
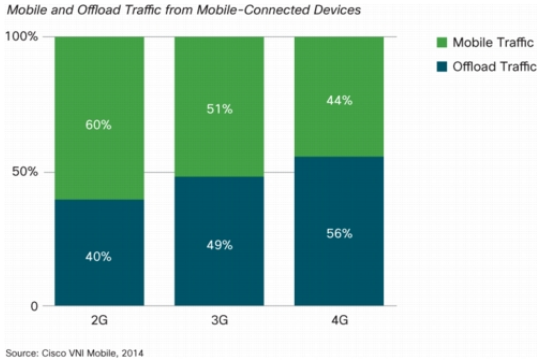

Fig. 5: Mobile data and offload traffic in 2018.

VoIP is a protocol which enables transport of voice data through wireline/wireless network that uses IP address. VoLTE is a signal protocol which enables transport of voice through 4G LTE network. Advantages of VoLTE are following: unlike VoIP, VoLTE use different channels for transport of video and voice what results in better QoS; VoLTE use IP Multimedia Subsystem which enables better synchronization of phonebook, sms and calls and also provides higher speed for data then 3G and VoIP; Average VoLTE download speed is 30 higher then VoIP, for upload 3 higher, and response time is less. Even though VoIP has surprised PSTN it has disadvantages such as noise, errors in transmission and call interruption. These disadvantages are overcome with VOLT which provides greater speed, quality, and reliability without noise and echo.

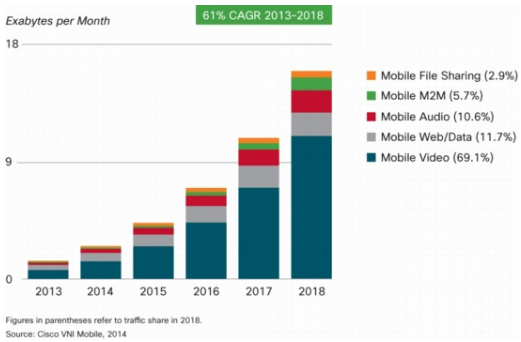

Fig. 6: Mobile video will generate 69% of mobile data traffic in 2018

Mobile Internet revolution was started in 2007 by Apple Iphone. Even though first Iphone supported just EDGE (236kb/s), that is fist phone designed to directly support web. Five generations of Iphone later, users of mobile Internet expect the same speed and experience offered by fixed Internet and desktop with high performances. There is a question: which applications are used more and also, which generate more traffic? Web traffic mostly consists of video (youtube, IPTV) and file sharing (dropbox, rapidshare, mediafire). Other traffic including web surf, VOIP and games is just 20% out of total traffic. [12]

Great deal of 4G network traffic will have multimedia interactive content. Mobile operators all over the world have experienced explosive growth of mobile Internet usage, especially after introducing *flat rate* tariffs and smart devices.

Video applications obviously precede in demands for bigger flow. In order to respond to these demands and support new generation networks, operators turn to 4G technology.

It is interesting to compare usage of PC against smartphones in 3 application categories: video, web surf and social networks. Bigger screen wins in 2 out of 3 categories because social networks users care more about online presence apart from type of device.

According to BEREC, data roaming has increased for 630% in EU from 2007 to 2012. During this period of time, roaming price was reduced and penetration of smartphones got up what explains growth in roaming data traffic. That is not the case in BH which is not in EU and regarding the fact that subscribers has high roaming tariffs, data traffic in roaming is not frequently used. It is also interesting that globally, 4G Internet is mostly used in roaming by Blackberry consumers (65%), Iphone (25%) and Android (10%). Also, data traffic mostly consists of video (30-40%), file sharing at PC, then email and audio with smartphone.

V. EVOLUTION OF SERVICES AND BUSSINESS CASE OF 4G MOBILE INTERNET

Gap between impressive traffic growth and much less growth in incomes has huge effect on mobile operators. From 2010 to 2012, data traffic incomes have risen for 8%, but traffic demands double every year.

In 2012, 4G had generated 19% more traffic then 3G and EDGE and even though 4G represents only 0.9% of mobile communications, it makes 14% of mobile data traffic.

As in fixed broadband Internet market, mobile operators should increase ARPU and find good pricing strategy in order to persuade subscribers in benefits of accepting more expensive 4G service. Comparing to other regions, EU market falls behind in traffic incomes as well as market share. According to some research, globally, US has 33%, China 17%, a EU 28% out of total market value of mobile data services [13].

In regard to amount of traffic, it is estimated that in 2012 EU market will not take even 5th place globally and Asia, North America and Pacific will generate 2/3 out of total traffic.

VI. 4G COVERAGE

By the end of 2012, approximately 96.3% of population was covered by HSPA (3G) networks in EU.

EU coverage with LTE (4G) has tripled in 2012 and took out 26.2% in Scotland and 90% in Portugal. LTE covers mostly urban area [13]. 4G is introduced in FYR of Macedonia, Spain, Ireland, Island and Netherlands. In

Bosnia and Herzegovina, one operator has tested 4G base station in 2013, in Banja Luka area.

VII. CONCLUSION

Great advantage in introducing 4G technology is represented by its flexibility, speed and QoS with negligible delay in transmission and connection. Globally, mobile data traffic of the fourth generation is being used more than the wifi, and customer base of new services based on this new technology is constantly increasing.

It is undeniable that implementation of new technologies are taking big steps forward in Bosnia and Herzegovina. There is no doubt that BH operators will follow the technology progress but market size and economy situation will certainly influence investments in new technologies as well as the speed of implementation of new services. The Agency is ready for implementation of Telecommunications Policy Framework which is about to be adopted and which schedules issuing LTE licenses in 2015.

Creating Regulatory Environment for Cloud Services

Suada Hadžović, Rešid Šeremet
Communications Regulatory Agency BiH, Mehmeda Spahe 1, 71 000 Sarajevo, Bosnia and Herzegovina
shadzovic@rak.ba

***Abstract* — Cloud Computing is at an early stage in Europe and the various players in the European markets can still influence how the legal framework will be designed. This paper present current initiatives of creating EU regulatory environment in order to support the development of Cloud services which can enable nations both to reap the benefits of Cloud services and mitigate some of the risks associated with them.**

***Keywords* —Regulatory, Cloud Computing, Services**

I. Introduction

While some years ago applications mainly run on servers on their own premises or dedicated data centres, now applications are outsourced to large Cloud service providers and run in a few large data centres. A simple example of Cloud Computing is Yahoo email, Gmail, Hotmail etc.

There is no universal approach for Cloud Computing, rather it is a concept covering many different services, different categories of Cloud (public, private, hybrid), and different types of user (large or small media enterprises, consumers). In Cloud Computing concept users do not see or need to know about the Cloud, they just see services [1].

Many studies indicate that Cloud Computing has substantial economic potential, therefore, EU urges Cloud Computing uptake, but users still have some reservations over security and confidentiality of information in the Cloud.

The EU market for Cloud is some years behind the US market in terms of size and maturity. The most important barriers for the growth of Cloud in Europe relate to concerns by both suppliers and users about compliance with regulatory obligations. They sometimes have to comply with different national law and that such compliance is uncertain and costly [2].

This article is structured as follows. After this introduction, Section II provides an overview of Cloud Computing definitions and types; Section III presents three main actions of EU Cloud Computing strategy; Section IV shows growth potential of Cloud Computing; Section V deals with information regarding deployment while in Section VI short conclusion is drawn.

Suada Hadžović, Regulatorna agencija za komunikacije BiH, Mehmeda Spahe 1, 71000 Sarajevo, BiH (telefon: 387-33-250600, e-mail: shadzovic@rak.ba)

Rešid Šeremet, Regulatorna agencija za komunikacije BiH, Mehmeda Spahe 1, 71000 Sarajevo, BiH (telefon: 387-33-250600, e-mail: rseremet@rak.ba)

II. Cloud Computing definitions and types

The most widely accepted Cloud Computing definition is this one by US National Institute of Standards and Technology (NIST): Cloud Computing is a model for enabling convenient on-demand network access to a shared pool of configurable Computing resources (e.g. networks, servers, storage, applications and services) that can be rapidly provisioned and released with minimal management effort or service provider interaction [3].

Basically the Cloud is the online offering of IT as a service. According to NIST, Cloud Computing is composed of five essential characteristics, three service models based upon service provided, and four deployment models based upon location of Cloud [3].

Cloud Computing essential characteristics by NIST definition:

- On-demand self-service;
- Broad network access;
- Resource pooling;
- Rapid elasticity;
- Measured service.

