output currents of a number of basic building blocks, built around a basic current squarer, and a constant current, the circuit presenting the disadvantage of a relatively large complexity. The circuit proposed in [2] is based on approximating the required function using the first three terms of its Taylor series expansion. The approximations can be implemented by adding the output currents of a weighted current square, a weighted current amplifier (or attenuator) and a constant current. The errors are relatively large and, additionally, the range of the input variable is restricted. It was proposed in [3] a structure for synthesis of analog exponential functions, based on approximating the exponential function using rational functions. The circuit presents the important limitations of realizing only the exponential function and of an implementation in bipolar technology.

II. MATHEMATICAL ANALYSIS OF THE APPROXIMATION FUNCTION

In order to implement an improved accuracy analog function synthesizer circuit, the proposed method is to use a general continuous approximation function, $g(x)$, having a Taylor series that can be made to match a multitude of continuous mathematical functions, $f(x)$. The original function $g(x)$ that can approximate many continuous mathematical functions $f(x)$ has the following expression:

$$g(x)=\frac{p^2}{q}\frac{x}{1-\frac{q}{p}x}+\left(n-\frac{p^2}{q}\right)x+m \qquad (1)$$

m, n, p and q being constant parameters, depending on the particular function that must be approximated. In order to evaluate the capability of $g(x)$ function to approximate a continuous function $f(x)$, the Taylor series expansion for $g(x)$ must be determined.

III. IMPLEMENTATION OF THE FUNCTION SYNTHESIZER CIRCUIT BASED ON THE PROPOSED APPROXIMATION FUNCTION

A. The block diagram of the function synthesizer circuit

The proposed block diagram of the original function synthesizer circuit is presented in Figure 1.

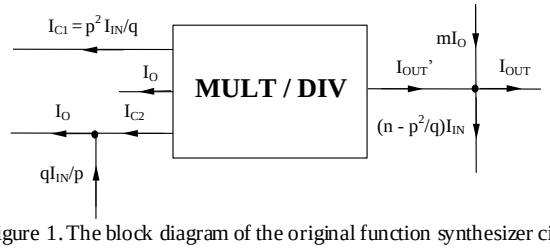

Figure 1. The block diagram of the original function synthesizer circuit

The core of the structure is represented by the "MULT / DIV" block, that must have the following expression of the output current I_{OUT}':

$$I_{OUT}' = I_O \frac{I_{C1}}{I_{C2}} \tag{2}$$

I_{C1} and I_{C2} represent the input currents of the "MULT / DIV" block, while I_O is a reference current. So:

$$I_{OUT}' = I_O \frac{(p^2/q)I_{IN}}{I_O - qI_{IN}/p} = I_O \frac{\frac{p^2}{q}\left(\frac{I_{IN}}{I_O}\right)}{1-\frac{q}{p}\left(\frac{I_{IN}}{I_O}\right)} \tag{3}$$

The output current of the circuit having the block diagram presented in Figure 1 will have the following expression:

$$I_{OUT} = I_{OUT}' - \left(n - \frac{p^2}{q}\right) I_{IN} + mI_O \tag{4}$$

Using the notation $x = I_{IN}/I_O$ and relation (1), it results that I_{OUT} current represents the third-order approximation of $f(x)$ function:

$$I_{OUT} = I_O g(x) = I_O g\left(\frac{I_{IN}}{I_O}\right) \cong I_O f(x) \tag{5}$$

B. The implementation of the "MULT / DIV" circuit

The proposed method for designing a current multiplier/divider circuit uses as circuit cores two current squaring circuits (Figure 2).

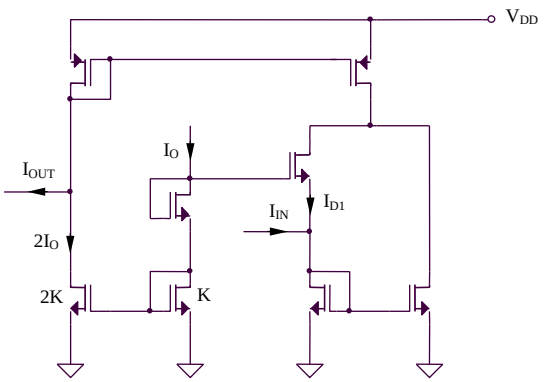

Figure 2. The implementation of the "SQ" block

For MOS transistors from Figure 2, the equation of the translinear loop can be expressed as follows:

$$2V_{GS}(I_O) = V_{GS}(I_{D1}) + V_{GS}(I_{D1} + I_{IN}) \tag{6}$$

The expression of the output current will be:

$$I_{OUT} = 2I_{D1} + I_{IN} - 2I_O = \frac{I_{IN}^2}{16I_O} \tag{7}$$

where:

$$I_{D1} = I_2 - (I_1 - I_O) + \frac{(I_1 - I_O)^2}{4I_2} \tag{8}$$

and:

$$I_{D2} = I_2 - (I_1 + I_O) + \frac{(I_1 + I_O)^2}{4I_2} \tag{9}$$

The original proposed implementation of the "MULT / DIV" block is presented in Figure 3. The expression of the output current for the circuit presented in Figure 3 will be:

$$I_{OUT} = I_{D2} - I_{D1} + 2I_O = I_O \frac{I_1}{I_2} \tag{10}$$

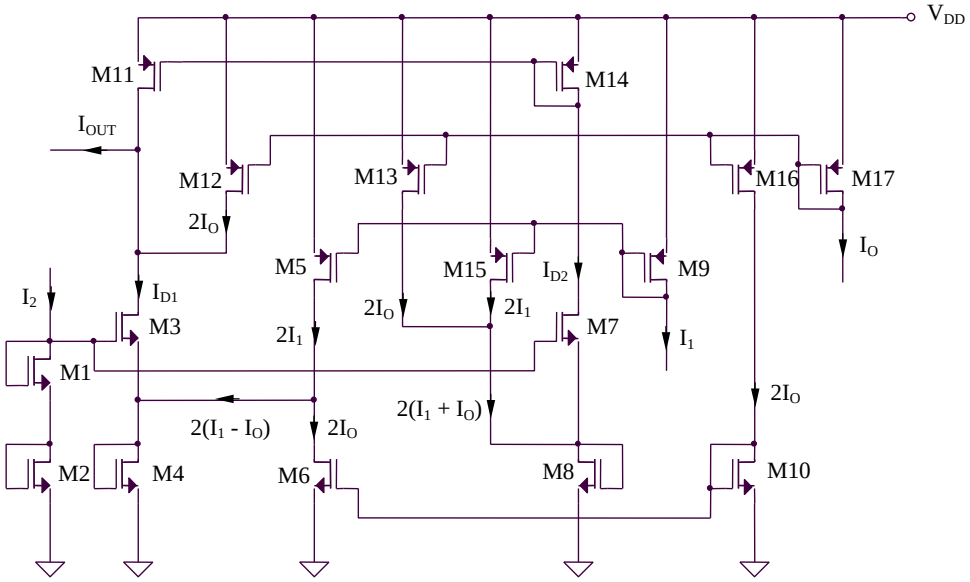

Figure 3. The implementation of the "MULT / DIV" block

The aspect ratios of MOS transistors are presented in Table 1.

TABLE 1. THE ASPECT RATIOS OF MOS TRANSISTORS FROM FIGURE 3

M	M1	M2	M3	M4	M5	M6	M7	M8	M9
W/L	4.5/ 0.9	4.5/ 0.9	4.5/ 0.9	9/ 0.9	4.5/ 0.9	4.5/ 0.9	4.5/ 0.9	4.5/ 0.9	4.5/ 0.9

M	M10	M11	M12	M13	M14	M15	M16	M17

The frequency range of the proposed multiplier/divider circuit is estimated to be very good, as a result of using exclusively MOS transistors biased in saturation region, correlated with a current-mode operation of the circuit.

IV. SIMULATIONS

The SPICE simulation $I_{OUT}(I_{IN})$ for the squaring circuit proposed in Figure 2 is presented in Figure 4. The I_O current is equal with $1mA$, while the range of I_{IN} current was chosen to be between 0 and $3mA$.

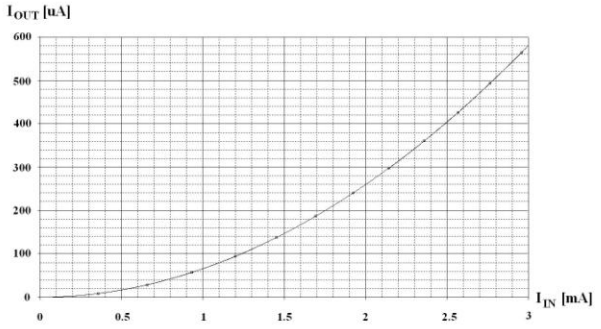

Figure 4. The SPICE simulation $I_{OUT}(I_{IN})$ for the squaring circuit

The simulated approximation error $\varepsilon_{SQ}(I_{IN})$ for the squaring circuit from Figure 2 is shown in Figure 5. The error is smaller than 0.01% for an extended range of the input current.

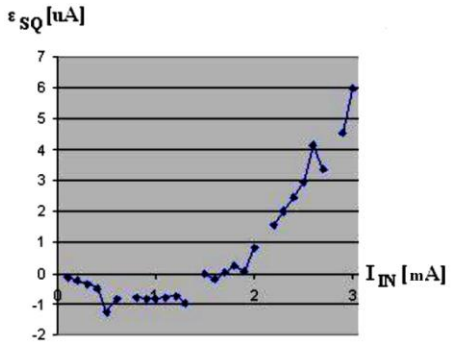

Figure 5. The simulated approximation error $\varepsilon_{SQ}(I_{IN})$ for the squaring circuit

The SPICE simulation $I_{OUT}(I_1)$ for the multiplier/divider circuit proposed in Figure 3 is presented in Figure 6. The I_O and I_2 currents have the following values: $I_O = 20\mu A$ and $I_2 = 20\mu A$, while the range of I_1 current was chosen to be between 0 and $20\mu A$.

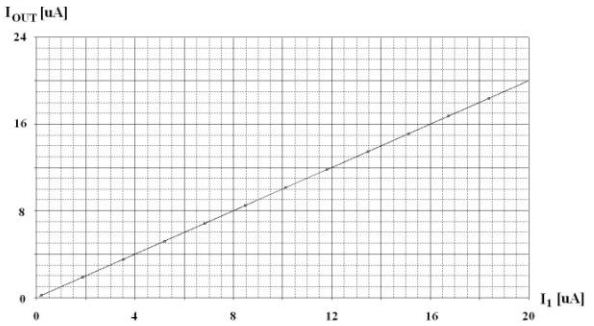

Figure 6. The SPICE simulation $I_{OUT}(I_1)$ for the multiplier circuit

The simulated linearity error of $I_{OUT}(I_1)$ characteristic for the multiplier/divider circuit from Figure 3 is shown in Figure 7. The linearity error is smaller than 0.013% for $I_1 = 20\mu A$.

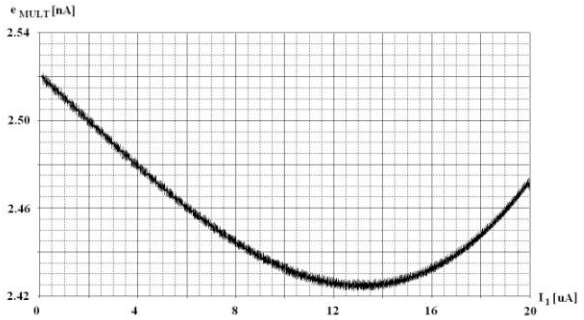

Figure 7. The simulated linearity error of $I_{OUT}(I_1)$ characteristic for the multiplier/divider circuit

For the same multiplier/divider circuit proposed in Figure 3, a transient analysis was performed. The I_O current is a sinusoidal current with an amplitude of $40\mu A$ and a frequency equal with $1kHz$, while I_1 current is a sinusoidal current having an amplitude of $0.5mA$ and a frequency of $30kHz$. The I_2 current is a continuous current, equal with $1mA$. The SPICE simulation of the output current is presented in Figure 8.

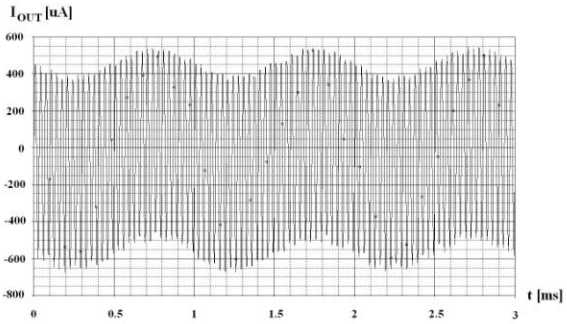

Figure 8. The SPICE simulation $I_{OUT}(t)$ for the multiplier/divider

The SPICE simulation $I_{OUT}(I_2)$ for the multiplier/divider circuit proposed in Figure 3 is

presented in Figure 9. The I_O and I_1 currents have the following values: $I_O = 20\mu A$ and $I_1 = 50\mu A$, while the range of I_2 current was chosen to be between 0 and $4mA$.

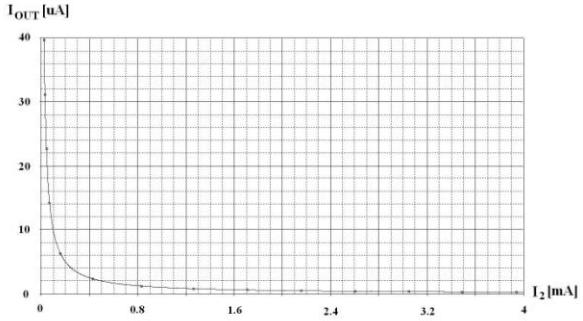

Figure 9. The SPICE simulation $I_{OUT}(I_2)$ for the multiplier circuit

A comparison between the simulated and the theoretical estimated results for the proposed multiplier/divider circuit is shown in Table 2.

TABLE 2. COMPARISON BETWEEN THE SIMULATED AND THE THEORETICAL ESTIMATED RESULTS FOR THE MULTIPLIER/DIVIDER CIRCUIT

V. CONCLUSIONS

It was proposed, analyzed and implemented an original analog function synthesizer circuit The original structure can implement any continuous mathematical function, the circuit accuracy being excellent. Because of the third-order approximation of the computational structure, the range of input variables is relatively large comparing with previously reported similar circuits. An important additional improvement of the structure accuracy was obtained using a current-mode operation and providing an independence of the circuit performances on technological errors. The possibility of realizing a multitude of circuit functions is based on the increased modularity and controllability of the proposed function synthesizer circuit. The supply voltage was $1.8V$, while the implementing technology was $0.18\mu m$ CMOS. The theoretical estimated results are confirmed by SPICE simulations, resulting an approximating error smaller than 0.01% for the composing squaring block and smaller than 0.013% for the composing multiplier/divider block. Comparing with similar designs, the proposed multiplier/divider structure has better performances related to its linearity and to the maximal range of the input currents.

***Abstract*—The conventional binary weighted array SAR ADC is the common topology adopted to achieve high efficiency conversion, i.e. with less than 10 fJ/conversion-step, even requiring extra effort to design and simulate full custom sub-fF capacitors. This paper presents the design and the optimization of an asynchronous SAR ADC with attenuation capacitor achieving an efficiency similar to conventional binary weighted array converters but adopting standard MiM capacitors. A monotonic switching algorithm further reduces the capacitive array consumption while an asynchronous and fully-differential dynamic logic minimizes the digital power consumption. A 10-bit prototype has been fabricated in a 0.13-μm CMOS technology. At 0.5-V supply and 200-kSps sampling frequency, the ADC achieves a SNDR of 52.6 dB, an ENOB of 8.45, and a power consumption of 420 nW, corresponding to a figure-of-merit (FOM) of 6 fJ/conversion-step. This efficiency is comparable to the best results published so far and it's the lowest among ADCs in 130-nm or less scaled technology. The ADC core occupies an area of only 0.045 mm^2.**

***Index Terms*—ADC, analog-to-digital conversion, nonlinearity, mismatch, asynchronous logic, successive approximation register.**

I. Introduction

In energy-limited applications, such as wireless sensor nodes, implantable medical devices or portable amusements, the adoption of ultra-low power circuits is mandatory in order to extent the system battery lifetime. Analog-to-digital converters (ADCs) featuring moderate sampling rate ($0.01 - 1$ Msps) and resolution (8-10 bit) are key components in such devices. Among different converter architectures, successive approximation analog-to-digital converter (SA-ADC) is the best choice due to its good trade-off among power efficiency, conversion accuracy and design complexity. In such converters, the primary sources of power consumption are the digital control circuit and the capacitive DAC array. While the digital power consumption benefits on the technology advancement, the power consumption due to the capacitive array is limited by the capacitor mismatch that is almost technology-independent. For this reason, a great number of DAC topologies and switching algorithms have been proposed in order to reduce DAC power consumption without penalty in terms of accuracy [1]–[3]. The latest trend is to rely on the high linearity properties of the conventional binary weighted (CBW) array adopting full-custom unit capacitance in the sub-fF range [4]–[6]. In fact, the minimum capacitor value supplied by a general-purpose design-kit is much larger than necessary to meet the linearity requirements, resulting in a considerably large array capacitance and hence in a high switching power. Thus, this approach requires extra-efforts to model and design the highly-matched unit capacitance or an error correction technique, the latter increasing area and circuit complexity. The purpose of this work is to demonstrate that a binary weighted with attenuation capacitor (BWA) converter [1] can achieve efficiency well below 10 fJ/conversion-step and a remarkable compactness, without requiring the design, modeling and accurate simulations of custom capacitors. The DAC power consumption is further reduced by applying to the BWA array an efficient switching procedure as the monotonic algorithm proposed in [3]. Moreover, an asynchronous and fully-differential dynamic logic is proposed. Thanks to the decreased number of transistors and the differential architecture, the digital power consumption is reduced helping to improve the converter efficiency. The proposed 10-bit SAR converter, shown in Fig. 1, has been integrated in $0.13 - \mu$m CMOS technology. At 0.5-V supply, the ADC achieves an efficiency of 6 fJ/conversion-step, in line with the best conventional binary weighted topologies but adopting as unit element a standard MiM capacitance of 34 fF.

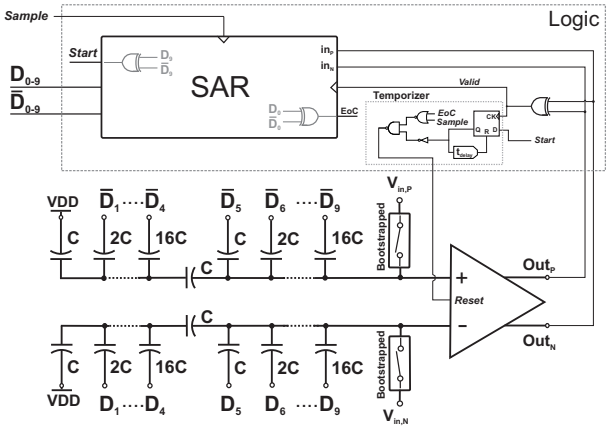

Fig. 1: Schematic of the proposed 10-bit converter.

The paper is organized as follows. Section II is devoted to a comparison between the traditional CBW and the bridge-capacitor DAC architecture in terms of power consumption and linearity due to statistical mismatch. The role of the parasitic capacitances in the BWA topology is also highlighted. Section III describes in detail the implementation of the switched capacitor network, of the asynchronous dynamic logic and of the dynamic comparator, while measurement results are shown in Section IV. Finally, conclusions are drawn in Section V.

II. Comparison between CBW and BWA topologies

The capacitive array typically serves as both sampling capacitance and feedback DAC, its linearity usually limiting the overall converter performance. The single-ended conventional N-bit binary weighted array is depicted in Fig. 2(a), where C_u is the unit capacitance. The main alternative to this

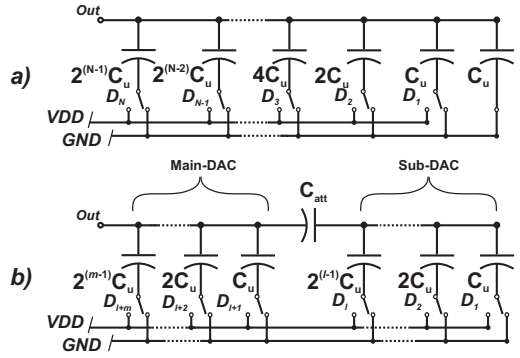

Fig. 2: N-bit CBW (a) and $(m+l)$-bit BWA (b) capacitive DAC.

TABLE I: COMPARISON OF THE CBW AND BWA ARRAYS

	CBW	BWA
C_{tot}	$2^N \cdot C_u$	$\left(2 \cdot (2^{\frac{N}{2}} - 1) + 1\right) \cdot C_u$
$\sigma_{DNL,max}$	$2^{\frac{N}{2}} \cdot \sigma\left(\frac{\Delta C}{C_u}\right)$	$2^{\frac{3N}{4}} \cdot \sigma\left(\frac{\Delta C}{C_u}\right)$
$\sigma_{INL,max}$	$2^{\frac{N}{2}-1} \cdot \sigma\left(\frac{\Delta C}{C_u}\right)$	$2^{\frac{3N}{4}-1} \cdot \sigma\left(\frac{\Delta C}{C_u}\right)$

structure is the binary weighted with attenuation (or bridge) capacitor array [1], shown Fig. 2(b). It features an attenuation capacitor, C_{att}, in order to divide the array into two binary weighted sub-arrays: a main-DAC and a sub-DAC of m and l capacitors, respectively. In particular, since this topology is intended to reduce the overall capacitance, we'll refer to the BWA architecture with equal main- and sub-DACs (i.e. m=l=$N/2$) and $C_{att} \cong C_u$, which has been shown to be the most energy efficient among possible combinations [2]. In this section, the impact of the capacitance mismatch and parasitics on the performance of both CBW and BWA arrays is accurately handled.

A. Capacitive mismatch analysis

The effect of capacitive mismatch in the DAC array is to degrade the linearity of the overall converter. The nonlinearity is usually quantified in term of differential nonlinearity (DNL), integral nonlinearity (INL) and effective number of bits (ENOB). However, while a precise formulation of the relationship between capacitive mismatch and ENOB is still lacking, the maximum standard deviations of DNL ($\sigma_{DNL,max}$) and INL ($\sigma_{INL,max}$) have been analytically derived as function of the unit capacitance relative standard deviation $\sigma\left(\frac{\Delta C}{C_u}\right)$ for the most common adopted capacitive arrays [2]. Table I shows the expressions of the overall capacitance, together with $\sigma_{DNL,max}$ and $\sigma_{INL,max}$, as function of $\sigma\left(\frac{\Delta C}{C_u}\right)$ [2], [7], for a N-bit BWA and CBW single-ended array. The standard deviation of the unit capacitor can be expressed in terms of Pelgrom mismatch coefficient, k_c, and specific capacitance, c_{spec}, being

$$\sigma\left(\frac{\Delta C}{C_u}\right) = k_c \cdot \sqrt{\frac{c_{spec}}{2C_u}}, \tag{1}$$

where the factor 2 takes into account that ΔC is referred to the single capacitance with respect to the nominal value. Considering the same number of bits and the same unit capacitance for both the topologies, the single-ended BWA array features an overall capacitance which is approximately a factor $2^{\frac{N}{2}-1}$ lower than in the CBW architecture.

Unfortunately, the effect of mismatch on static nonlinearity is a factor $2^{\frac{N}{4}}$ larger in the BWA than in the CBW array.

TABLE II: CAPACITANCE COMPARISON

	k_c $[\% \cdot \mu m]$	c_{spec} $[fF/\mu m^2]$	$k_c^2 c_{spec}$ $[\%^2 \cdot fF]$
Custom MoM (lateral) [10]	4	0.192	3.07
Custom MoM (1 layer) [11]	53	0.12	337
Custom MoM (2 layers) [11]	32	0.24	242
Custom MoM (lateral) [6]	0.5	0.25	0.1
Standard MiM (130 nM UMC)	0.95	1	0.9
Standard MiM (65 nM ST)	0.5	5	1.25

Thus, to achieve the same $\sigma_{DNL,max}$ the unit capacitance in the BWA array has to be a factor $2^{\frac{N}{2}}$ larger than in the conventional array. In this case, the overall array capacitance of the BWA network is approximately twice that of a CBW array, independently on the number of bits. In [2] the average switching energy for the CBW and the BWA topologies is analytically derived. In fact, when sized to have the same $\sigma_{DNL,max}$, the average switching energy consumption of the conventional array is a factor 1.91 lower than in the BWA topology.

Now, let us suppose to size a 10-bit capacitive array of a SA-ADC adopting a technology with k_c=$1\% \cdot \mu m$ and c_{spec}= $1fF/\mu m^2$. In order to achieve $3\sigma_{DNL,max}$<0.5 [5], [8], a unit capacitance of about 59 and 1.8 fF is needed for the BWA and CBW array, respectively. Moreover, the latest trend is to shrink further the value of the unit capacitance to reduce as much as possible area and power consumption [3], [6], [9], relying on the fact that ENOB is not compromised even with larger $\sigma_{DNL,max}$ [4]. Since capacitance smaller than 10 fF are not available among standard design-kit MiM and poly capacitors, the CBW topology requires a custom design of the array capacitors and an extra effort for their characterization, which needs dedicated CAD tools [6]. Table II shows a comparison of recent published custom capacitors with MiM capacitances from the 130-nm UMC and 65-nm ST-Microelectronics design-kit in terms of both Pelgrom coefficient k_c and specific capacitance c_{spec}. It's quite evident that custom capacitors can feature significantly worse matching properties with respect to standard MiM capacitances. The only exception is the custom lateral MoM capacitances presented in [5], which shows even better matching properties but having required a sophisticated simulation tool.

Thus, the unit capacitance in the BWA and CBW arrays that assures the same nonlinearity has to be sized taking into account the different k_c and c_{spec} parameters of custom and standard capacitors, leading to a ratio between the overall array capacitances of

$$\frac{C_{tot,BWA}}{C_{tot,CBW}} \cong 2\frac{\left(k_c^2 c_{spec}\right)_{standard}}{\left(k_c^2 c_{spec}\right)_{custom}}. \tag{2}$$

The product $k_c^2 c_{spec}$ for all the available custom capacitors as well for the standard MiM capacitances is also shown in Table II. The adoption of the custom capacitors proposed in [10], [11] results in a larger capacitance, and thus power consumption, of the CBW array than of the BWA network featuring standard MiMs. Only with the custom capacitance design in [6] the CBW array overwhelms the BWA architecture. In addition, Table II shows that custom capacitors typically present a specific capacitance much lower than those achievable with standard MiMs, even by a factor of 10,

resulting inefficient in terms of area and making more critical the array layout.

B. Effect of parasitic capacitances

Let us now discuss the impact of the parasitic capacitances on the linearity performance of the two considered DAC topologies. It is commonly assumed [2] that the parasitic capacitance connected to the top-plate nodes can degrade the linearity performance of the BWA converter, even if constant and voltage independent, while in the conventional array it only causes gain error without affecting the linearity. Let us try to be more quantitative expressing the voltage at the output node of the BWA array in Fig. 2(b) with $m{=}l{=}N/2$ and $C_{att}{=}C_u$. By indicating with C_{main} and C_{sub} the overall capacitance of the main- and the sub-DAC, respectively, and with $C_{par,main}$ and $C_{par,sub}$ the parasitic capacitances at the top-plate node of the corresponding array, the analog output voltage results

$$V_{out} \cong \left[\frac{\sum_{i=\frac{N}{2}+1}^{N} D_i \cdot C_i}{C_{main} + C_{par,main}} + AR \cdot \frac{\sum_{i=1}^{\frac{N}{2}} D_i \cdot C_i}{C_{sub} + C_{par,sub}} \right] V_{DD}, \tag{3}$$

C_i being the capacitance associated to the bit D_i and AR the attenuation ratio

$$AR \cong \frac{C_u}{C_{main} + C_{par,main}}. \tag{4}$$

Equations (3) and (4) show that only the parasitics $C_{par,sub}$ affects the linearity, since its effect on the value of the DAC output voltage is not constant for different input signals, while $C_{par,main}$ only causes gain error. In particular, $C_{par,sub}$ is responsible of a deterministic pattern of the DNL, and hence of the INL. The differential nonlinearity shows a peak every $2^{\frac{N}{2}}$ codes whose amplitude is

$$DNL_{peak} \cong \frac{\left(2^N - 2^{\frac{N}{2}}\right) C_{par,sub} + C_u}{2^N C_u}. \tag{5}$$

Eq. (5) highlights that $C_{par,sub}$ has to be lower than C_u in order to assure a monotonic behavior of the converter, i.e $DNL{<}1$. In order to verify the accuracy of the proposed analysis, a transistor-level simulation has been performed on a 10-bit single-ended BWA converter with a unit capacitance of 100-fF and a $C_{sub,par}$ of 50 fF. The simulation results are shown in Fig. 3. As expected, the DNL has a periodic pattern featuring a peak every 32, i.e $2^{\frac{N}{2}}$, codes of about 0.48 LSB, close to 0.49 as predicted by (5), while the INL is the range -0.5/0.5. The simulated ENOB is 9.85, suggesting that the parasitic capacitance at the top-plate of the sub-DAC can be as large as C_u without determining a severe ENOB drop.

III. Circuit design

The scheme of the proposed 10-bit AD converter is shown in Fig. 1. In order to achieve a better common-mode noise rejection and less distortion, a fully-differential topology has been adopted.

A. Capacitive array and switching algorithm

Being the converter fully-differential, the capacitive DAC is realized by means of two 10-bit binary weighted arrays with attenuation capacitor, one per branch. The fully-differential

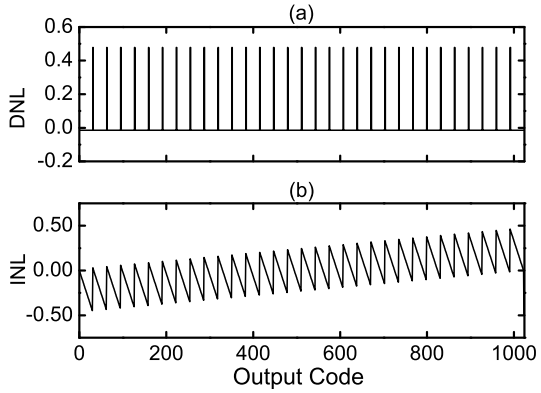

Fig. 3: Simulated DNL (a) and INL (b) for a 10-bit BWA DAC featuring C_u=100 fF and $C_{par,sub}$=50 fF.

structure allows to reduce $\sigma_{DNL,max}$ and $\sigma_{INL,max}$ by a factor of $\sqrt{2}$ with respect to the single-ended counterpart featuring the same unit capacitance [8], i.e. the same nonlinearity is obtained with half the unit capacitance. In order to further reduce the array power consumption, an efficient switching procedure, as the monotonic algorithm [3], has been applied to the capacitive DAC. In fact, the conventional trial-and-error search procedure [2], even if simple and intuitive, is not energy efficient, especially when unsuccessful trials occur.

The proposed capacitive array samples the differential input signal directly on the top of the two main-DACs via bootstrapped switches, which allow low-voltage operation, with the bottom-plates connected to the positive power supply, V_{DD}. After the switches are turned off, the first comparison is done without switching any array capacitance. According to the comparator output, the largest capacitor on the main-DAC corresponding to the positive input signal is switched to ground while the the other one remains at V_{DD}. The ADC repeats the procedure until the LSB is decided. For each cycle, only a capacitor is switched reducing the charge transfer and thus the array power consumption. Note that the proposed BWA array with monotonic switching scheme has the same overall capacitance of the original fully-differential BWA architecture, i.e. about $2^{\frac{N}{2}+2}C_u$. The monotonic switching scheme determines a significant efficiency improvement, reducing the average switching energy from 81.5 $C_u V_{DD}^2$ to roughly 32 $C_u V_{DD}^2$, i.e. by a factor of 2.5 with respect to traditional switching approaches.

Another advantage of the monotonic switching algorithm is that it reduces the effect of capacitor mismatch on the non-linearity of the converter. It can be verified following the same procedure adopted in [12] that the effect of mismatch on both $\sigma_{DNL,max}$ and $\sigma_{INL,max}$ is reduced by a factor $\sqrt{2}$ with respect to the traditional algorithm. This allows to adopt half the unit capacitance without impairing the linearity of the DAC, thus further reducing the array power consumption.

Based on statistical simulations, the unit capacitance was set to 34 fF, close to the technology minimum of 17 fF. Also the attenuation capacitance was set equal to C_u. With this value, the effect of capacitor mismatch is expected to keep the $\sigma_{DNL,max}$ lower than 0.5 LSB, while the total capacitance is 4.28 pF. A particular care was dedicated to the minimization of the sub-DAC top-plate parasitic capacitance, which was limited to about 15 fF, according to parasitic extraction tools.

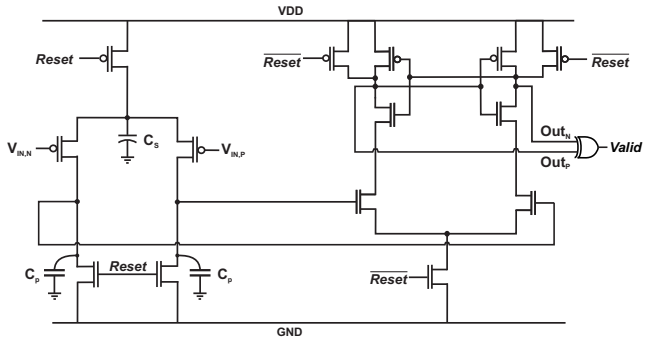

Fig. 4: Schematic of the dynamic comparator.

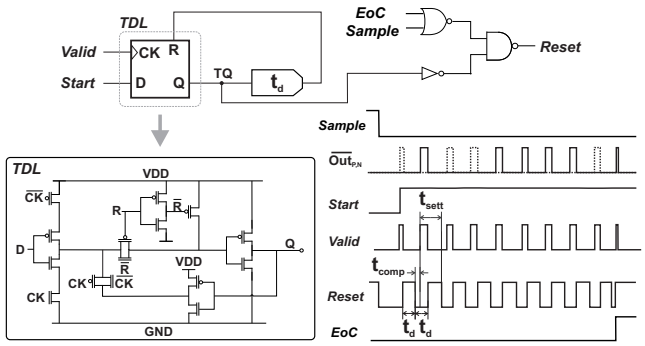

Fig. 5: Logic temporizer and timing diagram.

B. Dynamic Comparator

A two-stage dynamic comparator, shown in Fig. 4, has been adopted since it does not consume static current, thus being suitable for energy efficient design. It consists of a first stage similar to the one adopted in [9] followed by a differential latch. Since the monotonic algorithm makes the common-mode input voltage varying from $V_{DD}/2$ to 0 along the conversion cycle [3], the input stage features a PMOS diffetential pair. The operation is determined by the $Reset$ signal, which is generated by the logic circuit (see Fig. 1). Before the comparison takes part, the first stage output nodes are pre-charged low by a positive $Reset$ signal. Its falling edge stops the pre- charging phase and starts the amplification of the input signal. In fact, as $Reset$ becomes low, a current starts to flow into the differential pair charging the parasitic capacitances C_p at the drain nodes of the input transistors. The voltage on the two capacitors increases at a different speed, the difference depending on the input signal, $V_{in,p}$-$V_{in,n}$. As the first stage output nodes approximates the threshold voltage of the second stage input transistors, the latch starts to amplify the signal until the positive feedback takes over providing a rail-to-rail differential output. Consequently, the $Valid$ signal is pulled high to enable the asynchronous control logic. According to simulation, the first stage differential gain is about 5, high enough to make the noise of the second stage negligible. Thus, the equivalent input noise of the comparator is mainly determined by the input differential pair, its transistor working in weak-inversion region to maximize the comparator efficiency. The equivalent integrated input noise of the comparator is approximately [9]

$$v_{n,rms} \cong \sqrt{\frac{kT}{C_p}} \cdot \sqrt{\frac{8kT}{qV_T}}, \tag{6}$$

V_T being the threshold voltage of the second stage input transistors. In order to make this noise negligible with respect to the LSB for $V_{DD} = 0.5$ V, i.e. $(2 \cdot 0.5V)/2^N \cong 1$ mV, the parasitic capacitance has to be larger than approximately 3.3 fF. In the proposed comparator, the two parasitic capacitances are about 15 fF.

The comparator also determines the converter offset, which is mainly set by the first stage. The second stage contributes with both a static and dynamic offset [13]. However, its contribution to the comparator offset is negligible since if follows a gain stage. Even with a capacitance mismatch of 1 fF at the latch outputs, the input-referred offset is lower than 500 μV, i.e. half the LSB, while the static offset is lower than 250 μV rms. Moreover, the offset due to the second stage does not depend on the input signal, thus not affecting the converter linearity. As far as the first stage offset contribution, the main problem is that it depends on the common mode input voltage, which decreases during the conversion cycle due to the monotonic switching procedure. This dependence lead to distortion [3], [14]. In fact, the offset voltage of the comparator can be expressed as

$$V_{os} \cong \Delta V_T + \frac{V_{GS} - V_T}{2}\left(\frac{\Delta\beta}{\beta}\right), \tag{7}$$

where ΔV_T is the threshold voltage offset of the differential pair transistors, $V_{GS} - V_T$ is the effective voltage of the input pair and $\Delta\beta$ is the overall conductivity mismatch between the input transistors. In particular, the second term depends on the common mode voltage degrading the converter linearity. The simplest way to reduce its effect is to force these transistors to work in subthreshold region, thus minimizing the term $(V_{GS} - V_T)/2$, and to increase their area, slightly degrading the comparator power consumption performance.

Finally, a capacitor $C_s \cong 100$ fF has been added to the source of the first stage input transistors. Its effect is to reduce the kickback noise due to the falling edge of the $Reset$ signal. In fact, the PMOS current generator of the first stage must be sized large enough to guarantee an adequate current during the comparison. This can result in a capacitive coupling between its gate, its drain, and the capacitive arrays, which are connected to the comparator input nodes. In such conditions, at the first $Reset$ falling edge a charge is injected into the two DACs which determines a voltage drop at the top-plate of each array. If the two comparator input nodes are at the same voltage, the same amount of charge is induced on the two arrays since the two gate-source capacitances of input transistors are equal. However, when a differential signal is applied to the comparator, the two capacitances are different. This induces a signal- dependent charge on the two DACs, thus causing nonlinearity. The effect of the tail capacitance C_S is to reduce the amount of injected charge.

C. Asynchronous Logic

The SAR logic generates the necessary commands to control the comparator and the capacitive DAC. In order to reduce its power consumption, an asynchronous dynamic logic has been designed. By using a dynamic logic, less transistors are needed to implement the same functionality, while being asynchronous it requires only a low-speed sampling clock instead of an oversampled clock, thereby saving power.

The timing is assured by a logic temporizer (see Fig. 5) implemented using a dynamic latch (TDL) with a delayed

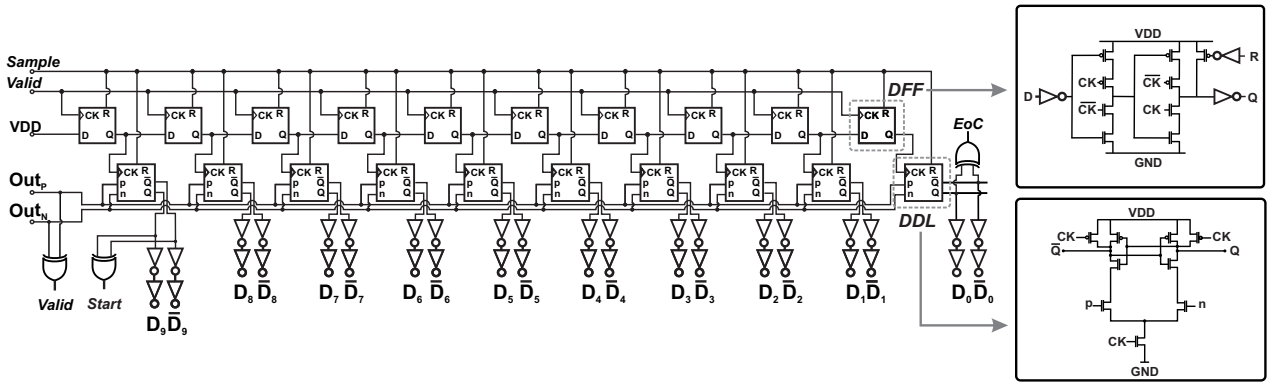

Fig. 6: Schematic of the asynchronous logic. The insets show the dynamic differential latch (DDL) and the dynamic flip-flop (DFF).

feedback loop. Its function is to enable the comparator, wait for its decision and then reset it for a time sufficient to assure the settling of the DAC voltage. Its working principle is briefly described in the following. At the end of the sampling phase, i.e. at the falling edge of the $Sample$ signal, the comparator evaluates the most significant bit (MSB) and enables the temporizer through the $Valid$ signal, which marks the end of each successful comparison. Only when the bottom plates of the MSB capacitors are switched, the $Start$ signal becomes high and remains in this state till the end of the conversion. Its rising edge triggers the first transition of the TDL output (TQ), causing the reset of the comparator ($Reset$=1) for a time $t_d \cong 75$ ns fixed by the delay unit and forcing $Valid$ to zero. At the end of the reset phase, the comparator evaluates the MSB-1 bit and sets high the $Valid$ signal. However, the comparator is not resetted till the falling edge of TQ has completed the feedback path, i.e. after a time t_d. Thus, the reset signal resembles a square wave with a period of $2t_d$. Since the comparator takes approximately $t_c \cong 10$ ns (see Fig. 5) for a decision, a time of $t_{sett} = 2t_d - t_{comp} \cong 55$ ns is left to the logic circuit and to the array to switch and settle, respectively, during each bit evaluation phase. When also the least significant bit (LSB) has been evaluated, the EoC rises and the conversion stops till the end of the successive sampling phase keeping the comparator in the reset state.

Fig. 6 shows the logic circuit implementing the successive approximation algorithm. It features a first row of dynamic flip-flops (DFFs) and a second row of dynamic differential latches (DDLs). The design goal was to minimizing the capacitive load of the most active signal lines, i.e. the $Valid$ signal and the outputs of flip-flops, latches and comparator, in order to reduce the power consumption. The DFFs show a C^2MOS structure, with the clock pin connected to 2 n-gates and 2 p-gates. Thus, each DFF output is loaded by 2 n-gates and 3 p-gates, while the DDL outputs are directly connected to a minimum area inverter that drives the corresponding array capacitors. Moreover, since the monotonic algorithm requires the bottom plates of all capacitors to remain at V_{DD} during the sampling phase, a key choice was to implement the DDL as a differential latch (Fig. 6), making possible to use a single set of 10 elements shared by both arrays, instead of 10 elements per each array. In fact, the outputs of the DDLs are kept high till the positive edge trigger performed by the related DFF output, then they switch according to the state of the comparator decision. Finally, the total differential capacitance loading the comparator is equal to 10x2 n-gates (plus 4 n- and 4 p-gates due to the XOR gate generating the $Valid$ signal).

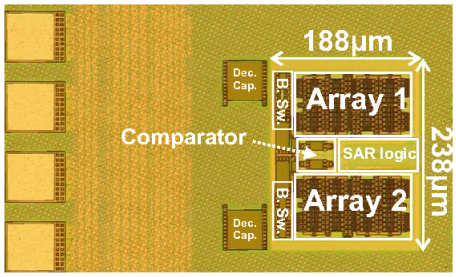

Fig. 7: Die photo of the proposed ADC.

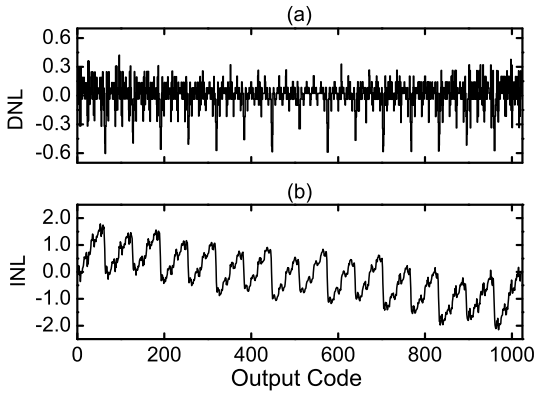

Fig. 8: Measured DNL and INL.

IV. Measurement Results

The ADC has been fabricated using a 2P8M 0.13-μm CMOS technology featuring 1.11-fF/μm^2 MiM capacitors. The converter occupies an area of 188 μm x 238 μm, as shown in Fig. 7. The performance of the ADC have been measured at 0.5-V supply for 8 samples. The average measured results are summarized in Table III.

The static performance of the ADC in terms of DNL and INL are shown in Fig. 8. The measured DNL and INL are -0.4/0.5 and -2/2 LSBs, respectively. Since each test chip shows a similar pattern and since the effect of the comparator has been accurately minimized, the DNL/INL performance are mainly due to the stray capacitances induced by the layout routing. This effect is well captured by accurate post-layout simulations.

Fig. 9 shows the output spectra at 0.5-V supply, 200-kSps sampling rate and for an input sinewave at 5.13-kHz and 96.48-kHz frequency, i.e. well below and slightly below the

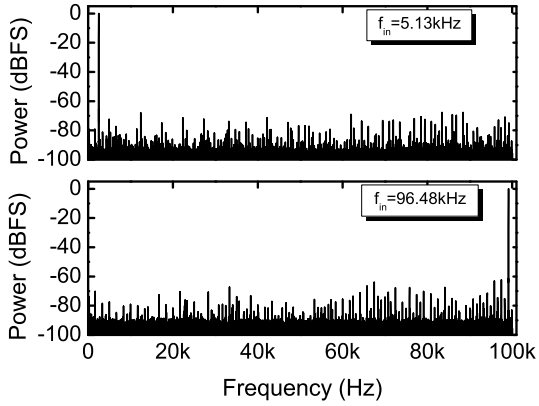

Fig. 9: Measured spectrum at 200-kSps sampling frequency with an input sine-wave at 5.13-kHz and 96.4-kHz frequency.

TABLE III: COMPARISON WITH THE-STATE-OF-THE-ART

	[1]	[9]	[3]	[6]	[8]	this work
Topology	BWA	CBW	CBW	CBW	CBW	BWA
Tech. (nm)	180	65	130	65	130	130
Unit cap. (fF)	120	0.5	4.8	0.25	13.5	34
Res. (bit)	10	10	10	10	10	10
Area (mm^2)	0.24	0.026	0.052	0.076	0.19	0.045
Voltage (V)	1	1	1.2	0.6	0.4†	0.5
Freq. (MSps)	0.1	1	50	0.04	1	0.2
ENOB (bit)	9.4	8.7	9.18	9.4	9.1	8.45
Power (μW)	3.8	1.9	826	0.072	0.052	0.42
FOM (fJ/step)	56	4.4	29	2.2	94.5	6

† A dual supply scheme is adopted: AVDD=1V, DVDD=0.4V.

Nyquist frequency. At low frequency, the average measured SNDR and SFDR are 52.6 and 67.5 dB, respectively. The resultant ENOB is 8.48 and its standard deviation considering the 8 tested samples is limited to 0.04. When the input frequency is increased near the Nyquist rate, the measured SNDR and SFDR drop to 50.8 and 62.1 dB, respectively.

The overall power consumption at 200-kSps sampling rate is 420 nW. Based on post-layout simulations, 50% of the power is due to the logic, 35% to the comparator and only 15% to the array. The leakage current is about 15 nA, thus becoming significant only at lower sampling rates.

To compare the proposed ADC with other works featuring different sampling rates and resolutions, the Figure-of-Merit (FOM) proposed in [15],

$$FOM = \frac{P_{diss}}{2^{ENOB} \cdot f_{sample}}, \tag{8}$$

is adopted. The FOM of the proposed ADC at the nominal supply of 0.5 V and for a 200-kSps sampling rate is 6 fJ/conversion-step. Table III shows that the proposed DAC well compares in terms of efficiency to the best recent published works, without adopting a CBW topology and sub-fF custom capacitors, and even being integrated in a older technology. It's worth noting that, since 85% of the power consumption is due to the digital circuits (asynchronous logic and comparator), the adoption of a more scaled technology would reduce the power consumption improving the efficiency of the converter. If compared to the converters implemented in 0.13-μm or less scaled technology, the proposed ADC is by far the best in terms of FOM. Finally, note that the proposed ADC favorably compares with the other converters in terms of area, with the exception of the work in [9] that adopts high-density custom capacitors and a conventional binary weighted array. The ADC proposed in [8] features a CBW array with 2 standard MIM capacitors connected in series in order to decrease the unit capacitance, but determining a large waste of area and an efficiency that is not so high as in other CBW realizations.

V. CONCLUSIONS

This paper presents a high efficient SA-ADC in 130-nm CMOS technology. It has been designed adopting a binary-weighted with attenuation capacitor array featuring a linearity and a total capacitance similar to a conventional binary weighted array but without requiring critical full-custom sub-fF capacitors. The design and the layout of the array has been accurately optimized in order to reduce the parasitic capacitances at the top-plate node of the sub-DAC which degrade the linearity. Moreover, an efficient switching scheme has been adopted in order to further reduce its power consumption. Finally, an asynchronous and fully-differential dynamic logic decreases the transistor count minimizing the digital power consumption. A prototype has been integrated and successfully tested showing an efficiency comparable to the state-of-the art converters even if realized in a less-scaled technology.

***Abstract*—The optimal design of SAR ADCs requires the accurate estimate of nonlinearity and parasitic effects in the feedback charge-redistribution DAC. Since the effects of both mismatch and stray capacitances depend on the specific array topology, complex calculations, custom modeling and heavy simulations in common circuit design environments are often required. This paper presents a novel MATLAB-based numerical tool to assist the design of classic, split and with attenuation capacitor binary weighted capacitive array topologies with an even number of bits from 6 to 14. The tool allows to perform both parametric and statistical simulations taking into account capacitive mismatch and parasitic capacitances in order to compute both differential- (DNL) and integral nonlinearity (INL). SNDR and ENoB degradation due to static non-linear effects is also estimated. An excellent agreement with the results obtained by the available circuit simulators (e.g. Cadence Spectre) is shown but featuring up to 10^4 shorter simulation time.**

***Index Terms*—Analog-to-digital conversion, numerical simulations, charge redistribution successive approximation registers.**

I. Introduction

In power-limited applications, such as portable instruments, wireless sensor networks or implantable biomedical systems, the use of ultra low-power analog-to-digital converters (ADCs) extends the battery life and limits heating phenomena. Due to their energy efficiency, successive approximation register (SAR) converters represent the best choice when moderate resolution and speed are required. The performance requirements of such converters are represented by static metrics, such as differential-non-linearity (DNL) and integral-non-linearity (INL), and by dynamic metrics, such as signal-to-noise-plus-distortion ratio (SNDR) and effective-number-of-bits (ENoB). All of these parameters mainly depend on the quality of the capacitive array, which implements the feedback charge-redistribution (CR) digital-to-analog converter (DAC). In the last decade, several novel CR-DAC topologies have been proposed for the design of SAR ADCs with outstanding efficiency [1], [2] and adopted in various integrated systems demonstrating their suitability for general purpose applications [3] [4]. The capacitive DAC plays a dominant role in degrading the overall performance of a SAR ADC as long as it is affected by mismatch and parasitic capacitances. Mismatch effects on DNL and INL can be considered statistical and they are well known for the most common array topologies [5]. Differently, the parasitic capacitance contribution is deterministic and strongly depends on the array architecture.

However, precise relationships that quantify the effects of both capacitor mismatch and parasitic capacitances on static and dynamic metrics still lacks. Thus, the designer has to size the DAC unit capacitance handling complex equations to target the desired requirements and quantify the converter nonlinearities running long transient simulations. Unfortunately, in common circuit design and simulation environments, like Cadence, such simulations are quite time-consuming and require heavily post-processing of the raw data, limiting the design time of the converter. Moreover, statistical simulations, like MonteCarlo analyses, are quite impractical since they require a large number of runs, at least 100, to achieve confident results.

This paper presents a MATLAB-based numerical tool to assist the design of the capacitive DAC adopted in SAR ADCs. The proposed tool implements the model of the three most common DAC topologies, such as the Classic Binary Weighted (CBW) [6], the Split Binary Weighted (SBW) [7] and the Binary Weighted with Attenuation Capacitor (BWA) [8] array, both single-ended and fully-differential, and allows to choose the switching algorithm between the conventional [6] and the monotonic scheme [9]. The numerical models take into account all possible mismatch and parasitic effects, giving the possibility to estimate by means of both statistical and parametric simulations the converter DNL, INL, SNDR, ENoB and power consumption.

The paper is organized as follows. In Section II, a brief overview of the array topologies is given, resuming the effects of mismatch and parasitic capacitances on both DNL and INL. Section III describes how the different array models are implemented and simulated with the proposed tool. Section IV shows the most significant results, which are in agreement with Cadence Spectre analyses but achieved with a considerable time saving. Finally, conclusions are drawn in Section V.

II. Converter topologies

In a generic N-bit capacitive DAC, as the one shown in Fig. 1, each digital code is associated with a particular configuration of the bottom switches that produces the corresponding output voltage. In an equivalent SAR ADC implemented by means of such a DAC in the feedback path, this voltage marks an input transition level between two adjacent digital codes. It derives that the conversion accuracy depends on the actual size of each capacitive bank. As a consequence of the technologic mismatch and parasitics, the capacitance of each block can differ from its nominal value and can be in general expressed as

$$C_i = 2^{i-1}C_u + C_{par,i} + \sum_{j=1}^{2^{i-1}} \delta_j \qquad i = 1, ..., N \qquad (1)$$

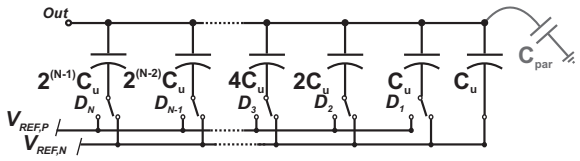

Fig. 1: Schematic of a N-bit CBW array.

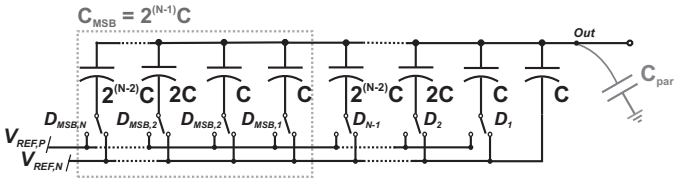

Fig. 2: Schematic of a N-bit SBW array.

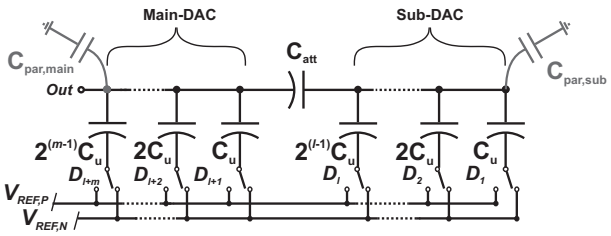

Fig. 3: Schematic of a $(m+l)$-bit BWA array.

where $C_{par,i}$ is the parasitic capacitance related to i^{th} capacitive block and δ_j is the mismatch equivalent capacitance affecting the unit capacitor. The effect of the parasitic capacitances $C_{par,i}$ can be considered deterministic, depending on layout inaccuracies, capacitor geometry and wirings. On the contrary, the capacitor mismatch can be modeled as a Gaussian distribution of the unit capacitor value with a mean equal to the nominal capacitance, C_u, and a standard deviation equal to [10]

$$\sigma_C = \frac{C_u k_c}{\sqrt{2A}} = k_c \cdot \sqrt{\frac{c_{spec} \cdot C_u}{2}}, \tag{2}$$

k_c, C_u, A and c_{spec} being the Pelgrom mismatch coefficient, the unit capacitance, the area and the specific capacitance, respectively. In presence of mismatch or parasitics, the DAC output voltage levels differ from their ideal values being not equally spaced and determining a nonlinearity in the ADC input-output characteristic. Another important parasitic in the charge-redistribution array is the stray capacitance connected to top-plate node of the array to a fixed voltage node, e.g. C_{par} in Fig. 1. This parasitic capacitance causes a gain error in the converter characteristic but in some ADC topologies [5] it can also affect the converter nonlinearity.

A. Conventional Binary Weighted Array (CBW)

The classic binary weighted array [6], depicted in Fig. 1, is the most common topology, its linearity being affected only by the mismatch and parasitic capacitances connected between the top- and the bottom-plate nodes of each capacitance block, C_i. The statistical DNL and INL depend on the technology mismatch and vary with the output code. In a single-ended configuration, the maximum standard deviation of the DNL occurs in correspondence of the converter mid-code, being [5], [7]

$$\sigma_{DNL,CBW} = 2^{\frac{N}{2}} \cdot \frac{\sigma_C}{C_u}, \tag{3}$$

while the correspondent INL maximum standard deviation is

$$\sigma_{INL,CBW} = 2^{\frac{N}{2}-1} \cdot \frac{\sigma_C}{C_u}. \tag{4}$$

In a fully-differential configuration, these results have to be divided by a factor $\sqrt{2}$ [11].

In this array topology, the parasitic capacitance related to the top-plate node, C_{par}, causes a difference between two adjacent output voltage levels to be smaller than the nominal value. This turns into a gain error without affecting the converter linearity.

B. Split Binary Weighted Array (SBW)

The split DAC topology [12] is shown in Fig. 2. It consists of a binary weighted array where the MSB capacitor implements a binary weighted sub-array that perfectly reflects the structure of the remaining banks.

This DAC topology features an improved switching efficiency [12] and also a reduced impact of the capacitors mismatch. In fact, the maximum standard deviation of DNL and INL, which still occurs at the mid-code, is a factor $\sqrt{2}$ lower than in the CBW array topology [7] being

$$\sigma_{DNL,SBW} = 2^{\frac{N-1}{2}} \cdot \frac{\sigma_C}{C_u} \tag{5}$$

$$\sigma_{INL,SBW} = 2^{\frac{N-2}{2}} \cdot \frac{\sigma_C}{C_u}. \tag{6}$$

These relations are referred to a single-ended configuration while a fully-differential topology is a further $\sqrt{2}$-factor less sensitive to mismatch. Moreover, as in the CBW array, only the parasitics connected between top- and bottom-plate nodes of each array capacitor limit the converter nonlinearity.

C. Binary Weighted Array with Attenuation Capacitor (BWA)

A single-ended BWA array [13] is shown in Fig. 3. An attenuation capacitor C_{att} divides the DAC into two binary weighted arrays, main- and sub-DAC, of m and l capacitors, respectively. In this work, we'll refer to the architecture shown in Fig. 3, with the same number of bits in the main- and sub-DAC (i.e. $m = l = N/2$) and $C_{att} = C_u$, which has been shown to be the most energy efficient [5] among all the possible choices. For the same unit capacitance, this topology is more sensitive to capacitor mismatch with respect to CBW and SBW arrays because of the reduction of the overall DAC capacitance. In fact, the maximum σ_{DNL} and σ_{INL} are

$$\sigma_{DNL,BWA} = 2^{\frac{3N}{4}} \cdot \frac{\sigma_C}{C_u} \tag{7}$$

$$\sigma_{INL,BWA} = 2^{\frac{3N}{4}-1} \cdot \frac{\sigma_C}{C_u} \tag{8}$$

which are a factor $2^{\frac{N}{4}}$ larger than in the conventional topology. As far as the parasitic effect, the linearity is degraded also by the stray capacitance connected to the top-plate node of the sub-DAC, $C_{par,sub}$ in Fig. 3, which determines a dependence on the input code of the DAC output voltage, while the parasitic capacitance connected to the main-DAC, $C_{par,main}$, only affects the converter gain [5].

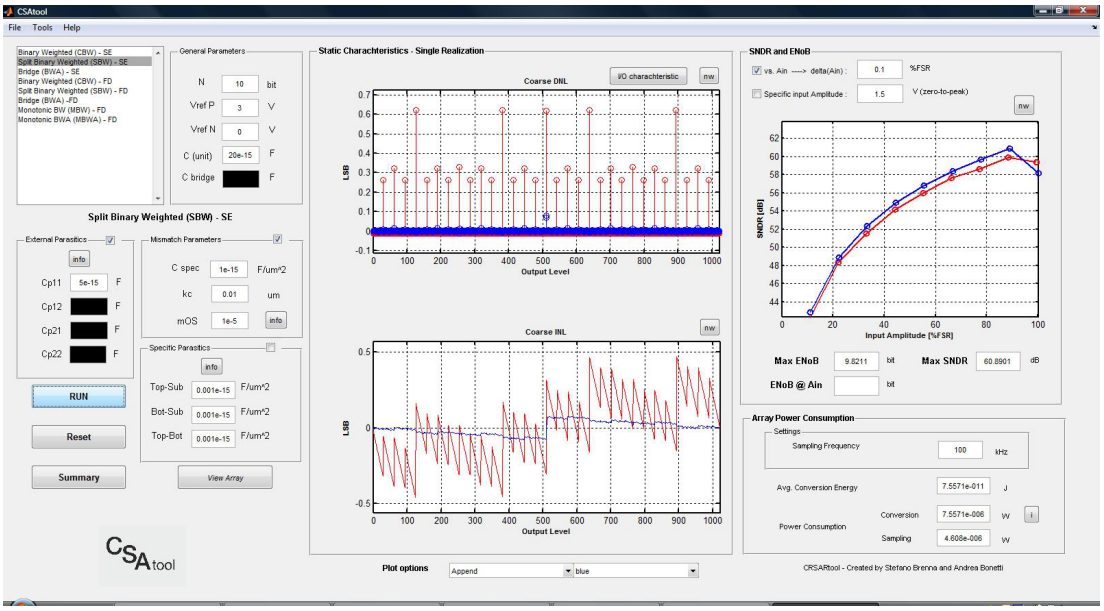

Fig. 4: Screenshot of the Graphic User Interface.

III. CSA MATLAB Simulation Tool

The proposed simulation platform (CSAtool, Charge-redistribution SAR ADC tool) is implemented in MATLAB and allows to evaluate the linearity, either static and dynamic, and the array power consumption of each array topology. Both statistical and deterministic effects due to capacitor mismatch and parasitics can be taken into account once evaluating the ADC performance. The tool provides a graphic user interface (GUI) which is shown in Fig. 4. A behavioral model is defined for each array topology and for a number of bits from 6 to 14. The model does not simply implement the known equations that estimate the nonlinearity (maximum standard deviation of DNL and INL) and the average power consumption of the different topologies. It reproduces the behavior of a specific circuit architecture, which is described by functional capacitive blocks, including the effects of mismatch and parasitics (see Fig. 5). The simulations can be performed with a high degree of customization, giving the possibility to accurately evaluate the impact of mismatch, through both single or multiple statistical runs, and also of the parasitics of each specific array capacitor, thus representing a suitable alternative to Cadence MonteCarlo and post-layout simulations. This section is devoted to the description of the different converter models that are implemented in the proposed tool.

A. CBW model

In a generic SAR ADC, the analog-to-digital conversion is effectively performed by comparing the input analog voltage signal with subsequent voltage levels generated by the capacitive DAC. For a N-bit converter, the input signal is compared with N successive DAC output levels. In a conventional binary weighted topology, the DAC output voltage at each conversion step can be written as

$$DAC_{out,CBW} = FSR \cdot H \tag{9}$$

where FSR is the full scale range of the converter and H, as shown in Fig. 5, is the scalar product

$$H = \frac{1}{C_{tot} + C_{par}} \times \bar{C} \times \bar{D}' \tag{10}$$

where C_{tot} is the total capacitance of the array, C_{par} the parasitic capacitance shown in Fig. 1, $\bar{C}$ the vector of the array capacitances C_i (see (1)) and $\bar{D}$ the vector of the digital word updated at each conversion cycle,

$$\bar{C} = \left[\begin{array}{ccc} C_1 & \dots & C_N \end{array} \right] \tag{11}$$

$$\bar{D} = \left[\begin{array}{ccc} D_1 & \dots & D_N \end{array} \right] \tag{12}$$

The digital word $\bar{D}$, which encodes the DAC output levels at each conversion step, is determined by the adopted switching algorithm. By means of (10), (11) and (12), it is possible to compute the ADC conversion characteristic.

B. SBW model

The simple model described in the previous section can be extended to the SBW architecture of Fig. 2. The MSB capacitor is implemented as a sub-array and the switching scheme differs from the conventional algorithm [12]. Thus, the DAC output voltage can be expressed as

$$DAC_{out,SBW} = FSR \cdot \left(H_{MSB} + H_{1,MSB-1} \right), \tag{13}$$

H_{MSB} and $H_{1,MSB-1}$ being coefficients related to the MSB and the residual capacitance array, respectively,

$$H_{MSB} = \frac{1}{C_{tot} + C_{par}} \times \bar{C}_{MSB} \times \bar{D}'_{MSB} \tag{14}$$

$$H_{1,MSB-1} = \frac{1}{C_{tot} + C_{par}} \times \bar{C}_{1,MSB-1} \times \bar{D}'_{1,MSB-1}. \tag{15}$$

Thus, the conversion voltage level is set by two different N-bit words, $\bar{D}_{MSB}$ and $\bar{D}_{1,MSB-1}$, and two vectors of capacitances, $\bar{C}_{MSB}$ and $\bar{C}_{1,MSB-1}$, related to the MSB sub-array and to the residual array, respectively.

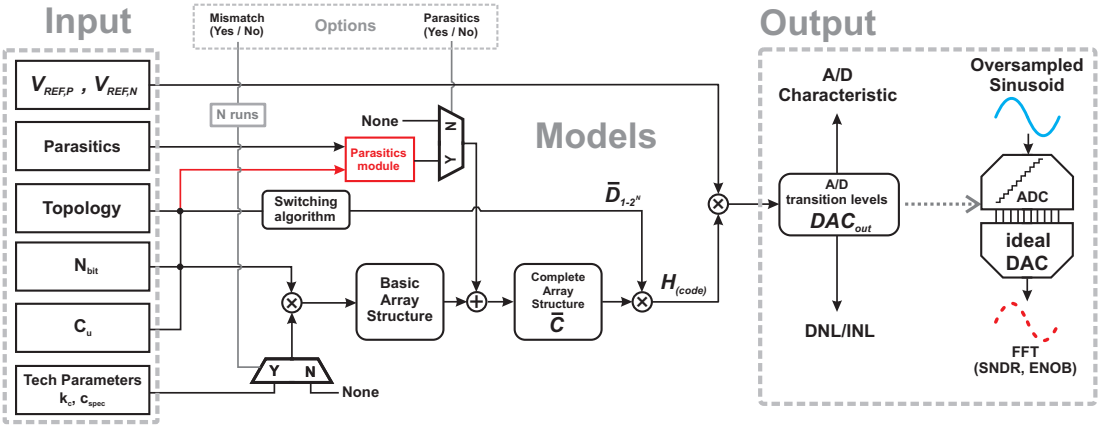

Fig. 5: CSAtool block diagram.

C. BWA model

As for as the BWA topology concerns, two equal capacitive arrays must be considered: the main-DAC, which is connected to the MSB switches, and the sub-DAC, related to the least significant bits. Let us indicate as $C_{tot,main}$ and $C_{tot,sub}$ to the overall capacitance of the main-DAC and of the sub-DAC, respectively, and as $C_{par,main}$ and $C_{par,sub}$ the parasitic capacitance at the top-plate node of the corresponding DAC (see Fig. 3). Due to the presence of the attenuation capacitor, C_{att}, the sub-DAC contribution to the overall DAC output voltage is reduced by an attenuation factor AR,

$$AR = \frac{C_{att}}{C_{tot,main} + C_{par,main} + C_{att}}, \tag{16}$$

$C_{tot,main}$ being the total capacitance of the ideal main-DAC, while $C_{par,main}$ is the parasitic capacitance connected to the top-plate node of the main array. Thus, the DAC output in the BWA topology is evaluated as

$$DAC_{out,BWA} = FSR \cdot (H_{main} + AR{\cdot}H_{sub}), \tag{17}$$

where H_{main} and H_{sub} are coefficients related to the main- and sub-DAC,

$$H_{main} = \frac{1}{C_{tot,main} + C_{par,main} + C_{att}} \times \bar{C}_{main} \times \bar{D}'_{main} \tag{18}$$

$$H_{sub} = \frac{1}{C_{tot,sub} + C_{par,sub} + C_{att}} \times \bar{C}_{sub} \times \bar{D}'_{sub}. \tag{19}$$

where $\bar{C}_{main}$, $\bar{C}_{sub}$, $\bar{D}_{main}$ and $\bar{D}_{sub}$ are the capacitance and digital output code vectors related to the main- and the sub-DAC,

$$\bar{C}_{main} = \left[\; C_{\frac{N}{2}+1} \quad \dots \quad C_N \; \right] \tag{20}$$

$$\bar{C}_{sub} = \left[\; C_1 \quad \dots \quad C_{\frac{N}{2}} \; \right] \tag{21}$$

$$\bar{D}_{main} = \left[\; D_{\frac{N}{2}+1} \quad \dots \quad D_N \; \right] \tag{22}$$

$$\bar{D}_{sub} = \left[\; D_1 \quad \dots \quad D_{\frac{N}{2}} \; \right]. \tag{23}$$

IV. Simulation Results

The CSAtool implements in MATLAB the three above-mentioned converter topologies by considering each array capacitor as a composition of unit elements, C_u, each with its own variability that depends on technologic parameters, i.e. k_c and c_{spec}. This simple modeling approach allows to accurately take into account the effects of mismatch and stray capacitances, which affect the converter linearity. The tool allows to run both nominal and statistical simulations in order to accurately evaluate the DNL and INL taking into account at the same time capacitor mismatch and parasitic effects. The tool also allows to estimate the degradation of both SNDR and ENoB due the converter nonlinearity. These two parameters are evaluated by feeding the real ADC with an oversampled sinewave of variable amplitude and re-converting the digital output signal to an analog waveform by means of an ideal DAC. Hence, the signal-to-noise ratio and the effective number of bits are evaluated by performing a FFT on the DAC output. Both SNDR and ENoB can be estimated while considering both deterministic parasitic effects and the contribute of statistical capacitor mismatch on multiple runs. Thus, CSAtool allows to obtain results accurate enough to be compared with post-layout and MonteCarlo simulations in Cadence Virtuoso environment but with a large improvement in terms of simulation time. In this section, the simulation results for the three converter topologies are shown and compared to both analytic expressions and Cadence results in terms of accuracy and simulation time. The presented results are related to converters featuring a 20-fF MiM unit capacitor with a specific capacitance of $1fF/\mu m^2$ and a Pelgrom coefficient of $1\% \cdot \mu m$.

A. Static metrics

The estimate of parasitic contribution to static non-linearity has been evaluated by means of the CSAtool and compared with Cadence Virtuoso simulation results. A single-ended SAR ADC has been designed in Cadence Virtuoso adopting a VerilogA description for the logic circuit and the comparator, while the feedback DAC has been implemented with ideal capacitors. Arbitrary parasitic capacitances have been added between the main capacitor top- and bottom-plate nodes in order to estimate their effect on the converter nonlinearity. Hence, the input-output characteristic has been evaluated by means of a transient simulation applying a full-scale ramp as input signal. To reduce the simulation time, only the converter input and output values have been saved. The strobe and the sampling periods have been chosen short enough to guarantee

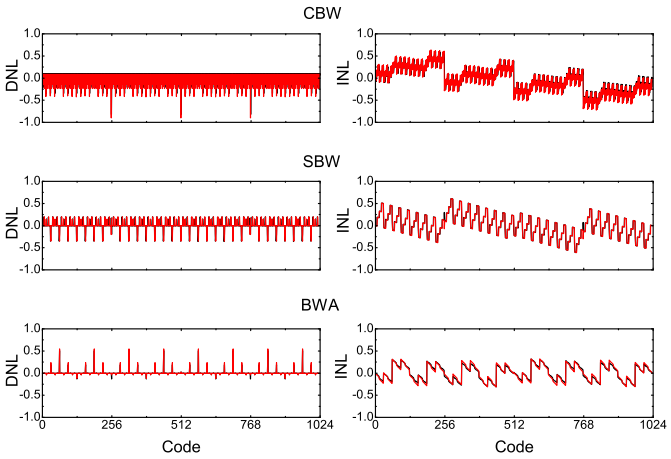

Fig. 6: Comparison between DNL and INL estimated by Cadence simulations (black lines) and by CSAtool (red lines) for a given pattern of parasitic capacitances and for each converter topology.

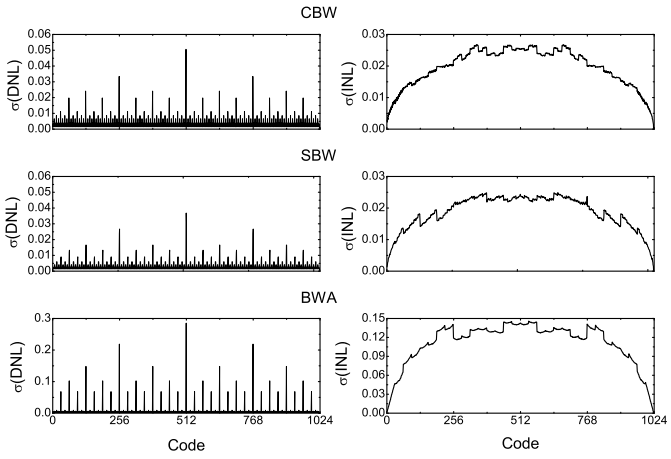

Fig. 7: Standard deviation of DNL and INL as a function of the output code for a CBW, SBW and BWA 10-bit converter.

at least 100 points per each conversion level, thus keeping the systematic error on the DNL below 1%. Fig. 6 shows the comparison between the DNL and INL characteristics obtained by CSAtool and Cadence Spectre simulations for the three converter topologies affected by parasitics extracted in Assura. The error between the CSAtool and Cadence results is never larger than 0.05 LSB, confirming the good accuracy of the implemented converter models.

Fig. 7 shows the results obtained by the CSAtool once the capacitor mismatch has been considered in terms of standard deviation of DNL and INL. Since a MonteCarlo simulation performed in the Cadence environment requires at least 100 runs to achieve confident results, thus being impractical, the effect of capacitor mismatch has been compared to the analytic expressions by using (3), (4), (5) and (8). Table I compares the maximum values of DNL/INL standard deviation, i.e. σ_{DNL} and σ_{INL}, computed by the CSAtool running 100 simulations and the estimates obtained by the analytic expressions. The error between estimates and CSAtool results is always lower than 0.005 LSB.

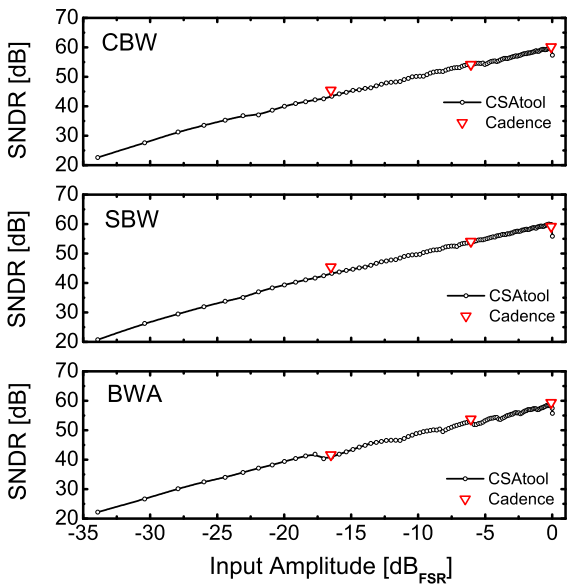

Fig. 8: SNDR as function of the input signal amplitude for the three converter topologies.

B. Dynamic metrics

The dynamic metrics have been computed in the CSAtool for the three single-ended converter topologies (with added parasitic capacitances) and compared to Cadence simulation results. The Cadence test-bench is similar to the one described in the previous section. The input signal is a sinewave at 1-kHz frequency but featuring a variable amplitude, while the sampling rate has been set to 30 kHz.

Fig. 8 shows the SNDR evaluated by means of Cadence Spectre simulations and CSAtool as function of the input signal amplitude (referred to the full scale range) for the three converter topologies. The maximum discrepancy between the Cadence and CSAtool results is always lower than 0.45 dB. However, it's worth pointing out that the CSAtool allows to easily compute the SNDR vs. input amplitude curve, while the same simulations in Cadence takes a long time allowing to compute only few points of the dynamic characteristic. This can results in a not correct evaluation of the SNDR peak and thus of the ENoB.

C. Power consumption

The models implemented in the CSAtool allow to evaluate the array switching energy as function of the output code.

Fig. 9 shows the average switching energies as function of the number of bits for the three considered single-ended arrays evaluated by means of the analytic expressions [5],

$$E_{ave,CBW} \cong 0.66 \cdot 2^N \left[C_u \left(V_{REF,P} - V_{REF,N} \right)^2 \right] \quad (24)$$

$$E_{ave,SBW} \cong 0.41 \cdot 2^N \left[C_u \left(V_{REF,P} - V_{REF,N} \right)^2 \right] \quad (25)$$

$$E_{ave,BWA} \cong 1.25 \cdot \left[C_u \left(V_{REF,P} - V_{REF,N} \right)^2 \right]. \quad (26)$$

The average energy evaluated with the CSAtool for the same arrays is also shown in Fig. 9 as symbols, showing a good agreement with the theoretical estimates.

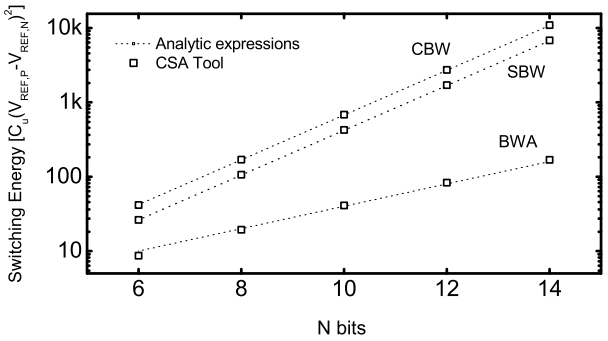

Fig. 9: Average switching energy for the three converter topologies. Dashed lines refer to analytic equations, symbols refer to CSAtool results.

TABLE I: ESTIMATES OF $\sigma_{DNL,max}$ AND $\sigma_{INL,max}$

	$\sigma_{DNL,max}$		$\sigma_{INL,max}$	
Topology	CSAtool	Equation	CSAtool	Equation
CBW	0.0502	0.0506	0.0249	0.0253
SBW	0.0351	0.0358	0.0252	0.0253
BWA	0.286	0.286	0.143	0.144

D. Simulation time

Table II reports a comparison between the simulation times needed to compute the static and dynamic metrics with the CSAtool and Cadence environment. The simulation times refer to a CBW converter with a number of bits from 6 to 14 and to a single simulation run. All the simulations have been performed with a 3-GHz Pentium Xeon featuring a 4-Gbyte main memory. For the same accuracy (i.e. DNL lower than 1%), the CSAtool features an improvement in terms of simulation time up to about 10^4. Finally, it's worth pointing out that the CSAtool allows to estimate the static nonlinearities and the dynamics metrics in presence of statistical mismatch and parasitic capacitance effect allowing to perform a MonteCarlo simulation over a large number of runs. Table III shows the simulation time for a MonteCarlo analysis of 100 runs. For a 14-bit converter, i.e. the worst case, the tool allows to compute the static and dynamic metrics in less than 10 minutes, while the same analysis cannot be performed in a reasonable amount of time in Cadence Virtuoso envirmonment.

V. CONCLUSIONS

In this work, a fast and accurate simulation tool for the analysis and design of charge redistribution SAR capacitive DACs and ADCs is presented. A graphic user interface MATLAB environment supports the implemented models that allow to simulate both technology mismatch and parasitic effects on linearity. The proposed tool overwhelms the conventional simulation method based on transient analyses in terms of computation time for a given accuracy and does not require a fine calibration of simulation parameters (points per conversion step, strobe period, etc.). In particular, the method is helpful every time a fast analysis and an accurate sizing of commonly-used converter architectures is needed. The proposed CSAtool can be downloaded with encrypted scripts from ftp://ftp.elet.polimi.it/outgoing/Stefano.Brenna.

***Abstract*— Multipliers are important components that dictate the overall arithmetic circuits' performance. The most critical components of multipliers are compressors. In this paper, a new 5:2 compressor architecture based on changing some internal equations is proposed. In addition, using an efficient full-adder (FA) block is considered to have a high-speed compressor. The number of transistors in the proposed design is less than the best existing 5:2 compressor architectures. Three 5:2 compressors are considered for comparison. The proposed architecture is compared with the best existing designs presented in the state-of-the-art literature in terms of power, delay and area. Architectures are simulated in 90-nm CMOS technology under 1 V supply voltage. The simulation results show that the proposed compressor improves power and delay by 24.59% and 18.54% respectively, compared to two of the best existing architectures. In addition, voltage scaling and temperature analysis show that the proposed architecture outperforms the other designs from power-delay product (PDP) point of view in comparison to the aforementioned designs.**

Keywords—5:2 compressor; multiplier; high-performance arithmetic circuit; low-power design

I. INTRODUCTION

Rapid growth of using multipliers has attracted lots of researchers' attention into making high-performance multipliers to consume less power and operate faster. Multiplication process includes three steps: 1) partial product generation; 2) partial product reduction; 3) final addition with carry propagating. The second step makes the worst-case delay, consumes the main part of power, and occupies the high fraction of silicon area. To decrease the latency of this step, compressors have been widely employed. Therefore, designing a low-power and high-speed compressor is an important issue that should be raised to have a proper multiplication and subsequently a fast arithmetic computation.

5:2 compressors are widely used as building blocks of multipliers [1, 2]. Lots of architectures for 5:2 compressors have been proposed in the literature [3-6]. By a vast research on these structures, it has been revealed that the structures presented in [4] and [6] have better performance than others. In [4], the authors have proposed a new 5:2 compressor. They have simulated their proposed compressor by CMOS XOR-XNOR modules and two different multiplexer implementations. In [6], the authors have proposed a new structure based on a new realization of 5:2 compressors' truth table.

In this paper, we propose a new 5:2 compressor by applying some changes to the structure proposed in [4] to have a high-speed and low-power compressor. We use Carry Generator (CGEN) modules to produce C_{out1} and C_{out2} signals. We also make use of a high-performance CMOS FA to produce main output signals.

The paper is organized as follows: in Section II, we describe two architectures proposed in [4] and [6]. In Section III, we explore our proposed compressor. In Section IV, the simulation results and comparison are detailed. Finally, in Section V we conclude the paper.

II. BACKGROUND

Every 5:2 compressor has seven inputs and four outputs. Five inputs are primary inputs and the rest are two input carries which receive their values from the previous stage of one bit lower in significance. All the seven inputs, as well as output Sum bit have the same weight. The other three output bits weight one bit higher order.

A 5:2 compressor with five primary inputs X_1, X_2, X_3, X_4, X_5 and two output bits Sum and Carry along with carry input bits, C_{in1} and C_{in2}, and carry output bits, C_{out1} and C_{out2}, is governed by the following equation:

$$x_1 + x_2 + x_3 + x_4 + x_5 + C_{in1} + C_{in2} = Sum + 2\left(Carrry + C_{out1} + C_{out2}\right) \quad (1)$$

Various structures for 5:2 compressors are available in the literature. The simplest implementation of 5:2 compressor is obtained by cascading three full-adders in a hierarchical structure. The structure has a critical path delay of 6Δ where Δ refers to delay of XOR-XNOR, XOR, MUX or CGEN module, as their critical delay difference is trivial.

The structure of 5:2 compressor with critical path delay of 4Δ has been proposed in [7]. A modified structure has been proposed in [8], which has a critical path delay of 5Δ. In [3, 4] and [6] authors have proposed architectures with a critical path delay of 4Δ.

As shown in [4, 6], designs presented in these papers have better performance than others. The results of these two papers urged us to use these structures for our survey. These two designs are introduced below.

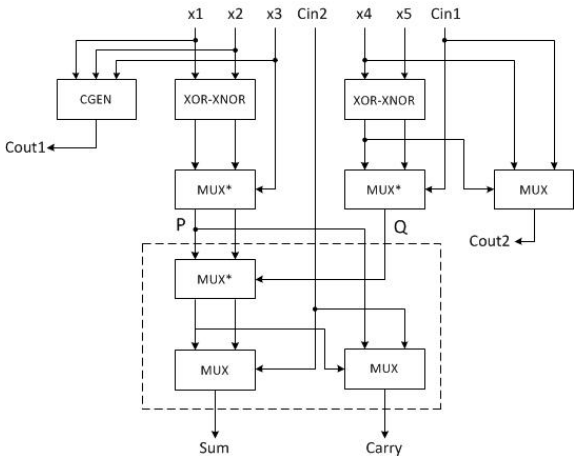

Fig. 1. 5:2 compressor architecture proposed in [4]-Arch-07

A. *The compressor proposed in [4]*

Since CMOS implementation of MUX performs better than a XOR gate in terms of power and delay [9], in [4] the authors have proposed a 5:2 compressor based on using multiplexers in place of XOR gates as shown in Fig. 1. In CMOS implementation of the MUX and XOR-XNOR blocks, as shown in Fig. 2(b) and Fig. 5(a), outputs and their complements are generated. But, complement outputs are not being utilized in architectures proposed in [3, 7, 8, 10]. If the output of multiplexer is used as select bit of another multiplexer, it can be used efficiently, and an extra stage to compute the negation in multiplexer structure can be saved. The authors used CMOS-CGEN in their architecture to produce C_{out1} signal. Fig. 3 shows the CMOS implementation of CGEN module. The architecture proposed in [4] will be called ***Arch-07*** in the rest of this paper and is depicted in Fig. 1.

Arch-07 is one of the most efficient architectures that exist for 5:2 compressors and has been used in [2, 11, 12].

The authors performed simulation by using CMOS multiplexer and XOR-XNOR modules which are depicted in Fig. 2(b) and Fig. 5(a), respectively. In addition, Fig. 2(a) has been used in Arch-07 as the MUX block of intermediate stages.

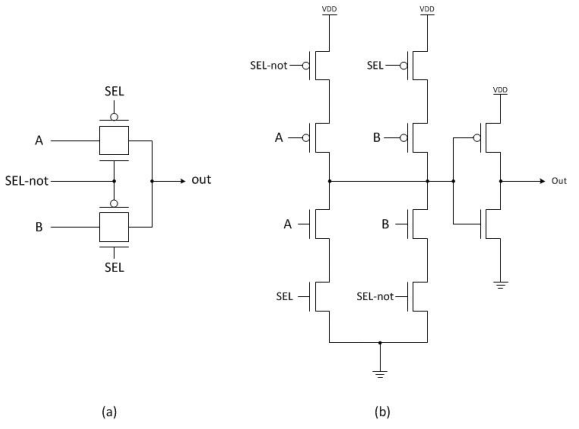

Fig. 2. (a) Transmission Gate implementation of multiplexer (b) CMOS implementation of multiplexer

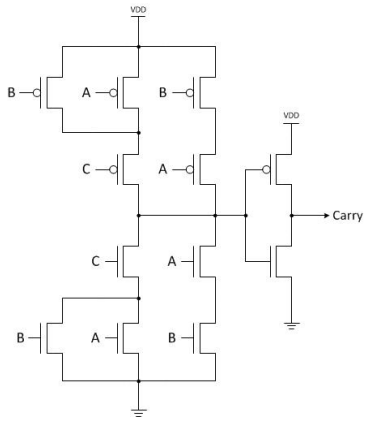

Fig. 3. CMOS implementation of Carry Generator module

B. *The compressor proposed in [6]*

In [6], authors have proposed architectures with a critical path delay of 4Δ. Pass-transistor logics and static CMOS logics have been used based on a new understanding of 5:2 compressors' truth table. This architecture is depicted in Fig. 4 and will be called ***Arch-13*** in the rest of this paper. CMOS-CGEN modules have been used to produce C_{out1} and C_{out2} signals, in this architecture. This block is also a main block of 7-2 compressor proposed in [13].

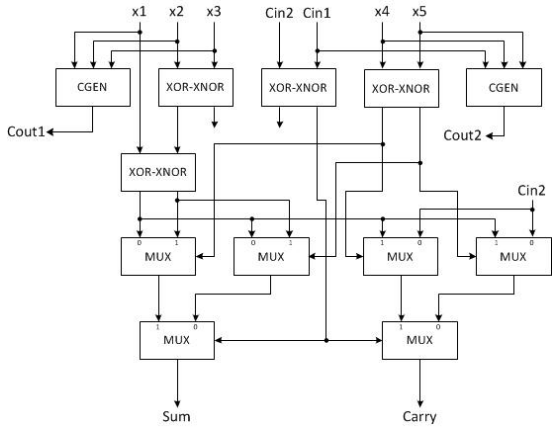

Fig. 4. 5:2 compressor proposed in [6]-Arch-13

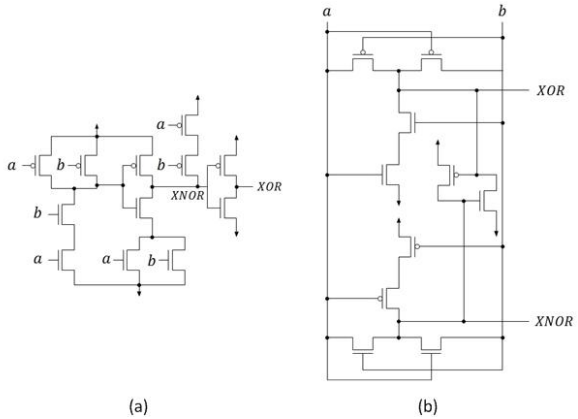

Fig. 5. (a) CMOS implementation of XOR-XNOR module (b) XOR-XNOR module proposed in [3]

In Arch-13, XOR-XNOR modules of Fig. 5(b) are used to feed complementary inputs of MUXs. In addition MUX modules of Fig. 2(a) have been used in this architecture. The authors have claimed power and latency reduction by decreasing middle stage capacitances.

III. PROPOSED COMPRESSOR

In this section the proposed architecture is introduced. Two improvement approaches are used to propose the new 5:2 compressor architecture. First, by a closer look at dashed box of Fig. 1, it represents the functionality of a conventional FA and can be replaced by variety of FAs presented in the literature. This replacement is expected to lead to considerable speed improvement, due to 34% faster operation of CMOS FA in comparison to two cascaded CMOS XOR gates, as it is explained in [14]. Therefore, the CMOS FA presented in [15] is used in our proposed 5:2 compressor architecture.

To further improvement, we make some changes to internal equations of the 5:2 compressor to eliminate final Not gates of the CMOS FA. By doing so, we could have reduced power dissipation as well as improved operational speed. To achieve this goal, we have to use XNOR gates instead of XORs of the second stage of the architecture. Hence, we propose the architecture which is shown in Fig. 6. This design uses 82 transistors in its architecture (i.e. 6 transistors less than Arch-13). The proposed design will be called ***New Arch*** in the rest of this paper.

In this architecture, FA-not is CMOS FA which it's final Not gates have been eliminated. This module is shown if Fig. 7.

As shown in Fig. 6, CGEN modules have been used to produce C_{out1} and C_{out2} output signals. The CMOS-CGEN which has been shown in Fig. 3 is used in the proposed architecture. In addition, outputs of the XOR gates have been fed to inputs of the XNOR gates, as it can be seen in Fig. 3. This way, outputs of the XNOR gates are negation of what it was before for conventional 5:2 compressors and by replacing a FA-not instead of a FA we can have valid Sum and Carry signals.

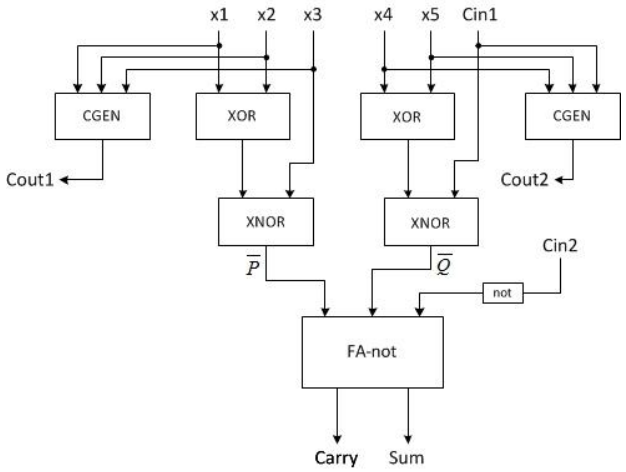

Fig. 6. Proposed 5:2 compressor design-New Arch

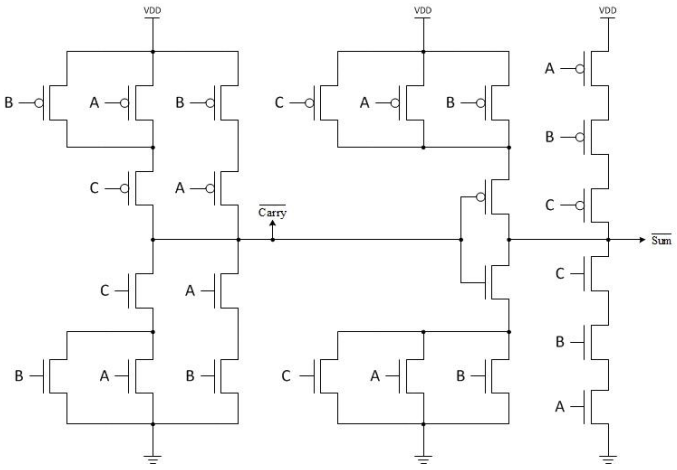

Fig. 7. CMOS implementation of FA-not cell

We know the following equations:

$$\begin{aligned} \bar{x} \oplus \bar{y} &= x \oplus y \\ \overline{x \oplus \bar{y}} &= x \oplus y \end{aligned} \tag{2}$$

Therefore, (3) and (4) proves the accuracy of the mentioned methods.

$$\begin{aligned} \overline{\left(\overline{P} \oplus \overline{Q}\right) \oplus \overline{C_{in2}}} &= \left(P \oplus Q\right) \oplus \overline{C_{in2}} \\ &= P \oplus Q \oplus C_{in2} \end{aligned} \tag{3}$$

$$\begin{aligned} \overline{\left(\overline{P} + \overline{Q}\right) \cdot \overline{C_{in2}} + \overline{P}\overline{Q}} &= PQ + PC_{in2} + QC_{in2} \\ &= \left(P + Q\right) \cdot C_{in2} + PQ \end{aligned} \tag{4}$$

It is worth mentioning that $\overline{P}$ and $\overline{Q}$ are nodes which represent XNOR gates outputs of the proposed architecture and have been shown in Fig. 6. In addition, they are logical complement of P and Q nodes, respectively, which have been shown in Fig. 1.

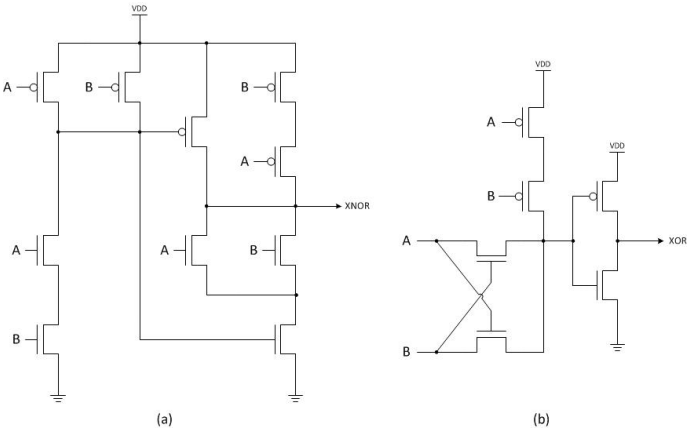

Fig. 8. (a) CMOS implementation of XNOR gate (b) XOR gate using pass-transistor logic presented in [16]

The logic equations governing the proposed 5:2 compressor architecture are detailed in (5)-(8):

$$Sum = x_1 \oplus x_2 \oplus x_3 \oplus x_4 \oplus x_5 \oplus C_{in1} \oplus C_{in2} \tag{5}$$

$$C_{out1} = (x_1 + x_2) \cdot x_3 + x_1 x_2 \tag{6}$$

$$C_{out2} = (x_4 + x_5) \cdot C_{in1} + x_4 x_5 \tag{7}$$

$$\begin{aligned} Carry = &\left((x_1 \oplus x_2 \oplus x_3) + (x_4 \oplus x_5 \oplus C_{in1})\right) \cdot C_{in2} \\ &+ (x_1 \oplus x_2 \oplus x_3) \cdot (x_4 \oplus x_5 \oplus C_{in1}) \end{aligned} \tag{8}$$

The XOR and XNOR gates which have been used in the proposed architecture are shown in Fig. 8.

IV. SIMULATION RESULTS AND COMPARISON

A. Simulation environment

The simulations have been performed by HSPICE software. All the simulations are targeted for TSMC 90-nm technology. The circuits under test are simulated at 1 V supply voltage. It should be noted that all inputs are driven by frequency of 200MHz.

The simulation environment for 5:2 compressor is shown in Fig. 9. Three cascaded compressors are used due to the fact that the critical path of some data patterns may cross neighboring compressors in the same stage of CSA tree. The dashed line in Fig. 9 indicates the most probable scenario of such potential critical paths. The delay is measured from the earliest input signal reaching 50% of the supply voltage to the latest output signal reaching 50% of the supply voltage for each input cycle. The worst case is the largest delay among all input data.

B. Results and comparisons

The proposed architecture is compared to two of the best existing 5:2 compressor architectures in terms of power, delay and area. Therefore, three different 5:2 compressor designs are simulated: Arch-07, Arch-13 and the proposed architecture.

The simulation results for 1V supply voltage at ambient temperature of 25°C are tabulated in Table 1. Bold numbers represent the best ones among the three architectures in each figure of merits. In addition, the last raw of the table shows the improvement percentage of our proposed architecture in comparison to the best of the existing ones.

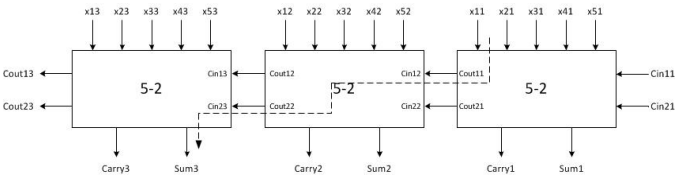

Fig. 9. Simulation environment

TABLE I. SIMULATION RESULTS IN 25°C WITH THE 1V

	Power [µw]	*Delay [ps]*	*Power-delay product [fj]*	*Transistor count*
Arch-07	6.18	228.3	1.41	90
Arch-13	6.66	210.3	1.4	88
New Arch	**4.66**	**168.2**	**0.78**	**82**
Improvement percentage	24.59%	18.44%	44.28%	6.82%

As it can be seen in the table, New Arch reduces power by 24.59% in comparison to Arch-07. In addition, New Arch reduces delay, PDP and transistor count by 18.44%, 44.28% and 6.82%, respectively, in comparison to Arch-13.

We have also performed voltage scaling and temperature analysis. For voltage scaling analysis, 5:2 compressors have been simulated at temperature of 25°C under supply voltages ranging from 0.8V to 1.2V. Fig. 10 shows PDP versus supply voltage of the three 5:2 compressor architectures.

For temperature analysis, the architectures have been simulated in the wide temperature range of 20-120°C with 1V supply voltage. Fig. 11 shows PDP versus temperature of the three 5:2 compressor architectures

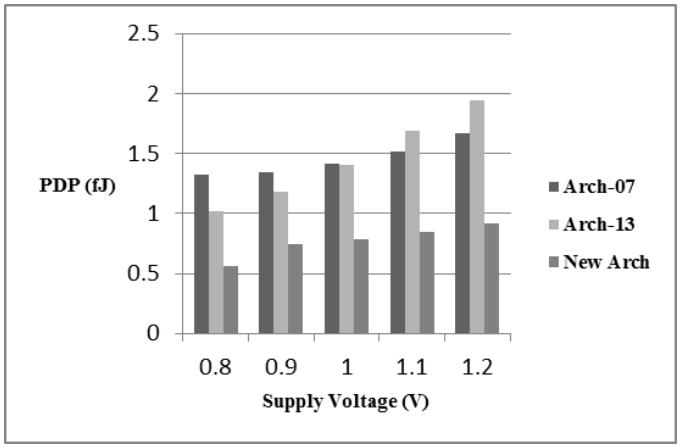

Fig. 10. Power-delay product Vs. supply voltage

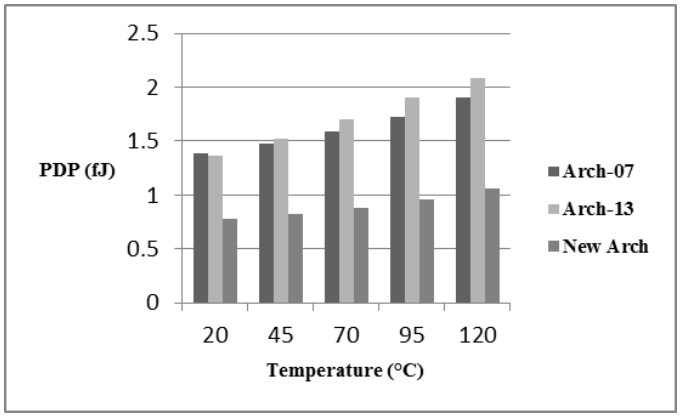

Fig. 11. Power-delay product Vs. temperature

Fig. 10 and Fig. 11 show that the proposed architecture outperforms the other two designs from energy efficiency point of view. These figures as well as Table 1 show up to 45% improvement in PDP of the proposed architecture in comparison to the best existing ones.

V. CONCLUSION

In this paper, we proposed a new 5:2 compressor architecture by changing some internal equations. The new compressor is proposed by presenting a module named: FA-not. This module is obtained by eliminating final Not gates of a CMOS FA block. In addition, CMOS-CGENs are used to produce C_{out1} and C_{out2} signals. By applying these methods, we have come up with a 5:2 compressor which uses 82 transistors.

Simulation and synthesis are performed by HSPICE software; and all inputs are driven by the frequency of 200MHz. It is concluded that among the three simulated architectures, the proposed architecture consumes the lowest power, operates faster and consequently is the most energy efficient one. The proposed architecture, in term of PDP, shows 44.28% improvement compared to the best existing architecture.

Abstract – This paper presents a fully integrated application specific integrated circuit (ASIC) for the readout of multiple electrochemical sensor signals. It consists of an analog router that routes readout circuits to various sensors, a 10-bit successive approximation register analog to digital converter (SAR ADC), two digital to analog converters (DAC), a multiplexer and I2C/SPI serial interfaces for connection to micro-controller (MCU). The ASIC is fabricated in a 0.35-µm CMOS technology, occupies an area of 1.5 × 3.0 mm^2, and consumes a current of 3.2 mA from a 3.3 V supply. All calibration and configurations are set using the I2C/SPI serial interface connections.

I. INTRODUCTION

In agriculture applications, low cost, ease of use, reliability and functional flexibility[1][2] are essential considerations for design. To measure sensor signals of different types, an adaptive universal signal conditioner has been designed. Integrating a micro-controller (MCU) with this universal sensor interface ASIC combines analogue and digital processing capability and allows customization to different applications. Such an arrangement enhances performance while simultaneously reduces cost and power when considered as a system.

In this paper, a sensor ASIC that integrates a 16-channel reconfigurable interface, a 10-bit SAR ADC and two 10-bit DAC is presented. The sensor interface performs signal readout for current and voltage output sensors, providing a unified interface for heterogeneous mix of sensors. The ASIC supports serial interfaces I2C/SPI that permits communication with an MCU that sets configuration, calibration, control and sensor data readout and processing. This multi-sensor interface can be re-configured to satisfy the readout and signal processing needs of many different sensor applications, providing flexibility and lowering costs.

This paper is divided into three main sections. The system architecture and circuit implementation are explained in Approach and Methods section. The Results and Discussion section presents simulation results and physical layout. Finally, the conclusions are drawn in the last section.

II. APPROACH AND METHODS

The architecture as shown in Fig. 1 consists of an analog router which connects 24 inputs to 4 different input multiplexers depending on sensor type (2/3/4 port sensors). This allows as many as 6 sensors (max. 4 port) to be connected simultaneously in addition to provision for external sensor readout through open ports as shown in Fig. 2. The input multiplexers routes the sensor signals to the respective readout circuits before connecting to a 16:1 multiplexer which output to an external filter.

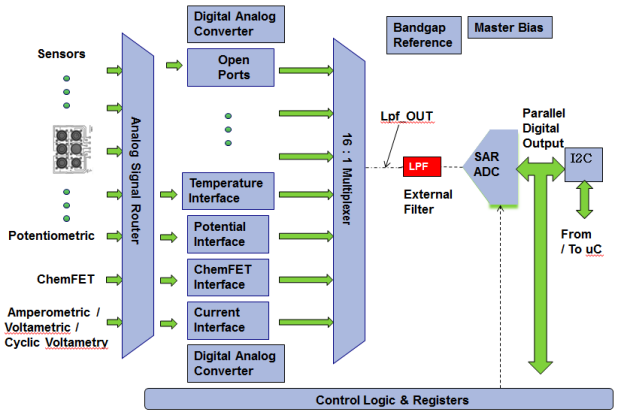

Fig. 1 – Architecture of sensor ASIC

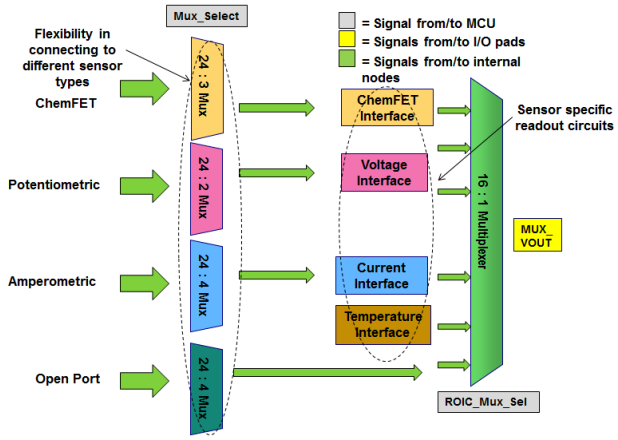

Fig. 2 – Analog signal router connection block diagram

Signals output from external filter then passes through an ADC to be digitized and serialized. All the control

sequence are controlled and configured through I2C interface by external micro-controller. Outputs from the two 10-bit DAC connect to all sensor readout circuits and also to the SAR ADC, allowing it to be used as reference signals for calibration and to set offsets if needed.

A. ELECTROCHEMICAL SENSOR READOUT CIRCUITS

The three readout integrated circuit (ROIC) designed is for chemical field effect transistors (ChemFET), current (Amperometric) and voltage (Potentiometric) sensors. ChemFET [2] sensors are field effect transistors with gates replaced by an intrinsic electrolyte layer covered by a dedicated ion selective membrane. It is used for measurement of a specific ion mole activity from a dissolved solution composing of other ions. The readout circuit [3] for the designed ChemFET sensor interface is depicted in Fig. 4, where provisions are made for various settings of input sources, gain, dc shift and biasing.

The Amperometric readout circuit [4] shown in Fig. 5, is configurable for two, three or four electrode type current sensors. A trans-impedance amplifier converts the current input to voltage where its gain is selectable before being converted to digital output by ADC later. The sensor bias can be set either through internal DAC (programmable) or external pin.

The Potentiometric readout circuit designed, shown in Fig. 6, is a conventional three op-amp type with programmable settings for gain and offset.

B. DATA CONVERTERS

Both the analog to digital converter (ADC), Fig.7 and digital to analog converter (DAC), Fig.8 designs have 10 bit resolution and uses resistor string DAC sub-block in order to minimize area. Two DAC's are designed for use to set direct current (DC) offsets and provide reference signals for calibration. The outputs from the DAC can be selected to route to various readout circuits and to ADC.

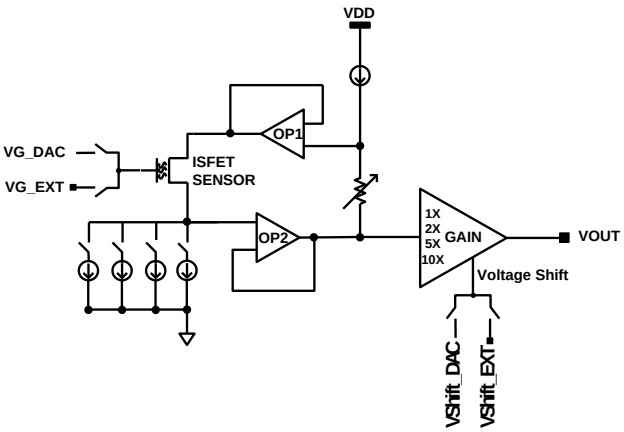

Fig. 4 – ChemFET sensor readout circuit

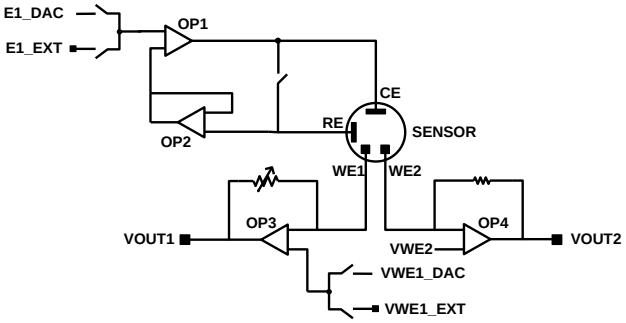

Fig. 5 - Amperometric sensor readout circuit

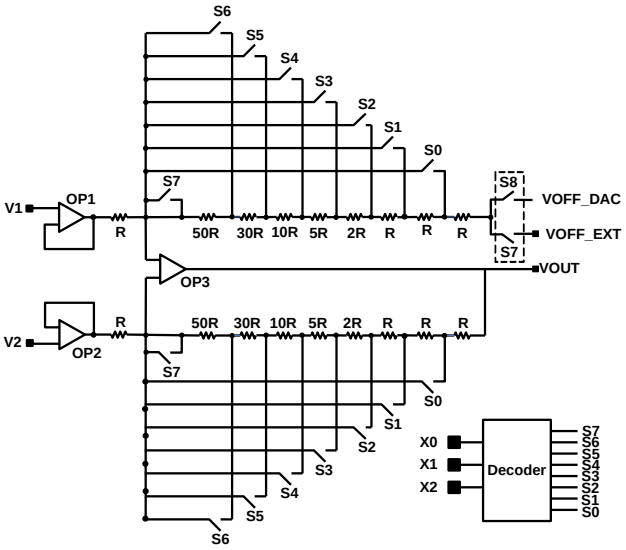

Fig. 6 - Potentiometric sensor readout circuit

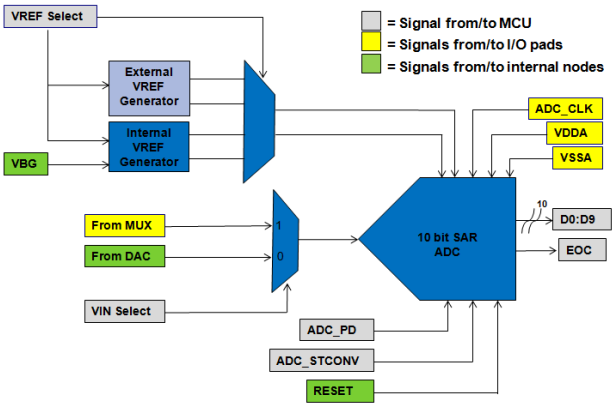

Fig. 7 - 10 bit Successive Approximation Analog Digital Converter

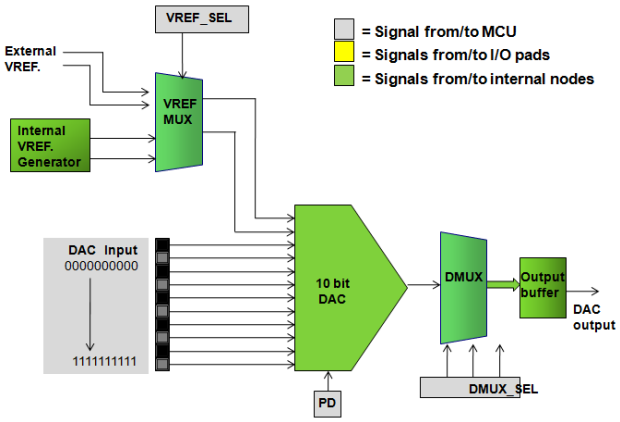

Fig. 8 - 10 bit Resistive string Digital to Analog converter

C. SERIAL INTERFACES

All data into and out of ADC, DAC and other ROIC blocks uses either I2C or SPI interface, Fig 9 to reduce pin count. The serial interfaces are also used for setting configuration data as well as command from external MCU.

The Serial Interface consists of START and STOP detection logic to identify the beginning and end of data packet. The Bit Counter and State Machine are used to keep track of operation and serially shift in or out data from or to the data base. These data are written into/read from the Register Bank, which are used to interface with analog circuitry.

III. RESULTS AND DISCUSSION

This circuit was simulated and taped out using 0.35um CMOS process technology. The layout of the sensor ASIC is shown in Fig. 10 while the measurement setup used for characterizing the taped-out chip is shown in Fig. 11, where in addition to bench equipments being connected, an I2C/SPI host adapter with its associated software is also interfaced in order to provide stimulus and read response through I2C/SPI protocol.

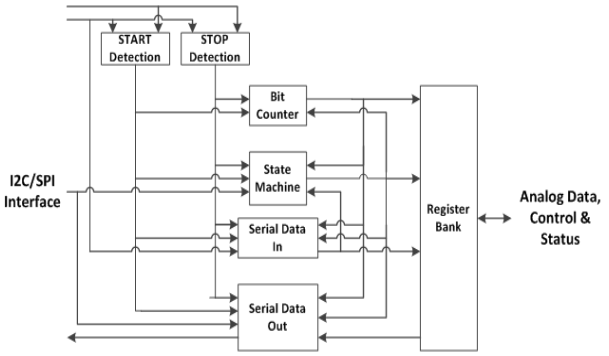

Fig. 9 - Serial Interface

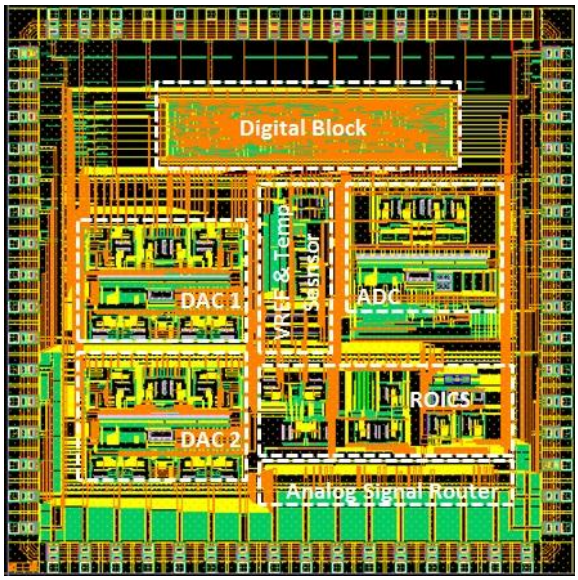

Fig. 10 - Layout implementation of sensor ASIC (5mm x 5mm) [6] ©2013 MIMOS Berhad

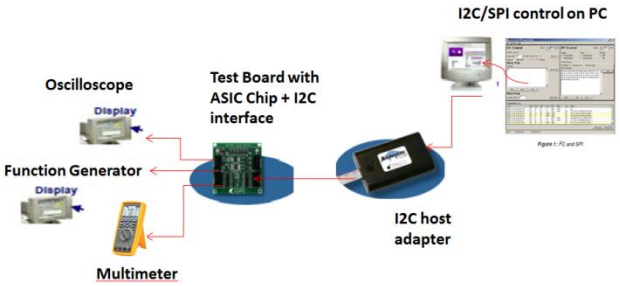

Fig. 11 – Test setup used for sensor ASIC characterization

Fig. 12 shows the functional test result for DAC block where three sets of ten consecutive codes, representing the lower, middle and upper DAC ranges were input through I2C interface and DAC ouput voltage measured at pin Lpf_OUT (refer to Fig. 1), which is the output of 16:1 multiplexer. The result (13 out of 14 chips tested) shows that transition from one code to the next consecutive code was correct, i.e. ~2mV (equivalent to one least significant bit, LSB) for reference of 2 volt for a 10 bit DAC.

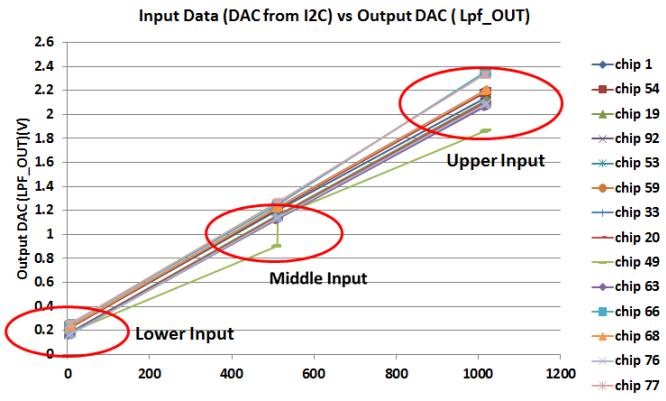

Fig. 12 – DAC block functional test result

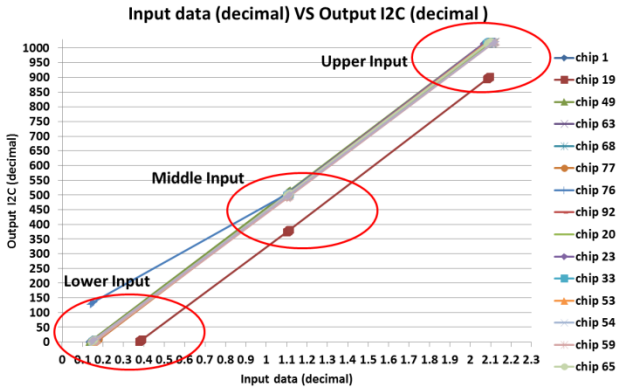

Fig. 13 – ADC block functional test result

The ADC block was functionally tested for three sets of ten consecutive codes (Fig. 13), representing the lower, middle and upper ADC ranges. In this case the ADC input was increased until ten consecutive codes from those ranges were exercised. Zoom-in results for the functional tests are depicted in Fig. 14, Fig. 15 and Fig. 16. The results show that the ADC increase by one code for approximately 2mV change in input for a 2V reference which corresponds to 1 LSB (least significant bit) and also the increase are linear over those ten codes.

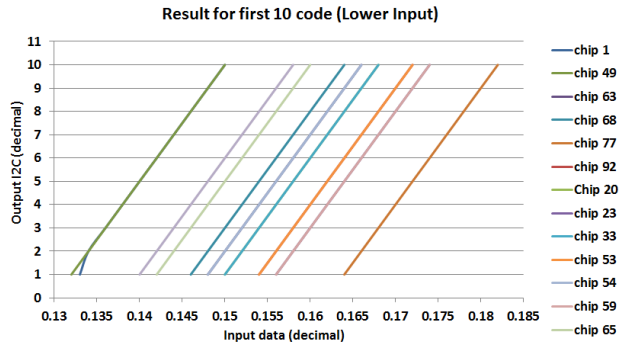

Fig. 14 – ADC block functional test result for first 10 lower code

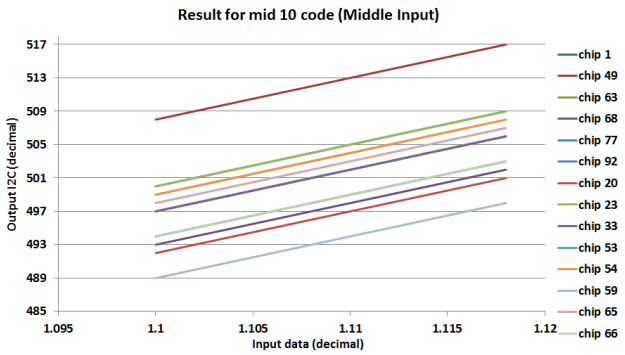

Fig. 15 – ADC block functional test result for first 10 middle code

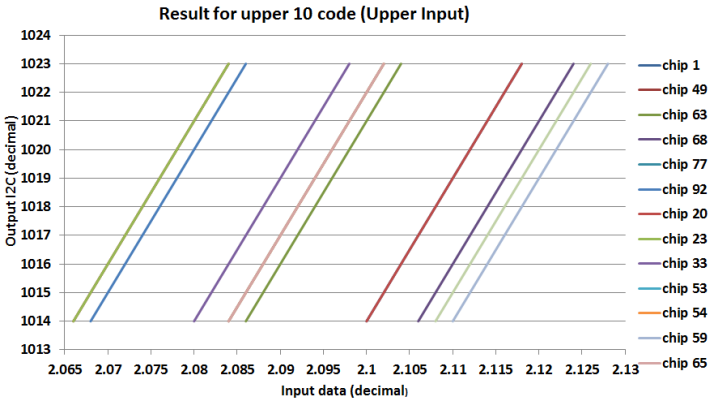

Fig. 16 – ADC block functional test result for first 10 upper code

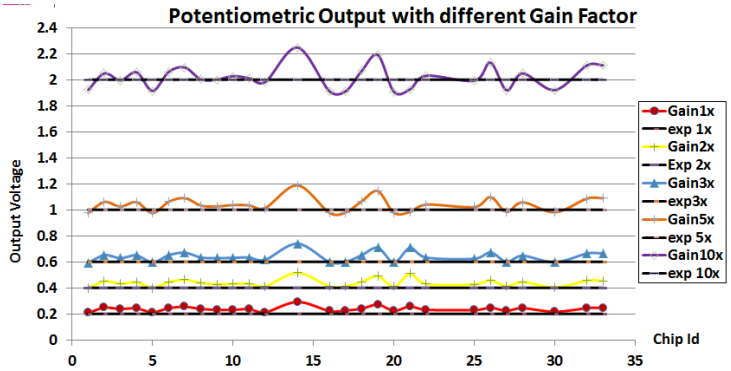
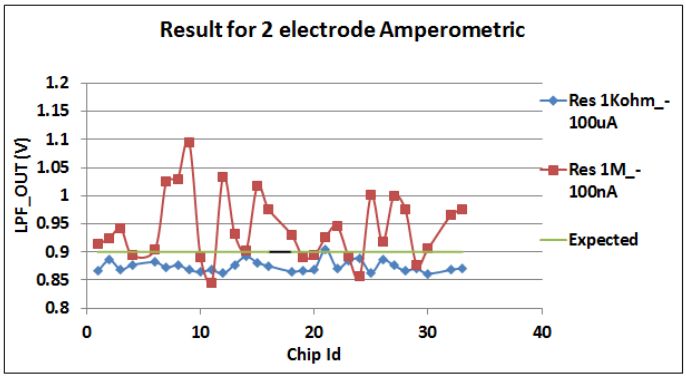


Output Voltage	Gain factor				
	1x	2x	3x	5x	10x
Min (V)	0.208	0.396	0.591	0.975	1.906
Max (V)	0.292	0.515	0.74	1.188	2.247
Average(V)	0.237	0.438	0.64	1.039	2.019

Note : exp refers to expected value from simulation data

Fig. 17 – Potentiometric ROIC block functional test result

For potentiometric readout circuit characterization, the input was set at 0.2V and gain set to 1x,2x,3x,5x and 10x respectively. The test result is as shown in Fig. 17 where the output voltage matches the expected value within 15% error for smaller gain values (1x,2x,3x) and within 25% error for larger gain values (5x,10x).



Voltage(V)	1K ohm	1M ohm
Min	0.8616	0.845
Max	0.9045	1.007
Average	0.8743	0.923

Note : Expected refers to parameter value from simulation data

Fig. 18 – Amperometric ROIC block functional test result

The Amperometric readout test result shown in Fig. 18 is for a 2 electrode configuration using external resistor of value 1 Kilo-ohm and 1 Mega-ohm for gain setting with bias current of 100 uA and 100 nA set respectively at WE1 (see Fig. 5). The gain-select using internal resistors was verified not working. The input voltage VWE1_EXT_AMP I set to 1V and the theoretical output voltage was calculated to be 0.9V. The result shows that with resistor of 1K-ohm the output was within 5% of expected value however using 1M-ohm resistor results in greater output error, as much as 22% from expected value.

Finally for the ChemFET sensor block (Fig. 4), a commercial ion sensitive field effect transistor (ISFET) sensor was used to test the readout circuit. ISFET sensor can detect pH of solution by the output voltage read out from ChemFET block. Fig. 19 and Fig. 20 shows the voltage output read-out using a drain source voltage (V_{DS}) bias of 1V and 0.5V respectively with bias current set at 100uA. The result shows that 18 of the 19 chips tested shows fairly constant output voltage for the different pH buffer solutions used i.e. ph4, ph7 and pH10.

Fig. 21 and Fig. 22 shows for those same drain source voltage and current bias, the output voltage change for each step of pH change. The result shows the sensitivity of the sensor together with readout circuit. This is in line with theoretical calculated value of ISFET sensor sensitivity of 55 mV/pH.

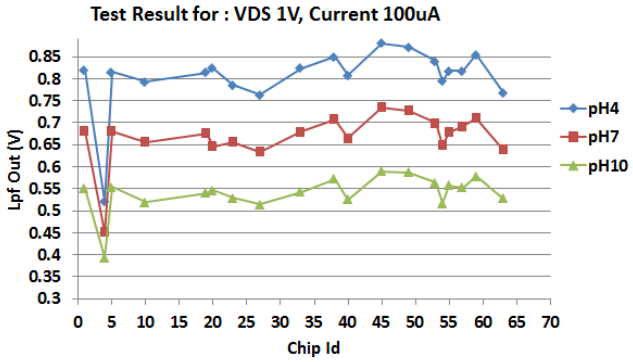


Fig. 19 – ChemFET ROIC block functional test result 1

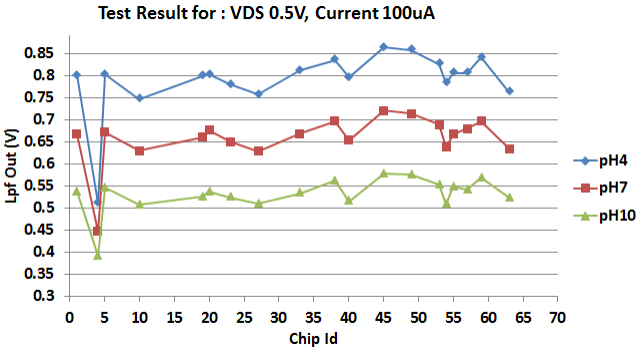

Fig. 20 – ChemFET ROIC block functional test result 2

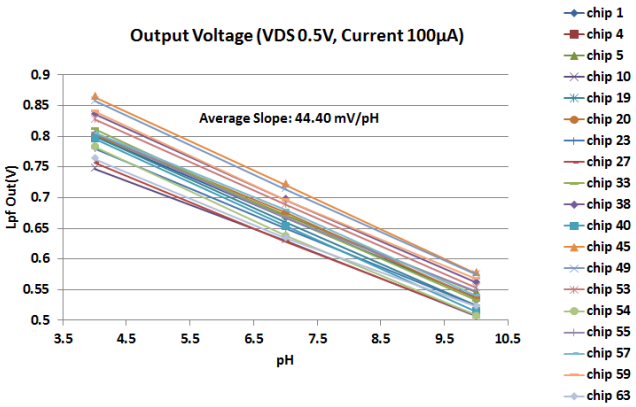

Fig. 21 – ChemFET ROIC block functional test result 3

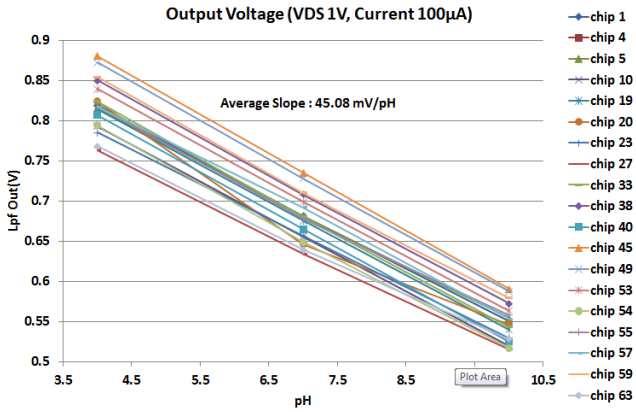

Fig. 22 – ChemFET ROIC block functional test result 4

So far, functional result has been shown for each individual block within the ASIC chip. Currently more extensive characterization work is still undergoing to check the linearity of the ADC, DAC and the interface with micro-controller.

IV. Conclusion

A sensor ASIC has been designed that caters to electrochemical sensor readout in agriculture applications with features of small area, low pin count, high re-configurability and power down options. The sensor ASIC has been fabricated and functionally tested to satisfy its performance criteria.

Application of charge amplifiers with Polyvinylidene Fluoride materials

A.S. Marinov*, Or. P. Stanchev* and E. B. Bekov*
* Technical university of Varna/Department of electronics and microelectronics, Varna, Bulgaria
or.stanchev@gmail.com

Abstract - The current paper proposes an improved specialized charge amplifier as an interface for measurement based applications that utilize Polyvinylidene Fluoride (PVDF) material. As this material and its interfacing electronics are still being researched, most of the applications and topologies are in development. PVDF material characteristics are reviewed and set as a basis for the design of the proposed charge amplifier. Experimental results of the proposed circuitry are compared to conventional voltage amplifiers. The charge amplifier characteristics and benefits are presented and discussed. Methodology for design of charge amplifier, applied to several measurement applications that utilize PVDF, is discussed.

I. INTRODUCTION

Transducer materials convert one form of energy to another and are widely used in sensing applications. The piezoelectric polymer sensors are among the fastest growing technologies on the sensor market. There is a considerable number of applications where the piezoelectric polymer film could be a proper solution.

The polyvinylidene fluoride (PVDF) is a polarized fluoropolymer which has very high piezo-activity. It is also pyroelectric, producing electrical charge in response to changes in temperature.

The PVDF material is extruded into a thin film that is flexible, lightweight and tough plastic. It also can be directly attached to a structure without disturbing its mechanical motion. The piezo film properties as transducer include [1]:

- Wide frequency range from 10^{-3} Hz to 10^{8} Hz;
- Vast dynamic range from 10^{-8} to 10^{6} psi;
- Low acoustic impedance that is close to water, human tissue and adhesive systems;
- High elastic compliance;
- High voltage output that is 10 times higher than piezo ceramics for the same force input;
- High dielectric strength, withstanding strong fields up to 75 V/μm where most piezo ceramics depolarize;
- High mechanical strength and impact resistance;
- High stability, resisting moisture, most chemicals, oxidants and intense ultraviolet and nuclear radiation;
- Fabrication into unusual designs;
- Ability to be glued with commercial adhesives.

The piezo film has acoustic impedance that is very close to water and human tissue. This feature makes it suitable for medical applications. It is also used in the automotive industry and other areas for vibration sensing, impact sensing, accelerometers, audio and ultrasonic applications. Application in meteorological sensors is also being researched [2][3].

A major drawback is that the piezo film is relatively weak electromechanical transmitter when compared to ceramics, particularly in low frequency applications. Also the PVDF material is not recommended for use at temperatures above 100 °C. If the electrodes of the film sensor are exposed, became very sensitive to electromagnetic radiation. Therefore good shielding techniques should be used for high EMI/RFI environments.

The typical piezo film sensors are rectangular elements of piezo film with silver ink screen printed electrodes on both sides and protective coating. The construction is shown on Fig. 1. The PVDF film strip has thickness of 9, 28, 52 or 100 μm. Forces or stresses applied to the PVDF elements are considered in three main dimensions – length, width and thickness. The highest conversion is obtained when the mechanical force is applied to the PVDF element over its thickness, because of the very small cross-sectional area and thus relatively small

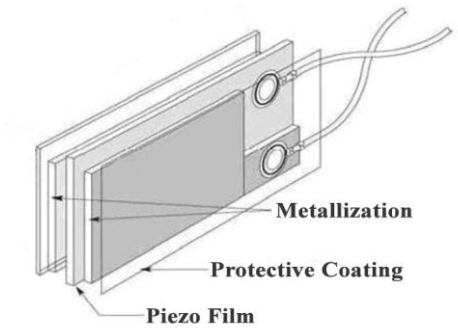

Figure 1. Construction of PVDF film sensor [1]

The carried out research is realized in the frames of the project BG051PO001-3.06-0005, Program 'Human Resources Development', Ministry of education, youth and science, Bulgaria.

longitudinal forces. They create very large stresses within the material. After applying mechanical force, electrical charge occurs on the surface of the PVDF element. This charge is directly proportional to the mechanical deformation and causes a voltage between the electrodes on the surface of the element.

The developed charge of the PVDF sensor elements for small stress is given by:

$$Q = A \cdot d_{3n} \cdot X_n, \text{ for } n = 1, 2 \text{ or } 3 \quad (1)$$

where Q is the developed charge, A is the conductive electrode area, d_{3n} is the piezoelectric coefficient, X_n is the applied stress and n is the axis of applied stress.

The output voltage of the PVDF sensor elements for small stress is given by:

$$V = g_{3n} \cdot X_n \cdot t, \text{ for } n = 1, 2 \text{ or } 3 \quad (2)$$

where V is the output voltage, g_{3n} is the piezoelectric coefficient, X_n is the applied stress, t is the film thickness and n is the axis of applied stress.

The equivalent circuit of piezo film sensor is shown on Fig. 2. It consists of capacitance and a voltage source. Fig. 2 shows the simplified equivalent circuit. The series capacitance represents the piezo film capacitance and the voltage source amplitude is equal to the open circuit voltage of the piezo film. This simplified equivalent circuit can be used in most cases except at very high frequencies that are close to the ultrasonic wave range.

II. USING AMPLIFIERS WITH POLYVINYLIDENE FLUORIDE

The Polyvinylidene Fluoride is a new material and in the technical literature there is limited information considering the material and the interface circuits for PVDF sensors. The interface circuits' manufacturers offer solutions that usually are not fully described or powered with single supply [6].

The presented research is focused on investigation of the interaction between PVDF sensor elements and interface circuits, especially the comparison between charge and voltage differential amplifiers.

A. Voltage Amplifiers

The piezo film sensor can be used as a voltage source when the information value is the output voltage, generated between the electrodes. As the primary output of the PVDF sensor is charge, the indirect voltage is obtained by placing a resistor in parallel to the output (Fig. 2). The parallel resistance and the piezo film capacitance form RC group and due to the frequency response of this network it acts like a high-pass filter. The cut-off frequency of the filter is given by:

$$f_c = 1 / (2 \cdot \pi \cdot R \cdot C) \quad (3)$$

For low frequency measurement the resistance has to be high enough to ensure that the cut-off frequency is below the operational one so that signal reduction is avoided.

When the PVDF sensor is used for vibration or low stress measurement, the voltage output has to be amplified. A typical one stage non-inverting amplifier configuration is proposed by the piezo film manufacturers to be used when high signal to noise ratios are desirable [1]. The non-inverting configuration has high input impedance that is desirable.

When the signal to noise ratios are low an instrumentation amplifier circuit is more appropriate in that case for precise measurements due to its very high common-mode rejection ratio and input impedance [4].

The advantage of the voltage amplifier can be seen when ambient temperature is considered. The voltage sensitivity variation over temperature is smaller than the charge sensitivity variation. Consequently, voltage amplifiers with piezo film exhibit less temperature dependence.

When the piezo film sensors are used with voltage amplifier the capacitance of the film and the connecting cables have adverse effect on the measurement network transfer function.

B. Charge amplifiers

The PVDF film sensors have capacitive nature and charge amplifiers can be used. Fig. 3 shows a basic charge amplifier structure, proposed by the piezo film manufacturers [1]. The gain of the given charge amplifier is the ratio between the piezo film sensor characteristic capacitance C and the feedback capacitance C_f. The output voltage of the charge amplifier is determined by the charge Q developed by the piezo film and the feedback capacitance C_f of the charge amplifier.

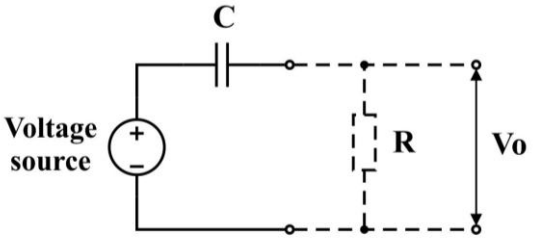

Figure 2. Equivalent circuit of piezo film sensor [1]

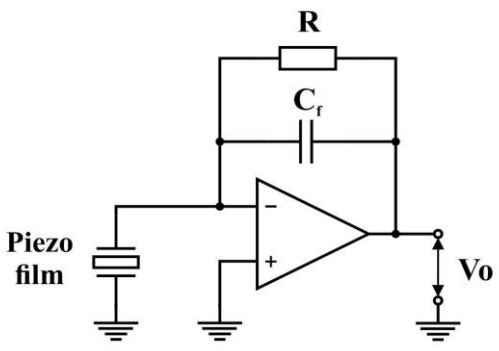

Figure 3. Basic charge amplifier [1]

The output voltage is given by:

$$V = - Q / C_f \quad (4)$$

The output voltage is very likely to drift. A proper compensation technique is placing a resistor in parallel to the feedback capacitor. This resistor creates a time constant which is independent from the film capacitance and can be precisely controlled. It determines a cut-off frequency that limits the input signal which is similar to the high-pass filter that is present in the piezo film voltage amplifier topology. The time constant for charge amplifier is given by the feedback capacitor C_f and the parallel resistor R:

$$\tau = R \cdot C_f \quad (5)$$

The piezo film is very sensitive to EMI disturbances. It also has strong pyro sensitivity for the thermal radiation in the range from 7 to 20 μm and care must be taken when designing low frequency mechanical sensors to avoid disturbances from ambient temperature changes. Common-mode rejection can be used to isolate either very low frequency mechanical strain from simultaneous pyro-effects and EMI.

The most critical part of the measurement network is the input resistance. The input resistance affects low frequency measurement capability and the signal amplitude. The charge amplifier requires operational amplifiers having high input impedance and low bias current so that operational amplifiers with JFET input stage transistors are appropriate. A high input resistance avoids charge leakage from the feedback capacitor and low bias currents prevent feedback capacitor from parasitic charging and discharging.

Considering different amplifier topologies a two stage differential dual supply charge amplifier is proposed for processing the signal from PVDF sensor element [5][6]. It has similar advantages in noise cancellation like the instrumentation amplifier. The first stage consists of input buffer charge amplifiers with low gain close to unity, high input impedance and high rejection ratio. The second stage consists of differential amplifier with high gain, providing the necessary output signal magnitude. A major problem with the two stage charge differential configuration is the matching condition between the feedback capacitors and resistors that could cause asymmetry.

III. Methodology for PVDF Charge Amplifier Design

The proposed methodology for design of charge amplifier for PVDF film sensor consists of the following steps:

- Selection of a proper sensor according to application specifics;
- Determination of the signal bandwidth and possible noise frequency (for example the 50 Hz grid supply voltage);
- Calculation of the maximum charge, generated by the piezo film sensor, due to the maximum applied force (1) and the piezo strain constants;
- Choosing a charge amplifier topology (one stage or two stage differential) due to the expected signal to noise ratio;
- Choosing proper high input impedance JFET operational amplifiers;
- Calculation of the feedback capacitor, depending on the amplifier topology and desired output signal magnitude (4);
- Calculation of the time constant (5), liming the signal lowest frequency;
- Calculation of the output low-pass filter, limiting the signal spectrum.

IV. Experimental Verification

A. Experimental Setup

The proposed voltage and charge amplifiers are compared experimentally. Both amplifiers have one stage and use high quality JFET OPA2141 operational amplifiers [8].

The experimental setup is shown on Fig. 4. It has the following principle of operation. A vibration generator applies simultaneously a mechanical stress on two identical PVDF film sensors, mounted under similar conditions. The developed charge of the first piezo film and the output voltage of the second piezo film are amplified via charge and voltage amplifiers. The amplifiers' outputs are filtered with low pass filters. The two measurement networks are independent, but operate under the same conditions. Measurements are taken with digital oscilloscope and processed with personal computer

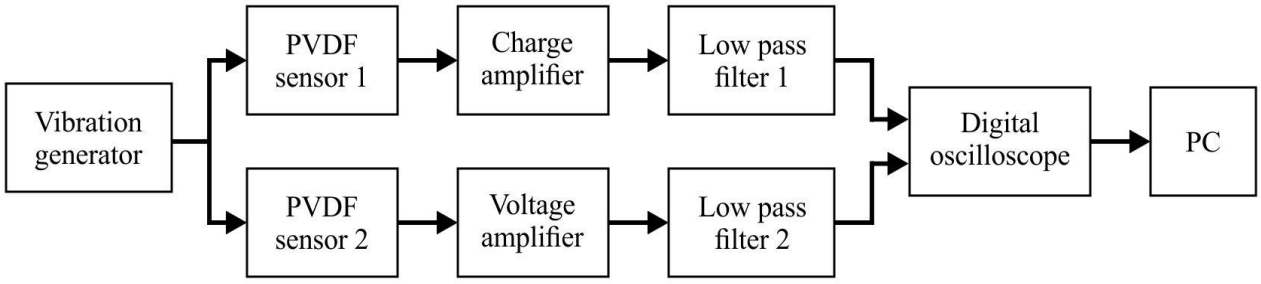

Figure 4. Experimental setup

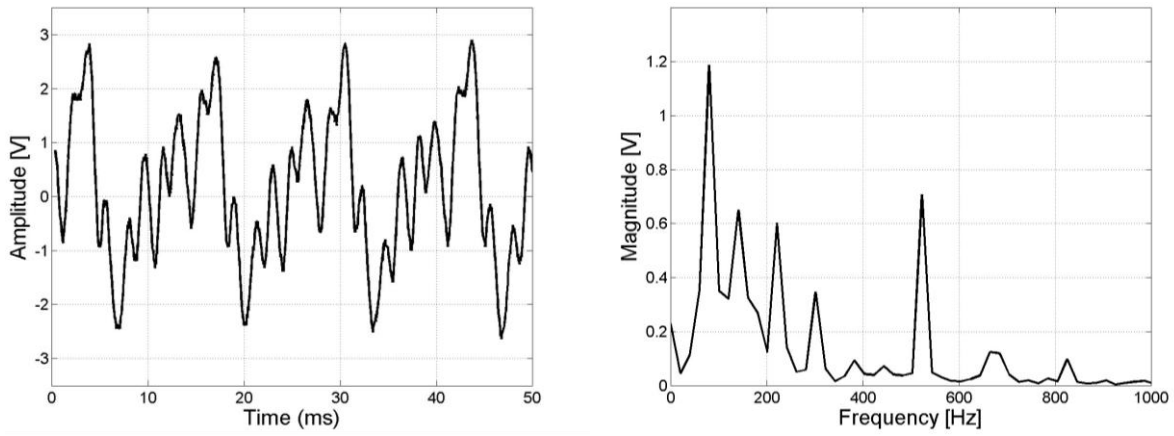

Figure 5. Charge amplifier output at periodic impact – time domain signal and frequency spectrum

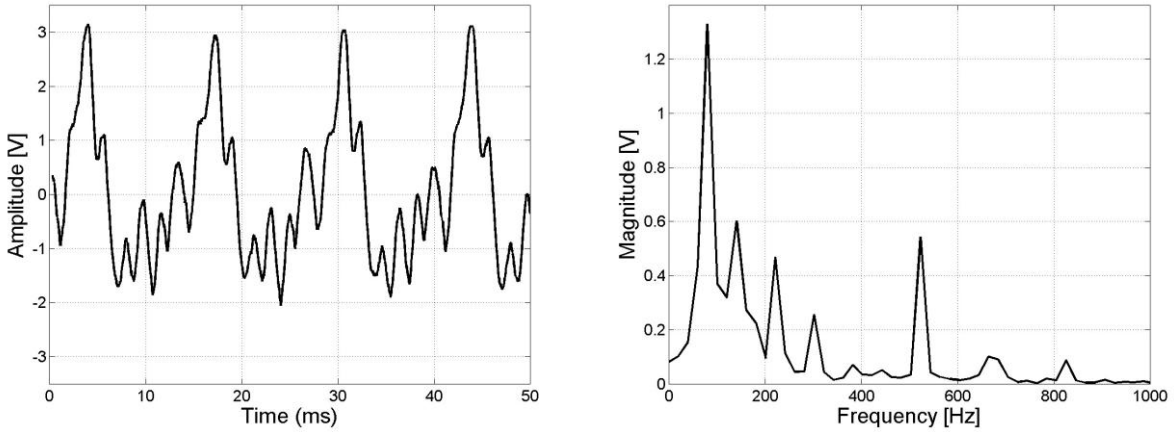

Figure 6. Voltage amplifier output at periodic impact – time domain signal and frequency spectrum

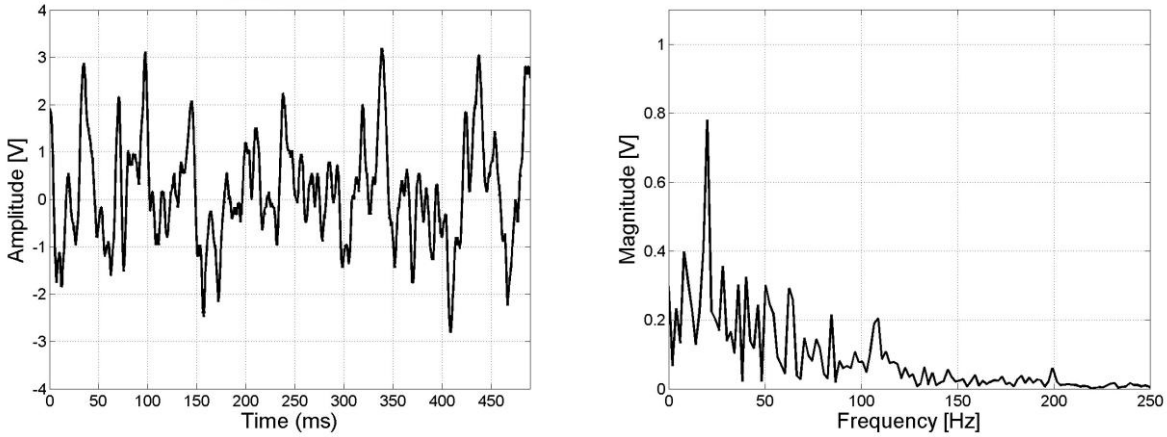

Figure 7. Charge amplifier output at aperiodic (random) impact – time domain signal and frequency spectrum

and specialized software for signal processing.

The used sensors are two LDT4-028K PVDF film strips with 28 μm film thickness and 11 nF capacitance [7].

The examined charge amplifier has a similar structure to the amplifier shown on Fig. 3. The feedback consists of 1.5 nF capacitor and 3.3 MΩ resistor with a gain of 7.33 and 5 ms time constant. The amplifier PCB layout is designed due to the specifics for charge amplifier input pins routing and shielding [1].

The examined voltage amplifier has a standard non-inverting single operational amplifier structure. A 56 kΩ feedback resistor and 56 kΩ input resistor are used with a gain of 2. Parallel to the input a 510 kΩ resistor is placed setting the voltage mode and giving a 28.3 Hz cut-off frequency.

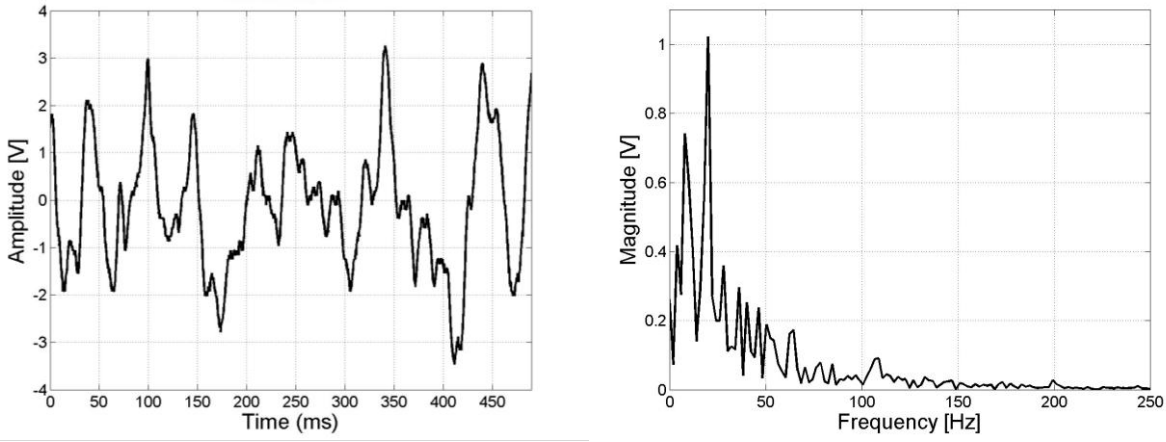

Figure 8. Voltage amplifier output at aperiodic (random) impact – time domain signal and frequency spectrum

The passive output low pass-filters limit the signal bandwidth to 400 kHz (matching the ADC input signal requirements).

Both amplifiers are powered with filtered DC dual supply that has extremely low voltage ripple as the charge amplifier is very sensitive to unstable power supply.

B. Experimental Results

The experiment is accomplished in two parts – in the first part a periodic vibration is applied to the piezo film sensors and in the second – a vibration with aperiodic (random) nature. The time domain signals and frequency spectra of the output signals of both amplifiers are shown on Fig. 5 and Fig. 6 from the first part and on Fig. 7 and Fig. 8 from the second part of the experiment.

The experimental results demonstrate that the charge amplifier provides better resolution of details in the output shape of the signal, especially when the piezo film sensor output has more oscillatory nature. The signal frequency spectrum consists of more high harmonics with bigger magnitude so that the signal carries more information for the primary excitation of the sensor.

V. CONLUSION

The Polyvinylidene Fluoride sensors are more and more used in important areas like medicine and automotive industry. Thus the measurement networks and interfaces for data processing of the sensors' outputs are constantly developed and improved.

The piezo film sensors have enhanced capacitive nature so that using charge amplifiers is recommended. It is experimentally proven that they provide better resolution of details in the output shape of the signal and in the frequency spectrum, when the piezo film sensor output has more oscillatory nature. A configuration for differential charge amplifier is discussed. A methodology for charge amplifier design is proposed and used for experimental amplifier design.

Abstract – Investigation of transdermal drug delivery system, based on silicon injector chip with silicon microneedles and PZT (lead zirconate titanate) actuated micropump, for drug delivery such as insulin is reported. First, basic skin properties and dosing requirements are reviewed. Next, the whole system and its components (injector chip, micropump, drug container) are discussed. Based on this, microneedles injector chip design is discussed and prototypes fabricated. Then, design of PZT actuated micropumps is discussed and prototypes fabricated. From measurements on fabricated micropumps, fluidic parameters are evaluated. Basic requirements for drug container, control electronics and power supply parameters are also presented. Finally, maximum drug delivery, based on measured prototype micropump parameters, through the prototype injector chip is determined.

I. INTRODUCTION

Microneedles transdermal drug delivery systems are recently gaining influence in various medical applications. When designing a transdermal drug delivery system, good knowledge of the skin is essential as its anatomy and properties will determine many important parameters of the whole system. Human skin acts as a natural barrier and protects the body from surroundings. When we want to deliver a drug through the skin, we have to break this barrier in some way. To do this efficiently, we have to know exactly how skin functions. Skin is composed of three layers (Figure 1), from top to bottom they are: stratum corneum, epidermis and dermis [1]. The most upper layer, stratum corneum, is a natural barrier which we have to break or remove to effectively deliver drug into the body. Stratum corneum is made of dead skin cells and is approximately 10 to 20 μm thick. Epidermis is made of keratinocytes and contains no blood vessels. It is approximately 50 to 150 μm thick [1]. Dermis is the bottom layer, which contains blood vessels and nerve endings. If we want to painlessly deliver a drug into the skin, we have to break stratum corneum and deliver the drug into dermis, from where it will diffuse into the blood vessels and then into the body.

Next we need to know what kind of drug will be injected in the body and what the required quantities are. This will determine the flow rate and drug container capacity. Viscosity of drug solution will also be an important issue for proper determination of flow rate needed.

In our case transdermal drug delivery system will be mainly used for delivery of insulin for basal needs. Standard insulin preparations contain 100 U/ml of active substance. Healthy human body daily produces on average 0,7 units of insulin per kg of body mass (0,5 – 1,0), that is about 50 units in the whole day for an average person with body mass of 70 kg. Approximately half of the produced insulin is used for covering basal metabolic needs. There are two types of diabetes, Type 1 and Type 2. Patients with Type 2 diabetes still have some own insulin and so need smaller doses, therefore transdermal drug delivery system should be able to deliver up to 0,30 ml of insulin preparation daily for Type 1 patients and less for patients with Type 2 diabetes. Based on those facts, drug delivery system should be capable to inject an appropriate amount of drug, depending on the patient's individual needs. It is desirable that the dose of the drug would be easily adjustable for every patient.

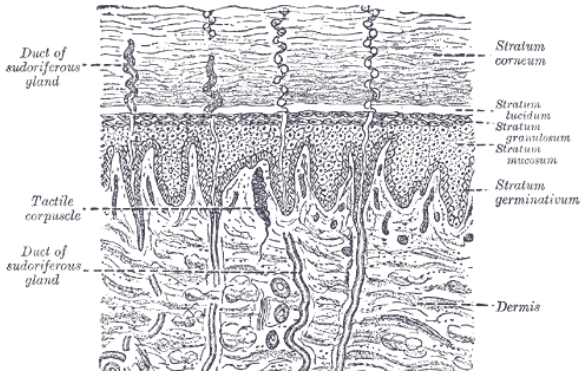

Figure 1: Skin cross-section [2].

II. MICRONEEDLES TRANSDERMAL DRUG DELIVERY SYSTEM BASICS

Main components of an advanced, autonomous microneedles drug delivery system usually consist of: injector chip with microneedles, micropump, drug container, control electronics and power supply. All components should be small enough to fit in the compact microhousing that could be attached on the skin.

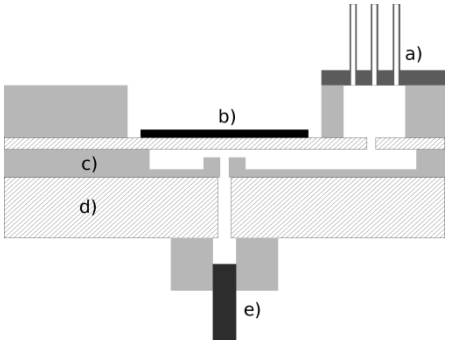

Figure 2: Assembled system: a) silicon micronedles array; b) PZT actuator on glass membrane; c) PDMS layer with micropump structure; d) support glass; e) fluidic connection

All components are assembled together as shown in Figure 2 (electronics and power supply are not presented), with smallest possible number of assembly steps.

III. SILICON MICRONEEDLE INJECTOR CHIP

Microneedles can be made from many different materials. Silicon is one of the standard MEMS materials, from which different types of precise 3D microneedle structures can be made. This is why silicon was selected for our microneedle injector chip material. As injector chip will be in contact with living tissues, silicon biocompatibility is also an important issue in this case [3].

Based on skin anatomy, microneedles must be long enough to pierce stratum corneum and deliver drug to the epidermis where capillaries are present to take and transport the drug into the body. On the other side, needles must not be too long to penetrate deeper into the tissue where nerves begin, to avoid pain. Combined, dermis and stratum corneum are typically around 110 µm thick. As the skin bends when needle is inserted by force, we need longer needles than the thickness of stratum corneum, but short enough not to pierce the dermis. Also based on findings of different authors, we concluded that the needles should be 150-200 µm long [4], [5], [6].

As we have an array of many needles, insertion force is distributed uniformly across the whole array. Insertion force should be small enough to enable simple insertion of the injector chip by hand. Therefore, to achieve small insertion force, microneedles must have sharp tips.

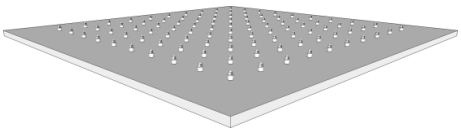

Figure 3: Design of 10x10 matrix injector chip.

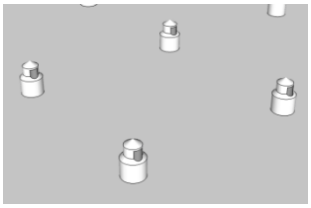

Figure 4: Detailed view of 10x10 microneedle array design, distance between needles is 1mm.

Figure 5: Detailed view of designed single microneedle with side opening.

Total delivered drug flow through all needles is directly dependent on needle bore and number of needles. Obviously, if we have smaller needle bore, we must add more needles to the array, to achieve equal flow rate.

For our first prototype we decided to fabricate 200 µm long needles with base diameter of 130µm and bore diameter of 50 µm. On injector chip there will be a 10x10 matrix of 100 needles (Figure 3). Figure 4 represents a detailed view of the injector chip. The needles will have sharp tips to guarantee minimal needed insertion force and side openings to prevent clogging after insertion (Figure 5).

The basic fabrication process for injector chip with microneedles consists in our case of proper interchanging silicon anisotropic and isotropic etching steps.

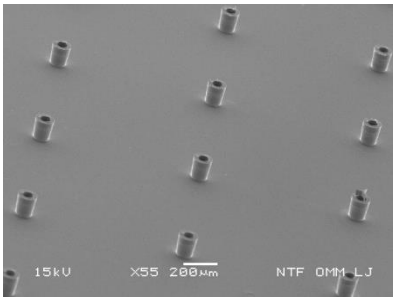

Figure 6: Fabricated prototype injector chip with hollow microneedles.

Recently we have successfully fabricated prototype injector chips, containing arrays of 10x10 microneedles, one type with 200 µm high solid sharp microneedles and second type with 200 µm high hollow microneedles with opening on the top. On Figure 6, fabricated injector chip with hollow microneedles is shown. Fabricated injector chips will enable us to set up experimental system for evaluating basic parameters of needle penetration and to investigate properties of injecting drug liquids through the skin into the body.

IV. PZT ACTUATED MICROPUMP

Micropump is the main active component of the system and must be capable of producing high enough pressure and liquid flow to achieve delivery of adequate drug dose. At the same time micropump should be small enough and as thin as possible. Piezoelectric actuated pump can fulfill all this requirements [7].

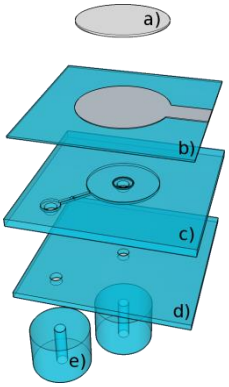

Figure 7: Designed micropump structure: a) PZT actuator; b) glass membrane with conductive glue; c) PDMS layer with micropump structure; d) support glass; e) prototype fluid connectors

Selected prototype micropump is in our case made from PDMS, which is cast into the silicon mold. Mold is created with our standard MEMS processing for the fabrication of two level structures. PDMS structure is afterwards bonded on support glass and glass membrane on the other side of the structure. PZT actuator with contacts is attached on a glass membrane as shown in Figure 7. All used materials in contact with drug solution are known to be biocompatible. More details on PDMS micropump design and fabrication are given in [8].

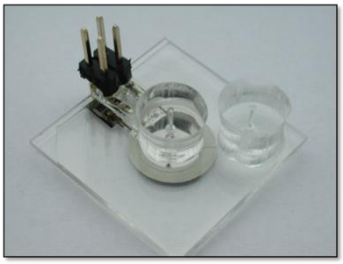

Figure 8: Assembled micropump prototype.

Assembled micropump prototype is shown on Figure 8, with two throttles achieves maximal backpressure of 450 mbar (50 kPa) and maximal flow rate of 2,4 ml per minute (144 µl/s). Micropump test actuation signal has amplitude of 250 V and frequency of 110 Hz.

V. DRUG CONTAINER, CONTROL ELECTRONICS AND POWER SUPPLY

Container capacity should be large enough to hold volume of drug solution. For example, based on a typical patient daily need (0,30 ml), container should have capacity of 1 ml for autonomy of three days, before refilling or changing. Because drug container is in contact with drug solution, it will be made from biocompatible materials. As drug container has only limited capacity, option to refill or exchange whole drug container without replacing entire system is under study.

Control electronics also presents some unique design challenge. For actuation of PZT element on micropump, rather high voltages are needed. Control system will also have to incorporate some time/dosage control and possibility of adjustment on demand. Because the system should be autonomous, small power consumption and size will be critical.

Power supply is mainly limited by small size of the system and will have to supply enough power for micropump actuation and electronics over a predetermined period of time. In addition to integrated battery, it is possible to include some sort of energy harvesting device. That could provide all or some extra power for the system, depending on actual system consumption and harvesting device power generation capacity.

VI. DISCUSSION

Pressure needed to inject drug solution in the tissue depends on many different factors, as are skin properties on site where needles are inserted, depth of insertion, clogging and others, so it is nearly impossible to asses all this analytically.

The basic microfluidics parameters of our problem are connected by the following equations [9]

$$\Delta P = \frac{128\mu LQ}{n\pi d^4}$$

$$\Delta P = aQ + b \qquad (1)$$

$$Q = \frac{100b\pi d^4}{128\mu L - \pi d^4 a}$$

The first equation gives pressure drop on injector chip at volumetric flow rate Q of fluid with dynamic viscosity μ, through needles with bore diameter d, channel length L and number of needles n. The second equation is our approximation for measured linear connection between micropump generated backpressure and flow rate. In the third equation, derived from first and second equation, maximum possible volumetric flow rate is given as a function of injector chip, micropump parameters and viscosity of used fluid.

For now, we can calculate volumetric flow rate when microneedles are not inserted into skin. This calculation will provide us the theoretical maximum possible volumetric flow rate through given microneedle array. For pressure difference we will use actual backpressure that our prototype micropump can achieve, that is 450 mbar. Maximum flow at zero backpressure is therefore 2,4 ml per minute. From measured data we can derive needed coefficients a and b in second equation of (1). As insulin solution contains more than 90% DI water, we will in our calculations as a first approximation use the viscosity of DI water.

Calculations based on given equations have revealed basic relations between critical parameters of delivery system. As a practical example, if we could deliver drug into the skin with this rate, only two delivery intervals in duration of approximately 5 seconds daily would be enough to deliver daily amount of 0,30 ml of drug solution to the patient with Type 1 diabetes.

VII. CONCLUSION

Investigation of a microneedles transdermal drug delivery system is reported. Design and fabrication of system basic components such as injector chip with silicon microneedles and PZT actuated micropump, for drug delivery such as insulin, is presented. Based on skin properties, microneedles injector chip design is discussed and prototype injector chips were fabricated. Design and fabrication of PZT actuated micropumps and evaluation of fluidic parameters for manufactured prototype micropumps is reported. Basic requirements for drug container, control electronics and power supply parameters are discussed. Finally, maximum drug liquid flow through the prototype injector chip, based on measured prototype micropump parameters, was determined.

Abstract - Modern industrial quality monitoring systems are based on optical fibre sensors, microelectronic sensory technology and miniaturized infrared spectroscopy systems based on low-power, low-cost, high-efficient and innovative hardware solutions. The proposed paper presents development work related to create remote control system for monitoring water pollution petrochemical products using optical fibre refractometer.

I. INTRODUCTION

The current European Water Framework Directive, implemented in the European Union (EU) is a structured programme for management of water resources through Integrated River Basin Management (IRBM), with the aim to achieve overall good quality of water by 2015. This is accomplished through careful monitoring of surface water and groundwater habitats in Europe and implementation of stepwise improvements gradually to attain a 'good ecological status' which is the ultimate goal [1].

Environmental water quality, also called ambient water quality, relates to water bodies such as lakes, rivers, and oceans. Water quality standards for surface waters vary significantly due to different environmental conditions, ecosystems, and intended human uses. Pollutants may take various forms and as a consequence, several types of continuous on-line measurement may be performed. Sensors may be installed to provide indicative measurements or specific parameters may be monitored when the potential pollutant is known. A typical water pollution monitoring system may therefore comprise a suite of instruments or sensors to cover various aspects of chemical and physical water quality [2,3].

Monitoring is a process by which the industry measures its emissions, releases, and/or parameters of its performances that are to provide information on the release of polluting materials and/or performance of control technologies. It provides secret or public information on the nature of pollutants emissions and/or the performance of purification plant. Industrial monitoring of emissions from the industry is performed by the purification plant` s operator, in accordance with appropriate, defined and amended programme for taking samples and in accordance with accepted measuring protocols (standards or analytical methods or evaluation methods).

Data on industrial monitoring, integral control and pollution prevention in Oil and Petrochemical Industry are important for environment pollution prevention. By defining the place of pollution we determine control and pollution reduction measures with the possibility of choosing the type of monitoring and the dynamic of measuring the pollutants. The designed modern industrial water pollution monitoring system presented in the paper is based on optical fibre refractometer technology based on low-power, low-cost, high-efficient and innovative hardware solutions, including WWW remote control. In Chapter 2 is described architecture of photonics multimedia web-based laboratory system. Chapter 3 contains design of interactive web controlled fibre optic refractometer instrument. Experiments and results are presented in Chapter 4. Conclusions are covered in Chapter 5.

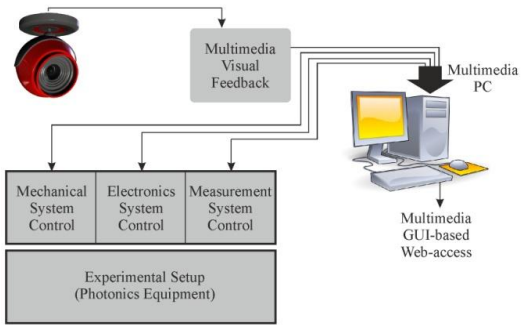

Figure 1. The architecture of monitoring system with optical fibre refractometer.

II. MONITORING SYSTEM WITH OPTICAL FIBRE REFRACTOMETER

The architecture of monitoring system with optical fibre refractometer is on Figure 1. The core of the system is experimental setup to realize chosen photonics equipment - Fibre Optic Refractometer. Experimental setup is controlled trough three data acquisition systems: a) Mechanical b) Electronics and c) Measurement, to provide a desired laboratory function of the photonics equipment and measurement of its parameters. The used simple web-camera assists for multimedia visual feedback in the telelaboratory (monitoring system).

Fibre optics sensors of various constructions are valuable devices for wide industrial applications [4,5]. Using fibre optics technology and micro-optics is possible to design innovative fibre optic index of refraction transducer that has unique properties. Basically it consists of input - output pair of simple multimode fibres that interrogate a small lens. The cone of light injected into the lens from the input fiber is internally reflected from inside surface of the lens and focused back into the output fibre. When the outer surface of the lens is in contact with a liquid, the attenuation of the light reaching the output fibre depends strongly on the refractive index of the liquid. Depending on the construction and design of such a transducer, this transducer may have a wide dynamic range. Its relative sensitivity, i.e. the ratio of fractional change of the optical intensity for a given change in index of refraction, is substantial, (of the order of 5 to 10) over a wide range of index, e.g. n = 1.3 to 1.6. For convenience, usually employed lenses have diameter from 5 to 1 mm. In principle, it should be possible to go to even smaller diameters, e.g. 250 to 300 microns - so that relatively small catheter type transducers are feasible. Since the basic design is quite simple it also is possible to produce extremely rugged transducer elements that are suitable for field/industrial applications [6,7,8].

This fibre optic small, probe type structure transducer elements, can be easily inserted into the top of liquid containers or through a simple fitting can be simple to insert in a flow line. It is essential to combine these very practical and versatile transducers capable of detecting small changes of index of refraction with "smart" data acquisition and signal processing technology to develop versatile and practical instruments. Refractometers frequently are used for medical, pharmaceutical, industrial fluid, chemical, petrochemical, plastic, food, and beverage industry applications. For example, they are used for measuring the concentrations of aqueous solutions: as the concentration or density of a solute increase, the refractive index increases proportionately. Included in such measurements is the percentage of sugar in fruits, soft drinks, canned syrups and other solutions. They also are used to determine the salinity of aquariums and of solutions used in food processing, the freezing point of coolants and deicing fluids, the charge status of acid batteries, the serum protein and urine specific gravity, etc.

Almost all currently available classical refractometers employ a prismatic element on which the liquid sample is placed. These instruments yield an output that is based on the degree of a light beam at the liquid-prism interface. In the simplest refractometers, the index is determined visually, via a lensed viewing tube, by observing where the output beam intersects a graduated scale. In more modern, digital type instruments, the degree of bending is measured automatically using a linear photodetector array [1,4]. Since the index of refraction is strongly dependent on temperature and also, to a lesser degree, on wavelength, these effects must be corrected for in designing and/or using such instruments. They are of major importance when one attempts to determine an index of refraction to 1 part in 10.000 or better, which is the desired sensitivity for a high quality, laboratory type instrument. Their importance can easily be seen in the case of water, for example, which has a temperature coefficient $\Delta n/\Delta T$ of 1,5 parts 10.000 per °C.

As with any other refractometer, any instrument that employs this fiber optic based transducer must be capable of correcting for the intrinsic temperature dependence of a liquid's index of refraction [4,9]. In addition, however, for an intensity type fiber optic sensor, other corrections and precautions must be taken especially if, as already mentioned, a precision of 1 part in 10.000 is to be attained. It will be necessary to employ low noise electronic circuitry and/or correct for photodetector dark current, especially at higher indices, where the output light intensity is strongly attenuated. It also will be necessary to correct for light source and photodetector temperature sensitivities and for any stray light that might affect the photodetector. In one sense, in terms of capabilities of today's microprocessor controlled "smart" sensor technology, it should be straightforward to design instruments that automatically "massage" the raw transducer data to correct them for each of these effects.

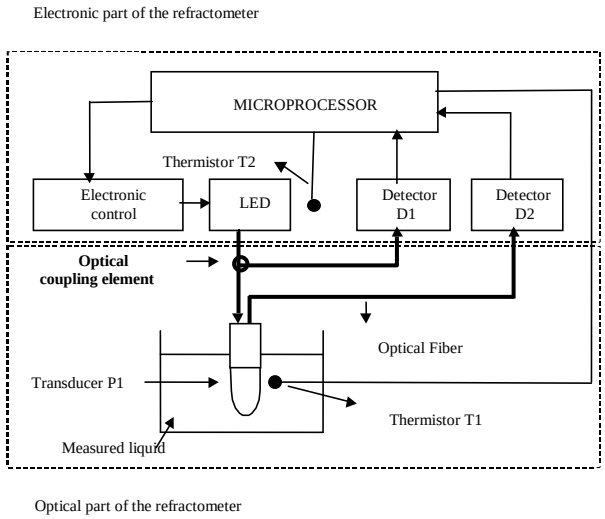

Figure 2. Block diagram outlining the design of a basic fiber optic refractometer.

Referring to the block diagram in Figure 2, the basic system, as presently conceived, consist of the following elements: a light emitting diode (LED) or semiconductor laser diode (LD) light source and its electronic driver/pulser; a monitor photodetector to determine the output light level of the use light source, a second photodetector to record the return light from the transducer; and a microprocessor to automatically control the system and process the data from the various elements. It will compute the ratio of the intensity of the transducer output for an unknown liquid and that recorded earlier for a standard liquid, e.g., water.

The microprocessor will then determine an index value, either by a comparison and interpolation process between this ratio and those in a calibration data lookup table, or by computation using a transducer response equation. In addition, the temperature of the liquid sample and of the source/detector module will be measured simultaneously with the index, to correct for their temperature dependence. The liquid sample temperature

will be determined using a thermistor, as indicated in Figure 2, or using a fiber optic temperature sensor in applications requiring an all dielectric transducer, e.g., for use in explosive or high voltage environments [10,11].

III. WEB-CONTROLLED MONITORING SYSTEM ARCHITECTURE

This equipment was developed with the appropriate Measured Liquid Magazine, Sensor Module Positioner, Control Servomotors, Heating Element, Sensor Cleaning Element, Visual Camera Feedback, Control and Communication Software (Figure 3) to create an interactive web controlled Fibre Optic Refractometer instrument. Sensor Module Positioner controls using servomotor the on (measured) and off (non-measured) position of the sensor head. Measured Liquid Magazine is based on the revolver system controlled by servomotor and provides the change of measured liquid (5 different liquids are possible one liquid is used for Sensor Cleaning Element if necessary – oil, petrochemical product measurements, etc.). Heating Element provide controlled heating of the measured liquid. Visual Camera Feedback was added to the system to provide students with the feeling to be virtually present at the measurement place and also as visual feedback for verify correct function of the mechanical parts of the instrument [11,12].

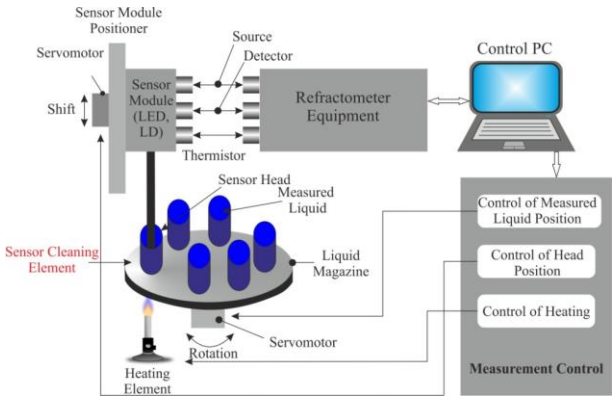

Figure 3. Web-controlled remote monitoring system design.

The complete system was set together with the two (Laboratory Refractometer Client Server and Refractometer Server) servers based on LabWindows. Operation of needs approval and authorized permission to be granted in advance through the local internet service provider. Therefore, and in step to avoid such complications the system was operated and tested using the internet network available on University campus.

IV. EXPERIMENTS AND RESULTS

Performance of the developed fibre optic refractometers was evaluated by various test measurements; this is here demonstrated by results of several classical experiments.

The first experiment was to measure the refractive index of various liquids. As field tests we used some calibration liquids of known index of refraction. They make it difficult to clean the sensor face however.

We recommend keeping the containers of the mixtures sealed when not in use since they tend to drift in index, though this is not much of a problem. We frequently make up relatively large sample, e.g., 100 to 200 ml, and then use one half for our measurements for while and after a week or two, take a reading in the other half that has been kept well sealed. That way we can determine if there has been any shift in the index of our measurement sample. The results of measured index of refraction are depicted on TABLE I (Food products) and TABLE II (Petrochemical products), and are in very good success as compared with results obtained by classical methods (e.g. the refractive index of water at 20°C is 1.3330 or propylene glycol at 20°C has a refractive index of 1.4312).

TABLE I. RESULT OF FOOD PRODUCTS MEASUREMENTS

Serial Number	**Refractive index of various liquids**		
	Liquid products	***Refractive index***	***Temperature (℃)***
1.	Water	1.3333	21
2.	Distilled water	1.3331	23
3.	Vinegar	1,3358	23
4.	Pepsi cola	1,3461	23
5.	Coca cola	1,3417	23
6.	Synthetic alcohol	1.3620	21
7.	99% alcohol	1,3611	23
8.	LACALUT Mouthwash	1,3572	23
9.	Rapeseed oil	1,4697	23
10.	Sunflower oil	1,4682	23
11.	Olive oil	1,4662	23

TABLE II. RESULT OF PETROCHEMICAL PRODUCTS MEASUREMENTS

Serial Number	**Refractive index of various liquids**		
	Liquid products	***Refractive index***	***Temperature (℃)***
1.	Propylen glycol	1.4268	21
2.	Engine oil MOL Arol 2T	1,4791	23
3.	Gear grease Madit PP80	1,4806	23
4.	Oil Mobil VS-200	1.4399	21
5.	Oil Mobil motor 5W-50	1.4678	21
6.	Brake fluid Castrol	1,4424	23
7.	Gasoline Natural 95 Slovnaft	1,4565	23
8.	Gasoline Natural 95 OMV	1,4572	23
9.	Diesel Slovnaft	1,4591	23
10.	Diesel OMV	1,4609	23

The second experiment was to measure the change in refractive index depending on the temperature of the liquid and third experiment was to measure the refractive index changes depending on the concentration of the liquid. The test measurement is the data on the index

refraction of propylene glycol/water mixture are good to use since it is simple to clean the sensor after dipping in the various solutions, since it is necessary that the sensor face be clean and dry to get a good reading in air and also before dipping in water to get a calibration/comparison reading. Even though the index varies with wavelength we take the water reading at 20°C to correspond to an index of 1.3330, and refer all other readings to this value. The dn/dt for water in the range 15 to 30°C is 0.0001 per degree °C, while that for 100% propylene glycol is 0.0003. Thus for glycol/water solutions one could assume a linear dependence of dn/dt, that is, for example assume dn/dt=0.0002 for a 50% solution. In all instruments with automatic temperature compensation, it is assumed that they are to be used with water solutions, and it is assumed that dn/dt=0.0001. We may use also propylene glycol, either 100%, taking its index to be 1.4312, or 100% plus a few mixtures. Additional results are measured for the second experimenter (change refractive index depending on the temperature):

1) *Engine oil MOL Arol 2T:*
   a) *Range: 20 - 75ºC*
   b) *dn/dt: - 0,00035/ºC*

2) *Rapeseed oil:*
   a) *Range: 20 - 75ºC*
   b) *dn/dt: - 0,00035/ºC*

3) *Olive oil:*
   a) *Range: 23 - 75ºC*
   b) *dn/dt: - 0,00004/ºC*

Additional results are measured for the third experimenter (changes refractive index depending on the concentration):

1) *Alcohol:*
   a) *Range: 10 – 99%*
   b) *dn/dc: 0,00032/%*

2) *Sugar solution (sugar in water):*
   a) *Range: 9 – 50%*
   b) *dn/dc: - 0,0018/%*

3) *Saline solution (salt in water):*
   a) *Range: 0 – 36%*
   b) *dn/dt: - 0,0013/%*

CONLUSIONS

Development work related to create remote control system for monitoring water pollution petrochemical products using optical fibre refractometer in the Applied Photonics distance education courseware was presented. The system modules structure enables its accommodation to solve remote access trough WWW to various photonics equipments for a relative large pool of students. The system was experimentally tested with module Fibre Optics Refractometer Instrument. Future work includes adding more modules to the system and designing more web-based equipments to enhance teaching and learning of subject Applied Photonics.

***Abstract*—This paper presents the characterization of various types of SubMiniature version A (SMA) connectors. The characterization is performed by measurements in frequency and time domain. The SMA connectors are mounted on microstrip (MS) and conductor-backed coplanar waveguide (CPW-CB) manufactured on high-frequency (HF) laminates. The designed characteristic impedance of the transmission lines is 50 Ω and deviation from the designed characteristic impedance is measured. The measurement results suggest that for a given combination of the transmission line and SMA connector, the discontinuity in terms of characteristic impedance can be significantly improved by choosing the right connector type.**

***Index Terms*—SMA connector; microstrip; conductor-backed coplanar waveguide; measurement; characterization**

I. Introduction

The omnipresent interconnect used in RF measurements is the SubMiniature version A (SMA) connector. The SMA connectors are used to connect measurement equipment and they are usually de-embedded as they are considered an intrinsic part of the transmission line. Nevertheless, the de-embedding is feasible only in the useful frequency range of the SMA connector-to-transmission line transition where insertion and return losses are not prohibitively large.

The S-parameters and time domain reflectometry (TDR) measurements are commonly used to verify SMA connector-to-transmission line transition performance [1], [2]. This is often performed for single connector type only [3], [4] and in limited frequency range [5], [6]. In this work various SMA connector types are mounted on microstrip (MS) and conductor-backed coplanar waveguide (CPW-CB). The MS and CPW-CB transmission lines are manufactured on low-loss high-frequency (HF) laminates. The measurements are performed up to 18 GHz for the following SMA connector types: vertical through hole (TH), vertical surface mount (SM), end-launch (EL) and reusable end-launch (SW). Furthermore, TDR measurements are performed to extract the characteristic impedance profile of the connectors with the best performance.

This paper is structured as follows: Section II presents the measurement set-up, MS and CB-CPW transmission line parameters and geometrical parameters of SMA connector footprints. Section III compares the measurements performed on various types of SMA connectors mounted on MS and CPW-CB transmission lines. The conclusion is given in Section IV.

II. Measurement Set-up

A number of structures for characterization of SMA connectors are manufactured on two-layer HF laminates. The structures consist of two SMA connectors mounted on transmission lines of different type and length. Several examples are shown in Fig. 1.

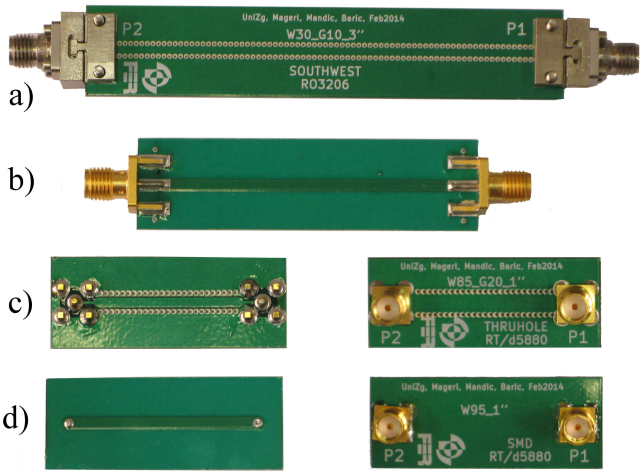

Fig. 1. Examples of the manufactured structures for characterizing SMA connectors: a) SW connectors mounted on a 3 inch CPW-CB line on RO3206 laminate (bottom layer view), b) EL connectors mounted on a 2 inch MS line on RO3206 laminate (top layer view), c) TH connectors mounted on a 1 inch CPW-CB line on RT/duroid 5880 laminate (top layer view on the left and bottom layer view on the right), d) SM connectors mounted on a 1 inch MS line on RT/duroid 5880 laminate (top layer view on the left and bottom layer view on the right).

A. Design of Transmission Lines

Two Rogers HF laminates are used: RT/duroid 5880 ($\varepsilon_r = 2.2$) and RO3206 ($\varepsilon_r = 6.15$). Parameters of the HF laminates most important for the design of transmission lines are summarized in Table I. The HF laminates have two metal layers.