Classification based upon service provided:

- *Software as a Service (SaaS)*
  Customers use applications (e.g. CRM, ERP, e-mail) from multiple client devices through a Web browser on multi-tenant and shared infrastructures without the need to manage or control the underlying resources
- *Platform as a Service (PaaS)*
  Customers use programming languages, tools and platforms to develop and deploy applications on multi-tenant and shared infrastructures with ability to control deployed applications and environments without the need to manage or control the underlying resources
- *Infrastructure as a Service (IaaS)*
  Customers use processing, storage, networks, other computing resources with ability to rapidly and elastically provision and control resources to deploy and run software and services without the need to manage or control the underlying resources. [4].

Classification based upon location of Cloud:

- *Private Cloud*
  In this Cloud both the consumer of Cloud services and the provider of those services exist within the same enterprise.
- *Public Cloud*
  In this Cloud both the consumer of Cloud services and the provider of those services exist in separate enterprises.
- *Community Cloud*
  This is form of public Cloud known also as a vertical Cloud. It is consist of public Clouds organized around a group of competing/cooperating businesses in a particular vertical market.
- *Hybrid Cloud*
  This Cloud combines multiple elements of public and private Cloud, including any combination of providers and consumers, and may also contain multiple service layers.

The above classification (most common types) is well accepted in the industry. But we can find a more granular classification on the basis of service provided, i.e [5]:

- Storage-as-a-service;
- Database-as-a-service;
- Information-as-a-service;
- Process-as-a-service;
- Application-as-a-service;
- Platform-as-a-service;
- Integration-as-a-service;
- Security-as-a-service;
- Management/Governance-as-a-service;
- Testing-as-a-service;
- Infrastructure-as-a-service.

Additionally, we can find term Everything as a Service (EaaS, Xaas, *aaS) which is a concept of Software components across the network.

Monitoring-as-a-Service (MaaS) has become increasingly popular over the last decade. It is the outsourced provisioning of security, primarily on business platforms that leverages the Internet to conduct business. Since the advent of Cloud Computing, its popularity has grown even more. Security monitoring involves protecting an enterprise or government client from cyber threats. A security team plays a crucial role in securing and maintaining the confidentiality, integrity, and availability of IT assets. The major functionality of MaaS is to monitor the working of all the three layers SaaS, PaaS and IaaS.

Cloud Computing – Primary Characteristics [4]

- On-demand self-service;
- Ubiquitous network access;
- Location independent resource pooling;
- Request driven provisioning and scheduling;
- Measured service / Pay-per-use.

Cloud Computing advantages

- Business revenue and growth;
- Agility and flexibility;
- Cost reduction;
- Innovation;
- Increased Reliability;
- Environmentally Friendly;
- Portability/Accessibility;
- Unlimited storage capacity;
- Improved performance;
- Device independence;
- Improved document format compatibility;
- Easier group collaboration.

Cloud Computing challenges

- Data integrity and security;
- New technology and incompleteness;
- Bandwidth Costs;
- App performance could suffer;
- Data might not be Cloud-worthy;
- Too big to scale.

III. EUROPEAN CLOUD COMPUTING STRATEGY

The EU Cloud Computing strategy, subtitled "Unleashing the Potential of Cloud Computing in Europe" was launched by the European Commission in September 2012. It describes the strategic plan of the European Commission aiming to enable and facilitate the adoption of Cloud services in the public and private Cloud Computing sector across the EU, outlining the most important and urgent actions. Three key actions are [2]:

- *Safe and Fair Contract Terms and Conditions*
  New model contract terms for Cloud Computing should ensure consistency and fairness in contracts for Cloud Computing services across EU. The European Commission places a number of requests on how data is handled and contemplates the model contract terms covering, for example: data preservation after the contract is terminated; data disclosure and integrity; data location and transfer; data ownership; data portability between services; and subcontracting. The model contract terms also will incorporate new mechanisms that will be introduced by the proposed EU data protection regulation.
- *Cutting through the Jungle of Standards*
  The European Commission's stated aim is introducing a new, pan-European certification schemes for Cloud Computing, including data protection. ENISA and other relevant parties are asked to assist in this process. These certification schemes focus on data protection, especially data portability, and increased transparency of Cloud service providers' security practices. Although the Commission has provided a detailed list of factors to be considered by these new certification schemes, it should be noted that participation in the schemes will be voluntary.
- *Establishing a European Cloud Partnership (ECP)*
  ECP brings together industry experts and public sector users to work on common procurement requirements for Cloud Computing in an open and fully transparent way. Part of the ECP is the *Cloud-for-Europe (C4E) initiative,* aim to help Europe's public authorities

procure Cloud products and services, so as to build trust in European Cloud Computing.

Overview of these actions is shown in Fig. 1.

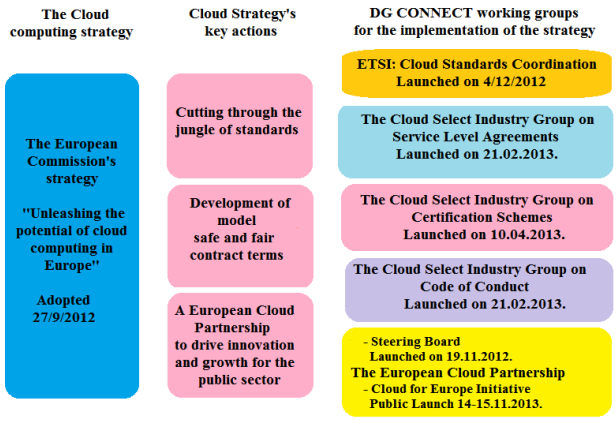

Fig.1. European Cloud Computing Strategy

IV. The Growth Potential of Cloud Computing

The European Commission contracted IDC (provider of data-driven research and analysis) to undertake research on Cloud Computing. IDC Report titled "Quantitative Estimates of the Demand for Cloud Computing in Europe and the Likely Barriers to Up-take" make comparisons between two recognized scenarios. It is estimated that first scenario named "No Intervention scenario" of Cloud adoption could generate up to €88 billion of contribution to the EU GDP in 2020. Instead of that, second scenario named "Policy-driven scenario", could generate up to €250 billion GDP in 2020. Therefore, policy driven scenario bring €162 billion over the no intervention scenario. Additionaly, IDC estimates that cumulative impacts would be even stronger, i.e. for the period 2015-2020 of some €940 billion in the "Policy-driven" scenario, compared to €357 billion in the "No Intervention" scenario [6]. These scenarios comparison is shown in Fig. 2.

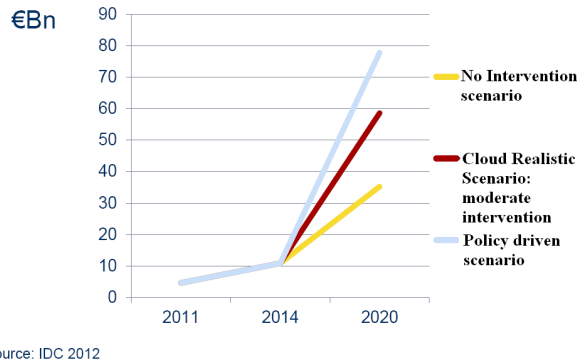

Fig. 2. EU Cloud Computing Market Growth

Considering only the potential of creation of new jobs, IDC estimates that in the "Policy-driven" scenario Cloud-related workers could exceed 3.8 million, against some 1.3 million in the "No Intervention" scenario. However, this does not take into account the jobs that would be lost or the workers displaced by Cloud-related reorganization of business processes and productivity increases.

Estimations about the creation of around 400,000 new SMEs over a period of 5 years and 3.8 million of jobs created indirectly by Cloud indicate that Cloud Computing deserves attention [7].

V. Cloud Computing Deployment

In November 2013, the European Commission has published a study on analysis of Cloud best practices and pilots for the public sector. The study provides a detailed analysis of Cloud initiatives at national level and deployments in the public sector in ten EU Member States. It identifies best practice use cases and proposes pilots for those application areas where current Cloud take-up is absent or however limited.

The study show that in the ten Member States covered by the study, the deployment of Cloud in the public sector is at a very early stage. This overview across the Member States is summarised in Table 1. [8].

	UK	IT	NL	FR	DK	DE	ES	PT	BE	AU
Privacy and security concerns	√	√	√	√	√	√		√	√	√
Regulatory issues	√	√	√		√	√			√	√
Financial issues			√		√					√
Technical issues (i.e. interoperability, techn. maturity, reliability)	√	√	√	√	√		√		√	√
Issues in SLAs (due to the immaturity in practice and market)		√	√				√	√	√	√
Changes in job content, skills and processes	√	√		√	√					√
Cooperation between administrations	√	√			√	√		√		
Cultural barriers and perceptions by users and public sector	√	√		√	√		√	√		√

Table 1. Main Cloud Computing barriers in EU countries

Based on study's analysis of the key stakeholders' needs and requirements, IDC report present recommendations for the most relevant policy actions which should be included in the European Cloud Computing Strategy to create a "Cloud friendly and proactive environment" in the EU and maximize the chances of achieving the benefits identified in the "Policy-driven" scenario.