Table II presents the dimensions of MS and CPW-CB transmission lines designed to have a 50 Ω characteristic impedance. The values are obtained using ADS LineCalc [7]. For a given HF laminate, the MS line characteristic impedance is defined only by the trace width, therefore the choice of

TABLE I
ROGERS HIGH FREQUENCY LAMINATE CHARACTERISTICS

	RT/duroid 5880	**RO3206**
substrate thickness	787.4 μm (31 mil)	1.27 mm (50 mil)
Cu thickness	17 μm	35 μm
ε_r	2.2	6.15
$tg\ \delta$	0.0004	0.0027

TABLE II
MICROSTRIP AND CONDUCTOR-BACKED COPLANAR WAVEGUIDE 50 Ω TRANSMISSION LINE DIMENSIONS

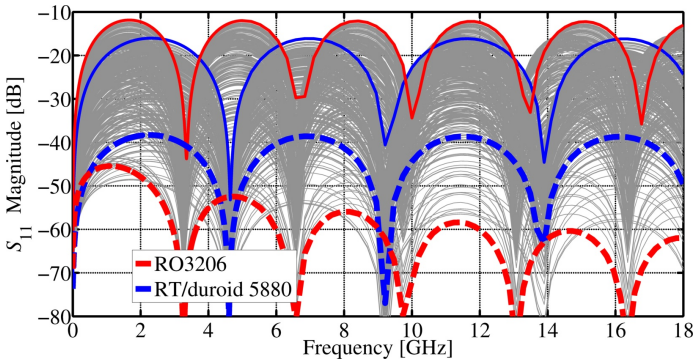
	RT/duroid 5880	**RO3206**
MS (w)	2.413 mm (95 mil)	2.032 mm (80 mil)
CPW-CB (w/g)	1.778 mm / 254 μm (70 mil / 10 mil)	762 μm / 254 μm (30 mil / 10 mil)
CPW-CB (w/g)	2.159 mm / 508 μm (85 mil / 20 mil)	1.27 mm / 508 μm (50 mil / 20 mil)

the MS line trace width is unique for a given characteristic impedance. However, the CPW-CB line characteristic impedance is defined by the trace width and the gap size between the trace and the ground plane. This allows design freedom to make CPW-CB lines more robust to the PCB manufacturing process tolerances. Monte Carlo simulations are performed in Agilent ADS [7] in order to analyze the influence of PCB manufacturing process tolerances on the characteristic impedance of CPW-CB transmission lines. A ±63.5 μm (±2.5 mil) tolerance is associated with the CPW-CB line trace width and gap size. Fig. 2 presents Monte Carlo simulation results for the return loss of 50 Ω CPW-CB lines with 3 different gap sizes. According to the simulation results, a gap size increase from 127 μm (5 mil) to 254 μm (10 mil) increases the worst-case return loss by ≈10 dB, while the gap size increase from 254 μm (10 mil) to 508 μm (20 mil) increases the worst-case return loss by only ≈5 dB. This indicates that CPW-CB lines with larger gap sizes have a reduced sensitivity to the variation of geometrical parameters. Based on the simulation results, the CPW-CB lines used in measurements are designed with gap sizes of 254 μm (10 mil) and 508 μm (20 mil), as indicated in Table II.

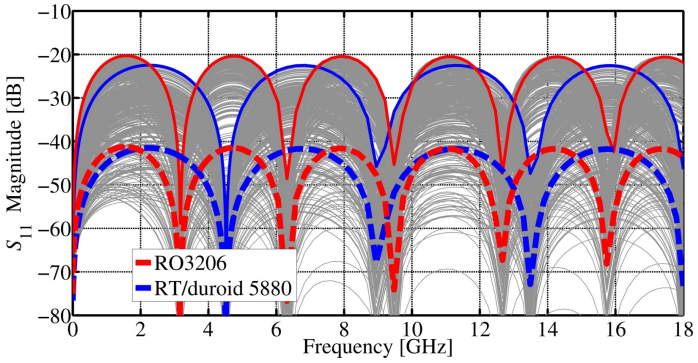
The CPW-CB ground planes placed on top and bottom layers are connected by vias positioned along the line length as shown in Fig. 1 c). The via drill diameter is equal to 0.45 mm (17.7 mil) and the spacing between vias is 1.016 mm (40 mil), which is less than $\lambda/8$ in the frequency range up to 18 GHz for both HF laminates. The geometrical parameters of vias are identical for all characterized structures.

B. SMA Connectors

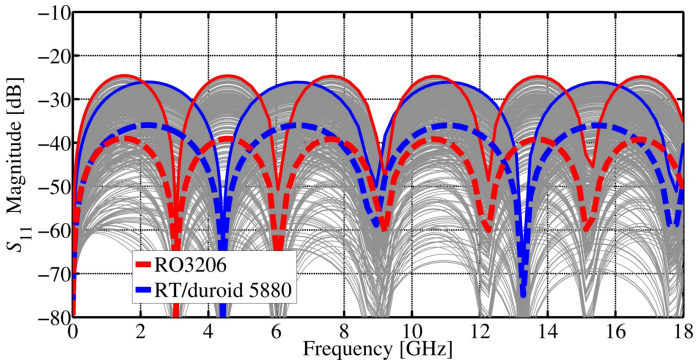
The SMA connector footprints are designed according to the manufacturer recommendations. The footprint drawings and design considerations are described in this section.



(a) 50 Ω CPW-CB: g = 127 μm (5 mil).
RO3206: w = 381 μm (15 mil), RT/duroid 5880: w = 1.27 mm (50 mil).



(b) 50 Ω CPW-CB: g = 254 μm (10 mil).
RO3206: w = 762 μm (30 mil), RT/duroid 5880: w = 1.778 mm (70 mil).



(c) 50 Ω CPW-CB: g = 508 μm (20 mil).
RO3206: w = 1.27 mm (50 mil), RT/duroid 5880: w = 2.159 mm (85 mil).

Fig. 2. Monte Carlo simulation results for the return loss of 50 Ω CPW-CB lines with 3 different gap sizes: a) 127 μm (5 mil), b) 254 μm (10 mil), c) 508 μm (20 mil). Nominal cases are represented by dashed lines and worst cases by solid lines. Statistical model: $g = g_{nom} + \Delta g$, $w = w_{nom} - \Delta g$, Δg = uniform(-2.5 mil, 2.5 mil), 250 trials.

1) Vertical connectors: Two vertical SMA connectors are used: through hole (TH) [8] and surface mount (SM) [9]. The connectors are mounted on the bottom layer of the PCB. Fig. 3 presents the top layer layout of the TH and SM vertical connector footprints. The reference planes and ground plane edges on the bottom layer are represented by dashed lines. A short fixture line extending from the signal pin of the connector to the reference plane is part of the TH and SM connector footprints. In the TH connector case, the fixture line has a width

of 508 µm (20 mil). The presented TH connector footprint has the same layout for all characterized structures, therefore the fixture line has a different characteristic impedance for the RO3206 laminate compared to the RT/duroid 5880 laminate.

The width of the SM connector fixture line is equal to the trace width of the transmission line extending from the footprint. The diameter of the antipad (dashed line in Fig. 3b) is recommended by the SM connector datasheet.

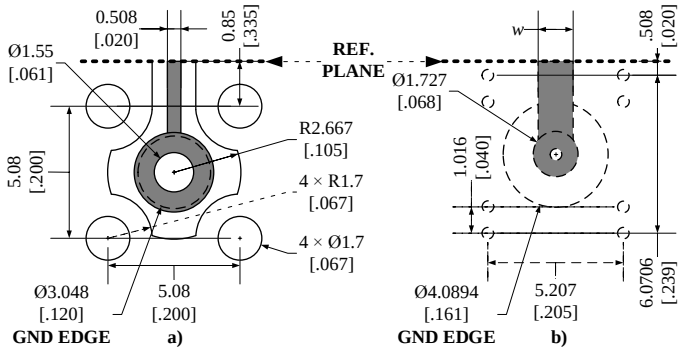


Fig. 3. Top layer layout of vertical connector footprints: a) TH connector and b) SM connector. Reference planes and ground plane edges on the bottom layer are represented by dashed lines.

2) End-Launch connectors: Two end-launch connectors are used: end-launch (EL) [10] and reusable end-launch (SW) [11]. Fig. 4 presents the top layer layout of the EL and SW end-launch connector footprints. The reference planes are represented by dashed lines, and the ground plane on the bottom layer is uniform. Both EL and SW connector footprints are inherently CPW-CB lines because of the ground pads next to and below the signal pad, as it can be seen in Fig. 4. In order to minimize signal reflections, the EL and SW connector footprints are designed as 50 Ω CPW-CB lines. The EL connector signal pad has the width w equal to the trace width of the transmission line extending from the footprint. The gap g between the signal pad and the ground pads of the EL connector footprint is calculated to result in a 50 Ω CPW-CB line. Since the EL connector is designed for laminates with a thickness of 1.575 mm (62 mil), it is mounted only on the RO3206 laminate.

The structures for the characterization of vertical and end-launch SMA connectors are designed as follows. A reference plane is defined for each SMA connector, as shown in Figs. 3 and 4, and 50 Ω transmission lines of different lengths are placed between the reference planes of two identical SMA connectors, as shown in Fig. 1. The transmission line lengths used on the RT/duroid 5880 laminate are: 25.4 mm (1 inch) and 50.8 mm (2 inch). Lengths used on the RO3206 laminate are: 25.4 mm (1 inch), 50.8 mm (2 inch) and 76.2 mm (3 inch). In order to have a ground plane that extends at least 3 trace widths on each side of the transmission line on all characterized structures, the width of all PCBs is equal to 7 times the maximum designed trace width (7 × 2.413 mm = 16.9 mm). The characterization of the proposed structures is performed by measuring two-port S-parameters using a vector network analyzer (VNA) in the frequency range from 10 MHz to 18 GHz, and by TDR measurements.

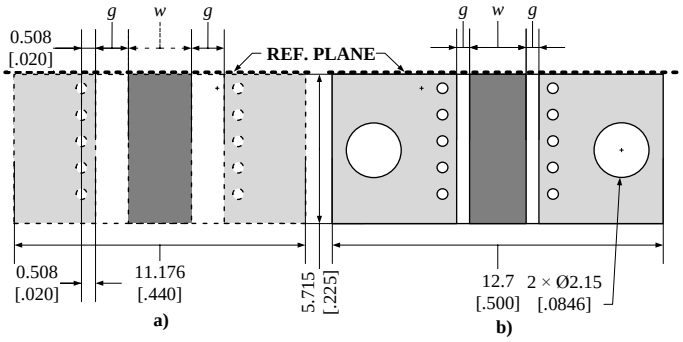

Fig. 4. Top layer layout of end-launch connector footprints: a) EL connector and b) SW connector. Reference planes are represented by dashed lines. The ground plane on the bottom layer is uniform.

III. Measurement Results and Discussion

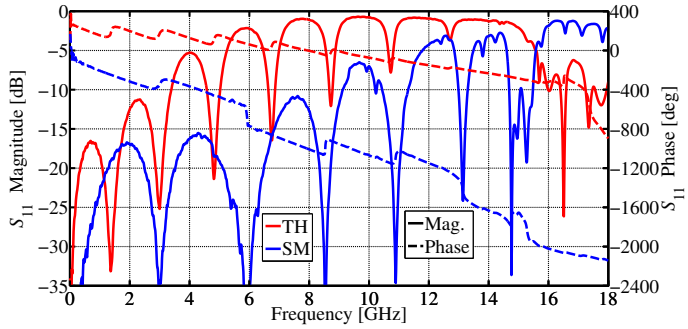
(b) S12

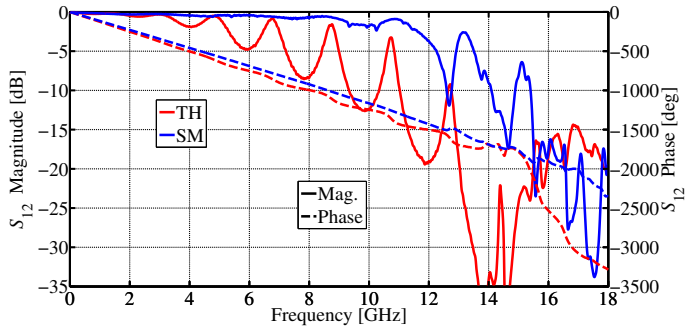
Fig. 5. S-parameter measurement results of TH and SM connectors mounted on MS lines (l = 25.4 mm (1 inch), w = 2.413 mm (95 mil)) on the RT/duroid 5880 laminate: a) return loss (S_{11}), b) insertion loss (S_{12}). Magnitude is represented by solid lines and phase by dashed lines.

Fig. 5 presents S-parameter measurement results of the TH and SM connectors mounted on MS lines (l = 25.4 mm (1 inch), w = 2.413 mm (95 mil)) on the RT/duroid 5880 laminate. The return loss (S_{11}) is shown in Fig. 5a and the insertion loss (S_{12}) is shown in Fig. 5b.

The TH connector has excellent matching with 35 dB return loss in the range up to 3 GHz, and 10 dB return loss in the

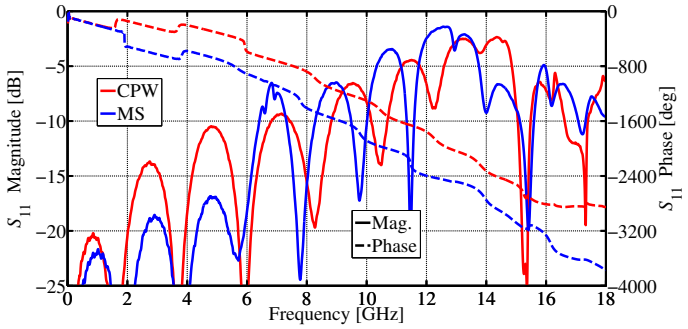


(a) S11

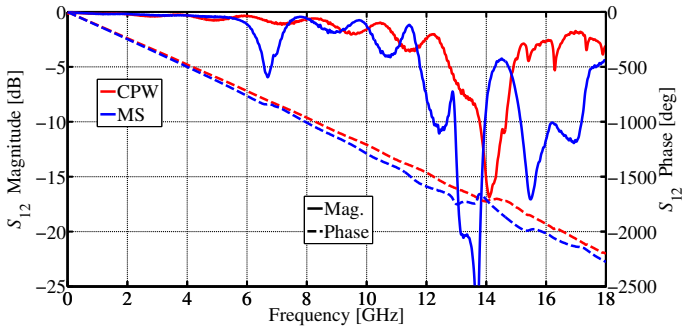


(b) S12

Fig. 6. S-parameter measurement results of TH and SM connectors mounted on CPW-CB lines (l = 25.4 mm (1 inch), w = 762 µm (30 mil), g = 254 µm (10 mil)) on the RO3206 laminate: a) return loss (S_{11}), b) insertion loss (S_{12}). Magnitude is represented by solid lines and phase by dashed lines.



(a) S11



(b) S12

Fig. 7. S-parameter measurement results of EL connectors mounted on CPW-CB line (l = 25.4 mm (1 inch), w = 1.27 mm (50 mil), g = 508 µm (20 mil) and MS line (l = 25.4 mm (1 inch), w = 2.032 mm (80 mil)) on the RO3206 laminate: a) return loss (S_{11}), b) insertion loss (S_{12}). Magnitude is represented by solid lines and phase by dashed lines.

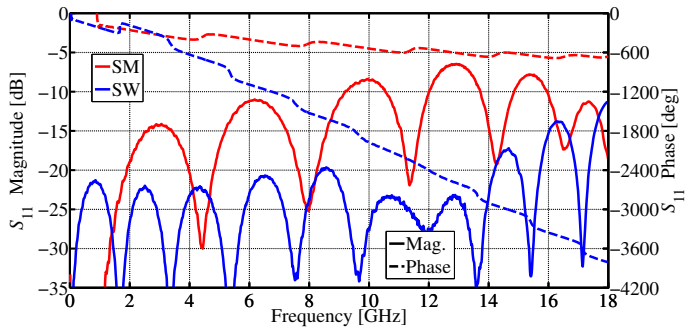
range up to 7 GHz. However, above 7.5 GHz the TH connector is poorly matched, partially because of the non-50 Ω fixture line in the TH connector footprint, shown in Fig. 3. The TH connector insertion loss 3 dB point is reached at 8 GHz. The SM connector has 10 dB return loss up to 9 GHz and 7.5 dB return loss in the entire measured frequency range. The SM connector insertion loss 3 dB point is reached at 17 GHz and is within 4 dB in the entire measured frequency range.

The TH connector shows better overall performance compared to the SM connector on the RT/duroid 5880 laminate in the frequency range up to 4 GHz. The S_{12} phase response is more linear for the SM connector than the TH connector in the frequency range above 7 GHz. It also shows that the SM connector is electrically shorter than the TH connector, which is consistent with the connector physical dimensions. Measurement results of the TH and SM connectors mounted on CPW-CB lines (w = 2.159 mm (85 mil), g = 508 µm (20 mil) and w = 1.778 mm (70 mil), g = 254 µm (10 mil)) on the RT/duroid 5880 laminate show performance similar to the results presented in Fig. 5.

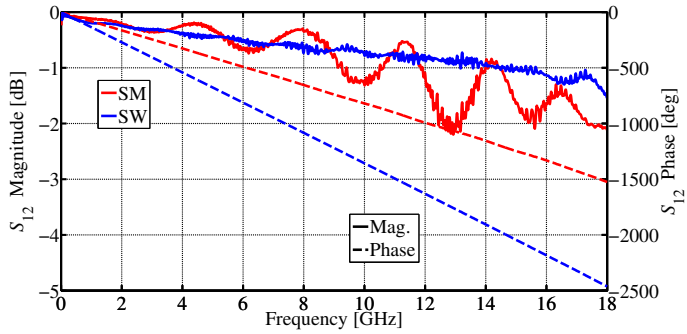
The TH and SM connectors are compared further for the RO3206 laminate. Fig. 6 presents S-parameter measurement results of the TH and SM connectors mounted on CPW-CB lines (l = 25.4 mm (1 inch), w = 762 µm (30 mil), g = 254 µm (10 mil)) on the RO3206 laminate. The return loss (S_{11}) is shown in Fig. 6a and the insertion loss (S_{12}) is shown in Fig. 6b. The TH connector has 10 dB return loss up to 3.3 GHz and the insertion loss 3 dB point at 5 GHz. The SM connector has 10 dB return loss up to 9 GHz and the insertion loss 3 dB point at 12 GHz.

The SM connector shows better overall performance than the TH connector on the RO3206 laminate in the frequency range up to 15.5 GHz. For frequencies above 15 GHz both connectors have more than 15 dB insertion loss. The S_{12} phase response for the SM connector has better linearity than the for TH connector. Measurement results of the TH and SM connectors mounted on MS lines (w = 2.032 mm (80 mil)) and CPW-CB lines (w = 1.27 mm (50 mil), g = 508 µm (20 mil)) on the RO3206 laminate show similar performance to the results presented in Fig. 6.

The overall performance of the TH and SM connectors on the RO3206 laminate is worse than on the RT/duroid 5880 laminate. The causes may be as follows. The RO3206 laminate is 482.6 µm (19 mil) thicker than the RT/duroid 5880 laminate and it has a ≈2.8 times higher dielectric constant. This results in smaller trace widths and gap sizes of 50 Ω transmission lines, which makes them more sensitive to PCB manufacturing process tolerances, as shown in Section II. Also, the RO3206 laminate has ≈7 times higher losses than the RT/duroid 5880 laminate, which results in higher insertion loss for the same line length. The TH and SM connectors show similar performance for both transmission line types regardless of the HF laminate used. However, this is not the case for the EL



(a) S11



(b) S12

Fig. 8. S-parameter measurement results of SW connectors mounted on CPW-CB line (l = 25.4 mm (1 inch), w = 762 μm (30 mil), g = 254 μm (10 mil) on the RO3206 laminate compared to the SM connector mounted on CPW-CB line (l = 25.4 mm (1 inch), w = 1.27 mm (50 mil), g = 508 μm (20 mil) on the RT/duroid 5880 laminate: a) return loss (S_{11}), b) insertion loss (S_{12}). Magnitude is represented by solid lines and phase by dashed lines.

connectors, as shown next.

Fig. 7 presents S-parameter measurement results of the EL connectors mounted on CPW-CB line (l = 25.4 mm (1 inch), w = 1.27 mm (50 mil), g = 508 μm (20 mil) and MS line (l = 25.4 mm (1 inch), w = 2.032 mm (80 mil)) on the RO3206 laminate. The return loss (S_{11}) is shown in Fig. 7a and the insertion loss (S_{12}) is shown in Fig. 7b. The MS line test case shows better overall performance compared to the CPW-CB line test case in the range up to 6 GHz. Although the EL connector is rated up to 18 GHz, both cases show more than 5 dB insertion loss in the range above 12 GHz. Further, a 6 dB dip in the insertion loss is observed for the MS line test case in the range between 6 GHz and 8 GHz, regardless of the MS line length used. This dip is therefore attributed to the EL connector performance.

The MS line test case has 10 dB return loss up to 7 GHz and the insertion loss 3 dB point at 6.4 GHz. The CPW-CB line test case has 10 dB return loss up to 6.8 GHz and the insertion loss 3 dB point at 12.5 GHz. A 17 dB dip in the insertion loss is observed for the CPW-CB test case in the range between 12 GHz to 15 GHz, which is probably due to the connector-to-transmission line transition. This transition may be improved by optimization using a 3D EM simulator. The S_{12} phase response shows better linearity for the CPW-

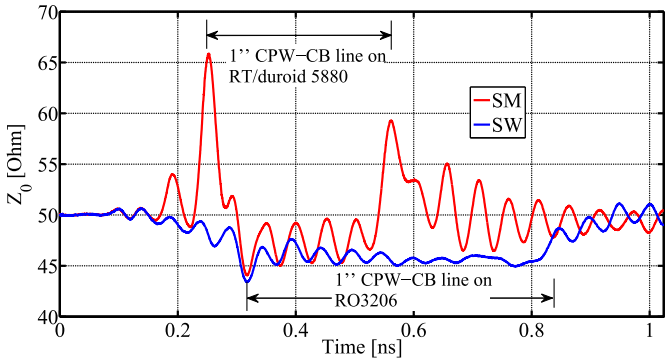


Fig. 9. Characteristic impedance profile of SW connectors mounted on CPW-CB line (l = 25.4 mm (1 inch), w = 762 μm (30 mil), g = 254 μm (10 mil)) and the SM connector mounted on CPW-CB line (l = 25.4 mm (1 inch), w = 1.27 mm (50 mil), g = 508 μm (20 mil)) on the RT/duroid laminate, obtained by TDR measurements. Other port of the transmission lines is terminated in 50 Ω.

CB line test case than for the MS line test case. Also, it shows that both structures have similar electrical length. This is an expected result because the same connector, transmission line length and HF laminate are used in both cases. Measurement results of the EL connectors mounted on CPW-CB line (w = 762 μm (30 mil), g = 254 μm (10 mil)) on the RO3206 laminate show similar performance to the results of the CPW-CB line test case presented in Fig. 6.

Reusable end-launch (SW) connectors show the best performance of all measured connectors. Fig. 8 compares S-parameter measurement results of the SW connectors mounted on CPW-CB line (l = 25.4 mm (1 inch), w = 762 μm (30 mil), g = 254 μm (10 mil) on the RO3206 laminate with with measurement results of the SM connector mounted on CPW-CB line (l = 25.4 mm (1 inch), w = 1.27 mm (50 mil), g = 508 μm (20 mil) on the RT/duroid laminate. The latter has the second best performance of all characterized structures. The return loss (S_{11}) is shown in Fig. 8a and the insertion loss (S_{12}) is shown in Fig. 8b.

The return loss of the SW connector is superior to all measured connectors, with 20 dB return loss up to 14 GHz and 10 dB return loss in the entire measured frequency range. The SW connector has far less ripple in the S_{12} magnitude response than the SM connector. Both connectors have insertion loss within 3 dB in the entire measured frequency range. Great linearity is observed in the S_{12} phase response for both connectors. The SW connector performance may be even further improved by designing a taper in the SW connector footprint, as described in [12].

Since they show the best performance, the SW and SM connectors are further compared in the time domain. TDR measurements are made using a 20 GHz sampling oscilloscope with TEK SD-24 sampling heads capable of launching signals with voltage swing of 250 mV and rise time of 30 ps. Fig. 9 presents the characteristic impedance profile extracted from the TDR measurements for the SW and SM connectors, which represents the time domain equivalent of the frequency domain measurements presented in Fig. 8. The transmission

line characteristic impedance can be observed from the 0.3 ns mark, and it equals ≈47.5 Ω for both test cases. The the transmission line in the SM connector test case is electrically shorter than in the SW connector test case due to a lower dielectric constant of the HF laminate used. The SM connector introduces a 15 Ω discontinuity in the characteristic impedance profile, while the SW connector does not significantly alter the characteristic impedance profile.

IV. Conclusion

The measurement results of various SMA connector types are presented, namely the vertical through hole (TH), the vertical surface mount (SM), the end-launch (EL) and the reusable end-launch (SW). The SMA connectors are mounted on 50 Ω MS and CPW-CB lines manufactured on two different HF laminates. The TH connector shows good return loss and insertion loss performance only in the frequency range up to several GHz. The SM connector mounted on CPW-CB line on the RT/duroid 5880 laminate shows the second best performance of all measured SMA connectors. Even though the EL connector is rated up to frequency of 18 GHz, due to the high insertion loss it has limited usability up to ≈13 GHz for the CPW-CB and up to 6 GHz for the MS line. The SW connector show the best performance of all measured SMA connectors, with excellent matching, low insertion loss and great S_{12} phase response linearity in the entire measured frequency range.

Abstract – The paper presents measured radiated emissions of an electronic module in the frequency range 150 kHz – 200 MHz using the TEM cell method. The TEM cell measurement method is explained and measurement results for different orientations of the electronic module are presented. An explanation for the differences in the measured radiated emissions for different module orientations is given.

I. INTRODUCTION

Measurement of radiated emissions of electronic device is essential part of EMC testing. This testing process should ensure proper operation of the measured equipment in complex environment in which electronic equipment must operate. In the environment, devices are exposed to the influence of other electromagnetic fields, on which they must be immune. On the other hand, to reduce the influence of a particular device on its environment and also to reduce the overall amount of electromagnetic pollution, the requirements are set to limit the emissions of electromagnetic fields.

The required immunity levels and allowed emission levels are defined for different types of equipment by appropriate standards. These standards prescribe the methods for immunity tests, as well as the methods for measurement of different types of emissions which electronic devices generate.

This work presents results of radiated disturbance measurement for analyzed electronic module (power supply module of a more complex modular system) in the TEM cell.

The TEM cell method [1]–[4] provides simple, affordable and reliable tool for the measurement of the radiated emissions of the electronic devices.

In the following chapters, firstly the analyzed electronic module is presented, and then the TEM cell and measuring method is explained. In the remainder of this paper the measurement results are presented and discussed, and then conclusions are given in Section V.

II. ANALYZED CIRCUIT

In this work a power supply module of a complex modular electronic system intended for industrial applications is analyzed. This system should be capable of working in highly complex environments, exposed to high levels of disturbances from the environment.

In order to reliably perform its operation, the system needs a quality power supply. The power supply module analyzed in this paper powers the system with quality and stable 5 V supply voltage, obtained from the 24 V input battery voltage. Battery voltage is usually very "dirty", exposed to severe disturbances, voltage drops and over-voltages. Therefore, the analyzed power supply module, besides the output voltage regulation, has to perform protection and electrical isolation. On the one hand, it must be resistant to interferences and protect powered devices from disturbances, but on the other hand, it must not pollute the environment with its emissions.

In this paper the emission of the radiated disturbances of the power supply module is analyzed. The power supply module is shown in Figure 1 and the block-diagram of its central component is presented in Figure 3.

Schematic of the power supply module is shown in Figure 2. The central component of the analyzed power supply circuit is the DC/DC converter (component A1 in Figure 2). It ensures galvanic separation of the input and output voltage and regulation of the output voltage. Additionally, it implements protection functions, like the protection from short-circuit on the output or protection from overheating.

As it can be seen on the block-diagram (Figure 3), the function of galvanic separation is achieved by means of inductive coupling between primary and secondary circuit

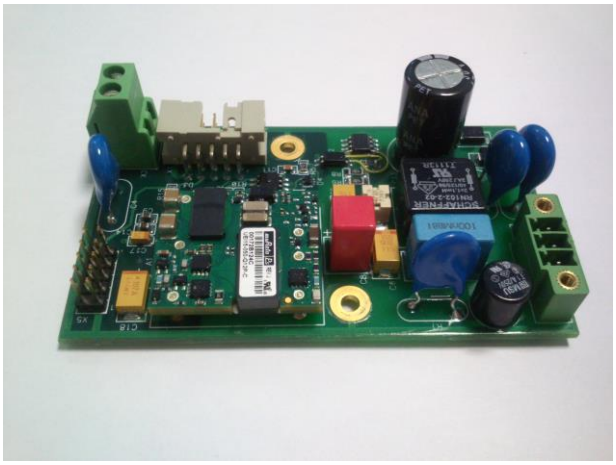

Figure 1. Picture of the analyzed power supply module.

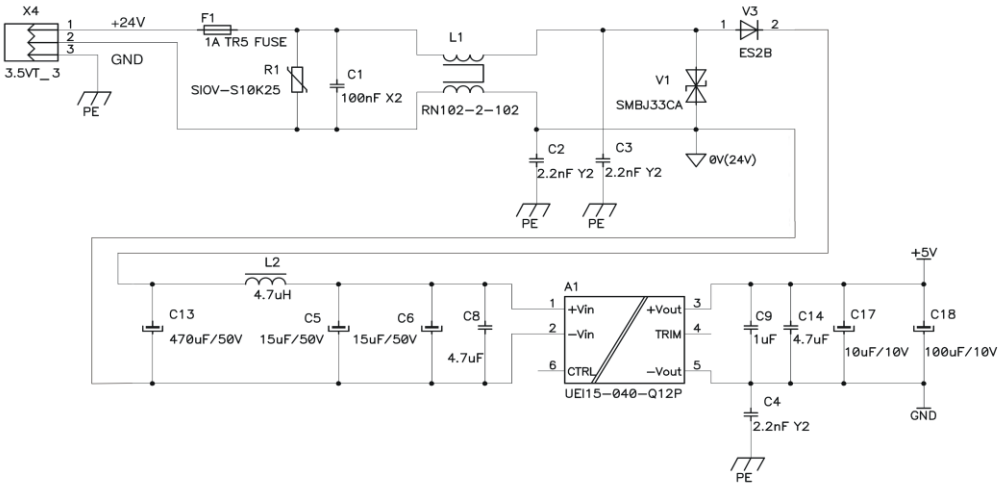

Figure 2. Schematic of the analyzed power supply module.

of the DC/DC converter. This inductive coupling between the primary and secondary side of the DC/DC converter is expected to be the main source of radiated disturbances.

The DC/DC converter used in this circuit is UEI15-050-Q12P-C [5] produced by Murata Power Solutions. The operating frequency of the DC/DC converter is 350 kHz.

The level of radiated disturbances is measured in the TEM cell by the modified method described in [6]–[8].

III. TEM CELL AND MEASUREMENT METHOD

TEM (Transverse ElectroMagnetic) cell is a rectangular coaxial waveguide in which electromagnetic waves propagate in transverse electromagnetic mode and by that create specific fields appropriate for different test procedures [9]. Mechanical design of coaxial waveguide ensures that the external conductor completely encloses the inner conductor (septum). Because of that, TEM cell does not emit electromagnetic energy that could affect nearby equipment. On the other hand, the inner of the waveguide is protected from external fields.

The principal cross-section of the TEM cell is shown in Figure 4. As it can be seen, the main part of the cell consists of the external conductor and septum, placed in the mid-point between upper and lower wall of the cell.

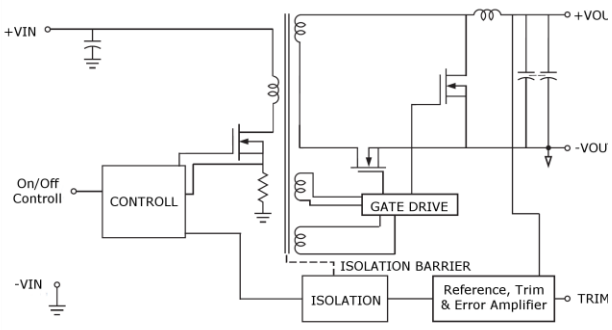

Figure 3. Block-diagram of the DC/DC converter.

In the external top wall there is an opening of 100 mm × 100 mm that enables access to the cell interior and placement of the equipment under test (EUT).

This opening is closed by adapter board on which EUT is placed and which provides all necessary connections between the EUT and outside world. The dimensions of the middle part of the TEM cell and tapered ends are selected to provide 50-Ω characteristic impedance through the whole cell [10].

At the ends of the TEM cell there are connectors that allow connection of external equipment. Generally, one port is used for connection of the measuring equipment: spectrum analyzer or disturbance generator, while the other port is terminated by a 50-Ω termination.

The IEC 61967-1 standard recommends placement of the EUT on the adapter board sized 100 mm × 100 mm. This adapter board performs multiple roles. On one hand it closes opening in the TEM cell external conductor and ensures reliable galvanic connection with it.

This is essential for preservation of a homogenous field within the TEM cell. On the other hand, this adapter board enables mounting of the EUT as well as all required electrical connections with the equipment outside of the TEM cell.

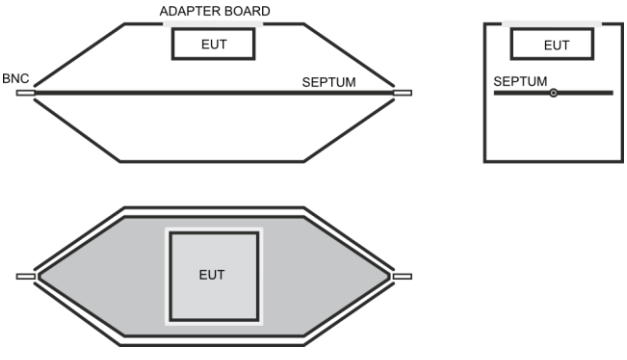

Figure 4. Principal cross-section of the TEM cell.

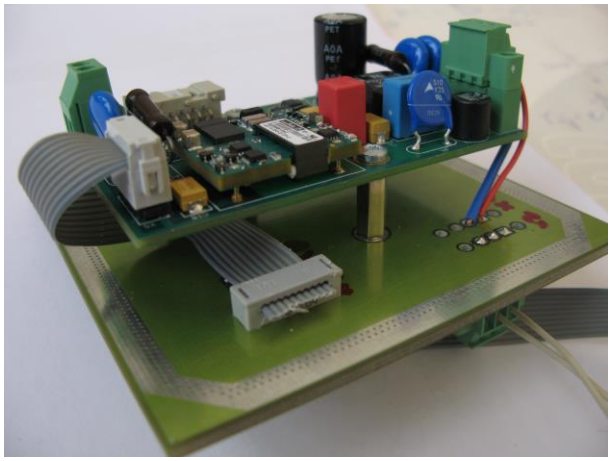

Figure 5. Power supply module mounted on the adapter board.

Because of its shape, the adapter board can be placed in TEM cell in four different orientations relative to the TEM cell port-to-port axis.

The mounting of the analyzed power supply module to the adapter board is shown in Figure 5. This way of mounting is deviating from the recommendations of the IEC 61967-1, since this method is intended for testing of integrated circuits. However this is a simple way how a module to be tested can be placed within a TEM cell.

To measure radiated emissions of the analyzed EUT, one port of the TEM cell is terminated by a 50-Ω termination, while the other port is connected to the spectrum analyzer Rohde&Schwartz FSP7 intended for measurements in the frequency range 9 kHz to 7 GHz. EUT is powered by a 24 V laboratory power supply, and the output is loaded by a variable resistor. The TEM cell used for measurement is FCC-TEM-JM2 [11], produced by Fischer Custom Communications, Inc.

IV. MEASUREMENT RESULTS

A series of measurements of the EUT is made. To facilitate the comparison of the measurement results, all measurements are performed with the same spectral analyzer settings: frequency range = 150 kHz – 200 MHz, reference level = -20 dBm, att = -10 dB, RBW = 3 kHz, VBW = 10 kHz and 8001 points.

As the adapter board can be placed in four different orientations, four sets of measurements are performed. For each orientation, seven measurements are performed:

1. EUT is placed within the TEM cell but without external wiring (supply and load);
2. external wiring is connected to the adapter board, but power supply is turned-off;
3. EUT is connected and power supply is turned-on. EUT is loaded with different loads: 0 mA (0% rated output current); 500 mA (25%), 1000 mA (50%), 1500 mA (75%) and 2000 mA (100%).

The output current is set by a variable resistor and during the whole measurement cycle the output current and voltage are monitored. The output current is kept constant during the whole measurement cycle within ±10 mA of the declared value.

The measurement results are presented below. To reduce the amount of unnecessary detail in representation of the results, the recorded spectrum is processed and spectrum envelope is calculated.

The measurement is started by placing the EUT mounted on the adapter board to the TEM cell. First the measurement is performed without connected wiring. Result is shown in Figure 6. It can be noticed that the spectrum is very similar in all four orientations.

This measurement represents the basic state of the TEM cell. It can be seen that the measured spectrum is practically flat – white noise. This is an expected result since the TEM cell is a closed metal box with the properties of the Faraday cage and there are no electromagnetic field sources within the TEM cell.

In the step 2 all necessary wiring is connected (power supply, load resistor, ampere meter and voltmeter), but the power supply is still turned-off. The result is shown in Figure 7.

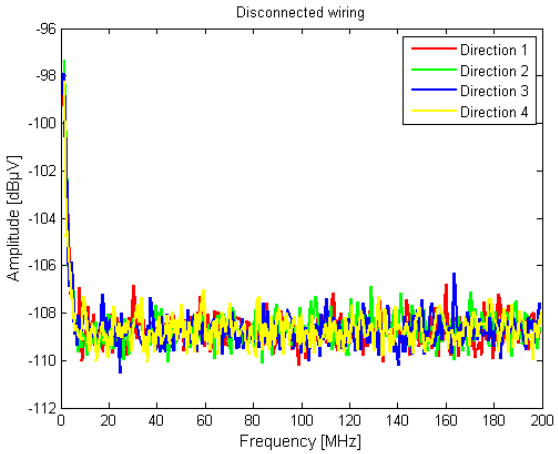

Figure 6. Spectrum in TEM cell with disconnected wiring, all four orientations.

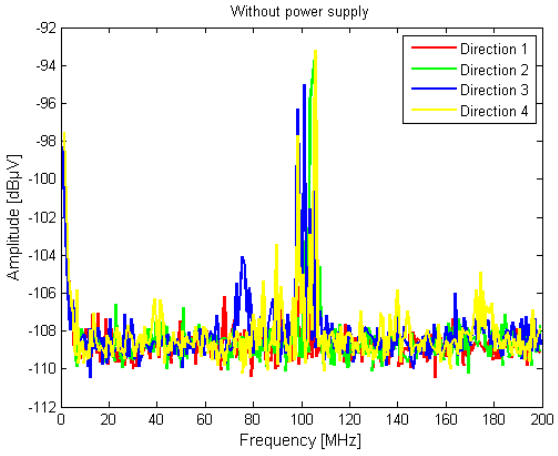

Figure 7. Spectrum in TEM cell with connected wiring, but without power supply, all four orientations.

The measured spectrum shows two distinctive spectral components, with amplitude of 14 dBµV above background noise level in the frequency range around 100 MHz. It can be concluded that this is the frequency range of FM radio, and that test wiring acts like antenna. This could be eliminated by placing the whole measurement system in a Faraday cage.

In the step 3 the EUT is powered and its output is loaded with different output loads. If the output load is 0, the DC/DC converter on the EUT is active, its control electronics is operational and the current through its internal coils is modulated. As expected, the spectral component at 350 kHz (DC/DC converter switching frequency) appears, as well as its higher harmonics, which is shown in Figure 8.

If this spectrum is analyzed in a wider range, up to 200 MHz (Figure 9), it can be seen that in the frequency range to 10 MHz the amplitude of radiated disturbances is falling, as expected. However, the amplitude is increasing again at the higher frequencies. At approx. 17 MHz there is a spectral component with the amplitude of 8 dBµV higher than the component at DC/DC converter switching frequency and the maximal amplitude is at approx. 115 MHz and it is 14 dBµV higher then amplitude on the switching frequency. Compared to the not-powered device case, the maximal increase in disturbance amplitude is 42 dBµV.

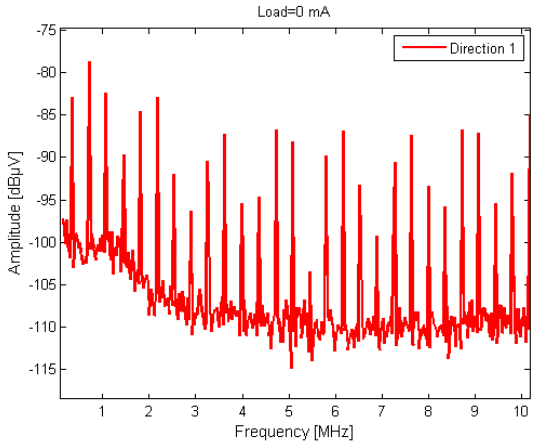

Figure 8. Spectrum in TEM cell in frequency range 150 kHz–10 MHz, with power supply, direction "1".

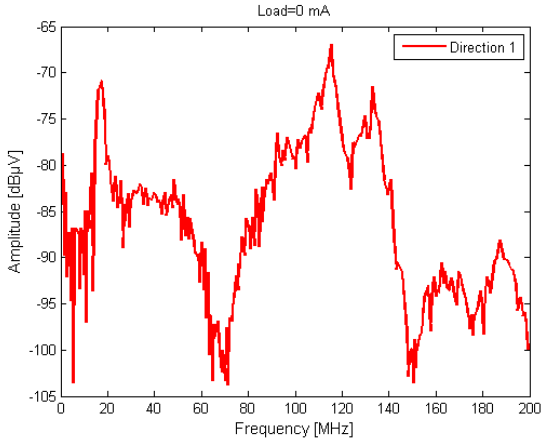

Figure 9. Spectrum amplitude envelope in frequency range 150 kHz–200 MHz, with power supply, direction "1".

If the measured spectrum amplitudes for all four directions of the adapter board are shown in the same image (Figure 10), it can be seen that on the same frequency, disturbance amplitudes of particular spectral components heavily differ, depending on the adapter board orientation. So, for instance, at 53.3 MHz the difference between direction "2" and direction "3" is larger than 20 dBµV.

In Figure 11 the spectrum amplitudes for all four directions and with 100% output load are shown.

Similarly as in the case of unloaded EUT, differences in the amplitude of radiated disturbances spectrum can be observed. But those differences are far smaller compared to unloaded EUT.

A more detailed analysis of the spectrum for orientation in direction "1" is shown in Figure 12. The spectrum is shown for different output loads. The load is changed in steps of 25 %, from 0 mA (0 %) to 2000 mA (100 % of the rated load).

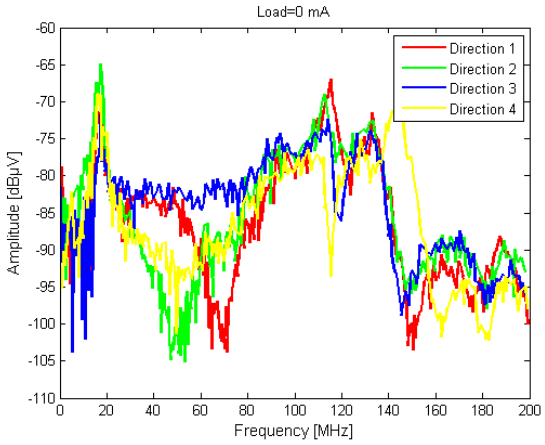

Figure 10. Spectrum amplitude envelope in frequency range 150 kHz–200 MHz, 0% load, all directions.

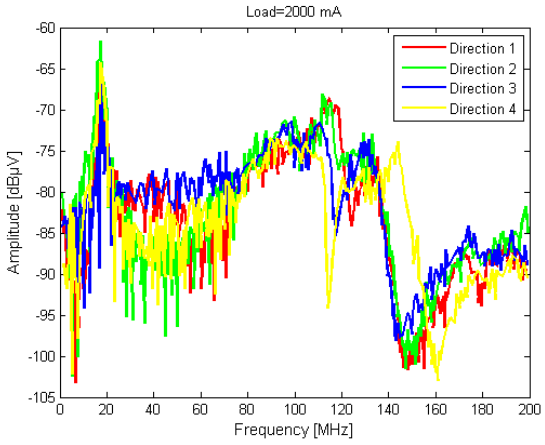

Figure 11. Spectrum amplitude envelope in frequency range 150 kHz–200 MHz, 100% load, all directions.

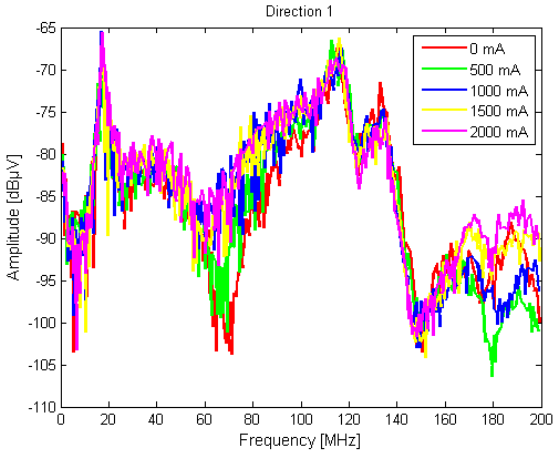

Figure 12. Comparison of the spectrum for the different output loads in direction "1".

By analyzing the measured spectrum it can be seen that, in most of the observed frequency spectra, with the increase of the load, i.e. the increase of the current through the DC/DC converter coil, the amplitude of the emitted electromagnetic radiation is increased. However, in some parts of the analyzed frequency spectrum this is not the case.

This behavior is probably the result of the operating mode of the output voltage regulator of the DC/DC converter.

Also, it is possible that these spectral components are related to the specific resonances of the TEM cell/module set-up or the resonances of the module PCB

V. CONCLUSION

The measurement method for measuring the emissions of electronic modules using the TEM cell is shown. The presented results show that this method enables relatively inexpensive, simple and reproducible procedure for measurements of electronic module emissions. An alternative to the presented method is to perform measurements in a semi-anechoic chamber, i.e. in Faraday cage with absorbers on the walls, which is much more expensive.

The measurement results show that the spectrum of the radiated noise of the analyzed power supply module is much richer than it could have been expected. Furthermore, the maximum emission is not at the switching frequency of the DC/DC converter (350 kHz), but at more than 300 times higher frequency, at 115 MHz.

The results also show the dependence between the measured emissions of the electromagnetic field of the power supply module and its load and orientation within the TEM cell. The measurements have shown that the amplitude of the radiated emissions does not grow uniformly with the increase of the output current. There are bands where the amplitude of the radiated emissions is the largest when the output of the power supply module is not loaded, i.e. the output current is zero.

In order to verify the presented measurement method and the results, it would be opportune to repeat all measurements in a semi-anechoic chamber and compare the results.

***Abstract*—In this paper the model of a system for measuring small currents, which generates the digital signal proportional to the input current, was designed. The analysed measuring system is the part of a larger microelectronic mixed-signal integrated chip (SoC – System on Chip), and it is located between the input sensor and the external digital device. Since the part that mostly contributes to the noise inside the whole measuring chain is at the input of the chain, the measurement method is analyzed to minimize the impact of noise. Because the noise is not definite, the simulation of measurement by the model was made using statistical principles. Performing multiple measurements of the input value (in our example it is current I_d) it is possible to calculate its mean value and standard deviation. It was shown that the measured quantity can be calculated from the mean value and that the standard deviation represents an amount of noise. Depending on the standard deviation it is needed to do either less or more sequential measurements to determine the reliable measured output digital value.**

I. INTRODUCTION

Information processing devices that are placed between the sensor and the external circuit are often used in the practice. In this paper we present a model of one such system. The model is used for the functional analysis of a sub-circuit of a microelectronic integrated circuit, which is located between an input sensor and an external device for further digital data processing or value representing (e.g. microcontroller, LCD screen). The circuit under consideration generates a digital value proportional to the input analogue small current, considerably exposed to the noise (highly-sensitive, digital, integrated ampermeter) [1].

The considered circuit is convenient for a broad area of measurements and further analysis, using sensors where a non-electrical quantity (e.g. light, physical, chemical or electrochemical) has been transformed to electrical quantity (voltage or current). The application is very broad: bioindustry, medicine, ecology (water and air pollution), agriculture, food production, aviation, instrumentation, military and automobile industry, etc.

The MATLAB/Simulink model shows a principle to measure small input values. Using the model, we analyse the impact of the noise at the integrated measurement chain (realized as microelectronic integrated circuits on 180nm TSMC technology shown in Fig. 1) at the final output values [2].

II. NOISE

The main challenge in the system for measuring small input currents is noise. Noise is produced by random fluctuations of voltages and currents in the physical elements of electrical circuits, and as such represents a fundamental limitation in the precision of the measurements. In microelectronic systems there are several noise categories: internal noise (thermal, 1/f, shot, etc.), external noise (environment impact, interference etc.). Other effects include offset, finite open-loop gain and slew-rate of operational amplifiers, signal lines crosstalk, etc. [3].

Since in microelectronic devices and circuits it is very difficult to treat, quantize and measure the noise, an equivalent input RMS noise (root mean square noise) is used [4]. Basically, the equivalent input noise is a measure how much noise is added to the input current signal. Such representation of the noise at the input of the model does not have any impact on the functional or operational behaviour of the model and it is also independent of gain and current range settings. The value of all noise contributors in the system (all operational amplifiers, switches, sample & hold, current/voltage converter, etc.) is obtained from laboratory measurement as total RMS value at the output of the processed microelectronic chip. This combined RMS output noise value, also incorporating system's frequency behaviour, is then referred to the input of the model as the equivalent input noise. The effect of offsets of operational amplifiers is reduced by offset cancelation circuits.

Furthermore, this all gives ability using the model to run simulations of the integrated, complex microelectronic system.

III. MODEL IN MATLAB / SIMULINK

In the analysis of the model we will study the parts of the modelled measuring chain. As shown in Fig. 1, the integrated microelectronic measurement system consists of current-voltage converter (I/V converter), differential amplifier (diff. builder), programmable-gain amplifiers (gain chain), sample and hold circuit (S&H circuit) and analogue-to-digital converter (A/D converter).

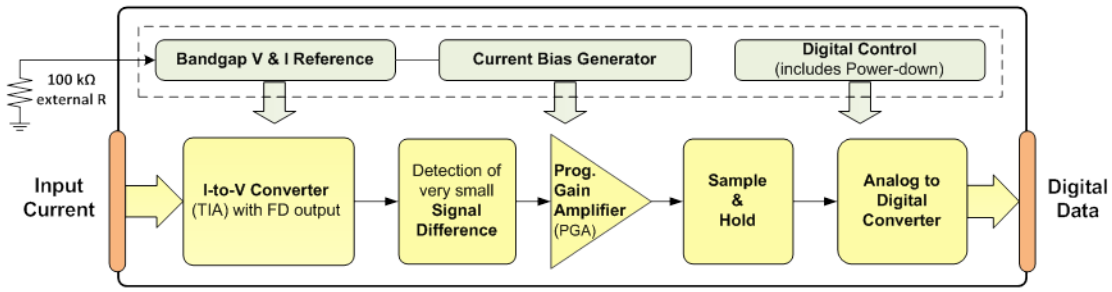

Figure 1. Block scheme of the measuring chain of low-noise, small-current-measurement system.

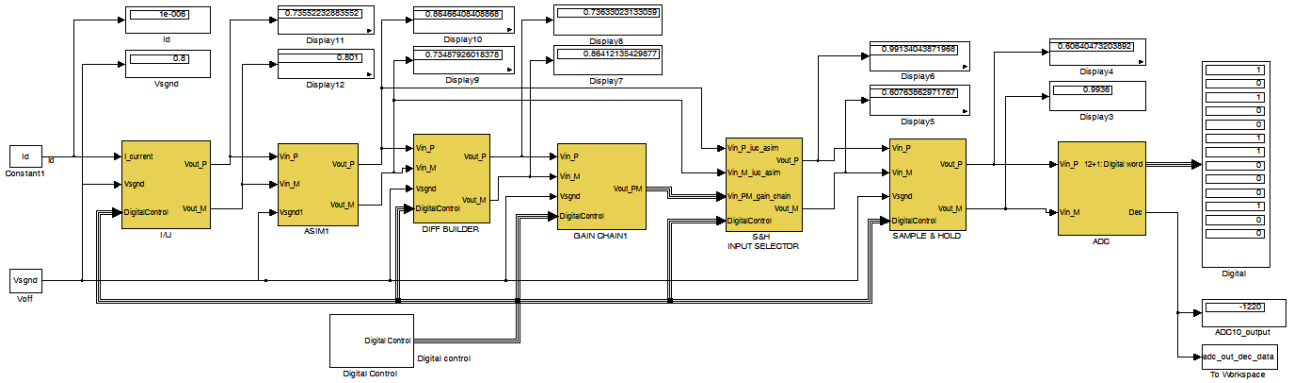

Figure 2. Model of the complete low-noise, small-current-measurement system in MATLAB/Simulink.

All blocks, except the A/D convert, are modelled with their own frequency behaviour. The model is built in MATLAB / Simulink tool [5] and is shown in Fig. 2. It is realized by 8 blocks, and additional blocks for measuring and displaying the output value. At the input there is a current source I_d, and a reference voltage V_{sgnd}. Each part of the system is described as follows.

A. *Current-to-voltage converter*

Current-to-voltage converter is the first block in the MATLAB/Simulink model and is shown in Fig. 3. Its purpose is to convert input current to voltage. It has three control signals: *az* (auto-zero), *cr_select* and *noise_select*.

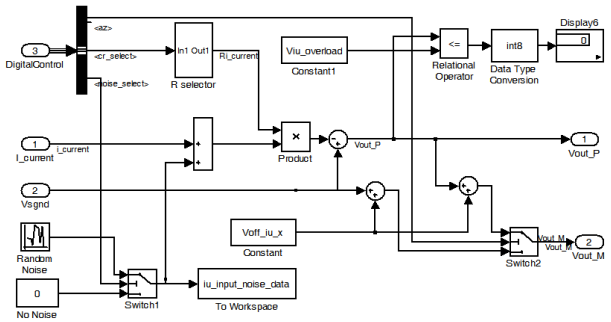

Figure 3. Model of the current-to-voltage converter.

The auto-zero signal controls the auto-zeroing process in order to eliminate offsets of operational amplifiers. When *az*=1, the block samples the combined voltage offset since this mode configures the circuit in the way it is equivalent to input current being zero (I_d =0). When *az*=0, the output has the voltage offset superposed to the useful signal. When those two output signals are subtracted, only the value of useful signal remains. The signal *cr_select* has 3 bits and controls the input current range by selecting the transresistance of the I/V converter, modelled as shown in Fig. 4. When *noise_select* is 1, the random noise is added to the input current. Once the noise is added, it propagates through the signal chain to the output of the model, so it is possible to perform simulations of measurements.

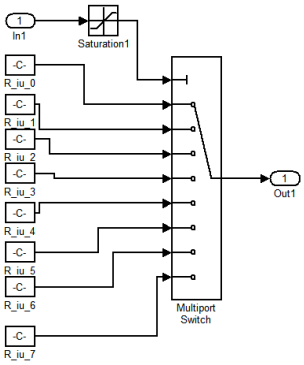

Figure 4. Reistance selector model in current-to-voltage converter.

B. *Symmetric converter*

The symmetric converter is shown in Fig. 5. The I/V converter and the symmetric converter operate as one block. The main purpose of the symmetric converter is to produce differential symmetrical signal. Thus, the current-to-voltage converter and the symmetrical converter together convert measured input current to a symmetric differential voltage signal since it is more robust to interference. As shown below, it is very important to reduce noise in the input stages, because they mostly contribute to the output total noise (see [6]).

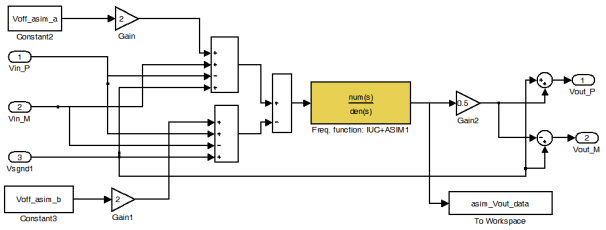

Figure 5. Model of the symmetric converter.

C. *Differentiator*

The next block in the chain is a differentiator and is shown in Fig. 6. The differentiator is the block where subtraction of the offset from useful signal from the I/V converter is done.

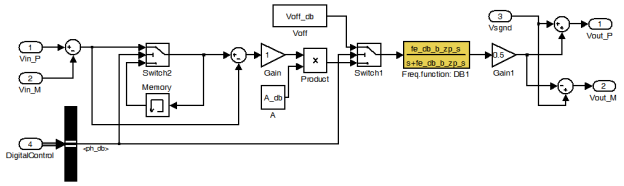

Figure 6. Model of the differentiator.

It operates in two phases, which are controlled by the signal *ph_db*, which serves to make a difference between the two input current sampling (I_d and I_d =0), i.e. the difference between the previous (t–1) state and current state (t).

$$\begin{aligned} &ph_db = 1, \quad \Delta V_{out} = V_{off} \\ &ph_db = 0, \quad \Delta V_{out} = -A\left[\Delta V_{in}(t-1) - \Delta V_{in}(t)\right] \end{aligned} \tag{1}$$

D. *Cascade amplifier*

The fourth block is a cascade amplifier, which consists of four-amplifier stage with bypass and gain control shown in Fig. 7. It determines the overall gain of the chain. Four amplifiers (instead of one) are used for practical reasons of circuit realization and also because of stability and impedance reduction. Since the overall gain of the integrated measurement system is specified before the designing and modelling the measurement system, the number of the gain stages is determined by achieving the gain and to have appropriate gain linearity.

The amplification of every amplifier can be programmed to be 3 or 6 and the maximum gain of the whole block is 6^4 = 1296. The multiplexer with bypass path is used if the desired stage gain is one. Therefore, it is possible to realize only the amplification which is the product of gains 1, 3 and 6 in 4 amplifiers. The final gain of the gain chain is gain multiplication of each stage, given by:

$$G_{final} = G_1 \cdot G_2 \cdot G_3 \cdot G_4 . \tag{2}$$

By setting the gains of the stages in the cascade amplifier, it is possible to optimize the quality of the measurements of small input currents.

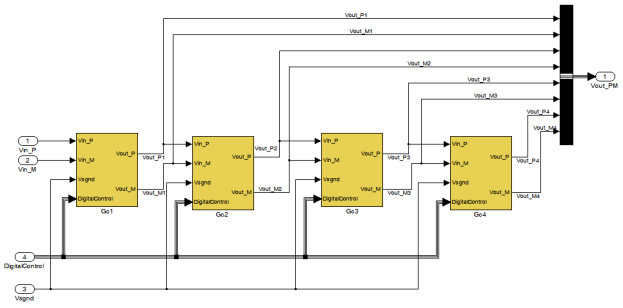

Figure 7. Model of the cascade amplifier.

As shown in Fig. 10 below, showing model of every amplifier in the cascade, each of these 4 amplifiers is controlled by 3 control signals *ph_gc*, *gain* and *ByPass* in the following way: when *ByPass*=0 and *gain*=1 then the gain is 6, when *gain*=0 then the gain is 3; when *ByPass*=1 then the gain is 1.

Each gain stage operates in two phases defined by the control signal *ph_gc*:

$$\begin{aligned} &A)\,\text{For } ByPass = 0 \\ &1)\; ph_gc = 1\ [\text{phase of samplig input signal } \Delta V_{in}(t)] \\ &\qquad \Delta V_{out} = V_{off} \\ &2)\; ph_gc = 0 \\ &\qquad \Delta V_{out} = -Gain\left[\Delta V_{in}(t-1) - \Delta V_{in}(t)\right] \\ &B)\,\text{For } ByPass = 1 \\ &\qquad \Delta V_{out} = \Delta V_{in}(t) \end{aligned} \tag{3}$$

The *noise factor* is a figure-of-merit for a circuit with respect to noise (see [6]–[8]), defined by:

$$F = \frac{S_i / N_i}{S_o / N_o} = \frac{N_o}{N_i} \cdot \frac{1}{A_a}, \tag{4}$$

where S_i and N_i are signal and noise powers at the input, respectively, while S_o and N_o are the same quantities at the output. A_a is system power gain.

If we consider a multistage amplifier (e.g. gain chain), where each stage has its corresponding noise factor F_1, F_2, etc., then the overall noise factor F of the cascade is given by the Friis formula (see [7], [8])

$$F = F_1 + \frac{F_2 - 1}{A_1} + \frac{F_3 - 1}{A_1 A_2} + \ldots + \frac{F_N - 1}{A_1 A_2 \cdot \ldots \cdot A_N}, \tag{5}$$

where A_1, A_2, …, A_N are the maximal power gains of each stage. From (5) and A_i>1; (i=1, 2, …, N) it follows that to minimize the noise factor F of the whole cascade structure, it is most important to have the first block with minimum noise factor F_1.

E. *Sample and Hold and Multiplexer block*

The sample and hold circuit is shown in Fig. 8. There is one control signal *ph_sh* that controls when the circuit takes the sample and when the circuit will let that sample propagate to the next block.

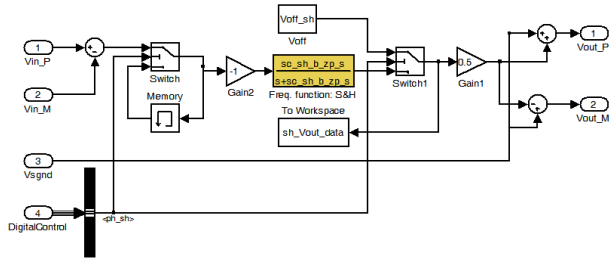

Figure 8. Sample and hold circuit.

The memory elements are capacitors that are charged and discharged, accordingly.

The multiplexer block, shown in Fig. 9, is controlled automatically depending on the state of bypass control bits, so user is not able to change or control block's functionality. The purpose of multiplexer block is to minimize impact of the amplifiers noise in the gain chain blocks in the case when gain = 1 by bypassing the particular gain stage or whole gain chain.

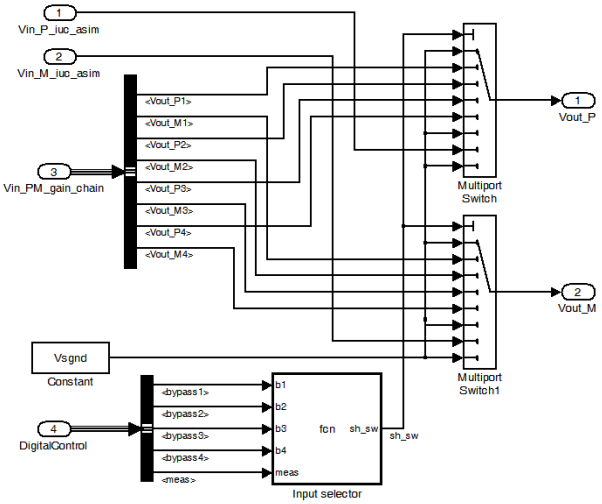

Figure 9. Multiplexer blok (Sample and Hold input selector).

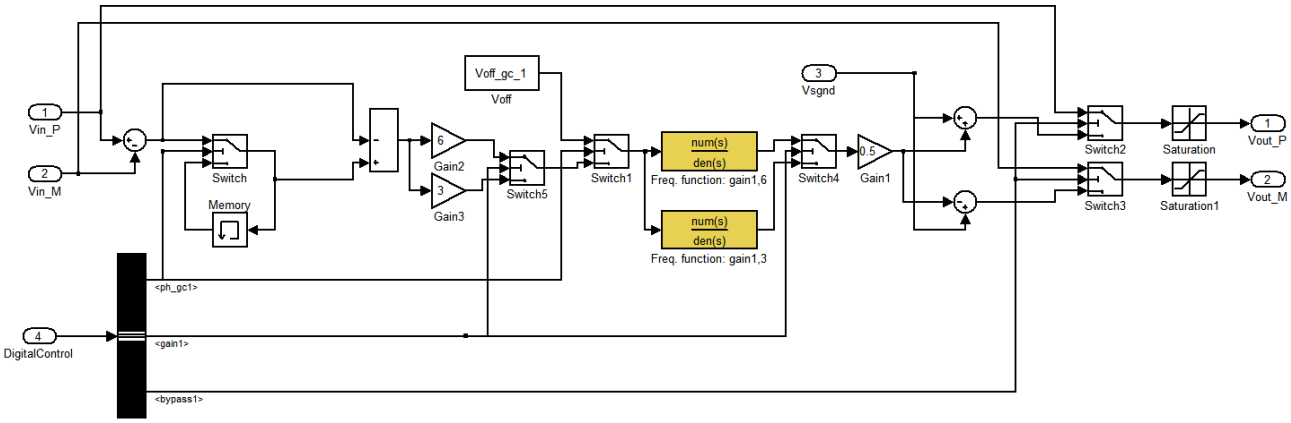

Figure 10. Model of every amplifier in the cascade.

F. Analog to digital converter

The last block in the chain is ideal analogue-to-digital converter and is shown in Fig. 11. It takes the voltage values stored in S/H circuit and converts them to a digital word. The digital word at the output has 13 bits, of which one bit defines the sign. The conversion is performed according to the formula

$$D_{Integer} = \frac{\Delta V_{in}}{V_{range}} \times 2^{N-1}, \qquad (6)$$

where V_{range} is the output voltage range, and N is the number of the bits (excluding the sign bit), and $D_{Integer}$ is integer value of binary output. Using MATLAB functions we convert measured values from the decimal to the binary system. Thus, we finally obtain a binary word displayed using 13 bits. Using a display in the model, the decimal value is shown too.

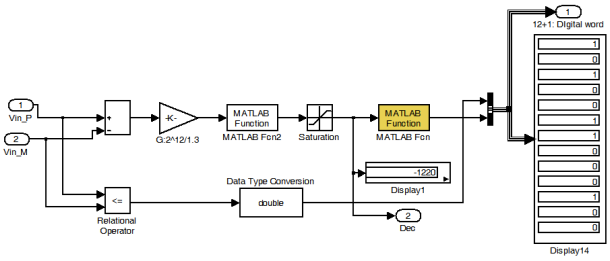

Figure 11. Analog to digital converter.

Finally, there also exist *digital control block* in the model, which contains all the signals with respective wave forms that control other blocks. The control waveforms are shown in Fig. 12.

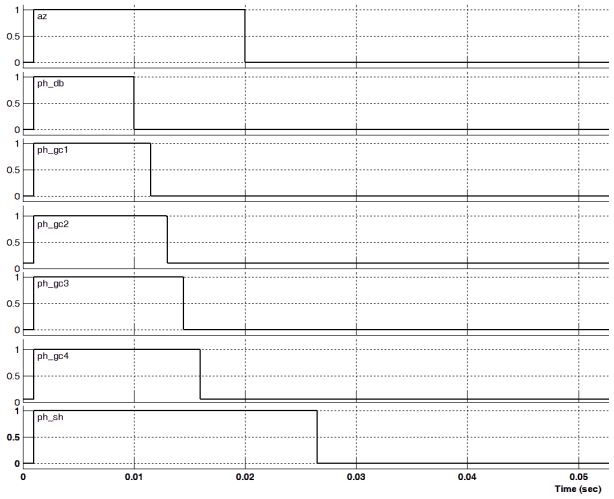

Figure 12. AZ and PH signals at control block.

IV. Operation Of The Model

Running the simulation of the system for small input currents measurement using the MATLAB/Simulink model is performed with *statistical* method of measurement, i.e. the statistical method will make the final calculation of measured quantity [4]. Small input current I_d is not uniquely determined because of the influence of the noise, but it is possible to calculate the mean value and deviation of a set of values obtained from multiple measurements (i.e. samples).

The optimized measurement means to determine the sufficiently large number of multiple measurements. By that, the method of measuring the output quantity with noise is to eliminate the noise by calculating the mean value and standard deviation. The measurement error and the quality of the resulting quantity (value of the mean) are determined by the number of measurements (*sample_size*), and the value of standard deviation. The standard deviation of the output quantity represents the value of RMS noise.

In the simulation of measurements, the automated multiple measurements are performed using a script in MATLAB [5]. As explained in the model description above, using signals *gain* and *ByPass* the gains in cascaded amplifier are determined. The simulations have been run for the gains of the whole system as G=1, 54, 324, 648 and the highest gain G=1296. The input current amount is used for simulation: I_d=5.124[μA]. The random noise generator is set at the input of the model adding the noise to the measured input current I_d.

The numbers (*sample_size*) of sequential running the simulation of the measurement are 5, 10, 20, 50 and 100 (the results are given in Table I). The mean values and standard deviations of the measurements are calculated using a script in MATLAB.

The mean value represents the measured value of the input current, whereas the standard deviation represents the value of the noise (RMS noise). This conclusion comes from the noise nature of a random signal with the normal (Gaussian) distribution of amplitudes and zero mean.

Consider the obtained mean values and standard deviations of the simulated measurements in Table I that vary as a function of gain and the number of measurements. In the case of higher gains (G=54, 325, etc.), the simulated input current at the input is divided by the total gain, in order to produce the same output digital value. In the columns "StdDev" standard deviations of the measurements are displayed and they represent the RMS value of the output noise. In the columns "Mean" the measured / simulated value of the signal (input current) is displayed in the digital form and is within the voltage range V_{range} defined by (6). The ± sign is dependent on the positive or negative gains of the amplifier stages, and it can be neglected (absolute value is used). It is shown that for higher gain the output RMS noise is also higher (higher standard deviation). With higher number of sequential measurements the obtained "Mean" values are nearer to the correct value of measured input current I_d.

V. Conlusion

In this paper we presented the model of a system for measuring small input currents. The model is built using MATLAB / Simulink and it is shown that it is possible to use such model to perform the simulation of the circuit solution that is the part of a mixed-signal IC chip. It is also shown that the noise is the limiting factor in measuring small input currents. The increased noise for higher gains produces the higher standard deviation. Given that the gains are large, and noise is also large, it is necessary to perform a larger number of sequential measurements of the same input value. According to the final value theorem (Gauss distribution), the calculated mean value (as the representative of measured input value) is reliable only after a sufficient number of measurements (see [4], [9]). The expected measurement error δ is given as:

$$\delta = \frac{\sigma}{\sqrt{N}}, \qquad (7)$$

where σ is the standard deviation and N the number of performed sequential measurement.

Therefore, if the standard deviation as a measure of noise is lower, the required number N of sequential measurements (sampling) is also lower. Conversely, if the standard deviation is higher (higher level of noise that comes with higher gain), to have the same level of measurement error, more measurements are needed to be performed and finally the correct mean value can be calculated, reliably representing the measured value (trusted value) [4].

Abstract - The development of production and increasing usage of light electric vehicles such as electric bicycles and electric scooters entails development of batteries, battery chargers and fast charging algorithms. Batteries with different nominal electrical characteristics and production technologies are currently in use. Among them, lithium - iron batteries are increasingly being used. The differences in basic characteristics of batteries and standardization issues require fast identification of various battery types and adapting of charging algorithms according to nominal current, voltage, capacity and state of charge.
This paper describes a method for determining the nominal current for unknown $LiFePO_4$ battery connected to the stationary filling station for charging electric bicycles. A prerequisite for determination of the rated current is identification of current-voltage curve at the moment of connection and identification of the number of cells. The algorithm for determining these parameters is given in the first part of the paper. The second part deals with determination of the nominal current for $LiFePO_4$ battery based on current-voltage response to the selected battery charging algorithm.

I. INTRODUCTION

Light electric vehicles (LEV) are more and more used for transportation of people and goods, especially in urban environments, tourist resorts and protected national or nature parks. Different kind of rechargeable battery types are used for main and auxiliary drives power supply, but lithium-ion based batteries are increasingly used due to their high energy density and compact size [1]. Other battery types, such as Lead-acid, NiCd and NiMH, are still used because of the significantly lower prices. Lithium iron phosphate batteries ($LiFePO_4$) are the safest and with longer cycle life than any other lithium-ion based battery. It has excellent thermal and chemical stability [2] as well so it is expected that $LiFePO_4$ battery will be widely used as energy storage element especially when it comes to portable electronics.

Necessity for light electric vehicles will increase in the near future so there is a need to develop infrastructure i.e. stationary filling stations network. Filling stations would enable user not to just recharge his vehicle battery at many different locations but also to recharge it fast. Main problem with it is that there is no standard present at the moment that defines battery type, nominal voltage, capacity and discharge rate of a battery that would be used in such a vehicle. Since charging has to be done as fast as possible an algorithm has to be developed to determine basic battery parameters and adjust charging algorithm according to them so that the battery would not be damaged or destroyed. Battery can be seriously damaged if its temperature rises above normal rated working temperature [3]. So battery charging algorithm has to be tuned in such a way to transfer most of its energy in form of battery capacity and as less energy possible in form of temperature. Pulse charge method reduces polarization and thus decreases battery temperature rise [4, 5]. Stationary filling stations will not be able to measure battery temperature since most of the LEVs does not have any kind of communication interface. So it is important to determine battery nominal current to tune pulse charging algorithm in a way that we can be sure that battery temperature will not exceed upper limit value.

II. EXPERIMENT SET UP

A. Battery

Batteries convert electrochemical energy to electrical energy with utilization of chemical reactions of oxidation and reduction. During the process, energy losses occur due to dipole polarization, ion migration through electrolyte, uneven ion concentration, accumulation of by products in the nearby of electrodes and electric resistance of electrodes. So, voltage-current relation depends mostly on chemical reaction parameters, not electrical. That is why there is no unique equivalent electrical model of a battery and they differ according to battery type and parameters which have to be observed and analyzed. Equivalent battery model that we use for battery voltage-current and voltage - open circuit voltage (OCV) relations is shown in Fig. 1. E_{m0} voltage source represents OCV of a battery. First RC parallel compound models battery voltage change as state-of-charge (SOC) changes and the second one models significant battery voltage rise when SOC of battery converges to 100%. Resistance R_0 models battery energy losses that linearly increase with load. Current source I_p models battery response when it is in the state of saturation and/or repletion by injecting current to the equivalent electrical model of a battery [6].

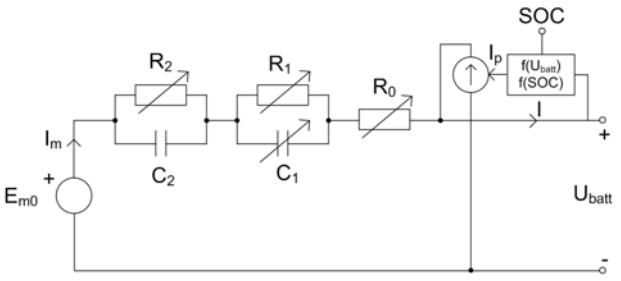

Fig 1. Equivalent electrical model of a battery

Battery terminal voltage equals:

$$U_{batt} = E_{m0} + U_{R0} + U_{R1} + U_{R2}, \quad (1)$$

where

$$U_{R0} = (I + I_p) \cdot R_0. \quad (2)$$

Total RC compound current is

$$i(t) = i_{Cx}(t) + i_{Rx}(t) = C_x \cdot dU_{Rx}/dt + U_{Rx}/R_x \quad (3)$$

so compound voltage can be expressed as

$$U_{Rx}(t) = (I + I_p) \cdot R_x - R_x C_x \int dU_{Rx}. \quad (4)$$

Thus, current-voltage relations of an equivalent model of a battery is stated as follows:

$$U_{batt}(t) = E_{m0} + (I + I_p) \cdot (R_0 + R_1 + R_2) - R_1 C_1 \int dU_{R1} - R_2 C_2 \int dU_{R2}. \quad (5)$$

Laboratory experiments were performed on the $LiFePO_4$ batteries that consists of cylindrical power cells. Batteries that were tested have different parameters and number of cells. Cells parameter specification is shown in Table I.

TABLE I. CELL PARAMETER SPECIFICATION

$LiFePO_4$ power cell		
	Battery 1 (Cell)	**Battery 2 (Cell)**
Parameter	***Value***	***Value***
Nominal capacity	10000mAh (0,5C)	15000mAh (0,5C)
Nominal voltage	3.2V	3.25V
Inter impedance	≤10mΩ	≤8mΩ
Maximum charge current	3C (30A)	2C (20A)
Maximum charge voltage	3.65 ± 0.05V	3.65 ± 0.05V
Discharge stop voltage	2.0V	2.2V
Work temperature - charge	0~45ºC	0~45ºC
Work temperature - discharge	-20~60ºC	-20~60ºC

B. *Control, Power and Measurement*

Block schematics of elements and connections used in experiment is shown in Fig. 2. Charging algorithm is developed using *Matlab* software which is in charge of controlling *Magna* current source. Communication is established using TCP/IP communication protocol and control using SCPI commands. *Magna* current source is connected directly to battery terminals by means of 16mm^2. To eliminate any errors due to voltage drop in power supply cables, output current source voltage is externally measured at the battery terminals.

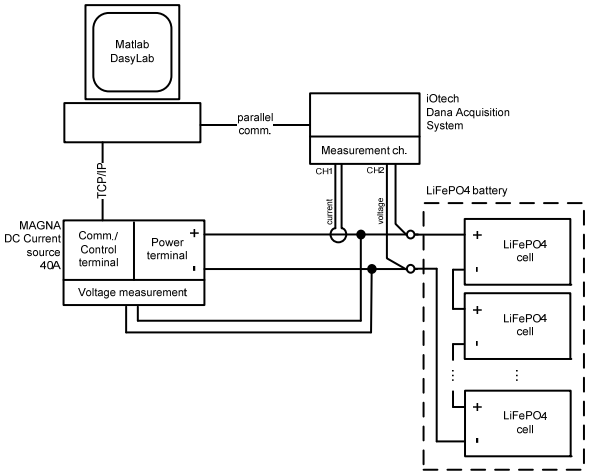

Fig. 2. Block schematics of experiment set up

iOtech WaveBook Data Acqusition System is used for recording battery voltage and current during charging process. *WaveBook* is configured using *DasyLab* software which is also used for data analyses.

III. OBSERVATION AND RESULTS

$LiFePO_4$ battery OCV - SOC relation can practically be divided in three areas depending on the SOC (as SOC changes from 0-100%): aperiodically, linear and exponential voltage increase area, Fig. 3.

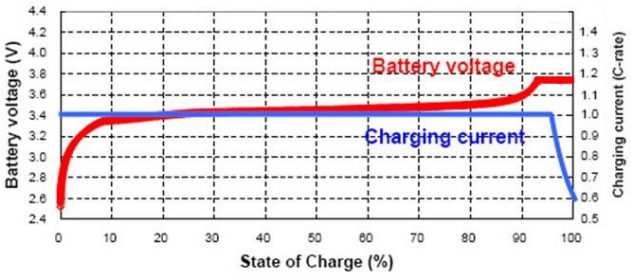

Fig. 3. OCV - SOC curve - aperiodical, linear and exponential voltage increase

While applying impulses of current to the battery we can observe the change of battery terminal voltage gradient to determine in which of those three areas of OCV - SOC curve battery momentarily is. Relation of initial voltage gradient in order to the SOC of the battery (charging current equals 0.5C) is shown in Fig. 4.

When the battery is in the exponential voltage increase area of OCV - SOC curve it basically means that

is already fully charged and no additional charging is required. Contrary to that, if the battery is in the area of aperiodical voltage increase, it means that the battery is almost completely empty.

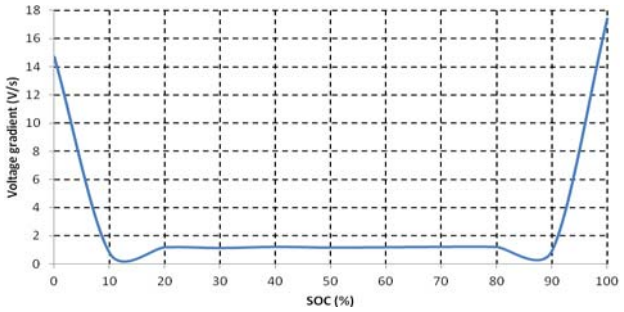

Fig. 4. Initial voltage gradient in relation to SOC (charging current = 0,5C)

To be able to make any conclusions, battery first needs to be charged until it reaches linear voltage increase area of OCV-SOC curve. Since $LiFePO_4$ battery accepts charge very well when it is discharged to low SOC values, transition to linear area can be done in under a minute.

When we reach this linear area and then apply charging current (up to 0.9C) battery cell terminal voltage value is certainly in the span of 3.2 and 3.4V. Uncertainty of 0.2V allows us to determine number of cells[1] of the battery if it has up to n = 16 cells. Because of all of the other uncertainties in the system, this number in practice is n = 14. Information of number of battery cells is important for nominal current determination because it is based on fixed terminal voltage levels of a battery cell. Voltage measured at the battery terminals is scaled down to single cell voltage level and that is one of entry values of the nominal current determination algorithm. Since number of cells determination is already done, we can be sure that the battery is in the linear area of OCV - SOC curve. Under this condition, when constant current is applied to the battery, its terminal voltage will at first start to aperiodically[2] increase up to a certain level. This takes some time, after which voltage continues its slow linear increase (Fig. 5.). Figure 5. also shows an example of how voltage gradient differs when different charging current is applied (at the same SOC).

Linear increase slope is so small that voltage is practically constant value until battery reaches SOC of nearly 100%. As the input current increases, voltage level increases accordingly, Fig. 6.

Experiment included charging of the batteries of different kind of nominal voltage and nominal parameters with following input current values: 0.5C, 0.8C, 1C, 1.2C, 1.5C and 2C. The results are shown in Table II.

[1]It is meant on number of cells connected in series within one branch of a battery.

[2]This aperiodical voltage increase mustn't be confused with aperiodical voltage increase at very low SOC. They differ by battery terminal voltage gradient behavior when charging current is applied. In this case we already know that the battery is in the linear area of OCV-SOC curve and no further check is required.

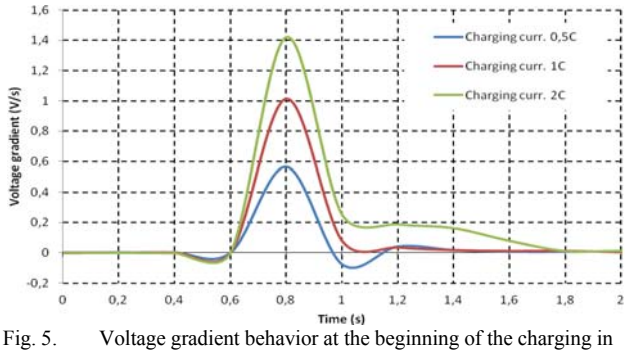

Fig. 5. Voltage gradient behavior at the beginning of the charging in relation to different charging currents at the same SOC

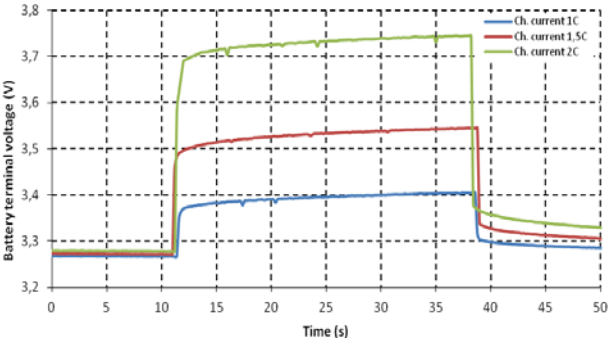

Fig. 6. Battery terminal voltage in relation to charging current

For every experiment that was conducted with defined current values, battery terminal voltage is within boundaries shown in Table II. Since battery terminal voltage rise is not stepwise, we also monitor battery terminal voltage gradient during its aperiodical increase. Most right column of the Table II. shows maximum gradient that appeared during experiments for specified current values.

TABLE II. EXPERIMENT RESULTS

Charging current	Battery terminal voltage span (V)	Battery terminal voltage gradient span (mV/s)
0.5C	3.22 - 3.28	≈ 0
0.8C	3.26 - 3.33	≤ 0.9
1.0C	3.35 -3.43	≤ 2.53
1.2C	3.41- 3.49	≤ 3.32
1.5C	3.55 - 3.65	≤ 4.44
2.0C	3.65 - 3.75	≤ 9.0

Having information of voltage levels and voltage gradient behavior allows us to determine nominal current of a battery up to a certain level of accuracy. This level of accuracy is good enough for setting initial parameters of pulse charging algorithm. The aim that we aspire to is to determine nominal current to a better accuracy level throughout pulse charge algorithm and then adjust parameters according to new input values. Adapting the pulse charge algorithm while actually charging the battery decreases necessary charging time.

IV. $LiFePO_4$ BATTERY NOMINAL CURRENT DETERMINATION ALGORITHM

Fig. 7. shows nominal current determination algorithm. Values of current, time and voltage gradients boundaries are set according to common batteries available in market for LEV-s and experience gained during the laboratory experiments.

At the very beginning of the algorithm process, small charging current is applied and it is increasing stepwise while voltage gradient is being monitored. If gradient reaches 100mV/s, its value is memorized and the process is repeated once more. In the case that gradient exceeds 100mV/s value again, it means that the battery is either in the state of aperiodical voltage increase or in the state of exponential voltage rise. We can differ these two states by comparison of two voltage gradient levels that have just been measured. If its value has risen it means that the battery is in the exponential area i.e. it is already fully charged and thus, charging process is finished. However, if it has reduced, battery is in aperiodical area and needs to be charged until it reaches linear voltage increase area. We consider that the battery has reached that area when the voltage gradient reduces under the value of 1mV/s. In the case that gradient value doesn't exceed 100mV/s at all, battery is already in the state of linear voltage increase so we can proceed to battery nominal current determination.

A 30 second pause follows to let the battery terminal voltage to come near to steady state value and then the determination begins. At first, charging current of 5 amps is applied to the battery terminals since it is the smallest expectable nominal current value of electric bike batteries. As algorithm proceeds, current is increasing in steps of 1 amp every 5 seconds. During that process voltage and voltage gradient are analyzed and compared to data from the database (Table II.). When voltage level and its gradient correspond to the values in the Table II., row 3 (charging current of 1.0C), temporary charging current is considered to be nominal.

Nominal current value is the output of this algorithm and the input of the pulse charging algorithm which is yet to be developed.

CONCLUSION

Experimental tests performed on LiFePO4 power cell batteries show recognizable behavior of battery terminal voltage in relation to input current. Thus, conclusions of number of battery cells and their nominal current can be made. A $LiFePO_4$ battery nominal current determination algorithm has been proposed. Determined nominal current is used as initial condition for adjusting the pulse charge algorithm. Pulse charge algorithm must be developed in such a way to adapt its initial parameters during charging process according to new data obtained out of constant measurements.

100 nA Power Management Circuit for Energy Harvesting Devices

D. Vinko and G. Horvat
University of Osijek, Faculty of Electrical Engineering, Department of Communication, Osijek, Croatia
davor.vinko@etfos.hr

Abstract – This paper presents a power management circuit suitable for energy harvesting devices. Energy harvesting methods provide very low instantaneous power which is not sufficient to continuously power a wireless sensor node. Presented power management circuit is designed to turn on the wireless sensor node when the voltage across storage capacitor reaches 5 V and turns it back off as the voltage drops to 4.5 V. In such operating conditions maximal current that power management circuit draws is under 100 nA. Laboratory model of a power management circuit is realized and the performance measurements for various inputs were conducted. Additionally, a mathematical model of the power management circuit is derived and compared with measurement results.

I. INTRODUCTION

Energy harvesting is gaining more popularity as an energy supply for low power electronics. Various applications in powering wireless sensor nodes [1]-[3] have been reported. Energy harvesting, also known as power scavenging, uses variety of methods to generate useful power. Most common methods of energy harvesting include harvesting energy from RF radiation, ambient light, vibration, small scale wind energy harvesting, thermal energy, and bioelectricity. All of these energy harvesting methods are able to provide low instantaneous power. Available instantaneous power ranges from 1 µW to 5 mW [4], [5].

Majority of the applications require higher instantaneous power. For example, wireless sensor nodes require up to 60 mW as peak power consumption while the RF part of wireless sensor node is active [6]. Since energy harvesting methods cannot be used as continuous power supplies, they can be used in applications where real-time response is not required.

Wireless sensor nodes can be used to monitor weather. It is sufficient for a wireless sensor node to send the data at a very low sampling rate (e.g. weather information; couple of times per hour). This means that a sensor node can collect and store harvested energy over a longer period of time, and use stored energy for a short active period for data transmission. For that an additional power management circuit is needed which monitors the amount of harvested (stored) energy and which turns on the sensor node when enough energy has been harvested.

Power management circuit acts as mediator between energy harvesting circuit and the load. Main design guideline for power management circuit is to reduce the circuit power consumption to a minimum. Significant percentage of energy harvesting methods can only provide instantaneous power in the range of few tens of µW, therefore the power management circuit must be designed with even lower power consumption. This ultra-low power consumption requirement refers to a period during which the device collects and stores energy from energy harvesting circuit.

Common energy harvesting circuit comprises of energy harvester followed by voltage multiplier, rectifier circuit and storage capacitor [7]. Voltage multiplier uses low amplitude AC voltage from energy harvester and generates higher DC voltage. The energy harvesting circuit (together with voltage multiplier) can be replaced and modeled with Thevenin voltage and resistance. Without loss of generality, Thevenin voltage can be set in the range of 10 V, while the Thevenin resistance must correspond to the reported instantaneous power available from various energy harvesting methods. For available power ranging from 1 µW to 5 mW, the Thevenin resistance ranges from 50 MΩ to 10 kΩ, respectively, giving maximal instantaneous DC current of energy harvesting circuit from 200 nA to 1 mA.

Load circuit is intended as a low power electronic device, such as wireless sensor node. With inherently nonlinear power consumption profile (power up, active operation, RF activity), the maximal power consumption is reported during RF activity [8] and is under 100 mW. To model a majority of available wireless sensor nodes, the load circuit can be modeled as a device which requires 5 V supply voltage and 50 mA continuous current, which gives an average power consumption of 250 mW [9].

Additionally, as the load circuit operates in cycles, device powered using power management circuit can be modeled by the energy required to complete a single operating cycle. Such modeling enables optimization of energy storage and power management, what will be discussed in more detail in following section of the paper.

This work was sponsored by J. J. Strossmayer University of Osijek under project "Passive Wireless Sensor Network".

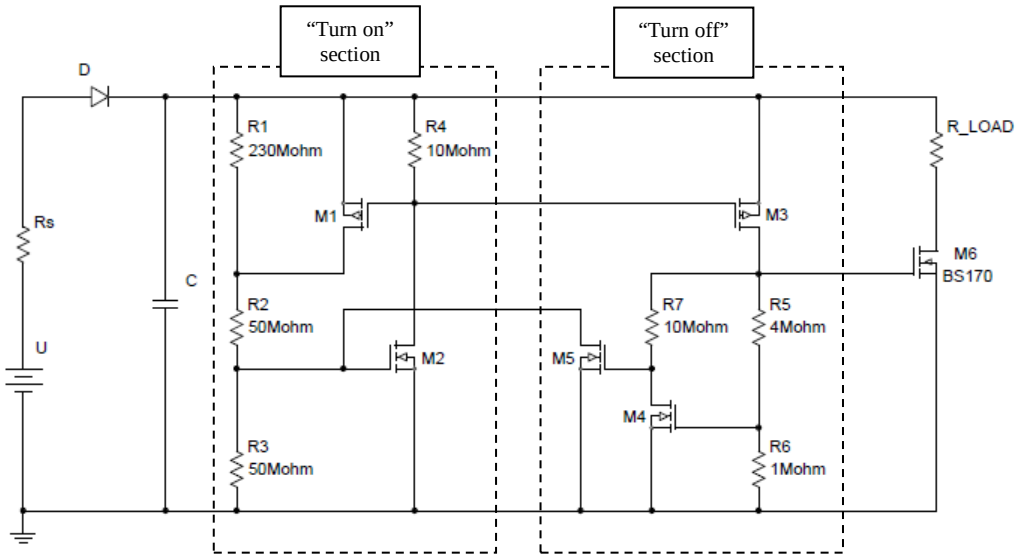

Figure 1. Schematic of the power management circuit

II. Power Management Circuit

The schematic of proposed power management circuit (PMC) is given in Fig. 1. Voltage source U and resistor R_S represent the energy harvesting circuit, while resistor $R_{_LOAD}$ represents a load circuit. Diode D serves as a rectifier and capacitor C is storage element which collects harvested energy.

There are two operating phases of power management circuit: the charging phase and the discharging phase. In charging phase the energy harvester is charging the capacitor C with disconnected load. In discharging phase, the energy stored in capacitor C is used to supply the load. This way an energy harvesting method with low current capability can be used to power a load with higher current demand.

The PMC is divided in two sections: "Turn on" section and "Turn off" section, which monitor charging and discharging phases, respectively. "Turn on" section uses voltage divider (resistors R_1, R_2 and R_3) to monitor the voltage across capacitor C during charging phase. High value resistors were used to minimize the power consumption during charging phase. This is important due to fact that the majority of energy harvesting methods is only able to provide instantaneous power in the range of few tens of µW [3].

When the voltage across capacitor C reaches "turn on" level, the transistor M_2 turns on and pulls gates of M_1 and M_3 to the ground, thus turning them on and starting the discharging phase. Transistors M_3 acts as a switch for "Turn off" section and also for the load circuit (represented with resistor $R_{_LOAD}$ on Fig. 1). Load can be driven directly by transistor M_3 or by additional transistor M_6 which can supply higher load current. Transistors M_1 to M_5 are CMOS transistors integrated in HCC4007UB integrated circuit and their maximal drain current is in the range of few mA. To test the PMC with loads that require up to 50 mA, the additional transistor BS170 (M_6 in Fig. 1) with maximal drain current of 500 mA is added.

With connected load circuit the charge stored in capacitor C discharges and voltage across capacitor drops. Voltage divider (R_5, R_6) in "Turn off" section keeps transistor M_4 turned on as long as voltage across capacitor C is above "turn off" level. When the voltage across capacitor C drop below "turn off" level, transistor M_4 turns off, causing transistor M_5 to turn on. M_5 then turns off transistor M_2, which turns off all transistors in PMC, and starts the charging phase again.

In applications such as wireless sensor networks, the energy harvesting is used to power the wireless sensor nodes. For each sensor node the energy required for one operating cycle can be measured. With known required energy the needed capacitance of capacitor C value can be calculated.

Energy consumption ΔE of a load circuit during discharge phase is equal to difference of energy stored in capacitor C at the beginning (E_{max}) and at the end (E_{min}) of discharging phase, (1).

$$\Delta E = E_{max} - E_{min}\,. \tag{1}$$

With capacitor C charged to a voltage level U, the energy stored in capacitor is equal to:

$$E = \frac{1}{2} C U^2 \tag{2}$$

and the energy consumption ΔE can be derived from maximal and minimal capacitor voltage levels (U_{max} and U_{min}) , which correspond to a beginning and the end of the discharging phase:

$$\Delta E = \frac{1}{2} C \left(U_{max}^{\ 2} - U_{min}^{\ 2} \right). \tag{3}$$

From (3), for known required energy per operating cycle, a needed capacitance value can be expressed as:

$$C = \frac{2\Delta E}{U_{max}^{\ 2} - U_{min}^{\ 2}}\,. \tag{4}$$

A. *Mathematical Model of charging process*

Charging process of proposed power management circuit is modeled by schematic given by Fig. 2.

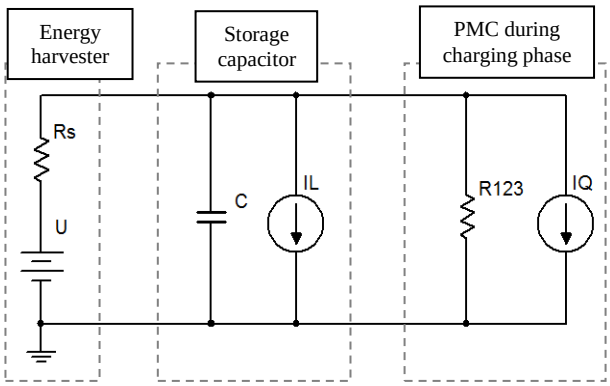

Figure 2. Charging process model

Energy harvester is modeled as voltage source U with series resistance R_S (equal to Fig. 1.). Leakage current of storage capacitor is modeled as current sink I_L. During charging phase the only active part of the power management circuit is resistive divider (R_1, R_2 and R_3) which is represented as their series equivalent R_{123}. Additional current sink (I_Q) was added to represent quiescent current found in CMOS transistors used in PMC (IC HCC4007UB).

Differential equation of the charging process equals to:

$$\frac{du_C}{dt}+u_C\frac{1}{C}\left(\frac{R_S+R_{123}}{R_S R_{123}}\right)=\frac{U-R_S\left(I_L+I_Q\right)}{R_S C}. \quad (5)$$

When solved, the expression for voltage across storage capacitor during charging phase is:

$$u_C=\left[U-R_S\left(I_L+I_Q\right)\right]\frac{R_{123}}{R_S+R_{123}}\left(1-e^{-\frac{R_S+R_{123}}{R_S R_{123}C}\cdot t}\right). \quad (6)$$

Time needed to charge a storage capacitor to a certain voltage level U_C is:

$$t_{U_C}=-\frac{R_S R_{123}C}{R_S+R_{123}}\ln\left(1-\frac{U_C}{U-R_S\left(I_L+I_Q\right)}\cdot\frac{R_S+R_{123}}{R_{123}}\right). \quad (7)$$

Unknown values of leakage current I_L and quiescent current I_Q can be calculated using measured time t_{Uc} needed to charge the storage capacitor C to a voltage level U_C:

$$I_L+I_Q=\frac{U}{R_S}-U_C\frac{R_S+R_{123}}{R_S R_{123}}\left(1-e^{-\frac{R_S+R_{123}}{R_S R_{123}C}\cdot t}\right)^{-1}. \quad (8)$$

Maximal achievable voltage across storage capacitor is then:

$$U_{C_{MAX}}=\left[U-R_S\left(I_L+I_Q\right)\right]\frac{R_{123}}{R_S+R_{123}}. \quad (9)$$

III. MEASUREMENT RESULTS

Experimental verification of presented power management circuit is performed on laboratory model using discrete components. The power supply U and R_S (Figs. 1. and 2.) represents energy harvester. Reported energy harvesting methods [4], [5], [7] significantly vary in output voltage (and output current) they can provide. Also, various approached are used to ensure voltage levels sufficient to power wireless sensor nodes. Depending on voltage levels available from energy harvester some use voltage multipliers (lower voltage levels from energy harvester) and some voltage down converters (higher voltage levels from energy harvester). Therefore, without any loss of generality, a power supply (U and R_S) used in measurements can be set to a fixed value of U = 10 V, while the series resistance R_S is varied during measurements to provide wider range of energy harvester output current. With R_S ranging from 10 kΩ to 50 MΩ a maximal output current of energy harvester ranges from 1 mA to 200 nA, respectively. Then the maximal instantaneous power that energy harvester can provide ranges from 5 mW to 1 µW, which is in concordance with reported energy harvesting methods [4], [5].

Values of resistive dividers (R_1, R_2, R_3 and R_5, R_6) were chosen as such that the load circuit turns on when the voltage across capacitor reaches 5 V, and turns back off when the voltage drops to 4.5 V. This can be seen in Fig. 3 which shows the voltage across storage capacitor (upper trace) and voltage across load circuit (bottom trace).

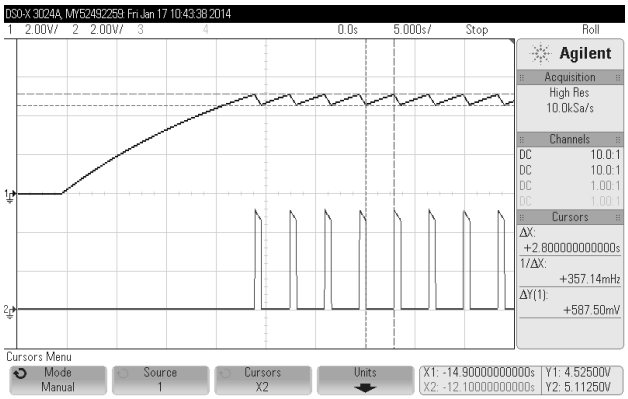

Figure 3. Voltage across storage capacitor and load circuit

Measurement shown in Fig. 3 is done with storage capacitor C = 470 µF, resistor R_S = 50 kΩ and resistive load $R_{_LOAD}$ = 10 kΩ. With measured turn on and turn off voltage levels equal to 5.1125 V and 4.525 V, respectively, the energy delivered to resistive load per operating cycle is equal to 1.3 mJ (3). This amount of energy is sufficient to power one operating cycle of wireless sensor node [6], [9].

With resistor R_S = 50 kΩ the measured charging time between two operating cycles of PMC is 2.8 seconds. With higher values of R_S the charging time is increasing, due to lower current available from energy harvester. To find a minimal current from energy harvester sufficient to charge storage capacitor and power a resistive load in repetitive cycles the following measurement is conducted. Resistor R_S values were varied from 10 kΩ to 5 MΩ for the PMC with storage capacitor C = 470 µF, and the

charging time between cycles is measured. Besides charging time, it is important to measure the "on" and "off" voltage levels so that the measurement results can be compared with mathematical model of the presented circuit (7).

Results are shown in Fig. 4. Due to high capacitor value (C = 470 µF) and low charging current, the charging time is rather large and is in the range of several minutes (for higher values of R_S). Since the charging time is measured by oscilloscope (Agilent DSO-X 3024A) where maximal time interval which can be measured is 500 s, minimal operating current could not be measured.

Therefore, to reach minimal operating current, additional measurements were performed with higher values of R_S and lower capacitance of storage capacitor C = 1 µF. Fig. 4 also shows calculated charging time values using mathematical model (5)-(8). Parameters in mathematical model also include leakage current I_L and quiescent current I_Q whose values are unknown. In order to extract correct I_L+I_Q value from measurements, the following expression is derived from (7):

$$I_L + I_Q = \frac{U}{R_S} - \frac{R_S + R_{123}}{R_S R_{123}} \cdot \frac{U_{on} - U_{off} e^{-\Delta t \frac{R_S + R_{123}}{R_S R_{123} C}}}{1 - e^{-\Delta t \frac{R_S + R_{123}}{R_S R_{123} C}}}. \quad (10)$$

With higher R_S (lower input current) the impact of leakage and quiescent currents is more emphasized. R_S value is increased up to a point where the storage capacitor could not reach the turn on voltage. The measurement results for the highest value of R_S at which the PMC could still operate were then used to calculate I_L+I_Q value. This point is marked by an arrow in Fig. 4. Using measured values of charging time, "turn on" and "turn off" voltage levels, the value of I_L+I_Q = 61.87 nA is calculated from (10).

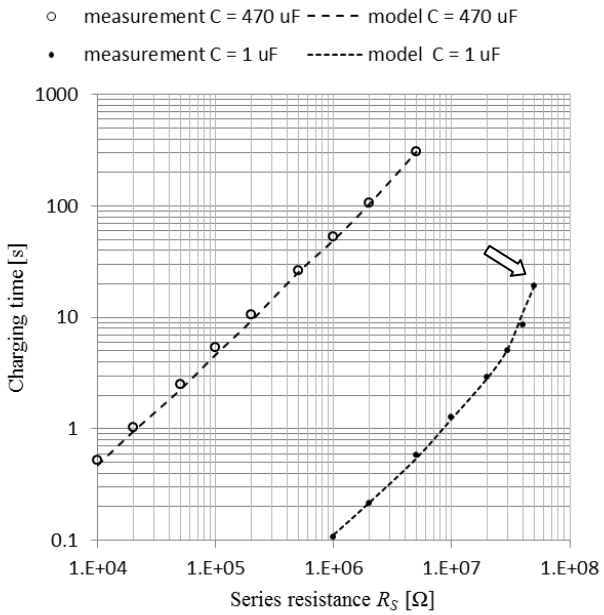

Figure 4. Comparison of measured and calculated values of storage capacitor charging time for different values of resistance R_S

Component datasheets provide wide range for both leakage and quiescent current values. Leakage current value for tantalum capacitor ranges from 0.01 nA/µFV to 10 nA/µFV, with typical value being 0.1 nA/µFV. For a presented PMC with maximal voltage across storage capacitor of 5 V and capacitance of 1 µF, the leakage current ranges from 0.05 nA to 50 nA , with typical value of 0.5 nA. Quiescent current for HCC4007UB integrated circuit ranges from 10 nA (typical value) to 250 nA (maximal value). The calculated value of I_L+I_Q = 61.87 nA is well within values provided by component manufacturers.

Together with current drawn by voltage divider R_{123}, the overall current demand of PMC during charging phase is well under 100 nA. This is in concordance with value of R_S = 50 MΩ at which the PMC could still operate. Namely, with turn on voltage level U_{on} = 5 V, the maximal current from energy harvester at the end of the charging phase is 100 nA.

Such ultra-low current consumption (together with storage capacitor of 470 µF) ensures that ripple voltage from voltage multiplier/rectifier (in paper represented by DC voltage source U) stays under 100 µV. With 0.5 V difference between turn on and turn off voltage level, ripple voltage has almost no effect on the performance of the PMC.

IV. CONLUSION

Presented power management circuit is designed to act as a biasing circuit between energy harvester and wireless sensor node. The harvested energy is collected over a longer period of time, and when sufficient energy is stored, it is used to power a wireless sensor node for a short time interval. Measurements on laboratory model of power management circuit are performed and results agree with proposed mathematical model. With operating voltage level of 5 V, maximal current that power management circuit draws is under 100 nA. This makes it suitable for usage with almost all energy harvesting methods, since it can operate with 1 µW of input power.

The future work will address the issue of rather high quiescent current in more detail. The aim is to reduce current consumption of power management circuit even further by implementing devices with lower quiescent current.

***Abstract*—This paper presents the system for the evaluation of operation of a depletion-mode silicon carbide (SiC) power junction field-effect transistor (JFET). The main part of the system is a dc-dc step-down converter which represents realistic operating conditions for the switching devices in a synchronous buck configuration. In order to test the importance of the dead-time value on the operation and efficiency of the synchronous buck converter, a precise two-channel time-delay pulse signal generator is developed and its operation is described. The ability to precisely regulate control signal parameters of the high-side FET and low-side FET (switching voltage and current, operating frequency, duty cycle, dead-times, etc.) is needed in order to fully characterise SiC power switches. The functionality of the complete system is verified by measurements performed under various operating conditions.**

***Index Terms*—SiC JFET, buck converter, time-delay signal generation**

I. INTRODUCTION

In switched-mode power supply systems (SMPS), switching devices are submitted to a broad range of switching frequencies as well as voltage and current levels at their terminals. Although silicon (Si) power switching devices have been used in the industry for many years, their switching behaviour is far from being ideal. The two most disadvantageous effects, high voltage drop during on- and high leakage current during off-state, significantly increase power losses, i.e. reduce the highest achievable power conversion efficiency. The most important advantages of SiC power devices over silicon ones include capability of sustaining high voltages and currents, operation at higher frequencies, higher thermal conductivity and, consecutively, lower on-resistance [1].

In order to realize a SiC power switch having the best possible characteristics, the status of the developed SiC power devices is being frequently reviewed [2]–[5]. It has been shown that SiC MOSFET would be the device of choice as soon as the SiO_2/SiC interface and reliability issues are solved. On the other hand, operation of the JFETs is not dependent on the quality of gate dielectrics, but relies primarily on pn-junction performance [2]. In this way, SiC JFET designs are still more interesting for power switching applications, because of the higher quality of the conduction channel, achievable low on-resistance, high-frequency operation and high-voltage endurance.

The normally-on property of a depletion-mode JFET counts as a main drawback when this device is used in a dc-dc converter. However, the enhancement-mode (normally-off) JFETs require a narrow and relatively low doped channel to ensure the normally-off property which disturbs the on-state performance [6]. Moreover, the normally-off SiC JFET requires a more complex gate driver circuit in terms of a significantly larger gate voltage that is required to fully turn-on the device [7], [8]. Therefore, in order to completely exploit the advantages of the SiC transistor technology, the focus of the SMPS design is set on the depletion-mode (normally-on) SiC power JFETs. It is possible to turn a normally-on behaviour of the SiC JFETs into a normally-off by using a „Baliga-pair“ (Si MOSFET/SiC JFET cascode switch) [1]. The behaviour of „Baliga-pair“ is well known and studied in depth [7], [9]–[11]. It was shown that this cascode is suitable for operation of the normally-on SiC JFET, at the expense of increase in total on-resistance. In order to reduce the on-resistance and increase the switching speed, the driving circuit should be capable of providing high voltage and current to the cascode switch.

Section II presents an overview of the developed evaluation system based on a synchronous buck dc-dc converter. Section III presents the developed dual-channel precise time-delay signal generator used to estimate an influence of the driving signal parameters on the operation of the device under test (DUT). The functionality of the

complete system is verified by the measurement results given in Section IV. The conclusion is given in Section V.

II. The SiC JFET Evaluation System

In order to characterise the behaviour of the SiC JFET as a power switch, a synchronous buck converter capable of high input voltages and currents and very fast switching speeds is developed. The system is mainly based on the Semisouth SSJHB12R085-1 evaluation board [12]. As a device under test (DUT) which is to be characterised and used to prove the functionality of the evaluation system, the SJDP120R085 SiC JFET in a TO247 package produced by Semisouth Laboratories is chosen. It has a breakdown voltage of 1200 V and an on-state resistance of 0,085 Ω. The pinch-off voltage equals -5 V while the reverse gate breakdown voltage is -15 V [13]. The DUT is placed in a „Baliga-pair“ configuration together with the Infineon's BSC059N04LS power MOSFET. This MOSFET has an on-resistance of 5,9 mΩ and is capable of sustaining a drain current of 73 A and a drain-source voltage of 40 V. A gate-source threshold is 1,5 V and a gate-source breakdown voltage equals ±20 V.

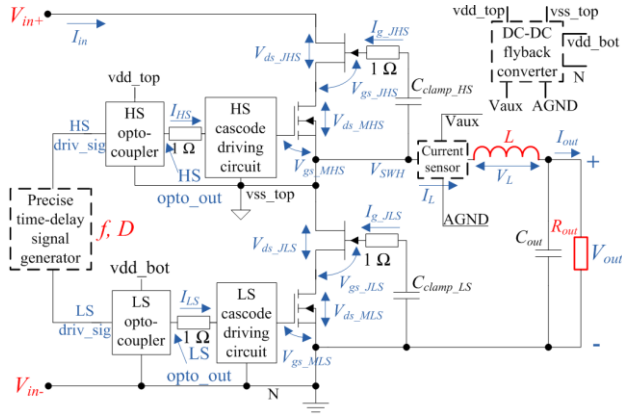

Fig. 1. Simplified circuit diagram of the SiC JFET evaluation system.

The simplified circuit diagram of the developed system is shown in Fig. 1. The central part of the system is the synchronous buck converter with corresponding driving circuit. The synchronous dc-dc converter contains high-side (HS) and low-side (LS) SiC JFET power switch, in the aforementioned cascode configuration, which operation is to be evaluated. The traditional cascode switch circuit exhibits some disadvantages like limited control of the switching speed [14], [15], so the capacitor-clamped cascode is used. The capacitors C_{clamp_HS} and C_{clamp_LS} store the Miller displacement charge during turn-off and then recycle this charge at turn-on to quickly charge the SiC JFET input capacitance for a fast turn-on transient [12], [14]. Both driving signals, generated by the precise time-delay signal generator, are optically coupled to the cascode driving circuit. The externally added inductor L and load resistor R_{out} (Fig. 1), as well as the input voltage V_{in}, switching frequency f and duty cycle D, are chosen according to the voltage and current valuesapplied to the DUT, i.e. the SiC power JFET. The flyback-based dc-dc converter providing three separate outputs of 15 V is used to supply the HS and LS driving circuit as well as the current sensor placed on the evaluation board and used to record the waveform of the inductor current. The measurable voltages and currents are marked in Fig. 1.

III. The Precise Time-Delay Signal Generator

In order to synchronously drive the cascode switches, the drive signal generator is implemented as a dual-channel precise time-delay square wave generator. Apart from the signal frequency, one channel is controlled separately from the other. It is required that the generator be able to produce signal frequencies of up to 10 MHz and duty cycle values up to 50%. The most relevant requirement of the developed generator is the ability to precisely adjust duty cycle and time-delay of the generated signal.

The block diagram of the developed pulse generator is presented in Fig. 2. It can be observed that every channel has its own block for a pulse-width modulation (PWM) and time-delay regulation while they share the signal from the local oscillator.The buffer stages, drawn as the blocks with right-point triangle in Fig 2., are placed in between every stage of the pulse generator in order to prevent the input impedance of the following stage from affecting the preceeding stage.

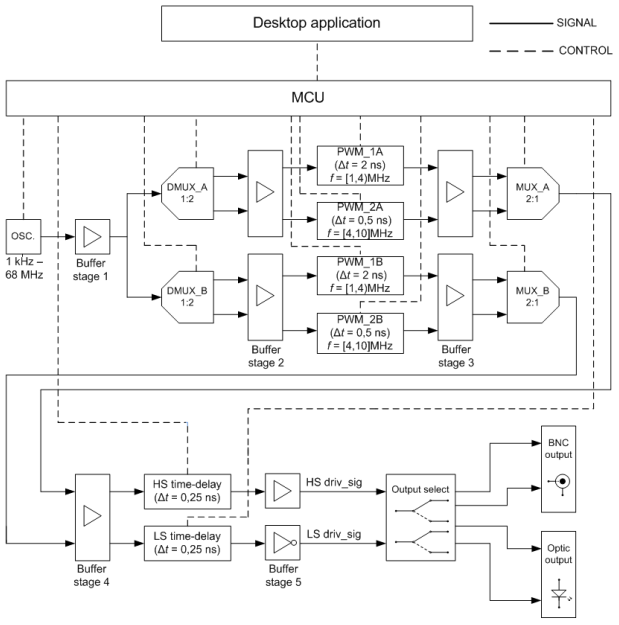

Fig. 2. Block diagram of the signal generator.

Both PWM and time-delay stage are realized using the 8-bit programmable timing element with fixed time-step value. The pulse width of every channel is determined using the time-step of either 2 ns or 0,5 ns. The highest achieveable pulse width for the former one is

$(2^8–1)\cdot 2$ ns = 510 ns while the maximum pulse width for the later one equals 127,5 ns. In a low frequency range (f < 4 MHz), the 2ns-PWM block is used to obtain the demanded duty cycle values while for higher frequencies the 0,5ns-PWM block is active. The frequency „border" of 4 MHz is chosen for the purpose of satisfying the trade-off between achieving the duty cycle values up to 50% and keeping the high pulse-width resolution. This border can easily be changed, either to higher or lower values, in order to obtain higher duty cycle values or to achieve more precise pulse-width adjustment. The time-delay stage uses the same timing element, but with a time-step of 0,25 ns for the whole freqency range of interest.

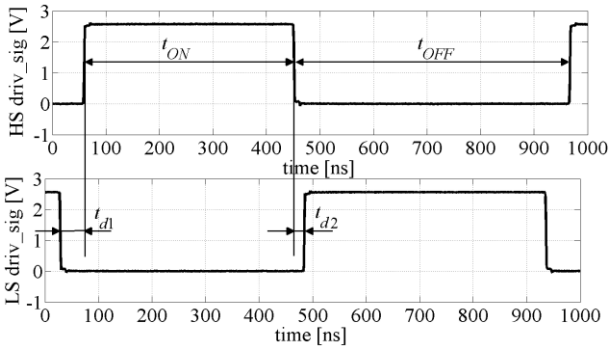

Fig. 3. The HS and LS driving signal for the SiC JFET evaluation board (f = 1,1 MHz; t_{ON} = 380 ns; t_{OFF} = 520 ns; t_{d1} = 27 ns; t_{d2} = 46 ns).

The HS and LS driving signals for the evaluation board are presented in Fig. 3. The waveforms are recorded using the Agilent MSO7034B oscilloscope and probe configuration as follows: 1:1 ratio, DC coupling, bandwidth limit: OFF, input impedance: 50 Ω. Two dead-times, t_{d1} and t_{d2}, are tuned using the time-delay and PWM property of the pulse generator, respectively. The t_{d1} increases with differential delay between HS and LS driving signal, while t_{d2} depends on the pulse width of either HS or LS driving signal.

The performance of the PWM and time-delay stage is presented in Fig. 4. The precision of adjusting the pulse width of the LS driving signal at lower (f < 4 MHz) and higher frequencies (4 MHz ≤ f < 10 MHz) is shown. The property of the pulse generator to adjust the pulse-width with a time-step of 2 ns at lower frequencies and 0,5 ns at higher frequenices, when one-step increment is applied, can also be observed. The bottom waveform presents the ability of the time-delay stage to tune the differential delay between generated signals with a time-step of 0,25 ns. Due to the maximum of 255 time-steps, the highest achievable delay equals 63,75 ns. Both generated pulse signals are brought to the evaluation board via the 50 Ω BNC cables. It is also possible to use the optical transmission to drive the SiC JFET power switches, but this part of the signal generator is not yet tested.

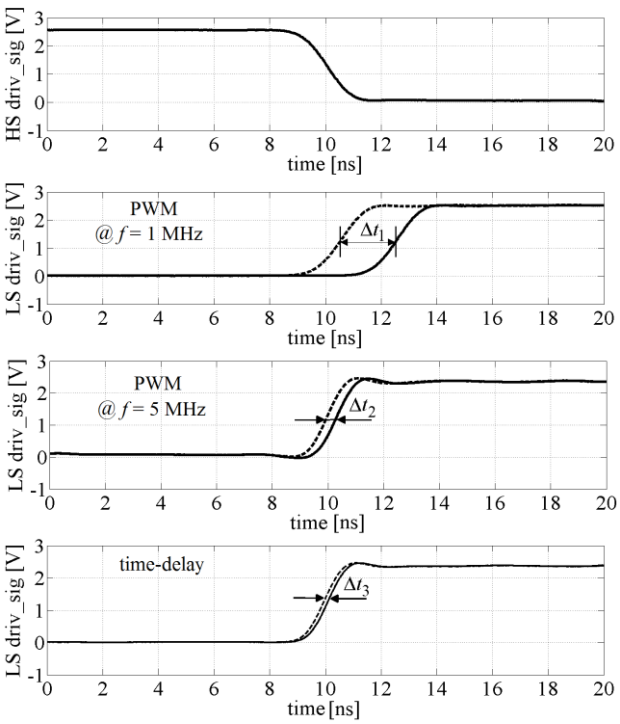

Fig. 4. Measured resolution of the PWM and time-delay stage – before (dashed line) and after (solid line) a one time-step increment is applied (Δt_1 = 2 ns; Δt_2 = 0,5 ns; Δt_3 = 0,25ns).

Since digital PWM and time-delay devices are constrained by their bit-resolution, the precision of adjusting the duty cycle of generated signals directly depends on the signal frequency. Furthermore, the operation of both PWM and time-delay stage is limited by the maximum amount of 255 time-steps.

IV. Measurement Results

A. Transient analysis

In order to prove the functionality of the developed evaluation system, the time-domain waveforms at the relevant test points from Fig. 1 are recorded. The chosen signal and system parameters used to verify the performance of the evaluation system are: f = 200 kHz; t_{d1} = t_{d2} = 180 ns (D = 0,43); V_{out} = 3,3 V; I_{out} = 2 A (R_{out} ≈ 1,67 Ω); L = 6 µH, C_{out} = 10 µF.

The relationship among the generated signals, optocoupler outputs and gate-source voltages of HS and LS driving MOSFETs is presented in Fig. 5. The optocoupler inverts the driving signal and provides the peak-peak output voltage equal to its supply voltage. The cascode driving circuit, proposed in [12], acts as a negative bias network by lowering the dc value of the driving signal in order to increase the turn-off time of the cascode switch. The dead-times t_{d1} and t_{d2} should be as short as possible, yet long enough to avoid the shoot-through effect.

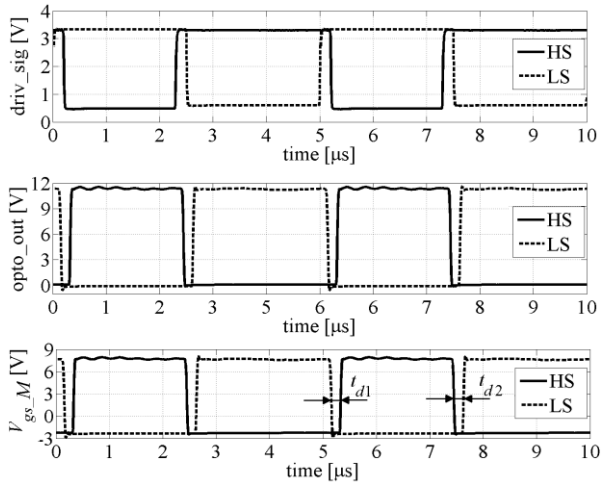

Fig. 5. Operation of the optocoupler and driving circuit (f = 200 kHz; t_{d1} = t_{d2} = 180 ns).

The operation of the low-side cascode switch is verified by the measured voltage and current waveforms shown in Fig. 6. The high-side cascode switch could be analysed in the same way, but the measurement procedure is slightly more complicated due to the difference between the high-side reference potential and ground potential.

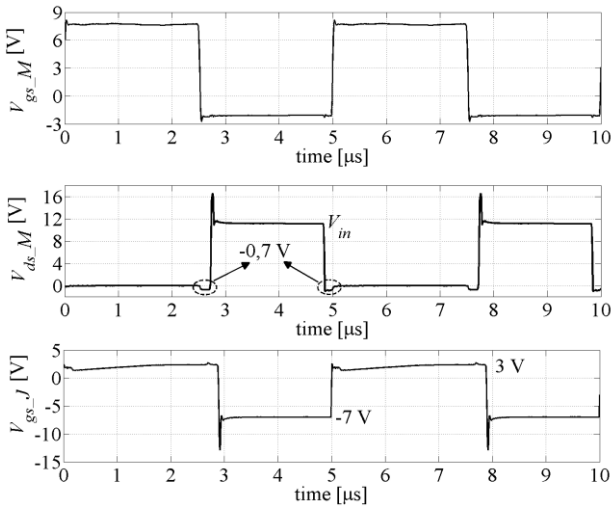

Fig. 6. Operation of the low-side cascode switch.

During the off-state, the drain-source voltage V_{ds_M} of the driving MOSFET equals input voltage V_{in} while, during the conduction mode, the voltage drop is negligible. The voltage drop of approximately -0,7 V, present during both dead-times, is caused by the negative current flowing through the MOSFET body diode and the channel of the JFET due to its normally-on structure. The voltage spike, observed at the beginning of the turn-off process of the LS cascode switch, is caused by the decrease of the reverse cascode current and parasitic inductance between MOSFET and JFET terminals. At the end of the turn-off process, the voltage spike is limited by the junction potential of the body diode.Finally, the gate-source voltage of the normally-on SiC JFET v_{gs_J} is positive (3 V) during the conduction mode in order to reduce the on-resistance. The blocking mode is ensured by the v_{gs_J} of -7 V so the normally-off property is established.

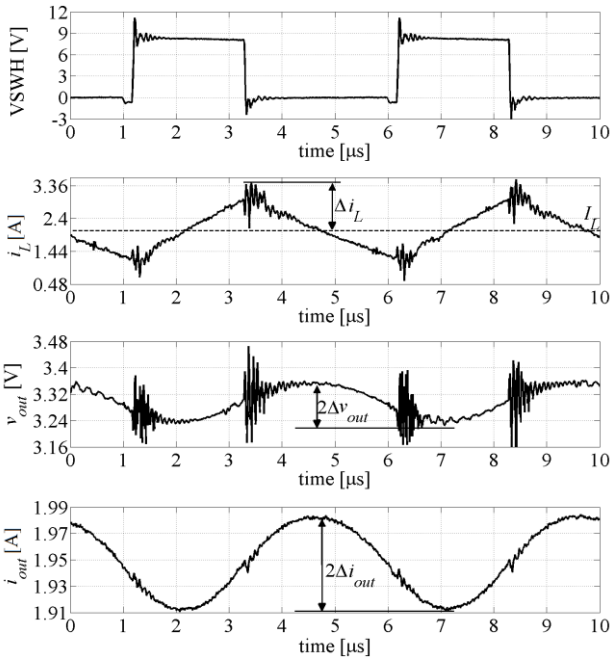

Fig. 7. Operation of the dc-dc evaluation system ($\Delta i_L \approx 1{,}3$ A; $\Delta v_{out} \approx 60$ mV; $\Delta i_{out} \approx 35$ mA).

The operation of the complete evaluation system is presented in Fig. 7. The voltage at the switching node VSWH contains parasitic oscillations. The ringing frequency of approximately 20 MHz is determined by the LC resonance in the current loop formed by the input decoupling capacitor, parasitic loop inductance and both high-side (on-state – R_{on}) and low-side (off-state – C_{oss}) cascode switch [16]. The waveform of the inductor current $i_L(t)$ is obtained form the current transducer LEM LTS 15-NP. The driving signal and system parameters, chosen to verify the operation of the complete system, ensure that the system operates in the conduction mode (CCM) as it is shown in Fig. 7. Since only an ac component of the inductor current I_L flows through the output capacitor C_{out}, i.e. $i_c(t)$=$i_{L_ac}(t)$, the output voltage is given by

$$v_{out}(t) = v_c(t) = \frac{1}{C}\int i_{L_ac}(t)dt. \qquad (1)$$

When the $i_{L_ac}(t)$ is positive, the C_{out} is being charged. Therefore, between the two zero-crossings of the $i_{L_ac}(t)$, the $v_{out}(t)$ changes between its minimum and maximum value. The output voltage $v_{out}(t)$ contains an undesired ripple because of the incomplete attenuation of the switching harmonics by the low-pass output LC filter. This voltage ripple causes the ripple of the output current $i_{out}(t)$ through the load R_{out}. The waveform of the output current $i_{out}(t)$ is recorded using the Agilent N2783B current probe with a transfer ratio of 0,1 V/A.

B. Evaluation of the SiC JFET power switch

The operation of the SiC JFET in a buck converter application is evaluated by measuring the converter efficiency and output voltage ripple under various operating conditions. The values of non-varied parameters are shown in Table I. The focus is set on the evaluation of the SiC JFET in a low-voltage buck converter under five test cases (TC) as described by Table I. Moreover, every test case is additionaly analysed by varying the load resistance R_{out}.

	f_{SW}	V_{out}	L	t_{d1}	t_{d2}

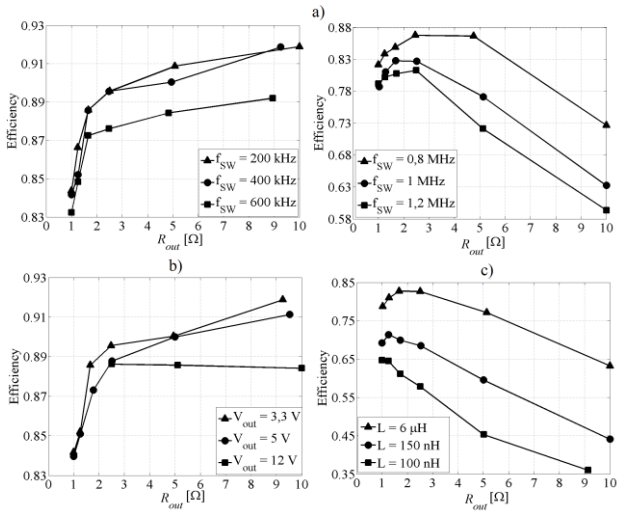

Fig. 8. a) TC1: V_{out} = 3,3 V; b) TC2: f_{SW} = 400 kHz; c) TC3: V_{out} = 3,3 V; f_{SW} = 1 MHz .

The measured power conversion efficiency of a synchronous buck converter as a function of the load resistance and switching frequency as a parameter is shown in Fig 8a. The curves in Fig. 8a (f_{SW} < 0,8 MHz) could be approximated by the function $R_{out}/(a+R_{out})$ where constant a represents the resistance of the inductor wire [15]. For high values of f_{SW}, the efficiency decreases for R_{out} > 2,5 Ω because the converter operates in a discontinous conduction mode (DCM). Due to the fixed t_{d1} and t_{d2}, an increase of the f_{SW} causes the decrease of the duty cycle. This leads to the higher switching losses as well as the lower efficiency. However, the SiC JFET/Si MOSFET cascode switch in low-voltage applications is able to operate with power coversion efficiencies higher than 0,8 even for the output voltages up to 12 V as seen in Fig. 8b. The operation in the DCM is more obvious in Fig. 8c. The f_{SW} of 1 MHz was chosen for a better comparison of the obtained results. For higher R_{out} and lower L, the converter goes „deeper“ into the DCM and the efficiency decreases accordingly.

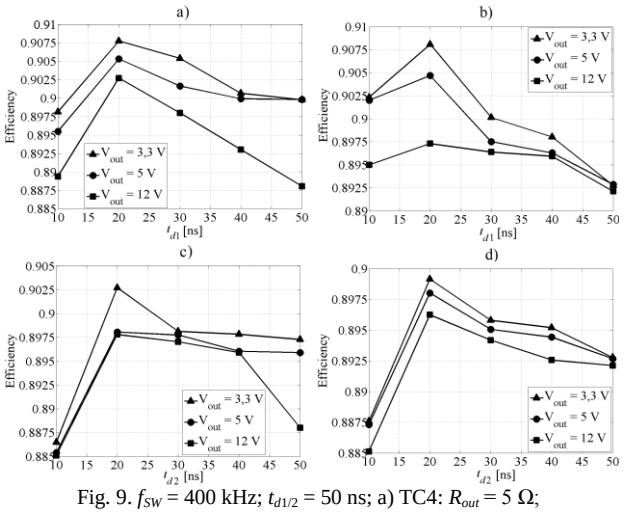

Fig. 9. f_{SW} = 400 kHz; $t_{d1/2}$ = 50 ns; a) TC4: R_{out} = 5 Ω; b) TC4: R_{out} = 2,5 Ω; c) TC5: R_{out} = 5 Ω; d) TC5: R_{out} = 2,5 Ω.

The influence of t_{d1} and t_{d2} on the power conversion efficiency is presented in Fig. 9. Due to the non-zero rise and fall times of the driving signals, short dead-times cause a shoot-through, i.e. significant decrease of the efficiency. As t_{d1} or t_{d2} increases, the power losses caused by the conduction of the low-side body diode increase accordingly. However, the time t_{d1} in TC4 (Fig. 9a and 9b) is more dominant on the efficiency than the time t_{d2} in TC5 (Fig. 10c and 10d). As t_{d1} gets longer, current through the low-side body diode delivers more charge to the parasitic output capacitance of the low-side cascode switch. This causes higher voltage spikes (Fig. 6 and 7), i.e. higher switching losses, due to the higher di/dt at the end of t_{d1}. On the other side, when t_{d2} has ended, the current through the low-side switch does not instantaneously fall to zero, but it switches its path to the Si MOSFET/SiC JFET channel.

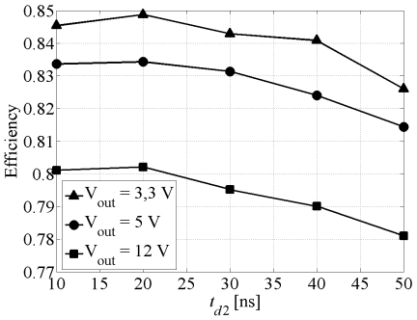

Fig. 10. TC5: f_{SW} = 1 MHz; t_{d1} = 50 ns; R_{out} = 2,5 Ω.

The f_{SW} of 1 MHz causes higher switching losses, i.e. decrease of the efficiency as shown in Fig. 10. The higher f_{SW} causes higher influence of t_{d2} on the efficiency because of the shorter period T=1/f_{SW}. Therefore, the low-side body diode conducts, i.e. causes conduction losses, for a longer part of the period T of the driving signal.

The output voltage ripple Δv_{out} is also an important figure-of-merit of the operation of the SiC JFET power switch in dc-dc converter applications. The Δv_{out} against

the R_{out} and V_{out} is presented in Fig. 11. Due to the parasitics imported by the voltage probe into the converter's output node, the Δv_{out} is calculated by multiplying the output current ripple Δi_{out}, measured by the used current probe, and the load resistance R_{out}.

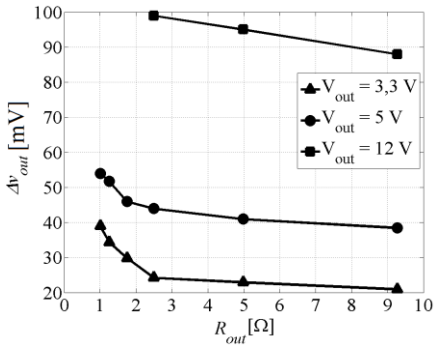

Fig. 11. The calculated output voltage ripple Δv_{out}.

In a computer power supply having a 3,3 V, 5 V or 12 V output, the output voltage ripple is normally required to be less than 1% of the output dc voltage [15]. It can be seen in Fig. 11 that the SiC JFET fulfills this condition for $R_{out} > 1{,}5\ \Omega$.

V. CONCLUSION

The system for evaluation of a normally-on SiC JFET power switch based on a buck converter is presented. The operation of the precise two-channel signal generator is described. The ability of the signal generator to adjust the pulse width and relative time-delay of the generated signals with sub-nanosecond precision is verified by the time-domain waveforms.

The transient analysis proved the proper operation of the Si MOSET/SiC JFET cascode switch as well as the performance of the complete evaluation system.

The presented system is not designed as an automated control system (using the adaptive dead-time property) like common synchronous dc-dc converters. Instead, the system enables the analysis of the influence of many signal and system parameters on the operation of the SiC JFET as a power switch in a cascode configuration.

It is shown that the near-zero dead-time, i.e. the short dead-time values, leads to the significant decrease of the power conversion efficiency because of the non-zero rise and fall times of the driving signals. However, the shorter rise and fall time increases the frequency bandwidth of the switching signals and cause significant electromagnetic emissions. Using the precise time-delay signal generator for evaluation of the operation of power switches, it is possible to estimate the necessary dead-time values for reaching the highest possible efficiency.

It was shown that the Semisouth SJDP120R085 SiC JFET in a synchronous buck converter with low output voltages (V_{out} < 12 V) operates with a power conversion efficiency higher than 0,8 for switching frequencies up to 600 kHz. Besides that, the low output voltage ripple justifies the usage of a SiC JFET in low-voltage dc-dc converter applications.

Abstract – This paper describes an implementation of a proportional-integral-derivative (PID) controller with an iterative error compensator for a DC brushless motor to improve the quality of a photocopier. The parameters of the iterative error compensator are determined by using particle swarm optimization algorithm. The proposed controller reduces the effects of repetitious unknown load torque on the DC brushless motor by compensating the motor torque based on the motor velocity from the previous sequences. The proposed controller is compared to a PID controller under various load torques.

Keywords–PID controller, derivative-free optimization, iterative learning

I. INTRODUCTION

Many sources of noise and disturbances exist in a photocopier due to its complicated mechatronics. The main source of disturbance is the load torque that is generated by feeding paper and other components during the printing. The load torque of the brushless DC (BLDC) motor is not predictable, because the load torque depends on the variable working environment of the photocopier such as humidity, temperature and its part tolerances. To achieve the high performance photocopier system under unpredictable disturbance, precise and robust motor controlling is required.

In this paper, we focus on the control of a DC brushless motor that is used in a photocopier under uncertain disturbances. The PID controller is used as a feedback controller to stabilize and to follow the target velocity.

The goal of this paper is to keep the velocity of the BLDC motor as stable as possible while using a simple controller and optimization-based controller training procedure. To minimize the effects from those repetitious disturbances and modeling uncertainty, the idea of an iterative learning feedforward control [1] is used in this paper. Theoretically, a feedforward compensator based controller can eliminate errors due to the disturbances [2], [3]. The iterative error compensator is used in this paper to reduce the effect of disturbances based on the velocity measured in the previous sequences. In the case of a photocopier, the standard feedforward control theory cannot be used because it requires precise modeling of a control structure and that is very difficult to accomplish due to the complexity of the photocopier and the wide tolerances of its parts caused by the mass production. To circumvent this problem, an algorithm based on optimization is used in this paper. Survey of the literature shows that this approach is feasible and efficient, e.g. methods that improve the behavior of the control structure in a repetitious sequence [4] [5], iterative learning control with PID feedback controller for the linear motor system in [6], genetic algorithm based iterative learning controller used to determine a manipulator's input in [7] and [8], iterative learning control based on Kalman filter for a quadrocopter follows a desired trajectory [9] and other.

The main advantages of the controller presented in this paper is its simplicity and the ability to reduce the velocity error without the requirement of the modeling of the overall control structure. The controller presented in this paper is accomplished by optimizing the iterative error compensator parameters by using the particle swarm algorithm [10], [11].

The outline of this paper is as follows: Section II explains working principle of the photocopier including the model of BLDC motor. In Section III, the proposed controller and its learning algorithm are explained. Simulation results are presented in Section IV. Finally, the conclusions are given in Section V.

II. STRUCTURE AND OPERATION PRINCIPLE OF THE PHOTOCOPIER

Fig.1 presents a simplified photocopier (laser printer) schematic that includes laser units, photosensitive drums, an intermediate transfer belt, a paper feeder, a fuser and a paper exhaust tray. The laser unit controls the exposure of the laser beam on the photosensitive drum by ON/OFF control or pulse width modulation (PWM) control, thereby forming an electrostatic latent image on the surface of the photosensitive drum respectively. The drum forms a visible image by developing the electrostatic latent image formed by the laser unit with toner, and superposes and transfers such visible images to the intermediate transfer belt. The intermediate transfer belt transfers the color visible image to the paper. The fuser fixes the color image transferred onto the paper.

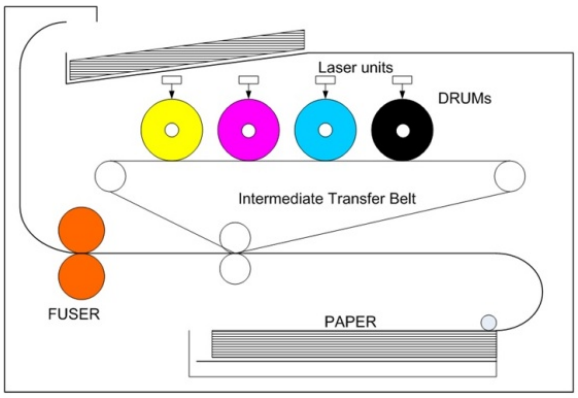

Figure 1. Schematic cross-sectional view illustrating a photocopier.

We focus on the BLDC motor that controls the velocity of the drum in the photocopier. In the following model, a three-phase BLDC motor with trapezoidal back electromotive force (EMF) is used [12] [13]. This BLDC model is based on the assumption that the stator losses are negligible. The electrical equations are:

$$V_a = Ri_a + L\frac{di_a}{dt} E_a \quad (1)$$

$$V_b = Ri_b + L\frac{di_b}{dt} E_b \quad (2)$$

$$V_c = Ri_c + L\frac{di_c}{dt} E_c \quad (3)$$

where V_a, V_b and V_c are the terminal phase voltages [V], i_a, i_b and i_c are the phase currents [A], R is the armature resistance [Ω] of the BLDC, L is the armature self-inductance [H] and E_a, E_b and E_c are the motor back EMFs [V]. In the three-phase BLDC motor, the back EMFs and the rotor angle are described by:

$$E_a = K_w f(\theta_e)\omega \quad (4)$$

$$E_b = K_w f(\theta_e - \frac{2\pi}{3})\omega \quad (5)$$

$$E_c = K_w f(\theta_e + \frac{2\pi}{3})\omega \quad (6)$$

$$\theta_e = \frac{p}{2}\theta_m \quad (7)$$

where f is a function of the rotor position whose shape is a normalized trapezoid, K_w is the back EMF constant [V/(rad.s^{-1})], θ_e is the electrical rotor angle [rad], ω is the rotor speed [rad/s], p is the number of pole pairs and θ_m is the mechanical rotor angle [rad]. The total output torque T_e [Nm], caused by each phase and the mechanical parts is represented by:

$$T_e = \frac{E_a i_a + E_b i_b + E_c i_c}{\omega} \quad (8)$$

$$T_e - T_l = J\frac{d\omega}{dt} + B\omega \quad (9)$$

where T_l is the load torque [Nm], J is the inertia of the rotor [kgm^2] and B is the damping constant [Nms/rad].

III. PID CONTROLLER WITH ITERATIVE ERROR COMPENSATION OPTIMIZED BY PARTICLE SWARM OPTIMIZATION

A. PID controller with the iterative error compensator

The block diagram of a BLDC motor control is shown in Fig. 2 while Fig. 3 shows a block diagram of the proposed PID controller with the compensator. The controller block generates the gate signals based on the rotor velocity and the hall signals. There are five main blocks in Fig. 3. The PID controller is used to follow the target velocity and to stabilize the velocity of the BLDC motor. The PID parameters are tuned by the Ziegler-Nichols (ZN) closed-loop tuning method [14]. Due to its simplicity and semi-empirical nature the ZN method is interesting in those applications where quick tuning realization (in the sense of simple step or limit-cycle test) is preferred to precise parameter adjustment. In this paper, an auxiliary iterative error compensator compensates for the ZN method's imprecision. The error memory and the torque memory store the velocity error *e(t,m-N)* and the output torque $\tau_c(t,m-N)$ of the compensator respectively which are measured in the Nth sequence, where N is the iteration number of the global best value in the particle swarm optimization (PSO) (discussed in Section III.B), t and m represent a time index and an iteration index, respectively. The proportional-derivative (PD) type iterative error compensator block (whose parameters are optimized by PSO) compensates the torque based on the velocity error from the error memory block. These iterative error compensator acts in parallel to the main PID controller enabling a partial feedback that adapts the PD action of the PID controller. The torque controller block generates the gate signals based on the hall signals from the BLDC motor and the output of the PID and the compensator. The input of the torque controller $\tau(t,m)$ is represented by:

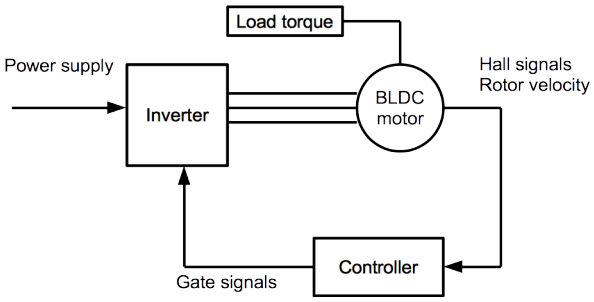

Figure 2. BLDC motor drive.

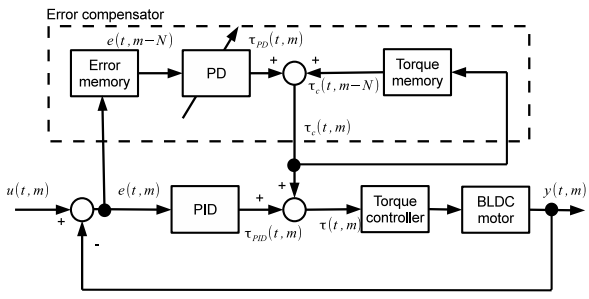

Figure 3. PID controller with proposed iterative error compensation.

$$\tau_c(t,m) = \tau_{PD}(t,m) + \tau_c(t,m-N) \quad (10)$$

$$\tau(t,m) = \tau_{PID}(t,m) + \tau_c(t,m) \quad (11)$$

where $\tau_c(t,m)$ is the output torque of the proposed compensator, $\tau_{PD}(t,m)$ is the output of the PD controller block and $\tau_{PID}(t,m)$ is the output torque of the PID controller block.

B. Particle swarm optimization for the PD-type iterative error compensator

The particle swarm optimization is used to iteratively build the PD-type iterative error compensator. The PSO is one of the evolutionary computation algorithms and is inspired by flocking birds in nature [10]. The calculation cost of the PSO is low because of the simple equations it uses. One of the benefits of using the PSO is the fact that its optimization converges fast [11].

The basic PSO algorithm consists of the velocity and position equations [10], [11] written as:

$$v_i(k+1) = \phi(k)v_i(k) + \alpha_1[\gamma_{1i}(p_i - x_i(k))] + \alpha_2[\gamma_{2i}(G - x_i(k))] \quad (12)$$

$$x_i(k+1) = x_i(k) + v_i(k+1) \quad (13)$$

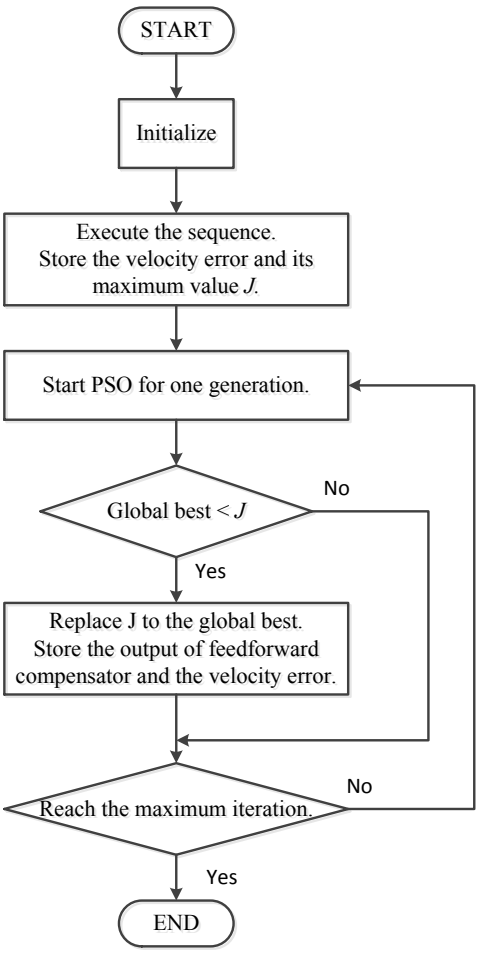

Figure 4. Flow chart of the learning iterative error compensator.

where i is the particle index, k is the discrete time index, v is the velocity of the ith particle, x is the position of the ith particle, p is the personal best position found by the ith particle, G is the global best position found by the swarm, ϕ is the inertia and α is the acceleration constant. In this paper, the PSO algorithm solves the cost function J:

$$J = \max(\|u_k - y_k\|) \quad (14)$$

where k is a natural number and $k>0$. This cost function is derived for the purpose of minimizing the maximum of the velocity error that causes an asynchronous behavior between other drums in the photocopier. Fig. 4 represents a flow chart of the learning procedure for the iterative error compensator used to reduce the maximum velocity error.

In the initialization block, the velocity error and its maximum value J are stored after each iteration. Next, the parameters of the PD controller in the iterative error compensator are set by the PSO and the cost function is evaluated. If the global best value is smaller than J, J is replaced by the global best value. The error memory block stores the velocity error and torque memory block stores the output of the iterative error compensator using the global best PD parameters. After that, the current number of iteration is checked and repeated until the maximum number of allowed iterations.

IV. RESULTS

To test the effectiveness of the proposed PID controller with the iterative error compensator, we

TABLE I. PSO PARAMETERS

Description	Value
Maximum number of iterations	100
Population size	24
Acceleration constant α_1	2
Acceleration constant α_2	2
Initial inertia weight	0.05
Final inertia weight	0.001

TABLE II. BLDC MOTOR SPECIFICATIONS

Description	Value
Nominal voltage	24 V
Stator phase resistance	0.307 Ω
Stator phase inductance	0.188 mH
Inertia	$1.21 \cdot 10^{-10}$ kgm^2
Machanical time contant	13 ms
Friction factor	0 Nms
Pole pairs	7
Torque constant	53.4 mNm/A
Stall torque	3740 mNm

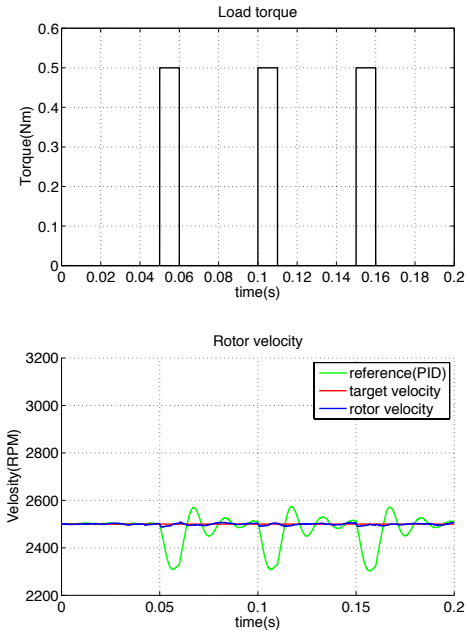

Figure 5. Velocity of the rotor under pulsed load torque.

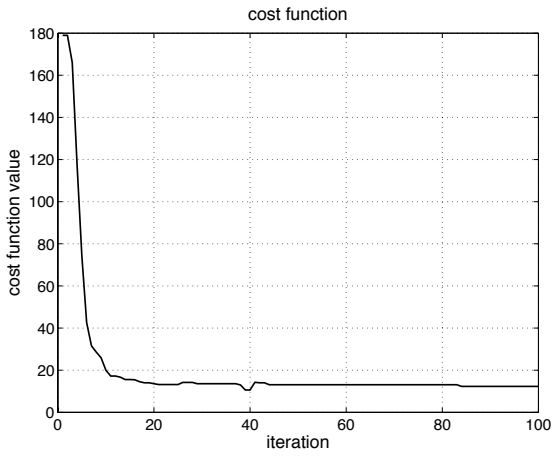

Figure 6. Convergence of the cost function J under pulsed load torque.

generate three types of disturbances: saw tooth, square pulse and uniform random disturbances. The PSO parameters for the optimization of the iterative error compensator are shown in Table I and the motor specifications used in these simulations are shown in Table II. Using these settings, the simulation results of the BLDC motor with three kinds of disturbances are shown.

Fig. 5 and Fig. 6 show the simulation results and the convergence of the cost function *J* during the optimization under the pulsed load torque. This pulsed load torque is presumed to be related to the paper feeding. In Fig. 5, the blue line shows the rotor velocity [rotation per minute (RPM)] that is optimized by the proposed controller, the green line is the rotor velocity [RPM] controlled by the PID controller without the iterative error compensator and the red line represents the target velocity [RPM] (input value to the controller). As it can be seen in Fig. 5, the proposed iterative error compensator reduces the drop of

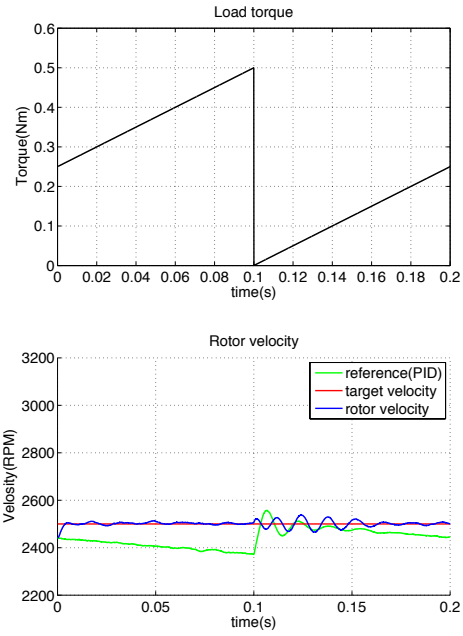

Figure 7. Velocity of the rotor under saw tooth wave load torque.

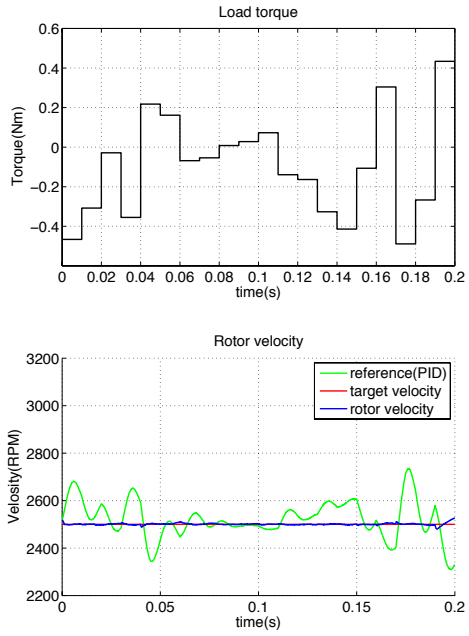

Figure 8. Velocity of the rotor under uniform random load torque (maximum amplitude: 0.5 Nm).

the velocity by 93.8%. The cost function *J* does not change significantly after 20 generations, as shown in Fig. 6. This result indicates that the iterative error compensator is able to reduce the velocity error without modeling of the control structure.

In Fig. 7, the simulation result under the saw tooth load torque is shown and the proposed compensator reduced the velocity error by 54%, where the blue line shows the rotor velocity [RPM] that is optimized by the

proposed controller, the green line is the rotor velocity controlled by the PID controller without the iterative error compensator and the red line represents the target velocity. This saw tooth disturbance is presumed to be caused by the eccentricity in the mechanical construction of the photocopier.

Fig. 8 shows the simulation results under the random signal with the maximum amplitude of 0.5 Nm. Fig. 6 shows that the result is improved 88.5%, where the blue line shows the rotor velocity that is optimized by the proposed controller, the green line is the rotor velocity controlled by the PID controller without the iterative error compensator and the red line represents the target velocity.

V. CONLUSION

In this paper, an implementation of the PID controller with the iterative error compensator for the control of the BLDC motor in a photocopier is presented. The parameters of the compensator are determined by using the particle swarm optimization. It is demonstrated that the modeling of the entire control structure is not necessary. The controller is tested under three types of disturbances commonly found in photocopiers. In each case, the simulation results show that the controller is able to reduce the velocity error of the BLDC motor caused by the unpredictable repetitious disturbances.

Abstract - The increasing trend of DC/AC induction motor converters implementation in a wide range of driving applications is becoming a fact that could not be neglected any more. This fact challenges the designers of the DC/AC induction motor converters to constantly seek performance improvements and cost reductions on an everyday basis.

The paper describes some of the design improvements of a DC/AC induction motor converter for use in light commercial electrical vehicles. The implementation of design changes is based on electrical analysis, simulation results and also on the previous prototype testing. The goal of design activity presented in the paper is a design of an improved DC/AC induction motor converter with higher performance, enhanced reliability and optimized production cost. The paper concludes with a proposal of a new DC/AC induction motor converter design and concludes with some simulation results.

I. INTRODUCTION

Nowadays various traditional driving systems (e.g. combustion driving system) are being in majority replaced with different alternative solutions. The predominant and most prevalent alternatives could be found in different variations of driving systems realised with different types of electrical motors. In applications such as light commercial vehicles (golf carts, forklifts…) or other auxiliary systems (electrical assisted steering …) the electrical driving system is commonly realised with an induction motor. The induction motor has many advantages compared to DC motor or to motor with permanent magnet. But still the motor type selection depends on several factors which are defined either by the end application or by customer. Beside the material cost and its construction robustness of an induction motor itself, it requires a more complex DC/AC induction motor converter in order to obtain a sufficient level of the driving system efficiency. Some basic information about different electrical motor types and motor control algorithms could be found in [1, 2].

For efficient driving of an induction motor, a DC/AC induction motor converter is required. A DC/AC induction motor converter is positioned between the electrical energy source/battery and the induction motor. The DC/AC induction motor converter could be splinted in to two main parts where the first part is used for high current density switching and electrical power distribution between the battery and the induction motor. The second part of the DC/AC induction motor converter represents an electrical circuit which executes the driving algorithm and services the user input commands. The driving algorithm used for DC/AC induction motor control in this paper is based on Field-Oriented-Control approach [3].

But we must be not mislead with an impression that changing to the alternative driving systems is necessarily fully justified. The decision for the transfer to electrical driving systems should consider all aspects such as performance, size, weight, mileage distances…

The DC/AC induction motor converter is the main part of such electrical driving system. Therefore this paper focuses on some DC/AC induction motor converter design aspects with the goal of optimizing performance, materials and production costs.

II. DC/AC INDUCTION MOTOR CONVERTER

The DC/AC induction motor converter discussed in this paper was designed for induction motor driving systems with battery voltage of 96V and continuously providing a phase current of $220A_{RMS}$.

The construction of the DC/AC induction motor converter is based on the patented approach [4] of the DC/AC induction motor converter assembly. For converting the battery supply to the proper power signal for the induction motor phase a power module is used. The power module is realized as two serially connected switches where the “high-side” switch is connected between the positive terminal of the battery and the induction motor phase connector while the “low-side” switch is used to apply the negative battery potential to the connected phase terminal. Fig 1. shows a block scheme of the DC/AC induction motor converter realized with three power modules, capacitor board and connection terminals to the battery and induction motor phases.

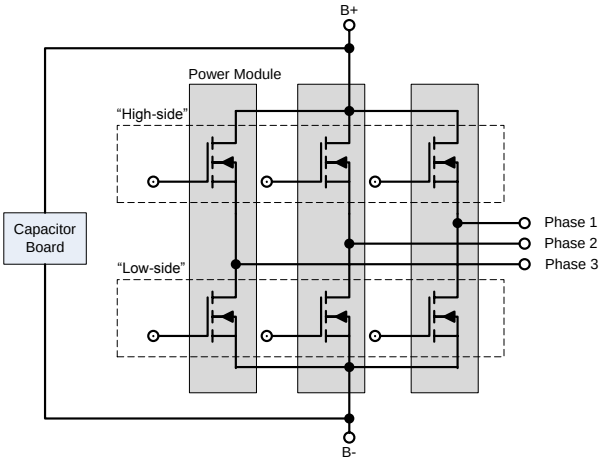

Figure 1. A block scheme of DC/AC induction motor converter – power modules with the capacitor board

Each switch, either "high-side" or "low-side", consists of a number of connected in parallel semiconductor power devices. The number of in parallel connected semiconductor power devices depends on the required switching current densities and voltage ratings. Since the battery supply voltage applied of the discussed DC/AC induction motor converter ranges up to 96V the selection of semiconductor power MOSFET devices is justified.

For more convenient production, handling and economical aspects, the DC/AC induction motor converter switching part is realized modularly as individual power modules. Fig 2. is showing a prototype sample of the power module.

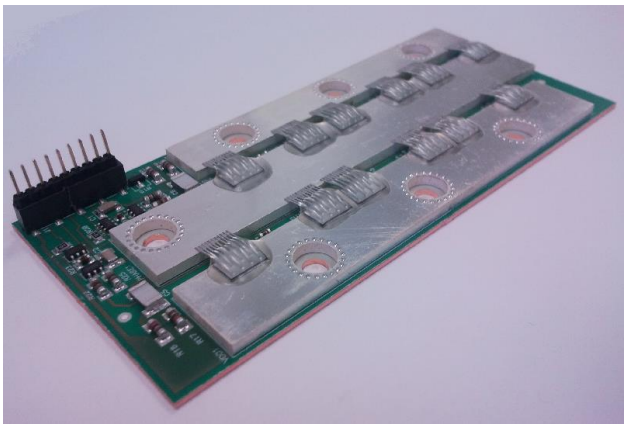

Figure 2. Power module photo

The three power modules are connected to several bus bars with different potentials. These bus bars form some sort of three dimensionally structured interconnection network which practically define the electrical circuit topology. The introduced three dimensionally structured interconnection network provides low resistance and low parasitic electrical paths between power modules and as well minimizes the influences of the parasitic inductance of all other internal electrical paths where high current densities are distributed (induction motor phases and battery terminals) [4].

An important part of the three dimensionally structured interconnection network is also formed with the capacitor board. The capacitor board is used to support the capacitor elements and additionally provides electrical connection of battery terminals B+ and B- to each of the power module. The main feature of the capacitor boards positioned near power switches is to provide adequate electrical charge necessary for the efficient switching of the power MOSFET devices. Switching of high current densities only with the connected battery source, because of the cable connection parasitic and internal battery resistance, would not be functional.

In order to improve some of the prototyped DC/AC induction motor converter performance, additional re-design actions of capacitor board and power MOSFET driver circuit have been performed. In the following paragraphs the focus of each re-design features is presented. It also must be noted that the encountered design improvements are based on the previously developed prototype and available measurement results show in Fig 3.

Figure 3. DC/AC induction motor converter prototype

A. Capacitor board

The main reason for capacitor board performance improvement was to enhance higher capacitor board ability of providing required electrical energy to the connection terminals of the power modules. Besides establishing more efficient electrical connections between capacitor board – power modules – battery terminals also higher total capacitance has been achieved.

The previous designed PCB board was realised with the standard 4-layer FR4 material with copper configuration (70 µm/ 70 µm/ 70 µm/ 70 µm) and consisted of 9 pcs of 1000 µF and 6 pcs of 1.5 µF capacitor elements. The calculated total ripple current of such capacitor block was 20,970 mA [5]. The capacitor board of the prototyped version of the DC/AC induction motor converter is shown in Fig 3.

The improved version of the capacitor board was designed with the same FR4 material configuration but the number of the capacitor elements was increased to 12 pcs of 1000 µF and to 11 pcs of 1.5 µF. The total capacitance of the capacitor board as well as the ripple current capability was therefore increased for approximately 30%.

To the design of the new capacitor board additionally also a driver circuit was added. Fig 4. shows the realized improved capacitor board with the driver circuit on a single PCB.

Figure 4. The PCB capacitor board with driver circuit of the improved prototype

Although the number of capacitors is increased from 9 pcs to 12 pcs the main feature of the improved prototype version could be found in the reduction of the PCBs. Instead of two separated PCBs, capacitor board and driver board, the new improved version only require design and manufacturing of a single PCB board. Since the PCB area of the prototyped version is increased for ≈10% the cost reduction could be identified in lower production costs of the PCB, manufacturing handling / assembly and final assembly of the PCB in to each power module and battery terminals. On the other hand, the increased number of capacitor for 30% increases the DC/AC induction motor converter performance of providing a 10% higher phase current and on the other hand also lower power losses could be expected.

In order to improve voltage distribution of the B+ and B- potential simulations of prototype version and 3D model of the improved power stage were analysed with FEM method in COMSOL® simulation environment were performed.

The distribution of the battery potential on the prototyped version of the power stage is shown in Fig 5.

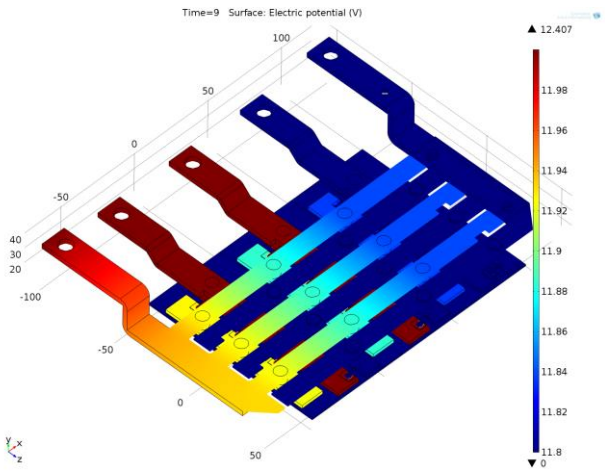

Figure 5. Distribution of the B+ battery potential of the prototyped version

The connection of B+ and B- battery terminals to the capacitor board were realised from the opposite side of positioned power modules. The simulation analysis of the potential distribution indicates that the battery terminals potentials are not equally distributed over the entire surface of the capacitor board. Therefore the B+ and B- potentials were not equally distributed to the terminals of individual power modules. Those potential differences influence the switching and also to quasi-static performance of the power MOSFET devices of the power modules.

The distribution of the battery potential on the improved prototyped version of the power stage is shown in Fig 6.

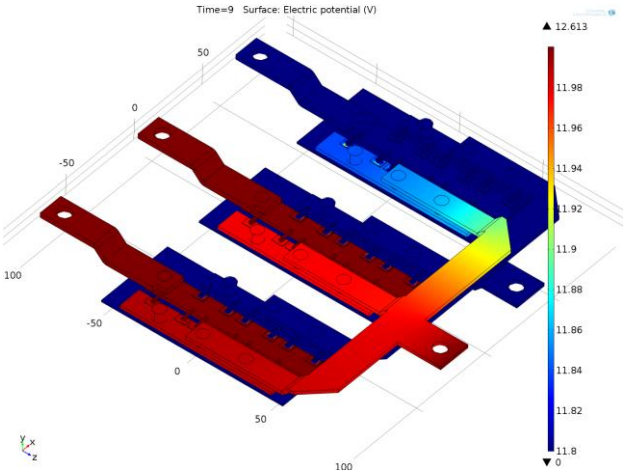

Figure 6. B+ battery voltage distribution of the improved 3D prototype version

The purpose of the improvement was to achieve more uniform distribution of the various voltage potentials to/from capacitor board and consequently also to optimize the resistance and parasitic influence of the connections. This improvement also provides better performance of the built-in capacitor elements. Fig 6. shows the B+ battery potential distribution on the power module terminals of the improved design where voltage distribution on each power MOSFET of the observed switch is more evenly distributed compared to the prototyped version shown in Fig 5.

Beside the differences of the voltage distribution the new improved version also exhibits lower absolute voltage drops from the battery connection terminals to each power module as well as to the capacitor board. The simulated voltage drop differences between both versions are estimated to be close to the factor of 2.

Both simulation results shown indicate the same situation in time domain: two switches (phase V and W) are active (conduction state) while the phase U is not active. The simulation results are indicating only the voltage distribution of battery potential distribution to each individual power MOSFET device of the connected power modules, since the influences of the capacitors placement was not included in full.

B. Driver circuit

The driver circuit of the power switches could be considered as one of the important parts of the DC/AC induction motor converter. The driver circuit represents a link between the low power circuit / converter unit and high power circuit / power modules on the other side. The functionality of the driver circuit is conditioning the logic signals from the converter unit to adequate driving signals for the power switches. In case of driving a three phase induction motor the driver circuit consists of six drivers where three drivers are used for driving the "low-side" switches and three for the "high-side" switches. Driving the "high-side" switches require floating power supply for the drivers while the "high-side" power switches are referenced to phase terminal which floats between B+ an B- battery potential during operation. Some of the gate driver circuits for power MOSFET devices together with some design consideration are presented in [6, 7]. Fig 7. shows the connection of the reference for "high-side" and "low-side" for the driver circuits.

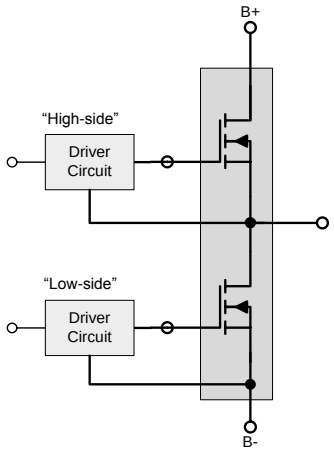

Figure 7. Driver circuit connection for "high-side" and "low-side" driver circuit

In order to achieve higher current densities switching capabilities of each power switch of power module is often realised with multiple in parallel connected power MOSFET devices. Each power MOSFET requires a driving signal with enough current capability for effective switching. The requirements for a driving signal current capability increases with either faster switching performance requirements and/or with adding additional power MOSFET switches. Although the power MOSFET device is voltage controlled the term signal current capability refers to as a function of a gate driver circuit. The signal current capability of the driver circuit directly influences on the switching performance (slew rate) of the gate voltage of the switched MOSFET. Another important issue directly correlated to the properties of controlled power MOSFET devices and as well as with the power module layout, is the ability of independent control of the switching behaviour of the power MOSFET gate terminals.

Fig 8. illustrates the electrical schematic of driving signal switching control with an embedded resistor network and diode. The control of the IC driver output current is defined with the resistance R_{ON} for switching the power MOSFET on. For controlling the IC driver sink current when the power MOSFET is switched off the total resistance of parallel connected R_{ON} and R_{OFF} resistor has to be taken into account.

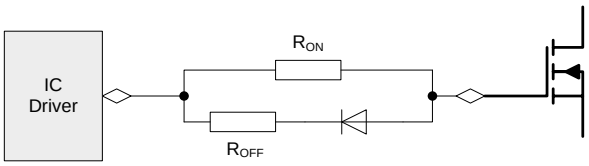

Figure 8. The driver circuit with the resistor network for controlling the switching current to the MOSFET gate terminal

A new design of the gate driver circuits for controlling parallel connected power MOSFET is realized on the same substrate on which the power devices are assembled which minimises the parasitic influences of the connections, since the gate control source/sink terminal is positioned closer to the gate terminals of the power MOSFETs. The main advantage of the proposed circuit is the option to independently control the amount of switching current provided to the MOSFET gate terminal. The proposed circuit show in Fig 9. enables the switching of the control signals of high current densities required for effective switching of the connected gate control terminals. The prototype version driver current capabilities are limited to 1A/2A source/sink current capability since the improved driver circuit is able to provide 51A of continues current in both source/sink operation.

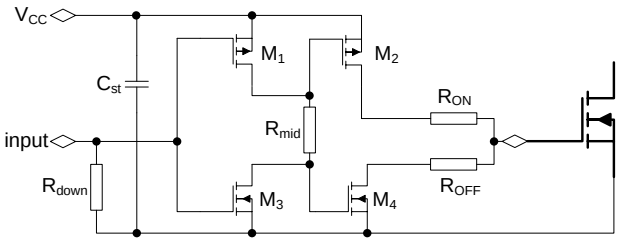

Figure 9. The driver circuit realised with non-overlapping circuit

The circuit schematic in Fig 9. shows the circuit for a single gate control. The same circuit is used for both the "high-side" and "low-side" power switches. The reference for the "high-side" power switch as well as for the driver circuit is connected to the phase potential. Since the phase potential is floating between B+ and B- battery potential an additional floating power supply source for the "high-side" driver circuit must be provided together with the capacitor element C_{st}.

The circuit consists of four MOSFET transistors (M1 – M4) connected in a full-bridge topology with an resistor R_{mid} used for preventing overlapping operation. The capacitor C_{st} is used as a bootstrap capacitor for providing the electrical charge for circuit operation. The capacitance of the bootstrap capacitor depends on the circuit power consumption and operating frequency of the application which is in this case the PWM frequency used for driving power switches within DC/AC induction motor converter. The resistors R_{ON} and R_{OFF} are used for limiting the switching on and off gate current respectively.

III. CONCLUSION

The paper introduces some design aspects for improved performance of the DC/AC induction motor converter. The improved design of the capacitor board and driver circuit performance was based on the measurements of the prototyped converter version and electrical simulations. The improved prototype also introduces implementation of a single PCB, where capacitor board is combined with driver circuits, with increased charge storage capability performance. The paper also highlights some optimization of manufacturing costs of the capacitor and driver PCB. The improved construction parts of the DC/AC induction motor converter promises the increased performance, estimation of approx. 10% high phase current capability, which will be in the future works also confirmed with additional measurements of the DC/AC induction motor converter in the laboratory as well as in the field.

Microcontroller implementation of dynamically adaptable control of stepper motor with continuous second derivative of speed curve

Josip Divić, Jurica Đurić and Koča Vrančić
College for Information Technologies (VSITE), Klaićeva 7, 10000 Zagreb, Croatia
josip.divic@vsite.hr, jurica.duric@vsite.hr, koca.vrancic@vsite.hr

Abstract - Stepper motor control is well known and in literature thoroughly studied subject for parameters of position, speed and acceleration.

Stepper motor speed control with dynamically adoptable parameters of target speed and maximal allowed acceleration, requiring continuous change of acceleration (continuous second derivative of speed function) presents challenge to microcontroller implementation on factors of processing power and/or available memory array.

Authors failed to find this kind of algorithm described in available literature, and consider it important for practical solutions of speed control in physical systems susceptible to oscillations.

Paper offers theoretical basics and presents methods for construction of control algorithm.

I. BASICS OF STEPPER MOTOR CONTROL

When considering control of stepper motors, three basic real-time parameters are subject to our influence: (i) windings current, (ii) step direction (CW or CCW) and (iii) time interval between two adjacent step pulses.

Winding current control and its influence is a broad subject of its own, and is not discussed here. Providing that the current is high enough to perform a valid step and constant enough to avoid excessive noise and resonance, it does not influence speed profile behavior in a substantial way.

Step direction parameter derives from angular velocity. It is generally assumed throughout this paper that all steps are in the same direction (regardless which), except in the special case when deceleration profile reaches zero speed, in which moment motor rotation can be halted or continued in another direction maintaining the same acceleration vector, thus changing direction of rotation.

Step interval is the main parameter of stepper motor movement control. Since any stepper motor, by design, travels the same angular distance α for every step performed, stepwise average angular speed is inversely proportional to the step duration, i.e. time interval δt between two adjacent step pulses:

$$\omega = \frac{\alpha}{\delta t}\ [\mathrm{rad/s}] \qquad (1)$$

Angular acceleration is achieved by differing δt for two adjacent step intervals:

$$\omega' = \frac{\delta\omega}{\delta t} = 2\alpha\frac{\delta t_1 - \delta t_2}{\delta t_1 \delta t_2 (\delta t_1 + \delta t_2)}\ [rad/s^2] \qquad (2)$$

Observe that acceleration is influenced by ratio and absolute values of δt_n and δt_{n+1}, what further complicates calculation of δt_{n+1} in attempt to control acceleration. For the constant acceleration ω', which is common request placed upon stepper motor control circuits, exact equation for calculating δt_1 to δt_n can be produced.

Total motor angular distance:

$$\theta(t) = \int_0^t \omega(t)\,dt = \frac{\omega' t^2}{2} = N\alpha\ [\mathrm{rad}] \qquad (3)$$

where N is total number of equidistant steps (integer, ≥0). Exact time for the nth step pulse is therefore:

$$t_n = \sqrt{\frac{2n\alpha}{\omega'}}\ [\mathrm{s}] \qquad (4)$$

Note that pulse at t_0 does not produce angular velocity, but merely energizes windings and brings motor shaft in the nearest discrete ("start") position. δt_n is calculated as time difference between two adjacent discrete moments [1], [2]:

$$\delta t_n = \delta t_1\left(\sqrt{n} - \sqrt{n-1}\right)[\mathrm{s}] \qquad (5)$$

Measurement of time is discrete in digital world, represented by the count of microcontroller timer in this case

$$\delta t = \frac{c}{f} \qquad (6)$$

Depending on the context, time interval can be stated in both notations further on in the paper.

Any acceleration ramp can be calculated exactly from (5), but not in the real time, at least not with computational power provided by standard microcontrollers.

Furthermore, δt_1 value has to be kept and used as an acceleration-vise constant for all subsequent δt_n calculations.

Historically, two approaches have been used to overcome this problem. First one is to use ramp table, where δt step timings are precalculated, stored in microcontroller memory array and accessed successively. Waste of memory space is obvious drawback of this solution. Benefit of this approach is that application of any sort of customized speed ramp profile is possible.

Second approach is based on pivotal work of David Austin [1]. He showed that by using Taylor series approximation, (5) can be simplified without significant loss in precision:

$$\delta t_n = \delta t_{n-1} - \frac{2\,\delta t_{n-1}}{4n+1} \tag{7}$$

Austin's approach relay on knowledge of exact angular position, i.e. counting number of steps *n* from start and awareness of number of steps *m* until stop. This approach can therefore be reliably used to conduct motor shaft rotation from known angular position θ_1 to known angular position θ_2. Both parameters need to be available for ramp calculation before movement starts.

II. RAMP TABLE LIMITATIONS

Number of steps to achieve angular speed ω starting from standstill at constant acceleration ω' can be calculated from:

$$\omega = \sqrt{2\omega'\theta}\ [\mathrm{rad/s}] \tag{8}$$

and (3). When substituted:

$$N = \frac{\omega^2}{2\omega'\alpha} \tag{9}$$

Microcontroller memory usage for ramp table is 2N bytes, since 8-bit resolution of timer counts *c* is not sufficient for smooth operation. Note that total number of steps N is inversely proportional to the acceleration, and proportionally to the second power of maximum angular speed. Standard stepper motors have 200 steps per revolution, resulting in α=0,031416 rad. At acceleration ω'=1 rad/s^2, and usual maximum applicable motor speed ω_M=6.000 rad/s (just under 1.000 revolutions per minute), ramp table memory size for 2N would yield 1,15 GB from (9).

That is absurdly large value, inapplicable for any microcontroller. It can be, however, implemented as virtual ramp table, demonstrated in chapter (VI).

III. CONTINUOUS ROTATION MODEL SPECIFICS

What if actual shaft angle (angular position) is of no relevance for control mechanism, and goal (target) angular position does not exist? What if the only available control parameters are current speed and acceleration, with target speed as dynamically changing input parameter, and with system defined maximum allowed acceleration? Furthermore, discontinuous change of acceleration can be prohibited in order to prevent inertial forces induced oscillations in the controlled mechanism.

Examples of that system are continuous process feeders of any kind, or dynamically balancing vehicles like Segway.

Authors were surprised not to find solutions for this kind of control algorithm in available literature, and have decided to design their own.

IV. ADAPTABLE SYSTEM CONTROL MODEL

Three parameters of rotating stepper motor are monitored in control model, at any given moment: (i) angular speed, represented by δt_n or ω, (ii) acceleration ω'_k and (iii) acceleration change $\omega'' = \frac{\delta\omega'}{\delta t}$. Target speed ω_d is input variable. Maximum allowed acceleration $\pm\omega'_M$ and maximum allowed change of acceleration $\pm\omega''_M$ are model constants.

In the special case when $c_n = c_d$ and acceleration ω'=0, no change of speed is required, so $c_{n+1} = c_n$. In all other cases, when $c_n \neq c_d$, motor speed must be changed until $c_n >= c_d$, without violating constraints of ω'_M and ω''_M.

V. VSITE APPROXIMATION

If continuous angular acceleration is started from standstill, equation relating acceleration and speed is

$$\omega = \omega' t\ [\mathrm{rad/s}] \tag{10}$$

From (4) and (10) yields (11)

$$\omega_n = \omega' \sqrt{\frac{2n\alpha}{\omega'}} = \sqrt{2\omega' n\alpha}\ \ [rad/s] \tag{11}$$

If we approximate that angular speed at the half angle of nth step ω_n is the average speed of that step, we get

$$\sqrt{2\omega'\alpha\left(n - \frac{1}{2}\right)} \cong \frac{\alpha}{\delta t_n} \tag{12}$$

yielding VSITE approximation for step duration

$$\delta t_n = \frac{\alpha}{\sqrt{\omega'\alpha\,(2n-1)}} \tag{13}$$

In discrete time domain it is transformed by (9) in

$$c_n = \frac{\alpha f}{\sqrt{\omega' \alpha (2n-1)}} \quad (14)$$

In order to achieve full resolution of c_n over available binary range in integer arithmetic, factor p has to be introduced

$$c_n = \frac{\alpha f p}{\sqrt{\omega' \alpha p^2 (2n-1)}} \quad (15)$$

Factor p has to fulfill both conditions

$$p \leq \frac{2^{32}-1}{\alpha f} \quad (16)$$

$$p \leq \sqrt{\frac{2^{32}-1}{\omega'_M \alpha (2n_M-1)}} \quad (17)$$

where n_M is

$$n_M = \frac{{\omega_M}^2}{2\omega' \alpha} \quad (18)$$

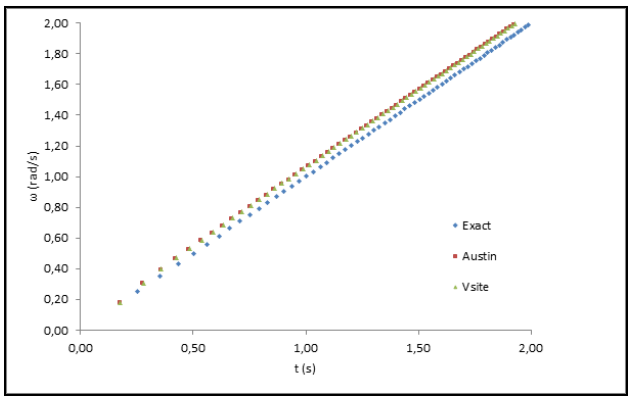

Figure 1. Comparison of constant acceleration speed ramp calculation methods

Authors argue that VSITE approximation is superior to Austin's:

- No further simplification is needed. One square root can be calculated on the fly in the integer arithmetic without exceeding the time budget.
- Each δt_n is calculated "fresh", without cumulative error of previous steps.
- δt_n is related to input parameters α, ω' and n, where n represents virtual ramp table position index. This is crucial, because it offers all the benefits of the ramp table, without consumption of the available memory.
- Formula is valid through whole domain: Compared to Austin in [1], it does not require compensation of the first step, nor special case calculation for the "zero step". Zero step is avoided altogether, movement starts with the first step as it should [3].

VI. VIRTUAL RAMP TABLE BENEFITS AND DESIGN

Ramp table normally consists of precalculated array of timer counts c for all steps from the first step after standstill c_1 until c_m, inversely proportional to ω_1 and ω_M, respectively. Each ramp table has intrinsic acceleration profile, typically constant acceleration ω'_u over the whole range.

Increase in angular acceleration, while using the same constant acceleration ramp table, can be achieved by skipping k steps (integer, $\geqslant 1$):

$${\omega_{n+1}}^2 - {\omega_n}^2 = 2\omega'_u \alpha \quad (19)$$

$${\omega_{n+k}}^2 - {\omega_n}^2 = 2\omega'_u k\alpha = 2k\omega'_u \alpha \quad (20)$$

Skipping k steps effectively reduces angular distance between two discrete motor speeds (ω_n and ω_{n+k}) from kα to α, yielding new inter-step acceleration

$$\omega'_k = k\omega'_u \quad (21)$$

Equation (21) is exact for continuous speed function, and accurate enough for discrete step speeds. Simulation shows that for typical $\alpha=\pi/100$, $\omega'=1$ and $1<k<10$, acceleration error is below 1% and diminishing from third step after stand-still onwards. For first three steps ω'_k is lower than expected, and therefore does not violate ω'_M and ω''_M constraints.

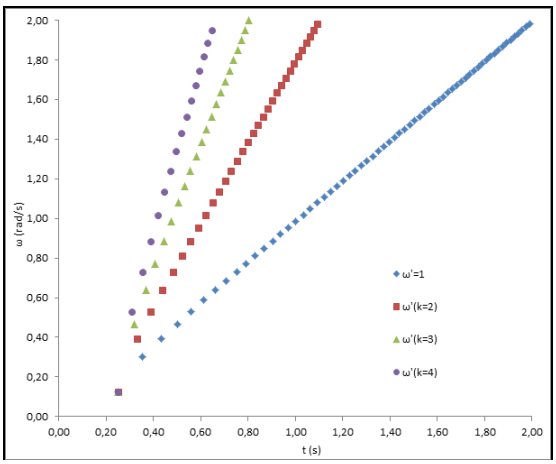

Figure 2. Dependence of acceleration profiles on factor k

Therefore, when designing virtual ramp table, ω'_u should be chosen as low as possible, and afterwards its multiples used for acceleration profiles.

VII. ACCELERATION CHANGE CONTROL

Ramping acceleration up in discrete steps k is shown in (21). Constant increase of acceleration is achieved if *k* is incremented in the constant time intervals until k_M is reached.

$$\omega''(t) = \frac{\delta \omega'_k}{\delta t} = \omega'_u \frac{\delta k}{\delta t} \quad (22)$$

In order to obey constraint of $\pm\omega''_M$, the same process has to be done at the end of speed ramp profile, ω' has to

be gradually lowered, reaching $\omega'=0$ exactly at the moment when $\omega=\omega_d$. It is possible for small changes of ω that acceleration ramp-down has to start before ramp-up is completed (before k_M is reached), so universal formula is needed for determining break point speed ω_B at which acceleration ramp-down must commence in order to land at desired speed ω_d.

We are starting from angular velocity:

$$\omega(t) = \frac{1}{2}\omega'' t^2 + \omega'_0 t + \omega_0 \qquad (23)$$

where ω'_0 and ω_0 are initial acceleration and initial speed respectively. It can be substituted with (21) to give equation for ω_b

$$\omega_b = \omega_d - \frac{1}{2}\omega'' t^2 - k\omega'_u t \qquad (24)$$

In our case, where ω_d has to be reached at the end of interval where $\omega' = \omega'_u$ (k=1), (24) gives break point speed

$$\omega_b = \omega_d - \frac{k(k+1)}{2} \times \frac{{\omega'_u}^2}{\omega''} \qquad (25)$$

Both ω'^2_u and ω'' are systemlevel constants.

If (25) is substituted with

$$\omega = \frac{\alpha f}{c} \qquad (26)$$

c_b becomes

$$c_b = \frac{(2\alpha f\omega'') \times c_d}{(2\alpha f\omega'') - k(k+1)\omega'_u{}^2 c_d} \qquad (27)$$

When condition $c_n \leq c_b$ is reached, acceleration ramp-down has to commence. Term $2\alpha f\omega''$ is separated in parentheses because it should be precalculated, it is systemlevel constant.