The policy actions for removing key regulatory barriers should be the following [6]:

- Harmonising and clarifying personal data protection and privacy protection rules across the EU, protecting citizens' rights but simplifying bureaucratic requirements, no matter where the data is and developing additional instruments such as standard clauses, codes of conduct or Binding Corporate Rules for international data transfer.
- Clarifying data jurisdiction regulation and providing EU-wide guidelines about which laws apply to data stored in the EU member state or elsewhere
- Favour the identification and removal of local laws and regulation that limit the use of Cloud services

The European Union Agency for Network and Information Security (ENISA) in its annual report of November 2013 on government Cloud Computing in the

EU also states that the Cloud uptake in EU is not accelerated as expected. ENISA attributes this situation to a several issues that still need to be solved to give a boost to the public sector to adopt [9]:

- Lack of a concrete and unanimous definition of governmental Clouds;
- The Cloud uptake in national level is slow due to lack of national Cloud strategies, privacy and security constraints, lack of legal and contractual frameworks and relative immaturity of the Cloud market;
- Research needs to be promoted since many areas are still "undiscovered".

	Early adopters	Well Informed	Innovators	Hesitants
Political and legal aspects (Cloud strategy)	Cloud strategy exists	On-going implementation of a Cloud strategy	Mainly limited to the Innovation and the digitalisation of the public administration	No Cloud strategy exists
Status (Governmental Cloud)	Mainly implemented governmental Cloud or supporting initiatives	The gov-Cloud is not fully developed (in most cases at design/prototype stage)	Gov-Cloud solutions exists, but very jeopardised and not integrated into a high level national vision	No gov-Cloud exists
Type of Cloud Implementation	Private Cloud (except UK where is public Cloud)	Private Cloud (except Sweden where is community Cloud)	Public/Private Cloud	NA
Motivation for adopting Cloud	Innovation, Competitiveness, efficiency, job growth	Efficiency and cost saving, flexibility	Harmonisation of ICT, innovation in the public administration	Competitiveness and attraction of investments

Table 2. Classification of governmental Clouds in EU

ENISA study has presented the Cloud Computing status of a majority of EU countries. According to the classification of governmental Clouds across the EU, summarised in Table 2, the countries in particular groups are:

- *Early adopters:* UK, Spain and France.
- *Well - Informed*: The Netherlands, Germany, Republic of Moldova, Norway, and Ireland, Finland, and Slovak republic, Belgium, Greece, Sweden and Denmark.
- *Innovators*: Italy, Austria, Slovenia, Portugal and Turkey.
- *Hesitants*: Malta, Romania, Cyprus, and Poland.

General conclusion is that due to great diversity of Cloud solutions and the different approaches, it is difficult to reach a consensus on fundamental aspects of Cloud security such as: common Cloud contract clauses, common Cloud services model etc.

In terms of Table 2 classification, Bosnia and Herzegovina and neighbour countries belong to the *Hesitant*s group of countries which planning to implement governmental Cloud in the future to boost competitive business, but currently have no strategy or Cloud initiatives in place. But, it is sure that to the extent that the Cloud approach relies on access to communications infrastructure, then some regulation under the telecommunications framework may be guaranteed.

VI. Conclusion

Cloud Computing is a developing area and its full strengths and weakness are not yet completely researched, documented and tested. But it is sure that contains a number of issues, not all of which are unique to Cloud, that are concerns for all IT hosted services.

Additionally, despite the fact that Cloud Computing is considered as a key growth area for the ICT sector and as a key enabler of growth in ICT-using industries, it is not a solution for all consumers of IT services.

Currently, more than half of EU businesses and consumers already use some kind of Cloud services, but full adoption of the Cloud model is still far away, hindered by a wide range of bottlenecks and barriers.

Given the potential economic and social benefits of Cloud Computing, the European Commission has an interest in eliminating unnecessary obstacles to the adoption of Cloud services, while safeguarding the public interest in relevant areas such as security, consumer protection, privacy, and others.

Recent studies show clearly the potential benefits for the EU economy and industry of a proactive policy action, able to remove the main barriers to Cloud adoption.

A number of recent EU activities try to enable and facilitate the faster adoption of Cloud Computing in all sectors of the economy, helping to cut costs, boost productivity and promote the creation of growth and jobs.

Generally, the Cloud uptake in national level in EU countries, Bosnia and Herzegovina and neighbour countries is slow due to lack of national Cloud strategies, privacy and security constraints, lack of legal and contractual frameworks and relative immaturity of the Cloud market.

Emergency communication in IMS network: challenges in implementation

Ivan Krevatin*, Ivan Visković**
*Service and Platforms Development Department
**Core Network Development Department
Hrvatski Telekom
Zagreb, Croatia
ivan.krevatin@t.ht.hr, ivan.viskovic@t.ht.hr

Abstract—**Emergency communication is an important part of communication for the telecoms not only due to regulation but primary due to their responsibilities to the customers and the role they have in society. This paper describes the challenges which we are facing when implementing emergency communication in IMS network regarding the architecture and special requirements demanded by the Regulator and emergency service centers. In focus are: the architecture for customers accessing the service over fixed access and the possible implementations for customers that are accessing the service over LTE (Long Term Evolution) network.**

Keywords: emergency call handling; location based services; IMS; geolocation;

I. INTRODUCTION

Migration of legacy (PSTN) services to IMS (IP Multimedia Subsystem) domain brings several challenges regarding the implementation and replication of existing services and their behaviour. Emergency communication is one of them. Apart for its vital role that it has in the community and telecom's responsibility for its customers (both users in need and emergency centres), this field is strictly regulated by local laws and often under special observation by the Regulator. We can distinguish four main requirements that we are facing when handling emergency communication in telecom network: (1) localization of the customer, (2) selection of the nearest PSAP (Public Service Answering Point), (3) recognition and prioritization of emergency calls, and (4) alternative routing of calls in case of unavailability of dedicated PSAP. Things get more complex if you consider that PSAP and customers belong to different operators. Migration of PSAPs from PSTN to IMS network generally requires special technical solutions. In this paper we will focus on the IMS network architecture for emergency call handling and analyse the challenges when implementing the solutions for localization of customers and selection of nearest PSAP for both fixed and mobile access. It is clear that since IMS is a convergent network main parts of the solution are independent of the type of access but still the Long Term Evolution (LTE) network comes with new challenges. Voice over LTE (VoLTE) that is based purely on PS (Packet Switched) domain brings an entire new set of technical requirements to the user equipment (UE) and to the network for the support of the emergency call handling. The standardization of this topic is still open and leaves several options in implementation. In this paper we bring this topic to discussion by presenting possible solutions.

The paper is organized as follows. Section II shortly presents the requirements for emergency call handling and organization of Croatian emergency services, Section III describes the IMS network architecture focused on the elements involved in emergency call handling. Section IV describes the specifics of emergency calling from fixed access and possibilities for user localization. In Section V options for implementation of emergency call handling in LTE environment are presented. Section VI summarizes the conclusions of this paper.

II. OVERVIEW OF THE REQUIREMENTS

The existing emergency calls infrastructure has evolved together with the PSTN network following the capabilities of all actors: UE of the user in need, the network and the equipment at the PSAP. The requirements and regulation arose from that capabilities taking into account the importance and sensitivity of the subject. With the evolution of the communication, first by the introduction of mobile phones and now by moving the communication to IP which is not just IP based voice but has evolved to a real-time multimedia communication, the requirements, possibilities and expectations change. An overview of the requirements that are placed on the implementation of the IP based emergency communication can be found in [2] and [3].

Emergency service consists of enabling the user in need to reach the appropriate PSAP that is responsible for serving the area from which the user is calling. The user dials one of the emergency numbers which are dedicated for such service from the national Regulator. In Croatia this is done by HAKOM (Croatian Post and Electronic National Agency). Emergency numbers are assigned per service type for five types of services: fire brigade, medical emergency, police, sea rescue and Croatian automobile club; and one unique number for all types of emergencies (112 service). PSAP organization is mostly based on county principle (one PSAP per county) but there are services with smaller responsibility areas for each of their answering points and also national centres with only one central answering point in the country. The organization of PSAPs is not static but changes in terms of changing the responsibility area and changing the final destination number to

which the emergency call is routed. There are possibilities that PSAP changes its telecom operator but the delimitation of responsibilities and routing principles of emergency calls between operators are still not properly regulated. All this changes have to be promptly and properly handled by the operator(s) whose network is affected.

Croatian regulation regulates emergency communication with several laws which comprise following areas: availability of the service, definition and usage of service numbers, user's location, interconnection requirements, billing of the service and accessibility of the service for impaired persons. All this requirements have to be mapped into technical requirements on the telecommunication platform responsible for providing the service. In addition to this in VoLTE scenario special care must be taken in the years of coexistence of LTE and CS (circuit switched) radio coverage where single radio voice call continuity (SRVCC) is expected to ensure the consistent and seamless service and in the cases when there will be no possibilities to fall back to CS. One of the key factors in these scenarios is the transfer of the user's location information to the network which is responsible for routing the emergency call. IMS brings new challenges and possibilities like emergency registrations, handling emergency communication in roaming, emergency video and text communication, new possibilities for location delivery etc.