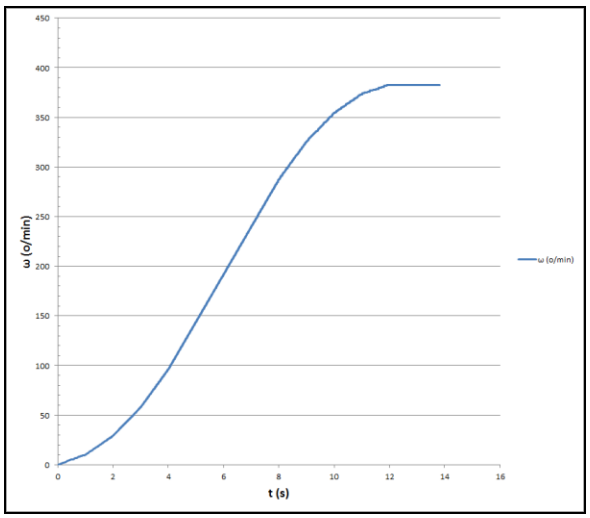

Figure 3. Continuous second derivation speed curve

VIII. CONCLUSION

Authors believe to have demonstrated method for implementation of dynamically adaptable control of stepper motor. VSITE approximation for calculating δt_n and using virtual ramp table for acceleration control allow for speed changes with continuous second derivative.

Optimized Coupled Band-Pass Filters

***Abstract*— In this paper we compare two versions of fourth-order band-pass (BP) filter section realized as coupled structure, having negative feedback around two Biquadratic sections in cascade, usually designated as Biquartic section (i.e. it is the fourth-order band-pass section). The frequency response of a filter is subject to vary from the nominal values due to the effects of aging, changing working conditions, the fabrication tolerances of passive and active elements, etc. In order to maintain the filter's characteristics inside given specifications at the time of manufacture, and as long as possible, the main requirement is to design filters with reduced sensitivity to component tolerances. The Biquartic section has significantly reduced sensitivities to the changes of passive element values, particularly within the pass band, in comparison to common cascade design. For that purpose this structure is very suitable for use as a building block of narrow band, high order BP filters. The sensitivities are further reduced by using three-amplifier biquadratic block instead of more sensitive single-amplifier block. We investigated the sensitivities of two versions of biquartic section with two extreme combinations of second-order sections q-factor values, using Schoeffler's measure, the dynamic range, and output thermal noise using analysis in PSpice. Biquartic sections used throughout the examples are realized as reduced amplifier version retaining the low sensitivities of biquartic design. They also possess simple tuning features and simple design; design equations are given.**

Keywords: Band-pass filters, Low-sensitivity filters, Low-noise filters, Biquartic section, Cascade realization, Schoeffler's sensitivity.

I. INTRODUCTION

Often in practice band–pass (BP) filters of high-order and narrow pass-band are difficult to be realized. They possess very high pole-Q factors, and therefore have very high sensitivity to component tolerances. This problem is becoming more pronounced if such band-pass filters are realized in integrated-circuit form, because on-chip component tolerances are much larger than those in discrete form. One of the efficient solutions of this problem is reducing the sensitivity using negative feedback: a coupled structure [1], [2].

In this paper we present the reduced-amplifier design of the coupled fourth-order BP filter with *low sensitivity* which is referred to as Biquart. We analyse the sensitivity of the obtained filter using Schoeffler's measure, on various examples and different designs. In the design we also wish to have the possibility of easy tuning the center frequency and the pass-band width without deteriorating the amplitude-frequency characteristics. It is also desirable that the new structure provides lower signal distortion and output thermal noise, as well.

II. HIGH-ORDER BP FILTERS DESIGN

To design high-order ($2N^{th}$–order) geometrically symmetrical BP filters we start from N^{th}-order low-pass (LP) prototype filter with the transfer function:

$$T_{LP}(S)=\left[\frac{k_{LP0}\cdot\gamma}{S+\gamma}\right]^{\eta}\prod_{i=1}^{(N-\eta)/2}\frac{k_{LPi}\cdot\omega_{LPi}^2}{S^2+\left(\omega_{LPi}/Q_{LPi}\right)\cdot S+\omega_{LPi}^2}, \quad (1)$$

where η=1 if the filter order N is odd, η=0 for N even, γ is the frequency of the negative real pole for N odd, ω_{LPi} and q_{LPi} are parameters of the $(N-\eta)/2$ complex-conjugate pole pairs, and the k_{LPi} are pass-band gains. If (1) is realized in the cascade form we take care of the sequence of realizing the individual Q-factors such that $Q_{LPi}<Q_{LPi+1}<Q_{LPi+2}<\dots$. Using common LP–BP transformation:

$$S=\frac{s^2+\omega_0^2}{Bs}, \quad (2)$$

where ω_0 is the desired center frequency, and B is the desired pass-band width of the band-pass filter, we realize the BP transfer function of the general form given by:

$$T_{CBQ}(s)=\left[T_{b0}(s)\right]^{\eta}\prod_{i=1}^{(N-\eta)/2}T_{BQi}(s),\ \eta=\begin{bmatrix}1 & \text{for } N \text{ odd}\\ 0 & \text{for } N \text{ even}\end{bmatrix}, \quad (3)$$

where we realize $(N-\eta)/2$ BP fourth-order sections in cascade, and one second-order section if the LP prototype filter was odd. The transfer function of second-order section has the form given by (4) (without index i).

Each $T_{BQi}(s)$ in (3) is fourth order transfer function and we will continue to call it Biquartic transfer function, while the network which implements such a function is called Biquartic section or "Biquart" (hereafter BQ). $T_{b0}(s)$ is second order transfer function and is referred to as Biquadratic section or "Biquad". The BP filter of higher order having the transfer function defined by (3) is referred to as "Cascade of Biquarts" (hereafter CBQ).

III. BIQUARTIC SECTION

Biquartic section, which realizes each fourth-order BP transfer function $T_{BQi}(s)$ in (3) is the main subject of this paper. It will be realized by cascading two BP Biquadratic sections (of second-order) applying a negative feedback, as shown in Fig. 1 (see [1], [2]).

Gain β represents the feedback coefficient (β>0), A is an input gain, and $T_{b1}(s)$, $T_{b2}(s)$, are the second-order BP

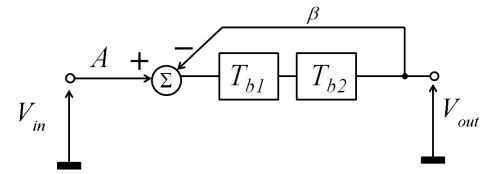

Figure 1. Biquartic BP section.

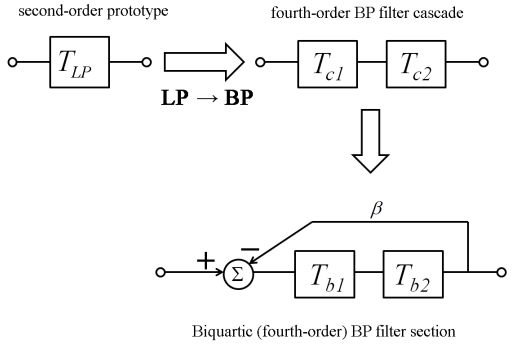

Figure 2. Complete procedure of the calculation of the fourth-order BP Biquartic section starting from second-order LP prototype via cascade.

Biquadratic sections with voltage transfer functions given by:

$$T_{bi}(s)=\frac{k_{bi}s}{s^2+(\omega_{bi}/Q_{bi})\cdot s+\omega_{bi}^2};\ i=1,2. \tag{4}$$

Voltage transfer function of the Biquartic section in Fig. 1 is given by:

$$T_{BQ}(s)=\frac{V_{out}(s)}{V_{in}(s)}=\frac{AT_{b1}(s)T_{b2}(s)}{1+\beta T_{b1}(s)T_{b2}(s)}=\frac{N_{BQ}(s)}{D_{BQ}(s)}. \tag{5}$$

The complete procedure in designing of one BP fourth-order BQ section in CBQ, from the second-order LP prototype filter over the cascaded fourth-order BP filter is shown in Fig. 2. The realization starting from the 1st-order LP producing the 2nd-order BP filters if the filter prototype order N was odd is well-known.

A. Determination of the coefficients of the cascade

In the first step in Fig. 2 it is shown the common LP–BP transformation applied on the second-order LP prototype filter and the obtained fourth-order BP filter in the cascade structure. The transfer function of a second-order LP prototype is given by (1) for N=2. Combining (2) and (1) we obtain $T_{BP}(s)=N(s)/D(s)$ in the form:

$$T_{BP}(s)=\frac{k_{LP}\cdot B^2\omega_{LP}^2\cdot s^2}{s^4+B\omega_0^2\frac{\omega_{LP}}{Q_{LP}}s^3+\left(2\omega_0^2+B^2\omega_{LP}^2\right)s^2+B\frac{\omega_{LP}}{Q_{LP}}s+\omega_0^4}. \tag{6}$$

Transfer function of the fourth-order BP cascade in Fig. 2 has the form:

$$T_{CAS}(s)=\prod_{i=1}^{2}T_{ci}(s), \tag{7}$$

where $T_{c1}(s)$ and $T_{c2}(s)$ are the second-order Biquadratic sections with BP voltage transfer functions given by:

$$T_{ci}(s)=\frac{k_{ci}s}{s^2+(\omega_{ci}/Q_{ci})\cdot s+\omega_{ci}^2};\ i=1,2. \tag{8}$$

We substitute (8) into (7) and rewrite it in the form:

$$T_{CAS}(s)=\frac{k_{c1}k_{c2}\cdot}{s^4+\left(\frac{\omega_{c1}}{Q_{c1}}+\frac{\omega_{c2}}{Q_{c2}}\right)s^3+\cdot s^2}\cdots$$
$$\cdots\frac{}{+\left(\omega_{c1}^2+\omega_{c2}^2+\frac{\omega_{c1}\omega_{c2}}{Q_{c1}Q_{c2}}\right)s^2+\left(\frac{\omega_{c1}^2\omega_{c2}}{Q_{c1}}+\frac{\omega_{c1}\omega_{c2}^2}{Q_{c2}}\right)s+\omega_{c1}^2\omega_{c2}^2}. \tag{9}$$

If we equate the coefficients multiplying the potentions of complex variable "s" in the denominator of (9) and (6) we obtain the system of equations:

$$\frac{\omega_{c1}}{Q_{c1}}+\frac{\omega_{c2}}{Q_{c2}}=B\frac{\omega_{LP}}{Q_{LP}} \tag{10}$$

$$\omega_{c1}^2+\omega_{c2}^2+\frac{\omega_{c1}\omega_{c2}}{Q_{c1}Q_{c2}}=2\omega_0^2+B^2\omega_{LP}^2 \tag{11}$$

$$\frac{\omega_{c1}^2\omega_{c2}}{Q_{c2}}+\frac{\omega_{c1}\omega_{c2}^2}{Q_{c1}}=B\frac{\omega_{LP}}{Q_{LP}}\omega_0^2 \tag{12}$$

$$\omega_{c1}^2\omega_{c2}^2=\omega_0^4 \tag{13}$$

Combining (10) and (12) we obtain the condition for determining solutions:

$$(\omega_{c2}-\omega_{c1})(Q_{c2}-Q_{c1})=0. \tag{14}$$

Two solutions are possible depending on the poles of the LP prototype:

1. $\omega_{c1}=\omega_{c2}=\omega_0$ for real poles of the LP prototype.
2. $Q_{c1}=Q_{c2}=Q_c$ for conjugate-complex poles of the LP prototype.

In what follows we choose conjugate-complex poles of the LP prototype (case 2) and the system of equations (10)–(13) is simplifying into the system:

$$\frac{\omega_{c1}+\omega_{c2}}{Q_c}=B\frac{\omega_{LP}}{Q_{LP}} \tag{15}$$

$$\omega_{c1}^2+\omega_{c2}^2+\frac{\omega_0^2}{Q_c^2}=2\omega_0^2+B^2\omega_{LP}^2 \tag{16}$$

$$\omega_{c1}\omega_{c2}=\omega_0^2 \tag{17}$$

Rearranging and grouping equations of the latest system, we arrive at expressions for Q_c, ω_{c1} and ω_{c2} of the cascade realization (Geffe equations) [3]:

$$Q_c=\sqrt{\frac{Q_{LP}\omega_0}{B\omega_{LP}}}\times\sqrt{Q_{LP}X+\sqrt{Q_{LP}^2X^2-1}};\quad X=2\omega_0/(B\omega_{LP})+B\omega_{LP}/(2\omega_0), \tag{18}$$

$$\frac{\omega_{c2}}{\omega_0}=\frac{\omega_0}{\omega_{c1}}=\frac{B\omega_{LP}}{2Q_{LP}}Q_c+\sqrt{\left(\frac{B\omega_{LP}}{2Q_{LP}}Q_c\right)^2-1}. \tag{19}$$

If we equate numerator in (9) and (6) we obtain:

$$k_{c1}\cdot k_{c2}=k_{LP}\cdot B^2\omega_{LP}^2. \tag{20}$$

B. Voltage transfer function of the Biquartic section

Consider the transfer function of the Biquartic section in Fig.1 given by (5). Since the positions of the poles of $T_{BQ}(s)$ is determined by the product $\beta k_{b1}k_{b2}$, i.e. not only by β, we will use the designation F ($F=\beta k_{b1}k_{b2}$) in order to simplify the expression. We rewrite (5) in the form:

$$T_{BQ}(s)=\frac{Ak_{b1}k_{b2}\cdot}{s^4+\left(\frac{\omega_{b1}}{Q_{b1}}+\frac{\omega_{b2}}{Q_{b2}}\right)s^3+\cdot s^2}\cdots \\ \frac{}{+\left(\omega_{b1}^2+\omega_{b2}^2+\frac{\omega_{b1}\omega_{b2}}{Q_{b1}Q_{b2}}+F\right)s^2+\left(\frac{\omega_{b1}^2}{Q_{b1}}+\frac{\omega_{b2}^2}{Q_{b2}}\right)s+\omega_{b1}^2\omega_{b2}^2} \quad (21)$$

Poles of the transfer function are determined by the denominator of the Biquartic transfer function:

$$D_{BQ}(s)=D(s)+Fs^2=D(s)+\beta k_{b1}k_{b2}s^2. \quad (22)$$

It is evident that for F=0 (β=0, k_{b1}, $k_{b2}\neq 0$) the BQ consists of the two Biquads connected in the cascade, and $D(s)$ represents the denominator of (6), i.e. of the cascade.

Consider the commonly used cascade realization and compare it with the Biquartic section (both of fourth order) shown in Fig. 2. If we equate the coefficients multiplying the potentions of complex variable "s" in (21) to (9), we obtain the system of equations:

$$\frac{\omega_{c1}}{Q_{c1}}+\frac{\omega_{c2}}{Q_{c2}}=\frac{\omega_{b1}}{Q_{b1}}+\frac{\omega_{b2}}{Q_{b2}} \quad (23)$$

$$\omega_{c1}^2+\omega_{c2}^2+\frac{\omega_{c1}\omega_{c2}}{Q_{c1}Q_{c2}}=\omega_{b1}^2+\omega_{b2}^2+\frac{\omega_{b1}\omega_{b2}}{Q_{b1}Q_{b2}}+F \quad (24)$$

$$\frac{\omega_{c1}^2\omega_{c2}}{Q_{c2}}+\frac{\omega_{c1}\omega_{c2}^2}{Q_{c1}}=\frac{\omega_{b1}^2\omega_{b2}}{Q_{b2}}+\frac{\omega_{b1}\omega_{b2}^2}{Q_{b1}} \quad (25)$$

$$\omega_{c1}^2\omega_{c2}^2=\omega_{b1}^2\omega_{b2}^2 \quad (26)$$

Because it is given above [see (18) and (19)]:

$$\omega_{c1}\omega_{c2}=\omega_0^2,\quad Q_{c1}=Q_{c2}=Q_c, \quad (27)$$

we have:

$$\omega_{b1}\omega_{b2}=\omega_0^2, \quad (28)$$

and we choose

$$\omega_{b1}=\omega_{b2}=\omega_0. \quad (29)$$

Now the system of equations (23)–(26) is simplifying into the system (note that (23) and (25) have become identical):

$$\frac{\omega_{c1}+\omega_{c2}}{Q_{c1}}=\omega_0\left(\frac{1}{Q_{b1}}+\frac{1}{Q_{b2}}\right), \quad (30)$$

$$\omega_{c1}^2+\omega_{c2}^2+\frac{\omega_0^2}{Q_c^2}=2\omega_0^2+\frac{\omega_0^2}{Q_{b1}Q_{b2}}+F. \quad (31)$$

Rearranging it we obtain the condition for determining solutions:

$$(\omega_{b2}-\omega_{b1})(Q_{b2}-Q_{b1})=0. \quad (32)$$

We have two equations (30) and (31) and three unknowns to be determined Q_{b1}, Q_{b2} and F. One of the unknowns can be freely chosen (therefore we have one degree of freedom). We choose pole Q factors of the sections T_{b1}, T_{b2} to have two limiting values of Q-factors:

1. Sections T_{b1}, and T_{b2} have identical Q-factors.
2. One of the sections T_{b1} or T_{b2} has an infinite Q-factor.

Between these two limiting cases for Q-factors there are infinite possibilities, which turn to be more sensitive, and we do not treat them separately.

C. Equal Q-factors Q_{b1}=Q_{b2} [4]

The sections T_{b1} and T_{b2} are becoming identical, and we have:

$$Q_{b1}=Q_{b2}=\frac{2\sqrt{\omega_{c1}\omega_{c2}}}{\omega_{c1}+\omega_{c2}}Q_c. \quad (33)$$

$$\omega_{b1}=\omega_{b2}=\omega_0=\sqrt{\omega_{c1}\omega_{c2}}. \quad (34)$$

Feedback factor F takes the value defined by an expression:

$$F=(\omega_{c2}-\omega_{c1})^2\left(1-\frac{1}{4Q_c}\right). \quad (35)$$

D. One Q-factor is in infinity: Q_{b2}=∞

One Q-factor is becoming infinite, while other has the value:

$$Q_{b1}=\frac{\sqrt{\omega_{c1}\omega_{c2}}}{\omega_{c1}+\omega_{c2}}Q_c. \quad (36)$$

Pole frequencies are the same as in the previous case:

$$\omega_{b1}=\omega_{b2}=\omega_0=\sqrt{\omega_{c1}\omega_{c2}}. \quad (37)$$

Feedback factor F is then given by:

$$F=(\omega_{c2}-\omega_{c1})^2+\frac{\omega_{c1}\omega_{c2}}{Q_c^2}. \quad (38)$$

IV. EXAMPLES

In this section we realize three examples of the active-RC BP filters: one for the cascade (CAS) case in the Section III.A, and two for the Biquartic (BQ) cases in the Sections III.C and III.D. Consider two approximations: *i*) Butterworth (with normalized LP prototype parameters: ω_{LP}=1, Q_{LP}=0.707107), and *ii*) 0.5dB-ripple Chebyshev (ω_{LP}=1.231342, Q_{LP}=0.863721 [a higher pole-Q case]) that are transformed into BP characteristics with normalized center frequency ω_0=1 and bandwidth B=0.1. Filters are then denormalized to the frequency 10kHz. The active realization is shown in Fig. 3 and the element values are in Table I. Corresponding amplitude-frequency characteristics are shown in Fig. 4.

Generally, the transfer function of each Biquad shown in Fig. 3 has the form given by (4), with:

$$\omega_{bi}=\sqrt{\frac{R_{Fi}}{C_{i1}C_{i2}R_{i1}R_{i3}R_{bi}}};\ Q_{bi}=C_{i1}R_{i2}\sqrt{\frac{R_{Fi}}{C_{i1}C_{i2}R_{i1}R_{i3}R_{bi}}};\quad k_{bi}=\frac{R_{Fi}}{C_{i1}R_{0i}R_{i1}};\quad i=1,2. \tag{39}$$

Note that in this realization we do not use a separate operational amplifier for negative feedback. Instead, we lead the output signal to the positive input of the first operational amplifier in the first biquad. As a consequence the feedback factor F is determined by:

$$F=\beta\cdot k_{b1}\cdot k_{b2}=\beta\cdot\left(1+\frac{R_{F1}}{R_{01}}+\frac{R_{F1}}{R_{b1}}\right)\cdot\frac{1}{R_{11}C_{11}}\cdot k_{b2}, \tag{40}$$

where

$$\beta=R_{F3}/(R_{F3}+R_{03}). \tag{41}$$

It is evident from (39) that for $R_{i2}=\infty$ the pole-Q factor is infinite (e.g., for $R_{22}=\infty$ in Fig. 3 there is $Q_{b2}=\infty$).

We choose value of R_{F3} and calculate R_{03} depending on F:

$$R_{03}=\frac{R_{F3}}{F}\left[\left(1+\frac{R_{F1}}{R_{01}}+\frac{R_{F1}}{R_{b1}}\right)\cdot\frac{1}{R_{11}C_{11}}\cdot k_{b2}-F\right]. \tag{42}$$

It is evident from (40) and (41) that for $R_{03}=\infty$ and $R_{F3}=0$ the feedback factor $F=0$ and the circuit in Fig. 3 becomes cascade of Biquads.

Using (39)−(42) we calculate normalized elements of filter examples and denormalize the filter to the center frequency f_0=10kHz and bandwidth B=1kHz. We choose denormalization resistance R_0=1.591kΩ in order to obtain denormalization capacitance C_0=10nF. The obtained values are given in Table I. In order to provide maximum dynamic range it will be needed to perform gain optimization in the next step, which is in this case not possible in the simple non-iterative way. It is needed to perform numerical optimization or the optimization in an iterative way.

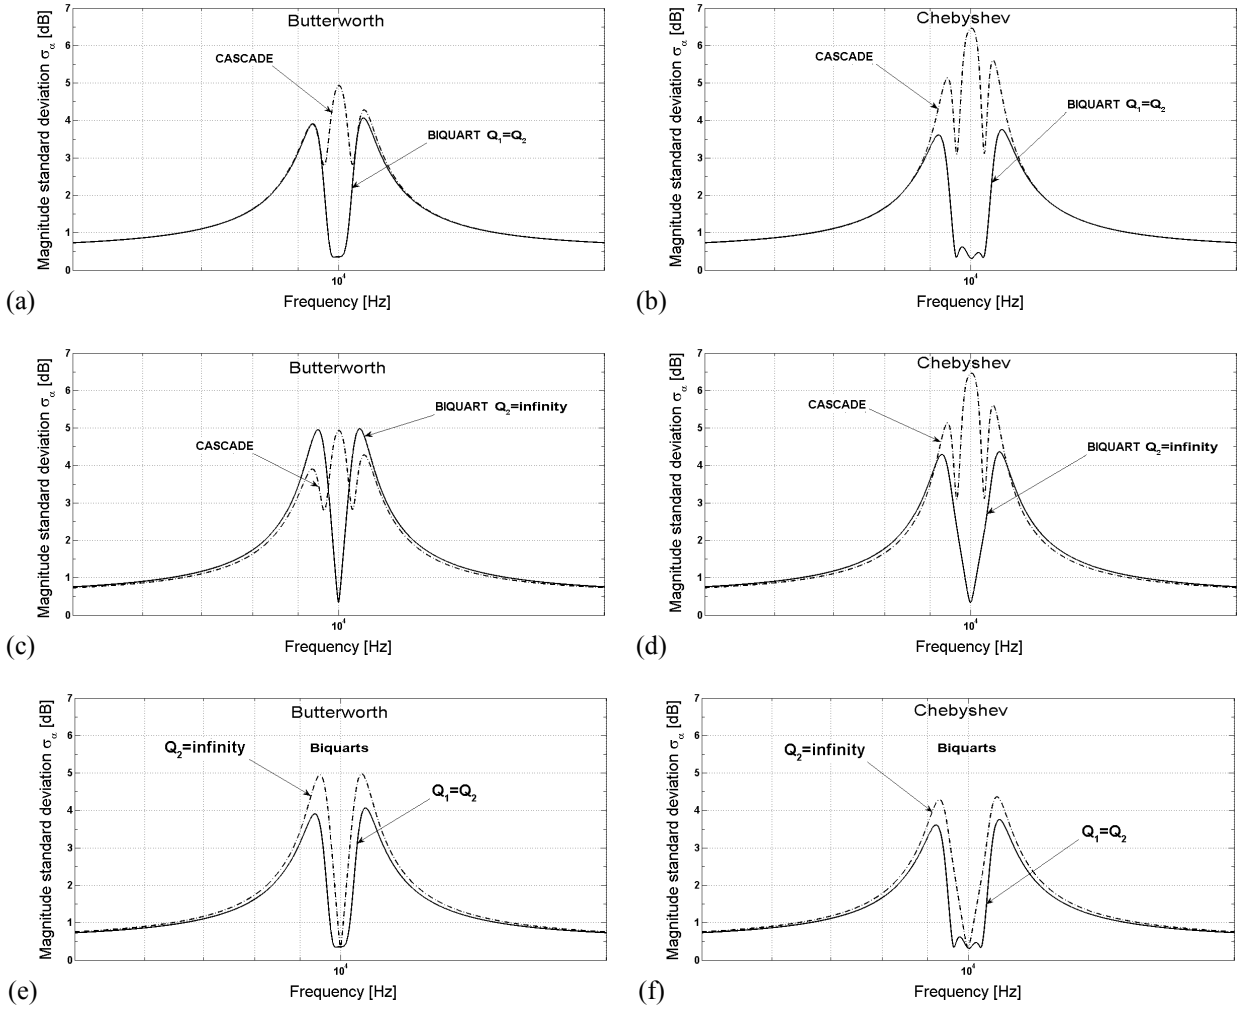

Figure 5. Simulated Schoeffler sensitivities of filter examples in Table I using Matlab. (a), (c), (e) Butterworth. (b), (d), (f) Chebyshev.

V. RESULTS OF SIMULATION AND MEASUREMENT

The sensitivity to component tolerances and output thermal noise, are compared for the cases of cascade (in Section III.A) and for the two BQ realizations: *i*) equal Q-factors: $Q_{b1}=Q_{b2}$ (in Section III.C); and *ii*) one Q-factor is in infinity: $Q_{b2}=\infty$ (in Section III.D). Sensitivity analysis is performed using MATLAB procedures given in [5], assuming relative changes of resistors and capacitors to be uncorrelated random variables, with a zero-mean Gaussian distribution and 1% standard deviation. The standard deviation (which is related to Schoeffler's sensitivities) of the variation of the logarithmic gain $\Delta\alpha$=8.68588 $\Delta|T_{BP}(\omega)|/|T_{BP}(\omega)|$[dB], with respect to passive elements, is calculated for filter examples from Table I and shown in Fig. 5. We conclude that low-sensitivity BP filters can be designed using CBQ filters with equal Q-factors: $Q_{b1}=Q_{b2}$. Using the Altium Designer program output thermal noise spectral density of filter examples in Table I was generated and shown in Fig. 6. In the simulation a model of TL081/TI (Texas Instruments) FET input opamp, having typical values, as found in the data-sheets $e_{na}(f)$=17nV/√Hz and $i_{na1}(f)\approx i_{na2}(f)$=0.01pA/√Hz is used. From Fig. 6 one can conclude that the minimum noise possesses CBQ filters with equal Q-factors: $Q_{b1}=Q_{b2}$.

Measurements were performed on the same examples realized on separate printed circuit boards using 1% passive elements and TL081/TI opamps. For each filter, the output noise spectral density was measured using a typical university lab environment. The measurement equipment consisted of a high-quality HP 4195A Network

Analyser, which measures the spectrum of noise (Spectrum mode). Detailed description of measurement procedure and equipment is given in [6]. Measured results are shown in Fig. 7, and reconfirm the results obtained by simulation.

VI. CONLUSION

In accordance with a simulated sensitivity by Schoeffler in realizations of amplitude-frequency characteristics large discrepancies in implementation with one infinite Q factor are expected. Thus, better results are gained using Biquartic sections with identical Q factors. Deviations in amplitude-frequency characteristics are predictable in shifting of the center frequency and amplitude distortion. Observing Schoeffler sensitivities it is visible that the sections with one infinite Q factor have increased sensitivities at the band-edges.

In order to reduce the overall sensitivities we use the three-amplifier biquads as building blocks for biquartic filter because of their considerably lower sensitivities comparing to single-amplifier structures, at the expense of the increased power consumption.

The sensitivity differences between the two CBQ cases are smaller on Chebyshev filter frequency response. Since Chebyshev transfer function has higher Q-factors than Butterworth it leads us to conclusion that the differences are smaller in the highly selective BP filters. The cascade structure has considerably bigger sensitivities in all cases.

Measured spectral density of circuit output thermal noise is very close to the simulation results. We note better results in Biquartic sections with identical Q factors. Both Biquartic realizations are preferable over the common cascade structure. In all measurements and simulations wins Biquartic section with identical Q factors and imposes as an optimal realization of low- sensitive filters.

ACKNOWLEDGEMENT

The authors wish to thank M. Sc. Kristijan Bago for measurements made on the filter examples in this paper.

Abstract - Grid connected converters present a key element in modern systems for harvesting renewable energy sources. Each of these converters, non-dependent on the converter topology, requires a grid synchronization algorithm. This is not a new requirement for such converter types, but design and development of applicable algorithms requires a lot of time and resources. This is especially evident in high power converters on which grid codes are applied. This paper shows an accelerated development method applied on a complex PLL structure resulting with a code suitable for deployment on real-time control system.

I. INTRODUCTION

For correct operation of grid-connected converters basic prerequisite is synchronization with grid voltage accomplished through a grid synchronization algorithm. Modern synchronization algorithms have a few different approaches, and the most common ones are different versions of PLL (Phase-locked loop) structures. Just like their associated converters, they are roughly divided into PLLs for single-phase converters and PLL algorithms for three-phase converters. This paper focuses on PLL algorithms for three-phase converters only. This is done mostly, since they are regularly of higher power output, due to specific requirements of different national grid code requirements [10][12], including low voltage ride through (LVRT) capability [6][7], which are applied to these converters. Research explained further on is to be applied to an in-house developed photovoltaic grid-connected inverter which uses a form of voltage oriented vector control (VOC) [13] as shown in Figure 1. As it can be seen, quality of the extracted angle will dictate performance of the control algorithm and the converter itself.

II. DEVELOPMENT AND TESTING OVERVIEW

During the development, the idea was to create synchronization algorithm and implement the structure into the real converter without any major subsequent changes in the PLL structure which is usually necessary when carrying over simulations-based algorithms into real converters (e.g. influence of discretization). For such goals to be achieved, both PLL algorithm and the inverter had to be implemented on the system as close as possible to the target system. As an ideal platform, a hardware-in-the-loop system, shown in the Figure 3. coupled with DSP control board (same as in target converter) was used. Selection of an appropriate baseline-algorithm was done and explained in detail in authors' recent work [18]. For algorithm development, focus was set on a decoupled double synchronous reference frame PLL (DDSRF-PLL) due to its benefits over other structures [1][3] which was compared with synchronous reference frame PLL structure (SRF-PLL), and grid angle extracted from measured voltages in αβ–frame. After initial testing using simulation software (of both synchronization algorithms and grid with disturbances) and verification of the results, system was further developed using only hardware in the loop system and associated DSP.

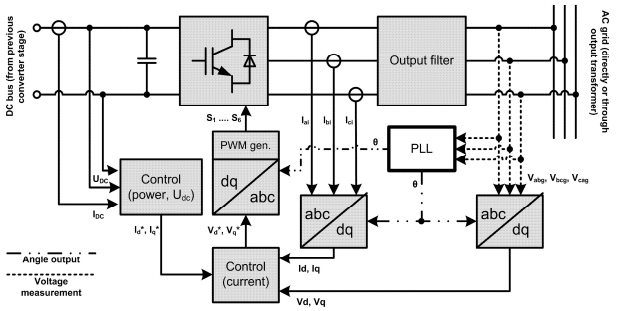

Figure 1. Block diagram of inverter VOC control algorithm

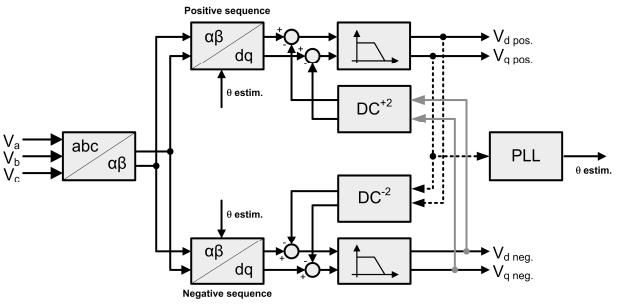

Figure 2. Block diagram of the starting PLL algorithm

Figure 3. Hardware in the loop system used for the development

Several sets of tests for various disturbances, either predefined in grid code requirements, or found as a compilation of different grid code requirements [7][10], have been applied to the PLLs. These included symmetric voltage drops, asymmetric voltage drops (i.e. short circuits), phase changes including extreme conditions equal to *phase skipping* and frequency changes. The most important test, which gave questionable results and required further research, explained in this paper, was testing of operation in grid polluted with higher harmonics. Although operating marginally satisfactory in some cases [6], in-depth testing with waveforms which could occur if the converter is changing its operation regime, i.e. switching from grid-connected operation into micro-grid (or as a worst case, into stand-alone operation with local loads) and vice versa, has shown inadequate results, as shown in Figure 4. (figure shows real-time recording from DSP system connected to the hardware-in-the-loop system). *VDN* and *VQN* are *D* and *Q* components of positive rotating transformation while *VDM* and *VQM* are inverse rotation components. *U1_JH* and *U1_JHP* are input and estimated voltage waveforms of a single phase. The found problem (i.e., bad phase and voltage estimation in harmonics-polluted grid) is known and elaborated in the literature [2]-[5]. Authors proposed pre-filtering structure based around the second-order generalized integrator (SOGI) shown in Figure 5. which suppresses higher harmonics, allowing the rest of the DDSRF structure to be optimized for required dynamics.

III. EXTENSION OF PREFILTERING STRUCTURE

Although results showed that large amounts of higher harmonics have been successfully attenuated [18], some deficiencies have been encountered. These are based around inherent downsides of the SOGI structure [14], most easily seen and described as phase estimation error found in system response during start-up and in responses in similar step-changes in the input. Although it seems that system can be further optimized, this is not the case as the system is to be used in phase estimation of grid voltages with high amount of harmonics, and any further tuning of the system results with the distorted output which is then transferred through the succeeding DDSRF structure and into the estimated phase. A possible solution, as described in the [8] was therefore tested.

A. Extended system description

Second order generalized integrator is described with transfer function according to (1). Transfer functions across the direct and quadrature components (outputs of the system) are given with (2) and (3) respectively. These equations show the idea behind the presented structure, i.e., the filter bandwidth is not a function of the central frequency but filter gain and the amplitudes of both outputs are the same as in the input signal. A simple modification to second order generalized integrator structure shown in Figure 5. can be made as shown in Figure 7. First difference between previous SOGI structure and filtering structure presented here is in redirecting both integrator outputs as error signals back to the integrator inputs of the phase-shifted signal, while this was true only for the quadrature integrator output in the case of generalized integrator filter. Second difference is that input error signal is now split into two branches with separate gains (outer loop with single gain is not shown in Figure 5.). This filtering structure has, again, two separate outputs with 90° phase offset. For such structure transfer functions across direct and quadrature component are given with (4) and (5) respectively.

$$G_{filt}(s) = \frac{s \cdot \omega_S}{s^2 + \omega_s^2} \tag{1}$$

$$G_D(s) = \frac{k \cdot s \cdot \omega_S}{s^2 + s \cdot k \cdot \omega_S + \omega_s^2} \tag{2}$$

$$G_Q(s) = \frac{k \cdot \omega_s^2}{s^2 + s \cdot k \cdot \omega_S + \omega_s^2} \tag{3}$$

$$G_{DK}(s) = \frac{k_{DK} \cdot s - k_{QK} \cdot \omega_S}{s^2 + s \cdot k_{DK} - k_{QK} \cdot \omega_S + \omega_s^2} \tag{4}$$

$$G_{QK}(s) = \frac{k_{QK} \cdot s + k_{QK} \cdot \omega_S}{s^2 + s \cdot k_{DK} - k_{QK} \cdot \omega_S + \omega_s^2} \tag{5}$$

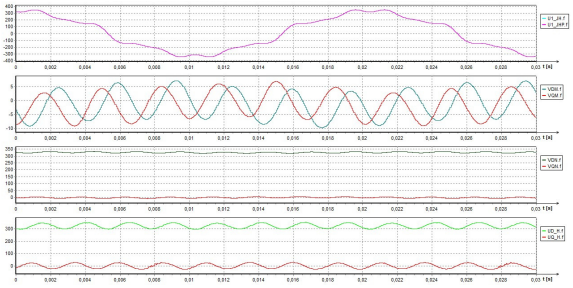

Figure 4. Baseline PLL algorithm behaviour in harmonics-polluted grid

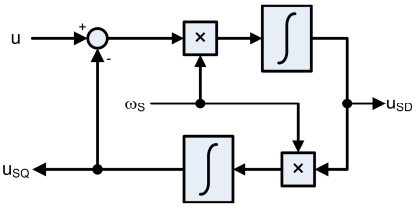

Figure 5. Schematic of second-order generalized integrator (SOGI)

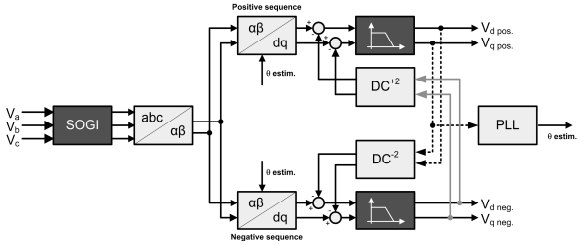

Figure 6. Modified DDSRF-PLL structure with added pre-filtering structure

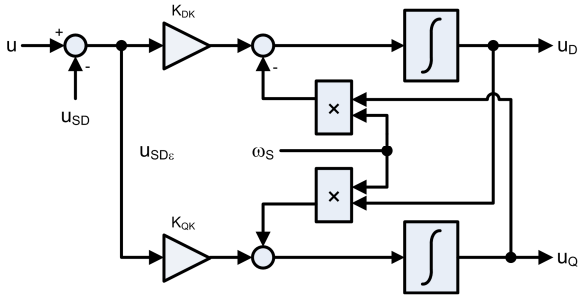

Figure 7. Transformation of SOGI structure

B. Output components' estimation

Two different approaches were tested for designing the presented filtering structure. First is an iterative, heuristic process which starts with generalized integrator settings. This is accomplished by setting the K_{QK} factor to 0 which basically converts the extended structure back to generalized integrator filter. K_{DK} factor is now tuned. Time constant (convergence) of the SOGI structure is given with (6), while the time constant of the extended general integrator structure is given with (7).

$$\tau = \frac{2}{k \cdot \omega_S} \tag{6}$$

$$\tau = \frac{2}{k_{DK}} \tag{7}$$

Since literature suggests that settling time for second order system is $t_S=4.6\times\tau$, [17], it is implied that, in practice, optimal gain for SOGI structure is *k=sqrt(2)*. For frequency of 50Hz this equals to settling time of roughly 20ms. For clear understanding, Figure 8. and Figure 9. give (initial) step response of second order generalized integrator structure for several different settling times. Shown tuning range is from 0.8 to √2 in 0.2 steps. Further increase of K_{DK} factor does make improvements, but, as it can be seen from Figure 8. , improvements are limited and a phase offset error (i.e. delay if viewed as sinusoidal values) after startup always exists, as shown in Figure 9. After a base value for K_{DK} was set, K_{QK} factor was changed in steps (equivalent outputs for K_{QK} settings are not shown). Acquired results show that gain increase creates perceivable change in the filter behavior. More precisely, maximum error at the output can be reduced by a large amount (more than 40% in tested cases), but in the same time, as a downside, overshoot increases and with further gain increase, inadmissible oscillations occur. Such behavior will be seen as *hunting* of the input signal which will be transferred to DDSRF structure resulting false values of phase angles. This deficiency will be passed further on into the rotating transformations and current controllers which destabilize the control system. It should be emphasized that it can be seen that while extending SOGI structure, position of the multiplication with ω has been changed prior to summation point. Due to this fact, a scaling factor, approximately same as the angular frequency, had to be incorporated into the gain blocks so that the results are comparable with the starting general integrator structure. Also, it should be noted that throughout the paper, graphs dedicated to extended structure are designated as *Kalman* due to reasons explained further on in the text.

After the system was tested using clean input sine signal and iterative procedure gave a satisfactory response, a setup was extended using a higher harmonic generator. Basic setup in simulation models uses percentage harmonic shares as described in [7]. For previously described implementations in real-time system this had to be changed due to limitations of the hardware in the loop system (only first four higher harmonic components were used on hardware in the loop system). For testing in simulation software as described further on, all harmonic components where used. Also, a set of output gain blocks named *weight* was added by which all harmonic components can be changed by same amount, i.e. this allowed us to change the output THD. Structure was tested with THD between 2.5% and 20% but test results are given for 7.5% total harmonic distortion. System was tested in the same way as in the case without harmonics. Results show the same qualitative change in filter behavior, but the optimal setting found using iterative procedure differs from the one for the clean signal. Obviously, analytical calculation must include influence of signal distortion to be valid for such environment. Therefore, another iterative procedure was done with distorted input signals, and this resulted with different settings as shown in Figure 11. Results show that the system, although the gains were found satisfactory, does not behave optimally. Iterative procedure with noisy input signals also proved very time consuming, as it does not select correct pairs of K_{DK} and K_{QK} gains at the same time.

C. Alternative approach

Due to problems described previously, a different method for finding filtering structure gains was selected. This procedure is the optimal gain calculation using the Kalman state estimator. Due to this method, *Kalman filter* designation is used further on in the text (*Kalman* designation in all figures). This method uses a state-space model of the structure, i.e. the part of the filtering structure in Figure 7. from gain outputs to integrator outputs (i.e. oscillators), process and measurement noise data. For this approach, procedure described in [15] and [16] was used. Output of the estimated direct component is measured output *y*, while the gain outputs are noise inputs *w*. Measured inputs *u* are non-existent. According to mentioned literature, for (continuous) plant model described as (8) and (9), and which satisfies requirements given with (10) and (11), a Kalman state estimator can be constructed.

$$\dot{x} = \mathbf{A}x + \mathbf{B}u + \mathbf{G}w \tag{8}$$

$$y = \mathbf{C}x + \mathbf{D}u + \mathbf{H}w + v \tag{9}$$

$$\mathbf{E}\left(w\right) = \mathbf{E}\left(v\right) = 0, \mathbf{E}\left(ww^T\right) = \mathbf{Q} \tag{10}$$

$$\mathbf{E}\left(vv^T\right) = \mathbf{R}, \mathbf{E}\left(wv^T\right) = \mathbf{N} \tag{11}$$

$$\dot{\hat{x}} = \mathbf{A}\hat{x} + \mathbf{B}u + \mathbf{L}\left(y - \mathbf{C}\hat{x} - \mathbf{D}u\right) \quad (12)$$

$$\begin{bmatrix} \hat{y} \\ \hat{x} \end{bmatrix} = \begin{bmatrix} \mathbf{C} \\ \mathbf{I} \end{bmatrix} \hat{x} + \begin{bmatrix} \mathbf{D} \\ \mathbf{0} \end{bmatrix} u \quad (13)$$

$$L = \left(\mathbf{P}\mathbf{C}^T + \bar{\mathbf{N}}\right)\bar{\mathbf{R}}^{-1} \quad (14)$$

$$sys : \mathbf{A}, \left[\mathbf{B}\mathbf{G}\right], \mathbf{C}, \left[\mathbf{D}\mathbf{H}\right] \quad (15)$$

Kalman filter is described with (12) and (13), while the filter optimal gain L is found solving algebraic equation (14). This equation was solved using numerical computing tools which require the system to be expressed using matrices given with (15). Given the continuous structure model in form (8) and (9), according to [8], gains shown in Figure 7. can be found analytically by solving (14) which gives gains expressed as in (17) and (16). q are elements of process noise covariance data matrix (diagonal matrix $\boldsymbol{Q}$) and r is scalar representing measurement noise covariance data matrix $\boldsymbol{R}$. Such representation gives the both filter gains with values that are dependent on the two parameters, q and r as previously defined. First parameter selection was done on clean input signal, as in previous cases. Parameter q was set at $q=1$, while the parameter r was variated between 1×10^{-4} and 1×10^{-8}. For each of the settings, gains were found and the simulation of the filtering structure was performed. Some of the results are given in Figure 12. Best solution found in this case yielded very high gains and the tracking of the input signal was extremely good, as it can be seen from selected (reference) output, compared to SOGI structure (see Figure 14. Similarly to results in previous procedure, selected settings for clean input signal did not work correctly when the input signal was highly distorted. Therefore, values in process noise covariance data matrix (i.e. parameter q) had to be modified. A range of values has been tested but satisfactory results were found for $q=0.05$. Parameter r was changed in the same range of values as in the previous case. Behavior of the system during the tuning is presented in the Figure 13. Alteration of parameter values in matrices resulted in generally lower gains than those found in the previous case, and, as presented in Figure 15. gave a system which did not track the input signal as good as in the case of clean input signal, but still much better than any of settings found by iterative process (see Figure 10. and Figure 11. for reference).

$$k_{QK} = \omega_S \cdot \left(1 - \sqrt{1 + \frac{q}{r \cdot \omega_s^2}}\right) \quad (16)$$

$$k_{DK} = \sqrt{\frac{2 \cdot q}{r} - k_{QK}^2} \quad (17)$$

More precisely, there is no initial delay with the used procedure and the settling times are lower with same or better output waveform. Higher gains, as it can be seen in Figure 13. , will not give better results as the output signal becomes increasingly distorted in that case. Also, further tuning can be considered obsolete as presented structure is a pre-filter for DDSRF which can handle small distortions in the output of the pre-filter. To further examine filter behavior, linear analysis has been performed on developed filtering structure and compared to the SOGI. Results are given as Bode plots. Figure 16. shows Bode plot for filter settings found with iterative procedure. Results show that extended filter will have generally similar frequency response to SOGI filter if the input signal is not very distorted, but the phase angle characteristic is much flatter in frequency range under the resonant frequency. This feature is the main reason for correct phase-tracking of the input signal. Same analysis done on the filter designed using Kalman estimator method shows that found gain values give a different system behavior. Namely, high-gain model has completely flat amplitude characteristics extending much above the filter resonant frequency, which, when phase characteristics is taken into account, converts the filter structure into low-pass filter rather than band-pass filter of the starting SOGI structure. This is the reason why such filter does not work as expected with highly distorted input signals. Tuning the system for satisfactory operation with large amounts of higher harmonics leads, again, to a different filtering behavior, as shown in Figure 17. Gain values are here much lower and give the system much like the one shown in Figure 16.

D. Real-time system implementation

Designed Kalman filter was tested on real-time system based on the Texas Instruments DSP coupled to the hardware in the loop system shown in Figure 3. DSP was programmed using proprietary graphical programming tool GRAP, which uses highly optimized assembler code. Results shown in the following pictures are taken through the same proprietary software. System response with the settings as those in Figure 14. (high gains) are given in Figure 18. Bottom picture shows direct (estimated) component output overlaid over first harmonic of the input signal. Figure 19. shows the high-gain filter behavior with distorted input signal. The results show, as expected, bad filter performance. Figure 20. shows the case with filter settings optimized for high input signal distortions (for distorted signal only). It is clear that the system behavior is as expected through simulation software, although the simulated structure is created (and parameters found for) continuous system, while the target system is necessarily discrete. The slight difference does exist and can be seen comparing Figure 20. to Figure 15. , but this is also due to difference in input signal harmonic content. In conclusion, it is not necessary to include discretization effects in filter design for a control system with such a high operating frequency.

IV. CONCLUSION AND FURTHER WORK

Implemented extended PLL structure proved to be adequate for the converters on which the grid code requirements apply (high-power grid-connected ones). The tested algorithm gave excellent results for all disturbances, both theoretically and practically. Addition of filtering structure extended into Kalman filter solved the observed problems with initial PLL, initial delay on input step changes and optimization of the structure with

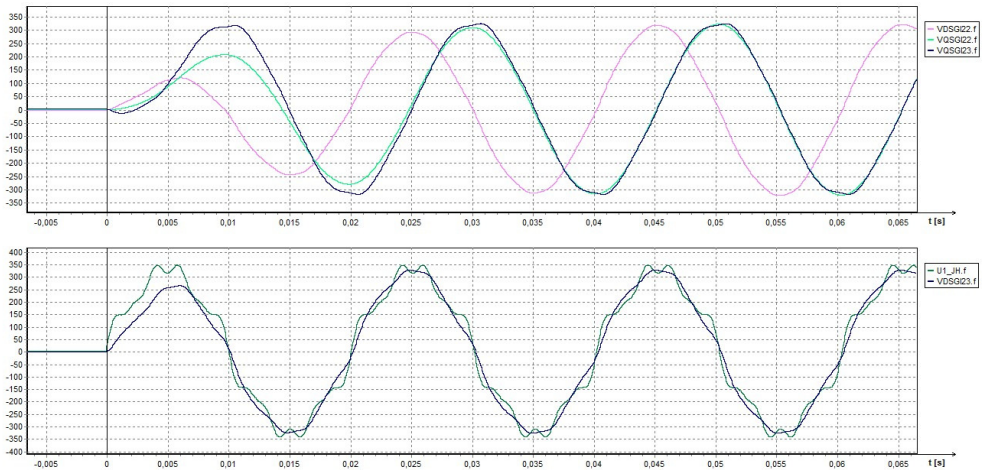

Figure 20. Filtering structure behavior on real-time system (distorted input signal, low gains)

high input signal distortions (large quantities of higher harmonics). Kalman estimator design procedure also proved to be a valuable tool as the system can be designed with exact, optimal set of parameters, given that the input variables are found correctly. Hardware in the loop system proved itself to be a valuable research tool as the implementation could be done directly in the real-time system and influences of the real-time system on algorithm and system stability, such as discretization effects, could be observed. In future, stability of the proposed PLL algorithm will be further analyzed and results from testing on a real converter will be shown.

Software simulation of LDPC codes and performance analysis

C. Sandu, I. Florescu, C. Rotaru
University POLITEHNICA Bucharest,
Iuliu Maniu 1-3 Blvd , Bucharest, ROMANIA

Abstract – In this paper we will analyze the influence of using Low Density Parity Check LDPC codes in different channels environment. The performances of LDPC codes are estimated in several scenarios. The simulation software gives us the possibilities to choose between different communications channels according to the encoding matrix used. Also we can adjust a number of parameters, thing that help to find the optimal solution depending on the decoding error rate or Bit Error Ratio (BER). Optimal combinations between parameters, the encoding matrix and structures design are obtained, related to required performance or Signal Noise Ratio (SNR) ranges. The sets of parameters and criteria introduced are discussed as the simulation results, also.

I. INTRODUCTION

Robert Gallager introduced Low Density Parity-Check, just a decade after Shannon's work was published. Gallager made a crucial innovation by introducing iterative decoding algorithms; this showed that significant fraction of channel capacity can be achieved at low complexity [1]. In the early 1980's, Tanner has provided a graphic representation of LDPC and other coding scheme, which are now referred by Tanner's diagram.. He proposed that the problem be solved by decomposing decoding codes in simpler codes from their structure and he introduced the concept that is now known as min-sum decoding algorithm. Tanner also has foreseen the huge potential of parallelism, allowing simple codes to be processed simultaneously due to their low complexity. [2]

A low density parity check code is a code with a linear matrix having a parity check matrix sparsely populated. Considering a regular LDPC code with parity matrix given by **H**:

$$\mathbf{H} = \begin{bmatrix} 1 & 0 & 1 & 0 & 1 & 0 & 1 & 0 \\ 1 & 0 & 0 & 1 & 0 & 1 & 0 & 1 \\ 0 & 1 & 1 & 0 & 0 & 1 & 1 & 0 \\ 0 & 1 & 0 & 1 & 1 & 0 & 0 & 1 \end{bmatrix}$$

Figure.1

We assign to each bit of a code word a V_S: $s \in \{1...m\}$, where each variable is also corresponding to a column in **H** matrix. Therefore, each row of **H** represents a restriction on parity check with code, c_r: $r \in \{1...m\}$. The participation of variable v_s in restriction control is suggested by an element different from zero at the position (r, s) in **H**. Variable nodes and check nodes can also have values associated with them. Symbols v_s and c_r are used to designate both the nodes and to represent the values. We call the number of one elements in the row or columns as *weight.* Each line in **H** is a parity check constraint. If the values assigned to the variable stack are a valid code word, then $c_r = 0$ for all $r \in \{1...m\}$.

$v_1+v_3+v_5+v_7=c_1$

$v_1+v_4+v_6+v_8=c_2$

$v_2+v_3+v_6+v_7=c_3$

$v_2+v_4+v_5+v_8=c_4$

Gallager defines a regular structure for LDPC codes as follows: ***a regular LDPC code with (n, j, i) is a code block of length n that has a parity check matrix of weights for row and column, exactly j on column and exactly i on column.*** [1]

By contrast, irregular LDPC codes allow variables to participate in various numbers of controls and enable possibility to apply restrictions to control numbers different from variables. An irregular LDPC code can be described by the weight vector distribution line and column of the parity check matrix of his.

LDPC codes are a class of linear block codes. Thus, they can be encoded using the generator matrix but in absence of structure within the code, as the data block increases this method requires to the decoder large storage and related processing requirements. Although H is built to be sparsely populated, the code generator matrix, G, is generally charged. Therefore encoders can become considerably slower and lager when block n is increased. [3] macaky

Iterative decoding of LDPC codes: the code word transmitted, x, is exposed to noise from the channel. The decoder provides an estimate of the transmitted information, based on code restrictions and received vector y. Message values are calculated at each node based on local code restriction. **H** matrix is easily calculated due to the low number of components. Decoding algorithms with multiple levels of decision shall use the information received. Considering the channel used a priori vector of values is generated by y and performs the function of transmission for decoder. An a posteriori vector of values is returned when

decoding process ends. *x* is produced by imposing a tougher admissions on this vector.

Sum-product algorithm can be used to perform decoding light admittance coefficient diagram, when each node is considered a local processor. Bidirectional edges are used to carry messages between processors during each iteration step.

The algorithm of two level of decision decoding can be applied for additive white Gaussian noise AWGN, binary erasure and symmetric binary channels. If the information is carried by the receiving vector, then it is downloaded.

LDPC codes can be considered a serious competitor to turbo codes. They admit a wide range of tradeoffs between performance and decoding complexity and they can do an asymptotically better performance than turbo codes. High encoding complexity is one of the major criticism.

The contribution of this paper is to provide a BER analysis in magnetic channels and binary channel. Also, this paper presents two versions of sum-product algorithm with their BER analysis. [4]

The remainder of this paper is organized as follows. Section II discusses about the communication channels that we approach. In Section III, we present the software simulator, improvements and functional terms. Section IV presents simulation results. Conclusions are drawn in Section V.

II. COMMUNICATION CHANNELS AND ALGORITHMS USED

The rapid growth of storage capacities and transfer rates imply increased density information recording disk, which requires the development of efficient coding methods and efficient methods for information detection on *magnetic channels (PR IV, EPR IV, E2PR IV)* which is necessary to preserve the integrity of the recorded data. Coding information is essential in magnetic recording channel structure, thus preventing major problems than can affect the timing of the read-write head with magnetic disk and data integrity. For studying magnetic channel we will use the channel with AWGN), this type of channel has a good practical relevance.

The sum-product algorithm SPA is used in binary channel. A binary channel with a stationary ergodic noise is a binary-input, binary-output channel whose output in response to a transmitted binary vector ***t*** is given by

r = ***t*** + ***n*** *mod* ***2,*** where ***n***, the noise vector, has a probability distribution that is a) independent of ***t*** and b) stationary and ergodic. [5].

Algorithm I: SPA decoder: (probability domain):

1. Initialization:

Sending messages: $\mu_{vs\to cr}(0)=0$, $\mu_{vs\to cr}(1)=0.5$ and $\mu_{cr\to vs}(0)=\mu_{cr\to vs}(1)=0.5$ (1)

2. Priority setting:

Using each symbol received is calculated: $u=2y_s/\sigma^2$ (2)

Calculate: $p_s(0)=e^u/(1+e^u)$ and $p_s(1)=e^{-u}/(1+e^{-u})$ (3)

3. Control variable:

We suppose $\delta_{VS}=\mu_{VS\to cr}(0)-\mu_{VS\to cr}(1)$ and calculate: $\delta_{Cr\to v}=\prod_{vs\in\Gamma(cr)\setminus v}\delta_{vs}$ (4)

From each control c_r to each variable $u\in\Gamma(c_r)$ is transmitted: $\mu_{cr\to u}(0)=1/2(1+\delta_{cr\to u})$ and $\mu_{cr\to u}(1)=1/2(1-\delta_{cr\to u})$ (5)

4. Variable check:

From each variable v_s for each $c\in\Gamma(u_S)$ is transmitted:

$$\mu_{v_S\to c}(0)=\gamma p_S(0)\prod_{c_r\in\Gamma(v_S)\setminus c}\mu_{c_r\to v_s}(0) \quad (6)$$

and

$$\mu_{v_S\to c}(1)=\gamma p_S(1)\prod_{c_r\in\Gamma(v_S)\setminus c}\mu_{c_r\to v_s}(1) \quad (7)$$

The normalization factor γ is selected so that $\mu_{vs\to c}(0)+\mu_{vs\to c}(1)=1$. (8)

5. A posteriori calculations:

For each symbol is calculated:

$$q_s(0)=\gamma p_s(0)\prod_{c_r\in\Gamma(v_s)}\mu_{c_r\to v_s}(0) \quad (9)$$

and

$$q_s(1)=\gamma p_s(1)\prod_{c_r\in\Gamma(v_s)}\mu_{c_r\to v_s}(1) \quad (10)$$

The normalization factor γ is selected so that $q_s(0)+q_s(1)=1$.

6. Stop/ continues:

Is calculated $\hat{x}$ from: $\hat{x}_s=q_s(1)>1\setminus 2$ (11)

If H $\hat{x}=0$ then operation is completed successfully, so if the limit of iterative operation is reached, operation

should be terminated and declared a failure, otherwise return to step 3 is done.

Algorithm II: SPA decoder: (probability registration domain):

1. Initialization:

Initialize messages: $\mu_{vs\to cr} = \mu_{cr\to vs} = 0$ (12)

2. **Priority setting**:

Using each symbol received is calculated: $u = 2y_s / \sigma^2$ (13)

3. Control variable:

From each control c_r to each variable $v \in \Gamma(c_r)$ is transmitted:

$$\mu_{c_r \to v} = 2\tanh^{-1}\Big(\prod_{v_s \in \Gamma(c_r)\setminus v} \tanh(1 \setminus 2\mu_{v_s \to c_r})\Big) \quad (14)$$

4. Variable check:

From each variable v_s for each $c \in \Gamma(u_S)$ is transmitted:

$$\mu_{v_s \to c} = p_s + \sum_{c_r \in \Gamma(v_s)\setminus c} \mu_{c_r} \to v_s \quad (15)$$

5. A posteriori calculation:

For each symbol is calculated:

$$q_s = p_s + \sum_{c_r \in \Gamma(v_s)} \mu_{c_r \to v_s} \quad (16)$$

6. Stop/ continues:

If all check al passed $\prod_{v_s \in \Gamma(c_r)} q_s > 0$ (17)

then the operation ends being declared a success, else if the iteration limit is reached then the operation ends being declared a faiure, otherwise we must return to step 3.

Algorithm III is based on Gallager work [1]:

III. SOFTWARE SIMULATOR

In this paper we used CAMAG software to analyze the influence of LDPC codes in magnetic channels [6]. This in house build software is dedicated to read/write processes for multiple encoding/decoding processes, R/W parameters and interference noise. In our case we used CAMAG packages for LDPC codes with the above algorithms.

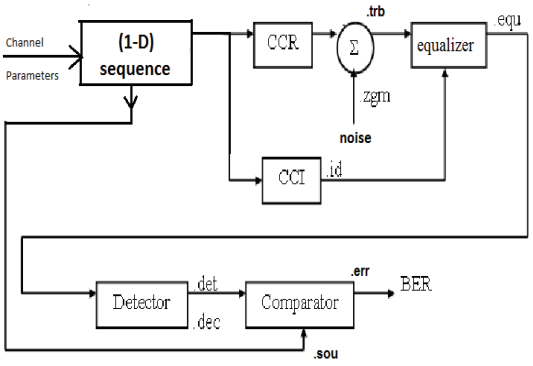

Figure 2. Block diagram of CAMAG[7]

The first block performs a precoding of data to reduce propagation of errors that could occur in detection. The formula for precoding is: (1+D2) mod 2 for PR4 channel; (1-D+D2+D3) mod2 for EPR4 channel and (1-2D+2D3+D4) mod2 for E2PR4 channel. For read/write head we used 1-D operator to simulate the characteristic differential [7].

We used for binary channels a implementation of algorithms for binary channels that are based on the sum-product algorithms and low-density pseudo-random irregular matrices based on M. Neal Radfors's programs [8].

Creating a matrix can be done by in ways: first one is based on randomly distribution of the same amount of 1s between columns, the second one similar, but also try to make rows having the same number of 1s. The software can create only R=1/2 LDPC matrix. Parity bits generating is done using spare matrix properties of **H = [A|B].**

For decoding LDPC code is used either iterative belief propagation, either sum-product algorithm (SPA). We tested in this paper Hard-Decision (bit-flip) decoder.

For decoding 0/ 1 message, if the majority is 1 is choose 1, else is choose 0. This is a simple implementation can be an introduction to message passing algorithms.

Others algorithms for decoding that derivate from SPA algorithm are Log-Domain SPA decoder and Simplified log-domain SPA decoder.

IV. RESULTS

We used for our test a matrix with ½ rate which has *M*=500 and *N*=1000, where *M* is number of rows and *N* is number of columns, recording density is 3. The LDPC matrix was created with the second method where we have approximately the same number of ones on each row. We considered *Eb/No* ration from 0 to 3. Input message is 1000 bits long and BER calculation includes parity bits, for brevity.

In first chart we made a comparison between PR IV magnetic channel and binary channel.

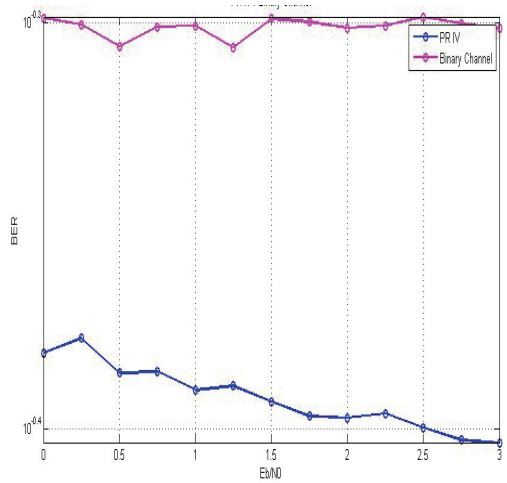

Figure 3. PR IV magnetic channel and binary channel comparison

In the second chart is the comparison between EPR IV magnetic channel and binary channel.

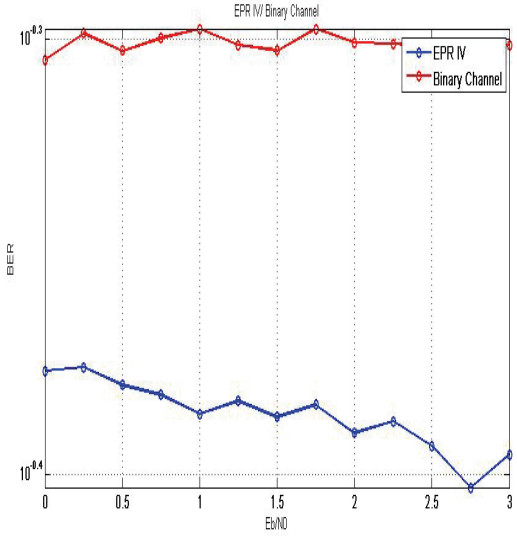

Figure 4. EPR IV magnetic channel and binary channel comparison

The third chart compare E2PR IV magnetic channel with the binary channel.

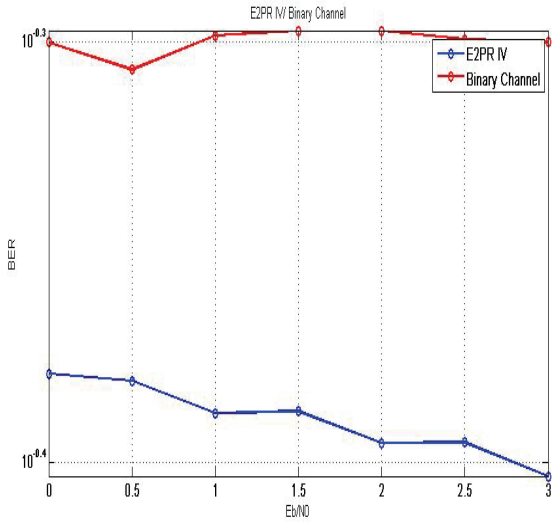

Figure 5. E2PR IV magnetic channel and binary channel comparison

V. CONCLUSION

We can observe that over scenario and parameters that we have tested, the difference between magnetic channels PR IV, EPR IV and E2PR IV and binary channel is not significant. BER obtained on the binary channel was in every scenario better than the BER obtained on magnetic channels.

We can see that the BER drops with the complexity of the channel but the cost for implementation represents an important criteria.

***Abstract*—This paper presents a concept and implementation of modern smart monitoring and control system for building automatization. The system is designed to enable significant reduction of energy consumption and carbon footprint by increasing the energy efficiency of the building under control. The system consists of a *Linux*-based remotely accessible main embedded control unit, a custom designed programmable logic controller named *littlePLC*, and a propriatery low-power Wireless Sensor Network (WSN). The energy flow is optimized by using a Model Predictive Control (MPC) algorithm that runs on the main control unit. The main control unit communicates with *littlePLC*, which serves as an interface that controls the parameters and state of HVAC systems in the building. The feedback information for MPC is gathered by means of the WSN, which consists of various sensor node types, such as temperature, air pressure, humidity, VOC and CO_2. The WSN nodes are connected in a star type network topology, with a communication HUB connected to the main control unit. The information gathered by WSN are used in the MPC algorithm in order to calculate and estimate the requirements for heat corrections, with respect to ventilation and weather predictions.**

I. Introduction

One of the main concerns today is energy generation, consumption and preservation. Since the reserves of fossil fuels are limited, the use of alternative energy sources need to be encouraged. Large part of the engineering community considers solar energy being one of the most perspective alternative sources, whether directly by using solar heat and light or indirectly by using the wind, tidal changes and similar effects generated by the Sun's emitted energy. Apart from considering sustainable sources, it is also important to improve the efficiency at which the energy is consumed.

The focus in the research community is to reduce energy wasted in residences in order to improve global energy efficiency. Residential buildings consume a major part of all produced electrical energy, in particular, the residential and commercial sectors use almost 40% of overall energy used in the world, while in European countries 76% of energy goes towards comfort control in buildings and houses – heating, ventilation and air conditioning (HVAC) [1]. According to some other studies, at least 20% of total energy produced is consumed in residences [2].

On one hand, today's architecture often puts an emphasis on passive methods for improving energy efficiency. On the other hand, an approach that is not as widespread in residential buildings is active control of humidity, ventilation or air conditioning systems. By using such active monitoring and control approaches, significant improvements in energy efficiency can be achieved. Such smart buildings can produce energy, consume it, store it for later use and even return it to the electrical grid [3]. Having efficient distribution of the produced and stored energy between HVAC systems, a building can achieve a positive influence on the network, meaning that it requires zero energy from the electrical grid [4].

Generally, there is a large and increasing demand for integrated system solutions that would facilitate a design of energy efficient buildings by employing smart and adaptive control techniques. These systems must provide means for advanced HVAC monitoring and control, sensory data gathering, system interoperability, flexiblity, blending into ecosystem of mobile and web tehnologies etc. Large amount of work has been undertaken in the field of smart home monitoring and control and various approaches for building systems for energy efficient buildings has been proposed [5]–[7]. There are also numerous of proprietary commercial closed system solutions. In this research we propose a modular, open system architecture for smart automation of energy efficient home, optimized for low-cost, flexibility and interoperability. The proposed implementation was built from the state-of-the-art open hardware and software components, as well as custom designed electronic modules, that provide an optimal price-performance ratio and that can be easily adapted for various usage scenarios. The system enables easy customization, both in terms of adding new software functionality or additional hardware peripheral extensions. An important part of the system solution is Model Predictive Control (MPC) framework, which is the key to energy efficient smart home usage scenario.

The paper is organized as follows. The Sec. II brings the general idea of the home automation system through a short overview. The Sec. III briefly describes a commercial embedded processor as an important element of the smart house. The advanced control approach used for controlling such house, namely the MPC, is given in Sec. IV. WSN developed by the team is shown in Sec. V. A custom made PLC named *littlePLC* is presented in Sec. VI. Finally, the conclusion and future work are given in the last section.

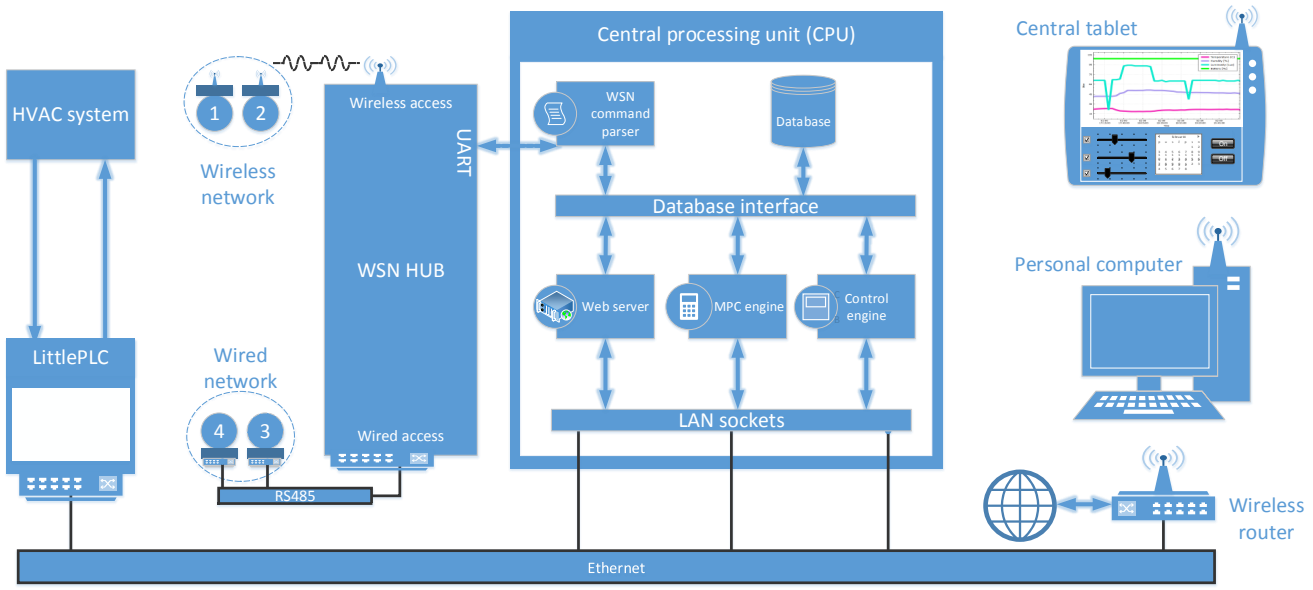

Fig. 1: Block diagram of the system

II. System overview

The overall system structure shown in Fig. 1 can be logically divided into four subsystems:

- Central Processor Unit (embedded processor)
- Model Predictive Control algorithm (*MPC*)
- Programmable Logic Controller (*littlePLC*)
- Wireless Sensor Network (*WSN*)

The CPU provides the necessary computing resources that need to run the control algorithm. The MPC algorithm uses a mathematical model of the building, input from the WSN and predictions of future conditions from the weather forecast service to efficiently maintain good living conditions in the home. The WSN has a star topology. It consists of a HUB connected to the main processor and nodes scattered around the building. Nodes provide various measurements such as temperature, air pressure, humidity, etc. The (*littlePLC*) controls the actuators of the system, namely a heat pump for heating and cooling. It was designed as an alternative to commercially available PLCs while paying heed to the industries standards.

III. Central Processor Unit

The CPU chosen for the project is *BeagleBone Black*. It runs the MPC algorithm and interfaces towards each of the subsystems. An embedded processor was chosen for its small size and power consumption [8]. A *Linux* distribution is installed on the board, allowing for a number of advantages, such as using script based programming languages (*i.e. Python*) or database programming languages (*i.e SQL*). Thread management provided by an operating system is also necessary, since the system will have multiple tasks implemented in separate processes. The processor gathers data from the WSN via a custom hardware plug-in (HUB). The HUB is designed to fit as a cape plug-in for the *BeagleBone Black*. Communication is achieved such that the HUB sends standardised data packages over serial communication which are then written into a database on the *Beaglebone*. Data gathered from the WSN serves as input for the MPC algorithm.

IV. Model predictive control

In the vein of previously presented general idea of sustainable, affordable and energy efficient concept of the house, energy management stands in the focus of the concept. Thus, an optimal control system approach which respects constraints resulting from desired occupant comfort as well as actuators' constraints was to be used. Such requirements on optimal energy consumption were satisfied using MPC approach as suggested in recent works [9]–[11].

The general idea of MPC is to use a model of the process as well as the weather forecast (i.e. outdoor temperature, insolation, humidity, etc.) in order to predict the future evolution of the system and to compute a control actions which ensure the fulfilment of demands. In particular, a custom made heat pump serves as a controlled actuator, while insolation and outdoor temperature are considered as disturbances within such model. Ventilation system available in the house also contributes notable heating flows and therefore is included into computation of demands on the actuator.

The basic concept of MPC is to use a dynamic model, constraints of the process and current measurements to forecast system behaviour and to produce the optimal decision according to performance criteria – the control move at the current time. Therefore, the control action is obtained by solving a finite horizon optimal control problem at each sampling instant in which the initial state is the current state of the house. The result of this optimization

is a finite control sequence and only the first action in this sequence is applied to the plant. A block diagram for this approach is given on Fig. 2.

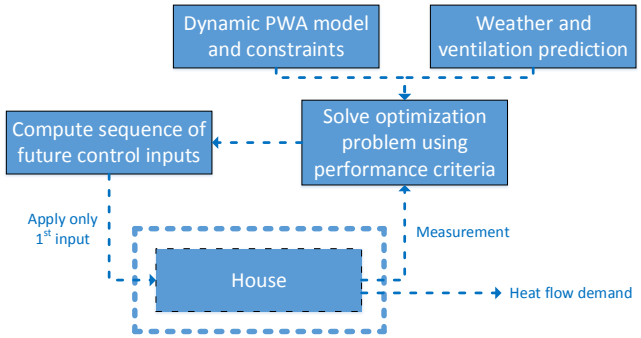

Fig. 2: Block diagram of the MPC control approach

A. MPC framework

Apart from typical materials that are often used in buildings and houses, recent studies have proved the efficiency of Phase Change Material (PCM) which has a dominant non-linear behaviour [12]. Consequently, the model of the house which arises from this fact can not be well described as pure linear one. Still, the characteristics of PCM can be well described using a piecewise affine (PWA) model, which brings the same formulation of the model of the house.

Aforementioned PWA time invariant dynamic system is given with the following continuous system:

$$\dot{x}(t) = \begin{cases} A_1\, x(t) + B_1\, u(t) & \text{if } \delta_1 = 1, \\ \quad \vdots & \\ A_s\, x(t) + B_s\, u(t) & \text{if } \delta_s = 1, \end{cases} \tag{1}$$

where $\delta_i \in \{0, 1\}$, $\forall i = 1, .., s$ are variables satisfying the condition

$$\sum_{i=1}^{s} \delta_i = 1, \tag{2}$$

at the particular moment in time. The previous representation of the model arises in gainscheduling, where the linear model is switched among a finite set of models, according to changes of the operating conditions. δ_i can be considered being a function of state of the system as well as input variable. In principle,

$$[\delta_i = 1] \leftrightarrow [x; u] \in \mathcal{C}_i \tag{3}$$

where $\mathcal{C}_i$ is a subspace of the space of feasible x and u.

The model given in (1) represents a continuous time model, which is discretized using zero-order hold discretization approach with 1 h sampling time in order to be used within the discrete MPC, with states x and inputs $u = [u^a\ u^d]$. Input u^a corresponds to heat demands for controlled actuator, namely the heat pump and u^d corresponds to non-controlled disturbances. The MPC takes into account the predictions $U^d = (u^d_{t|t}, u^d_{t+1|t}, ..., u^d_{t+N-1|t})^T$ obtained from the weather forecast service and determines the controlled input $U^a = (u^a_{t|t}, u^a_{t+1|t}, ..., u^a_{t+N-1|t})^T$ on the horizon N minimizing a cost function (subscript t represents a discrete moment). This approach also respects constraints of the actuator and can be formalized as follows:

$$\begin{aligned} &\min_{U^a} \textstyle\sum_{k=0}^{N-1} \|u^a_{t+k|t}\| \\ &\text{s.t. } u^a_{t+k|t} \in \mathcal{U}^a \end{aligned} \tag{4}$$

where $\mathcal{U}^a$ represents the feasible space for the actuator. As stated previously, the MPC problem also takes into account the limitations on states of the system. Namely, $x^a_{t+k|t} \in \mathcal{X}$, where $\mathcal{X}$ represents the limitations of the system states (both spaces $\mathcal{U}^a$ and $\mathcal{X}$ are constrained using linear inequalities). In principle, space $\mathcal{X}$ inherently possesses limitations on the temperature inside the house. The remark regarding previous discussion is given in the following subsection. Detailed solution to such formulated problem is given in [13].

B. Implementation remarks

The mathematical model of the house used within this project was gained in the vein of [14], where the model of the house is generated through suitable RC network. The state vector x contains the voltage levels on corresponding capacitances, which corresponds to temperatures of particular wall or room. Such gained mathematical model was consisted of 40 states.

The first step towards implementation of the MPC algorithm was to identify the mathematical model of the system (1). For this reason, an accurate model of the house was built using a commercial software for dynamic multi-zone simulation application to study thermal indoor climate conditions. The response of such model was thus used for validation of mathematical representation of the house developed in Matlab. This control approach assumes the accuracy of the mathematical representation of the house. Therefore, some identification technique still needs to be developed to be used on-sight, since the house changes its characteristics in time.

In order to have well estimated states of the house a wireless sensor network was built. More details on it follow in the next section.

V. Wireless Sensor Network

As discussed in previous section, the CPU requires various measurements as feedback for the control algorithm. Wireless approach was chosen since it requires no additional wiring. The wireless nodes are self contained and can be placed around the house without impairing its visual appeal. The sensor nodes send measurements to the WSN HUB, which then relays the data to the CPU. The advantage of such a topology is that the idle radio times of the battery powered nodes are significantly reduced. The HUB is connected to a fixed power supply and its radio frequency (RF) connection is online perpetually. Each node has a sleep interval in which the device powers down and consumes as little electrical energy as possible. The node wakes up to send its

measurements and, for a short period it listens for incoming traffic from the HUB. This allows for the HUB to send commands to the node, i.e. command for setting the sleep interval duration. The node spends an short amount of time in receive mode if it is not called out by the HUB. This allows for quick transition back to the power down mode, saving energy and extending battery life.

Power consumption was reduced by using low power microcontroller units (MCU). The chosen processor for the wireless nodes is the *PIC18F26K22* microcontroller. It interfaces the measurements from the sensors placed on the node and communicates with the RF transceiver. Generally, the *PIC18F* series of microcontrollers offers an extremely low-power management technology suitable for reducing the energy consumption of sensor nodes.

Even though most basic sensor nodes are designed to be wireless, some sensors require a wired connection. For example, most CO_2 sensors require a warm up period during which the heater on the sensor sets the adequate temperature for gas percentage readings, whence the power consumption duty cycling is not possible. Another example of such a sensor is a smoke detector. The appearance of smoke requires an instant detection for safety reasons. In such situations, active time cannot be duty cycled with sleep modes and the battery drain is increased drastically. A wired solution (RS485 communication with a 12 V power supply) is proposed as an alternative in this kind of situations.

A single sensor node consists of an MCU board, containing either a regulated battery power supply or a 12 V supply line, a processing unit and a communication interface. The sensor unit is a plug-in board. The block diagram of a sensor node is shown on Fig. 3. Sensor node duty cycling and estimated

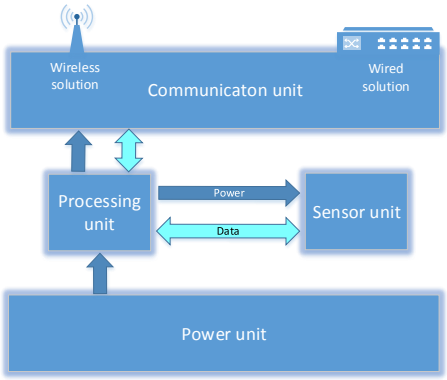

Fig. 3: Sensor node diagram

current drain are given on Fig. 4, where T_{mc} is a measurment collection time, T_{mr} is a measurement report time, T_{nc} is node configuration time and T_s is sleep time. Active time is sum of T_{mc}, T_{mr} and T_{nc}.

Voltage from the battery is regulated using a low drop-out linear regulator. The batteries selected are Li-Po cells as they have a high energy density and provide enough energy to achieve long up times. Battery lifetime can be roughly estimated with omitted self discharge current as:

$$t_{up} = \frac{E_b}{I_{on}\,\delta + I_{sleep}\,(1-\delta)}, \tag{5}$$

where E_b represents battery capacity, δ stands for duty cycle coefficient (share of active time in overall time), while I_{on} and I_{sleep} represent average current in active and sleep mode, respectively.

Example: Using a 1000 mAh Li-Po battery with a duty cycle of 0.01% while assuming active current of 20 mA and sleep current of 1 μA yields $t_{UP} = 38.05$ years.

The transceiver integrated circuit chosen for the wireless sensor nodes is *nRF24L01+* [15]. It is often used in ultra low power wireless node designs [16], [17]. The chosen integrated circuit is a RF transceiver operating in the 2.4 GHz frequency band. It was chosen since it provides multiple useful features, such as automatic packet handling, 6 data pipes, power down modes, etc.

The sensing units are different for every node type. Sensor boards can be designed independently since the plug-in header predicts the usage of standard serial interfaces (e.g. SPI, I2C, UART). Proposed sensor nodes include a temperature measurement node, an air pressure and humidity measurement node, an ambient light sensor node, a gas and CO_2 detector.

VI. LITTLEPLC

The PLC is a standard component of industrial automatization. It is a device dedicated to controlling electrical machines (i.e. motors, compressors, pumps, heaters, etc.), monitoring system operation, and providing a control interface to the supervising personae. There are many commercially available PLCs, most of them developed for highly demanding tasks of industrial control. Using such a device for control of a house is not financially viable. A small PLC was designed to significantly reduce the cost of the whole system of automatization.

LittlePLC was designed for use in milder environments. It does not have an industrial grade temperature operating range, nor is resistant to an aggressive atmosphere, but it provides a large advantage over a standard PLC's processing power. It was designed to provide a platform for easier implementation of complex control algorithms with a lower price than industrial equipment.

An ARM based MCU is the main processing unit of *LittlePLC* (in particular the *STM32F407* microcontroller [18]). The device was designed as a modular system that allows the variation of the number of inputs and outputs using expansion modules. Similarly to standard PLC's, *LittlePLC* provides analog and digital inputs and outputs (Fig. 6). All inputs, outputs and communications with the outside world are galvanically separated from the microcontroller to ensure reliable operation and to protect the internal circuitry. There are several ways of communicating with external devices or users (RS485, Ethernet, GSM, SD card, as shown on Fig. 6). The *littlePLC* is shown on Fig. 5.

LittlePLC can be divided into following subsystems:

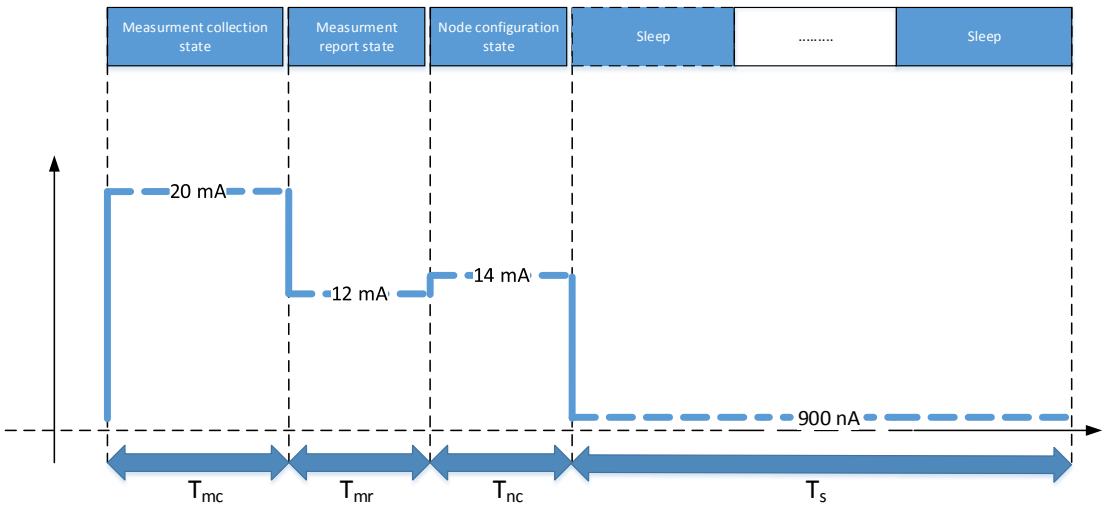

Fig. 4: The operation cycles of the sensor node and provides estimated currents for each state

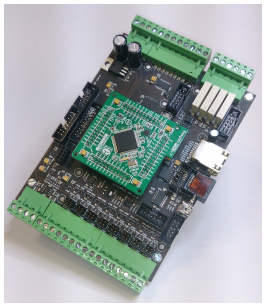

Fig. 5: littlePLC

- Motherboard (*MCU, real time clock, SD card interface, etc.*)
- Communication layer (*GSM, ethernet and USB communication modules*)
- Control layer (*analog and digital outputs and inputs, RS485 standard bus*)

In the system described in this article, *littlePLC* communicates with the CPU via Ethernet. The CPU issues HVAC control commands to the *LittlePLC*, based on the MPC algorithm results. *LittlePLC* then issues controls to the HVAC systems. (i.e heat pump, condensing heater, ventilation, air conditioning, etc.) Any errors that may appear during operation are reported to the CPU. The main advantages of using *LittlePLC* for HVAC systems control are lower price, and increased processing power.

VII. Conclusion

In this paper we presented an architecture and implementation of a modular smart automation system for energy efficient housing that was optimized for low-cost, flexibility of system configuration, and interoperability with other technologies. The core of the proposed system consists of the Central Processor Unit (CPU), Wireless Sensor Network (WSN), Programmable Logic Controller (*littlePLC*), and Model Predictive Control algorithm of the building HVAC system (MPC). The loosely coupled system framework enables easy adaptation for various specific usage scenarios, both in adding the new hardware system components, and the additional software services. *Linux*-based CPU promotes an open system approach design which enables adding a new functionality as new system process that integrates with rest of the system through the dedicated IPC messaging protocol. The WSN was optimized for energy efficient smart home monitoring usage scenario, and it provides low cost multifunctional sensor nodes, with ultra low power consumption and simple messaging protocol, without an unnecessary overhead often met in similar existing solutions. Furthermore improvements in lowering the overall system costs and in providing the extra features usually met in high-end industrial PLCs have been achieved by means of the custom developed *littlePLC*. Finally, the MPC control algorithm plays a key role in a system that enables significant energy efficiency improvements.

All described system components were tested in a prototype implementation of the smart home automation system. The initial development phase encompassed the design and implementation of hardware and software components of CPU, WSN and *littlePLC*, which were put together to form a basic core of the proposed system. The experimental tests showed that the proposed architecture and components were well chosen both in terms of achieving the low cost of the overall solution and satisfactory system performance.

The future work will encompass the installation of the described system into the actual smart building, assessment of system components performance under realistic working conditions, adjustment of the MPC algorithm to the realistic house model, and experimental tests under the conditions of real-world environment. The most interesting part of the future research will be the answer how much energy savings can be achieved by using the proposed system, what is

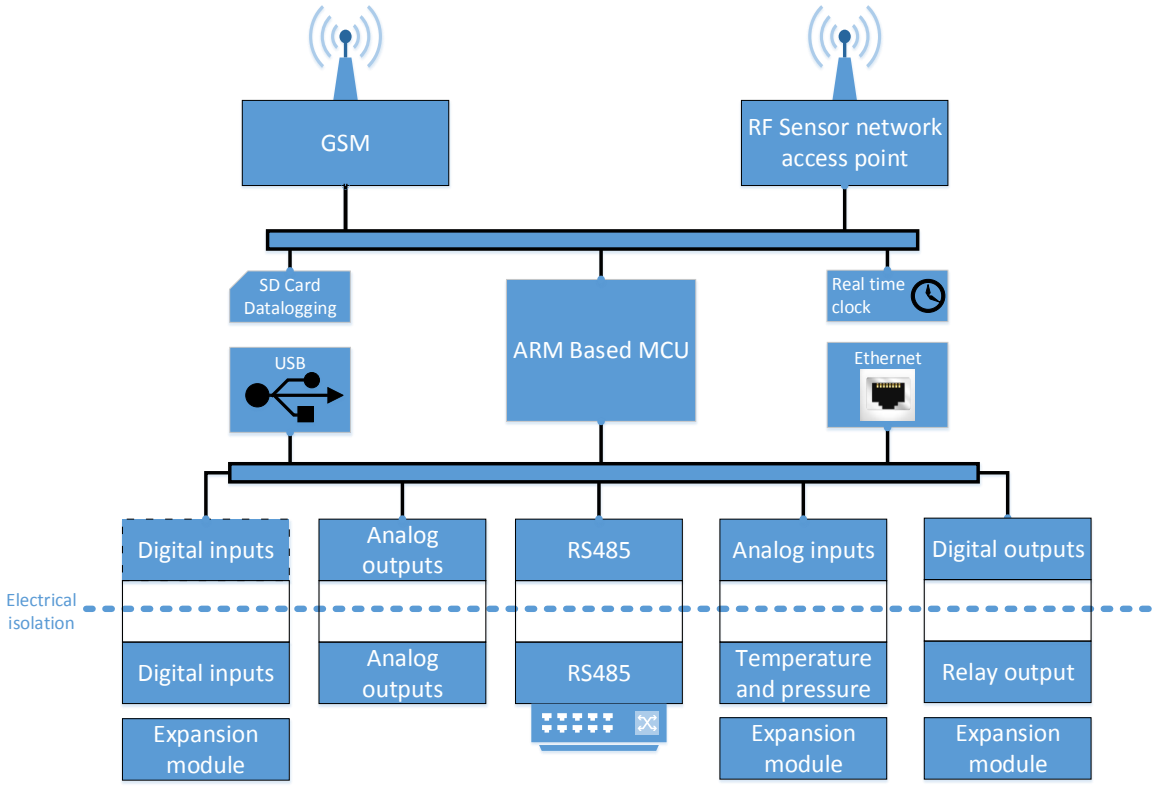

Fig. 6: Block diagram of the littlePLC

impossible to answer beforehand, but also difficult to assess without the custom developed system for this purpose. Beside the basic system core described in this paper, we plan to extend the basic system functionality by providing additional modules and services, such as smart entry control subsystem, human behaviour patterns learning and monitoring, remote access system control, configuring and controlling system configuration over smartphone or tablet etc.

ACKNOWLEDGMENT

We would like to thank to the members of the UNIZG team of the University of Zagreb for their collaboration on *mem**brain*** project (*http://www.membrain.com/*).

Remote Laboratory for Testing Processor Cores in FPGA Device

Kristjan Saksida and Andrej Trost
University of Ljubljana, Faculty of Electrical Engineering, Ljubljana, Slovenia
Andrej.Trost@fe.uni-lj.si

Abstract – In the paper we present generic hardware verification structures for efficient testing of the custom processor cores in FPGA devices. Hardware verification environment consists of hardware debug structures: control machine, memory access port, input and output data buffers and interface logic. The verification structures are integrated and synthesized with the processor core under test and implemented on the FPGA device. The structures can be customized and easily integrated in the hardware development flow. A software support for the hardware verification consists of a data acquisition driver running on the server with HTML5 graphical interface. The software enables either local testing or setup of a remote laboratory for testing of the processor cores. The application of the remote laboratory in the educational process is presented. The presented hardware verification structures are optimized for testing the soft programmable processor cores and are vendor independent. The software support is based on open languages and protocols and the scripting tools enable quick customization. We present advantages of our solution compared to commercial general purpose on-chip logical analyzers. The benefit of our approach is that it can be used with the standard programmable design tools on the low cost platforms and provides two abstraction levels of debugging.

I. INTRODUCTION

Field Programmable Gate Array (FPGA) devices are used for building Systems-on-Chip (SoC) composed of processor cores and custom logic [1]. There are a lot of hard and soft general purpose processor cores available for the system designers and the capacity of modern FPGA devices enables implementation of many cores in a single device. Application specific circuits and systems can be optimized using custom designed processor cores. The custom processor core development is also part of the digital systems educational process [2].

Software simulation of a complex processing core is time consuming process and typically only some basic tests are performed. Comprehensive tests are executed in hardware using implemented processor core and hardware verification structures. Hardware verification on the FPGA device is much faster and more accurate. A drawback of hardware verification is limited visibility and control of the internal circuit operation. The FPGA vendors provide embedded logical analyzers to enhance visibility of the internal signals and provide some basic control [3]. A full visibility can be provided using scan chains [4] and better control by integrating test bench in the hardware [5].

We are focusing on testing processor cores used in FPGA devices for performance non critical tasks as a replacement for complex state machine logic. The processor core can be tailored to specific application requirements and the task of testing is to eliminate bugs in the design process. The design error can be either in the core logic, the processor software or in the interface logic. For the efficient debugging process it is important to provide tools covering various levels of abstraction [6]. The logical analyzer tools for hardware debugging cover only the lowest hardware abstraction level. In the paper we focus on the specific hardware verification structures for testing embedded processors used in the programmable devices.

Programmable devices are used in digital electronics education process and several remote laboratories were developed for supporting distance learning [7-10]. Programmable development boards are connected to a computer used for design implementation, board configuration and hardware testing. The remote laboratories provide server environments for distant control of the design and hardware verification process.

In the paper we present general requirements for testing embedded processor cores, setup of a remote digital design laboratory and our remote processor testing environment. The processor testing remote laboratory is used in the educational process.

II. EMBEDDED PROCESSOR TESTING REQUIREMENTS

In order to provide generic hardware verification structures for testing different processing cores, we identified common features of soft processor cores in FPGA devices.

A hardware verification environment should cover at least two abstraction levels. In the low abstraction level, the important signals should be sampled in order to detect processor logic and bus protocol related bugs. In the higher level, data transactions on the processor data bus should be sampled and initiated in order to emulate processor environment. Specifically, peripheral bus transactions should be saved in internal buffers for control and analysis of the processor running a test program.

A. Embedded Processing System

An embedded processing system in FPGA device consists of (a) a processing core, (b) program memory and (c) interfaces. Small processors used for control tasks often

execute a bare-metal application saved in memory blocks inside the FPGA device. A peripheral bus is used for communication with the interfaces and the rest of the system. We can summarize testing requirements for the various parts of the system:

a) Hardware verification interface should provide control of the processor core by driving reset and clock signals. The important processor control signals should be sampled with a logical analysis module.

b) The verification interface should provide access to the program memory in order to load test programs.

c) The verification interface should be connected to the peripheral bus emulating transactions to the external interfaces.

B. Educational Embedded Processor Core

In order to demonstrate the embedded processor testing system, we use a small generic processor architecture presented in [11]. The processor core and a program memory are described in a hardware description language VHDL. The core architecture supports 4 to 32-bit data bus and is optimized for FPGA devices. The core design is used as a soft CPU template in the educational process. Only a basic set of instructions are given in the initial design and the students are encouraged to extend the instruction set with other general and application specific instructions.

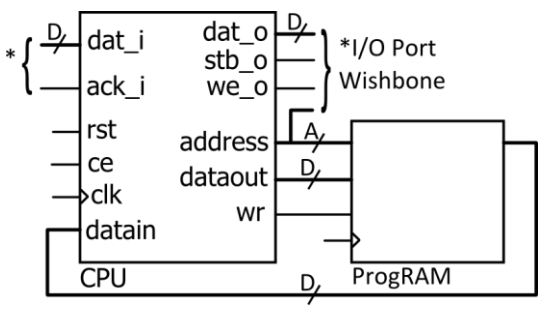

Figure 1. Educational embedded processing system

Block diagram of the educational embedded processing system is presented in Figure 1. The system is composed of a CPU core and a program memory. Processor control signals are: clock (clk), reset (rst) and clock enable (ce) used for stopping the processor during test in order to enable long time verification with limited hardware buffer resources [12]. This signal can be replaced by dedicated clock resources and clock multiplexers in the hardware test structure.

The generic processor architecture provides D-bit data bus and A-bit address bus. The processor peripheral interface is a Wishbone compatible master input and output bus. Wishbone is an open-source synchronous bus architecture, which is commonly used in digital systems on a chip [13].

III. REMOTE LABORATORY SETUP

The remote laboratory software is based on open languages and protocols PHP, MySQL, HTML, JavaScript and JSON running on Apache server, as shown in Figure 2. Remote laboratory client side requires only a web browser which supports HTML 5 canvas object. The web page requires HTML version 5 due to the use of a canvas feature used for displaying waveforms of the sampled data.

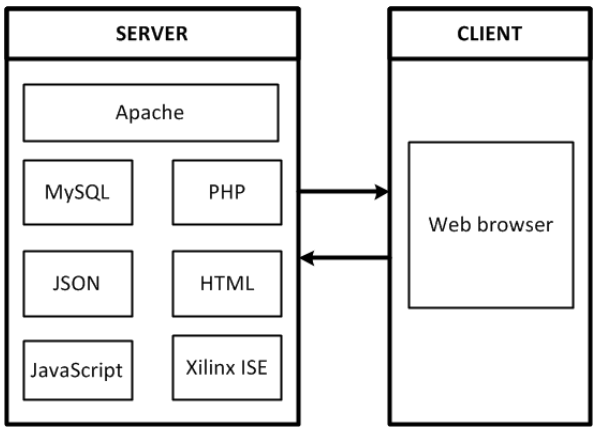

Figure 2. Software components of a remote laboratory

The Xilinx ISE tools for design synthesis, implementation and FPGA configuration file formatting are installed on the server. The PHP script calls individual tools of the Xilinx ISE enabling remote design implementation flow and programming of the FPGA device on the board.

The user on the client side needs an account, which enables him to log in to the server and get 30 minutes of a reserved laboratory session. The MySQL provides a base of users and user login feature.

Server side PHP script sends instructions and data from the web page through the serial port to the board and collects verification output data. The received data is decoded and sent to JavaScript in JSON format. On the client browser the JavaScript routine draws signal waveform into the canvas area.

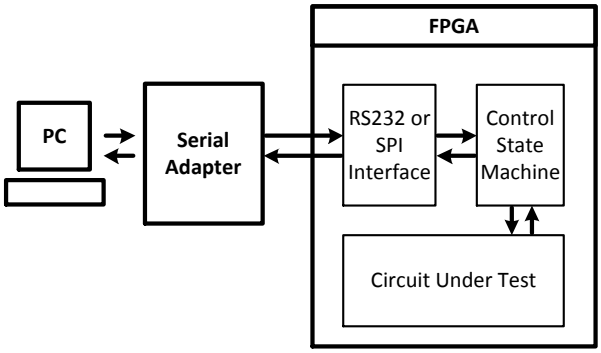

Figure 3. Hardware verification structures

The hardware of our remote laboratory is composed of a Xilinx Spartan-3E FPGA development board Basys2. The development board is powered through USB device configuration connector. A serial adapter on expansion connector is used for serial data connection to the host computer. Figure 3 shows hardware verification structures used for testing circuits on the development board.

The circuit under test is connected to a control state machine (CSM) providing input and output registers and control signals. The input and output register length is adjustable using generic VHDL parameters. When testing embedded processors, the control state machine enables writing and reading to the processor memory. The width and the depth of the memory can also be adjusted in 4-bit slices covering most of the processor bus width configurations. The CSM is connected to serial interface, asynchronous RS232 at 115200 baud or synchronous SPI at 3 Mbit/s. The selected serial interfaces provide enough bandwidth for our testing purpose and occupy a small area in the FPGA device. Commands on the serial interface are used for reading and writing the registers and the processor memory.

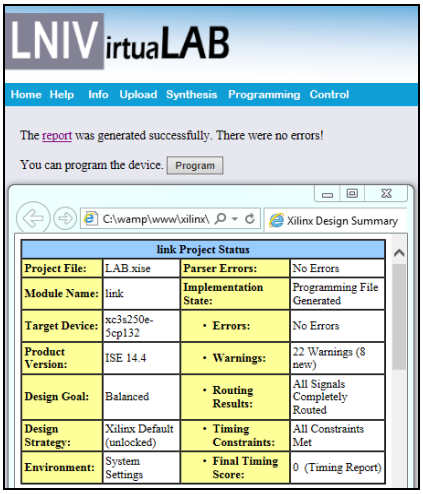

Figure 4. Client view of the virtual laboratory

A generic hardware test structure is available to the user which connects his circuit under test, uploads VHDL files to the server and runs remote implementation process. When the process is finished, a report provided from the tools is available as presented in Figure 4 and the user can program the board and start hardware verification.

IV. Embedded Processor Testing System

During development of the educational remote laboratory, we realized the need for more specialized processor verification structures. The specialized processor testing system components are presented in Figure 5. The design in programmable device contains three top level components: a serial verification interface (IF), a control state machine (CA) and a test wrapper (TEST).

The test wrapper includes the CPU core and processor specific hardware verification structures. The processing system program memory component is replaced with memory access port (MAP). The memory access port contains control logic and additional memory bus, used for accessing memory during test. A selected set of processor control signals is connected to trace data buffer (TDBUF). The TDBUF is similar to the logical analyzer component used for low abstraction level signal sampling and debugging. The processor peripheral input (pin) and output (pout) Wishbone bus are connected to data buffers IDBUF and ODBUF. The data buffers are designed as FIFO memory blocks holding the data for the higher abstraction level debugging. The buffers occupy only a small portion of FPGA resources. Table 1 summarizes data buffers area utilization for different data width and buffer depth of 31 locations. Figure 6 shows almost linear Look-Up Table (LUT) utilization depending on a data buffer depth for a fixed data width of 12 bits.

TABLE I. FPGA UTILISATION OF 31 LOCATION DATA BUFFERS

Data Width	Slices	FF	LUT	LUT %
8	19	13	70	1
12	34	14	90	1
16	40	14	110	2
32	72	16	192	3
64	134	16	350	7

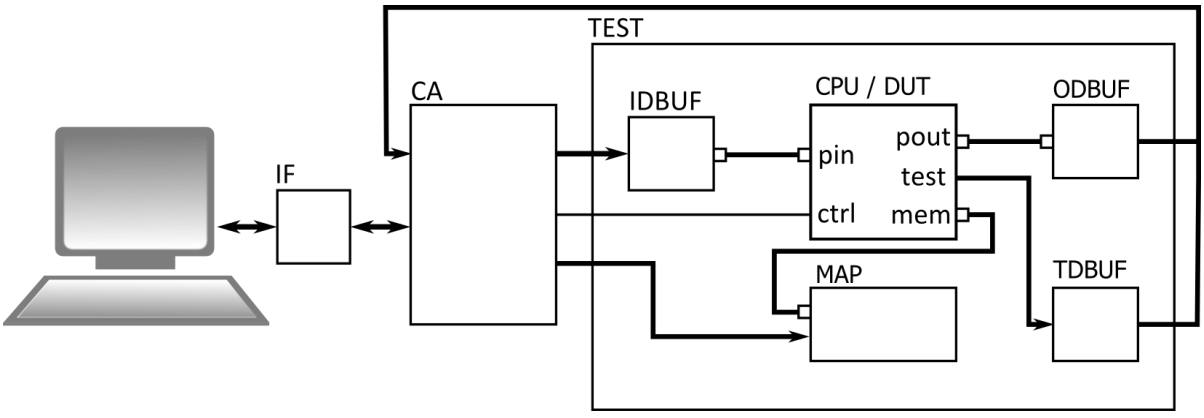

Figure 5. Embedded processor testing system components

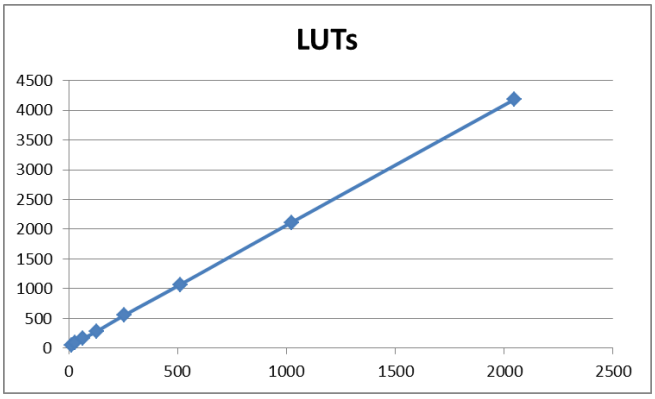

Figure 6. Data buffers LUT utilisation depending on the buffer depth

The control state machine requires 7% and serial UART interface 5% of the available LUT in 100k gate Spartan-3E device. A simplified state diagram of the control state machine is presented in Figure 7. The system starts in the state Idle and the serial commands change the state to:

- Prog – writing program data to memory access port,
- Set – setting the input data buffer,
- Read – reading output data buffer,
- ReadT – reading trace buffer,
- Reset – resetting the CPU core,
- runN – running the CPU for specified number of cycles or until breakpoint and
- runT – running the CPU until trace buffer is full.

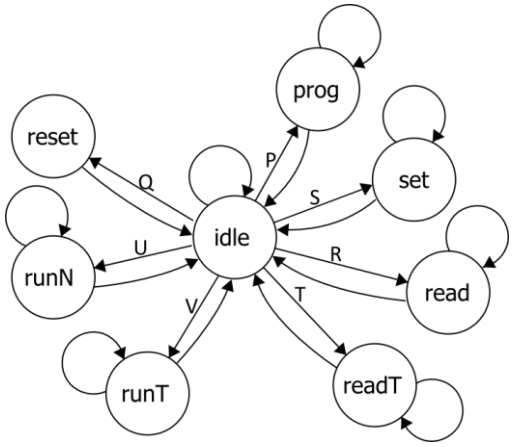

Figure 7. Simplified state diagram of the control state machine

Peripheral data bus can be used for debugging with a breakpoint. One of the peripheral addresses is used to trigger break in the run cycle. This setup requires almost no additional hardware resources and provides convenient means of high abstraction level processor debugging.

A. Educational Remote Laboratory

For testing the educational processing system, we set an educational remote laboratory OpenLAB. The goal of the OpenLAB is remote testing of the processing core designed at the digital integrated circuits course. The processor testing flow in OpenLAB is presented in Figure 8.

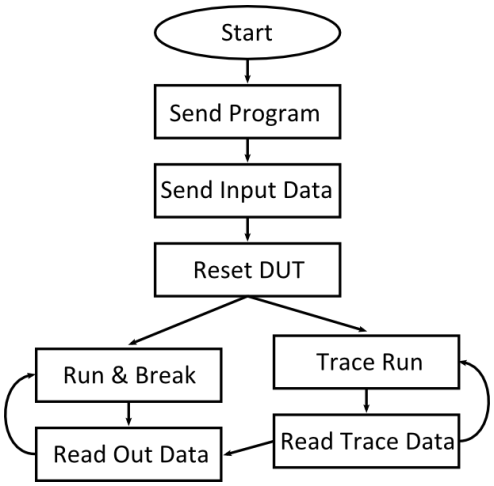

Figure 8. OpenLAB processor testing flow

The user is first required to send a test program to the processor already implemented on the board. The code should be in raw hexadecimal format. Then some input data is set on the web page to be stored to the input FIFO buffer (IDBUF) and the processor is reset.

The low abstraction level test is initiated with trace button. The processor is run until trace buffer is full and the output data is presented on the signal waveform. The higher level of test is performed by running the program for desired amount of cycles or to the breakpoint and reading out the data. The system allows consecutive execution of both levels of testing as many times as required by the test program.

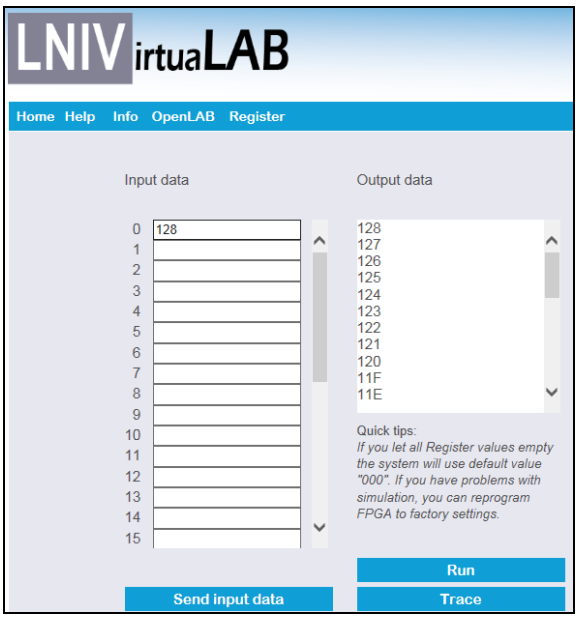

Figure 9. OpenLAB part of the web page

Figure 9 shows part of the OpenLAB web page for testing educational 12-bit processing system. There are 31 data cells for the input data buffer and listing of the output data buffer in 3 digit hexadecimal format. There is also an input window to enter the program code, which is transferred to RAM after pressing the Program button. A Factory settings button is used for complete board reset and loading the initial test code.Upon pressing Run button, the processor is enabled for the preset number of cycles and the processed output data is displayed in the output data area. Figure 9 shows an example output of a small program reading one input value (128), counting down and sending the results to output bus.

The waveform on the Figure 10 presents the sampled processor signals:

- data input (data_in) and output (data_out) bus,
- address bus (adr),
- execution state (st), memory control (wr) and
- Wishbone port control signals (stb, we).

We can observe behavior of listed signals through 32 clock cycles. The processor is stopped after the trace and by pressing the trace button again we are able to sample next 32 cycles, so the trace length is not limited to the hardware buffer size.

V. CONCLUSIONS

In the paper we presented hardware verification structures and remote laboratory used for testing embedded processor cores. Testing a complex hardware on the programmable development board requires implementation of the hardware verification interfaces. The FPGA vendors provide logical analyzer modules for low level in-circuit testing. These modules are designed for specific FPGA families and are not included in the free versions of the tools.

We initially designed a generic hardware verification remote laboratory, where device under test is connected to the generic input and output registers connected to the test environment. Testing the embedded processors with such environment proved to be tedious and error prone work and a more specialized environment was required for the successful implementation in the educational process. We identified common features of the soft embedded processors and designed generic processor testing components. The Wishbone bus used for peripheral connections is a common SoC bus structure and bridges are available for other processor busses.

The hardware components enable testing on two levels of abstraction which is more effective for understanding the core operation and eliminating the design bugs. By using the presented technologies we are able to implement an educational remote laboratory focused on the debug process. Our further work will focus on the test system automation and testing on even higher abstraction levels.

Abstract – High performance computing (HPC) systems are omnipresent in processing huge amounts of data. However, power consumption of these systems is becoming far from negligible, forcing software developers and hardware providers to deviate from usual performance plans, and to address power consumption and costs. As a result, small-scale applications are becoming infeasible to run on those systems, making room for the power-efficient HW newcomers, such as SoC (System on Chip), to take that role. The idea of composing a large number of small SoCs in a computing cluster can result in a powerful, green, and a simple platform capable of delivering enough performance for the small applications while maintaining low energy consumption and costs. In this paper we present a system composed of four LAN-interconnected dual-core ARM based SoC devices, powered by a single power supply. We investigate applicability of such a system by monitoring its performance and energy efficiency and stability while using common HPC paradigms: message passing and thread programming.

Keywords: energy efficiency, SoC, computer cluster, HPC, performance, stability

I. INTRODUCTION

In today's technologically advanced society energy is becoming a very expensive and scarce resource, making energy efficiency as one of the most dominant and omnipresent issues in virtually all existing computing systems. In some systems the total energy costs of running can exceed the initial investment in only few years, signifying the need to drastically reduce power consumption of the existing systems [1, 2].

On the other hand, High Performance Computing (HPC) systems are characterized by the ability to perform very complex tasks very effectively performance-wise. The energy efficiency of these systems is not a primary concern [1, 3], although "performance no matter what" approach is slightly fading away, a trend which was started by the "Green Destiny" project 2001 [12]. New metrics appeared to re-evaluate HPC computing, such as number of floating point operations per watt consumed starting a completely new era of power efficient HPC. The green aspect of the HPC systems is popularized the Green500 list [13], currently topped by the machine capable of achieving roughly 4500 MFLOPS/W. Still, the scale of current HPC systems is still too large, making their use for the small-scale applications infeasible. Smaller and more end-user oriented parallel applications along with the importance of the energy awareness in the future computing systems [4] imply that new steps have to be undertaken in the design of energy efficient HPC systems.

The emergence of the new architectures (e.g. see [7]) opens up new possibilities regarding small-scale HPC computing, expanding domain of HPC use, and starting a stream of new approaches. One of the approaches in the increase of HPC energy efficiency by using small, low cost, low power ARM based devices as the compute cluster nodes [5, 8, 10, 11]. Following the trend of using ARM processors in HPC clusters in this paper we propose an ARM based cluster composed of 4 dual core A20 SoC (System on Chip) using a Cubieboard2 embedded system (Fig. 1).

The Cubieboard2 is a SoC based on ARM Cortex A-7 dual core processor running on 1GHz, containing 1 GB of DDR3 memory and 4GB of internal NAND flash. From communication point of a view the Cubieboard2 includes 10/100 Ethernet and USB 2.0 ports. Maximum power consumption of the board is set at 2A at 5VDC input (10W). On the operating system side is supports various UNIX based operating system. We have tested performance, energy efficiency and stability of our proposed platform in order to evaluate its applicability as a small-scale HPC machine [6, 9].

The rest of the paper is organized as follows: Section II describes the test platform and metrics used within the paper. In Section III we show performance results of our platform, alongside with platforms power and stability

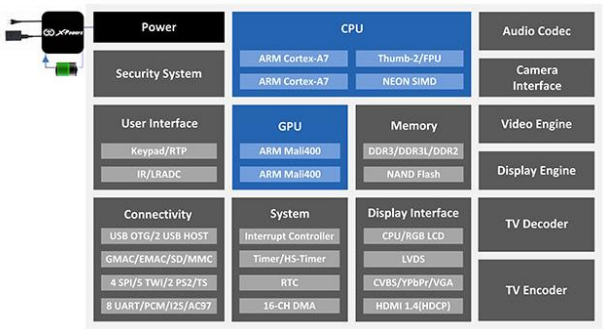

Figure 1. Block diagram of A20 processor [6]

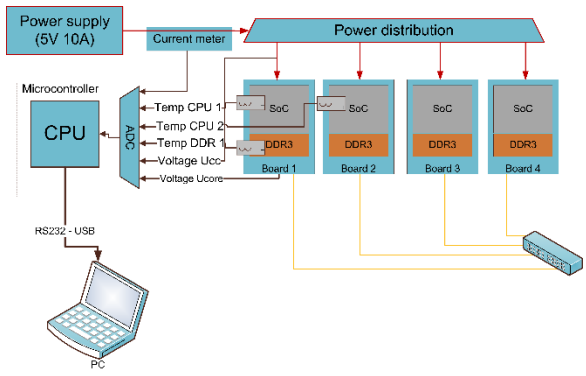

Figure 2. Proposed measurement testbed

aspects. Finally, Section IV concludes the paper along with the plans for our future work.

II. MEASUREMENT TESTBED

Testbed platform used for measurements consists of a small-scale computing cluster composed of four SoC based boards connected to a power supply through a power distribution hub. Constant voltage is controlled using a digital power supply set at 5.0V, maximum available electrical current is 10A. The boards are interconnected via 10/100BASE-T Ethernet Switch operating at full-duplex speed, used for remote access and command exchange between boards. The platform setup (measurement testbed) is shown in Fig. 2.

As various parameters affects the performance, stability and power consumption of SoC based systems the proposed testbed also incorporated three temperature sensors, two voltage sensors and a Hall-effect based electrical current sensor to monitor the effect of these parameters on the aforementioned parameters. In order to digitally represent data Atmel's AVR microcontroller was used to perform analogue to digital conversion and sample the data in regular intervals. The functionality of the measurement testbed is divided into performance, power and temperature components.

A. *Performance measurement*

The test algorithm is a distributed matrix multiplication

$$\mathbf{X} = \mathbf{M} \times \mathbf{N}, \quad \mathbf{M}, \mathbf{N} \in \Re^{n \times n}, \tag{1}$$

which is a large scale SIMD operation consisting of add and multiply operations. Many of HPC benchmarks, such as NPB (NAS Parallel Benchmarks) [14] rely on highly optimized routines for matrix-vector and matrix-matrix product from parallel libraries such as PBLAS and SCALAPACK making the aforementioned operations to be considered as a widely-accepted HPC benchmark. The complexity of (1) is $O(n^3)$, although there are more efficient methods, such as generalized Coppersmith–Winograd algorithm, having a complexity of $O(n^{2,3727})$, [15]. Nevertheless, the goal is to put a high computational load to the processing units and their interconnection, making (1) as a practical option. The total number of operations is considered to be $2n^3$, with each iteration having one multiplication and one addition. We ignore other operations, such as loop iterators, since their number is not significant to the total number of operations.

The algorithm has been parallelized using message passing interface (MPI) using C++ compiled with a g++ compiler

B. *Electrical current measurement*

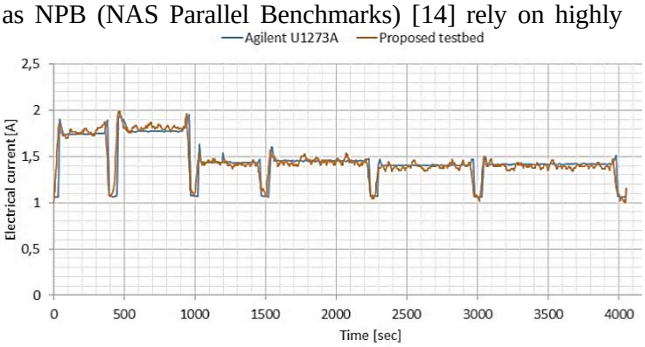
The process of electrical current measurement is a process of outmost importance in analyzing power efficiency of SoC systems. In order to create self-sustaining system capable of real-time measuring and data delivery towards PC an ACS712 Hall-based electrical current sensor was used to convert electrical current value to voltage value. The transfer function of a sensor can be approximated as:

$$I[A] = (U - U_0) \cdot k, \tag{2}$$

where U is the output voltage of a sensor, U_0 is the bias voltage at I = 0A (can be represented as $U_{CC}/2$) and k is the slope of a transfer function.

The voltage value of a Hall sensor is fed towards a 10bit ADC integrated within the microcontroller. After ADC conversion the voltage value is converted to electrical current value and sent towards PC at regular intervals using a UART communication.

As the error in electrical current measurement must be lowered to a minimum the proposed testbed is compared with Agilent U1273A True RSM Multimeter to estimate the amount of the introduced error from the proposed measurement testbed. The process of measurement validation was performed using a logging Multimeter (Agilent U1273A) and the proposed testbed. The result of a measurement validation are shown on Fig. 3 and Fig. 4.



Figue 3. Measurement validation of the proposed testbed (electrial current)

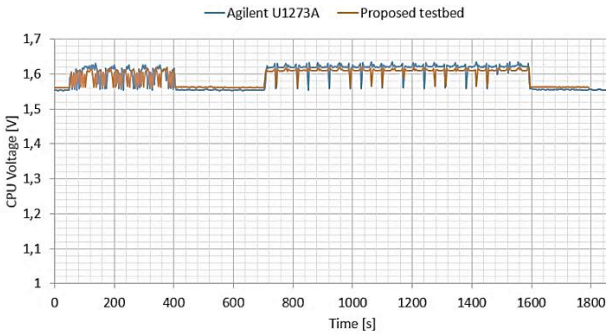


Figure 4. Measurement validation of the proposed testbed (voltage)

As seen from Fig. 3-4 the values obtained from the proposed testbed are in correlation with the data from the Agilent multimeter. The oscillations of the testbed data are due to the higher sampling frequency and the fact that the Agilent Multimeter uses a low-pass filter to filter the high frequency data. Also, the overall error of the measurement (if Agilent multimeter is used as a reference meter) is below 5%. Main reason of using the proposed testbed for electrical current measurement is the ability to distribute current sensing among multiple SoC boards, enabling the measurement of individual power consumption for SoC systems within a cluster.

C. *Voltage measurement*

Second part of the system consist of two voltage probes used to measure voltage values within the system. The most important voltage is the power supply voltage that tends to vary upon different types of load. The voltage measurements have been conducted using a voltage divider connected to an ADC input. Depending on the maximum voltage measured the voltage divider is constructed accordingly. As the voltage of a power supply is important in calculating the consumed power the voltage measurement are validated using a logging Multimeter (Agilent U1273A). From the results it can be concluded that the proposed testbed error is less than 3% compared to reference meter.

D. *Temperature measurement*

Last of the testbed analysis incorporates temperature measurements of SoC cores and memory. We have chosen to measure three temperature values: the temperature of CPU core for SoC Board1 and Board2, respectively, and the temperature of DDR3 memory for SoC Board1. The temperature measurement is performed using analog LM35 temperature probe that outputs linear voltage proportional to temperature. The transfer function of a temperature sensor can be approximated as:

$$T[°C] = U \cdot k_t, \tag{3}$$

where U is the output voltage of a sensor, k_t is the slope of a transfer function $(k_t = 100°C/V)$. Thus temperature values can be digitally represented for each temperature sensor. To enhance the precision of the measurements each sensor was calibrated using Agilent U1273A and K-thermocouple. Accuracy of the temperature sensors can be estimated within the range of +/- 0.2 ^{0}C.

III. EXPERIMENTAL RESULTS

Similar to the classification of the testbed setup in Section II we classify the measurement results of our platform. The first measurement shows performance aspects of our cluster, making the initial insights of its usability, and setting base for other measurements. Secondly, we analyze the power consumption and its energy efficiency, and finally we consider potential stability issues using temperature measurements during specific load profiles.

TABLE I. PERFORMANCE TEST PROFILES

Profile no.	Platform configuration		Software configuration
	Number of nodes (boards)	Total number of cores	Type of operations
1.	4	8	FLOP
2.	4	8	IOP
3.	4	4	FLOP
4.	4	4	IOP
5.	2	4	FLOP
6.	2	4	IOP

A. *Performance results*

Since the platform consists of low power nodes (SoC Boards), the performance is not the main objective aimed by this platform. However, considering that other measurements rely on performance (e.g. power efficiency) we first present and discuss the platform computational power. The tests are divided into 6 different profiles, shown by Table I. We used 2 types of software configurations to stress out the possible differences regarding different types of the load, one using integer operations (IOPs) and one using floating point operations (FLOPs). Both software configurations were conducted on three different hardware configurations: 4 nodes full load (8 cores), 4 nodes half load (4 cores total, load balanced) and 2 nodes full load (4 cores) to analyze different computation and communication setups.

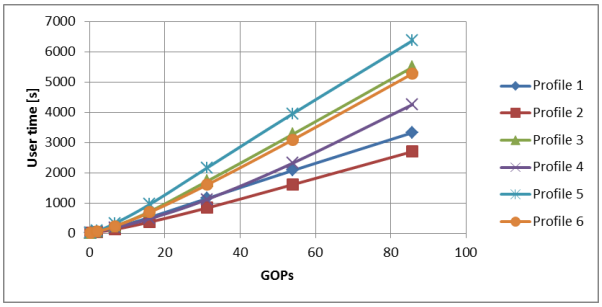
We observed user time (total execution time)

$$t_{user} = t_{comp} + t_{comm} \tag{4}$$

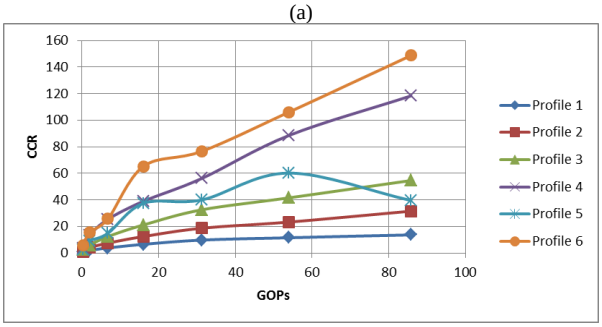
and computation to communication ratio (CCR)

$$CCR = \frac{t_{comp}}{t_{comm}}, \tag{5}$$

since those metrics illustrate the most important performance output of our platform. Measurements of both metrics are given in Fig. 5. User time shows good scalability of the proposed platform with the problem size increase (Fig 5a), although load balanced profiles (3rd and 4th) tend to deviate from this rule because of the bigger

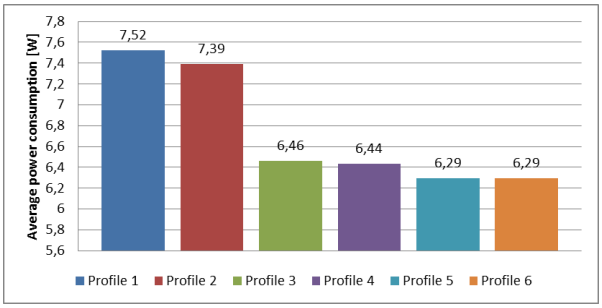


(a)

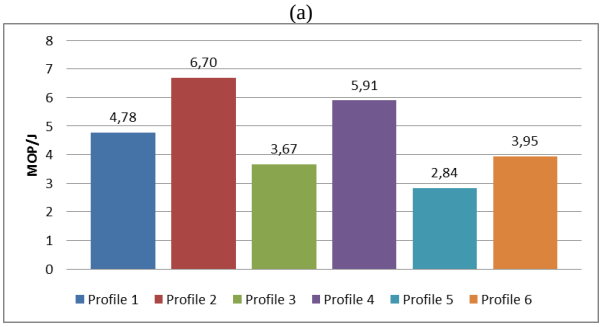


(b)

Figure 5. Performance results: (a) user time, (b) computation to communication ratio



(a)



(b)

Figure 6. Power consumption: (a) average power consumption, (b) energy efficiency

overheads. However, load balanced profiles show better user time results than full node load due to the smaller number of cache misses and light shared memory access of the former. The best configuration performance-wise is shown to be the 8-core profiles, achieving up to 90 MIPS (mega integer operations per second) and 75 MFLOPS (mega floating point operations per second) which is almost three times the performance of a 60W 2.4GHz Pentium 4 desktop CPU tested in [16] (achieving roughly 33 MIPS). On the other hand, the CCR metric (Fig. 5b) is in favor of the profiles 5 and 6, regardless of their lowest user time performance, while 8-core profiles are showing the worst results (because of the network congestion increase). The latter implies that by putting tasks in close configurations could be used for software with the smaller computational load with significant communication demands. Profile 5 results shows the network bottleneck for more complex and intensive loads, making sudden drop of CCR beyond 50 GOPs implying the network congestion beyond this point, where the increased computational performance cannot compensate for the communication overheads.

B. *Power efficiency*

We calculated the cluster instantaneous power consumption using current and voltage measurements explained in Section II.B and Section II.C respectively. The power was calculated using:

$$P_{avg} = U \cdot I, \tag{6}$$

which enables the calculation of the profile power efficiency by:

$$\mu = \frac{n_{OPs}}{P_{avg}}. \tag{7}$$

The platform power efficiency is expressed in number operations per second per watt (OP/Ws, or more commonly millions of OP/Ws, MOP/Ws), which is equivalent to the operations per Joule (OP/J, MOP/J), as a common energy efficiency metric of computing systems used in [12, 13, 16]. The true value of our tested cluster lies in its small physical size, and its low power consumption which rarely peaked 8 W. Fig. 6a shows the average power consumption of the test profiles from Table I. The highest power consumption occurred during test profile 2, indicating that floating point operations apply more stress to the platform than the integer ones. The smallest power stress comes from the profiles 5 and 6 due to their low communication traffic, and the fact that 2 nodes are not used at all (their memory and peripherals are idle). Additionally, profiles 5 and 6 show the smallest power consumption, but since their low performance cannot make up for it, that makes them the least energy efficient of all tested profiles. The overall energy efficiency of the proposed platform ranges from 2.8 to 6.7 MOP/J, making our platform up to 7 times more efficient than a 3.14GHz dual-core AMD PC platform (PP2) used in [16]. If we consider performance comparable to the power-hungry desktop processors, such a small-scale cluster makes an affordable alternative for the small-scale distributed processing.

C. *Stability*

Stability was tested by measuring temperatures during different types of varying loads, shown in Fig. 7. The Linux shell scripts were made to quickly alternate from load to idle, making short load bursts in order to stress the platform. The core time increase during stress is shown in Fig. 8. Additionally, we used 2 different burst types, the first with small run times of approximately 5 s (light load, longer period of time) and second with half a minute load (heavy load, shorter period of time), both interrupted with 2 s pauses. Bigger idles (5 min) were made between short-burst and long-burst tests in order to cool the platform, and to simulate some idle times in real applications. We recorded temperatures of the frontend node, T(node1), one

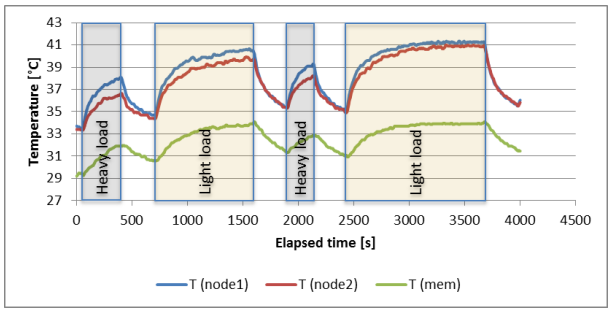


Figure 7. Stability, temperatures

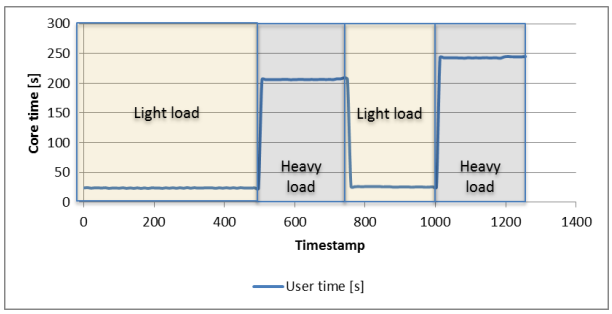

Figure 8. Stability, core time

worker node T(node2) and main memory T(mem). The temperature measurements were made according to the procedure from Section II.D under the ambient temperature of 24.6 °C.

Fig. 7 shows the temperature trace, making an obvious difference from idle time and load time on one hand, and light and heavy load on the other. The temperatures rise up to 41°C for the CPU and 34°C for the memory which is only 16.4°C and 9.4°C increase over the ambient temperature. Fig. 8 shows the behavior of the total user time during light and heavy load in the second experiment which shows no significant increase of the execution time during time (and the temperature stress). Only a small increase of the user time is visible towards the end of the execution, which is negligible. Therefore, the platform can be considered stable during varying load and temperature increase.

IV. Conclusion

This paper presents a low-power, energy-efficient HPC cluster based on four ARM SoC based boards. The usability of the proposed computational cluster is analyzed by testing the three most important metrics in the HPC domain: performance, power consumption and stability via 6 different test profiles.

In order to measure power consumption and other related parameters the testbed incorporates a microcontroller dedicated in analogue to digital conversion and sampling. The parameters monitored consist of three temperatures, two voltages and total electrical current of the boards. The proposed measurement testbed was compared with existing referential easement device and from the results it can be concluded that the error of the proposed measurement testbed is below 3% compared with reference meter.

Performance results show that our simple test cluster, although limited by its hardware, can deliver enough computational power for the small-sized distributed applications, with averages up to 90 MOP/s. Slight network bottlenecks occurred, but only during heavy loads due to the lack of communication optimization of the benchmark software.

Additionally, tested platform's power consumption rarely exceeded 8 W, with the highest averages of ~7.5 W and it energy efficiency reached up to 6.7 MOP/J (4.8 MFLOP/J) which makes it a perfect candidate for the energy-efficient small-scale computing.

The stability of the proposed platform was analyzed using temperature measurements under different load stress tests, showing no sign of problems, and keeping user times constant at all temperature levels. The slight increase of the user time occurred under high temperatures, but they were negligible.

Electronic interpretation of selected lessons in fuzzy mathematics

dkovac@pfst.hr

Abstract - Dedicated electronic hardware has been used to interpret selected lessons in fuzzy mathematics. DeMorgans Laws were simulated in an electronic environment and that simulation was then used as a base to illustrate how the law of excluded middle is violated by fuzzy sets. In that context the problem of fuzzy grade of inclusion is briefly analysed and simulated electronically.

I. INTRODUCTION

The theory of fuzzy logic can be developed using the concepts of fuzzy sets similar to how the theory of crisp bivalent logic can be developed using the concepts of crisp sets. Specially there exist an isomorphism between sets and logic [2]. This means that a good foundation in fuzzy sets is necessary to develop the theory of fuzzy logic. On the other hand, in real practice, a number of fuzzy logic gates and circuits were developed to build more complex circuits. In this paper we are going to show how some elements of fuzzy mathematics can be interpreted in hardware environment.

In the second and third section of this paper we will deal with DeMorgans law(s) and use the obtained results to show some difference between crisp and fuzzy sets (law of excluded middle in fourth section).

Later (sections five and six) , we will show how a dedicated hardware detector can be used to indicate the grade of inclusion of two triangular fuzzy sets.

The detector of grade of inclusion is designed using *min-max-Op-Amp* technique [3] [4].The second idea of this paper is to design dedicated fuzzy hardware that can be used for different purposes as process modelling, control, etc.

II. UNITY SQUARE

A set (Cartesian product) $S_x \times S_y$, where

$S_x = \{x : x \in [0.1],\ \ x \in R\}$

and

$S_y = \{y : y \in [0.1],\ \ y \in R\}$,

is called the *unity square* and is denoted as S_1^2. Its (first) subset Δ consisting of ordered pairs, i.e. elements $(x, y = x)$ is called a diagonal of S_1^2 [1]. Its (second) subset $\overline{\Delta}$ consisting of ordered pairs, i.e. elements $(x, y = 1 - x)$ is called a transverse of S_1^2.

The diagonal can be seen (perceived) as a fuzzy set (1):

$$A = \{(x, y = \mu_A(x)) : x \in [0,1], \mu_A(x) \in [0,1]\}, \qquad (1)$$

where the function $\mu_A(x)$ is the corresponding membership function. In the very same way, the *transverse* can be seen (perceived) as a fuzzy set (2) :

$$\overline{A} = \{(x, y = \mu_{\overline{A}}(1-x)) : x \in [0,1], \mu_{\overline{A}}(1-x) \in [0,1]\} \qquad (2)$$

where $\mu_{\overline{A}}(1-x)$ is the corresponding membership function. It is obvious that these two membership functions are correlated over the purposed *unity square* (3):

$$\mu_{\overline{A}}(1-x) = 1 - \mu_A(x) \ \text{ for all } \ x \in [0,1] \qquad (3)$$

In the theory and practice of fuzzy sets the membership function $\mu_{\overline{A}}(1-x)$ is usually denoted as $\mu_{\overline{A}}$ and respresents the complement of the membership function $\mu_A(x)$.

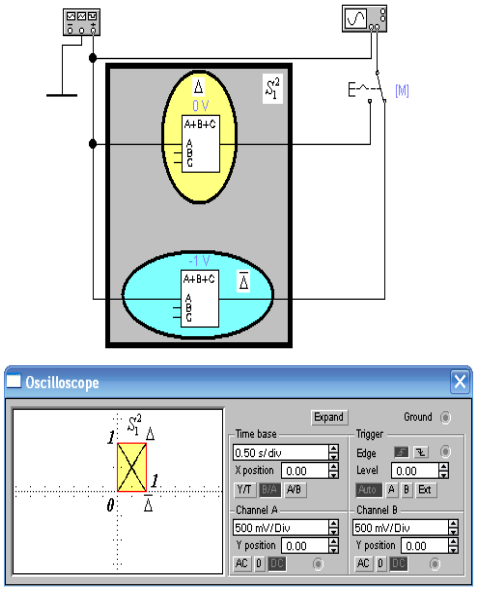

Figure 1. *Unity square*

III. SOME PROPERTIES OF FUZZY SETS; DEMORGAN'S LAWS

Consider fuzzy sets *A* and *B*, in the universe *X* , whose membership functions are given by terms (4 and 5):

$$\mu_A(x) = \min(1, \max(0, x)) \text{ for } 0 \le x \le 1 \quad (4)$$

$$\mu_B(x) = \max(0, \min(1, 1-x)) \text{ for } 0 \le x \le 1 \quad (5)$$

and shown in Fig. 2. Oscillographs a) and b) shown in Fig. 2 represent unlimited membership functions defined above, while oscilograph c) represents limited membership parts according to given relations. Their intersection is a fuzzy set (D) containing all the elements that are common to both sets, in a „fuzzy sense“. The membership function of the resulting set $A \cap B$ is given by (6):

$$\mu_D \equiv \mu_{A\cap B}(x) = \min(\mu_A(x), \mu_B(x)) \quad \forall(x) \in X \quad (6)$$

A graphic i.e., oscillograph (membership function $\mu_D(x)$) representation of the intersection of the two given fuzzy sets is shown in Fig. 3. Now, consider a fuzzy set *D* in the same *X*. Its complement is a fuzzy set whose membership function is given by (7):

$$\mu_{\bar{D}} \equiv \mu_{\overline{A\cap B}}(x) = 1 - \min(\mu_A(x), \mu_B(x)) \quad \forall(x) \in X \quad (7)$$

A graphic representation of the complement of the fuzzy set *D* is shown in Fig. 4. DeMorgan's laws are particularly useful in processing (simplifying) expressions of crisp sets (and logic), but they can be used in the „fuzzy domain“, as well. This means that the first DeMorgan's Law holds for our case as it is shown Fig. 4. One must know that, for the sake of simplicity, only straight line parts of given membership functions, i.e. lines $y = x$ and $y = 1 - x$, respectively were used to proof the following relation (8) (see Fig. 2 and 5):

$$\overline{A \cap B} = \overline{A} \cup \overline{B} \quad (8)$$

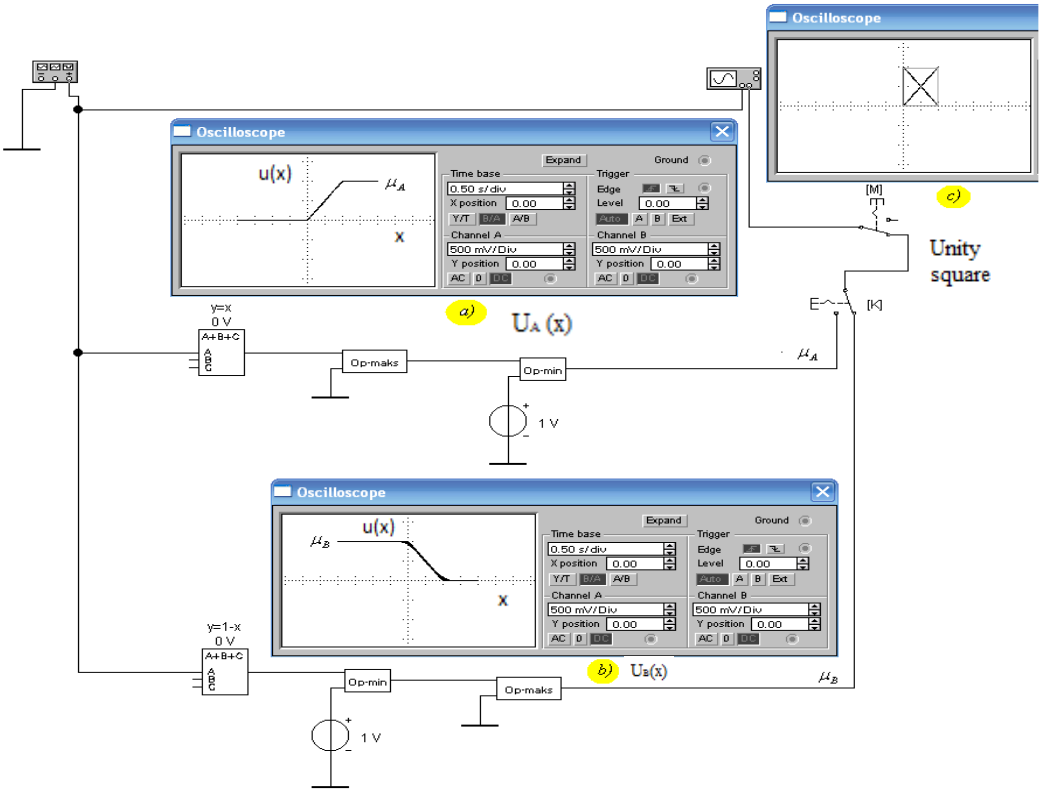

Figure 2. Complementary character of two circuits generating two membership functions is obvious

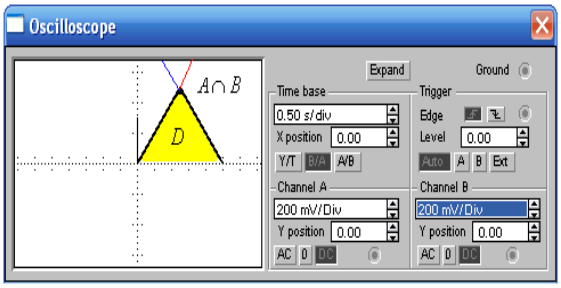

Figure 3. Two fuzzy sets in the same universe *X* are intersected using *Op-Amp* [2]

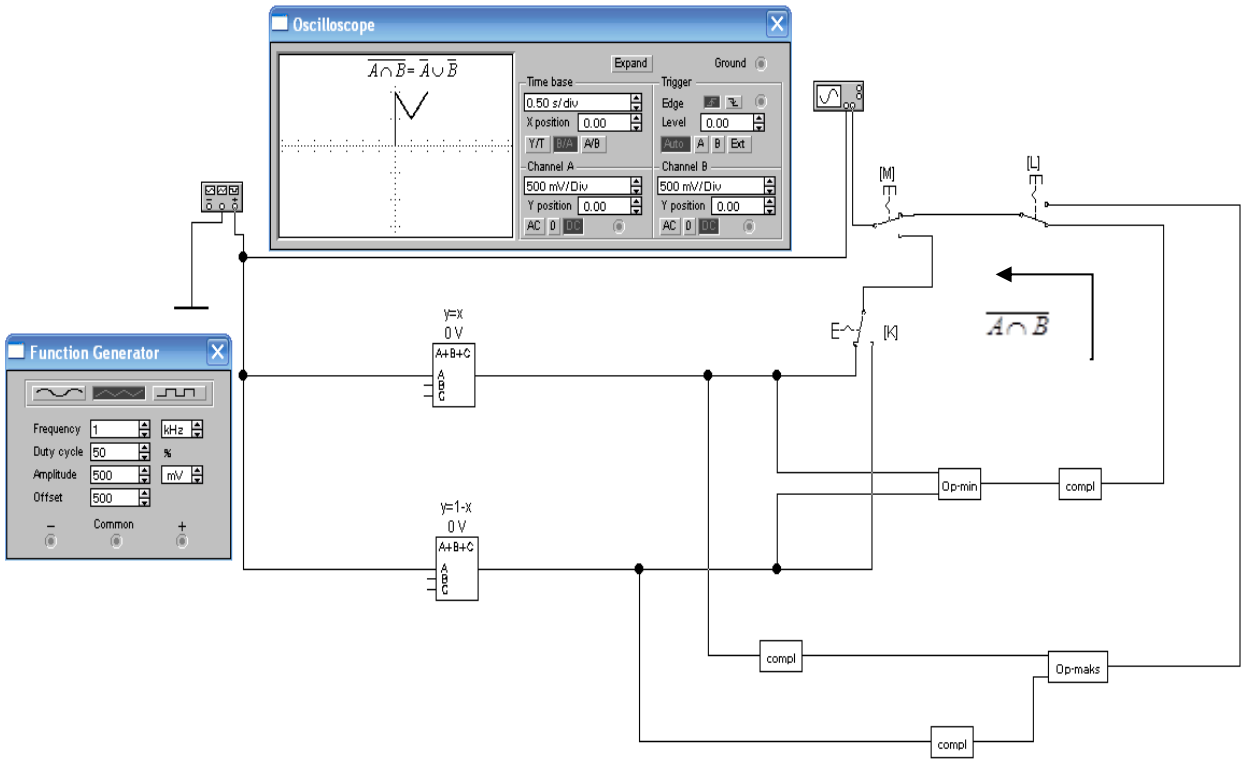

Figure 4. De Morgan's law $\overline{A \cap B} = \overline{A} \cup \overline{B}$

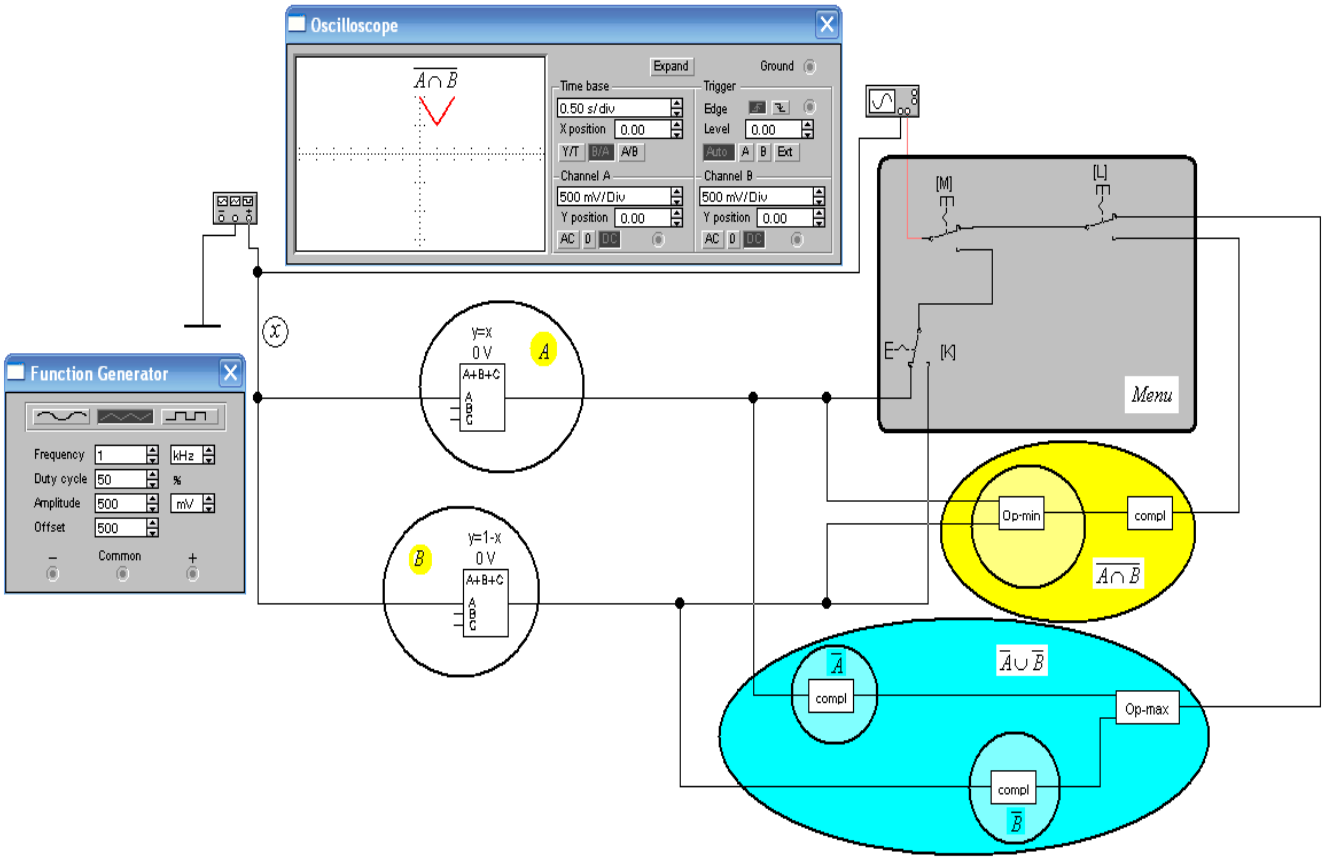

Figure 5. De Morgan's law $\overline{A} \cup \overline{B} = \overline{A \cap B}$

Note that the second DeMorgans Law expressed as a term $\overline{A \cup B} = \overline{A} \cap \overline{B}$ can be interpreted in hardware environment on a very similar way. In this context, Fig. 6 shows that the laws of exclusion, which are satisfied by crisp sets, are not satisfied by fuzzy sets. In particular the union of a fuzzy set $A \cap B$ and its complement $\overline{A \cap B}$ is not equal to the universal set, but is a subset of the universal set. Furthermore, the intersection of a fuzzy set $A \cap B$ and its complement $\overline{A \cap B}$ is not a null set and may have non-zero membership value(s) (see Fig. 5). These exclusion properties of a fuzzy set are not a shortcoming. In fact, they enable fuzzy logic to be more practical and versatile than crisp logic.

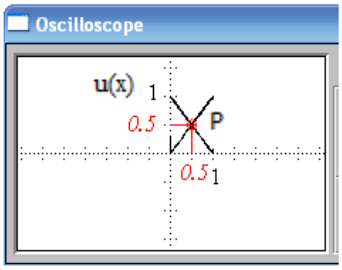

Figure 6. Fuzzy set $A \cap B$ and its complement $\overline{A \cap B}$

IV. SOME PROPERTIES OF FUZZY SETS; THE LAW OF EXCLUDED MIDDLE

We are going to use another example to illustrate how the law of excluded middle is violated in fuzzy set environment. A triangular membership function (see Fig. 7) is used to represent a fuzzy set *A*. Its complement $\overline{A}$ is shown on the same oscillograph which is obtained by subtracting the original membership function from 1 (see Fig. 8 and Fig. 9). The original circuit shown in Fig. 8 is converted to sub circuit called compl. (see Fig. 9) The union of *A* and $\overline{A}$ is performed using *max* gate as it is shown in Fig. 9.

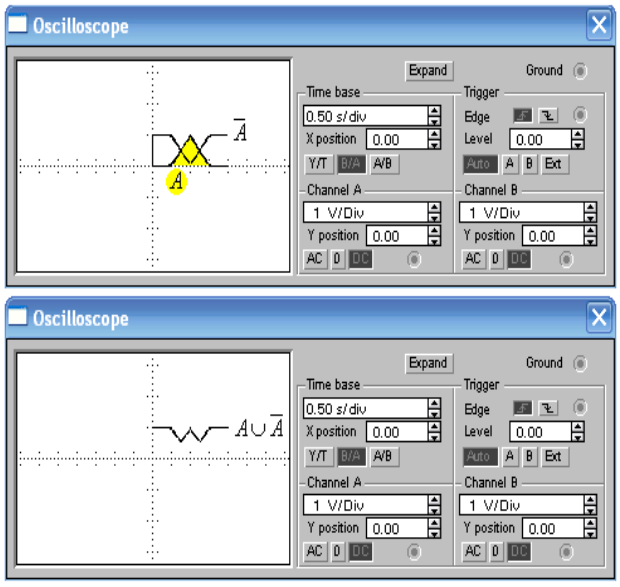

Figure 7. An example of exclude middle in fuzzy sets

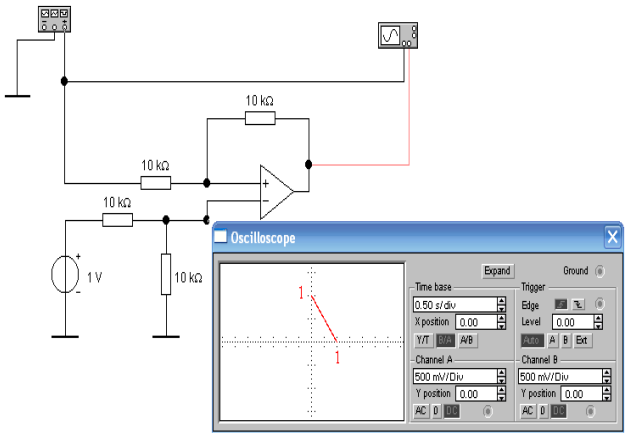

Figure 8. Simple *Op-Amp* complement circuit (compl)

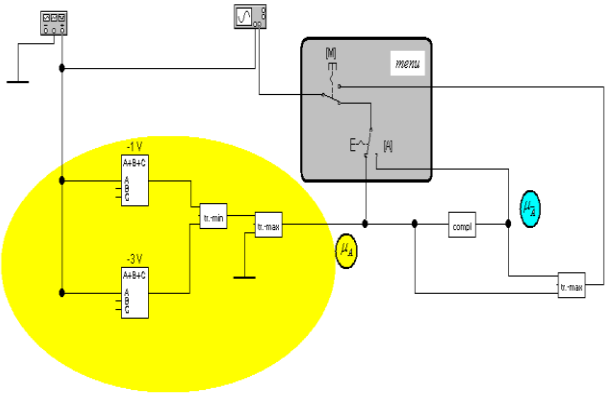

Figure 9. Electronic interpretation of an example of excluded middle in fuzzy sets

Now it is convenient to introduce a notion of, so called, *relative complement* [6].

V. RELATIVE COMPLEMENT

Operation of *relative complement* in the domain of fuzzy set can be modeled in hardware as relative complement gate accorcing the following definition [6].
Definition: Assume *A* and *B* are two fuzzy subset of *X*. The *relative complement* of *B* with respect to *A*, denoted $E = A - B$, is defined as the fuzzy subset *E* of *X* (9), where for each $x \in X$:

$$E(x) = \max[0, A(x) - B(x)] \qquad (9)$$

For example let's asume:

$$A = \{0/a,\ 0.2/b,\ 0.5/c,\ 0.6/d,\ 0.9/e,\ 1/f\}$$

and

$$B = \{1/a,\ 0.8/b,\ 0.5/c,\ 0.4/d,\ 0.1/e,\ 0/f\}$$

then

$$E = A - B = \{0/a,\ 0/b,\ 0/c,\ 0.2/d,\ 0.8/e,\ 1/f\}.$$

If $A = y = x$ and $B = y = -x+1$ are fuzzy sets from the „*unity square*“ then *E* can be expressed in an electronic environment as it is shown in Fig. 10.

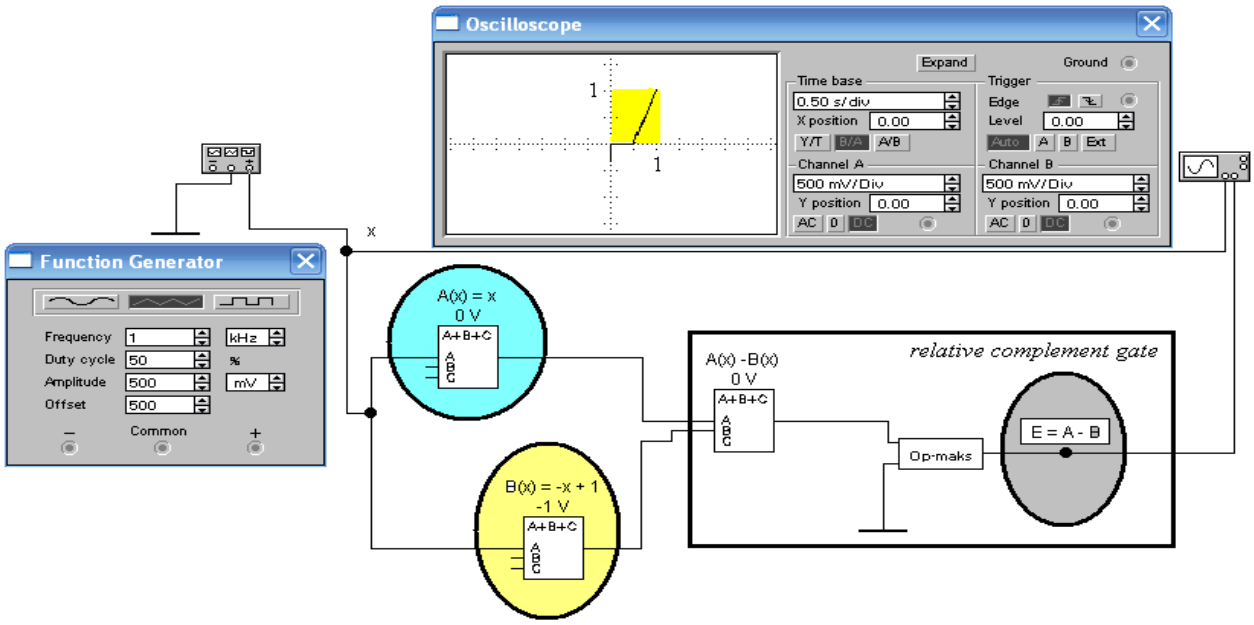

Figure 10. Operation of the relative complement in the domain of unity square; membership functions $y = x$ and $y = - x + 1$ represent fuzzy sets *A* and *B* respectively . One can easily find out that the previous example is related to this electronic model.

VI. SOME PROPERTIES OF FUZZY SETS; GRADE OF INCLUSION

In the context of fuzzy logic, a set, say *A*, may be partially included in another set, say *B*. Then it is convenient to define a grade of inclusion of a fuzzy set *A* in another fuzzy set *B*. This may be interpreted as the membership function of the fuzzy relation $A \subset B$. In a specific application one can use min (instead more general *T-norm*) to define a grade of inclusion (10) [2]:

$$\mu_{A\subset B}(x) = \begin{cases} 1 & \text{if } \mu_A(x) \le \mu_B(x) \\ \mu_B(x) & \text{otherwise} \end{cases} \qquad (10)$$

Consider an electronic fuzzy membership generator (see Fig. 10) that can deliver two fuzzy sets shown on the top of Fig. 12 [4]. According to relation (10), the grade of inclusion of *A* in *B* is given by solid line on the oscillograph (see bottom of Fig. 12). That line is generated by so called detector of grade of inclusion showed in Fig. 12. Besides standard transistor min and *max* gate, the detector includes comparator (*m-M-comp*) [5]. The design of that comparator is based on *min-max-Op-Amp* technique [5] as it is shown in Fig. 11. *Max* gate is used along with very steep straight line (*Op-Amp*) and ground level line to establish the raising edge of the comparator. In the second design step a min gate is used to limit the raising edge to a certain level (battery voltage).

Characteristic shown in Fig. 11 can be used to express (AI – model) wholesaler agent behaviour in the process of newspaper distribution and control [5]; in the very beginning of a tourist season wholesaler agent ignores small and sporadic orders coming from local operators. Then, as the season "grows" local orders are accepted up to a certain level. After, according to publisher's wish the control is dismantled by setting order(s) to a certain maximum level(s). Such and similar characteristics (models of human acting) can be regarded as a kind of *event filters* [5].

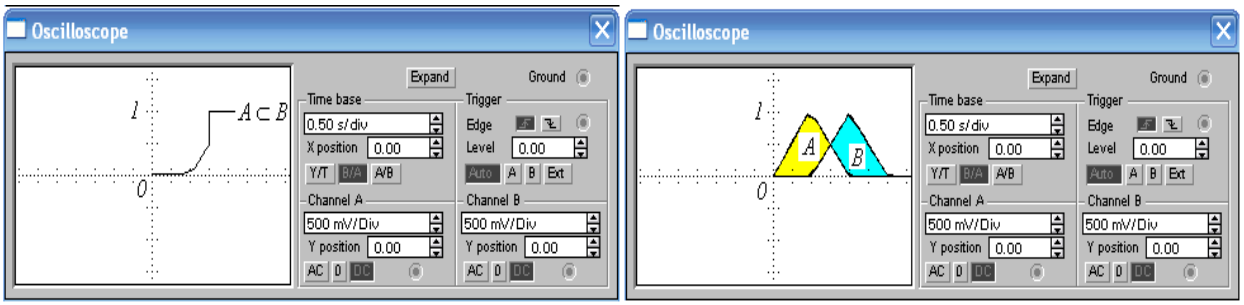

Figure 11. An example of *grade of inclusion*

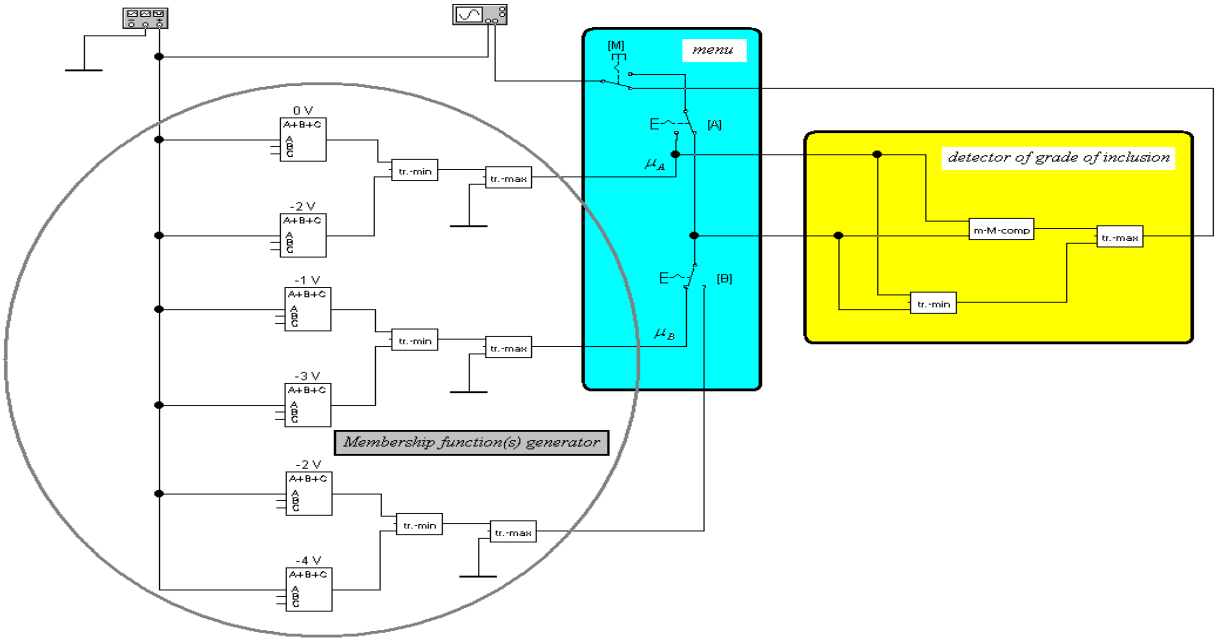

Figure 12. Electronic simulation of a problem; *grade of fuzzy set inclusion*

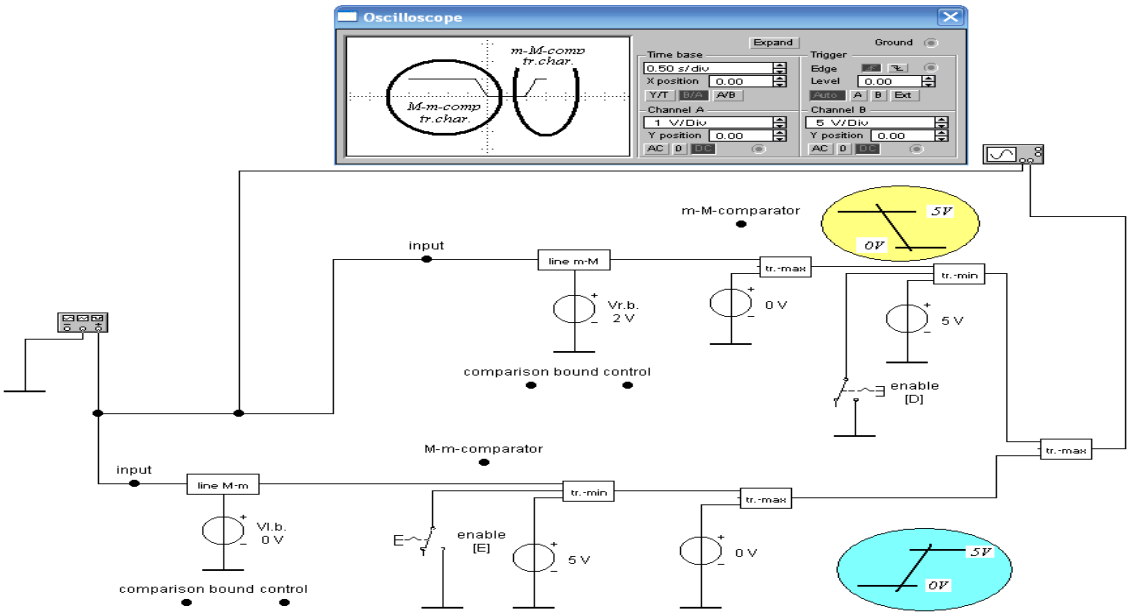

Figure 13. Electronic design of *m-M-comp* and *M-m comp*

VII. CONCLUSION

Electronic hardware environment was used to present some mathematics of fuzzy sets. DeMorgans Law electronic presentation was extended to the problem of exclude middle in fuzzy sets. That problem was modelled in two different ways. In the context of fuzzy logic mathematics original detector of grade of inclusion has been designed. That detector has been used to interpret the grade of inclusion for two triangular fuzzy sets. The design of the presented detector is based on so called *min-max-Op-Amp* technique. Future investigations of hardware implementations of functions used in fuzzy mathematics can be based on *min-max-mid op-Amp* technique.

Fuzzy gates interchangeability

Darko Kovačević, Toma Karađole and Jure Vrsalović
Falcuty of Maritime Studies, University of Split, 21000 Split, Croatia
dkovac@pfst.hr

Abstract - The idea of this paper is related to possible conversions of min, max and mid fuzzy gates functions. If we want to convert basic min and max gate function to another logical function, for some reason, that can be done on several ways. For the beginning one can convert only gate inputs. In the second case only gate outputs can be inverted. The third kind of the gate interchangeability is done by the combination of inverting inputs and outputs. At the end, it is possible to design min, max and mid gates to be controllable through gate inputs information (inputs voltages).

I. INTRODUCTION

In the second section of this paper we are going to show that the function(s) of fuzzy gate(s) can be interchanged in the way similar to standard logic gate function interchangeability. The simplest way of "gate change" is achieved by adding a complement gate on *min* or *max* fuzzy gate inputs. The complement gate can be added on fuzzy gates outputs, if one wants to change a gate function on the other way. Finally, the complement gates can be simultaneously added to inputs and outputs to change agate function. On the other hand (Section III.), fuzzy *min* or fuzzy *max* can be used as a design tool for other kinds of fuzzy gates in a manner similar to design of complex gates in digital electronics [1].
Also, we are going to show that standard fuzzy gates can be used to support logical operations in the domain of crisp sets. Note that standard digital gates, in principle, cannot support fuzzy logic operations.

A dedicated fuzzy logic gates ($\max/^{c}\min$) with inherent (designed) interchangeability mechanisms will be briefly explained in the fourth section.
At the end of this paper, a new kind of a complex fuzzy gate called *mid* gate will be shown. That complex gate can perform one of three functions*: min*, *max* and *mid* what depends of straight gate input information.

II. USING COMPLEMENT GATES TO CONVERT GATES

Consider a fuzzy set A in the universe X. Its complement $\overline{A}$ is a fuzzy set whose membership function is defined by:

$$\mu_{\overline{A}}(x) = 1 - \mu_A(x) \quad \text{for all } x \in X$$

as illustrated in figure 1.

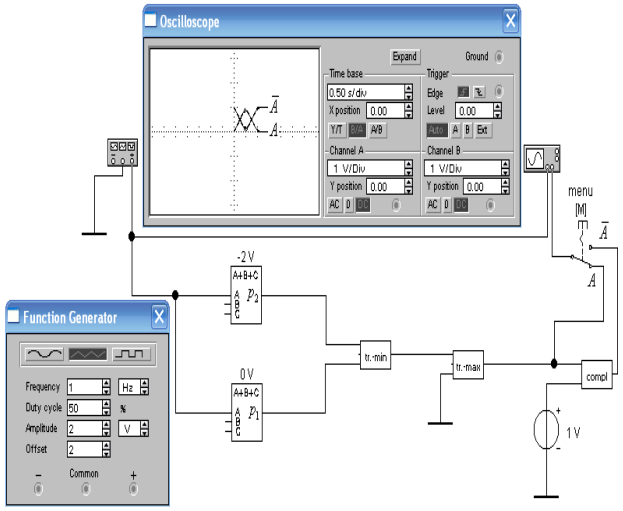

Fig. 1. Fuzzy-set complement of fuzzy logic NOT

The complement in fuzzy sets corresponds to the negation (NOT) operation in fuzzy logic, just as in crisp (bivalent) logic.
In the „unity square" (see Fig. 2) we can define two sets B and C by two membership functions

$$\mu_B(x) = x$$
$$\mu_C(x) = 1 - \mu_B(x)$$

The "unity square" can be used as an explanation tool for gate interchangeability, DeMorgan's laws etc.

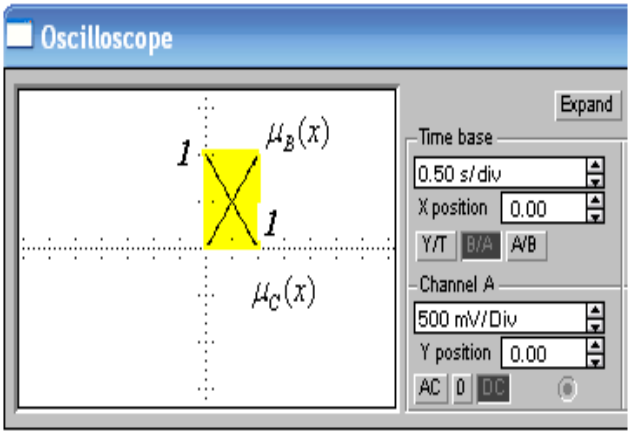

Fig. 2. „Unity square" along with its characteristic membership functions $\mu_B(x)$ and $\mu_C(x)$ for $x \in [0, 1]$

A. Inverting outputs

Sometimes there is necessity to convert basic *min* and *max* gates to another logic function. [1] That can be done easily with the use of complement gates.
Ones, only output is inverted to get desired logic function (see Fig. 3.). Inverting the outputs leads us to easy predictable results; *max gate* is converted to $\overline{\max}$ *gate*. On the same way $\overline{\max}$ *gate* can be converted to *max gate*.
In a very similar fashion it is possible to design conversion of *min gates* to $\overline{\min}$ *gates* (and vice versa) as it is shown in Fig. 4. Note that $\overline{\min}$ *gates* can be designed in quite different way (see Fig. 5).

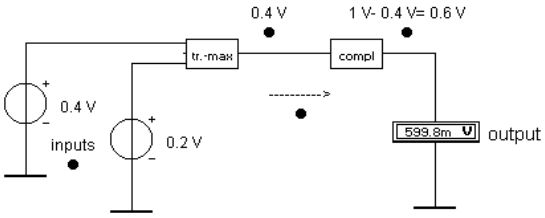

Fig 3. Conversion by complementing output; $\overline{\max}(x, y) = \overline{\max}(0.2,0.4) = \overline{(0.4)} = 0.6$. In the case that inputs are 5Vand 0V respectively, then the output will be 0V

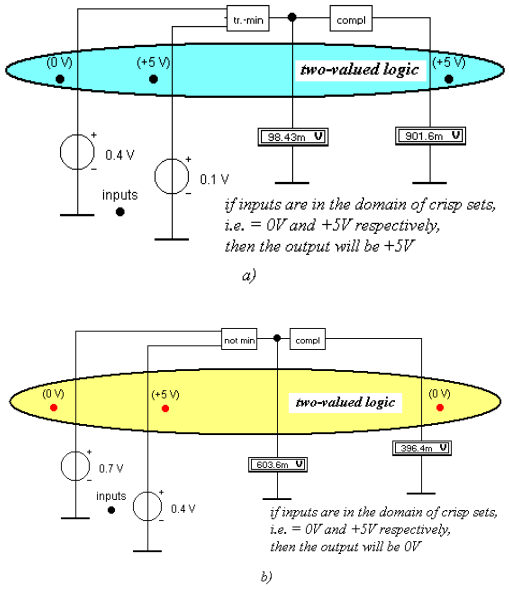

Fig 4. Conversion: a) *min gates* to $\overline{\min}$ gates and b) $\overline{\min}$ gates to *min gates*

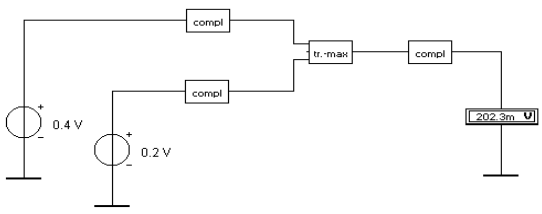

Fig 5. *Max gate* to $\overline{\min}$ *gate* conversion

B. Inverting inputs

In this section, gate inputs will be inverted to achieve conversion. For instance, if both inputs of *max* gate are inverted, the gate becomes a $\overline{\min}$ *gate* (see Fig. 5.).

C. Inverting inputs and outputs

It is possible to invert inputs and outputs of *min (max)* gates to get different logic gates. For example, if inputs to *min gate* are inverted along with inversion of the gate output, then *max gate* will be designed (see Fig. 6.).
In the very same way, max gate be converted to min as it is shown in Fig. 7.
In a similar way, a $\overline{\max}$ *gate* can be converted to $\overline{\min}$ *gate* (see Fig. 8.).

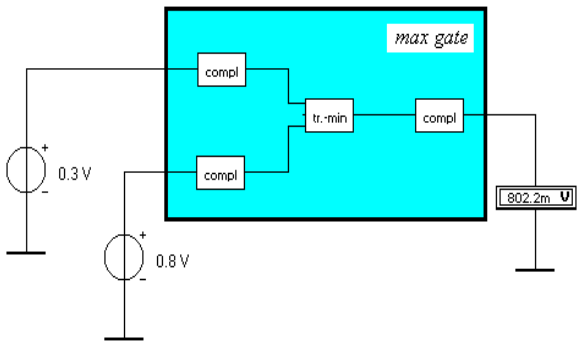

Fig 6. Converting *min gate* to *max gate*; for inputs 0.3V and 0.8V the output will be 0.8V (see Fig.2. for reference)

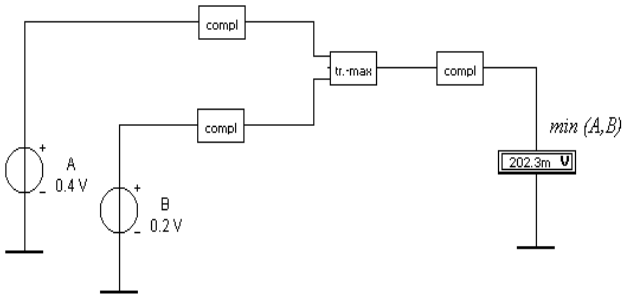

Fig. 7.Interchanging gate function; min (0.4V, 0.2V) = 0.2V (refered to «unity squre»)

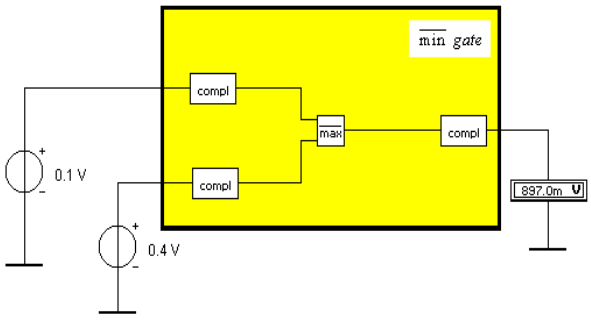

Fig 8. $\overline{\min}(0.1V,0.4V) = 0.9V$ (refered to «unity squre»)

III. $\overline{\min}$ GATE AS A UNIVERSAL GATE

Like in classic digital circuit environment, $\overline{\min}$ *gate* can be used as a sort of "universal gate"; when wired they can be used to create any of other logic functions (see figure 9 and 10). According to Fig. 9 $\overline{\min}$ *gates* are used to design (realize) *min gate*. In similar manner, universal $\overline{\min}$ gates can be used for the realization of max gates (see Fig. 10.).

Using "universal" $\overline{\min}$ *gates* it is possible to design classic *ex-or* gates that support crisp set operation (bivalent logic) as it is shown in Fig. 11 Note that such kind of *ex-or* gates cannot support logic operations in the domain of fuzzy sets [2]. Fuzzy ex-or gates have been designed on an entirely different way [2]. Fuzzy ex-or gates have been designed on an entirely different way [2]. In general, multiple use of one kind of inverting fuzzy gates (e.g. $\overline{\min}$) is good enough to make any combinational function in crisp logic domain.

A picture gallery (see Fig.11.) shows functionality of *ex-or* gate designed in *min-max-Op-Amp* technique to handle crisp set operation.

So far, we can conclude that dedicated fuzzy gates, depending on current inputs can be used to handle logic operations in domains of fuzzy and crisp sets.

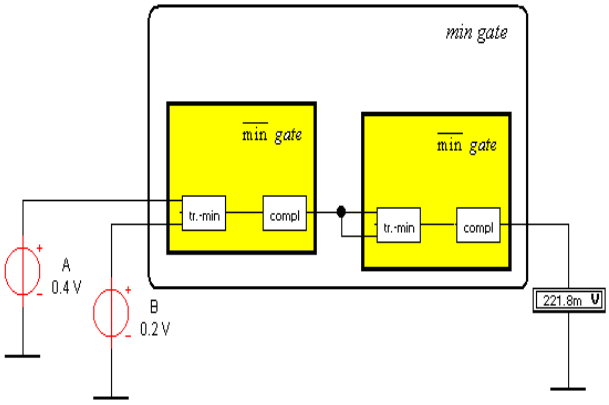

Fig. 9. Wired "universal" $\overline{\min}$ *gates* perform *min function*

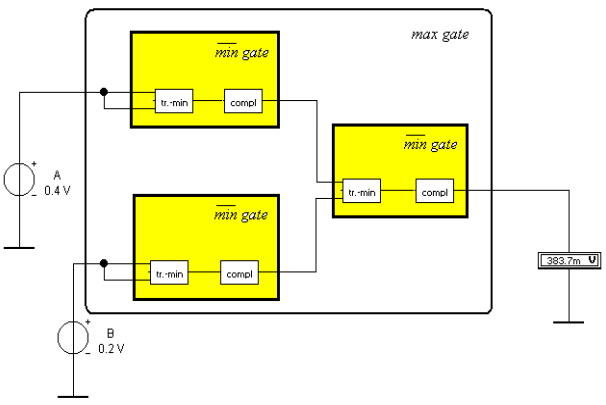

Fig. 10. "Universal" $\overline{\min}$ *gates* design of *max function*

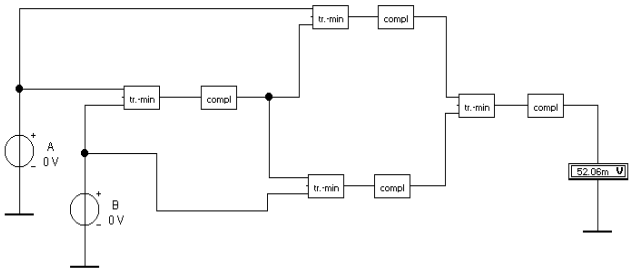
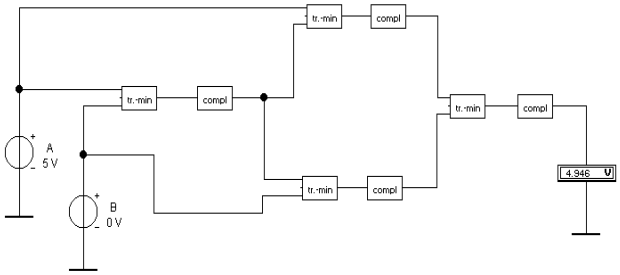
IV. INFORMATION CONTROL OVER MIN (MAX) GATES TO ACHIEVE MAX (MIN) GATES INTERCHANGEABILITY

A. Changable min and max gates (min/max gate)

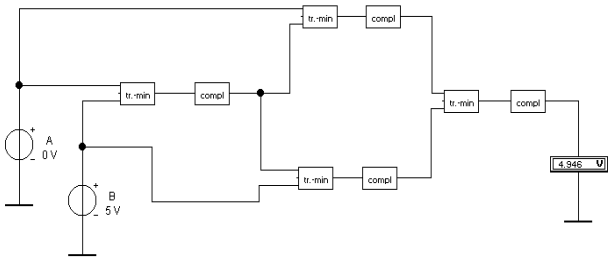
Min or *max* gate designed in *Op-Amp* technique [3] can be easily, „in hardware" , transformed to perform *max* or *min* function, respectively (see Fig. 12. and 13.). We can talk about information controled interchangeability, ie. *min/c max* gates.



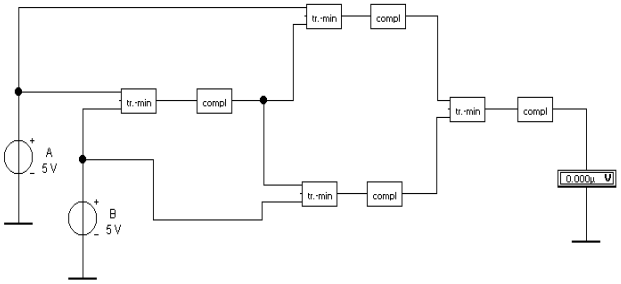
a) Ex-or (A, B) = "0" (0 V)



b) Ex-or (A, B) = "1" (5 V)



c) Ex-or (A, B) = "1" (5 V)



d) Ex-or (A, B) = "0" (0 V)

Fig 11. Classic ex-or designed in $\overline{\min}$ *gates* technique
We have used ex-or gate to notify ability of using fuzzy gates in crisp logic operations.

The mentioned interchangeability is based on mathematical definition of min (max) gate operation [2]:

$$\min(x,y)=\frac{1}{2}(x+y-|x-y|)$$

$$\max(x,y)=\frac{1}{2}(x+y+|x-y|)$$

Changing the sign of the third term the logic operation of the *min (max) gate* can be exchanged (see Fig.12. and Fig. 13.).

The interchangeability of the original three inputs *min (max) gate* in the *Op-Amp* technique can be achieved in the very same way :

$$\min z,\min(x,y))=\frac{1}{2}(z+\min(x,y)-|z-\min(x,y)|)$$

$$\max(z,\max(x,y))=\frac{1}{2}(z+\max(x,y)+|z-\max(x,y)|)$$

The sign of the third term must be interchanged to perform min or max operation of three inputs *min/ᶜmax* gate.

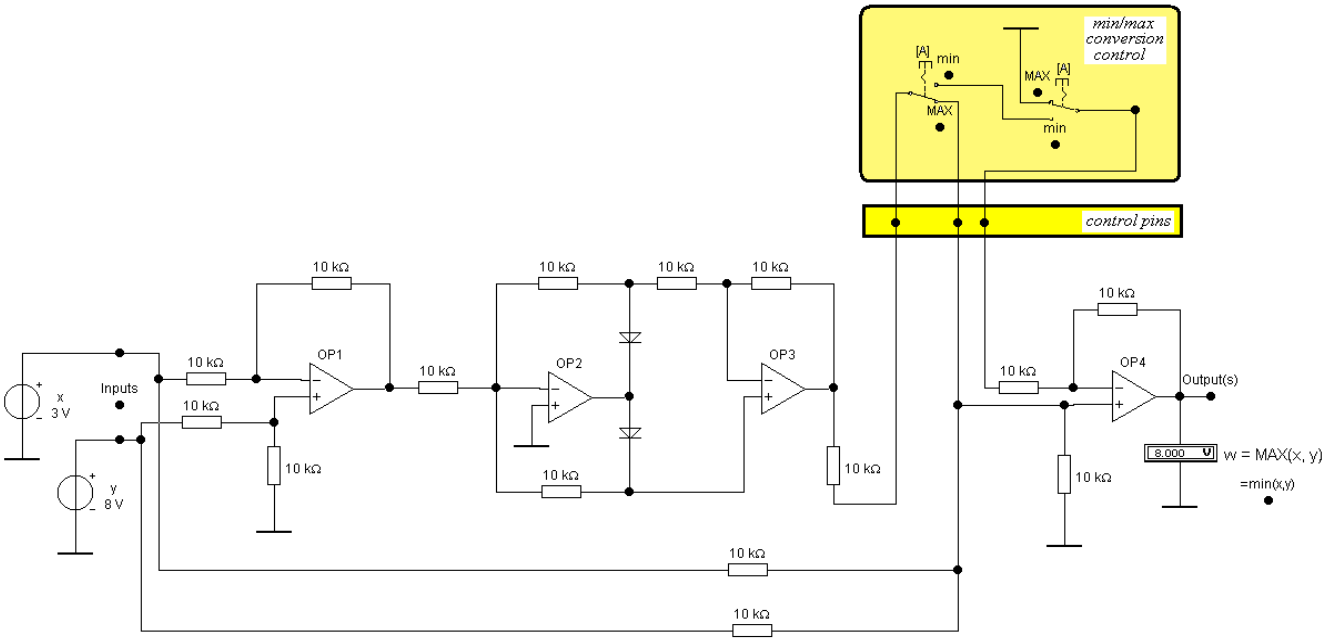


Fig. 12. The state of two inputs *min/ᶜmax* gate is set to perform *max* function. Switch(es) A ($\overline{A}$) flips from one position to another interchanging the circuit logic function.

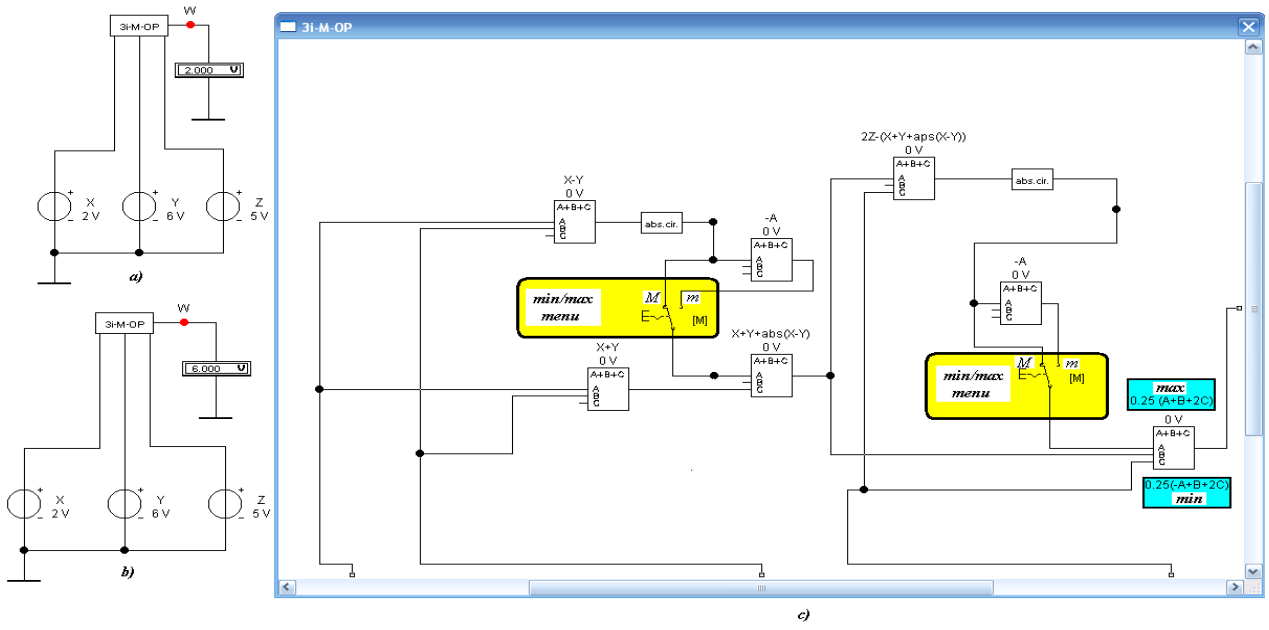

Fig. 13. The state of three inputs $\max/^{c}\min$ gate;
a) min gate performing, b) *max* gate performing, c) circuit scheme

Interchangable *min/c max* gates can be used as an element of an anology *electronic sorting device* (*sorting network*) capable to exchange the way of sorting analog data (input voltages).

Sorting network are comparison networks that always sort their inputs (see Fig.14.) [4]. A comparison network is composed solely of wires and comparators (see Fig. 14.). A comparator shown in Figure 14., is an electronic device with two inputs, *x* and *y* and two outputs *x'* and *y'*, that performs the following function:

$$x' = \min(x, y)$$

$$y' = \max(x, y)$$

If the gate control changes, the $\max/^{c}\min$ gate state will be interchanged and therefore outputs of the electronic comparator will be exchanged; *x'* switches from 5.000 V to $x' = \max(x, y) = 9.000$ V and y' switches from 9.000 V to $x' = \min(x, y) = 5.000$ *V* . In that way it is possible to design controlled sorting; monotonically increasing sorting network (see Fig. 15.) can be transformed in monotonically decreasing sorting network (see Fig. 16.) due to input information. Doing sort in an analog hardware can be important in different applications. In an AI model scenario of the newspaper distribution and sell process, an intelligent agent (process operator) wants to establish, so called, *pilot based coupling control* over a certain newspaper [2]. Prior to any decision he (she) must do sorting of current orders and remnants to get correlation coefficients among the newspaper and newsstands in the area of distribution. For that purpose orders (remnants) can be marked adding a small denoting voltage to orders (remnants) in a row. Numerical codes of newsstands are introduced in sorting as it is shown in figure 15.

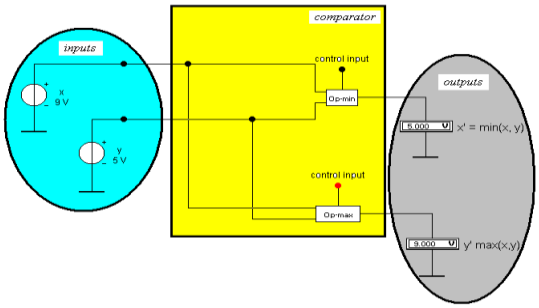

Fig. 14. A electronic comparator with applied inputs *x* and *y* generates outputs *x'* and *y'*.

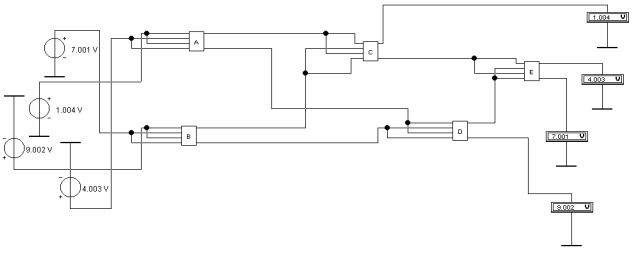

Fig. 15. Monotonically increasing sorting network.Input voltages remnants are deliberatively marked (1,2,3,4) to correlate newstands and corresponding remnants

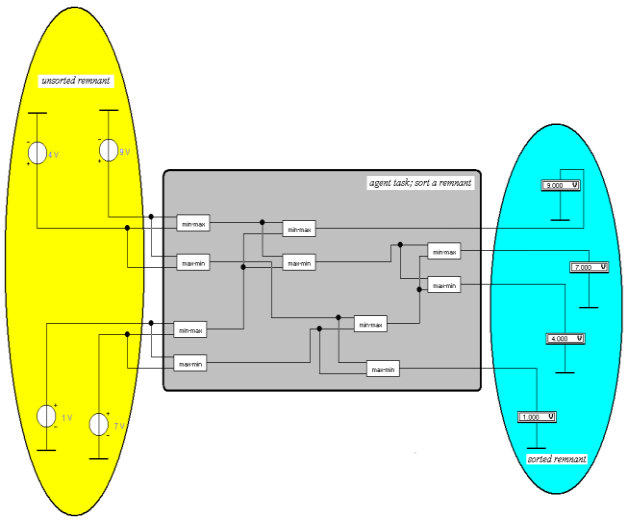

Fig 16. Agent task; sort the remnant prior to any control decision; monotomically decreasing sorting network

B. Mid gate interchangeability

The operation of *mid* which plays an important role in modelling a part of certain kind of intelligent (hardware) agent can be expressed as [2]:

$$\text{mid}(x,y,z) = y \quad \text{iff} \quad x < y < z$$

and is independent of input's possitioning, i.e. gate action will be correctly performed pying no regard to arragment of applied input voltages.

In the text to follow we will (slide)show how *mid* gate can perform *min* and *max* operations, as well (see Fig. 17,18 and 19.).

One must take charge of *control menu* (control switch M) to decide upon using *mid* or *min*(*max*) gates. Once, when you want to choose between *min* and *max* gate, you need to apply (control input C) zero voltage (information) for *min* gate (see Fig. 18.) and +5V (information) for *max* gate performing (see Fig. 19.), respectively.

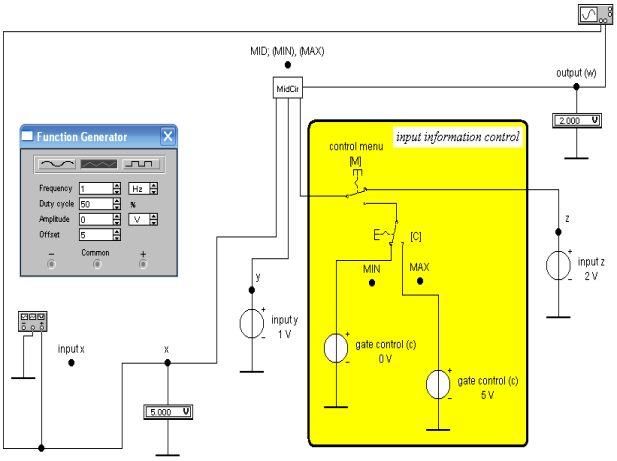

Fig. 17. The response of *mid* gate when control menu switch is set to applied input z;
mid(x,y,z) = *mid*(1,2,5) = *mid*(5,1,2) = *mid*(2,1,5) = ...2

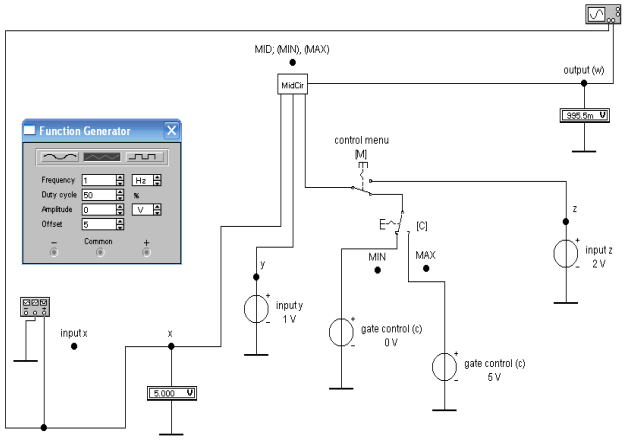

Fig. 18. $mid \xrightarrow{M-C_{\min}} \min(5,1) = 1$

When control menu M is set to input gate control switch C, one can select „0“ to establish *min* operation of *mid* gate.

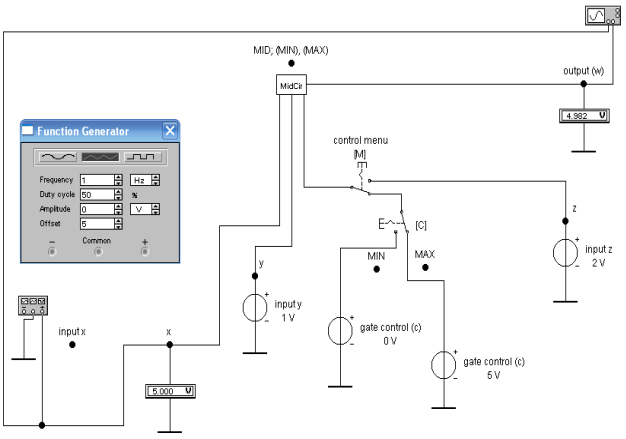

Fig. 19. $mid \xrightarrow{M-C_{MAX}} \max(5,1) = 5$

When gate control is set to +5V in C-menu, the *mid* gate will perform *max* function.(bivalent or fuzzy)

Performing *min* or *max* functions accordingly, means that the complex *mid* gate can be included in fuzzy gates family. Aditional promising features of *mid* gate will be the subject of the future work.

V. CONCLUSION

Different ways of fuzzy *min*, *max* and *mid* gates interchangeability have been investigated in this paper. We have started interchangeability experiments using complement gates in the manner that is known in digital electronics; complementing inputs and outputs (or both). Then we have designed voltage control over original min and max gates to achieve inherent interchangeability. At the end, an information control over inputs has been used to pick out among logic operations performed by original, so called, mid gates.

Finally, we can conclude that interchangeability in the domain of fuzzy gates can be done through:

- gate combinations
- control incorporated in dedicated hardware design
- controlled information applied to gate inputs

Additional promising features of mid gate, in the area of control, will be the subject of the future work.

ACKNOWLEDGMENT

The result presented in the paper obtained in the scientific research project No. 250-2502209-2364 and the international research project “ The possibilities of reducing pollutant emissions from ships in the Montenegrin and Croatian Adriatic implementing Anex of MARPOL convention” supported by the Ministry of Science Education and sport of the Republic of Croatia.

Solving mathematic problems in electronic environment, finding global and local minimum and maximum function values

Ivan Madunić, Darko Kovačević. Lovre Perković and Toma Karađole.
Falcuty of Maritime Studies, University of Split, Split, Croatia
dkovac@pfst.hr

Abstract - A dedicated hardware simulation tool is used to solve specific mathematical as well as electronic problem: finding global minimum and maximum function values (coordinates in Cartesian coordinate system). A new class of peak detectors based on fuzzy *min* and *max* gates has been proposed. Hardware methods, having pure mathematical background, in detecting x-coordinates of function extremes are explained, too.

I. INTRODUCTION

There are numerous applications in which it is necessary to determine the peak value of some input waveform.

The simplest, but very problematic, method is to use diode and condenser. The highest point of the input waveform charges up condenser, which holds that voltage value while diode is back-biased.

A better circuit, using *Op-Amp* and feedback from capacitor solves some simple peak detector problems but new ones are introduced; finite slew rate of *Op-Amp*, input bias current etc. [1].

The most of these problems can be solved by more complex circuits [1]. One of such circuits is shown (see figure 1).

In this paper we are going to introduce a new class of simple peak detectors that are based on *min-max-Op-Amp* technique [2]. These circuits will be used in a very special applications; finding extremes of different functions in a time domain or in a dedicated phase plain domain [3].

Obtained information about extremes can be used in different purposes (for example in a process control).

In the second section we will refer to the mathematical presentation of a function extremes very briefly, *min* and *max* detectors definitions will be presented in the third and fourth section.

Finding global maximum and global minimum of a function in an electronic environment (EWB - analog circuit domain) will be presented in the fifth section of this paper.

A "hard" problem for "math-community", i.e. finding maximum and minimum of discontinuous functions can be elegantly solved using *min* and *max* detectors as it is described in two last sections of this paper.

The concept of this paper is based on picture preferred presentation for the sake of clarity [2].

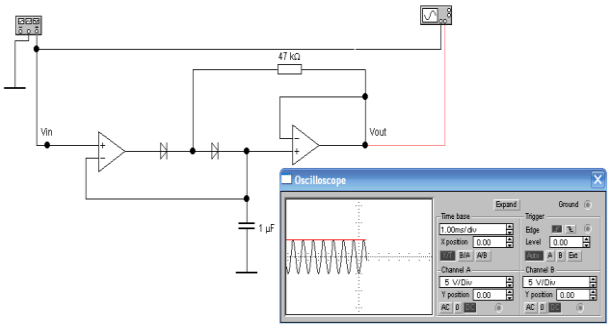

Figure 1. Improved peak detector

II. PROPERTIES OF CONTINUOUS FUNCTIONS; MINIMUM AND MAXIMUM

If f (v_{in}) is continuous in the interval $[V_a, V_b]$ then it has the following properties (among others properties not mentioned here):

- f (v_{in}) is a bounded function: there are numbers V_m and V_M such that $V_m < f(v_{in}) < V_M$ for all $v_{in} \in [V_a, V_b]$
- f (v_{in}) has a largest and a least value in the interval $[V_a, V_b]$.

-The least value of f(v_{in}) on $[V_a, V_b]$ is called the minimum off(v_{in}) on $[V_a, V_b]$, the largest value is the maximum off(v_{in}) on $[V_a, V_b]$ and the difference between the two is called the oscillation off(v_{in}) on $[V_a, V_b]$ as it is shown (see figure 2) [4].

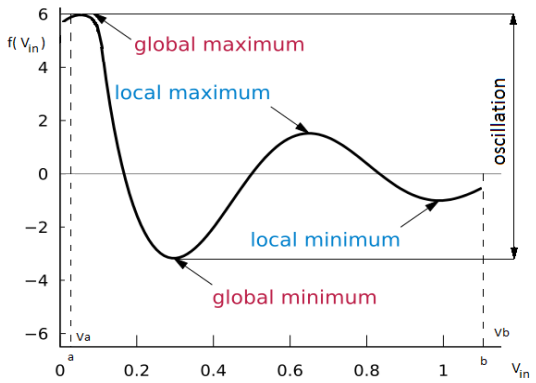

Figure 2. Oscillation of a function

III. MIN PEAK DETECTOR

A transistor *min* circuit along with a capacitor is used to design a peak detector (see figure. 3.) capable to detect a voltage minimum (V_{min}) of a function $y \equiv f(V_{in})$ (1) :

$$y_{min} \equiv V_{min} = V_{out_{min}} = \min(V_{in}, V_{out}) \qquad (1)$$

A buffer is used for the sake of isolation. Note that antoher max circuit can be used for isolation, too.

IV. MAX PEAK DETECTOR

A transistor max circuit having a feedback from a capacitor is used to design a peak detector (see Figure. 4.) capable to detect a voltage maximum (V_{MAX}) of a function $y \equiv f(V_{in})$ (2):

$$y_{MAX} \equiv V_{MAX} = V_{out_{MAX}} = \max(V_{in}, V_{out}) \qquad (2)$$

Again, an *Op-Amp* is used for the sake of isolation. An option is to use high input differential amplifier to compensate peak error [5].

V. FINDING GLOBAL MAXIMUM AND GLOBAL MINIMUM ELECTRONICALLY

A. *Example No.1.*

In this section we are going to show how(global) maximum and (global) minimum of a certain function can be found using *min* and *max* detectors respectively
Plot the graph of the function

$$f(x) = \frac{2x}{1+x^2} \text{ for } x \in \Re .$$

and show that $f(x)$ is continuous on its whole domain. Find its maximum and minimum values and show that it attains every value between these extremes.
Find the difference (oscillation) between maximum and minimum. Use EWB or similar simulation programme to achieve these tasks.

B. *Graph*

The electronic graph of the function is shown (see figure 5). and enlarged in figure 6. From those figures we can see that the shown part of the function is a continuous curve, indeed. The graph is displayed in the phase space (oscillograph) for the function that is designed gradually (see figure 5).

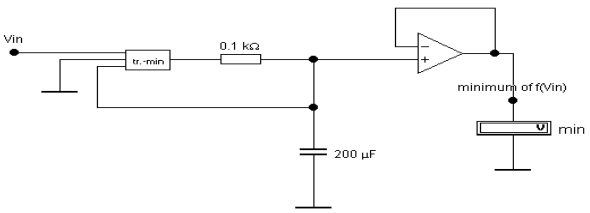

Fig. 3. Simple *min* peak detector with *Op-Amp* follower.

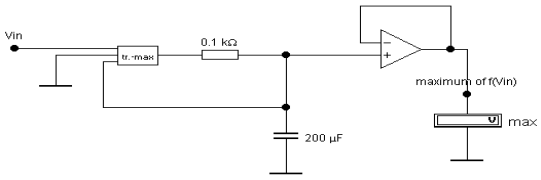

Figure. 4. Simple max peak detector with Op-Amp follower

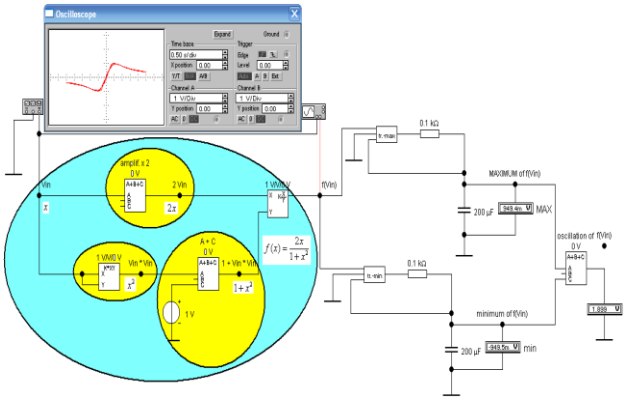

Figure. 5. Voltmeters are showing minimum and MAXIMUM values of the function

C. *Continuity*

One can use one of oscilloscope pointer lines (see Figure 6.) and move it from left-hand end to right-hand end without noting any disruption along the shown length of the curve (function). In mathematics we can prove this more formally as follows. Select any point x_0 of the domain of the function. Then we have to show that the term $|f(x) - f(x_0)|$ can be made as small as we please by taking x_0 sufficiently close to x. The term (3):

$$\frac{2x}{1+x^2} - \frac{2x_0}{1+x_0^2} = \frac{2(1-xx_0)(x-x_0)}{(1+x^2)(1+x_0^2)} \to 0 \qquad (3)$$

converges to zero as $x \to x_0$

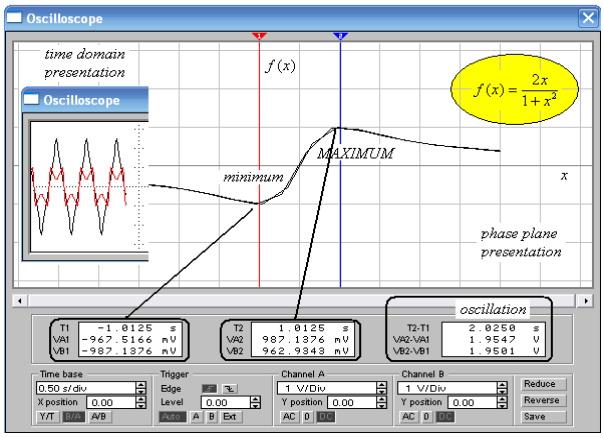

Figure 6. Oscillograph of the function and measurements extremes and oscillation on the function $f(x) = \frac{2x}{1+x^2}$

In an electronic environment an oscilloscope having two moveable pointer lines can be used to simulate described mathematical continuity model (3) as it is illustrated (see figure 7).

D. *Maximum and minimum:*

The proof that the function takes every value between its least and largest values actually determines those values in this simple example.
Let us find values of *x* that corresponds to the given *y* in the range of $f(x)$.

From the term $y = \frac{2x}{1+x^2}$ we can easily come to the term $yx^2 - 2x + y = 0$. This gives two values for x for each $y \in (-1, 1)$ (terms (4) and (5)):

$$x_1 = \frac{1-\sqrt{1-y^2}}{y}, \quad y \neq 0 \qquad (4)$$

and

$$x_2 = \frac{1+\sqrt{1-y^2}}{y}, \quad y \neq 0 \qquad (5)$$

The maximum and minimum values for *y* are -1 and 1 respectively, and corresponding values for *x* are -1 and 1. In electronic environment getting corresponding values of *x* is a little bit tricky.
First, the electronic model of the relation $yx^2 - 2x + y = 0$ must be realized as it is shown (see figure 8. and figure 9.). Then one must vary Y_{MAX} input to get corresponding *x* coordinates of the function extremes.

E. *Example No.2.*

Design a complete electronic model (*an extreme detector*) for the function $f(x) = \max(0; -(x-1)^2 + 3)$ to get its extreme (take x and y coordinates) in a compact circuit. The function f(x) is a shifted inverted parabola limited to positive values f(x)>=0 using the max circuit (see figure 11.). *Max peak detector* is used to get Y_{MAX} and the corresponding model for finding X_{MAX} completes the required electronic model.

Figure 11. illustrates every step in the model design. Note that a standard squarer is used to obtain square-rooter circuit (see figure. 10.).

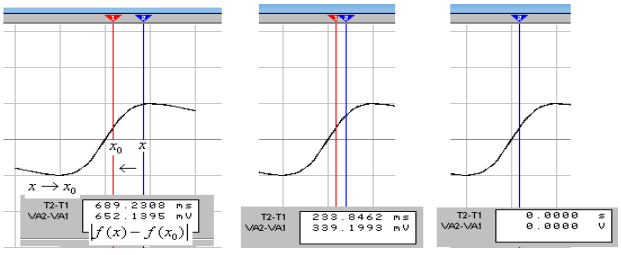

Figure. 7. Tracking continuity by an oscilloscope;

$$f(x) \to f(x_0) \text{ as } x \to x_0$$

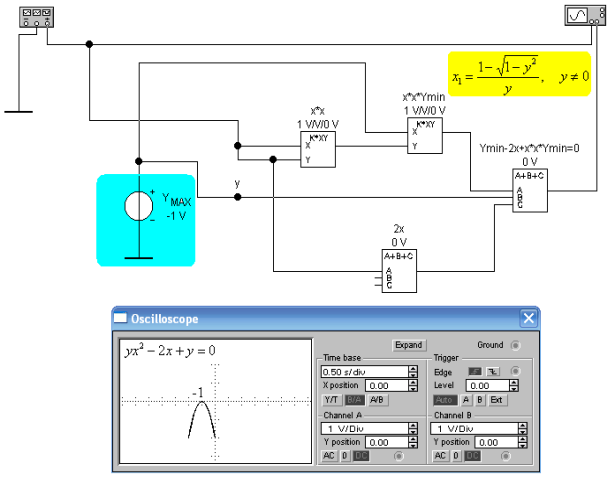

Figure. 8. Electronic solution (x-coordinate detector) for

$$x_{min} = \frac{1-\sqrt{1-y^2}}{y}, \quad y \neq 0$$

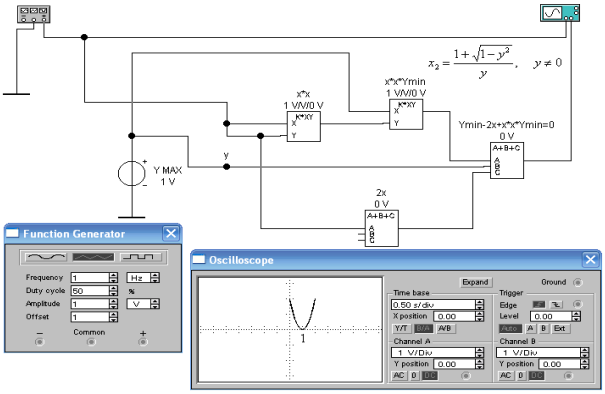

Figure. 9. Electronic solution (x-coordinate detector) for

$$x_{max} = \frac{1+\sqrt{1-y^2}}{y}, \quad y \neq 0$$

The output of the square root circuit can be defined as (see figure 10.):

$$y = A(x - y^2)$$

$$\frac{y}{A} = x - y^2$$

$$y^2 = x - \frac{y}{A}$$

For $A \to +\infty$ the output is $y^2 = x$ and finally

$$y \neq \sqrt{x}$$

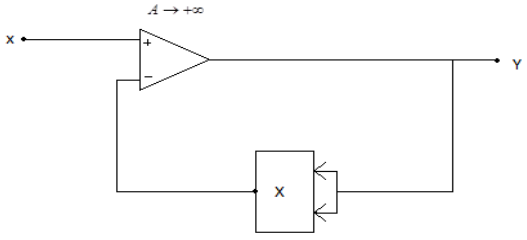

Figure 10. Model of square root as an inverse function

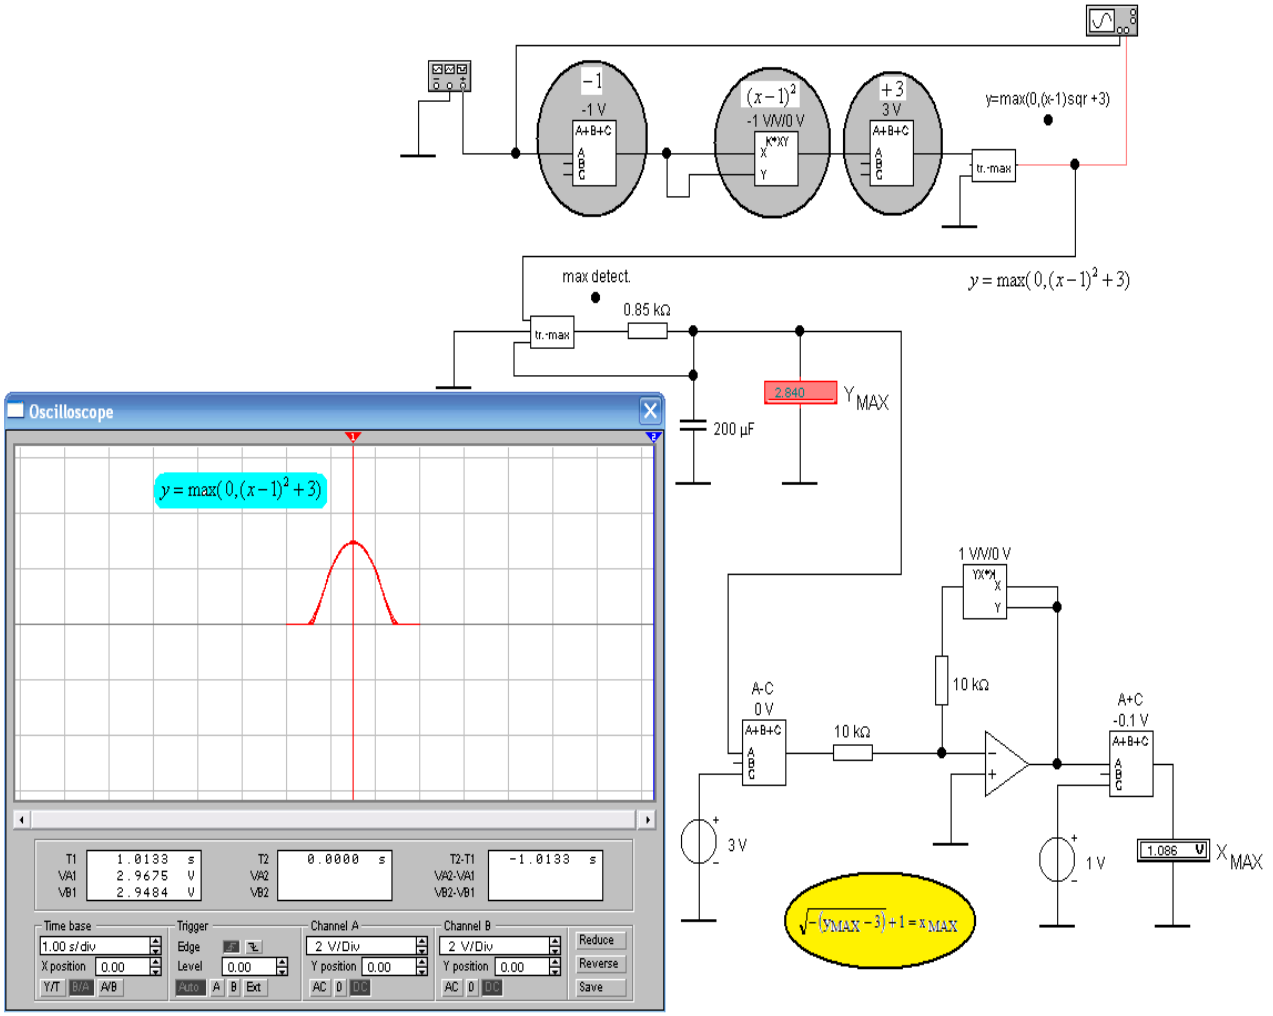

Figure 11. Electronic solution for the function $y = \max(0;-(x-1)^2+3)$ and the function extreme (*x*,*y* coordinates):

$$y_{MAX} \equiv V_{out_{MAX}} = \max(V_{in}, V_{out}),\ V'_{out} = \sqrt{-(y_{MAX}-3)}+1 = x_{MAX}$$

VI. FINDING MAXIMUM OF DISCONTINUOUS FUNCTION

When locating minimum and maximum of discontinuous functions mathematicians sometimes do some tricks, if possible [4]. For an electronic engineer finding the maximum of the function (6)

$$f(x) = \min((x)^2, (x-2)^2) \text{ for } x \equiv u_{in} \in [0,2] \quad (6)$$

is not „a big deal“ (see figure 12.). Input variable x corresponds to input voltage u_{in}. The function *f(x)* in electrical environment can be expressed as $u_{out} = \min((u'_{in})^2, (u'_{in}-2)^2)$ and the function domain $x \in [0,2]$ can be realized as $u'_{in} = \min(U_b, \max(0, u_{in}))$ where $U_b = 2$ V. Then a *min* detector is used to find out the extreme of the function (see figure 13.).

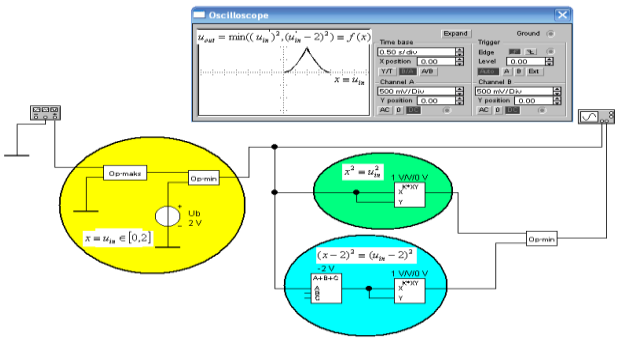

Figure. 12. Electronic realisation of the function $f(x) = \min((x)^2,(x-2)^2)$ for $x \equiv u_{in} \in [0,2]$

Realisation of the circuit (function) begins with so called *interval generator* $u'_{in} = \min(2; \max(u_{in}, 0))$, and then two common multipliers are used to generate the parabola u^2_{in} and the shifted parabola $(u_{in}-2)^2$.

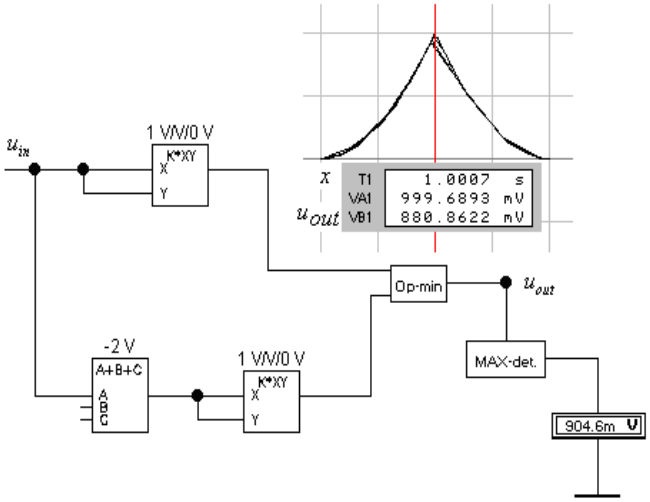

Figure 13. Electronic maximum of the function

$$f(x) \equiv u_{out} = \min((u_{in}')^2, (u_{in}' - 2)^2)$$

for $u_{in}' = \min(2, \max(0, u_{in}))$

un buffered max detector is used to "find out" the extreme of the function having discontinuity at $u_{in}' = 1$.

VII. FUZZY HEIGHT

Height of a fuzzy set

The height (hgt) of a fuzzy set is the maximum value of its membership function. Specifically, for a fuzzy set *A* in a universe *X*, with membership function μ, the height is given by term (7):

$$\mathrm{hgt}(A) = \sup_{x \in X} \mu_A(x) \qquad (7)$$

In a electronic hardware environment (see figure 14. and figure 15.) height of a fuzzy set can be interpreted as (8):

$$\mathrm{hgt}(A) = \max(f(V_{in})) \qquad (8)$$

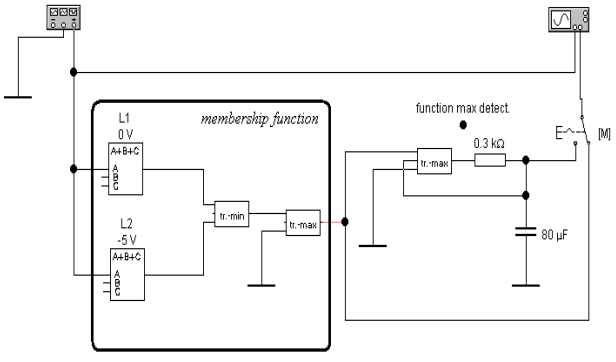

Figure 14. Fuzzy membership function *hgt peak detector. For detector output isolation and their max gate can be used efficiently used.*

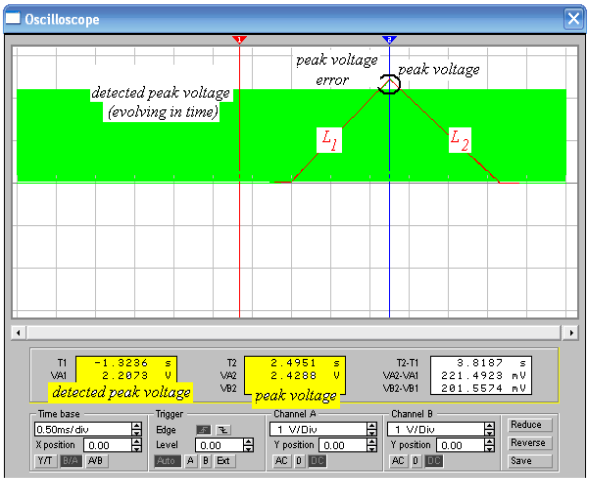

Figure 15. For the membership function $\mu_A(x) = \mathrm{maks}(0, \min(L_1, L_2))$ max peak detector error using EWB is about 8%. When using Multisim ver.13 the error is about 1 %

The height may be termed the modal grade of the fuzzy set, and the corresponding element value (i.e., the value of *x* where the membership grade peaks) may be termed the modal element value, or simply modal point [5].

VIII. CONCLUSION

A simple, new class of hardware peak detectors based on *min-max (Op-Amp)* technique is introduced and some applications in mathematical environment were briefly explained. Virtual electronic work-bench was used to find extremes of some functions, even in situations where classic mathematical methods failed. These circuits can have a additional (extended) characteristic; they are able to compare peak values with a pre-set voltage levels. Future work related to both kind of *min-max Op-Amp* peak detectors must go in to directions:

- hardware improvement of detectors
- finding the way to process (detect) local minimum and maximum

Abstract - Functional electrical stimulation (FES) of the common peroneal nerve (CPN), to correct gait, has been shown to be a useful means for the restoration of functional movement in the lower extremities of hemiplegic individuals. Motor function over a twenty-nine year period of selective stimulation of the CPN with an implantable stimulator to correct drop-foot in a 56 year old patient with left-sided hemiplegia, was evaluated. Partial restoration of dorsal flexion and well balanced eversion of the affected foot was achieved by selective stimulation of superficial region of the CPN innervating mostly the tibialis anterior and partly peroneus longus and peroneus brevis muscles. It was shown that the system is suitable for very long-term FES providing improved muscle function. Namely, even after 29 years of daily FES of the CPN, a functional and reliable recruitment of fibres within the CPN was still achieved, thus providing an appropriate dorsal flexion and eversion of the affected foot. It was found that the stimulation-associated-mechanical trauma to the CPN elicited some minor non-age-related loss of the larger myelinated nerve fibres. Electrophysiological and biomechanical measurements however, have not revealed any functional signs which could be attributed to the damage of the CPN.

I. Introduction

Functional neuromuscular stimulation (FNS) of the common peroneal nerve (CPN) to correct gait has been shown to be a useful means for the restoration of functional movement in hemiplegia [1, 2, 3]. FNS is applied during the swing phase of the affected leg dorsiflexing the foot so that patients walk faster and more steadily [1, 2, 3].

Raising the affected foot, the patient releases the heel switch that turns the external unit on, thus transmitting the radio-frequency signal via the antenna to the implant and the nerve. At the beginning of the stance phase, FNS is turned off by closing the heel switch [1, 2, 3, 4, 5]. In FNS of a CPN, the recruitment of slow motor units was desired to optimize postural holding and function against gravitational forces [6, 7].

The present study was aimed at demonstrating the results on functionality of the implant implanted in a hemiplegic patient and comparing these results with those obtained with the implant implanted ten years before. The main goal, however, was to preserve an appropriate dorsal flexion and eversion of the affected foot with selective FNS of the particular superficial region of the CPN innervating mostly the tibialis anterior (TA) and partly peroneus longus (PL) and peroneus brevis (PB) muscles.

II. Materials and Methods

It was demonstrated in peripheral nerves that electrodes placed proximal to the branching point provide the ability to activate selectively an individual muscle [8, 9]. The CPN lies between the tendon of the biceps femoris and lateral head of the gastrocnemius muscle, winds around the neck of the fibula, between the PL and the bone, and divides beneath the muscle into the superficial peroneal nerve, deep peroneal nerve and recurrent tibial nerve. They arise just distal to the head of the fibula, and are directed forwards, diverging in their course, beneath the PL muscle.

It was presumed that at the level above bifurcation of the CPN, fibres belonging to TA muscle lie mostly within the particular region of the deep peroneal nerve and fibres belonging to PB and PL lie mostly within the particular region of the superficial peroneal nerve [9]. In order to achieve strong dorsal flexion and moderate eversion of the foot, three muscles TA, PB and PL (Fig. 1a), must be activated via selective stimulation of a superficial region of the CPN (Fig. 1b), comprising both aforementioned particular regions.

Informed consent was obtained from a 56-year-old patient with left-sided spastic hemiparesis, who recovered from an ischemic stroke occurred in January 1983. The first generation implantable stimulator (not shown in this paper) was implanted in 1984. However, wire console shaped loop anode broke out after ten years of daily use.

In the year 1995 the implant was replaced with the second generation monopolar one (Fig. 1c). The figure shows the monopolar half-cuff and the bulk body of the implant (dimensions of 22X22 mm). A platinum common electrode (geometric surface ~100 mm^2) was integrated on one side of the body. The leads exited the body on one of four sides through the feed-through. The half-cuff with a platinum electrode (Fig. 1c) was constructed considering both, the aforementioned requirements and the results of modelling monopolar selective FNS of superficial regions and fibres with different diameters in the CPN [3, 10, 11, 12].

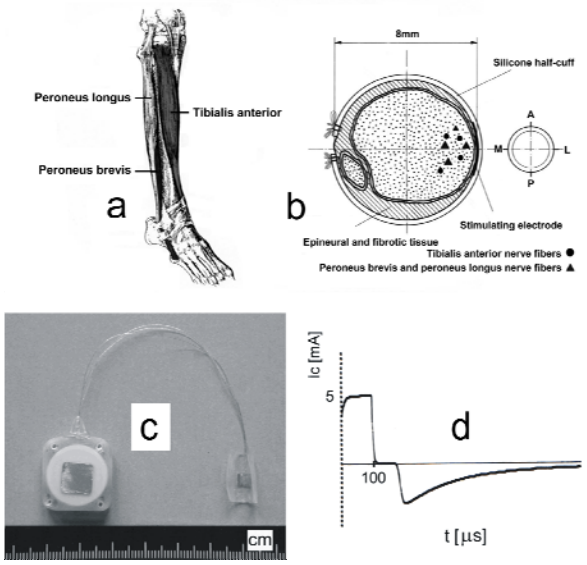

Fig. 1 (a) Muscles to be stimulated, (b) Fixation of half-cuff on the CPN, (c) Implantable stimulator, (d) Stimulating pulse.

The stimulus (Fig. 1d) was a current biphasic pair with rectangular cathodic component i_c which could be preset within the external unit between 1 and 10 mA and exponential decaying anodic component i_a. The width of the cathodic component t_c could be set by the patient from 0 to 500 µs, while the frequency f and the time delay t_d between the cathodic and the anodic part of the stimulus was preset at 22 Hz and at 50 µs, respectively [13].

This implant provided satisfactorily functional results for next ten years. However, due to forces generated by muscle activities and forces imposed from outside of the body the lead wires of the stimulating electrode broke. Consequently, the implant was replaced with the same monopolar one in March of 2008.

In local anaesthesia the CPN behind the lateral head of the fibula was exposed. To activate mainly the TA, PL, and PB, the stimuli had to be delivered to the cathode situated above the specific site on the CPN. To find this site, the half-cuff was moved above different sites until position eliciting optimum movement of the foot was detected [2]. Afterwards, the site was tested using different values of i_c and t_c while the f and the t_d remained preset at 20 Hz and 50 µs, respectively. Finally, the half-cuff was fixated at four corners as shown in Fig. 2a and 2b.

The external unit (Fig. 3) consists of: (a) transmitter that generates RF signals, (b) antenna that transmits RF signals through the skin to the implant and (c) heel switch which triggers the transmitter synchronously with the swing phase.

FNS started 14 days after surgery while gait analyses were performed 6 months after surgery. In the gait kinetics measurement performed in the year 2000, movements of the left leg segments were tracked with a 6-camera Vicon Motion System (model; Vicon 370 Datastation). For recording surface electromyograms (EMG) of 10 muscles a Noraxon (Myosystem 1200, Finland) was connected to the 64-channel analog data input.

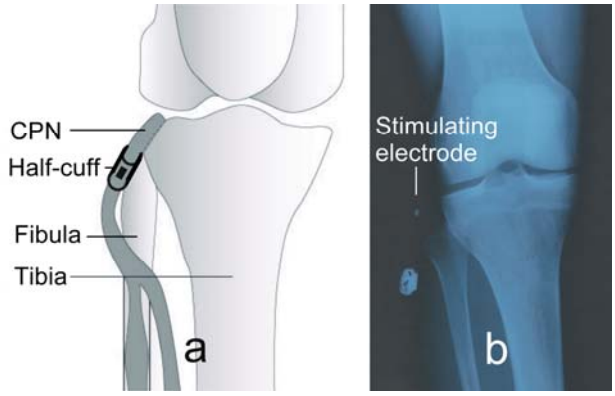

Fig. 2 (a) Site of half-cuff fixation, (b) X-Ray picture of the implant.

An off-line analyses were performed by a PC running the Vicon Polygon software.

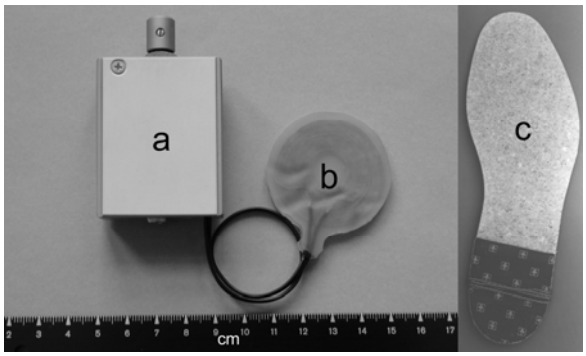

Fig. 3 (a) External transmitting unit, (b) Transmitter antenna and (c) Synchronizing heel switch.

In the year 2009 however, the measurements and analyses were performed using a 6-camera Vicon motion analysis system (model Vicon MX; Oxford Metrics Ltd, Oxford, United Kingdom) collecting ground reaction force data at 100 Hz. Illumination, video data collection, and analog-to-digital conversion of transducer input (force plate and EMG data) were synchronized and controlled by the Vicon MX, which was interfaced and controlled by a Pentium-based PC running the MS Windows operating system. For recording surface electromyograms (SEMG) of 12 muscles a Noraxon (Telemyo 2400T, Finland) was connected to the 64-channel analog data input. EMG signals were collected at 1080 Hz and were synchronized with the Vicon system for simultaneous collection. The off-line analyses were performed using the Vicon Polygon and Vicon Nexus software.

In both trials the patient landed on the two force platforms (model OR 6-7; Advanced Medical Technology, Inc, Watertown, MA, USA), which were used to collect ground reaction force data were collected at 1080 Hz and synchronized with the Vicon system.

Standard analyses included basic statistical analysis of a set of temporal and spatial parameters of gait, calculation and averaging of three dimensional

goniograms in the hip, knee, and ankle, rectifying and averaging of EMG signals, and finally calculation and averaging kinetic variables (forces, torques, powers) in the main joints of lower extremities. Two separate sessions of trials were performed with each measurement: one without stimulation and one with stimulation. All other conditions remained unchanged. The measured data were analysed using the method of Grieve [14] and compared to the normative data taken from Winter [15] if available, if not, the data from our own data base was used.

III. Results and Discussion

The results showed that after fifteen years the speed of stimulated gait significantly increased. After twenty-five years, however, the difference in the speed of stimulated and even non-stimulated gait increased even more.

It was observed that EMG activity of the left muscle triceps surae (TS) was weak during the swing phase while a slight increase in EMG activity during the weight acceptance phase was observed. Within the remaining part of the gait cycle a constant lowered tonic activity was present. This pattern was described as a typical sign of spasticity of the TS. Furthermore, ankle goniograms and length of the muscle soleus (SOL) and muscle gastrocnemius (GAST) demonstrate contractures in TS. Besides missing push off, one consequence of impairment in GAST was also weak knee flexion, especially at the beginning of the swing phase. Consequently, a patient has performed the swing phase with explicit circumduction, which was also confirmed by significantly increased external pelvic rotation during the left swing phase. The patient compensated for his inability to perform the left swing phase by generating additional power in the knee and hip, and with the right side. As additional compensation, the missing left push off also caused a shortening of the right step. It could be concluded from EMG of the left TA that this muscle was actually not affected and the pattern seemed to be almost normal. In the ankle goniogram recorded in the last measurement, a significant move towards dorsal flexion (~10°) could be observed while the shape of the first one was almost identical. Perhaps this difference could be attributed to different footwear used in the two 10-year separated measurements. Slightly increased EMG activity and the rather stable shape in all muscular groups in the second measurement could perhaps be attributed to a higher walking speed.

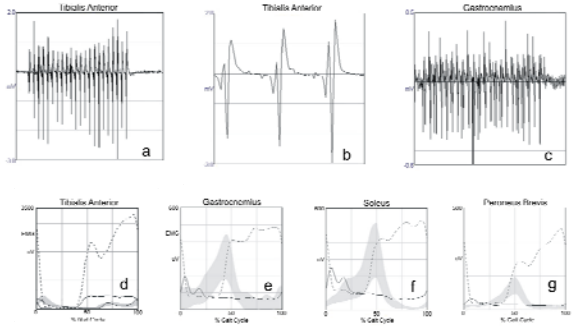

Fig. 4 (Upper) SEMG in the TA, plot (a), and plot (b), and GAST, plot (c). Plots (a) and (c) show entire FNS time interval while plot (b) shows a shape of activation in motor units, elicited by an individual stimulating pulse (M-wave). (Lower) Rectified and averaged SEMG in muscles TA, GAST, SOL and PB during FNS. Solid lines - measurement without FNS, dashed lines - measurement with FNS and grey thick line - normative data.

It could be seen in Fig. 4 (lower part), representing EMG recorded in TA, PB, SOL and GAST, that all these muscles were stimulated. Perhaps, some other muscles like, for instance, TS innervated by fibres of the CPN whose stimulation was not considered in the model, were also stimulated. Accordingly, a rectified EMG activity in the TA, PB, and TS (Fig. 4, lower) had the following maximum values: 3 mV, 1 mV and 0.5 mV, respectively. It was observed that without stimulation there was no normal EMG activity of the flexor TA while EMG activity of the PL could be considered as normal. However, with selective stimulation of the CPN both EMG activity of the TA and PL could be observed.

Plots (a), (b) and (c) in Fig. 5 clearly demonstrate the effectiveness of stimulation by showing a position of center of pressure (COP) along the sole (X direction) (COPX) and, especially plot (d) by showing the ankle goniogram. Furthermore, correction of ankle inversion, which should be elicited by stimulation of the PL and PB, was favorable in the measurement performed in the year 2000 as shown in Fig. 5.

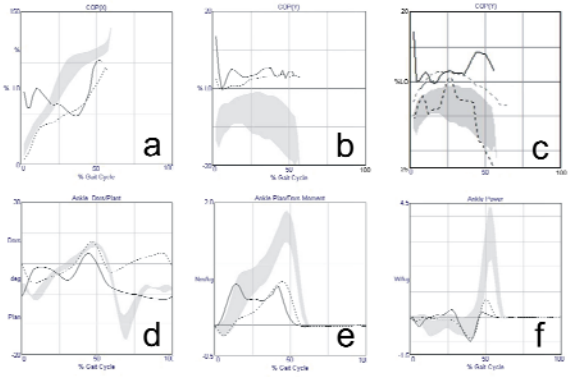

Fig. 5 (Upper) A trajectory of COP along the sole. Plot (a) and plot (b) measured at 2009, plot (c) measured at 2000. (Lower) An influence of FNS on increase in dorsal flexion plot (d), on torque in the ankle plot (e) and, on push off power plot (f). Solid lines-measurement without FNS, dashed lines-measurement with FNS and grey thick line-normative.

Dorsal flexion in the swing phase was significantly larger, thus enabling heel contact. Moreover, a co-activation of TS, elicited by unexpected stimulation, actually stabilized the ankle at heel contact and additionally contributed to heel contact becoming more steady. FNS significantly improved the shape of the ankle torque plot in the sagittal plane. However, as a consequence of severely affected TS, amplitude in the mid stance was heavily decreased. In fact, during this interval, TS was only able to produce passive tonic activity. Immediately after heel lift off, stimulation was turned on, thus causing activity to appear in these muscles and, consequently, contributing to the push off. This could be seen in plot (e) of Fig. 5, showing the torque in the ankle.

Results also revealed that left support lasted longer. Furthermore, more steadily heel contact decreased compensational pelvic movement and thus stabilized flexion/extension within the hip.

IV. CONLUSION

In comparison to similar systems developed elsewhere [2], the presented system requires a relatively simple procedure of implantation and is suitable for a wide population of patients.

Electrophysiological measurement results obtained using the method of needle electromyography showed a minimum sign of functional damage induced by the cuff or by the stimuli to the CPN. Namely, within the twenty-nine year period of FNS a slightly reduction (about 5 m/s) of conduction velocity of the CPN and weak pathological spontaneous activity, in the TA and in the PL was observed [6]. A value of the conduction velocity measured in 1993 was 55 m/s, seven years later, in 2000 was 52 m/s and nine years later in 2009 was 50 m/s.

It was also observed that cuff implantation resulted in thickened epineurium and endoneural connective tissue. A connective tissue growth, in greater extent in the CPN segment located closer to the implantation site. On the other hand, vascularization was appeared almost normal.

In this particular case, an obvious cause of damage to the CPN could include the use of a tight elastic band over the implanted region. Examination of the legs however, did not show a more severe loss of muscle control over the legs and feet and muscles atrophy.

ACKNOWLEDGMENT

A method for time-domain analysis of respiratory sinus arrhythmia

R. Trobec and V. Avbelj
Department of Communication Systems, Jožef Stefan Institute, Ljubljana, Slovenia
{roman.trobec; viktor.avbelj}@ijs.si

Abstract - Respiration-related heart rate variability – respiratory sinus arrhythmia (RSA) – is clearly related to vagal activity. Usually it is analysed in frequency domain. An improved method for the assessment of the RSA in time-domain is proposed and evaluated on a control group of 12 healthy volunteers (9 male, 3 female; age 31-70). The method is based on a measurement of respiration rate, combined with a reliable beat-to-beat heart rate determination. RR intervals of each respiration cycle are superimposed to obtain average RSA. The study of RSA in the time-domain can provide more information about the adaptation process and possible parasympathetic response of the heart, e.g. after heart surgery, because the shape of a typical RSA curve and its phase (relative to the measured breathing) are obtained. The time domain analysis of RSA is simple and does not need forced timing of respiration. We confirmed that the proposed methodology could be used in ambulatory and remote monitoring environments to follow the long-term changes in the RSA.

I. INTRODUCTION

Respiratory sinus arrhythmia (RSA) is a respiratory-related heart rate variability (HRV) observed universally in vertebrates [1]. The largest part of this variability is mediated through the vagus, so RSA has been used as an index of cardiac vagal control [2, 3]. It was reported [4] that different methods of heart surgery could influence the heart rate variability [5, 6]. With transplantation, the donor heart is completely disconnected from the central nervous system, but a small level of RSA still remains. This residual RSA is of non-neural origin and can be related to perfusion pressure [7] and to mechanical stretch of the donor sinus node in the atrium wall caused by changes in venous return [8]. Small values of RSA can arise from imperfections in measurement due to slight time variations of the fiducial point in the QRS complex caused by changes in the cardiac electrical axis during breathing [9, 10].

The study of RSA after heart transplantation can provide a unique model to assess the process of adaptation and possible re-innervation of this complex transplanted organ [11]. Most studies have used the frequency domain approach, together with programmed breathing, periodic neck suction and other manoeuvres [12, 13, 14]. Only rarely has the time-domain approach been used [15, 16].

The standard techniques for assessment of the parasympathetic re-innervation such as scintigraphy, positron emission tomography, or baroreflex stimulation, are rather complex or can influence the conscious of patients biasing the results. This study was designed to characterize RSA in cardiac transplanted recipients while allowing spontaneous breathing. We hypothesise that the phase between the spontaneous breathing signal and the measured RSA could be an indicator of the vagal re-innervation. The shape of the RSA near the maximal intratoracial pressure can give further information about the HRV control loop. The method for assessing RSA was first developed for an unpublished preliminary investigation of sympathetic re-innervation of transplanted hearts in our previous study [4]. We have further refined the method to become a more sensitive tool for investigating RSA. We confirmed that the proposed methodology could be used in ambulatory and remote monitoring environments [17, 18] to follow the long-term changes in the RSA.

II. METHODS

The study [4] was approved by the National Medical Ethics Committee of the Republic of Slovenia. Written informed consent was obtained from all the subjects before the study. A control group of 12 healthy volunteers (9 male, 3 female; age 31-70) was enrolled. None of the control subjects was receiving any medication or had a history of cardiovascular disease. 15 patients (age 30-71) 0.5-8.1 years after heart transplantation were also included in the study for an ongoing detailed analysis, not published yet.

The surface electrocardiogram, using bipolar lead CM5, was recorded with high sample rate of 1800 Hz and resolution of 2 μV (DEKG recording device, Intekom, Slovenia). For each subject, an 8.5-minute ECG recording was obtained in the supine position after 5 minutes rest. Breathing was recorded simultaneously (16-times lower sample rate) with a small mass temperature sensor placed in front of the nose (thermistor 10K3MCD1, Betatherm, Ireland).

The recordings were analyzed offline with a custom-made computer program. The moments of the maximal amplitude of the R-waves (R) in the ECG were determined by an automated computer-based peak detection algorithm [19]. The time intervals between neighbouring R peaks (RRI), together with the absolute times of the R peaks, were used in further analysis. The fiducial point in the respiration cycle (E) was defined as the maximal rate of change in the exhaled air temperature. The intervals between consecutive exhalations are denoted by EEI. The E event was determined again by an

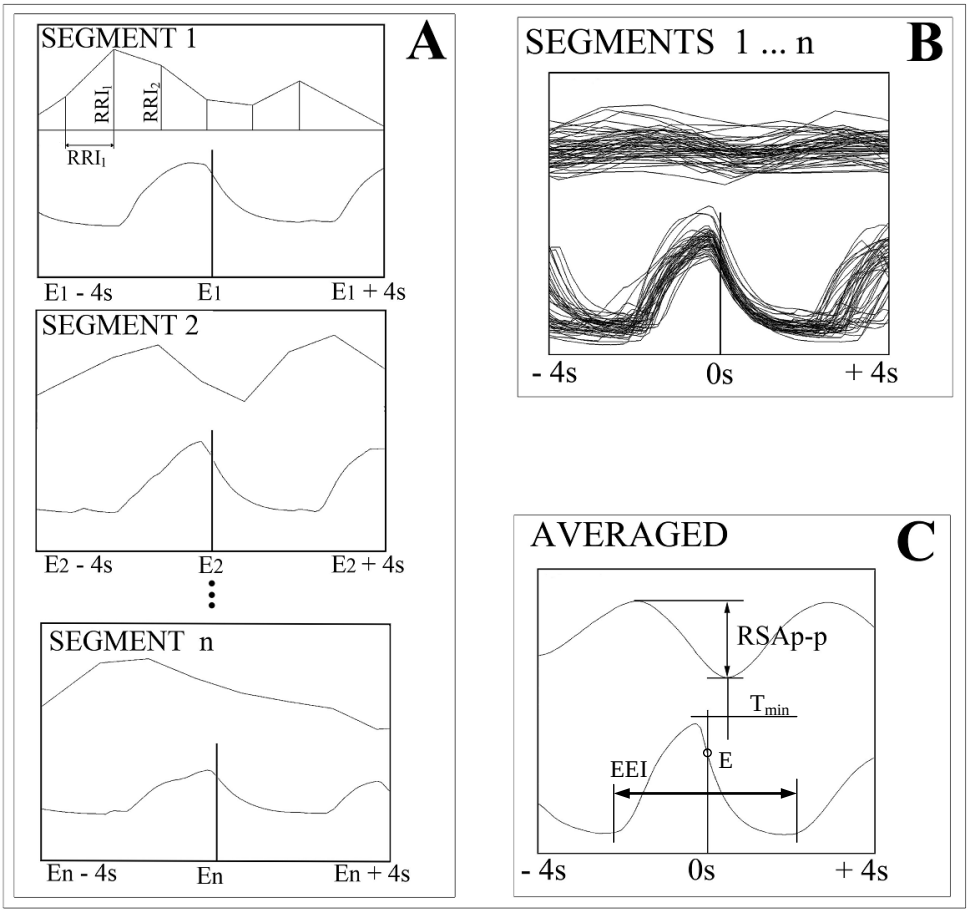

Figure 1. The method for RSA shape extraction. (A) The time (R_i) at the peak point of R-wave was determined for all R-waves in the ECG recording. HRV was presented as a series of R events at R-wave peak times with amplitudes $RRI_i = R_i-R_{i-1}$. All RRI points were connected by lines and re-sampled at 100 Hz. The E events were obtained from the respiration recording, calculating maximal negative slope in the respiration signal. (B) 8-second segments of HRV and respiration signal with E events placed in the middle were superimposed and (C) averaged, giving the RSA pattern and respiration curve. RSAp-p is the peak-to-peak RR-interval deviation during respiration cycle, EEI is average respiration time, and T_{min} is interval between E and the nearest minimum in RSA.

automated computer-based detector; nevertheless, a final visual inspection was applied to ensure correct time determination of the R and E events. HRV patterns of 8 seconds segments (± 4 s around E) were superimposed and averaged with each respiration cycle. The main reason for the HRV is the respiration and therefore we termed the heart variability as RSA. The time difference between the fiducial point E in the respiration cycle and the nearest minimum in the RSA is denoted by T_{min}. The time-domain analysis of RSA and respiration was performed on the resulting two averaged signals. The method for RSA shape extraction is shown in Figure 1 for a person from the control group.

III. RESULTS

Typical results of the described method, obtained from a healthy subject, are given in Figure 2. On the left plot (a), aligned HRV segments in the range of ± 4 seconds around E event, which are supposed to happen at time 0 s, are shown with green curves. Average RSA segments over 2 minutes windows are shown with colour curves. We can conclude that just small time invariance is present in the 8.5 minutes recording because all averaged signals are quite similar. The RSA is coherent with the respiration with RSAp-p = 60 ms. Aligned respiration signals are shown in the same way on the central panel (b). The sinusoidal RSA signal shape follows from logical deduction that RRI increases if the inner thorax pressure decreases and vice versa. Note that RRI is increasing soon after the maximum intensity of exhalation (E event).

On the right panel (c) the coherence and the phase between the RSA and the respiration signal are given for comparison with the frequency-domain analysis. As expected, there is a significant coherence in the respiration frequency band with a stable phase of $\varphi = -110^{\circ}$, which is in relation with the delay between the maximal values of RSA and E events in the respiration signals. However, no further information about the RSA shape is obtained from the frequency-domain analysis.

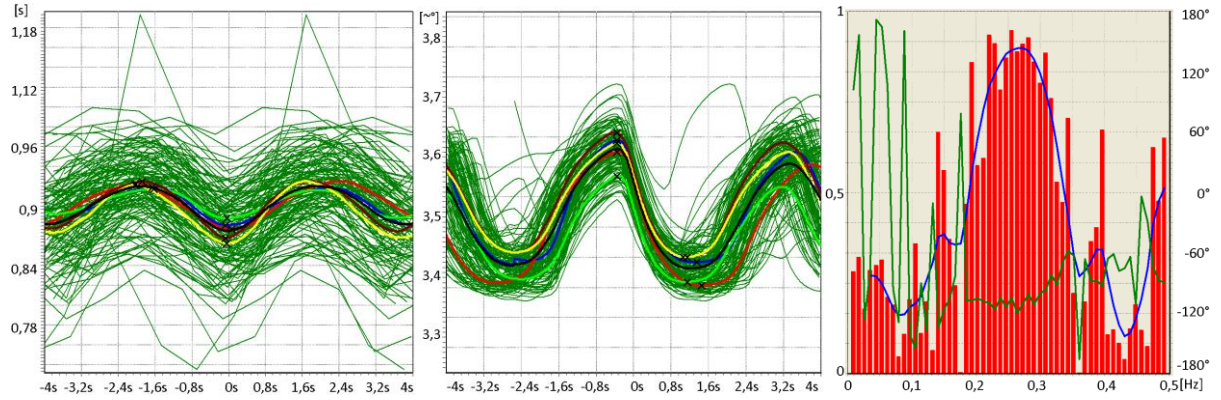
Measurements of the control group are quite uniform and all similar to the representative case shown in Figure 2, which is confirmed by the statistical data in Table 1. RSA signals increase after a fixed delay T_{min} from the fiducial point of the maximum intensity in the exhalation cycles (E event), indicating decreased heart rates as a consequence of increased intrathoracic pressures around E event. The phases of both series possibly reflect the cause-effect relation between exhalation and decreased heart rate.

TABLE I. STATISTICAL VALUES OF HEART BEATS, RESPIRATION, RSA AND T_{MIN} FOR THE CONTROL GROUP.

	Controls (n=12)
RRI [ms]	822 ± 134
EEI [s]	3.97 ± 0.59
RSAp-p [ms]	23 ± 15
T_{min} [s]	0.19 ± 0.17

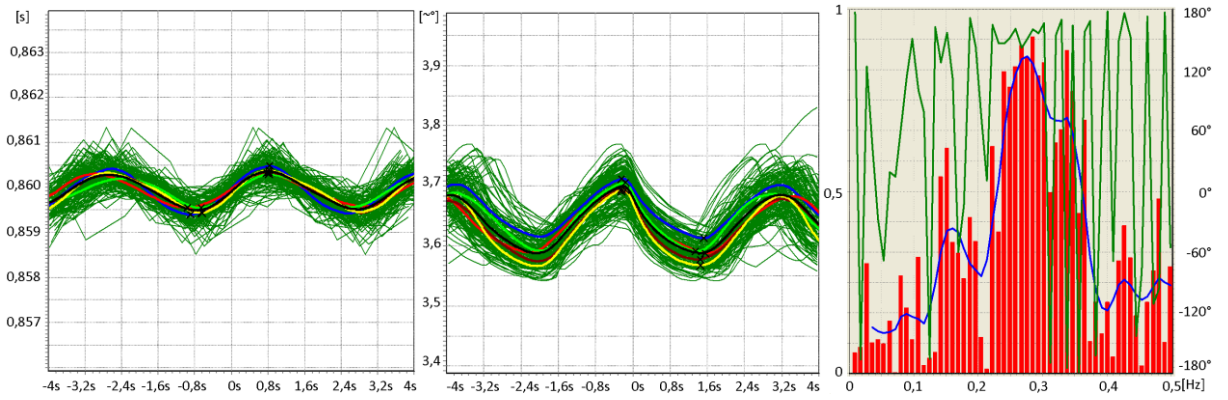
between HRV and respiration peak, and it seems that this value is also unreliable.

Preliminary results from measured RSA and respiration curves from the remaining patients are quite divergent in amplitudes and shapes and therefore more in-depth analysis are needed. However, they are evidently statistically different from the control subjects.



(a) (b) (c)

Figure 2. (a) Aligned HRV segments (green), around E event at time 0 s, for a typical control subject. Average RSA from 2 minutes windows are shown with different colours. (b) Same as in (a) but for the respiration signal from thermistor. (c) Coherence between RSA and the respiration signal with corresponding phase.



(a) (b) (c)

Figure 3. (a) Aligned HRV segments (green), around E event at time 0 s, for a patient with an active pacemaker. Note that the y-scale is smaller as in Figure 2. Average RSA from 2 minutes windows are shown with different colours. (b) Same as in (a) but for the respiration signal from a thermistor. (c) Coherence between RSA and the respiration signal with corresponding phase.

An additional control measurement of a patient with a pacemaker is shown in Figure 3. The pacemaker was set to a constant frequency in order to evaluate the performance of the proposed method. The RSAp-p should be absent in this case, however we obtained 0.9 ms. This result is probably a consequence of variations in the R-wave shapes because of movements of the thorax and the ECG electrodes during breathing. We can conclude that only RSAs with RSAp-p > 1 ms can be identified with our method and considered as valid.

We still have sinusoidal RSA signal shape, but it seems that "effect" (RRI increase) is here app. 800 ms before "cause" (thorax pressure increase at E event). The phase $\varphi = 150°$ (see Figure 3(c)), expresses just the delay

IV. CONCLUSION

The time domain analysis of RSA is simple and does not need the metronomic breathing and other manoeuvres, like stimulation of carotid baroreceptors by vacuum pulses, that can influence the parameters of conscious breathing. The method presented can be applied retrospectively to ECG measurements in cases where breathing pattern is measured simultaneously or can be reconstructed from the ECG data [20]. The proposed methodology can be used in ambulatory environment to measure the vagal activity or to follow the level of functional re-innervation of transplanted hearts.

The proposed time-domain analysis could be a complementary method of RSA investigation because of

several reasons. HRV segments in aligned sections were averaged and therefore inherently filtered to produce a diagram of RSA with the evident response to the respiration cycle, regarding the phase and shape of the control mechanisms. The frequency components of the RSA corresponding to the breathing stay unaffected, while other components, either short-term or long-term, are reduced due to the averaging process. The method does not require periodic signals and therefore allows spontaneous breathing. It allows sub-interval analysis in order to explore time invariability of each measurement. The method is appropriate for analyses of signals with extremely low variability.

The proposed time-domain analysis of RSA can elucidate the vagal activity, level of re-innervation and other processes after heart surgery. We demonstrated, on a small investigated group, that RSA shape, amplitude and phase are stable and consistently support the cause-effect relation in control subjects. However, preliminary analysis of measurements from patient after heart transplantation indicates that the amplitude and phase are not stable and do not consistently support the cause-effect relation. The preliminary results also indicate that the shapes of RSA curves are significantly different between patients, which remains to be clarified with further research.

ACKNOWLEDGMENT

The authors gratefully acknowledge the help of Andrej Šmigoc in preparing the presentation of the method for RSA shape extraction in Figure 1.

***Abstract*—Regularization methodologies are an integral part in dealing with ill-posedness of inverse problem in electrocardiograhy, expressed in terms of potential distribution on the epicardium. In order to systematically evaluate various regularization techniques under controlled conditions, we employed progressively more complex idealized source models (from single dipole to triplet of dipoles) to calculate body surface potentials, which served as an input data to the inverse problem. In total, we examined, 13 different regularization techniques and found that non-quadratic methods (total variation algorithms) and first-order and second-order Tikhonov regularizations outperformed other methodologies.**

I. Introduction

It has been shown that there is an infinite number of internal electrical heart sources that can produce the same potential distribution on the body surface [1], [2]. Therefore, to solve such ill-posed inverse problem, an equivalent source model has to be presupposed. Some of the models, e.g., single dipole or single quadrupole, are rather crude approximations of the entire heart's electrical activity, while other models, e.g., epicardial potentials, can be actually measured. The inverse solution that employs the potential distribution on the epicardial surface as an equivalent source model or electrocardiographic imaging (ECGI) [3] has been widely studied in electrocardiography due to its inherent ill-posedness [4]–[7]. A plethora of regularization techniques have been applied to gauge wildly oscillating inverse solutions, however, there is a growing need to compare, structure, and unify those diversified regularization methods. In particular, such a comparison requires the use of the same volume conductor and the same cardiac source models in order to eliminate other sources of variation in results. In this study, we employed the same volume conductor model as in a related study [8] to systematically evaluate the performance of 13 different regularization techniques using progressively more complex idealized source models (from single dipole to triplet of dipoles).

II. Methods

A. Problem formulation

The equivalent potential distribution on the epicardial surface can be found from a known potential distribution on the torso surface - which can be in principle obtained using multichannel ECG devices [9] - by solving generalized Laplace's equation subjected to Cauchy boundary conditions [4]–[7]. Such a boundary-value problem must be in an arbitrarily shaped volume conductor approximated on a discretized solution domain as the system of linear equations. For the homogeneous and isotropic model of the human torso, this can be achieved by means of the boundary element method (BEM), which relates the potentials at the torso nodes (expressed as an m-dimensional vector Φ_B) to the potentials at the epicardial nodes (expressed as an n-dimensional vector Φ_E)

$$\Phi_B = \mathbf{A}\Phi_E \tag{1}$$

where $\mathbf{A}$ is the transfer coefficient matrix ($m \times n$) and $n < m$. The transfer coefficient matrix depends entirely on the geometric integrands which can be calculated analytically [10], [11]. In principle, the epicardial potential distribution could be simply found in the form of a pseudo inverse; however, the matrix $\mathbf{A}$ is ill-conditioned, i.e., its singular values are limiting to zero with particular gap of separation in the singular value spectrum, which yields an unstable solution. A number of approaches have been developed to control the wild oscillations of the solution and the ones we have used and described in more details in the related study [8] are divided into three groups

1) Tikhonov regularizations: zero order (ZOT) [12], [13], first order (FOT) [7], [14] and second order (SOT) [13],
2) iterative techniques: truncated singular value decomposition [15] (zero order (ZTSVD), first order (FTSVD), and second order (STSVD)), conjugate gradient [16] (zero order (ZCG), first order (FCG), and second order (SCG)), ν-method (NU) [15], and MINRES method [16],
3) non-quadratic techniques [7], [17]: total variation (FTV), and total variation with Laplacian (STV).

We used geometry based on the torso shaped outer boundary, defined with m=771 nodes, and an internal, barrel-shaped cage with n=602 electrodes, which surrounded all sources (surrogate for the epicardial surface) [8].

B. Selection of sources

We created a cylindrical source space, consisted of 744 dipoles in 248 positions, which were arranged in 8 axial planes 10 mm apart along the polar z-axis, see Fig. 1. There were three perpendicular dipoles in each position: normal (radial, $\vec{p}_\rho$) and tangential (along the polar angle, $\vec{p}_\varphi$) to the cage side surface, and alongside the polar axis ($\vec{p}_z$). In the first and second source (axial) planes there were 7 source positions (Fig. 1c), one in the center and 6 arranged along a concentric circle with a radius of 10 mm (nodes of hexagon with side 10 mm). The center of the bottom plane was at (-16, 45, 230)

mm in the Cartesian coordinate system of the torso-cage model. In the next two source planes (Fig. 1d), there were 19 positions on each plane, 7 as in the first and second planes and 12 arranged on an additional concentric circle with a radius of 20 mm (nodes of a dodecagon with side 10 mm). In the next two source planes, there were 37 positions on each plane (Fig. 1e), 19 as in the previous two planes, and 18 on an additional concentric circle with a radius of 30 mm (equivalent to the nodes of an octadecagon with a side length of 10 mm). In the last two source planes, there were 61 positions on each plane (Fig. 1f), 37 as in the previous two planes and 24 on an additional concentric circle with a radius of 40 mm (nodes of tetracosagon with sides of 10 mm).

From the above source space, we selected three different idealized source models:

1) single dipoles at 16 different locations and 3 different orientations (in total 48 combinations),
2) pairs of dipoles at 324 combinations, and
3) triplets of dipoles at 24 different combinations.

For single dipole source, we selected sources in four planes at levels (z_i in mm): bottom plane ($z_0 = 230$, Fig. 1c), two planes in the middle ($z_1 = 260$, Fig. 1d and $z_2 = 270$, Fig. 1e), and upper plane ($z_3 = 300$, Fig. 1f). On each plane, we selected four positions (in cylindrical coordinates ρ – radial distance, φ - polar angle, and z – height), one in the center (polar axis) and three on the outermost circle of a given plane (ρ_0=10, ρ_1=20, ρ_2=30, ρ_3=40 mm) at polar angles φ=-180°, -120° and -60°, see Figs. 2a–c.

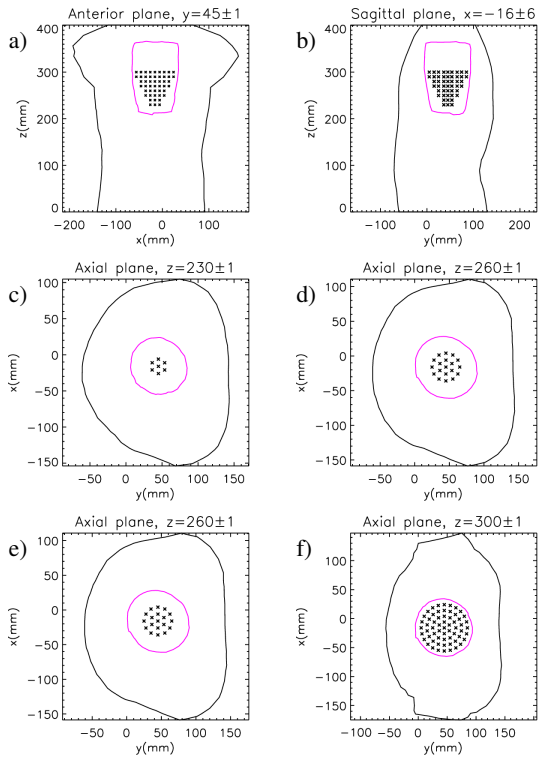

Fig. 1. Cross-sectional views of dipole positions denoted by a) Anterior, b) Sagittal and (c through f), Axial planes at different z levels. Torso and cage borders are displayed with black and magenta colors, respectively. On each plane, sources within x or y or z levels ± tolerance are displayed. The polar axis of the cylindrical cage is at x=-16 mm and y=45 mm.

For dual dipole sources, we selected single dipole sources in three planes at levels (z_i): two planes in the middle ($z_1 = 260$ and $z_2 = 270$), and in the upper plane ($z_3 = 300$), see Figs. 2d–f. Note, that we kept the same notation of planes as in the case of single dipole sources. On each plane, we selected only dipoles in the outermost circle with radial distances ρ_1, ρ_2 and ρ_3, respectively. We put the first single dipole on the right side (polar angle φ=-180°). The other dipoles are then positioned in angular steps of $\Delta\varphi_i$ in the anterior part

$$\varphi = -180^\circ + \Delta\varphi_i,\ -180^\circ + 2\Delta\varphi_i,\ \ldots, 0^\circ,$$

where $\Delta\varphi_1$=30°, $\Delta\varphi_2$=20° and $\Delta\varphi_3$=15°, with 6, 9 and 12 additional dipole positions in the three selected planes, respectively. We combined dipoles along the same direction (3 parallel $(\vec{p}_\rho, \vec{p}_\rho)$, $(\vec{p}_\varphi, \vec{p}_\varphi)$, $(\vec{p}_z, \vec{p}_z)$ and 3 anti-parallel $(\vec{p}_\rho, -\vec{p}_\rho)$, $(\vec{p}_\varphi, -\vec{p}_\varphi)$, $(\vec{p}_z, -\vec{p}_z)$ combinations), as well as dipoles 6 orthogonal combinations ($(\vec{p}_\rho, \vec{p}_\varphi)$, $(\vec{p}_\rho, \vec{p}_z)$, $(\vec{p}_\varphi, \vec{p}_\rho)$, $(\vec{p}_\varphi, \vec{p}_z)$, $(\vec{p}_z, \vec{p}_\rho)$, $(\vec{p}_z, \vec{p}_\varphi)$).

For 3-dipoles sources, we selected single dipole source positions that approximately form nodes of equilateral triangle. We formed six different triangles, which are named according to either an approximate cross-sectional plane where triangle nodes are positioned (Anterior and Sagittal) or a part of the cage (torso) where most nodes are positioned (Right) with added approximated distance between dipoles (side of a given triangle) in mm. We selected six triangles. The first node of Anterior–80 (Fig. 3a) and Sagittal–80 triangles is positioned in the center of the bottom plane ($z_0 = 230$).

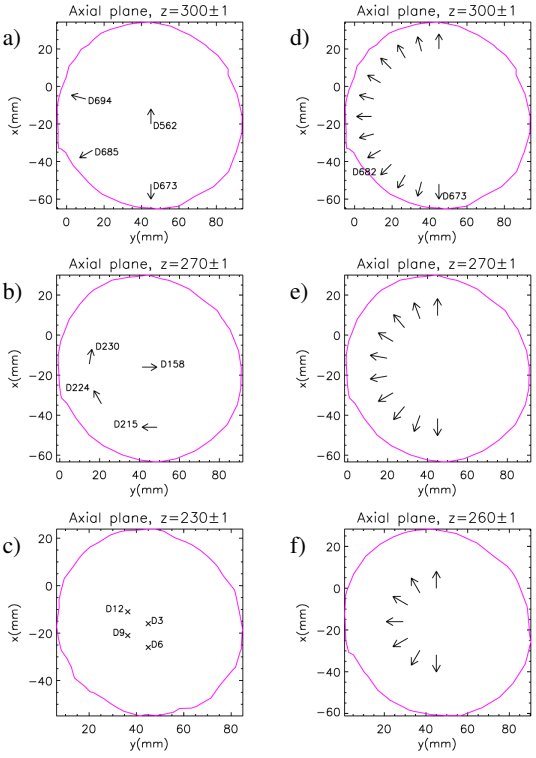

Fig. 2. Selected positions for single dipoles in different planes: a) z_3=300 mm (radial dipoles $\vec{p}_\rho$ are displayed), b) z_2=270 mm (dipoles along the polar angle $\vec{p}_\varphi$ are displayed) and c) z_2=260 mm (axial $\vec{p}_z$ dipoles are displayed). Labels denote dipole numbers in 744–dipoles source space (Fig. 1). Selected positions of dual dipole sources in planes: d) z_3=300 mm, e) z_2=270 mm and f) z_2=260 mm. Dipoles normal to the cage side ($\vec{p}_\rho$) surface are displayed.

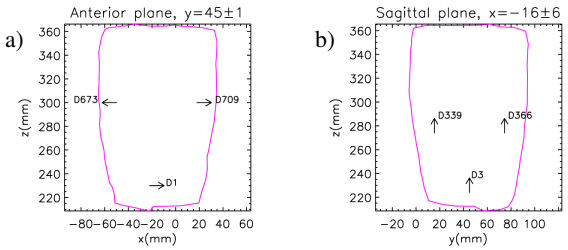

Fig. 3. Positions of triple dipole sources in a) Anterior–80 (radial $\vec{p}_\rho$ are displayed) and b) Sagittal–60 (axial $\vec{p}_z$ are displayed) triangles.

The other two nodes are positioned in the outermost circle (ρ_3=40 mm) of the upper source plane ($z_3 = 300$), with polar angles φ=(-180°, 0°) and (-90°,90°), respectively, see Fig. 3. Similar scheme was used also for constructing Anterior–60 and Sagittal–60 (Fig. 3b) triangles, where the other two nodes are positioned in the outermost circle (ρ=30 mm) of the source plane at z=280 mm. The first node of the Right–57 triangle is positioned in the center of the source plane at z=260 mm and the other two nodes are positioned in the outermost circle of the upper source plane at z_3, with polar angles φ=(-180°, -90°). The first node of the Right–42 triangle is positioned in the center of plane at z=250 mm and the other two nodes are positioned in the outermost circle of the source plane at z=280 mm, with polar angles φ=(-180°, -100°). For each triangle, we formed four 3-dipoles sources

1) normal with dipoles $(-\vec{p}_z, \vec{p}_\rho, \vec{p}_\rho)$
2) tangential with dipoles $(\vec{p}_\rho, -\vec{p}_z, \vec{p}_z)$
3) along the polar angle $(\vec{p}_\varphi, \vec{p}_\varphi, \vec{p}_\varphi)$, which are also all tangential to the cage side surface
4) axial with all dipoles along polar axis $(\vec{p}_z, \vec{p}_z, \vec{p}_z)$.

C. Data simulation and evaluation

For all selected single, dual and triple dipole sources, we simulated data at 602 leads of the cylindrical cage and at 771 nodes on the torso surface using boundary element method (BEM) [18]. In order to test the inverse solution, we added to the BEM calculated potential maps on a body (torso) surface 10 different random noise distributions at level (S/N=40 dB), where $S/N = 20\log_{10}\frac{\mathrm{RMS(signal)}}{\mathrm{RMS(noise)}}$. For each simulated data with added noise on the torso surface, we applied all 13 regularization techniques from section II-A to reconstruct the potential distribution on the cage surface. As a measure of reconstruction accuracy, we used the relative error (normalized RMS error) $\mathrm{RE} = ||\Phi_\mathrm{E}^\mathrm{r} \Phi_\mathrm{E}^\mathrm{m}||_2 / ||\Phi_\mathrm{E}^\mathrm{m}||_2$, and the correlation coefficient, $\mathrm{CC} = \Phi_\mathrm{E}^\mathrm{r} \cdot \Phi_\mathrm{E}^\mathrm{m} / ||\Phi_\mathrm{E}^\mathrm{r}||_2 ||\Phi_\mathrm{E}^\mathrm{m}||_2$, where $\Phi_\mathrm{E}^\mathrm{m}$ are the directly-computed cylindrical-cage potentials and $\Phi_\mathrm{E}^\mathrm{r}$ are the reconstructed potentials. Since there are no specific clinical thresholds for RR and CC, we also compared qualitative features of both simulated and inversely computed potential maps, (e.g., areas of negative potentials and positions of extrema).

III. Results

Table I summarizes average reconstruction results for single, dual and triple dipole models with 40-dB input noise. Results show that NU and MINRES are the worst for all source configurations. Zero order methods (ZOT, ZCG, ZSTSVD) are also much worse than their first and second order equivalents (FOT, SOT, FTSVD, STSVD, FCG, SCG, FTV, STV), so we display results for those methods only in other tables. Best reconstruction results for all source configurations are on average obtained with FOT, SOT, FTV and STV methods. FTSTVD and STSVD methods have good performance only for single dipoles. FCG and SCG methods under-perform in reconstruction of dual dipoles.

Table II displays results for single dipoles in different directions. Results show that dipoles oriented along the polar angle (tangential to the cage surface) are slightly worse than results for dipoles oriented along the polar axis and for radial dipoles (normal to the cage surface). Table III displays results for single dipoles in different planes. Results show that the quality of reconstruction depends on a distance of sources from the cage surface. The best results are obtained for the plane z_1, where the selected dipoles on the outer circle are ∼27 mm from the side surface. The worst results are obtained for the plane z_3 where the selected dipoles are ∼10 mm from the side surface. The selected dipoles on the plane z_2 are ∼18 mm from the side surface. The selected dipoles on the bottom

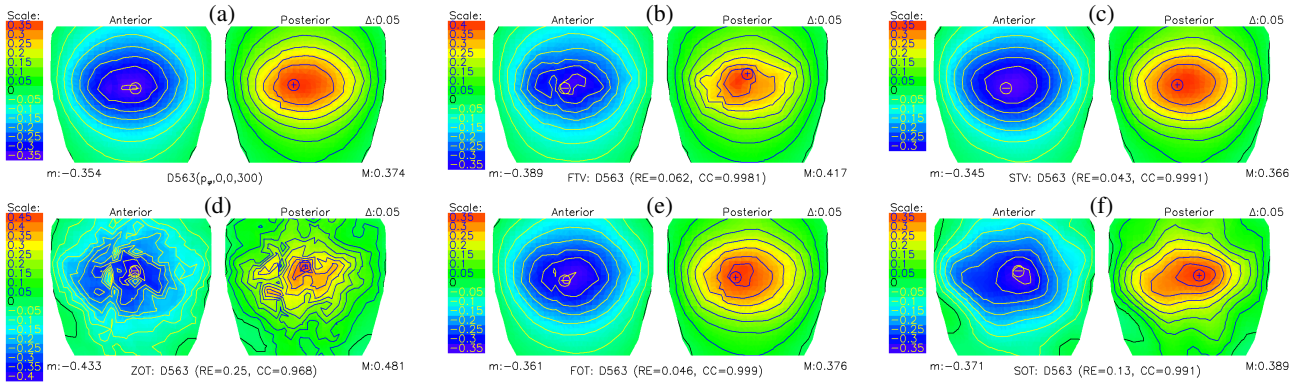

Fig. 4. a) Cage potential distribution due to single dipole positioned in the center axial plane z_3=300 mm, oriented towards the anterior side of the torso. D563(p_φ,0,0,300) bellow the map denotes dipole number in the 744-dipole source space from Fig. 1, dipole orientation and coordinates in cylindrical coordinate system, respectively. Note, that this dipole is located in the same position as the dipole D562 in Fig. 2a. "M" denotes maximum potential, "m" denotes minimum and Δ step between iso-potential lines potential for a given map, respectively. Inversely computed cage potentials using b) FTV and c) STV (first and second order total variation algorithm), d) ZOT, e) FOT and f) SOT (zero, first and second order Tikhonov regularization methods. Below each reconstruction map, RE and CC values are displayed. Each map is displayed on the anterior and posterior cage side, where vertical direction corresponds to cage height in the range $z \in [218, 360]$ mm, and horizontal direction corresponds to polar angle multiplied with the cage radius at a given height (note, that in Figs. 1-3 torso and cage cross-sections in the zx, zy and xy planes are shown).

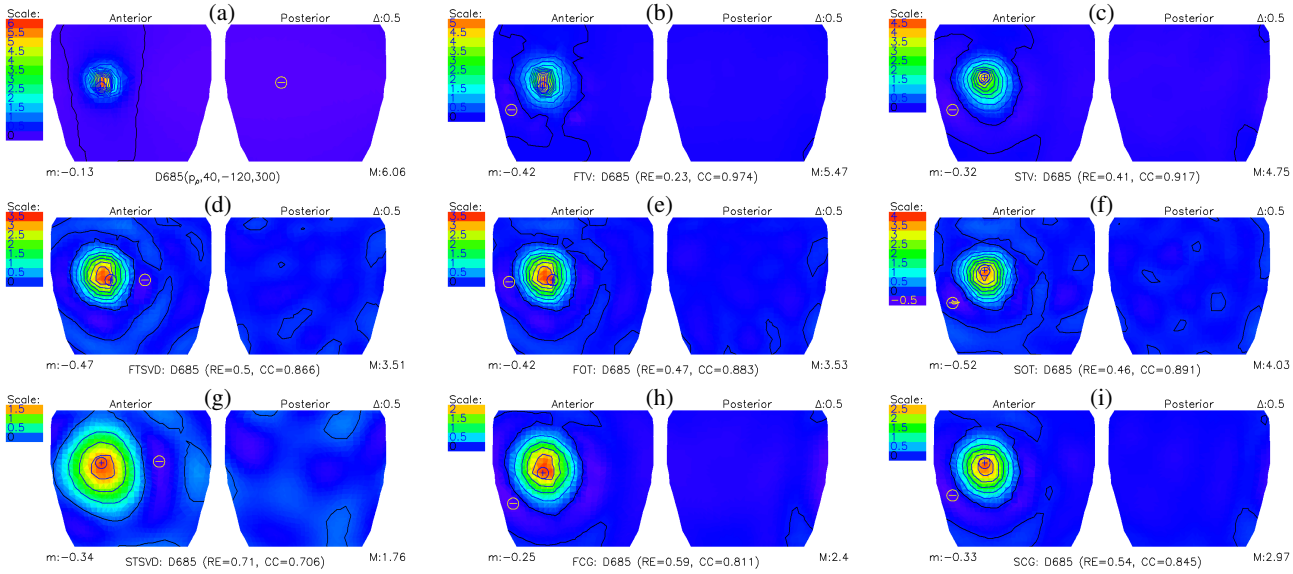

Fig. 5. a) Cage potential distribution due to single dipole positioned closed to the cage surface (ρ=400 mm, φ=-120°, dipole D685 in Fig. 2a) in the axial plane z_3=300 mm, oriented towards the cage surface (p_ρ). Inversely computed cage potentials using b) FTV, c) STV, d) FTSVD, e) FOT, f) SOT, g) STSVD h) FCG and i) SCG.

plane z_0 are ∼33 mm from the side surface, but they are only ∼18 mm from the cage bottom surface.

Fig. 4 compares directly simulated cage potentials with inversely computed potentials using ZOT, FOT, SOT, FTV, and STV, for a single dipole source near the cage center. Isopotential map forms a nice symmetrical dipolar pattern distributed over the whole cage surface in this case. Results clearly shows that ZOT performs worse than FOT and SOT, similar conclusion can be reached for other zero-order methods (ZTSVD and ZCG) as well as for MINRES and NU methods. The lowest/highest values of RE/CC were obtained with STV and FOT methods.

Fig. 5 compares directly simulated cage potentials with inversely computed potentials using FTV, STV, FOT, SOT, FTSVD, STSVD, FCG, and ZCG, for a single dipole source near and oriented normal to the cage edge. In this case, isopotential map has non-zero values in a rather small region, while FTV method clearly outperforms other methods.

Table IV displays results for dual dipoles in different planes. Like in the case of single dipoles (Table III), the quality of reconstruction depends on a distance of sources from the cage surface. Table V displays results for different orientations of dual dipoles. It seems that dual dipole orientations have no effect on the quality of reconstructed results, the anti-parallel orientations gives

STV	0.40±0.15	0.90	0.41±0.16	0.90	0.46±0.20	0.86

on average only slightly worse results than parallel and orthogonal orientations. The same conclusion is also valid for different combinations of parallel, anti-parallel and orthogonal dual dipoles.

Fig. 6 compares directly simulated cylindrical-cage potentials with inversely computed potentials using SCG, SOT, STV, FOT, and FTV, when the two dipoles were 30.6 mm apart. It is evident that two distinct extrema were reconstructed only when using SOT (relative error of 0.56) or FTV (0.44); it is interesting that for this specific example, the Laplacian was a more suitable operator than the gradient when applying Tikhonov regularization, while the opposite was true for the total variation technique. When taking averages, however, the difference among regularization techniques in the reconstruction of two-dipole potential distributions on the cylindrical-cage surface was small and results were nearly identical when using, FOT (0.43±0.17), SOT (0.43±0.14), FTV (0.42±0.17), or STV (0.42±0.17). These observations point toward the often-neglected notion that qualitative features of reconstructed maps may show different comparative assessment than do quantitative summary statistics (e.g., relative error), and that in some instances, smaller relative errors may not mean more potent qualitative discrimination of localized events.

Table VI displays results for different groups of triple dipoles. Like in the case of single dipoles (Table III) and dual (Table IV), the quality of reconstruction depends on a distance of sources from the cage surface. The worst results are for Anterior–80 and Sagittal–80 triangles, where all nodes are close to the cage surface. On the other hand, we got almost prefect results for triple dipoles on nodes of Right-42 triangle, which are all quite deep inside the cage. Dipoles in this configuration are also relatively

close to each other (∼42 mm), so they are not likely to generate a complex potential distribution on the cage surface.

Table VII displays results for different orientations of triple dipoles. The worst results are obtained for tangential $(\vec{p}_\rho, -\vec{p}_z, \vec{p}_z)$ orientation. Fig. 7 shows results for a such triple dipole source in Anterior–80 (Fig. 3a). It is interesting to note, that all reconstructed maps have similar pattern for all presented methods, but none can focus 3 dipole sources: one on the bottom source plane (z_0), which is not clearly seen in this view of BEM calculated map (Fig. 7a), and the other two on the left

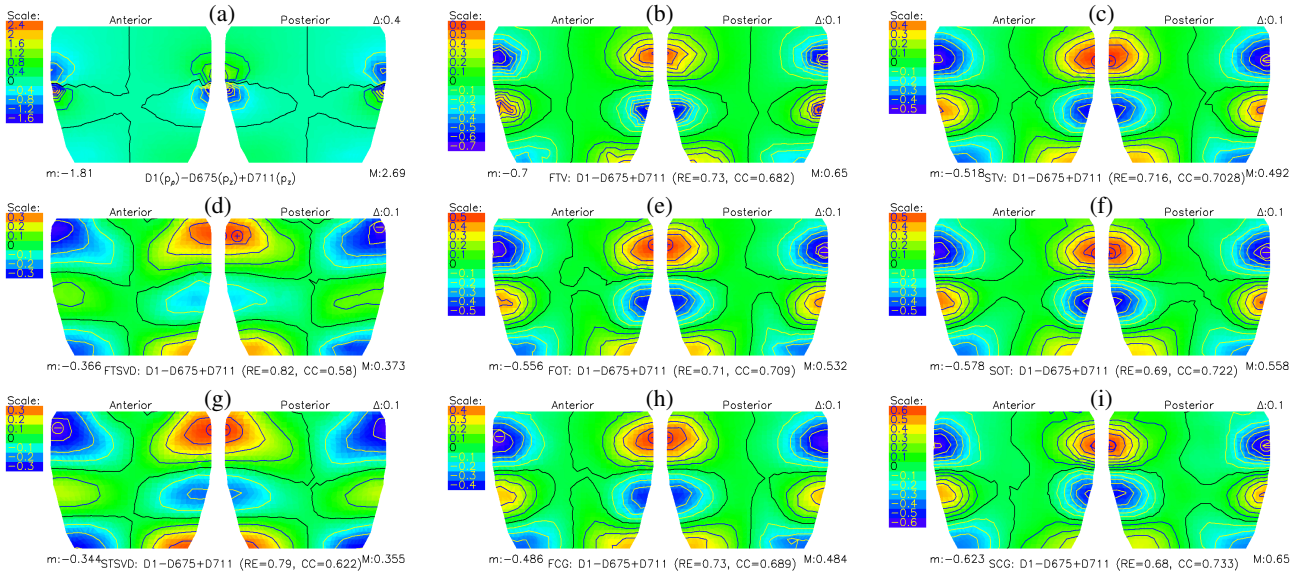

Fig. 7. a) Cage potential distribution due to triple dipoles in Anterior–80 triangle positioned closed and oriented tangentially $(\vec{p}_\rho, -\vec{p}_z, \vec{p}_z)$ to the cage surface. Inversely computed cage potentials using b) FTV, c) STV, d) FTSVD, e) FOT, f) SOT, g) STSVD h) FCG and i) SCG.

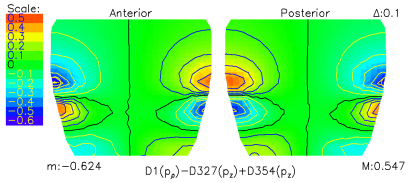

Fig. 8. Cage potential distribution due to triple dipoles in Anterior–60 triangle oriented tangentially $(\vec{p}_\rho, -\vec{p}_z, \vec{p}_z)$ to the cage surface.

and right side of the upper source plane(z_3). However, one can clearly deduce from reconstructed maps the presence of 3 dipoles, but a bit deeper because the dipolar patterns are more spread. In fact, these reconstructed maps look more related to the corresponding source in Anterior–60 triangle, where dipoles are closer to each other (60 instead of 80 mm) and are not so close to the cage surface, see Fig. 8.

IV. Conclusions

The main finding of our study is that - for idealized source models - non-quadratic methods (total variation algorithms) and first-order and second-order Tikhonov regularizations outperformed other regularization methodologies. This study is a necessary step in comprehensive validation of various regularization methodologies by comparing them systematically and under controlled conditions.

Single-Dipole and Dual-Dipole Inverse Solutions in Electrocardiography

Vojko Jazbinšek and Rok Hren
Institute of Mathematics, Physics and Mechanics, Ljubljana, Slovenia

***Abstract*—In this study, we closely examined the performance of inverse solution in terms of equivalent dipole source model. To simulate potential distribution on the body surface, we employed an analytical model of a single current dipole (or a pair of current dipoles) placed within the homogeneous isotropic volume conductor consisting of two non-concentric spheres. Using these data, we evaluated the accuracy of recovering both location and orientation of the single or dual dipole sources. In total, we examined 24 different dipole locations and found that the location of fitted single and dual current dipoles virtually coincided with the original source for high S/N ratios.**

We extended investigation to more complex geometry, where a computer model of the human ventricular myocardium was used to simulate activation sequences initiated at eight sites positioned on the epicardial surface of the atrio-ventricular ring. From these sequences, 117-lead body surface potentials were simulated on a realistic torso surface and were then used to localize single and dual accessory pathways employing single or dual equivalent dipoles. Average localization errors were 5 and 12 mm for the single and the dual accessory pathways, respectively, what could be useful additional information prior to electrophysiological study.

I. Introduction

Mathematical modeling of both source and volume conductor remains one of the prerequisites for any quantitative interpretation of electrocardiographic data. One of the most often used approaches to solving the inverse problem in electrocardiography involves calculating the position and moment of an equivalent single dipole source in the model of the human torso [1]–[3]. It has been widely recognized that the equivalent single dipole approximation is adequate only when cardiac activity is confined to a single, relatively small volume, e.g. arising owing to ectopic foci and accessory pathways between the atria and ventricles. It thus appears intuitive that, in the presence of multiple ventricular events, more complex equivalent generators consisting of two [4] or more equivalent dipoles would achieve better accuracy and therefore a better understanding of the underlying cardiac process. This is particularly important when localizing those accessory atrioventricular connections presented in Wolff-Parkinson-White (WPW) syndrome that consist of dual parallel fibers [5]. As radiofrequency ablations of such multiple aberrant pathways are considered difficult [6], it is desirable to obtain as much information as possible regarding the accessory pathways location and anatomy (a single pathway as against multiple ones) prior to the invasive procedure.

In this simulation study, we explored the possibility that approximation by two dipoles could be used to localize regional activation of dual accessory pathways. In the first part, we employed simple analytical conducting sphere model that may serve as an efficient tool in examining performance of electrocardiographic inverse solution in terms of models, which use either single current dipoles or dual current dipoles. In the second part, we employed an anatomical computer model of the human ventricular myocardium to simulate activation sequences initiated on the epicardial surface of the atrio-ventricular ring, and from these sequences we simulated body surface potentials on a realistic torso surface. The results may be useful in providing additional means for assisting electrophysiology study during radiofrequency ablations of dual accessory pathways.

II. Methods

A. Conducting sphere model

In the first part of this study, we used a pair of homogeneous and isotropic non-concentric spheres and placed either a single current dipole or a pair of two dipoles inside of the smaller sphere. The potentials at an arbitrary point $\vec{r}$ inside a sphere with radius R and conductivity σ can be calculated analytically [7]

$$V(\vec{r}) = \frac{\vec{p}}{4\pi\sigma R^3}\cdot\left\{\frac{R^3(\vec{r}-\vec{r}_p)}{|\vec{r}-\vec{r}_p|^3}+\frac{1}{r_{pi}^3}\left(\vec{r}-\frac{r^2}{R^2}\vec{r}_p\right)+\frac{1}{r_{pi}}\left[\vec{r}+\frac{(\vec{r}\cdot\vec{r}_p)\vec{r}-r^2\vec{r}_p}{R^2(r_{pi}+1)-(\vec{r}\cdot\vec{r}_p)}\right]\right\}, \quad (1)$$

where $\vec{p}$ and $\vec{r}_p$ are dipole moment and position, and

$$r_{pi}=\left[1+\left(\frac{r_p r}{R^2}\right)^2-2\frac{(\vec{r}\cdot\vec{r}_p)}{R^2}\right]^{1/2}. \quad (2)$$

Note, that in the original formula (13) in [7], the $(\vec{r}\cdot\vec{r}_p)$ is expressed as $(r_p r\cos\varphi)$, where φ is the angle between $\vec{r}$ and $\vec{r}_p$. For the surface potential, $r\equiv R$, $Rr_{pi}=|\vec{R}-\vec{r}_p|$, (1) is simplified to formula derived by Brody et al. [8]

$$V(\vec{R}) = \frac{\vec{p}}{4\pi\sigma R^3}\cdot\left\{2\frac{R^3(\vec{R}-\vec{r}_p)}{|\vec{R}-\vec{r}_p|^3}+\frac{R}{|\vec{R}-\vec{r}_p|}\left[\vec{R}+\frac{(\vec{R}\cdot\vec{r}_p)\vec{R}-R\vec{r}_p}{|\vec{R}-\vec{r}_p|+R-r_p\cos\varphi}\right]\right\}. \quad (3)$$

We approximated the thoracic surface by the homogeneous conducting sphere with the unity radius ($R=1$), and the epicardial surface by a smaller sphere with a radius of $R_E=0.5$, positioned eccentrically

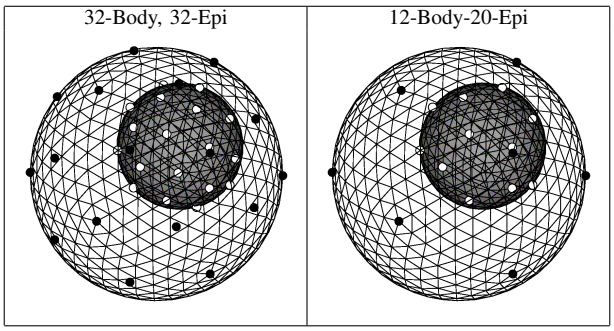

Fig. 1. Lead systems used in the fitting procedure: i) 32-leads on the body, ii) 32-leads on the epicardium and iii) combination of 12-leads on the body and 20-leads on the epicardium. Leads on the body (outer sphere) are denoted with •, leads on the epicardium(inner sphere) are denoted with ◦.

$\vec{r}_{\mathrm{E}} = (0.1, -0.2, 0.3)$. The body and the epicardial surfaces were tessellated using 1280 and 720 triangles (642 and 362 nodes), respectively. The tessellation of the body surfaces was generated by refinement of icosahedron in four steps and the epicardial surface was generated by refinement of truncated icosahedron in two steps. In this paper, we tested three electrode systems, each having 32 leads, see Fig. 1.

We put the single dipole source model in the total of 24 locations, 12 in nodes of icosahedron positioned near the center of the body surface and 12 in nodes of icosahedron positioned near the center of the epicardial surface, see Table I. In each of the positions, we put 3 single current dipoles pointing along axes of the Cartesian coordinate system, which gives total of 72 single dipole sources.

For the dual dipole model, we combined node positions of both source icosahedrons from Table I to construct 12 most close positioned pairs (mean distance 0.178 ± 0.069), 12 most distant positioned pairs (mean distance 0.696 ± 0.026), and 12 pairs of corresponding nodes shifted by $\vec{r}_{\mathrm{E}}$ (median, $||\vec{r}_{\mathrm{E}}|| = 0.374$), see Table II. In each of the pairs, we put either 3 parallel or anti-parallel or perpendicular dipoles pointing along axes of the Cartesian coordinate system. For each type of distance (close, median, distant) and each type of direction (parallel, anti-parallel, perpendicular), we therefore obtain 36 dual dipole sources.

For all single and dual dipole sources, we calculated potential maps on three lead systems from Fig. 1 using (1). In order to test the inverse solution, we added to the analytically calculated maps 7 different noise levels (*S/N*=10,15,...,40 dB), where

$$S/N = 20\log_{10}\frac{\mathrm{RMS(signal)}}{\mathrm{RMS(noise)}}. \qquad (4)$$

For each analytically calculated map and for each noise level, we generated 10 different random noise distributions and performed the inverse solutions either for a single-dipole model or dual-dipoles model.

As a measure of localization accuracy, we used the distance between the recovered location(s) and original location(s) of dipole(s). In addition, we also calculated relative errors between noisy $\mathbf{V}_{\mathrm{n}}$ and fitted $\mathbf{V}_{\mathrm{f}}$ maps

($\mathrm{RE_{fn}}$), and between analytical $\mathbf{V}_{\mathrm{a}}$ and fitted maps ($\mathrm{RE_{fa}}$):

$$\mathrm{RE_{fn}} = \frac{||\mathbf{V}_{\mathrm{f}} - \mathbf{V}_{\mathrm{n}}||_2}{||\mathbf{V}_{\mathrm{n}}||_2}, \ \mathrm{RE_{fa}} = \frac{||\mathbf{V}_{\mathrm{f}} - \mathbf{V}_{\mathrm{a}}||_2}{||\mathbf{V}_{\mathrm{a}}||_2}, \qquad (5)$$

where $||\mathbf{F}||_2 = \sqrt{\sum_i F_i^2}$ denotes 2-norm.

B. Anatomical ventricular model

In the second part of this study we simulated body surface potentials following a methodology that was presented in detail elsewhere [9], [10]. First, we positioned an anatomical model of the human ventricles (Fig. 2) in the homogeneous boundary-element torso model [11] at the hearts anatomical location documented by radiographic images. Secondly, we simulated an activation sequence using a ventricular model [13] that features an anatomically accurate geometry, with a resolution of 0.5 mm, an intramural structure with rotating anisotropy and a computational implementation of a propagation algorithm based on combining a cellular automaton with bidomain models [14], [15]. From this realistic activation sequence, we calculated extra-cardiac electric potentials employing the oblique dipole model of cardiac sources in combination with the boundary element torso model [9]. The infinite medium electric potentials $\mathbf{\Phi}_\infty$ was determined from the discretized equation

$$-4\pi\sigma_0\mathbf{\Phi}_\infty = \sigma_1 \int \frac{\nabla v_m \cdot \boldsymbol{r}}{r^3} dV + \sigma_2 \int \boldsymbol{a}\boldsymbol{a}^T \frac{\nabla v_m \cdot \boldsymbol{r}}{r^3} dV, \ (6)$$

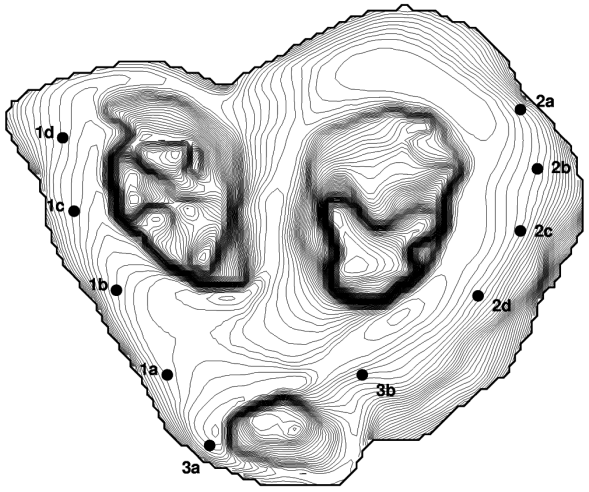

Fig. 2. Basal view of human ventricular model shown with 10 sites of accessory pathways, which are related to locations obtained with clinical studies [12]. Layers are 1 mm apart, and each is represented by smoothed contour line to achieve better rendering of shape. Accessory pathways labeled 1 are located at right anterolateral to right posterolateral region, those labeled 2 are at left posterolateral to left anterolateral region, and those labeled 3 are at right or left anteroparaseptal region (see Table III). Right ventricle is to left, left ventricle is to right, and pulmonary artery is at bottom.

where the integrals were evaluated over the ventricular volume; v_m was the transmembrane potential calculated using the propagation algorithm; σ_0 was the conductivity of the homogeneous monodomain; σ_1 and σ_2 were conductivities characterizing anisotropic myocardium; $\boldsymbol{a}$ is the local direction of the fiber axis; and $\boldsymbol{r}$ is the distance from the source point (each activated cell) to a field point. To compute the body surface potentials we used a fast forward solution [16], [17]. To account for the influence of the torsos outer boundary on localization results, we used, in addition to the standard male torso model, an individualized male torso model [9] to simulate body surface potentials generated by the ventricular model[1]. As before, the two-dipole inverse problem was solved using the standard male torso model. For each activation sequence, we simulated body surface potentials (at 117 sites on both the anterior and posterior torso) at 4 ms increments, within the first 40 ms after the onset of activation. As a measure of the accuracy of the localization, we used the localization error, defined as the three-dimensional distance between the locations of the best-fitting pair of dipoles and each of the two accessory pathways in the ventricular model.

Macchi et al. [18] and Taccardi et al. [19] pointed out that electric potentials during the initial phase of activation resemble those of two opposing dipoles oriented along the major axis and located near the ends of an elliptical wavefront of the propagated activation. To test this hypothesis, we first assessed the performance of a two-dipole generator in localizing single accessory pathways. We simulated electric potentials corresponding to sequences initiated at ten single pacing sites in the right anterolateral/posterolateral segment, in the left posterolateral/anterolateral segment, and in the right/left anteroparaseptal segment of the atrioventricular ring (Fig. 2). Using these simulated potentials, we solved the two-dipole inverse problem and specifically verified whether the positions of the reconstructed dipoles corresponded to the leading edge of the activation wavefront. The results of this study can be found in Section III-B1.

[1]We altered the geometry of the outer surface of the torso and the position of the ventricular model in the torso, but did not change the size of the ventricular model.

TABLE III. ANATOMICAL DESCRIPTION OF DUAL SITES

	Abbreviation	Anatomical description	Distance*
1a-1b	RAL	Right anterolateral	18
1a-1c	RAL	Right anterolateral/ right lateral	18
1a-1d	RAL/RPL	Right anterolateral/ right posterolateral	48
2a-2b	LPL/LL	Left posterolateral/ left lateral	11
2a-2c	LPL/LL	Left posterolateral/ left lateral	23
2a-2d	LPL/LAL	Left posterolateral/ left anterolateral	36
3a-3b	RAP/LAP	Right anteroparaseptal/ left anteroparaseptal	30
1b-2b	RAL/LPL	Right anterolateral/ left posterolateral	139

*Distance in mm measured along atrioventricular (AV) ring

Next, we solved the inverse problem using the sequences initiated at eight different pairs of pacing sites in the same segments of the AV ring (Fig. 2 and Table III). Gaussian noise at the root-mean-square (RMS) levels of 2.5 μV, 5 μV and 20 μV was added to all simulated body surface potentials. We generated ten different noise distributions for each noise level, and, with these data, the two-dipole inverse problem was solved. The results of this study can be found in Section III-B2.

To compare the accuracy of the two-dipole model inverse solution with that of the single-dipole inverse solution, we also calculated the inverse solution for the single-dipole model for the simulated data described above. For this inverse solution, we used methods described earlier [13]. When using the individualized male torso model, Gaussian noise at the RMS level of 5 μV was added to the simulated body surface potentials. The results of this study can be found in Section III-B3.

III. RESULTS

A. Conducting sphere model

Table IV and Fig. 3 display average single dipole source localization errors (Δr) and REs calculated with different lead system and noise levels, where

$$\Delta r = ||\vec{r}_f - \vec{r}_p||_2\,, \tag{7}$$

and $\vec{r}_f$ and $\vec{r}_p$ are fitted and original dipole locations, respectively. Results clearly show that for high *S/N* ratio (40 dB) location of the single current dipole almost coincide with the original source for all lead systems. The 32-Epi lead system outperforms the other two in terms of localization error. On the other hand, relative fit errors RE_{fn} are almost the same for all lead systems. Note, that fitted potential maps are more similar to the analytical maps than noisy maps ($RE_{fa} < RE_{fn}$).

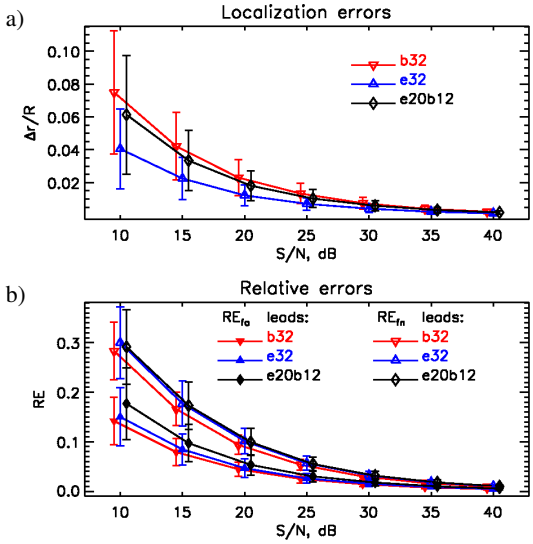

Fig. 3. a) Localization errors ($\Delta r/R$) and b) relative errors (RE_{fn} and RE_{fa}) vs. noise levels for single dipole sources.

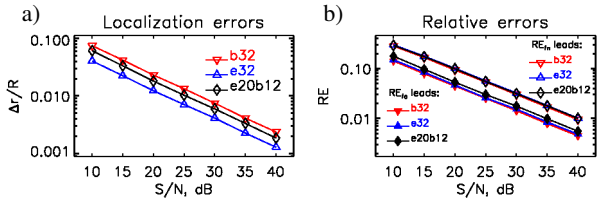

Fig. 4. Logarithmic scaling of a) localization errors and b) relative errors for single dipole sources.

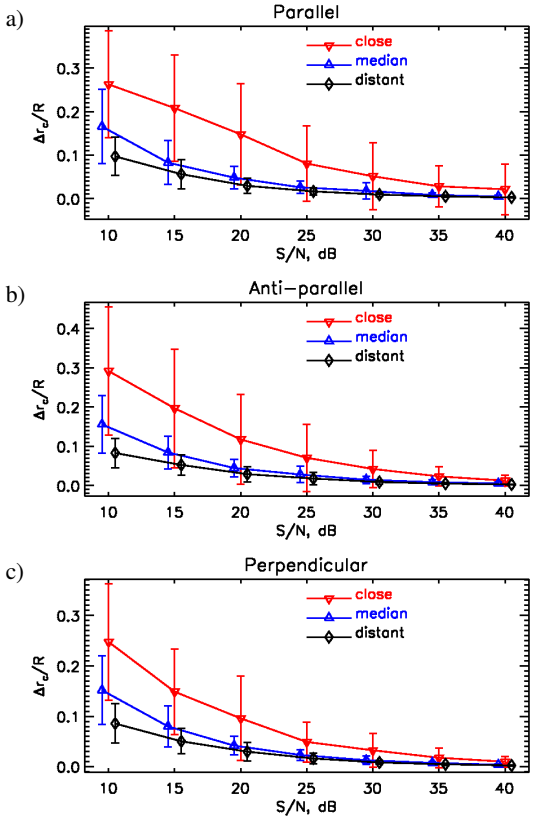

Fig. 5. Localization errors ($\Delta r_c/R$) calculated with 32-epi lead system for dual dipole sources with a) parallel, b) anti-parallel and c) perpedicular mutual directions and different distances between dipoles that forming dual sources.

Fig. 4 displays Δr and REs in logarithmic scale. We observe linear dependence of both $\log(\Delta r/R)$ and $\log(\mathrm{RE})$ vs. *S/N*. According to Eq. (4), both Δr and RE are therefore proportional to noise RMS value.

Table V displays average dual dipole source localization errors (Δr_1, Δr_2 and Δr_c) and REs calculated by 32-Epi lead system using data with different noise levels generated with dual dipole sources with different mutual distances and orientations. Localization errors are defined as distances between the recovered locations ($\vec{r}_{f1}$, $\vec{r}_{f2}$) and original locations ($\vec{r}_{p1}$, $\vec{r}_{p2}$) of both dipoles. Combined error is defined as

$$\Delta r_c = \sqrt{\Delta r_1^2 + \Delta r_2^2}, \qquad (8)$$

and it is shown in Fig. 5. Results show that distance between dipoles in the dual dipole source model plays an important role in the source localization procedure. In the presence of noise, locations of close positioned dipoles are poorly recovered. On the other hand, mutual orientation between dipoles is not so important.

B. Anatomical ventricular model

1) Localization of single accessory pathway using two-dipole model: Fig. 6a shows a typical example of localization of a single accessory pathway when the two-dipole model is used under ideal noise-free conditions. Localization of a pair of dipoles is shown at different time instants for an activation sequence initiated at the left lateral site (2c). Both reconstructed dipoles are initially in the sequence located close to the site of an accessory pathway, but later become separated by the distance that is progressively increasing with time. The distance between the leading edge of the simulated wavefront and the locations of the two corresponding, reconstructed dipoles is, on average, 3 mm (range 1-5 mm) during the first 28 ms of an activation sequence. This observation strongly supports the notion that progressive separation of the two dipoles reflects the propagation of an activation wavefront. Although the two-dipole model reflects well qualitative features of the propagated activation wavefront, it is less suitable for localizing the single sites of early activation than the single-dipole model. Fig. 7 comprehensively compares the accuracy of the localization when both models are used, with the evident superiority of the single-dipole model. The reason for the poorer performance of the two-dipole model is the fact that such a model, as explained above, localizes both leading edges of the activation wavefront, which are progressively moving away from the actual site of pre-excitation.

2) Localization of dual accessory pathways in presence of different noise levels: Fig. 6b illustrates localization results for the pair of right anterolateral/lateral accessory pathways with the two-dipole model. We can see that dipoles are clearly separated and located close to the actual locations of accessory pathways. In this specific case, the localization errors ($\pm$SD) attained a minimum 20 ms after the onset of activation (11$\pm$1 mm and 5$\pm$1 mm), see Table VI, where the first three columns summarize the localization results for the three noise levels. RMS

** Averaged over 360 samples (36 dual dipole sources × 10 random noise distributions) for different *S/N* and groups of distances and orientations between two single dipoles that forming dual dipole sources.

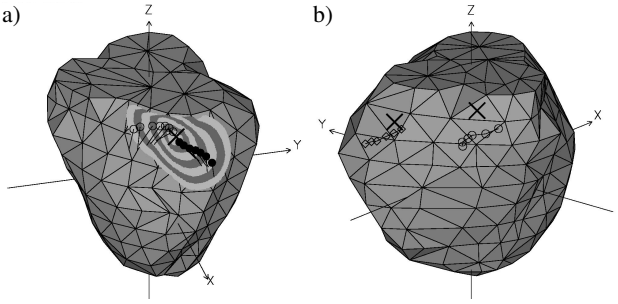

Fig. 6. a) Localization of left-lateral single accessory pathway. Inverse solutions were performed under no-noise conditions. (×) Onset of accessory pathway; reconstructed positions: (○) first and (●) second dipoles, where short lines indicate directions of reconstructed dipole moments. Alternating light and dark gray zones represent projection of activation isochronal surface on epicardial surface, 4-28 ms after onset of activation.
b) Localization of right anterolateral/right lateral (case 1a-1c) dual accessory pathway using two-dipole model. Positions of two dipoles reconstructed at different time instants, 16-36 ms after onset of activation, are shown with epicardial surface. Inverse solutions were obtained with Gaussian RMS noise of 5 μV added to simulated body surface potentials. (×) Onset of each accessory pathway; reconstructed dipoles: (○) first and (◇) second dipoles.

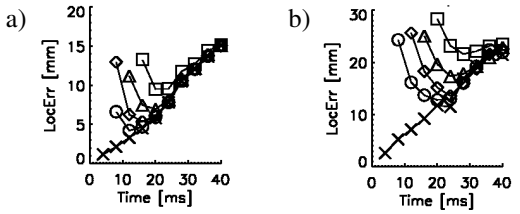

Fig. 7. Localization errors a) for a single dipole source and b) for a two-dipole source model averaged over 8 single accessory pathways, 4-40 ms after onset in presence of different noise levels: (×) no noise; (○) RMS noise level of 2.5 mV; (◇) 5 mV; (△) 10 mV; (□) 20 mV.

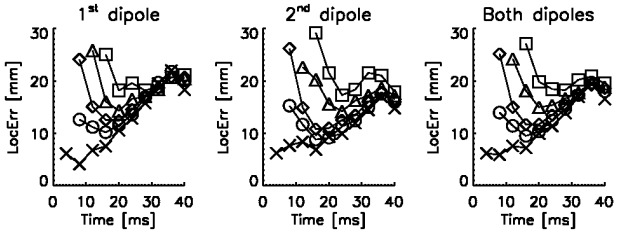

Fig. 8. Localization errors for dual accessory pathway with two-dipole source in presence of different noise levels: (×) no noise; (○) RMS noise level of 2.5 mV; (◇) 5 mV; (△) 10 mV; (□) 20 mV.

levels of the simulated body surface potentials were, at 20 ms after the onset of activation, between 104 μV (case 2a-2b) and 164 μV (case 1a-1c). We found that two-dipole localization errors for typical measuring conditions (RMS noise level of 5 μV) reached a minimum between 12 ms and 24 ms after the onset of activation (Fig. 8). For such measuring conditions, the average localization errors were between 5 and 21 mm (12±6/11±6 mm at 20 ms for the first/second dipole, respectively). Localization errors were, on average, smaller for the pairs of accessory pathways located on the right side (8 mm for cases 1a-1b, 1a-1c, 1a-1d) than for those located on the left side (14 mm for cases 2a-2b, 2a-2c, 2a-2d).

3) Localization of dual accessory pathways in the presence of modeling errors: Localization errors due to inaccuracies in rendering individualized torso boundaries (i.e. in the presence of modeling errors) were, in general, larger than those due to noise and reached their minimum between 16 and 28 ms after the onset (the last column in Table VI). The errors were, on average, in the range of 11-39 mm (24±18/30±13 mm at 20 ms) for the body surface potentials. Visual inspection of inversely calculated dipole positions revealed that they were often distal to the actual locations of accessory pathways and sometimes fell outside anatomically plausible (ventricular) region.

*Three-dimensional distances (±SD) between each of two accessory pathways and two reconstructed dipoles are shown. In the first three columns standard torso model was used for the forward solution with different Gaussian noise RMS level of 2.5, 5 and 20 μV. In the last column the individualized torso model was used for the forward problem solution with Gaussian noise RMS level of 5 μV. The standard torso model was used for the inverse problem solution in all cases. See Table III for anatomical descriptions of accessory pathways. Label N% indicates rejected inverse solutions as percentage of total number of inverse solutions. We rejected all solutions for which the magnitude of the stronger of the two dipoles exceeded the weaker dipole by a factor of 5.

IV. CONCLUSIONS

In this simulation study, we revisited a well-known bio-electromagnetic model that substitutes true cardiac sources with idealized equivalent single and dual dipole sources. We constructed a simplified analytically solvable source and volume conductor model for evaluation electrocardiographic inverse problem solutions. Both fitted single current dipoles and dual current dipoles virtually coincided with the original source for high S/N ratios. In the presence of higher noise we found that i) lead systems positioned closer to sources are more efficient and ii) dual current dipole location recovery is sensitive to the distance between the original dipoles.

Our anatomical model of the human ventricles provided us with means to investigate quantitatively the performance of such a model for more realistic electrocardiographic inverse solutions. The results of this study demonstrate that a source model consisting of two dipoles embedded in the realistically shaped torso volume conductor model could be useful in localizing dual accessory pathways providing that i) we know the torso geometry of a given patient ii) we have a priori knowledge of the presence of dual accessory pathways. Both aspects need to be determined non-invasively to be of clinical use.

Abstract

Objective was to evaluate security of sutures fixated with automatic knot fastener Cor-Knot and compare to United States Pharmacopeial Convention (USP) regulations for use in minimally invasive surgery.

In vitro we measured the knot pull-apart force (KPAF) for two 2-0 B.Braun PremiCron suture lots - Lot#1-9364 (24 sutures); Lot#110095 (24 sutures), fixated using Cor-Knot devices.

USP Class I minimum average 2-0 suture KPAF is defined as 28.24 newtons. For Lot#1-9364 we measured 46.84 ± 1.97 N (mean ± std dev); for Lot#110095 it was 54.08 ± 2.57 N. There were no statistically significant differences between the two lots (F-test, p=0.102). KPAF for all 48 tested knots was higher than USP Class I. Minimal KPAF - 39.27 N (suture P/N M0027845; Lot#110095) is approximately 11 N above the USP recommendation.

To conclude, Cor-Knot-fastened 2-0 B.Braun PremiCron sutures showed a much higher KPAF compared to the USP regulation recommendations.

I. INTRODUCTION

In minimally-invasive-surgery procedures, although varying from one surgeon to another based on experience, the time required to manually make each individual suture knot is significantly longer than in open-surgery procedures, mainly due to a distorted, restricted field of view and limitations in the available range of instrument and hand movements [1]. For the purpose of speeding up the process, thus reducing the operation time, numerous devices for automatic suturing and/or knotting have been or are being developed.

The device used in this study (Cor-Knot by LSI-Solutions), is an automatic knot-making device, which utilizes small titanium rings to make "metal knots". Each knot is made by crimping a titanium ring, after the two ends of the suture loop have been routed through it. The friction between the crimped ring and the suture ends holds the "metal knot" in place, eliminating the need to manually tie several knots to prevent the suture loop from coming loose. After the ring has been crimped in place, the device also cuts the suture ends at a safe distance from the ring, doing the precise cutting work by itself, so assisting the surgeon.

To ensure the safety of newly-developed medical devices, all United-Stated-based manufacturers must comply with United States Pharmacopeial Convention (USP) regulations. The USP Class I knot pull-apart force safety regulations apply to devices the purpose of which is to fixate surgical suture loops in place (knot-fastener devices), Cor-Knot being an example of such a device.

II. OBJECTIVE

In our study, we tested the knot pull-apart force of knots made with the titanium fastener Cor-Knot. The measured results have been compared to USP Class I safety regulations for use in human minimally invasive general and cardiovascular surgery, which recommend a minimum average 2-0 suture (a suture with a diameter of 0.3 mm, used in minimally-invasive cardiac surgery) knot-pull tensile strength (doubled for tests with suture loops) to be 28.24 newtons.

III. METHODS

We used two suture lots of 2-0 B.Braun PremiCron sutures: Lot #1-9364 (24 sutures) and Lot #110095 (24 sutures). The sutures were fastened with the titanium fastener Cor-Knot, which fixates the suture by crimping a titanium fastener around two suture tails, followed by cutting the two tails at a length approximately 1.5 mm away from the titanium fastener. The pull-apart force was measured for both suture lots, using a Lloyd Instruments Chatillon LRX Plus tensile testing machine using a 2.5 kN Load Cell.

To prepare the samples for the knot pull-apart test, two suture tails were loaded through the Cor-Knot titanium fastener in the Cor-Knot device tip using a Quick-Load-Unit wire snare in routine fashion [1]. With the suture loop placed around a 1.25 inch diameter sizing cylinder, the Cor-Knot device purple lever was squeezed to crimp the fastener, trim the suture, and release the fastener from the device [2]. In order to perform the knot pull-apart test, each suture loop sample was loaded into the Chatillon LRX Plus with one side of the loop placed around an upper hook and the opposite side of the loop placed around a lower hook. The lower hook was affixed to a platform on the base of the machine while the upper hook was affixed to a crosshead that was driven upwards to apply tension to the specimen. The test setup is shown in Figure 1.

The Chatillon LRX Plus was set to move the heads apart at 5.5 inches per minute. Throughout the experiment, we collected the current force data. For the knot-breaking force variable we took the highest measured force for each suture [3].

IV. Results

The tensile strength of Lot #1-9364 was 46.84 ± 1.97 N (mean ± std dev) – min. 41.46 N, max. 51.28 N, and for Lot #110095, it was 54.08 ± 2.57 N (mean ± std dev) – min. 39.27 N, max. 50.36 N, respectively. There were no statistically significant differences between the two lots (F-test, $p = 0.102$).

Comparing tensile strength for both lots fastened with Cor-Knot with the USP Class I safety regulations, the tensile strength of knots fastened with Cor-Knot showed higher values for all 48 individual tested knots [Figure 2]. The minimal tensile strength measured was with suture P/N M0027845 of Lot #110095, and was 39.27 N, which is 11.03 N above the USP-recommended strength of 28.24 N.

V. Conclusions

Cor-Knot titanium-fastened 2-0 B.Braun PremiCron sutures of two tested lots showed a much higher knot pull-apart force compared to the USP Class I safety regulations-recommended minimal average knot-pull tensile strength. The use of Cor-Knot is safe and reliable, and may be recommended for use in human minimally invasive general and cardiovascular surgery as a routine knot fastener, especially in combination with endoscopic surgery.

Control and Optimization of Complex Biological Systems

Draško Tomić, * Božica Pernarić, **

Abstract – Healthy and stable state of complex biological systems lies in the narrow region between chaos and frozen state. The cause of chaos is often small initial change in starting conditions, quickly spreading and leading to system wide changes. For example, few microbial pathogens can quickly lead the host to the serious illness and even death. By the definition, an attractor in a certain dynamical system is a set of physical properties toward which this system tends to evolve, regardless of the starting conditions. It is not easy to control chaos and move system from attractor back to the stable state. This is even more difficult in case of hyperchaos with more attractors. Existing control strategies are passive; modify control parameters and wait until system lends in a future, hopefully stable state. At there is a clear need for more efficient control strategy, we propose the optimization of the matrix representing an evolution operator of the system under the control. Matrix elements are system state functions, and function variables are control parameters. Eventually, optimizing this matrix with respect to some goals can help to drive system back to stability. On the case of Samoyed dog lady attacked by methicillin-resistant and multi-species bacterial pathogens, we were able to identify the chaotic system with at least three attractors; two of them leading the system into the illness, and one driving it back to the healthy state. Consecutively, we established the matrix of its evolution operator and discussed some ways of the matrix optimization, in a hope our approach might help to develop therapies that are more efficient. Not of the less importance, we hope our experience with integrative therapy including standard therapeutics, herbal extracts and homeopathic remedies could help a clinician confronted with a similar case.

Key words: complex biological systems, chaos control, evolution operator, attractor, matrix optimization, integrative therapy

I. INTRODUCTION

Complex biological systems are dynamic and adaptive systems consisting of billions of cells interacting at multiple spatial and temporal scales.

Given that relatively small initial changes can eventually cause great and difficult to predict changes, we can say that the complex biological systems are also highly nonlinear dynamic systems, and small initial changes are starting conditions. However, there are changes that we call diseases, and that may lead complex biological system into undesirable state, from which he is not able to escape without intervention from outside, i.e. therapy. Speaking in the framework of chaos theory, system is in the trapping region of chaos, and will remain there until eventually external stimulus while help him to escape from there. By analyzing dynamic systems captured into the chaos, one can find an amazing fact that there is a sub-region within space, seeming to attract the system there. This phenomenon is of the outmost importance in the theory of chaos, and its name is strange attractor. Lorenz attractor [1] is the most famous example of such phenomenon, because not only it was the first, but also for his interesting shape resembling butterfly wings, as can be seen from Fig. 1:

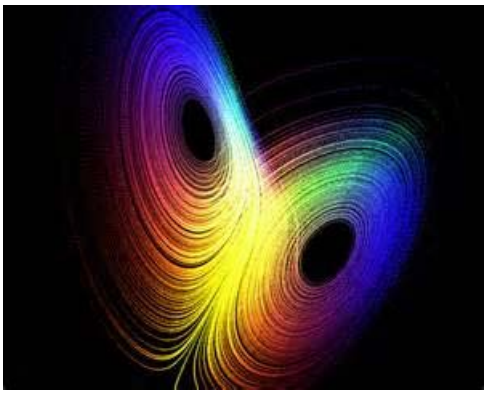

Fig.1: Lorenz strange attractor

On the other side, and despite of the fast development of new drugs, now day is not easy to fight even simple, non-complicated bacterial infection. The reason might seem to be obvious, i.e. ever increasing bacterial resistance to antibiotics and genome transfer of this resistance among various bacterial strains and even species.

However, many bacterial species developed additional surviving strategies, like ability to penetrate deep in the tissues, autonomous movement, and production of toxins able to damage not only host, but also other competitive bacteria. Therefore, the clinician treating bacterial infection eligible for up to twenty potential drugs may need to provide answers on many other questions; Should I treat the infection or not? Which is the best drug or combination for that pathogen and patient? Which dosage is optimal? Should we give the drugs together, or at some interval? Should the drug dose and interval change over time? How long administration can take place? What is the metric of success? In case of the host invaded by several bacterial species, answering these questions is even more difficult, and the complexity of therapy might be far beyond standard therapeutic protocols. Clearly, the treatment parameter space available is huge and the options virtually infinite. That is where mathematical modelling may help. By simulating millions of treatment combinations in a fraction of the time, one can help the clinician to make better decisions that have a greater chance of success. An attempt to develop mathematical models of therapies is not so frequent, because they appear complicated to model, and because of ever evolving complex, dynamical system. From our work on real case described in the next session, has come a clear conclusion: biological system under simultaneous attack of various microbial pathogens is indeed complicated and complex, but incomprehensible it is not. However, it requires a lot of collaboration between clinician, microbiologists and patient's family, is time consuming, and expensive. While development of new and more effective drugs remains the dominant goal in microbiology, clinician able to simulate millions of treatment combinations in a fraction of the time might make better decisions that have a greater chance of success. Moreover, it does not mean that mathematicians and their models will replace clinicians. It will allow placing the complete system in an integrated framework, from which it will be possible to examine the impact that change of one or several components has on the whole system. As it will be clearer in the next section describing a real case, the infection of complex biological system with multi-species bacterial pathogens is very hard to control. Failure to integrate mathematical and computational models into biology and therapy, will inevitably limit our progress with diseases of such complexity. Clinicians need to use advanced quantitative methods to integrate known data with underlying evolutionary-first principles to make predictions about the unknown outcome. By doing so one can develop personalized therapeutic strategies for complex diseases that are as dynamic and adaptive as host they are attacking. Besides, mathematical theory of complex nonlinear systems, aka chaos theory [2], is already available, and can help us to analyze and control such systems. Among several approaches available in chaos theory, one is to establish spectral evolution operator of the system analyzed [3].

In addition to physics, spectral analysis of complex systems has been successful in the analysis and optimization of human walk [4] and high performance computing [5]. For this reason, in this work we investigated spectral analysis applicability on complex biological systems infected by multi-species bacterial pathogens.

II. CASE STUDY

Mini Vini, 8 years old and 23 kilogram weighing female Samoyed dog lady came to the referring veterinarian because of the frequent urination, i.e. pollakiuria and blood in urine, hematuria. The dog already had a history of urinary tract infection, caused by Escherichia Coli and Staphylococcus spp., cured with amoxicillin/clavulanic acid and enrofloxacin antibiotics. Besides, there was the history of the serious diarrhea, probably caused by an excessive use of antibiotics. The current diet was a commercial vet food, vaccinations were current, and the dog was not receiving any medication. Ultrasound examination of bladder revealed urolithiasis and formations on bladder walls, as on Fig. 2:

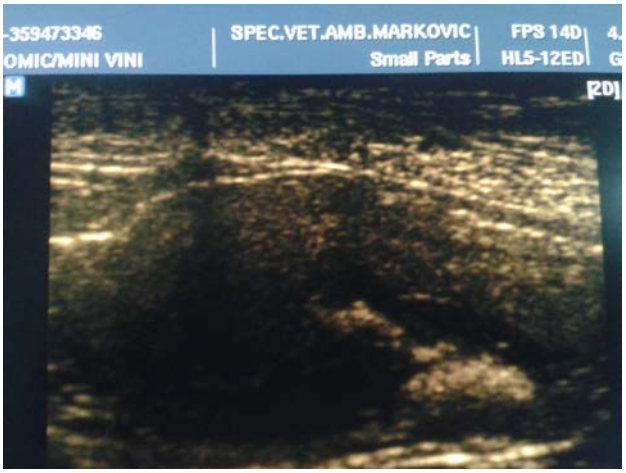

Fig 2: Ultrasound image of bladder

Urine analysis showed ph value was high and up to nine, with high number of leukocytes and erythrocytes. Blood analysis revealed anemia. Subsequently, antibiotic therapy with amoxicillin/clavulanic acid followed, until urine values came to normal values. Besides, as without the cystoscopy it was not possible to define the cause of formations on bladder walls, we accompanied the antibiotic therapy with an extract from Uncaria tomentosa herb, supposed to have some anti-cancer properties. About two months later, ultrasound examination showed no changes on bladder walls. However, hematuria and pollakiuria repeated several weeks later, with similar values of urine found at the first examination.

This time urine microbial analysis revealed Staphylococcus pseudintermedius. Because of the

possible microbial resistance on antibiotics, dog owner decided to start an alternative therapy with Arctium lappa herb, known for his in vitro activity against Staphylococcal species [6]. We accompanied the therapy by struvite prescription diet and DL-Methionine, urine acidifier. About two months later, urine control parameters came to normal values, and urine sediment analysis under microscope showed crystals dissolving. For the next three months, patient continued with the same diet and acidifier, accompanied with Rowatinex, herbal remedy known to be effective against cristalliuria [7]. Several months passed before the next UTI symptoms repeated, and this time microbial analysis of urine revealed E. coli. Repeated therapy with amoxicillin/clavulanic acid followed. Besides, and to avoid the recurrence of UTI, we accompanied the antibiotic therapy with immunotherapy, i.e. with Uro-Vaxom, known to significantly suppress the recurrence of UTI caused by E. coli. Because E. coli was still present on the subsequent microbial urine analysis, we continued therapy with ciprofloxacin. Following the next microbial urine analysis, E. coli was not present, however this time Enterococcus faecalis and Staphylococcus pseudintermedius, both resistant to all approved veterinarian antibiotics, showed their presence. Besides, ultrasound examination of the bladder revealed many urine stones, and the blood analysis showed extremely high values of triglycerides and alkaline phosphatase values. For this reasons, we discontinued further antibiotic therapy and struvite prescription diet, and started combined therapy with the preparations from Arctium lappa, Uncaria tomentosa, Cinnamonum zeylanicum, Hydrastis canadiensis, Origanum compactum and Punica granatum herbs instead. According to [9], [10], [11] and [12], these herbs express in-vitro antimicrobial activity against Enterococcus and Staphylococcus species. We also accompanied the therapy with herbal and homeopathic remedies from AllergicPet, which according to the producer, can help dissolve bladder stones and fight UTI. About two months after starting this alternative therapy, urine analysis showed no presence of Enterococcus, and ultrasound bladder examination showed massive dissolution of struvite stones. However, Staphylococcus was still present, but this time showing no antibiotic resistance. As urine ph value was above seven, and Uva Ursi herb is supposed to have antimicrobial activity above this value, we started the therapy with this herb, accompanied with herbal tea from Betula pendula [13], until UTI symptoms gone. Subsequent bladder ultrasound examination found no crystals, however mud was still there. After discontinuance of Uva Ursi therapy, which might cause serious side effect if applied for more than a two weeks, UTI symptoms returned in a few days, and subsequent urine analysis revealed E. coli again. Antibiogram showed its sensitivity to a broad spectrum of antibiotics, including amoxicillin/clavulanic acid.

Besides, and as the intake of Uva Ursi should not be given more than a five times per year, therapy with amoxicillin/clavulanic-acid followed. At the end of this antibiotic therapy urine analyses showed it sterile. However, UTI symptoms returned only few days after. For this reason, we started therapy with Uva Ursi again. As at this time urine was acidic, we accompanied therapy with Basenpulver, which might increase the alkalinity of urine. Despite our expectations, E. coli showed no sensitivity to Uva Ursi, and UTI symptoms worsened. Therefore, we discontinued its further use, and tried therapy with D-mannose, at dosage of 2 grams per every 4 hours. D-mannose is non-digestible synthetic sugar, therefore completely flushed out several hours after the intake. However, its chemical structure is similar to those of oligosaccharide, the component of protective glycoprotein plagues on bladder wall. For this reason, E. coli might stick to D-mannose sugar molecules and host is able to flush it from bladder by urination. Very recently, pilot study proved the efficiency of D-Mannose [14]. After several days of the treatment with D-Mannose, urine dipstick values returned to normal values, however UTI symptoms returned soon after discontinuing the intake of D-mannose. Therefore, we applied the therapy with amoxicillin/clavulanic acid and subsequent microbial analysis showed sterile urine. Only several days later UTI symptoms recurred. In compliance with antibiogram, new therapy cycle with sulfametoxazole/trimetoprim antibiotic followed. At the same time, and to prevent possible UTI recurrence, we started a long-term supplemental therapy with d-mannose, forskolin and Cranberry fruit extract. E. coli is able to attach and penetrate in bladder wall, thus hiding from antimicrobial agents. According to [15], forskolin, an extract from Coleus forskohlii herb, can elevate host cAMP levels, thus forcing pathogenic bacteria out of bladder epithelial cells. Proanthocyanidin is an active component present in Cranberry fruit and can prevent the adhesion of E. coli to bladder wall [16]. After finishing the antibiotic therapy, urine analysis revealed it sterile, without leukocytes and leukocyte esterase present. At the time of the submitting the revised version of this paper, urine was sterile for a several weeks, and we were proceeding with supplemental therapy with Uro-Vaxom, D-mannose, Cranberry and forskolin therapy, all in order to prevent E. coli recurrence. On the other side, mud in the bladder was still present. Therefore, and in order to prevent a possible recurrence of recurrent Staphylococcus and Enterococcus based UTI, we are continuing to apply herbal preparations of Arctium lappa, Cinnamonum zeylanicum, Origanum majorana and Hydrastis canadiensis. Besides, and in in order to get completely free of mud, we are continuing to give homeopathic remedy for struvite stones dissolution, plus DL-Methionine and vitamin C.

III. THE CONTROL OF DYNAMIC SYSTEM

During the therapy course, periodical weekly analasys of urine with dipstic took place. Among the ten urine parameters available on diagnostic dipstick, we concentrated of the following, relevant for UTI:

- Number of leukocites in urine, abbreviated LEU, ranging from 0 to 500 per microliter; no leukocites is normal value.
- Acidicy of urine, abbreviated ph, ranging from 5 to 9; expected values are in range from 6 to 7.
- Protein in urine, abbreviated PRO, ranging from 0 to 500 mg/L; no proteins in urine is normal value.
- Urine specific gravity, abbreviated SG, ranging from 1000 to 1030; expected values are in a range from 1015 to 1025.
- Number of erythrocytes in urine, abbreviated ERY, ranging from 0 to 250 per microliter; no erythrocytes are normal value.

Besides, monthly periodical analysis of urine on microbes took place. The normal value is zero number of microbes, the significant number of microbes is at $>10^3$, and high is as $>10^6$ microbes in microliter of urine. When microbes are present in urine, usually antibiogram with about ten or more antibiotics takes place, and microbes tested on their sensitivity against specific antibiotics. We also performed the blood tests, either periodically or on demand. There are several dozens of blood parameters significant for the severity of the infection and the side effects of therapy. For the sake of simplicity, we will not consider these parameters, however for the goal of our paper it is important to note that together with urine parameters, number of state parameters can readily jump over 50. Making together with available control parameters, i.e. antibiotics, herbal and homeopathic medications active against one or more microbe species, one quickly confronts with a very complex dynamic system. During a therapy, we noticed that a system under the microbial attack moves to two regions, both with high number of leukocytes in urine. However, under the attack of Escherichia coli and Enterococcus faecalis urine ph was acidic, while under the attack of Staphylococcus species was alkaline. By plotting ph values versus leukocyte numbers, we realize the existence of two regions. We encircled them with blue, as can be seen in Fig. 3:

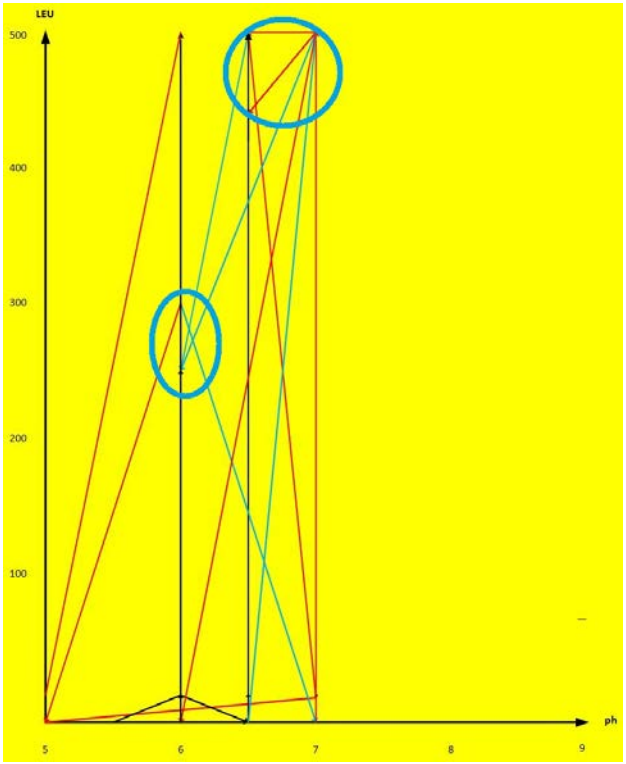

Fig. 3: Number of leukocytes versus ph urine values

In the former figure, lines signify the development of the system from one state to another. Moreover and for the sake of visibility, we denoted with red lines the cases when number of leukocytes was rising and with blue when it was failing over the time. Finally, with black lines we denote cases where red and blue lines are connecting same states. What we found is that leukocyte number correlates with severity of the infection. For example, with number of leukocytes approaching 500, additional symptoms like hematuria and pollakiuria quickly take place. In addition, ph and leukocyte values change very quickly, and there are two regions where they tend to reside, which we cycled in blue. Furthermore, we realized several phenomena that support our assumption that the system under observation is chaotic. It moves quickly from one state to another, it is not possible to predict which state it will reach, and even small elevation of ph value above 6.5 starts the process of massive struvite stones dissolution, thus releasing a huge number of bacteria cocooned in them. Besides, and as states are grouped within two regions encircled blue in Fig. 3., we might assume that this system has at least two attractors: One due to the pathogens E. Coli and Enterococcus Faecalis, another due to the Staphylococcus intermedius. Besides, it is quite possible that at least one additional attractor due to the forces keeping the system in the healthy state exists. For the reasons explained, we assume that system observed is chaotic, and because there are several regions of attraction, we suppose the presence of hyperchaos [17].

The current strategies of controlling hyperchaos in systems with even low number of attractors are passive; change control parameters, and wait until system transit from the current into the next state. If the next state is also the stable state, then we can say control was successful. Otherwise, one needs to change control parameters again, hoping that system will eventually land into the stable state next time. It is clear that passive control strategies are not appropriate in many cases, especially in those when right control can made a narrow line between life and the death. Therefore, we need more advanced control strategies for chaotic and especially hyper-chaotic systems.

IV.CALCULLATING MICROBES

During the therapy course, we focused on three groups of state parameters: first group of parameters obtained by reading urine dipstick, second group obtained by performing microbial analysis of urine and antibiogram, and the last group of parameters resulting from blood analysis. Besides, we regularly checked the quantity and state of urine stones via ultrasound and under the microscope. As therapeutic, i.e. control parameters, we used several antibiotics according to antibiograms, herbal preparations with in-vitro proven activity against bacteria found, D-Mannose sugar, struvite prescription food low in phosphates, proteins and magnesium, but high in fat. Additionally, we applied Uro-Vaxom, Rowatinex, herbal and homeopathic remedies against stones and UTI from Allergic Pet, vitamin C and DL-Methionine as urine acidifiers and Basenpulver, which alkalizes urine. All state and control parameters are viewable from Fig. 4:

State parameters	**Abb.**	**Control parameters**	**Abb.**
Specific gravity	SG	Ciprofloxacin	CFX
Acidity	PH	Amoxicillin	AMX
Leukocytes	LEU	Enrofloxacin	EFX
Nitrites	NIT	Sulfametoxazole/ trimetoprim	SMX
Proteins	PRO	Cranberry	CB
Blood in urine	BL	Uncaria tomentosa	UT
Urine stones	UST	Arctium lappa	AL
Triglycerides	TG	Cinnamon zeylanicum	CZ
Erythrocytes	ERY	Rosa canina	RC
Alkaline phosphatase	AP	Coleus forskohlii	CF
E. coli	EC	Origanum compactum	OC
Enterococcus faecalis	EF	Hydrastis canadiensis	HC
Enterococcus faecalis resistant	EFR	Uva Ursi	UU
Staphylococcus pseudintermedius	S	Punica granatum	PG
Staphylococcus pseudintermedius resistant	SR	Betula pendula	BP
		D-Mannose	DM
		Struvite prescription diet	SD
		Uro-Vaxom	UX
		Rowatinex	RW
		Homeopathic remedy against stones	HR1
		Homeopathic remedy against UTI	HR2
		Vitamin C	UD1
		DL Methionine	UD2
		Basenpulver	UA

Fig. 4: State and control parameters

Further, we introduce the evolution operator of the system, with functions describing status parameter changes over the time. As a response to the therapy, state parameters, with control parameters as variables, change over the time, and the system advances through the time space. In [3], there is a mathematical definition of evolution operator and its discrete presentation in form of iterated map given. Here, we express the intermediate form of the evolution operator for this case and for some parameters, as can be seen on Fig. 4:

Fig 4: The evolution operator of UTI

State parameters are nonlinear functions of control parameters. As functions are unknown, we denote them with **x**. By setting up these functions, one can establish the algebraic form of evolution operator, and finally perform an optimization with respect to the given goals. In case of UTI case described here, there are two goals. One is to get completely free of pathogens, and another, not of less importance, is to get rid of struvite crystals, which are reservoirs of pathogens on a long-term basis. If optimization is successful, values of control parameters guarantee the most efficient therapy. In addition, the most efficient therapy means to delete pathogens as fast as possible, without introducing any serious side effects. However, the functions mentioned before are of very high complexity; good example could be analytically modeling an activity of Coleus forskohlii, supposed to wipe out pathogen from bladder epithelia.

V. CONCLUSION AND FUTURE WORK

The scope of this paper is not to find out the optimal therapy for this case, but to establish directions for the future work. The work to perform this might seem to be enormous, however disserves our full attention, both because bacteria become more resistant on therapeutics than ever, and because the costs of developing new antibiotics are sky rocketing. On the other side, sophisticated biomechanical models are developing at an ever-increasing rate, thus enabling us to simulate on Supercomputers, even at a fine scale, quite complex biological systems. However, some questions still wait for answer; How long will our optimization process execute? How big is an error between optimal and optimized solution? The final, but by far not easier question remains: Is there an algorithm able to perform an optimization of my problem available at all? Now, one of the most promising ways seems to be the semidefinite optimization of the spectrum of the matrix representing evolution operator. For example, this approach was successful in optimizing human walk [4] and speeding-up Supercomputer [5]. Therefore, it is likely to expect that the same or slightly modified approach will help us to improve complex therapy protocols as well. Lastly, we hope our integrative therapy approach, i.e. the combination of the standard, herbal and homeopathic medicine can help clinicians to overwhelm similar cases and provide a cure to the severe UTI diseases.

VI. ACKNOWLEDGMENT

We would like to thanks Boris Habrun and Gordan Kompes, both from Croatian Veterinary Institute, for their fruitful advices regarding the treatment process.

We would also like to thank lovely Samoyed dog Mini Vini, for her enormous patience, collaboration, and for her faith we will cure her illness.

Abstract - An accurate and efficient computer-aided mammography diagnosis system plays an important role as a second opinion to assist radiologists. Finding an accurate and robust computer-aided diagnosis system for classification of the abnormalities in the mammograms as malignant or benign still remains a challenge in the digital mammography. In this paper, a fully autonomous classification system is presented and it consists of the three stages. The input Regions of Interest (ROIs) are obtained using an efficient Otsu's N thresholding and further subjected to a number of preprocessing stages. After preprocessing stage, from the ROIs, a group of 32 Zernike moments with different orders and iterations have been extracted. These moments have been applied to the neural network classifier. The experimental results show that the proposed algorithm is efficient comparing to the ground truth table given in the Mammography Image Analysis Society (MIAS) database.

Keywords: computer-aided diagnosis, mammography, segmentation, neural network, Zernike moments

I. INTRODUCTION

Breast cancer represents the major cause of death by cancer among women. Cancer is a disease in which cells in a part of the body become abnormal and form more cells in an uncontrolled way. In most cases, the cancer cells form a tumor. With breast cancer, the cancer originates in the tissues that make up the breasts. They may also invade nearby tissues and spread to lymph nodes and other parts of the body.

Breast cancer tumors typically do not produce symptoms until they are relatively large at advanced stages. Most breast cancer tumors at earlier stages are benign and not yet malignant and life-threatening. Thus, the early detection of the breast cancer masses can increase the survival rate for patients. Mammography has been one of the most reliable methods for early detection and diagnosis of the breast cancer, typically through detection of characteristic masses and/or microcalcifications (such as tiny deposits of calcium). Although mammography is a sensitive procedure for detecting breast cancer, it lacks high diagnostic accuracy and it is difficult to interpret [1].

Therefore, an accurate and efficient computer-aided mammography diagnosis system plays an important role as a second opinion to assist radiologists. Finding an accurate and robust computer-aided diagnosis system for the classification of the abnormalities in the mammograms still remains a challenge.

In the past two decades, a lot of research has been invested in computer-aided analysis and diagnosis of breast mammograms. Several computer-aided diagnosis (CAD) systems have been developed for the detection and classification of breast masses in mammograms using various image features such as shape, fractal dimension, image moments and laws texture features, e.g. [2 – 7].

Polakowski [2] used shape, size, contrast, and Laws texture features for the classification of masses using a neural network classifier. Brzakovic [3] proposed a classifier that employed four features: size, shape, edge distance variation, and edge intensity variation. Classification of masses using fractal dimension features was proposed in [4]. Rangayyan [5] utilized the "acutance" feature to discriminate between benign and malignant tumors based on averaged gray-level differences between the inside and outside of a tumor boundary. In [6] different combinations of shape features including compactness, Fourier descriptors, moments, and chord-length statistics were examined. Parabolic modeling method to characterize a tumor's boundary was proposed in [7].

Mass classification problems were investigated in [8,9] with different Gabor features and successive enhancement learning based weighted support sector machine. The Gabor feature extraction technique is used to extract multi-scale and multi-orientation texture features. Masses in mammogram are classified using Extreme Learning Machine (ELM) based classifier as proposed in [10]. Automatic mass classification into benign and malignant was presented in [11] based on the features extracted from the contourlet coefficients using non subsampled contourlet transform. The mammogram images are classified by using a classifier based on support vector machine. Discrete wavelet transforms decomposition and an artificial neural network classifier is used for malignant/benign masses classification of region of interest in mammograms is proposed in [12].

A classification using multilayer perceptron network with a novel learning rule was developed in [13]. The features include circularity, Zernike moments, contrast

and average gray level. Decision making is performed in both feature extraction and classification stage.

Classification of breast masses as proposed in [14] is based on shape and texture descriptors, i.e. masses and non-masses. The shape descriptor includes eccentricity, circularity and convexity. Artificial neural network is then used to categorize the masses, which performs benign-malignant classification on region of interest, as explained in [15]. The textural features used for characterizing the masses are mean, standard deviation, entropy, skewness, kurtosis and uniformity. Support vector machine (SVM) and wavelet decomposition was investigated for classifying the masses in [16]. Decision making is performed in both stages: in feature extraction stage and classification stage.

In this paper we mainly concentrate on the recognition of two general masses: benign masses and malignant masses. The input ROIs are obtained from the digital mammograms using Otsu's segmentation algorithm. In order to classify types of masses present in the ROIs, we use 32 Zernike moments as features. In the last stage of algorithm, segmented masses are classified using resilient backpropagation neural networks.

II. MATERIALS AND METHODS

Fig.1 presents the block diagram of the proposed method for the classification of benign and malignant masses in breast mammograms. It involves four major stages. First, image preprocessing of the digitized mammogram is used to suppress noise and improve the contrast of the image. Second, image segmentation is used to identify the masses in mammograms, i.e. to detect the Regions of Interest (ROI). In the third phase, features are extracted and selected for classification of mass. Finally, the classification of masses is conducted.

A. Image preprocessing

Prior to the image segmentation it is necessary to improve the image quality using appropriate noise removal and contrast enhancement techniques. Digitization noises such as straight lines present in the majority of acquired mammogram images are filtered using a two-dimensional (2D) median filter with a 3×3 neighborhood. The edges of the images, however, are replaced by zeros. Image acquisition can induce different artifacts, background noise, scratches that could influence the reliability of the segmentation process.

Most of the mammograms have non-uniform background and very little contrast in the breast tissue region. So image enhancement is required before segmentation. As enhancement technique was selected *contrast-limited adaptive histogram equalization* (CLAHE) [17]. CLAHE operates on small regions in the image, called *tiles*, rather than the entire image. Each tile's contrast is enhanced, so that the histogram of the output region approximately matches a specified histogram distribution. The neighboring tiles are then combined using bilinear interpolation to eliminate artificially induced boundaries. The contrast, especially in homogeneous areas, can be limited to avoid amplifying any noise that might be present in the image.

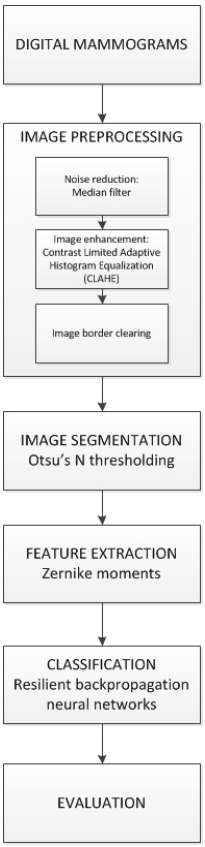

Figure 1. Block diagram of the proposed method

After image enhancement, the automatic thresholding and image border cleaning were applied to suppress the light structures connected to the image border and thus to identify the foreground in the image. The labels on the image as well as the pectoral muscle are removed, since they can disturb the detection of the breast cancer and reduce the rate of accuracy of the CAD system.

B. Segmentation

The objective of the second processing stage is to identify the masses in mammograms. Generally, the identification of different masses is a very difficult task due to rich variations of gray level intensities in mammograms. In this paper we have used Otsu's N segmentation algorithm for segmentation of digital mammogram images. This algorithm represents an optimum global thresholding method proposed by [18] and later modified by [19] to threshold the image with multiple thresholds.

A multiclass Otsu's thresholding has been used to find the Region of Interest (ROI). Otsu's thresholding is a nonparametric and unsupervised method of automatic threshold selection for the image segmentation [19]. It is a simple procedure that utilizes the zeroth- and first-order moments of the graylevel histograms and it maximizes the between class variances, while minimizing the within class variances. Otsu's N segmentation can be described as follows.

Let the pixels of the input image be represented in L gray intensity levels $[0,1,...,L-1]$. The number of pixels

at level i is denoted by n_i . In order to simplify the discussion, the gray-level histogram is normalized by the total number of image pixels.

Suppose that N thresholds, k_j , $j = 1,...,N$, have been selected and they were used to threshold the image into $N+1$ classes, $C_1, C_2, ..., C_{N+1}$. Thus, class C_1 consists of pixels with intensity values in the range $[0, k_1]$, class C_2 consists of pixels with intensity values in the range $[k_1, k_2 - 1]$, etc. Using this thresholding, the probability, P_j , that a pixel is assigned to class C_j is given by the cumulative sum,

$$P_j = \sum_{i \in C_j} p_i \,, \tag{1}$$

The mean intensity values of the pixels assigned to class C_j is given by

$$\mu_j = \frac{1}{P_j} \sum_{i \in C_j} \quad , \tag{2}$$

while the global mean is given by

$$\mu_T = \sum_{i=0}^{L-1} i p_i . \tag{3}$$

Using discriminant analysis, Otsu defined the between-class variance of the thresholded image as

$$\sigma_B^2 = \sum_{j=1}^{N} P_j \left(\mu_j - \mu_T \right)^2 . \tag{4}$$

The optimal thresholds $\{k_1^*, k_2^*, ..., k_N^*\}$ are chosen by maximizing σ_B^2 as follows:

$$\begin{aligned} &\{k_1^*, k_2^*, ..., k_N^*\} = \text{Arg Max } \{\sigma_B^2(k_1, k_2, ..., k_N)\}, \\ &0 \le k_1 < ... < k_N < L. \end{aligned} \tag{5}$$

Fig. 2 shows typical mammogram and the output of each step during preprocessing and segmentation.

In order to solve the dependency problem of Zernike moments on translation, ROIs obtained after segmentation are centered by translation of the centroid of the mass into the center of the image ROI.

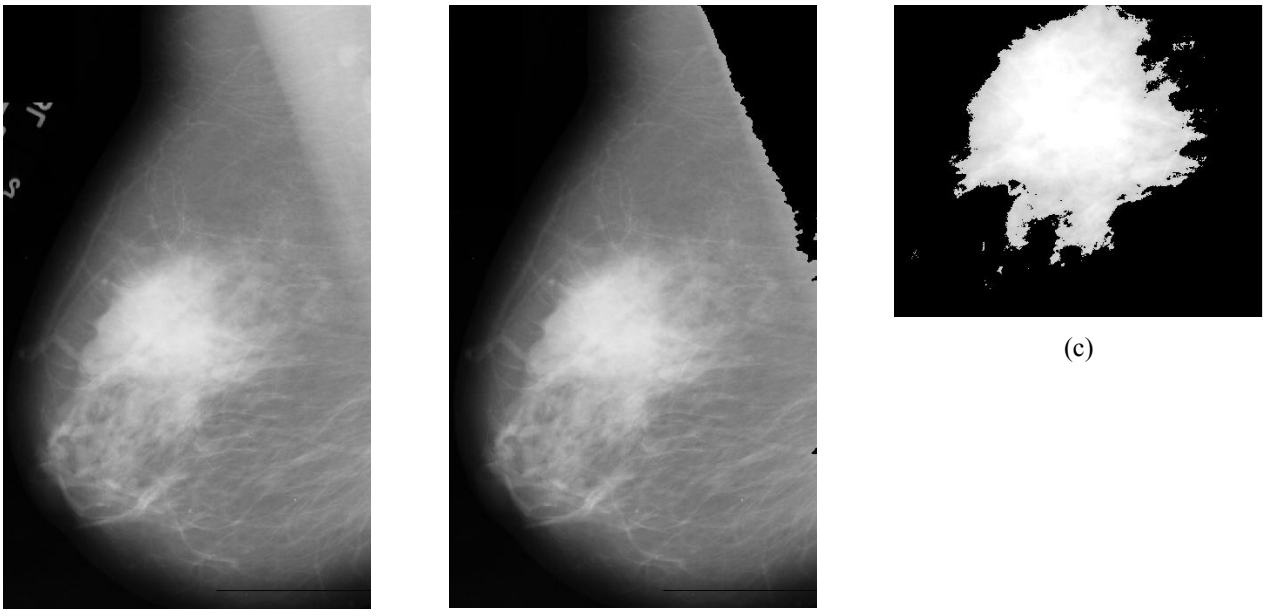
C. *Feature extraction*

Zernike moments represent a set of descriptors obtained using complex kernel functions based on Zernike polynomials. The main characteristic of these moments is their ability to describe a shape with minimum information redundancy (due to their orthogonality property), the robustness in noisy environments, and the fact that these moments are invariant to an arbitrary rotation of the describing shape.

The computation of Zernike moments from an input image includes three steps: computation of radial polynomials, computation of Zernike basis functions and computation of Zernike moments by projecting the image onto the Zernike basis functions [20 – 23]. For a digital image, the Zernike moment of order n , with repetition m is given by

$$Z_{nm} = \frac{n+1}{\pi} \sum_x \sum_y f(x,y) [V_{nm}(x,y)]^* , \tag{6}$$

where $x^2 + y^2 \le 1$. To compute Zernike moments of an image, the center of the image is taken as the origin and the pixel coordinates must be mapped to the range of the unit circle. The part of the original image inside the unit circle can be reconstructed with an arbitrary precision



(a) (b) (c)

Figure 2. Different segmentation steps. (a) Original Image. (b) Image after marking foreground. (c) Obtained ROI.

using

$$f(x,y) = \lim_{N\to\infty} \sum_{n=0}^{N} \sum_{m} A_{nm} V_{nm}(x,y), \quad (7)$$

where the second sum is taken over all $|m| \le n$, such that $n-|m|$ is even. $V_{nm}(x,y)$ is 2D Zernike basis function

$$V_{nm}(x,y) = V_{nm}(r,\theta) = R_{nm}(\rho) e^{jm\theta}, \quad (8)$$

where $\rho = \sqrt{x^2+y^2}$ is the length of the vector from the origin to a pixel (x,y), $\theta = \arctan(y/x)$ is the angle between the *x*-axis and the vector ρ in the counter-clockwise direction, and $R_{nm}(\rho)$ is a radial polynomial defined as follows

$$R_{nm}(\rho) = \sum_{s=0}^{\frac{n-|m|}{2}} (-1)^s \frac{(n-s)!}{s!\left(\frac{n+|m|}{2}-s\right)!\left(\frac{n-|m|}{2}-s\right)!} \rho^{n-2s} \quad (9)$$

High order Zernike moments have a large computational complexity and represent high sensitivity to noise. But with careful selection, these moments can be better descriptors of shape and density characteristics than the low-order Zernike moments. As in [23], a group of 32 low-order moments which satisfy the following conditions have been used:

$$Features = \left\{ Z_{n,m} \right\} \forall \begin{cases} 3 \le n \le 10 \\ |m| \le n \\ n-|m| = 2k \\ k \in \mathrm{N} \end{cases} \quad (10)$$

D. Classification

Neural networks have been successfully applied in many pattern recognition and machine learning systems. According to literature, the backpropagation algorithm is the most popular method for supervised training of multilayer neural networks. It employs gradient descent to attempt to minimize the squared error between the network output values and the target values for these outputs.

In the backpropagation neural networks, during training, the error must be propagated from the output layer back to hidden layer in order to perform the learning of the input-to-hidden weights. Multilayer networks typically use sigmoid transfer functions in the hidden layers. Sigmoid functions are characterized by the fact that their slope must approach zero as the input gets large. This causes a problem when using steepest descent to train a multilayer network with sigmoid functions, since the gradient can have a very small magnitude, and therefore cause small changes in the weights and biases, even though the weights and biases are far from their optimal values. Therefore, it is desirable to use resilient backpropagation training algorithm to eliminate these negative effects of the magnitudes of the partial derivatives. Only the sign of the derivative is used to determine the direction of the weight update, while the size of the weight change is determined by a separate update parameter. The weight update follows a simple rule: if the derivative is positive, which means an error increasing, the weight value is decreased by its update value, and if the derivative is negative, the weight value is increased by its update value.

The resilient backpropagation algorithm is generally much faster than the standard steepest descent algorithm and it requires only a modest increase in memory consumptions.

In this research, the input images were split in three sets intended for training, validation and testing of the neural network. The number of hidden layers and their nodes are being changed until the best network topology, which yields the best accuracy, is found. The final neural network consists of one input, one hidden and one output layer. The input and hidden layers have 32 nodes which match to the number of utilized features. The sigmoid function has been utilized as the activation function of all internal nodes. The output layer has one node which uses linear activation function.

III. EXPERIMENTS AND RESULTS

In this paper, the digital mammograms used for experimentation were taken from the Mammography Image Analysis Society (MIAS) database. It contains 322 digital mammograms belonging to the left and right breast of 161 different women. The acquired mammogram images are classified into three major classes: malignant, benign and normal, all of which are subdivided into five categories as follows: circumscribed masses, speculated masses, ill-defined masses, architecturally distorted masses and asymmetrical masses. From the viewpoint of breast tissue, these images have been categorized into three different classes: fatty, fatty-glandular, and dense-glandular. The images are digitized at 200 micron/pixel and padded in order to obtain all images with a size of 1024 × 1024 pixels. The digital mammograms are gray-scale images with an 8 bit pixel depth.

Through inspection of the segmented masses, it was noticed that the best result is for round-shape masses that have well-defined edges and they are segmented almost precisely. For non-circular cases, most false detections occurred for calcifications which consist of very small spots in mammograms, and speculated masses which are not segmented quite well.

Receiver operating characteristic (ROC) analysis was conducted to evaluate the classification system performance. The following terms, beside the area under ROC curve, were used as benchmark functions of proposed system:

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad (11)$$

$$Sensitivity = TPR = \frac{TP}{TP+FN} \quad (12)$$

$$Specificity = \frac{TN}{TN+FP} \quad (13)$$

where FP, FN, TP and TN denote false-positive, false-negative, true-positive and true-negative answers, respectively. Fig. 3 illustrates the ROCs of the system, separately for each type of masses.

The system yielded a malignant mass versus benign mass classification accuracy represented as an area (A_z) under ROC curve of 0.8920. The proposed approach tested on the MIAS database, resulted in 90.4 % success rate for classification malignant from benign masses using resilient backpropagation neural network. The sensitivity was 0.9216 and specificity was 0.9608.

It is a difficult task to critically compare the presented approach with various methods present in the literature due to several reasons. For example, the mammogram database used for the evaluation of the methods is different, the sample mammograms used for the experiments are different or a different experimental setup is used [8]. Table 1 shows a performance comparison of our method with other techniques on the basis of sensitivity, specificity and accuracy. The quantities that are not reported in the corresponding research works are indicated with dash symbol. The comparisons with the other classification systems published in the literature have confirmed the potential of the proposed method for further investigation.

IV. CONLUSION

In this paper, a novel computer-aided diagnosis system has been presented for mass detection and classification in breast mammography images. The proposed system is a fully autonomous. Input ROIs are obtained from the digital mammograms using image preprocessing and Otsu's N thresholding. After the first stage, a group of 32 Zernike moments with different orders and iterations are extracted from the ROIs. These moments have been applied to the resilient backpropagation neural network classifier.

Experimental results show that the proposed technique is able to classify efficiently malignant and benign mass types of abnormalities in digital mammograms.

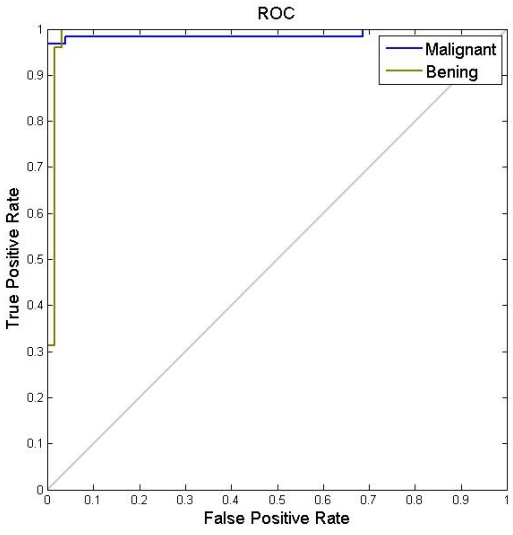


Figure 3. ROCs of the system

TABLE I. COMPARISON WITH STATE-OF-THE-ART METHODS BASED ON SENSITIVITY, SPECIFICITY AND ACCURACY

Author's name	Sensitivity	Specificity	Accuracy (%)
Menut et al. [4]	-	---	76.0
Hussain [9]	-	---	99.0
Gorgel et al. [16]	0.9470	0.7140	84.8
Islam et al. [15]	0.9091	0.8371	---
Proposed method	0.9216	0.9608	90.4

Nevertheless, there is the need to perform tests with a larger database and more complex cases in order to obtain a more precise behavior pattern.

Abstract – ***Thermal food preservation is a standard technique for reducing the microbial levels in food. The use of high pressure carbon dioxide (HPCD) has been proposed as alternative "cold pasteurization". It is known that excess CO_2 exerts inhibitory effects on cell growth and even cell death. For cell disruption and consequently cell death we can also use a method of a rapid decompression from a pressure vessel, known as a "cell bomb". In this study we have evaluated the effects of CO_2 on CHO cell growth and effects of a rapid decompression from relatively low pressure, 500 kPa. A rapid pressure decompression had no effect on cell growth. When CHO cells were exposed to the medium with dissolved CO_2 we noticed a small decrease in cell viability in exposures longer than 45 minutes.***

Key words: pasteurization, cell viability, CO_2

I. INTRODUCTION

Thermal food preservation is an old but almost standard technique for reducing the microbial count of foods. However, it has undesirable effects on organoleptic and nutritious quality of food, especially on its vitamin and mineral content.

Therefore nonthermal processing alternatives have been proposed, like electroporation and high hydrostatic pressure. Irreversible electroporation occurs when high electric field applied results in leakage of cellular components, which leads to cell death [2]. Preservation of food by electroporation maintains color and flavor, and the antioxidant levels are unaffected. During the last few years microbial deactivation using electric pulses has been proved in a variety of foods and beverages [3]. The effectiveness of the procedure depends on several parameters, e.g., pulse amplitude, duration, frequency and polarity, and temperature [4], that still have to be optimized. Although high hydrostatic pressure method maintain the quality of food as well as electroporation, it also has some limitations (the occurrence of pressure resistant vegetative bacteria after successive pressure treatments, the large investment costs, undefined regulatory and product safety related issues) that obstructing widespread use of the technology [1].

Interesting method for cell disruption using high hydrostatic pressure is also rapid decompression or the "cell bomb" method. In this process, cells are placed under high pressure (usually nitrogen or other inert gas up to about 170 MPa) within appropriate pressure chamber. The pressure is rapidly released. The rapid pressure drop causes the dissolved gas to be released as bubbles that ultimately lyse the cell [3].

Relatively new non-thermal pasteurization technique is the use of high-pressure carbon dioxide. In this process, food is contacted with either sub-or supercritical CO_2 for a certain amount of time in the series or continuous manner. Under such conditions (Tc = 31,1°C in Pc = 7,38 MPa) CO_2 has the unique ability to diffuse through solids like a gas, and dissolve materials like a liquid. Additionally, it can readily change in density upon minor changes in temperature or pressure. Using this technique gas (CO_2) pressure applied for preservation purposes is much lower (generally < 20 MPa) as compared to the high hydrostatic pressure method. Although a number of theories have been proposed to explain the bacteriostatic action of pressurized CO_2, the exact inactivation mechanisms are still under consideration [1].

Due to promising effects of CO_2 alone, it is also a good candidate for combined treatments, particularly in combination with ultrasound where it can produce additional cavitation seeds. For evaluation of combined treatment effects, it is important to be familiar with the effects of individual therapies. For this reason, we focused in the present study on the effects of CO_2 saturated medium on CHO cells. We evaluated the concentration of CO_2 in CO_2 saturated cell media, exposed CHO cells in CO_2 saturated medium for various time intervals and followed their 24h viability. We also tested »cell bomb« that was constructed using relatively low CO_2 pressure, i.e. 500 kPa.

II. METHODS

A. The cells

Ham's nutrient mixtures (F-12 HAM), trypsin/EDTA, fetal bovine serum (FBS), L-glutamine, crystal violet, phosphate buffered saline (PBS), antibiotics crystacillin and gentamicin were purchased from PAA Laboratories (PAA Laboratories, Pasching, Austria). Chinese hamster ovary cells CHO (European Collection of Cell Cultures, Salisbury, UK) were cultured in the humidified atmosphere at 37°C and 5% CO_2 in an incubator (Kambič, Semič, Slovenia). Cell growth media were supplemented with 10% fetal bovine serum (FBS), antibiotics (gentamicin, crystacillin) and L-glutamine. Cell growth medium was prepared at least 24 hours before experiments.

After adherent cell line reached 80-90% confluence in 150 cm^2 culture flask (TPP, Trasadingen, Switzerland), cells were carefully rinsed with 10 ml of Phosphate Buffered Saline (PBS) and detached using 10 ml of 0.25% trypsin/EDTA. Trypsin was present in the flask for 30 seconds. After trypsin solution was removed, cells were harvested and centrifuged (1000 rpm, 5 min, 4°C), and then re-suspended at concentration of $4*10^6$ cells/ml. Before each experiment cell suspension was carefully mixed by repeated pipetting until homogeneous suspension was obtained.

B. Preparation of a liquid saturated with CO_2

Pressurized carbon dioxide (CO_2) gas at 2 MPa was purchased from Messer Slovenia (Messer, Ljubljana, Slovenia). Pressure regulator valve kept output pressure in tubing at 500 kPa. Tubing was connected to a 0.5 liter plastic bottle, with a drilled hole on the "stopper", where the tubing was inserted into the bottle. A 75 ml of growth medium or water was added into the bottle. CO_2 gas was introduced into the liquid by increasing CO_2 partial pressure of air above liquid using compressed gas at 500 kPa for 300 s. The growth medium was slowly depressurized to ambient pressure for 10 seconds, and was used in experiments immediately after.

A CO_2 dissolved in water forms carbonic acid. Therefore after CO_2 pressurization of cell media a drop of pH is present that is exhibited as a color transition of pH indicator Phenol Red. A pH decrease was measured using SG2 pH meter (Mettler Toledo, Greifensee, Switzerland).

C. Concentration of CO_2 in the liquid

The concentration of dissolved gas in the liquid was determined by measuring system (Figure 1) adopted the modified Van Slyke manometric method. The method is not gas selective and it is easy to use.

The measuring system consists of a cylindrical container in which there is airtight rubber bladder, which is connected with the exterior through the tube. Cylindrical vessel concludes with a narrower dipstick, which closes above with the sealing screw. Before use rubber bladder is inflated and sealed. Then through the dipstick the cylindrical container is filed with a known volume of liquid and then the system is hermetically sealed. The pressure of the bladder is balanced with air pressure and the initial fluid level on the dipstick is marked. The air is sucked from the bladder with the vacuum pump; therefore the pressure inside the measuring system is reduced. Reduced partial gas pressure results in the release of gases from liquid. Gases are removed from the liquid until they reach a balance defined by Henry's Law, between the partial pressure of the gases above the liquid and the concentration of gases dissolved in the liquid. The speed of removing gas from the liquid is accelerated by shaking the device. After switching off the pump and equalizing the pressure in the bladder to the air pressure, the extracted gases accumulate on the top of the measuring tube. Then the volume of liquid displaced with the gases is measured. Experience has shown that the above procedure should be repeated three to four times. By knowing the initial volume of liquid and assuming the gas density a concentration of dissolved gases in the liquid can be calculated.

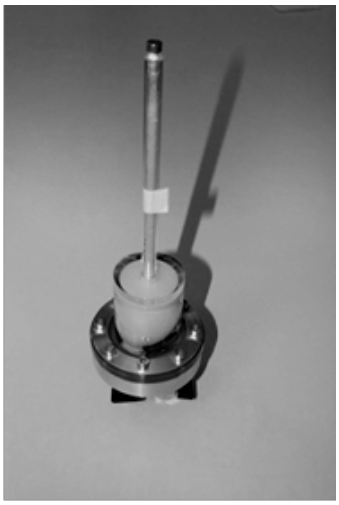

Figure 1: A measuring system for measuring the concentration of dissolves gases by the modified method of Van Slyke.