III. ARCHITECTURE OF THE SYSTEM

The IMS emergency call handling network architecture is depicted in Figure 1. The IMS network contains elements that are dedicated for handling emergency sessions, they are: Proxy Call Session and Control Function (P-CSCF), Emergency Call Session and Control Function (E-CSCF), Routing Determination Function (RDF), Location Retrieval Function (LRF) and Emergency Access Transfer Function (EATF). These elements are shown in the Figure 1 together with other network elements that form IMS based telecom network architecture. Emergency calls are routed based on the location of the terminal from which the service is accessed. Location is retrieved from the Location Function (LF) element in the access over e2 interface. The method for determination of the location and network element LF are different in the case the user is accessing the service over the fixed or mobile access. As per [3] one of the main architectural principles is that emergency services are independent from the access network with respect to the detection and routing of emergency sessions.

In the fixed access the location retrieval is done in the NASS (Network Attachment Subsystem) with CLF (Connectivity session Location and repository Function) [5] as key element for matching user's IP address to the physical location of the access line. In the mobile access, location of the user vary and location accuracy depends on various factors such as if it is network or terminal provided and which methods are applied. Network elements for location retrieval may be the Policy and Charging Rules Function (PCRF) or Gateway Mobile Location Centre (GMLC). Apart from routing purposes, in some cases (local regulation) it is required to transfer the location information to the PSAP in real time during the emergency session. This can be done over Le interface or in the SIP messages in case of an IP capable PSAP connected directly to IMS network.

The E-CSCF is the IMS network entity, introduced in [3], with the responsibility to route the emergency requests, query the LRF for the proper routing information/PSAP destination and retrieve location information if not included in emergency request. The E-CSCF receives emergency session establishment requests from a P-CSCF. The P-CSCF detects emergency session establishment requests, queries elements of access network for location information, prioritizes emergency sessions and forwards them to E-CSCF. It also handles emergency registrations and performs various security tasks regarding emergency and regular sessions. The LRF and RDF are key elements responsible for proper routing of emergency sessions; LRF may also contain a Location Server (LS). The E-CSCF queries LRF for routing information, information provided by the LRF to the E-CSCF includes the routing information and other parameters necessary for emergency services, which are subject to local regulations. LRF is responsible for delivering location information to PSAP. The EATF [4] is a network entity that provides IMS based mechanisms for enabling service continuity of IMS emergency sessions. It is a function in the serving (visited if roaming) IMS network, providing the procedures for IMS emergency session anchoring and PS to CS Access Transfer in cases of coexistence of LTE and CS.

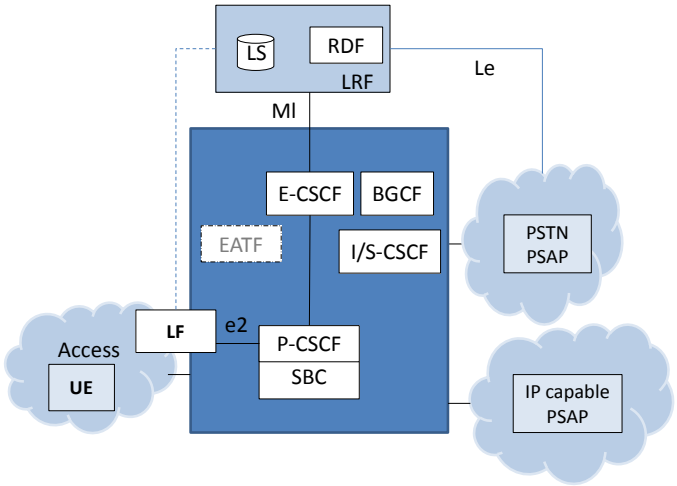

Figure 1. IMS based emergency call handling network architecture

A. *Location information*

As it can be seen from the architecture, location information is a key parameter for routing emergency calls. Standards define a number of mechanisms for providing location information for emergency support [3][6]: (*i*) it can be inserted by UE as the Geolocation header field or P-Access-Network-Info (PANI) header; (*ii*) P-CSCF can query the access network and insert it in the PANI header; (*iii*) it can be allocated as a location reference that relates to the call by LRF which can obtain the location information by querying NASS or GMLC; (*iv*) E-CSCF can query Home Subscriber Server (HSS) and insert it in the PANI header.

Location information can be transferred to PSAP in the Geolocation header field, in PANI header if allowed by configured policies or independent by SIP protocol which is more likely if PSAP is not in the IMS network. Location information is subject to privacy constraints and has to be handled accordingly.

B. Location Retrieval Function

Standards define that Location Retrieval Function (LRF) is the element that selects the PSAP address for the emergency session but don't define the mechanisms that should be implemented to support such selection. In the implementation in Hrvatski Telekom, LRF consists of the RDF and LS with following roles: RDF implements a set of rules for PSAP selection. Basic rule is to match the provided location to the PSAP's responsibility area. This matching is done in geospatial domain by first defining a set of polygons corresponding to PSAP responsibility areas and then querying for the polygon that contains the geo coordinates of the location of the user. LS has the role to provide additional location information to PSAP such as the civic address of the user and any other useful information. This information is delivered over Le interface using calling number as a key with which PSAP queries the LS. LRF itself communicates with E-CSCF over the Ml interface from where it gets the location information containing geo coordinates and reference to civic location, and the short code of the emergency service.

Challenges in implementation of such system consist in: (*i*) defining PSAP responsibility areas with polygons on digital maps; (*ii*) providing fast responses to the spatial queries under stress of the system; (*iii*) assuring proper availability of the system; (*iv*) handling border situations when coordinates of user location are on the border between polygons or outside of all polygons; (*v*) updating user information in LS; (*vi*) applying privacy policy to LS by allowing PSAP to query information only about users that have called emergency service in certain period of time and (*vii*) assuring the flexibility of the system to handle new requirements in incoming VoLTE scenario.

IV. EMERGENCY CALLS IN FIXED ACCESS

Generally, there are four types of users in fixed access that can access emergency services over IMS network: (*i*) user accessing the service over IP-MSAN emulation of POTS; (*ii*) user accessing the service over broadband (BB) access from the operator's network; (*iii*) business user accessing the service over SIP trunk; (*iv*) user accessing the service over public internet. All these users access the service over the SBC whose responsibility is to recognize the type of access an add a location parameter to SIP header i.e. the P-Access-Network-Info (PANI) header [6]. In the case when the user is accessing the service over IP-MSAN, his location is fixed to the location at the user's premises where his phone is installed. The location could be obtained dynamically based on the port on the IP-MSAN but often in implementations more users are hidden behind a single IP address. In such cases it is a real challenge to pass the port ID to the IMS network i.e. in the SIP signalization which often leads to proprietary solutions. Since the location of the IP-MSAN user is fixed, the common way to deal with this issue is to store the location in the HSS which will then be queried by E-CSCF. If this is the case then care should be taken for the situations when the same user is accessing the service over different types of access. When the user is accessing the service over BB access of the operator's network it is common that a dedicated Virtual Local Area Network (VLAN) for Voice over IP (VoIP) traffic is used and that the UE obtains its IP address from the NASS. The link between the IP address, additional network information obtained from Dynamic Host Configuration Protocol (DHCP) Option 82 and physical location information is stored in CLF which is connected to P-CSCF over e2 interface. After the setup of this mechanism it is important to keep this link between logical network and physical (user) location up to date with every new installation or changes in the network. With this mechanism in place, the user can change his location within operator's network (i.e. become nomadic) and the network will update the information about his physical location each time his UE registers for the service. Business trunking users present a real challenge in determination of the location of the user since the location of the terminals could be out of operator's control and the capabilities of terminals to provide their own location are questionable. The main task of the network for such users is to provide proper routing of emergency calls and the precision of the micro location should be agreed with the customer and properly communicated to the PSAP. The location of the users accessing the service over public internet can't be easily determined. It is important to recognize such type of access and pass this information to the PSAP. In some countries PSAP organizations dedicate call center lines handle to such calls. If the user calling from public internet is authenticated and its UE provides location information, such information can be trusted and passed to PSAP.

V. EMERGENCY CALLS IN LTE ENVIRONMENT

The 4th generation of mobile networks LTE (Long Term Evolution) is based on PS domain only and voice services solution for LTE/EPC (Evolved Packet Core) is realized in IMS network. There are two approaches for VoLTE emergency service realization in IMS network: (*i*) CS fallback based solution and (*ii*) IMS network based solution.

A. CS fallback based solution

CS fallback based solution relies on LTE standardized procedures where CS domain on 2G/3G technology is used for voice service execution. The CS fallback procedure is defined to support voice service in early LTE implementation; CS fallback [7].

If CS fallback procedure is used for emergency service in VoLTE, UE needs capability to recognize emergency service request in aim to start the procedure. Otherwise, emergency service request must be recognize by IMS network which then inform UE that CS fallback procedure need to be started. Localization of the customer and selection of the proper PSAP is done in CS domain on the way as it is realized for 2G/3G

access. The solution requires network support of CS fallback procedures and UE support of CS fallback mechanism. The solution based on CS fallback enables fast implantation of emergency service for VoLTE service in networks where CS domain already exists.

B. IMS network based solution.

IMS network based emergency service does not rely on legacy CS domain emergency call solution. However, it is required that emergency call is continuous when user moving from LTE domain to CS domain, in network where CS domain exists. Thus IMS network need to support SRVCC functionality for emergency call with EATF function for call anchoring and transferring [8]. Network support of the functionality is crucial in early LTE implementation if LTE network is not widely spread and there is a limited coverage. IMS network architecture for VoLTE emergency call is shown on Figure 2.

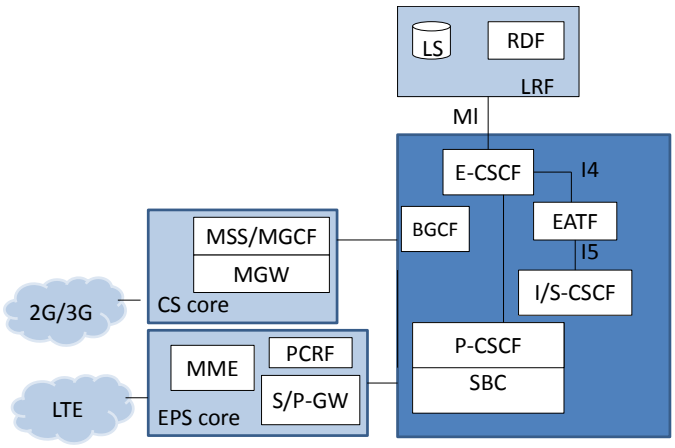

Figure 2. IMS emergency handling network architecture for VoLTE

Due to nature of mobile networks and user mobility, retrieval of proper user location information is a challenge. According to location information, IMS network discover proper destination; PSAP point and route emergency call to the PSAP point. In addition, it could be required by a local regulatory that location information must be transferred to PSAP to be used by that point. Thus, implementation of emergency service in IMS network for mobile users requires solution for user location information retrieval. There are a several type of location information which can be used; CGI (Cell Global identity), CSG Id (Closed Subscriber Group Identity), GI (Geographical Identifier), PLMN Id (Public Land Mobile Network Identifier). The most relevant and for the most network sufficient location information is Cell Id. There are a several solutions defined for location information retrieval [6][9]. In addition, according to network architecture and network elements capabilities various solutions are possible. In general, solution can rely on UE terminal capability or can be based on network capability to retrieve location information.

VI. CONCLUSIONS

In this paper we presented the IMS based emergency network architecture and the challenges we are facing when implementing emergency communication for both fixed and mobile users. Crucial thing is to localize the user to be able to perform proper routing of emergency calls and deliver the user location to PSAP. We have seen that the possibilities for the localization of the user depend on the type of access and type of the service that is provided to the user. IMS network architecture includes dedicated elements for handling emergency sessions, but the service itself has to be designed to conform to local regulations. In transition period where part of PSTN network is migrated to IMS, meaning that PSAPs and users are found in both domains, special care has to be taken in routing emergency calls between networks. Once the migration is finished it will be possible to use full potential of IMS and enable new forms of emergency communication like chat or video sharing. We can expect that this new forms of emergency communication will be included in local regulation as well.

Emergency call in LTE network can rely on legacy CS network, based on CS fallback mechanism. This solution requires small adoption of IMS network and enables fast deployment of emergency service in LTE network. However, IMS network based solution is seen as target for emergency service in LTE network. The solution requires implementation of additional functionalities in IMS network to support voice continuity between IMS network and CS network and to support retrieval of user location information.

Sažetak - Sektor telekomunikacija je važan segment razvoja svake države. Kako je tržište telekomunikacija bilo u stanju zakonitog monopola, povećanjem njegove važnosti povećava se regulacija prvobitnog stanja prema stanju konkurencije pri čemu bitnu ulogu imaju regulatorna tijela. U radu je prikazana evolucija regulacije telekomunikacija u Evropskoj Uniju i analizirano međupovezivanja kao ključne mjere telekomunikacione politike. Rad daje opći prikaz regulacije u sektoru telekomunikacija u Bosni i Hercegovini, sa osvrtom na regulaciju međupovezivanja. U BiH na tržištu telekomunikacija, liberalizacija je provedena, no potrebne su daljnje regulatorne akcije nadležnih tijela kako bi se postiglo stanje konkurentskog tržišta po uzoru na razvijene države EU, kojoj BiH teži.

Summary - The telecommunications sector is an important part of development of each country. As the telecommunications market was in a state of legal monopolies, increasing its importance means increasing regulation of the original state to state competition where regulators have an important role. This paper presents the evolution of telecommunications regulation in the European Union and analysis of interconnection as a key measure of telecommunications policy. The paper gives a general overview of regulation in the telecommunications sector in Bosnia and Herzegovina, with emphasis on the regulation of interconnection. In Bosnia and Herzegovina in the telecommunications market, liberalization has been implemented, but there is a need for further regulatory action of the competent authorities in order to achieve a state of competitive markets of developed countries of the EU, which it seeks.

Ključne riječi: telekomunikacijsko tržište, regulacija, liberalizacija

Key words: telecommunication market, regulation, liberalization,

I. UVOD

Evropski sektor telekomunikacija je imao karakter jakog državnog monopola u pružanju usluga. Vlasti su u mnogim državama smatrale da je neophodno da zadrže kontrolu u sektoru telekomunikacija zbog značaja koji telekomunikacije imaju u slučaju rata ili neposredne ratne opasnosti i učešća u bruto društvenom proizvodu. Asocijacije potrošača su zastupale stav da je konkurencija najbolji način da se osiguraju povoljnije cijene usluga i unapredi kvalitet usluga u sektoru telekomunikacija. Evropska komisija je zaključila da je monopol u sektoru telekomunikacija u suprotnosti sa evropskom politikom unutrašnjeg tržišta, te da je davanje posebnih prava za upravljanje mrežama i pružanje usluga kršenje prava konkurencije.

II. EVOLUCIJA REGULATORNOG OKVIRA U EVROPSKOJ UNIJI

A. Regulatorna reforme

Evropska komisija je ključna normativna institucija odgovorna za širenje telekomunikacija u Evropi. Komisija EU je 1987. godine, objavila Zelenu knjigu o razvoju zajedničkog tržišta za telekomunikacione usluge i opremu, sa ciljem da se prilagode zahtjevima jedinstvenog tržišta EU.[1] U ovom dokumentu, Komisija je predložila da se uvede konkurencija na telekomunikacionim tržištima i postigne veći stepen harmonizacije, kako bi se iskoristile prednosti jedinstvenog evropskog tržišta. Akcioni program Komisije EU sadržavao je slijedeće:

- Uspostavljanje evropskog instituta za standardizaciju u oblasti telekomunikacija - ETSI (European Telecommunications Standards Institute);

[1] Towards a dynamic European economy: Green Paper on development of market for telecommunications services.

• Razdvajanje regulatornih i operativnih aktivnosti u državama članicama EU;
• Primjena pravila konkurencije u telekomunikacija.

Nakon objavljivanja Zelene knjige iz 1987. godine, objavljene su i:
• Zelena knjiga o satelitskim komunikacijama iz 1990. godine;
• Zelena knjiga o mobilnim komunikacijama iz 1994. godine; i
• Zelena knjiga o liberalizaciji iz 1995. godine.

Komisija je 1990. godine izdala Direktivu kojom se države članice EU obavezuju da povuku sva prava za pružanje telekomunikacionih usluga, izuzev na govornu uslugu, mobilnu telefoniju i satelitske usluge.[2] U periodu od 1994. do 1996., Komisija je serijom direktiva proširila usluge sa kojih se skidaju ekskluzivna prava i tako obuhvatila satelitske komunikacije, mreže kablovskih i mobilnih operatera i govorne usluge. Regulacija se odnosila na standardizaciju i liberalizaciju radi stvaranja jednakih tržišnih uvjeta za sve države članice EU:

(1) Standardizacija: Glavna je zadaća komisije bila usmjerena na stvaranje jedinstvenog tehničkog standarda u Evropi, što je rezultiralo uvođenjem digitalne GSM tehnologije. To je bio veliki korak naprijed, zato što su postojeći analogni sistemi bili međunacionalno inkompatibilni.