The concentration of CO_2 gas, which is dissolved in the medium F-12 HAM, after 300 second exposure to the bottle at a positive pressure of 500 kPa can be calculated according to Henry's Law:

$$p = k_H * c, \quad (1)$$

where p is the gas pressure above the solution, c is the concentration of gas and k_H is the Henry's constant, which depends on the solute, the solvent and the temperature (T).

Temperature dependence is described by the equation

$$k_H(T) = k_H(T^0)e^{[-C\left(\frac{1}{T}-\frac{1}{T^0}\right)]}, \quad (2)$$

where $k_H(T^0)$is the Henry's constant at room temperature (25 °C) and at 29.41 atm/mole/L, T_0 is room temperature (25 °C) and c is a constant for the CO_2 that is 2400 K [4].

D. CO_2 Cell bomb

Plastic bottle (Kokta, Droga Kolinska, Slovenia) filled with 20 ml of the cell suspension with a density of $4 * 10^4$ cells/ml was exposed to CO_2 overpressure of 500 kPa for 300 seconds. The bottle was connected through the control valve, which reduced the output pressure to 500 kPa, to the cylinder with compressed CO_2 with overpressure of 2 MPa. After the 300 second exposure a decompression is performed in two ways: by the slow opening of the bottle (15 seconds) and by the rapid opening of the bottle (< 1 second).

E. Cells in CO_2 saturated media

The PCR microtube (Sorenson BioDcience, Salt Lake City, UT, USA) was poured with 180 µl of cell culture medium or cell culture medium with added CO_2 gas. Then 60 µl of cell suspension with a concentration of $4 * 10^6$ cells/ml is added to the cup, so the final concentration of the cells in 240 µl of cell suspension was 10^6 cells/ml. Cells were exposed to a medium with added CO_2 up to 60 minutes. After the exposure the 80 µl of the

sample was planted on the plate with 96 wells and 20 ml of cell medium F-12 was added to the sample. Cells were incubated for 22 hours and then checked for their survival.

Control exposure was done in normal cell medium and served as a reference for normalization of the results.

Exposure of the cells to a medium with added CO_2 was carried out in four independently repeated experiments.

F. 24 hour cell viability

Cell viability was tested by means of CellTiter 96 AQueous One Solution Assay (MTS). After 22 hour incubation at 37°C and 5% CO_2 in an incubator (Kambič, Semič, Slovenia) 20µl of MTS reagent was added to each well. The cell plate was incubated for another 3 hours in an incubator. The absorbance was measured using micro plate reader Infinite M200 (Tecan, Männedorf, Switzerland). Cell viability was defined as:

$$x = \frac{OD_v - OD_{oz}}{OD_k - OD_{oz}} * 100\% \quad (3)$$

where x is percentage of viable cells, OD_v absorption value of treated cells, OD_k absorption value of control cells (100 % viability) and OD_{oz} absorption value of HAM F-12 media.

All results are reported as a mean value of 4 experiments. The spread of the data is given by standard deviation. The difference between the experimental and control group was analyzed using SigmaStat 11 software (Systat Software, Chicago, IL, USA) and determined with the use of t-test. The statistically significant difference was indicated by $p < 0.05$.

III. RESULTS

A. Concentration of CO_2 in distilled water and in CO_2 saturated HAM media

Using the system for measuring the concentration of dissolved gas in the liquid by the modified Van Slyke method the concentration of dissolved gases in the tap water, deionized water and in the cell medium HAM F-12 was measured. The results are presented as an average value of three independent experiments (Figure 2).

The average concentration of dissolved gases in tap water is 30.3 mg/l, in deionized water is 18.5 mg/l and in the cell medium HAM F-12 is 26.7 mg/l. The average density of the air at room temperature, $\rho = 1.184$ mg/l, was used as the density of the gas in the calculation of a concentration of dissolved gases in the liquid.

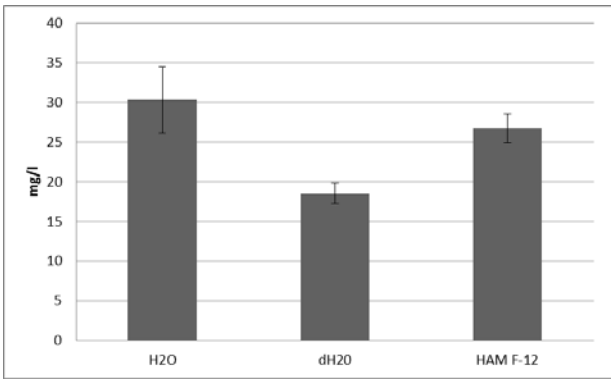

Figure 2: The concentration of dissolved air in tap water (H2O), deionized water (dH2O) and cell medium (HAM F-12) in miligrams per liter.

Cell culture medium was exposed to increased CO_2 partial pressure for 300 seconds. For comparison the same procedure was applied to deionized water as well. In these two cases we measured the volume of liquid that was displaced with the air and CO_2 gas. Therefore this volume was reduced with the volume of liquid that was displaced with the air alone. An average density of CO_2 at room temperature, $\rho = 1.842$ mg/l [8], was used as the density of the gas in the calculation of a concentration of dissolved CO_2 in the liquid. The results are presented as an average value of four or five independent experiments (Figure 3).

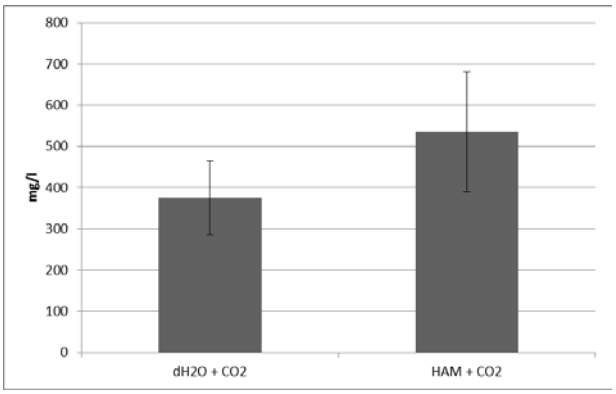

Figure 3: The concentratin of dissolved CO_2 gas in deionized water (dH2O + CO2) and in cell medium (HAM + CO2) in miligrams per liter.

The average concentration of dissolved CO_2 in deionized water is 375.2 mg/l while in the cell medium HAM F-12 is 535.1 mg/l.

B. pH of CO_2 saturated HAM media

After the cell medium was saturated with CO_2 it was closed in the PCR tube. The pH dropped from 7.6 to 5.85. After 30 minutes it stabilized at 5.93 (Figure 4).

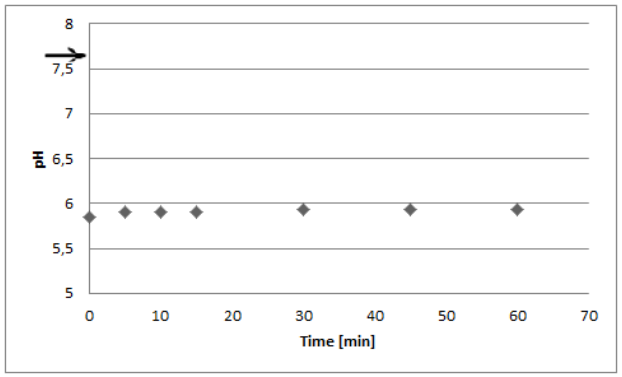

Figure 4: pH of the cell medium after saturation with CO_2. The arrow indicates the reference value of pH of the medium, i.e. 7.6.

C. *Cell viability in CO_2 saturated medium*

The cells in the PCR tube were exposed to CO_2 saturated medium. The PCR tube was closed during the exposure, therefore the reduced level of pH was maintained, as shown in figure 4. Cell viability test showed a reduction of viable cells after 60 minutes of exposure to CO_2 saturated medium (Figure 5).

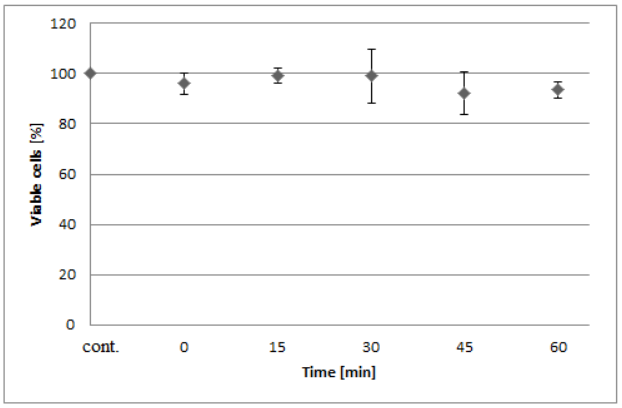

Figure 5: The percentage of viable cells exposed to CO_2 saturated medium. The cell viability was normalized to the control.

D. *CO_2 Cell bomb*

Immediately after decompression the cells were observed under a microscope (Zeiss AxioVert 200) at 400x magnification. There were no visible changes of cell morphology (Figure 6).

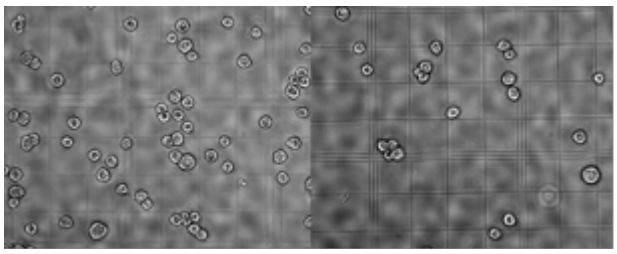

Figure 6: Cells after fast (left) and slow (right) decompression. There is no visible damage on cells.

Cell viability test showed no difference between the fast and slow decompression (Figure 7).

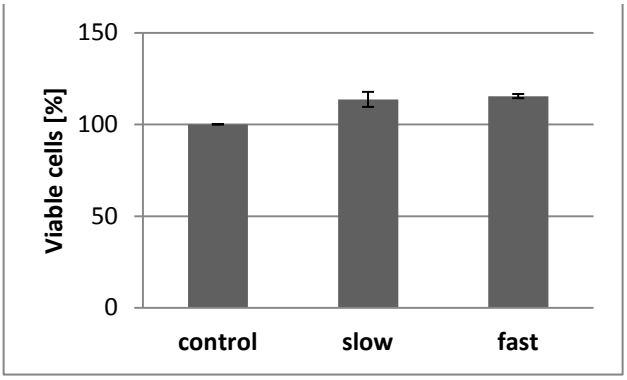

Figure 7: The percentage of viable cells after slow and fast decompression. The cell viability was normalized to the control.

IV. DISCUSSION

The use of CO_2 for preserving food started in 1939 with the study by Brown et al. [9] where apple cider was carbonated and microbial inactivation changes were record. Unlike toxic chemicals, CO_2 has less impact on the environment, leaves no residue on the food and is recyclable. Therefore its effects are still under consideration, especially in combination with some others nonthermal food preservation methods like electroporation and sonoporation.

In the present study, we analyzed the effects of CO_2 saturated medium on CHO cells. CO_2 is soluble in water and under increased partial CO_2 pressure the gas solubility even increases. The average concentration of dissolved CO_2 in the cell medium HAM F-12 after increasing CO_2 partial pressure above the medium to 500 kPa for 300 s was 535.1 mg/l. In comparison, the average concentration of dissolved CO_2 in deionized water under the same conditions was 375.2 mg/l.

CO_2 reacts with H_2O and forms carbonic acid. It causes a pH cell medium decrease from 7.6 to 5.8. We examined the cell survival in CO_2 saturated media over a period of 60 minutes. The results show that 45 minute exposure of cells to the medium with added CO_2 does not affect the cell survival. Longer exposure slightly reduced the proportion of viable cells.

Slow and fast decompression at relatively low pressure of 500 kPa, has no adverse effect on the cells. We assume that a small increase in the number of cells, which was detected in the slow and fast decompression, is the result of a slightly different handling of the cells in the control and the cells during the experiment.

According to presented results it can be concluded that short-term exposure of the CHO cells to cell medium with an increased concentration of CO_2 up to 535.1 mg/l has no adverse effect on CHO cells.

V. CONCLUSION

CO_2 addition is an alternative technique for reducing the microbial levels in food. Additional research is necessary for CO_2 alone or in combination with other agents to achieve levels of microbial deactivation known in thermal food preservation.

Abstract - Despite several methods that exist in different fields of life sciences, certain biotechnological applications still require microscopic analysis of the samples and in many instances, counting of cells. Some of those are drug delivery, transfection or analysis of mechanism fluorescent probes are used to detect cell viability, efficiency of a specific drug delivery or some other effect. For analysis and quantification of these results it is necessary to either manually or automatically count and analyze microscope images. However, in everyday use many researchers still count cells manually since existing solutions require either some specific knowledge of computer vision and/or manual fine tuning of various parameters.

Here we present a new software solution (named CellCounter) for automatic and semi-automatic cell counting of fluorescent microscopic images. This application is specifically designed for counting fluorescently stained cells. The program enables counting of cell nuclei or cell cytoplasm stained with different fluorescent stained. This simplifies image analysis for several biotechnological applications where fluorescent microscopy is used. We present results and validate the presented automatic cell counting program for cell viability application.

We give empirical results showing the efficiency of the proposed solution by comparing manual counts with the results returned by automated counting. We also show how the results can be further improved by combining manual and automated counts.

I. INTRODUCTION

Cell counting is one of the most fundamental tools in biology, medicine, and other life sciences. Several methods exist for quantification of different phenomena, but substantial part uses fluorescent dyes in combination with various protocols in order to analyze different processes. Fluorescently stained cells can be analyzed using flow cytometry[1], spectrofluorometry[2] and/or fluorescent microscopy[3]. There are of course other existing solutions for counting cells without the use of florescence, like counting with counting chambers (hemocytometer)[4], but those can be time consuming and also require detachment of the cells, which can result in their loss and damage. Fluorescent microscopy is also a standard method for visualization and quantification of different phenomena and many researchers rely on microscopic images and image analysis tools to obtain reliable quantitative data. Cell counting using microscopic images can be automated, and several semi-automatic and fully automatic solutions have been developed. In practice, however, such solutions require some additional input regarding various image parameters, such as thresholds, approximate nuclei distances, contrast settings, etc. These parameters require specific knowledge of image processing, which is not common among life-science experts.

Currently, several programs for cell counting are already available. From many commercial solutions, such as MetaMorph [5] (Molecula Devices, Downingtoetn, PA, USA), BioQuant [6] (Image Analysis Corporation, Nashville, TN, USA), Image-Pro [7] (Media Cybernetics, Bethesda, MD, USA) and SynenTec [8], to free software such as ITCN ImageJ Plugin [9] (US National Institute of Health, Bethesda, MD; USA), CellProfiler [10], UTHSCSA ImageTool (University of Texas Health Science Center, San Antorio, TX, USA) [11] and CellC [12]. However, all of the existing solutions require some additional input or even some image pre-processing of the raw images, which is not only time-consuming but can also be also less user-friendly for life scientists [13].

Besides the human factors, full automatisation of cell counting faces several technical obstacles. Some of the most common problems, are: i) a wide variety of assays and cell types resulting in a range of objects which are hard to generalize, ii) this can be even more problematic due to uneven illumination and other equipment related factors, such as electronic and/or optical noise that lead to images having variable contrast and quality [14], iii) cells can have a varying density in the cell culture and can overlap [15], iv) extracellular debris and internal cell structures can interfere with the recognition algorithm, giving false results and v) depending on the microscopy technique used, images can have low contrast therefore detection of individual nuclei in multinucleated cells is difficult.

In this article we present a novel structured method for effective cell counting which does not require any specific knowledge of image processing. The method is specifically designed for counting fluorescently stained cells, that are used in many applications from assays for measuring cell viability [16] to determination of transfection efficiency [17–19]. We also show that the presented solution has been already intensively implemented for cell counting of different sets of experiments and it has drastically improved the typical workflow of researchers, as it is shown in our empirical evaluation.

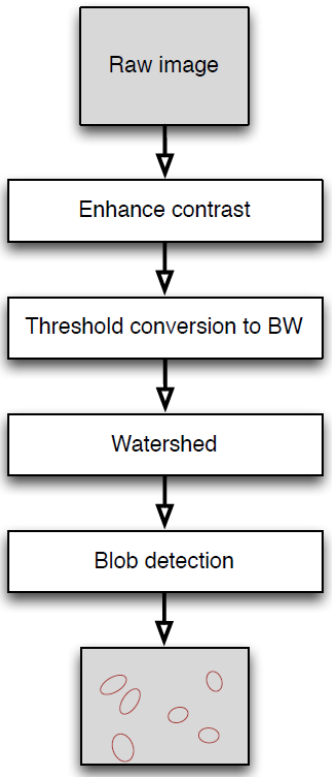

Figure 1. Schematic overview of the cell-counting method

II. MATERIALS AND METHODS

A. *Algorithm used*

The presented program was written in C\# and uses an open source C\# framework designed for developers and researchers in the fields of Computer Vision and Artificial Intelligence (AForge.NET [20]). The algorithm used in the program can be viewed as a simple dataflow of images passing through various image processing algorithms. The sequence of these algorithms was determined empirically by trying to overcome as many problems on a sample set of images as possible. The schematic overview of our method is shown in Fig. 1 and will be described in detail below.

The algorithm first addressed the problem of the image contrast, which is can be really low on microscopic images and not necessarily distributed evenly throughout the image due to uneven illumination or other optical problems. The contrast of the image is thus improved using the Contrast Limited Adaptive Histogram Equalization (CLAHE) algorithm [21–23]. It differs from ordinary histogram equalization in the respect that the adaptive method computes several histograms, each corresponding to a distinct section of the image, and uses them to redistribute the brightness values of the image. It is therefore suitable for improving the local contrast of an image and bringing out more detail. In our solution, the image is cut into 64 (8 × 8) disjoint sections and histogram equalization is applied on each part independently. Within each image part, local maximum and minimum pixel intensity are calculated and the intensities are proportionally adjusted to the scale ranging from 0 to 255. The individual parts are then recomposed again using interpolation at image borders. The final image has better contrast and can reveal more local information (Fig. 2).

Next step is converting grey-scale images to black-white images where the object borders are defined using a threshold algorithm. In this step, Otsu Threshold algorithm [24], [25] was used, as it gave slightly better results compared to other tested algorithms (Huang, Renyi entropy method, and other). In this algorithm, the threshold value t is defined as the value that gives the minimal intra-class variance defined by:

$$\omega(t)\,\sigma_1^2(t) + \omega_2(t)\sigma_2^2(t)$$

where ω_1 (ω_2) is the probability that the pixel value in the image is lower (higher) than t and σ_1^2 (σ_2^2) is the variance of the pixel values lower (higher) than t.

In cell cultures, cells tend to grow in close proximity, touch or even overlap, resulting in connected objects on the images. To split the overlapping (touching) objects, the Watershed algorithm [26] was applied. The image is eroded on the watershed lines, which usually represent exactly the borders between different cells. This enables the detection of individual cells, even multinucleated and overlapping cells (Fig. 2). Next, the connected regions are counted using classical blob detection algorithm [27], which counts the objects separated by black background.

Although the counting algorithm is robust, as we will show in the following sections, the miscounts can still occur on more problematic images. To correct erroneously counted objects, a function was added to the user interface that enables the user to add or remove objects from the count with a mouse click. This will be

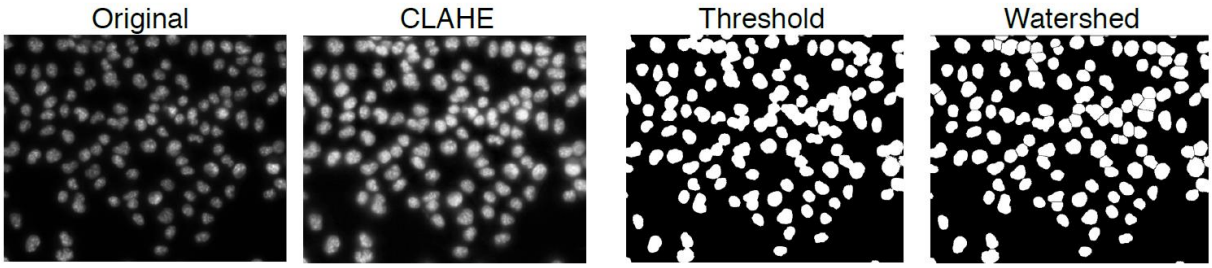

Figure 2. A sequence of images produced by the program on a sample image.

referred as a semi-automatic counting henceforth.

B. Cell culturing

The experiments used for program validation were done on Chinese hamster ovary cells (CHO) grown in Ham's tissue culture medium for mammalian cells (HAM) supplemented with 10% fetal bovine serum (FBS) at 37°C in 5% CO_2-enriched air at saturation humidity. All experiments were performed on 24 h old cell cultures in exponential growth phase.

C. Nanoparticles and cell viability

The cell viability experiment was performed as described previously [12]. Briefly, cells were incubated with increasing concentration of polycationic polymer coated magnetic nanoparticles for 24 h and stained with two fluorescent dyes; Hoechst 33342, which stained all cell nuclei, and propidium iodide (PI), which differentially stained only dead cells. At least 15 visual fields at 200 × magnification were taken of each sample for each used fluorescent dye using a fluorescent microscope (Zeiss 200, Axiovert, Germany). The images were recorded by MetaMorph imaging system software (Visitron, Germany) and saved in TIF format.

D. Cell counting

The algorithm was developed and optimized based on microscopic images obtained from several different types of experiments and experimental repeats, but for evaluation of the program efficiency, one random experiment was selected.

Cells on the images of the selected experiment were counted using only CellCounter (automatic), by manually correcting CellCounter's results (semi-automatic) and by manually counting using ImageJ software (manual) (v1.45s, National Institute of Health, USA). Three people counted the experiment independently to determine inter-personal error. Counting time was noted for each counting step. Results are expressed as mean ± standard error (SE).

III. Results and Discussion

We have developed an algorithm for automatic cell counting of fluorescently stained cells. As an example to evaluate the program, cells were stained with blue fluorescent dye Hoechst and with red fluorescent dye PI. The program can also be used to count cells or objects labeled with other fluorescent markers, like green fluorescent protein (GFP) [13], [14].

The algorithm of our program works by improving the contrast of bright objects on the images (in our case fluorescently stained nuclei and/or cytoplasm) and converts the obtained grey-scale images to black-white images on which the automatic counting is applied. As such, the program does not require images with objects that have only clear borders and was found quite flexible/robust in determining accurate numbers of cells even if the quality of images is not ideal. As seen from Fig. 3, the program is able to count cells on out of focus images with relatively small errors. This allows less accurate and thus faster acquisition of images for counting. Also, because the algorithm does not rely on size or shape of the objects, the program can be applied to fluorescent images of any appropriately stained cell line, as already confirmed for several different cell types (results not shown).

Cells of the same experiment were stained with Hoechst, which stains all cell nuclei, thus giving us the total number of the cells (Fig. 4), and with PI, which only stains dead or damaged cells (Fig. 5, Fig. 6). This combination of dyes can be used to determine cell viability [12]. To obtain the number of viable cells, which was the purpose of the experiment, the number of dead cells was subtracted from the number of all cells (Fig. 7).

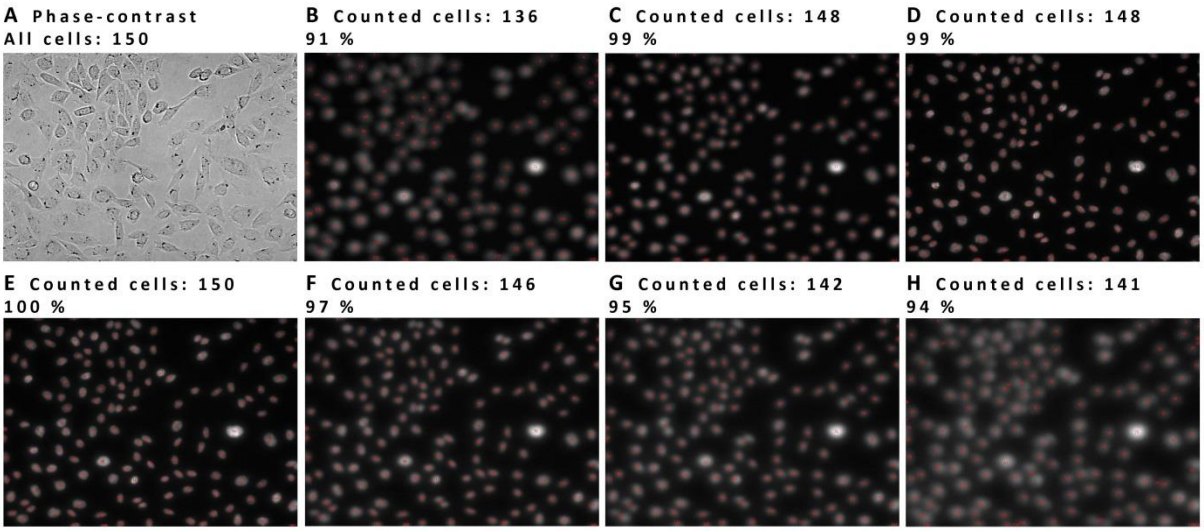

Figure 3. A demonstration of the robustness of the program. The figures are images of Hoechst stained nuclei on the same visual field obtained on different out of focus planes, under (B, C, D) or above (F, G, H) the plane in focus (E). The total number of cells was obtained by manually counting the cells on phase contrast image. Above each image are given the total number of automatically counted cells and the percentage of the cells compared to manual count. The fluorescent image in focus (E) gave a 100% counting accuracy.

All images were counted by three users to obtain the inter-personal error and the differences in obtained counting results for all three applied counting methods; manual, semi-automatic and automatic counting.

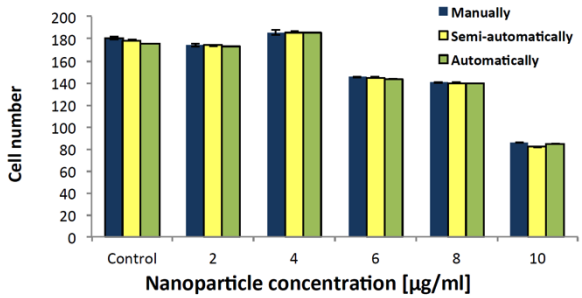

Figure 4. Comparison of counting results obtained by counting fluorescently stained cell nuclei to determine the total number of CHO cells after exposure to increasing concentration of nanoparticles for 24 h. Three counting methods were used: manually by counting Hoechst positive cells using ImageJ software, semi-automatically by correcting CellCounter counts and automatically by using CellCounter only. The results presented the average percentage of viability for separate samples compared to non-exposed control obtained by independent counting of the same experiment by three users with corresponding standard error (N=3).

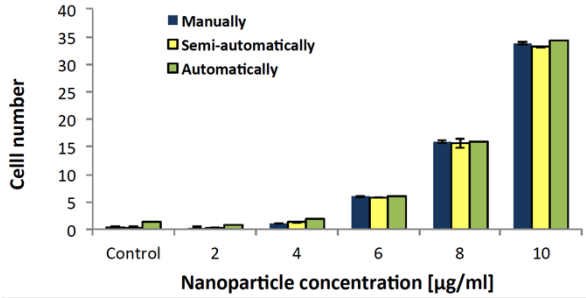

Figure 5: Comparison of counting results obtained by counting fluorescently PI stained cell to determine the number of dead CHO cells as a measure of cytotoxicity of increasing concentration of nanoparticles for 24 h. Three counting methods were used: manually by counting PI positive cells using ImageJ software, semi-automatically by correcting CellCounter counts and automatically by using CellCounter only. The results presented are average cell numbers for separate samples obtained by independent counting of the same experiment by three users with corresponding standard error (N=3).

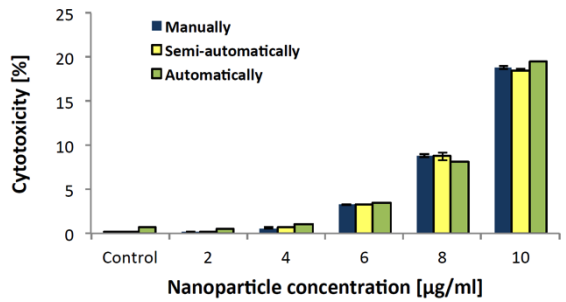

Figure 6. Comparison of counting results obtained by counting fluorescently stained cell nuclei to determine the number of dead CHO cells as a measure of cytotoxicity of increasing concentration of nanoparticles for 24 h. Three counting methods were used: manually by counting PI positive cells using ImageJ software, semi-automatically by correcting CellCounter counts and automatically by using CellCounter only. The results presented the average percentage of toxicity for separate samples compared to the number of all cells in non-exposed control obtained by independent counting of the same experiment by three users with corresponding standard error (N=3).

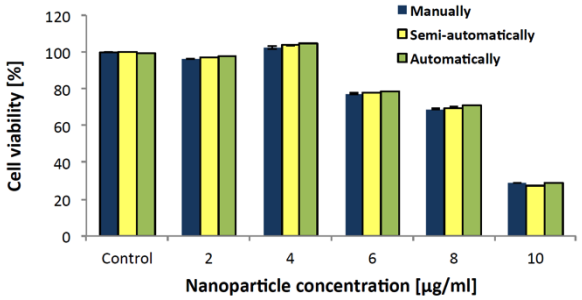

Figure 7. Comparison of counting results obtained by counting fluorescently stained cell nuclei (stained with Hoechst) reduced by the number of dead cells (stained with PI) to determine the viability of CHO cells exposed to increasing concentration of nanoparticles for 24 h. Three counting methods were used: manually by counting Hoechst positive cells using ImageJ software, semi-automatically by correcting CellCounter counts and automatically by using CellCounter only. The results presented are average cell numbers for separate samples obtained by independent counting of the same experiment by three users with corresponding standard error (N=3).

The counting results for all three counting methods showed reasonably good correlation and small standard errors, indicating also a relatively low inter-personal error as shown in Figs. 4-7. The differences between manual or semi-automatic counting and automatic counting are mostly due to two or more objects in substantial contact being counted as one or due to objects positioned predominantly outside of the margin of the image. Generally, we observed better performance in images with fewer and randomly scattered objects. On the other hand, the program had problems recognizing the right objects on images with low contrast, either images with no cells or with dimly stained cells. Still, the obtained differences are small compared to the expected deviations between repeated experiments, indicating the algorithm is robust enough and can be used as a helpful aid for image analysis.

Simultaneously, time required for counting with each counting method (automatic, semi-automatic or manual) was recorded for all three users. As seen from Fig. 8, the

program significantly reduces the time necessary to count the acquired images from hours (manual counting) to minutes (semi-automatic counting) or even seconds (automatic counting), depending on the required accuracy of the results.

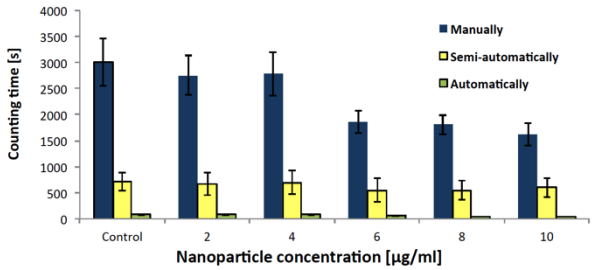

Figure 8. Comparison of counting time using three counting methods: manually by counting Hoechst and PI positive cells using ImageJ software, semi-automatically by correcting CellCounter counts and automatically by using CellCounter only. The results presented are average counting times for separate samples of three independent users with corresponding standard error (N = 3).

Moreover, the requirements of installation of CellCounter program are minimal, the interface is user friendly (Fig. 9), requiring no additional image manipulation or tuning of parameters to get reliable results (RAW images as obtained from the microscope can be used). Images can be loaded through the interface or by simple drag and drop action. The program counts the cells automatically as soon as the user selects the image, and allows simple corrections to the program count by adding or removing hits on the selected image with simple mouse clicks. The program also enables to skip a non-representative image. The results are automatically ordered and can be easily copied to clipboard to transfer them to the editing program of choice.

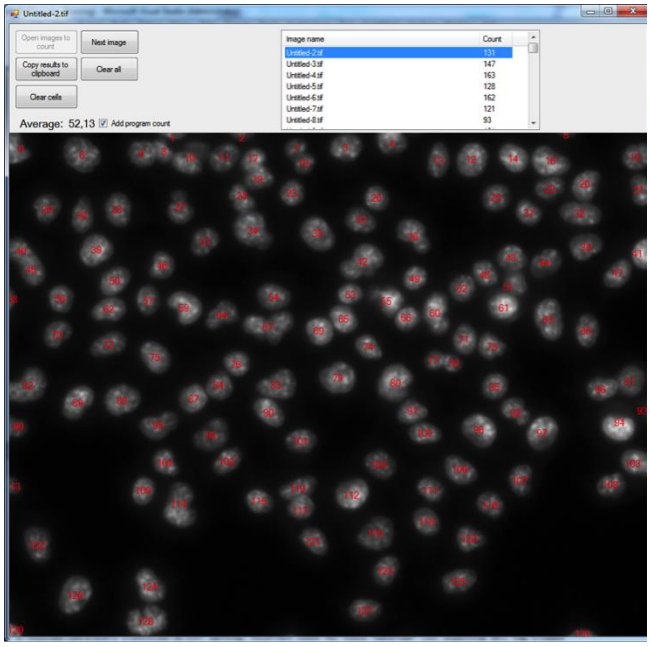

Figure 9. A screenshot of the CellCounter program interface showing the result of one automatic count. Each object (cell) is labeled so the user can quickly assert the accuracy of the counting event.

IV. Conclusions

In this article, we present an alternative solution for automatic and semi-automatic counting of cells on fluorescent microscopic images. As we showed in this paper, the program enables consistent, robust, fast and adequately accurate determination of fluorescent cells and can therefore be applied to a range of different applications in different fields of life sciences where fluorescent labeling is used for quantification of different phenomena.

Acknowledgment

The authors would like to thank David Karlaš for the help with the program and Klemen Strojan and Maja Jankovec for their help with the manual cell counting. This work was supported by Slovenian Research Agency within project J4-4324, young researchers program and MRIC UL IP-0510 Infrastructure program.

Morphological Changes of Pressure Pulses in Oscillometric Non-Invasive Blood Pressure Measurements

V. Avbelj

viktor.avbelj@ijs.si

Abstract – The oscillometric method is the most widely used method for automatic non-invasive blood pressure measurements. An oscillometric device computes systolic and diastolic blood pressures from pressure oscillations in the cuff during slow deflation. Normally only the envelope of the pressure oscillations in the cuff is used. A closer look at these oscillations shows that the morphology of the oscillation pulses is changing during the deflation. The evolution of morphology is different from person to person indicating that further information about cardiovascular status is present in the data morphology. We present a set of morphology characteristics of pressure oscillations in a small group of adults. Greater knowledge of morphology could lead to a better accuracy of blood pressure monitoring in the medical and home use.

I. INTRODUCTION

A stethoscope in hands of a doctor together with an inflatable cuff and a manometer are the requisites for non-invasive determination of blood pressure parameters by the method of Riva-Rocci and Korotkoff, which is still the reference non-invasive method (auscultatory method). An automatic blood pressure meter is one of the most popular medical instruments used at home. These devices mostly use oscillometric method, where the blood pressure parameters are estimated from small oscillations of the pressure in the cuff during its deflation. Nowadays, such oscillometric devices are replacing the conventional auscultatory method also in the clinical environment.

During an oscillometric measurement, first the cuff on the arm is inflated until the blood circulation stops. Many devices also measure the small pressure oscillations during the inflation to stop inflating the cuff with regard to individual blood pressure. After that, the device slowly deflates the cuff and measures the pressure. It is recommended that the deflation rate of 2-3 mmHg/s is used [1]. The amplitude of small pressure oscillations first rises and then falls. At the end, the cuff is completely deflated at a fast rate (Figure 1). Currently available automated blood pressure measuring devices use oscillometric method based on empirically derived algorithms (patent protected) to calculate the systolic (SBP) and diastolic (DBP) blood pressure [2]. There are two basic algorithms for calculation of the SBP and the DBP from the oscillometric measurement.

The study was supported in part by the Slovenian Research Agency under grant P2-0095.

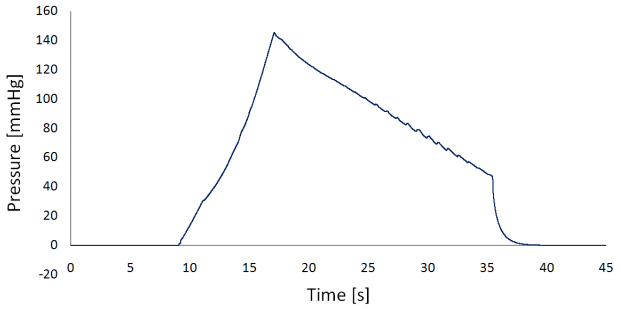

Figure 1. Pressure in the cuff during the complete measurement cycle. Pay attention to small oscillations during the deflation portion of the procedure.

The first is based on the determination of the pressure at the peak of the oscillometric envelope. This peak emerges around the mean arterial pressure (MAP). From the MAP, the SBP and the DBP are computed, in simple cases, as empirically defined fixed ratios relative to the MAP. For example, if the ratio for DBP was defined as 0.7 the DBP value is determined as pressure at the time, where the amplitude of the oscillometric envelope is reduced to 0.7 of its' maximal value. The second algorithm is slope-based where the inflection points of the oscillometric envelope define the SBP and the DBP [3]. The SBP is the pressure where the derivative of the envelope has a maximum and the DBP where the derivative has a minimum. In this case, the determination of the peak value of the envelope is not needed.

In a study of Jazbinsek et al. [4] authors compared oscillations of the pressure in the cuff with the Korotkoff sounds obtained from a microphone implanted in the cuff. They found that the higher frequency portion of the microphone signal can be directly related to the conventional auscultatory method and that the shape of this signal can be used for automatic determination of the SBP and the DBP.

The oscillometric envelope of real measurements is rarely a monotonically rising or falling function; therefore, the determination of the peak of the envelope and the derivatives is not a simple task (Figure 2). To solve this problem, the known algorithms attempt to smooth the oscillometric envelope appropriately. Some do this in the time-domain, for instance by filtering, others in the frequency-domain. The result is much smoother envelope of the oscillometric signal that enables "correct"

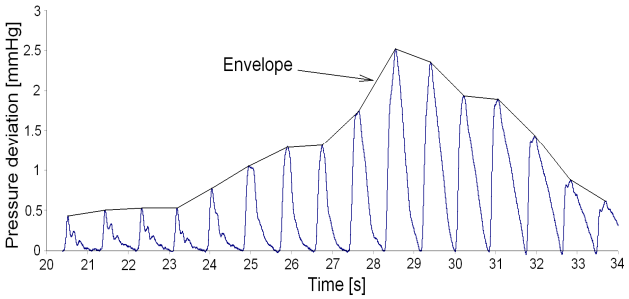

Figure 2. Raw oscillometric signal presented as zoomed pressure deviations from the down-sloping deflation pressure shown in Figure 1. An example of an envelope is shown as lines connecting the peak values of the oscillometric signal.

determination of the peak and the derivative of the signal. However, any process of smoothing definitely throws away the high frequency information of the raw signal.

In the study of Van Moer et al. [5] authors proposed a method based on a frequency-domain signal-processing approach. They linearize the oscillometric blood-pressure measurements by removing some spectral components of the raw signal and thus obtain a smooth envelope. The pressure at the peak of the envelope is declared as the MAP from which the SBP and the DBP were computed as fixed ratios to the MAP (0.52 and 0.7 respectively). Comparing the SBP and the DBP to the values from commercial non-invasive blood pressure meter (NIBP) and to the values obtained by the golden standard auscultatory method, authors concluded that their linearization is more capable of avoiding the extreme values since the procedure is less sensitive to outliers, noise, and leakage effects in comparison to the results from NIBP.

Is it worth throwing away high frequency components of the oscillometric signal? In this paper, we observe the oscillometric signal in time-domain, trying to preserve all frequency components. The main objective is to determine how the morphological changes in the oscillometric signal which occur during the deflation of the cuff could be used in blood-pressure measurements.

II. METHODS

A commercial and approved NIBP (Omron M6, HEM-7001-E) [6] was adapted with an additional pressure transducer and custom designed amplifier connected with a glass Y shaped piece to the rubber tube near the cuff. During blood pressure measurements the amplified signal was sampled with a digital oscilloscope (PicoScope 4424). The resolution was enhanced by oversampling (19.6 kHz) filtering and decimation to a final 100 Hz low-pass filtered output signal that was stored on a laptop computer for further processing.

A typical measurement is shown in Figure 1. At first, a fast inflation can be observed at a constant rate up to 30 mmHg when the adaptive inflation takes place up to 145 mmHg where the deflation begins. After some transitional instability of the pressure during the first seconds of the deflation, the deflation rate is constant (4.9 mmHg/s) till the end of the measurement when a fast deflation occurs. We made 40 measurements of blood pressure with 5 subjects. Each subject was measured once, except the one that was measured on 5 consecutive days with up to 8 measurements per day. We present here only the measurements of two subjects, where the first had low blood pressure values and the second had high. The repetitive measurements (36) of one subject will serve for the analysis of repeatability of the procedures in the future research.

To compare the pressure oscillation waveforms, the signal of the deflation part was segmented beat by beat. The segments were superimposed as shown in Figure 3. The synchronization point was set in the middle of the first upslope portion of each segment. The start time 0 s of each segment was set to 76.5 ms before the synchronization point. Thus the whole beginning portion of the upslope signal could be seen. The pressure deviation at start time was set to 0 mmHg (clamping).

III. RESULTS

Thorough examination of the pressure pulses of a person with a low blood pressure (NIBP values: SBP - 93 mmHg, DBP - 62 mmHg) shows the characteristics listed below. At Beat 1, which is the ninth beat (-9 in Figure 3) before the beat with the maximum pressure pulse M, three distinct waves can be seen with maximal amplitude of around 0.4 mmHg. Next three pulses (-8, -7 and -6) have also three distinct waves but with a little bit larger amplitudes. Pulse -5 has three waves, with the first much larger than the following two, and with the amplitude of the first wave 0.75 mmHg. Pulse -4 has the first two waves nearly fused and after the second wave, the signal falls down to the third wave.

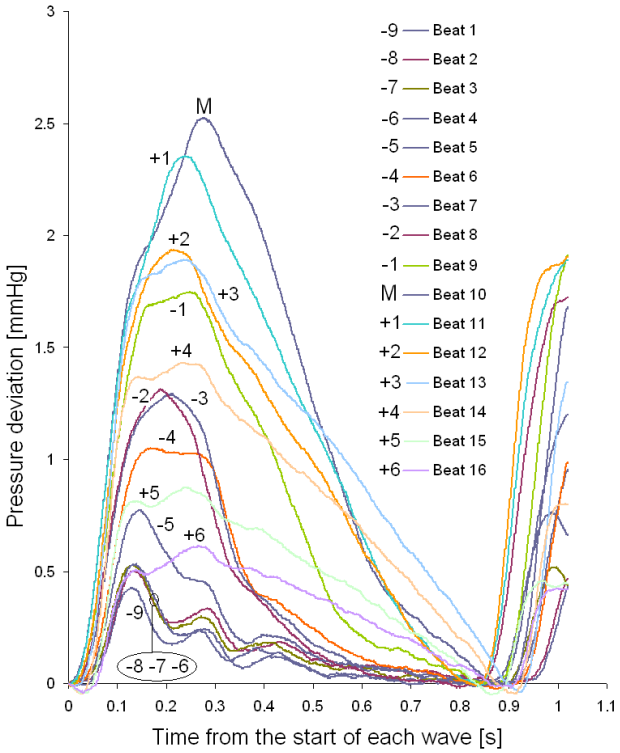

Figure 3. Aligned pressure pulses during deflation of a cuff. The pressure pulse with maximal amplitude that occurs in beat 10 is denoted by M. The previous beat is denoted by -1 and so on. The signals are taken from the measurement presented in Figure 1.

Pulses -3 and -2 are very similar with only a single peak, which is probably a fusion of the first two waves, with a fast down-slope up to time 0.35 s, where the slope changes. Pulse -1 is also modulated by three waves and has a fast down-slope that reaches the half amplitude around 0.45 s. The next pulse M has the maximal amplitude and also a fast down-slope that reaches the half of amplitude around 0.5 s. Pulse +1 with some lower amplitude, has lower down-slope rate as pulse M, but reaches the half of amplitude value at the same time as the pulse M. Finally, last five pulses (+2, +3, +4, +5 and +6) have similar morphologies and progressively lower amplitudes and down-slope constants. The largest difference of the pulses before M in comparison to the pulses after M is in the down-slope portion of the signal. In fact, the morphology of the pulses determines if a pulse is before or after the pulse M.

Another example from a person with a high blood pressure (NIBP values: SBP - 144 mmHg, DBP - 90 mmHg) is shown in Figure 4. As in Figure 3, the first two pulses (-14 and -13) in Figure 4 have distinct three waves but they are more fused. Again the pulses before M, up to the pulse -5, have fast down-slope portion. After that the down-slope portion needs progressively more time to reach the baseline level. In distinction to the previous example, here three pulses before M and one pulse after M have nearly the same amplitude as pulse M but again progressively needs more time to reach the baseline level as one observes the pulses from -3 to +1. A significant distinction between pulses -1 and M is shown in Figure 5. In pulse M, there is a slope transition point at 0.32 s where the pressure begins to fall with a slower rate.

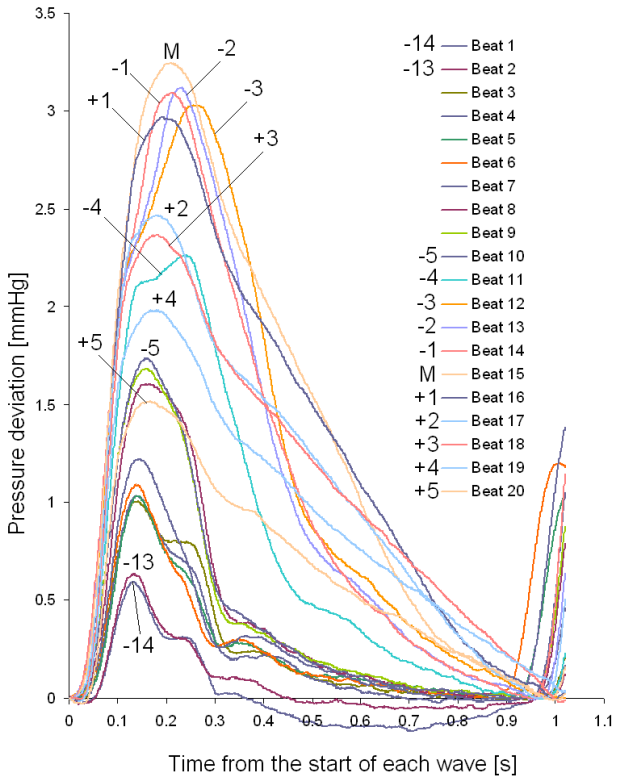

Figure 4. Aligned pressure pulses during deflation of a cuff from a person with a high SBP and DBP. The pressure pulse with maximal amplitude is denoted by M.

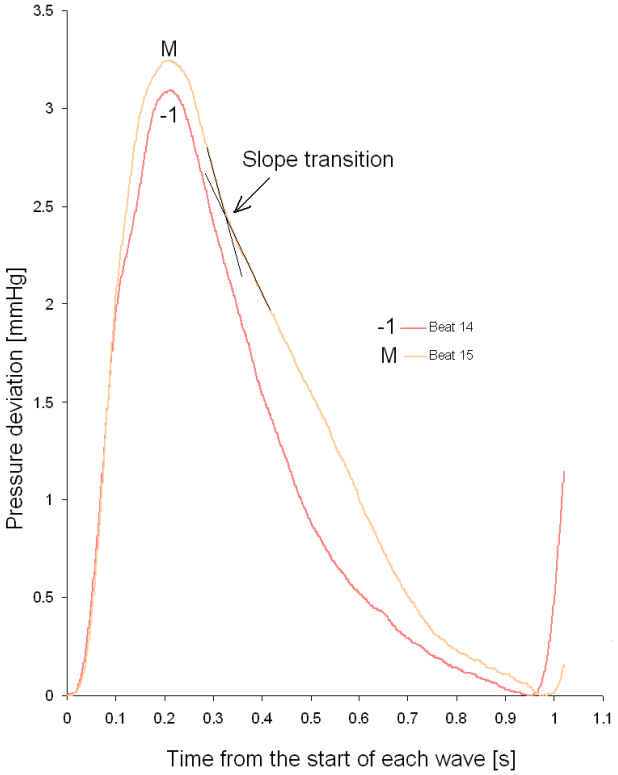

Figure 5. Different morphologies of the two successive pressure pulses (-1 and M) with a slope transition in pulse M.

Note that pulses before M, starting with pulse -1, have no such transitions so close to the peak of the pulse. We can conclude that the morphology of pulses holds additional information as in the previous case from Figure 3.

IV. Discussion and Conclusions

Today, oscillometric blood-pressure devices heavily depend on the envelope of the oscillometric signal. The smoothing of the envelope can produce better results on average, but still there are many failed results – outliers. To the best of our knowledge the presented study includes, for the first time, all the information of the oscillometric signal with no attempt to smooth out the envelope. A thorough examination of the measured signals with the proposed approach can enhance the accuracy of future oscillometric blood-pressure devices. We believe that losing information by smoothing the measured signals does not pay off.

In the future research of "what is going on" under the cuff during the measurement, it would be of great help to have an ECG signal and a respiration signal measured at the same time. A lot of previous research work was published that is related to applications of body sensors. In a previous work [7], it was shown in an animal study, that vessel clamps, equipped with force sensors, can provide an ECG signal with additional information about the blood-pressure inside the vessel. However, additional sensors should be unobtrusive not to further influence the blood pressure measurements.

A lot of studies and technological developments have been done elsewhere to improve the acceptance of body

sensor technology. Modern ECG sensors are non obtrusive, multifunctional, lightweight and battery powered wireless devices presented in our previous papers [8-11]. The problem of synchronization of independent wireless sensors was addressed in [12] and in another study [13], where the question if the heart rate variability could be assessed through blood pressure measurements is discussed. Cuff sensors can use a smart phone for the acquisition device as described in [14]. The positions of the electrodes should be carefully selected [15], so with the use of three pairs of electrodes, also the standard 12-lead ECG could be synthesized [16].

It is known that the procedures, performed during blood pressure measurements can influence the value of the blood pressure (white coat syndrome). Also, an occlusion of arteries in the arm by the cuff can do the same. In future validations of the NIMBs, the precise measurements and analyses [17] of physiologic parameters are needed with high resolution and multichannel devices [18].

We have shown that contemporary NIMB devices for measurements of blood pressure do not take full advantage of the available signal. The details in the morphology of oscillometric signal designate the vicinity of the maximal pulse wave so the envelope is not needed. If we have both, the envelope and the evolution of the details in the pulse waves, the pressure values could be determined with higher reliability. We analysed only the measurements of 5 subjects, therefore definite conclusions will be possible after an extended analysis of measurements from many different people. It is also possible that the details in morphology have additional information about the status of cardiovascular system, but this has yet to be determined.

Further efforts will be needed to improve the outcome of this routine and broadly accepted non-invasive blood pressure measurement procedure that could provide, possibly with added sensors on the cuff or body, higher value of the diagnostic outcome.

ABSTRACT

INTRODUCTION: Pedicle screw fixation is a standard procedure of spinal instrumentation. The aim of this work was to evaluate accuracy and safety of using personalized guiding templates for pedicle screw placement on thoracic spine.

METHODS AND RESULTS: We performed a computer tomography (CT) scan of the spine specimen to acquire virtual 3D model of the spine. Computer software (EBS™, Ekliptik, Slovenija) was used to design drill templates according to pedicle trajectories. Drill templates were then printed out of the biocompatible polymer using 3D printing technology. Templates were placed on the anatomic specimen vertebras anchoring at three sites – on the lamina at the base of the superior articular process on both sides and at the tip of the spinous process. Holes were drilled, and 3,5 mm screws inserted from T1 do T7 (7 pairs) using custom template for each vertebrae. CT scan was obtained after screw placement to evaluate screw positions. 13 screws were inside of pedicle trajectory without violation of pedicle wall with the tip inside of the vertebral body. One screw perforated medial pedicle wall.

CONCLUSION: The potential use of such a navigational template to insert thoracic pedicle screws in spinal instrumentation is promising. This novel method could improve the accuracy of pedicle screw insertion and reduce the operating time and radiation exposure of spinal fixation surgery.

I. INTRODUCTION

Pedicle screw fixation is a frequent procedure of spinal surgery. Accurate screw placement is essential to avoid injury to the adjacent structures - the vessels, nerves, and viscera[1]. Pedicle screw placement is complex and technically demanding procedure with a steep learning curve[2]. There is limited visibility of spinal anatomical landmarks during surgery; so, it is important to gain a conceptualization of anatomy of the spinal structures that are hidden from direct view[3]. The accuracy with which screws are inserted in the pedicle has a direct effect on the surgical outcome[3]. The basis for pedicle screw placement is freehand technique where screws are placed according to the anatomical landmarks[2]. Multiple methods for improving the accuracy of pedicle screw placement were developed. Some examples of currently available guided screw insertion include, but are not limited to: intraoperative fluoroscopy, fluoroscopic and CT-guided computer-assisted surgery (CAS), pedicle probes that guide pedicle screw insertion using ultrasound or tissue conduction measurements, and electrophysiological monitoring techniques. According to the literature the percentage of misplaced pedicular screws is as high as 21% in freehand technique and as low as 3% in CT guided screw placement[4].

In the last 5-6 years the idea of personalised guiding templates for pedicle screw placement has evolved[6-8]. These templates are designed (using preoperative CT) to fit in a unique position on the individual's bone, and they have carefully designed holes to guide the drill through a pre-planned trajectory[7-9]. A rapid prototyping device is used as a three-dimensional printer to produce the shape of reference areas on the bone surface. One of the main advantage of this method is significantly reduced time of the usage of ionizing radiation during surgery[10-13]. It also has economical benefits in comparison to computer assisted surgery which is expensive and has high depreciation costs[5-13].

The aim of this work was to evaluate accuracy and safety of using personalized guiding templates for pedicle screw placement on the thoracic spine.

II. METHODS AND RESULTS

From the Institute of Anatomy of the Medical Faculty of Ljubljana we obtained one cadaveric spine specimen for the purpose of this study. We performed a helical computer tomography (CT) scan of the spine specimen to acquire virtual 3D model of thoracic spine. Specialized computer software for preopertive planing (EBS^{TM}, Ekliptik, Slovenija) was then used to design laminar drill templates according to predetermined pedicle trajectories (Figure 1).

Templates were specially designed to fit and lock on the lamina during the procedure. The templates fit in a unique position on the individual vertebrae, and they have carefully designed holes to guide the drill through a pre-planned trajectory. Drill templates for each vertebrae (T1-T7) were then printed out of the biocompatible polymer using 3D printing technology. The templates have a special metallic drill sleeve with inner hole corresponding to drill bit diameter. These metallic sleeves also prevent formation of debris from the template itself when drilling.

Cadaveric spine specimen was then prepared for the procedure – skin, subcutaneous tissues and fascia were incised, erector muscles were striped periosteally and retracted preserving interspinal and supraspinal ligaments. 3D drill guide templates were placed on the vertebras anchoring at three sites – on the lamina at the base of the superior articular process on both sides and at the tip of the spinous process (Figure 2). Holes were then drilled with power drill (Figure 3), probed and 3,5 mm steel screws were inserted. Screws were inserted from the first to seventh thoracic vertebrae (7 pairs) using custom template for each vertebrae.

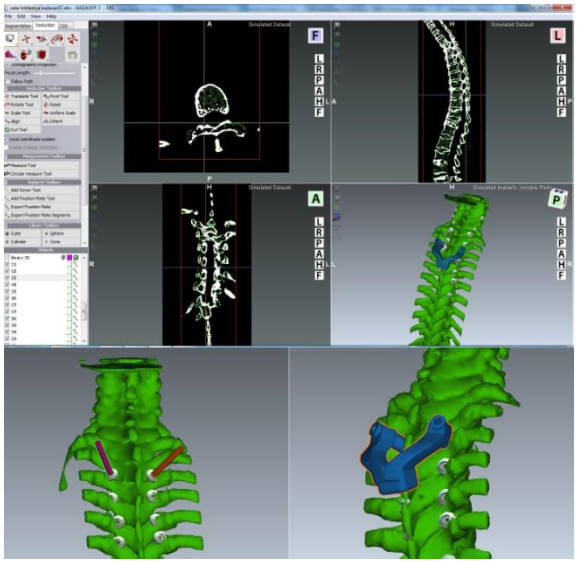

Figure 1. Designing templates using virtual 3D model of the spine.

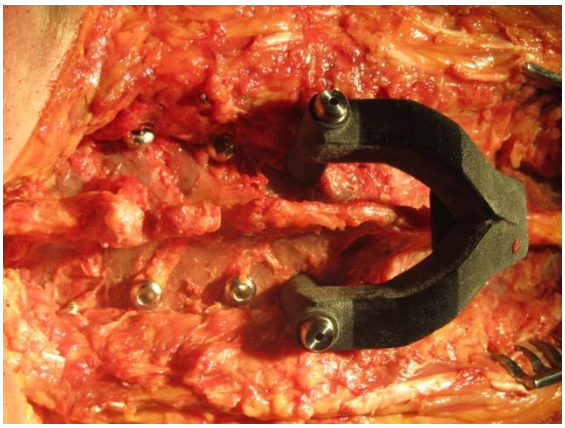

Figure 2. Template fitted on third thoracic vertebrae (T3)

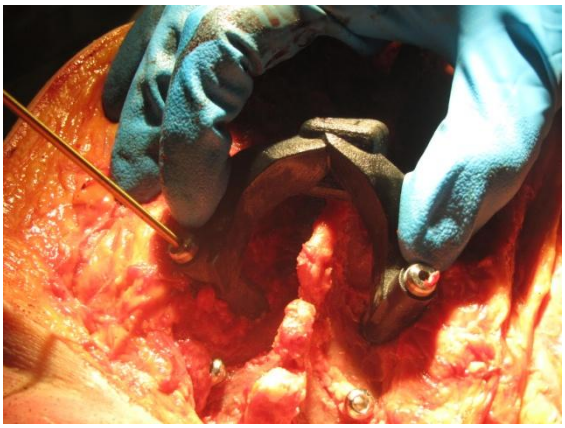

Figure 3. Template fitted on third thoracic vertebrae (T3)

CT scan was again performed (Figure 4) after screw placement to evaluate screw positions. Analysis showed that 13 out of 14 (92,9%) screws were inside of pedicle trajectories without violation of pedicle wall with the tip inside of the vertebral body. One screw violated medial pedicle wall in an "in-out-in" fashion.

III. CONCLUSSION

The potential use of such a navigational template to insert thoracic pedicle screws in spinal instrumentation is promising. When comparing it to a freehand technique, which has a 69% to 94% accuracy rate[14], this novel method could improve

Figure 4. CT scan after screw placement.

the accuracy of pedicle screw insertion. In comparison to fluoroscopic and CT guided pedicle screw insertion it could reduce the operating time and radiation exposure of the patient and the surgical team[10,12]. This method is also economically favorable in comparison to computer assisted navigation. As the freehand technique has a very steep learning curve[2], with this method a learning curve was not obvious.

Downsides of this method are relatively lengthy manufacturing process of the templates and possible manufacturing faults[10]. For the designing of the templates the surgeon needs to have computer skills and has to be familiar with the preoperative planning software to minimize possible human factor faults during production of the templates. This method also can not be used in minimally invasive spinal surgery, because good exposure of the posterior spinal elements is essential for correct placement of the templates[5-8].

iHELP emergency care network

Andraž Ogorevc*, Borut Lončarevič **, and iHELP TEAM***
* MIDS d.o.o., Ljubljana, Slovenia
**iHELP WORLD LTD, London, UK
info@ihelp-world.com

Abstract - The idea for the iHELP project originates in 2011. Disturbing statistics related to cardiovascular disease (i.e. 224 people a day die from sudden cardiac arrest in UK) made us think about how to enable the general public with an accessible and above all faster assistance, which is essential in order to ensure survival. The aim of the iHELP project is to have the largest rescue network that will be present locally and globally, and thus offer faster emergency help! We want to reduce the current high rate of mortality in the event of sudden cardiac arrest; increase the awareness about possible ways to help victims of cardiac arrest; assist local communities in setting up the defibrillators; and help business partners save their customers and employees, because this way whole society can save a lot of money. iHELP project has set a goal to place around 20,000 Automatic External Defibrillators (AED) in the world in five years, and by doing so we will enable a greater probability of survival in the event of sudden cardiac arrest.

I. INTRODUCTION

Cardiovascular Diseases (CVD) are one of the main problems of modern society. Sudden cardiac arrest is the leading cause of death in the world. 74% of cardiac arrests happen in front of laic eyewitnesses [1]. In Europe, cardiovascular diseases cause 45% of deaths among people aged 75 years or younger. Emergency Medical Service (EMS) treated 38 cases of cardiac arrest per year per 100,000 residents outside the hospital [2]. According to the experts [3] there are 5 to 6 cardiac arrests per day in Slovenia, on average that is around 2,000 per year. At sudden cardiac arrest rapid response is crucial, because after 4 to 5 minutes without the implementation of Basic Life Support (BLS) irreparable damage to the brain occurs [4].

So-called chain survival [5], which provides a useful metaphor fort the elements of the Embedded Control Concepts (ECC) systems, is composed of five links, which must be continuously connected to each other. The first link is intended for early identification and quick 112 call. In the second link we buy time with high-quality Cardiopulmonary Resuscitation (CPR). The third link is intended for early defibrillation, where caused heart rhythm disorder requires electric shock(s). The fourth link in the chain is intended for keeping the heart and brain working. The latter carry out specially trained teams of EMS. The last link is integrated post-cardiac arrest care.

Resuscitation or implementation of the CPR by the laity and early defibrillation saves lives. With implementation of CPR we follow the prescribed algorithm that determines the type and sequence of actions [6].

More than 17.3 million people worldwide die of cardiovascular diseases every year (in Europe, more than 4.3 million of which more than 700,000 deaths are result of sudden cardiac arrest). The number of people, who die from CVDs, mainly from heart disease and stroke, will increase to reach 23.3 million by 2030 [7]. Cardiovascular diseases are the leading cause of death in the world (they are responsible for 48% of all deaths worldwide, *2008*) [8]. The number is so high mainly because of the short time frame in which the cardiac arrest victim can still be saved and most of those who witness cardiac arrest either cannot or dare not help.

II. MOTIVATION

On the basis of the regulation [9] must the EMS unit from receiving the call (directed questions, first aid instruction) until the time they leave the starting location, take two minutes or less. Before mentioned healthcare organizations standards are overviewed by their internal control, which evaluates if the EMS team performance is successful. The EMS team in the vehicle should consist of a three-member team with a doctor, equipped with a monitor defibrillator, a crash kit and oxygen tank.

After the departure of intervention unit towards the scene, time for the journey and the preparation of the team to help the injured is needed. After adding the time of all procedures we soon discover that the intervention in less than 10 minutes is a great success. Because of this finding, we ask ourselves whether there is a way to improve the response time of the implementation of basic resuscitation procedures in the event of sudden cardiac arrest.

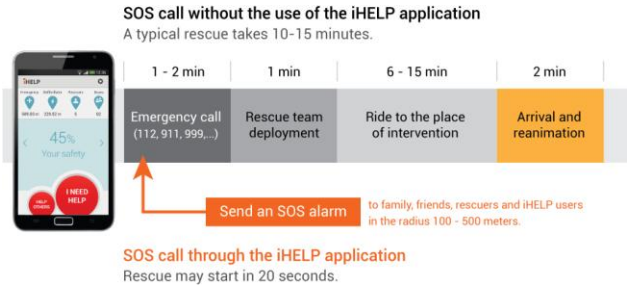

Figure 1. SOS call protocol [10]

Imagine that you are walking down the street with a friend. Suddenly your friend collapses due to a cardiac arrest. You call for help. Passers-by (lay people) who are afraid to help, because they do not know the basics of first aid, CPR, let alone how to use a defibrillator (What is a defibrillator and where are they?) run to you. You call emergency medical assistance at 112. Due to the traffic jam, ambulance will arrive after about 8-15 minutes, unfortunately your friend only has four minutes before his brain cells will start to die and as result irreversible damage will occur. What would you do?!

In most cases, you would not know what to do and this is one of the main reasons why 33 people die due to cardiac arrest worldwide every minute, (there are 7% chances of surviving sudden cardiac arrest). Statistics show that according to best scenario, rescuing takes about 8-15 minutes or more, depending on LOCATION, weather and time (traffic jams). With our solution, the arrival of rescuers can be in less than 20 seconds after we activate iHELP rescue network: family members, friends, Emergency Medical Service (EMS – 112/999), rescue workers in the field and iHELP users or laymen who are in the immediate vicinity of the unfortunate event. Due to the rapid arrival of help, the probability of survival rises up to 70% in the case of sudden cardiac arrest!

III. iHELP PLATFORM AND MOBILE APLICATION

iHELP mobile application offers users a quick and easy sending of multiple SOS alarm messages to family members, friends, professional rescuers and all users of iHELP mobile application within a radius of 300 meters or more from the victim. The application provides first aid training, overview of the nearest defibrillators, faster communication between family members in occurrence of critical events, reminder for taking pills. Application also calculates the safety of the user's at specific location; how far away are the emergency rooms, police and fire station, it shows the distance to the defibrillator, how many users are in the immediate vicinity and how far away are the family members or friends. With this information we can calculate the probability of response and arrival of help in a specific time! The great advantage of the iHELP system is that we inform the patient about the state of response for help: how many people have received SOS alarm message and how many have responded to help, and when will they arrive!

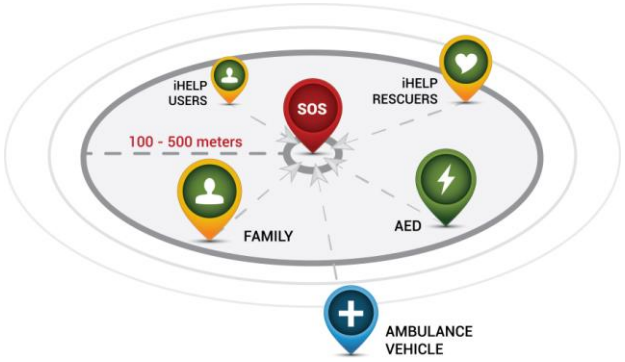

Figure 2. iHELP users

A. *iHELP Bracelet*

iHELP bracelet, which will work in situations where the user does not have a phone at hand, can easily send SOS message to family members, friends or professional rescuers. With holding down the button on the bracelet for three seconds, the Bluetooth on bracelet is activated and it sends wireless SOS signal to the mobile phone, which must be within a radius of 20 meters. Then iHELP mobile application automatically sends SOS message (geo-location of the injured person and all necessary information) to responsible person or rescuers (family members, friends, or to the SOS centre, if the client has a signed contract).

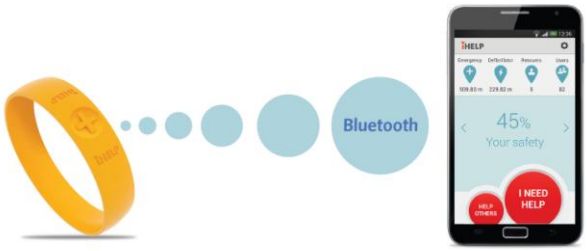

Figure 3. Bluetooth connection

With new version of the bracelet equipped with special health sensors (measuring heart rate, body temperature, the level of oxygen in the blood and measuring of G-force), which will recognise the problem of "sudden cardiac arrest". Bracelet will than automatically send a SOS signal to the victim's phone and in short time iHELP application will send SOS notifications to emergency contacts (ICE), professional rescuers and to all iHELP users in vicinity of the victim.

B. *Build a Care Network*

iHELP project is built in three steps:

Step 1: Create strong movement (community) through iHELP mobile application. Invite volunteers and

professional rescuers, coordinators, ambassadors and non-profit organizations to the iHELP project.

Step 2: establish contacts with strategic partners (socially responsible companies / cities / countries), invite to the story Heart Friendly Companies (Cities).

Step 3: Establish a marketing network and build users brand trust. iHELP – SAFETY IN THE PALM OF YOUR HAND!

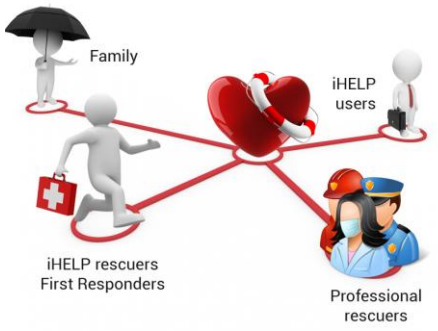

Figure 4. Care network

To create a strong movement we propose a significant involvement of volunteers in modern m-Health system. This aspect was underestimated in all previous investigations. Based on recent positive practical experiences and evidences, e.g. immediate active assistance in life threatening situations by medical events or natural disasters, we expect that the users of iHELP services can considerably benefit from this social dimension. The amount of people ready to cooperate on volunteer basis is surprisingly high, for example in Slovenia, there are 150.000 members of fireman organization, which represent 7.5 % of population, 10.000 retired individuals able to provide first aid. There are also other professionals who are able to offer first aid: 33.000 medical staff and 16.000 members of police and army staff. We will analyse the diversity of volunteering motives in two different EU regions (central Europe and west Europe) and find the optimal solution to increase the common benefits of people in need and volunteers.

We will also consider inclusion of other technologies, such Telemedicine application [11] and The Confidence system [12], into our intelligent platform for saving lives. Telemedicine application provides a comfortable option for telemonitoring of the heart activity of cardiac patients during their normal activities. It also helps prevent life threatening events by transferring most important results and alarms directly to medical personal.
The Confidence is ubiquitous care system, which was designed to support independent living of elderly, by detecting falls and unusual movement that may indicate a health problem.
The combination of these two technologies and iHELP application could mean a significant improvement of survival rate, homecare, overall health care system and it would reduce its expenses at the same time. We must take into consideration that sudden cardiac arrest is leading cause of death in modern society and that European population is aging rapidly, threatening to overwhelm the society's capacity for taking care of its elderly members.

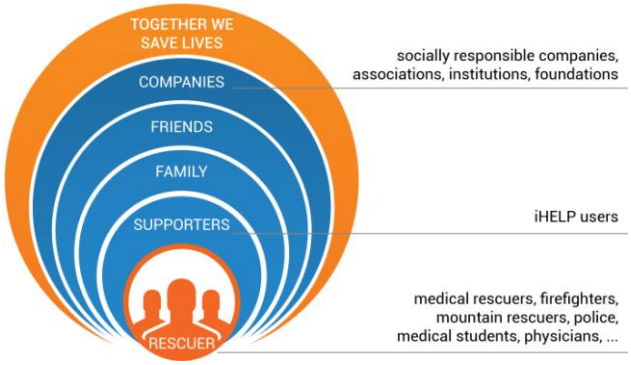

Figure 5. Community

IV. CONSLUSION

iHELP project was based on a worrying statistics of cardiovascular diseases and with death related to it. With iHELP project we wanted to connect people in interpersonal volunteer help, but now it is evolving into something much greater. iHELP project is creating a new kind of social network, which is not taking place only in the virtual world but also in real life. Its users can save lives and theirs lives can be saved by other users, their family, close friends, volunteers, professional medical staff, etc. The project combines Information and Communication Technologies (ICT) knowledge with basic human needs and natural survival instinct. Its development and usage are based in a way that encourages preventive actions and at the same offer iHELP users extra security in cases of severe illnesses, cardiac arrests or any other injuries. iHELP project strengthens bonds inside of community, develops interpersonal solidarity and creates new social norms.

Norwegian University of Science and Technology (NTNU), Trondheim, Norway

***Abstract*—The report issued by Alzheimer's Disease International in 2009 estimated that 35.6 million people worldwide would be suffering from the disease in 2010, and the number was estimated to 115.4 million in 2050. Development of safe and effective disease treatments is, therefore, an urgent matter. Understanding the physical mechanisms underlying the neuronal network could enable scientists to invent new treatment strategies and techniques. Development of different invasive and non-invasive techniques of stimulating the region of the brain, that is malfunctioning owing to a neurodegenerative disease from the outside of- or inside the body, became plausible considering the recent findings in biology and neuroscience. This paper does not delve with any specific treatment fashion in terms of technique being deployed, but discusses one possible strategy formation of controlling the neuronal communication, which might be applicable in general. Specific graph theory concepts are deployed and integrated from a theoretical neuroscience perspective, with the main motivation of altering the performance of neuronal communication in order to slow down, halt or reverse mental disorders, such as Alzheimer's, depression, schizophrenia, autism etc., that reduce quality of life.**

I. Introduction

Neuronal nano-communication between neurons underlies all the processes taking place in nervous system. Neurons are specialized cells that generate electrical pulses called action potentials (APs), or spikes, in response to electrical or chemical inputs (usually) collected by compartments called dendrites. Generated response is then transmitted down through the nerve fiber called axon, that serves as communication channel connecting the neurons. The difference in electrical potential between the interior of a neuron and the surrounding extracellular medium, hyperpolarization and depolarization, are what forms the AP pulse shape. Hyperpolarization makes the neuron's membrane potential more negative due to the positively charged ions (Na^+, Ca^{2+}, and K^+) flowing out, or negatively charged ions (Cl^-) flowing in. Conversely, depolarization makes the membrane less negative. A structure that further allows a neuron to pass a message generated, i.e. an electrical pulse, to another cell is called the synapse. Synapses transfer signals from one neuron to another through neurotransmitter molecules released into the synaptic cleft. When an AP reaches the presynaptic membrane, it will depolarize, leading to opening of voltage controlled calcium ion-gates (VCCGs) and an influx of extracellular calcium ions, Ca^{2+}, into the presynaptic terminal. A rise in intracellular calcium concentration, hereinafter referred to $[Ca^{2+}]_i$, from its resting concentration increases the probability that vesicles (small bubbles within a cell that store various neurotransmitters) docked onto the neuronal membrane releases neurotransmitters enabling neurons to further transmit the message generated. Adequate message propagation is fundamental for reliable neuronal communication. Any disruption leads to malfunctioning brain.

In case of malfunctioning network on board, an interest is to develop either non-invasive or invasive methods that can control neuronal communication (excluding the 'traditional' pharmaceutical drug delivery approaches which effects are highly debatable). In terms of non-invasive methods, recent studies performed showed that electromagnetic radiation (EMR) exposure and magnetic fields (MF) can improve the cognitive abilities of the brain eliminating the possibility that the positive effects were caused by increased temperature [1]–[3]. In terms of invasive methods, an ideal futuristic approach is to develop nano-machines based on graphene or carbon nanotubes, that can deliver drugs, mimic neurotransmitters, or expose neurons to EMR/MF at very specific targets, minimizing risk of side effects [4], [5]. With such devices, one becomes less dependent on specific physical relationships since the possibilities of neural control ranges from field exposure to delivery of specific chemical agents and mimicking of certain neurotransmitter molecules.

The objective of this paper is to develop a possible graph-based strategy of driving the neuronal communication through controlled concentration of calcium ions,Ca^{2+}, since findings from neuroscience proved they play a crucial role in neuronal communication performance. It is believed that any disruption in the processes that regulates calcium concentration levels (referred as *calcium dysregulation*), will lead to dramatic changes in neuronal functioning. A possible treatment in brains with calcium dysregulation is, therefore, to develop techniques that re-establish proper calcium regulation. It will be shown in Section II that $[Ca^{2+}]_i$ can be altered through changes in membrane's potential evoked either by drugs, external fields, nano-machines, or other means such as optogenetics (a neuromodulation technique employed in neuroscience that uses a combination of techniques from optics and genetics to control and monitor the activities of individual neurons), or classic "current clamp" technique (used to stimulate a neuron

via electric current that enters a cell by means of glass micropipettes (electrodes)). This paper promotes a usage of specified graph theory concepts for selection of targeted neurons whose controlled $[Ca^{2+}]_i$ overcome calcium dysregulation issue and lead to adequate formation of strategy assisting in treatment and diagnosis of neuronal diseases. Since graph theory has recently started being utilized in neuroscience, the most appropriate graph theory measures for the analysis of brain have not been selected. Nonetheless, a set of those that might have certain relevance for neuronal nano-communication performance analysis and neuroscience applications are deployed here. Treated neurons shall further be able to affect the behavior of its postsynaptic neurons, as long as they are (somehow) treated long enough to make relevant processes reach the steady state.

II. Relation between Intracellular Calcium Concentration and Membrane's Potential

Having a strategy defined in this paper being confined to neuronal communication dependent on $[Ca^{2+}]_i$, it seems reasonable to state a relation between $[Ca^{2+}]_i$ and neuronal response characterized with its membrane potential fluctuations.

The $[Ca^{2+}]_i$ can be expressed by the following differential equation [6]

$$\frac{\mathrm{d}[Ca^{2+}]_i}{\mathrm{d}t} = -I_{Ca} - \frac{[Ca^{2+}]_i}{\tau_{Ca}}, \tag{1}$$

where I_{Ca} is the total calcium current through the membrane, and τ_{Ca} is the time constant for cytosolic Ca^{2+} removal. i_{Ca} is mainly flowing into the neuron since external concentration, denoted as $[Ca^{2+}]_e$, is much greater than internal, i.e. $[Ca^{2+}]_e >> [Ca^{2+}]_i$. Typical resting values are $[Ca^{2+}]_e \sim$ 1 mM scale and $[Ca^{2+}]_i \sim 100$ nM scale. Rather few ions are needed in order to raise $[Ca^{2+}]_i$ significantly. A concentration of around 10 μM require about 300-400 Ca^{2+}. The solution to (1) is

$$[Ca^{2+}]_i(t) = e^{-\frac{t}{\tau_{Ca}}} \int_0^t e^{\frac{t'}{\tau_{Ca}}} I_{Ca}(t')\mathrm{d}t'. \tag{2}$$

The Goldman, Hodgkin and Katz (GHK) equation [6] relates I_{Ca} to $[Ca^{2+}]_e$ and $[Ca^{2+}]_i$

$$I_{Ca} = \mathscr{P}_{Ca} 2vF \frac{[Ca^{2+}]_i - [Ca^{2+}]_e e^{-v}}{1 - e^{-v}}, \tag{3}$$

where $v = 2V_mF/(RT)$, V_m is the membrane potential, F is Faraday constant, R is the gas constant, and T the absolute temperature (in Kelvin). $\mathscr{P}_{Ca}$ is the cell membranes permeability to Ca^{2+} and works as a constant of proportionality between molar flux density over a unit membrane area and the concentration difference over the membrane, i.e. $S = -\mathscr{P}_{Ca}\left([Ca^{2+}]_i - [Ca^{2+}]_e\right)$. According to (3), I_{Ca} directly depends on the membrane potential. One possible way of controlling $[Ca^{2+}]_i$ is through change in membrane voltage V_m, since it also drives the $[Ca^{2+}]_i$ according to (2). Hence, to change the neuronal membrane potential, it is sufficient to inject or induce a convenient current.

In what follows, an answer to the following question will be given: *How to recruit the neurons whose $[Ca^{2+}]_i$ is to be controlled when large-scale malfunctioning network is to be treated?*

III. Graph Theoretical Modeling of Neuronal Connectivity

The anatomical configuration of brain networks can quantitatively been characterized by graph representing either inter-neuronal- or inter-regional connectivity. If inter-neuronal connectivity is analyzed, structural networks can be described as graphs which are composed of vertices (nodes) denoting neurons, that linked by edges representing their physical connections, i.e. synapses. Conversely, if inter-regional connectivity is analyzed, graph theory describes structural networks as graphs which are composed of nodes denoting brain regions, further linked by edges representing axonal projections. The former approach is subject in this paper. Thereby, graph G, representing neuronal network that consists of V set of vertices and E set of edges, denoted as $G(V,E)$, is analyzed here. Concerning the notation, both of the terms node and vertex denoting neuronal cells will be equally present.

Quantitative characterization of anatomical patterns can be mathematically described through matrices, such as the adjacency matrix (AM), also called the connection matrix. An AM is with non-zero entries a_{ij} if the connection, i.e. synapse, is present between neurons i and j; otherwise, a_{ij} is zero. For any given synapse, the synaptic weight (strength) will depend on the number of vesicle release sites n, the release probability p, and a measure on the postsynaptic effect q. Although we lack a formula describing release probability as a function of $[Ca^{2+}]_i$, and thereby w_{ij}, a formula for w_{ij} as a function of $[Ca^{2+}]_e$ has been experimentally found by Dodge and Rahminoff [7],

$$w_{ij} \sim \left(\frac{[Ca^{2+}]_e/K_c}{[Ca^{2+}]_e/K_c + [Mg^{2+}]_e/K_m + 1}\right)^a, \tag{4}$$

where K_c and K_m are equilibrium constants of calcium and magnesium, respectively. a is the number of independent sites Ca^{2+} must bind to in order to release neurotransmitters. Depending on the nature of the ion flow, the synapses representing connections can have either an excitatory, depolarizing, or inhibitory, hyperpolarizing, effect on the postsynaptic neuron. Hence, excitatory and inhibitory synaptic connections correspond to positive and negative a_{ij} values in AM, respectively.

Anatomically, many compartments (e.g. dendrites) of single presynaptic neuron i can be connected to postsynaptic neuron j, making a numerous synaptic connections. In presented analysis, it is assumed that weights of all the connections are superimposed resulting a_{ij}. Furthermore, each two neurons can both be the pre- and postsynaptic ones to each other, in which case they mutually share two connections represented by different values of a_{ij} and a_{ji} in AM. Additionally, the graph $G(V,E)$ representing neuronal network is directed due

to the one-way axonal transmission[1]. This ultimately makes the $G(V,E)$ being directed, weighted, and signed. Excluding the self-connections, all diagonal elements of AM are zero.

With the neuronal network mapped (usually by means of functional magnetic resonance imaging (fMRI) or electrophysiological techniques, such as electroencephalography (EEG) and magnetoencephalography (MEG)), one can reveal the connectivity patterns and structure formed of densely connected clusters linked together in a small-world network [8]. Small-worldness combines high levels of local clustering among neurons, associated with high efficiency of information transfer and robustness, and short paths, that link all neurons of the regional network. Small-world organization is intermediate between that of random networks, characterized with short overall path length and low level of local clustering, and that of regular networks, characterized with long path length accompanied by high level of clustering. Such a structure is essential not only for regions of specialized neurons, but also for the brain in general, since it combines two fundamental functioning aspects: *segregation*, where the similar specialized neuronal units are organized in densely connected groups that are interconnected, and the functional *integration*, which allows the collaboration of a large number of neurons to build cognitive states [9].

IV. Strategy of Diagnosis and Treatment of Neuronal Disorders

As shown, graph interpretation of neuronal connectivity provides researchers with connectional relationships between individual neurons and ability to computationally analyze the connectivity patterns. Although this research is mostly confined to formation of adequate strategy assisting in diagnosis and treatment of neurons struck by mental disorders, e.g. hippocampal neurons, two-dimensional spatial representations of a local subnetwork of 131 neurons with 764 unidirectional connections within *Caenorhabditis elegans* rostral ganglia (available in [10] and [11]), can be used for analysis without any loss of generality.

In terms of network quantification, the first parameter that can be easily computed is the average connection density, k. Value of k represents the number of all non-zero entries in AM, divided by the maximal possible number of connections, i.e. $n^2 - n$ (n stands for number of vertices in V set) for a directed graph, excluding self-connections. The sparser the $G(V,E)$, the lower its average connection density. The average connection densities vary depending on the particular anatomical structure. For instance, connected cells across the entire cerebral cortex typically produce k values ranging from 10^{-7} to 10^{-6} [12]. Conversely, local connection densities are significantly higher as shown for analyzed *Caenorhabditis elegans* network, where $k = 0.0449$ in particular. Although the result suggests a dense property of network, k value in addition to binary, unweighted, and, at this point still unsigned AM, does not provide a detailed insight into the functional organization of the region. Nonetheless, potential application of average connection density is in diagnosis: decreased k value of monitored brain subnetwork can mark disorder producing increased failures in neuronal links.

To keep the reasoning as realistic as possible, modification of 20% of the number of synapses in AM, is introduced giving them negative weights (considering inhibitory synapses) according to (4). Modified $G(V,E)$ is visualized as shown in Fig 1. Spatial two-dimensional positions represent the position of the soma of individual neurons. X-axis colormap ranging from -10 to 10 is used to differentiate between inhibitory and excitatory synapses. Note that distribution of inhibitory and excitatory cells is not temporal, unlike the time-variable synaptic weight values. Different patterns the synaptic weights form are beyond the long terms potentiation (LTP) and long term depression (LTD) processes. LTP refers to strengthening of the connection between neurons, and is usually initiated when the activity of connected neurons are synchronized (or highly correlated). LTD refers to a weakening of the connection between neurons, and is usually initiated when the activity of neurons are nonsynchronized (or have low correlation). Synchronized and nonsynchronized neuronal activity in the hippocampus is crucial for memory formation. During learning, the LTP and LTD processes will create memory as certain connection patterns in the (hippocampal) neuron network.

Presented spatial and temporal visualization can also be used in neuroscience as one possible way of diagnosis. For instance, significant reduction of clustering and loss of small-worldness might provide a *clinically useful diagnostic marker* indicating an Alzheimer's disease [8], [13]. Moreover, graph theory measures can be used to create a certain *visualization tool* that might lead to efficient and effective process of human regulation of $[Ca^{2+}]_i$. In what follows, concepts build upon the outdegree, clustering coefficient, and node and edge centrality criteria are presented.

A. Centrality Criterion

Neurotransmitter release process and modification of post-synaptic neuron's conductivities drive the neuronal abilities to communicate and build reliable connections. Potential cellular changes, however, should be designed to avoid small-scale alterations. To produce large-scale effects and effectively cure a brain region of interest, 'important' targets should be determined.

In graph theory and network analysis, centrality of a vertex measures its importance within a graph. Centrality concepts were first developed in social networks, but produce general answers to questions like "how influential a person is within a social network", "how important a room is within a building", and "how well-used a road is within an urban network". In this study, centrality is applied to examine *how involved a cell is in neuronal communication system* in order to identify those to be monitored, "guided", and controlled in terms of $[Ca^{2+}]_i$. There are variety of measures of centrality that

[1]Axon conducts the APs typically in a direction outward from the soma. This propagation is called orthodromic propagation. Antidromic propagation in the reverse direction is not excluded under a certain scenario.

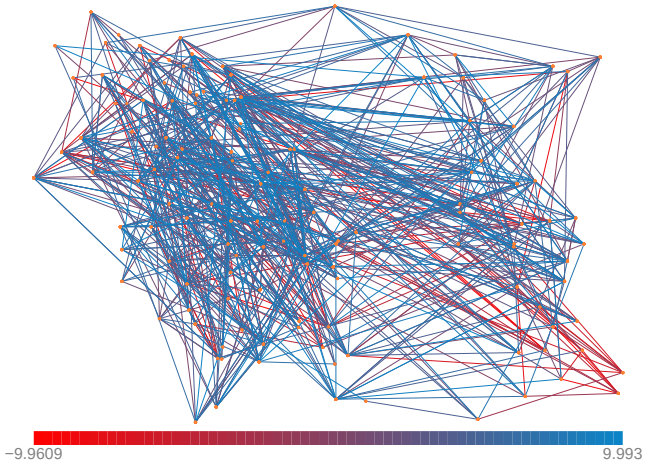

Fig. 1. Two-dimensional spatio-temporal pattern of weighted excitatory and inhibitory synapses. Red lines denote the inhibitory connections, whereas blue lines denote excitatory ones.

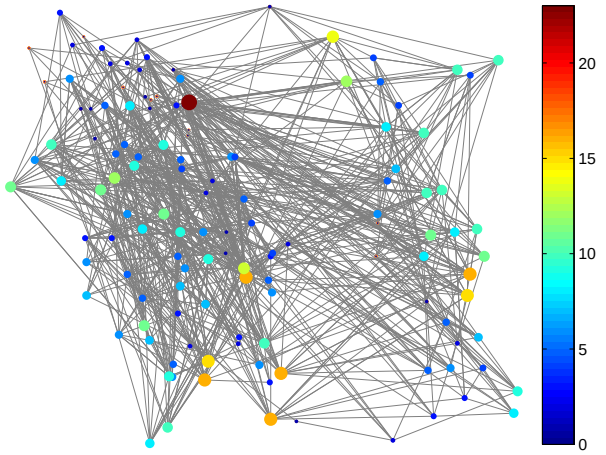

Fig. 2. Representation of neurons according to the outdegree criterion. Blue color indicates cells with no importance communication-wise. Important and potentially treated neurons are orange and red colored.

focus on different concepts and definitions, such as degree, betweenness, closeness, and eigenvector. As historically first, conceptually simplest, and very useful measure of centrality, degree is applied here to find neurons with the most numerous synaptic connections. Additionally, betweenness centrality is also deployed in what follows since that criterion is introduced as a measure for quantifying the control of a human on the communication between other humans in a social network [14]. Conversely, closeness and eigenvector centrality do not qualify themselves as usable criteria in this study due to the unmatched physical interpretations. For instance, closeness can be regarded as a measure of how long it will take to spread information from analyzed vertex to all other vertices sequentially, thereby being completely irrelevant in $[Ca^{2+}]_i$ regulation strategy.

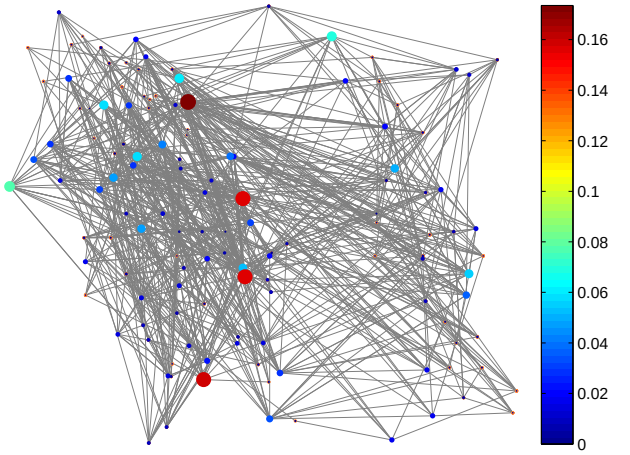
1) Outdegree centrality: The degree of a vertex in a network is the number of edges attached to it. Computationally, degree is the sum of vertex's indegree and outdegree values defined as the number of incoming (afferent) or outgoing (efferent) edges, respectively. In many cases, vertices with the highest degrees in a network play important roles in functioning of the system. Hence, degree can be a useful guide for focusing attention on the system's most crucial elements. In particular, outdegrees, $od(v)$, are of interest here due to the obvious functional interpretation: high outdegree of analyzed neuron indicates a large number of potential functional targets, i.e. receivers. Although the corresponding values are subject to constraints due to the growth, tissue volume, or metabolic limitations [12], the criterion satisfactorily qualifies an adequate neurons whose $[Ca^{2+}]_i$ is to be regulated. In such a way, any message sent from identified and treated neuron will be effectively spread throughout the network reaching the maximum number of recipients. Outdegree centrality criterion visualizes the $G(V,E)$ in a way shown in Fig. 2.

2) Betweenness centrality: Betweenness centrality also measures a vertex's or edge's importance in a network. If σ_{hj} is the total number of shortest paths from h to j, and $\sigma_{hj}(i)$ is the number of these shortest paths that pass through the vertex i, the betweenness of vertex i is defined as [9]

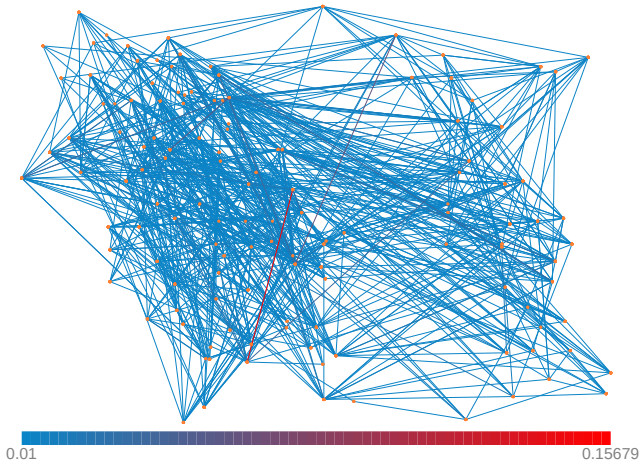
$$b_i = \sum_{h \neq j \neq i} \frac{\sigma_{hj}(i)}{\sigma_{hj}}. \tag{5}$$

The calculated value may be normalized by dividing through the number of pairs of vertices not including v, i.e. $(n-1)(n-2)$ for directed graphs. Analogously to the vertex betweenness, the betweenness centrality of edges is calculated as the number of shortest paths among all the possible vertex couples that pass through the given edge. Vertices and edges with high centrality values are assumed to be crucial for the graph connectivity and, thereby, shall be monitored in potentially malfunctioning brains. Neurodegenerative disease removing important neurons and synaptic connections leads to both anatomically and functionally disconnected clusters. The most important edges, called bridges, are particularly important for decreasing the average path length among neurons in a network, and for speeding up the information transmission.

Computationally, betweenness centrality of all vertices in $G(V,E)$ requires calculation of the shortest paths between all pairs of vertices. Inhibitory and excitatory cells, as well as synaptic weights that change versus time depending on LTP and LTD, should not be taken into account when calculating neurons' betweenness. Thus, for finding shortest paths of a binary directed graph with positive edge (but with no cycles), Floyd-Warshall algorithm (also known as Floyd's algorithm, Roy-Warshall algorithm, Roy-Floyd algorithm) is deployed. The algorithm compares all possible paths through the graph between each pair of vertices. An execution finds the lengths of the shortest paths between all pairs of vertices, though it does not return details of the paths themselves. When applied to local *Caenorhabditis elegans* subnetwork, Floyd-Warshall algorithm visualizes the network as shown in Fig. 3(a). Most



(a)



(b)

Fig. 3. (a) Representation of neurons according to the node betweenness centrality criterion. Red markers identify the most influential cells in the region. Death of these cells would produce two weakly connected- or even disconnected clusters which is further ruinous in terms of both anatomical and functional connectivity. (b) Representation of neurons according to the edge betweenness centrality criterion. Similarly, red lines denote crucial synaptic junctions which disunity produce harmful effects.

important neurons are again colored in red as ones that are either to be monitored in order to prevent disorders producing malfunctioning network, or whose $[Ca^{2+}]_i$ is to be regulated in case disorder has already took place. For analyzed network consisting of 131 frontal neurons, 4 cells are identified as essential in preserving the proper communication. In general, *the higher the number of important neurons, the lower the network robustness*.

Distance matrix that results the Floyd-Warshall algorithm execution provide calculation of average path length, l_{avg}, also one of the most important and basic graph theory measures. Short average path length is basically what makes the brain efficient in information transfer from one part to the other. It is also a function of degree (e.g. for a random network $l_{avg} \approx \log(n)/\log(< k >)$) ($< k >$ is the average degree). In brains with Alzheimer's disease, one can typically observe an increase of average path length, as described by Stam et. al in [15]. The average path length is calculated as

$$l_{avg} = \frac{1}{N(N-1)} \sum_{i \neq j} d(i,j),$$

where $d(i,j)$ denotes the shortest distance between i and j, and $d(i,j) = 0$ if j cannot be reached from i. For network analyzed here $l_{avg} = 3.1277$.

The Girvan-Newman algorithm extends the definition of node betweenness to the case of edges, defining the edge betweenness as the number of shortest paths between pairs of nodes that run along it. Edge betweenness may be interested in this study as a way of detecting important synapses. However, preserving those synapses is not trivial since execution of Girvan-Newman algorithm does not return details on the source and sink vertices, or equivalently the pre- and post-synaptic neurons. Therefore, information about the specified cell, whose $[Ca^{2+}]_i$ should be regularly kept, is missing. Nonetheless, it would not be superfluous if important synapses are visualized (see Fig. 3(b)).

B. Clustering criterion

The cluster coefficient of a vertex, $\gamma(v)$, is defined in [16]. As a measure of the degree to which vertices in a $G(V,E)$ tend to cluster together, it indicates how many connections are maintained between a vertex's neighbours. In particular scenario with directed graph on board, neighbours are all those neurons that are connected through an incoming or outgoing synaptic connections to the central neuron v. The ratio of actually existing connections between the neighboring neurons and the maximal number of such connections possible defines the neuron's cluster coefficient. If neuron does not have any

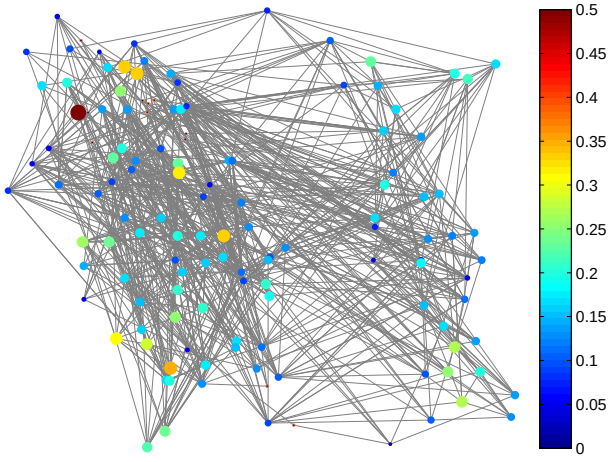


Fig. 4. Representation of neurons according to the clustering coefficient criterion. Red colored cell points to a region consisting of neurons that mutually share structural connections and function in a closely related manner.

neighbors, then $\gamma(v) = 0$, by convention. The average of the cluster coefficients determines the cluster coefficient of the $G(V,E)$. Albeit $\gamma(v)$ does not provide the information about the number or size of clustering groups, and only captures local connectivity patterns involving the direct neighbours of the central vertex [12], high $\gamma(v)$ points to a neuronal region consisting of groups of units that mutually share structural connections and function in a closely related manner. Accordingly, high $\gamma(v)$s set candidates whose controlled $[Ca^{2+}]_i$ properly regulates communication within the entire cluster (see Fig. 4). Note that cluster-based strategy might be destructive communication-wise, since $\gamma(v)$ can candidate an inhibitory cell which calcium is to be controlled.

V. Conclusion

This paper elaborates a significance of intracellular calcium concentration, $[Ca^{2+}]_i$, in performance of neuronal communication. High concentration levels usually lead to synchronized neuron firings, or equivalently, synaptic strengthening, whereas moderate levels lead to unsynchronized firings, or synaptic weakening. This paper also helps in development of an effective graph-based strategy of neurons selection whose electrical properties should be altered in order to evoke certain changes in $[Ca^{2+}]_i$ and communication abilities. Neuronal network is first described as graph and then quantitatively characterized through the adjacency matrix (AM). Specified graph theory concepts are utilized in formation of adequate strategy assisting in diagnosis and treatment of neuronal diseases. A set of graph theory measures that might have certain relevance for neuroscience applications is stated and deployed in this study to create a visualization tool that helps in selection of targeted neurons whose $[Ca^{2+}]_i$ is to be controlled. In such a way, problems in aging brains, strongly noticeable in brains with neurodegenerative diseases such as Alzheimer's disease, can be overcome. However, computationally demanding handling of huge AM describing large-scale networks, that are more likely to be recorded with functional magnetic resonance imaging, electroencephalography and magnetoencephalography, is not analyzed in this paper. Since an adult human brain has more than 100 billion neurons, recorded subnetworks can contain up to a billion cells forming an AM which presumably is to be stored in segments due to the limited memory resources. Segments of data should probably be further processed in a parallel or sequential computation fashion.

Use of 3D preoperative planning program in understanding of articular fracture treatment

M. Tomaževič*, A. Fischinger, A. Kristan*, D. Kreuh**, M. Cimerman*
* University Clinical Center Ljubljana, Department of Traumatology, Ljubljana, Slovenia
** Ekliptik l.t.d., Ljubljana, Slovenia

Abstract - Human joint is a complex 3D structure. When fractured, weight bearing articular surfaces of the joint have to be anatomically reduced and biomechanically stable coupled to the diaphysis with correct alignment of axis and rotation. To achieve this, soft tissue envelope should be traumatized as little as possible. We organized a course on preoperative planning of articular fractures with the use of computer 3D planning software, so surgeons could achieve the goal.

16 surgeons with different experiences of articular surgery, from residents to consultants, attended the course. First ordinary planning was done with 2D X-ray and CT images; later planning of the same cases was done with the use of 3D planning program. We compared chosen approach, reduction and use of implants in two fracture cases of knee joint. First was simple unicondylar and second complex bicondylar fracture of proximal tibia. Computer program used was EBS (Ekliptik, l.t.d.)

In the simple case plan remained the same in 61,5 % participants. In more complex case participants changed their plan in 100%.

3D preoperative planning is essential for understanding and treating articular fractures. 3D preoperative program is useful as an educational and as a working tool.

I. INTRODUCTION

Human joint is a complex 3D structure. It enables controlled movements in several planes. Due to movements even small incongruences can cause early posttraumatic arthrosis. In weight bearing joints, due to these incongruences, posttraumatic arthrosis can develop even sooner.[1], [2] Ligaments, joint capsule and muscles have an important role in stability of the joints. When there is a fracture in the joint we call these fractures articular fractures. Basic principle of treating articular fracture is to anatomically reduce the joint surface and to couple it in correct alignment to the diaphysis. In that way the length, axis and rotation of bony structure are assured and biomechanical bone preposition for the joint to work is done. [3] By achieving this, the stabilizing structures should not be additionally injured during the approach. To achieve all these goals the operation must be planned.[4] To plan correctly fracture should be understood, visualized and reduction planned. When reduction of the fracture fragments is planned, plan of fixation should be made. When all this steps are known the approach can be chosen and positioning of the patient can be planned. At the end closure of the wound and post-operative care can be planned. The key element to all this is to understand the fracture.

To be able to better understand the fracture, many computer programs for 3D visualization, segmentation and fracture reduction simulation were developed. [5]–[7]. But to our knowledge none of these programs could be completely operated by a surgeon. In cooperation between surgeons and computer engineers EBS software was developed called EBS (Ekliptik l.t.d.). EBS software uses DICOM images from CT and enables simulation of the classic X-ray, 3D reconstruction, fracture segmentation, fracture reduction and virtual fracture fixation. All the steps can be done on regular PC by the surgeon himself. Process from 3D reconstruction to virtual fracture fixation is shown with Fig 1-4. The procedure depends on the speed of computer, complexity of the fracture and on surgeon's skills from 10 – 60 minutes[8].

Preoperative planning course was organized, where 3D planning software was used. During the course we evaluated, whether software helps in understanding of the articular fractures. Our hypothesis was, that deeper understanding of the fracture will have influence on preoperative planning.

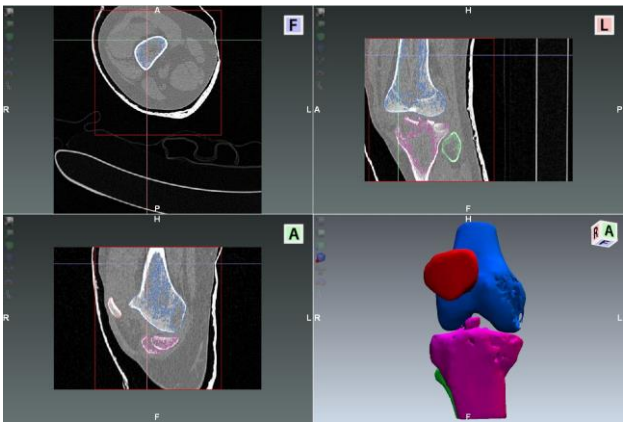

Figure 1: 3D model is built from DICOM images

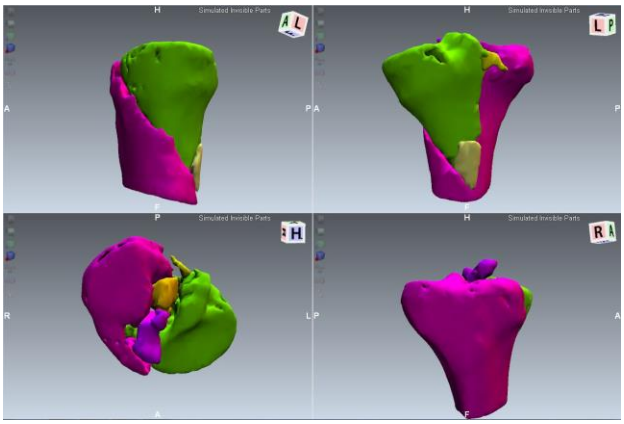

Figure 2: Fracture segmentation is done by the surgeon himself semiautomatic.

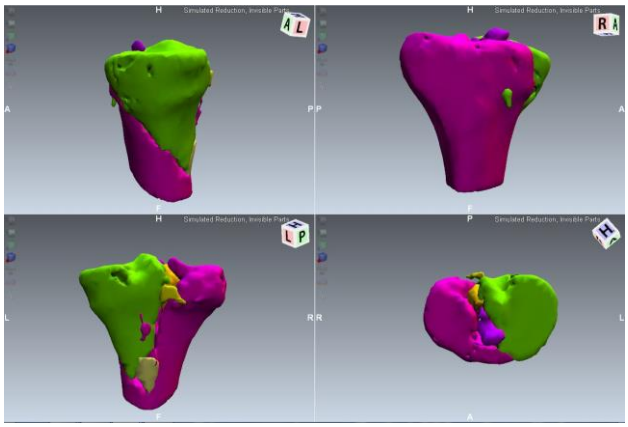

Figure 3: Fracture is virtually reduced.

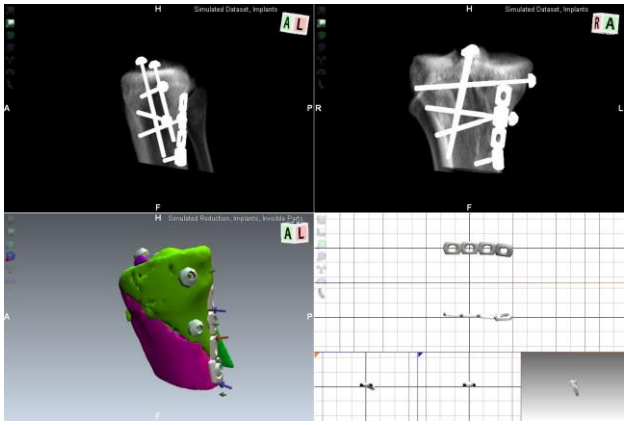

Figure 4: Virtual fixation of the fracture can be done. Contours of the plate can be seen and X-ray simulation can be done.

II. MATERIAL AND METHODS

Preoperative planning course with the use of EBS software was organized twice. 16 surgeons attended the courses. Each course was divided into two parts. First part was theoretical; it consisted of preoperative planning theory and instructions for the use of EBS software. Second part was practical; it consisted of real cases where preoperative planning was done. Planning for each case was done with the help of questionnaire. Attendants filled questionnaires with positioning of the patient, use of antibiotics, planned approach, reduction procedure, type of fixation, planned use of implants, and closing of the wound. Study of the fracture was first done with ordinary technique from classic X-ray images and 2D CT images. After this part first questionnaire was filled out. Later the study of the same cases was done with the help of EBS software. After EBS study second questionnaire was filled out. Evaluation of preoperative questionnaire was done whether there was a change in planned approach, position of the patient, planned reduction, type of fixation and choice of implants.

Due to unknown reason, three of the attendants did not return the questionnaire or only EBS questionnaire was filled out. For that reason we could evaluate only 13 questionnaires. Statistics was done only on approach, reduction type and implants where answers could be transformed in to nominal values; other answers were too long, subjective and descriptive and could not be transformed in to nominal values.

For comparison two cases of the same region were chosen; first one was simple unicondylar fracture of the proximal tibia and second was a more complex bicondylar fracture of the proximal tibia.

For 3D preoperative planning EBS software (Ekliptik l.t.d., Slovenia) was used.

Statistics was calculated with chi square test and due to small group likelihood ratio test was done. IBM SPSS Statistics 20.0 software was used.

III. RESULTS

Presented results show how preoperative planning with EBS software influences the understanding of the fracture. Better understanding of the fracture affects the choice of approach, choice of reduction technique, and choice of planned implants for fracture fixation. Results for the first and second case will be presented separately. First case was fracture of the proximal tibia according to Schatzker classification grade I, and second was fracture of the proximal tibia according to Schatzker classification grade IV.

A. Fracture of the proximal tibia Schatzker I

All the answers in first questionnaire were compared with the answers of the EBS questionnaire for each individual attendant. 5 attendants (38,5%) changed their plan at least at one point after planning with the use of EBS was done. With 7 attendants (61,5%) plan remained the same.

The planned operative approach remained the same with all the attendants. 12 decided for anterolateral approach and one for MIPO approach with ordinary and EBS preoperative planning. Statistics was done with chi square test, and the influence on approach was statistically insignificant at the level of $p = 0,05$ ($p = 1$).

There was a statistically important change in planned reduction type after the preoperative planning with EBS. Statistics was done with chi square test, and due to small number of attendants also with likelihood test and it was significant at the level of $p = 0,05$ ($p = 0,029$). The results are shown with graph in Fig. 5. Trend towards direct reduction is seen, arthrotomy (surgical opening of joint) is abandoned and indirect reduction remains the same.

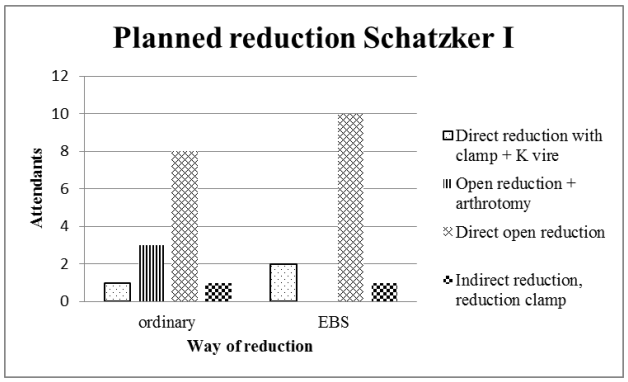

Figure 5: Planned way of reduction with ordinary and EBS preoperative planning in Schatzker I case

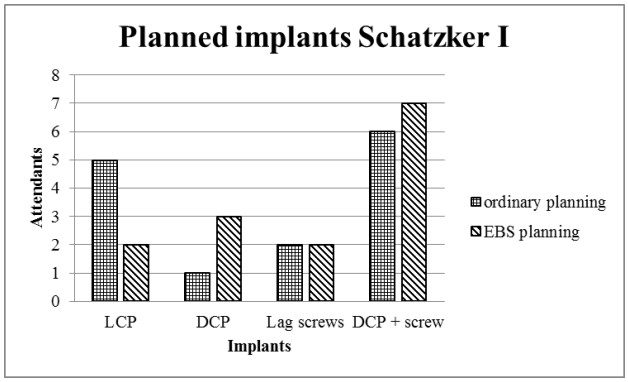

Figure 6: Planned use of implants with ordinary and EBS preoperative planning in Schatzker I case. (LCP – locking compression plate, DCP – dynamic compression plate)

Statistically important change in planned use of implants is also seen after the preoperative planning with EBS. Statistics was done with chi square test and likelihood test and it was significant at the level of p = 0 0,05 (p= 0,01). The results are shown in Fig. 6. After understanding of the fracture is better there is place for older not so expensive implants like dynamic compression plate (DCP).

B. Fracture of the proximal tibia Schatzker IV

All the answers in first questionnaire were compared with the answers of the EBS questionnaire for each individual attendant. 13 attendants (100%) changed their plan at least at one point after planning with the use of EBS was done.

There was a statistically important change in planned approach after the preoperative planning with EBS was done. Statistics was calculated with chi square test and likelihood ratio. It was significant at the level of p = 0,05 (p = 0,014). The results are shown in graph in Fig. 7. Planned medial approach is abandoned because the key for fracture reduction is at the posterior aspect of the tibia but the main fragment is on the medial side. All the attendants have decided for posteromedial approach with or without arthroscopy.

There was a statistically important change in planned reduction type after the preoperative planning with EBS. Statistics was calculated with chi square test and likelihood test. Change in planned way of reduction was significant at the level p = 0,05 (p = 0,000). As seen on Fig. 8 three ways of reduction that were planned with ordinary preoperative planning were completely abandoned after preoperative planning with the use of EBS software. There was a sliding mechanism of the fracture that needed a buttress plate to hold it in place and additional screws for stability were needed.

Statistically important change in planned use of implants is also seen after the preoperative planning with EBS software. Statistics was done with chi square test and likelihood test and it was significant at the level of p = 0 0,05 (p= 0,007). The results are shown in Fig. 5. It can be seen that after EBS preoperative planning choice of implants is a lot more uniform. A lot of implants that were planned with classic preoperative planning were completely abandoned after preoperative planning with the use of EBS software. There is less implants planned to be implanted and the implants are very low profile so that do not interfere with soft tissues.

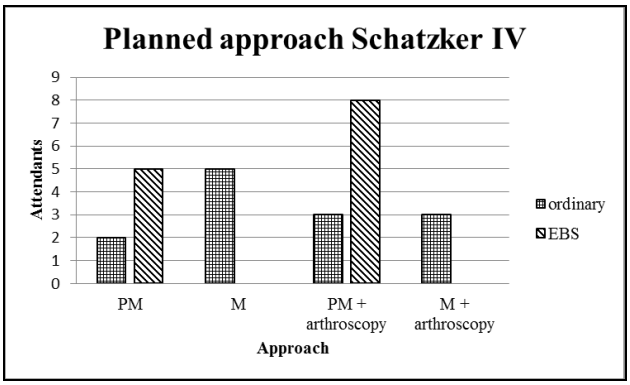

Figure 7: Planned approach with ordinary and EBS preoperative planning in Schatzker IV case (PM – posteromedial, M – medial)

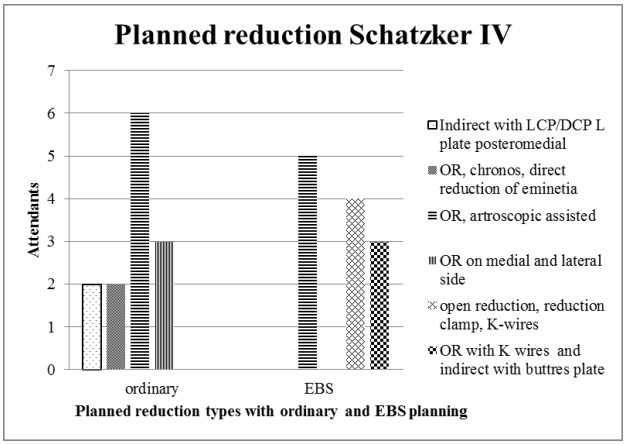

Figure 8: Planned way of reduction with ordinary and EBS preoperative planning in Schatzker IV case (OR – open reduction, Chronos – bone substitute)

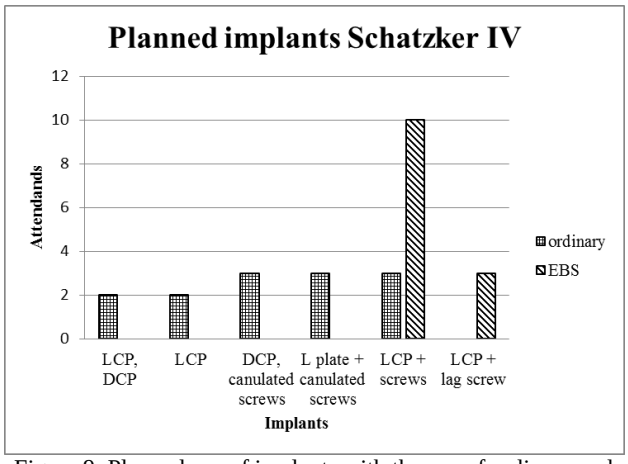

Figure 9: Planned use of implants with the use of ordinary and EBS preoperative planning (LCP – locking compression plate, DCP – dynamic compression plate, L plate – DCP in shape of an L)

C. *Comments on results*

It was expected that with easier Schatzker I case there will not be any statistically important differences. As it shows even in simple case the differences in preoperative planning exists. This means that even in simple case 3D image and fracture plane imaging helps to better understand the fracture.

It is seen that in more complex case the choice of treatment was a lot more uniformly spread among the attendants after the preoperative planning with EBS software. We assume that is because fracture understanding is easier when 3D model is seen and all the fracture planes are visible. Of course there is never just one solution to the problem, but usually when there are too many it is difficult to decide which one is good and which is not.

IV. CONLUSION

Fracture treatments are taught by classifying the fractures and according to fracture classification choose the appropriate approach and fixation. Unfortunately most of the classifications are based on 2D imaging. With 3D imaging understanding of the fractures is more profound. Until now 3D imaging was difficult to use in a preoperative planning. There was no appropriate 3D preoperative planning software. Making 3D solid models took too much time and it was too expensive.

With 3D preoperative planning software an important step toward understanding of the fracture patterns and fixation was made. By doing this study we proofed that 3D preoperative planning changes the thinking pattern about the fractures and improves understanding of the appropriate fracture fixation.

By significant changes in preoperative plan with the use of 3D preoperative planning program we proofed that 3D preoperative planning software changes understanding of the articular fractures in a better way.

3D preoperative program showed useful as an educational and as a working tool by making users to better understand the fracture.

Education of cosmetic device users in Slovenia

Špela Elizabeta Soklič* and Jure Jelenc **
* Stane Žagar Primary School, Kranj, Slovenia
** Iskra Medical d.o.o., Ljubljana, Slovenia
jure@iskramedical.eu

Abstract - The education of cosmetic device users in Slovenia and across Europe is diverse. Although their level of knowledge varies, almost all users are allowed to perform the same cosmetic procedures. In Slovenia, all major stakeholders in the field of cosmetics are interested in increasing the level of knowledge of all participants, since knowledge and experience is the best assurance for safety and efficacy as well as customer satisfaction. This article reviews the education system and Slovenian organizations providing formal education in the discipline. The tremendous rate of biomedical innovation in cosmetic devices forces experts to get novel knowledge through education outside the government-regulated framework. Informal education provides a fast and efficient way to educate users in new procedures, but requires user's critical thinking since it is often commercially oriented. The rate of biomedical innovations implanted in the novel cosmetic procedures represents challenges to both formal and informal education. Lecturers face students' questions about novel procedures available on the market on a daily basis. For them, a big challenge is to be continuously acquainted with the new biomedical innovations implemented in the field so that they can provide evidence-based answers.

I. INTRODUCTION

Cosmeticians practice a broad range of cosmetic procedures on the skin, face, nails and lips [1]. The English language refers to them with multiple expressions that are not necessarily synonyms: aestheticians, estheticians, cosmetic therapists, cosmetologists, beauticians, beauty practitioners, beauty therapists… The general scope of their activities is treating non-medical skin problems that are limited to the upper layer of skin (the epidermis) [2]. Even though in practice they employ therapeutic modalities that are known to penetrate through all layers of skin. Prime examples of such modalities are electrical current therapies, light therapies, ultrasound therapies, and application of creams optimized to enhance intradermal delivery. However, cosmeticians in Slovenia generally do not use technology that would allow them to physically penetrate the skin with the device itself.

The education of cosmeticians in Slovenia is diverse. Although their level of knowledge varies, the majority of professionals are allowed to perform the same cosmetic procedures. In the following sections, we will review the education system in Slovenia (Fig 1) and describe organizations that provide formal education in the discipline.

II. EDUCATION IN COSMETICS IN SLOVENIA

A. FORMAL EDUCATION IN COSMETICS IN SLOVENIA

Compulsory basic education consists of a nine-year primary school attended by pupils aged six to fifteen years [3]. After completing primary school, students may continue their education at any upper secondary school [3]. Education in cosmetics is possible at the second education level and above. Organizations that offer education in cosmetics are listed in Table 1. Post-compulsory education begins with upper secondary education. It is divided into general upper secondary education (4 years), technical upper secondary education (4-5 years) and vocational upper secondary education (2-4 years). General upper secondary (Gymnasium) schools provide general education and are aimed at pupils who plan to continue with tertiary education. Upper secondary vocational and technical education and training are divided into broad technical/vocational fields, within which several courses are available [3]. One of them is a 4-year cosmetic therapist course, which is also offered as a one to two year adult requalification program for adults that have already finished other secondary education programs.

Adults, who have acquired a secondary vocational qualification and have at least 3 years of work experience, may acquire a secondary technical education in an alternative way by taking a master craftsman, foreman or managerial examination with the competent association. In the field of cosmetics, the competent authority for the master craftsman exam is the Chamber of Craft and Small Business of Slovenia with the program for Master craftsman of cosmetics. Several competent associations offer managerial examinations for Massage therapists, Manicure specialists, Pedicure specialists and Make-up artists. The duration of the education needed to achieve these qualifications varies from 2 weeks to half a year.

Tertiary education in Slovenia comprises higher vocational college education and higher professional and academic education [4]. The short-cycle higher vocational college education has become a special part of the tertiary education system. It lasts two years and focuses on acquisition of practical knowledge and skills

in specific occupations. The two-year short-cycle higher vocational college education allows students to acquire a degree in Cosmetics. There are several types of higher education institutions in Slovenia: universities, art academies and independent higher education institutions. Most of these institutions are now introducing the Bologna process [4]. Currently, the Higher School of Applied Sciences (VIST) offers a 3-year professional education, which gives the student a bachelor's degree in Cosmetics, and a second two-year academic education, which gives students a master's degree in Cosmetics. The Faculty of Pharmacology at the University of Ljubljana offers bachelor's and master's degrees in Cosmetology, but is excluded from Table 1 due to differences in aims of the study. At the moment, there is no doctoral study of cosmetics in Slovenia.

B. INFORMAL EDUCATION IN COSMETICS IN SLOVENIA

The tremendous rate of biomedical innovation in cosmetic products and cosmetic devices forces users and scholars to acquire novel knowledge. Like in every discipline, novel discoveries are first presented to experts in scientific journals, but are generally introduced to end users through informal education. A number of currently omnipresent devices in the business are the result of biomedical innovations over the last decades. Examples of these, now routinely used, technologies include light-based devices for hair removal and skin rejuvenation, low-frequency ultrasound and high-intensity ultrasound for local fat tissue reduction, radiofrequency devices for skin rejuvenation and wrinkle reduction, delivery vehicles and nanotechnology in cosmetics products. However, new methods pose new risks of complications during and after the procedures [10]. Most of these methods were invented and introduces to the cosmetic procedures only recently; therefore majority of cosmetic professionals gained no information about them during their formal education. Informal education provides a fast and efficient way to educate users in new procedures. Key stakeholders organizing informal education in Slovenia are the Chamber of craft and small business of Slovenia, education institutes, and companies that sell cosmetic products. Common forms of informal education include congresses, fairs, journals, invited lectures, and seminars with hands-on experiences. The majority of these events are at least partly sponsored by companies; therefore they require user's critical thinking since they can be commercially oriented. In Slovenia all major stakeholders in the field of cosmetics are interested in increasing the level of knowledge of all participants, since knowledge and experience is the best assurance for safety and efficacy as well as customer satisfaction.

III. DISCUSSION

Formal education in cosmetics in Slovenia offers a variety of levels in cosmetic education. The length of education varies from a few weeks to nine years for students that finished 4-year secondary education, 3-year bachelor education and 2-year master's degree. At the moment, the first generation of master students is finishing their education. But in the cosmetic saloons, private medical offices, spas and wellness centers there is a number of cosmetics professional with tertiary education

and an even greater number of cosmetic professionals with secondary school education. To the authors' knowledge, there is no published data on professional knowledge and expertise actually acquired by students in different levels of education or different educational organizations at the same level. At the secondary school level, the title of beauty therapist is granted after the student successfully passes a nation-wide exam. However, the standardized, practical exams are led and graded by teachers from the school that the student attended. Therefore, the possibility to compare results from different schools by these exams is severely limited.

Students wanting to enroll in cosmetic programs, organizations looking to hire new professionals and, most importantly, the end customers are limited in obtaining information about the quality of knowledge and expertise gained by students in formal cosmetic education programs.

To start their own private cosmetic practice, a cosmetician needs not only a formal education, but also a license (craft license) from the Chamber of Craft and Small Business of Slovenia [11]. However, the same license is issued for all formal education levels in cosmetics. Therefore, despite big differences in the level and duration of their education, all professionals are allowed to employ the same methods in their work.

The use of novel technologies is usually supported by informal education, which provides a significant amount of knowledge to both the lecturers in formal education and to the cosmetic professionals. The rate of biomedical innovations introduced into cosmetics is forcing lecturers and organizers of informal education to cooperate. The lecturer should be careful to accept only evidence-based claims as a valid answer to their questions. When in any doubt, all cosmetic professionals should gain the expert opinion of an experienced medical doctor to assure safety of their customers. Supplying cosmetic professionals with state-of-the-art, scientifically sound knowledge is crucial if cosmetic education is to gain the respect it deserves.

IV. Conlusion

Formal education for cosmetic professionals in Slovenia is diverse, ranging from secondary education level to a tertiary Master of Cosmetics program. The rate of biomedical innovations introduced into cosmetics forces lecturers and organizers of informal education to cooperate. All major stakeholders in the field of cosmetics are interested in increasing the level of knowledge of all participants, since knowledge and experience are the best assurance for safety and efficacy as well as customer satisfaction.

CONFLICT OF INTEREST

Jure Jelenc currently serves as a Head of research in Iskra Medical, a company that produces medical and cosmetic devices. As such, he is frequently involved in informal education of cosmetic device users. He also serves as a guest lecturer at organizations offering formal cosmetic education.

Abstract - The increasing size of the elderly population is driving the development of ambient assisted living systems and telehealth. The recognition of the user's everyday activities and detection of alarming situations are important components of such systems. Moreover, the monitoring of vital signs, like the ECG, has a key role in telecare and telemonitoring systems. Therefore, in this paper we propose a system that monitors the user by combining an ECG sensor and two accelerometers. Our system recognizes the user's activities and detects falls using the accelerometer data. The ECG data is analyzed in order to extract relevant physiological signals: heart rate, respiration rate, etc. In order to improve the reliability and robustness of the system, the measured accelerometer signals can be combined with the ECG signal in order to detect anomalies in the user's behavior and heart-related problems. The proposed proof-of-concept system could contribute significantly to the quality, unobtrusiveness and robustness of the health care and patient safety.

I. INTRODUCTION

The world's population is aging rapidly, threatening to overwhelm the society's capacity to take care of its elderly members. The percentage of persons aged 65 or over in developed countries is projected to rise from 7.5% in 2009 to 16% in 2050 [1]. This is driving the development of innovative ambient assisted living (AAL) technologies to help the elderly live independently for longer and with minimal support from the working-age population [2, 3, 4]. To provide timely and proper assistance, AAL systems must understand the user's situation and context, making activity recognition (AR) an essential component [5, 6, 7]. Fall detection (FD) is an important component of many AAL systems because almost half of the hospitalizations of the elderly are caused by falls [8]. Fear of falling is an important cause for nursing home admission [9], and "the long lie" (not being able to get up and call for help) is an important predictor of death within six months [10].

The introduction of modern information and communication technologies (ICT), as support to medical activities, can increase the efficacy of the health care system and decrease its costs. Numerous studies have confirmed the benefit of the development of telecare systems [11, 12]. The proposed mobile approaches to telecare rely on body sensor networks that collect and manage recorded vital data [13].

This work was partly supported by the Slovene Human Resources Development and Scholarship funds and partly by the CHIRON project - ARTEMIS Joint Undertaking, under grant agreement No. 2009-1-100228. The authors acknowledge the financial support from the state budget by the Slovenian Research Agency under Grant P2-0095.

This paper presents a system that combines two sub-systems that correspond to the type of the sensor-data they analyze: (i) electrocardiograph (ECG) sub-system, and (ii) accelerometer (ACC) sub-system.

The ECG sub-system is based on Wireless Bipolar Body Electrode (WBBE) [14] that captures and preprocesses body surface potential signals [15]. An additional feature is the ability to extract hidden information from the body surface potential, like the respiration rate [16], or combine synchronized data from three sensors for reconstruction of the standard 12-lead ECG [17, 18].

The ACC sub-system uses two 3-axial ACCs attached on the user's chest and right thigh. By using data analysis techniques it recognizes user's activities and detect falls in real-time. The architecture of the sub-system is based on: (i) rules, which detect falls, recognize postures (static activities) and ensure the behavior of the sub-system is predictable and robust, and (ii) classifiers trained with machine learning (ML) algorithms, to recognize dynamic activities, for which the rules are not sufficiently accurate. The ACC sub-system was evaluated at the EvAAL-2013 AR competition [19] and awarded the first place. The evaluation was performed in a living lab using several criteria: recognition performance, user-acceptance, recognition delay, system installation complexity, and interoperability with other systems.

The rest of this paper is organized as follows. First, the design of the prototype system is given with a brief functional description. Next, the sensors and the methods for analysis of the sensor data are described. The operation of the system is presented in the Experiments section. Finally, the conclusions are summarized and some directions for future work are given.

II. SYSTEM DESCRIPTION

The current prototype system (see Fig.1) consists of an ECG sensor and two wearable ACCs. The ECG sensor is placed on an appropriate position on the user's chest. The ACCs are attached on the user's chest and the right thigh using elastic Velcro straps. The data analysis is performed on a laptop using the raw sensors data acquired through Bluetooth. However, for the future implementation of the system, we are considering a smartphone implementation and combining the chest ACC and ECG sensor into a single device. Moreover, this device is planned to be multifunctional [20, 21], and beside the ECG and ACC data, should also measure: body temperature, body humidity, skin resistance, light, etc.

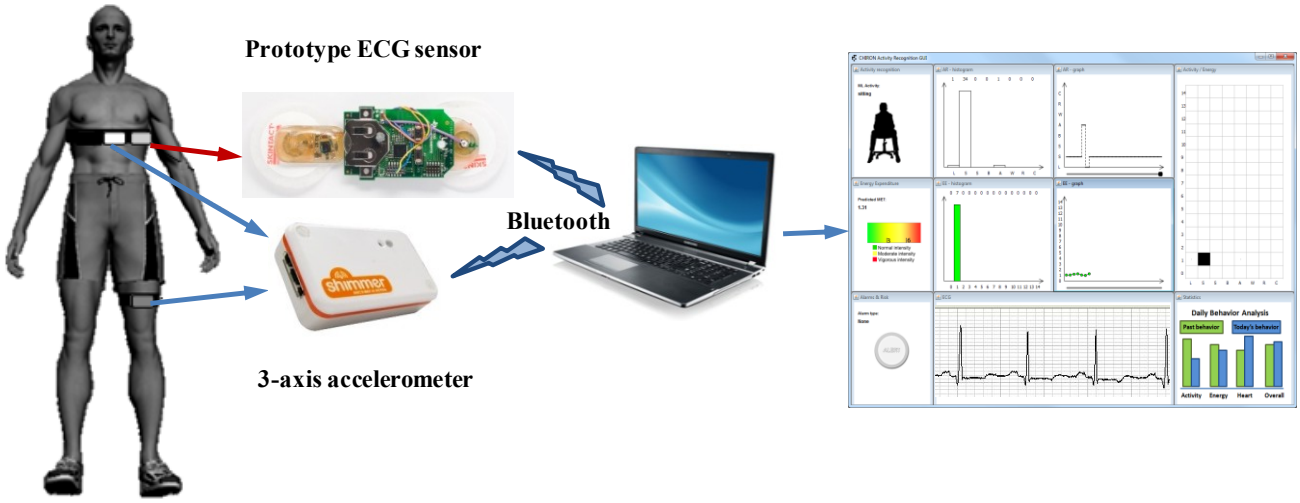

Figure 1. System design. Combination of the two solutions: ACC and ECG sub-systems.

A. *ECG sensor*

The ECG wireless body sensor designed from two self-adhesive electrodes positioned 5 cm apart, analog front-end, ultra-low-power (ULP) microcontroller and ULP Bluetooth V4.0 radio, ceramic chip antenna, and lithium coin battery, is shown in Fig.1 [22].

The analog front end is designed to suppress radio frequency interference. Signal amplification and filtering is made with a band-pass filter (0.15 Hz to 250 Hz, -3dB) before entering the microcontroller's 10-bit A/D converter with sampling frequency of 125 Hz for monitoring, and up to 1000 Hz for diagnostic and research cases. The 16-bit microcontroller (Texas Instruments, MSP430F2274) has 32 kB of FLASH, 1 kB of RAM and on-chip temperature sensor, all with an average power in active mode of 270 uA at 1 MHz. The microcontroller has enough peripheral lines to support other on-board sensors, like 3-axis accelerometer, skin temperature sensor and others. The Nordic Semiconductor's chip nRF8001 was used to support Bluetooth radio connectivity in peripheral (slave) mode. We have chosen lithium coin battery CR2032 as a power source for the body sensor. The nominal cell capacity is 220 mAh at discharge current of 200 uA, but due to pulse operation, a realistic capacity of 180 mAh can be expected.

B. *Accelerometer*

An accelerometer (ACC) is a sensor that measures the acceleration applied to the sensor and also the constant Earth's gravity. When the ACC is at rest, only Earth's gravity is measured. Using this information, the velocity of the sensor and also the sensor orientation can be estimated and therefore used for AR and FD. The platform used in this study has a 3-axis ACC, uses Bluetooth communication, and has 2 GB of storage, which is enough to store 3 months of sensor data for offline analysis. However, for the needs of this study, only real-time data acquisition and analysis was used. A potential, more in-depth, offline analysis is considered for future work.

III. METHODS

A. *ECG Data Analysis*

The measurement of ECG with sufficiently high amplitude and time resolution can support, besides standard heart rate analysis, also heart rate variability analysis [23], repolarization variability [24], ST-segment denivelation [25], detection of atrial fibrillation [26], characterization of arrhythmias, syncopes [27], sleep apneas, etc. Further, advanced approaches enable obtaining additional information from the recorded sensor signals. Two of them are listed below.

1) *Extraction of hidden information from WBBE*

It is known that body surface potentials include a lot of information that can be used for the estimation of personal medical status. As a successful case, we refer to the respiration rate extraction directly from WBBE [16]. We confirmed that several DLs on positions near the center of the chest provide adequate signals for ECG-derived respiration (EDR) algorithms that can reliably extract respiration rates from variations in the R-peak amplitudes. The EDR techniques, relevant to our work, are based on the observation that the positions of WBBEs on the chest surface move relative to the heart. Additionally, the transthoracic impedance varies as the lungs fill and empty. The proposed methodology is accurate enough for most practical cases and therefore useful for mobile health applications based on body sensors.

We have shown that a single WBBE is enough for the extraction of the respiration rate. However, if more electrodes are available, they can be applied to improve accuracy and robustness of the EDR results.

2) *Synchronized WBBEs on strategic positions*

The 12-lead ECG is the gold standard in cardiology and lies at the center of the decision pathway for the evaluation and management of patients. However, the conventional 12-lead ECG is obtained from ten electrodes connected with wires to a data collecting device. Its application therefore imposes obtrusion and has negative effects on patient's comfort. Moreover, due to the fact that the standard positions of the precordial electrodes are

often difficult to locate accurately, particularly in seriously damaged patients, the application of the conventional 12-lead ECG device can be impractical.

We have shown [17] that a small number of WBBEs − as few as three − can reliably reproduce a standard 12-lead ECG and are, therefore, suitable for real wireless applications. The proposed approach can be personalized in the sense that optimal positions of sensors and transformation matrices can be calculated for each individual [18].

B. *Accelerometer Data Analysis*

The ACC sub-system pipeline is shown in Fig.2. First, the sensors transmit the raw acceleration data over Bluetooth to the processing unit, i.e., laptop. The data from both sensors are then preprocessed: synchronized, filtered and segmented. Then the pipeline splits in two. On one side, the segmented data are transformed into feature vectors for the AR module, which recognizes the user's activity. On the other side, the FD module checks the acceleration for falls. If a fall pattern is recognized, the user's orientation is checked. If the orientation corresponds to lying, a fall is detected. Both the AR and FD modules are evaluating the user's situation every 250 milliseconds using the last 2 seconds of sensor data. For instance, if the current system time is denoted with t, the FD module evaluates fall events in the [t – 2 s, t – 1 s] interval, and the [t – 1 s, t s] interval is used to check if the user's orientation corresponds to lying. If the fall event is detected and the orientation is correct, the reported activity is falling, otherwise the reported activity is computed with the AR module in the [t – 2 s, t s] interval. The system thus reports the user's activity and detects falls with a two-second delay.

In the following sections, the AR and FD methods are briefly described. More details can be found in our previous work, [28, 29, 30] for AR, and [28, 31] for FD.

1) *Activity Recognition*

In the AR module, the activities are recognized by a three-level scheme [30]. The AR scheme was developed after empirical analysis of the data, which showed that some activities (such as cycling) are better recognized by a classifier trained only to distinguish that particular activity from the others. Therefore, on the first level, the feature vector is fed into a classifier trained by the Random Forest ML algorithm to distinguish cycling from the other activities. If the activity is not classified as cycling, the feature vector is passed to the second level, where the activities are recognized by rules. On this level, only the features that represent the sensor orientation the best are used (using component of the acceleration that corresponds to the gravity). The following activities are recognized at this level: sitting, lying, bending, and upright posture. If the recognized activity is the upright posture, the third level of AR is used to distinguish between standing and walking. The feature vector is fed into another Random Forest classifier, which is trained to separate these two activities.

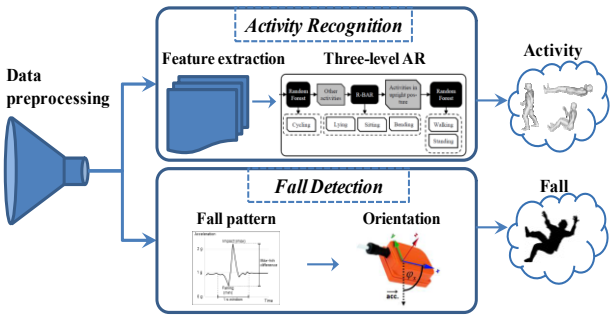

Figure 2. The data and recognition flow in the ACC sub-system.

2) *Fall Detection*

A typical acceleration pattern during a fall, measured by an ACC placed on the abdomen, is a decrease in acceleration followed by an increase [30]. This is because an ACC, when stationary, registers around 10 m/s^2 acceleration (denoted also as 1 g), and during free fall 0 m/s^2 acceleration. When a person starts falling, the acceleration decreases from 1 g to around 0.5 g (perfect free fall is never achieved). Upon the impact with the ground, a short strong increase in the acceleration is measured.

To detect fall patterns, we used the length of the acceleration vector to ignore the direction of the acceleration. The minimum and the maximum acceleration within a one-second window were measured. If the difference between them exceeded 1 g and the maximum came after the minimum, a fall pattern was found. We augmented the fall-pattern detection with the measurement of the user's orientation after a potential fall. We assumed that the orientation of the user's body after a fall couldn't be upright. Therefore, a fall was detected if a fall pattern was detected and the orientation in the next second was not upright.

IV. EXPERIMENTS

A. *ECG sensor performance results*

ECG signals from proximal electrodes have different appearance than the signals from standard ECG. An example is shown in Fig.3. The baseline is wandering and complete disappearance of the P, S and U waves can be observed. Note that the R and T waves could have opposite polarity, which is rarely seen in standard ECG leads. It is evident that the position of the electrodes has a significant impact on the measured ECG signal. Detailed analyses are possible only after significant preprocessing targeted to specific goals, e.g. heart rate determination, arrhythmia identification and characterization, ST segment denivelation, etc.

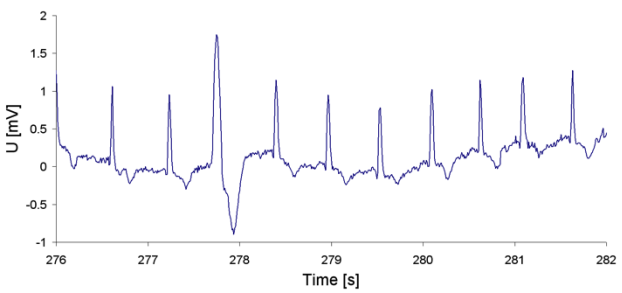

Figure 3. Raw ECG signal from electrodes at a distance of 5 cm. The person is walking around. The third heart beat is a ventricular extra systole with large amplitude and prolonged timing of the QRST complex.

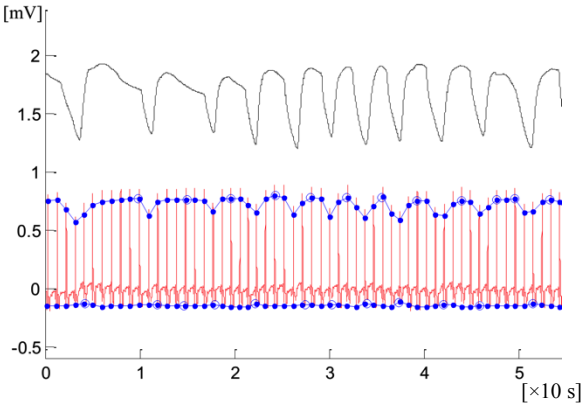

Figure 4. 53 seconds interval of an ECG (red) measured with a WBBE positioned in the chest center and 11 respiration intervals (black) measured by a thermistor near the front of the nose. 58 R-peaks (blue filled points) are detected and all 12 respiration interval are identified (blue circles).

For example, to determine the respiration rate, we found the best positions for the respiration body sensor [16] and proved that a single sensor of body surface potentials difference on proximal skin electrodes can be used for combined measurements of respiratory and cardiac activities (Fig.4).

B. Activity Recognition & Fall detection

The evaluation of the ACC sub-system was performed in order to check the recognition performance of the methods, using a pre-recorded dataset. The evaluation was performed on a complex, 90-minute scenario, recorded from 10 people. The scenario was designed to capture the real-life conditions of a person's behavior, although it was recorded in a laboratory.

Table I shows the performance of the ACC sub-system. The performance of the AR is high, achieving 99.04% F-measure score averaged over all activities. The performance of the FD shows that 93.3% of the falls were detected (recall value), and 66.7% of all the fall detections were actually falls (precision value), giving the final F-measure of 77.8%. The detailed FD results (Table II) show that the first event – tripping (quick uncontrolled fall) was detected each time (15 out of all 15 events). The next event, fainting, was detected 13 out of 15 times. The next two events were the non-fall events that are difficult to distinguish from the fast falls because of the high acceleration. Because the FD module also checks the user's orientation after a potential fall, it was able to distinguish quickly sitting on the chair from the falls. However, this was not the case for quickly lying in the bed (13 detections − which are false because the event is non-fall). For correct recognition of this event, additional information would be needed, e.g., user's location [31].

C. Concurrent ECG and Accelerometer Data

Fig.5 shows activity experiment with concurrent measurements from ECG and ACC sensors when the user is lying, sitting and walking.

ACC sensors give clear information for distinguishing walking from sitting or lying. One can also notice lower beat rates in lying and sitting compared to walking, which implies eventual lower energy expenditure. Detailed analysis of ECG indicates also that beat rate of lying is even lower that the one while sitting, which is supplementary information. With longer measurements, the long-term changes in the beat rate variability could give additional information about the time scale. Eventual extra systoles could point out a susceptibility to arrhythmia, etc.

TABLE II. ACC SUB-SYSTEM–AR AND FD RESULTS

Performance	*Activity Recognition*	*Fall Detection*
Recall	99.22%	93.33%
Precision	98.85%	66.67%
F-measure	99.04%	77.78%

TABLE I. FD DETAILED RESULTS

	Events	*Detected/All*
Fall events	Tripping	15/15
	Fainting	13/15
Non-fall events (false detections)	Quickly lying	13/15
	Quickly sitting	1/15
	Other	0

V. CONCLUSIONS

We showed that the fusion of ECG and ACC sensors data can provide supplementary information about the status of the monitored user. Based on this, it is possible to better understand the context of user's health state and activity and therefore better reason about his/her health and behavior status. The reasoning may include classification of the detected anomaly into several levels: (i) low-risk warning, e.g., higher heart-rate detected during sedentary activity, (ii) medium-risk warning, e.g., gait anomaly detected, (iii) high-risk warning e.g., very high heart-rate detected during longer period of time, and (iv) alarming situation detected that requires medical attention, e.g., the user has fallen and is lying without movement.

We are currently developing and testing a new multifunctional sensor node that consists of several sensors to obtain synchronized data about vital bio-signs and activities of the monitored users. For the final implementation of the system we plan three-phase

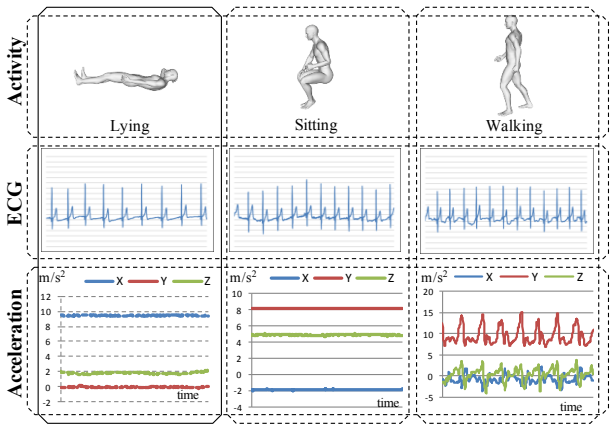

Figure 5. Concurrent ECG and ACC data.

monitoring and data analysis: (i) short-term behavior and health analysis - focusing on the last several minutes of data (alarming situations, falls, arrhythmias); (ii) medium-term behavior analysis - focusing on the past day (gait analysis); and (iii) long-term behavior analysis (daily/weekly anomalies) related to heart problems, less active days, etc.

Abstract - Obesity is considered an endemic within the whole European continent, just as in most part of the developed world. Obesity poses an increasing risk, childhood obesity has more than doubled in children and tripled in adolescents in the past 30 years. To assess the impact of obesity we need to take into account the severity of the problems that obesity might cause, as risk is usually interpreted as the product of probability of occurrence and severity. In the last few decades, increased occurrence of several morbidities was casually linked to obesity. Recently health problems targeting children have increasing trends in well developed countries. Our research is focusing on obesity related health problems in children, and our offered ICT solutions enables healthcare service providers to remotely monitor patient's (children's) activities and weight. The solution also helps to assign workout programs to the children according to the collected sensor data. The used workout programs base not only on widely used sport activities (etc. running or gymnastics), but cover non-conventional sport activities like playing with interactive game consoles at home. The system contains an Android based DAQ (Data Acquisition Device), sensors and a server side portal, which collects all measured patient information in the data center. The solution combines existing; self developed client and server side applications and frameworks, and commodity sensor solutions. The main goal of our work is to adapt the already existing monitoring solution to children. Kids behave and use such monitoring environments differently due to their different perception and knowledge level. They need different GUIs; they live different lifestyle as elderly patients. The communication lines of the system are compliant to the EU and national regulations. The developed system was tested and a prototype system was installed successfully in a real environment. Sensor data acquisition on the personal mobile device enables both end-users and care givers/professionals to provide better and more effective health monitoring and facilitate patient's treatment. The paper describes the internal architecture of the software solution and its main functionalities.

Obesity treatment, health monitoring, telemedicine, sensor data acquisition

I. INTRODUCTION

Obesity is considered an endemic not only in Hungary but within whole European continent, just as in most part of the developed world. According to, 1.5 million Hungarian is definitely obese, whilst an additional 2.7 million can be considered overweight. Together, this is almost the half of the Hungarian population. To assess the risk of obesity we need to take into account the severity of the problems that obesity might cause, as risk is usually interpreted as the product of probability of occurrence and severity. In the last few decades, increased occurrence of several morbidities was casually linked to obesity, such as non-insulin dependent diabetes mellitus (NIDDM), stroke, ischemic heart disease (IHD), immunological and reproductive dysfunctions and certain neoplasms. From these, stroke and IHD is amongst the first three in the list of mortality rates in Hungary. These all confirm that obesity poses a significant risk, high enough to be interesting from the public health point of view as well. Early intervention is needed to prevent the onset of obesity and obesity-associated comorbidities, which intervention should be focused to be the most effective. Early, focused intervention presumes however an efficient screening method which can select those people who are prone to obesity even when they are healthy otherwise. This screening has many difficulties in practice, starting as early as how to measure obesity. In the frame of our national scale project a combined Diabetes & Obesity monitoring solution have been developed for children.

This paper shows how we have built up our remote patient monitoring environment using a client side software, gaming console to increase children's motivation to do exercises and the DrHealth portal.

II. SYSTEM OVERVIEW

Recently health problems targeting children have increasing trends in well developed countries. The platform is focusing on Diabetes and Obesity related health problems in children, enables healthcare service providers to remotely monitor patient's (children's) blood sugar level and weight. The solution is also help to assign workout programs to the children according to the

collected sensor data. Workout programs not only supporting widely used sport activities (etc. running or gymnastics), but cover non-conventional sport activities like playing with interactive game consoles at home. The system contains Android based DAQ (Data Acquisition Device) connected with external sensors, a gaming console and a server side portal, which collects all measured patient information in the central data center. The solution combines existing; self developed client and server side applications and frameworks and already developed sensor solutions. The main highlight of the project is to adapt the already existing monitoring solution to children. Kids behave and use such monitoring environments differently due to their different perception and knowledge level. They need different GUIs; they live different lifestyle as elderly patients. The communication lines of the system are compliant to the EU and national regulations. Security is a pivotal point of the system. Health records and patient sensor are transported in an encrypted way.

A. *DAQit - Mobile data acquisition framework*

DAQit Framework is a mobile data acquisition (DAQ) solution, which collects personalized health information of the end-user, store, analyze and visualize it on the smart device (DroidHUB) and optionally sends it towards to the datacenter (DrHealth) for further processing. The smart mobile device is capable to collect information from a large set of various wireless (Bluetooth, and WiFi) and wired (USB) sensors.

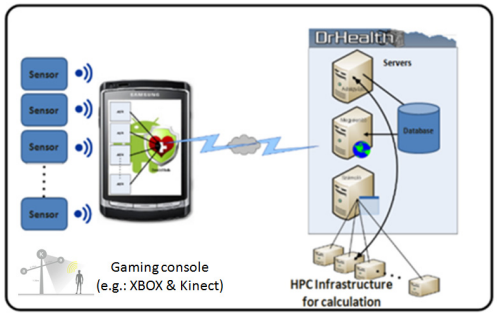

Figure 1. System overview

Embedded sensors of the mobile device provide additional useful status information (such as: user location, magnetic or noise level, acceleration, temperature, etc.). The user interface of our software solution is suitable for different skilled users, highly configurable and provides diary functionality to store information (can act as a diet log, or even can be used as a pain diary).

B. *DroidHub – DAQ on smart client devices*

DroidHub is an Android based mobile data acquisition solution implemented within the DAQit framework. DroidHub has the following basic software functionalities/features:

- Multi-language support (English, German, Italian, and Hungarian).
- Silent sensor DAQ mode (automatic data collection) via Bluetooth.
- Health status visualization (with statistics and data mining facility).
- Manual DAQ mode (optionally GUI initiated sensor data collection).
- Data compression and encryption during data transmission.
- Automatic sensor data pre-evaluation at the DroidHub.
- Full featured location aware mobile emergency alarm.
- Real-time sensor data forwarding to the central data collector server
- Store and forward mode to enable offline data collection

C. *DroidHUB - Sensor set*

Sensors can provide digital fingerprint of the patient's/person's psychophysical status and performance. A wide range of sensors is supported to collect detailed and accurate information about the patient's health status remotely:

• patient's blood glucose/sugar level

• patient's actual pulse, and oxygenization level

• patient's ECG signals

• patient's blood pressure

• patient movement within the house, with the usage of wall mounted sensors

• patient medication, with sensors of the medicament dispenser

• patient's eating habit, with sensors placed on the refrigerator

• patient activity (non-invasively rest/activity cycles, motor activity)

• patient's weight

• environmental information, about room temperature, humidity etc.

Figure 2. DroidHub sensor set and the GUI

We categorize sensors according to their data collection methods: active or passive type sensors. In our solution we are using a wide range of sensors (both passive and active) to collect detailed and accurate information about the patient remotely. Some of our

measurements are used for long-term monitoring (minutes-hours-days), others are just being able to provide snapshot measurements (e.g.: blood glucose level checking). Long term monitoring can become an invisible health data acquisition during patient activities.

Sensor name	Data collection type	Long-term monitoring	Snapshot like measurement
ECG holter	passive	yes	yes
Blood pressure holter	passive	yes	yes
Blood glucose meter	active	no	yes
patient's actual pulse	passive	yes	yes
Oxygenization level (SpO2)	passive	yes	yes
Simple ECG	active	no	yes
Blood pressure	active	no	yes
Movement (wall mounted sensors)	passive	yes	no
Medication (medicament dispenser)	passive/active	yes	no
Eating habit (sensors placed on the refrigerator)	passive	yes	no
Rest/activity cycle monitoring, gross motor activity	passive	yes	no
Weight	active	no	yes
Environmental information (room temperature, humidity etc.)	passive	yes	yes

Table 1. Sensor and measurement

1) Diary / reminder services

Besides pure data collection our DroidHub enables to do correlation analysis of stored data series. Reminders are intended to notify user in pre-defined appointments about data collection needs. This feature enables to track data in certain periods like measuring patient's blood glucose level on a regular basis.

D. Game console support - Training facility

Our solution is compatible with different type of game consoles such as the Wii[1] or XBOX 360 [2] equipped with the Kinect™ [3] sensor. Kinect is a motion sensing input device developed by Microsoft for the Xbox 360 video game console and Windows PC. It has a built-in RGB camera (640×480 pixels @ 30 Hz), an IR emitter, plus an IR depth sensor, a multi-array microphone, and a 3D accelerometer. It has an operational range between 40 cm and 3 m. Obesity and diabetes requires significant training activities. Motivation is a key factor, which is very hard to increase sometimes in obese children. We have created a metrics to evaluate available games on the software game market. We have checked gamer statistics of the last 5 years, and collected feedbacks about the major, well-known console games. We have identified interactive games which have good acceptance levels by children (kids like it, according to the game statistics). We are targeting special games which are using motion sensors to control the game. We have combined the game console and our DroidHub equipped with activity sensors. We are able to measure the full energy consumption of the gamer during their play.

E. DrHealth - Data management center

On the server side we have realized a generic Data Center and a portal based graphical user interface. The GUI is a Liferay [4] based open source, service-rich front-end with the following features:

- Data management and data sharing
- Data visualization (multi-sensor)
- Real-time monitoring
- Strong authentication
- Easy-to-use web interface
- Data analysis
- Data storage

It supports full training programs composed of training exercises. The portal can be used to develop training programs. The portal based GUI is accessible via the Internet after the required user authentication. Instead of real-time monitoring, the practitioners can access the uploaded and archived training data. The defined training programs and the collected sensor data about each exercise are archived to the user's data space. The GUI is capable to let practitioners search and retrieve their patient's training data.

Figure 3. Multiuser (a) and single user (b) activity/health monitoring

DrHealth is collecting all the activity information and calculate the burned calories of the kids during the training activities.

III. SUMMARY AND FUTURE WORK

We have built up a combined obesity and diabetes monitoring solution with our DAQit framework, which is using external sensors, and game console systems as training devices to stimulate and monitor patient's training activities. Sensor data acquisition on the personal mobile

device enables both end-users and care givers to provide better and more effective health monitoring and facilitate prevention. We have integrated the DAQit framework with various indoor game console systems (Wii, and Microsoft XBOX). The patient can play with the game console and health parameter measurements tracking the effectiveness of the activity. The server side system enables both patient and practitioners to do comparative analysis between the trainings, and later reuse the data also for trend analysis. The developed solutions provide important feedbacks about training efficiency and health status both to the patient' parents and to the medical experts.

IV. ACKNOWLEDGMENTS

The projects have been supported by the European Union. The authors would like to thank GOP-1.1.1-11-2012-0055- Dialogic „DIALOGIC – Mathematical model based decision support system for diabetes monitoring" for its financial support. This work makes use some of the results produced by the AALAMSRK project (Research & development of assisted living patterns and their integration into decision support system to promote the quality of life at home), Hungarian National Technology Programme, A1, Life sciences project. Authors would like to thank for their financial support hereby.

***Abstract*—In this work, isometric contraction of triceps brachii muscles are analyzed using surface electromyography (sEMG) signals and multifractals. The signals are recorded from 20 healthy adult volunteers at three different angles of elbow flexions namely 30º, 60º and 90º using standard experimental protocol. The recorded signals are preprocessed and subjected to Multifractal Detrended Fluctuation Analysis (MF-DFA). The three extracted MF-DFA features namely, peak exponent event, rare exponent event and smooth exponent event, are used for further analysis. The results show that multifractal spectrum response are distinct for all the three angles of flexion. It is observed that multifractal spectrum is shifting from higher order exponents to lower order with the increase in the angle of flexion. The features are statistically highly significant between 30º and 90º flexion. The smooth exponent is found to be statistically highly significant for both 60º-90º and 30º-90º flexion. It appears that this method of multifractal technique is an useful approach to understand muscle contractions in fatigue and in varied clinical conditions.**

Keywords—Surface EMG; Isometric Contraction; Triceps Brachii; Multifractal; Detrended Fluctuation Analysis;

I. INTRODUCTION

Muscle tissues are categorized into smooth, cardiac and skeletal muscles based on their structure and functionality. The skeletal muscles are striated and attached to skeleton to facilitate movement, force generation and interactive action through the process of excitation, extension and contraction. Muscle tissues are made up of muscle fibers and innervated by alpha-motoneuron, and together they form the basic functional unit of neuromuscular system known as motor unit [1-2]. Based on the motor unit ability to contract and resistant to fatigue, they are classified into slow-twitch and fast-twitch muscle fibers [3]. The slow-twitch muscle fibers are fatigue resistant and their properties are useful for endurance-based activities like repeated contraction with lesser force [4]. The fast-twitch muscle fibers are prone to fatigue but provide good contraction and force in rapid time [5]. The percentage of slow-twitch and fast-twitch fibers vary based on skeletal muscle function and purpose. The triceps brachii is normally a three-head muscle in the upper arm and running along the humerus bone connected to the shoulders and elbow [6]. The triceps brachii is antagonist muscle and biceps brachii is agonist muscle providing stability to arm for different interactive actions and flexions. The maximum force and power output produced by muscle are influenced by numerous factors such as muscle fiber size, muscle length, angle and physical properties of the fiber-tendon attachment, fiber to muscle length ratio, fiber type, number of cross-bridges in parallel, rate of force development, and force-frequency relationship [7].

The study of muscles during elbow flexion is gaining field of sports medicine [8], rehabilitation [9], robotics, myoelectric and prosthetics control [10-12]. The muscle activities of the biceps brachii and brachioradialis showed angle-related changes in the order of 55° (largest value) followed by 70° and 90° [13]. The muscle length is dependent on angle of joint and is found to influence the muscle force [8]. A study conducted by Kim indicated that the angular variations due to flexion has an influence on the muscle and activation behavior [14].

The Surface Electromyography (sEMG) is a non-invasive technique of recording the electrical activity of muscle contractions [15]. The varying intense contraction increases the complexity of analyzing the sEMG signal [16]. The presence of high frequency (small time scales) and low frequency components (large time scales) can complicate the analysis of sEMG signals in analysis [17].

There is an increasing evidence that physiological signals are generated by complex self-regulating system and may have fractal structure [18-19]. The fractals are referred to a signal that can be split into smaller parts that is approximately similar to a reduced-size of whole signal. This property is called self-similarity and proposed by Mandelbrot [20]. The multifractal analysis based on detrended fluctuation analysis (MF-DFA) is introduced to determine the scaling properties and for detecting the long-range correlation for non-stationary series [21]. This MFDFA method is successfully implemented in heart rate variability [18], human gait analysis [22] and EEG [23]. The patterns of sEMG exhibit self-similarity

property [24]. The area of singularity spectrum based on fractal technique is computed in isometric contraction for biceps brachii [25]. Distinct features are reported for biceps brachii muscles during isometric contraction [26-27].

The aim of this work is to analyze of sEMG signals recorded from triceps brachii muscle during isometric contraction using multifractal detrended fluctuation technique at various angles of flexion. Three different features are derived from the multifractal spectral approach and are used for further analysis.

II. METHODOLOGY

A. Experimental Protocol and Signal Acquisition

In this study, 20 healthy volunteers without any history of neuromuscular disorder, participated in performing an isometric contraction of elbow extension by moving the forearm. A dumbbell measuring 6-kilogram is given to the participant for exerting the load on the muscles. The experimentation protocol is explained to each participant before the start of the study, and written informed consent form are collected. The subject is requested to maintain upright body position and hold the dumbbell at 30º, 60º and 90º flexion (dumbbell is parallel to the ground). Each participant is advised to perform this exercise using his or her dominant hand for a duration of at least 3 seconds and signals are recorded.

B. Signal Acquisition

The skin around the triceps brachii area is cleaned and abraded before placing the surface electrodes (Ag/AgCl electrodes: 1cm diameter; 3 cm inter-electrode distance). The reference electrode is placed on the elbow. The sEMG signals are recorded from the triceps brachii muscle in a bipolar configuration. The signals are amplified (Gain=1000) and sampled at 10000 Hz with Biopac MP36 system (24-bit data acquisition; CMMR 110 db) [16]. The signals are preprocessed offline using a butterworth band-pass filter (10Hz – 400 Hz), filtered using a notch filter (50 Hz). The signals are down sampled at 1000 samples per second for computational reasons.

C. Multifractals and Detrended Fluctuation Analysis

The term fractal is related to statistical self-similarity. The class of signal with varying singularity exponent and regularities is called as multifractal. The detrended fluctuation analysis (DFA) method is proven to be useful in revealing scaling properties of monofractal signals and in identifying the extent of long-range correlations in non-stationary time series [22] . The multifractal generalization of DFA (MF-DFA) is based on the identification of scaling of higher order moment related to power-law dependent signal length. The MF-DFA technique consists of below steps:

Step 1: For the sEMG sequence, x_k, of length N, the integrated signal profile $Y(i)$ is computed as

$$Y(i) = \sum_{k=1}^{i} [x_k - \mu \quad] \tag{1}$$

$i = 1 \ldots N;\ \mu\ is\ mean$

The profile is then divided into N_s segments of equal length s without any overlap ($N_s = N/s$). The length N may not be multiple of time scale s and may lead to a profile tail remainder. Hence the same procedure is repeated from the other side of the series to get $2N_s$ segments.

Step 2: For each segment $\boldsymbol{v}$, the local trend is calculated by fitting a polynomial $\boldsymbol{y_v}(\boldsymbol{i})$. The variance is then determined as

$$F^2(s, v) = \frac{1}{s}\sum_{i=1}^{s}\{Y[N - (v - N_s)s + 1] - y_v(i)\}^2 \tag{2}$$

Step 3: The qth order mean fluctuation function is obtained by averaging over all possible segment length s,

$$F_q(s) = \left\{\frac{1}{2N_s}\sum_{v=1}^{2N_s}[F^2(s, v)]^{q/2}\right\}^{1/q} \tag{3}$$

Step 4: The above steps are repeated for various scales to establish a relationship between detrended fluctuation function, $\boldsymbol{F_q}$and the size scale s as

$$F_q(s) \sim s^{Hq} \tag{4}$$

where Hq is called the generalized Hurst exponent. The power-law scaling is represented as a linear function on the double log plot for different range of s by the fluctuation function. This relationship is represented as

$$H_q(q) = [\tau(q) + 1]/q \tag{5}$$

The generalized Hurst exponent and the multifractal spectrum is related by Legendre transform [21] and deriving the multifractal parameters as

$$Dh\,(Hq) = q[Hq - Hq(q)] + 1 \tag{6}$$

where Dh is the Hausdorff dimension and Hq is the generalized Hurst exponent.

D. Features of Multifractals

The organization of multifractal series is characterized by evaluating number and size of fractal sets that influences the time scale. Based on the multifractal spectrum, it is possible to derive the quantity and quality of irregularities in the time series [21]. The shape of the spectrum is dependent on the periodic pattern. Higher value of Hurst exponent in the time series is an indication of more periodicity and less complexity. The sEMG signal are subjected to MF-DFA with 1000 samples (1 second data) and then continued with a 75% overlap for the duration of the recorded signal. This procedure is repeated for all the three angles of isometric contraction. The multifractal spectrum is averaged for each angle for analysis. The features used in this study are explained below [21],[23]

Peak Exponent Event (PET): The value of generalized Hurst exponent in multifractal spectrum is taken as peak exponent when the Hausdorff dimension equals one. If there are more than one Hausdorff dimension having a value of one, then the least exponent is considered as peak exponent.

Rare Exponent Event (RET): The left most value of generalized Hurst exponent in the multifractal spectrum is defined as rare exponent event. This feature is a representation of non-stationary characteristics of the signal.

Smooth Exponent Event (SET): The right most value of generalized Hurst exponent in the multifractal spectrum is defined as smooth exponent event. This feature is a representation of stationary characteristics of the signal.

E. Statistical Analysis

Analysis of Variance (ANOVA) is an inferential method that is used to test the equality of three of more population means. In this study, one way ANOVA test is performed to investigate the effects of mean value of peak exponent, smooth exponent event and rare exponent event for each angle of isometric contraction. Post-hoc procedure ($p<0.05$) is used with Tukey to investigate differences between features for different angles.

III. RESULTS AND DISCUSSIONS

A. Raw sEMG signals and demographic data

The demographic data for 20 participants are represented in Table I. The representative sEMG signal from triceps brachii muscle at 30º, 60º and 90º are shown in Figure 1. The magnitude, frequency response, amplitude and pattern of sEMG signals are found to be complex during the isometric contraction at various angle of flexion. At 90º flexion, the amplitude of sEMG signals appears to be increasing steadily. The duration of the experiment performed by different participants varied from 3 seconds to 8 seconds. For computation purpose, the entire duration is considered and normalized.

B. Scaling Exponent function

The value of multifractal scaling exponent $\tau(q)$ plot for various values of q (ranging from -10 to 10) is represented for isometric contraction in Figure 5 for the three angles of flexion. The scaling behavior is varying for both positive and negative values of q and with angle of flexion. This is an indication that the sEMG signals are exhibiting multifractal behavior during isometric contraction. The scaling function at 30º flexion is having highest slope for q indicating influence of both small and large fluctuations. This may be due to lower firing rate of the motor units and relatively lesser force needed to sustain the contraction in isometric position at 30º as compared to higher angles. At 30º, the scaling exponent varied from 4.5 and -14 during isometric contraction. The larger variation of scaling exponent are indication of higher multifractal behavior during 30º than in 60º and 90º. This may be due to increase of self-similar behavior and higher multifractal property for 30º as compared to higher angles of flexion.

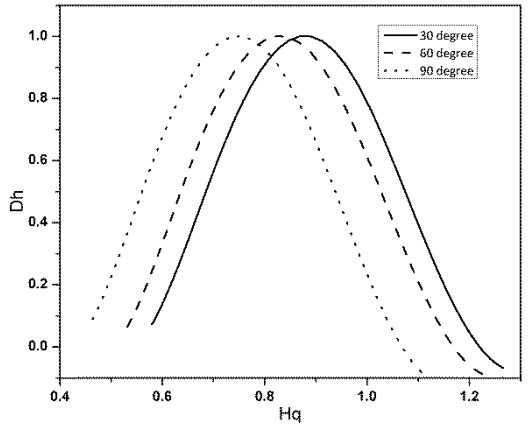

Figure 4. Average Multifractal Spectrum for Isometric Contraction

C. Genralized Hurst Exponent function

Figure 3 is the representation of averaged generalized Hurst exponent of sEMG signals for three different angle of flexion during isometric contraction. The decreasing exponent function with increasing moment is an indication that sEMG signals are exhibiting multifractal characteristics. This is observed for all the three angles of flexion. The values of Hurst exponent is found to be highest in 30º angle of flexion. Since the values of Hq are higher when q is lesser than 0, this is an indication that exponent function is dependent on smaller fluctuations in the sEMG signal than with the larger fluctuations. The highest impact of small fluctuation is observed at 30º flexion ($q < 0$) and highest impact of large fluctuations are also observed at 30º flexion ($q > 0$). The motor unit synchronization is higher when the muscle is flexed at 30º than higher degree of flexion. This is also seen in the Figure 1 where the amplitude of sEMG signals are relatively lower for 30º flexion and maximum at 90º flexion. The trend also indicates that sEMG signals are more stationary and lesser complex when the flexion is minimum (at 30º flexion) and increases with angle with respect to vertical axis.

D. Multifractal Spectrum

Figure 4 is the representation of average multifractal spectrum with various degree of elbow flexion in isometric contraction. The peak exponent is highest for 30º (0.89) and lowest at 90º (0.75). This is an indication that the sEMG signal in multifractal analysis experiences a left shift with the increase in elbow flexion. There is a steady decrease in self-similarity of the sEMG at 90º as compared to 30º flexion. This may be due to increase in motor unit activation for sustaining greater force in 90º flexion. The muscle has to exert maximum force as compared to 30º flexion. There is also a visible increase of large amplitude of sEMG at 90º. The trend indicates that with increasing angle of flexion, complexity of sEMG signals increases and thereby shifting the spectrum to lower values. The smooth exponent event and rare exponent event are also reducing with increasing angle due to the left shift of the spectrum.

The values of these three features are found to be statistically significant in all the three angles of flexion (Table II and III). This may be due higher activation at 90º flexion. The elbow at 90º position has greatest influence on triceps brachii muscle and hence higher firing rate leading to increased recruitment and de-recruitment of motor units. However in fatigue conditions, there is also a higher degree of synchronization due to these changes and thereby pushing the spectrum to higher regions. The smooth exponent event is showing statistically significance (> 0.05) for both 60º-90º and 30º-90º.

TABLE II. MF-DFA FEATURES FOR ISOMETRIC CONTRACTION WITH VARYING ANGLE OF FLEXION

Features	**30º**	**60º**	**90º**
	Mean (± SD)	**Mean (± SD)**	**Mean (± SD)**
Peak Exponent Event	0.89 (0.10)	0.84 (0.11)	0.75 (0.11)
Smooth Exponent Event	1.26 (0.10)	1.22 (0.13)	1.12 (0.13)
Rare Exponent Event	0.58 (0.11)	0.53 (0.11)	0.45 (0.09)

TABLE III. ANOVA ANLYSIS FOR THREE FEATURES AT THREE ANGLE OF FLEXION

Features	**Sigma for 30º- 60º**	**Sigma for 60º- 90º**	**Sigma for 30º- 90º**
Peak Exponent Event*	0	0	1
Smooth Exponent Event*	0	1	1
Rare Exponent Event*	0	0	1

{* At the 0.05 level, the population means are significantly different
Sigma as 1 indicates that the mean difference is significant at 0.05 level
Sigma as 0 indicates that the mean difference is not significant at 0.05 level}

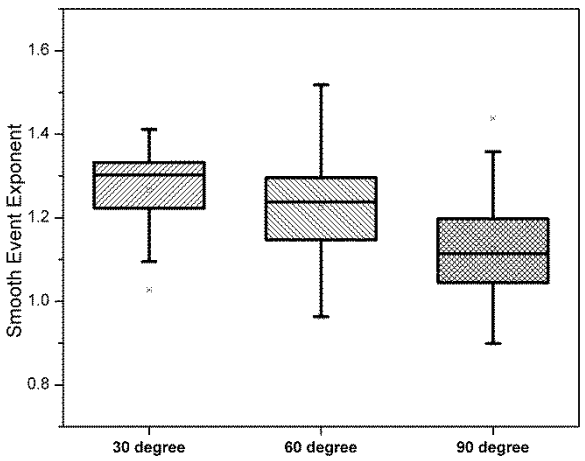

Figure 5. Smooth exponent event for three angles of isometric contraction

IV. CONCLUSION

In this work, isometric contraction of triceps brachii is analyzed using multifractal detrended fluctuation analysis. Three different features are extracted and are used for further analysis. Three different elbow flexions are considered for this study. The features from scaling exponent and multifractal spectrum are exhibiting multifractal characteristics sEMG signals during isometric contraction. The multifractal characteristics behavior is also observed in three angles of flexion.

The results show that the triceps brachii muscles are activated differently during isometric contraction at various angles of flexion. The signals are having highest multifractal characteristics when the participants are holding the dumbbell at 30 degree and the complexity of sEMG signals increases with increasing flexion.

The features computed such as peak exponent, rare exponent and smooth exponent are found to be statistically significant. The smooth exponent event appears to be useful feature for studying the isometric contraction. The study could further be extended to compare the variations of other muscles in the upper arm during isometric and dynamic contraction, and in studying various neuromuscular conditions.

DISTRIBUTED COMPUTING

Improving data-parallel construction of δ_N-Nets with Maximum Dispersion

P. Zinterhof
* University of Salzburg/Department of Computer Science, Salzburg, Austria
peter.zinterhof3@sbg.ac.at

Abstract - Linear nearest-neighbor search in high-dimensional data exposes high computational complexity. In order to minimize search complexity we employ optimal δ_N-nets of rank N, which consist of a sub set of N vectors out of an initial code book E, yet approximate all En vectors of E by the least error (denoted by the number theoretical concept of dispersion) of all possible selections of N vectors.

In this paper we demonstrate a substantially improved algorithm, which results in a reduction of computational complexity from previously O (En N^2- N^3) to O(En^2). We demonstrate computational feasibility both on CPU- and GPGPU-based systems for any desired accuracy in the approximation of codebook E by some δ_N-net for real-world problem sizes in the range of En = [10^7..10^8]. In addition to the high speedup that can be achieved by the new algorithm, the GPGPU implementation typically shows speedups of one order of magnitude over a CPU implementation.
We also give a practical example of image segmentation within computed tomography scans in order to show one potential application of this new approach.

I. INTRODUCTION

Machine learning is now a rapidly growing field with myriads of already existing and potential future applications in science, technology, and economy. In this paper we want to focus on the well-known machine learning method of principal component analysis (PCA), which transforms potentially correlated data into linearly separable, uncorrelated 'principal components' or feature vectors. One of the most important characteristics of PCA is the fact, that the number of output features is usually much smaller than the number of data items in the original input data. Thus, PCA essentially acts as a dimensionality reduction scheme, which often forms the basis for building robust pattern recognition systems. Correspondingly, our motivation to employ PCA has been the task of image segmentation in computed tomography (CT)-scans, in which we found PCA to be valuable in that it does not suffer from over-fitting as many neural network based approaches often do.

Our application takes small image patches (64x64 pixels) from CT-scans, that comprise our labeled input data. In the next step, all principal components are computed, but only the 32 (out of 4096) most eminent components are being put into a code book data structure for later use in the recall process. In the recall (or segmentation) phase, again small image patches are taken and transformed into short vectors of 32 PCA-values. In the final classification step, new vectors are being compared to the vectors in the code book, based on their Euclidean distance. The unknown vector is then assigned the same image class as the 'winning' vector in the code book, which is the vector with minimal Euclidean distance to the previously unknown vector. Unfortunately, our impulse of refining segmentation quality by increasing the number of samples in the training phase also led to an increase in computational complexity. As has been described in [1], any attempt of optimizing this code book lookup, will fail on high dimensional data and all sorts of clustering-, and kD-trees-algorithms break down in this task, due to the 'curse of dimensionality'.

This leaves us with linear search within a large array of short vectors of length 32. Obviously, in addition to employing parallel computation, one of the most efficient ways to improve recall speed is to actually decrease the size of the code book itself. In a way, we would have needed some form of PCA on the PCA-based code book vectors themselves. But as the single components already are linearly separable, we do not consider this approach feasible. Instead, in the following chapters we will shortly recall the concepts of Metric Dispersion and δ_N-Nets(see [2] for the full definitions) and then show how the construction of δ_N-Nets can be vastly improved in terms of computationally complexity. δ_N-nets can then be used to approximate the original code book (or any set of vectors, for that matter) of feature vectors which greatly speeds up the process of segmenting of CT-scans.

II. METRIC DISPERSION

In the following section we recapitulate the main definitions from [6]. Four properties are defined for metric d(x,y)

$$d(x,y) \geq 0, x,y \in E \quad (1)$$

$$d[x,y] = 0 \Leftrightarrow x=y \quad (2)$$

$$d[x,y] = d[y,x], \forall\ x,y \quad (3)$$

$$d[x,z] \leq d[x,y] + d[y,z], \forall\ x,y,z \quad (4)$$

with $d(x,y) = \sqrt{\sum_{k=1}^{s}}$ defined in a finite vector space $E \neq 0$ over $\mathbb{R}^s$.

The dispersion δ_N for N points in E is defined as

$$\delta_N = \delta(x_1, x_2, \ldots, x_N) = max_{x \in E}[min(d(x, x_k))] \quad (5)$$

As E is a finite vector space, $max[min(d(x,x_k), k = 1,2,\ldots,N)]$ is finite, too. Furthermore, it is $\delta_N \geq \delta_{N+1} \geq \delta_{N+2} \ldots$

Now, let

$$min(d(x,x_k), k = 1,\ldots,N) \geq min(d(x,x_k), k = 1,\ldots,N,N+1) \quad (6)$$

for all $x \in E$. Then for all $y \in E$

$$max_{x \in E} min\, d(x,x_k), k = 1,\ldots,N) \geq min(d(x,x_k), k = 1,\ldots,N,N+1) \Rightarrow max_{x \in E} min\, d(x,x_k), k = 1,\ldots,N) \geq max_{y \in E} min(d(y,x_k), k = 1,\ldots,N,N+1) \quad (7)$$

and hence $\delta_N \geq \delta_{N+1}$. In other words, metric dispersion δ_N is equal to the radius of the largest hyper-sphere S that can be put around any point in E without getting into contact or incorporating any other point of E. More details on metric spaces and dispersion can be found in [2] and [5], respectively.

III. Related work

As pointed out in [6], the mathematical concept of dispersion has initially been developed by E. Hlawka. Dispersion deals with discrepancy measures of uniform distributions of N points, which may also be the case for our algorithm. But the proposed algorithm itself is not limited to uniform distributions. Another overview on the mathematical concepts and foundations can be found in [1]. As our work on δ_N-nets starts with [6], one can find some of the main ideas described there, too. The proposed algorithm shares motivation of approximating a code book of feature vectors as in [6], but we do not consider it a simple adaptation of the previous algorithm. Instead, it is a rather different approach, which also might be seen when comparing the extremely improved computational performance of the new algorithm.

IV. Improved Construction of Δ_N-nets

A. Algorithm

The construction of δ_N nets is based on an iterative algorithm, in which two seed points x_1, x_2 are chosen, such that (5) is fulfilled and dispersion δ_N net with N=2 is obtained.

Next, based on the seed points, dispersion δ_3 is computed by finding point x_3, which is given by $max[min(d(x_1,x_k), d(x_2,x_k)])$. Obviously, In order to find point x_k, we have to determine Euclidean distances between all pairs x_1, x_k and x_2, x_k. The crucial point here is the fact, that we do not only compute $max[min(d(x_1,x_k), d(x_2,x_k)])$, but also retain the minimum distance of each point in E to x_1, x_2.

At this stage we already have the next 'winning vector' x_k, with k=3 along with an array (D) of distances $[min(d(x_1,x_k), d(x_2,x_k)])$. Furthermore, we can update array D repeatedly by computing d(y, x_k) for all remaining points y in E and store the local minimum D[y] =min(D[y], d(y,x_k)). Also, the new maximum max(D[y]) is being computed 'on the fly' during the same iteration, which will mark the next 'winner' x_{k+1}. So we have an iterative computation of the $(k+1)^{th}$ vector during updates of the minimum distances of vector x_k in array D.

The most important aspect of this new algorithm, compared to (6) happens to be its linear O(N) complexity of the update process of array D. At no point during construction of a δ_N-net we have to compute more than N Euclidean distances for each vector of Dn, that is, one computation for each of the N iterations. This is in stark contrast to (6), where complexity linearly grows with each new vector M that we add to the δ_N-net, giving total complexity O((N-M)*(M)) for the mth vector. In other words, adding vectors to some δ_N-net is of constant complexity now, were it has been of exponential complexity in the previous algorithm.

For typical applications (see results section), we frequently encounter vector sets E with N = 10^6 to 10^7. These numbers proved to be of intractable computational complexity, even for decently sized clusters of GPGPU-accelerated systems. We therefore had to limit the number of vectors in E and especially limit the size of the resulting δ_N-net to modest levels of 10^4 - 10^5. Still, the observed run times frequently had been in the range of several weeks!

The described algorithm makes it feasible to compute very large δ_N-nets including all vectors of E, not just small sub sets of E, without having to resort to a supercomputing system.

```
find seed points x1, x2
update distance array D, declare follow-up winner X

for k=3: N
  xk = UpdateD (X)
  X=xk
next k
```

Figure 1: pseudo-code for construction of δ_N-nets

B. Data-parallel Implementation

We employ two functions that are based on CUDA for C for finding both seed points x_0, x_1 and for finding points x_k, respectively (Fig. 1). As distances between any two points are symmetric (3), the search for maximum distances in E are of triangular form. The CPU based driver routine loops over all N points of E (En), repeatedly calling a CUDA function 'GPU_MaxDistance (Xk)' for each point $0 \leq x_k \square En$. The number of threads in each CUDA block is given by 32 x BLO, with 'BLO' being an arbitrary integer constant, such that the product of 32 by BLO is smaller than the maximum number of supported threads per CUDA block on a given NVIDIA GPGPU. The rationale of this particular number of threads is that we aim to achieve good memory coalescing (hence multiples of 32 threads) and also good utilization of shared memory. By moving BLO copies of the vector x_k (line 11) into local shared memory, we avoid potential conflicts in memory access later on in the main loop (line 23 ff.). The same principle is enacted in line 26, where a block of BLO vectors is copied from the code book into local shared memory. We are then able to perform Euclidean distance computations strictly off-line, based on local shared memory only. This frees up the memory bus of the accelerator for access by additional CUDA blocks. Euclidean distance computations for a given vector are performed in parallel by all 32 threads in a WARP (line 32 ff.), but only one thread is scheduled to determine the nearest neighbor of the vector within our code book array 'base_d'. After having sifted through the entire code book, there do exist BLO local minima (nearest neighbors), which have to be reduced to a single global maximum (line 62 ff.). Again, only one thread of each WARP operated this procedure, but as this is a global operation that potentially interferes with CUDA threads of different CUDA blocks, a binary semaphore is used for arbitration. As no explicit semaphore constructs are offered in CUDA, the desired functionality of the semaphore is implemented by an atomic compare-and-swap function. By busy-waiting for value 0 on a global variable 'sema' and atomically setting it to the block index of the calling thread, access of one and only one thread is ensured. Global atomic operations are notoriously expensive on GPUs and some further optimization step could involve a slightly different scheme, which would restrict thread-synchronization to each CUDA block. Thus a number of gridDim.x maxima would arise instead of one truly global maximum as in the code shown (fig.2, lines 67 ff.). In preliminary tests we have moved the final computation of the maximum back to the CPU, which showed a slight improvement in execution times, but also increased code complexity to some extent.