(2) Konkurencija: Druga posljedica regulacije bila je kreiranje zdravog okruženja za razvoj konkurencije. Prijelaz na digitalnu tehnologiju iskorišten je kao prilika za promjenu stanja. Propisano je da moraju postojati najmanje dva različita dobavljača GSM usluga u području 900 MHz, i određeno je da u području 1800 MHz država mora omogućiti frekvencijski pojas za još najmanje jednog operatera.

Tabelarni pregled uvođenja liberalizacije u državama EU prije zvaničnog stupanja na snagu regulatornog okvira dat je u narednoj tabeli.

Tabela 1: Proces liberalizacije u EU prestupanja

Velika B	1981 1985 1991	Liberalizacija u VAN mrežama Konkurencija u analognim uslugama Liberalizacija tržišta fiksnih veza
Švedska	1981 1991	Konkurencija na mobilnom tržištu Konkurencija na tržištu fiksne telefonije
Finska	1988 1993	Konkurencija u prenosu podataka Konkurencija na svim tržištima
Danska	1992 1993 1994 1995 1996	Liberalizacija mobilnog tržišta Konkurencija u prenosu podataka Otvaranje iznajmljenih linija Konkurencija u širokopojasnim uslugama Puna liberalizacija
Njemačka	1989 1993	Odvajanje regulatornih od operativnih funkcija Liberalizacija opreme, VAN-usluga,
Francuska	1989 1992 1999	Konkurencija u analognim mrežama Konkurencija u digitalnim uslugama Konkurencija u uslugama i infrastrukturi
Holandija	1992 1997	Liberalizacija za prenos podataka Puna liberalizacija u sektoru

[2] Commission Directive 90/388/EEC of 28 June, Official Journal L 192 (24 July 1990).

Države članice EU usvojile su 1993. godine Rezoluciju Vijeća (93/C213/01)11[3], kojom se sa 01.01.1998. godine liberalizuju sve govorne usluge, uz tranzicioni period od pet godina za manje razvijene države (Portugal, Grčka, Irska i Španija) i do dvije godine za Luksemburg. Navedeni paket direktiva predstavljao je osnovu koja je korištena za izradu Zakona o komunikacijama u Bosni i Hercegovini, koji je stupio na snagu 2003. godine.

Regulatorni proces u sektoru telekomunikacija u EU sadržan je u Rimskom Ugovoru[4] i Ugovoru iz Mastrihta[5]. Rimski ugovor koji je stupio na snagu 01.07.1987. godine, formirao je jedinstveno, umjesto zajedničkog tržišta u EU. Na osnovu Ugovora iz Mastrihta postavljeni su osnovni ciljevi evropskih integracija koji su podrazumjevali uspostavljanje unutrašnjeg tržišta, stvaranjem sistema koji će spriječiti narušavanje konkurencije i harmonizaciju nacionalnih zakonodavstava država članica, nakon čega je uslijedila liberalizacija tržišta, harmonizacija nacionalnih propisa i primjena prava konkurencije. Tržište telekomunikacija EU otvoreno je 1998. godine, po usvajanju Direktive o otvorenim mrežama[1], koja predstavlja osnovnu direktivu regulatornog okvira EU za telekomunikacije iz 1998. Evropska komisija je u okviru regulatornog paketa iz 1998. donijela i Smjernice[12] za primjenu prava konkurencije u sektoru telekomunikacija i primjeni prava konkurencije prilikom zaključivanja ugovora o pristupu mreži, kako bi se novim pružaocima usluga omogućio pristup do krajnjeg korisnika.

Nakon liberalizacije telekomunikacionog tržišta u EU, novi pružaoci usluga su dobili priliku da konkurišu uvođenjem novih servisa, pružaoci Internet usluga i usluga mobilnih mreža bilježili su porast broja korisnika, kvalitet servisa je poboljšan, a cijene su padale. Ovakav razvoj je omogućio globalnom snižavanju cijena komuniciranja, investiranju u nove servise i mreže, doprinoseći povećanju zaposlenosti.

Komisija je predložila nov regulatorni okvir za elektronske komunikacije koji je predvidio:
1) uklanjanje suvišne regulative,
2) efikasniju konkurenciju,
3) pojednostavljenje administrativnih procedura,
4) zaštitu korisnika.

Predloženim mjerma se rješava:
• Zajednički regulatorni okvir;
• Autorizacija elektronskih komunikacionih usluga;
• Pristup elektronskim komunikacionim mrežama;
• Zaštita privatnostu u elektronskom sektoru i
• Razvezivanje lokalne petlje.

[3] Council, 'Council Resolution of 22 July 1993 on the Review of the Situation in the Telecommunications Sector and the Need for Further Development in that Market,' Official Journal of the European Communities C 213 (6 August 1993).

[4] Uspostavljen jedinstvenim evropskim aktom (SEA), prvom važnom reformom Rimskog ugovora, koji je potpisan u februaru 1986., a stupio na snagu 01.07.1987. godine. Ovim Aktom je trasiran put za formiranje jedinstvenog umjesto zajedničkog tržišta.

[5] Ugovor iz Mastrihta (Mastrihtski Ugovor) o EU, je potpisan u Mastrihtu februara 1992. a stupio na snagu novembra 1993. godine.

B. *Regulatorni okvir iz 2002. godine*

Regulatorni okvir iz 2002. godine stupio je na snagu jula 2003. (osim Direktive o privatnosti i elektronskim komunikacijama koja je na snazi od 31. oktobra 2003.) i sastoji se, pored Uredbe o otvaranju lokalne petlje[14] i Odluke o radiofrekvencijskom spektru[10] i, iz Okvirne direktive[2] kojom su utvrđeni principi zaštite konkurencije i korisnika, i četiri direktive koje se bave različitim regulatornim pitanjima iz oblasti elektronskih komunikacija:
(1) Direktive o izdavanju dozvola[3] koja treba da osigura jednostavnu proceduru izdavanja dozvola za mreže i usluge primjenom režima općeg ovlaštenja;
(2) Direktive o pristupu i međusobnom povezivanju[4] koja treba da omogući pristup drugog operatera infrastrukturi pod definisanim uslovima;
(3) Direktive o univerzalnom servisu[8], kojom se utvrđuje minimalni skup usluga koji treba da bude dostupan svim korisnicima; i
(4) Direktive o zaštiti privatnosti[5].
Od posebnog značaja u pogledu stvaranja povoljnijih uslova za konkurenciju u mrežama za pristup je donošenje odredbe Parlamenta i Vijeća EU o razvezivanju lokalne petlje[6].

C. *Regulatorni okvir za elektronske komunikacije*

Prvi akt koji je Komisija usvojila u postupku revizije regulatornog paketa iz 2002. godine je Preporuka Komisije 2007/879/EC o tržištima podložnim uvođenju ex ante regulative[7], koja je korak u pravcu ukidanja regulative elektronskih komunikacija u pojedinim sektorima. Preporukom je predviđeno uklanjanje 11 tržišta sa liste relevantnih tržišta predviđenih preporukom iz 2003. godine. Osnovni ciljevi revizije regulatornog okvira bili su: jačanje nezavisnosti regulatornih tijela; smanjenje regulatorne intervencije u onim oblastima gde je postignut zadovoljavajući nivo konkurencije; brže procedure za prenosivost broja, bolju zaštitu privatnosti i sigurnosti. Usvojena je i Uredba o romingu[15] kojom su ograničeni iznosi naknada za usluge međunarodnog rominga za govorne pozive koji počinju i završavaju na teritoriji EU. Evropski parlament i Vijeće ministara usvojili su Uredbu o izmjenama i dopunama Uredbe o romingu[16], kojom je utvrđeno da period važenja Uredbe o romingu treba produžiti i nakon 2010. godine, i njenu primjenu treba proširiti na pružanje usluga SMS poruka i prenosa podataka u romingu.
Izmjenjene i dopunjene su direktive EU iz 2002., i to:
- Direktiva 2009/140/EC o izmjenama i dopunama Okvirne direktive 2002/21/EC za elektronske komunikacione mreže i usluge, Direktive 2002/19/EC o pristupu i međupovezivanju elektronskih komunikacionih mreža i Direktive 2002/20/EC o izdavanju odobrenja za mreže i usluge;
- Direktiva 2009/136/EC o izmjenama i dopunama Direktive 2002/22/EC o univerzalnim uslugama i pravima korisnika koja se odnose na elektronske komunikacione mreže i usluge, Direktive 2002/58/EC o zaštiti privatnosti u elektronskih komunikacija i Uredbe 2006/2004 o zaštiti potrošača.

Uredbom (EC) No 1211/2009, osniva se evropski regulator za elektronske komunikacije BEREC[17] (Body of European Regulators for Electronic Communications), koji ima obavezu da osigura fer konkurenciju na telekomunikacionom tržištu EU. Novo regulatorno tijelo se formira od šefova 28 nacionalnih regulatornih tijela EU i predstavnika Komisije i država kandidata za ulazak u EU (Turska i Makedonija, bez prava glasanja). Ovo tijelo okuplja predstavnike regulatornih tijela EU i pruža okvir za razmjenu iskustava među regulatorima i saradnju sa Evropskom komisijom, u cilju stvaranja jedinstvenog tržišta elektronskih komunikacija. BEREC će donositi odluke većinom glasova, a u slučajevima sporova između nacionalnih administracija, dvotrećinskom većinom. Komisija je dobila ovlaštenje da u saradnji sa BEREC-om, donosi obavezujuće odluke u situacijama kada nacionalno regulatorno tijelo kreira prepreke funkcioniranju jedinstvenog tržišta.

Regulatorni okvir iz 2009. godine uspostavlja regulatorno okruženje koje osigurava razvoj tržišta za telekomunikacione mreže i usluge u korist građana EU, te pruža visok nivo pravne sigurnosti za poticanje ulaganja u sektor i pruža dovoljnu fleksibilnost da odgovori zahtjevima dinamičnog razvoja tržišta i inovativnih tehnologija. Revidirani regulatorni okvir za elektronske komunikacije EU je implementirala 2011. godine.

D. *Međupovezivanje*

Međupovezivanje je postalo ključni instrument telekomunikacione politike sa porastom različitih mreža koje su morale da budu inter-operabilne. Pojam međupovezivanja se prema IUT definiše kao: „Komercijalni i tehnički aranžmani po kojima provajderi povezuju svoju opremu, mreže i usluge da bi omogućili korisnicima da imaju pristup mrežama korisnicima i uslugama drugih provajdera“.[9]

Postoji: paralelno, vertikalno i horizontalno međupovezivanje. Paralelno međupovezivanje je aranžman po kojem se dominantni operateri povezuju sa operaterima koji su dominantni u drugim regionima. Njihov odnos je partnerski, zajednički šire mrežu za svoje korisnike i utvrđuju zajednički cijenu. Drugi aranžman se javlja između provajdera koji nudi međumjesne telefonske razgovore i lokalnog operatera. Horizontalno međupovezivanje je aranžman gde se konkurenti za ista tržišta telekomunikacija i korisnici povezuju. Odnosi uključuju veze unutar i između entiteta i industrija:
- Postojeće i nove lokalne telefonske kompanije;

[6] Regulation (EC) No 2887/2000 of the European Parliament and of the Council of 18 December 2000, OJ L336/4, 30.12.2000.
[7] Commission recommendation of 17 December 2007 on relevant product and service markets within the electronic communications sector susceptible to ex ante regulation in accordance with Directive 2002/21/EC of the European Parliament and of the Council on a common regulatory framework for electronic communications networks and services.

- Domaći i međunarodni operateri;
- Privatne mreže;
- Kompjuterske mreže;
- Satelitska mreža i kablovska televizija.[19]

E. Uspostavljanje jedinstvenog tržišta

Početkom 2013. godine na sednici Evropskog Vijeća predviđeno je da Komisija predstavi mjere za uspostavljanje jedinstvenog tržišta informacionih i telekomunikacionih tehnologija na teritoriji EU. Ovaj prijedlog se nastavlja na glavne direktive iz 2002. godine, izmjenjene i dopunjene 2009. godine. Cilj ovog prijedloga je uspostavljanje i stvaranje jedinstvenog tržišta elektronskih komunikacija sa konačnim ciljem potpune integracije i liberalizacije. Jedinstveno tržište elektronskih komunikacija podrazumjeva da[15]:

− privredna društva koja osiguraju elektronske komunikacione mreže i usluge mogu vršiti djelatnost i pružati usluge bez obzira na mjesto nastanka ili mjesto u EU na kojem se nalaze njihovi korisnici,

− privredna društva i građani elektronskim komunikacionim uslugama mogu pristupiti sa bilo kojeg mjesta u EU, bez ograničenja ili neopravdanih dodatnih troškova.

Uspostavljanjem jedinstvenog tržišta elektronskih komunikacija podsticalo bi se ulaganje, inovacije i nadmetanje na području mreža i usluga, kao i nadmetanja u pogledu cijena. Ove mjere trebale bi promovisati ciljeve utvrđene u Digitalnoj agendi za Evropu i stvoriti jedinstveno digitalno tržište. Ovaj predlog ima za cilj da uspostavi ravnopravne uslove za sve učesnike na tržištu elektronskih komunikacija u EU kako bi se rizik ulaganja u sektoru sveo na što manju mjeru. Izazovi pri stvaranju jedinstvenog tržišta ogledaju se u:

− harmonizaciji uslova za pristup: davanjem garancija mobilnim operaterima koje se odnose na uslove dodjele i usklađenosti rokova za pristup spektru za bežični širokopojasni pristup u EU,

− otklanjanje prepreka u sistemu davanja odobrenja koja se primjenjuju na pružanje usluga tako da odobrenje dobijeno u jednoj državi članici važi u svim ostalim državama članicama,

− zaštita korisnika u EU stvaranjem jednakih uslova za sve.

I. REGULACIJA TELEKOMUNIKACIJAMA U BOSNI I HERCEGOVINI

A. Regulacija telekomunikacija

Bosna i Hercegovina je tek 2004. godine počela ozbiljnije ulaziti u sferu informacionih i komunikacionih tehnologija, u čemu inače osjetno zaostaje, ne samo za razvijenim državama Evrope i svijeta, već i za većinom tranzicijskih država.

Područje telekomunikacija u Bosni i Hercegovini uređeno je Zakonom o komunikacijama[8], kojim je uređeno područje telekomunikacija, način i uvjeti obavljanja telekomunikacijskih usluga i djelatnosti, prava i obaveze davatelja i korisnika telekomunikacijskih usluga, izgradnja, održavanje i upotreba telekomunikacijske infrastrukture i opreme, radijske opreme i telekomunikacijske terminalne opreme, upravljanje radiofrekvencijskim spektrom, te obavljanje nadzora i kontrole u telekomunikacijama. Zakon je usklađen sa starim regulatornim okvirom EU (22 direktive iz područja telekomunikacija), koji su države članice EU počele primjenjivati 1998. Postojeća zakonska regulativa ne prati novosti na telekomunikacijskom ržištu, niti prati nove izazove koje ono donosi.

U procesu usvajanja i provođenja EU propisa, a u cilju postizanja evropske perspektive za BiH, neophodno je izvršiti reformu sektora telekomunikacija, primjenjujući zakonske i podzakonske akte koje je propisala Evropska komisija. Primjena regulative se odnosi na usvajanje Zakon o elektronskim komunikacijama kao krovnog dokumenta koji regulira sektor elektronskih komunikacija u BiH, jer postojeći Zakon o komunikacijama se bazira na regulatornom okviru iz 1998. godine. Kako bi se usvojili principi novog regulatornog okvira, a primjenjujući evropske smjernice, odluke i preporuke, u BiH treba donijeti i set podzakonskih akata koji uređuju određenu oblast, a naslanjaju se na novi regulatorni okvir EU.

Novim regulatornim okvirom potrebno je ukinuti prepreke za ulazak novih sudionika na tržište kako bi se, uvođenjem slobodne konkurencije, korisnicima omogućio odabir davatelja usluge. Regulacija telekomunikacijskog tržišta treba da ide ka deregulaciji, odnosno tržište ne smije biti opterećeno mjerama regulacije. Hoće li u budućnosti biti više ili manje regulacije ovisit će prvenstveno o konkurenciji na telekomunikacijskom tržištu, gdje veća konkurencija znači i manje potrebe za regulacijom.

Liberalizirano tržište telekomunikacija omogućava privlačenje kapitala za ulaganje u telekomunikacijske mreže i uvođenje novih usluga, povećanje broja telekomunikacijskih operatora i davatelja usluga koji se međusobno natječu i time pomažu u kvaliteti usluživanja korisnika usluga. Pojavom konkurencije povećava se kvaliteta pruženih telekomunikacijskih usluga te snižava cijena za iste ili slične usluge koje korisnici telekomunikacijskih usluga očekuju.

Regulatorna agencija za komunikacije mora osigurati postizanje konkurentskih uvjeta regulacijom pristupa mrežnim resursima operatera sa značajnom tržišnom snagom što je osnova ostvarivanja konkurencije na svim telekomunikacijskim tržištima. Tržište treba biti otvoreno u segmentu usluga kao i u segmentu infrastrukture te svakako treba biti otvoreno za direktna strana ulaganja.

[8] Zakon o komunikacijama Bosne i Hercegovine, objavljen u „Službenom glasniku BiH“, broj: 31/03, usvojen 02.09.2003. godine.