Construction of all subsequent vectors of the δ_N-nets works analogously, with the algorithmic addition of storing local minima in an array and by masking out those vectors from E that already have become part of the δ_N-net. Masked vectors need not be taken into account any more and thereby reduce the computational load.

```
1   __global__ void GPU_ MaxDistance (
2               const float *  __restrict__ base_d,
3               int Xk,

```

Figure 2: CUDA code for finding maximum Euclidean distance to a given vector in an array of vectors

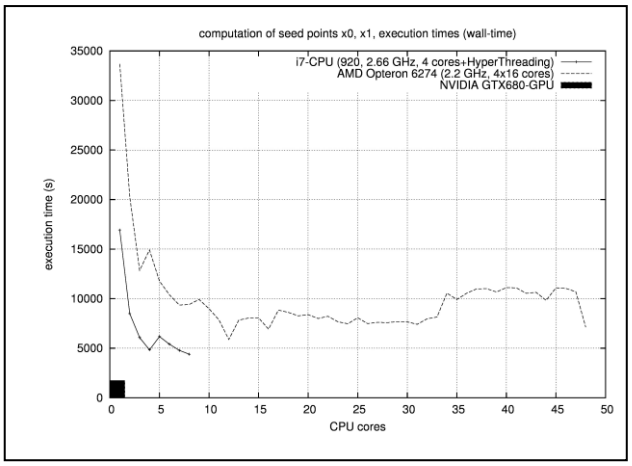

Figure 3: Scalability of seed point generation

V. RESULTS

We have tested the algorithm by implementing it both on standard CPU-multiprocessors and NVIDIA GPGPUs, respectively.
Figure 3 displays both scalability and performance of the generation of seed points for a δ_N-net with E=1 million for an INTEL i7-desktop CPU, a quad-socket system based on AMD Opteron server CPUs (SuperMicro), and a consumer GPGPU from NVIDIA. Parallelization has been based on GCC 4.4.3 with OpenMP and CUDA 5.5, respectively. The GPGPU has been operated in the i7-desktop system for all GPGPU-related tests.

On the i7-CPU the algorithm scales very well for up to 4 processing cores. By employing Intel HyperThreading we get only marginal improvements at the maximum of 8 cores. Given the ratio of memory per floating point operation of 4:3 we are inclined to attribute nearly constant execution times for core counts higher than 4 to a saturation of the memory system ('hitting the memory wall').
In the case of the quad-socket Opteron System very similar effects can be observed. Scalability is good for up to 12 cores, where peak performance is reached. total Execution times do not benefit from employing higher numbers of CPU cores.

CPU-code has been compiled with optimization (-O5 -funroll-loops), but without explicit use of SIMD instructions.

GPGPU-code outperformed any number of CPU-cores by a factor of at least 3.

Table 1 reflects a comparison of the i7-system and two different NVIDIA GPGPUS in the main task of constructing δ_N-nets. The latter two examples (rows 3 and 4 of table 1) can directly be compared to previous results given in (6). They emphasize the tremendous increase in performance which is a direct result of the new algorithm, far less of potential advances in computing machinery during the last two years.
In the case of a δ_N-net of 15.000 vectors out of a code book of 6.3 million entries, one single i7-core (2.66 GHz) running the new algorithm clearly outperforms two NVIDIA GPGPUs (GTX480, Fermi) running the previous algorithm (6) by a factor of 1.6, whereas a single GTX680 (Kepler) card excels by a factor of 69.85.

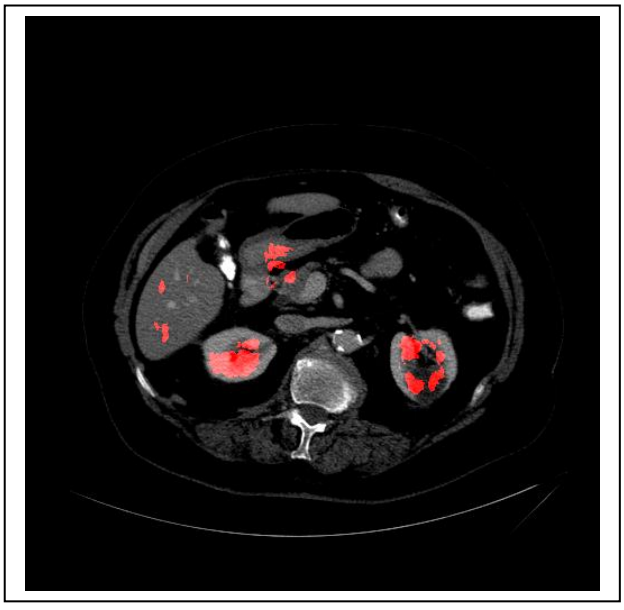

Figure 4: Segmentation based on random selection of 500k entries

Table 1: Computation of δ_N-nets, (wall-) times in s, factors in line 2 denote the speedups over the CPU versions.

	i7-CPU, 2.66 GHz	**NVIDIA GTX680**	**NVIDIA GTX 480**
Δ_N-net:50k vectors, E=100k vectors	543.94 1.0x	32.70 16.6x	51.75 10.5x
Δ_N-net :500k vectors, E=1m vectors	54433.2 1.0x	2642.84 20.5x	2856.46 19.0x

In a joint project with Salzburger Landeskrankenhaus (SALK) we developed a principal component (PCA) algorithm for segmenting computed tomography scans (CT). Data taken from some 80 patients have been labeled manually for training and by applying PCA a code book consisting of several million entries has been built from scratch. Each entry of this code book can be described as a vector of 32 float values (32 bit), along with some label data, e.g. 'kidney', 'cyst', etc.

By transforming previously unseen and hence unlabeled data of some new patient into vectors of 32 principal components, we can sift through the code book and find that entry 'W' (winner) with least Euclidean distance to the unclassified vector. Classification of that vector is then simply a matter of reading the label data accompanying the winning code book vector.

In reality, the process of segmenting an entire CT scan involves several million lookup calls in a code book of – again – several million entries. Obviously, this can be very time consuming and therefore we resorted to clusters of GPUs.

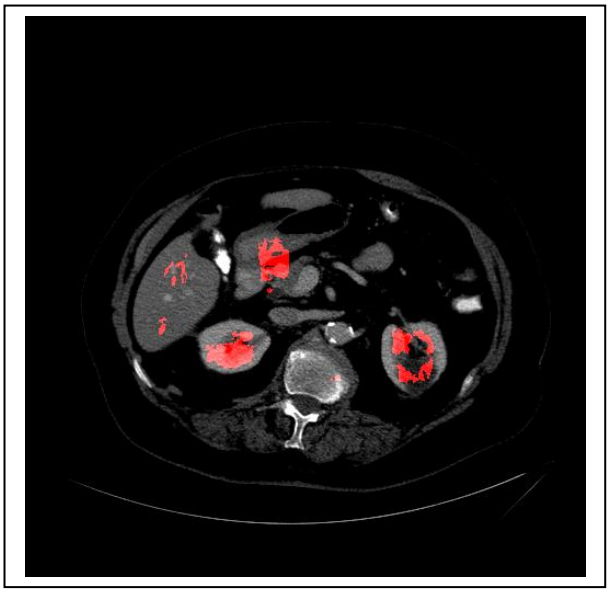

Figure 5: Segmentation based on a δ_N-net, N=500k entries

But even with the help of powerful compute accelerators run times had to be brought down further and we finally applied δ_N-nets for the approximation of very large code books.

Fig. 4 and Fig. 5 give an impression of the output of the segmentation process based on 500.000 vectors. Concerning Fig. 4, vectors have been chosen randomly, whereas Fig. 5 has been based on the corresponding δ_N-net.

False negatives could be reduced substantially over randomly chosen vectors, which we used the base line. Also, the number of correctly labeled pixels has been up by 25 % compared to the base line.

We therefore consider δ_N-nets a suitable approach for accelerating certain lookup operations in PCA-vectors.

VI. CONLUSION

We have given an overview of the mathematical concept of metric dispersion, on which we have based our improved algorithm for the construction of δ_N-nets. The improvement makes it computationally feasible to build very large δ_N-nets out of vast code books even on CPU-based hardware. We also demonstrate, that the new algorithm neatly fits into the data-parallel programming paradigm that recent GPGPUs rely on. Thus, we are able to effectively use GPGPUs during all algorithmic steps and hence improve execution times by at least one order of magnitude.

So, our contribution is two-fold. Firstly, we describe a new, much improved algorithm for the construction of δ_N-nets. Secondly, we show that efficient use of GPGPUs is possible in order to gain further speedups and construct δ_N-nets in reasonable time.

Further work will involve optimizations of the GPGPU implementation by employing multiple GPGPUs.

Abstract - The term 'big data analytics' emerged in order to engage in the ever increasing amount of scientific and engineering data with general analytics techniques that support the often more domain-specific data analysis process. It is recognized that the big data challenge can only be adequately addressed when knowledge of various different fields such as data mining, machine learning algorithms, parallel processing, and data management practices are effectively combined. This paper thus describes some of the 'smart data analytics methods' that enable a high productivity data processing of large quantities of scientific data in order to enhance the data analysis efficiency. The paper thus aims to provide new insights how various fields can be successfully combined. Contributions of this paper include the concretization of the cross-industry standard process for data mining (CRISP-DM) process model in scientific environments using concrete machine learning algorithms (e.g. support vector machines that enable data classification) or data mining mechanisms (e.g. outlier detection in measurements). Serial and parallel approaches to specific data analysis challenges are discussed in the context of concrete earth science application data sets. Solutions also include various data visualizations that enable a better insight in the corresponding data analytics and analysis process.

I. INTRODUCTION

'Understanding climate change, finding alternative energy sources, and preserving the health of an ageing population are all cross-disciplinary problems that require high-performance data storage, smart analytics, transmission and mining to solve' [1]. Scientific disciplines face huge challenges in data processing with the ever increasing amount of scientific data [1,2,3]. This raises the demand for *'smart data analytics methods'*, which are required to provide a very concrete set of tools, techniques, frameworks, and infrastructures in order to perform *'big data analytics'* with real data sets. This is one of the important elements of data-intensive science [3] among others such as preserving and managing large-scale data sets for their *'active re-use'* (e.g. in-situ validations with real measurement data sets during a computational simulation on large-scale computing resources).

In order to effectively perform data-intensive science, it is important (i) to understand its relationship to other important and closely related concepts (e.g. machine learning algorithms, data mining practices, etc.), and (ii) to understand what are the fundamental techniques for efficiently using available resources (e.g. high performance computing, high throughput computing, big data sharing and access, etc.). Hence, by considering (i) and (ii), we want to achieve a *'high productivity data processing'* using a systematic approach and thus refine with this term the often generally used term 'big data analytics' with concrete methods. A wide variety of data analysis and analytics were arbitrary but we require a principled and systematic set of methods that guides the *'smart data analytics processes'*. This enters the field of process models such as the Cross Industry Standard Process for Data Mining (CRISP-DM) [4]. We require *'innovative perspectives on data'* as described by Provost et al. [5] who mentions that a *'data-science perspective provides practitioners with structure and principles, which give the data scientist a framework to systematically treat problems of extracting useful knowledge from data'*. This is particularly useful when the general data analytics step (performed by data scientists) precedes the often scientific domain-specific data analysis.

In earlier work [6], we already gave insights into several concrete *'big data processing approaches'* (e.g. iterative map-reduce, scientific workflows, databases, massively-parallel processing algorithms, visualization and steering, etc.) that we leverage in the context of large-scale computing (e.g. PRACE [7]) and collaborative data infrastructures (e.g. EUDAT [8]). This paper goes a step further in disentangling the set of closely interrelated *'big data analytics concepts'* described above in order to understand which techniques can be applied on which compute and storage resources to solve one specific data science problem. We provide methods in the context of two concrete data-intensive science case studies from the earth science domain we work with in a systematic fashion using CRISP-DM and selected algorithms and resources: (a) outlier detection [21] in measurement devices data, and (b) data classification [21] of multi-spectral images.

This paper is structured as follows. After the introduction to the problem domain, Section II provides a background to the concrete earth science data sets in question and briefly surveys systematic ways to perform *'data science'* with selected required concrete techniques. Section III offers the reader then methods in context of our two case studies well embedded in the overall systematic way of performing a high productivity processing of data. The paper ends with some concluding remarks of several findings and outlines future work elements.

II. Background and Related Work

A wide variety of process models exist that bear the potential to support 'smart data analytics processes' with a concrete structure that often refer to 'phases' with certain 'steps'. CRISP-DM [4] (cf. Figure 1) is the most suitable one that we refined for our (parallel) smart data analytics since it clearly outlines *'six concrete phases'* that are typical for a data mining project: *(a) problem/business understanding; (b) data understanding; (c) data preparation; (d) modeling; (e) evaluation; (6) deployment*. Given the page restriction, we summarize them only briefly based on the CRISP-DM user guide [9] including refinements towards *'smart data analytics'*, but would like to emphasize that we perform our work on the scientific data case studies using the CRISP-DM as a useful backbone process. To the best of our knowledge, a generally accepted *'big data analytics process model'* for science and engineering problems is not existing except disconnected approaches from several business domains (e.g. predictive/customer analytics processes, etc.).

The *'(a) problem/business understanding phase'* includes general steps (aka tasks) such as determining the objectives and goals (e.g. data analytics success criteria), performing a situation assessment (e.g. inventory of computing and storage resources). In phase *'(b) data understanding'*, the tasks includes the creation of a couple of reports about the initial data (collection and data sets), including data (collection) description, exploration options, and data quality statements. The third phase *'(c) data preparation'* refers to tasks that accurately described the data sets in question, their rational for inclusion/exclusion as well as required work on cleaning data or reformatting data if needed. The phase *'(d) modeling'* includes the selection of modeling techniques, test designs and related parameter settings to build the model. This phase depends highly on the scientific question that drives the 'smart data analytics' process as well as the next phase *'(e) evaluation'*, which stands for several tasks related to assess the analytics results w.r.t. the initial success criteria described in phase (a). The final phase *'(f) deployment'* enables a systematic way of performing analytics on a regular basis including a monitoring and maintenance plan. In our given context of *'smart data analytics'* we apply the CRISP-DM process not as an iterative process, but rather as a cyclic one refining information and models of phases as required.

According to Marbán et al. [10], CRISP-DM is the *'de facto standard for developing data mining and knowledge discovery projects'* that was one of the facts influencing our decision to use the CRISP-DM as a backbone process for our *'smart data analytics'* case studies. Another process model often mentioned in context and named after its phases is 'Sample, Explore, Modify, Model, and Assess (SEMMA)' [11] mostly driven by the SAS Institute. Although used in the business domain alongside a dedicated commercial tool, it rather concentrates on the modeling tasks in data mining compared to CRISP-DM that includes a more comprehensive 'perspective' on the overall data analytics process.

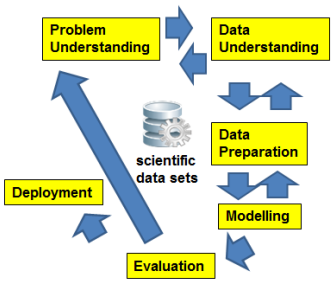

Figure 1. CRISP-DM process model (*modified from [9]*)

After the introduction of the major structure of performing *'smart data analytics'* in a systematic way, we briefly introduce our two data-intensive case studies in order to have a focus on relevant and concrete techniques required. The field (and overlaps) of data mining, machine learning, knowledge discovery, and (parallel) data analysis & analytics is very large and thus we need to concentrate on two very specific problems given real world data sets. At the same time we face the challenge that many algorithms in the field of machine learning, artificial intelligence, or data mining have not a long history in taking advantage of parallel and distributed computing techniques in the field of *'high performance computing (HPC)'* and *'high throughput computing (HTC)'*. In this contribution, it is the rate of interconnection of computing nodes that differentiates HPC (i.e. fast interconnect within clusters, e.g. Infiniband) from HTC (i.e. moderate interconnect, e.g. usual Ethernet as found in Grids and Cloud infrastructures today).

The first case study raises the demand to tackle the problem of *'automatic outlier/anomaly detection'* in measurement data sets that are part of the PANGAEA data collection [12]. With 7.9 billion data items (2013), better sensor equipment during the years, and its constant growing factor contribute to name this data source as *'big data'*. Hodge et al. [13] present a good survey of principles in outlier detection referred to as different types: *'Type 1 – Determine the outliers with no prior knowledge of the data (unsupervised clustering)'*; *'Type 2 – Model both normality and abnormality (supervised classification)'*; *'Type 3 – Model only normality or in a very few cases model abnormality (novelty detection and recognition) '*. We re-use these principles, but require a more fine-grained perspective when tackling a concrete data set with more elaborate elements for parallel approaches than mentioned in [13].

The second case study tackles the problem of *'classification of multi-spectral images'* in data sets that are part of data collections acquired by the Quickbird satellite [14]. This is just one *'sensor'* of many similar data sources that enable the study of changes in land usage, agricultural and forest climates. Experts refer to case studies like this as *'remote sensing science'* that aims to interpret information using sensors that are not in direct physical contact with the object being observed. Classification algorithms that work with these datasets have to treat both spectral and spatial information in order to obtain a satisfactory level of detection accuracy. A survey of related work in classification principles is nicely summarized by Moguerza et al. in [15] as follows: *'support vector machines (SVMs) have increasingly turned into a standard methodology in the computer science and engineering communities'*.

III. METHODS FOR SMART DATA ANALYTICS

Innovative methods for smart data analytics require a solid foundational basis in order to enable a high productivity processing of *'big data'* (i.e. towards petabytes) rather than being only usable with data sets of sizes that we often used in the past (i.e. gigabytes, terabytes). We therefore suggest that the methods are well embedded in a *'collaborative data infrastructure (CDI)'* design with additional services that optimize data access and provide added value with services that enable data sharing, persistence, and safe replication. In earlier work, Riedel et al. [16] proposed a *'data infrastructure reference model'* that follows a CDI approach and that consists of computing and storage resources relevant for our proposed concrete analytics methods. The design approach and some of its services (e.g. the B2SAFE safe data replication service) are currently implemented as part of the EUDAT data infrastructure.

In contrast to the rather elaborated reference architecture top-down work of the National Institute for Standard (NIST) big data working group [18], we aim to provide in this contribution a bottom-up approach based on concrete scientific case studies and their required reference architecture elements. In [6] we therefore suggest a derived concrete architecture design tailored for *'big data analytics'* in a context of a CDI while this section aims to refine this architectural setup based on concrete techniques and tools that are used in the context of two specific case studies. Scientific results of them are expected to be published in domain-specific publications and thus this paper focusses on the pure technical findings of combining a wide variety of available tools and frameworks for *'smart data analytics'*. Selected elements of the CRISP-DM process model tailored to our problem domain are given in context of the two case studies while full reports are already available or expected to become available as part of the EUDAT data infrastructure.

A. Automatic outlier detection in measurement datasets

By following the tailored CRISP-DM model phase *'(a) problem/business understanding'* we define the goal to automatically detect outliers in large quantities of measurement data, because manual *'quality control'* is slow, error-prone, and becomes increasingly impossible as the amount of data set grow significantly in type and volume. The architectural setup in Figure 2 illustrates selected parts of the inventory of computing and storage resources such as the PANGAEA collection archive (i.e. community storage data sets) and HPC resources (i.e. computing nodes available at the Juelich Supercomputing Centre and UoIceland respectively).

Selected elements of phase *'(b) data understanding'* include the task to collect initial data out of the large PANGAEA data collection that in our case refers to initial measurement datasets acquired by a cabled underwater observatory sensor in the open Swedish Fjord Koljoe Fjord (approximately 100 KM north of Gothenburg) installed as part of the HYPOX2 project [17]. The data sets are provided by PANGAEA data scientists that preserve and manage data sets in their own domain-specific data infrastructure.

The third phase *'(c) data preparation'* includes tasks of describing the structure of the data. In our case study we work with datasets that consists of a time series of a month/file (i.e. tab separated data files) with underwater measurements. We furthermore had to remove some metadata elements in the plain data files that created problems when using it with the R Statistical Computing tool [20].

The phase *'(d) modeling'* includes the selection of modeling techniques and in our case also the related appropriate outlier detection algorithms. There are currently two parallel approaches we explore as part of our 'smart data analytics' methods: (i) using the statistical computing tool R with the RMPI and outlier package (cf. Figure 2); (ii) using a new implementation by G. Fox et al. of the DOoR algorithm described by Bhaduri et al. in [22]. The automation of the approach is provided by using a HPC middleware (i.e. UNICORE [23]) that provided a seamless access to large-scale supercomputers. R scripts and the execution of outlier algorithms are performed with this system using workbench tools (cf. Figure 2).

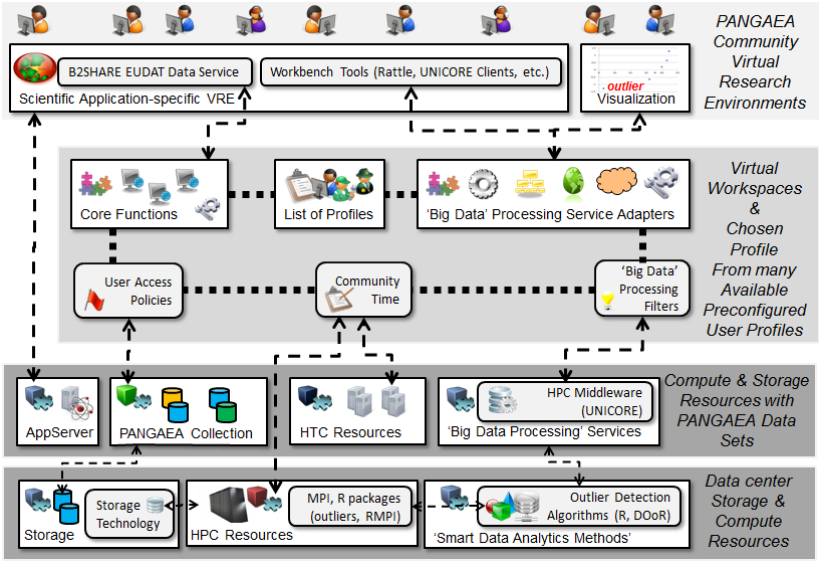

Figure 2. Architectural deployment for the automatic outlier detection in PANGAEA measurement datasets.

The *(e) evaluation'* phase, which stands for several tasks related to assess the analytics results w.r.t. the initial success criteria described in phase (a) is twofold: Firstly on a technical basis using data mining techniques; secondly, results of the automatic outlier detection are regularly shared with scientific experts from PANGAEA by using the *'B2SHARE EUDAT Data Service'* (cf. Figure 2). They evaluate which *'smart data analytics'* elements make sense and what approaches are not helpful. In addition, often used outlier data visualizations are available (e.g. normal probability plots, boxplots, histograms) as needed to further support this process (cf. Figure 2 top right).

The final phase *'(f) deployment'* enables a systematic way of performing automated outlier detection on PANGAEA datasets once the tests with initial datasets have been shown successful over time. This concrete 'smart data analytics method' is well embedded in a sustainable data infrastructure offering storage resources and services mostly independent of project funding, because of a network of trusted data centers in EUDAT and PRACE.

B. *Classification of multi-spectral images*

We start again with our tailored CRISP-DM process model, but perform a quicker walk-through as the ideas of each phase are the same, but the given data analytics problem is usually different. In phase *'(a) problem/business understanding'* we define the goal of performing a data classification of buildings in street map with high accuracy using multi-spectral image datasets. These data sets constantly grow in volume and thus require a more powerful classification approach and thus we define a *'speed-up of data classification'* as a clear objective in this particular case study. The architectural setup in Figure 3 illustrates selected parts of the inventory of computing and storage resources such as parts of the Quickbird satellite data collection (i.e. community storage data sets) and HTC resources (i.e. computing nodes available at the UoIceland and as part of FutureGrid [24] respectively).

Phase *'(b) data understanding'* include the task to collect initial multi-spectral image data sets out of the large commercial Quickbird data collection that in our case is done by the domain scientists that work with us.

In the phase *'(c) data preparation'* we perform tasks to describe the structure of the data. In our case study we work with datasets that are in fact different types of images acquired by the QuickBird satellite: (i) a high-resolution panchromatic image or resolution 0.6m and a low-resolution (2.4m) multi-spectral image.

The phase *'(d) modeling'* includes the selection of modeling techniques and in our case also the related appropriate parallel data classification algorithm. As described above, one of the most commonly applied principle technique in data classification are support vector machines (SVMs) [21]. There is currently one parallel approach we explore as part of our 'smart data analytics' method: using Twister [25,26] as shown in Figure 3. Twister improves the original map-reduce [27] approach (e.g. used in Apache Hadoop [28]) with iterative capabilities, which can be used to train an SVM classifier as described by Zhang and Fox in [29]. We need to mention here that the implementation in turn is based on the widely known libSVM library [30].

Also in this case study, the *(e) evaluation'* phase is twofold: Firstly on a technical basis using machine learning techniques separating the labelled data in three distinct sets: training data, test data and validation data; secondly, results of the data classification results are regularly shared with scientific experts by using the *'B2SHARE EUDAT Data Service'* (cf. Figure 3). They evaluate which *'smart data analytics'* elements make sense and what data classifiers have not enough accuracy. In addition, visualizations are available (e.g. speed-up diagrams compared to serial approaches) as needed to further indicate that the training time of the SVM classifier was significantly faster. This is especially the case when considering the observed used manual approaches by using Matlab SVMs [31].

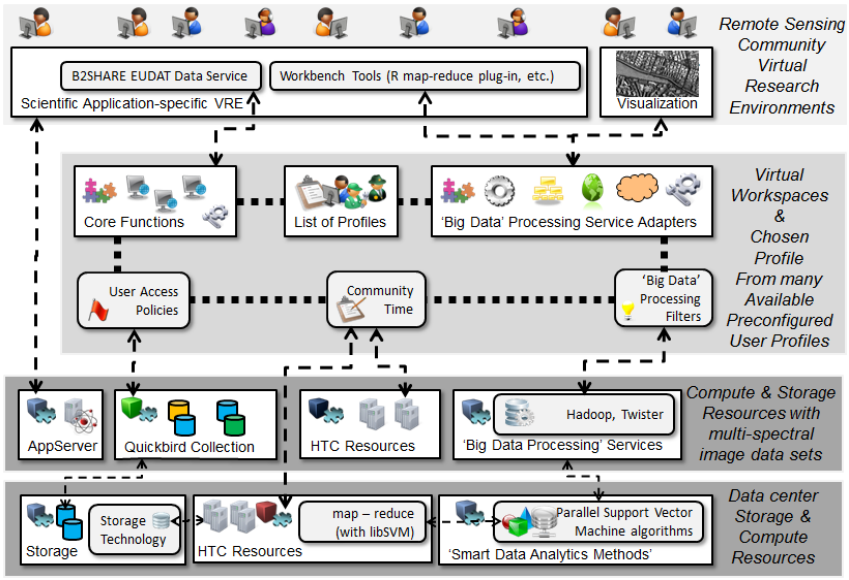

Figure 3. Architectural deployment for the data classification using parallel support vector machines for Quickbird masurement datasets.

The final phase *'(f) deployment'* enables a systematic way of performing data classification of multi-spectral image datasets once the tests with initial Quickbird image datasets have shown good accuracy of the trained parallel SVM classifiers. This concrete *'smart data analytics method'* is well embedded in a sustainable data infrastructure offering computing and storage resources mostly independent of project funding, because of a network of trusted data centers in EUDAT with computational resources .

IV. CONCLUSIONS

This section gives the reader some concluding remarks although we are in the early phases of our *'smart data analytics process'* in the described case studies – but that is a process that might be never finished given the ever increasing amounts of big data sets. We are nevertheless able to derive some initial conclusions about structuring the process and thus performing *'big data analytics'* in a systematic way in the concrete area of *'outlier detection'* and *'image data classification'* of scientific datasets. Detailed findings that relate to the clever and innovative combinations of technology required for the 'smart data analytics' described in this paper are actively contributed and discussed as part of the Big Data Analytics (BDA) [19] interest group of the Research Data Alliance (RDA). This enables the guidance of non-experts for *'big data analytics'* and sharing of findings with the broader community (e.g. with members of the US NIST big data activities).

We firstly conclude that the general reference model design of a CDI offers 'added value services' (e.g. data sharing, replication, access optimization, data transfers) to the *'smart data analytics process'*. It offers a solid foundation to perform *'higher level analytics'* based on concrete algorithms and tools without the need to tackle simple problems such as deploying data transfer protocols. We observe that services like B2SHARE represent an important element in a seamless cooperation between general data analytics experts and scientific domain-specific experts for rather temporary scientific data results whereby only a fraction qualifies for long-term data preservation (e.g. using the B2SAFE EUDAT data service).

Secondly we are able to conclude that the CRISP-DM is well suited as a backbone for a process we referred to as *'smart data analytics'* although being originally designed for traditional data mining and knowledge discovery. Tailoring this model by describing large-scale compute and storage resources, clarifying the concrete machine learning algorithms and data mining techniques, tools, and service deployments make the approach feasible to guide the *'high productivity data processing'* of large quantities of scientific data. These findings are considered to be part of a report compiled by the RDA BDA group.

Thirdly, we can conclude that the architectural setup of the method for automatic outlier detection is plausible, however, we also have to acknowledge that the work on tailoring the algorithm to the specific problem at hand requires many (parameter) configurations (e.g. within the HPC system UNICORE). Nevertheless, we identified all the required elements and implementations in order to use the method in practice today. Tailoring the CRISP-DM process model, when performing outlier detection, is very useful too, because of many reasons one of which is the clarity of describing all relevant aspects of the concrete proposed method (resources, data, algorithms, tools, etc.). This clarity is an important fact during the communication of the general data analytics expert and the PANGAEA scientists. Using an easy and open approach for sharing the data for validation purposes by using the B2SHARE EUDAT data service was generally viewed as an important element of the method.

We can further conclude that the architectural setup of using parallel SVMs for classification of multi-spectral image data is possible to implement today. Nevertheless, the parameter tuning and creating the classifiers is not straightforward and needs time to achieve reasonable results. These findings are important, but further raise the demand for several software packages that need to be maintained and installed on relevant underlying hardware resources (i.e. Twister and libSVM). Hence, achieving a speed-up required for 'big data' is possible, but also requires a distributed system (e.g. with map-reduce). Using CRISP-DM and the B2SHARE EUDAT data service was equally useful in this case study as described in the concluding remarks of the previous case study.

ACKNOWLEDGMENT

The work is partially funded by the EUDAT project that is co-funded by the EC 7th Framework Programme (Grant Agreement no: 283304). We thank Robert Huber (MARUM Bremen, Germany) for his close cooperation in the context of the PANGAEA outlier detection case study. We are also grateful to Gabriele Cavallaro (University of Iceland) for his close cooperation in the context of the spectral image analysis. We further thank Geoffrey Fox and Zhanquan Sun for their consultation and sharing of implementations in context of parallel data analytics algorithms. Finally, thanks to Tomas Philip Runarsson for his advice in mathematical aspects of statistical data mining algorithms.

***Abstract*—Matrix multiplication is a widely used algorithm in today's computing. Speeding up the multiplication of huge matrices is imperative for scientists and they are trying to discover the fastest algorithm. Blocking the matrices reduces the cache misses since both blocks can be stored in L1 cache and thus only the first access of an element will result in cache miss and all other access will be a cache hit. However, choosing the block size is not the only optimization. In this paper we analyze the impact of various block size ($M \cdot K$ and $K \cdot N$) on the performance. The realized experiments use different parameter values for K and predefined values of the parameters M and N, to test algorithm behavior in different cache regions.**

The results of the experiments show three phenomena. The first phenomenon is that if M is greater than N, then choosing the first block $M \cdot N$ will achieve a significantly greater speed. The second states that, if the second parameter N is increased for constant M has no significant influence on the performance. Finally, the third phenomenon is that the speed decreases significantly if N is increasing for constant M.

***Index Terms*—Cache Memory, Matrix Multiplication, Processor, Performance.**

I. Introduction

Today's world is unthinkable without efficient matrix multiplication. Apart of being an essential linear algebra algorithm for solving linear systems of equations, it is widely used for linear transformations in image processing. That is, moving some points (translation), changing left- and right-handed ordering (reflection), and a combination of both are all operations that require matrix multiplication. The increased image size and resolution require faster operations, and if possible, in real time.

Matrix multiplication is a compute intensive algorithm with $O(N^3)$ complexity, memory demanding with $O(N^2)$ complexity. It is also defined as a cache intensive algorithm [1] of order matrix size N because each element is accessed N times. Due to these characteristics, the matrix multiplication requires huge computing (faster CPU with huge cache and big RAM memory) and storage resources for multiplying greater matrices. Big matrices cannot be placed in the cache memory, which generates a lot of the cache misses and reduces the algorithm performance.

Sscientists are enforced to optimize the algorithm for a specific hardware parameters. Dividing the matrices to blocks and multiplying each block among each other enforces the multiplications to work only with a small amount of data that can be stored in the L1 cache, which significantly improves the performance, especially when multiplying greater matrices [2].

However, the cache size is not the only important cache parameter. Cache replacement policy and cache type (inclusive or exclusive) are important cache parameters, but they impact more the naive matrix multiplication algorithm, rather than the blocking algorithm, since the number of cache misses is reduced. However, cache line (and the matrix elements' size), cache levels, n-way set associativity are more important, especially the latter [3]. In our previous work [4], we improved the blocking algorithm by choosing the blocks as rectangles, rather than squares. This was more emphasized for AMD processors due to their small associativity. In this paper, we extend this research to determine the optimal block size of the blocking algorithm, that is, we analyze the impact of the selected sizes ($M \cdot K$ and $K \cdot N$) when the same number of operations is executed. Several default values for the parameters M and N are chosen, and the value of parameter K varies within a given range for the behavior in different cache regions to be analyzed [1].

The rest of the paper is organized as follows. Section II presents the related research that we found in the literature, which speed up the matrix multiplication. We present the testing methodology used for the experiments in order to provide reliable results in Section III. The results of the experiments are presented in Section IV. The results are discussed in Section V. Finally, we conclude the paper and present the plans for future work in Section VI.

II. Related Work

This section presents the various techniques to speedup the matrix multiplication algorithm. We have grouped them in several classes: Reducing the number of operations, reducing the average memory access time, using many core processors and parallelization, and other various techniques will speedup the matrix multiplication. Anchev et al. [5] overviews several different techniques. An obvious speeding up is to run the multiplication on a faster CPU, but the CPU clock frequency is reaching a limit [6], also known as power wall.

A. Speeding up by reducing the number of operations

The goal of the researchers is to reduce the asymptotical power of N (matrix size) for matrix multiplication algorithm, i.e., the number of floating point operations. The first revolutionary reduction was proposed by the well known Strassen's algorithm [7], which reduced the power from 3 to 2.8, replacing some multiplication operations with add. Several other authors decreased this value to 2.3727 [8].

However, these theoretical improvements are efficient only for huge matrices that cannot be stored in the memory, and the cache size does not affect the average behavior a lot.

B. Using parallelization

Greater speedup is achieved if parallelization is used. Matrix multiplication algorithm is a school example of good algorithm for parallelization because it does not have data dependency. There are many examples of parallelization on CPU by using OpenMP, MPI, and MPI with OpenMP. Another example is using CUDA, or even MPI with CUDA if GPGPU cluster is used, as well as using the data flow and systolic arrays [9].

C. Speeding up by reducing the average memory access time

The total execution time consists of two parts: the processing time and the memory access latency. Therefore, the idea of speeding up the average value of memory access can provide a sufficient speedup, usually higher than the approach based on reducing the number multiplication operations.

Matrix multiplication is a cache intensive algorithm and its performance depends on the cache memory behaviour. Ristov and Gusev showed why and when the performance drawback will appear for a particular cache memory parameters [3]. A possible solution to avoid the associativity problem is padding the first element of the matrix [10].

Another very important algorithm is blocking the matrices. This algorithm even increases the number of operations, but significantly reduces the average memory access time. Our improved 2D/1D algorithm [4] is faster than the blocking algorithm with squared blocks for AMD processors due to their small associativity.

In this paper we focus on reducing the memory access time since this speeds up the cache intensive algorithms.

D. Other techniques

Drevet et al. [11] analyzed the optimization techniques for small matrix multiplication. Loop unrolling is another technique that uses the processor pipelining.

III. Testing Methodology

In this section we present the testing methodology used for the experiments as we can achieve reliable results.

A. Testing Algorithm

We use a multiplication of two matrix blocks. Denote the blocks of the first matrix A by $BA_{M \cdot K}$ and the blocks of the matrix B by $BB_{K \cdot N}$. The matrix elements are stored as double precision numbers, each with 8 bytes.

TABLE I
Test cases

Test Case	Notation	$BA_{M \cdot K}$	$BB_{K \cdot N}$
1	56x56	$56 \cdot K$	$K \cdot 56$
2	56x224	$56 \cdot K$	$K \cdot 224$
3	56x896	$56 \cdot K$	$K \cdot 896$
4	224x56	$224 \cdot K$	$K \cdot 56$
5	224x224	$224 \cdot K$	$K \cdot 224$
6	224x896	$224 \cdot K$	$K \cdot 896$
7	896x56	$896 \cdot K$	$K \cdot 56$
8	896x224	$896 \cdot K$	$K \cdot 224$
9	896x896	$896 \cdot K$	$K \cdot 896$

B. Testing Environment

The testing environment consists of Intel(R) Xeon(R) CPU X5647 @ 2.93GHz with 8GB RAM memory. The CPU is quad core, and each core has its own private L1 (32KB) and L2 (256KB) caches. All 4 cores share L3 cache of 12MB.

The server is configured with Linux Ubuntu 12.04 operating system and C++ is compiled with gcc compiler.

C. The Test Cases

Several test cases are conducted with predefined values of parameters M and M, and by varying all integer values of the parameter K in a given region to analyze the performance for fitting the blocks in all cache regions. The region $1 \leq K \leq 600$ was used for smaller predefined values of M and N, and the region $1 \leq K \leq 300$ for greater values.

The three values of M and N, i.e., 56, 224 and 896 are chosen to avoid the associativity problem [3]. That is, 56 matrix elements can be placed in 7 cache blocks, rather than problematic 8 blocks. The other two values are a product of 56 by 4 and 16, again avoiding associativity problem. Each combination of pairs (M, N) covers fitting of blocks in corresponding cache regions L_1 to L_3. L_4 is used as a level 4 cache or main memory if missing.

D. Test Data

We measure the execution time $T(M, N, K)$ for a particular value of the parameter K in each test case. Next, we use $T(M, N, K)$ to calculate the *Speed* $V(M, N, K)$ in each test case by using the definition for effective speed [12]. That is, the speed $V(M, N, K)$ is calculated by dividing the number of operations and measured execution time as defined in (1), for each test case for particular values of the parameters M and N.

$$V(M, N, K) = \frac{2 \cdot M \cdot N \cdot K}{T(M, N, K)} \tag{1}$$

E. Test Goals

The test cases have three goals. The first goal is to determine which pair of block sizes provides better performance if the blocks have the same number of elements, but exchanged parameters. That is, to compare the performance of test case pairs (2, 4), (3, 7) and (6, 8). For example, we multiply the blocks of test case 2 where $M_2 = 56 < N_2 = 224$. Figure 1

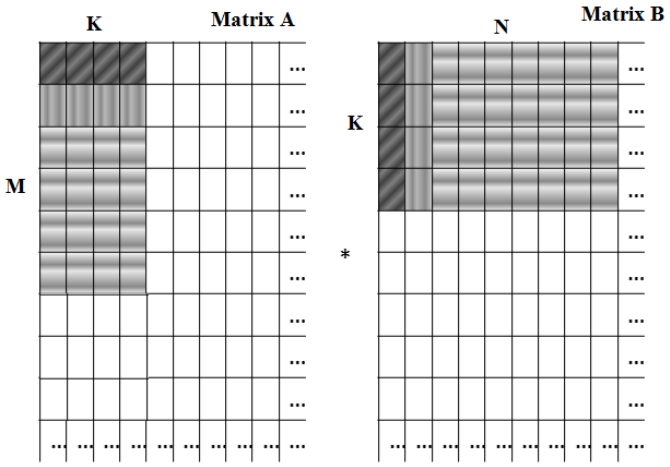

Fig. 1. Example of test cases 2, 3 and 6, where $M < N$ (Horizontal Rectangle)

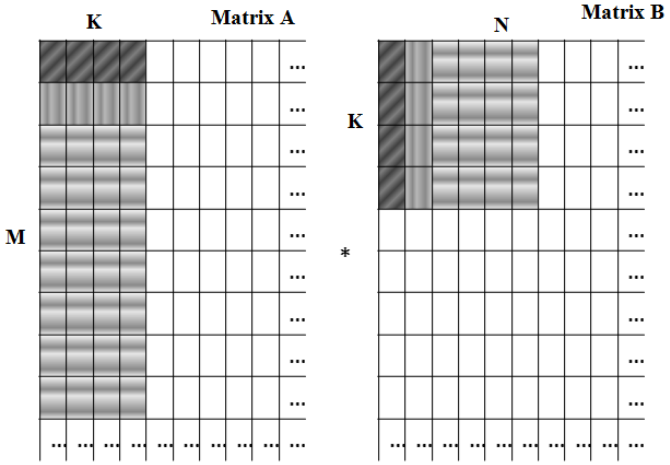

Fig. 2. Example of test cases 4, 7 and 8, where $M > N$ (Vertical Rectangle)

depicts an example of test case 2 with $M = 6 < N = 9$. The parameter K is variable.

Further on, we compare the achieved speed with test case 4, whose values for the parameters M and N are exchanged, that is, $M_4 = N_2 = 224 > N_4 = M_2 = 56$. Figure 2 depicts an example of test case 4 with exchanged values of test case 2, i.e., $M = 9 < N = 6$. The parameter K also varies.

The second goal is to determine the impact of the parameter M and the third goal is to determine the impact of the parameter N, varying the parameter K as explained in Section III-C.

IV. The Results

This section presents the results of the experiments. We are analyzing which block matrix rectangle multiplication provides the best performance for the same number of operations. Further on, we analyze the performance impact of the parameters M and N, while one of them is constant.

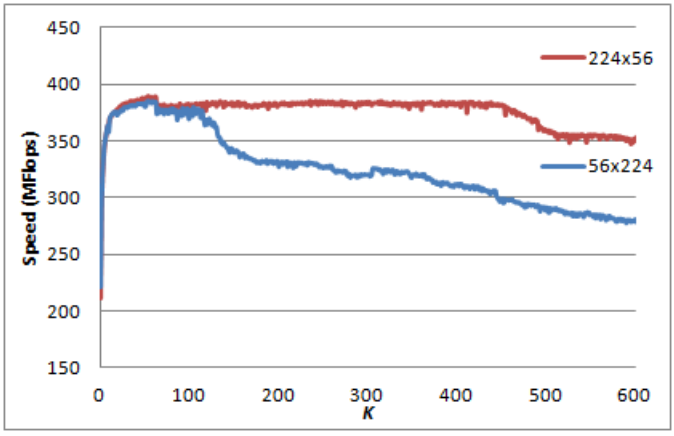

Fig. 3. The speed as a function of parameter K for test cases 56x224 vs 224x56

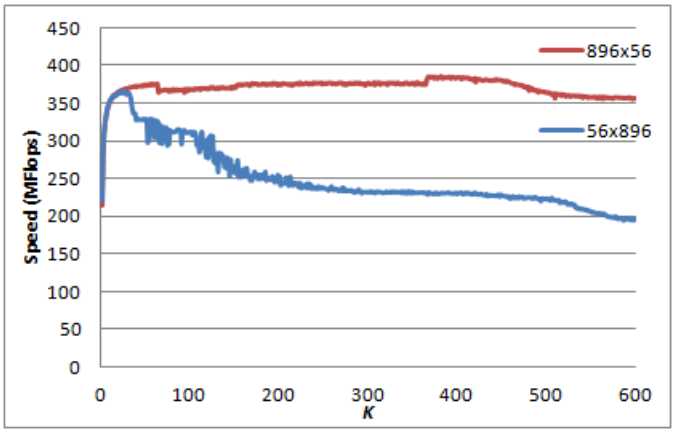

Fig. 4. The speed as a function of parameter K for test cases 56x896 vs 896x56

A. Horizontal or vertical rectangle

Figure 3 compares the results of test cases 56x224 vs 224x56. Both curves are identical until $K = 116$ when the speed for test case 56x224 decreases when K is increased. This is the point when both matrices together exceed L2 cache of 256KB.

The comparison of the results of the test cases 56x896 vs 896x56 is depicted in Figure 4. Very similar results are observed as the previous comparison. That is, both curves are identical very shortly until $K = 35$, which is also the point when both matrices together exceed the L2 cache size.

Very similar results are achieved of the comparison of the test cases 224x896 vs 896x224, which are depicted in Figure 4. The threshold is $K = 30$ depending of the L2 cache size.

B. Performance impact of the parameter M

This section elaborates the results of the comparison of the test cases to determine the impact of a particular rectangle height, that is, M, if the other parameter N is constant.

Figure 6 compares the results of test cases 56x56, 224x56 and 896x56, that is, different values of M for constant value

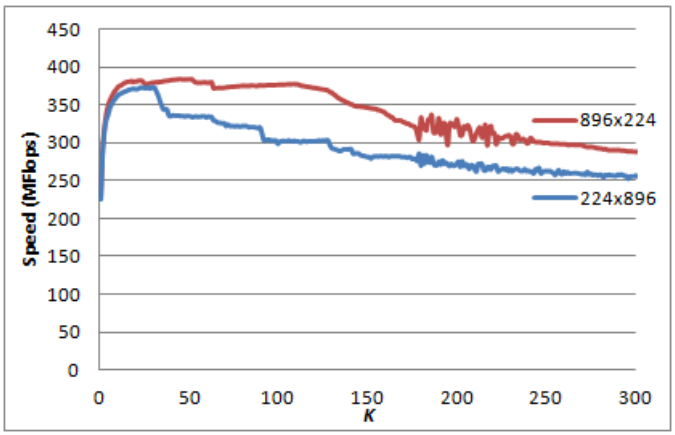

Fig. 5. The speed as a function of parameter K for test cases 224x896 vs 896x224

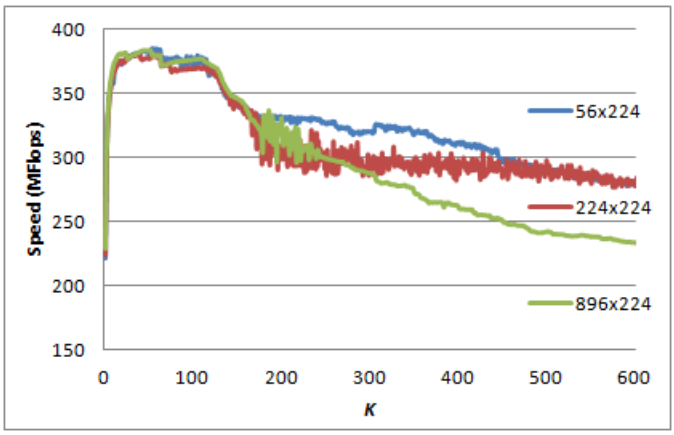

Fig. 7. The speed as a function of parameter K for test cases 56x224, 224x224 and 896x224

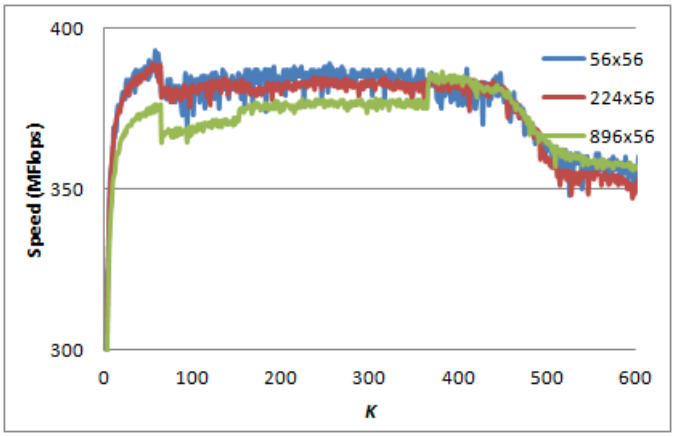

Fig. 6. The speed as a function of parameter K for test cases 56x56, 224x56 and 896x56

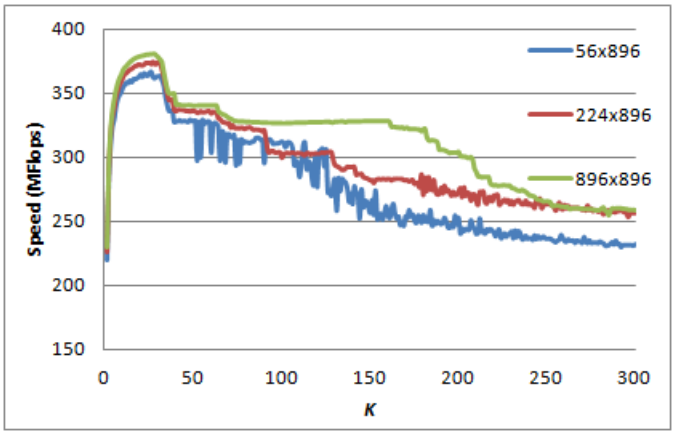

Fig. 8. The speed as a function of parameter K for test cases 56x896, 224x896 and 896x896

$N = 56$. All three curves are similar regardless of the parameter K. This means that increasing the parameter M does not impact on the performance.

Two regions are observed with a threshold $K = 450$, i.e., the left region with greater performance, and the right region with lower performance. Also, there is a small discrepancy for the test case 896x56. It has worse performance than others in the left region, but better performance in the right region.

Similar results, but moved to the left, can be observed in Figure 7, which compares the results of the test cases 56x224, 224x224 and 896x224. These matrices are greater than those with $N = 56$, and therefore, the performance of the test case 896x224 suffers for greater K. But still, all three curves have very similar performance until $K = 160$.

Figure 8 depicts different results for test cases 56x896, 224x896 and 896x896 compared to both previous comparisons for huge K. However, for small K, the curves are also similar.

C. Performance impact of the parameter N

This section elaborates the results of the comparison of the test cases to determine the impact of particular rectangle width, that is, N, if the other parameter M is constant.

Figure 9 compares the results of test cases 56x56, 56x224 and 56x896, that is, different values of N for constant value $M = 56$. The results show that increasing the parameter N negatively impacts the algorithm performance, which is emphasized for greater values for parameter K.

The same conclusion can be derived when comparing the test cases 224x56, 224x224 and 224x896, whose results are depicted in Figure 10. Also, the results of the comparison of the test cases 896x56, 896x224 and 896x896 are similar, as Figure 11 depicts.

V. Discussion

A general conclusion for the three comparisons of the test cases to determine the impact of parameters M and N with the same number of operations (greater height or width of the block rectangle) is that choosing a rectangle depends only when both matrices cannot be placed in L2 cache, favoring the rectangle with greater M, that is, the vertical rectangle. Another important result is that the speed is increased until L2 for horizontal rectangle, while the speed keeps its value for

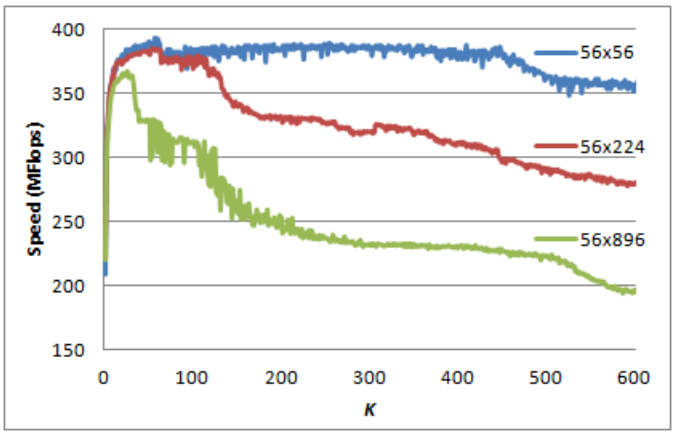

Fig. 9. The speed as a function of parameter K for test cases 56x56, 56x224 and 56x896

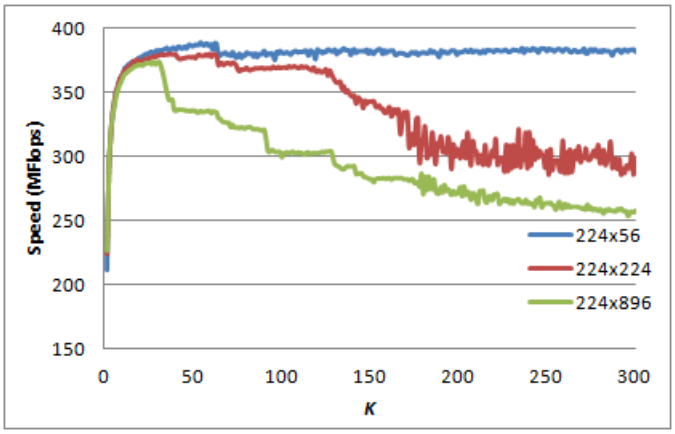

Fig. 10. The speed as a function of parameter K for test cases 224x56, 2224x224 and 224x896

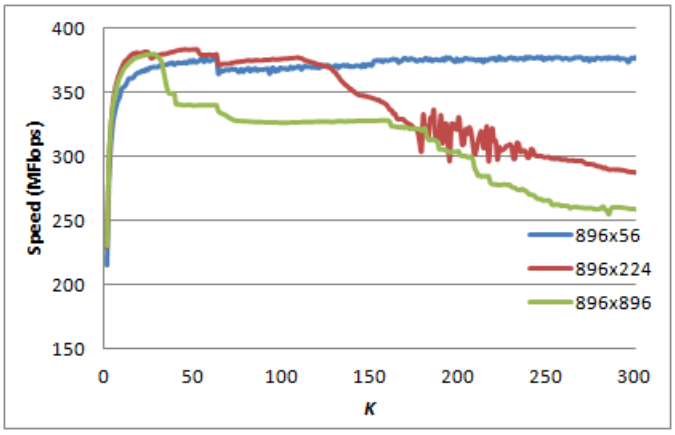

Fig. 11. The speed as a function of parameter K for test cases 896x56, 896x224 and 896x896

vertical rectangle. This leads to conclusion that the blocking can be choosed with greater blocks since the number of operations will be smaller, and thus the overall execution will be faster than traditional blocking.

The impact of the separated parameters M and N is also analyzed. Their impact on the algorithm performance is totally different, but the common feature is that the impact is increased for greater values of parameter K.

Comparing the figures 6, 7 and 8, we can conclude that the parameter M has a small impact to the performance, especially for smaller values of the parameter N. Again, this also leads to the similar conclusion, that blocks can be even greater than L1 cache.

The conclusion for the parameter N is totally opposite. Figures 9, 10 and 11 concludes the same, that is, the increasing of the parameter N significantly reduce the algorithm performance.

VI. Conclusion and Future Work

Dividing matrices into blocks that can be placed in L1 cache speeds up the matrix-matrix execution because it reduces the cache misses. That is, once the block matrix elements are placed in the L1 cache, they are used several times by their common multiplication.

The results of the experiments conducted in this research show three phenomena:

- Choosing as much greater height M of the first matrix provides better performance for the same product $M \cdot N$;
- The value of the parameter M can be chosen arbitrary, and therefore, it should be selected according to the value of already selected value of parameter N; and
- Parameter N should be as small as possible.

Apart of these phenomenons, we determine that greater speeds can be achieved if both blocks (by one of each matrix) are greater than L1 cache size, but smaller than the L2 cache size. These results could speed up the matrix multiplication with blocking the matrices even more.

Although these results are compliant with our previous results for AMD CPU [4], we will conduct the same experiments on AMD CPUs, as well as increase the number of the experiments for other values of parameters M and N. Another research will be towards parallelization of these experiments using multi-core CPUs, as well as GPUs, which also have set associative caches.

Extensible Framework for Execution of Distributed Genetic Algorithms on Grid Clusters

D. Georgiev* and E. Atanassov*
* Institute of Information and Communication Technologies, BAS, Sofia, Bulgaria
dobromir@parallel.bas.bg, emanouil@parallel.bas.bg

Abstract - Genetic algorithms are effective metaheuristic optimization methods, based on the principles of natural selection and genetics. Although they are able to find adequate solutions in acceptable time for small problems, their execution time increases rapidly for problems with large search space and complex fitness landscape. Computational grids provide an appropriate platform for the execution of parallel genetic algorithms. However, when using multiple grid clusters for a single computational task, one has to comply with a number of technical and administrative limitations.

In this paper we describe a new implementation of GA, written in C++11, which provides a mechanism for parallel execution and an extensible programming interface. Our framework utilizes MPI, ZeroMQ and the newest generic programming facilities of C++, enabling the execution of a distributed GA on multiple grid clusters. Various tests were performed on clusters from the European Grid Infrastructure, which prove the efficiency of our approach.

I. INTRODUCTION

Genetic algorithms (GA) are metaheuristic optimization techniques, based on mechanisms analogous to those in biological evolution. Using the concept that environmental pressure enforces natural selection, these algorithms perform a heuristic search by iteratively evaluating a group of points in the search space, called a population, and replacing some of the individuals with newly generated ones. Due to their black-box nature and their ability to find adequate solutions in acceptable time, they have been successfully applied in a variety of disciplines [5], [4]. However, with the increase of the problem size and the complexity of the function to be optimized, the necessary time to find good solutions increases greatly [1]. This has motivated a lot of efforts for improving the runtime of genetic algorithms and one of the most promising approach thus far is to use parallel implementations of Gas [6], [7], [8].

Currently, there exist a few open source implementations of GAs written in C or C++. However, most of them are not portable between platforms, have not been updated for the past few years and are developed for compilers which at the time of development did not support important new features from the C and C++ standards. In some C++ implementations this is obvious when we take into consideration the sparing use of templates and standard containers. This combination of programming practices and old target platforms have led to code, which is hard to modify and extend for parallel execution. On the other hand, there have been several efforts for creating a new GA library, written in idiomatic C++ with heavy usage of templates and the generic programming approach. However, most of these projects have not yet been able to build a strong community of developers and are either still in design phase or are in stagnation with unresolved bugs, which renders them practically unusable. This motivated our work in developing our own general purpose genetic algorithm library.

These issues with the available GA implementations impede the development of parallel implementations.

There are three main types of parallel genetic algorithms (PGA) [5]:

- Global or master-slave GAs
- Fine-grained parallel GAs
- Distributed GAs

The master-slave GA uses a single population, like the normal GA, but evaluation of the fitness function is distributed among several slave processors, while the master processor executes all other steps in the GA. This approach is simple to implement as it does not require a lot of changes to the original algorithm and it is widely used when the evaluation of the fitness function dominates the overall runtime. This type of PGAs are suited for both shared-memory and distributed-memory platforms.

The fine-grained parallel GA is suited for massively parallel hardware like GPUs. It uses a single population, which is spatially distributed among the different processors. However, selection and reproduction are limited to small overlapping neighborhoods.

The distributed genetic algorithms (DGA) also known as multi-deme GAs, are one of the most widely used GAs, despite their inherent complexity [10], [3]. In DGAs, the individuals are distributed among several populations and periodically populations exchange individuals. This exchange is called migration. Despite their popularity, they are one of the hardest to comprehend as the effects of the migration are not fully understood. The multi-deme GAs are also called distributed GAs because they are usually implemented on machines with distributed memory - supercomputers or clusters [11]. Since the computation to communication ratio is high, they are usually classified as coarse-grained, which makes them

suitable for execution on geographically distributed computing resources, for example grids, as well as volunteer computing and desktop computing initiatives.

Numerous variations of these algorithms are possible [9]. The DGA with a combination of the global GA is particularly suitable for clusters of multi-core servers, where each node executes a master-slave GA with migration between nodes [12]. On the other hand the combination of DGA with fine-grained GA can be effective on clusters of GPU-equipped nodes.

In this paper we present an implementation of a distributed genetic algorithm which executes by launching multiple grid jobs on different grid sites. Each job can be either a serial job, which executes a GA with migration and runs on a single processor or an MPI job, which executes a distributed genetic algorithm with migration both between the processes of the job and with other jobs.

Naturally, when considering parallel implementations of GAs and parallel execution, there are several possible target platforms. One of our main concerns when developing our framework for executing DGAs was to make it platform independent in the sense that it could be ran efficiently on grid, cloud and high-performance computing resources. Naturally this required a communication model and an implementation which are easy to tune for each type of resources and for an arbitrary combination of them. The developed model uses ZeroMQ for communication between each computational task and in the case of parallel tasks it utilizes MPI. Balancing between these two approaches enables effective execution on these three types of computational resources.

In this paper we describe our experience in executing the framework in grid [2] environment, particularly using the European Grid Infrastructure.

In the next section we describe our general purpose implementation of GAs, using C++ generic programming via templates. In Section 3 we lay out the technical features and limitations of the grid environment, which govern our communication patterns. In Section 4 we describe our parallelization approach and communication models as well as the functionality provided to end users. Experiments and benchmarks are shown in Section 5.

II. General purpose genetic algorithm library

For the purposes of this framework, we developed a general purpose GA library, called NAGA. Addressing the problems that we discovered in most currently open source GA implementations, we designed our library with extensibility and ease of use in mind. It is written in C++, using the latest edition of the C++ standard - C++11, taking into consideration which parts of the standard are supported by the major compilers to make the code as portable between platforms as possible. NAGA has been successfully tested with GNU Compiler Collection 4.4.x, Intel C++ Compiler 12.1.x and Microsoft Visual C++ 2010 and 2012. The core library provides several classes implementing GAs, selectors, crossover and mutation operators, etc. Each GA provides an interface which can be easily extended for developing a DGA.

III. Technical and administrative limitations of the grid

A core limitation of the computing environment provided by EGI is the inability for direct communication between grid jobs. In practice this limits the maximal number of processors a computational task may use to the maximal number of processors provided by a single grid site. Submitting a large grid job however, implies greater time the job stays in the execution queue until resources are freed. Also, jobs requiring more resources are usually given lower priority by the Local Resource Management System operating the grid site. Using multiple grid jobs, which communicate is impossible most of the times due to the usage of firewalls which filter inbound connections or due to compute nodes running behind a NAT. Additionally, most grid sites consider opening ports for inbound connections a violation of their acceptable use policy.

Another technical specificity of the grid is its high heterogeneity. Each provider may use different versions of several operating systems, different hardware and different versions of libraries. This usually results in different runtime of the same applications on different grid sites.

IV. Parallel implementation

A. Inter-job communication

There are several technical and administrative limitations of the European Grid Infrastructure. As noted earlier, the usage of firewalls, which filter inbound connections, or of private IPs on the compute nodes, requires any connection with the computational task to be initiated by the task itself. Naturally, this makes direct communication between grid jobs impossible. In our work we adopted an approach which resolves this problem, by introducing a new component, called a central server, which acts as a message broker for the inter-job communication. This central server is accessible through public Internet, i.e. computational tasks can directly connect to it.

It should be noted that using this message broker adds an extra layer of indirection, which implies an increase of the latency for each communication exchange. This necessitates using a high-performance communication library in order to mitigate the negative effects of the retransmission of messages. Another necessary feature that should be supported by the library is the capability to transmit messages asynchronously, i.e. the call should be non-blocking in normal circumstances. Additionally, the library should be portable between different platforms. When considering grid usage, the library should at least be able to run on the Linux distributions used in EGI - Scientific Linux, CentOS and other derivatives of Red Hat Enterprise Linux, as well as on Debian. The library should work efficiently even with a large amount of grid jobs, i.e., a large amount of messages.

We based our implementation on ØMQ (also ZeroMQ, 0MQ or ZMQ). ZeroMQ is a high-performance library for asynchronous messaging. It provides facilities for working with message queues, but does not require an

explicit message broker. It is written in C++ and provides an API for C, Python and over 40 other programming languages. It is compatible with POSIX Sockets and with Windows Sockets API (Winsock). ZeroMQ provides an API centered around sockets, which generalizes IP and inter-process communication sockets used in POSIX.

ZeroMQ provides three main types of network topologies and the appropriate types of sockets:

- Service bus - implements the standard request-reply pattern through the usage of REQ and REP sockets
- Data distribution tree - implements the publish-subscribe pattern, with subscribers being able to subscribe to specific messages through filters. It uses the PUB and SUB sockets.
- Parallelized pipeline - implements the push-pull pattern with support for multiple providers and workers. It uses the PUSH and PULL sockets.

Through the usage of these three pairs of sockets we define three distinct communication channels between the central server and each grid job - REQ-REP, PUB-SUB and PUSH-PULL. Each grid job has three sockets REQ, SUB and PUSH, while the central server has REP, PUB and PULL sockets.

The REQ-REP channel is used for initialization of the grid job. In several communication exchanges the grid job requests and receives a unique identifier, possibly seed values that other computational tasks may have saved and a permission to begin running the GA.

The PUSH-PULL channel provides a method for passing messages from the grid job to the central server. As, in contrast to REQ-REP, PUSH-PULL does not require a confirmation that the message is received, the grid job can continue working on the GA immediately after the ZeroMQ API call. Each of the messages is prefixed with the grid job ID.

In its event loop the central server polls the REP and PULL sockets and processes any messages that may have arrived. In the case of an incoming request on the REP socket, if the message states the grid job doesn't yet have an ID, the server generates a new ID and creates a new entry which describes the new task. The server sends a reply consisting of the new ID. Subsequent requests from the grid job may require individuals to be inserted in the otherwise completely random population and a request to begin work. Messages incoming on the PULL socket consist of individuals and are always prefixed with the grid job ID. Depending on the message, these individuals are either stored as the best ones found by the grid job thus far or are inserted in the migration queue. The migration queue is a list of queues, with different queues for each of the grid jobs. When the individuals are sent to the central server as part of a migration, they are inserted in the queue of the grid job and a response form a randomly chosen queue is returned. The probability of choosing a queue is proportional to its size.

The third communication channel uses the PUB-SUB sockets. After an identifier is granted to each grid job, it subscribes itself to all messages beginning with its ID and beginning with the ID dedicated to the central server - 0. The PUB-SUB channel serves two major purposes. After the migration group is chosen from the migration queue as described above, it is prefixed with the ID of the grid job and sent through the PUB-SUB channel. As the PUB-SUB channel does not require a confirmation that the message is received, the central server continues work immediately after the ZeroMQ call. The second major use of PUB-SUB channel is to send control messages to the grid jobs. Each control message is prefixed with the central server ID and is treated as a signal and all grid job receive it as they are subscribed to messages with said prefix. This provides a mechanism to control the formed distributed system and is the main way for enforcing balancing, proper termination and monitoring of the grid jobs.

This topology allows for non-blocking messaging between the central server and the grid jobs and most notably all communication channels are initiated by the grid jobs.

B. Using parallel jobs

The specified system is independent of the manner of execution of the grid jobs, i.e. it can be applied to jobs consisting of independent processes and to parallel jobs using MPI. However, when considering MPI jobs, using a single communication endpoint is more efficient for several reasons:

Using a single job ID for all the processes in the grid job will ensure that a message between two of the processes cannot be sent through the central server. Such messages could only be sent through a communication channel specific to that job - MPI.

- Although the quantity of the messages will remain unaltered, the necessary data structures for each job, thus the total memory used by the central server will be an order of magnitude less.
- This approach enables transferring all communication related tasks to a single process of the grid job.
- MPI implementations are optimized for communication between tightly coupled servers. That is why we give MPI precedence over ZeroMQ when considering communication within a single grid job.
- Using a single process to control MPI and ZeroMQ communications within a single tasks enables the other processes to work asynchronously and resolves the problem of implicit synchronization. When considering fitness functions whose runtime depends on the exact input, this is a quality that the distributed system should possess.

Given these reasons, we used a modification of the master-slave communication pattern typically used with MPI. While most implementations of the master-slave model require the master to take an equal part in the computations and do additional tasks like preprocessing,

postprocessing and overall management of the slave processes, we have chosen to completely separate the master of all computations related to GA itself. In our implementation the master slave is in charge of all communication with the central server - global communication, and also manages all communication within the grid job - local communication. While this means that one of the processes of the grid job will not do any actual computations, this enables all slave processes to work asynchronously and to perform minimal work in regard to communication [13].

A single iteration of the main loop of a slave process can be roughly described as a sequence of a GA iterations, local communication and global communication. During both local and global communication, the slave process sends a message to the master process, through non-blocking MPI calls, and probes if it has incoming MPI messages. It should be noted that local and global communications do not occur on each iteration of the GA.

The master uses two queues to manage the local and global communication. The local queue stores individuals sent from one slave process to another as part of a migration, while the global queue stores individuals sent by other grid jobs. In a single iteration of its event loop the master probes for incoming MPI messages and polls the ZeroMQ SUB socket. Incoming migration from the SUB socket is stored in the global migration queue, while signals are immediately sent to all slave processes using MPI. There are several types of MPI communication exchanges between the master and the slaves, each marked with a special tag:

- Global communication exchange - the master receives a message containing a number of individuals to be sent to a different job. If the global migration queue is not empty it returns the first subpopulation to the slave. After that, the master prepends the grid job ID to the message and sends it upstream to the central server using the PUSH-PULL channel.
- Local communication exchange - in this case the master receives a message containing a number of individuals to be sent to a different process in the same job. If the local migration queue is not empty, it replies to the slave process with a group of individuals. After that it inserts the message in the local migration queue.
- Upstream results - in this case the slave process sends to the master the best results found so far. The master sends them upstream to the central server.
- Slave-to-master signal - in this case a slave process sends a signal to the master process. Signals may be sent to signify that the GA job should terminate due to reaching some computational limit, reaching a plateau of the fitness function, or finding a solution satisfying some criteria.
- Master-to-slave signal - in this case the master has received a signal on the SUB socket and sends it to each of the slaves.
- Slave-to-master signal acknowledge - used to signify to the master that the slave process has acted upon the signal appropriately.

C. Heterogeneity

The described system is heterogeneous in two aspects. Firstly, each grid job may use a different number of processes and carry out global communication at different rate. Additionally the different grid jobs may execute on different grid sites with different hardware configuration - processors, memory, interconnect. While the first aspect can be easily controlled by the user, the second is not subject to control. The heterogeneity of the computational grid may lead to unbalanced computations and give precedence to some populations over others. Periodically using the PUB-SUB channel, the central server sends control signals to each grid job containing the ratio between the quantity of the migration groups originating from each of its slave processes and the average for all processes in the system. Using these numbers, each grid job can improve the global migration rate by increasing the number of iterations per global communication. This improves the balance between the populations of different grid jobs, without lowering the rate of local communications within each grid job.

D. End user functionality

Naturally, such a dynamic and complex system could easily become hard to manage even for experienced users and requires easy to use tools for management. This is why we developed a web-based interface to monitor and manage grid jobs. The interface is a stand-alone process which runs the Python web framework Tornado. User requests are sent through the REQ-REP channel to the central server. Using the web interface the user can extract the best results so far as well as various statistics about the jobs. The web interface also provides means for terminating any or all of the jobs.

Results of the execution of the GA can be stored on the central server and flushed to a file upon terminating the grid jobs and the server. Additionally, the user may use the result stores provided by the framework. They are both stand-alone Python processes with a specific ID that utilize the PUB-SUB channel to store the best results in a SQLite database or in a file in a log-like manner.

It should be noted that the result stores and the web-based interface are not necessarily running on the same machine as the central server and they conform to the

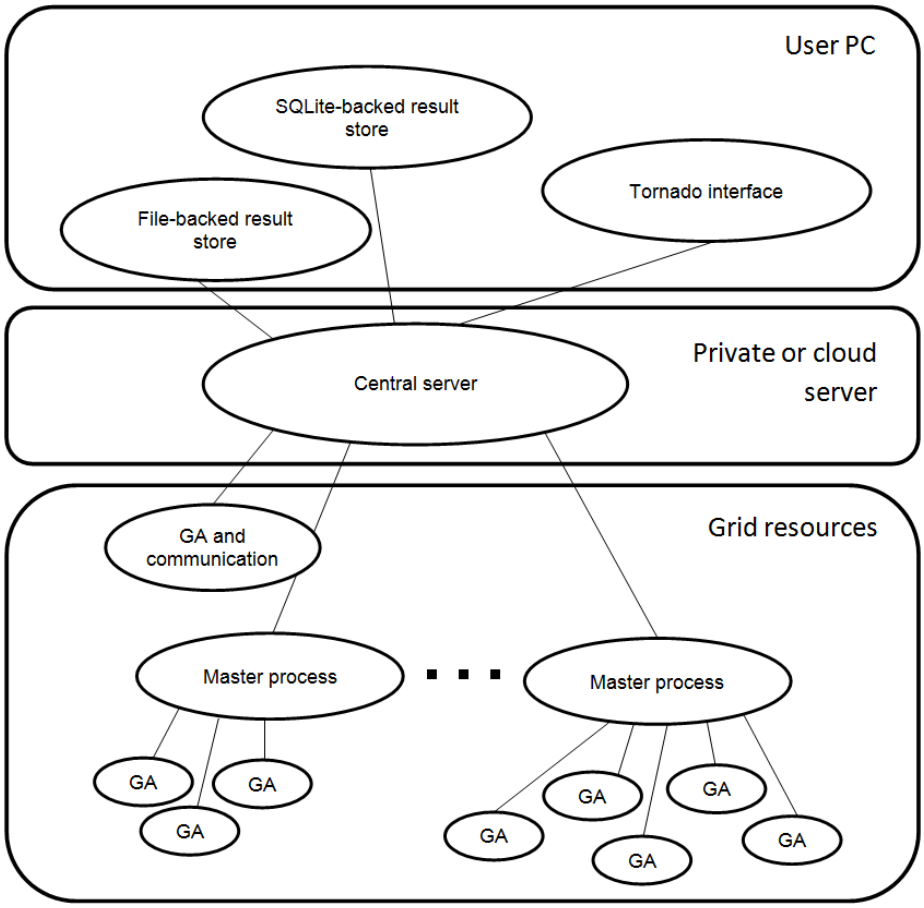

Figure 1. A schematic representation of the fully deployed system

same limitations as the grid jobs. This ultimately enables the user to run the central server on a machine accessible through public Internet, whether private or cloud resources, while grid jobs are ran on various grid sites and the result stores and the web interface run on his or her personal computer as presented in Figure 1.

We have also developed a code generation tool, which generates C++ code based on an XML file describing the GA. This enables users with limited knowledge of C++, who need only the core features of the library to actively use it.

V. Experiments and Benchmarks

The presented benchmarks were all performed using grid sites from EGI. Efficiency is presented both in terms of parallel efficiency and in processed genomes until a solution is found. Due to the randomness involved in the GAs results are averaged among several experiments. The chosen problem for the benchmarks is 3-SAT, which is a special case of the boolean satisfiability problem and is an NP-complete problem.

In our experiments the genome is a binary vector representing the boolean variables. The fitness function is the number of satisfied clauses of the problem. We used the roulette wheel selection (RWS). Migration is based on RWS when determining which individuals to be sent to other GA instances and RWS with inversed weights for determining which individuals should be replaced. The population size is 500. The crossover operator implements two-point crossover, while the mutation operator flips a bit with probability 0.9, or tries all possible flips of a bit and chooses the best one with probability 0.1. Table I shows the number of needed iterations for different configurations.

Table II represents the parallel efficiency in terms of throughput. The last two columns show the parallel efficiency.

TABLE I. Needed iterations for different configurations. Grid jobs are defined with the notation number_of_communication_processes + number_of_copmute_processes

Configuration	*Processes*	*Compute processes*	*Iterations*
1	1	1	52387
1+4	5	4	78253
1+4,1+2	8	6	83452
1+4, 2*(1+2)	11	8	92488
16*1	16	16	170046
2*(1+15)	32	30	231017
2*(1+15), 1+7	40	37	262459
8*(1+7)	64	56	471559
4*(1+15)	64	60	516154
8*(1+15)	128	120	1278933
6*(1+15), 8*(1+7), 16*(1+3)	224	194	1859213

TABLE II. PARALLEL EFFICIENCY WITH DIFFERENT CONFIGURATIONS. GRID JOBS ARE DEFINED WITH THE NOTATION NUMBER_OF_COMMUNICATION_PROCESSES + NUMBER_OF_COPMUTE_PROCESSES

Configuration	*Processes*	*Compute processes*	*Populations per second*	*Parallel efficiency*	*Parallel efficiency of compute nodes only*
1	1	1	237	100.00%	100.00%
1+4	5	4	936	78.99%	98.73%
1+4,1+2	8	6	1401	73.89%	98.52%
1+4, 2*(1+2)	11	8	1851	71.00%	97.63%
16*1	16	16	3011	79.40%	79.40%
2*(1+15)	32	30	7032	92.72%	98.90%
2*(1+15), 1+7	40	37	8654	91.29%	98.69%
8*(1+7)	64	56	13115	86.46%	98.82%
4*(1+15)	64	60	13671	90.13%	96.14%
8*(1+15)	128	120	27408	90.35%	96.37%
6*(1+15), 8*(1+7), 8*(1+3)	224	194	45089	84.84%	97.96%

VI. CONCLUSION AND FUTURE WORK

The presented framework demonstrated excellent parallel efficiency in terms of throughput of individuals. The communication model used in the framework overcomes the technical and administrative limitations of the grid environment and allow for usage of both serial and parallel MPI jobs. The model is designed to be portable and does not enforce any particular limitations on the execution environment, making it suitable for execution on cloud and HPC resources as well. The usage of both ZeroMQ and MPI provide support for complex topologies. This allows the user not only to comply with any resource limitations, but to experiment and analyze the effects of different migration patterns.

The developed general purpose genetic algorithm library NAGA uses the newest edition of the C++ standard and provides an easy to use interface, which enables easy extension of the provided core functionalities and it can be used for implementing other evolutionary algorithms as well. The heavy use of templates allows for significant code reuse, while preserving the speed of C++.

Many evolutionary algorithms which require no common knowledge among all the individuals can be easily implemented through our framework e.g. differential evolution and memetic algorithms. However, parallel versions of algorithms like particle swarm optimization, which are based on common knowledge, require carefully chosen communication strategies in order to preserve the speed of execution.

***Abstract*—Loop unrolling is a well known technique, which usually results with speedup of a program that contains loops. The effect is obtained by reducing the operations that require counter increases and branch jumps at the end of the loops.**

This paper analyzes the impact of loop unrolling on various processor types and memory patterns. The experiments show a high correlation between the cache and the problem size. The loop unrolling results with a higher speedup for the execution of a smaller size problem, while it does not have impact for a problem whose size is greater than the capacity of the last level cache size, due to the huge number of cache misses.

Another important result is that the loop unrolling achieves greater speedup on Intel, rather than AMD CPU. In this paper we analyze and discuss the various behaviors of loop unrolling.

***Index Terms*—AMD, Intel, Performance**

I. Introduction

Recent trends in programming tend to build heavy applications. Yet, many communities work tirelessly in the field of code optimization since we live in a time where the computing power is becoming a utility offered as a service. Optimizing algorithms can be achieved in many ways. Some of them try to optimize code based on processing architectures, while others find different and better algorithms that do the same job more efficiently [1], [2].

Compilers, on the other hand, which are build to be smart, compile based on certain architectures in order to optimize the translated assembly code and to provide the best performance [3]. Compilers are the Queen of Computing Science and Technology and they have long been the bridge from applications to systems [4]. Nowadays, they determine which architectural features should be implemented in the new hardware, as well as which new language features will be effective for software developers. There are a lot of optimization methods that the compilers implement.

Loop unrolling (also called loop unwinding) is one of the most common methods that the compilers implement to optimize the loops. It utilizes the CPU pipeline in the best possible way. Other methods for loop optimization include: peephole optimizations, local optimizations, global optimizations, machine code optimization, etc.

The goal of the loop unrolling is to increase the program performance by reducing branching penalties and pointer arithmetics and increasing the efficiency of pipelining [5]. The process of loop unwinding is often achieved by dispersing the innermost loops to several independent instructions. Therefore the level of usage of this method was limited because it had to be specified by the user for maximum performance. In order to eliminate this limitation, loop quantization was introduced as a general technique for automatically unwinding multiply nested loops [6].

Loop unrolling directly impacts on program speedup by achieving ILP (Instruction-level parallelism) and has its slight impact on power consumption and energy usage [7].

The loop unrolling optimization method can be used on the popular Graphics Processing Units (GPUs), as massively parallel processors with tremendous computational power and high memory bandwidth. Optimizing programs on this kind of platforms run up to 70 percent faster when compared to the unoptimized versions [8].

In this paper we target the loop unrolling optimization technique and try to find the impact of cache memory on the performance when it comes to computation intensive algorithms. 2 hypothesis are target in this research: *H1* The cache bunch size proportionally impacts the speedup, and *H2* The speedup does not depend or lightly depends on the hardware architecture.

Some of the most used and most optimized algorithms are the linear algebra algorithms, therefore we used the matrix-matrix multiplication (MMM) algorithm to find the required correlation of software optimization that are build based on hardware properties. This algorithm contains three nested loops, it is cache intensive and generates large number of cache misses, making it a good testbed to find a correlation and test the hypothesis.

The rest of the paper is organized as follows. The related work is presented in Section II. Section III describes the used methodology for the experiments. The results of the experiments and a comparison of different levels of loop unrolling are presented in Section IV. We discuss these results in Section V. The conclusion and future work are specified in Section VI.

II. Related work

This section presents the related work of the loop unrolling technique correlating with the hardware and the MMM algorithm performance and optimization.

A. MMM optimization methods

Anchev et al. presents a nice overview of several optimization techniques for the MMM algorithm [9]. Similar research that provides an overview of cache optimization techniques is presented by Kowarchik and Weis [10]. They all conclude that the optimizations according to the cache memory can yield a significant execution speedup, especially when they are applied to numerically intensive codes. Furthermore, future computer architecture trends motivate research efforts to focus on memory hierarchy optimizations.

The optimization of a linear algebra algorithms can be also oriented towards reducing the number of operations that are executed. Furthermore, the MMM algorithm may be accelerated asymptotically. Coppersmith and Winograd [11] made a novel use of the Salem-Spencer Theorem, which gave a fairly dense set of integers with no three-term arithmetic progression. The first revolutionary reduction for the MMM algorithm was proposed by well known Strassen's algorithm [12], which reduced the power to 2.8. Several other authors decreased it to 2.3727 [13].

Gusev et al. [14] provide an optimization of the MMM algorithm using hybrid blocking algorithm that preserves the number of operations and yet provides speedup compared with the original algorithm. The CPU affinity may also be used in order to provide better performance. Velkoski et al. [15], [16] conclude that using loosely coupled cores with private L3 cache is better than using tightly coupled cores with shared last level L3 cache when the problem size fits L3 cache of loosely coupled CPU cores, but in the same time cannot be placed in only one L3 cache of tightly coupled CPU cores. Gusev and Ristov derived an interesting conclusion about the MMM algorithm in a virtual environment, that is, it is better environment when the problem size fits in the private per core cache memory, but the performance suffers in the shared memory [17].

B. The loop unrolling method usage

The loop unrolling optimization method is widely used while compiling programs for high performance solutions. It is not applicable to FOR-loops only. Huang and Leng [18] generalize the loop unrolling method for any loop construct. Kisuki et. al [19] discuss how to simultaneously select the tile sizes and unroll factors in order to optimize the programs via iterative compilation.

Automatic source-to-source transformation is presented by Cronsioe et al. [20], who prove that the loop unrolling approach can achieve up to 67% performance gain on high performance and low energy consumption machines.

Stephenson and Amarasinghe [21] predict the unroll factors using supervised classification. Using this method, they managed to correctly predict the enroll factor for 65% of the loops in their dataset and provide 5% overall performance improvement for the SPEC 2000 benchmark suite.

We found contradictory results observed in different research papers about the energy consumption. Ayala et. al [22] present how loop unrolling techniques can decrease the energy consumption of the Multiprocessor System-on-Chip architectures up to 60%. Nevertheless, Seng and Tullsen [23] find that loop unrolling provides a very minor benefit in terms of reducing energy.

C. Loop unrolling in hardware solutions

The loop unrolling method is often used when optimizing the programs for hardware based solutions. Furthermore, the loop unrolling method hides the memory latency [24].

The loop unrolling method can be implemented when using variety of devices. Kurra et al. [25] study the effect of the loop unrolling factor on the controllers generated during High Level Synthesis (HLS).

Dong et al. [26] study the performance impact of the loop unrolling method when it is executed on reconfigurable hardware boards, i.e., FPGAs. Loop division on multiple smaller loops is proved to be appropriate when using performance aware devices such as FPGAs [27]. Since the loop unrolling method is not the only one, Dragomir et al. [28] propose a combined technique (loop unrolling and loop shifting) in order to relocate the function calls for kernel based reconfigurable FPGAs.

Optimizing loop performance is also required on clustered VLIW architectures. Yi et al. [29] describe how loop unrolling method alongside with unroll and jam can enhance the parallelism of the loop in order to limit the effects of inter-cluster data transfers.

The loop unrolling method is highly effective for optimization when high performance architectures are considered. Lokuciejewski and Marwedel [30] present loop unrolling method tailored towards real-time systems and achieve an average reduction of up to 13.7%.

We have not found any research paper that analyzes the performance of loop unrolling on various hardware architecture for different cache size for cache intensive algorithms.

III. Testing methodology

To provide reliable results we define a relevant testing methodology, where each test case is tested upon its correctness.

A. Testing algorithm

The MMM algorithm defined in (1) is used to create test data.

$$C_{N \cdot N} = A_{N \cdot N} \cdot B_{N \cdot N} \tag{1}$$

Each element c_i of result matrix $C_{N \cdot N}$ is calculated as an inner product of row i of matrix $A_{N \cdot N}$ and the column j of matrix $B_{N \cdot N}$, for each $i, j = 0, 1, \ldots, N-1$. For simplification, we use squared matrices $A_{N \cdot N}$ and $B_{N \cdot N}$. Each matrix element is stored as double precision number (8 bytes).

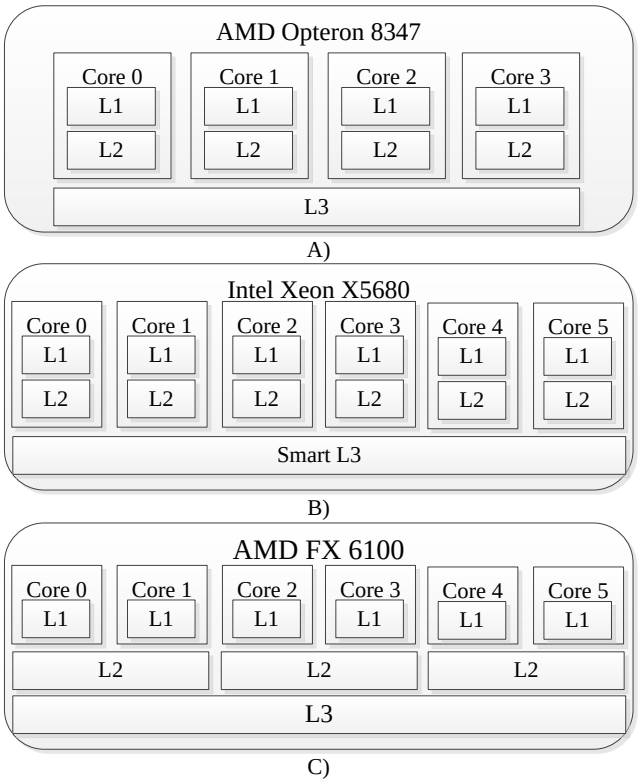

Fig. 1. CPU architectures

B. Unrolling the MMM algorithm

Five implementations of the MMM algorithm are used, such that each implementation is sequential execution with different bunch of loops unrolled. Furthermore, the code is compiled using the GCC 4.5 compiler with no optimization in order to evade its loop unrolling and other optimizations. The implementations are:

- *Implementation 1:* 1 only loop, (no loop unrolling);
- *Implementation 2:* 2 loops are unrolled;
- *Implementation 3:* 4 loops are unrolled;
- *Implementation 4:* 8 loops are unrolled; and
- *Implementation 5:* 16 loops are unrolled.

C. Testing environments

Three different architectures are used as testing environments: AMD(tm) Opteron(tm) 8347, Intel(tm) Xeon(tm) CPU X5680 and AMD(tm) FX 6100. Since the AMD Opteron 8347 is a representative of the older Barcelona architecture, we used the newer AMD processor with the Zambezi architecture. The following sections briefly describe the architecture of the three CPUs.

1) The AMD(tm) Opteron(tm) 8347 architecture: It has 4 cores each with 64KB private L1 (both data and instruction) cache and 512KB private L2 cache. Additionally, all four cores share 2MB L3 cache (Figure 1-A).

2) The Intel(tm) Xeon(tm) CPU X5680 architecture: This CPU has 6 cores, each with 32 KB 8-way set associative L1 data cache dedicated per core and 256 KB 8-way set associative L2 cache dedicated per core. All 6 cores share 12 MB 16-way set associative Smart L3 cache (Figure 1-B).

3) The AMD(tm) FX 6100 architecture: The AMD(tm) FX 6100 CPU has 6 cores, each with 64 KB 4-way set associative L1 data cache private per core. There is 3×64 KB of 2-way associative instruction L1 cache. Each instruction cache is shared between 2 cores. There are 3×2 MB of 16-way associative L2 shared exclusive caches. All cores share the L3 cache that is sized 8 MB and has up to 64-way associativity (Figure 1-C).

D. Experiments

Five different experiments are executed, such that each experiment corresponds to particular implementation of the algorithm defined in Section III-B. In each experiment we use the same single core of a CPU using $GOMP_CPU_AFFINITY = 0$. Many test cases are conducted in a single experiment, such that the MMM algorithm is executed varying the matrix size N, where $N = 16, 32, \ldots, 2000$.

E. Test data

The execution time $T(U)$ is measured for each test case in each experiment. Based on this parameter, we calculate the *Speed* $VU(U)$ using (2) in order to compare the performance impact of loop unrolling optimization method on multiple architectures with different core and cache architectures. The parameter U denotes the bunch size of the unrolling and it has several values $U \in \{1, 2, 4, 8, 16\}$.

$$VU(U) = \frac{2 \cdot N^3}{T(U) \cdot 10^9} \tag{2}$$

We introduce the *Relative Speedup* $R(U)$ as defined in (3) to compare the impact of unrolling bunch size on a particular environment and test the hypothesis H1.

$$R(U) = \frac{VU(U)}{VU(1)} \tag{3}$$

IV. Evaluation of results

This section presents the achieved speed of all test cases in realized experiments defined in Section III-B. Evaluation determines the correlation between the CPU cache size, the loop unrolling bunch size and the problem size.

A. The results on the AMD Opteron 8347 CPU

Figure 2 presents the speed for different levels of loop unrolling on AMD Opteron 8347 processor. We observe the existence of 2 different regions. In the first region ($0 < N < 512$) a greater speed is achieved and the differences in speed are observed for different loop unrolling levels. In the second region ($512 \geq N < 2000$), there is no visible difference based on the loop unrolling level and the speed converges.

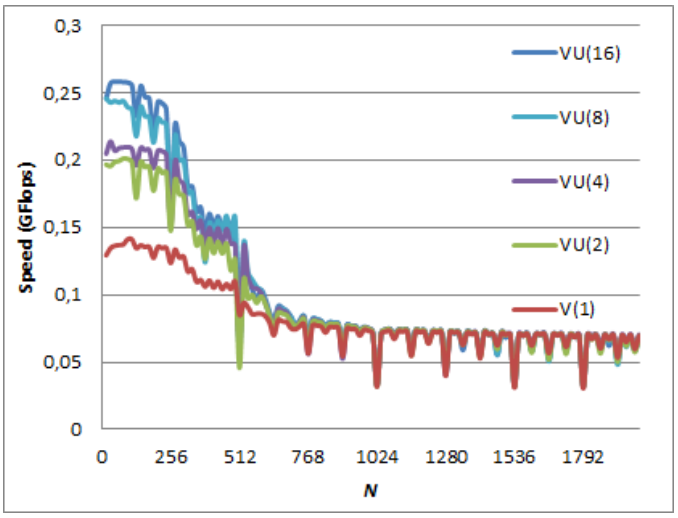

Fig. 2. Speed $VU(U)$ for the experiments executed on AMD Opteron 8347

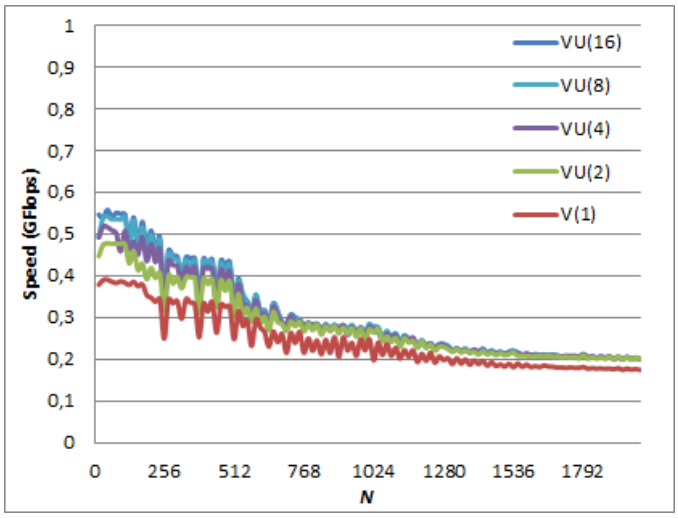

Fig. 3. Speed $VU(U)$ for the experiments executed on Intel Xeon X5680

For smaller matrices the speed is proportional to the loops that are unrolled. The greatest speed is measured for the MMM algorithm with loop bunch size 16, while the lowest speed is measured for the implementation without loop unrolling.

The regular drawbacks at $N = 512, N = 640, N = 768, \ldots, \ldots$ appear due to cache associativity problem. Ristov and Gusev [31] present detailed theoretical analysis and proof for its appearance.

B. The results on Intel Xeon X5680 CPU

The speeds for different levels of loop unrolling executed on Intel Xeon X5680 processor are depicted in Figure 3. Compared to the previous architecture, we can not distinguish the same regions since the experiments with no loop unrolling never converge with the rest of the implementations' results. The implementations with loop unrolling create the same two regions as the previous CPU, with the only difference, i.e., the performance is similar when the loops are unrolled with 8 or 16 bunches. Yet, we can observe that the speed is proportionally dependent for the smaller matrices ($N < 512$).

C. The results on AMD(tm) FX 6100 CPU

Figure 4 depicts the achieved speed for different levels of loop unrolling on the new Zambezi core architecture by AMD, i.e., the AMD(tm) FX 6100 CPU.

The loop unrolling in this case proves to be essential since in each section the number of unrolled loops proportionally increases the speed of the algorithm.

Nevertheless, for very small matrices ($N < 128$) we observe the greatest speed. Except the loop unrolling with bunch size 8 and 16, all other implementations are registered with speed degradation for greater matrices. Another degradation of performance is also observed for the other scenarios on different stages.

Another important conclusion is that the implementations of the loop unrolling with bunch size 8 and 16 tend to have the

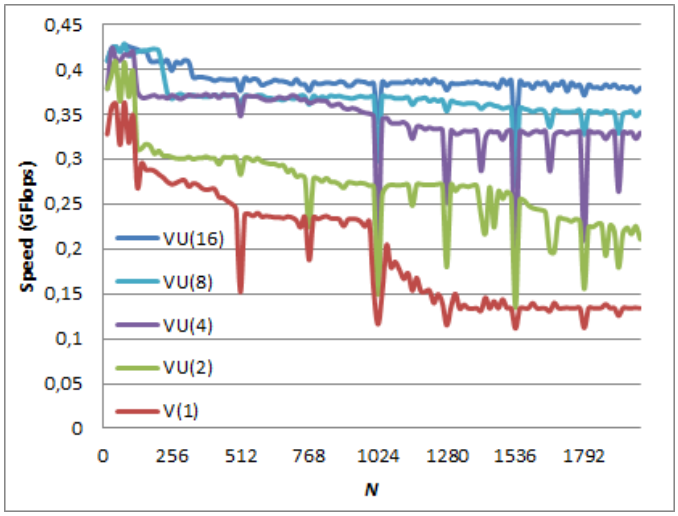

Fig. 4. Speed $VU(U)$ for the experiments executed on AMD FX 6100

stable speed for each test case. Moreover, the scenario with bunch size 8 provides better performance than the implementation with bunch size 16 for matrix size $N < 256$.

V. Discussion

In this section we will discuss the results gathered from the experiments and plot the conclusions from this paper. In Section IV we observed how the loop unrolling optimization method impacts the speed for different matrix sizes. We will expand our discussion by making a comparison for different levels of loop unrolling, as well as whether a relevant conclusion can be derived for the hardware impact on the loop unrolling.

A. Loop unrolling bunch size impact

This section analyzes the loop unrolling bunch size impact on a particular CPU through the relative speedup.

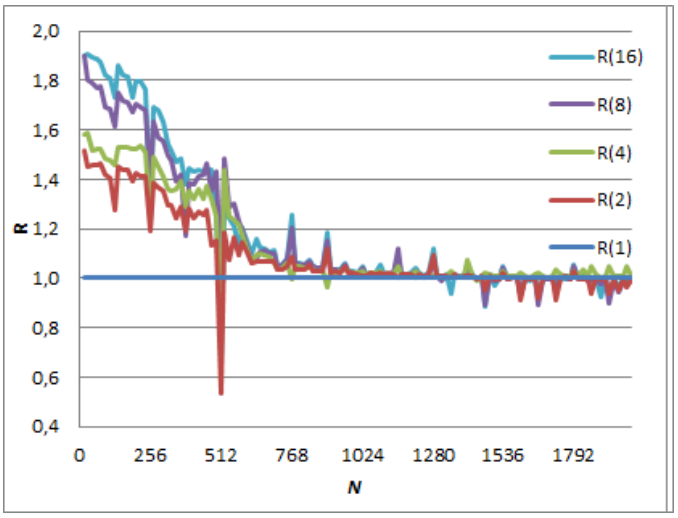

Fig. 5. The relative speedup $R(U)$ for the experiments executed on AMD Opteron 8347

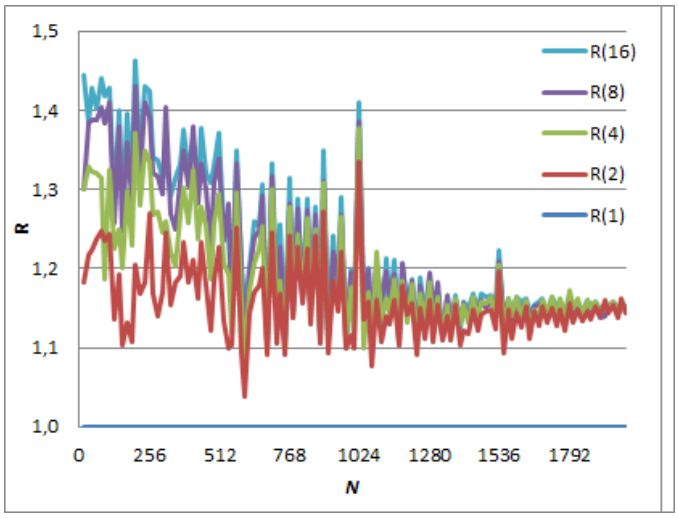

Fig. 6. The relative speedup $R(U)$ for the experiments executed on Intel Xeon X5680

1) Bunch size impact on AMD Opteron 8347: The speedup provided by the method of loop unrolling on AMD Opteron 8347 is presented in Figure 5. For larger matrices, that is, when they cannot be stored completely in the last level cache, the loop unrolling method on this architecture does not make any difference. The speedup proportionally increases with the number of unrolled loops. The loop unrolling is without effect when the number of cache misses increases, because the response mostly depends on the memory access, rather than the operations.

2) Bunch size impact on Intel Xeon X5680 CPU: Figure 6 presents that regardless of the matrix size and/or number of unrolled loops, the loop unrolling optimization method speed ups the response time on the Intel Xeon architecture. Therefore the loop unrolling optimization must be highly regarded in these architectures. The speedup in this case is proportional to the number of unrolled loops for smaller matrices and it diverges to the value speedup when using bunch size 2 for greater matrices that cannot be placed in the last level L3 cache.

3) Bunch size impact on AMD(tm) FX 6100 CPU: In Figure 7 again we observe the greater relative speedup for all matrix sizes and levels of loop unrolling. Additionally, we observe totally opposite results on the Zambezi AMD architecture. The greater relative speedup is recorded for larger matrices than for the smaller matrices. This confirms the previous observation from Section IV where we state that the loop unrolling provides sustainable performance of the MMM algorithm.

The larger number of unrolled loops results with increased speedup. This is most emphasized for larger matrices. Therefore, when compared with previous CPU architectures, a small paradox occurs, since the loop unrolling optimization method provides better performance when the number of memory accesses and cache misses increase.

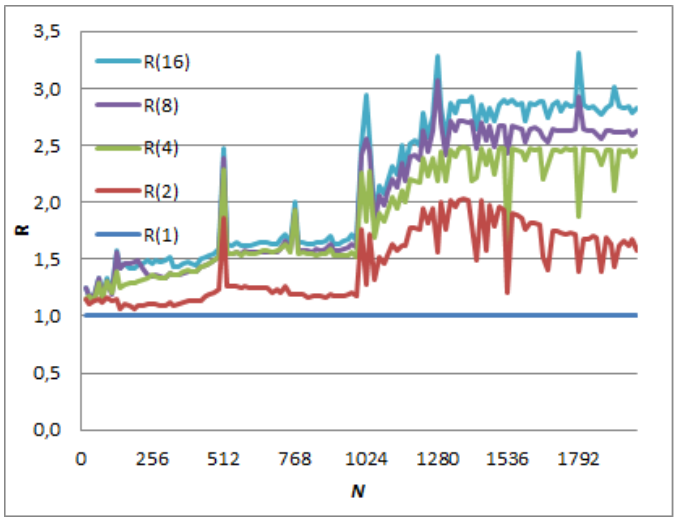

Fig. 7. The relative speedup $R(U)$ for the experiments executed on AMD FX 6100

VI. Conclusion and Future Work

In this paper we compared the loop unrolling technique for algorithm optimization using the dense MMM algorithm. We measured the performance for three processors manufactured by two different manufacturers AMD and Intel. The experiments were conducted varying the bunch size of loop unrolling and the matrix sizes.

Two different conclusions can be derived. The first conclusion is that the loop unrolling speeds up the cache intensive algorithms for the greater bunch size. However, the speed up depends on the CPU architecture. This is more emphasized for smaller matrices that can be placed in private per core cache memory on AMD Opteron and Intel Xeon, while it is significantly emphasized for greater matrices on the AMD Zambezi architecture.

Although the AMD Opteron and Intel Xeon are different vendor CPUs, the MMM algorithm with and without loop unrolling is very similar, compared to the AMD Zambezi architecture. The difference is in the cache organization and its associativity. This proves our hypothesis that there is a correlation between the CPU cache architecture and organization.

We will continue our research towards mathematically modeling the dependency of loop unrolling optimization technique and its correlation with the cache memory architectures and its capacity. Afterwards, we will try to generalize this theory with other most used algorithms that have loops, such as dot product with one loop, or matrix-vector multiplication with two loops. All these algorithms will be executed on more different CPU architectures, both with sequential and parallel implementation.

***Abstract*—Development of a Software as a Service cloud solution is not a trivial task. Apart from traditional software life-cycle, the developers should implement elasticity and scalability, which are probably the biggest challenges from software organizational and architecture aspect. In this paper we present the way we addressed several challenges concerning development of such a solution by designing several versions that reflect various implementations. The final organization was selected to be the one that offers the best performance among various candidates.**

***Keywords-bug reporting, issue tracking, software as a service, cloud computing, elasticity*.**

I. Introduction

Companies around the world develop various software products every day. Their relationship with the customers depends on the quality of software they deliver. Modern software engineering principles and concepts introduce customers in testing processes early in the development process in order to design more reliable applications. This is especially important in terms of increasing the customer satisfaction and efficient development, such as the iterative spiral design or agile software development [1].

Almost every company uses at least one software application. A lot of small and medium companies cannot afford to buy expensive systems, but, still they need to improve some processes in the company or relationships with the customers. Customer relation software solutions usually use an approach where a software solution keeps track and manages with issues that happen between the company and customers. Such an example is the issue tracking system, or bug reporting software where issues (bugs) are reported by customers, a ticket is associated to the given issue (or bug) and the company provides a service that maintains the list of tickets, (issues or bugs) until they are approved to be finalized.

In many software projects, ticket issuing (bug tracking systems) plays a central role: they allow users to communicate with developers to let them know about any problem and to request new features. In addition, developers can keep track of any unresolved issues or bugs, and request more information from users [2].

A lot of software applications were developed and offered on the market, even as free solutions, but non IT companies still have the problem of installation, management, maintenance and upgrades of these applications. This kind of solutions are usually self-hosting solutions that require appropriate hardware and software architecture, which is an extra investment for non IT companies.

Cloud solutions can solve the problem for both IT and non IT companies, offering issue tracking (or bug reporting systems) as a service [3]. Bug reporting delivered as a service has attracted research recently. For example, TaaS (Testing-as-a-Service) [4], is proposed as another prominent service, that enables enterprise and consumers to save the cost of complicated maintenance and upgrade effort. It provides a very high range of permutations and combinations to test the product and examine its performance, including a bug reporting system.

Several approaches use conventional ticket issuing (or bug reporting) systems, hosted on a PaaS (Platform as a Service) to obtain a cloud solution. For example, it is conceivable to automate the process of creating the development and test environments on demand using Amazon EC2 and expanding a bug tracking system [5]. However, these approaches do not have the flexibility that a SaaS (Software as a Service) solution provides, and do not offer a high level of scalability and elasticity. In this paper we present a software development process to design and develop a SaaS solution for a ticket management system (TMS).

The rest of the paper is organized as follows. Section II presents the essential concepts about TMSs and cloud computing, including several development phases from traditional bug reporting systems to a modern one. The challenges of a modern TMS and its architecture are presented in Section III, while the cloud solution software engineering is presented in Section IV. We discuss the benefits of this cloud solution and compare it with several existing architectures and organizations in Section V. Finally, Section VI is devoted to conclusion and future work.

II. Background

Cloud computing is essentially the next phase of innovation and adoption of a platform for computing, networking, and storage technologies designed to provide rapid time to market and drastic cost reductions [6].

Computation, storage, networking infrastructure, as well as development and deployment platforms are made available on-demand within minutes. Sophisticated futuristic applications are made possible by the abstracted, auto-scaling computation platform provided by cloud computing [7].

Cloud computing offers flexibility and financial benefits. It also lowers the entry point to high performance computing, allowing organizations to leverage computing power that they neither have the capital budget, nor the operational expertise for. Halpert [8] explains that cloud computing hasn't drastically altered existing technologies, but rather it has succeeded as a result of the collaboration of several existing technologies.

TMSs and their other implementations like bug reporting systems or issue tracking systems, are those systems, where a ticket is associated to a given object, such as reported bug, and the software monitors the processes around the ticket's life-cycle.

Some of the existing products are open source, while the others are commercial. Although a lot of companies have developed their own systems, these solutions usually take a lot of time and resources. After developing them, companies must take care for its maintenance and continue developing the upgrades. Also there is an extensive list of open source and free solutions, or commercial solutions which can provide.

An example of analysis of existing bug reporting solutions is given by Gushev et al. [3]. Hosting such a solution can cause a lot of problems to companies, including additional resources for management and administration. Therefore, a cloud solution can save a lot of resources and time.

These systems can be used both for quality assurance and task management. They allow companies to collect, track and assign tasks related to user satisfaction, for example, software development, when a new product or a service launches during beta testing and marketing research. A web based solution can benefit from a worldwide access by any user.

The system provides a centralized overview of tickets and their state. The list of pending items provides valuable input for quality assurance.

III. Design of a Cloud TMS

A. System Concept and User Requirements

The overall scenario is presented in Figure 1. Users click on menu options or active buttons and links sending a request to the system. The system starts the generation of web pages and sends the response to the user.

TMS application defines five different types of user groups: Application administrator (AM), Manager (PM), Resolver (RE), Customer manager (CM) and Customer (CU). The basic design of the Ticket Management (Bug Reporting) application consists of 3 segments. The first segment is the main application management (AM), the second segment is the provider (PM, RE) and the third segment is the customer (CM, CU). AM can create managers to manage the subscriptions. PM can create users of all groups except AM. RE user changes the ticket (bug) status after resolving. CM user can create other CM or CU users. CU creates a new ticket (reports a new bug) and answers to changed statuses. PM decides who will respond to tickets or associate workers on different modules of a given project (application) and CM decides who will report bugs for a given module.

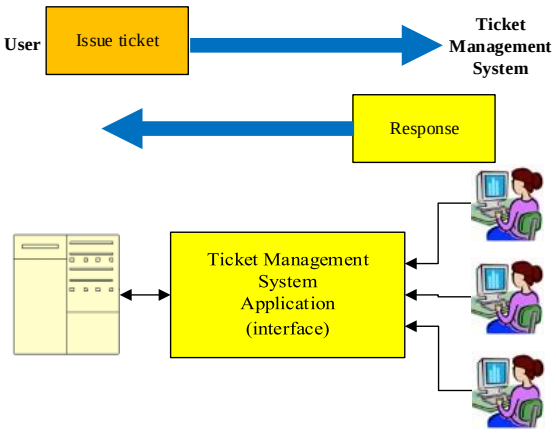

Fig. 1: Overall Scenario

TABLE I: User Access Rights

ID	Functions	AM	PM	RE	CM	CU
F1	Registration of company	Yes	No	No	No	No
F2	Customer administration	Yes	No	No	Yes	No
F3	Bug reporting	No	No	No	Yes	Yes
F4	Bug status administration	No	Yes	Yes	No	No
F5	Approving of corrections	No	No	No	Yes	Yes
F7	Create test cases	Yes	Yes	Yes	Yes	Yes
F8	Execute test cases	Yes	Yes	Yes	Yes	Yes
F9	Summary reports	No	Yes	Yes	Yes	Yes
F10	Detailed reports	No	Yes	No	Yes	No
F11	Site analytics	Yes	Yes	No	Yes	No
F12	Email notifications	No	Yes	Yes	Yes	Yes

Table I presents user characteristics by identifying basic and powered functions to each user group.

B. Ticket life-cycle

Functioning of the TMS includes tracking of various ticket states. An initiator creates a ticket (or issue), and then the system starts to process the ticket (or issue) until the initiator closes the issue (or ticket). Several states are defined in the ticket life-cycle, as depicted in Figure 2.

A *new* state is a result of the initiation activity that creates a ticket (an issue or a bug). Acknowledged or *pending* or open state is a kind of flag for the customer indicating that the supplier has opened the ticket or is aware of it. It will certainly mean that the supplier reads the ticket issue (reported bug) and will soon associate it to a resolver. Assigned or *in progress* state is an indicator that shows that the issue (bug) was assigned to a resolver to solve it. After finalizing the resolving activity and providing all corrective measures for a given bug or fixing the opened issue, the state changes to *resolved* or fixed state. *Rejected*, feedback or reopened state is a result of an activity by a customer for rejecting the provided answers for the ticket or solved bugs. *Closed* state is the final state in the lifecycle that appears as a result of verified confirmation that the issue is closed or bug was solved.

Three core functions correspond to the ticket management: ticket creation, resolving and approving. CU, CM and RE user

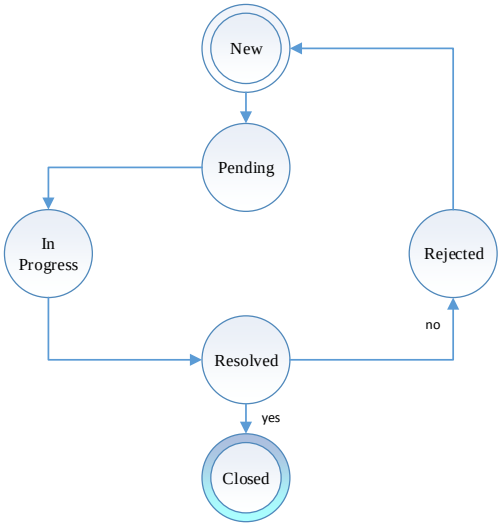

Fig. 2: Life-cycle of a ticket

groups can create a ticket (report a bug). Usually the system is intended for users from the CU group to create a ticket, but a more general system (as defined here) makes a possibility for users from the RE group to create a ticket, reporting an issue.

Issuing a ticket starts its lifecycle. The next step is identification of a moment when somebody has opened a ticket and is aware of its content, as associated with the pending state. Then the ticket state cannot be changed by customers (users from a CU or CM group), and only those responsible to resolve it (users from a RE or CM group) can change its state to resolved. CM users can allocate another users from the RE group to respond if necessary to realize the core resolving function and move across three progress states from pending, via in progress to resolved.

When a ticket issue is resolved, once again the ticket initiator can change its status by approving it. A careful inspection of the provided answer or the solution can lead to approval or rejection. If the ticket initiator sends an approval, then the ticket life cycle terminates with the closed state. If there is a rejection, the ticket status is once again associated to the pending state starting the life-cycle once again. It means that all the work on resolving the ticket issue (bug) is not satisfying the customer and it has to be analyzed once again seeing it in the to-do list of the responsible resolver (or users from the RE group).

C. Functional Description

The main TMS functions are explained as follows:

- ***Registration of a company*** - AM fills all necessary details about the company and sends them to the database. TMS saves those details in the database and returns a message to AM.
- ***Customer administration*** - A user sends request to TMS with user details. TMS receives those details and updates the database. Then it returns a response message.
- ***Administration of resolvers*** - A user sends a request to TMS with user details. TMS receives those details and updates the database. Then it returns a response message.
- ***Ticket issuing*** - CU sends a request to TMS with details. TMS receives those details and updates the database. Then it returns a response message.
- ***Resolving*** - RE responds to the ticket. TMS updates the database and returns the response message to CU.
- ***Approving*** - CU approves or rejects the response. TMS receives those details and updates the database.
- ***Creating test cases*** - CU creates test cases for review of functionalities. TMS stores those details and available to all interested parties.
- ***Summary reports*** - A user sends a request to TMS and receives a specific type of report with requested information.
- ***Detailed reports*** - A user sends a request to TMS with a specification of details and receives a detailed report.
- ***Site analytics*** - A user sends a request to TMS for site analytics and receives appropriate content as response.
- ***Email notification*** - A user sends a request to TMS for a change in a ticket state as an e-mail identification.

TABLE II: Client server scenario of TMS transactions

Role	Activity	Description
User	Create and submit a request	A user creates and submits a request to TMS
TMS	Receive and process a request	TMS receives and processes the request

D. Activity description and process rules

Table II describes a typical scenario in the client server model and the simplified activity diagram for core ticket management functions is presented in Figure 3. A customer can create a new ticket and the TMS saves the ticket details in the database. Each request is completed and does not inherit from the referenced requests. TMS returns a message to the users when the ticket associated to them changes its state as defined in Figure 2. RE can update the ticket status and CU can approve or reject this response. Additionally, the user can specify various reports, including summary, detailed reports and site analytics for all actions performed on the TMS. Finally, TMS responds by providing a relative message on the web interface or can send an e-mail or other personal message to the users. Information constraints relevant to this collaboration are captured in the referenced request data model(s).

E. Data model

Figure 4 shows the UML diagram of the models and their relations. The Database Provider level abstracts the logic for access to the database and enables an efficient programming interface for its use. In this level all the semantic for physical access to the database is encapsulated through collection of Database Provider objects. The internal structure of the database consists of several models. Each model of the internal

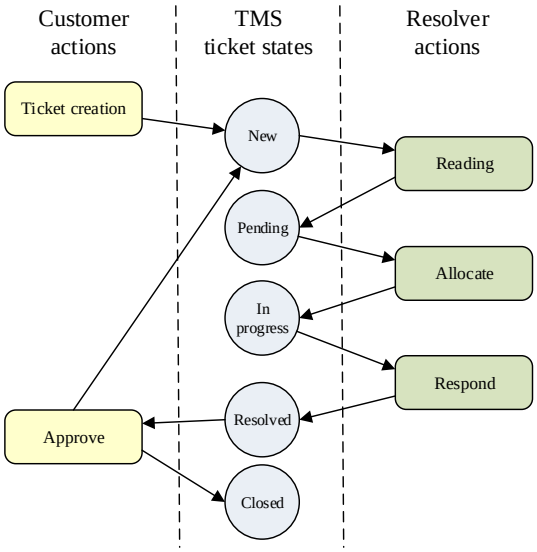

Fig. 3: Simplified activity diagram

TABLE III: TMS basic architecture modules

SMM	CMM	CFM
General settings	Company management	Create a ticket
Subscription admin	Company defaults	Change a ticket status
Finance management	Company subscriptions	Create test-cases
Users admin	Projects and modules	Execute test-cases
System reporting	Company users admin	Summary reports
System analytics	Customer management	Detailed reports
Security	Reporting	Site analytics
E-mail settings	E-mail settings	E-mail notification

structure of the portal describes one business area. Each model can consist of several sub-models.

IV. SaaS solution

This section presents basic software modules and organization principles to exploit elasticity and scalability.

A. Basic architecture modules

TMS consists of three core modules: System management module (SMM), Company management module (CMM) and Core functions module (CFM). The Additional functional module (AFM) is optional. Functionalities of all modules are described in Table III.

SMM is the core of TMS cloud solution. This module is general for all companies. It manages all resource provisioning in the cloud. This module is always active to provide user management, company subscription management, authentication, authorization etc.

CMM is specific for a company that uses the TMS as a service for its customers. This module is responsible for all general configurations within a company.

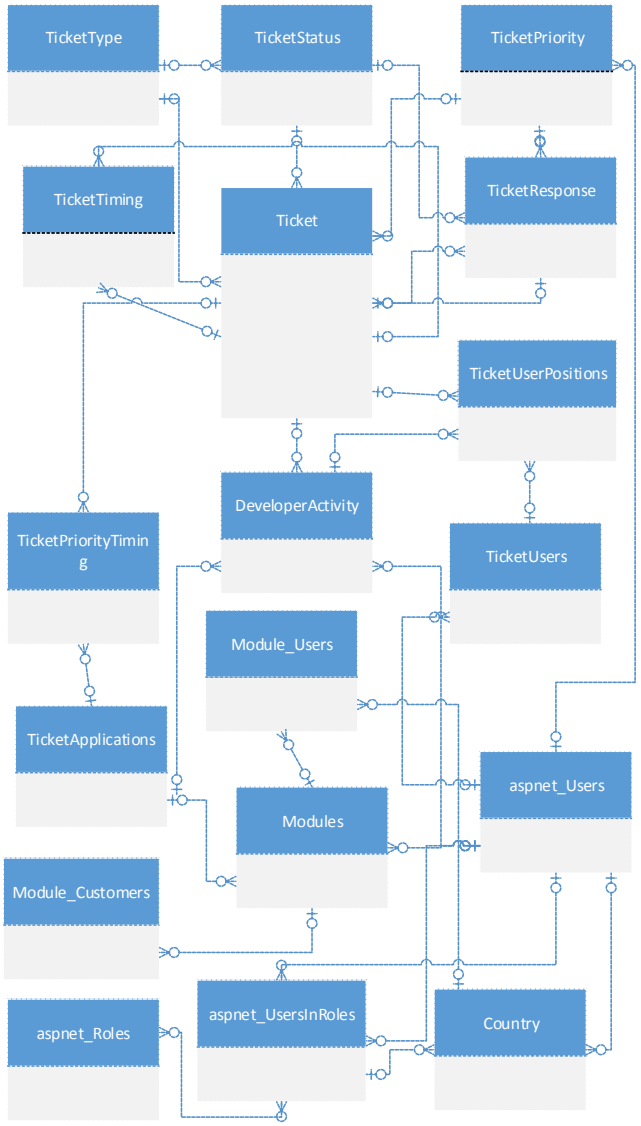

Fig. 4: Simplified version of data model

Apart from defining relations with the customers, it is always active by providing user management, customer management, project and module management, etc.

The basic CFM is also a company specific module. This module is responsible for all essential process to realize ticket management (bug reporting) within a company. It enables a connection between companies (providers) and their customers. This model provides functionalities such as: ticket creation, responding by a resolver, customer approving of the response, creation and execution of test-cases etc.

The Additional functional module (AFM) is dedicated for add-on functions, such as enabling a possibility to create and execute test cases, especially useful for bug reporting systems. There are also other types of add-ons that are possible and are beyond the limits of this paper.

TABLE IV: Classification and clustering into modules

Functionality	Static / Dynamic	Module
registration	Static	SMM
customer admin	Static	CMM
resolver admin	Static	CMM
ticket issuing	Dynamic	CFM
ticket reading	Dynamic	CFM
allocating resolvers	Dynamic	CFM
resolving	Dynamic	CFM
approving	Dynamic	CFM
test-case creation	Static	AFM
test-case executing	Dynamic	AFM
reporting	Static	CMM
notification	Dynamic	CFM

B. Design concepts

Probably the biggest challenge in developing a SaaS solutions is enabling elasticity and scalability. Most users do not think about this when developing a solution, although these characteristics define the main difference between the cloud solutions and the conventional web applications. A conventional approach to solve this issue is enabling an automated resource broker, which analyzes the processor utilization and if a processor where a virtual machine (VM) is allocated gets close to the saturation, then a new VM is activated. This approach works with allocation of threads, and whenever a new transaction is started, the new thread is scheduled to corresponding thread. This extension with resource broker is designed mainly in the operating system or VM scheduler.

However, our approach is not based on this idea, since the tests have shown that it lacks flexibility and often the scheduling requires a lot of resources and takes longer processing time. Web services provide better performance when the resources are orchestrated in many smaller VMs, rather than one big VM [9].

Our approach is based on determination of static and dynamic software parts in the execution [10]. Then the dynamic parts are scheduled on separate smaller VMs, which require less resources and offer higher performance. The static processing is realized via the conventional approach of allocating threads on appropriate VM via resource broker of the VM broker scheduler. This approach offers higher throughput and easier management, and also increased performances. Also, this will improve the performance since each VM will work with smaller database, which will improve the query response time. The design process concerns a two step procedure: the first step is classification of static and dynamic parts, and the second is developing a new architecture to support elasticity and scalability. The result of the classification is presented in Table IV. The next section presents the organization of the new cloud-based TMS.

C. Optimized cloud organization

The new proposed TMS is presented in Figure 5. The static VM (always active) contains the SMM module, while the other

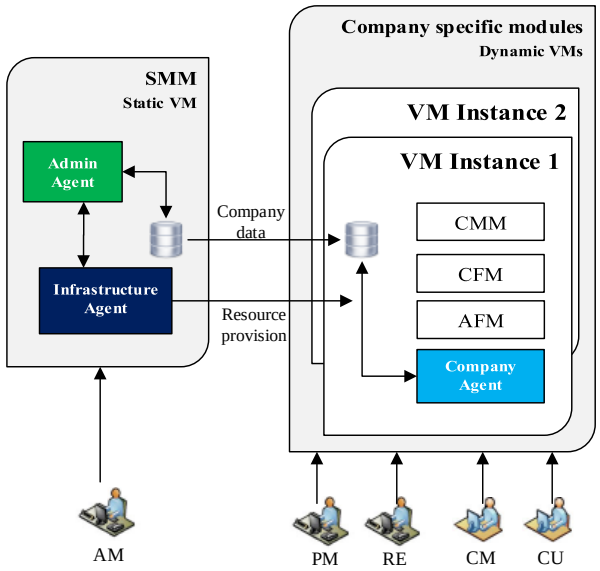

Fig. 5: TMS cloud model

VMs are dynamic and can work in two different modes, the Active mode when there is at last one active company and Inactive mode when there isn't any active company. They contain three modules, i.e., CMM, CFM and AFM.

This system has the very important Broker module in order to communicate with different company specific modules and acts as a role of system service orchestrator. Figure 5 presents three agents that are a part of the Broker module. So let us explain how this system organization works.

SMM is the main module of this system. This module can be hosted either on a bare metal server, or on a fixed static VM with constant resources. It is always able to provide authentication and authorization on the system, company registration, subscriptions and contracts, finance management, user management etc. This module uses two agents:

- *Admin agent*, which provides authentication and authorization, user management, company registration etc.
- *Infrastructure agent*, which communicates with authentication and authorization module of Admin agent to create and shut down the instances in the Company specific module providing the optimal resource utilization and reducing the overall cost for renting the hardware resources.

All other VMs are dynamically associated for each company subscribed to the system. They can be activated when a user of a company authenticates to the system, providing a ticket management function.

Each dynamic VM hosts two core software modules: the CMM module, which provides general management of the company and the CFM module, which realizes the specific ticket management, independently for each company. Additionally dynamic part of the AFM module is hosted on each dynamic VM.

The *Company agent* is hosted on the same VM, to enable a communication with SMM and data synchronization between the SMM and VM.

Note that the static parts of the AFM i CMM will be part of the admin agent and be present in the SMM.

V. Discussion

Open source solutions usually offer complete TMS (Self-Hosted) that can be downloaded and installed by a company. However, this initiates a situation, where companies must have their own hardware and software architecture or to upgrade the existing to fulfill the requirements of the TMS they choose. The installation process is not an easy one, which enforces the companies to employ a person who knows how the system works. Each upgrade for the system must be installed manually. Upgrades usually come with compatibility issues. All these issues can cost the company a lot of time and resources. Also, a company should provide test environment where each patch or new version will be tested prior deploying in the product environment.

A typical IaaS (Infrastructure as a Service) hosting implementation actually requires a self-hosting solution, and the customer is released of worries to buy the server and maintain it. The PaaS solution requires also a self-hosting solution, but in this case the customer uses a platform with an operating system and runtime environment, and even a database offered by the cloud provider. A real cloud implementation is the development of a SaaS solution, where the cloud provider gives a complete service to its customers.

The purpose of developing this type of software or introducing application is to realize web service for bug reporting. This service will be offered as a cloud computing solution to other companies in the facilitation process with customers when delivering software or other products.

Customers often asks themselves what happens when the technology goes forward and the existing applications need to be upgraded to work properly. Sooner or later, something will go wrong [11]. Usually that happens after the testing phase, when the customers start to use your system. For that reason the companies need a good support software for bug and issue tracking.

A lot of developed TMS systems are self-hosting solutions, and recently some have developed cloud solutions. The cloud solutions are more flexible, scalable and most importantly cost effective than self-hosting solutions for companies [3].

Some cloud solutions try to solve the bug reporting duplication problem and the negative impact of it in the development and maintenance process [12]. But on the other hand, bug duplicates are not considered as harmful, because they often provide additional information [11]. Our solution solves this problem by categorization of bugs. Every developer and customer is responsible for a specific module.

Cloud solutions must serve a lot of concurrent customers, so the performance is very important. In this paper we intend to describe only the cloud architecture that offers efficiency, scalability and the best performance, while in [13] we focus on the performance analysis.

VI. Conclusion and Future Work

We have developed a new cloud based system that works in optimized mode. The main functions were classified into static and dynamic components and then clustered into specific modules SMM, CMM, CFM and AFM. Three more agents were designed to allow optimized resource scheduling: Admin Agent, Infrastructure Agent and Company Agent. Our design uses a static VM hosting the SMM with Admin and Infrastructure Agents. The dynamic VMs instances are invoked whenever the admin module triggers a need. Each dynamic VM consists of three modules CMM, CFM and AFM and the Company agent.

The purpose of developing this type of software or introducing application is to realize a web service for ticket management (bug reporting). This service can be offered as cloud computing solution to other companies in the facilitation process with customers for customer satisfaction, quality assurance or when delivering software or other products.

In the future we plan to develop a SaaS solution that deals with these issues and open questions, and realize series of experiments to analyze the performance and the cost of the new cloud based TMS concept.

***Abstract*—Digital revolution offers instant information on millions of web sites. In plenty of available data, customers are interested to find information in context of appearance of an object or a certain property as soon as it is published by a given site. Some sites offer push notification to customers if they are subscribed to such a service. However, not all sites implement push service, and in these cases customers frequently visit the web site and wait for an occurrence, such as sport result, rank list, etc. In this paper we present how an intelligent software agent can realise this task instead of users that are manually visiting the web site and send information as if the web site has implemented a push service.**

This novel idea is good for both customers and web site providers. Customers would subscribe to get the information as soon as it is available, and web site providers would like to enable push service without changes in the web site software, that might be very costly. Provision of this kind of notification can be realised via sophisticated mobile phone alerts, text messages, twitter or Facebook notification, or even supported by new operating systems like Maveriks OS or web sites such as Google notifications. In this paper we present details and benefits of a such system.

***Index Terms*—push service, notification, alert service, cloud computing, intelligent agent**

I. Introduction

Remote access to web content is of utmost importance. Searching for information on the Internet can sometimes be the most straightforward job, but on other occasions a laborious and frustrating task for both experienced and casual users [1].

The fact that being well informed is key to almost everyone can surely be counted amongst the reasons for the expansion of social networking.

Borgatti et al. [2] indicate that people are gathering a considerable amount of information from shared informations by their friends and/or acquaintances.

Additionally, Lerman [3] expresses the need of aggregated news on a single website or software makes the news aggregators very popular and a successful business possibility. Powered by additional social information this process may provide an effective social recommendation system.

Furthermore, people are creatures of habit when it comes to web activity, which is very similar to the actual ”autopilot” navigation that is present in nature [4]. We all have our daily routine when it comes to starting the day on the web. Some do it when they wake up, others at their workplace. What is in common is that we all do it, except that we just have different habits such as opening the mail inbox, replying emails, checking the daily news and friends' activities, etc.

Not all sites provide push services and enable notifications. In fact, there are only few sites, such as sport news or similar information sites that send push information to customers. The new digital era initiates situations where, a lot of people are waiting for a notification to appear on certain web pages. For example, one would like to find out if there is a change in a given property associated to a certain key phrase. In this case the user is frequently visiting all those web sites looking for a given text or keyword.

Yet, overwhelmed by more important daily activities, the web occupation is often limited. This is one of the reasons for the success of feed gathering systems that provide data from multiple sites on a single web site or software based on the user required feed. Understandably, this kind of systems are expected from the popular web search engine providers such as Google, Microsoft, Yahoo etc. Clearly, the reason for this is their engine that is able to provide quick news indexing and availability to the users.

Indeed, Google Reader [5] was one of the most popular solutions that provided this functionalities to the users by using the popular RSS [6] (Rich Site Summary) news feed to gather information across the Web.

The problem occurs because not all sites provide RSS feed for their content. Our motivation is to build a cloud based system that provides an engine for site indexing and automatic feed creation for all of the sites. The overall idea is to realise this as a Service.

The expected affliction here is the performance issue since we are not just gathering RSS feeds but also crawl sites that do not offer this possibility. Therefore, in order to provide a scalable and elastic service, we find cloud computing to be a valid solution to do so.

We call the new service Alert Notification as a Service (ANS) because of its notification nature, and place it in the Cloud as a novel cloud service. Additionally, the service provides a possibility of a variety of notification services such as: Email, Facebook Notification, Skype Notification, Google Cloud Messaging (GCM) [7], SMS, Twiter, LinkedIn etc.

This novel cloud service can be offered to the end user, but also to the cloud service providers in order to provide better indexing for their hosted sites, and they can also offer this as a Service. By doing this, the sites will not be burdened with the RSS feed requirement and in the same time the users may get to the much needed results quicker and in the form they require.

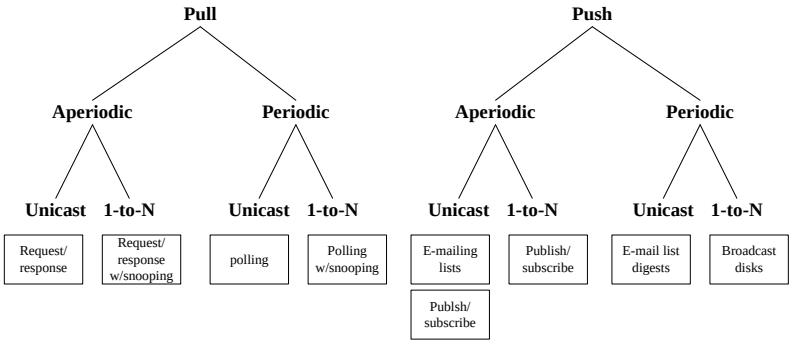

Fig. 1. Data delivery options for notification [8]

This paper concentrates on the development of a web service that will automatically visit all these web sites and alert if there is a change in the existing text or appearance of a certain keyword phrase. It will act as a kind of an intelligent agent and will periodically visit the pages instead of users to find a particular occurrence of their interest.

The rest of the paper is organised as follows. Related work in the area of push notification services and news feed services is presented in Section II. Section III describes the concept of ANS. The details of the system requirements and initial system architecture are discussed in Section IV. In Section V, we present the proposed system architecture intended for push notifications delivery. Section VI discusses the notification as a service system. The conclusion is specified in Section VII.

II. Related Work

In this section we will discuss some similar currently popular services and software solutions and compare it to our approach. The huge variety in offer of similar solutions confirms the popularity of this kind of systems.

We already started discussing similar software possibilities such as Google Reader in Section I. This is just an honourable mention to the software that Google released. Yet, the solution was discontinued and as of July 15, 2013 all subscription data is permanently and irrevocably deleted [5]. Google reader was an RSS feed aggregator and since it was deprecated a lot, for other solutions emerged to replace it.

Just by using the alternative to list [9] we can find more than 200 applications present that will offer similar services [10]. Some notable mentions are: Feedly [11], NewsBlur [12], Feedspot [13], etc. Almost all of these solutions offer a way to organise and read web content that is automatically aggregated on a single website or a software. Additionally, some of the solutions even offer statistics and synchronisation among multiple devices or even between friends when integrated with social networks.

Recently, Google released a new popular solution called Google Alerts that allows users to monitor the web for interesting new content based on search queries [14]. Besides the initial popularity of the system, one cannot miss out the more than few issues that the system has [15].

Therefore a lot of professional level and entry level applications are available on the market as both open source and proprietary solutions. Dembak [16] identified popular alternatives for this system. We will just mention some of them and summarise their functionalities. Talkwalker, Social Mention, Mention, Trendrr, Bloomberg Professional, Meltwater News, etc. are some of the popular solutions that provide functionalities for easy tracking information on specific pages or on the Web. Functionalities such as alerts in real time from web via email or in a RSS feed reader, social engine tracking, news importance ranking, analytics are available in these solutions.

There are various technologies that can be used to develop a notification service. The basic technology used was the push concept. Push technology stems from a very simple idea with ”in-your-face” nature [8]. Rather than requiring to explicitly request (i.e., ”pull”) the information that they need, data can be sent to users without having them specifically ask for it.

Push technology has evolved in last 15 years, and even the WWW consortium is trying to establish a description of Push API [17]. It defines how a web application can use an API via the user agent that will communicate to the push server and application server. HTML5 also supports the push technology [18] by defining Server-Sent Events (SSE) and standardising Comet for all standards-compliant web browsers. The Server-Sent Events specification ”defines an API for opening an HTTP connection for receiving push notifications from a server.” [19].

Push and Pull technologies use different data delivery options [8], as presented in Figure 1. Aperiodic pull is using the request response communication, while the periodic one is using polling. Push technology pushes the information without request or polling. In this case the user has to subscribe for a service. If a site would like to realise a push service, then the corresponding technology has to be used and this requires more resources.

Push notifications may be delivered via various methods which include standardised protocols (e.g. Server-Sent Events [SSE], the GSM Short Message Service [GSM-SMS], SIP MESSAGE [RFC3428], or OMA Push [OMA-PUSH]), or via

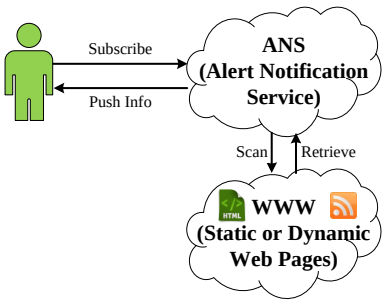

Fig. 2. Concept of ANS

browser-specific methods.

RSS is a realisation of push technology or a web feed, usually used for syndicated news service when one would like to read all the content that is pushed by a given server. Restful services are those Resource oriented architecture [20] and Representational State Transfer (REST) [21] can be used to realise push by concentrating on the roles of the components, the constraints of their interaction with other components and their interpretation of significant data elements. One of the alternatives is using SOAP while building web services. The main idea is to change the standard client server communication with a stateless communication by sending a representation of each application state with appropriate links.

Pushlets are another example of a push notification technology [22], where the server never terminates the response and the client is automatically notified about new events.

III. Concept of ANS

Our new solution helps all those sites that would not like to invest a lot of resources to implement various push services. They will still remain the same static or dynamic web sites. The concept of the ANS is presented in Figure 2. The user subscribes to the service and chooses the notification delivery method. Then the ANS is performing all the tasks, by frequent scanning the existing web site and finding a specific condition for an alert to occur.

In our solution we build all technology resources, similar to those described in W3C specification of a Push API [17]. However, we design a creation of a full service and do not require that the user has to change their concept of realisation the web application. Our service is realised as a web application where a user can register and subscribe using any web browser and can specify the way the notification can be received by choosing any conventional methods like e-mail, text message, social network or operating system notification.

Main functionalities can be summarised as in Table I.

Upon registration one can login to the main admin page. The main admin page can allow to define the alerts by selecting web pages and corresponding text to appear or to be changed from the last occurrence. Two main functionalities are possible within this activity:

TABLE I
Main functionalities of the Alert Notification Service

Functionality	Description
Definition	Specification of a web page, search key phrase, a property or occurrence of a keyword as an alert
Scanning	Crawling, visiting the web page and retrieving the required web content
Triggering	Controlling the crawling frequency, comparing the content with alert constraints and triggering the alert
Delivery	Activating the delivery channel and transmitting the alert message

- Select a web page where there is a change in text occurrence. For example, one would be interested to know when a new published paper will be indexed in a particular database, such as ieeexplore, and which paper, if more papers are waiting for publishing; and
- Select a web page with occurrence of a given text phrase. For example, my name has appeared in a blog or news.

The next functionality is selection of delivery method. The user can select among various delivery channels, such as personal message delivery via electronic mails or text messaging on a mobile device, personal messaging on social networks, or recently as a functionality of the operating system, such as Maveriks OS, or functionality of the web browser, such as Google Chrome.

The main functionality is realisation of scanning the existing web sites. Actually, the system should be able to do what a typical user is doing when visiting a web page, looking for an information. It means not just visiting a certain web page and finding an occurrence of a text within a paragraph, but also clicking on certain buttons or entering a value in certain fields. It will simulate a human entering data on an interactive web page, with a possibility to select a certain radio button or an item in a drop down list, to enter a value in a certain text field, or to click an activation button. Then the system will be able to trace the file and find a predefined keyword phrase, by detecting if there is a change in the context or in the occurrence of the keyword phrase.

This new system will enable the web sites that do not have push notification, alerting system or use corresponding API to realize alert notification. It will actually build push notification for any web page.

The alerting system can be realized conventionally by e-mail, skype, twitter or facebook messaging, or can be realized as a web page where one can see notifications, or as an add-on tool for the web browser. An example of occurrence is the alert bell on Google chrome.

It can be thought of as a system for users who would like to be notified for a certain change, or for cloud service providers who would like to build push functionality for classical web sites that do not support this technology.

IV. System Requirements

In this section we will discuss details of the system requirements and define the initial system architecture.

The system can be a service for users who would like to be notified about occurrence of a key phrase on a certain web page. The user interface should enable definition of the alerts and browsing of the results. Additionally, the ANS system may be offered to cloud service providers who would like to build push functionality for classical web sites that do not support this technology.

The main system functionalities are specified in Table I. Here we elaborate details of each functionality.

A. Definition

The system should allow user friendly definition of alerts. An alert can be defined by providing the following information:

- **key phrase** The user is looking for a certain key phrase in the web content. It may be one word or a sequence of several words. For example, one might look for a certain ranking to find if a name of a given person appeared in the list;
- **keyword as property of the key phrase** The user is looking for a certain property of the key phrase or just defining an occurrence of the keyword. For example, one might likes to find out the ranking of the person in the list and retrieve the position number;
- **alert constraint** The user should be able to define when to trigger an alert. For example, it may be an occurrence of a key phrase, change in its property, such as position number, combination with other keywords, or when the occurrence is changed etc.;
- **web page** The user is providing the url of the required web page;
- **defining a macro** The user should be able to define a macro of provided keyboard or mouse actions that leads to a occurrence of a specific web page content. For example, one might click on a certain radio button, select an option in a drop-down list, enter a specific text, click on action button in the given web page to filter the web content and dynamically choose the web content;
- **scanning frequency** The user must be able to select how often the site should be crawled for updates; and
- **delivery channels** The user should be able to select delivery channels for alert notification. For example, one might select e-mail and SMS text message on a mobile device as notification delivery channel.

B. Scanning

Scanning is realised as a crawling engine that will frequently visit a certain web page and execute various selection or activation actions. The final output is retrieving the web content on the visited web page, avoiding as much junk information as possible.

The prerequisite for this requirement is different from all existing software solutions that mostly use RSS feed from a specific site to retrieve a corresponding web content. This service must be able to extract information from any web site by crawling through its content. The crawling frequency is a parameter that can be defined by the user.

Additionally a user can select a web site that is offering RSS feeds and use this service as a kind of filter that selects a key phrase occurrence as defined alert. In this case the crawling is not started, and this functionality is actually a typical news aggregation functionality.

C. Triggering

Triggering refers to implementation of the main core control in the web service. Once the web content is retrieved by the scanning service, it is analysed and cleared from junk information. The selected information is then compared to the definition of the alert constraint. A positive outcome of the alert constraint condition triggers an alert message which is then scheduled for transmission via delivery channels.

This functionality is also novel compared to other present similar systems. The innovative approach is required in order to extract just a predefined selected part of the web content that the users need. Let's say that we want to follow the stock information on various stock exchanges. We can just simply follow the web page RSS feed with plenty of junk information and then extract the required information. The system must provide the user means to select a specific information. Definition of alert constraint is the realisation of an agent that checks if a certain condition is fulfilled triggering an appropriate alert. Then this triggers a push notification via selected delivery channels.

Additionally the user must be able to record the user interface input to filter the web content. It consists of several mouse and keyboard actions for a given web page that result in presentation of a specific content. For example, the user may be a scientist who is interested when a new journal paper is referenced on IEEEXplore database. The user should be able to navigate to the IEEEXplore search enter the search query he desires and check if in the list of the papers there is some change. The whole navigation and input on the page should be recorded in order to enable repeated query of the same request.

The whole functionality must have a web interface i.e. all the activities should be recorded using just web browser. This provides the means to use the same functionality across multiple platforms and additionally across multiple devices.

D. Delivery

When the alert is triggered the corresponding delivery channel is activated.

The system can activate a push notification to the end users as a kind of a real time notification using various messaging channels. The users can define some of the following delivery channels to get alert notifications:

- personal messaging via Email;
- personal messaging via text message (SMS) on a mobile device;
- personal messaging via social networks, like Facebook, Twiter, LinkedIn, etc.;

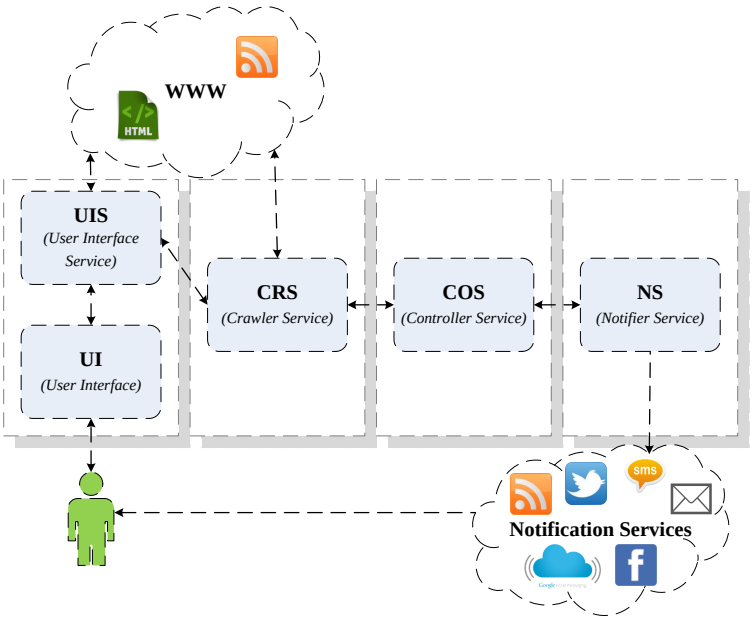

Fig. 3. Architecture of ANS

- cloud messaging, like Google Cloud Messaging (GCM);
- operating system notification, such as Maveriks OS, IOS, etc.;
- web browser notification, such as Google Chrome; and
- news feed delivery RSS.

This is also a functionality, which is not provided by the other similar solutions.

E. Other functionalities

Next we present other functionalities that may define the user interface of the complete ANS service. We start with content organisation and grouping. This functionality enables better user experience and is performance bound. The system is expected to be used by multiple users and often some will request similar if not even the same queries. Therefore, the system must organise and group the queries based on a required web page, or a specific query. This way the system should visit one single page and index it for information ones to cover as much as possible user queries.

The next functionality concerns the statistics of usage and alert generations. It may be important for future use to analyse typical behaviour and schedule corresponding resources for cloud service providers and site owners. The final goal is to realise an intelligent agent that will predict user activities and provide an information faster, and with greater accuracy.

The overall system should be compatible with different notification methods. It should support all existing push notification technologies and provide an API that can communicate with other web pages, push notification systems, RSS feeds, or similar scheduling systems, such as calendars. Realisation of an API that communicates with other systems and can integrate with operating systems and web browsers from one side, and web and push servers from other side is another feature of our service compared to the other similar systems.

V. ANS System Architecture

The main architecture of the new defined ANS system is presented in Figure 3. Core modules are realising the main functionalities. The main User Interface Service (UIS) brought by a web browser realises the functionality to define the alerts, including recorder and simple web interface components.

The Crawler Service (CRS) realises the scanning functionality and outputs appropriate content to the Controller Service (COS), which realises the triggering functionality. COS activates the CRS on a specific timing to realise frequent web page scanning. It also analyses the provided content, filters the relevant information from the junk and stores the relevant data. If the condition defined by the alert constraint is fulfilled it triggers the Notifier Service (NS) which realises the delivery functionality. NS activates corresponding notification channels to the users.

Additionally the system requirements must be performance and power aware. Therefore the system must be scalable and flexible in order to provide virtually unlimited scalability.

VI. Discussion

The advantages of push technologies are straightforward [8]. The traditional pull approach requires that users know a priori when and where to look for data or that they spend an inordinate amount of time polling known sites for updates and/or hunting on the network for relevant sites. Push relieves the user of these burdens.

There are several problems with the implementation of the push technology. The web technology changes a lot and the crawler system might need constant update to enable quality

TABLE II
AUTONOMOUS SOFTWARE AGENT PROPERTIES THAT OUR SYSTEM HAS

Property	Description
reactive	responds to a change in required information for a given content
autonomous	controls the process of triggering without direct human interaction
continuous	runs as continuous process over time
trustworthiness	adheres to learned behaviour and is truthful

scan of the web page and allow transfer of the related content from the web site to the system. Thus the system can make a good decision to find out if a condition for triggering occurs.

This system acts as an autonomous software intelligent agent according to the definition given in [23]. It scans the web page instead of the users and finds if a certain condition is fulfilled. The environment is the web, sensing correlates to scanning, and the action that produces change of state is comparison. The algorithm of realisation of the intelligent agent in this case follows a simple principle to learn by an example given by the user and sense the relevant information from the collected content.

The described online learning system with adaptive testing has several important agent's properties as presented in Table II. Our intention was not to present all characteristics and agent features, as given by Badica et al. [24] but to cover the most essential and specific properties analysed by our system.

Another problem is the realisation of the decision making algorithm that triggers an action. It is not a simple comparison of two strings, but it is realised by a rather complex actions. This happens since various technologies can hide the relevant information. For example, the information can be positioned it in tables, frames, in-line text, or various modules, so the realisation of the web scanner needs a careful algorithms to include all relevant cases. Various browsers present the relevant information with different algorithms, so when the user learns the crawler, has to be careful to use appropriate browser, which is supported by the crawler.

VII. CONCLUSION

In this paper, we have introduced a new system that actually builds on all those classical web sites, where the user is pulling information and realises the push of required information. In this case the user specifies what can trigger and push the information to the user. The system is built as a software as a service cloud solution.

One might think that this system is just an agent that provides push functionality to the conventional web sites. Instead of recompiling the software on enormous dynamic web sites and realise push technology for them, this system enables adding just a service with the same functionality that one can subscribe. In reality it repeats the actions, one frequently performs when looking for a certain information, and acts if a human reads the site and finds out a change in information he/she is looking for. This is represented as an alert and the user will be informed as soon as there is a change in information he/she is looking for.

Modern operating systems, like Maveriks, IOS or others include alert notification features if there is a change in some system information, like calendar events, received mail, finished actions, etc. Some modern web browsers also build notification alerts, such as Google Chrome, which is looking for a news on different web sites which correlates to the one the user is interested. This is a part of the conventional Google sprawling action, which compares users keywords with new scanned web pages. However, this is quite different from our service, which looks for a change in information in a predefined web page.

Adding functionalities of our newly introduced system may be part of all new releases of modern operating systems and web browsers. They are beneficial for both the users looking for a change in information or by providing push technology to conventional web site, beneficial for enormous number of cloud and web site providers.

Crowd computing to support EGI scientists

Jozsef Kovacs, Robert Lovas
MTA SZTAKI, Budapest, Hungary
{jozsef.kovacs, robert.lovas}@sztaki.mta.hu

Abstract – The International Desktop Grid Federation (IDGF) aims to collect scientists, IT operators, developers, etc. who are interested in Desktop Grid computing and related technologies. In the on-going EU Framework Programme 7 "International Desktop Grid Federation - Support Project" (IDGF-SP) there is a special focus on spreading the technology among institutes and universities by providing support in different areas like desktop grid installation, maintenance, application porting, dissemination and other topics. The members of IDGF-SP are therefore continuously maintaining and improving a network of volunteer and campus-wide BOINC projects to form a reference, production level infrastructure. The IDGF-SP infrastructure consists of volunteer and institutional BOINC projects, bridges to/from EGI (European Grid Infrastructure) type grids (e.g. gLite), cloud resources, science gateways, monitoring and accounting systems, and virtualization support for the volunteer resources. The infrastructure is currently open for EGI scientists through bridges. Several EGI communities are already utilizing volunteer resources with their own applications while the aim of the newly established EGI Virtual Team is to increase the number of these communities and success stories. The paper introduces the IDGF-SP infrastructure, its usage by the supported communities and some of the most interesting technical challenges of the integration to the EGI ecosystem. We will also show how the overall usage is moving towards crowd computing where human intelligence and other resources from citizens might be also utilized in scientific experiments.

I. INTRODUCTION

There are over a billion PCs in the world, and most of these PCs can be located in citizens' homes and, to a lesser extent, in universities. Huge portion of these computers remain idle most of the time but a few millions of them are already active in supporting science in a volunteer computing grid and use their idle time to run scientific applications. The potential growth of this computing capacity is obviously enormous. Many Desktop Grids have therefore decided to found the International Desktop Grid Federation (IDGF) [1] to help each other improving their e-Infrastructures.

The IDGF-Support Project [2] is working on giving IDGF a boost in two important areas. First, it helps considerably with increasing the number of citizens that donate computing time to e-Science. Targeted communication activities and setting-up a network of "ambassadors" is one of the possibilities. On the other hand, it also helps universities' e-infrastructures to include otherwise idle PCs from their class rooms and offices. In addition IDGF-SP collects and analyses data that will help deploying idle PCs in an effective and energy efficient way. It has been shown that Desktop Grids can contribute to Green IT if used in the correct way. IDGF-SP collects data to underpin and advocate best practices. As a result of IDGF-SP, the number of citizen volunteers donating computing to e-Science increases. By employing unused PCs in private Desktop Grid, universities and other research organizations, they saves on their costs on providing computer capacity for their scientists. The federation helps strengthening the co-operation amongst Desktop Grid e-Infrastructure operators. IDGF-SP encourages and helps the participating Desktop Grid providers to integrate their infrastructures into the main e-Science environment.

In the IDGF-SP consortium, the members are operating desktop grid sites with different setup an operational policies. SZTAKI is operating two umbrella BOINC [3] projects called EDGeS@home and SZTAKI Desktop Grid that hosts applications from different scientific areas. The first devoted to European scientists while the second is serving Hungarian scientists. Another example is AlmereGrid, the first CityGrid in the world. It runs a large Volunteer Grid in production and several Grid and Cloud test environments. The main goal of the AlmereGrid volunteer Desktop Grid is to involve citizens, companies and organizations in the city of Almere into helping science. The focus on the city means AlmereGrid can participate in events in the city, organizes exhibitions, goes to schools, etc. "Mathematics is fun, and everybody can help with finding new mathematical results." That is the main message of ABC@Home. They operate one of the largest Volunteer Desktop Grids in the world, with the goal of working on the last Theorem of Fermat. However, just as important is to get younger generation involved in this. Hence ABC@Home works together with several organizations to provide a lecture programme and practical mathematical exercises for kids. They can test the mathematics themselves and then see how it works on the Volunteer Desktop Grid. Charity Engine from the UK takes a complete different approach than traditional volunteer grids. With Charity Engine the calculations done are paid for by the organizations that do the calculations. The money earned by Charity Engines is donated to a number of charities. To even encourage people more to participate, part of the money collected by Charity Engine is used in a prize draw amongst people that donate computing time. Another directions is the University of Westminster Local Desktop Grid (WLDG) that connects laboratory PCs of the University of Westminster (London, UK) into a BOINC based Desktop Grid infrastructure. The university is set over four main campuses and some additional smaller locations in Central- and North-West-London each of them offering a variable number of Windows based dual core PCs for teaching purposes. Over 1600 of these ma-

chines are connected to the WLDG serving the various research areas in the University.

The second chapter of this paper gives an overview about the IDGF-SP infrastructure (and its underlying technologies) that includes among others the above described Desktop Grids. The third chapter outlines its integration to the most relevant European representative of e-Infrastructures (EGI). The fourth chapter shifts the focus onto the scientific user communities, and the last chapter shows the ways how the different key players of Desktop Grids, i.e. the volunteers and the scientific users can converge to each other through citizen science and crowd-computing.

II. THE IDGF-SP INFRASTRUCTURE

The IDGF-SP infrastructure (see Figure 1) contains a core set of volunteer and campus desktop grid sites (introduced previously). Currently, seven sites are associated as core sites, meanwhile new sites can join to the infrastructure. Each site has its own operational policy; however there are some common points. Most of the sites are providing 3G Bridge [4] service in order to provide interface for incoming jobs. Through 3G Bridge, jobs can typically arrive through gLite [5] virtual organizations (upper left corner) or Scientific Gateways (bottom left corner).

EGI user communities can submit their own applications to this infrastructure. To support non-validated and non-preregistered BOINC applications, we are providing the GBAC [6] virtualization mechanism. Whenever a job for a non-registered application arrives, it is encapsulated inside a virtual machine (set up by GBAC) on the volunteer resources (upper right corner) based on the VirtualBox virtualization software. BOINC has a support mechanism to handle virtualization on the volunteer resources. The other source of jobs can arrive through web-based scientific gateways like the publicly accessible Autodock portal [7] providing several execution scenarios based on the well-known Autodock molecule docking software.

There are a big number of applications ported for BOINC, they can be accessible from different repositories (middle left) like the one called EDGI [8] where applications have a deployable version for BOINC. In case of user request, administrators can download and install the selected applications. Most of the applications are also uploaded and documented in the EGI repository.

BOINC projects are operated/maintained and monitored continuously by admins. Automatic monitoring system also detects situations when long delay occurs for some jobs. Due to voluntarism, the computing resources are untrusted and unreliable. BOINC can handle unreliability however, to handle jobs having to much delay, a mechanism is automatically initiates: new cloud resources with SLA (bottom right corner) are instantiated on-demand and delayed jobs are redirected to those reliable resources. The redirection mechanism contains a job selection, cloud resources management and job reassignment functionalities.

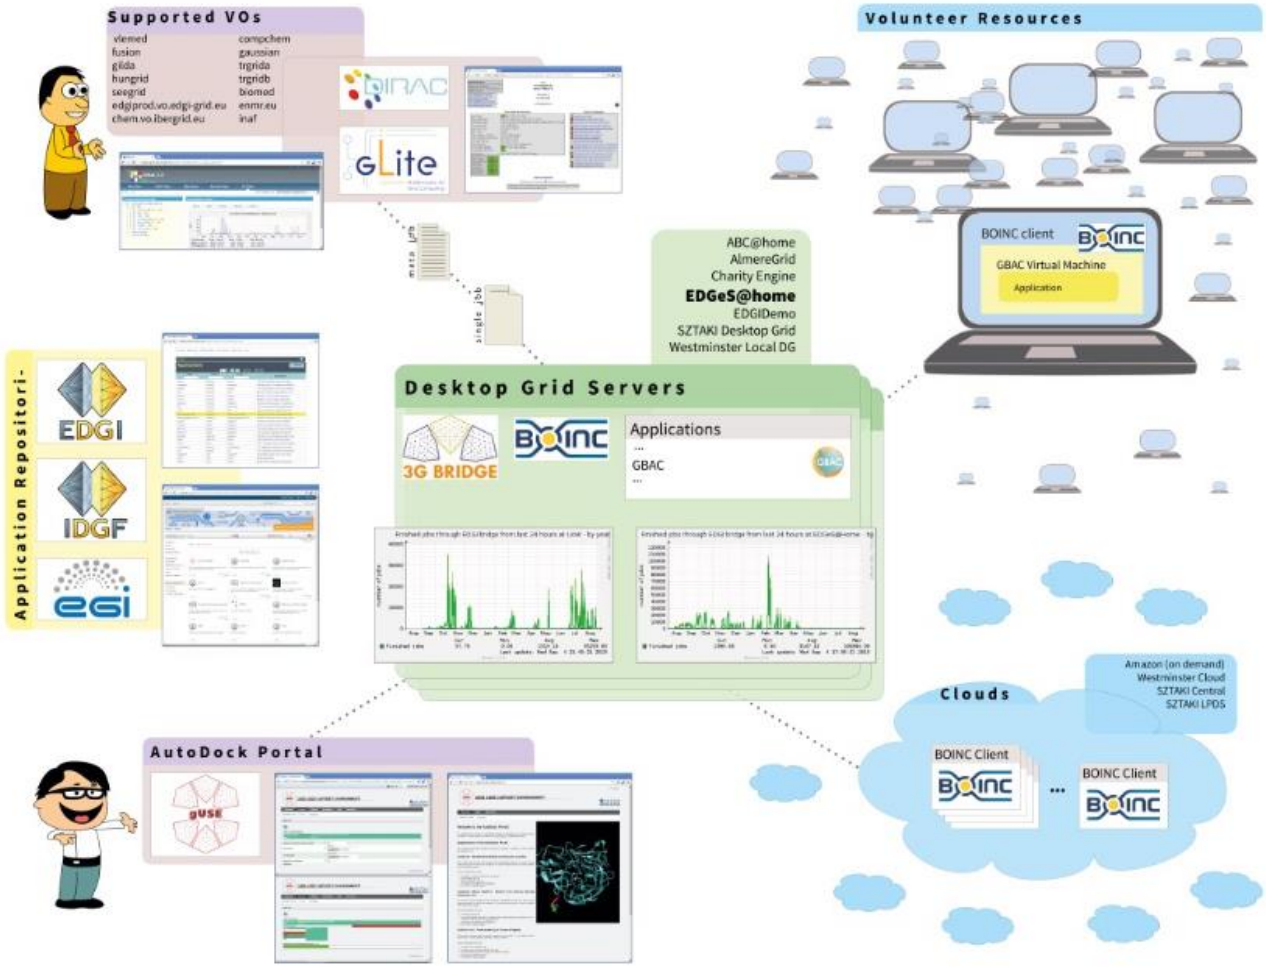

Figure 1 Overview of the IDGF-SP infrastructure

The overall infrastructure is operated and managed by the consortium members providing user, volunteer and infrastructure support, too.

III. INTEGRATION WITH EGI

The IDGF-SP project has a strong focus on the EGI related research communities [9]. At the EGI Community Forum (May 2013), IDGF-SP has started organizing a new Virtual Team in the frame of EGI-InSPIRE [10] project in order to improve its presence/acceptance further and to promote Desktop Grids among the EGI scientific communities. After the negotiations and feedbacks received from the potential invited partners and from the EGI.eu experts, the VT proposal has been officially approved by EGI and the Desktop Grid VT [11] has been launched (with open call for participation) in October 2013.

The project provides support for EGI communities to help them executing their application on the IDGF-SP infrastructure. To execute the applications in a seamless way integration of the IDGF-SP infrastructure into the EGI ecosystem is an important goal [12]. There are activities targeting technology tracking to keep the software components up to date with the recent requirements while there are also activities to increase the level of integration in different areas like job execution, accounting, user support, etc. Based on the bridging technology - the EDGI project developed - it is already possible to submit jobs from gLite to Desktop Grids, however there are other aspects of integration that are missing or not fully implemented. Recent results in terms of integration are as follows:

1) launched the IDGF Support Unit [14]

In cooperation with the EGI GGUS team, the IDGF-SP project has set up a support unit in order to provide the EGI compliant support service for the EGI scientists and resource providers. The support unit collects Desktop Grid experts from various areas (application porting, infrastructure maintenance, etc.), is registered and accessible through the GGUS ticketing system [15] operated by EGI.

2) completed the accounting related integration [12]

The EGI accounting system is based on the APEL accounting tool that collects accounting data from sites participating in the EGI infrastructure.

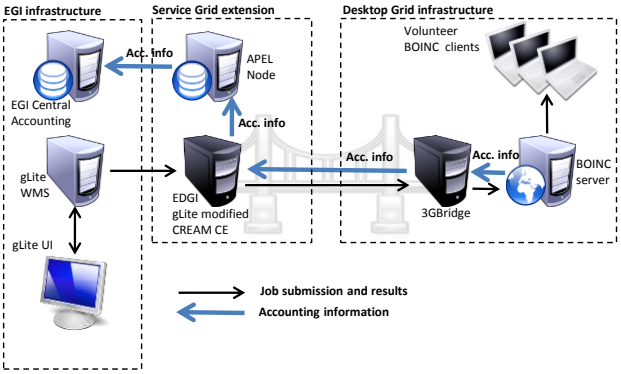

Figure 2 Overview of the combined EGI – DG accouting architecture

The accounting information is gathered from different sensors into a central accounting database where it is processed to generate statistical summaries. These are available through the EGI Accounting Portal [16] for view in different details by Users, VO Managers, Site Administrators, etc. In order to attach the Desktop Grid site as accounting information provider, it must 1) generate accounting information for each job, and 2) must deliver it to the appropriate service. The Desktop Grid site represented by a BOINC server by default keeps track of the workunits and gathers accounting information from the clients about the finished workunits in its database. This information is collected by the 3G Bridge tool for each individual job once a job is finished. The modified CREAM Computing Element queries this information for each job and synchronizes with the site level Apel [17] node. This Apel node acts as a sensor in the Apel network and regularly sends the accounting information of the site to the central EGI accounting server. Finally, the EGI users can browse accounting information about the attached DG sites through the EGI Accounting Portal [16].

3) offered EDGeS@home capacities into the EGI Federated Resource Pool [18]

One of the largest IDGF-SP volunteer project offered for the EGI scientists as a distributed computing infrastructure is the EDGeS@home BOINC-based project. EDGeS@home has already provided more than 300 Million Cobblestones in BOINC terminology computing power for the scientists since October 2009. In a nutshell, BOINC's unit of credit (the Cobblestone) is granted based on the computations performed by the volunteer's computer, and equals to 1/200 day of CPU time on a reference computer that does 1,000 MFLOPS based on the Whetstone benchmark. Using EGI metrics, it would mean also millions of CPU hours. Figure 3 shows the recently provided CPU hours in the EGI accounting portal for executing the workunits (jobs) originated from WeNMR.

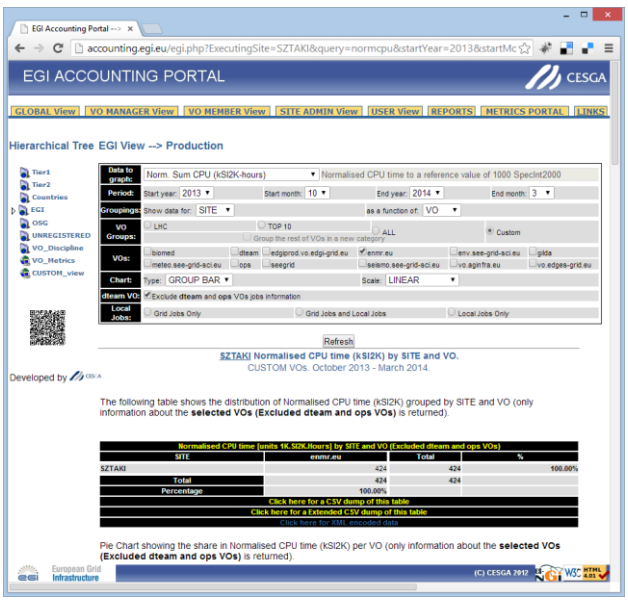

Figure 3 Accounting info presented by the EGI accounting portal

IV. SUPPORTING USER COMMUNITIES

In this section, the most representative usage scenarios are introduced through several user communities already utilizing volunteer resources with the help of IDGF.

WeNMR [19] is a Virtual Research Community supported by EGI, the largest one within the life science area. According to their introduction; WeNMR aims at bringing together complementary research teams in the structural biology and life science area into a virtual research community at a worldwide level and provide them with a platform integrating and streamlining the computational approaches necessary for NMR and SAXS data analysis and structural modelling.

Thanks to the virtualization (by GBAC) and to the bridging technology IDGF maintains, the WeNMR grid is able to forward jobs submitted by their scientific users to volunteer resources behind the dedicated computing element (cr2.edgi-grid.eu). Currently, jobs for the CNS application are regularly submitted to EDGeS@home. The Crystallography & NMR System (CNS) has been designed to provide a flexible multi-level hierarchical approach for the most commonly used algorithms in macromolecular structure determination. However, this software required some dependencies (deployed binaries, environment variables, etc.) to be resolved which was easily applied by the virtual machine GBAC sets up on the volunteer resources.

The DIRAC [20] (Distributed Infrastructure with Remote Agent Control) project is a complete Grid solution for a community of users needing access to distributed computing resources. DIRAC forms a layer between a particular community and various compute resources to allow optimized, transparent and reliable usage. The Workload Management System with Pilot Jobs introduced by the DIRAC project is now widely used in various grid infrastructures. This concept allows aggregating in a single system computing resources of different nature, such as computational grids, clouds or clusters, transparently for the users.

In this scenario, the DIRAC automatic pilot submission mechanism makes sure that as many pilots are running as possible. It submits pilots to a dedicated computing element (cr2.edgi-grid.eu) which forwards them as GBAC jobs to EDGeS@home. Once a volunteer starts running a GBAC workunit with the DIRAC pilot, the pilot comes to live and starts downloading and executing DIRAC jobs on the resource. In contrast to the previous scenario, the job submitted to the IDGF infrastructure is not performing the computation by itself, but rather attaches the resource to another grid to receive computational jobs. This is a non-regular, but interesting use case.

BioVeL [21] is a virtual e-laboratory that supports research on biodiversity issues using large amounts of data from cross-disciplinary sources. BioVeL offers the possibility to use computerized "workflows" (series of data analysis steps) to process data, be that from one's own research and/or from existing sources.

In this third scenario, two BioVel applications (BBGC and BBGC-MuSo) has been ported to BOINC as native applications. The ported applications have been deployed on EDGeS@home and jobs can be submitted through the 3GBridge interface. The BIOVEL portal exposes different workflow executions as services for the users. By executing a given workflow, jobs (for the aforementioned two applications) are generated and submitted. Similarly to the first two scenarios, a high-level portal hides the details of handling the underlying grid.

The fourth scenario is implementing a different approach in terms of job generation and submission. Mathematicians from the Department of Computer Algebra of the Eotvos Lorand University of Sciences is working on discovering the distribution of prime numbers based on the Riemann-Siegel [22] function. The main objective of this research is to generate lots of large values of the zeta function, in order to reveal new patterns related to prime numbers. For this purpose, the zeta-search application has been developed which is able to predict the value of the zeta function for a given number.

This application is an ideal parameter sweep one, where the parameter is a single number (increasing towards infinite) and output is the predicted value of zeta-function. Currently, SZTAKI Desktop Grid is hosting the application, thousands of jobs are continuously generated for the volunteer resources. In this scenario job generation has been fully automated and performed locally on the BOINC server, no need for user interface in this case.

V. TOWARDS CROWD COMPUTING

Citizen science can be considered as a new and innovative approach in order to involve the general public in scientific processes in several ways. This special approach helps people understand what scientists are dealing with in their 'ivory towers' by letting the 'outsiders' (i.e. citizens) participate and engaged in various scientific research and experiments.

One of the main aims of the FP7 SOCIENTIZE project [23] is to "promote the usage of science infrastructures (dedicated and external resources), including professional and amateur scientists, and also sets up a network where infrastructure providers and researchers recruit volunteers from a general public to perform science at home".

Figure 4 Screenshot on on-going Mind Paths experiment using pyBossa by SOCIENTIZE (source: [24])

Socientize has been implementing a set of applications that enable volunteers to become scientists, encouraging active public participation in scientific research processes and showing the capabilities of open community based resources, such as

- Citizens scientists can help scientists collect data that will be analysed by professional researchers.
- Performing tasks that require human cognition, knowledge or intelligence such as image classification, image analysis from scientific infrastructure, transcription, and more e.g. within a web browser.
- Experiments with citizen sensor networks.
- Mental skill games related to science experiments (see Figure 4).

Some of the experiments from SOCIENTIZE are based on the PyBossa [25] platform. PyBossa is an open source platform for so-called 'crowdsourcing' online (volunteer) assistance to perform tasks that require the above mentioned human cognition, knowledge or intelligence. PyBossa was inspired by the BOSSA crowdsourcing engine but is has been implemented in Python language.

Concerning the background of a related application area; there is a long-term and active research activity at MTA SZTAKI / DSD in the field of plagiarism search, some results are already provided as service to the public:

1) Monolingual plagiarism search

The KOPI Online Plagiarism Search Portal [26] is an open service that enables the users to check for identical or similar contents between their own documents and the files uploaded by other authors. This check function works in any European language, due to the language-independent algorithm.

2) Check for translated plagiarism

KOPI is is able to identify quotations - and also their translations - taken from the English Wikipedia. KOPI can run searches in Hungarian, English and German (and according to the plans it is being continuously improved to support other languages as well).

3) Measuring the amount of citations

KOPI is able to measure the total amount of citations in a document in case the source is available; the overlap between two documents; and also the originality of a written work in a set of documents.

4) Find the original author

With its constantly growing database KOPI is able to find the original author of a work, or search for works which cite from a given document/author.

The KOPI users and the related user scenarios can be classified in 3 categories:

1) Higher education

For teachers KOPI gives the opportunity to compare theses and home assignments to all documents uploaded before, or to the KOPI database and to the full content of Wikipedia.

Students are also able to check their own written documents to see e.g. if the amount of citations has exceeded the limit set by their home institution. They can also protect their theses by uploading them under their names.

2) Research and development

Authors can upload their written materials to the KOPI Portal so they are free to be published anywhere. KOPI protects copyright by showing who used the document and the author can see if the other party cited his work accordingly or not. Reviewers can use KOPI to compare the submitted work with other works of the same author, with the sources cited, so they are able to screen out improper citations and self-plagiarism cases.

KOPI helps scientific conference organizers make the submitted papers as unique as possible; screen out repeated submissions; and search for interesting papers and authors of the same or similar topics.

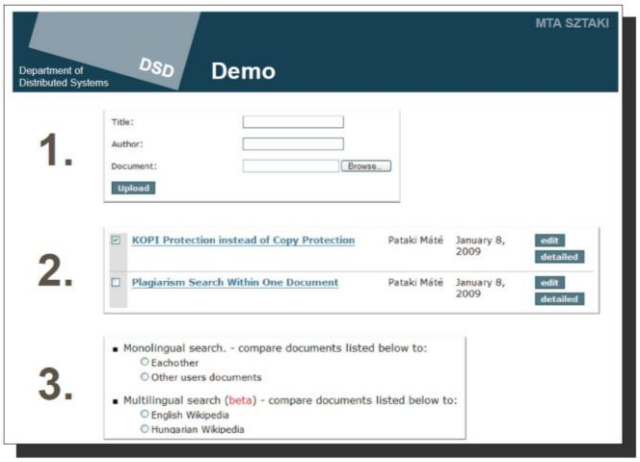

Figure 5 Screenshot from demo/presentation given by the representative of KOPI service at the 'Joint agINFRA and SCI-BUS workshop' supported by IDGF-SP (source: [27])

3) Companies, publishers

Contents of publications or corporate websites are often subject to plagiarism, so it is of great importance for press- and book-publishers, blog authors and for the online and offline media as a whole to protect their property from copyright infringement. They can easily do so by uploading their contents to the KOPI Portal, which will protect them against content theft by easily identifying the original author.

In general, the KOPI Plagiarism Search Portal enables all users to upload documents and start a plagiarism search using these documents. Uploaded written works are comparable with each other, and with the full database of the system. The users can check for plagiarism not only in tens of thousands of documents uploaded by the registered users, but can also compare documents to several digital data collections and the Wikipedia containing millions of entries and articles.

KOPI uses the SZTAKI Desktop GRID to pre-process the immense database of Wikipedia. In this way, the KOPI users can help improve the KOPI service by running the

Desktop Grid client on their machine. More details can be found in [26].

Joint research between IDGF-SP and SOCIENTIZE to involve more citizen scientists

The detected level of similarity (given in percentage) by the KOPI service sometimes leaves the final decision to the above listed users; whether the checked document has been the result of any kind of plagiarism or not. In order to enhance the KOPI service and provide more inputs for the KOPI related research activities at the same time, some joint activities have been initiated and partly negotiated between IDGF-SP and SOCIENTIZE projects. The collaboration is to cover the following topics:

1) IDGF-SP (KOPI) modifies the terms of use of the KOPI service that will optionally allow the KOPI service to send some pieces of the uploaded text to third-party contributors (to volunteers from SOCIENTIZE) if the KOPI user explicitly requests this new enhanced service.
2) IDGF-SP collects pieces of texts from the KOPI users (who explicitly requested this service) where the automatically detected level of plagiarism indicates that more consideration/attention would be required (i.e. the plagiarism cannot be detected with enough high certainty).
3) IDGF-SP provides these pieces of texts to the SOCIENTIZE project (in the given protocol and format, accepted by pyBossa) that must be compared and checked by the volunteers.
4) SOCIENTIZE project provides and operates the above described pyBossa framework as the required platform, and sends back the results from the volunteers to the KOPI service.
5) SOCIENTIZE and IDGF-SP advertise jointly the experiment to attract volunteers.
6) IDGF-SP contributes to the green paper of the SOCIENTIZE project.

The planned collaboration is to be formalized in a Memorandum of Understanding between the two projects.

According to the draft version of the green paper issued by the SOCIENTIZE project: "Citizen Science refers to the general public engagement in scientific research activities when citizens actively contribute to science either with their intellectual effort or surrounding knowledge or with their tools and resources." As the result of the above outlined joint activity KOPI with its enhanced service will form a special citizen science experiment where the volunteers (citizen scientist) might be classified in two ways:

Beneficiaries

- directly through the provided plagiarism search service (created by the researchers)
- indirectly through the better education of the citizens' children since the teachers will be able to use the enhanced KOPI service in their everyday work more efficiently

Active contributors

- with uploaded documents that serve input for plagiarism search,
- with their spare computer capacities to do preprocessing of all WIKIPEDIA articles time-to-time by the IDGF supported SZTAKI Desktop Grid
- with their human intellectual efforts to check documents where the plagiarism cannot be detected automatically with enough high certainty

Moreover, the entire experiment serves a solid base for multidisciplinary research activities in the fields of computer- and social sciences, and also linguistics. Some results have been already published in scientific journals and more publications are to be expected after the successful experiment.

VI. CONLUSION

Crowd computing has been gaining more and more attention. There are several benefits of the model; the scientists are able to harness the power of the general public, and the citizens will get more information and insight view about the science. As the paper illustrated, the number of application areas have been increasing, and IDGF is close to reach the level and the critical mass to be a fully integrated and vital part of the e-Infrastructure related ecosystem.

ACKNOWLEDGMENT

The research leading to these results has received funding from the European Union Seventh Framework Programme (FP7/2007-2013) under grant agreement no 261556 (EDGI) and under grant agreement no 312297 (IDGF-SP).

Obtaining Massive Data Sets for Contextual Experiments in Quantum Information

Mladen Pavičić
University of Zagreb, Faculty of Civil Engineering, Physics Chair, Zagreb, Croatia

***Abstract*—Finding even the simplest Kochen-Specker sets for contextual experiments—a hot subject in the field of quantum information theory, theoretically and experimentally—by brute force would take all the clusters on Earth more than the Age of Universe. Human ingenuity found about a dozen such sets in the last 40 years. I will present how our group reduced this finding of contextual needles in a haystack to a manageable task, by first visualising them via hypergraphs, human-derived from the space symmetries, and then running jobs that generate the sets—billions of them—in parallel.**

I. Introduction

A measurement of any observable of a classical system should yield the same value independently of whether we carry out the measurement of the observable simultaneously with another measurement of another observable of the same system or not. In other words, classical theories do not depend on arrangements in which measurements are carried out, i.e., on their "context," and we say that classical theories are *non-contextual* and that all their observables can be ascribed predetermined values.

In contrast, a measurement of an observable of a quantum system can yield different values depending on other measurements of another observables that we measure simultaneously with the considered observable. So, a quantum theory does depend on arrangements in which measurements are carried out and we say that quantum theories are *contextual* and that their observables cannot be ascribed predetermined values.

Not all experimental arrangements for a quantum system are contextual, though. Actually, until a few years ago only about a dozen such sets of quantum states to which no predetermined values can be ascribed were known. The sets are called Kochen-Specker (KS) sets and they are needed not only for a better understanding of quantum theories and measurements [1]–[3], but also for constructing of quantum gates in the field of quantum information and quantum computation and for handling quantum sets in general [4], [5]. So, it is of interest to know how often we can encounter such sets, i.e., how many KS sets we can generate.

II. Formalism

Let us first define KS sets more precisely.

Definition 1. Every KS set is a set of vectors in a Hilbert space $\mathcal{H}^n$, $n \geq 3$ to which it is impossible to assign 1's and 0's in such a way that:

1. No two orthogonal vectors are both assigned the value 1;

2. Not all of any mutually orthogonal vectors are assigned the value 0.

In this presentation we shall limit ourselves to $n = 4$, i.e., a 4-dim Hilbert space. Systems can be either a pair of qubits (qubit is a 2-dim quantum system) or a spin-3/2 particles. Sets of mutually orthogonal vectors in a 4-dim space we call tetrads. A KS set is a union of such tetrads.

Mutual orthogonality of 4 vectors in a 4-dim Hilbert space is represented by the following 6 nonlinear equations:

$$\begin{aligned}
\mathbf{a}_A \cdot \mathbf{a}_B &= a_{A1}a_{B1} + a_{A2}a_{B2} + a_{A3}a_{B3} + a_{A4}a_{B4} = 0,\\
\mathbf{a}_A \cdot \mathbf{a}_C &= a_{A1}a_{C1} + a_{A2}a_{C2} + a_{A3}a_{C3} + a_{A4}a_{C4} = 0,\\
\mathbf{a}_A \cdot \mathbf{a}_D &= a_{A1}a_{D1} + a_{A2}a_{D2} + a_{A3}a_{D3} + a_{A4}a_{D4} = 0,\\
\mathbf{a}_B \cdot \mathbf{a}_C &= a_{B1}a_{C1} + a_{B2}a_{C2} + a_{B3}a_{C3} + a_{B4}a_{C4} = 0,\\
\mathbf{a}_B \cdot \mathbf{a}_D &= a_{B1}a_{D1} + a_{B2}a_{D2} + a_{B3}a_{D3} + a_{B4}a_{D4} = 0,\\
\mathbf{a}_C \cdot \mathbf{a}_D &= a_{C1}a_{D1} + a_{C2}a_{D2} + a_{C3}a_{D3} + a_{C4}a_{D4} = 0.
\end{aligned}$$

Now, it might seem that the problem can be approached by a brute computational force. We ascribe values 0 and 1 to various sets of connected tetrads of vectors and as soon as we find a set for which we cannot do that it is a KS set. However, this is easier said than done because there are billions of such sets even if we limit ourselves only to unit components along each of four axes for all vectors. Besides, the equations are nonlinear and it is a hard problem with only a few equations, let alone billions.

Fortunately, in 2000 I realised that these equations can be reduced to a generation and then filtering of hypergraphs, in particular McKay-Megill-Pavičić (MMP) hypergraphs, which Brendan D. McKay, Norman D. Megill, and I defined previously for another purpose.

Definition 2. We define MMP hypergraphs as follows [6]

(i) Every vertex belongs to at least one edge;

(ii) Every edge contains at least 3 vertices;

(iii) Edges that intersect each other in $n-2$ vertices contain at least n vertices.

This definition enables us to formulate algorithms for exhaustive generation of MMP hypergraphs. In this work we shall work with subsets of a 60-75 (60 vertices - 75 edges) master set obtained by P. K. Aravind who derived it from another even bigger set using geometric symmetries [7]. From this master set we generate smaller hypergraphs that correspond to subsets of the 60-75 set with a specified number of edges deleted.

For any experimental application it is not viable to consider all KS (sub)sets but only those that can be experimentally

distinguished. Hence, we extract *critical* non-redundant non-isomorphic KS sets. "Critical" means that they are minimal in the sense that no orthogonal tetrads can be removed without causing the KS contradiction to disappear.

The "only" difficulty we face is the sheer size of these generated subsets—we are dealing with a haystack of 2^{75} or 38 sextillion subsets, in which we wish to find certain "needles," i.e., critical KS sets. In Sec. III we will present the algorithms and programs which enable us to deal with the haystack.

The hypergraphs we obtain reflect only the orthogonal structure of KS sets and do not in any way refer to the vector components of the original 60-75 KS set. This is yet another aspect in which the present method differs from the parity-proof method we used in [8], which relies on the vector components of the vectors in each KS set that were inherited from the original 60-75 set. For each hypergraph we can, however, find appropriate vector components with our program `vectorfind` or by interval analysis we developed in [6].

We encode MMP hypergraphs by means of alphanumeric and other printable ASCII characters. Each vertex is represented by one of the following characters: 1 2 3 4 5 6 7 8 9 A B C D E F G H I J K L M N O P Q R S T U V W X Y Z a b c d e f g h i j k l m n o p q r s t u v w x y z ! " # $ % & ' ( ) * - / : ; < = > ? @ [\ ] ^ _ ` { | } ~ , and then again all these characters prefixed by '+', then prefixed by '++', etc.

Each edge is represented by a string of characters that represent vertices within a single line. Edges are separated by commas. The line must end with a full stop. Skipping of characters is allowed. A line forms a representation of a hypergraph. The order of the edges is irrelevant. The numbers of vertices and edges are unlimited. We often present MMP hypergraphs starting with edges forming the biggest loop to facilitate their possible drawing.

In Fig. 1 we show a graphical representation of the minimal (26-13) critical KS set we found and which we shall now use to show a correspondence between the vector and the MMP hypergraph representation of any KS set.

Each vertex represents a vector in a 4-dim space. For instance, G= $\{1,0,0,0\}$, F= $\{0,1,0,0\}$, E= $\{0,0,1,0\}$, D= $\{0,0,0,1\}$. They are mutually orthogonal and that means they form an edge—GFED. Our program `vectorfind` can assign all vectors, that correspond to edges from the 26-13 set, component values from the set $\{0,\pm1,\pm(\sqrt{5}+1)/2,\pm(\sqrt{5}-1)/2\}$ and that means that the system of equations that define all orthogonalities for the 26-13 does have a solution. Now our program `states01` (which exhaustively verifies all possible assignments) checks whether all the vertices can be ascribed 0 and 1 according to the KS rules 1 and 2 above and verifies that it is not possible. The main point here is that we can always go from MMP hypergraphs to vectors and back and that `states01` works with MMP hypergraphs. MMP hypergraphs are linear while the system of equations describing mutual orthogonality of vectors are nonlinear. Therefore the evaluation of MMP hypergraphs by means of `states01` is exponentially faster than solving nonlinear equations and this is what makes our generation of KS sets feasible. While the algorithm used in `states01` is comparatively fast, the verification of KS sets for MMP hypergraphs with an odd number of edges can be even faster using our "parity proofs" algorithm described in [8].

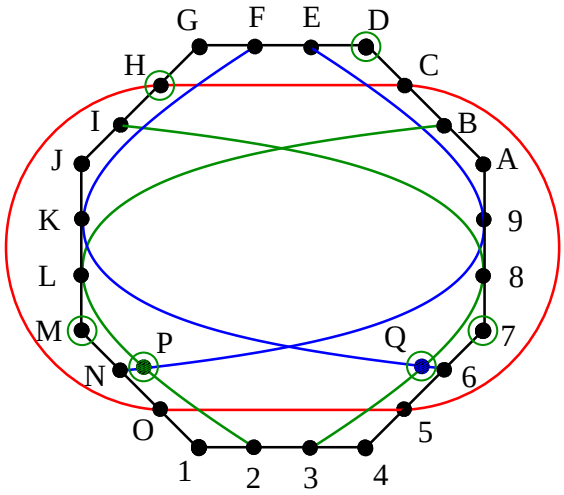

Fig. 1. The smallest KS set 26-13 (with 26 vertices and 13 edges). Possible assignments of 1s are indicated by circles (7,D,H,M,P,Q)—the remaining vertices can only be assigned 0s. Hence, all vertices in edge 1234 can only be assigned 0s and Def. 1 is satisfied. MMP encoding of the shown 26-13 reads: 1234,4567,789A,ABCD,DEFG,GHIJ,JKLM,MNO1,O5CH,2PLB,NP9E,6FQK,3Q8I..

We stress here that once we visualised, i.e., drew, MMP hypergraphs, we can drop the ASCII signs and compare and classify them graphically referring only to, e.g., the biggest loops they allow, the highest and lowest numbers of edges vertices allow, whether they allow parity proofs, the highest number of 1s vertices can be assigned, etc., all of which properties have their own role in experimental implementation of critical KS sets. Of course, we can always go back to vector representation so as to assign arbitrary ASCII signs to vertices and then run `vectorfind` on them.

III. Results

To generate critical KS sets we applied an algorithm and a program (`mmpstrip`) which strip edges from the master 60-75 MMP, then subsequently from the so obtained MMPs, and so on. The number of MMPs we can obtain in this way grows exponentially and in less then 10 steps it would make busy all CPUs and would overflow all storage capacities on the Globe.

Fortunately the greatest portion of the generated MMPs are isomorphic to each other and by using B. D. McKay's algorithm and program `shortd` which he derived from his program `nauty`, we are able to greatly reduce the number of MMPs we have to generate to eventually obtain the required critical KS sets. However, even their number is far too big for an exhaustive generation and even clusters with hundreds of CPUs cannot make more than 13 steps in an acceptable time.

Therefore the only option left is a probabilistic generation combined with 0-1 and isomorphic filtering. That excludes parallel processing on a cluster because the programs for stripping, isomorphic reduction, and 0-1 filtering are all probabilistic so far as the sequential steps are concerned (although,

of course, the end result is deterministic). Thus the times of parallel running greatly differ and it is much more efficient to put a large number of jobs in queue and rerun those that come out first. The details are as follows.

As shown in the flowchart 1, we first have to generate—by stripping edges—a sufficient number of MMPs, in several steps, to compensate for an inherent homogeneous distribution of critical MMPs in the generation "down-tree." After each step, i.e., with a sufficient number of MMPs within each step, we reiterate the procedure until we reach about " 10^{10} MMPs. Then we carry out a "random reduction" by means of `states01` which strips random edges from the input MMPs until they are critical.

brute force	10^{25} nonlinear equations	Age of the Universe
	⇓ bulk generation ⇓	
bare MMP isomorphic generation	10^{10} MMP hypergraphs	1 month cluster (100 CPUs)
	⇓ random reduction ⇓	
random stripping	10^{8} MMPs	$<$ 1 day cluster (100 CPUs)
	⇓ selective generation ⇓	
$0-1$ and isomorphic filtering	10^{4} MMPs	$<$ 1 hour cluster (100 CPUs)
	⇓	
isomorphic filtering	one MMP ($26-13$ KS set)	$<$ 20 min (1 CPU)

(1)

The majority of so obtained criticals are isomorphic and mixed. Therefore we have to rerun the random reduction and selective generation many times and each time we have to merge new MMPs with the already obtained ones so as to build a cumulative set of all possible KS. However, not even then can we be sure that we obtained samples of all kinds of MMPs. For example, after 3500 generated 60-41 critical MMPs (critical KS sets) among more than 1.5 billion critical KS sets we still have not obtained a single one with a parity proof although there is at least one because we obtained it via a parity algorithm from [8]. On the other hand a single 47-30 appeared only after 1 billion of generated KS criticals and it cannot be generated via the parity algorithm since it has an even number of edges. We present statistics of obtained critical KS sets in Fig. 2. Detailed presentation of all obtained results will appear in a subsequent publication.

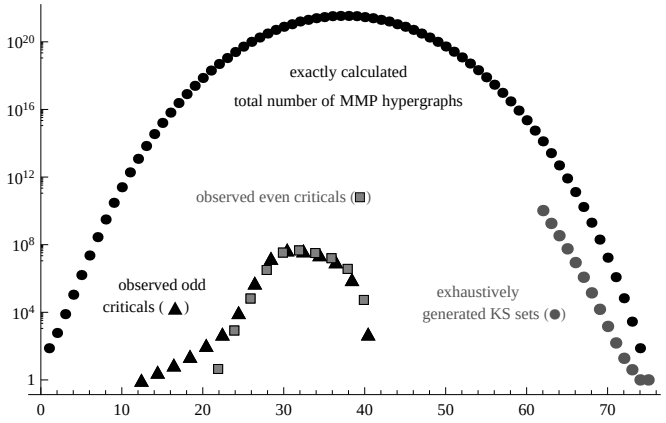

Fig. 2. Statistics calculated for subsets of 60-75 given on a logarithmic scale. There are more than 10^9 critical KS sets. Given numbers of critical KS sets with 13 to 27 edges (on the x-axis) are exhaustive. The number of criticals with 32 edges is the biggest; we estimate that they do not exceed 10^{10}. Given numbers of noncritical KS sets with more than 61 edges are also exhaustive.

Details of the programs `mmpstrip`, `states01`, `vectorfind`, and `shortd` and the algorithms behind them are given in [6]–[9].

IV. Conclusion

We have obtained a massive number of contextual sets, more specifically critical Kochen-Specker (KS) sets, by first translating a condition imposed on quantum states—orthogonality—into a condition imposed on correlated MMP hypergraphs and then handling the latter hypergraphs to generate the sets. In the standard Hilbert space the generation lead to huge sets of nonlinear equations and therefore to an exponentially complex problem. Generation of MMP hypergraphs is however a statistically polynomial problem and is therefore feasible, although lengthy as shown in the previous section. "Statistically polynomial" here means that although the algorithms behind the programs `mmpstrip` and `states01` might in general take an exponentially increasing time with larger sets, this on average does not happen because of the inner structure of the KS sets.

Obtaining large KS sets is important for better understanding of how quantum system behave and a better insight into their engineering within experiments. The most significant result we obtained is that efficiency of contextual measurements does not drop with large KS sets. Only the number of required measurement rises but the efficiency of each of them can be the same for some of the largest sets as for the smallest one. This is in contrast with most other quantum gates where the efficiency drops when the number of states increases, due to coherence problems. On the other hand, some of our previous conjectures based on a smaller number of sets [9] should be amended. For instance, the peak for the KS criticals turn out to be much lower, the distribution of them of a different shape, and the KS criticals with more than 41 edges nonexistent.

Also a very important contribution of a computational approach to contextual sets and similar problems is contained in our development of algorithms that enable solving huge systems of nonlinear equations via handling MMP hypergraphs on clusters. This is important not only because we already arrived at new results with new KS sets in 3-, 4-, and 6-dim Hilbert spaces, but also because it opens a new approach to solving systems of equations in an analogous way in other quantum and classical problems—whenever we can translate a condition imposed on a system of equations into a condition imposed on hypergraphs, we should be able to solve the system via handling and filtering the hypergraphs.

ACKNOWLEDGMENT

Computational support was provided by the cluster Isabella of the Zagreb University Computing Centre and by the Croatian National Grid Infrastructure. My special thanks go to Emir Imamagić for his generous help with problems I encountered while carrying out calculations on these clusters.

***Abstract*—Particle-based models are widely spread in the field of computer graphics, and mainly used for real-time simulations of soft deformable bodies. One of the high-demanding computational components of such physically-based simulations is numerical time integration. As the size of the models increases, this component becomes a potential bottleneck in the simulation process, thus parallelism must be deployed in order to preserve the real-time attribute. This paper presents an approach to parallel implicit numeric time integration for graphics clusters. To deal with very large models, we employ a static domain decomposition approach and we fully utilize the massively data parallel capabilities of GPU clusters. We discuss the parallel conjugate gradient algorithm used for time integration and we present a parallel method for generating the very large sparse matrices and vectors involved.**

I. Introduction

Modeling and simulating three-dimensional dynamic surfaces represents one of the main research areas of Computer Graphics and probably one of the most fascinating. The most prominent techniques for such simulations are physically-based methods, which have become an important part of the entertainment industry and are regularly employed in computer games, feature films and various computer based animations, for visual effects involving interacting fluids, textile materials, deformable and rigid bodies. However, taking into account that most such simulations need to be interactive and considering the computational expensive numerical methods employed, coupled with the very large sized models that the ever growing strive for realism demands, efficient parallel techniques must be developed in order to fully utilize modern High-Performance Computing (HPC) architectures such as the Graphical Processing Unit (GPU) and GPU clusters for real-time particle-based simulations.

One of the most important subdomain of physical-based modeling is particle-based modeling, where surfaces are approximated through sets of discrete points having various physical properties such as mass, volume, speed, acceleration. The behavior of such surfaces along with their interaction with the environment is governed by the laws of physics, more specifically by the forces that act upon particles. Particle-based modeling is a natural choice since in the real world interactions concerning deformable surfaces occur at a molecular level and, in theory, given a sufficient number of particles, any such surface can be accurately modeled. The particle-based model for simulating cloth was firstly introduced by Provot [1] and is still utilized in simulations where interactivity is a key requirement.

When used to simulate rigid cloth, such models generate systems of stiff differential equations with respect to time. In order to solve such systems one must employ numerical time integration. Implicit integration has the advantage of being unconditionally stable for large time steps, but can quickly become a major bottleneck as the size of the models increases, mostly due to operations involving the large sparse matrices of these systems. In computer graphics, the popular Conjugate Gradient (CG) algorithm is used to solve these differential equations, allowing balancing accuracy against simulation speed.

In our previous work towards particle-based simulation of 3D dynamic surfaces on graphics clusters we developed basic parallelization strategies for the time integration stage [2]. We proposed a data parallel approach for the velocity Verlet explicit scheme [3] and, by using a hybrid CPU/GPU parallelization technique and a sort-last approach to centralized visualization, we obtained interactive frame rates for models exceeding one million particles. This paper expands our previous work and presents a GPU cluster oriented approach to parallel implicit numerical integration for particle-based models. It is based on a parallel Conjugate Gradient algorithm implemented in the Vienna Computing Library (ViennaCL) [4], a high level linear algebra library for GPUs and Multi-Core CPUs. We propose a parallel method for updating the large sparse matrices that serve as input to the CG algorithm, tailored specifically to the particularities of the model used for simulating cloth and the Compressed Sparse Row format used by most linear algebra libraries. The rest of the paper is organized as follows: Section II highlights important related work. Section III presents an overview of the particle-based model used for simulating cloth. Section IV describes our approach for parallel implicit integration on GPU cluster. We report on performance measurements in section V.

II. Related Works

There are numerous approaches to physically-based simulation and the ways in which internal forces are computed differ considerably. However, all of them lead to a set of ordinary differential equations with respect to time, which have to be solved through numerical time integration. The equations in question usually describe the dynamic evolution of the simulated system as an initial value problem. Numerical solutions for such problems is an intensively studied field, and, for a detailed and comprehensive overview, we refer the interested reader to the standard textbooks by Hairer et al. [5]

[6] [7]. An analysis of time integration schemes in the context of pysically-based modeling in computer graphics can be found in the works by Hauth et al. [8] and Volino et al. [9].

Implicit integration methods have caught the attention of the computer graphics community after Baraff and Witkin [10] demonstrated their performance and stability for complex physically-based simulation scenarios.They used the semi-implicit Euler scheme and solved the arising linear system with a modified conjugate gradients method. This approach was adopted in numerous subsequent work and is still widespread today, although later research identified considerable numerical damping as an inherent drawback.

Among the first to implement Conjugate Gradient solvers on GPU were Bolz et al. [11] and Krüger and Westermann [12]. Their early implementations were based on fragment shaders and had to deal with the lack of scatter operations, limited floating-point precision and slow texture switching.

Keckeisen and Blochinger [13] published work focusing on parallelizing the numerical integration phase of cloth simulations using commodity PC clusters. Their stated goals were to develop an efficient parallel system for irregular cloth meshes, to achieve good scalability on relevant problem sizes, and to utilize a cost effective computing platform. Thomaszewski and Blochinger [14] continued on this direction by improving the physically-based simulation of cloth through parallelization of the collision phase as well as the numerical integration. Parallelization of the implicit numerical time integration phase was done at sparse matrix-vector multiplication level and on preconditioning, since implicit methods assume a number of sequential iterations in order to converge to a solution.In their subsequent work, Thomaszewski et al. [15] also explored parallelization on shared memory architectures. For implicit time integration they used static problem decomposition and solved the linear system arising in this context using a data-parallel preconditioned conjugate gradient algorithm.

The work of Verschoor and Jalba [16] is the most related to the research presented in this paper, in terms of the proposed solution for updating the large sparse matrices that the Conjugate Gradient algorithm uses. While their solution closely resembles ours, they use it in the context of elastically deformable models based on the Finite Element Method (FEM) and restrict themselves to experimenting on a single GPU equipped node. We also employ a *scatter* approach (i.e. all values of a local matrix are added to their corresponding values in the global matrix) instead of the *gather* strategy, due to the particularities of the particle-based model used for cloth that allow us to avoid any race conditions.

III. Particle-Based Simulation for Cloth

The parallelization techniques described in this paper apply to any specific approach for particle-based simulations, providing it uses implicit time integration. However, for our initial performance measurements we chose a simple particle-based model for cloth, the mass-spring model.

A. Particle-based Model

Mass-spring systems represent the simplest and most direct way of modeling deformable objects and from this simplicity comes their power. The mass-spring model most frequently used for simulating cloth and fabric was introduced by Xavier Provot [1] and is based only on simple, linear springs, thus avoiding complex particle interactions. Provot's model assumes that the mass of the cloth is concentrated in discrete points rather than being distributed along the surface, thus the realism of the model is conditioned by the density of particles. The model contains point masses and three different types of springs arranged in a rectangular grid, as illustrated in Figure 1:

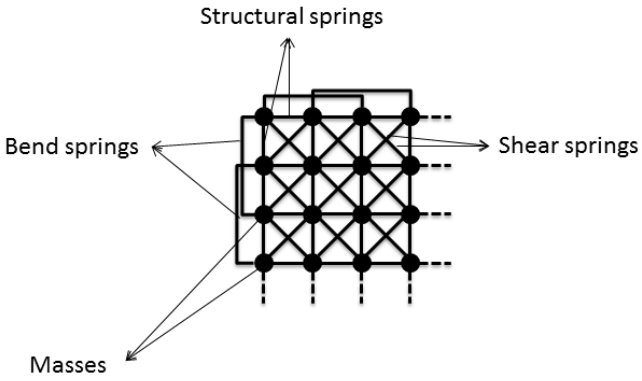

Fig. 1. Mass-Spring Mesh Model for Simulating Cloth

- Springs linking neighbor vertices horizontally and vertically are called "stretch" or "structural" springs;
- Springs linking neighbor vertices obliquely are called "shear" springs;
- Springs linking second degree neighbor vertices horizontally and vertically are called "bend" springs.

As their name indicates, each type of spring resists to stretching, shearing and bending respectively. Setting spring constants of these spring types independently enables us to mimic different types of cloth and rubbery objects.

The interaction potential between particles is given by internal and external forces acting on them. Internal forces are the elastic forces arising in springs and damping forces. To compute the elastic force between particle i and particle j we use Hooke's law of elasticity given by the formula:

$$\mathbf{F}_{i,j}^{el} = k \cdot \mathbf{x}_{i,j} \cdot (1 - \frac{l}{|\mathbf{x}_{i,j}|}) \tag{1}$$

where $\mathbf{x}_i$ and $\mathbf{x}_j$ are the positions of particle i and j respectively and $\mathbf{x}_{i,j} = \mathbf{x}_i - \mathbf{x}_j$, k is the spring's stiffness constant and l is the spring's rest length. The internal force acting on particle i due to elastic forces is computed by summing the forces between particle i and all its neighbors.

When considering the case of friction with air, complex drag effects may appear on real cloth surfaces. However, when considering the simulated case, if is often desirable to linearize the damping forces. House and Breen [17] defined the linearized version of mass-spring damping as related to the velocity of particles:

$$\mathbf{F}_{\mathbf{i,j}}^{\mathbf{damp}} = -\gamma \mathbf{v}_{i,j} \tag{2}$$

where γ is the damping factor and $\mathbf{v}_{i,j} = \mathbf{v}_i - \mathbf{v}_j$.

External forces can differ in nature, depending on the simulation. Forces most frequently included are gravity, wind and collision response.

In order to derive the behavior of such a system from its interaction potential, we must employ numeric time integration.

B. Numerical time integration

There are numerous approaches to particle-based simulation and the ways in which internal forces are computed differ considerably. However, all of them lead to a set of ordinary differential equations with respect to time, which have to be solved through numerical time integration. The equations in question usually describe the dynamic evolution of the simulated system as an initial value problem. The behavior of mass-springs systems is governed by Newton's second law of dynamics:

$$\mathbf{F} = m\ddot{\mathbf{x}} \tag{3}$$

where m is the mass and $\ddot{\mathbf{x}}$ is the second order derivative of displacement, namely the acceleration.

Implicit integration methods have caught the attention of the computer graphics community after Baraff and Witkin [10] demonstrated their performance and stability for complex physically-based simulation scenarios. They used the semi-implicit Euler scheme and solved the arising linear system with a modified conjugate gradients method. This approach was adopted in numerous subsequent work and is still widespread today, although later research identified considerable numerical damping as an inherent drawback. Unlike explicit integration, which compute the state of the next time step out of a direct extrapolation of previous steps, using derivative evaluations, implicit methods deduce the state of the next time step from an equation system expressing some "reversibility" from the extrapolated solution.

For our work we choose an implicit Euler integration approach, which uses the following discretization to compute the change in positions and velocities:

$$\begin{cases} \Delta\mathbf{x} = (\mathbf{v}_t + \Delta\mathbf{v}) \cdot \Delta t \\ \Delta\mathbf{v} = \mathbf{M}^{-1} \cdot \mathbf{F}(\mathbf{x}_t + \Delta\mathbf{x}, \mathbf{v}_t + \Delta\mathbf{v}) \cdot \Delta t \end{cases} \tag{4}$$

where $\Delta\mathbf{x}$ and $\Delta\mathbf{v}$ are the position and velocity increment respectively, $\mathbf{x}_t$ and $\mathbf{v}_t$ are the current position and velocity, $\mathbf{M}$ is a diagonal matrix of size $3n \times 3n$, with n being the number of particles in the model, containing 3×3 submatrices with each particle's mass on the main diagonal, $\mathbf{F}$ is the force acting upon a particle and Δt is the time interval over which we integrate.

In order to linearize this system of equations, $\mathbf{F}(\mathbf{x}_t + \Delta\mathbf{x}, \mathbf{v}_t + \Delta\mathbf{v})$ is approximated in the following way:

$$\mathbf{F}(\mathbf{x}_t + \Delta\mathbf{x}, \mathbf{v}_t + \Delta\mathbf{v}) = \mathbf{F}(\mathbf{x}_t, \mathbf{v}_t) + \frac{\partial \mathbf{F}}{\partial \mathbf{x}} \cdot \Delta\mathbf{x} + \frac{\partial \mathbf{F}}{\partial \mathbf{v}} \cdot \Delta\mathbf{v} \tag{5}$$

where $\frac{\partial \mathbf{F}}{\partial \mathbf{x}}$ and $\frac{\partial \mathbf{F}}{\partial \mathbf{v}}$ are Jacobians of $\mathbf{F}$. When substituting this, solving for $\Delta\mathbf{v}$, we obtain:

$$\begin{aligned} &\left(\mathbf{I} - \mathbf{M}^{-1} \cdot \frac{\partial \mathbf{F}}{\partial \mathbf{v}} \cdot \Delta t - \mathbf{M}^{-1} \cdot \frac{\partial \mathbf{F}}{\partial \mathbf{x}} \cdot \Delta t^2\right) \cdot \Delta\mathbf{v} = \\ &= \mathbf{M}^{-1} \cdot \left(\mathbf{F}(\mathbf{x}_t, \mathbf{v}_t) + \frac{\partial \mathbf{F}}{\partial \mathbf{x}} \cdot \mathbf{v}_t \cdot \Delta t\right) \cdot \Delta t \end{aligned} \tag{6}$$

with the unknown $\Delta\mathbf{v}$. The numerical solutions of large systems of linear equations of the form $\mathbf{A}\mathbf{x} = \mathbf{b}$, where $\mathbf{x}$ is an unknown vector, $\mathbf{b}$ is a known vector and $\mathbf{A}$ is a known, square ($n \times n$), symmetric (i.e. $\mathbf{A}^T = \mathbf{A}$), positive-definite (i.e. $\mathbf{x}^T\mathbf{A}\mathbf{x} > 0, \forall \mathbf{x} \in \mathbb{R}^n, \mathbf{x} \neq 0$) (or positive-indefinite) matrix, are obtained in real-time using the conjugate (CG) gradient algorithm [18].

C. Parallel Simulation of Cloth

Our parallelization approach for the particle-based model for cloth is similar to the one we employed in [2]. In order to provide context, we shall briefly describe the main techniques used in order to efficiently simulate cloth on graphics clusters.

For parallel simulation of cloth we proposed a static data decomposition technique which splits the computation into smaller equally weighted computation processes, with good data locality, between the GPU equipped nodes of a graphics cluster. This means partitioning the model of the cloth into groups of the same size and statically assign each group to a GPU which processes each particle in a different thread. The positions of neighboring particles that belong to different GPUs has to be communicated, therefore, in order to minimize the communication overhead, it is essential to split up the model in a way that ensures minimal length borders. To ensure minimal modifications to the kernels used for the single node version of the application, each node keeps an extended model, consisting of its own patch and neighboring particles that belong to other nodes, so called ghost-points, whose positions have to be synchronized at each step of the simulation.

We proposed a hybrid CPU/GPU parallel approach that allowed us to fully utilize the CPU for synchronization operations while the GPU performed the computational part, by modifying the sequence of steps in the simulation algorithm in a way as to allow these two steps to be out of phase. For centralized distributed visualization, we used a sort-last approach to parallel rendering, with optimized partial frame merging.

IV. Parallel Implicit Time Integration

In this section we will discuss in detail our approach for parallel implicit time integration on a GPU cluster, applied for simulating cloth. First we shall give details about the parallel CG algorithm and libraries used. Then, we will describe how the global left-side matrix of equation 6 (matrix A) is computed, taking into account the particularities of the particle-based model, and we will present our approach for efficiently updating it at every simulation step.

A. Parallel Conjugate Gradient

For a parallel implementation of the CG algorithm, we rely on the ViennaCL [4] library, which aims at providing standard data types for linear algebra operations on GPUs and multi-core CPUs. This open source library can be easily integrated into existing C/C++ applications and thus reduce code changes to a minimum. ViennaCL provides CUDA, OpenCL and OpenMP computing backends, enabling simple, high-level access to the vast computing resources available on parallel architectures such as GPUs. Moreover, ViennaCL operations that use the OpenCL backend can run in user-provided contexts and wrap existing memory with its own data types, making it even easier to integrate with our OpenCL-based application and allowing us to avoid unnecessary memory transfers.

The main bottleneck of the CG algorithm is represented by repetitive matrix-vector multiplications performed in order to minimize a residual and converge to a solution. The parallel CG in ViennaCL is based on a parallel version of sparse matrix-vector multiplication (SPMV). The large sparse A matrix from equation 6 is split into blocks and multiplication is carried out in parallel on all blocks using the GPU. The format used to store matrix A is Compressed Sparse Row (CSR), a storage format optimized for arithmetic operations, row slicing, and matrix-vector products. In order to accelerate convergence, we chose to use the CG algorithm with a simple Jacobi diagonal preconditioner, also supplied by the ViennaCL library. The main challenge encountered was the fact that matrix A changes at each simulation step, thus an efficient method for updating it was required in order to be able to use implicit integration for very large models.

B. Parallel Global Matrix Update

The idea behind efficiently updating the very large sparse A matrix is to employ data parallelism in order to compute and to place local entries into their corresponding location in global memory. For that, we must exploit the particular structure of the Jacobians from equations 5 and 6. They are $(3n \times 3n)$ matrices consisting of (3×3) submatrices. Elements (i, j) of the Jacobian for position and for velocity are defined as:

$$\left(\frac{\partial \mathbf{F}}{\partial \mathbf{x}}\right)_{i,j} = \frac{\partial \mathbf{F}_i}{\partial \mathbf{x}_j}, \left(\frac{\partial \mathbf{F}}{\partial \mathbf{v}}\right)_{i,j} = \frac{\partial \mathbf{F}_i}{\partial \mathbf{v}_j} \tag{7}$$

We can easily observe that these derivatives are non-zero only if the force acting on particle i depends on the position or the velocity of particle j, i.e. particle i and particle j are connected by a spring. Due to particles being connected as exemplified in figure 1, this results in a high degree of sparsity for the two matrices. Taking into account the physical formulation of forces from equations 1 and 2, we define the spring Jacobians for position and velocity as [19]:

$$\mathbf{J}\mathbf{x}_{i,j} = \left(\frac{\mathbf{x}_{i,j} \cdot \mathbf{x}_{i,j}^T}{\mathbf{x}_{i,j}^T \cdot \mathbf{x}_{i,j}} + \left(\mathbf{I} - \frac{\mathbf{x}_{i,j} \cdot \mathbf{x}_{i,j}^T}{\mathbf{x}_{i,j}^T \cdot \mathbf{x}_{i,j}} \cdot \left(1 - \frac{l}{|\mathbf{x}_{i,j}|}\right)\right)\right) \tag{8}$$

and

$$\mathbf{J}\mathbf{v}_{i,j} = \mathbf{I} \cdot \gamma \tag{9}$$

where $\mathbf{x}_{i,j}^T \cdot \mathbf{x}_{i,j}$ denotes the inner product and $\mathbf{x}_{i,j} \cdot \mathbf{x}_{i,j}^T$ denotes the (3×3) matrix which is the outer product. The spring Jacobians are added to the global Jacobians at positions (i, j) and (j, i), and subtracted at positions (i, i) and (j, j).

Using equations 8 and 9 we can now compute individual entries in the global Jacobians. Since $\mathbf{M}^{-1}$ is a diagonal matrix, multiplying the Jacobians with $\mathbf{M}^{-1}$ becomes trivial, thus the computation of each element of A becomes independent, except for elements on the main diagonal, where race conditions may occur. This encourages a scatter approach to updating the contents of matrix A, i.e. compute local elements and put them in their corresponding place in the global structure.

This leaves us with the problem of parallelizing the scatter operation. As we previously mentioned, the elements of the main diagonal must be processed sequentially in order to avoid race conditions, or to use atomic operations on the GPU which are far too slow and should be avoided.

The Compressed Sparse Row (CSR) format stores an initial matrix using three one-dimensional arrays, one containing the non-zero elements, one containing the index of the first nonzero element of each row and another containing column indexes of all non-zero elements. Considering that the structure of the model does not change during simulation, then we can observe that the second and third array of the CSR representation for matrix A do not change. This means that these structures can be precomputed in an initial step before the simulation begins, thus the only problem remaining is to parallelize the computation and insertion of values in the first array at their corresponding positions.

Figure 2 shows the structure of a Jacobian for a (4×4) grid of particles. Each non-zero element of row i (represented in color) is a (3×3) matrix that describes how particle i is affected by neighboring particles. Considering this, if we were to assign each such entry to a different GPU thread, then each thread would have to perform complex conditional logic in order to determine its position in the globally ordered list of neighbors (and thus the corresponding position to update in the CSR array), logic that GPU processors are ill suited for and that would cause a drastic decrease in performance. It is therefore preferred to assign each full row of the Jacobians

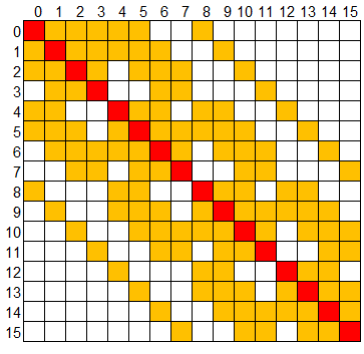

Fig. 2. Jacobian structure for a (4×4) grid of particles

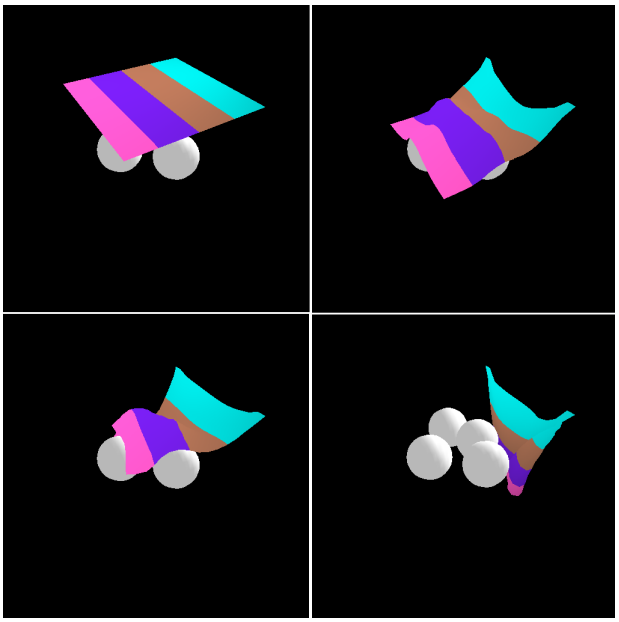

Fig. 3. Experimental scenario - Cloth colliding with spheres

to a different thread. In this way, each thread covers one particle and all its neighbors, and conditional logic is avoided by sequentially iterating through the entire globally ordered neighbor list. Elements on the main diagonal are computed and updated sequentially in a second step.

V. Experiments

The experiments were carried out on a graphics cluster consisting of four nodes with NVIDIA GeForce GTS 250 and NVIDIA GeForce 8800 GTS GPUs and Intel Core 2 Duo E8400 CPUs running on Debian 6.0.5 Squeeze, connected to a Gigabit network. The scenarios devised were aimed at evaluating the performance of the proposed solution taking into account factors such as the resolution of the model (i.e. number of particles) and the number of nodes used for the simulation. As criteria for measuring overall performance we chose the number of Frames per Second (FPS) which was considered relevant for a graphical application and a measure commonly used for evaluating parallel computation, the speedup. Each FPS sampling was performed after double the number of frames of the previously computed frame rate, with an initial threshold of 90 frames. To account for performance variations due to the load on the cluster, the final computed frame rate was the average of 10 successive samples over five consecutive runs. For evaluating the parallel global matrix update approach, we obtained the average computing time for both the sequential approach and the parallel one over a total of 500 frames.

The test scenario considered for all experiments was the simulation of a piece of cloth colliding with other objects in the scene, in our case four spheres as shown in figure 3. Each colored patch was handled by a different cluster node.

A. Parallel Global Matrix Update

The aim of this experiment was to evaluate the increase in performance obtained by using the parallel global matrix update approach when compared to a sequential one. Table I shows the average measured processing time for a complete matrix update using both methods, for model sizes starting at 256 (16×16) up to 65536 (256×256) particles. Due to the fact that the comparative measurements were taken on a single GPU equipped node, model resolutions of 262144 (512×512) or higher could not be simulated due to GPU memory limitations.

Nb. of particles	Sequential time (s)	Parallel time (s)
256	0.193	0.000038
1024	0.914	0.000038
4096	4.57	0.000038
16384	26	0.000038
65536	164	0.000038

TABLE I. Global matrix average update time

As can be observed, the sequential processing time and the parallel processing time are of different orders of magnitude mostly due to the high degree of parallelism of our model. Moreover, for model resolutions that can be simulated on a single GPU, the time for parallel updating the global matrix does not depend on the number of particles. This is due to the fact that all GPUs used in our experiments have the capability to launch jobs of work sizes that are greater than the size of our particle grid. This means that the number of parallel threads that the GPU launches is always equal to the number of particles, thus all particles are processed in parallel. One important drawback when using a sequential approach is the fact that computation for updating the matrix is carried in the CPU and the CG algorithm runs in GPU, thus there is a continuous transfer of data between host and device, which greatly lowers performance. The GPU parallel approach allows us to share the device memory between the updating procedure and the CG algorithm.

B. Parallel Implicit Integration

The aim of this experiment was to evaluate the overall performance improvement of the proposed parallel global matrix update technique coupled with the parallel conjugate gradient algorithm provided by the ViennaCL library when running the simulation on a graphics cluster with up to five

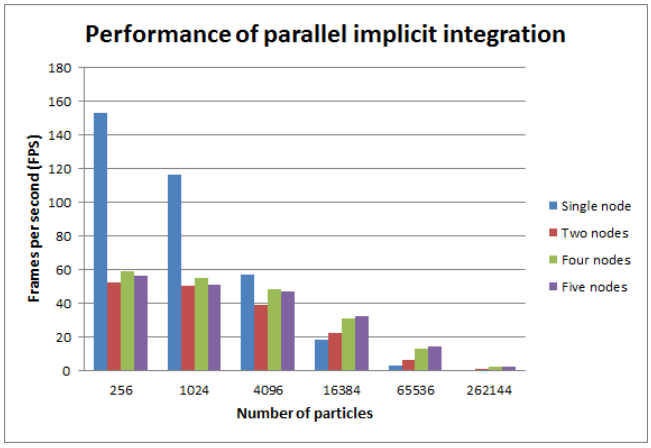

Fig. 4. Performance of parallel implicit integration

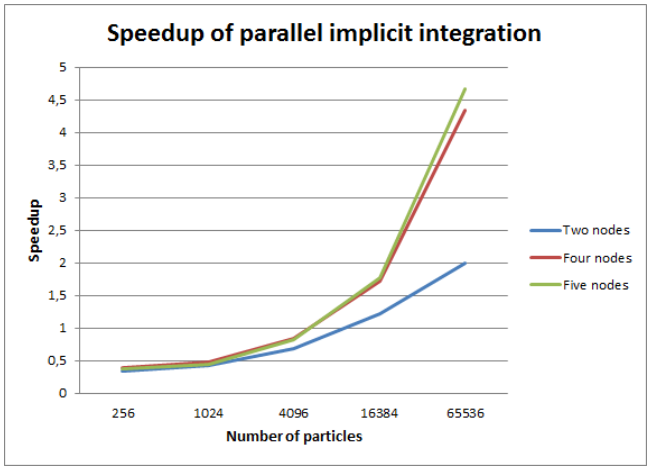

Fig. 5. Speedup

GPU equipped nodes. Figure 4 shows the frame rates obtained using two, four and five nodes, compared to the performance obtained on a single node.

As can be observed, the single node simulation achieves better performance for small model sizes (256 - 4096 particles) due to the fact that synchronizing ghost points and transmitting data for centralized visualization (when using more nodes) takes considerably more time than the numerical integration and the collision detection phases. However, as the resolution for the cloth model increases past 16384 particles, the computation becomes overwhelming for a single node, thus the advantage of model distribution becomes obvious. Model sizes were pushed up to 262144 particles, where all interactivity is lost (i.e. frame rates drop below 10 FPS) and the simulation on a single node can no longer be executed due to memory limitations.

As shown in figure 5, the solution offers good scalability in terms of speedup obtained when running the simulation of five cluster nodes. As more nodes are used, maximum speedup is obtained for a larger number of particles, and a method for determining the optimal number of nodes for a certain model size may also be derived from empirical data, providing that there are a sufficient number of nodes available in the graphics cluster used for testing.

VI. Conclusion

In this paper we presented a graphics cluster-based approach to implicit time integration for particle-based simulations. We focused on an efficient update technique of the large sparse matrix in Compressed Sparse Row (CSR) format that the Conjugate Gradient (CG) algorithm uses, taking into account the particularities of the particle-based model used for simulating cloth. We validated and evaluated the parallel efficiency of our approach through experiments on a GPU cluster with five processing nodes coupling our integration approach with parallelization techniques developed in previous work.

Because scalability is encouraging, we will further explore particle-based modeling on graphics clusters using more processing nodes and employing more complex collision detection techniques.

Abstract – Frequency table computation is a key step in decision tree learning algorithms. In this paper we present a novel implementation targeted for dataflow architecture implemented on field programmable gate array (FPGA). Consistent with dataflow model of computation, the kernel views input dataset as synchronous streams of attributes and class values. The kernel was benchmarked using key functions from C4.5 program for decision tree learning. For large datasets with many attributes – over 100,000 items, and over 60 attributes – the realized kernel, clocked at 333 MHz, outperforms the software implementation running on CPU clocked at 3.2 GHz.

Keywords – frequency table, dataflow, field programmable gate arrays, decision tree learning

I. INTRODUCTION

Histogram computation is one of the fundamental procedures used in many data mining algorithms. Its two-dimensional extension – frequency table computation – is a key part of the attribute selection step in decision tree learning algorithms [1]. Decision tree learning algorithms, as well as all other tools used in data mining, are faced with ever-growing size of analyzed datasets. This drives efforts to parallelize existing algorithms, develop new algorithms targeted for parallel and distributed computer systems, and develop new hardware platforms that provide high computational power [2].

One platform that is now gaining more ground in computing applications is field programmable gate array (FPGA). FPGAs are digital integrated circuits designed to be user-configured after manufacturing [3], [4]. An FPGA comprises an array of configurable logic blocks, memory blocks, configurable interconnect, input/output (I/O) blocks, and various specialized arithmetic and communication blocks. These elements together allow implementation of custom computational architectures that can be reconfigured on demand. The computational model that FPGA is most suitable for is the dataflow model.

Majority of computer systems implement a control-flow model of computation. In control-flow, the computation is defined by a sequence of operations that are executed in specified order. In dataflow model, computation is defined by a chain of transformations applied to a stream of data [5]. The dataflow is described spatially in form of dataflow graph. Each operation is represented by a node, and data flow between nodes is represented by edges. Dataflow graph naturally maps to hardware implementation. Operations are translated into hardware blocks that work concurrently, and edges are translated into data links. By dividing the graph into stages separated by registers, it is transformed into a pipelined structure suitable for implementing on FPGAs.

In this paper we present a novel implementation of frequency table computation targeted for dataflow architecture realized on FPGA. The kernel is developed for integration in C4.5 decision tree learning program [6], [7]. Frequency table computation is a key step in decision tree learning algorithms. Its result is used to calculate dataset split quality, usually Gini impurity or an entropy based measure such as information gain, which is then used for attribute test selection [1].

II. RELATED WORK

Frequency table computation on FPGA has been previously published as a part of efforts in implementing decision tree learning algorithms. FPGAs have been proven to be suitable of implementing data mining algorithms, though so far little attention has been directed to decision tree learning algorithms. Only a few attempts of using FPGAs to accelerate execution of decision tree learning have been reported [8], [9].

Chrysos et al. [9] implement frequency table computation on FPGA as part of HC-CART system for learning decision trees. Frequency table computation is implemented in Frequency Counting module. The module receives attribute-class label pairs. The pairs are used to generate addresses for frequency table locations which contents are then incremented by one. The contents of the frequency table are then copied over to other two auxiliary memories, and used to generate item frequencies for computing Gini impurity. In their implementation, all attribute-class labels received by the kernel have to be prepared by program running on CPU, and then preloaded to memory attached to FPGA. Input data is transferred from CPU to FPGA memory many times in the course of program execution. In our work, the data is transferred to FPGA memory (LMem) only once, at the beginning of the program. The kernel reads the data only from FPGA memory, and the only data transfer between kernel and CPU is sending the computed frequency tables to the CPU.

III. DATAFLOW ENGINE ARCHITECTURE

The Data Flow Engine (DFE) is programmed with one or more kernels and a manager. Kernel implements computation. It defines the computational architecture with scalar and stream inputs and outputs. Manager organizes data movement within the DFE. In managers, the kernels are instantiated and links to off-chip RAM (LMem), CPU or other DFEs are defined.

A. *Maxeler Vectis-Lite FPGA platform*

Maxeler platform is designed for implementing compute engines using the dataflow model of computation. The platform comprises an FPGA board, drivers, development tools, and API. Dataflow engine is described in Java, using API which provides objects and methods that can be compiled into hardware structures. The compilers translate the input Java code into VHDL code and create functions that implement interface for CPU code [10].

Maxeler Vectis-Lite board was used for realization of the DFE on FPGA. The board is a PCIe expansion board which houses an FPGA, and SDRAM. Basic information on the board is shown in Table I.

B. *Kernel architecture*

Architecture of the ComputeFreq kernel is shown in

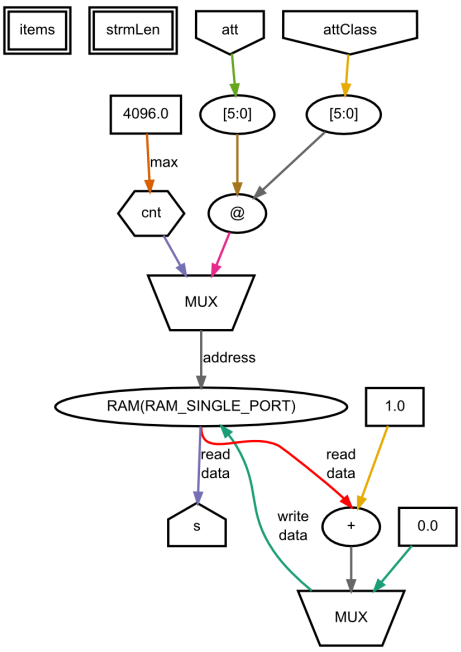

Figure 1. ComputeFreq kernel architecture for up to 64 unique attribute and class values ($N_A = 6$, $N_C = 6$).

TABLE II. FPGA RESOURCE USAGE BY THE DFE

Resource	Used	Total available	Utilization
LUTs	30053	297600	10.10 %
Flip-flops	43416	297600	14.59 %
DSP blocks	0	2016	0.00 %
Block RAM	105	2128	4.93 %

Fig. 1. The kernel has two scalar inputs for parameters: stream length (*strmLen*), and number of items (*items*). Stream length is the number of elements read from LMem, which requires all memory accesses to be made in 96 byte blocks. Number of items is the actual number of items of interest in the stream.

The kernel receives two 32 bit unsigned integer streams as input – one for attribute values (*att*) and the other for class values (*attClass*) of the items. The inputs are sliced so that the low N_A bits are taken from attribute and N_C bits from class value. The sliced inputs are concatenated to form the frequency table index, with.

Frequency table is stored in block RAM (BRAM). The BRAM is addressed by the frequency table index formed from attribute and class values. The value output from the BRAM is incremented by one and written back to the same location. The BRAM is configured as a single port RAM with read-first synchronization. The compiler tool automatically inserts registers in appropriate locations, which leads to latency inside the loop. To accommodate this latency, kernel's input streams are throttled to allow input of one element every m clocks, where m is the length of loop latency.

After all elements of interest are streamed in, contents of the BRAM are streamed out to the CPU through stream output *s* and at the same time reset to zero. This is achieved by using multiplexers to switch BRAM address port from table index to values generated by a counter. In the same manner the BRAM write data port is switched from incremented-by-one value to constant zero. Since there are no loop dependencies in this instance, the output stream is not throttled. One element is output every single clock. At the same time, any remaining elements in the input streams are read un-throttled (one per clock) and ignored. They are all read to ensure proper functioning of the DFE.

C. *Manager*

A single ComputeFreq kernel is instantiated in manager. Stream inputs *att* and *attClass* are linked to LMem, and use linear memory access pattern. Stream output *s* is linked to CPU. Scalar inputs *items* and *srtmLen* are also linked to CPU. The kernel parameters were set for up to 64 unique attribute and class values ($N_A = 6$, $N_C = 6$). The manager clock frequency was set at 100 MHz, while kernel clock frequency was set at 333 MHz.

DFE interface defines inputs for source addresses of data for input streams *att* and *attClass*, values for scalar inputs *items* and *srtmLen*, and destination address for output stream *s*.

With given parameters, frequency table stores 4096 32-bit words. Loop latency of the synthesized design is 5

clocks, which means that the DFE can process up to 66.6×10^6 items per second. FPGA resource usage by the DFE is given in Table II.

IV. Experimental Results

A. Benchmarks and test environment

Kernel was benchmarked by using code from C4.5 Release 8 decision tree learning program [11]. The normal tree building features from the original program were disabled. Only parts required for loading datasets and computing the frequency table were left operational. A function was added for transforming dataset into format appropriate for DFE and writing it to LMem. Time measurement was added to *ComputeFrequencies* function. For execution on DFE, the *ComputeFrequencies* function was modified to use function calls to the DFE, and copy the received result into the original frequency table data structure. From measured execution time, the function's throughput was computed by:

$$T_{a,i} = \frac{a\,i}{t_{a,i}} \tag{1}$$

where a is number of attributes, i is number of items, $t_{a,i}$ is measured execution time, and $T_{a,i}$ is throughput for dataset with a attributes and i items.

A set of 84 datasets was generated for the benchmark. All datasets have only nominal attributes with 63 unique attribute values (values from 1 to 63), and 64 unique class values (from 0 to 63). Number of items vary exponentially from 2×2^{10} to 4×2^{20} (2^{11} – 2^{22}) items, while number of attributes varies exponentially from 1 to 64 (2^0 – 2^6). Attribute and class values are generated randomly using uniform distribution.

Benchmark program was compiled using gcc compiler version 4.4.7. Benchmarks were run on workstation with Intel Xeon E5-1650 CPU running at 3.2 GHz, 16 GiB DDR3-1600 RAM, under Centos 6.5 Linux OS. The workstation is equipped with Maxeler Vectis-Lite FPGA acceleration board.

TABLE III. Measured execution times on CPU

Number of items	Number of attributes / Execution time						
	1	2	4	8	16	32	64

B. ComputeFrequencies CPU benchmark results

Execution times on CPU are given in Table III, and are shown in Fig. 2. For input datasets larger than 64×2^{10} items, execution time scales approximately linearly with number of items. There is a sharper increase in execution time visible for datasets with 8 or more attributes, in ranges for 128×2^{10} – 256×2^{10} items for 8 attributes, to 32×2^{10} – 64×2^{10} items for 64 attributes. Function throughput, shown in Fig. 3, more visibly illustrates this decline in performance. Throughput rises with number of items until a peak is reached at 16×2^{10} to 128×2^{10} items, depending on number of attributes. After this point it declines and quickly stabilizes to a constant value. Constant throughput corresponds to linear scaling of execution time with number of items. The largest constant throughput is 173×10^6 items per second for dataset with 1 attribute, and the lowest is 35.4×10^6 items per second for dataset with 64 attributes.

This decline in performance is most likely an effect of

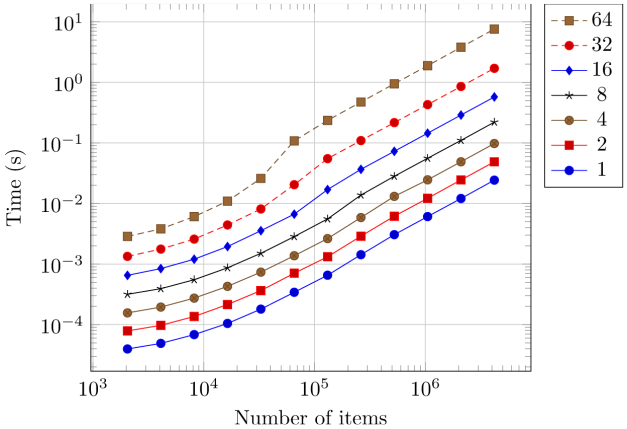

Figure 2. Execution time on CPU as function of number of items, measured for datasets with 1 to 64 attributes

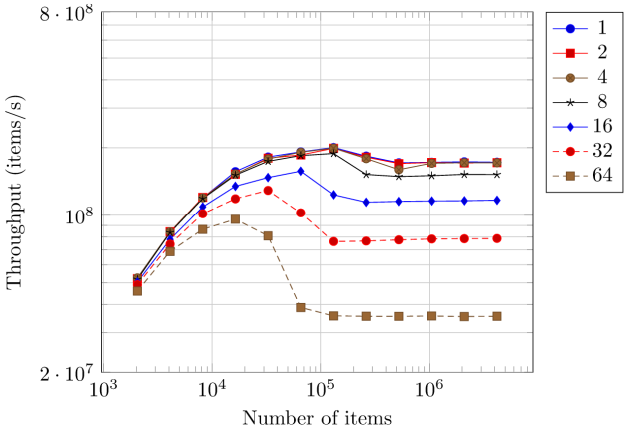

Figure 3. Throughput on CPU as function of number of items, measured for datasets with 1 to 64 attributes

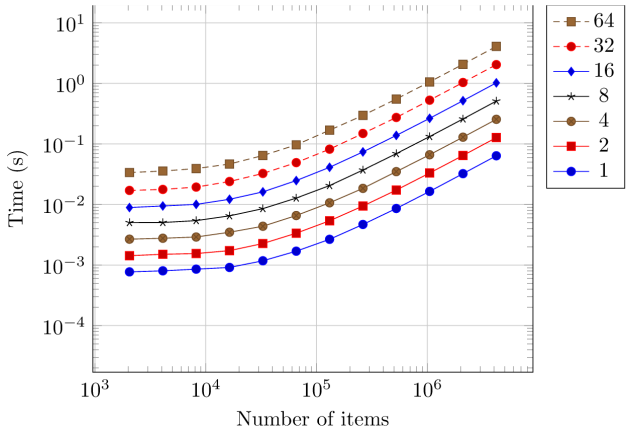

Figure 4. Execution time on DFE as function of number of items, measured for datasets with 1 to 64 attributes

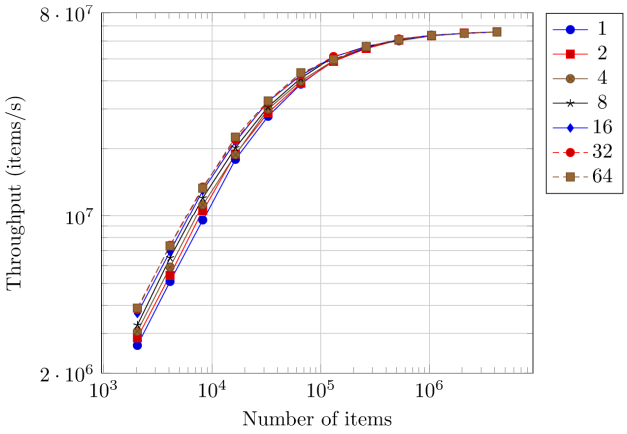

Figure 5. Throughput on DFE as function of number of items, measured for datasets with 1 to 64 attributes

CPU's cache system. Smaller sets are less affected by cache misses than larger sets. In addition, the dataset is stored in attribute major order. Since *ComputeFrequencies* function works by accessing the same attribute over different items, this leads to consecutive accesses to non-consecutive memory locations, which are more likely to result in cache misses.

C. *ComputeFrequencies DFE benchmark results*

Measured execution times on DFE are given in Table IV, and shown in Fig 4. Execution time scales linearly for datasets with more than 128×2^{10} items. While scaling is not linear for datasets with fewer items, there is no performance drop like the one present when executing on CPU. From throughput results, shown in Fig 5, it is visible that there is little difference in throughput between datasets with different number of attributes, and that the main factor is number of items. With 256×2^{10} and more items, throughput is fairly constant at 62.4×10^6 items per second, which is close to the theoretical maximum of 66.6×10^6 items per second. Lower performance with smaller datasets is a consequence of overheads of control and communication with the DFE. This overhead is independent from number of items in the dataset, but scales linearly with number of attributes, since the same set of function calls has to be made to process each attribute.

TABLE IV. MEASURED EXECUTION TIMES ON DFE

Number of items	Number of attributes / Execution time						
	1	2	4	8	16	32	64
2048	771,8 µs	1,428 ms	2,675 ms	5,017 ms	8,904 ms	17,06 ms	33,70 ms
4096	802,7 µs	1,507 ms	2,771 ms	5,041 ms	9,456 ms	17,74 ms	35,69 ms

D. *Comparison of the results*

To compare the results, ratio of execution time on CPU and time on DFE was calculated. The ratio is shown in Fig 6. Execution on DFE is in most cases significantly slower than on CPU. This is expected since the DFE runs on 333 MHz and works with DDR2 SDRAM clocked at 333 MHz, while CPU runs on 3.2 GHz and works with DDR3 SDRAM clocked at 800 MHz.

For small datasets DFE is at worst 20× slower than CPU. However, DFE's performance comes closer to the CPU's as number of attributes and items increases. For largest datasets (over 1×2^{20} items), DFE is at worst 2.6× slower than CPU. For datasets with 64 attributes, DFE outperforms CPU when number of items is larger than 64×2^{10}. Best performance – 1.80× faster than CPU – is reached when number of items is larger than 256×2^{10}.

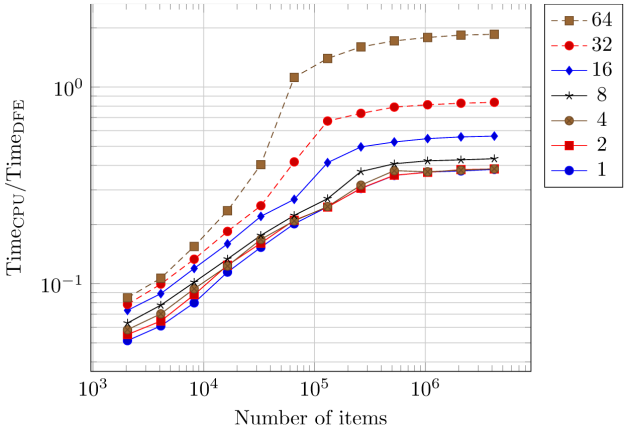

Figure 6. Ratio of execution times on CPU and DFE as function of number of items, measured for datasets with 1 to 64 attributes

V. CONLUSION

In this paper we have presented a novel implementation of frequency table computation on dataflow architecture. The architecture was realized on FPGA platform. From benchmark results it is clear that a single kernel DFE is outperformed by the CPU in most circumstances, but it does provide better efficiency when their clock rates are accounted for. The CPU runs at 3.2 GHz. Its best performance is 173×10^6 items per second which gives 18.5 clocks per item. The DFE runs at 333 MHz and its best performance is at 62.4×10^6 items per second which gives 5.34 clocks per item. Of the 5.34 clocks per item, 4 are consequence of the BRAM-adder-multiplexer-BRAM loop latency.

There are ways to design around the in-loop latency. One approach is by replicating the BRAM-adder-multiplexer structure as many time as needed (in this case it's 5 times), and "demultiplex" the input stream to each structure. Once the input streaming is complete, the final result is computed by summing the partial results from each BRAM. Such design could run with 1.34 clocks per items which would give 249×10^6 items per second. This exceeds maximum performance achieved on CPU.

In future work, a multi-kernel version of DFE will be developed which will allow simultaneous processing of several attributes. The kernel will be modified to lower the in-loop latency. This DFE is planned to be integrated with the C4.5 program as accelerator unit for processing nominal attributes. Given presented results, it is expected that the FPGA design that exploits parallelism will outperform conventional CPU.

ACKNOWLEDGMENT

The research leading to these results has received funding from the European Union's Seventh Framework Programme (FP7), under grant agreement no. 317882 – E2LP Embedded Computer Engineering Learning Platform.

Virtue - a Different Approach To Human/Computer Interaction

Zorislav Šojat, Tomislav Ćosić, Karolj Skala*
* RBI/CIC, Zagreb, Croatia
sojat@irb.hr, tcosic@irb.hr, skala@irb.hr

Throughout the development of computing tools usage and computer science, from the calculating machines up and into the present day computers, the major technical problem to be solved was the reduction of the amount of components and their bulk. This led inevitably to the use of serial processing. Only quite recently we started mass producing and using multi-processing. Though the nature itself is infinitely parallelised, the technical problems of computer development led also to the development of such software tools and programming languages which mirrored the serial nature of computers, so that the serialisation of parallel natural processes is performed by humans, the programmers. However, modern day developments of scientific and every-day needs for computing power have led to the introduction of multiprocessors, GPUs, clusters, grids and clouds of computers, as to ascertain enough processing speed, power and memory for very complex algorithms. However, the human/computer interaction that supports these developments is still heavily based on "classical" computer programming languages, serial programming, and the multi-computer environment is accessed only through programmed interfaces, where all the burden of parallelising the, now well known, serial algorithms is again the job of (human) programmers.

Virtue is a development primarily based on the idea - as there already is so much we know of mathematical, logical and other important basic algorithms used in many fields, and their computer implementation(s) - that we would be able to "raise" the level of computer "understanding" more towards the level of our own, human language communication. This means that, for example, mathematical operations in Virtue are performed not only on integers and reals (floats), but also on complex numbers, quaternions and octonions, and that they are freely intermixed. Or that all logical operations work also on multi-levelled and multi-dimensional logical values (and not just Boolean). These are mathematically well defined operations used very often in visualisations, as well as scientific modelling. Furthermore, another basic underlying idea of the development of Virtue is that the language developed may not destroy a possibly parallel structure of data, which then allows direct and user (human) independent automatic parallel execution. Within such an approach interactive sentences can be "decoded" (executed, performed, saved, used...) on a single processor, a multi-core, multiprocessor, GPU, cluster, grid or cloud system, or any combination of them.

Designed on these basic principles, Virtue is a language which proposes a different approach, by keeping the inherent parallel structure of natural algorithms, and doing the parallel processing by itself, if it is algorithmically possible. Virtue is a syntactically very simple, yet semantically extremely complex language, offering no "reserved words", synonyms, automation of memoisation, multiple word contexts, combined data types of anything Virtue supports (e.g. functions, symbol names, scalars, multidimensional sub-structured arrays etc.), stochastic processing, multivalued and multidimensional logic operations, multidimensional sub-structured file access structures, continuations etc.

Therefore, due to this semantic richness and grammatical simpleness, in Virtue, for example, the text of the algorithm for Conway's "Game of Life" necessitates only 12 language tokens (7 words, 14 numbers in 3 vectors and 2 delimiters) in one sentence.[1]

Further development of the idea allows for development of a more syntactically rich very high level human oriented machine interaction language, which, combined with additional artificial intelligence components, appropriate ergonomic human presentation/sensory interfaces and with the integration of user style association memory, we sincerely hope can help the future development of Computer Science and Usage Practice.

I. INTRODUCTION

The challenges of the modern day world, the development of sciences and the development of social networking change quite radically the way computers are used as compared to the time when most of the basic computer construction principles were innovated. By basic computer construction principles we primarily mean the basic computer architecture based on monolithic processors executing serially specific instructions on individual values. Though many of the challenges of multiprocessing, execution parallelism, big data, cluster, grid and cloud computing are more or less, on the architectural level, solved, and throughout the development of computing a lot of physical and technical problems of multi-processing cooperation were solved and are being solved, there is still a huge lack in the development of appropriate human oriented interfaces with these (primarily hardware/firmware/systemware) complex integrated and/or dispersed computing systems.

Modern age computing needs to solve several important problems. We have to deal with enormous amounts of data which shall be mined, we necessitate High Performance Computing focusing on tightly coupled

[1] `MONADIC (1 1 1 1 0.5 1 1 1 1) [3 3] MONADIC RAVEL SUM (2.5 3 3.5) IDENTICAL ANY; MASK;.` This programme will work for any size of the "Game of Life" board.

parallel jobs for complex scientific and modelling applications, High Throughput Computing focusing on the efficient execution of a large number of loosely-coupled tasks, we need the Internet of Things, where individual appliances interrelate, and we need Personal Assistants...

And finally we have also a stringent need for High Productivity Computing, which stresses the importance of global Human-computer interaction results, i.e. the productivity, and not just the pure performance of the (already programmed) computer. High Performance Computing means speeding up the process of defining a problem to be solved and obtaining the results from the computer, that is shortening the overall problem solving time. That means that High Productivity Computing is primarily oriented towards shortening the time necessary to solve a new problem, that is, the time which is necessary for a Human to coordinate efforts with the Computer in getting an answer to a freshly thought out idea (i.e. problem to be solved).

The Virtue project is actually a product of a wish to integrate the present day computer science knowledge, as much as possible and feasible, into a consistent linguistic framework, with features which enable it to be "levelled up" towards the Human language communication possibilities, as to provide a personalised communication experience.

II. Present State of the Art

Throughout centuries of the development of computing equipment serial processing was more or less the only option, therefore, after the event of modern day computing, from the first half of the 20th century, and the development of programming languages, most of the computer-linguistic effort was put into the development of conventional serial programming languages. And, to cite John Backus from his ACM paper of 1978(!): "Conventional programming languages are growing ever more enormous, but not stronger. Inherent defects at the most basic level cause them to be both fat and weak: their primitive word-at-a-time style of programming inherited from their common ancestor—the von Neumann computer, their close coupling of semantics to state transitions, their division of programming into a world of expressions and a world of statements, their inability to effectively use powerful combining forms for building new programs from existing ones, and their lack of useful mathematical properties for reasoning about programs." "Programming languages appear to be in trouble. Each successive language incorporates, with a little cleaning up, all the features of its predecessors plus a few more." "Each new language claims new and fashionable features, such as strong typing or structured control statements, but the plain fact is that few languages make programming sufficiently cheaper or more reliable to justify the cost of producing and learning to use them." "For twenty years programming languages have been steadily progressing toward their present condition of obesity; as a result, the study and invention of programming languages has lost much of its excitement."

Now it is already 36 years after John Backus made this statement, so his statement would today cite "For almost 60 years...". Because, unfortunately, modern day developments continued down these lines with those very few extremely popular and very programmer unfriendly languages like C, C++, Java, and a whole bunch of their syntactic followers, then the popular "scripting" languages, and the vast overpopulation of all kinds of so called "Application Programming Interfaces" superimposed over the already overcrowded linguistic situation of those languages, including the fact that some of such "language extension" interfaces even claim to be "languages" (e.g. OpenGL claims to be a Graphical Language, but is actually a very complicated, even complex, API). We can actually see that what Backus said so many years ago is getting towards human limits of comprehension possibilities. And this basic problem is actually the main bottleneck of our present day human-computer productivity.

Imagine a mathematically simple and effective visualisation – a four-dimensional hypersphere to be rendered as simple asterisks showing all the dots inside the sphere's radius, and spaces outside, the third and fourth dimension to be shown as two-dimensional slices. By just looking at such a very elementary visualisation the basic structure of the hypersphere can be easily deduced. Now find a C, C++ or Java programmer and ask him to make a short program to show such a sphere to you... And now, after they have shown you this four-dimensional sphere, ask them to show to you how it would look like in 5 or 6 dimensions... Or, better, do not ask them to do any of that for you in such a language, as it would take quite a lengthy time even for the best. (A non-optimised solution which we prototyped in C for 4 dimensions has more then 130 lines of source code![2] An optimized version would take much longer to develop.) And it is a kind of "one-execution is enough" request and programme.

But with the all-penetrating spread of computer equipment, networking, and data collecting and serving there are vast and rapidly growing needs for new computer applications on all levels of the human civilisation.

We started tackling these problems systematically several years ago, and an investigation into basic principles of computer programming, as well as the principles by which we serialize the inherently extremely massively parallel universe around us into serial algorithms was performed - and a new approach taken.

One of the major points which started being obvious during the investigation of the programming principles is that most (or almost all commonly used) computer languages, being primarily serially oriented both in their

[2] The definition of a new Virtue verb "sphere" which solves the above problem for any number of dimensions up to 8 -- taking three scalar numerical objects, expressed as two two-dimensional numbers (complex - 2d, quaternion -3d or 4d, or octonion -5d, -6d, -7d or -8d) for the centre and the space-size, and a real number – the radius -- is this sentence: `TRIADIC SPACE CENTRE MAGNITUDE GREATER '*' MULTIPLY; OPERATOR @sphere SET.`

What it says is that you want to have asterisks wherever the radius is greater than the magnitude of the centered space elements. The verb SPACE (synonymous to INTERVAL) with a scalar numerical object makes a space of indices from 1 (or 1i1, 1i1j1, 1i1j1k1...). The word CENTRE is a simple synonym for the verb SUBTRACT.

semantics and in their syntax – i.e. in their whole grammar, enforce the de-contextualisation of their data structures mostly in their imperative parts. In other words this means that though a complex data structure may be declared in the language, the operations on that data structure are linguistically restricted on individual data elements from that data structure. As a consequence of this approach the context of the individual data elements in a data structure has been erased from the programme, leading to important information loss, and the language executor (compiler, interpreter, assembler…) has theoretically[3] no possibility to 'know' that the user is actually doing parallel processing in a serial way.

Interestingly enough, although obviously a consequence of the above-mentioned centuries of serial computing[4], there are not many computer languages at all which do not do this 'de-contextualisation' of their data structure operations – notably between these are APL and APL-children (APL2, J, K, A+…), and the 'array processing' linguistic branch. Unfortunately, of those few languages which keep the operations context available for the executing processor and therefore allow the processor (usually an interpreter, not the low level processing units) to make intelligent decisions on the automatic parallelisation of each particular operation on (possibly) different data structures[5] there is presently (2014) no publicly (particularly open-source) available parallel implementations we are aware of. Many so-called parallel programming languages actually necessitate explicit programmer description of the parallelistic execution, as well as (for example in Occam) explicit inter-serial-part-of-the-parallel-algorithm communication.

III. Approach

Based on the above, the approach was taken to define a new data processing language, or better to say a new data processing language family, which would allow reasonably simple algorithm description for complex data structures, and which would allow the lowest level "processor" to automatically distribute (parallelise) the operations execution on a set of processing units. Generally the idea is to have a hierarchy of languages, whereas the lowest level one, described on these pages, has to be as close to the computer hardware level as possible, given the imposed complexity, and should actually behave as a **Virtual Executor**. The job of the Virtual Executor is to do all the necessary execution and parallelisation during execution based on the data, i.e. data types and data structures. Therefore it could be said that the resulting Virtual Executor is parallely programme and data structure driven.

The idea of such a language system was born when clusters of computers and grids started being developed on top of single-processor, multiprocessor, multithreading and multicore computers, as well as supercomputers of different architectures.

The major question with these collections of systems is: How do we programme them in a uniform, efficient and reasonably simple way? How do we integrate computers of different speeds, processors, memory sizes, computation widths[6] and byte sexes?

Is it possible to develop a Language system which could cope with the necessities of High Productivity Computing, High Performance Computing, High Throughput Computing, Big Data, Visualisations, Internet of Things... and be seamlessly applicable to an indefinite number of processing stations?

"What might a language look like in which parallelism is the default? How about data-parallel languages, in which you operate, at least conceptually, on all the elements of an array at the same time? These go back to APL in the 1960s, and there was a revival of interest in the 1980s when data-parallel computer architectures were in vogue. But they were not entirely satisfactory. I'm talking about a more general sort of language in which there are control structures, but designed for parallelism, rather than the sequential mindset of conventional structured programming. What if do loops and for loops were normally parallel, and you had to use a special declaration or keyword to indicate sequential execution? That might change your mindset a little bit." (Guy Steele, Dr Dobbs Journal 24 Nov 2005).[7]

With these questions in mind the development of the Virtue system started several years ago.

IV. Virtue

The result of this approach is the first version of **Virtue** – a grammatically extremely simple, yet

[3] Practically it is possible to automatically regain a certain knowledge on the data element context in specific cases, as e.g. when a loop transiting an array has a fixed number of iterations – based on pre-execution knowledge (by the programmer) of e.g. how many elements are in the processed data structure. There are certain "parallelising" compilers on the market for several much used languages, but they can do the "parallelisation" of the algorithm described in a serial language only for very special cases. Theoretically, the lost context information is not regainable.

[4] It is probably important to mention that between humans, e.g. in mathematics, the algorithms (as for example mathematical formulas) are described in a contextfull way, however, due to our own restrictions, we always calculate the results stepwise, usually completing as much as possible work on one element of an array before proceeding to the next, which is usually by applying the given formula completely on individual data points. This inherently human approach may have also lead to the adoption of strictly serial programming languages in the past.

Parallel programming mindframe, on the other hand, starts with the same contextfull algorithm (e.g. formula), but, as opposed to the serial mindframe, executes not the whole formula on the first data structure element, and then again on the next, but executes the first operation from the formula on each data element of the structure (e.g. array) in parallel, before proceeding to the next operation from the formula.

[5] This is, naturally, dependent on a particular language implementation, although it is 'automatic' due to the fact that the actual execution parallelisation has to be developed by the language implementor, and the "programmer" does not have to think at all about how much and which of her (or his) algorithm is executed in parallel, and on how many computing resources.

[6] I.e. 32 or 64 bit, as well as other bit sizes – 8 and 16 for microcontrollers, possibly 128 or other number of bits for special computing equipment, half, normal and double, as well as extended floating point formats etc.

[7] In Virtue there are logical rules which define which combinations of objects can be processed in parallel and which must be processed in serial. These rules are internal and are actually inherently semantic regarding the verbs applied to the objects, i.e. data.

semantically extremely rich Language, which is internally and externally "resizeable". What we mean by "resizeable" is that the amount of words which are understood (i.e. executed) by Virtue can be effortlessly expanded (externally, by defining new words), and that the internal knowledge of computing can be both expanded and shrunken. So for example an embedded version of Virtue would have a reduced amount of words as well as data types, and a Visualisation version would have to know specific words, whereas a Modelling version could have special words for often used algorithms. Furthermore, the "resizeability" of Virtue is automated by it's possibility to encompass a wider range of computers, depending on the scale of the problem to be solved.[8]

Actually *Virtue* is defined to be a *Virtual Executor*, a kind of system-ware/between-ware, a *Language* system taking the role of an *Inter-actor* between a *Computer System* and a *Human*.

Let's look at the particulars of what we want to say with this definition of Virtue's aims:

A. Computer System

A computer system in the above definition is actually any possible hardware or software device which understands the grammar of Virtue. These then could be just simple appliances, or the Computer System could be a grid of supercomputers or whatever else, like server farms, clusters etc.

As said, any computer system can be part of the Virtue linguistic space, as long as it understands the common standardised Virtue Data structure. For new knowledge, i.e. when a computer system with less features (e.g. a Virtual Executor which can process only integer numbers) has to solve problems it can not solve based on these, it will automatically invoke (if possible) another network based Virtual Executor which knows how to process this data and/or words. New words, if they can be processed in a Virtual Executor, would be just transferred as explanations, but data which can not be locally processed will always stay on the computer that was asked to process this part of the overall data structure. From the perspective of the Human user, the data would appear as if it would be locally processed and saved.

And finally, the most important feature of a Computer shall certainly be to know at the lowest, hardware or firmware level of execution, that which in Computer Science, Mathematics, Logic... we already have developed as long proven methods and algorithms, and which are regularly used.

B. Virtual Executor

The Virtual Executor is actually the basic (or very expanded) Virtue linguistic system on a Computer system. It is the Virtual Executor who enables Computer systems to understands the Virtue language – so it is the Virtual Executor who is the collocutor in the Human-Computer interaction.

An important feature of a Virtual Executor is that all instructions and definitions ever written in the Virtue language will suddenly start being 10% faster, without any additional effort (except the installation of a better version of Virtue) if the Virtual Executor is sped up by 10%. Contrary to this, no C written executable programme in the world will suddenly start being faster if a new compiler version is available, which produces a 10% faster code, without the specific effort of recompiling all the executables.

C. Human

The Human is the driving force of Human development. To be able to express all of his Human innovation capacity, and to intelligently behave in the present day information-oriented world, it is necessary for her to be able to constantly process all kinds of data and thoughts.

In this sense a Human presently more and more needs an assistant, which will perform operations like computations, data searching and problem solving, he needs in the intellectual, informational field - something we for a long time use in the physical environment – amplifiers. To move a huge rock, we use an amplifier of our own feeble movements. To solve a huge problem, we need to use an amplifier of our huge problem solving abilities. We actually need this which William Ross Ashby decades ago said, we need a "computer as an intelligence amplifier". And exactly this is what is the final aim of Virtue – interactive communication with the Human, algorithm to Virtue – answer to Human. Or question to Virtue – algorithm to Human.

Virtue is aimed towards allowing the Computer to become an intelligent human assistant.

D. Language

Long years of investigations into Human languages, all the worlds linguistic efforts show that the Language is the primary means of Human external world model forming, and his absolutely prime and most developed communication and understanding system.

Therefore, it is absolutely essential, to be able to actually fully integrate computers into the modern world Human society as intelligence amplifiers, to raise the level of Computer's language understanding towards the level of a full Human language, i.e. allowing the Human-Computer interaction language to be able to provide external world models for both of them.

V. DATA TYPES

Virtue has complex data structures (scalars, arrays of any dimension, array elements which are themselves structures of scalars or arrays…) and diverse data types (booleans; multidimensional fuzzy logicals; characters; numbers – real, complex, quaternion, octonion; addresses; functions; labels; files; or possible specific types like planetary ephemeris, pixels etc.).

[8] The present experimental implementation of Virtue uses only SMP. Work is in progress to encompass TCP/IP communication protocols with other computers running the Virtue system, by which all those processors/computers become a single large compute-assistant. The internal architecture of the experimental implementation is already prepared for multi-computer parallelism.

The inclusion of e.g. functions as data types, inter-mixable with any other data-type, as well as the form in which the programme itself is internally represented - in the exactly same way as data, enables Virtue to use, for example, variable functions whenever necessary, or to define function parallelism (e.g. by applying a vector of functions to a vector of values).

Files are also scalar data types, which means that they can be inside a multidimensional structured array (there is no theoretical limit to the number of open files in Virtue, the same as with the dimensionality of arrays). Each use of an argument which is a File (or contains a File in its structure) will read the data from the file, and provide the data defined by a "prototype record" supplied when the file was opened (i.e. to open a file a name and a prototype record is given) for the pending operation. This linguistically very simple and understandable approach allows for very complex data manipulation across a huge range of input data-sets and processing systems.

Virtue has an almost fully orthogonal approach towards data – any operation that has sense is usable. However, nonsensical operations (like e.g. square root of a character) are strictly disallowed. The execution framework of Virtue is very forgiving, yet strict, in imposing the processing rules for different combinations of data structures and data types.[9]

Further important features of Virtue include the complete lack of reserved words or symbols[10], synonyms, word dependant hierarchical contexts, continuations, and the possibility to use any data whatsoever as a name for something else.[11]

VI. Serial versus Parallel processing

The Virtue Language is designed to keep as many logically parallel algorithmic structures expressed in such a way that the parallelism is obvious. However, an algorithm is, per definitionem, a series of operations, possibly intermixed with decision making.

Virtue tries to keep consistency inside the two sets of operations, the:

- serial operations
- parallel operations

However, it should be noted, that the whole language can be implemented on a purely serial computer, but can also be implemented on parallel data processing equipment (multiprocessor, vector, cluster, grid...). The consistency of semantic distinction between parallel (i.e. parallelisable) and serial (non-parallelisable) instructions in an program on many levels does not a-priory dictate the implementation of Virtue. Although multidimensional logical values are parallel constructs, it would be counter-productive to parallelise a logical operation on 2, 4 or 8 individual values (or wouldn't it?). However operations on conformable multi-dimensional arrays are also parallel constructs, but it would be very advisable to implement them in parallel on several independent processing units.

It is important to understand that not all constructs may be safely executed in parallel, although applied to conformable arrays of enough elements. Although, for example, the application of functions on vectors/arrays may be a parallel operation, it must be serialized if the function has side effects.

Such a strict distinction is necessary, as there is no a-priory order in parallel operations, and there is no communication possible between strictly parallely executing operations.

Already during the analysis and/or during the processing Virtue will introduce into the internal Data Description (in this particular case of a function) a flag indicating if it may be executed in parallel, or the processing must be serialised. So, for example, by using input/output commands or global variables in a function which otherwise could be executed parallely, Virtue will automatically flag that condition, and serialise the execution. In the same time, these conditions in a functional sentence will prevent it from being memoised.

As another example of usage of the Data Description, an argument whose any element was produced by a random number generator (which indicates stochastic processing) applied to a normally memoisable function will prevent the memoisation of this function with that particular argument. This is necessary as otherwise simulations relying on random number generation would not properly work if memoisation is used. It will, naturally, normally work with all data which was not produced by manipulation of a random number.

It is obvious that with such internal structures the Human does not have to take care of the way his problems will be solved on a hardware level – serially, parallely, or in a concurrent combination of the two (for example more processors executing different functions on a vector, and using vector processors to execute parallel operations inside those functions). Virtue will execute SIMD, MIMD, MISD and SISD, even concurrently, as possibly in the above example. This makes the Virtue system widely adaptable to the underlying hardware, as any of the hardware architectures possibly used will excel in at least some aspects of execution.

VII. The Implementation of Virtue

The Virtue Language is fully defined in it's primary form.

The computer implementation is presently in Alpha 0.6 state, and parallelisation is implemented on SMP systems.

[9] For example, a dyadic (two argument) operation on arrays whose dimensions are not equal is prohibited, except if one of the argument array dimensions is a subset of the other argument's array dimensions, or one of the arguments is a scalar.

[10] Except the symbol '::', which reverts any redifined internal Virtue word or symbol to its original meaning, and the symbol '.', which always marks the end of a sentence.

[11] For example the sentence `'A vector of numbers from 1 to 1000' 1000 INTERVAL AT SET.` will save the given string under the name of a vector from 1 to 1000. To recall the string from memory, such a vector shall be given, as for example: `900 INTERVAL (901 902) CATENATE 98 INTERVAL 902 + CATENATE GET.` This sentence will then give the answer "`A vector of numbers from 1 to 1000`".

The experimental implementation is constantly parallely developed and tested on a very wide range of different computers, ranging from the mid-1980-ies Sun3 (16MHz/16MiB and 20MHz/24MiB) workstations up to modern day blades, with various operating systems and their generations (SunOS, Solaris, NetBSD, FreeBSD, Linux, Win), various processors (68k, MIPS, SPARC, PowerPC, AMD, Intel), on 32 and 64 bit processors in single-processor and SMD multi-processor, multi-threading and multi-core computers. Such a wide range of computers, both historically and speed-wise, for the experimental Virtue implementations allows for a development of a very easily adaptable system, and the behaviour of the old Sun3 systems shows that even on them the execution seems very fast for the amount of data which can be represented in the memory of those computers[12].

The internal speed measurements which the Virtue Executor has (and they are important for the future multi-computer implementations, to allow load balancing) have provided us with quite a lot of important data on the behaviour of different computer systems and different processors, so an investigation into the "speed of a computer" is presently being performed, with some results to be presented soon.

VIII. Conclusion

Virtue is a pliable language, shrinkable and extensible, but generically compatible as a Language on all possible levels of implementation. Therefore it could be implemented in hardware, as a specific processor, it could be small and embedded, but it could automatically grow towards huge systems and big data. The idea of a Language even in the inter-computer communication, allows for Virtual Executors which do not recognise a word the user used, to consult (if on network) other known, but probably bigger Virtual Executors about the meaning of the word, and/or help in the execution of a task.

The final aim of this long-term effort is to provide a "human assistant", an intelligent, selflearning and selforganising "assistant" in this more and more complex life environment.

From the level of being a chip, or a programme in a chip, able to monitor, coordinate and regulate processes in complicated systems, up to the level of data mining in distributed environments, Virtue is aimed to provide a seamless integration.

As a mathematical processor, as a Grid Library Application, as a Modelling Tool, Visualisator or a data/calculation preprocessor...

[12] The classical double recursive algorithm for calculating the n-th number of a Fibonacci series could be expressed in Virtue for example thus: `MONADIC DUPLICATE 3 < @%a IF JUMP DUPLICATE 1 SUBTRACT Fibonacci! SWAP 2 SUBTRACT Fibonacci! ADD RETURN %a DISCARD 1; @Fibonacci SET.` The sentence, translated into English, says: "Check if the requested Fibonacci series element number is less then 3, if not subtract 1 from this number and calculate that Fibonacci (series element), then subtract 2 from the same number and calculate the Fibonacci, otherwise (if the number was < 3) jump to conclusion, forget that number and just return 1, then remember this phrase, which expects one object, as the word 'Fibonacci').

The calculation of all the first 1500 Fibonacci series numbers (slightly over the limit of IEEE double FP) on a 1987. Sun3/60 (SunOS 4.1.1, original Sun cc compiler, MC68020+MC68881, 20MHz, 24MiB 32-bit RAM - ~3MIPS, 192 kFLOPS) using this algorithm with the memoisation word RESULT - that is inputing the sentence `1500 INTERVAL MONADIC Fibonacci RESULT; EACH.` (in English: "Make an interval vector from 1 to 1500, then for each element of the vector calculate the Fibonacci, but first check if you already remembered the result.") - the vector of those first 1500 (!) Fibonacci numbers will be produced after just 27.827s, whereas the next time the same sentence is entered, the results will come in just 4.461s. Such speed is fully acceptable for normal work! Modern day common computers are several hundred times faster (not several thousand times, as would be expected from the MIPS/GIPS relationship. Just one example: a recently tested 1.67GHz Intel Atom in a reputable notebook with 2GiB 667.0 MHz DDR2 SDRAM memory, on Windows 7/32, Microsoft Visual Studio 2010 Express C compiler, performed the above operations in 0.21s (first time), and in 0.045s (afterwards), a speedup compared to Sun-3 of only around 100 times, despite the high sounding numbers. The reason is the more and more intensively felt "von Neumann bottleneck" - the memory vs. processor speed and channel constraints!)

Abstract - Scientific workflow systems aim to provide user friendly, end-to-end solutions for automating and simplifying computational or data intensive tasks. A number of workflow environments have been developed in recent years to provide support for the specification and execution of scientific workflows. Normal static workflows can poorly cope with the ever changing status of the existing distributed systems. During workflow enactment unforeseen scenarios may arise, which can cause significant delays, failed executions, or improper results. Manual workflow enactment has its obvious limitations, however automatic failover mechanisms require minimum an accurate information set about the workflow tasks and about the status of the underlying processing infrastructure. Dynamism can be defined at different abstraction levels and in different phases of the workflow lifecycle. In this paper we identify the requirements of dynamic workflows in general and provide a thorough survey about gUSE/WS-PGRADE's dynamic workflow handling capabilities.

Keywords: dynamic workflow, gUSE, workflow management system.

I. INTRODUCTION

Scientific workflow systems are used to develop complex scientific applications by connecting different algorithms to each other. Such organization of huge computational and data intensive algorithms aim to provide user friendly, end-to-end solution for scientists. However normal static workflows cannot cope with the ever changing status of the existing distributed system and the unforeseen scenarios that may arise during workflow enactment. These scenarios or exceptions may impact the workflow at various levels. Different classes of exceptions require different approaches in their handling and recovery in the various phases of the workflow lifecycle. Some cause only resubmitting the workflow, while others may result in changes even in the workflow model. Depending on the requested handling strategy we defined the levels at which the system should support dynamism.

A number of scientific workflow environments have been developed over the past decade to provide support for the specification and execution of scientific workflows (ASKALON [24], Triana [22], Taverna [5], Kepler [23], MOTEUR [25] and gUSE [10]). gUSE has been developed and maintained since 2008 by MTA SZTAKI. The gUSE enables scientific communities to compose and execute a workflow in a scientific application on different DCIs (such as clusters, grids, supercomputers, desktop grids and clouds).

In this paper we give a taxonomy of the dynamism in the context of the workflow lifecycle phases and the defined abstraction levels. According to the detailed taxonomy we give a thorough survey about the gUSE/WS-PGRADE's dynamic workflow capabilities.

The paper is organized as follows. In section II we give a brief overview of the dynamism, found in the literature. Section III identifies the different phases of the workflow lifecycle, introduces the definition and levels of dynamism and presents issues and their handling regarding dynamism. Section IV provides a thorough survey about dynamism in gUSE. Conclusion and future work in section V and the bibliography closes our work.

II. RELATED WORK

Very few papers give overall analysis of dynamism, they rather select one or few segments of it and propose solutions for them in a concrete workflow management system.

In his thesis Bahsi [1] studies the different workflow management systems (Apache Ant, Askalon, DAGMan, Kepler, Pegasus, Taverna, Triana etc.) and compare their capabilities in terms of dynamic and conditional structures they support. He found out that some systems have primitive logic elements that can be used to build advance conditional structures, others already have those high level ones. In addition, although some systems do not have conditional elements, some other mechanisms can be used for implementing the requested conditional behavior. Furthermore some system instead of returning an error code in case of certain failures, they cause the whole workflow to fail. This complicates building dynamic workflows.

Gil at al. [2] summarized the requirements of future scientific applications and the challenges that they present to current workflow technologies. The dynamic workflows and user steering topic was also investigated, and many expectations were determined, but the levels or phases of dynamism were not systematized. For example the workflow have to support dynamism in making decision about which steps to take next based on the available information in different scenarios (external events, workflow interoperability, user steering) or have to support dynamism in the appropriate user interface that enable scientist to make a complex exploratory process. The dynamic management of workflow was also conceived.

Lee et al. [16] in their research use Autonomic Computing methodologies, such as monitoring, analyses, planning and execution (MAPE) model to manage the long run scientific workflow execution processes.

Yu and Buyya [18] in his paper propose a general taxonomy that characterizes and classifies various approaches for building and executing workflows on grids. Their analysis affects the topic of dynamism in workflow design, scheduling and data management but they did not map these solutions to phases or abstraction levels. In their work among others they introduce automatic workflow composition and automatic data movement. In the former case the system itself generates the workflow according to the users' requirements, while in the latter case the system provides the mechanism to transfer intermediate data. They distinguish centralized, mediated and peer-to peer solutions

III. A SCIENTIFIC WORKFLOW LIFE CYCLE

A. Scientific Workflow Life Cycle

The various phases and steps associated with planning, executing, and analyzing scientific workflows comprise the scientific workflow life cycle (WFLC). The following phases are largely supported by existing workflow systems using a wide variety of approaches and techniques. [3]

Hypothesis Generation (Modification): Development of a scientific workflow usually starts with hypothesis generation. Scientists working on a problem, gather information, data and requirements about the related issues to make assumptions about a scientific process. From these data they build a specification which can be modified later during the whole lifecycle, or after the result analysis.

Experiment / Workflow Design: During the experiment an actual workflow is assembled based on this specification. This phase is the workflow development or design phase, which differs from general programming in many ways. It is usually the composition and configuration of a special-purpose workflow from pre-existing, more general-purpose components, sub-workflows, and services. During workflow composition, the workflow developer either creates a new workflow by modifying an existing one or composes a new workflow from scratch using components and sub workflows obtained from a repository. In contrast to the business workflow world, where standards have been developed over the years (e.g., WS-BPEL 2.0 [4]), scientific workflow systems tend to use a language set of internal languages and exchange formats (e.g., SCUFL [5], GPEL [6], and MOML [7]). Reasons for this diversity include the wide range of computation models used in scientific workflows and the initial focus of development efforts on scientist oriented functionality rather than standardization.

Instantiation: Once the workflow description is constructed, scientific workflow systems often provide various functions prior to execution. These functions may include workflow validation, resource allocation, scheduling, optimization, parameter binding and configuration. Workflow mapping is sometimes used to refer to optimization and scheduling decisions made during this phase.

Execution: After the workflow instantiation the workflow can be executed. During execution, a workflow system may record provenance information (data and process history) as well as provide real-time monitoring and failover functions. Depending on the system, provenance information generally involves the recording of the steps that were invoked during workflow execution, the data consumed and produced by each step, a set of data dependencies stating which data was used to

derive other data, the parameter settings used for each step, and so on. If workflow migration or adaptation (i.e.: change the workflow model or the running instance) is enabled or supported during execution (e.g., due to the changing environment), the evolution of such a dynamic workflow may be recorded as well in order to support subsequent event handling.

Result Analysis: After workflow execution, scientists often need to inspect and interpret workflow results. This involves evaluation of the results, examination of workflow execution traces, workflow debugging and performance analysis.

Data and workflow products can be published and shared. As workflows and data products are committed to a shared repository, new iterations of the workflow life cycle can begin.

B. Definition of dynamism

Dynamism on one hand is the ability of a system to react or to handle unforeseen scenarios raised during the workflow enactment phase, in a way to avoid certain failures or to recover from specific situations automatically or with user intervention. The adaptation to new situations may range from resubmitting a workflow to even the modification of a whole workflow model. On the other hand the dynamism is the opportunity to change the abstract or concrete workflow model or to give faster execution and higher level performance according to the actual environmental conditions and intermediary results. We distinguish several levels at the different lifecycle phases of a workflow. The *system level* concerns with those dynamic issues that are supported by the workflow management system. The *composition level* includes the language or the DAG support. With *task level solutions* large scale dynamism can be achieved if the system is able to handle tasks as separate units. *Workflow level* dynamism deals with problems which can only be interpreted in the context of a certain workflow. *User level* gives the opportunity for user intervention.

During design time, the workflow developer creates an abstract workflow model first (for example a DAG) [16][18], which contains the tasks (computational process), the structure of jobs and the data dependency between them. This model is independent from the exact computing infrastructure. To reach the required dynamism at this phase the system should give support at three different levels, namely system level, composition level, and the task level. Table [I.] summarizes the levels connected to the individual phases.

During the instantiation phase the abstract workflow to concrete workflow mapping takes place. [16][18] Depending on the system support and the status of the resources full or partial concrete model can be generated even before or during workflow execution. At this phase the dynamism also at three distinct level can be supported (system, task and workflow level, see table [1]). Scheduling also takes place at this phase.

The three above mentioned levels also appear during execution time. On one hand this is the phase where the various exception handling strategies, the monitoring and logging functions or the provenance based decisions are affected. On the other hand at this time happens resource reallocations, workflow instance or model changing and even the user intervention.

C. Related issues of the different phases of WFLC

The dynamism supported by the workflow management system can be interpreted in 4 phases of the above mentioned time intervals of the workflow lifecycle. (i.e.: design, instantiation, execution, analysis). The result analysis, log mining and the provenance is out of scope of this paper.

Design time

During design time, dynamism can be primarily supported by the modeling language at composition level. Several existing workflow managers have support for conditional structure in different levels. While some of them provide if, switch, and while structures that we are familiar from high level languages, some of the workflow managers provide comparatively simple logic constructs. In the latter case, the responsibility of creating conditional structures left to users by combining those logic constructs with other existing ones [1].

Heinl et al. [8], [9] gave a classification scheme for flexibility of workflow management systems. He defined two groups: flexibility by selection and flexibility by adaptation. Flexibility by selection techniques also should be implemented in the design time but of course they need some system level support. It can be achieved by advance modeling and late modeling.

The advance modeling technique means that the user can define multiple execution alternatives during the design or configuration phase and the completion or incompletion of the predefined condition decides the actual steps processed in run time.

The late modeling technique means, that parts of a process model are not modeled before execution, i.e. they are left as ‘black boxes’ and the actual execution of these parts are selected only at the execution time.

During this phase the system may also support task level dynamism in a sense, that sub workflows, or task from existing workflows should be reusable in other workflows as well. The modular composition of workflows also enables the simple and quick composition of new workflows.

TABLE I. ABSTRACT LEVELS OF DYNAMISM

design time (abstract wf level)	**system level**	**composition level**	**task level**	
	- black boxes - advance modelling technique	- language or graph structure	- modularity, reusability	
instantiation time (concrete wf level)	**system level**	**task level**	**wf level**	
	- breakpoints - incremental compilation - various protocol support - provenance based sched - multi instance activity	- task based sched. - late binding of data	- partitioning to sub workflows - parameter sweep appl. - wf based sched - mapping adaptation	
execution time	**system level**	**task level**	**wf level**	**user level**
	- exception handling (EH) - provenance based decisions - monitoring, logging - dynamic resource allocation	- resource alloca-tion	- alternate task - change the model	- user inter-ven-tion

Instantiation time

Static decision making involves the risk that decisions may be made on the basis of information about resource performance and availability that quickly becomes outdated. [11] As a result with system level support, benefits may appear either from incremental compilation, whereby resource allocation decisions are made for part of a workflow at a time (e.g. [12]), or by dynamically revising compilation decisions of a concrete workflow while it is executing (e.g. [13, 14, 15]). In principle, any decision that was made statically during workflow compilation should be revisited at runtime (e.g. [16])

Another way to support dynamism at system level during instantiation is using breakpoints. To interact with the workflow for tracking and debugging, the developer can interleave breakpoints in the model. At these breakpoints the execution of job instances can be enabled or prohibited, or even it can be steered to another direction. [10]

We also reckon multi instance activities among the above mentioned system level dynamic issues. Multi instantiation of activities gives flexibility to the execution of workflows. It means that during workflow enactment one of the tasks should be executed with multiple instance (i.e.: parallelism), but the number of instances is not known before enactment.

A way to allow flexibility in data management at system level is to support access to object stores using a variety of protocols and security mechanisms. [17]

A task level challenge for workflow management systems is to develop a flexible data management solution that allows for late binding of data. Tasks can discover input data at runtime, and possibly choose to stage the data from one of many locations.

At workflow level using mapping adaptations depending on the environment, the abstract workflow to concrete workflow bindings can change. Lee et al. [16] deal with this issue in details.

If the original workflow can be partitioned into sub-workflows before mapping, then each sub-workflow can be mapped individually. The order and timing of the mapping is dictated by the dependencies between the sub-workflows. In some cases the sub-workflows can be mapped and executed also in parallel. The partitioning details are dictated by how fast the target execution resources are changing. In a dynamic environment, partitions with small numbers of tasks are preferable, so that only a small number of tasks are bound to resources at any one time [3].

In scientific context the most important applications are parameter sweep applications over very large parameter spaces. Practically it means to submit a workflow with various data of the given parameter space. This kind of parallelization gives faster execution and high level flexibility in the execution environment.

Scheduling algorithms can also be task based (task level) or workflow based (workflow level) and with system level support the performance and effectiveness of the algorithms can be improved with provenance based information.

Execution time

In a dynamically changing environment, during workflow enactment unforeseen scenarios may result in various work item failure (due to faulty results, resource unavailability and so on). Many of these failures could be avoided with workflow management systems that provide more dynamism and support certain level of adaptivity to these scenarios.

We categorize the related issues into levels according to table [1].

The first level is made up from the failure of hardware, software or network component, associated with the work item or data resources unavailability. In these cases, either the exception handling may or should include mechanisms to detect and to recover from failures (for example restart the job or workflow or make some other decision based on provenance data), even with provenance based support. In all these cases possible handling strategies should be tracking, monitoring and gathering provenance

information in order to support users in coming to a decision.

The user level dynamism consists of scenarios where the system waits for user steering. Here we can rate the breakpoints, where workflow execution can be suspended and enabled again by the user. Also at this time happens the interpretation of the black boxes (late modelling technique).

Suspending a workflow and then continue with a new task by deviating from the original workflow model also gives more flexibility to the system at workflow level. In Heinl's taxonomy [8, 9] it is defined by flexibility by adaptation. In this case we distinguish adaptive systems and ad hoc systems. While adaptive systems modify process model on instances leaving the process model unchanged, in ad hoc systems the model migrates to a new state, to a new model [9].

IV. DYNAMIC SUPPORT IN WS-PGRADE/GUSE

The WS-PGRADE Portal [10] is a web based front end of the gUSE infrastructure. The structure of WS-PGRADE workflows are represented by directed acyclic graphs (DAG).

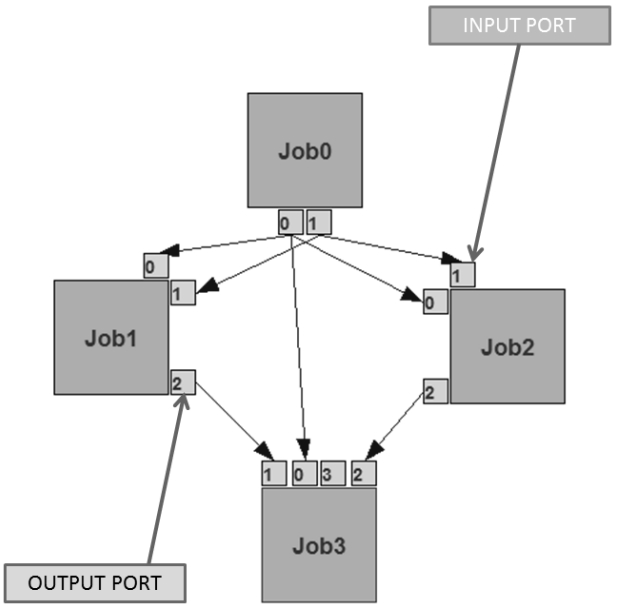
The nodes of the graph, namely jobs are the smallest units of a workflow. They represent a single algorithm, a stand-alone program or a web-service call to be executed. Ports represent input and output connectors of the given job node. Directed edges of the graph represent data dependency (and corresponding file transfer) among the workflow nodes. This abstract workflow can be used in the second step to generate various concrete workflows by configuring detailed properties (first of all the executable, the input/output files where needed and the target DCI) of the nodes representing the atomic execution units of the workflow.

The algorithm configuration determines the functionality of the job, the resource configuration determines where this activity will be executed, and the port configuration determines what the input data of the activity are and how the result(s) will be forwarded to the user or to other jobs as inputs. Fig 1.

After all the properties of the workflow have been set, it can be submitted resulting in an instance of the workflow. A concrete workflow can be submitted several times (for example, in case of performance measurements) and every submission will result in a new instance of the same concrete workflow.

A job may be executed if there is proper data (or dataset in case of a collector port) at each of its input ports and there is no prohibiting programmed condition excluding the execution of the job

Figure I. WORKFLOW COPOSITION IN GUSE



The execution of a workflow instance is data driven forced by the graph structure: A node will be activated (the associated job submitted or the associated service called) when the required input data elements (usually file, or set of files) become available at each input port of the node.

Design time

At composition level on the one hand the gUSE provide the possibility of creating embedding workflows. This enables the usage of the subroutine paradigm where workflow B can be used inside a parent workflow A by specifying that the executable of a certain node in A should be workflow B. [10] On the other hand multiple execution alternatives can be defined with specifying some condition on input parameters. In this way the completion or the incompletion of the condition during execution time determines the actual execution of the concrete workflow.

Instantiation time

At system level gUSE supports the use of breakpoints. The user may suspend or abort the execution of a running instance. A previously suspended workflow instance can be resumed at any time by the user. This way the user can observe the progress of workflow elaboration on the fly and can perform a service call instance level check-pointing when needed.

Parameter study executions are supported in the gUSE at workflow level. From an abstract workflow various concrete workflow can be generated with different input data from the parameter space, and even from one concrete workflow more instances can be produced by saving with unique ID-s in order to support performance analysis.

Multi instance activities are also supported with the configuration of job nodes to be generators and others to act as collectors. A workflow node (job) has generator property if the execution of the associated job or service call instance may produce more than one output data elements associated to given distinguished output port(s) [19]. It gives task level dynamism support.

The incremental compilation, data management flexibility and the late binding techniques are not supported in gUSE, however, all the tasks that a workflow model comprise of can be individually mapped to resources during the configuration phase of the WFLC.

Execution time

At system level exception monitoring is supported in the system (with breakpoints), and in case of software/hardware failures, resource unavailability, running failures, network unreachability the concrete workflows are only resubmitted. So problem solving in some of this cases need an administrator or user to be involved.

At user level the predefined breakpoints provide dynamism to the workflow developer.

In gUSE only the actually running instance may deviate from the original workflow model, leaving the model itself unchanged (Adaptive systems [7, 8]).

V. CONLUSION

In our work we introduced a detailed definition for dynamism that should be supported by dynamic scientific workflow management systems. We systematized the individual issues regarding dynamism into different levels at the various phases of the workflow lifecycle. According to our presented taxonomy we investigated the gUSE dynamic capabilities. In our future work we intend to improve the dynamic support of the SZTAKI gUSE system.

Abstract - This paper is focused on understanding techniques used to formally verify behaviour of business processes developed using WS-BPEL standard.

The first part of the paper gives an overview of WS-BPEL control-flow constructs. We analyze offered constructs and try to derive control-flow scenarios that can be built out of them. Derived complex control-flow scenarios are further discussed. Possible execution misbehaviour, which cannot be discovered by pure static analysis of WS-BPEL code, is identified. Misbehaviour can be any of the following: unreachable code, deadlock states, non-progress cycles (code is repeated without passing through progress state), or any other unwanted scenario, like unwanted execution order of activities, unwanted order of messages being exchanged and similar execution misbehaviour.

The second part of the paper describes techniques used for formal verification of any code in general with an emphasis on research how these techniques are exploited to verify WS-BPEL code. The final part of the paper concludes with the discussion how successful described work was in verification of possible identified misbehaviour from the first part of the paper.

I. INTRODUCTION

WS-BPEL [1] (in further text BPEL) is a main XML based paradigm that can be used to combine multiple, stateless web services into complex workflow processes. Even when there is only sequenced behaviour present, workflow structures can contain many complex paths that can be hard to compute by heart. When parallelism is added to the behaviour of the workflow system, situation becomes more complex and additional techniques are required to check the behaviour in early phases of the development. Techniques for formal verification come in handy in these situations.

This paper is concentrated on techniques used for formalization of BPEL processes (*called orchestrations*) and tries to give an overview of the existing work related to it. The paper is organized as follows. Section II presents offered BPEL activities and concludes with potential problems that can occur inside of BPEL executions. Section III introduces mechanisms used for formal verification in general. Section IV introduces two approaches related to formal verification of BPEL processes using mechanisms described in section III and it gives a comparative analysis of those approaches. Section V concludes the paper.

II. WS-BPEL ACTIVITIES

A. WS-BPEL basic activities

WS-BPEL (*BPEL in further text*) is widely accepted paradigm for integrating software applications (*exposed as services*) into complex business processes that span within and across organizational boundaries. Interactions in BPEL processes are expressed as compositions of communication activities (*invoke, receive, receive/reply, invoke/receive*) used for modelling different communication patterns between BPEL processes and integrated services (*in further text partner services*). Communication between BPEL processes and partner services can be *one-way*, *synchronous request-response* and *asynchronous request-response*. *One-way* pattern is utilized when a BPEL process invokes *one-way* operation of a partner service or when a partner service invokes *one-way* operation of a BPEL process. Synchronous *request-response* communication is utilized when a BPEL process invokes *request-response* operation of a partner service by sending message to a service, waiting for a response and receiving the response. Asynchronous *request-response* communication is utilized when a BPEL process invokes *request-response* operation of a partner service but it continues with its execution and does not wait for a response. In order for asynchronous communication to be performed, a BPEL process must have registered *one-way* operation that is used to asynchronously receive a response from a partner service when the response is ready. Communication activities come under basic BPEL activities together with *empty* (*do nothing*), *wait*, *throw* (*generate error*), *compensate* (*invoke compensation handler*) and *exit* activities.

B. WS-BPEL structured activities

Besides pure message exchange scenarios between BPEL processes and their partner services, the idea of BPEL is to capture business logic as well. This is carried out using structured activities that allow parallel, sequential and conditional execution, event and exception handling, fault and compensation handling and data manipulation.

Sequence activity allows all its child activities to be performed sequentially in the order in which they are

written. *Flow* activity allows all its child activities to be performed in parallel. Besides parallelism, flow activity supports conditional execution of its child activities using *links* that synchronize execution of a *source* activity and a *destination* activity. A destination activity cannot execute unless at least a source activity executes successfully. *Links* mechanism allows construction of extremely complex net of conditional executions. Cyclic dependencies are forbidden but everything other is allowed.

Pick activity is used for selective event processing. It contains several branches each of which corresponding to the occurrence of a specific event. Which branch is going to be selected and executed depends on the type of the event that has been raised. After the event raises and its corresponding branch starts its execution, other events can no longer be accepted by that pick activity. Types of the events accepted by the pick activity are: message events (*receipt of a special message type*) and time events (*expiration of a specific time-out*). *ForEach* activity executes its child scope activity N times sequentially or in parallel.

Other structured activities are well-known from most programming languages and thus they do not require detailed introduction: *switch* (*conditional routing*), *if* (*conditional behaviour*), *repeatUntil* (*repeatable execution*) and *while* (*repeatable execution*).

Scope is a special structured activity that enables segmentation of business logic into special units used for attaching event, fault and compensation handlers related to that business logic segment. Attached handlers contain logic which is executed when an event or a fault inside of a scope occurs and they are executed in parallel or after the termination of the scope. *Event handlers* are related to processing of an event and they execute in parallel with the scope. Events can be exceeded timeout or receipt of a specific message type. Time event handlers can have only one active raised instance (when the timeout is reached), while message event handlers are raised upon every receipt of a related message type and can have many raised instances during scope execution. Special type of time event handlers (*repeatEvery*) can have multiple active instances raised in parallel with the scope and they occur repeatedly after every duration period exceeds.

Fault handlers are related to processing an error that occurred in the execution of a scope they are attached to. When a fault occurs, it is caught by the corresponding fault handler and when that happens, the scope switches from its normal processing mode to its fault handling mode. Fault handlers can be defined for a custom fault type explicitly or they can be defined implicitly as default fault handlers. If faults are not handled successfully by fault handlers, they are re-thrown to the parent scope. The scope, in which a fault occurred and whose fault handler has been activated, are considered to have ended abnormally and they cannot be compensated.

Compensation is an odd term introduced with the BPEL specification. Compensation refers to application-specific logic that attempts to undo the work of a previously successfully completed scope. As with fault handlers, *compensation handlers* can be defined explicitly or implicitly. Compensation handler of a successfully completed scope is invoked by *compensate* activity from a fault handler or a compensation handler attached to the parent scope.

Regular termination of a scope begins when fault handler of a scope starts its execution. Termination of a scope means that all activities contained within it must be terminated. Forced termination of a scope begins when there is a need for terminating scope that is in a normal running mode. *Termination handlers* can be attached to a scope in order to override default termination handlers.

Control links (*mentioned previously*) can cross boundaries of all of these structured activities excluding repeatable constructs *repeatUntil*, *forEach*, *while* and *compensation handlers*.

C. WS-BPEL data manipulation activities

BPEL processes exchange data with their partner services. Exchanged data are manipulated inside of executions and can be used to identify the right instance of a BPEL process. *Variables* are constructs used for storing data and they can be defined as *XML types*, *XML elements* and *WSDL message types*. *Query languages* are used for retrieving parts of variables to get or set their values. Data manipulation is performed using *expressions*. *Assign* activity is used to assign values to variables using *data assignments*. It can be used to copy values from variables to variables or to insert new values generated using data expressions. Default query and expression language in BPEL is *xPath*, but it is allowed to define own query and expression languages. BPEL specification defines rules for binding WS-BPEL variables in *XPath* and it also defines some restrictions for usage of *XPath*.

D. Misbehaviour of WS-BPEL processes

BPEL processes are workflow processes that can have a complex net of parallel and conditional behaviour which is the main reason for trying to formalize BPEL processes. Conditional behaviour is introduced with the notion of links whose behaviour is going to be described in more detail now. Link connects a source and a target activity (Figure [1]). After the source activity completes, transition condition of the link (*Boolean expression*) is evaluated and its return value is set as a link status. After the link status is set, it is 'forwarded' to the target activity. When the target activity is ready for execution, it must wait to 'receive' statuses of all of incoming links. After all those statuses are received, join condition of the target activity (*Boolean expression*) is evaluated to determine if the target activity will be executed or not. Links can be used to develop extremely complex net of conditional behaviour and it is very hard and annoying to draw a map of all possible executions in order to verify them. It is much easier to use help of some formal verification techniques to do so.

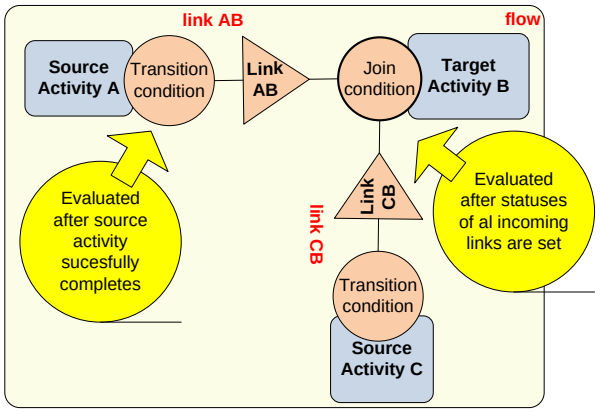

Figure 1. Links mechanism in WS-BPEL

Parallel behaviour is introduced with *flow*, parallel *forEach* and *event handler* activities. When parallel behaviour is present, it is important to verify all possible executions to see if there are executions with unwanted race conditions. Race conditions occur when shared resources are manipulated concurrently which can lead to possible data corruption. If race conditions are allowed, then semaphores are introduced to control access to shared resources. But still it is necessary to check if there are induced deadlocks or process starvations. An example of an unwanted race condition in BPEL processes would be a situation when some of variables referenced by the transition condition are modified in the concurrent path. As opposed, if this race condition is allowed, then the result of the transition condition evaluation may depend non-deterministically on the timing of behaviour among concurrent activities [1]. An example of a strongly forbidden (*by BPEL specification*) race condition is an existence of competing message consuming activities (*two or more receive activities that consume the same message must not be concurrently enabled*). An unwanted race condition would be also a situation when one parallel component initializes shared resource while the other reads it (*and reading of unutilized resource is erroneous*). This could lead to situations that one parallel component is trying to read a resource while the other parallel component did not finish an initialization of the resource. Example of this scenario in a BPEL process is a try to read a *partnerlink* before its *partnerRole EPR* is initialized which results with an error.

It is of big importance to formalize BPEL executions, in order to check absence of deadlocks, unwanted race conditions, process starvations and of any other system misbehaviour and to see if computational correctness of the process is preserved in its every execution.

III. FORMAL VERIFICATION

Formal verification is performed to check properties of or to simulate executions of distributed systems. The term '*distributed system*' refers to logically or to physically distributed systems. Logically distributed systems comprise parallel and asynchronous functional behaviour that shares common resources. Formal verification is applied not to distributed systems only but to sequential systems that contain complex synchronized functional behaviour.

Testing is a traditional way of verifying behaviour of a system but without 100% correctness. Classical testing techniques of modular systems are performed in such a way that functionality of each module is tested individually. After testing functional correctness of each module, integration testing is performed. If modules are executed sequentially and system's behaviour is not complex, then classical testing techniques of verifying functional correctness can be satisfactory, but even in these cases, formal verification methods can be complementary techniques to classical testing techniques especially when behaviour of the system is complex.

But what if functional modules of the system do not execute exclusively sequentially but there is parallel execution as well?! Parallel execution introduces new situations that can lead to computational incorrectness. Some of them have already been mentioned in the paper and those are: race conditions, data corruptions, delays, process starvations, deadlocks etc. With parallel and asynchronous behaviour state space can be extremely large so it is almost impossible to compute all possible combinations of speeds of parallel executions. Classical testing techniques will pass through some of possible executions but not through all and that is the main reason for appliance of formal verification techniques. Drawbacks of formal verification techniques are their computational complexity, time and memory consumption and not being user-friendly but they can give an answer with 100% correctness.

A. *Formal verification using finite state automata*

Finite state automata [2] and algorithms for traversing their states [3] form a strong mathematical basis upon which systems can be formally described and analyzed (*Figure 2*, *Figure 3*). In order to simulate or verify behaviour of the system, it needs to be formally described first. The first step of formal description is identification of parallel communicating components inside of the system's behaviour. After they are identified, each parallel component is expressed as a standalone extended finite state automation using *Promela* syntax. *Promela* is a language syntax used by Spin [4] which is the most

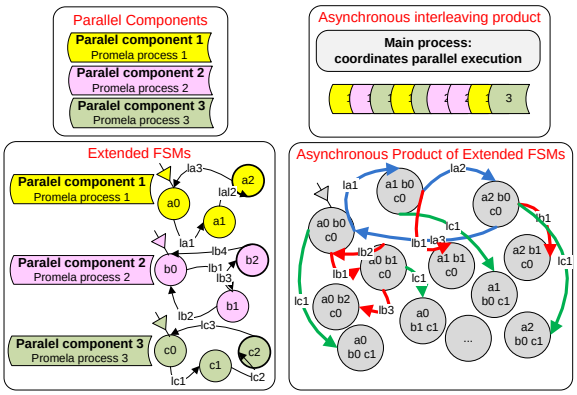

Figure 2. Mathematical basis of representing system's behaviour used in Spin

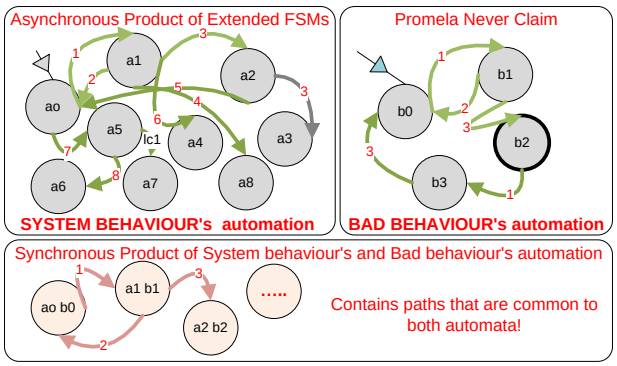

Figure 3. Mathematical basis of finding bad behaviour used in Spin

popular tool for formal verification based on finite automata. In order to express peace of code in *Promela*, it is important to define mapping rules from source syntax into *Promela* syntax which is the main challenge. When *Promela* processes are ready, they are executed in parallel and asynchronously, exchanging data using global variables or message channels. This is called *asynchronous interleaving product* and it corresponds to asynchronous product of extended finite state automata. A pure finite state automation of the system (*its whole state space*) is generated from the *asynchronous interleaving product* by its execution. Algorithms for simulation and verification [3] operate on pure finite state automation of the system (*state space of the system*).

1) Checking properties on finite state automata

Algorithms that traverse *state space of the system* are used for checking two types of properties: *liveness* and *safety* properties. *Liveness* properties must eventually be satisfied (*system eventually needs to be in an accepting state*) while safety properties must always be satisfied (*every state of the system needs to be an accepting state*).

Nested depth-first search algorithm (NDFS) is used for checking if *liveness* properties are satisfied and the procedure for its appliance is described hereafter. First, finite state automation of bad behaviour (*which contains cycles only with states where liveness property is not satisfied*) is specified using linear temporal logic (LTL) and afterwards it is transformed into *Promela* syntax (*called Promela never claim*). *Promela never claim* is executed synchronously with the finite state automation of the system. Synchronous execution of two automata corresponds to synchronous product of automata. A synchronous product of automata is a new automation that contains only those executions that are common to both automata. So after a synchronous product of the system's automation and *Promela never claim* is produced, *nested depth-first search algorithm* [3] is performed over the resulting synchronous product automation. Accepting states in the synchronous product automation are taken from *Promela* never claim, and those are exactly the states where a liveness property is not satisfied. Nested depth-first search algorithm checks if there are accepting states reachable from the start state and then it checks if those are reachable from itself. If there are such states, it proven that there is an example of the system's execution path where system never traverses an accepting state, i.e. it returns an example of the finite (*with stuttering extension*) or the infinite execution where a *liveness* property is not satisfied.

Some states in the system's automation can be marked as progress states. Progress labels are used to mark states that must be traversed eventually in every infinite execution of the system. The system is correct if it always eventually passes through the progress states and the system is not correct if there are non-progress cycles. Traversing progress states eventually is an example of a *liveness* property and it is checked in above described manner.

Mechanism for checking safety properties is the same as one used to check *liveness* properties, except a different algorithm over synchronous product is used. Safety properties are checked using regular *depth-first search algorithm* (DFS) [3] and can be checked on finite (*no stuttering extension needed*) and infinite executions. *Promela never claim* automation (*which contains violation of a safety property*) describes finite behaviour containing states where safety property is not satisfied. *Depth-first search algorithm* over synchronous product finds those states where safety property is not satisfied (*states where Promela never claim automation ends with its execution*).

2) Default checkings

When checking *liveness* or safety properties of the system, existence of deadlock states is implicitly checked as well. Deadlock states are the states in which the system cannot make a transition to any other state whilst at the same time that space is not marked as an end state. Behaviour of the system (*its extended finite state automation*) expressed as an interleaving asynchronous product of the parallel components (*asynchronous product of component extended finite state automata*) is considered to be in an end state if every parallel component s in its end state and all exchanged messages between them are consumed. Default end state of every parallel component is its curly brace, but it is allowed to define other states as end states.

Existence of unreachable states is implicitly checked as well when verifying liveness or safety properties of the system. Unreachable states represent the states of the parallel components that have never been traversed in the interleaving asynchronous product.

B. *Formal verification using Petri nets*

Petri nets [5] are graphical mathematical model for formalizing behaviour of parallel and asynchronous systems. Petri nets are applied to many systems because of their generality and tolerance. Any workflow system that contains parallel activities can be described by Petri nets. Complexity of resulting models is one of the main disadvantages of Petri nets. There are many offered tools for drawing, analysis and simulation of Petri models. Petri nets are nothing but directed, weighted graph with two types of nodes: *places* and *transitions*. *Arcs* are used to connect nodes (*places to transitions and transition to places*) and they are marked with their *weight factor* which is a number of parallel arcs. Places are marked with non-negative integer numbers called *tokens*. A marking of

a net is M-vector, where M is a number of states and M(p) is a token of a state p. States represent conditions for events to happen while transitions represent actual triggering of events. Every transition has its input and output places representing its pre-conditions and post-conditions. The main rule of Petri nets is the *rule of transition enabling and firing* which is used to simulate dynamical behaviour of the system. The rule of transition enabling and firing functions in the following way:

- Transition t is enabled if every input state p of transition t is marked with at least w (p,t) tokens where w(p,t) is a weight factor of an arc leading from p to t.
- Enabled transitions t can fire but it does not have to which depends on the actual occurrence of an event.
- Firing of enabled transition t removes w (p,t) tokens from every input state p of transition t and adds w (t,p) tokens to every output state p of transition t, where w (t,p) is a weight factor of an arc leading from t to p.

Petri nets can be used for different kinds of analysis since there are different interpretations of places and transitions (Table 1). One of the most common problems that can be answered with Petri nets is a *reachability* problem. The firing of an enabled transition will change the token distribution in a net according to the transition rule. An initial marking of a net is denoted with M_0 .A marking M_n is said to be reachable from M_0 if there exists a sequence of firings that transforms M_0 to M_n. The set of all possible markings reachable from M_0 forms its state place. The reachability problem for Petri nets is the problem of finding if M_n is in the set of all possible markings reachable from M_0.

The concept of *liveness* in the terms of Petri nets is closely related to the absence of deadlocks. A Petri nets is said to be live if no matter what marking has been reached from M_0, it is possible to ultimately fire any transition of the net by progressing through some further firing sequence which means that a live Petri guarantees deadlock-free.

Boundness is also checked with Petri nets. A Petri net is said to be bounded if for every place in every marking, the number of tokens does not exceed some finite number. A Petri net is safe if it is 1-bounded. *Reversibility* of a Petri net is its possibility of reversing to some home state from any marking (*any state*). *Persistence* of a Petri net assumes that for any two enabled transitions, the firing of one transition will not disable the other. A transition in a persistent net, once it is enabled will always stay enabled until it fires and this kind of nets is used in the context of analysing parallel systems. For more detailed explanation of Petri nets mechanism, the reader is referred to [5].

IV. FORMAL VERIFICATION OF WS-BPEL PROCESSES

Chapter III described techniques used for formal verification of workflow systems in general, while this chapter analyzes work related to formal verification of BPEL processes using techniques described in chapter III. The first part of the chapter describes work related to formalization of BPEL using finite state automata, while the second part of the chapter describes formalization of BPEL using Petri nets.

A. Formal verification of WS-BPEL using Petri-net

In [6] authors verified execution of standalone BPEL processes using Petri-nets. Petri-net model is obtained using developed mappings from BPEL control flow constructs solely into Petri-net constructs. Authors abstracted data manipulation aspects of BPEL execution, so their work has a goal to verify control flow solely. Mapped control flow construct are basic activities and structured activities (*sequence, flow, switch, pick, while*).

Scope, as a special structured activity used for event and exception handling, was also mapped to Petri-net. It is worth mentioning that mappings for scopes were defined even with event handlers, fault handlers and compensation handlers attached to them. Mapping for event handlers were made with the limitation that bounded number of message event handlers can be raised in parallel with the scope. They introduced this limitation in order not to get an unbounded net which is difficult to manage and which requires computationally expensive techniques.

When considering fault handlers, there are defined mappings for execution of all fault handling scenarios: scopes with general fault handlers, scopes with fault handlers related to process defined faults (*generated using throw activity*), scopes containing activities with *suppressJoinFailure* set to 'no', handling a fault occurred within a fault handler itself, handling a fault occurred within a scope with event handlers attached and dead path elimination for control links leaving a fault handler.

When considering compensation handlers, there are defined mappings for handling compensation invoked by the compensate activity and mappings for handling faults which happened during execution of a compensation handler itself.

When considering termination of activities, there are defined general mappings for termination of basic and structured activities (*with both values of suppressJoinFailure attribute*). Special mappings were defined for termination of *pick* and *while* structured activities because of their specific behaviour. There are also mappings for terminating hierarchy of copes and terminating a process due to execution of an exit activity.

TABLE I. SOME TYPICAL REPRESENTATIONS OF PLACES AND TRANSITIONS [5]

Input places	***Transitions***	***Output places***
Preconditions	Event	Post conditions
Input data	Computation step	Output data
Input signals	Signal processor	Output signals
Resources needed	Task or job	Resource released
Conditions	Clause in logic	Conclusion(s)
Buffers	Processor	Buffers

All mappings were defined for normal and skipping behaviour of activities, with and without control links attached to the activities. Since authors in [6] analyzed control-flow constructs in detail and have developed complete mapping for them, their formalization can be used to understand and analyze possible control-flow behaviours of BPEL processes but data layer of BPEL processes is totally abstracted. Authors explained that their formalization can be used for three scenarios:

- *Detection of unreachable code* - They use two techniques to detect activities that will never be executed, namely *relaxed soundness* which explores the whole state space and *transition invariants* which reduce state space but whose results are not necessary complete.
- *Detection of competing message consuming activities* – Competing message consuming activities are those activities that are active at the same time and that are waiting for the same type of message to come to the process. BPEL does not allow this scenario since it produces a race between those activities and this is strictly not allowed. In order to detect the existence of such activities, the whole state space must be searched.
- *Garbage collection of queued messages* – For every basic activity they annotate which type of messages can be consumed after activity's completion. So after this kind of analysis is done, the result is annotated BPEL process with markings for every basic activity. These markings can be used by BPEL engine afterwards to delete messages in an input queue which cannot be consumed anymore.

B. Formal verification of WS-BPEL using finite state machines

In reference [7] authors formalized asynchronous communication among multiple BPEL processes (*named peers*). Every peer has an attached input FIFO queue which it uses to consume messages sent to it by other peers. Authors named this kind of communication among peers as a *composite web service*. Their formalization (*of a composite web service*) consists of a conversation schema (*set of peers and types of messages exchanged between them*) and of each peer's behaviour. They introduced a *virtual watcher* that records *conversation*, i.e. the sequence of messages exchanged between peers. Exchanged messages are XML files and their types correspond to XML schemas. For each peer p_i, its behaviour is formalized using guarded automata (*extended automata*) with the following components: set of all incoming and outgoing message types for the peer, set of local variables, set of all states, an initial state, final states, and set of transitions. Local variables are represented as XML files as well. For every peer there are three types of transitions: receive transitions (*the receiving message is consumed from the input queue*), local transitions (*an internal action inside of the peer is performed*) and send transitions (*the peer appends the sent message to the input queue of the receiving peer*). Guards of the transitions in guarded automata are expressed as *XPath* expressions.

Formal behaviour of each peer (*expressed as a guarded automation*) is generated using mapping rules from BPEL into guarded automata. Guarded automata of the peers are later translated into *Promela* processes using mapping rules from guarded automata into *Promela*. Input queues of peers are translated to global message channels which are used by *Promela* processes to communicate asynchronously. A bound is put on the sizes of the input queues in order to get limited state space.

Authors used LTL formulas to check whether certain properties are present in the behaviour of the system. Atomic propositions (*used in LTL formulas*) are exchanged messages and predicates over exchanged messages. LTL formulas express if order of exchanged messages between BPEL processes is as wanted or if the right message response is returned according to a message content being sent as an input.

C. Comparative analysis of the two approaches

It can be concluded that authors in [7] did not abstract

TABLE II. COMPARISON OF THE APPROACHES IN [6] AND [7]

Property	Approaches to formal verification	
	Petri net approach [6]	***FSM approach [7]***
Appliance to an individual BPEL process or to communicating BPEL processes	Individual BPEL process	Communicating BPEL processes
Sequence of exchanged messages	Not reported	Yes
Complete coverage of all offered controls flow constructs with correct syntax	Yes	Not described
Concurrency inside of one individual BPEL process (*flow child activities, multiple raised event handlers, parallel forEach..*)	Yes	Not described
Data component (*data manipulation, data usage inside of BPEL execution*)	No	Yes
Race conditions (*multiple activities, that share the same resources, are active*)	Not reported	Not reported
Deadlocks, competing message consuming activities, garbage collection of input queue of a BPEL process	Contributions of the work	None reported
Usage of formal models for complete or partial automatic correction of BPEL code	Not reported	Not reported
"Not reported" means that the property is not reported in the paper and it is assumed it is not implemented.		

data component of BPEL processes as authors in [6] who were focused on detailed control-flow analysis solely. But while focusing on inter-communication between processes and preservation of data component, authors in [7] did not pay much attention to detailed formalization of control-flow semantics of each BPEL process (peer). They did not describe how they solved concurrency inside of execution of each peer (BPEL process), nor they were interested in detailed formal verification of a single BPEL process which can have complex behaviour with multiple parallelism and conditionals executions. Thus their work can be applied to verify inter-communication (*without abstraction of data component*) of multiple BPEL processes which execute in parallel and communicate asynchronously, but with no parallel execution inside of each BPEL process.

On the other side, authors in [6] analyzed control-flow component of BPEL specification in detail and they made a complete formalization of control-flow semantics of BPEL specification but with complete abstraction of data layer. Work in [6] refers to an individual BPEL process. Table 1 shows comparison analysis of the two approaches.

V. CONCLUSION

This paper gave an insight into the nature of BPEL specification. It was reported that BPEL processes can comprise many concurrent and conditional behaviour which, if not written properly, can lead to unwanted race conditions, deadlocks, process starvations and other system failures. Business logic can also become corrupted.

In order to override these problems, formalization techniques are use to check if there are unwanted scenarios in the behaviour of BPEL processes. Two approaches are introduced in this paper and it is concluded that they solve some problems but they are incomplete. According to the results of the comparative analysis (*Table 2*), they are somehow complement to each other.

Future work related to BPEL formalization is going to analyze BPEL specification in more detail in order to collect and organize as many as possible types of BPEL misbehaviours. Suitable approach for formalization of standalone BPEL processes and detection of unwanted misbehaviours will be suggested.

Hybrid MPI-OpenMP parallel optimization for thermo-fluid problems

M. Depolli
Jožef Stefan Institute/Department of Communication Systems, Ljubljana, Slovenia
matjaz.depolli@ijs.si

Abstract

This article deals with the minimization of the energy transport through the isolated enclosure by means of obstructing the fluid flow. The differentially heated cavity is partially covered with non-permeable obstacles that affect the natural convection flow. We seek the optimal position and shape of the obstacles to minimize the heat flux through the domain with the minimal cumulative size of the obstacles, i.e. we maximize insulation with minimal material needed. The task is performed by evolutionary multi-objective optimization of a local thermo-fluid solver, which comprises energy transport and incompressible fluid dynamics. An effective parallel algorithm is presented, in which the physical model is solved by a local meshless numerical method on shared memory architecture, coupled by optimization algorithm that exploits the distributed computer parallelism.

I. INTRODUCTION

In this article, a parallel simulation-based multi-objective optimization, i.e. the optimization is done on a simulated results, is presented. The principal incitement in this work is a minimization of energy losses in a differentially-heated air-filled cavity by placing obstacles in the cavity. The cavity is cooled on the top and heated on the bottom edge (Dirichlet boundary conditions), with left and right walls perfectly isolated (Neumann boundary conditions). The simulations begin with a stationary fluid, but the instable configuration of the case (heavier fluid on the top of a lighter one) soon leads to a pronounced natural convection flow patterns. The energy transport over the domain, i.e. energy losses, is therefore not governed only by diffusion but also convection. The most straightforward solution of the problem at hand would be to simply fill the whole domain with a good non-permeable insulator. However, our goal here is to minimize both the energy losses and insulating material consumption, therefore we only partially fill the domain with non-permeable obstacles to alter the air flow.

There are numerous examples of similar systems where one would be highly interested in such optimization, e.g. designing windows or other insulating elements for buildings, optimizing heat storage systems, optimizing heat distribution within rooms, etc.

If we want to solve the problem within reasonable time constraints, we need an effective implementation of numerical simulation and optimization tools. Solving the problem faster can be can be achieved by harnessing more processing power. The available processing power can be increased either by increasing the processing unit's clock frequency or by increasing the number of processing units. The clock frequencies are approaching their physical limits, therefore increasing the number of processing units is a more viable solution. Parallel processing, available today in most desktop computers or computer servers, can compensate for the lack of performance of a single processing unit only if an efficient parallelization of the computational method is known. Various application programming interfaces (APIs) for parallel programming are used to maximize the performance of parallel processing. Nowadays, the most widely used APIs for parallel programming are MPI for distributed-memory systems, and Ptreads and OpenMP for shared-memory systems [1]. There are several publications regarding the parallelization of different numerical schemes for various applied problems [2-6].

In this paper we present the efficiency of a shared-memory parallel simulator coupled with an evolutionary optimization on a modern cluster of multi-core computers. The numerical simulation is built on the popular variant of local point interpolation meshless method [7] where the collocation with the radial basis functions is used [8] combined with a local pressure-velocity [9] coupling to compute solenoidal flow.

Optimizer implements the AMS-DEMO algorithm [10], which is an evolutionary algorithm [11] for multi-objective optimization [12] of real-valued functions. Evolutionary algorithms are a subgroup of stochastic optimization algorithms [13] and can solve problems, for which only the cost (or evaluation) function is known.

II. PROBLEM DEFINITION

This paper deals with a straightforward natural convection simulation that includes energy transport, Navier-Stokes equation, mass continuity and Boussinesq approximation. There have been several numerical solutions of that type of problems published in the past [14-17]. The domain is a closed air-filled cavity with differentially heated horizontal walls with temperature difference ΔT and insulated vertical walls. Walls are Non-permeable and no-slip, i.e. velocity on all boundaries is set to zero. The problem comprises three coupled Partial Differential Equations (PDEs): mass (1), momentum (2) and energy conservation (3) equations and the Boussinesq approximation (4) used for the body force in the

momentum equation. The problem is thus stated with the following system

$$\nabla \cdot \mathbf{v} = 0 \,, \tag{1}$$

$$\rho \frac{\partial \mathbf{v}}{\partial t} + \rho \nabla \cdot (\mathbf{v}\mathbf{v}) = -\nabla P + \nabla \cdot (\mu \nabla \mathbf{v}) + \mathbf{b} \tag{2}$$

$$\rho \frac{\partial (c_p T)}{\partial t} + \rho \nabla \cdot (c_p T \mathbf{v}) = \nabla \cdot (\lambda \nabla T) \tag{3}$$

$$\mathbf{b} = \rho [1 - \beta_T (T - T_{\text{ref}})] \mathbf{g} \tag{4}$$

where $\mathbf{v}(u, v)$, P, T, λ, c_p, $\mathbf{g}$, ρ, β_T, T_{ref}, μ and $\mathbf{b}$ stand for velocity, pressure, temperature, thermal conductivity, specific heat, gravitational acceleration, density, coefficient of thermal expansion, reference temperature for Boussinesq approximation, viscosity and body force, respectively.

The problem at hand is solved with a strong-form local meshless numerical method [18], by a methodology that has been found a reliable and effective tool for solving complex multiphase problems [19-21]. The basic idea of the method is to use local approximations of the considered field to evaluate differential operators. The size and shape of local support, i.e. the subset of computational nodes used in the local approximation, is not restricted in any way. Although there is no restriction regarding the dimension of the system, we use the collocation approach, i.e. the number of support points is the same as the number of basis functions [22]. The temporal discretization is done through a two-level explicit time stepping.

To maintain the locality of the solver we employ the local pressure-velocity coupling [9], where instead of solving pressure correction Poisson equation, the pressure is simply corrected with the divergence of intermediate velocity. The local pressure-velocity coupling is similar to the artificial compressibility method that has been recently under intense research [23, 24] and also to the SOLA approach [25].

III. Simulation-Based Optimization

The obstacle setup is optimized by the means of evolutionary algorithm AMS-DEMO (Asynchronous Master-Slave Differential Evolution for Multi-objective Optimization) [10]. AMS-DEMO is a stochastic algorithm that works on a fixed-size set of solutions. Solutions are encoded as positions and sizes of the five obstacles (four floating point numbers per obstacle). Each solution is assessed on two criteria. First is the ratio of the domain space that is covered by obstacles, and second is the average vertical heat flux in the domain, normalized by the heat flux through an empty domain. Criteria are to be minimized, that is, minimal amount of material is to be used, and the energy losses generated by heat flux are also to be minimized.

Starting set of solutions (encoded as vectors) is randomly initialized, all further solutions are recombined from existing solutions. Optimization procedure consists of iterations over the whole population, where each solution is selected to act as a parent in recombination and crossover procedures once. Recombination creates a candidate solution, by calculating the vector difference between two randomly selected solutions, scaling it, and adding it to a so called parent solution. Crossover is then applied between the parent and the candidate, which has a predefined chance of selecting individual vector elements from either the candidate (crossover probability) or the parent (*1* – crossover probability), forming a new candidate solution. After formation, each solution is evaluated via simulation under both criteria and added to the working set of solutions (the population). Optimization procedure keeps the best solutions in population while it discards the rest. Best solutions are selected under the Pareto dominance criteria, which states that one solution is better than the other (dominates the other), when it is better under one criterion and equal or better under all other criteria. If given a pair of solutions, neither one solution dominates the other, the pair is said to be incomparable. A set of incomparable solutions, for which no known solution dominates any of them is said to be the Pareto optimal set or Pareto optimal front. The multi-objective optimization algorithm returns the Pareto optimal set as the result of optimization. If more solutions are incomparable than the population size, then the crowding distance [26] is calculated for each solution and the solutions with the lowest crowding distance are removed.

IV. Parallelization

The simulation-based optimization principle allows for two complementary parallelization principles to work together. The meshless simulator can be very efficiently parallelized for multi-core shared-memory machines, and can achieve even super-linear speedups [27]. It is less suitable for parallelization on distributed-memory systems, such as computer clusters, where the parallelization is more complex and in much less efficient. Therefore for the presented setup, the meshless simulator is limited to run on all cores of one computer but not on multiple computers.

AMS-DEMO, on the other hand, excels at minimizing the data dependencies of an evolutionary algorithm, and uses asynchronous message-passing to achieve near-linear speedups even on heterogeneous computer systems. It is therefore set up to use all the available computers but run only one instance of evaluation function – the meshless simulator – per computer.

Combining both algorithms on a cluster, AMS-DEMO efficiently feeds distributed machines with jobs, while individual machines efficiently employ all their cores for individual simulations. The result is an excellent usage of all available processing resources, subsequently enabling very high speedups. Otherwise impractical job of optimizing a complex fluid-flow problem via full simulation is thus feasible on a computer cluster.

V. Results

The experiments were run on a computer cluster, composed of 32 worker computers with a single quad-core Intel Xeon 5520 processor each. Although the computers are interconnected with 8 Gigabit Ethernet connections,

only one connection was used, with all the used computers connected to the same switch. The number of used computers varied between 1 and 32 for the experiments. Since the optimization algorithm is stochastic, each experiment was repeated 3 times to ensure the consistency of the results.

The simulations were left to converge to a steady state, characterized by the stopping criteria – temperature change between two consecutive time steps is lower than 0.01% in all nodes – or to run for a limited amount of time and then return an infeasible result, assuming the natural convection resulted in either chaotic or periodical solution [28]. The non-stationary solutions are excluded from consideration.

A. Simulation results

The simulation starts with fluid at rest and at constant temperature. Then the lower wall starts heating while the upper wall starts cooling down the surrounding fluid. The changes in temperature affect the density of the fluid resulting in a natural convection flow. In Figure 1 the steady state in the obstacle free domain is presented. The principal characteristics of flow can be seen, i.e. a global vortex, fueled by the differences between the top and bottom wall temperatures, fills the majority of the domain. Adding the obstacles obstruct the flow is obstructed (Figures 2 and 3) and consequently the convective part of the energy transport diminishes. By positioning the obstacles in an clever way, the heat flux over the domain can be greatly reduced at the relatively low cost in terms of material consumption (coverage).

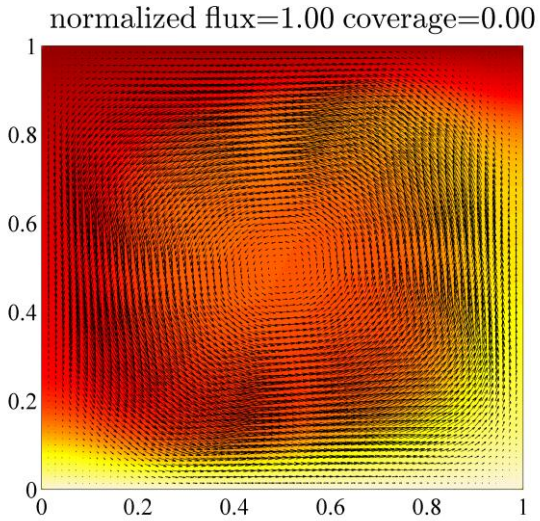

Figure 1. The temperature distribution marked by color and fluid flow marked by arrows inside the domain without obstacles.

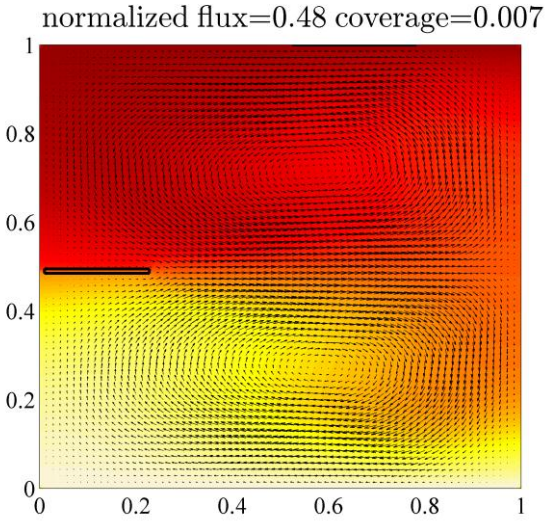

Figure 2. The temperature distribution marked by color and fluid flow marked by arrows inside the domain with obstacles positioned for the flux lowered by about half.

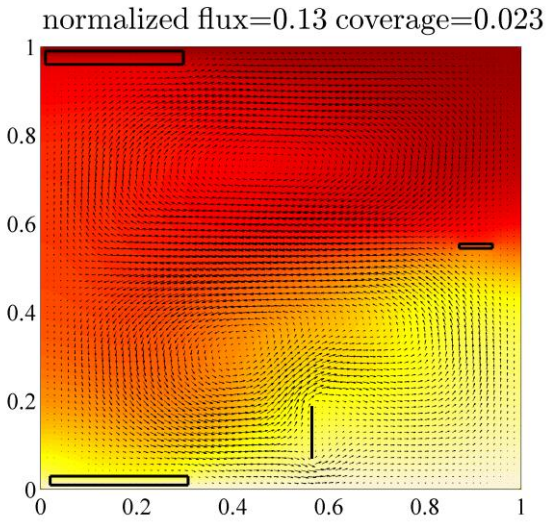

Figure 3. The temperature distribution marked by color and fluid flow marked by arrows inside the domain with obstacles positioned for the minimal flux.

B. Optimization Results

Optimization settings were selected by trying out several parameter sets and selecting the one that worked best on a computationally simplified test. The following optimization settings were selected:

- Population size of 50;
- Stopping criterion – 100.000 performed evaluations;
- Rand/1/bin scheme for differential evolution [12];
- Crossover probability 0.2;
- Scaling factor 0.5;

First, the convergence of the optimal solution set obtained by the AMS-DEMO optimization, is explored. To visualize the convergence of solutions, hypervolume indicator [12] is used to measure the quality of a set of solutions. In the given maximum number of evaluations, the non-dominated set of solutions mostly converged, as the hypervolume indicator shows in Figure 4. Although

the limits to which the solutions converged seem very different from the hypervolume plots alone, the plot of final non-dominated fronts in Figure 5 shows a different picture. A large portion of solutions – with the normalized flux of 0.2 or more – is covered quite similarly in all experiment repetitions. Only those solutions with the flux lower than 0.2 differ greatly among the runs. Half of the runs (three) do not find good solutions for low fluxes while the other half seem to have no such problems.

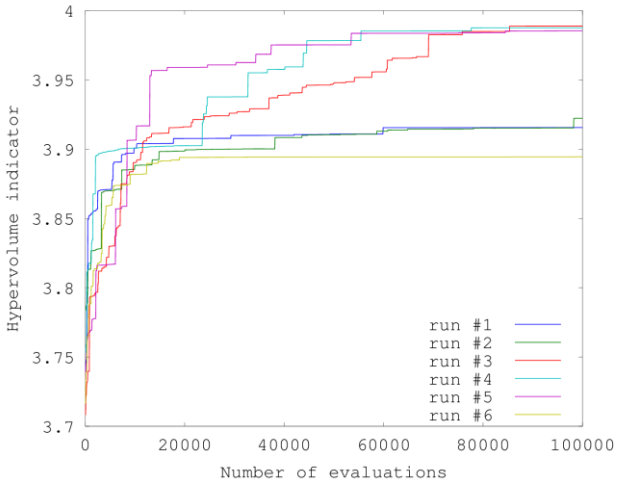

Figure 4. The hypervolume indicator for 6 test runs of the AMS-DEMO algorithm. Clearly visible are 2 sets of 3 runs, hypervolume of one set converging to clearly higher values than the other.

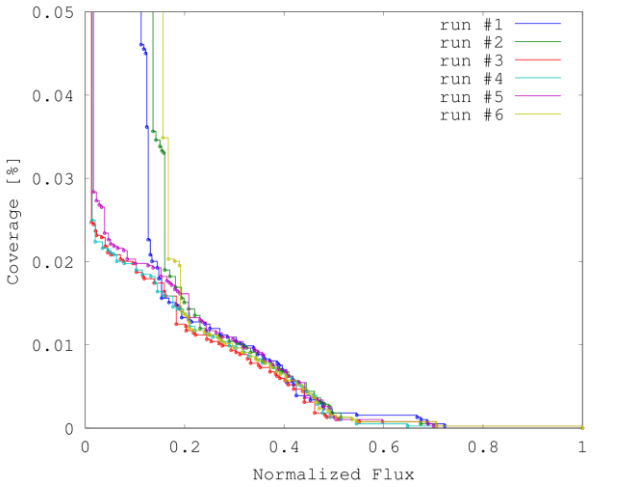

Figure 5. The final nondominated fronts of solutions (after 100.000 evaluations) for the same test runs as in Figure 4. The fronts make it clear that the runs, where hypervolume converged to lower values, had problems exploring the solutions with flux < 1.5 W/m.

Figure 6 shows a single algorithm run from another perspective – as the coverage of the dominated objective space with progressing number of performed evaluations. Dominated objective space contains all possible solutions that are dominated by at least one known solution. As can be seen from the figure, the optimizer quickly finds solutions that reduce the heat flow by about a half, but it takes a much larger number of evaluations after that for the solutions to evolve to allow only very low flow.

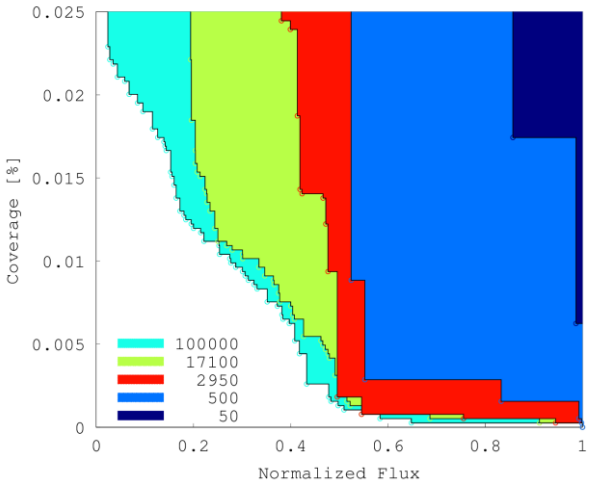

Figure 6. The evolution of the dominated objective space, for five checkpoints within a single optimization run. Checkpoints are made at after each shown number of completed evaluations. Spaces are plotted as overlapping polygons, with only their bottom-left border visible, dotted with solutions marked as colored circles. Note that theoretically, objective spaces extend to infinity at the top and right sides of graph.

We also compare the solutions according to their parameters, that is, we look at the obstacles within the domain for a single final non-dominated front of solutions in Figure 7. Patterns of the obstacle positioning are immediately visible.

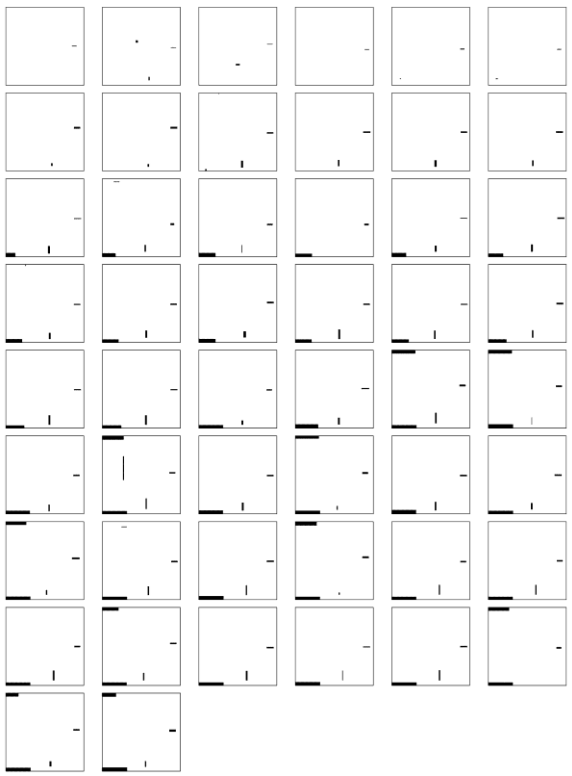

Figure 7. The nondominated solutions that were found during a single optiization run. Several patterns of obstacle positioning are clearly visible.

C. *Execution performance*

In this work, we are mostly interested in the efficiency of the parallelization, which we measure through parallel speedup. We divide parallel speedup into two categories,

one is the speedup of the simulator using all the cores of a single computer, and the other is the speedup of the optimizer, which distributes multiple simulator runs across multiple computers.

We measure the speedup of the simulator on 4 cores compared to running on a single core. For the selected domain settings of the simulator, we measure its parallel speedup on 4 cores to be 3.34. This is the speedup of the simulation, including also the serial procedures, such as reading from input, writing to output, and several other pre- and post-processing steps. For the calculation of speedup, we measure the whole execution time of the simulator executable, since the optimization procedure comprises of multiple calls to it. The simulator is otherwise capable of higher speedups, especially when longer simulations take place, reducing the relative ratio of the serial procedures. Speedups on multiple cores can, supplied an architecture with non-shared caches, even become super-linear [27], but do not in the presented case, since the non-shared caches of the used architecture are very small, compared to the number of nodes in the simulated domain.

Speedup of the optimization is much harder to calculate, since the parallel optimization does not traverse the same search space as the serial optimization does. As shown in [10], the convergence ratio of the optimization procedure is inversely correlated to the number of parallel worker processes that are executing evaluations. In the presented case, the number of parallel worker processes equals the number of computers. It is therefore expected that the convergence rate is lower for each added computer, yet measuring it exactly is much harder. In [10], it is shown that since the optimization is stochastic, the change of rate is only statistically significant when a large number of runs are made (more than 20), and when the number of parallel evaluations approaches the population size. For the presented case, since the population size is always larger than the number of computers and only a handful of repetitions are made for each test, the potential drop in the convergence rate is undetectable. Note that testing convergence rate more precisely is very time demanding, since it requires repeating the referential test on a single computer, which takes extremely long time to complete. Figure 8 shows the average parallel speedup calculated from 3 repetitions of an experiment. Since the convergence rate is probably reduced but we are not sure by how much, we only show the weak-speedup [10], which only takes the number of performed evaluations into the account, but not the convergence ratio. The jagged appearance of the graph is due to the stochastic nature of the optimization, mixed with varying-length simulation, and the limited number of repetitions.

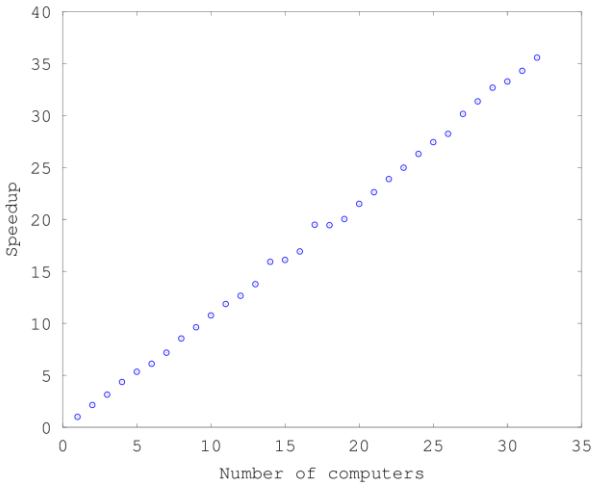

Figure 8. Weak speedup of the parallel optimization.

Altogether, the weak speedup of simulation based optimization is 123 at 32 computers with 4 cores each. The efficiency of such setup is almost ideal.

VI. CONCLUSIONS

In this paper we demonstrate parallel execution performance of coupled simulation and evolutionary optimization algorithm. From the execution point of view, the coupling bonds very well when executed on a computer cluster, with each application employing parallelization on a different hardware layer. On a 128-core cluster, a two orders of magnitude lower execution times were achieved than would be on a single core.

The execution time plays a crucial role in realistic optimization processes. For successful optimization process bigger optimization populations, as well as more dense computational nodal distributions in simulations are required. The execution time increases dramatically with refining those two parameters. In this paper we demonstrated the scalable Hybrid OpenMP/MPI parallel implementation of simulation based optimization that could be employed also to more complex optimization cases.

Abstract - The ever-increasing data production and availability in the field of bioinformatics demands a paradigm shift towards the utilization of novel solutions for efficient data storage and processing, such as the MapReduce data parallel programming model and the corresponding Apache Hadoop framework. Despite the evident potential of this model and existence of already available algorithms and applications, especially for batch processing of large data sets as in the Next Generation Sequencing analysis, bioinformatics MapReduce applications are yet to become widely adopted in the bioinformatics data analysis. We identify two prerequisites for their adaptation and utilization: (1) the ability to compose complex workflows from multiple bioinformatics MapReduce tools that will abstract technical details of how those tools are combined and executed allowing bioinformatics domain experts to focus on the analysis, and (2) the availability of accessible and flexible computing infrastructure for this type of data processing. This paper presents integration of two existing systems: Cloudgene, a bioinformatics MapReduce workflow framework, and CloudMan, a cloud manager for delivering application execution environments. Together, they enable delivery of bioinformatics MapReduce applications in the Cloud.

I. INTRODUCTION

Due to the advent of Next Generation Sequencing (NGS) [1], which can be described as the ability to decode the human genome in a massively parallel way, the amount of data in genomics has increased rapidly over the recent years. This remarkable increase in the volume of data is forcing affected institutions to consider novel approaches for storing the data and improving data analysis algorithm performances. However, for the bioinformatics domain experts without a background in computer science, utilizing these algorithms is often a challenging task because they require access to advanced compute infrastructure setup.

Well-established workflow systems in bioinformatics data analysis, such as Galaxy [2] or Taverna [3], enable scientists to access a large set of computational tools through an accessible web interface. Domain experts are able to compose complex pipelines consisting of multiple tools, while the systems keep track of all the parameter options and allow the analysis to be reproduced or shared. These systems abstract the details of how the available tools are run, and allow the domain expert to focus on the data analysis rather than the technical details required to run a tool or load the data. While these systems represent an indispensable value to today's research community, they are limited to the traditional tools (i.e., sequential, MPI, embarrassingly parallel) and traditional computational infrastructures (i.e., dedicated or cloud-based compute clusters and standalone workstations).

Given the large volume of data generated by NGS, novel algorithm parallelization methods are becoming increasingly important. One example of such a method is MapReduce [4][5], a straightforward programming model that allows efficient data parallelization. The MapReduce programing model (simply called MapReduce) allows users to process large amounts of data without understanding the underlying job execution environment complexity. In general, MapReduce provides a scalable way to parallelize large amounts of data using many inexpensive computational nodes and can simply be described as a general data-processing tool. However, not every algorithm can be efficiently parallelized with MapReduce. For example, parallelizing iterative algorithms with a lot of inter-process communication are better parallelized using the message-passing (MPI) model instead of MapReduce.

So far, the support for the MapReduce parallelization model in the field of bioinformatics has been available only on a per-tool basis (see Section 2). Such individual tools typically cover one aspect of an otherwise larger data analysis pipeline. While beneficial, these solutions require domain experts to manually compose different tools in order to ensure a complete pipeline. What is currently lacking is the ability to interactively chain multiple such tools and allow the domain experts to focus on the data analysis rather than on the mechanics of the pipeline. Although, the previously mentioned and popular workflow systems enable this level of abstraction for the traditional tools, currently they do not offer the support for the tools based on MapReduce parallelization model.

Realizing such a workflow platform requires a number of features, including: a graphical platform to integrate and execute available MapReduce tools, the option to easily reproduce experiments, the ability to extend the platform with additional or alternative tools, and a simplified access to the required computational infrastructure. In this paper, we describe each of these components and present a system that fulfils mentioned requirements. Moreover, we give an overview of bioinformatics applications that implement the

MapReduce model, some of which have already been integrated into the presented system.

II. BIOINFORMATICS MAPREDUCE APPLICATIONS

The most widely used open-source implementation of MapReduce programming model for large data batch processing is Apache Hadoop [6]. Hadoop also includes several sub-projects such as a distributed file system (HDFS) used for data storage in combination with MapReduce and Hadoop Pig, a high-level dataflow language to simplify the generation of MapReduce jobs. Within MapReduce, the user is responsible to write the *map* and *reduce* functions according to the algorithm's requirements. The MapReduce itself then achieves parallelization, data distribution, load balancing, and fault-tolerance on cluster architecture by appropriately invoking the *map* or *reduce* functions. Despite its potential, particularly for batch processing applications in bioinformatics, only a limited number of algorithms have adapted this model.

Table I gives an overview of currently available libraries and applications based on the MapReduce paradigm in the bioinformatics context. Utilizing these solutions often requires significant technical expertise, which may present a challenge for domain experts without a background in computer science or without access to the necessary MapReduce cluster architectures. To facilitate their adoption, several features that have already been delivered by graphical workflow systems such as Galaxy or Taverna, must be also fulfilled for the MapReduce applications. This includes a graphical platform to integrate and execute available MapReduce workflows, the possibility to reproduce experiments easily and a simplified access to a MapReduce cluster in private and public clouds. Libraries such as SeqPig [8] or BioPig [9] are helping biologists to use the aforementioned paradigms by abstracting the underlying Hadoop framework and providing high-level Apache Pig functions (or User Defined Functions (UDFs)). Nevertheless, a combination of algorithms to workflows, a standardized way to import/export data and an execution platform for algorithms in public or private cloud infrastructure is still lacking.

III. BIOINFORMATICS MAPREDUCE WORKFLOWS

Cloudgene [18] presents a web-based platform to create and execute workflows consisting of Hadoop MapReduce, Hadoop Pig and command line-based programs. It can be seen as an additional layer between Hadoop MapReduce and the end user that hides the complexity of the framework. Therefore, Cloudgene allows integrating different programs or algorithms within one platform that can be easily combined to workflows. The general architecture of Cloudgene is presented in Figure 1. As depicted, the client communicates with the server through a REST API. The server itself consists of three components: a workflow engine, a workflow manager, and a data manager. The workflow engine processes a previously generated workflow, specified on client side by utilizing Cloudgene's workflow definition language (WDL) and it is responsible for executeing MapReduce steps on a Hadoop cluster. Job details, including all metadata (e.g., status of a job), are analyzed by the workflow manager and then provided to the client. Finally, the data manager component has the responsibility of interacting with the Hadoop distributed file system (HDFS). In order to submit jobs or interact with HDFS, Cloudgene must be installed on a Hadoop

TABLE I. BIOINFORMATICS MAPREDUCE APPLICATIONS OVERVIEW

Area	Program	Description	Cite
Hadoop MapReduce libraries for Bioinformatics	Hadoop BAM	Manipulation of aligned next-generation sequencing data (supports BAM, SAM, FASTQ, FASTA, QSEQ, BCF, and VCF)	[7]

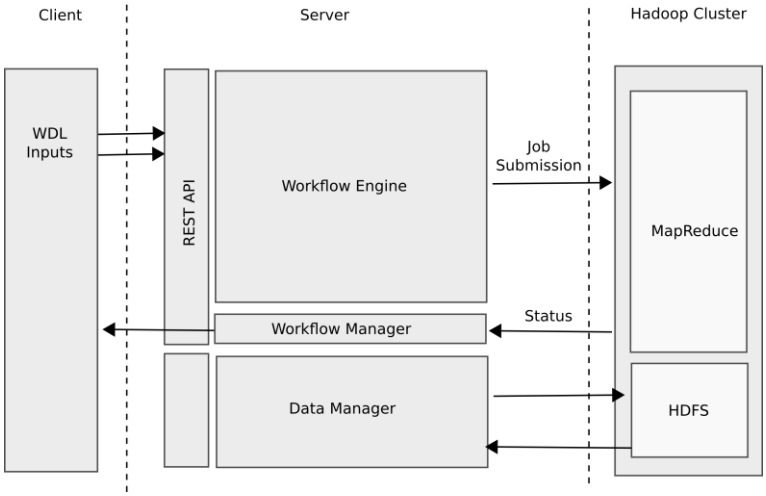

Figure 1. Cloudgene Architecture

cluster namenode.

Existing applications can be integrated into the workflow platform by utilizing Cloudgene's plugin interface. No adaptation to the source code is needed, while only a simple WDL manifest file including a header, input parameters, output parameters and the definition of the workflow itself need to be created. Figure 2. shows the integration process of CloudBurst [11] into Cloudgene. The manifest file includes all the aforementioned parameters. When launching Cloudgene, the manifest file is loaded and the client interface is automatically rendered using information from the file.

A project like Cloudgene lives from its integrated use cases. Therefore, several tools (Crossbow, MyRNA, CloudBurst and Seal) have been already integrated in Cloudgene and will be extended with additional applications in the future. Especially with Hadoop 2 (based on YARN), new algorithms utilizing other programming models than MapReduce will be most likely developed.

IV. BIOINFORMATICS MAPREDUCE WORKFLOWS IN THE CLOUD

Underlying a workflow system such as Cloudgene, functional compatible cluster architecture is a prerequisite for executing MapReduce jobs. Unfortunately, small to medium sized research institutes can hardly afford the acquirement and maintenance of own computer systems with adequate performance. A possible solution comes in the form of cloud computing, which opens the opportunity to use compute and storage resources or services on demand. Cloud computing provides the possibility to rent computer hardware from different providers (e.g., AWS, HP) and those can be used to analyze necessary datasets.

However, laborious challenges need to be addressed to make these resources available to the researchers. Specifically, although cloud computing provides a way to acquire computational resources on demand, the resources provided are either virtual machines on the Internet or specific programming libraries, which are unusable for domain experts because they require considerable configuration and ongoing management. A viable analysis solution thus needs to be accessible and deployable

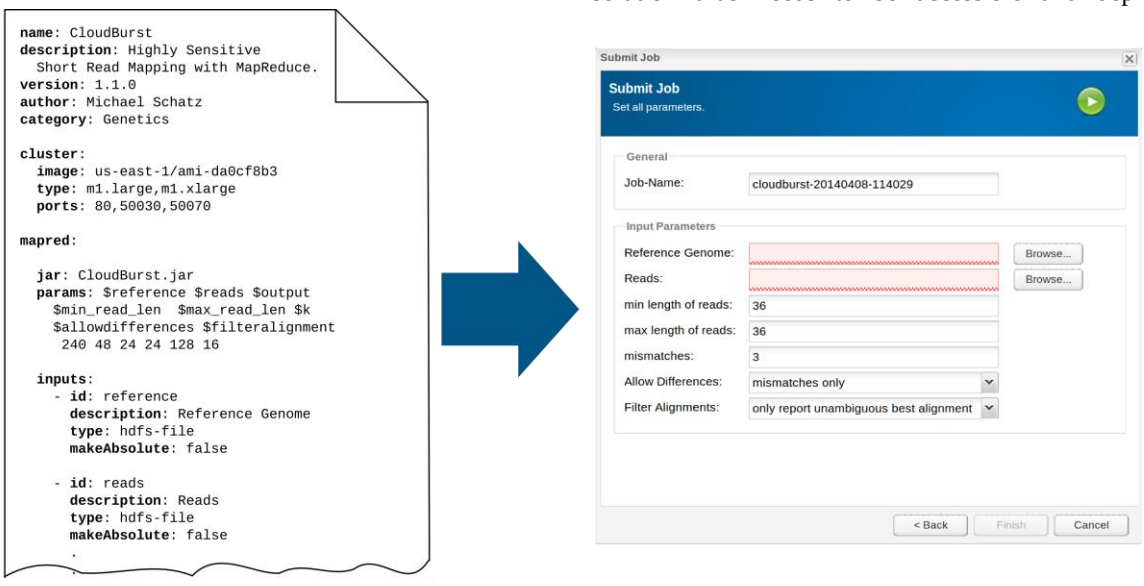

Figure 2. The integration process of CloudBurst into CloudGene

without informatics expertise while efficiently and automatically using dynamically scalable resources.

Commercial companies also offer higher-level services that provide functional MapReduce frameworks. Examples include AWS Elastic Map Reduce (EMR) service or the Rackspace Hortonworks. While these options represent a workable solution, they are also forcing the system to use a particular cloud infrastructure provider, thus locking the user down. Open source Hadoop cluster distributions, such as the Cloudera CDH or MapR M series offer alternatives to the Apache Hadoop distribution. These distributions need to be installed, configured, and managed on computational infrastructure comparable to the low-level cloud resources (i.e., virtual machines).

In response, as part of Cloudgene, Cloudgene-Cluster has been developed as a web-based system to acquire and configure a MapReduce cluster in the cloud. Cloudgene-Cluster allows the orchestration of a full working Hadoop MapReduce cluster, the installations of additional services such as Apache Pig and user specific libraries or software. On top of the cluster, Cloudgene's workflow engine is provided. The end result is that a user is able to access Cloudgene in the cloud without any limitations to an in-house cluster architecture or having to setup their own cluster. Although Cloudgene-Cluster provides an acceptable solution for providing a Hadoop cluster for the Cloudgene workflow application to utilize, its functionality is limited and, more importantly, borderlines the scope of an otherwise workflow system. Instead of developing a full-featured Hadoop manager within the workflow application, it is more beneficial to delegate resource orchestration step to another application.

To help in this regard, we have previously constructed a software system called CloudMan [18], which makes it possible to easily procure and configure a functional data analysis platform on a cloud infrastructure. The procured platform delivers a scalable cluster-in-the-cloud and a data analysis environment preconfigured with a number of applications. With its ability to be launched and managed via a web browser on a number of clouds, customized as necessary, and easily shared with collaborators, CloudMan makes it possible to readily utilize cloud resources in a research environment [20]. Notably, CloudMan provides access to the Galaxy application, preconfigured with dozens of bioinformatics tools and hundreds of gigabytes of reference genome data [21]. Beyond these user-level features exposed in a web browser, CloudMan offers a set of application execution environments: a batch scheduler environment via Sun Grid Engine (SGE), a MapReduce environment using Hadoop and SGE integration, and a support for federated job execution environment via HTCondor [22]. These enable a range of workloads to be readily executed atop procured cloud resources.

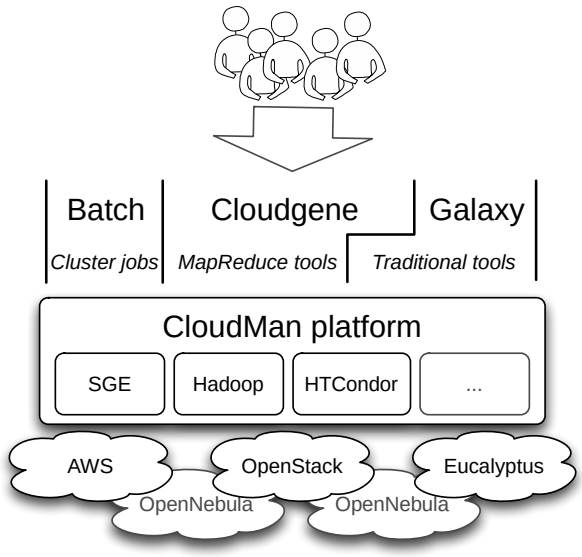

Figure 3. A layered view of the applications composing a flexible, functional tools ecosystem

Internally, CloudMan implements a service-oriented architecture that allows arbitrary tools to be described as services. Once implemented, these services are easily deployed within the CloudMan platform making the tools available (to the user or other services/tools). CloudMan further implements a service dependency management framework that allows services to specify other services as their prerequisites. This makes it suitable for wrapping the Cloudgene workflow application as a CloudMan service. Because CloudMan provides a number of cloud orchestration and scaling features as well as includes a Hadoop-based application execution environment [22], by specifying Hadoop as its prerequisite, CloudMan will ensure a functional Hadoop cluster to be available for the Cloudgene workflow application to utilize when started. This service-to-tools ecosystem is visualized in Figure 3.

Delegating the setup of the parallel compute environment to CloudMan opens the door for Cloudgene application to incorporate and make use of additional, big data, computational models (e.g., real-time data streaming). Comparable to the Hadoop environment, rather than needing to provide an implementation for provisioning the desired environment, such environment may be provided as a CloudMan service that can be simply requested by the Cloudgene application. The given environment will still need to be provided with the CloudMan platform. However, the expectation is that it will be possible to reuse much of the functionality already provided by the platform (e.g., cloud resource management), thus simplifying the service development process. Lastly, CloudMan platform already integrates a number of bioinformatics tools and a workflow system (Galaxy). As mentioned, Galaxy implements an execution model for the running jobs via the traditional batch scheduler. Adding Cloudgene into the platform, as a workflow system for MapReduce type applications, presents an opportunity to integrate the two job execution models.

V. CONCLUSION

The MapReduce model has proven to be a simple but effective programming model for implementing algorithms for the analysis of large datasets on large clusters and is thus very well suited for the Cloud. However, the usage of this paradigm is still limited to a small number of highly qualified domain experts.

Improving accessibility of solutions that utilize this concept is one of the first steps in democratizing access to the technology and reaping its benefits. In this paper, we summarize a number of software solutions that exist in the domain of bioinformatics that utilize the MapReduce programming model. In order to facilitate their utilization and integration, we then describe Cloudgene as a graphical workflow engine that allows these existing solutions to be easily chained together. This facilitates development of open-ended analyses and promotes acceptance of the technology. Finally, we identify a number of technical issues that still exist when trying to utilize this technology in the Cloud context and present an overview of a solution to overcome a number of those.

Microspheres as sensors to measure instant refractive index variation during phase transition of low melting substances

Hong-Bo Fu, Yao-Xiong Huang*
Department of Biomedical Engineering, Ji Nan University, Guang Zhou, China
tyxhuang@jnu.edu.cn

Abstract- Microspheres were used as sensors to perform real time in situ accurate measurement on the instantaneous refractive index / density variation during the liquid-solid phase transition of low melting substances. The measurements were carried by immersing microspheres in the substances in liquid state and analyzing their phase-contrast microscopic images during the phase transition from liquid to solid states. In this paper, the principle of the method and the experiments of using the method for different applications will be described.

I. Introduction

Understanding the phase behavior of low melting substances such as paraffin wax, agar gel, and polystyrene are of industrial importance. However the present methods have limitations to monitor the instantaneous process of the phase transition of the materials, especially unable to detect if the substances are spatially homogeneous or not during the phase transition. Considering microspheres can be used as a powerful sensory tool for different purposes [1,2] [3]. Here we describe a simple, innovative and accurate method for the measurement of the refractive index (RI) variation during the phase transition of some low melting point substances. RI was determined simply by immersing microspheres with known RI in the substances in liquid state and analyzing their phase-contrast microscopic images. Since the refractive index of a substance is a function of its density and other thermodynamic parameters, this method can be also used for density variation and other parameters monitoring during the phase transition of the substances.

II. Principle

When a microsphere with a RI of n_2 is immersed in a medium of n_1 ($n_2 > n_1$) and illuminated by a plane light wave propagating along its optical axis, due to the refraction effect, no parallel paraxial ray incident on the sphere's first surface will emerge to the periphery of its second surface, thus a dark ring appears in the image of the microsphere. The ratio between the radius of the central bright spot in the image of the sphere *r*, and the radius of the sphere *R*, is found to have a relation with n_2 and n_1 as follows[3]:

$$n_1 = n_2\left(\frac{3}{8}\sqrt[3]{X^2+\sqrt{X^4-X^6}}+\frac{3X^2}{8\sqrt[3]{X^2+\sqrt{X^4-X^6}}}+\frac{1}{4}\right)^{\frac{1}{2}} \quad (1)$$

Where $X = r/R$. Therefore, by using a microsphere with known refractive index n_2 and measuring both *r* and *R* , one can easily obtain the refractive index of its surrounding medium n_1.

III. Experimental

Several low melting point substances including paraffin wax, agar gel, and polystyrene were tested using the technique. The substances were set at the temperatures higher than their melting points at first, so all of them were in liquid states. Then some silica microspheres with diameters of 50-150 μm were immersed into the substances. The phase contrast images of the spheres were taken at a

frame rate of 25 f/s using a digital camera set in a phase contrast microscope as the temperature was lower down during their liquid-solid phase transition. Thereafter the values of *r* and *R* were measured and the variation of their RI during the phase transition was obtained by the calculation using equation 1.

IV. Results and discussion

As reported previously, the technique has a satisfied accuracy in determining RI of media. The standard deviation of the measurement depends on the precision of the image size measurement and is estimated to be 0.002–0.004 when using a 1M pixels camera for imaging. It can be improved by increasing the resolution of the imaging camera and using super-resolution method for measuring both *r* and *R* to as small as 10^{-6} [3]. By recording images with a video rate of 25frame/s, our technique was proved to be able to monitor the dynamic process of the liquid-solid phase transitions for the three substances. Fig.1 shows the typical images of the microspheres in the three substances when they had transited into solid states. Fig.2 gives the variation of the RI of paraffin wax vs. temperature during the phase transition. We can see that the technique can monitor the instantaneous variation of the material's properties. Since optical refraction takes place at the speed of light, the instant variation of the RI in the surrounding medium of a microsphere can immediately induce a change in the radius *r* of the image of the sphere. Therefore, by using a high speed camera for imaging, our technique can catch up very rapid RI/concentration variation, thus it is able to determine the phase transition point very accurately (see fig.2). On the other hand, as we can see in figure 1 that, by immersing several microspheres at different locations, we can simultaneously determine the RI/density distribution in various sites of the substances. So by this technique, one can also determine if the substances are spatially homogeneous or not during the phase transition. Compared with the other techniques, our method is not only of the advantages of simplicity, accuracy and fast response, but also there is almost no further interference on the sample after inserting the microsphere into it. The only needed operation is to capture the image at any desired moment, so easy and rapid real time in situ monitoring analysis on phase transition is possible. Furthermore, it can determine the instantaneous variation of the sample properties in micro-regions as small as several ten microns.

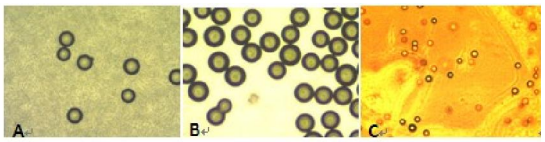

Figure1. The phase contrast images of microspheres in: (A) paraffin wax, (B) agar gel, and (C) polystyrene.

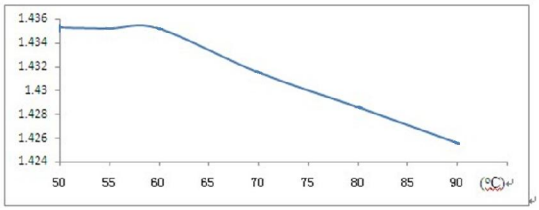

Figure2. The variation of RI vs. temperature observed using the microsphere method on paraffin wax.

V. Conclusion

The technique described here is an ideal one for many applications in which local RI/density at different sites in substances should be monitored from time to time, and even phase transition or other critical phenomena may take place. It can be applied to many fields of studies including material analysis, environmental monitoring, pharmaceutical and specialty chemical industries.

***Abstract*—Cloud Computing is a technology that moves the World forward. It helps the mobile users to run compute demanding applications on a remote cloud and access the results on their mobile devices. Usual processing of the cloud based applications is realized via a WAN connection. However, this approach is inefficient for real-time applications due to relatively huge WAN latency. Cloudlets solve this problem by exploiting the benefits of Cloud Computing without being WAN-limited. The cloudlet is a small cloud located near the mobile user. Cloudlets can perform the same processing tasks as a remote cloud by using Virtual Machines (VMs).**

In this paper we introduce the cloudlet approach to design a Multilingual Dictionary, which is a Cloudlet based application specifically developed to be processed on a near cloudlet as well as on a distant cloud. It will be used for translating words entered through a mobile device by using a VM deployment on the cloud/cloudlet and displaying the results on the mobile device. The initial version will support translation between two languages. Afterwards, it will be expanded to support multilingual translation.

***Index Terms*—Cloud Computing, Virtualization, Cloudlet, Dictionary, Virtual Machines**

I. Introduction

Mobile devices are becoming an essential part of everyday human life by being the most important and most proper communication tool. They have brought various functionalities to our fingertips. Mobile users can use mobile applications (iPhone apps, Google apps, Windows Phone apps, etc.) executing them on their mobile devices. However, mobile devices suffer from resource scarcity. They have limited resources and because of that, most of today's applications cannot be executed on the mobile device.

Alternative methods have been analyzed to obtain more resources and allow mobile users to use a wide variety of mobile applications [1],[2]. One of the alternative methods is using a cloud [3]. Cloud enables mobile users to use its resources and run applications, which provides mobile users the opportunity of running resource-demanding applications. It acts as an agent between the original providers and the mobile device [4].

Cloud resources allows service providers and users to adjust their computing capacity depending on how much is needed at a given time or given task. However, sometimes, the usage of cloud resources to execute mobile application can be a bad solution. Clouds are located far away from the mobile user and WAN delays can make this approach inefficient for real time applications. To solve this issue Satyanarayanan introduced the concept of cloudlets as a small cloud located near the mobile user [5].

A cloudlet is a trusted, resource rich computer, which can do the same tasks as a distant cloud [5]. This technology concept enables the mobile users to utilize nearby computers to obtain the benefits of cloud computing without WAN delays, congestions, failures. With this approach it is much easier to achieve better application processing due to the cloudlet's proximity.

The focus of this article is to measure the processing time and execution of a multilingual dictionary application running on a mobile device. The application will use cloud or cloudlet resources in order to translate the words and display the results back to the mobile device. Execution times of the word translation using cloud or cloudlet will be compared and conclusion will be made at the end of the article. In Section II we explain the reasons for research in this field, and the motivation for this article. Section III gives some related work done in this field. The use of mobile cloud computing as augmented execution is explained in Section IV. The architecture of the new concept is introduced in Section V including description of the augmentation process and some implementation details. Finally, the last sections are devoted to discussion about the new concept and conclusions of the implementation.

II. Motivation

With today's growth of the mobile market, there are lot applications which cannot be processed using only the mobile device. Some of the applications need additional resources in order to run smoothly [7], [8], [9]. For example, a lot of mobile users play games, taking pictures, upload videos, manage their personal data, such as Dropbox [10], Docusign [11], etc.

Mobile devices are not capable to run such application on their own. Additional resource should have been used in order for execution of these mobile applications to be faster. Using this starting point, the introduction of clouds or cloudlets is of huge help. There are numerous applications developed to use external resources for processing and present the result back on the mobile device. LinkedIn [12], Boomerang [13], SlideRocket [14], TripIt [15], UEFA.com [16], Zomato [17],

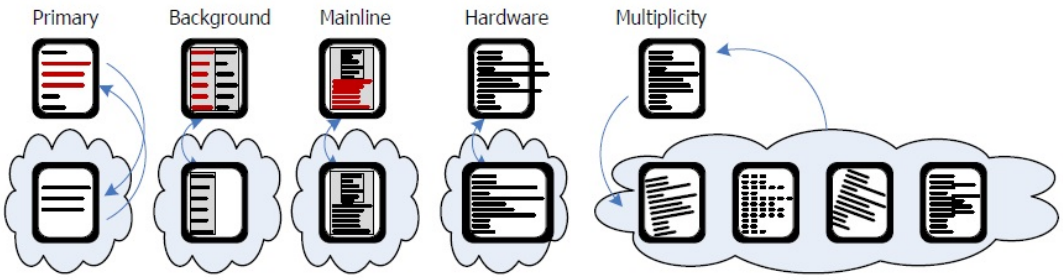

Fig. 1. Categories of Augmented Execution [6]

or Dropbox [10] are just some of the applications which are using cloud or cloudlet for execution.

The main idea of this article is to develop a multilingual dictionary which can use a cloud and cloudlet for processing. The user can enter a word for translation and view the corresponding meaning of the word in another language. Mobile device will be used to enter the words and see the results. Computing (translation) will be done on an external resource, cloud or cloudlet.

III. Related work

There are lots of real time applications which are using cloud or cloudlets to process big data. Most of them are applications for Weather forecast [18], Betting [19], Poker games [20], multilingual dictionaries, etc.

Remote execution of resource intensive applications for resource poor hardware is a well known approach in mobile computing. All remote execution applications run simple tasks on the mobile device and computation intensive tasks at the remote server. There are several research papers on saving power via remote execution, such as Rudenko et al. [21], Flinn et al. [22] and Satyanarayanan et al. [22].

Cyber foraging uses surrogates (untrusted and unmanaged public machines) opportunistically to improve the performance of mobile devices [23]. For example, both data staging and Slingshot use surrogates. In particular, Slingshot [24] creates a secondary replica of a home server at nearby surrogates. ISR provides an ability to suspend on one machine and resume on another machine by storing virtual machine images in a distributed storage system [6].

Coign automatically partitions a distributed application composed of Microsoft COM components. Few students from International Institute of Information Technology Bangalore have made a multilingual dictionary which can use cloudlet for processing and translation of the words [25]. Also Achanta et al. present a model of cloudlet-based multilingual dictionaries [26]. They are using a VM installed on the cloudlet to initiate the dictionary and then use it over a wireless network. Our approach is based on their ideas to realize the solution.

IV. The Using of Mobile Cloud Computing in Augmented Execution

Mobile cloud computing means that processing of the mobile based application will be done on a portable device. Mobile devices can execute resource intensive applications on a distant high performance computer server and support the client user interactions with application over the Internet. This may lead to increased WAN latencies due to distance between the mobile user and the remote cloud. WAN latency is the most important parameter for real time applications, since they can affect usability in a critical path of user interaction by degrading the crispness of system response even for trivial applications.

Thousands of users of the same applications access the cloud for processing and therefore the cloud-based approach can become inefficient. Solution of this problem is using cloudlets and doing the processing of the application on it. In the cloudlet-based approach, the application will first try to access the nearby cloudlet and realize the required processing. If there is no cloudlet nearby, the processing will be done on the cloud. In the worst case scenario, the mobile device should use its own resources to process the application and present the results to the user.

By using this approach, we will develop a mobile application solution that will be processed in a cloudlet. In case there is no cloudlet nearby, this task will be redirected on a remote cloud.

A. Augmented Execution

First of all we need to explain what augmented execution is in order to realize why external resources are required to overcome smartphones capabilities. Augmented execution refers to a technique used to overcome the limitations of smartphones in terms of computation, memory and battery [6]. Chun and Maniatis [6] propose an architecture which is seamlessly offloading execution from smartphones to external computational infrastructure where cloned replica of the smartphone's software is running. This provides the illusion that the mobile user has a more powerful device than they actually have.

The mobile device hosts computation and memory demanding applications. Some of the computation tasks can be offloaded to the cloud where cloned system image of the mobile device is running. Augmentation for asynchronous operations can operate in the background, while for synchronous operations it can be performed by blocking progress on the smartphone until the results arrives from the clone in the cloud. For concurrent operations, augmentation can also be

concurrent in the clone cloud or even speculative with ability to undo the operation on the smartphone according to the result from the clone.

Figure 1 shows five categories of possible augmented execution for mobile phones [6]. The *primary functionality* refers to functions where computer hungry applications are automatically split, user interface and low processing is done at the phone side, while high computation is offloaded to the infrastructure synchronously. The *Background functionality* does not need to interact with the users in a short time scale. This is functionality which typically happens in the background. Entire processes can be marked by the user or automatically interfered as background processes and migrated to the infrastructure. In this case, offloaded functionality can take the role of a virtual client. Even when the smartphone is turned off, background tasks continue to run. Later when the smartphone turns on, it can synchronize its state with the infrastructure [6].

Mainline functionality can be placed between primary and background augmentation. Here, the user may opt to run a particular application in a wrapped fashion, altering the method of its execution but not its semantics. Unlike background augmentation, mainline augmentation is interspersed in the execution of the application. *Hardware augmentation* compensates for fundamental weaknesses of the smartphone platform, such as memory caps or other constraints, and hardware peculiarities. Using faster hardware significant savings can be observed; faster processor and much more RAM memory will reduce the costs and make execution faster. The last category is augmentation through *multiplicity*. It uses multiple copies of system images executed in different ways. This approach can help running data parallel applications. Also this can allow applications to evaluate all possible choices for a decision before making that decision. With this functionality much energy is wasted at the infrastructure side to save a little bit on the mobile device [6].

Similar approach for using VM technologies to execute computation extensive software from mobile device to external infrastructure is explained by Satyanarayanan [5].

B. Virtual Machine Synthesis

Two different approaches can deliver Virtual Machine state to infrastructure. The first one is VM migration where an already executing VM is suspended, its processor, disk and memory state are transferred and finally VM execution is resumed at the destination from the exact point of suspension [5].

Similar approach of using VM technologies executing computation intensive software from mobile device is by using Dynamic VM Synthesis [5]. In the dynamic VM synthesis architecture, a mobile user exploits VMs to instantiate a customized service software on a nearby cloudlet and uses the service over Wi-Fi. In this case, a VM is dynamically delivered to the infrastructure. Mobile devices request small VMs overlay from the nearby cloudlet infrastructure which already owns the base VM from which this overlay was derived as shown on Figure 2 [27].

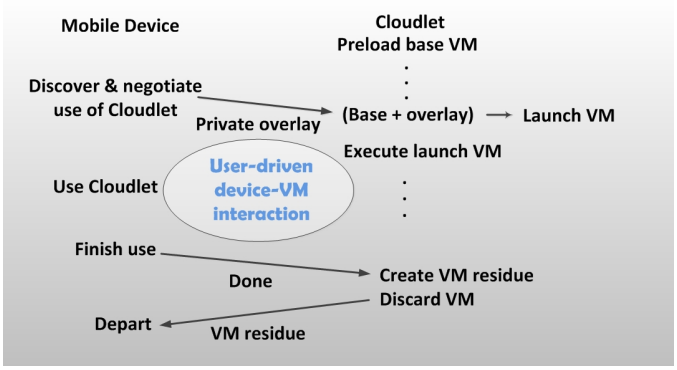

Fig. 2. Dynamic VM synthesis

The infrastructure applies the overlay to the base to derive the VM which starts executing in the precise space in which it was suspended. Our solution of a multilingual dictionary application is based on a cloudlet, which is a server that receives entered words from a mobile device, performs translation and returns the output for word synthesis. If the cloudlet is a cluster, VM's could be rapidly cloned to exploit parallelism.

The Dynamic VM synthesis process [26] is presented on Figure 3. The solution consists of the following:

- A small overlay VM is presented in the mobile device. A base VM is present in the cloudlet infrastructure.
- The dictionary overlay VM from the mobile device is delivered to the cloudlet where base VM is already presented?
- The cloudlet infrastructure applies the dictionary overlay VM to the base VM in order to launch VM.
- Launch VM command using cloudlet execute the application in the exact state from which the overlay was derived.
- The software in the Launch VM is a server that receives the input text from the mobile device, performs the translation and returns results to the mobile device.
- After the application is completed, the result is sent back to the mobile device.

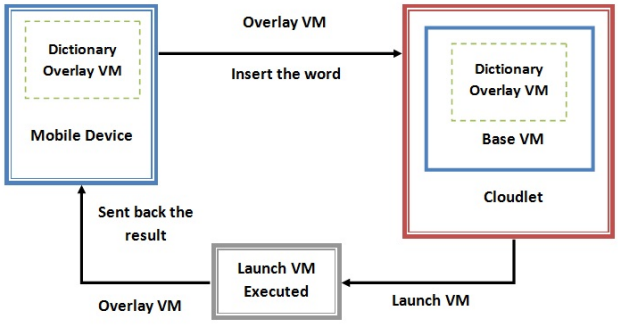

Fig. 3. Dictionary Dynamic VM synthesis diagram

C. Virtual Machine Overlay Creation

To develop this application we intend to use a Virtual Box, that is hosted Virtual Machine Manager for Linux. The base VM hosts a minimally configured guest OS.

The process of VM Creation [26] is presented in Figure 4 and is explained by the following actions:

- The tool creates VM overlays using base VM and executes install-script in the guest OS and the result is VM that has been configured for use by the mobile device.
- Next, the tool executes resume-script in order guest OS to launch the desired application and bring it to a state ready for user interaction. This VM is called "Launch VM" and is suspended. It can be resumed at runtime without delays of application launch.
- After creating the "Launch VM", the tool differentiate its memory and disk images with those of base VM to obtain the VM overlay.
- The last step is to compress and encrypt this overlay.

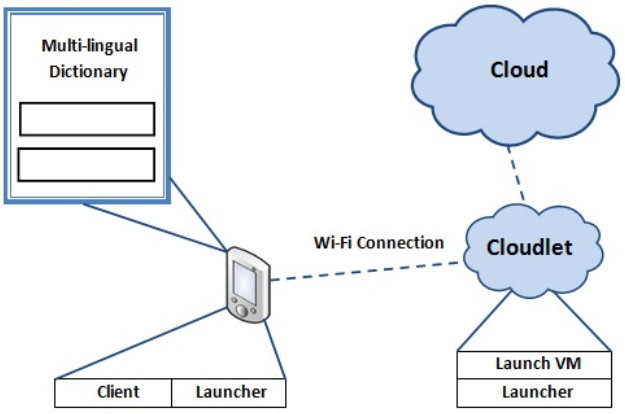

Fig. 4. Dictionary Virtual Machine Overlay Creation Algorithm

A TCP connection between the device and cloudlet is established after the creation of a VM. It is used for sending the input requests and receiving the results. After the mobile device sends the input request and the VM overlay, the cloudlet executes a script and applies the overlay to the base VM. The suspended VM is then launched and is ready to provide services to the mobile device. Once the suspended VM is in running state, the application is executed and the output is sent back to the mobile device.

V. Architecture of a Cloudlet Solution

In this section we explain the architecture of the newly proposed cloudlet-based multilingual dictionary solution.

A. Modeling the augmentation process

The augmentation process of the multilingual dictionary application is modeled by using an external cloudlet infrastructure. The new proposed model builds on an idea to augment smartphone application by utilizing heterogeneous computing

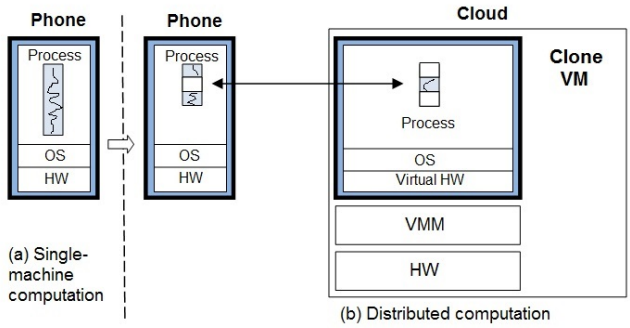

Fig. 5. Transformation from single to distributed execution model

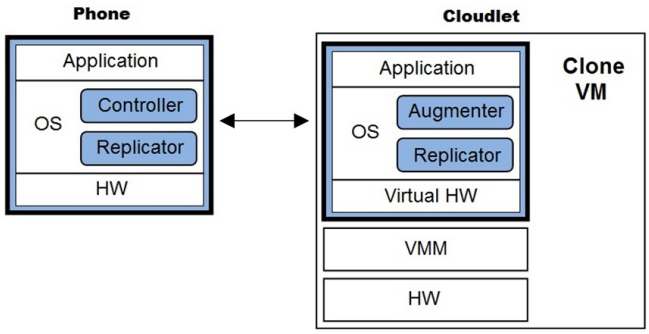

Fig. 6. High-level architecture of a cloudlet solution

platforms through cloning and computing transformation [26]. To do that, the system semi automatically transforms a single machine execution into a distributed execution where resource intensive execution is run in powerful clones. Figure 5 illustrates the high-level system model transformation from a single execution model into a distributed execution model.

Figure 6 presents our solution for augmented execution of the multilingual dictionary. It is performed in the following four steps:

- First clone of the smartphone is created within the cloud/cloudlet.
- The state of the primary phone and the cloud/cloudlet is synchronized periodically or on-demand.
- The whole application or parts of it are executed in the clone, on request or automatically.
- Results of the execution are sent back from the clone to the smartphone.

B. High level architecture model

The high-level view of architecture for the cloudlet-based multilingual dictionary is presented on Figure 6. All system components are running inside the operation system.

The Replicator is synchronizing the changes in phone software and state of the clone. Controller running in the smartphone invokes an augmented execution and returning its results back to the mobile device. While coordinating

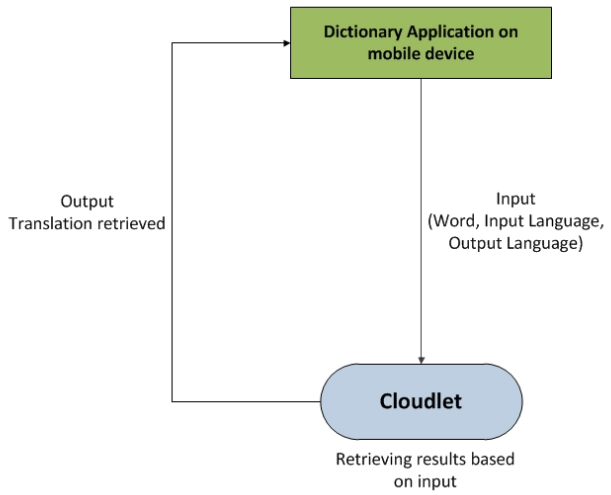

Fig. 7. Workflow Concept of the Cloudlet-based Multilingual Dictionary

the augmentation it interacts with the Replicator in order to synchronize the states. Augmenter running in the clone manages the local execution and returns the results.

C. Implementation Details

This Section contains implementation details on how the dictionary application will run on a mobile device. The user should enter the following input parameters: Input language in which the word will be entered, Output language to which the word has to be translated and the word which has to be retrieved, as presented in Fig. 7.

After the word is inserted and all other input parameters are specified, the cloudlet parses the data of the input language dictionary, looking in the database for specific input word and retrieves the correct meaning in the output language specified. Once the correct meaning is retrieved, it is sent back to the mobile device.

D. Client Cloudlet Interaction

Interaction between the client and the cloudlet is the main task. First step in this interaction is the request from the client to the cloudlet. After receiving the cloudlet's response, the client establishes the connection with it. Each client has a copy of the cloudlet configuration in the form of a patch file.

After the connection is established the cloudlet checks if it has the correct file. If it does, than the client does not have to send the file. Otherwise the client sends the patch file. After this, client sends the input file, containing input language, output language and the word for translation. When this file is copied to the guest OS, the execution starts and runs the dictionary application at the guest OS.

The translated word generated by the application is written as an output file and sent back to the client (mobile device).

VI. Discussion

The benefit of the cloudlet-based solution for the multilingual dictionary is performance based. We have argued that the current approach of using the mobile phone resources for a multilingual dictionary is relatively slow due to limited mobile phone resources. The cloud based approach using WAN connection is expected to be better and the cloudlet based solution will eventually offer the best performance.

Cloudlet approach is cost effective compared to cloud services. Resources required to establish a connection to the cloudlet are less compared to cloud. Application execution on the mobile device consumes a lot of the mobile's device resources (battery, memory, processing power). Also, a cloudlet uses Intranet or wi-fi which is free and available locally, compared to the distant cloud which requires an Internet connection.

Most of the people today that need translation of words or phrases are using web based dictionaries. We have realized user requirements research and performance analysis concluding about the average translation time to translate a word or phrase. Use of a mobile device with a wi-fi connection increases the average translation time to a double value of the average translation time.

According to the average response time delays for clouds and cloudlets we strongly believe that our approach will speedup the process and achieve better results. The expectations of average translation times for a word or phrase to be at most half the average translation time. This will be of great benefit for people who needs fast translation of the word and minor use of mobile's device resources.

Our solution is based on ideas introduced by Achanta et al. [26]. However, our solution does not plan to use datasets as in the Achanta's solution. To speed up the process of translation we introduce a table-based approach with predefined values for words and phrases with their corresponding translation. This approach saves time due to the time demanding operations that install and use a certain number of datasets on the cloudlet.

VII. Conclusion and Future work

Cloudlets are becoming the most important part in mobile application execution. With their use the user can execute resource rich applications without using mobile's device resources. In this paper we give a solution design of cloudlet based application, its architecture, execution and creation.

We explained details of the new approach to build a cloudlet based mobile application for multilingual dictionary by using the dynamic VM synthesis approach. The new model is presented with description of the VM overlay creation algorithm and the workflow concept. The described overall system architecture builds on the realization of augmenter and replicator modules for the cloudlet solution and the real multilingual dictionary application.

In the future we plan to deploy these solution for Android based mobile devices and compute execution times in both cases, with using cloudlet and cloud for execution of the application. From the results we hope that we can verify our theory that cloudlet offers better execution environment than the cloud and that running application on the cloudlet is much faster than running it on the cloud.

Mjolnirr: private PaaS as distributed computing evolution

D.I. Savchenko* and G.I. Radchenko*
*South Ural State University, Chelyabinsk, Russia
dmitry@mjolnirr.com, radchenkogi@susu.ac.ru

Abstract - Cloud computing became very popular during the last few decades. It provides convenient access to remote computing resources for individual users and organizations. However, there are still security issues arise if the private data is transmitted to the public cloud for processing. This issue can be resolved with private cloud systems. In this paper, we propose the design and implementation of a Mjolnirr private cloud platform for development of the private PaaS cloud systems. It provides infrastructure for cloud applications development, including software developer kit and message brokering system. Proposed cloud platform can be deployed on resources of a distributed computing system, including idling resources of personal computers. For a developer, a Mjolnirr application is represented as a collection of independent components communicating by a message exchange communication protocol.

Keywords - PaaS, Mjolnirr, Cloud computing, distributed system, message passing

I. INTRODUCTION

Cloud computing became very popular computing paradigm during the last decade [15], [25]. This approach to resource provisioning offers convenient access to computing resources, which makes it easy to use them for custom services development.

Before the introduction of the cloud-computing concept, there was an another distributed computing concept called "grid computing" [11]. It is still used by the scientific community to solve extra-large and resource-intensive scientific tasks. The name "grid" originated from the metaphor of the power grid. However, unlike electricity devices, integration of new resources to the grid-computing environment is not trivial.

Meanwhile, PaaS (Platform as a Service) [9] solutions provide the ability to create custom applications [6]. However, the problem is that the most PaaS solutions are deployed on remote hosting platforms. The owner of the application may not know exactly where his information is stored, as well as he cannot be sure about the safety and security of his information [20]. These issues might be solved by the private PaaS platform [10].

In this paper, we propose the design and implementation of the private cloud platform called "Mjolnirr". There are several solutions available now that provide private IaaS (VMWare Private Cloud, OpenStack) and PaaS (Yandex Cocaine, AppFog, Stackato) levels of service. Comparing to these solutions, main features of our approach are integrated messaging subsystem, flexible workload management and native UNICORE [24] grid environment integration module.

This paper is organized as follows. In section II we present the concept of the Mjolnirr cloud platform. In section III we describe the results of the analysis of existing cloud platforms and compare them with the Mjolnirr platform. In section IV we describe the architecture of the Mjolnirr platform and the component communication protocol. In section V we describe the implementation of the Mjolnirr platform and demonstrate the process of custom applications development. In section VI we describe the platform performance evaluation. In section VII we summarize the results of our research and further research directions.

II. MJOLNIRR PLATFORM CONCEPT

The Mjolnirr private cloud platform provides development of a Java-based private PaaS cloud infrastructure. A Java application or library can be implemented as a Mjolnirr-based service. The Mjolnirr platform provides infrastructure for cloud applications development, including software developer kit, message-brokering system. For a developer, an Mjolnirr application is represented as a collection of independent components communicating by message exchange. This approach allows development of flexible and scalable cloud applications.

Mjolnirr also provide integration with the UNICORE grid environment through the DiVTB [18] platform. The DiVTB (Distributed Virtual Test Bed) platform provides a task-oriented approach for solving specific classes of problems in computer-aided engineering through resources supplied by grid computing environments. Thus, Mjolnirr can be used to provide infrastructure both for scientific projects with the grid systems and in a business infrastructure.

During our research, we should:

- analyze technologies of cloud systems and private cloud platforms development;
- develop Mjolnirr platform architecture;

The reported study was partially supported by Grant Fund for Assistance to Small Innovative Enterprises in Science and Technology: "UMNIK" Programme, research project No. №0000829 and by RFBR, research project No. 14-07-00420-a.

- implement Mjolnirr platform;
- evaluate the performance and scalability of the Mjolnirr platform.

III. ANALYSIS OF EXISTING SOLUTIONS

An investigation shows that C-level executives and IT managers in enterprise companies have issues with integration of cloud computing in their data processing [5]. One of the most serious concerns is the possibility of data breaches. A cloud provider can give access to the company's private data (accidentally or intentionally) or may bring harm to the data owner [14], [21].

For the prevention of such privacy threats, it is possible to use the encryption of data that is stored in the cloud [19], [22]. However, this approach is effective only when cloud is used just for storage. If the data is processed in the cloud, it become available decrypted in the memory of the host, where the processing occurs [4]. In addition to this drawback, the owner of the data does not control the location of his virtual machine, so it can be moved to the physical computer with the virtual machine that contains malware. It may cause the ban of the virtual machine or forfeiture of a computer containing these virtual machines.

Nowadays, there are two ways to ensure the data security in the cloud. The first way is called "trusted computing". It ensures security of virtual machines in the cloud [7]. Nevertheless, your data cannot be completely safe. For example, in present IaaS clouds, the virtual machine can be dynamically moved to the other host, but the concept of trusted computing provides security only for virtual machines running on the same host. Otherwise, the concept of TCCP (Trusted Cloud Computing Platform) [12] solves this problem by creating the safe environment for running virtual machines. In fact, neither of these approaches solves the problem of VMs placement on the same host with a malicious VM.

Another way to deal with the security issues is to deploy the cloud infrastructure on the private hardware. In this case, the owners themselves will protect all the data. However, buying and maintaining of the hardware is more expensive than rent of computing resources [9], [10].

The simplest way is to create a private cloud system, and there are several different products existing in this area. They can be divided into two categories according to the level of abstraction – infrastructure (IaaS) solutions (e.g. OpenStack and VMWare Private Cloud), and platform (PaaS) solutions (e.g. Yandex Cocaine, AppFog and Stackato).

OpenStack [17] is a popular open source package for private cloud systems provision. It provides infrastructure layer based on virtual machines abstraction. Software developers should install web servers, load balancers and other specific services manually. It offers great opportunities, but IaaS maintenance is expensive. VMWare Private Cloud [16] also provides IaaS-level solution, but on a commercial basis. VMWare Private Cloud offers advanced virtualization capabilities, as well as, the commercial support.

Yandex Cocaine and AppFog platforms provide the ability to create private PaaS solutions based on application containers [2], [3]. These platforms allow development of a "Heroku-like" [13] application hosting. They provide a number of built-in modules and a server infrastructure. Stackato [1] provides all advantages of the mentioned solutions and provide local application store. Some of them use Docker [8] containers to provide isolated environment to the applications, but Docker can be used only on Linux hosts. However, all of the above solutions consider custom applications as a monolith and ignore its internal structure that is why it is not possible to automatically and effectively balance the load on the individual subsystems applications. In addition to this drawback, none of these solutions considers end-user workstations as computing resources providers.

We decided to create a Mjolnirr cloud platform, which solves these problems as follows:

- Using popular open source libraries and programming languages, as well as the opportunity to work not only on the server platform, but also on the

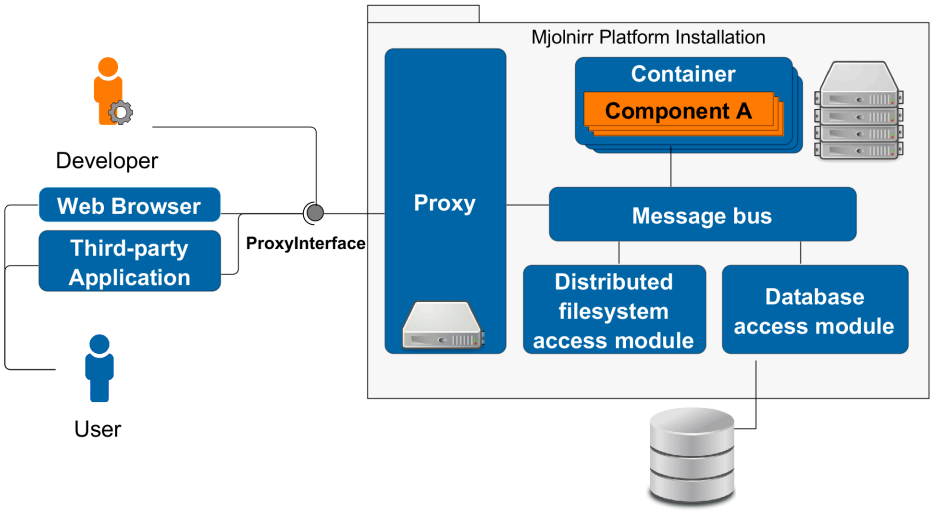

Figure 1: Mjolnirr platform architecture

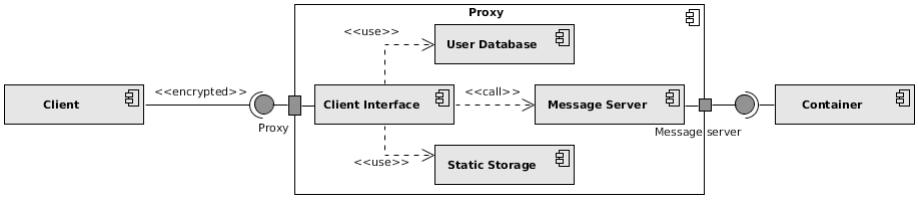

Figure 2: Mjolnirr proxy architecture

personal computers, using idling resources of the computer system, will provide cost reduction.

- Using popular programming languages, developer tools and SDK will provide ease of application development.

- Integration of new resources ease will be provided by the application architecture modularity and custom components reusability.

IV. ARCHITECTURE

Mjolnirr platform architecture is presented at the figure 1. The Mjolnirr platform consists of the following components.

- *Proxy* provides access to the cloud system for the external clients and manages the communication between cloud application components. Proxy is the only component that accessible from the external network;

- *Containers* are deployed on computing nodes and responsible for hosting of cloud applications components and message transmission. It can be deployed both on the personal computer and on the nodes of dedicated server;

- *Components* are custom applications, created to run in cloud environment. Each component has a unique name. UI components (applications) are multi-page applications, it means that applications has different representations for different actions, like different web-pages of one web-application;

- *Client* (browser or third-party application) is an application, which render user interfaces and provide user interaction with cloud applications, hosted in Mjolnirr platform. All clients should use encrypted channel and client certificates to communicate with the proxy.

A. Proxy

The Proxy (see fig. 2) provides access to Mjolnirr system from the external network. The Proxy performs the following actions:

- it stores and provides static resources (page layout descriptions, images etc.) of the deployed cloud applications in the Static Storage;

- it acts as a messaging server for the components of cloud applications;

- it handles client's requests to the Client Interface;

- it performs the authorization and authentication of users.

The external Proxy interface provides the following methods as RESTful API:

- *getUI (applicationName, pageName)* – returns the page layout description;

- *getResourceFile (applicationName, resourceName)* – gets the static file;

- *processRequest (componentName, methodName, args)* processes a client request, redirecting it to the first free suitable component. This method can be called directly from the application page (e. g. with JavaScript).

B. Container

The container (Fig. 3) provides cloud application component hosting. The container provides an API for remote components instances method invocation. The Mjolnirr installation can have any number of containers.

Any Mjolnirr-based application consists of independent components, which use a built-in messaging system, implemented in the basis of the Publisher-Subscriber pattern. The Proxy is responsible for message queue maintenance. The Message Server of the Proxy provides publisher-subscriber messaging service for cloud application components. Mjolnirr Containers subscribe to Message Channels that operates as a broadcast delivery – any message sent to the Message Channel will be transmitted to the subscribers of this channel. Each cloud application instance is subscribed on two types of Message Channels:

- Component Public Channel: every instance of the

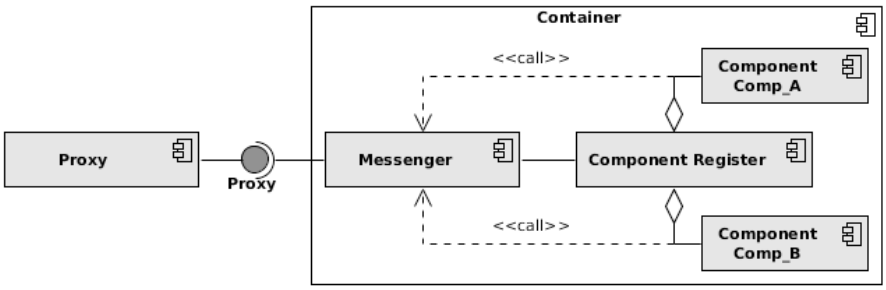

Figure 3: Mjolnirr container architecture

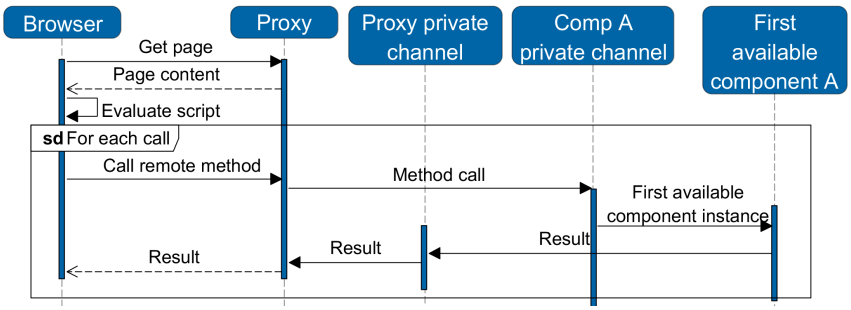

Figure 4: Mjolnirr container architecture

cloud application component is subscribed on this public channel. This a listener channel – when any message come to this channel, the appropriate component instance will be invoked.

- Instance Private Channel: provides direct communication between instances.

When container starts, it performs several initialization steps. The order of the container initialization:

- Container registers in the proxy database and receives the list of components to load in response;
- For each component from the list:
  - The container checks it's local cache, for each missing package container downloads it from the proxy;
  - Container runs the component;
  - Container subscribes on the Component Public Chanel and Instance Private Channel for the loaded component.

Container provides messaging API to the hosted component. Typical message transmission sequence looks like shown below (Fig. 4):

- when one component calls another component remotely, the container sends the call to a Component Public Channel (for example, when the *Comp_A* component calls the *Comp_B* component, the application *Comp_A*, will send the request to the channel *CPC_B*);
- The first available instance of the component in the cloud system processes the request;
- The response is returned to a private IPC channel of the instance that sent a message.

In addition, container has an opportunity to work in stand-alone mode. In this mode, the container does not support communication with other containers and acts as a stand-alone computing system (container and proxy at the same time).

C. Components

From the developer's point of view, Mjolnirr cloud application is a collection of independent components communicating by message exchange. Components represented as a package that contains the following information:

- manifest, that provides the interface of the component, including description of provided methods and their parameters;
- executables to handle incoming requests;
- static files, used in pages rendering (images, page layout descriptions and scripts) for UI provision.

Each component can be:

- Application Component: provides the user interface definition, scripts, styles and UI-specific actions. Optionally contains complex logic.
- Module Component: represents a single entity in the domain logic of the application. The Module Component provides data processing and storage, but doesn't provide interface and static files.

D. Clients

Mjonirr platform uses HTML and JavaScript to represent end-user interface in common Internet browser. But it's possible to consume Mjolnirr resources in third-party application because of using commonly used and standardized protocols.

V. Implementation

A. Components

Each custom component must have a manifest: an XML file that contains all the necessary information about the component's name, the name of the main class, list of methods and a list of parameters for each method. Sample manifest for the Calculator service is shown below.

```
<hive>
<application
  name="Calculator"
  classname="org.exmpl.Calculator">
  <methods>
   <method
     name="calculate"
     type="java.lang.String">
    <parameters>
     <parameter
       type="java.lang.String"/>
     </parameters>
    </method>
  </methods>
</application>
</hive>
```

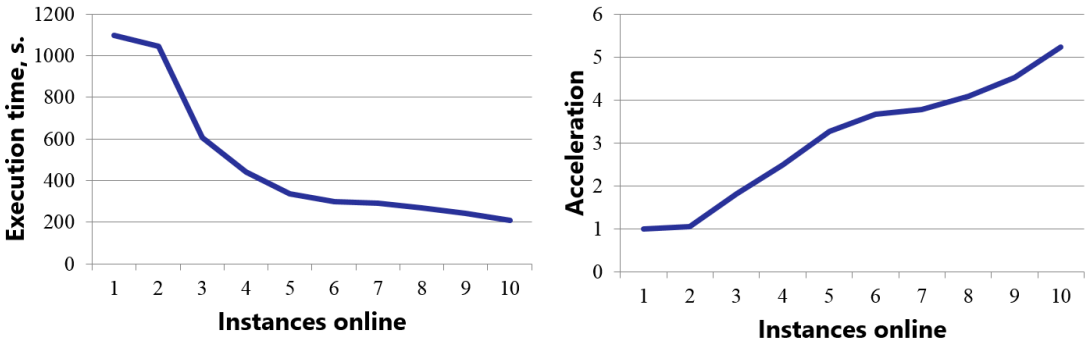

Figure 5: Performance evaluation

The container parses the manifest for each loaded component.

As stated above, the manifest must have the name of the main class as a fully qualified name of the facade class of the described components. Each facade class must have an implementation of the method "*initialize*". The container calls this method immediately after instantiating the component and passes the component *context there*. This context contains information about the working directory of the current application instance and the directory containing the configuration files.

B. *Messaging subsystem implementation*

Mjolnirr platform messaging subsystem is implemented on the basis of the open source HornetQ queue, which is built into the Proxy component. HornetQ was chosen for the following reasons:

- it can work in embedded mode;
- it provides high queue management performance [23].

The container provides messaging API to the components. Example of using messaging interface is shown below.

```
Communicator communicator =
        new HornetCommunicator();

YourResultClass result =
Communicator
     .sendSync(
        componentContext,
        "componentName",
        "methodName",
        argsList,
        YourResultClass.class);

communicator.send(
   componentContext,
   "componentName",
   "methodName",
   argsList,
   new Callback<YourResultClass>() {
       public void
       run(YourResultClass res) {}
   });
```

C. *UNICORE integration*

The Mjolnirr platform provides a UNICORE 6 integration module. This module uses DiVTB Server for communications with grid environment. It enables Mjolnirr applications to use UNICORE grid resources easily.

The concept of DiVTB allows users to split the supercomputing simulation in two phases - building experiment and launching the test stand. The main advantage of the DiVTB concept is the ability to use several times once set up the experiment.

UNICORE integration module provides the following methods:

- *uploadTestBed* – used for test bed archive uploading;
- *indexTestBed* – indexes specific text bed;
- *indexAllTestBeds* – indexes all available test beds;
- *createExperiment* – create experiment from one of the test beds;
- *startExperiment* – start experiment with specific parameters;
- *getStatus* – get experiment status (started, finished or failed);
- *getResults* – get experiment results.

VI. PERFORMANCE EVALUATION

Mjolnirr platform was evaluated using text-processing experiment. 1 gigabyte of text data was divided on 100 parts and distributed between available worker components for processing. Each worker divided text on words and counted frequency for each unique word. Pieces of work were distributed automatically – each worker polled Message Bus to receive new task. The results of the experiments are shown on the figure 5.

We used 1 virtual node with 2 CPU cores and 2048 MB RAM for proxy node and 10 virtual nodes with 1 CPU core, 512 MB RAM as worker nodes. Virtual machines were installed on the computing server node

with the following characteristics: 2 Intel Xeon X5680 CPU (6 Cores, 3.33 GHz) 12 GB DDR3 RAM.

Experiments have shown that the platform is stable. Average execution time on **10** containers was **219** seconds, comparing to **1107** seconds using 1 worker. Thus, acceleration of parallel word frequency counter task reached **5.3** on **10** worker nodes.

VII. CONLUSION

In this article, we described the design and implementation of a private cloud platform called Mjolnirr, which allows creating distributed cloud applications on private computing resources. Main features of the described platform are advanced messaging system and distributed computing support.

As a further development of the Mjolnirr platform we will investigate and implement application-level migration support, integration with the advanced resource monitoring systems, flexible adaptation to load changes, advanced system security and application store. The application store will reduce the number of duplicate software products and simplify the creation of individual business infrastructure to meet the needs of a particular company.

VISUALIZATION

Visualization Support for Code Development in EUROfusion Integrated Modelling

Leon Kos and ITM-TF contributors*

***Abstract*—The need for diverse visualization tools within integrated modelling is based on the requirement of physics codes to be coupled under the tailored database model from which these visualization tools read data. We discuss these visualization requirements for fusion integrated modeling, and the existing visualization tools developed within the scope of the European Integrated Modelling (EU IM) framework. The datastructure model provides fundamental description for data exchange between codes that are developed in a variety of programming languages. From this description in XML schema definition one can generate required language interfaces and database access layer routines. The persistent storage database has to efficiently support codes running on HPC with memory caching mechanisms. Visualization tools can be treated as one of the codes running in-situ or as post-process. The complexity of the fusion datastructure and several visualization tools requires that scientists describe standard visualizations in XML schema directly in order to instruct visualization tools what are meaningful visualizations available in the very database. Besides standard visualizations there are specific visualizations that cannot be easily described (as mapping or axes linking) without algorithm. For the custom visualizations we provide Python snippets collected in user-shared library. Interfaces to scientific workflow engine Kepler for visualization with VisIt visualization tool and Matplotlib are presented.**

I. Introduction

The Code Development for Integrated Modelling EUROfusion project aims to provide to the European fusion community a suite of validated codes for the interpretation of present experiments and predictive modelling of future reactors. This effort builds on the European integrated modelling platform and framework developed within the ITM-TF[1]. Verification and validation of predictive and interpretative simulation runs require that modelling platform allows combining experimental and simulation-data at various stages throughout scientific workflow development. Traceability (provenance) in Kepler[2] workflow engine used within the EU IM framework should provide easy verification and validation at the modelling level. Sharing workflows between scientists is "easy part" of the *workflow-based provenance* and must be accompanied with often *big data* that orchestrated codes needs to trace. Data model seems to be one of the challenges that cannot be universally addressed for all domains. Fusion-oriented framework DataSpaces [3] separates data model into server–client model with distributed hash tables with the goal of providing transparent memory-to-memory transfer (staging) to applications. For "expensive to get" data, *lookup* and metadata is provided in the DataSpaces three-layered architecture. The EU IM data model currently relies on a single-layered Universal Access Layer[4] (UAL) that concentrated on accessing a tailored (tokamak) datastructure description[5]. Data gathered within CPOs (Consistent Physical Objects) is used for "partitioned" interchange between codes in "strongly" coupled workflows. Similarly to CPOs, ADIOS system [6] provides *groups* that describe collections of data written at once. ADIOS as a HPC library for input/output (IO) provides simplified and configurable write strategy to parallel codes. The EU IM approach uses UAL library routines in upgraded fusion codes for data exchange through a structured CPOs database. Staging and write strategy is a part of the UAL configuration and can range from direct file access, memory-cached or parallel [7] access. The UAL back-end responsible for storage uses MDSplus and HDF5 database formats. Both formats are commonly used in scientific and experimental (fusion) environments. As mentioned before, single-layered UAL is providing simple IO with minimal number of functions to codes for fetching and storing CPOs. UAL adaptation to hashed client–server model as in DataSpaces, DART [8] asynchronous data communication layer or using ADIOS should not change the UAL front-end routines used in codes. Code specific data transport configuration and provenance can be governed by the workflow engine (e.g. as XML file used in ADIOS). For distributed workflows where database access is not easy to arrange on must rely on serialization of CPOs for exchange between compute sites. One such approach in fusion modelling is MAPPER project [9] that can couple codes with enveloping them into communication kernels and configure into workflow.

The EU IM effort turned its focus into creation of workflows for specific physics applications that can easily include similar physics codes for verification and comparison in integrated modelling. Key principle for these workflows is not UAL but rather *datastructure* description (ontology) consisting of CPOs. Consistency enforced by CPO data model requires that existing codes need to be "adapted" to be able to retrieve/store results in database. This task requires developer's knowledge of the code and CPOs description that needs to be mapped to each other in enforced units (MKSA and eV).

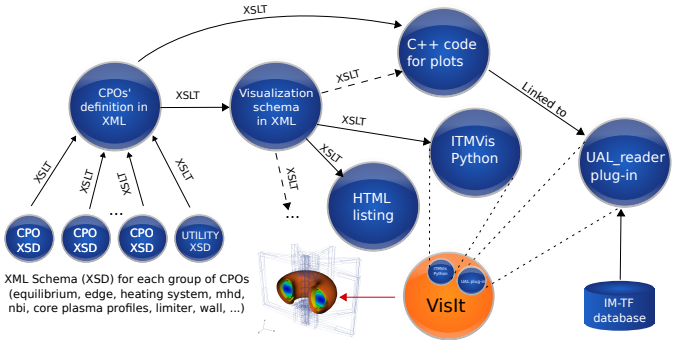

Fig. 1. XSLT flowchart for standard representation transformations used for visualization.

After (necessary) adaptation, code can be executed as a black-box within *scientific workflows* that couples different codes in a compatible way and sequence. Similarly to CPOs, ITER Integrated Modelling & Analysis Suite (IMAS) [10] foresees the development of a datastructure composed of Interface Data Structures (IDSs) as standardized entities for use between physics components. The collection of CPO descriptions form together a complete data model for diverse simulations that can also contain imported experimental data. This approach enables a direct comparison of results with the experiment and/or use experimental data as an input. The implementation phases and continuous development of the EU IM framework are simplified by the fact that the CPO data structures are described by an XML schema definition (XSD), which can be easily modified. This semi human-readable description allows rigorous validation, creation of data bindings and translations for different purposes. The XSD data-structure description is mainly used to generate CPO definitions in an XML format obtained by applying the XSL translation [11] (XSLT) language. Consistency of CPO definitions is assured by the XSD description, so that the derived CPO definitions in XML are consistent too. From the CPOs schema one can automate (through XSLT processing) generation of "include" definitions and UAL linking for all supported languages. From each CPO defined with XSD we then translate into single *CPODef.xml* file that includes complex and common structure types defined in *utility.xsd*. Figure 1 on the left shows this initial transformation from many CPO definitions into single CPOs' definition in XML. The fundamental purpose of *CPODef.xml* is a description of the EU IM persistent storage database. As most of the CPOs are time dependent, the EU IM database stores *slices* of each CPO during simulation iterations or experiment sampling. Slicing occurs at different time scales for each CPO depending on the physics involved [12, see Fig. 12 therein].

Described data model and its access is a basis for visualization tools that are aimed to support users in all stages of modelling framework usage. To support the diagnostic of the time-dependent data in CPOs, several visualization tools are used depending on the scales and *representation* of the data that is regularly used in simulations. For many simulations, custom visualization are created using general-purpose graphics libraries. To avoid such custom approaches and to provide *standardized* sets of visualizations EU IM aims to provide tools that can be used for visualizations without the need for scientists to manually program each *plot* and allow creation of reusable custom visualizations.

TABLE I
THE EU IM VISUALIZATION TOOLS CAPABLE OF UAL DIRECT ACCESS

EU IM Tool	Graphical plot config (user level)	Non-interactive processing	Input data pre-processing	Publication ready figures
ITMVis	no (basic)	yes	yes	yes - matplotlib
VisIt	yes (basic)	yes	limited	yes - raster gr.
Matlab	yes (expert)	yes	yes	yes - builtin
ISE	yes (basic)	no	no	no

II. VISUALIZATION SUPPORT IN THE EU IM FRAMEWORK

Graphical inspection of data in variety of ways becomes more difficult with increasing data complexity. As time is a key physical quantity of tokamak modeling, this quantity is included in nearly every CPO and can be assumed as an additional dimension when time-varying properties are inspected. Usually, time-dependent visualization is done by specifying a time point or selecting a cycle (frame or time-slice) from the UAL database. From that point data can be retrieved and visualized with different tools in a variety of ways. Visualization tools capable of accessing UAL data directly (without exporting or converting) were developed to provide required visualizations. Three approaches are used by the EU IM for producing visualization: (i) programming languages, (ii) general tools, and (iii) specialized tools with capabilities as shown in Table I. Scripting languages like Python and Matlab are suited for all kinds of data processing. However, their use requires development effort. Non-scripting languages (C++, Java, Fortran) for producing visualizations are even less attractive. They are used for application programming and within visualization tools. In fact, there are no general purpose tools available that can cover all aspects of usage. The Integrated Simulation Editor (ISE) was designed with Kepler [13] workflow control in mind in a "study"-like manner and currently only provides simple 2D signal editing and visualization.

A. ITMVis

One goal of the EU IM effort is to consolidate and extend the visualization capabilities of the platform, providing developers with tools for (automated) creation of specialized plots that can be easily distributed to end users and tools for creating plots for code/workflow development and debugging. Eventually, users will benefit from easy-to use, interactive tools for data exploration, easily available custom visualizations for specific physics problems/workflows and tools that are capable of producing publication-ready plots. Towards this goal the EU IM developed a structured 2D Python visualization library — ITMVis which unifies the existing approaches, provides extensibility and enables reuse of custom visualizations for various target visualization tools (back-ends). The ITMVis library encompasses the following:

1) A standard front-end consisting of command line Python scripts for accessing UAL database by prescribing run, shot, time, user, tokamak and CPOs needed for visualization.
2) A structured repository of code fragments for computing data required for plot, possibly combining data from various CPOs. For each plot *metadata* and *plotdata* function is provided.
3) A collection of "standard" processing functions which can then be shared among multiple visualization scripts.
4) Collects and makes code owned/developed by specific projects available to everybody in a central place and provides a plot sharing mechanism for users to reference exported visualization scripts.

Developers/users need to concentrate only in data processing and plot description by providing *metadata* and *plotdata functions*. Metadata describes the plot and verifies data availability so the user is informed whether a specialized plot can be produced or not. Only if a database contains the required data, the *plot data* function can be executed. To detect modules containing metadata and plot data functions in the Python search path, some function naming conventions are prescribed. Backends implemented as outputs are text, VisIt and matplotlib [14] library with several graphical formats. ITMVis implemented a Python library can be included in all Python scripts that can regularly include matplotlib along with UAL wrapper library that requires NumPy/SciPy stack.

B. VisIt

For complex 3D visualizations the EU IM effort adopted *VisIt* [15] visualization software (open-source, maintained by LLNL) upgraded with custom *UAL_reader* plugin developed under EUFORIA/JRA4 [16] project. VisIt is popular and extensible visualization software that provides various representation modes and data post-processing in interactive and non-interactive (batch or scripting) mode. With custom plugin is able to read CPOs from the the EU IM database directly. VisIt as a general visualization tool is capable of complex visualizations that are primarily 3D. Experimental data that is imported into UAL by the EU IM tool *exp2itm* mostly comes in 1D time-dependent (TD) form and can be inspected by surplus of graphing tools. VisIt role in workflows is primarily dedicated to inspection of 3D or even 4D data resulting from "integrated modeling". Normally, insight into 3D data is extracted by variety of *operators* at selected cycle (moment in time). Animation and *time-slider* can be useful TD tools for general overview of inspected phenomena. VisIt uses *FlipBook animation* for showing time-varying databases. Controls for moving though cycles/time are similar to many software players (or VCR). UAL plug-in for VisIt (UAL_reader) enables VisIt fusion data reads through the UAL in order to build the resulting visualization. In order to connect VisIt with UAL two components of the plugin was developed as shown in Fig. 2. Standard visualizations are fetched directly from the database. For custom plots ITMVis library is included through plugin-embedded Python interpreter and accesses database by Python

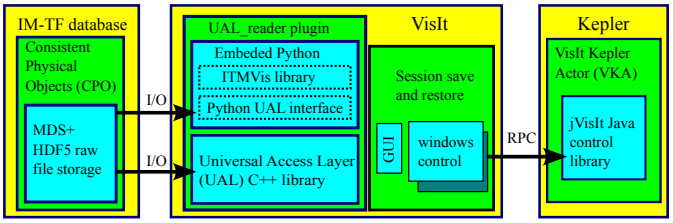

Fig. 2. Schematics and communication of basic components for visualization with VisIt under Kepler workflows.

UAL interface.

VisIt is built on top of *Analysis and Visualization Toolkit* (AVT) that has strong correlation to VTK Toolkit made by Kitware. Data structures from UAL needs to be represented in AVT compatible way. When CPO is read into memory all data is available and information on how this data can be "naturally" represented in coordinate system is being amended by physicists. "Natural" *representation* of data of interest is related to conventions and physicist's way of thinking. For example, one needs to decide which field represent x and y-axis for *1D Curve*. A representation is, in fact, a description of the visualization. There can be multiple representations of the same data. The *UAL_reader* plugin for VisIt (see Fig. 1) utilizes *representation tags* that are included in the XSD files describing the CPOs. This means that datastructure "knows" how it can be visualized. This is similar to the concept of *views* in SQL, which are stored in a database directly (except that these would be stored directly in the database). Representation tags are just a description that does not enlarge storage but facilitates views on data. Each representation consists of name, mesh type, links for the axes, and data attributes. The representation name is arbitrary and is shown as the last name in the VisIt path when adding plots. The data attribute can be either a scalar or a vector and describes the kind of data mapped on the mesh represented by one or more links. Meshtype describes the type of variable mapping in space. Several meshtypes exist: i) *curve* as a polylines plot, ii) *axis1D0* X axis given as a link1 vs. a bunch of curves from a matrix; iii) *mesh1D0* Contours (closed curves) as a (2D) surface mesh, iv) *rectlinear0* or *curvilinear0* meshes in 2D and 3D. Each meshtype can have a variable number of links (link1, link2 and/or link3) and thus different kind of visualizations that are constructed as VTK objects in VisIt. Links provide axis mapping to corresponding vectors or matrices that constitute a mesh. The topology name at the end of the meshtype means (0D - points, 1D - lines, 2D - surface, 3D - volume). The number at the end distinguishes variations of the same meshtype (0, 1, ...). If no topology is given, a general description is assumed (2D and 3D).

UAL_reader plugin is a basis for all kinds of visualizations with VisIt. As shown in Fig. 2 customized plots can be accessed through ITMVis library and *standard* plots by direct translation from datastructure. Both parts of the plugin are complementary and can be used together in a dashboard-style setup for *European Transport Solver* [12] shown in Fig. 3 where some difficult to combine data were rather prepared by custom plots.

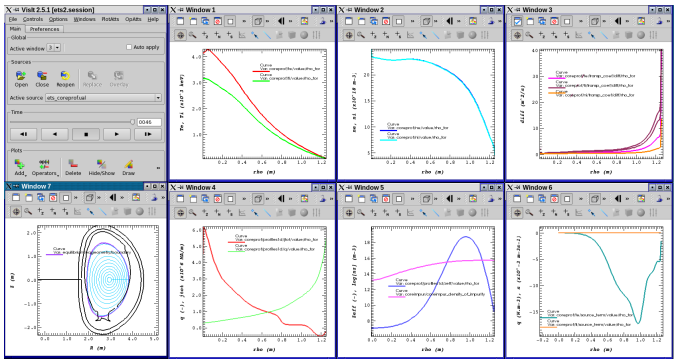

Fig. 3. European Transport Solver (ETS) convergence monitoring with VisIt.

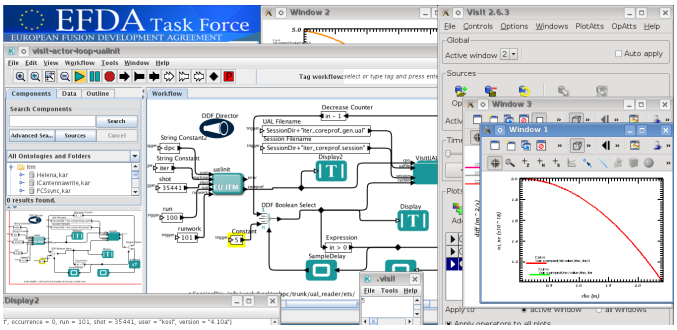

Fig. 4. The VisIt Kepler Actor – VisItUAL in a workflow within a loop reading data through the Universal Access Layer. Multiple VisIt windows configured with session save/restore mechanism are shown and updated during iterations.

C. Visit Kepler Actor

The EU IM selected the Kepler [13] scientific workflow engine which enables graphical programming of workflows. Data flow between processes (called *actors*) is modelled by wires. Through wires only small amount of data (signals) are passed, usually just single numbers, strings and structures with CPO names, which identify database entries. The Actual data exchange between IM actors encapsulating fusion codes is then implemented by direct access to the "real" data through the UAL library.

For inclusion of VisIt in the Kepler workflows the VisIt Kepler Actor (VKA) was developed. The VKA in Fig. 2 can restore session created previously within VisIt but with new source database. Session saved within VisIt graphical user interface (GUI) consists of all windows, applied plots, operators and attributes. This means that user can configure session under VisIt GUI inside or outside Kepler. Then user builds a particular visualization for the quantities of interest. Finally, user stores a VisIt session file which contains all the information needed to restore the state of VisIt when the session file is generated. In the second stage, the user launches Kepler, inserts the VKA to his workflow and add as parameter of the VKA the session file generated at stage 1. When the workflow is executed, once the VKA is activated by the workflow, one or several visualization windows will pop up with the data contained in the incoming database. The resulting visualization is rendered with the parameters contained in the session file. This means that session files are special tailored descriptions of visualizations with expected inputs. Normally most scripting languages (IDL, Matlab, gnuplot, ROOT, ...) that require visualization also generate scripts for visualization by coding. VisItUAL is a similar approach but without coding as user can with GUI save XML session file. Such session can then be shared and collected for visualizations of interest and used as standalone or within Kepler workflow. Such approach is useful for fusion codes and experiments that output complete results in UAL database but researchers are interested in specific phenomena and selected variables and ranges that needs to be monitored within larger scientific workflow supported by Kepler. For UAL database and CPO support composite actor Coupling VisIt to UAL is supported by UAL_reader database plugin. VisIt by design needs to open database provided as filename. UAL database plugin thus needs .ual file provided before it can open UAL within VisIt. Creation of this file can be manual with one line specifying CPO, shot and run. After UAL database is opened with VisIt than one can create a session file for restore within Kepler workflow. Fig. 4 shows such a workflow with user supplied visualization settings. Location of the *ualfile* is given for automatic creation at the specified location. This location can be the same as previously manually generated session file. VKA allows visualizations of multiple CPOs and includes its own GUI written in Java for controlling interactive work under Kepler and restoring VisIt GUI. It can also be used in a synchronized loop as in Fig. 4 that cycles through prescribed time steps found in CPOs.

D. The visualization schema

The *ITMVis* library tries to follow the VisIt data description by splitting visualizations of CPOs into meta-data and plot data. This separation is a natural choice for all tools that want to prepare a list of possible visualizations depending on data availability. It should be noted that not all CPOs are filled with data when running a particular simulations. The ITMVis library concentrates on *custom plots*, while the UAL_reader plugin works with *standard representations*. Standard representations are currently used for data visualization within some CPOs, where the structure of the data fields allows this. For visualizations using data from multiple CPOs, the *ITMvis* approach provides scripting/post-processing capabilities that can combine results and output them through different backends. VisIt combined with the *UAL_reader* plugin allows both representations (standard and custom) by embedding a Python interpreter in the plugin itself. Standard representations were not included in *ITMVis* initially, although this was possible by direct interpretation of *CPOdef.xml* or by Python code generation as in *UAL_reader* (where C++ code representing plots is generated from *CPOdef.xml* directly). The process of XSL translation shown in Fig. 1 with solid lines could be repeated for ITMVis too. From the experience gained in developing templates for C++ code used in *UAL_reader*, where 220000+ source lines are generated, we came to a conclusion that introducing an *intermediate* XML description that extracts representation data from the *CPOdef.xml* will

reduce the complexity of the XSLT process when applying it to several programming languages. This *visualization schema* is still in XML, except that it contains the standard representations described more naturally in a custom XML schema that is easily converted further with XSLT. The complexity of the XSLT code is thus reduced and distributed among XSL translations to and from *visualization schema*. Such an approach unifies standard CPO representations and can be extended with additional fields in the intermediate XML format for easier translation as required.

III. Discussion

Presented visualization tools discuss mostly coupling for the purpose of simulations at the workflow level which is in our case Kepler. Naturally, visualization tools described can also be used as a standalone. There are other uses for such tools which are handled differently. For example, control panels and simulation instrument-frameworks tends to create specialized dashboard-style GUI. Dashboards usually include additional control buttons with custom actions. Workflow parameter-control is included in Kepler by the *Runtime Window*, where built-in output-plotters are included as well. This is mostly insufficient for complex visualizations. For custom "publication-quality" plots one can use general Python actor developed by the EU IM and then use ITMVis with matplotlib. Note that ITMVis inclusion can be difficult in non-native Python implementations such as Jython (Python for the Java Platform) used in Kepler-provided Python actor. VisIt with corresponding plugin can mimics multi-instrument (cf. Fig. 3) as a multi-window setup that can be saved as a session and reused often. Still, this is not single dash-window although VisIt allows coding of custom controlling GUIs with jVisit.

VisIt uses remote procedure calls (RPC) mechanism for inter-process communication (IPC). In some sense the VKA is a complete IPC application as it includes its own-coded GUI using Java widgets and jVisIt for controlling communication. Communication with RPC in Fig. 2 is in the direction from VisIt to VKA and not opposite as one may expect [17]. The VKA therefore acts as a server and VisIt attaches as a observer to it with a random *hostkey* that is generated when VisIt client is launched by the VKA. Controlling VisIt is thus possible only by launching from the VKA. It is not possible to attach VisIt to the running workflow on demand. That is the reason for existence of *VisIt controller* GUI included with the VKA. To allow controlling of the visualizations at the workflow run time.

VisIt allows *in-situ* connection [18] for simulation code steering. It requires modification of the instrumented code to include VisIt-library *libsim* and provide meta-data and current state as mesh objects in a similar way as the (UAL) reader. EU IM framework provides a tool *ual_connector* that connects UAL database and VisIt in such way. Caveat of this tightly in-situ coupling for our analyses is that only current code state can be requested. This rules-out most time-dependent visualizations (e.g. for animations). Usage of libsim is therefore limited to the the initial usage intent. Getting time slider to work still requires UAL_reader post-processing.

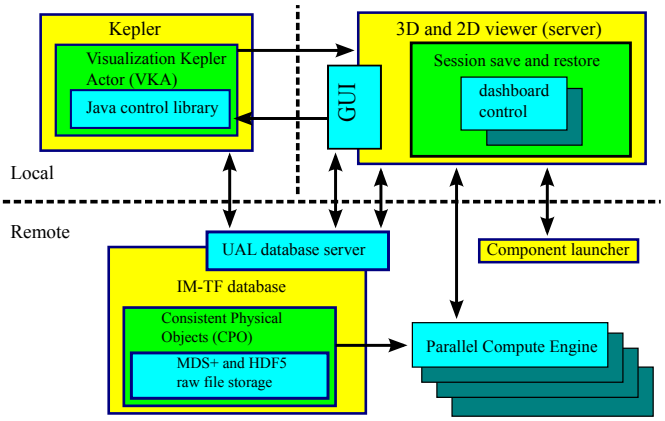

Fig. 5. Visualization architecture with remote database and computing. 2D and 3D viewer should allow remote connects and disconnects.

Obviously, different circumstances often merit different solutions. Concentrating on the past experiences in the field we can draft the visualization architecture in Fig.5, where the following properties for a general purpose 2D and 3D visualization tool (viewer) are sought:

1) It works as standalone application with usual (server-side) remote visualization engines. Local client may choose server-side or client-side rendering, depending on the client display graphics capabilities. Server side rendering with protocol like VirtualGL may be helpful for low-end clients. Current visualization tools (VisIt, Paraview) mostly use *legacy OpenGL code* for display and this impedes effective remote client-side OpenGL rendering that can be provided by *modern* OpenGL 2.1+ with GLSL. Most notable client-side display improvements of modern OpenGL are expected for 3D graphics manipulation.
2) Preferable, connections to remote visualization server may be session-aware allowing disconnects and reconnects from the viewer. Similar functionality is now exists in various remote desktop protocols where server holds a session that can be restored from different clients. Component launcher on remote side may took over of the visualization state handling and pass it to clients at session restore requests.
3) Session as a viewer configuration including visualization pipeline is saved into session file that can be restored at later time on request by Kepler.
4) Viewer as a client should act as a server too. Allowing connections and reconnects from Kepler. Kepler may launch viewer if there is no previously opened one. Viewer with its GUI can be launched as standalone and still allowing for Kepler to attach to it if having proper port and hostid assigned in the workflow.
5) GUI that comes with should be able to associate itself to running Kepler workflow for the purpose of workflow

steering. Actor for workflow instrumentation may not be the same as the Visualization Kepler Actor.

6) Viewer with mixed 2D and 3D windows can be tiled in a single canvas (dashboard) or built of multiple windows. *GUI Designer* for views may allow placing custom controls that can be user scriptable.

Clearly, present tools are not compliant to the above "desires". Reasons for most are linked to past computing architectures. Moreover, 3D visualization is closely linked to computer graphics capabilities. Our implementation with VisIt and developed tools resembles some of the above *requirements*.

Engineering still struggles to present results in plots with a single variable dependence. Rich 2D-graphing may seem not a good idea to be included into 3D visualization tool. However, limitations of VisIt and Kepler graphing brought custom 2D ITMVis library and virtually duplicated the effort needed. Not everything is well aligned in database and for that scripting can be found handy. Providing publication quality graphing is quite favorable for all tools. Offline rendering in such tools can further ease scripting. Scientists often prefer ease over performance. This fact should be considered in visualization tools by allowing graphical programming whenever possible and saving this configuration as visualization flowchart (session). Additionally, there are 3D cases (MHD, diagnostics, ..) where for comparison layout of the wall structure CAD model and some intersection (poloidal) from code needs to be presented. CAD inclusion in visualization tools can be done with premeshing of Bézier and NURB surfaces. Integrating a CAD "reader" would certainly ease visualization tool usage.

IV. Conclusion and outlook

Visualization in a mission to assist researchers in achieving their research goals needs to provide proper analytics with tools that tackle specific domain. Our introduction of the *visualization schema* into the *datastructure* unifies and reduces efforts required to develop different visualization tools. A set of *standard* visualizations provided by the visualization schema enables users to browse through CPOs available. In cases of custom requirements, scripting for plots can be used by *ITMVis* library that was embedded in VisIt UAL database reader. How to provide more sophisticated (algorithmic) mappings in the schema is ongoing question. Discussion on the present state and requirements for visualization tools may be considered as a general view for integrated modelling problematics and a starting point for a future work.

Fast Motion Estimation Algorithm Using Dual Bit-plane Matching Criteria

Changryoul Choi and Jechang Jeong
Dept. of Electronics and Communication Engineering, Hanyang University,
Seoul, Republic of Korea
denebchoi@gmail.com & jjeong@hanyang.ac.kr

Abstract - The constrained two-bit transform (C2BT) is recently proposed for low complexity motion estimation (ME) to reduce the high computational complexity of the typical two-bit transform (2BT) while maintaining the ME accuracy. And the bit-inverted Gray-coded bit-plane matching (BGCBPM) is also proposed to enhance the ME accuracy. In this paper, we propose a fast ME algorithm exploiting these two bit-plane matching (BPM) criteria. Using the low complexity image transformations of typical images into bit-planes and their corresponding matching criteria and another hybrid matching criterion, we can efficiently determine multiple candidate motion vectors and increase the ME accuracy substantially. Experimental results show that the peak-to-peak signal-to-noise ratio (PSNR) difference between the proposed algorithm and the typical sum of absolute differences (SAD) based full search algorithm is only 0.03 dB on average with negligible computational complexity increase.

I. INTRODUCTION

Since the multimedia data are abundant everywhere, the video compression technology is indispensable for reducing the multimedia data for transmission and storage in many applications. In video compression, the motion estimation (ME) plays one of the most important parts since it can reduce the temporal redundancy of multimedia data substantially using the temporal correlation between neighboring frames and deployed in many video coding standards [1-3]. In typical ME process, a current frame is partitioned into small rectangular blocks and a motion vector is calculated within its search range in the reference frames by estimating the most similar block according to some mathematical matching criterion such as the sum of absolute differences (SAD) or the sum of squared differences (SSD). This algorithm is called as a block matching algorithm (BMA). Although the full search BMA (FSBMA) can find an optimal motion vector according to some matching criterion, its computational complexity is so huge that it is not adequate for real time applications. To reduce the computational burden, many techniques have been proposed in the literature [4-15]. Among them, there proposed some techniques that use different matching criterion instead of the classical SAD or SSD to make the faster computation of the matching criterion itself exploiting the bit-wise operations [8-15]. These algorithms are called as bit-plane matching (BPM) based ME. Some advantages of these techniques over the typical SAD or SSD based ME algorithms can be summarized as follows: fast computation of the matching criterion and reduced memory bandwidth in the interim of ME process. These techniques include one-bit transform (1BT) [8], two-bit transform (2BT) [10], constrained 1BT (C1BT) [9], truncated Gray-coded BPM (TGCBPM) [11], weightless TGCBPM (WTGCBPM) [12], constrained two-bit transform (C2BT) [14], bit-inverted Gray coded BPM (BGCBPM) [15], etc. Although the BPM based ME succeeded in reducing the computational complexity, its ME accuracy is relatively poor compared with the SAD based ME, resulting in degraded reconstructed images. To remedy this situation, multiple candidate motion searches were proposed in [13].

In this paper, we propose a low complexity multiple candidate ME algorithm based on C2BT and BGCBPM. Since the image transformations of C2BT and BGCBPM are very low, we can efficiently determine the respective candidate motion vectors. And by using the hybrid matching criterion of C2BT and BGCBPM, we can determine another candidate motion vector. Adopting the multiple candidate motion search strategy into those candidate motion vectors dramatically enhance the ME accuracy.

The rest of this paper is organized as follows: In Section II, we review some previous works pertinent to our proposed algorithm. In Section III, the proposed algorithm is presented. Experimental results and analyses are given in Section IV. Finally, Section V provides conclusions.

II. PREVIOUS WORKS

A. C2BT based ME

In transforming original image frames into two-bit representations, the typical 2BT needs to calculate variances of the local blocks. This calculation of variances inevitably involves multiplication operations and renders the computational complexity of typical 2BT somewhat high [10]. By exploiting advantages of the typical C1BT and the typical 2BT, C2BT significantly reduces the computational complexity of transformation of image frames into two-bit representations while maintaining the ME accuracy [14]. By replacing the multiplication operations in variance calculation of 2BT with the simple thresholding technique, the two-bit representations of C2BT are attained as follows:

$$C_1(i,j)=\begin{cases}1, & I(i,j)\ge\mu\\ 0, & otherwise\end{cases}$$
$$C_2(i,j)=\begin{cases}1, & |I(i,j)-\mu|\ge D\\ 0, & otherwise\end{cases} \quad (1)$$

where μ is the mean of the local threshold window around the transforming block, D is a threshold, $I(i, j)$ are the pixel values of the transforming block and $C_1(i, j)$ and $C_2(i, j)$ are the two-bit representations of C2BT. The typical transformation block size is 8×8 as is the case of the typical 2BT. However, unlike the typical 2BT, the local threshold window is set to 32×32 to replace the multiplication (division) operations with the shift operations. And the corresponding matching criterion, the number of non-matching points (NNMP) is as follows:

$$\begin{aligned}
&NNMP_{C2BT,1}(m,n)=\sum_{i=0}^{N-1}\sum_{j=0}^{N-1}\{C_1^t(i,j)\oplus C_1^{t-1}(i+m,j+n)\}\\
&NNMP_{C2BT,2}(m,n)=\sum_{i=0}^{N-1}\sum_{j=0}^{N-1}\{C_2^t(i,j)\oplus C_2^{t-1}(i+m,j+n)\}\\
&NNMP_{C2BT,3}(m,n)\\
&=4\times\sum_{i=0}^{N-1}\sum_{j=0}^{N-1}[C_2^t(i,j)\bullet\{C_1^t(i,j)\oplus C_1^{t-1}(i+m,j+n)\}]\\
&NNMP_{C2BT,4}(m,n)\\
&=4\times\sum_{i=0}^{N-1}\sum_{j=0}^{N-1}[C_2^{t-1}(i+m,j+n)\bullet\{C_1^t(i,j)\oplus C_1^{t-1}(i+m,j+n)\}]\\
&NNMP_{C2BT}(m,n)=\sum_{i=1}^{4}NNMP_{C2BT,i}(m,n)
\end{aligned} \quad (2)$$

where $\oplus$ and $\bullet$ denote the Boolean XOR and AND operation, respectively.

B. BGCBPM based ME

TGCBPM and WTGCBPM use Gray-code mapping as transforming image frames into bit-planes, which is very simple compared to other bit-plane transformation algorithms using complex filtering operations. Let the gray-level of the pixel at location (m, n) be represented as follows:

$$f(m,n)=a_{K-1}2^{K-1}+a_{K-2}2^{K-2}+\cdots+a_1 2^1+a_0 2^0 \quad (3)$$

where K represents the pixel-depth and a_k ($0\le k\le K$-1) takes on either 0 or 1. Then the corresponding Gray-code representation is given by

$$\begin{aligned}
g_{K-1}&=a_{K-1}\\
g_k&=a_k\oplus a_{k+1},\quad 0\le k\le K-2
\end{aligned} \quad (4)$$

where $\oplus$ denotes the Boolean XOR operation and a_k is the k-th bit representation. After this transformation, TGCBPM and WTGCBPM use respective NNMPs as matching criteria. Compared with the previous BPM based ME algorithms, TGCBPM and WTGCBPM based ME show significant gains in terms of the ME accuracy [11-12].

Since all the matching criteria of BPMs try to replace the SAD or SSD with the bitwise operations for reduction of computational complexity, their output must be similar to the SAD or SSD in order to find a more accurate motion vector. To this end, BGCBPM was proposed [15]. In BGCBPM, the typical Gray code mapping is bit-inverted as follows:

$$h_k=\sim g_k,\quad NTB\le k\le K-1 \quad (5)$$

where K represents the pixel-depth, ~ represents the Boolean NOT operation, NTB is the number of truncated bits and g_k is the k-th Gray bit representation. And the corresponding matching criterion is as follows:

$$\begin{aligned}
&NNMP_{gram,1}(m,n)=\sum_{i=0}^{N-1}\sum_{j=0}^{N-1}\sum_{k=NTB}^{K-1}h_k^t(i,j)\oplus h_k^{t-1}(i+m,j+n)\\
&NNMP_{gram,2}(m,n)\\
&=2^{K-NTB}\times\sum_{i=0}^{N-1}\sum_{j=0}^{N-1}[h_{K-2}^t(i,j)\bullet\{h_{K-1}^t(i,j)\oplus h_{K-1}^{t-1}(i+m,j+n)\}]\\
&NNMP_{gram,3}(m,n)\\
&=2^{K-NTB}\times\sum_{i=0}^{N-1}\sum_{j=0}^{N-1}[h_{K-2}^{t-1}(i,j)\bullet\{h_{K-1}^t(i,j)\oplus h_{K-1}^{t-1}(i+m,j+n)\}]\\
&NNMP_{BGCBPM}(m,n)=\sum_{i=1}^{3}NNMP_{gram,i}(m,n)
\end{aligned} \quad (6)$$

where $\bullet$ denotes the Boolean AND operation, K represents the pixel-depth, NTB is the number of truncated bits, the motion block size is $N\times N$, and $-s\le m, n\le s$ is the search range. The kth most significant bit of the bit-inverted Gray-coded image frame of time t is represented as $h_k^t(i, j)$. In this case, the actual distortion between two pixels in terms of the SAD is proportional to the absolute difference between these transformed symbols and the corresponding matching criterion of BGCBPM actually shows this relationship, resulting in increased ME accuracy [15].

C. Multiple Candidate Motion Searches

In [13], the authors proposed multiple candidate motion searches based on two different matching criteria. They exploited the almost identical operations between two different matching criteria and did the dual motion searches with negligible computational complexity increase. The multiple candidate motion searches based on the weighted 2BTs (MCW2BT) can be summarized as follows [13]:

1) Find two best motion vectors using two different matching criteria, respectively.
2) If two best motion vectors with the respective matching criteria are the same, declare it as the best motion vector for the current block and go to 4).
3) Calculate SADs of the two best motion vectors

and declare the motion vector with less SAD as the best motion vector for the current block.

4) Go to the next current block.

III. PROPOSED ALGORITHM

To improve the overall ME performance, we adopt the strategy in [13] of multiple candidate ME exploiting the low complexity image transformations of C2BT and BGCBPM. Table I shows the average PSNR results of C2BT (D = 30) and BGCBPM when the motion block size is 16×16 and the search range is ±16. As can be seen from the table, the average PSNR performance of BGCBPM with NTB=5 is slightly better than that of C2BT. However, if we look into the average performance of each sequence, sometimes that of C2BT outperforms that of BGCBPM with NTB=5 (for example, the sequence of container). Therefore, there is enough room for improving the ME accuracy using the multiple candidate search.

TABLE I. AVERAGE PSNR RESULTS OF C2BT AND BGCBPM

	C2BT	**BGCBPM (NTB = 6)**	**BGCBPM (NTB = 5)**
football	23.71	23.64	23.95
akiyo	42.53	42.08	42.61
foreman	32.28	32.00	32.83
hall	33.62	33.22	34.03
container	38.20	37.67	37.70
dancer	30.94	30.48	31.16
table	28.51	28.31	28.62
news	36.86	36.81	37.04
Average	**33.33**	**33.03**	**33.49**

Besides these two candidates, we also propose to use another matching criterion which is a hybrid matching criterion as follows:

$$NNMP_{HYBRID}(m,n) = NNMP_{C2BT}(m,n) + NNMP_{BGCBPM}(m,n) \qquad (7)$$

Then, the proposed multiple candidate motion searches based on C2BT and BGCBPM can be described as follows:

1) Find three best motion vectors using three different matching criteria, respectively.

2) If three best motion vectors with the respective matching criteria are the same, declare it as the best motion vector for the current block and go to 4).

3) Calculate SADs of the three best motion vectors and declare the motion vector with the least SAD as the best motion vector for the current block.

4) Go to the next current block.

Note that the calculations of SADs are needed only when three best motion vectors are different, which is very rare as will be seen in the experimental results.

IV. EXPERIMENTAL RESULTS

The performance of the proposed algorithm was compared with 1BT, C2BT, BGCBPM (NTB=5 and NTB=6), AM2BT, and FSBMA using the measure of SAD. The first 100 frames of 17 CIF (352×288) sequences are used as test sequences. All the searching processes were in spiral order.

Table II shows the average PSNR comparison results when the motion block size is 16×16 and the search range is ±16. The average numbers of SAD calculations per motion block of AM2BT and the proposed algorithm are also shown in the table. Note that the maximum number of SAD calculations in one motion block is two for AM2BT and three for the proposed algorithm, respectively.

From the table, we can see that the performance of the proposed algorithm outperforms other BPM based ME algorithms. To be specific, the average PSNR of the proposed algorithm is better than that of 1BT by 1.19dB, that of C2BT by 0.35dB, and that of AM2BT by 0.28dB. The SAD calculations of the proposed algorithm are needed about 1 out of 5 motion blocks on average. The PSNR gap between the proposed algorithm and the FSBMA is within 0.03dB, which is very small, therefore we can regard the performance of the proposed algorithm is almost the same as that of the FSBMA.

V. CONCLUSIONS

In this paper, we propose a fast ME algorithm using two different BPM based ME algorithms. Using the low complexity image transformations of typical images into bit-planes and their corresponding matching criteria and another hybrid matching criterion, we can efficiently determine multiple candidate motion vectors and increase the ME accuracy substantially. Experimental results show that the PSNR difference between the proposed algorithm and the typical SAD based FSBMA is within 0.03dB, which is very small.

Abstract - Survey data in use in Civil Engineering consists of points described with XYZ coordinates. Closed shapes, like lakes described with a number of such points are immediately recognizable to humans although points are grouped in unconnected and unrelated lines. Automatic processing of those closed shapes is required if computer analysis is to be performed, i.e. we would like to produce a finite element mesh of the lake. In order to perform meshing one has to be able to determine whether a point is inside or outside of the space polygon, i.e. polygon edges have to be detected. Special computer procedures have been developed for edge detection. The most challenging part is detection of overlaps of edge lines which has been solved with specially modified Fourier transform procedure. Above procedures are applied on a real-life example for creating a finite element mesh of lake "Botonega" in Istria.

I. INTRODUCTION

Formation of finite element meshes is among the most important tasks in computer modeling (with finite elements used for discretization of the continuum problem). Great effort is devoted to generation of finite element meshes that have to obey some rules to be useful: mesh must correspond to the element type that will be used in the analysis regarding number of nodes per element side, number of nodes and elements has to be kept within given limits, ration of element sides should be between one and about two (distorted elements should be avoided).

Generation of finite element meshes is especially difficult for natural (not man-made) objects since they are highly irregular. Large natural objects like lakes present an additional difficulty by being huge and thus difficult to measure. Traditionally, data is collected through geodesic survey and the main concern is representation of large areas of terrain [1]. In civil engineering it is common to gain information about objects through geodesic survey, too. But here one is more interested in object limits then in areas. Results are groups of uncorrelated points suitable for human interpretation (humans immediately recognize interesting shapes and make conclusions about objects). Mesh of points for computer simulation is quite often produced manually [2], [3].

This work presents a procedure that starts with results of a geodesic survey and finishes with data suitable for automatic finite element mesh generation. Real-life data of Lake "Botonega" in Istria serve as an example.

II. EDGE DETECTION

A. *Data preparation*

The starting point in analysis is data from geodesic survey. In our example they consist of points in XYZ coordinate system describing edges and bottom of the lake. Details about data format could be found in our previous paper [4].

The main problem with geodesic data is that they are grouped and each group is not ordered in a way that forms a closed polygon. Namely, survey starts and ends at convenient points and the survey procedure is rarely performed in one "run". The result is a group of unordered points, see Fig.1.

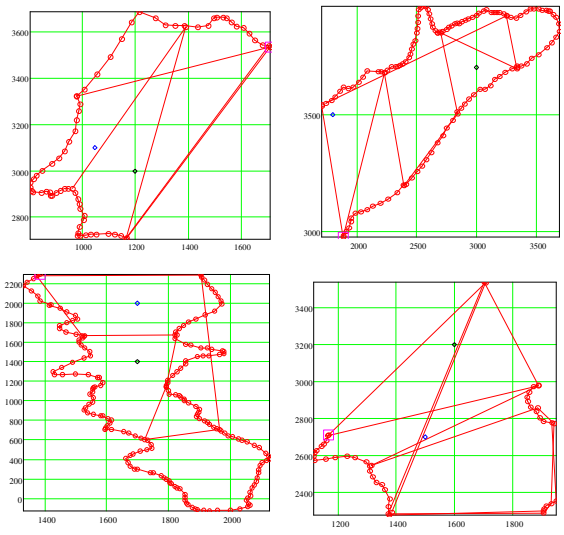

Figure 1. Ordering of points in the geodesic surway (points projected onto the surface of the land). Note the imaginary internal points.

Of course, human can immediately recognize a closed polygon that is represented when points are plotted but it is not so with a computer. Points have to be ordered so that in a vector that contains them the first point is the starting point and the last point is the ending one and the

points are connected neighbor to neighbor. That vector represents a closed polygon when the first and last point are connected.

Proper ordering of points in one group is achieved by applying an original algorithm that starts from a point inside the polygon. As a starting point we have taken center of gravity of unordered points. Area of the imaginary triangles is calculated, increase in the area sorts points in the counter-clockwise direction along the edge, see Fig.2.

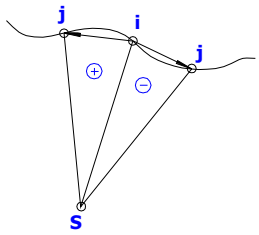

Figure 2. Edge points are oredered regarding the sign of the surface of an imaginary triangle.

Marching through the points is achieved with a proper selection of the next point applying a minimum distance algorithm.

For non-convex polygons this simple rule is not sufficient because not all points could be seen from one pole. In that case new internal point is generated as the gravity center of not visible points and the rule is applied again. The procedure is repeated until there are no "unreachable" points. Since there is known kinematical relation between internal points, proper ordering can be established. Process is repeated until periodicity is detected (using DFT). Resulting polygon is presented in Fig.3.

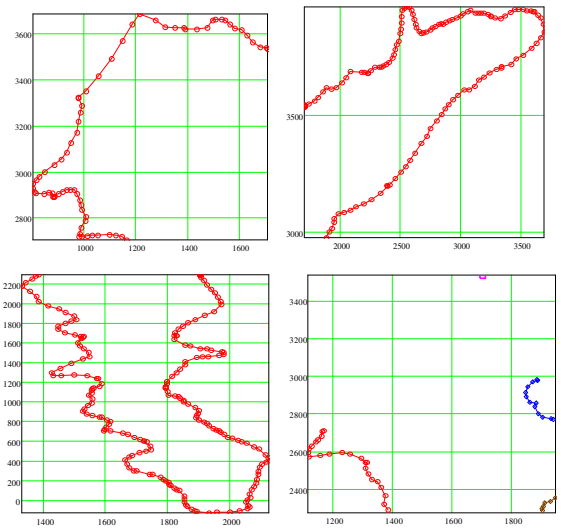

Figure 3. Ordering of points in the geodesic surway. Polygon is not necessarily convex.

Application of the mentioned procedure transforms data from Fig.1 into Fig.3. The basic problem with combination of group of points into a closed polygon can be illustrated with Fig.4.

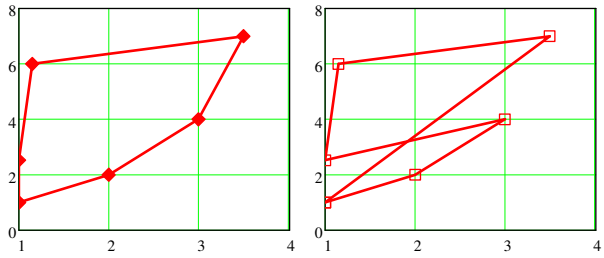

Figure 4. Connecting two groups of points to form a closed polygon.

In Fig.4 one ordering of points is "correct" and the other one is not. It can be easily proved that closed polygon has minimal area when calculated from partial sums along ordered points. However, application of this simple rule is not practical. For rotated points one would have to interchange x and y coordinates. That problem is not present if we take DFT of vector of points and compare their power spectra. It can be shown that the power spectra sum is proportional to the polygon area as described above. Consecutively applying the rule one can combine points into a closed polygon as shown in Fig.5.

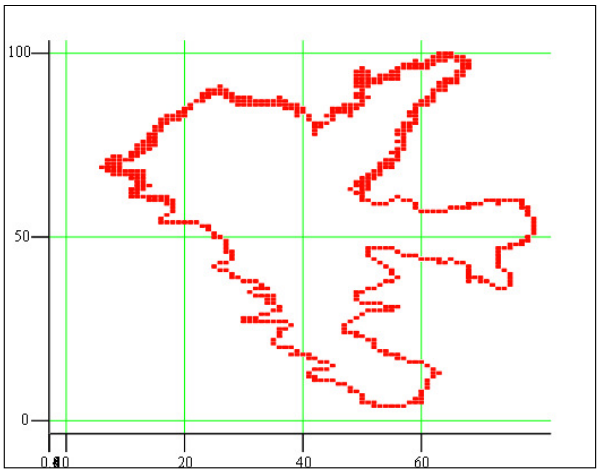

Figure 5. Closed non-convex polygon in normalized coordinates. Note that some points are multiple.

The whole lake "Botonega" is modeled using five polygons that are rotated and scaled in normalized coordinates. The resulting ordered points are presented in Fig.5. Take note that all four polygons from Fig.3 are present in Fig.5 (although scaled and rotated).

Note that due to rotation and scaling in normalized coordinates the edge is not everywhere represented with one line of points.

B. Detection of internal points

Edge of the lake is represented with non-convex polygon from Fig.4. The fact that the edge is not a single line of points (observe multiple points in Fig.4) is the source of confusion in edge determination procedure. Usual polygon fill algorithms [5] or [6] could not correctly

detect edges and fill the polygon (in order to determine inside points).

Edge detection is performed in normalized coordinates by dividing the data matrix into rows and columns. In each row edges are represented with 1 and the rest of terrain with 0 as in Fig.5.

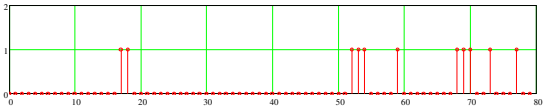

Figure 6. Representation of edges in data matrix. Note that some points are multiple.

Proper edge detection algorithm takes into account multiple points on the edge as well as existence of interior domains. Multiple points are taken into account by forming pairs of changes of data value. Internal domains are resolved by taking into account data from the previous and the next row. In Fig.6 we see red and blue line corresponding to in-line and neighbor rows parameters.

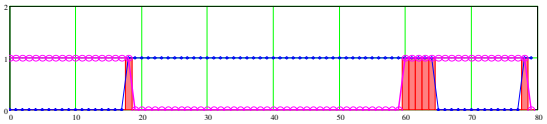

Figure 7. Row of the data matrix as interpreted by edge detection algorithm.

The result of the edge detection algorithm is completely filled non-convex polygon from Fig.4 i.e. internal points have been successfully detected.

C. Mesh generation

With internal points determined we could proceed with generation of the finite element mesh. A computer program has been generated that loops through the data matrix. Only if a point is inside the polygon, loop through the depth is executed and a series of finite elements is generated.

In the example of Lake "Botonega" we have used mesh sized 40 m by 30 m by 1.5 m in depth. Elements of this size would be too distorted so the mesh has to be scaled. Scaling is performed on the differential equation level using the similarity principle. The resulting mesh has 10402 elements and 83216 nodes and is shown in Fig.7. In order to perform calculations, this mesh has to be further processed, i.e. coincident nodes have to me merged. In each node a virtual sphere of given radius is inserted and all inside nodes are coalesced resulting with 15158 remaining nodes. Afterwards nodes and elements are consecutively renumbered. Details could be found in [7].

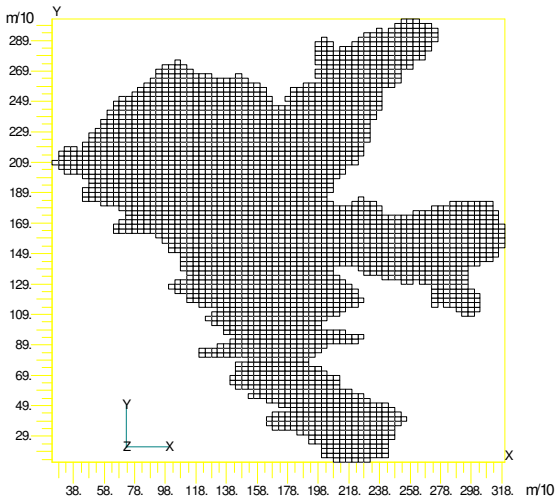

Figure 8. The resulting top layer of finite element mesh of Lake "Botonega".

Successful use of the obtained finite element mesh can be seen in Fig.8. Here we have presented thermal stratification in the lake as a result of calculations on the finite element model from Fig.7.

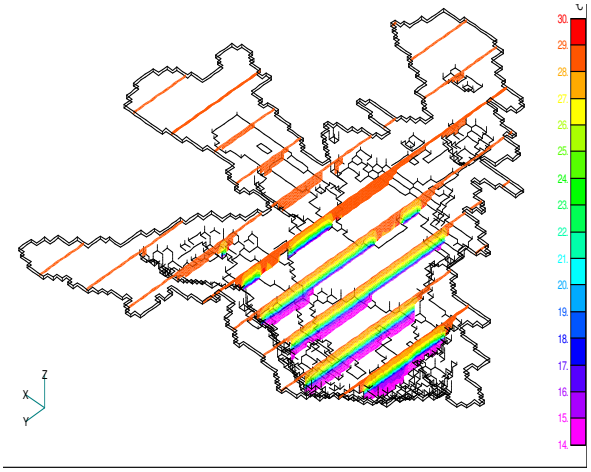

Figure 9. Calculation example using the resulting finite element mesh of Lake "Botonega".

III. CONLUSION

We have briefly presented the procedure for generation of a finite element mesh from uncorrelated geodesic data whose first part that describes interpolation of geodesic data is given in [4]. In this part we have presented formation of edges of the domain and determination of inside points.

Abstract - This paper is focused on the methods used to visualize meteorological factors based on the given data. Properties of the factors for which the data can be gathered were described and the methods of visualizing those properties have been examined. The program solution is centered around interaction with the weather data. The data itself is based on real measurements. It is possible to select an exact point in time for which the data exists, and that data is then visualized on a 3D model of a building, which allows the user to get an idea of the weather state. The model changes lighting, shadows, clouds, opacity and the rotation of a wind vane, based on the data. The data is also represented by graphs, which allow the user to track data changes over a period of time. Finally, since the solution uses large amount of data, a performance analysis was done to point out advantages and disadvantages of the visualization methods used.

I. Introduction

Meteorology is the scientific study of the atmosphere, and as such it is one of the most needed areas of science for everyday lives. It encompasses a vast array of factors which influence the behavior and appearance of the atmosphere.

The need for visualizing meteorological data comes from the fact that it's not easy for people to picture certain aspects of that data using numbers alone. However, those numbers are linked to the state of the atmosphere and visualizing them can give people a better and more clear understanding on the way they work and influence each other. This can be used in order to help plan construction of buildings or placing solar panels, where the effects of meteorological factors on surfaces need to be observed for longer time spans.

An important thing to notice in the visualization of the given data is that not all meteorological factors can be visualized directly, but it's possible to visualize the way they affect the surroundings, such as temperature causing heat blurs and mirages [1]. This paper describes some of the already existing ways to visualize given meteorological data using 2D and 3D graphics, along with graphs and charts.

II. Meteorological Data

Some of the most important factors in meteorology are the temperature, humidity, atmospheric pressure, speed and the direction of the wind, and also the amount of rainfall. In order to visualize those factors, it's important to know how they interact and what effect they have on their surroundings.

It's possible to divide the meteorological factors into those that can be visualized directly and those that can't. Something like temperature of the air, which is the measure of the amount of heat energy present in the air, is not a visible phenomenon, but the effects of the temperature on the surroundings are noticeable: heat haze, ice and mirages are just some of the manifestations of the current air temperature.

Wind speed and direction are also not visible phenomena because humans can't see the movement of molecules in the air, but their interaction with the objects such as trees, leaves, flags and windmills can be observed and measured. Winds are a direct consequence of differing amounts of air pressure in two different places.

Some of the visible factors are cloud coverage, amount of rainfall and insolation. Those can be visualized directly, without the need for visualizing intermediate objects or phenomena. However, they are influenced by other factors which must be taken into consideration to some degree.

A. Air Temperature

Air temperature is the most fundamental meteorological factor. It describes the amount of heat energy of air in a certain location. In terms of visualization, temperature can be visualized using graphs and heat maps, but in a 3-dimensional environment model, direct visualization isn't possible. However, air temperature does bring forth some interesting phenomena whose direct visualization in such a model is possible.

One of those phenomena is the appearance of so called mirages [1]. Mirages are a result of two layers of air with different density, which is a direct consequence of one layer being at a higher temperature than the other one. When air temperatures are high, heating of surfaces also occurs, and the air mass right next to the surface gets heated even further whereas the air further from the surface does not. The higher the air temperature is, the less dense the said air is, according to the ideal gas law [2]. The law states that

$$pV = nRT. \quad (1)$$

Assuming the volume, indicated by V in (1), is constant, the pressure p is inversely proportional to the temperature T.

Since the aforementioned two layers are of different density, light reflection occurs at the borderline of the two

layers when observed from a certain angle [3]. This results in a mirror effect for the viewer.

Another phenomenon affected by the temperature is the rainfall. Rainfall can vary between rain, snow and hail, and the type is largely dependant on the temperature. More of this will be discussed in the section focusing on visualizing rainfall.

B. Wind

Air molecules by themselves aren't visible to the human eye, but the effect of their movement on the surroundings is easily noticeable and possible to visualize. Wind speed is measured using anemometers. Therefore, the anemometer can be used as a way of visualizing the strength and speed of the wind. Because there are various different types of anemometers, it's necessary for visualization to select a type that's easy to model and visualize.

Since the wind direction should also be taken into account when visualizing wind data, the most suitable type would be the windmill-shaped anemometer [4]. Such anemometer is a combination of a wind vane and an anemometer. Wind speed affects the rotation of the windmill part, and wind direction affects the direction of the wind vane. Such rotations (around an arbitrary axis parallel to the xy plane for the windmill, and an arbitrary axis parallel to the z-axis for the wind vane) are easy to model. It's safe to assume that the speed of the windmill wing tip is equal to the speed of the wind multiplied by a certain coefficient. The angular velocity of the windmill would then be

$$\omega = \alpha v/r, \tag{2}$$

where v is the speed of the wind, and r the length of a wing. The coefficient can be any number, so one can be chosen depending on the other parameters and what is best suited for the model itself.

If the vector of the wind velocity is assumed to be parallel to the surface, i.e. the xy plane, the axis of the windmill rotation is then a line whose vector of direction is equal to the wind velocity vector. Following the assumption about the vector being parallel to the xy plane, wind direction can be represented by the angle between the velocity vector and an arbitrary starting vector. The starting vector is usually the direction of North, placed at 0 degrees. East is placed at 90 degrees, South at 180 degrees and West at 270 degrees.

Figure 1. Example anemometer model

C. Cloud Coverage

Speaking in the terms of meteorology on Earth, clouds are visible masses of water droplets suspended in the atmosphere [5]. Appearance of clouds happens almost daily, and the amount of cloud coverage is measurable. Scales for measuring cloud coverage typically range from 0 to 8 or from 0 to 10.

There exist various ways of modeling and visualizing clouds. Clouds can be represented either by solid models, by particle systems [9] or textures. In the terms of meteorology, since measurements of cloud coverage are taken from stations usually located on the ground, one can assume that the need for visualizing clouds will also happen in a model where the viewer is close to the ground, and therefore the most efficient solution is to use different textures for different amounts of cloud coverage.

Textures can by dynamically generated based on actual data or generated as an interpolation between minimum and maximum cloud coverage [7]. An example of texture interpolation using a modeling program called Blender3D can be seen in Fig. 2. Another option is to have pre-rendered textures for each degree of cloud coverage. This reduces the amount of calculation that needs to be done during the rendering of a model, but it's lacking in flexibility. Considering measurement scales for cloud coverage are relatively short and quantized, limitations of pre-rendered textures don't influence the look of the model as much as they would for a more dynamic model.

D. Insolation

Insolation is the amount of solar radiation received by the surface. It is influenced by cloud coverage to a lesser extent. Insolation amounts vary greatly throughout a year because they are not solely dependent on the position of the sun.

Position of the sun is important in a model involving meteorological data, but it can't be calculated by measuring insolation. It's therefore necessary to calculate the position based on the current date. A possible formula for calculating the position is described in [8]. The formula yields two coordinates in a horizontal coordinate system which has the viewer in the center, the solar azimuth γ, which represents the angle between north and the projection of the solar vector on the surface, and the zenith distance θ_z, which represents the angle between the zenith and the solar vector. Using these two coordinates, the exact position can be visualized. However, the distance of the sun from the viewer must be scaled along

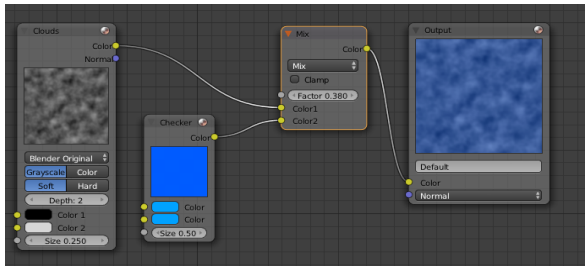

Figure 2. Texture interpolation between two textures in Blender3D

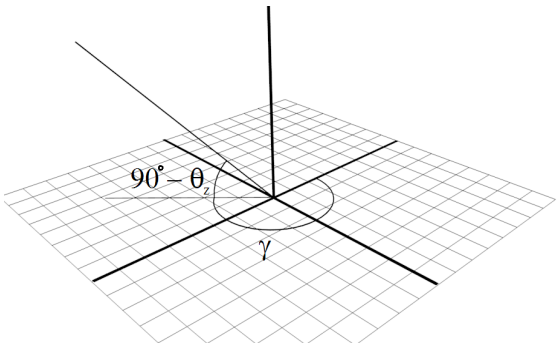

Figure 3. Solar coordinates in a horizontal coordinate system

with the illumination intensity in order to avoid using high distance values inside the model.

E. Rainfall

Rainfall can be visualized using a particle system. Measured amounts of rainfall can be related to the density of the particle system, while the vertical velocity of the particles can be assumed to be constant relative to the viewer and equal to the terminal velocity [10].

Type of rainfall varies between rain, snow and hail. Those types have different characteristics and causes, but it is safe to say that their terminal velocity is similar. The most prominent cause for the different types is the air temperature. Since the visualization is done based on real data, it is hard to deduce the type of rainfall from the data. It can be assumed that snow occurs at temperatures below zero whereas rain occurs at temperatures above zero. Hail is unpredictable and mostly short-term, making it redundant in terms of visualizing data collected on an hourly basis.

Another important factor in the visualization of rainfall is the influence of the wind. Strong winds make the rain and snow fall diagonally or sideways, increasing their horizontal velocities.

Particle systems make it easy to change the parameters for visualizing rainfall, such as particle velocity, vector of movement and the type and color of particles. If the clouds are represented with solid models, such models can serve as particle emitters. However, since clouds are often represented using textures, particle systems with invisible emitters are necessary.

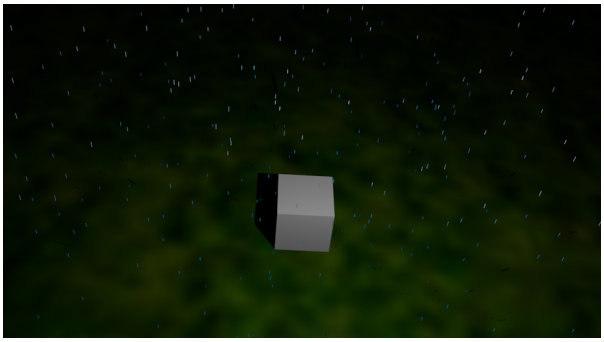

Figure 4. Rain as a particle system

F. Visibility

Visibility is related to the measurement of the distance in which an observer can make a distinction between objects or light sources. It is usually measured in kilometers and defined as the largest distance in which a black object can be seen in a light background [11].

Low visibility is usually caused by fog. Since an observer can move freely through the fog, it needs to be visualized in a way which distributes the fog relative to the observer. It can be visualized using particle systems or textures.

One downside of a particle system for fog visualization is the high amount of particles needed at low visibility. However, in modern computers, particle system fog visualization doesn't present a big problem and it results in more realistic scenes when combined with volumetric lighting [12].

Another way of visualizing fog is by using layers of semi-transparent textures. This method is fast and simple, but it cannot visualize advanced phenomena such as light scattering inside the fog.

III. 3D Model With Simulated Meteorological Effects

In order to demonstrate some of the more simple methods for visualizing meteorological data, a program solution has been made as an example. The program solution supports both rendering a 3D environmental model based on meteorological data at a certain point in time and displaying data for large periods using graphs.

A. Input Data

Available input data consists of real measurements taken at hourly intervals during a larger period of time, and it's contained inside a text file. Text file header contains information about the meteorological station that measured the data: name, geographic coordinates (latitude, longitude) and height above sea level. Each line contains measured data, measured at the interval of one hour. Measured data consists of year, month, day, hour, average wind speed, wind direction, maximum wind speed, air temperature, relative humidity, air pressure, insolation, rainfall quantity, rainfall length, cloud coverage and visibility. Data can easily be accessed for a certain date and time.

B. Graphs

Graphs provide an insight into data, and allow for tracking of changes over a certain period of time. Range of the data selected for the graphs can be arbitrary, which allows for greater flexibility when observing data. An example graph is shown in Fig. 5. A viable option would be selecting the sampling frequency for the horizontal data range, but since performance is not an issue, such option is not considered.

All graphs consist of the date being displayed on the x axis and the value for the measured data being displayed on the y axis. One exception is the wind direction graph,

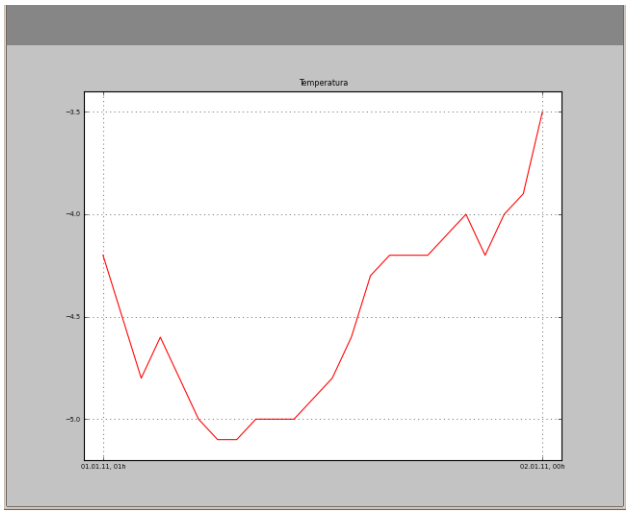

Figure 5. Air temperature graph

which instead displays the frequency of appearance of a wind direction in a polar graph.

C. 3D Graphic Model

Modeling a scene in order to visualize data consists of modeling the scenery and modeling the visual representations of data.

The scenery can be modeled after the real world, e.g. a building is defined. Because the scenery is mostly static, size of the scenery does not play a large part in the performance of the model, but again that depends on the complexity of the methods used for visualization.

For this example, the tools used were Blender3D [6], for the modeling of scenery and additional objects, and Ogre3D [13], for displaying a rendered scene inside a window. Ogre3D uses scene and resource Managers to organize assets necessary for rendering a scene. Resource manager's concerns are importing textures, materials and scene configuration, while the scene manager organizes models, cameras, particle systems and lighting.

Inside the scene manager, it is necessary to initialize a frame listener. Frame listener tracks changes in data and is usually called once per frame, but the calling frequency can be changed. For this example, only change that happens each frame is the rotation of the anemometer. Other changes happen whenever the read input has changed.

In order to visualize the sky and clouds, it is necessary to add a sky dome, as pictured in Fig. 6. A sky dome is a hemisphere placed over the scene. Textures can be placed on the dome which results in the visualized scene to be surrounded with the sky texture.

Since there's a need for detailed tracking of the wind direction and speed, anemometer changes can be followed. That makes necessity for one camera to be focused on displaying only the anemometer. Simultaneous display of multiple cameras can be achieved using multiple viewports, and in this case one viewport is nested inside the other, as can be seen in Fig. 7.

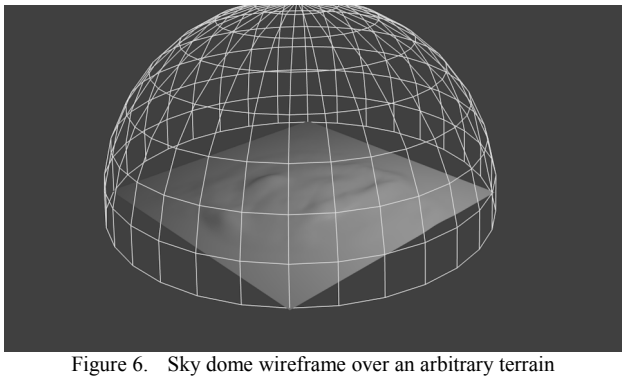

Figure 6. Sky dome wireframe over an arbitrary terrain

Another factor that plays a big role in the rendering of the scene is lighting. Position of the sun can be calculated, and therefore a directional light source can be placed inside the sky dome at the calculated coordinates. However, in small models, light source may continue providing ambient lighting for the model even after sunset. To counter this, ambient lighting must be set to darker values after sunset. Atmospheric refraction can also be simulated, which results in the sky having an orange hue near the time of sunset [14].

Ambient lighting is also dependant on the cloud coverage. The dependancy can be assumed as linear, even though it depends on the distribution of the clouds rather than the exact percentage of the sky covered.

IV. Conclusion

Simpler visualization methods are far from realistic looking in terms of visualizing meteorological data, but provide an insight into the state of the atmosphere at which the data were collected.

There are lots of ways in which various meteorological factors are related to each other, and therefore it is hard to make an accurate model based on small amounts of data. Still, based on the given data, some relations can be noticed and visualized.

3D volume localization using miniatures

Luka Šajn[1], Miroslav Radojevic[2] and Tomaž Dobravec[1]
[1]Faculty of Computer and Information Science
University of Ljubljana, Slovenija
[2]Biomedical Imaging Group of Erasmus MC
University Medical Center Rotterdam, Netherlands

***Abstract*—The prediction of the position of a given volume sample in a full body atlas, also known as a volume localization, is a part of an initial stage of image retrieval in most of the dedicated CAD systems. In this paper we present two methods for volume localization, namely histogram matching and classifier regression. Since the histogram matching method ignores the spatial orientation, it is used when the orientation of the volume cubes are not the same. On the other hand the classifier regression is much faster and can be used as a quick estimation and as a tool to reduce the scope of the initial problem. Both presented methods were tested on a dataset with 3962 volumes of a human body atlas. The accuracy and the speed of execution was compared and is presented in this paper.**

I. Introduction

3D volume localization problem is a problem of estimating the atlas coordinates of a given sample 3D volume (i.e. object, miniature). This is usually done by comparing the characteristics of a sample volume with the characteristics of other volumes with known coordinates. The coordinates of the most similar volume are returned as a result, as shown in Fig. 1.

To achieve this, one can use the method which compares the sample volume with the other volumes from the dataset and the coordinates are estimated as the interpolation of the coordinates of the most similar volumes, weighted by the degree of similarity. Another approach attempts to estimate the coordinates using classifier regression. Part of the problem is to find the matching volumes - this task can be viewed as the contents based image retrieval (CBIR) problem. One of the models to solve the CBIR is to treat the images as collections or histograms of the features [2] and compare the distances (dissimilarities) between the feature vectors. The resulting feature is the one with the lower distances, hence higher similarity. Potential features used for grey-level images

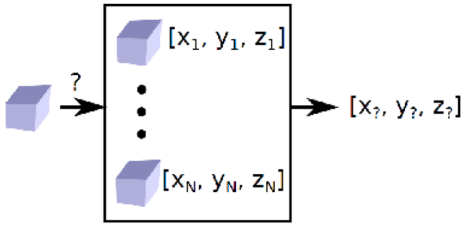

Fig. 1. Estimating the coordinates of the most similar volume

can be the very pixels, features that correspond to human visual perception, texture features such as global descriptors or Gabor features, or local descriptors such as SIFT or corner detectors [2]. Shape features such as Fourier descriptors, moment invariants and finite element models were surveyed in [12], graph based shape features were presented in [1]. A method for retrieving 3D datasets based on Local Binary Patterns (LBP) features [4] was introduced in [11] and compared with features such as 3D Wavelet Transforms and 3D co-occurence matrices. In this paper we use and compare two methods for the coordinate prediction, namely the histogram matching, which is presented in Section II-A, and the classifier regression, presented in Section II-B. The results of the comparison are given in Section III. We conclude the paper in Section IV.

II. Methods

Two methods for the coordinate prediction are used: histogram matching and the classifier regression.

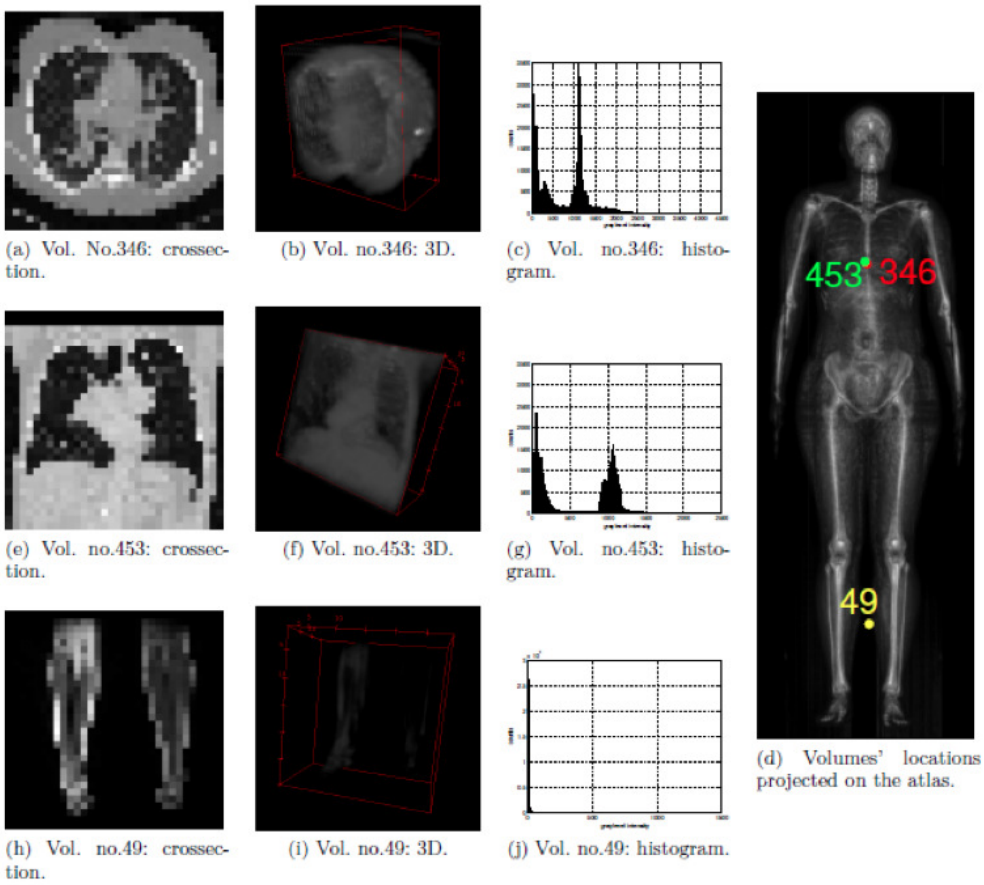
A. Histogram matching

The orientation of the sample volume is usually not the same as the orientation of the volumes in the dataset. Hence, it is necessary either to encounter for their proper alignment, or to use a measure independent to the orientation of the volumes. Such measures include histogram, rotation invariant image moments and local features. The first method presented in this paper compares the histogram of the samples with the histograms of all the other miniatures. The drawback of using histograms is the loss of spatial intensity distribution information. Some other rotation invariant feature extraction method such as SIFT or LBP in 3D [4] would be potentially suitable to overcome the problem of describing the spatial relations between voxels.

Figure 2 depicts three different volume samples in both 3D and cross-section version, their histograms and the detected locations within the human body atlas using the histogram matching method.

1) Histogram dissimilarity measures: There are several cross-bin and bin-to-bin dissimilarity measures to distinguish among histograms being compared [6]. Generally, cross-bin distances such as Earth Movers Distance (EMD) tend to be more robust and more discriminative than bin-to-bin measures when comparing two histograms [9].

Let L and M represent histograms being compared and each value $M(i)$ the count of the number of observations that fall



(a) Vol. No.346: crossection. (b) Vol. no.346: 3D. (c) Vol. no.346: histogram. (d) Volumes' locations projected on the atlas. (e) Vol. no.453: crossection. (f) Vol. no.453: 3D. (g) Vol. no.453: histogram. (h) Vol. no.49: crossection. (i) Vol. no.49: 3D. (j) Vol. no.49: histogram.

Fig. 2. Three volumes with their histograms and detected location within human body atlas.

into one of the disjoint intensity intervals. If n be the total number of observations and k the total number of bins, then the following holds:

$$n = \sum_{i=1}^{k} M(i)$$

Among the most popular bin-to-bin measures let us mention: histogram intersection, L_1 and L_2 norm, χ^2, and Jeffreys Divergence with calculation formulas (in respective order)

- $h(L,M) = \frac{\sum_j min(L(j),M(j)))}{\sum_j M(j)}$
- $L_1(L,M) = \frac{\sum_j abs(L(j)-M(j))}{N}$
- $L_2(L,M) = \frac{\sum_j (L(j)-M(j))^2}{N}$
- $\chi^2(L,M) = \frac{\sum_j (L(j)-M(j))^2}{\sum_j L(j)+M(j)}$
- $\mathrm{Jf}(L,M) = \sum_j \left(L(j) log \frac{2L(j)}{L(j)+M(j)} + M(j) log \frac{2M(j)}{L(j)+M(j)} \right)$

An important representative of the cross-bin histogram comparison method is called the Earth Movers Distance (EMD) [8], [9]. Fast implementation of the cross-bin histogram comparison EMD was used in our tests [8].

2) Weighting the coordinates: We have performed the tests by calculating all of the inter-histogram dissimilarities. After this calculation, ten most similar volumes were queried out of the base and used to estimate the coordinate. Estimation was based on weighted averaging where weights sum up to unit and each weight corresponds to the similarity level d_i and follows negative exponential function with slope determined by normalized variance of 10 selected dissimilarities.
The coordinates of the ten best matches (ranked with i) were weighted by exponentially decaying weights, derived from the variance of their dissimilarity measures. The resulting coordinates $[x_{est}, y_{est}, z_{est}]$ were calculated by

$$[x_{est}, y_{est}, z_{est}] = \sum_{i=1}^{10} w_i [x_i y_i z_i]$$

where $w_i = e^{-\lambda i}$ and $\lambda = max\left(\frac{d_i - mean(d_i)}{var(d_i)}\right)$.

Such weighting was used to overcome the influence of the outliers on the estimation since outliers can cause higher variance in general as shown in Fig. 3.

B. Classifier regression

Another approach to predict the coordinate values uses classifier regression. Classifiers such as 10-NN and Random Ferns

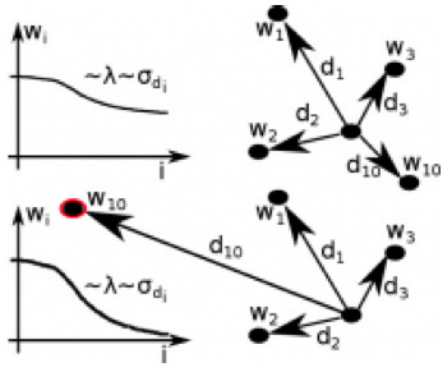


Fig. 3. The weights of the outliers are smaller than the weights of the neighboring candidates.

[7] use the image features and carry out the regression instead of usual crisp classification. PRTools Matlab library [3] is used for 10-NN implementation while Piotrs Matlab Toolbox [10] is used for Random Ferns implementation. Classifier scores are used to interpolate coordinates of those that were classified as being close to the test sample in a way typical for each classifier. Namely, averaging of the 10 nearest neighbors coordinates will be 10-NN regression. Similarly, in the case of SVM classifier usage, coordinates of the most similar ones separated by SVM will be interpolated. Features used for classifier regression are: mean, standard deviation, median, volume (actual number of pixels in the volume), centroid (1st order image moments), central moments (2nd order image moments), and the voxels themselves can be used as features, too. In cases when voxel intensities are used (Random Ferns classification), binary features need to be extracted - hence number of combinations can grow high. Therefore, volumes were resized using Gaussian pyramid before calculating the binary features.

III. Results

We tested the methods on a dataset which consist of 3926 volumes (miniatures representing body regions). Each of the volumes was resampled to $32 \times 32 \times 32$ image cube. Voxel intensities of the image cube are real values ranging from 0 to 4095. Each volume corresponds to certain spatial regions of the body as it was shown with dots (center points of the region) in Fig. 5. Volumes are actually resembling different regions of the body and they are taken from different orientations (transverse, coronal, sagital).

Results are presented for both approaches introduced in the Section II. "Histogram comparison" turns out to be quite precise at finding similar patches. However, the choice of the dissimilarity metric is very important. As mentioned, cross-bin dissimilarity is preferred since it is more robust. The performance of different metrics when matching histograms for query volume (object nr. 1540) shown together with its top 10 most similar patches from the database. Process finds 10 most similar volumes and interpolates their coordinates.

TABLE I

ESTIMATED POSITION ERRORS FOR DIFFERENT HISTOGRAM COMPARISON MEASURES (INTERSECTION, L1 AND L2 NORM, χ^2, JEFFREY DIVERGENCE AND EMD) FOR THE OBJECT NR. 1540

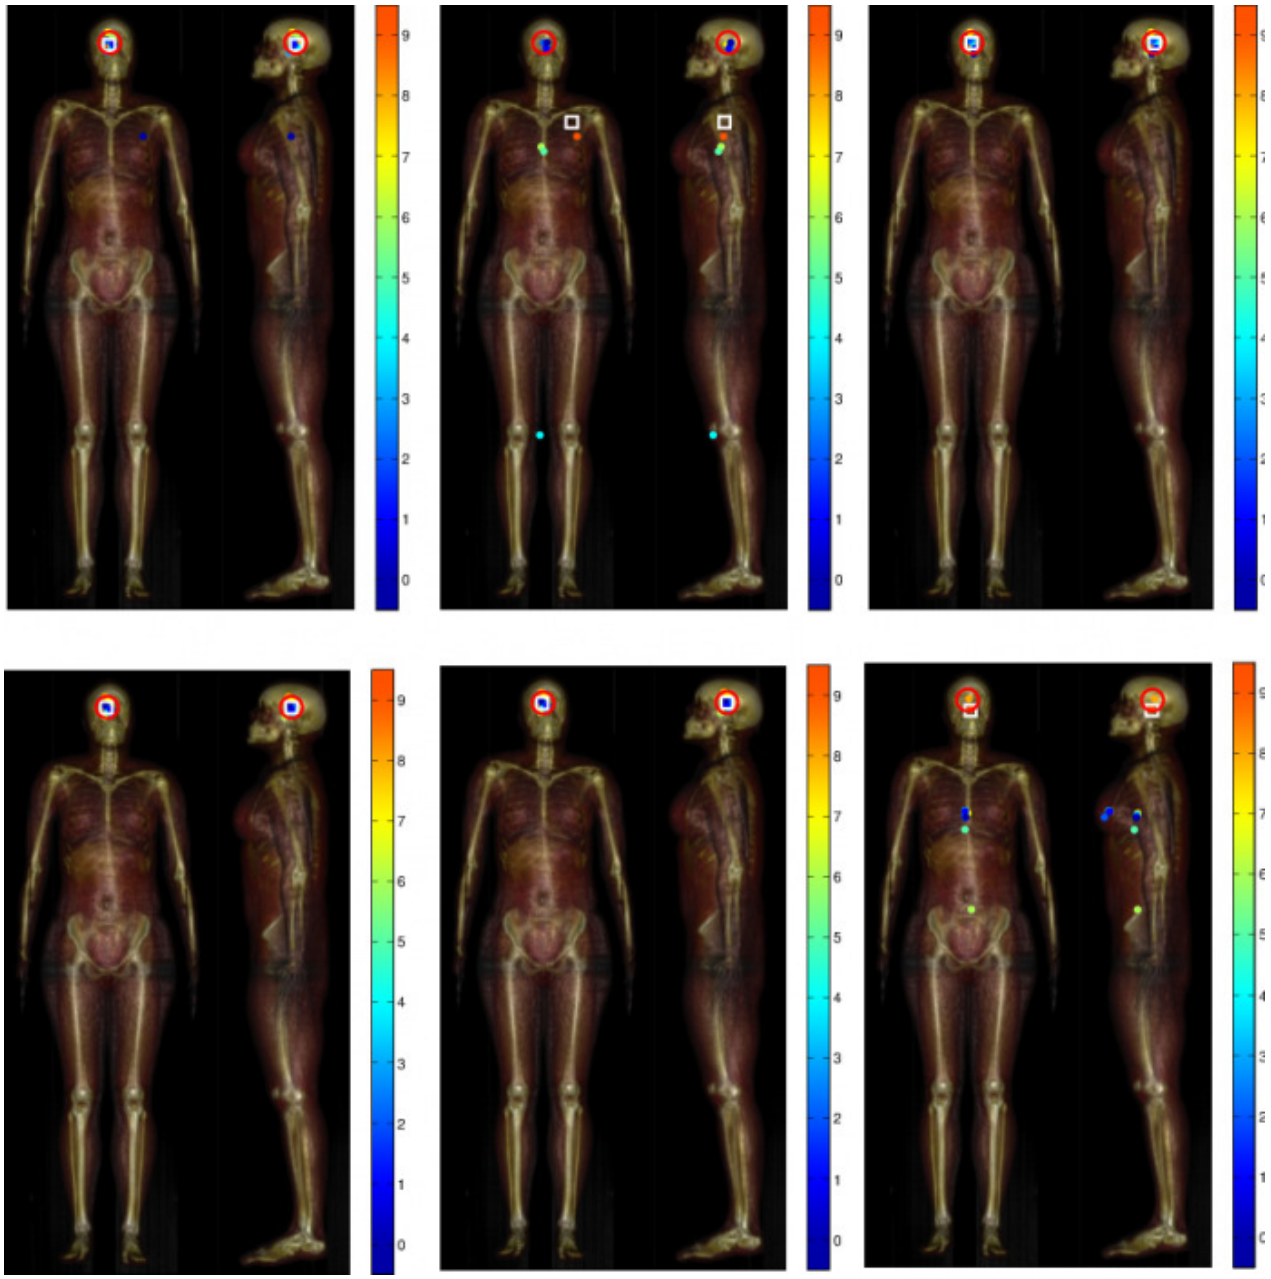

Fig. 6. Results of volume matching using histogram comparison for dissimilarity measures L1 norm, L2 norm, EMD, χ^2, Jeffrey divergence, and Intersect (from left to right, top to bottom).

EMD dissimilarity measure turns out to be the one that performs the best both in terms of accuracy and robustness, however it is slower and features used for matching are dependent on the database. Downside of its usage is computational cost, nevertheless fast implementation of EMD [8] used in this experiment provides satisfactory performance. What is still a potential problem with this approach is the fact that it is dependent on the data from the training set - since it is based on comparing the input with the training dataset. In that sense - classifier regression based approach with invariant

statistical/shape/moment based features would be interesting. Figure 6 show the results of volume matching using histogram comparison for dissimilarity measures: L1 norm, L2 norm, EMD, and χ^2, Jeffrey divergence, and intersection (from left to right, top to bottom). Predicted value is represented with white square, while the true value is described with red circle. Top 10 matching positions were shown as dots in jet color space - ranging from red ones that represent high ranking till the blue ones with low ranking. Estimation fails in case metric was not properly chosen. EMD turns out to be the one that performs the best both in terms of accuracy and robustness.

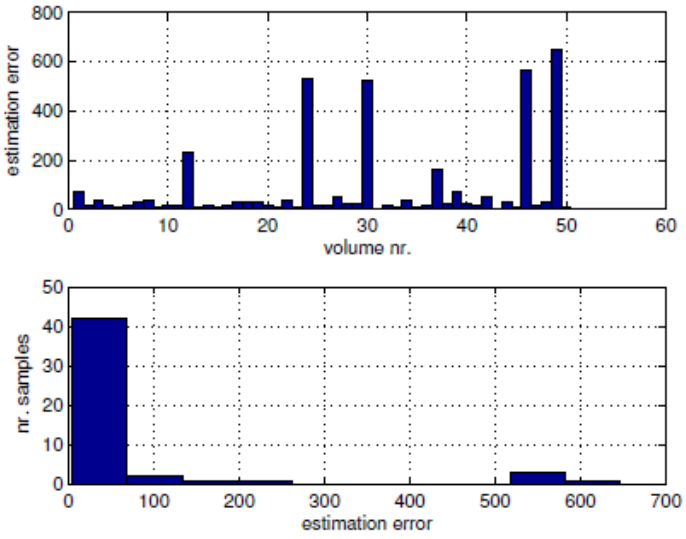

Fig. 7. Statistics for the absolute distance error between the position estimate and the actual position.

Finally, histogram matching was performed individually on 50 randomly chosen objects while the rest were used for matching with the test sample each time. Figure 7 shows the statistics for the absolute distance error between the position estimate and the actual position. Majority of discrepancies fall into 0-50 voxel distance range which suggests that the object was targeted. Usually, distances up to 50 absolute voxel values do properly guess the object since the main task is rough localization of the body region.

"Classifier regression" was based on independent features (such as volume mean, standard deviation, image moments, volume). As stated before - classifier score was the basis for the data regression. 10-NN classifier was used to find the neighbors in feature space and average the coordinates associated with them in order to carry out the regression. This process works much faster since it takes short time to extract the features and there is no need for comparison. It accomplishes the retrieval but the performance is lower as shown in the figure 8.

Regression accuracy is worse than the one obtained using histogram comparison and one of the causes is probably plain averaging of the feature-space-nearest-neighbor coordinates

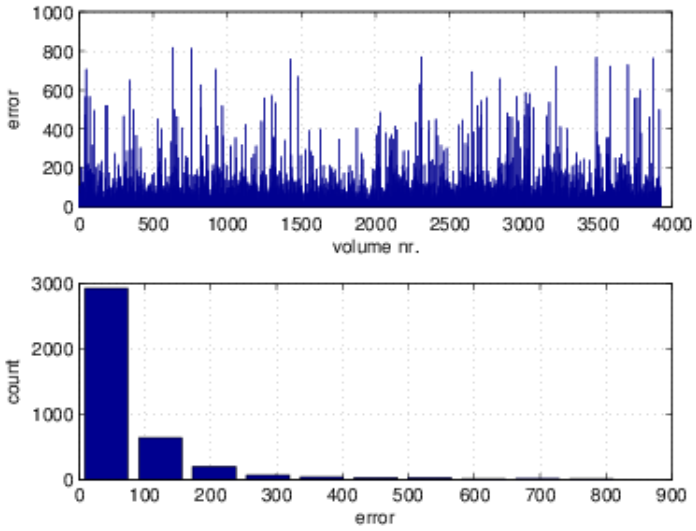

Fig. 8. Results of classifier regression (10-NN) based on independent features

(no weighting). The features used can influence the choice of the nearest neighbors. Finally, Random Ferns [7] were tested on position regression. They performed slightly slower than 10-NN regression, but had an overall lower average error calculated over 50 randomly chosen miniatures. Voxel intensities were used as the source for making binary features that this classification algorithm uses. Usage of statistic/shape features that were supplied to 10-NN did not perform as well as voxel intensities did. Binary features were chosen to be -1 or +1 for each possible pair of voxels. In case the first one from the pair was higher - feature was set to +1 and -1 was for the opposite case. Each miniature needed to be resized to $8\times8\times8$ using Gaussian pyramides and even after the reduction - quarter of the total number (every 4th) of the voxels was used for matching in the experiment due to processing time constrains. Results proved to be promising in spite of all the constrains.

IV. Conclusion

This paper summarizes the results obtained while developing 3D content based image localization framework. Two approaches have been examined - one based on comparing the histograms and another one based on the classifier regression. 10-NN and Random Ferns classifiers were used for the regression. The best performance in terms of accuracy was achieved by comparing histograms using the EMD (Earth Movers Distance) method. Classification regression using 10-NN proved to be slightly less precise but significantly faster, and the same conclusion can be made for Random Ferns that found their best performance by taking voxel values as features and compared the 3D patches for similarity. Average error on position prediction calculated on 50 random samples was lower than the one obtained using 10-NN. Nevertheless, Random Ferns classification was significantly constrained with reducing the feature number for the computational time

purposes, therefore its performance can certainly improve. Future work can include clustering of the coordinates into crisp classes so that further evaluation of position prediction performance can be estimated in a more appropriate way. 10-NN regression can be improved by using weighted average of the nearest neighbors or some additional features. Random Ferns regression can perform better with more elegant way of reducing features it uses. Finally, local feature extraction methods such as 3D SIFT or 3D LBP can be used.

***Abstract*—Image processing plays an important role in medical image analysis. The most popular methods for image processing and analysis are very resource hungry, which leads to some disadvantages in their applications even on a powerful desktop computers. On the other side, modern mobile devices are equipped with powerful processors with an efficient instruction architecture. This lead to better performance per watt than a desktop CPUs. This work investigates the performance of a widely used medical analysis algorithm implemented on a modern mobile devices and desktop CPU. The results obtained with ARM NEON instructions show speed improvements up to 2 times. As this research shows mobile devices cannot yet compete with powerful desktop CPUs, even with using highly optimizations or multiple threads. In the last part of the paper conclusions are drawn for acceptable image input and parameter sizes.**

I. Introduction

In Chandrakasan et al. [1] was one of the first arguments in favor of multicore microprocessors. Reason for using multicore processors is important for power savings, so dual-core microprocessor running at half of frequency of a single core microprocessor use about 0.6 times less power.
The trend of using more, but less powerful, processor cores dominates microprocessor industry in the last decade. Performance of mobile devices depends of power efficiency, and can be expressed as performance per watt.
In this work, we investigate the possibilities and limitations of well known Demons algorithm implemented for mobile Android device. Previous studies have investigate various image processing algorithms implemented on a mobile devices.
One of the first known work about image processing on Android mobile device were given by Wells [2]. This paper analyze the computation time of an image processing algorithm.
Mitra et al. [3] analyze the performance of various image processing algorithms implemented on ARM devices, and compares the results with an Intel CPUs, using SIMD (Single Instruction, Multiple Data) instructions.
In Luxemberger et al. [4] optical flow algorithms on ARM powered Android mobile phones were developed.
In Pulli et al. [5] authors compare performances of various algorithms on mobile Tegra 3 platform using OpenCV, and optimizations like NEON instructions, GLSL (OpenGL Shading Language), and TBB (Threading Building Blocks).
Welch [6] investigates SIMD instructions on a Cortex-A8 processor with NEON co-processor, using two image processing algorithms: bilinear interpolation and distortion. SIMD instructions exploits several pixels at once for bilinear interpolation algorithm with speed up factor of 2, and distortion algorithm optimize memory access by prefetching data, with a speed up factor of 3.
In Holgersson [7] author implements four different implementations of biquads IIR filters for audio processing, and evaluates results with/without fixed-point processing and NEON optimizations. Their optimizations is based on parallel filter run, memory operation efficiency and fixed-point processing.
In Wang et al. [8] authors implemented Edge-based Image Decomposition TV-L1 optical flow algorithm on a mobile phone running Android platform. The algorithm calculates optical flow between the two images.
OpenCV library [9] is a widely used open source computer vision and machine learning software library highly optimized for desktop processors. In recent time OpenCV was ported to mobile platform including Android, and includes optimized code for ARM processors. Several books about using OpenCV in Android exists today (see for example [10]).
All previously mentioned implementations use powerful instructions of the modern ARM processors for mobile devices, which increase their usage in a highly computational applications for various signal processing and computer vision tasks. To our knowledge there is no implementation of Demons registration method for mobile devices.
The main contribution of this work is implementation of the Demons registration algorithm (Thirion [11]) on ARM CPUs running Android.

II. Methods

A. Demons registration

The goal of image registration (see for example Zitova [12]) is to obtain a mapping from one coordinate system of one image to the coordinate system of the other image. The one of the most widely used deformable registration algorithm is Demons registration algorithm (Thirion [11]). This algorithm is widely known and yet simple to use (Figure 1). It has linear computational complexity (i.e. depends linearly with the input image pixel number). Also, it can be easily parallelized, where each pixel can be computed separately, there is no data dependence between the neighbors (see for example Muyan-Ozcelik [13]). Demons algorithm forces can be expressed with the Optical flow equation (Horn [14]).

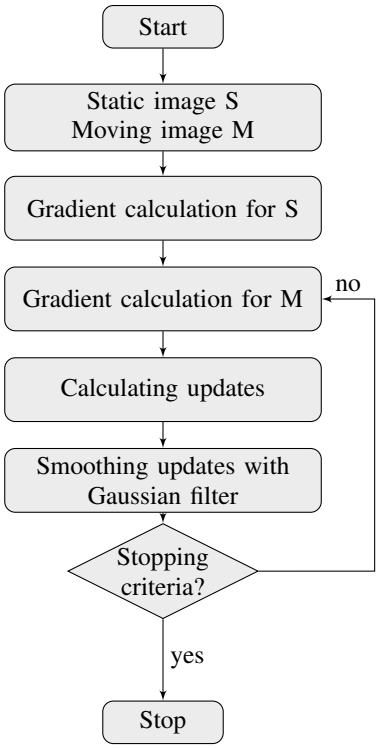

Fig. 1. Flowchart of Demons algorithm

B. Implementation for an Android device

Android platform is now a world dominant in mobile platform market. Android as a development platform use the Java Standard Edition with additional Android classes. Applications are developed in the Java language using Android Software Development Kit (SDK). For a low level interaction with hardware, a modified Linux kernel is used. For performance critical applications Native Development Kit (NDK) is unavoidable [15]. Therefore, part of the applications can be built with C/C++ language. NDK uses Java Native Interface (JNI) which is a standard way for Java platform to interact with the native code.

1) Optimizations for ARM platform: Several optimizations can be used with NDK. For Tegra 3 and Samsung Exynos platforms optimizations for ARM V7 instructions can exploit a specific NEON instructions.

2) SIMD Instructions: SIMD (Single Instruction, Multiple Data) operations use multiple data elements at once. These instructions dates back to Intel MMX (from 1996) set which gains popularity in multimedia applications. Intel MMX instructions yields significant speed-up comparing to the sequential instructions. This usually means the more processing power for the roughly the same energy consumption. Processors used in mobile applications today are usually 32-bit, with recent trend to switch to 64-bit. For example, ARM Cortex A9 processor (used in Tegra 3 chip) is a 32-bit processor. Therefore, operations using 8-bit and 16-bit data are performed in 32-bit registers. These operations can be executed at once. This is significant in multimedia applications and image processing tasks where the same operations can be executed on many image elements at once. Combination of SIMD instructions and parallel code execution is usually optimal for these algorithms.

TABLE I. OPTIMIZATION PARAMETERS FOR GCC COMPILERS

Platform	Optimization string
Desktop	-O2
ARMv7	-march=armv7-a -mtune=cortex-a9 -mfloat-abi=softfp -mfpu=neon
ARMv6	-march=armv6 -marm -mfloat-abi=softfp -mfpu=vfp

3) ARM Neon Architecture: ARM NEON [16] introduced instructions for ARMV7 for using with several data types. NEON implementation is 128-bits SIMD architecture extension which dates back for Cortex-A series processors. It has 32 registers, 64-bits wide, and dual view as 16 registers 128-bits wide. Datatypes can be signed/unsigned 8-bit, 16-bit, 32-bit, 64-bit, and single precision floating point.

C. Porting image registration library for Android platform

We use our developed C++ library for image processing and registration, which is a rather simple library for image loading, image processing and registration tasks. For image visualization Fast Light Toolkit (FLTK) [17] can be used. For the purposes of this study, library was ported from desktop to Android platform using Android NDK. Porting code with NDK is a relatively straightforward task.

III. RESULTS

For the evaluation of registration speed we chose two MRI liver images (Figure 2) obtained from [18]. Two slices (resampled to 256×256) were extracted from the dataset and can serve as the input in all our experiments. We use Demons registration algorithm (Figure 1) to align these images. As a result, deformation field is obtained, which is a vector field showing a mapping between each corresponding pixels in the two images. Single threaded version of Demons algorithm

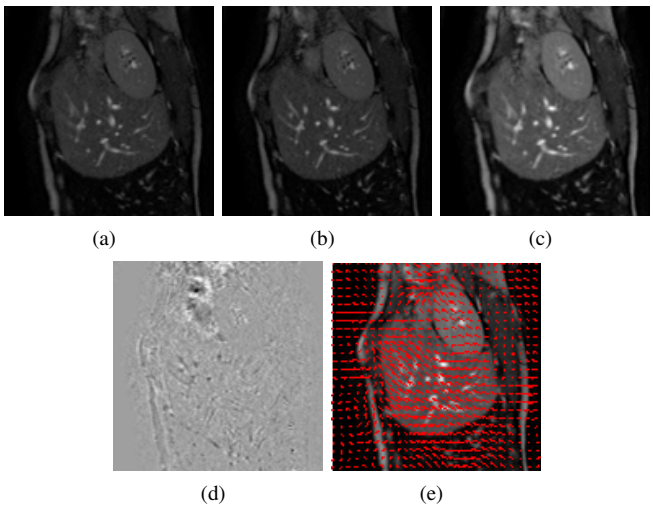

Fig. 2. An example for registration of liver MRI a) fixed image b) moving image c) registered image d) difference between registered and fixed image e) deformation field overlayed on static image

TABLE II. DEVICES SPECIFICATION

Device #	Processor/Model	Threads/Cores/GHz	Cache L1/L2/L3	Memory (GB)	SIMD	Power (W)
1	Intel® Core™ i5-2500	4/4/3.3	4x32/4x256kB/6MB	4	SSE4.2	95
2	Intel(R) Xeon(R) E5450	4/4/3	4x32kB/2x6MB/	8	SSE4.1	80
3	Intel Celeron M ULV	1/1/900MHz	1/512kB7/-	512MB	No	5
4	Samsung GALAXY S3	4/4/1.2	31kB+31kB/1MB-	1	Neon	3 (est)
5	Nexus7 2012	4/4/1.2	31kB+31kB/1MB-	1	Neon	1.1
6	Wildfire S	4/4/1.2	31kB+31kB/1MB-	512MB	No	1

TABLE III. RESULTS FOR DEMONS ALGORITHM (IN SECONDS).

	Parameters		Device #					
Image size	width	σ	1	2	3	4	5	6
256×256	7	1.0	1.5	1.2	34.3	8.6	9.7	30.1
	31	5.0	12.8	18.2	422.7	91.2	103.3	1033.8
	61	10.0	42.2	63.2	1549.9	338.8	379.6	4175.5
	121	20.0	144.7	245.9	5558.1	1351.2	1514.3	17414.5

were used for all experiments. It can be shown that 50 iterations is enough for Demons to converge. For each device several Demons Gaussian parameters are applied (Table III). All calculations have been carried using a single-precision numbers. For a chosen σ we calculate the filter, in pixels, with the following formula $width = 2 * (3 * ceil(\sigma)) + 1$ where the *ceil* is defined as $ceil(x) = \lceil x \rceil$. Four registrations has been runned on the each device (Table II). Obtained results are shown in the Table III, and in Figure 3.

The results can be grouped by device type to: desktop and mobile. Desktop devices for this study were, a small laptop, home PC and server machine, the last two typically used for image registration. Mobile devices varied in speed from older and newer cell phones, and a newer tablet. For the selected platforms we use the following software.

1) Desktop devices: For experiments on the desktop devices we use GCC 4.6.3 compiler on the corresponding machine with GNU/Linux with compiler optimizations (Table I). These results can be taken for ground truth.

2) Mobile devices: For developing for the mobile devices we used the Android NDK version r9 on GNU/Linux, with the GCC 4.6.3 compiler with the corresponding optimizations as shown in Table I.

All simulation results are given in Table III and Figure 3. As we can see from the obtained results Demons registration is iterative and CPU-intensive algorithm. Registrations can run in real-time for a smaller image dimensions and kernel widths, and their usage is restricted in medical practice. From the all runned experiments one can see that performance for the smaller Gaussian kernel sizes are almost identical. This means that for a relatively smaller deformations, smaller kernel width is needed. Due to a bigger cache size and better architecture wider kernel results are in favor of desktop CPUs. Poor results for Wildfire S is due to an older ARM architecture as well as a lower frequency. The results depends on the ARM CPU and it is slower from 1.1 to 9 times.

Exploiting multiple cores can bridge the gap between mobile and desktop CPUs for smaller Gaussian kernels.

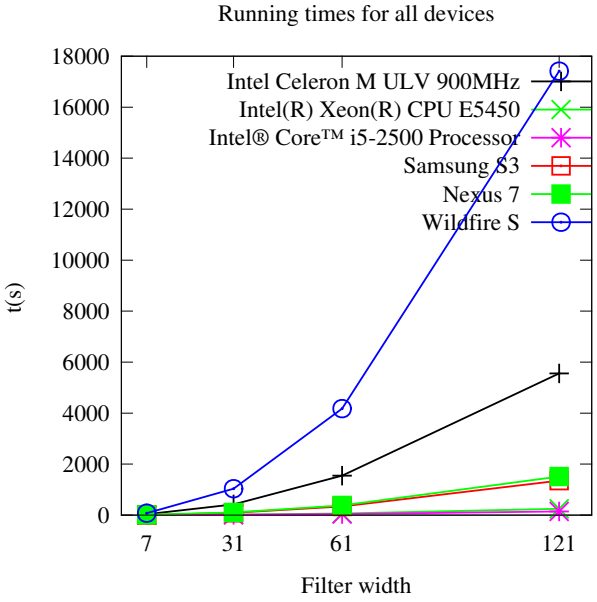

Fig. 3. Registration results for all devices

IV. DISCUSSION

This paper evaluates the performance of Demons image registration implemented on mobile ARM processors. For the experiments we choose a pair of liver MR images, and register them using a several pair of Gaussian parameters. Each experiment were carried on several desktop and mobile devices. Results shows, in general, that mobile devices cannot compete with desktop CPUs in highly demanding tasks like image registrations. Mobile CPUs can be used as an alternative with smaller Gaussian kernel widths, which corresponds to smaller deformations in the input images. The best results for the mobile devices were about 9 times slower than best running time on the desktop CPU.

Further research in this direction can evaluate tradeoff between registration precision and execution times regarding floating point optimizations in a way similar to the method in Holgersson [7]. Regarding speeding up the algorithm one possibility is multicore implementation of Demons algorithm on the ARM CPUs, i.e. implementation using TBB.

Abstract - With recent technological developments, modern computing systems are becoming more and more powerful. Common computers are capable of calculating more than 50,000 million instructions per second. Currently the biggest obstacle in computer usage is slow communication between the human and the computer. With innovation and development of novel (natural based) sensors capable of capturing positions and natural motion of human body a new, natural, way of interacting with computer is enabled.

This paper gives an overview of eye tracking technology, and presents its application in nature based human-computer interaction (HCI) systems by extending standard controllers, such as the keyboard and the mouse. Novel approaches enable HCI closer to the communication patterns of human beings. In addition, the usage of those concepts in applications for eye diseases and disorders diagnostics and rehabilitation is discussed.

Keywords: eye tracking, computer interaction, hci, oculography, medical diagnosis.

I. INTRODUCTION

The use of standard interaction devices (such as mouse and keyboard) for communication between human and computer is already addressed as one of the biggest obstacle in modern computer usage [1], [2]. In this research field even HORIZON 2020, the EU Framework Programme for Research and Innovation, recognized problem and necessity for improvement. In the year of 2014, one of the first opened calls in HORIZON 2020 Programme, is the special topic Multimodal and Natural computer interaction, in the section ICT 2014 - Information and Communications Technologies.

Recent development of intelligent sensors for capturing and recognizing natural human behaviours enabled novel approaches to answer to this problem by making human-computer interaction (HCI) a natural process. During last few years several different controllers emerged as products affordable for general population.

Microsoft Kinect controller is a multi-modal sensor which contains a RGB camera, an infrared (IR) emitter and an IR depth sensor, a multi-array microphone and a 3-axis accelerometer. With all of these inputs Kinect is able to determine its current orientation, to find the location of the sound source and the direction of the audio wave, to identify human in the scene, to find the location of human body parts, to recognize human body poses and gestures [3]. All of the calculations were performed by computer embedded into the device.

The Leap Motion controller is a small USB peripheral device produced by Leap Motion, Inc. This sensor contains two monochromatic IR cameras and three infrared LEDs. With its smaller observation area, higher resolution and acquisition rate the Leap Motion sensor differentiates from the Kinect. Unlike the Kinect, which is more suitable for whole-body tracking, the Leap Motion is used for acquiring positions, orientations and gestures of human hands and fingers in very high resolution and precision [4].

Eye tracking sensor also emerged as one of the most promising device for HCI and similar applications. During last few years several companies developed eye tracking sensors using different technology, however the devices were still too expensive for general public. In year 2013 Tobii announced a new device Tobii EyeX, a high accurate eye tracking device with affordable price for general population. The true benefit of eye tracking is opportunity to gather data for HCI even for the population with disabilities to use their limbs. The other important feature is a capability to use standard interaction methods, using keyboard and mouse, and gain an additional information to enhance the interaction. Based on those advances, the aim of this paper is to address new capabilities for HCI and new approaches for diagnostics and rehabilitation in the field of medical oculography.

II. EYE TRACKING TECHINQUES

The most popular and also commercially available method to measure the rotation of the eye is "corneal-reflection/pupil-centre" [5]. It is an optical tracking method without direct contact to the eye. This method uses benefits of corneal, which reflects a light directed into the eye. In order to decrease dazzling, infrared light is emitted to the eye. Light enters the retina and a large proportion of it is reflected back, making the pupil appear as a bright, well defined disc known as the "bright pupil" effect. This effect is achieved if the infrared light emitter is placed close to the optical axis of the infrared camera

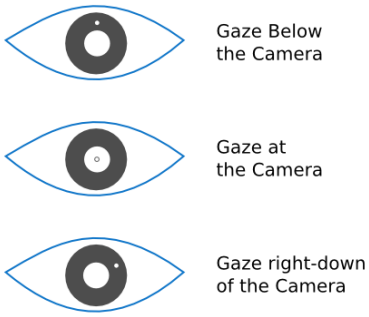

Figure 1. Corneal reflection

device. Setting emitter away from the optical axis will cause the pupil to appear dark. Additional data that can be collected with infrared camera is corneal reflection which is appearing as a small, but sharp glint Figure 1. Based on these two facts and data collected during calibration procedure, a point of regard (gaze point on the surface) or a gaze direction can be calculated using trigonometric calculations.

The complexity of estimation point of regard is depended on number of cameras and light sources. The point of regard can be estimated using one camera and one light source only if the head is completely stationary. Estimation of the point of regard with free head movements is enabled by using one camera and multiple light sources followed with multiple point calibration procedure. Theoretically, it is possible to have one-point calibration procedure to estimate point of regard if multiple cameras and multiple light sources are used. It has been shown that main sources of gaze estimation errors are the discrepancy between the shape of real corneas and the spherical corneal shape assumed in the general theory, and the noise in the estimation of the centres of the pupil and corneal reflections [6].

Limiting factors of the bright pupil method for eye detection are size of the pupil, environmental light and retinal reflection properties. The last one brings most concern and depending on these properties different approach is used, bright pupil or dark pupil technique [7]. This study has found correlation between pupil size and pupil intensity leading to conclusion that subjects with larger pupil sizes are producing higher intensity values. In general, bright pupil method gives higher precision values than dark pupil method. However, it has been shown that dark pupil method provides better results than bright method among ethnic groups, especially for African and Indian population. This bright/dark pupil effect raised the question of how applicable device would be in ethnic diverse country such as South Africa [8].

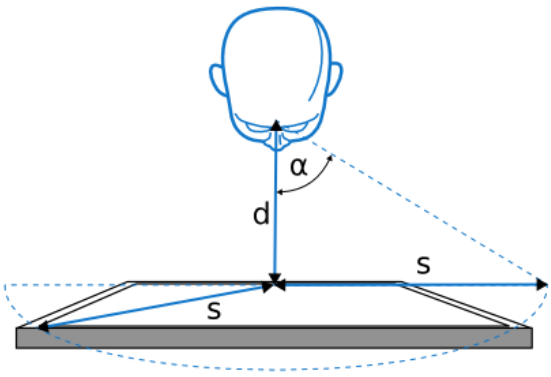

Figure 2. Optimal distance from eye tracker

Before the usage of the eye tracker the calibration procedure is needed to be carried out. During the calibration procedure, the participants are asked to look at the corresponding points also known as the calibration dots displayed on the projected area which is called Active Display Area (monitor, TV screens, projected displays etc.). Number of calibration points and calibration setup affects the accuracy of the results. In general, the more calibration dots, the better the accuracy. Calibration is usually performed on five or nine points. It is very important to have the correct distance to the monitor or the tracked object, otherwise the eye tracker cannot track the entire area. If the monitor or object is placed too close to the participant there is a risk that the gaze data for the corners of the display area of the monitor will not be collected [9]. To calculate optimal distance *d* from eye tracker following formula is used:

$$d = s / \tan(\alpha), \quad (1)$$

where *s* represent the distance from the bottom centre corner of display area to the upper right/left corner, α - optimal gaze angle which value depends on type of eye tracking device (known parameter). During calibration procedure, for each calibration dot an image is taken by the eye tracker, and then analysed to extract parameters for a psychological 3D eye model.

The gaze angle error is expressed as deviation in degrees between two lines where origin is determined by the position of the eye, calculated from images captured by eye tracker. Second point of the first line is determined by the subject's actual gaze point in the active display area, and the second point of the other line is the gaze point measured by the eye tracker.

Another parameter that effects on accuracy and precision of the eye tracker device is environmental illumination [9]. According to Tobii X2-30 eye tracker specification manual it is clearly visible that best accuracy and precision is achieved at illumination of about 300lx what represents the general ambient light levels in offices, classrooms, laboratories and public areas. Illumination above and below this value reduce precision and accuracy of the eye tracker. The main reason for the error is pupil dilation [10].

Constant exposure to the infrared light emitted by the eye tracker has a tiring effect on the eyes which is another concern to observe. The daily use of this technology could be limited if medical research shows harmful effect on the human eyes. Participants wearing glasses or even sunglasses had a better and enhanced bright pupil detection, only problems occurs during reflection from glasses or strong edges of the glasses [8].

III. CHARACTERISTICS FOR EYE TRACKER USAGE

The aim of eye tracking devices is to collect subject's eye activity while they are performing a specific task. The most common types of metrics used in analysis of human behaviour of the eye are fixation and saccades. Fixation are defined as inaction state of the eye above certain period of time. The threshold for this period is time varies typically between 100-200ms. Important attributes that describe fixation are: fixation duration, number of fixations and time to first target fixation. Graphically fixation is presented as circle determined by 2D coordinates with radius defined by duration of fixation. Lines that connect fixation points represent the movement of the eye from one focus to the other and are called saccades. The sequence of fixation and saccades are called a scan path. Collection of scan paths collected for certain period of time represent gaze plot. Generally gaze plots aren't appropriate for analysis for longer duration of time, because graph becomes overwhelmed with plotted data. As common type of visualization for this kind of problem is used heat map. Heat map gives the distribution of density fixation points, which mean heat maps belong to the class of time aggregated diagrams.

Currently eye tracking devices are mostly used in following research fields:

- Psychology studies
- Linguistic studies
- Human-computer interaction research
- Social interaction studies
- Research and studies using simulators
- Copy testing, digital campaigns and TV commercials
- Web and software usability studies of mobile interfaces and devices
- Studies of interactive television, gaming, virtual reality environments and control panels
- Usability studies of physical objects and industrial design
- Real-world interface studies that require a small eye tracker, such as studies of an ATM a ticket machine, or a control pane

IV. NATURAL EYE GAZE COMPUTER INTERACTION

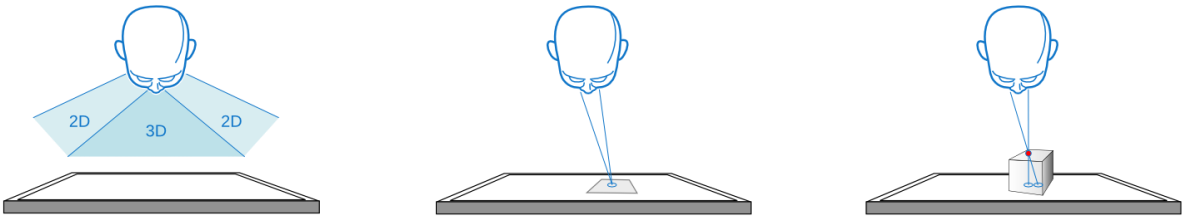
Communication between human and machine goes in two opposite ways - first direction represents visualization of data to be presented by machine to human, the opposite direction goes from human to the machine as commands. To understand how human interact with virtual environment on the computer we need to explain how human perceive a real content in natural environment. Each eye perceive scene from its specific field of view and creates a single 2D image. Left and right eye fields of view intersect in frontal area where two different images are gather for the same scene Figure 3. (a). Using information of left-right eye distance and location of the objects in left/right eye images human brain can calculate depth map (distance of objects in scene).

Interaction with 2D virtual content is enabled by tracking the eye gaze location on the monitor. This location is represent with pixels (x and y coordination of the point) or metrics (mm). Using this information machine can navigate through the content or recognize specific gestures as commands Figure 3. (b).

Unlike the 2D content for interaction with 3D content the depth value is necessary. Depth value can be obtained by extracting two different gaze points of each eye separately Figure 3. With information of 3D position of pupil-centre and 2D gaze point we can calculate gaze vector for each eye. Two vectors should intersect in a single point. This point is a real gaze point and have 3D position Figure 3. (c). This point also represents the focus of the user observation.

The base idea in creation advance HCI is to systematically collect and analyse this eye tracking data to learn behaviours of the user. With this information physical and emotional state of the user can be determined, and intentions detected. This information enables creation of optimal user-specific representation (visualization) of data structures to make interaction with context more natural.

It is important to emphasize that eye tracker cannot be used as primary input device for navigation. It is shown that eye movement input is faster than other current input media [11], [12] but the people are not accustomed to operate only by moving their eyes. Naturally human eye is an input sensor and is not adjusted to trigger actions what leads to conflicts [13]. Usage of the eye tracker for eye-gazed based interaction, problem is in determination of delta time to register input, if this time is too short it leads to Midas-Touch problem and if delta time it too long leads



a) Human perception b) Interaction with 2D virtual content c) Interaction with 3D virtual content

Figure 3. Perception and interaction with 2D and 3D virtual content

to tiredness [14]. Adding the fact how we interpret a perceptually uncertain stimulus [15], additionally raises the question of limited usage of the eye tracker.

V. MEDICAL OCULOGRAPHY DIAGNOSTICS

Taking into account the speed of sampling eye tracker device and its accuracy under optimal condition of working, it can be used in the field of ophthalmology as the instrument in examining cognitive visual function, vision deficiencies and to study oculomotor behaviour of the eyes. It can be used as instrument that replaces and automate current methodologies that relay on observation and as instrument that provide identification of diseases at a much earlier stage of progression. A lot of research has been done in investigating a relationship of disease on the stability of the eye. It has been shown that there is no difference in fixation stability between 12 young observers at mean age of 22 and 12 older observers at mean age of 70 years old [16]. Fixation stability in patients with age-related macular degeneration has been studied using eye tracker system thankfully its higher digital sampling rate rather than the scanning laser ophthalmoscope. Another benefit was that eye tracker allows non-invasive measurements free of artificial support and diagnosis a patient condition in more natural way than that of the scanning laser ophthalmoscope [17]. Saccadic eye movements during tracking, fixation and resting were investigated in schizophrenic and normal participants. It has been shown that the frequency of saccades was higher in schizophrenic's participants than in normal subjects in all of the experimental conditions [18]. Endeavour on replacement the currently used methodologies that relay on observation with automated ones can be seen more and more frequently in the field of ophthalmology. Such example is current research which goal is to investigate the usage of eye tracker as device for detection of strabismus and amblyopia at early stages of development [18], [19]. A feature of high sampling rate in eye tracking can be used to measure the frequency and amplitude of the nystagmus. The investigation of eye pupil dilation under various stimuli attracted a lot of attention among researchers. This phenomena has been connected with many different human emotional and physical states. The most interesting conclusions are:

- pupil dilation can be used as a measure of attention [20],
- visual detection and recognition responses with pupil dilation [21] and
- pupil dilation during visual emotional stimulations can be a measure of affective states of non-communicative individuals [22], [23].

Eye tracker can be used in research as instrument for studying others eyes diseases and also as instrument for diagnostic irregularities in eyes behaviour which would lead to detailed examination of certain eye disorders. Examination the sensitivity of the eye to the light and glare, colour vision changes, peripheral and central vision are some of the irregularities witch can be detected. After surgery of the eye it is usually necessary to conduct a set of eye exercises which is another potential usage of the eye tracker. This would lead to reduction of the load on the medical personnel to focus their importance on emergency cases.

VI. CONLUSION

With new advances in sensor technology a new approaches for HCI can be developed. New controllers should be used in addition with standard HCI input devices (keyboard and mouse). Introduced eye tracking device captures movement of eyes, which is considerably faster than other current input media. However eye tracker cannot be used as primary input device for navigation because people are not accustomed to operate only by moving their eyes and other problems mentioned previously, such as Midas-Touch problem.

Medical usage of eye tracking device is still novel and popular thematic in research. Such technology can approve current methods for oculomotor diagnostics to be carried out automatically. With this advances some eye disorders can be diagnosis in much earlier stages.

INVITED PAPER

Green ICT for Sustainability: A Holistic Approach

Slavisa Aleksic
Vienna University of Technology/Institute of Telecommunications, Vienna, Austria
slavisa.aleksic@tuwien.ac.at

Abstract – In the last three decades, the information and communication technology (ICT) sector has been growing very fast. There is no such example in human history that development of a technology has changed our way of life in such a rapid and fundamental manner. ICT has become an integral part of our everyday life including social interactions, business processes, technology and ecology. Due to the fact that ICT not only promises enormous potentials but also carries risks, it is extremely important to carefully evaluate and assess ICT systems and applications regarding their potential for improving the global energy productivity in a sustainable manner.

This paper concentrates on technologies and methods for achieving high-performance and energy-efficient communication networks. Main achievements and trends towards highly energy-efficient network infrastructure are briefly reviewed. A novel holistic framework able to efficiently treat energy, entropy, and exergy flows in heterogeneous systems through combining thermodynamic and communication approaches is presented.

I. INTRODUCTION

Although information and communication technology (ICT) has been making an enormous progress for more than thirty years and has already influenced many areas of our everyday life, its potential benefits and risks for the environment have gained the interest of the scientific research and broad community only since recently. Even though many extensive studies on energy efficiency of ICT systems have been carried out during the last several years, the influence of ICT on the environment has still not been sufficiently assessed and understood.

On the one hand, broad and intensive use of advanced ICT applications and services promises substantial improvements in many branches such as in industry, logistics, trade, healthcare, and education as well as in society. Furthermore, ICT applications can be used to optimize various processes and, consequently, to support new strategies and mechanisms for a sustainable exploitation of natural resources.

On the other hand, the ever increasing number of ICT equipment and intensive usage of ICT services lead to a continuous increase of ICT-related energy consumption. Additionally, the short lifetime of devices and services cause an increased usage of resources, production intensification, and more hazardous e-waste, which can harm the environment.

The aim of this paper is to briefly summarize recent progress in analyzing communication networks from the energy efficiency perspective and to discuss possibilities of developing and applying a holistic approach in assessing and studying environmental sustainability of different network concepts and ICT applications.

The rest of the paper is structured as follows. The next section summarizes the main trends and projections regarding communication networks, data centers and high-performance computers with particular emphasis on energy consumption. In Section III, we address the methods proposed so far to reduce energy consumption and increase energy efficiency of network infrastructures. Section IV discusses different metrics for energy efficiency. A holistic approach for analyzing sustainability of networks is briefly presented and discussed in section V. Finally, Section VI summarizes and concludes the paper.

II. RECENT TRENDS IN COMMUNICATION NETWORKS WITH PARTICULAR EMPHASIS ON ENERGY EFFICIENCY

The significance of considering energy consumption when developing new technologies and concepts for future networks becomes evident when observing the current situation and projections for the next five to ten years. Already in 2007, the ICT carbon footprint has been estimated to count for about 2 % of the total carbon emissions worldwide, which is comparable to the carbon footprint of the aviation sector [1]. At that time, the estimated ICT-related electricity consumption was above 17 TWh, which corresponds to the production volume of 15 medium-scale nuclear power plants. In 2020, the contribution of the ICT sector to the global carbon emissions is expected to increase to above 4 % [2]. It is worth noting that about 51 % of the ICT-related energy consumption is used by telecommunication infrastructure and data centers. However, it has been estimated that ICT-enabled solutions offer the potential to reduce overall annual emissions by 14.2 % of the projected total in 2020 [2]. According to a more recent estimation, this potential has been revised to 16.5 % [3]. Hence, both the ICT-related energy consumption and the abatement potential grow with time and it is not yet clear if ICT will rather become an important environment pollution source or an enabler for a more efficient and ecological resource management.

A. Increasing Bandwidth Demand

The continuous growth of Internet traffic has led to rapidly increasing capacity provided by network

infrastructure. Observations have shown that the main contributor to the traffic increase in the Internet is the traffic from residential customers [4]. This is mostly because of introduction of new bandwidth-hungry applications for residential users but also due to the fast growth of the number of broadband subscribers [5] as it is evident from Fig. 1.

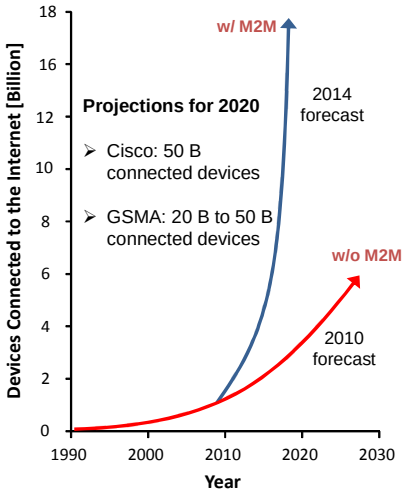

Figure 1. Recent trends in number of devices connected to the Internet [6]. M2M: Machine-to-Machine Communication.

Due to the concurrent growth of Internet traffic and the number of subscribers, both the number of network elements and their capacity are also expected to increase in the future. Recent introduction and wide penetration of smartphones and tablets confirm this trend. Furthermore, according to the vision of the "Internet of Things", it is expected that in the foreseeable future, a huge number of smart autonomous devices will communicate via the Internet, which is referred to as Machine-to-Machine (M2M) communication. As indicated in Fig. 1, it is projected that 50 Billion of smart autonomous devices will be connected to the Internet in 2020 [4]. For this reason, energy efficiency of both network and end-user equipment has become a very important issue.

Historical development and some projections for future trends concerning the growth of Internet traffic and the increase in router capacity and line data rate are presented in Fig. 2. In the past, user traffic was increasing by about 100 % per year. Within the last few years, this growth has slowed somewhat, so that the traffic volume in global communication networks is currently increasing by approximately 50 % per year [7]. In order to keep track with this increasing demand for bandwidth, the capacity of underlying network components has to increase too. However, when considering IP routers, the capacity per rack of equipment has been increasing with a lower rate than Internet traffic. As can be seen from Fig. 2, the capacity per rack was increasing by about 75 % per year for more than ten years. The increase in capacity has slowed in the last few years, which is mostly due to increased energy density and limited cooling rate. The increase of port (line) data rate has been also slowed down to some extent in the last several years. While in the past line data rate increased by a factor of four each three years or by a factor of ten per approximately six years, the step from 40 Gbit/s to 100 Gbit/s, which corresponds to an increase by a factor of 2.5, took more than three years. In order to keep the same increasing rate as during the last decade, the next generation optical transceivers operating at the line data rate of 1 Tbit/s should be already available.

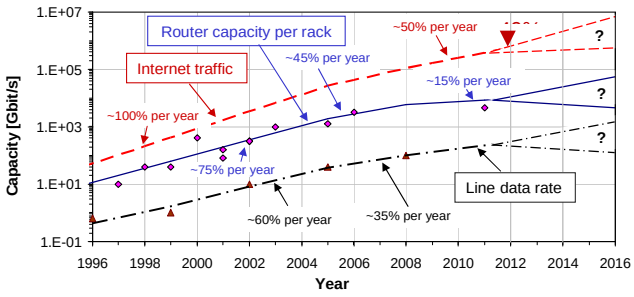

Figure 2. Recent trends in Internet traffic and router capacity [8].

Fig. 3a shows the estimated total power consumption of electronic routers for capacities up to 100 Tbit/s with some examples of electronic high-performance routers represented by the blue dots in Fig. 3a [9]. According to this figure, the router's power consumption increases linearly with bandwidth and each new generation of high-capacity electronic routers consumes more power than the previous one.

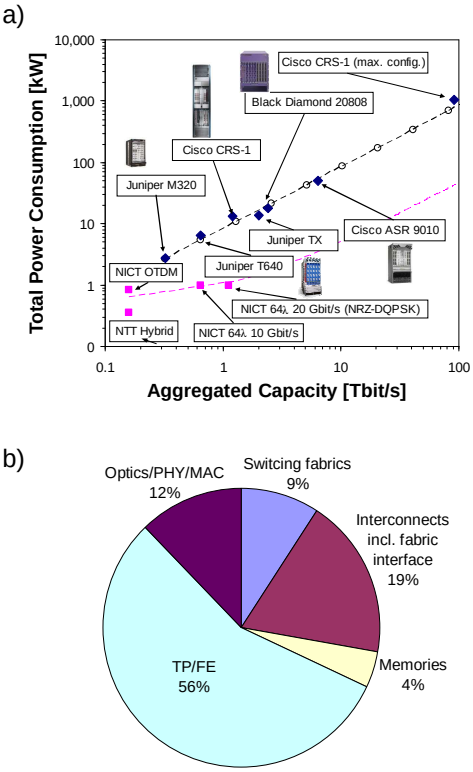

Figure 3. Power consumption of switches and routers [9]. MAC: Medium Access Control, PHY: Physical Layer Chip, TP: Traffic Processing, FE: Forwarding Engine.

About 60 % of the total power consumed by a router is related to IP traffic processing (see Fig. 3b – TP/FE and

Memories). Thus, the most potential for reducing the high power consumption of routers lies in simplifying the network concept in order to reduce the need for the complex and power hungry switching and processing at the packet level. A few examples of optically switched routers are also presented in Fig. 3a by the magenta dots and the corresponding dashed line. It should be noted here that data processing and storage elements realized using current optical technology usually have a quite limited complexity. Consequently, achievable performance of the optically switched routers is not as high as that of their electronic counterparts. Accordingly, the power consumption of an optical router is considerably lower than that of an electronic router assuming the same capacity.

B. Data Centers and Cloud Computing

Data center traffic has been showing an exponential increase mainly due to the introduction of emerging cloud computing applications. It has been estimated that for every byte of user data transmitted over the Internet, 1 GByte are transmitted within or between data centers [10]. While the amount of data-center traffic crossing the Internet is projected to reach 1.3 zettabytes per year in 2016, the amount of traffic within data centers has already reached 1.8 zettabytes per year [11], and by 2016 will grow by a factor of 3.6 to about 6.6 zettabytes per year. This corresponds to a compound annual growth rate (CAGR) of 31 % from 2011 to 2016. The key driver to this growth is cloud computing traffic that is expected to increase six-fold by 2016, becoming nearly two-thirds of the total data center traffic.

Another issue rising with the increase in the data center traffic is energy consumption. The direct electricity used by data centers has shown a rapid increase in the last years. The worldwide electricity use in data centers doubled from 2000 to 2005 and, from 2005 to 2010, it increased by about 56 % [12,13]. It has been estimated that data centers accounted for 1.3 % of the worldwide electricity use in 2010, being an important contributor to the worldwide energy consumption.

C. High-Performance Computing

Similar trends can be observed for large data centers and high-performance computers. Some examples of recently developed systems and projections for power consumption of high-performance computers (HPCs) are shown in Fig. 4. The red dots represent a selection of currently existing HPC systems, of which two illustrative examples are named. It is evident form Fig. 4b that already today large HPC systems consume several MW of electricity [14]. Future Exascale computer systems will probably consume more than 20 MW, which will set very high requirements on power supply and cooling systems. Therefore, a large effort has to be put into research and development of more energy efficient structures and technologies in order to make possible further scaling in both capacity and performance.

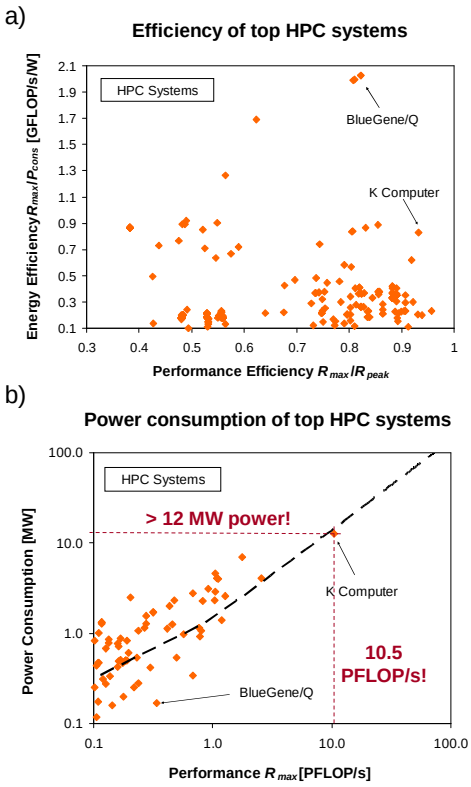

Figure 4. Recent trends in high-performance computing (HPC). Data taken from [14].

III. Methods for Improving Energy Efficiency of Communication Networks

It is widely recognized that future network elements must be able to provide high performance while featuring reduced power consumption. These high requirements can only be satisfied through a combined effort of research community, network designers, and network operators. Such an ambitious goal can be attained by developing and applying energy-efficient data transmission and processing systems, adaptive transmission links, dynamic power management and dynamically switching off or putting in sleep mode transmission links and line cards that are less utilized [15-19]. It has been shown that significant savings in energy consumed by network infrastructure can be achieved when optimizing both the network concept and the architecture of network elements with regard to energy consumption. Energy-efficient switching technologies and paradigms, power-aware routing and wavelength assignment (RWA) algorithms as well as multilevel traffic engineering and cross-layer optimization are examples of methods that can be applied at system level.

IV. Metrics for Energy Efficiency

There have been a number of metrics proposed and used to assess and compare communication systems and networks with respect to achievable reduction in energy consumption and energy efficiency. Some of mostly used metrics are listed in Table I. The most simple and intuitive metric seems to be absolute power consumption. However, absolute power consumption is not a measure

of efficiency because it says nothing about how useful the system actually is. Similarly, power consumption per subscriber, per area or even per bit of capacity does not consider the actual usage of the system. All these metrics presume a utilization of 100 %. Differently, energy consumed per bit of throughput considers the system performance and is therefore suitable for comparison purposes, but it still gives no idea of what would be theoretically possible, i.e., there is no relation to theoretical minimum energy dissipation.

TABLE I. ENERGY EFFICIENCY METRICS

Definition	Unit	Comment
Power consumption	[W]	no relation to usage at all
Power consumption per subscriber	[W/subscriber]	no relation to usage at all
Power consumption per area	[W/km^2]	no relation to usage at all
Power consumption per subscriber and area	[W/subscriber/km^2]	no relation to usage at all
Energy consumption per bit of capacity	[W/bit/sec ≡ J/sec]	no relation to usage at all
Energy consumption per bit of throughput	[W/bit/sec ≡ J/sec]	no relation to theoretical limit
EEF=10log$_{10}$[Energy/bit/($k_B T$ln2)]	[dBε]	inverse to efficiency

The recently proposed metric referred to as energy efficiency figure (EEF) [20] takes into account the theoretical minimum energy required to process one bit of information that can be calculated using the formula $k_B T$ln2 [21], where k_B is the Bolzmann constant and T is the absolute temperature. This theoretical limit can be used to compare heterogeneous systems and to indicate the theoretically possible improvements. However, EEF is, similarly to all other metrics listed in Table I, an inverse efficiency metrics. That means the higher its value the lower energy efficiency.

V. HOLISTIC APPROACH TO SUSTAINABLE NETWORKS

The overall impact of ICT on environment can be classified into direct, indirect and systemic effects [8, 22-24]. The direct effects comprise environmental impacts related directly to the life cycle of ICT infrastructure, including the production, use, recycling and disposal of ICT. The indirect impacts refer to environmental impacts that result from the use of software applications and ICT services that can lead to energy savings in other areas. Finally, the systemic impacts relate to environmental impacts that emerge from the medium or long-term changes of behavior and economic structures following from the availability of ICT applications and services and include all non-technological factors such as adjustment of individual lifestyles and rebound effects.

A study of the direct impacts should preferably include the whole lifecycle of the telecommunication network infrastructure and user devices. However, as briefly addressed in Section III, most of the studies accomplished so far concentrated on reducing the energy consumed during the operational (use) phase only [8,9,15,23,25].

Direct, indirect and systemic impacts can only be considered when applying a holistic approach such as the one illustrated in Fig. 5 [8]. The holistic approach presented here makes use of widely used thermodynamic tools to indicate and model energy and entropy flows within heterogeneous subsystems and through the boundaries between the systems, while taking into consideration peculiarities of each system. In particular, the potential of ICT applications and services can be evaluated and accessed by means of possible improvements of energy efficiency. The influence of the global communication network (the Internet) on the global energy productivity, environment and sustainable development can then be estimated by taking into account direct, indirect and systemic effects.

A. *Model of Communication Networks*

A model of communication networks representing the central part of the global system model as illustrated in Fig. 5 should take into account not only technological aspects and different realization options, but also social, economic, and demographic peculiarities as well as possible future developments. Such a model could

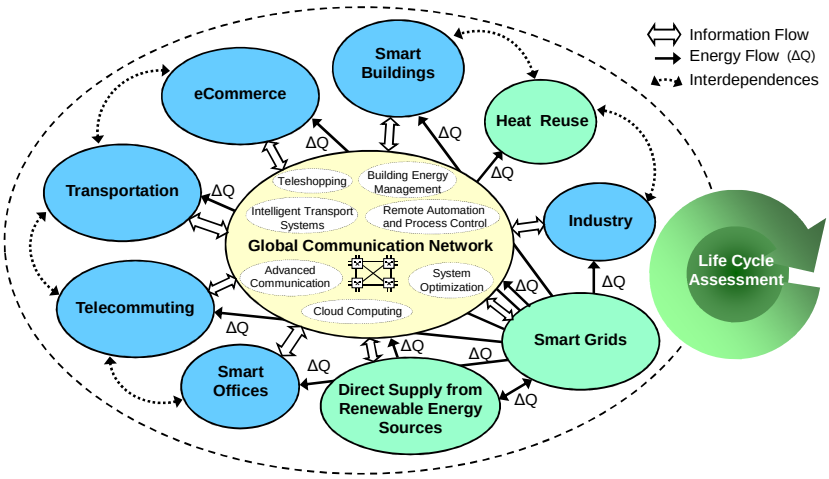

Figure 5. High-level illustration of the global system including the global communication network, applications and other subsystems that can make use of the global network infrastructure in order to improve the global energy productivity. The figure also shows information and energy flows as well as interdependencies within the global system.

Figure 6. Hierarchical approach to model performance and energy efficiency of the global communication network; b), c) and d) hypothetical examples of applications characteristics and user behavior: b) applications' characteristics, c) user behavior respective application use and c) an example presenting application-specific traffic over the day.

comprise a number of sub-models needed to study different network areas and technologies in a detailed manner, whilst the overall picture can be obtained by joining the individual sub-models together into a global hierarchical model with a manageable complexity. For this purpose, the global communication network can be divided into different areas based on geographical, technological, and operational aspects. For each network area, a different simulation model can be developed, which considers all peculiarities of the particular area such as suitable network technologies, topologies, configuration parameters and realistic traffic scenarios (see Fig. 6).

The sub-models can be connected to each other in a hierarchical manner, where the lowest hierarchy represents the network segment close to the traffic generators (i.e., end users' equipment) and the highest hierarchical level are high-capacity long-haul transmission links that interconnect continental-wide networks (i.e., intercontinental links). Presumably, the most logical way to divide the model of the global communication network into sub-models is to follow the network area principle, namely to model separately local, metropolitan, regional, national-wide, and continent-wide networks. For each of the sub-models we can consider different network concepts and transmission technologies as depicted in Fig. 6a. Statistical data on population, ICT applications and services as well as a model of user behavior can be used to set parameters of traffic generators. An illustrative example of how to define the traffic patterns is shown in Figs. 6b, 6c and 6d, in which the main characteristics of various applications such as average data rate, maximum data rate and appropriate distribution functions as well as average usage of each application over the day are taken into account. In this way, we can study the influence of new applications and include user behavior in order to define different scenarios for possible future developments. The interface between two sub-models, i.e., between two hierarchical levels, is defined by the amount and characteristics of the aggregated traffic sent/received by the gateway interconnecting these two network areas. The following steps can be made when developing a sub-model:

- First, network nodes are modeled by taking into account technological and architectural aspects.
- Then, the network sub-models are developed under consideration of different concepts, topologies, communication protocols, and traffic scenarios.
- The total power consumption of a sub-model is calculated using realistic values for each functional block and according to the actual utilization of network elements.
- Finally, the flow of information and energy through the entire global communication network can be identified and evaluated by defining and implementing the interfaces between the sub-models.

B. Exergy-based Life Cycle Assessment

In order to build a holistic framework, the model of communication networks briefly presented in the previous section can be extended by integrating some widely applicable tools of thermodynamics. A very useful quantity that stems from the second law of thermodynamics is exergy. It can be used to clearly indicate inefficiencies of a process by locating the degradation of energy. In its essence, exergy is the energy that is available to be used, i.e., the portion of energy that can be converted into useful work. Exergy analysis has been performed in industrial ecology to indicate the potentials for improving resource utilization and minimizing environmental impacts. The higher exergy efficiency is, i.e., the lower exergy losses, the better the sustainability of the considered system or approach.

Life cycle assessment (LCA) is a technique to evaluate environmental impacts of a product or a process over its entire life cycle (i.e., raw material extraction, manufacture, transportation, operational, maintenance, and recycling phases). LCA analysis provides a system perspective across the whole life time to define the system boundaries and aid decision making for system optimization and product selection. The approach that combines the exergy concept with the LCA analysis is referred to as exergy-based LCA (E-LCA). Since exergy-based analysis is a universally applicable method to assess process efficiency, it is well suited to investigate the sustainability of heterogeneous systems [27-29]. Recently, E-LCA has also been used to assess the sustainability of ICT infrastructure and applications [30-33]. The preliminary results of these studies have indicated the importance of a sustainable technological development able to ensure both high rate of innovations and increased service lifetime of ICT devices. Even though a fast technological development can lead to both the high performance and high energy efficiency of ICT equipment, the sustainability of the overall system is strongly influenced by short service lifetime of user devices, which causes a considerable increase in the total embodied exergy and thus high environmental impacts.

VI. CONCLUSIONS

Recent and future trends in the information and communication technology (ICT) sector and in particular in technologies and applications for communication networks indicate an urgent need for a significant improvement in energy efficiency. Since ICT has become an integrated part of our business and everyday life, the complex interdependences between ICT on one side and various areas of business and society that make use of ICT on the other can only be appropriately treated using a holistic approach. Such a holistic approach for analyzing heterogeneous systems has been briefly presented in this paper. It combines thermodynamic and communication approaches in a life cycle framework in order to assess the environmental sustainability of ICT technologies as a part of the global system.

TELECOM MARKET REGULATIONS

4G Mobile Internet, Services, Regulation and Mobile Operators in Bosnia and Herzegovina

Abstract – BH mobile Internet market is mostly presented by 3G data technology. Due to limitations regarding capacity, performances, speed and QoS, new technologies such as IMT-Advanced (4G) have been developed. This article presents an overview and statistics of mobile data usage in different technologies as well as representation of different kind of applications and devices globally and by region underling situation in Bosnia and Herzegovina. Introduction of 4G technology in BH is guided by Telecommunications Policy Framework which is about to be adopted and which foresees issuing of LTE licences in 2015.

I. INTRODUCTION

4G mobile Internet was originated as an answer to users demands for increasing capacity limitations, performances QoS and speed. Technology innovations have been followed by evolution in development of services, applications and devices. Will new 4G supported services represent competition to the classic voice, sms and mms communications offered by licensed telecom operators and will BH market be able to follow introduction of new technologies with the same speed with which they enter EU market?

II. QOS OF UMTS/GSM IN BOSNIA AND HERZEGOVINA

There are three licensed operators in Bosnia and Herzegovina for provision of GSM/UMTS services, and they are: BH Telecom, Mtel and HT Mostar. Comparison of penetration of mobile telephony with EU countries shows that BH with 87.25% is below EU average which was 127% in 2012. [1]

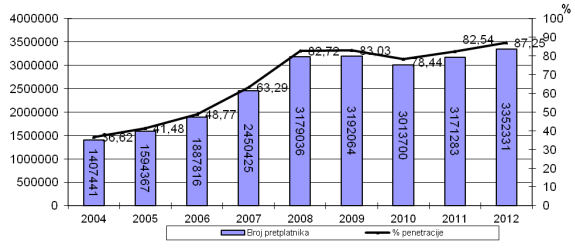

Fig. 1: Development of mobile telephony in BH 2004-2012 regarding penetration and number of subscribers

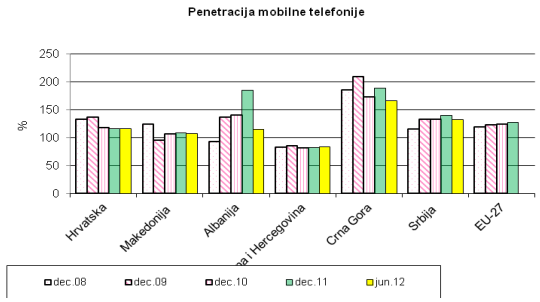

Fig 2: Penetration of mobile telephony, SEE region and EU-27 June 2012.

In regard to Article 8 of GSM License [2] issued by Communications Regulatory Agency (Agency), Decision on monitoring QoS of GSM services provides obligations in regard to methodology and kind of information which are needed for assessment of GSM QoS in BH. Mobile operators in BH are obliged to present data on QoS in line with established methodology and parameters.

Analyzing QoS of GSM/UMTS services, Agency has concluded that parameters of voice services had reached and mostly exceeded targeted values of quality (percentage of service accessibility is 96.8% which exceeds target of 95%, and call competition rate is slightly over 99%, while its target is 97%), in other words BH operators had accomplished to perform satisfactory quality of voice mobile services. [3][4]

In regard to SMS, differences between operators are more visible and values of parameters are between 90 and 99%. Also, parameter end-to-en delivery time shows that some operators need improvement in this segment. Similar is with MMS as well as data service.

Introduction of 4G network in BH market is guided by Telecommunications Policy Framework which is delivered by BH Council of Ministers. The Agency implements the Policy and new 2014-2017 Telecommunications Policy Framework is in the process of adopting. It is expected that the Policy orders issuing LTE licenses in 2015. The Agency has fulfilled its obligation to clear 61-69 channels predicted for LTE technologies. Also, introduction of digital TV is expected in June 2015. It is possible that the Agency will be instructed to make the Study for LTE license introduction in BH.

III. TECHNOLOGY EVOLUTION

In December 2010, ITU accepted only two technologies under name IMT –Advanced and those were: LTE-Advanced and Mobile WIMAX 2.0. Due to limitations in capacity, demands in utilization of radio frequencies, increasing of performances, flexibility, QoS and speed, new technologies are developed so GPRS/EDGE (2.5/2.75G) had evaluated into UMTS (3G), then HSPA (3.5G) into HSPA+ (3.75G). 3G data technology (HSPA) has imposed itself as responsible for the development of mobile Internet broadband access. Comparing data flow from 180kbps at EDGE, HSPA+ promises 42Mbps/22Mbps (down/up). With LTE (3.9G or super 3G) and LTE-Advanced (4G) mobile internet becomes even broader.

ITU statistic for 2013 states that 2.7 billion of people use Internet what is 39% of world's population. In developing countries 31% population is online and in developed 77%. Globally, Europe has the largest Internet penetration (75%) then follows America with 61%. In Africa, 16% of population uses Internet, what is half of Asia and Pacific penetration. [5]

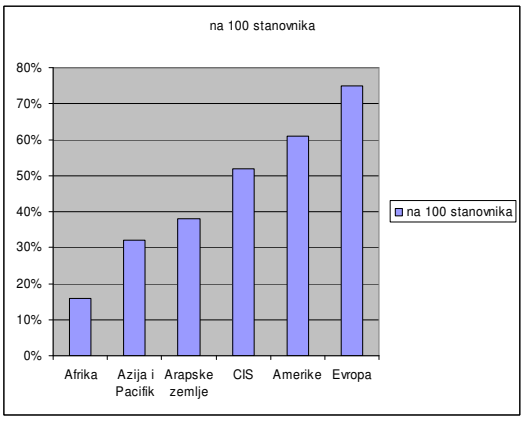

Fig. 3: Statistics by region 2013

When thinking of Internet, we always think of World Wide Web. IPV4 is dominant Internet protocol. Its successor IPV6 was originated as a result of IETF attempts from 1993 when first deficiency of address space was identified [6]. IPV6 forms base for future broadband Internet services. It is expected that new generation networks, based on IPV6 will replace those IPV4 based in order to overcome limitations in addressing, QoS, security and mobility.

Nowadays, content and online status is more important aspect of communications then ever. It is expected that future services and latest technology changes will introduce revolution in business world. Development of services will be guided by demands for new media, social networks, micropayments and real time contents.

IV. 4G MOBILE BROADBAND

ITU considers IMT-Advanced (International Mobile Telecommunications -Advanced), e.g. 4G to be the most advanced technology for global wireless broadband communications. The term was used for advanced technologies such as LTE and WIMAX and other technologies that exceed 3G potential. IMT-Advanced has a possibility to support high quality multimedia applications with huge number of services and platforms as well as improvement in performances and QoS. [7]; [8]. The term "IMT-Advanced" should be related to those systems and system components which support improvements after IMT_2000 [9]; [10].

Mobile broadband is marketing term for wireless Internet access via mobile device which experienced expansion thanks to 3G data technology (HSPA), devices with great possibilities and 2 million applications. 4G broadband Internet now represents the leader for innovations and development of devices, networks, software and technology. The greatest last year's innovations include usage of 4G possibilities, devices (smart phones, tablets) and development of over hundreds of thousands mobile applications. For the last couple of years, mobile Internet has introduced the revolution in device development and once 3G gets replaced with faster 4G, demands for mobile Internet will grow even higher.

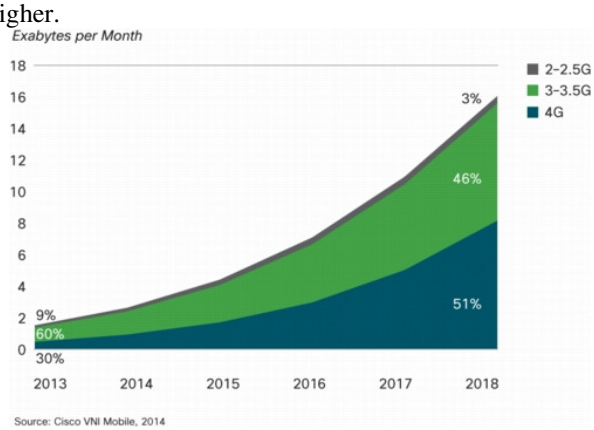

Fig. 4**:** 4G will take 51 % of total mobile Internet in 2018.

By June 2012 more then 5.6 billion consumers used GSM-HSPA, and that is ¾ of world population (7.6 billion). While 4G Internet costs are still higher then fixed, wireline broadband costs of Internet delivery continue to fall. [11]

One operator calculated that in LTE network, costs could grow up to 1€/GByte once penetration reaches 40% and consumption reaches up to 2GByte/month [12]. In Bosnia and Herzegovina that means: small market, huge investments in technology which supports competitive services such as VoIP. Yet, it is expected that during time 4G Internet demands grow up. Cisco data show exponential growth of data traffic compared to voice.