B. Pristup i međupovezivanje telekomunikacionih mreža

Međupovezivanje je povezivanje javnih telekomunikacionih mreža korišteno od strane privrednih društava, s ciljem omogućavanja korisnicima jednog privrednog društva da komuniciraju s korisnicima istog ili nekog drugog privrednog društva, ili pristupaju uslugama koje pruža drugo privredno društvo. Pružaoci usluga telekomunikacija sa značajnom tržišnom snagom koji pružaju usluge iznajmljivanja linija obavezani su, na tržištu na kojem dominiraju, istaknuti minimalnu ponudu linija za iznajmljivanje s tehničkim karakteristikama u skladu s direktivama EU. Pristup mreži daje se putem priključnih tačaka koje su dostupne na tržištu ili putem priključaka na zahtjev korisnika. Sporazumi o međupovezivanju zasnivaju se na nedskriminaciji i ravnopravnom pristupu telekomunikacionim mrežama. Regulatorna agencija za komunikacije (Agencija) je 2005. godine dala saglasnosti na Referentne interkonekcijske ponude (RIP) za tri dominantna operatora, koji djeluju na tržištu telekomunikacija u Bosni i Hercegovini: BH Telecom, Telekom Srpske i HT Mostar. RIP definira uvjete pod kojima drugi licencirani operatori mogu ostvariti međupovezivanje u mrežama dominantnih operatora u Bosni i Hercegovini. Ponuda sadrži principe međupovezivanja, osnovne tehničke, komercijalne i ugovorne aspekate međupovezivanja. U svrhu osiguranja međusobnog povezivanja, osigurana je zadovoljavajuće komunikacija između krajnjih korisnika. Međupovezivanje predstavlja ključnu odrednicu za potpunu liberalizaciju tržišta telekomunikacija u Bosni i Hercegovini. Referentnom interkonekcijskom ponudom (RIP) omogućava se uvođenje tržišne konkurencije s jednakim mogućnostima ulaska novih operatora na tržište. Od 2006. godine do 2013. godine na tržištu fiksne telefonije u BiH sklopljeno je 33 interkonekcijskih ugovora između postojećih telekoma i novih operatora, dok je trenuto važećih 22. Novi operateri realizuju značajan postotak međunarodnog prometa po nižim cijenama za krajnjeg korisnika.

IV. ZAKLJUČAK

Nakon liberalizacije u telekomunikacijama, koja je započela u SAD-u i Velikoj Britaniji, u protekle tri decenije ulagani su veliki napori u EU, na stvaranju povoljnog zakonodavno-regulatornog okruženja u kome će svoj poslovni interes ostvarivati svi učesnici na tržištu pod ravnopravnim uslovima, a korisnici uživati u prednostima većeg izbora usluga uz povoljnije cijene. Regulatorni okvir elektronskih komunikacija u EU iz 2009. godine, predstavlja osnovu za održivo regulatorno okruženje usmjereno ka rješavanju preostalih regulatornih izazova i osigurava prisustvo konkurencije i podstiče investiranje. Prva od sedam inicijativa strategije "Evropa 2020" je **Digitalna agenda** iz 2010. godine, koja predstavlja Akcioni plan Komisije za jačanje evropskog prosperiteta. Agenda ističe sedam prioritetnih oblasti za akciju:

1) jačanje povjerenja na Internetu,
2) brži pristup Internetu,
3) više investicija u istraživanje i razvoj,
4) postizanje veće interoperabilnosti,
5) unapređenje digitalne pismenosti,
6) primjena informacionih i komunikacionih tehnologija u rješavanju klimatskih promjena i
7) kreiranje jedinstvenog digitalnog tržišta.

Kako bi se na najefikasniji način povećala pravna sigurnost i transparentnost i kako bi se spriječile posledice rascjepkanosti evropskog tržišta elektronskih komunikacija, Evropska komisija je predložila primjenu pomenutih mjera za koje se očekuje da stupe na snagu u 2014. godini. Procjenjuje sa da će u EU nakon primjene ovih mjera, zahvaljujući većem konkurentskom pritisku, stvoriti povoljnije okruženje za nove investicije. Ovaj prijedlog predviđa da se na veleprodajnom tržištu pristupa na nivou cijele EU i da svi proizvodi budu dostupni i standardizovani. Ova mjera će omogućiti operaterima fiksnih mreža da usluge povezivanja koje pružaju svojim korisnicima širom EU budu visokog kvaliteta i jednaki za sve. Ovo će za posledicu imati pojačano tržišno nadmetanje kroz nova ulaganja operatera u infrastrukturu i nove usluge. Jednakim pravilima koja se odnose na kvalitet usluga osigurat će se sloboda korisnika da pristupe uslugama po svom izboru na osnovu uslova ugovora u čitavoj EU, a da se njihov pristup internetu ne ograničava.

Proces liberalizacije telekomunikacionog tržišta u Bosni i Hercegovini započet je prije 10 godina. Primjenjujuci Zakon o komunikacijama, kao i pažljivo sagledavajuci iskustava drugih regulatora iz razvijenih država i prateci trendove razvoja novih tehnologija, RAK je osigurao pravni okvir za liberalizaciju i otvaranje telekomunikacionog tržišta. Danas je to ostvareno u oblasti mobilne i fiksne telefonije, Internet usluga i širokopojasnog pristupa.

U narednom periodu potrebno je prilagoditi regulativu iz oblasti telekomunikacija propisima EU, a prije svega usvojiti novi zakon o elektronskim komunikacijama usklađen sa novim regulatornim okvirom EU iz 2009. godine. Gotovo sve države okruženja su već usvojile ovaj zakon, npr. Zakon o elektroničkim komunikacijama Republike Hrvatske (stupio je na snagu 1. jula 2008. godine), Zakon o elektronskim komunikacijama Republike Srbije (usvojen maja 2010. godine) i Zakon o elektronskim komunikacijama Crne Gore (usvojen 13.08.2013. godine). U cilju povećanja stepena konkurencije sektora telekomunikacija neophodno je nastaviti aktivnosti na analizi tržišta u skladu sa Preporukom Evropske komisije o relevantnim tržištima i važećim EU regulatornim okvirom, te Pravilom o analizi tržišta elektronskih komunikacija.

Abstract - Due to a declining market of telecom services, telecom providers are trying to expand their service portfolio to new markets based on cloud paradigm. To be successful with cloud services, telecom has to find offers that are interesting to their customers, that can be put on the market in short time and work with sufficient quality.

In this paper we will provide an overview of our approach for building portfolio of cloud services using locally developed and services developed by other cloud providers. In this approach all cloud services are seamlessly integrated, sold, supported and charged through local telecom channels. The overview will include description of the approach including high level architecture, main processes and cloud interface layer.

I. INTRODUCTION

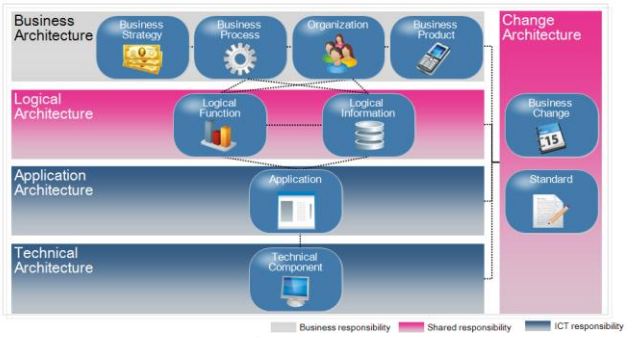
Due to a declining market of telecom services, telecom providers are trying to expand their service portfolio to new markets based on cloud paradigm. To be successful with cloud services, telecom has to find offers that are interesting to their customers, that can be put on the market in short time and work with sufficient quality.

To gain a market share, telecom providers has to build a portfolio of services attractive to their customers. As there is no a recipe on how to create a successful customer service, telecom providers are creating large number of services and hope that one in ten of services will be successful. To build services in shorter time, new business models are established in which telecom providers are partnering with external partners for cloud service delivery. Those new service delivery models can be summarized in 3 main types – integrate, distribute and co-sell [1]. As partners telecom providers are using *independent software vendors* (ISV), but also cooperating with other telecom providers from the same group operating in other countries.

Delivery of cloud services between providers requires several steps: contracting, building technical integration and operating cloud service. As building technical integration on service by service base will require too much time and effort, systematic approach that will enable mass service integration is needed. To define such approach we used industry best practices provided by organizations such as TM Forum for telecom processes and TOGAF for enterprise architecture.

II. SOLUTION ARCHITECTURE

Solution architecture represents a blueprint on how to create a solution to specific problem. Architecture is presented in several architectural views that communicate different aspect of solution to stakeholders. Architecture starts from business processes that solution has to cover, than it describes logical architecture from functional and information points, and at the end it describes how those functionalities are implemented in applications and technical infrastructure. We have adopted this approach as is described in TOGAF (The Open Group Architecture Framework) [9] and DT Architecture Meta-model [13] – see Picture 1.



Picture 1. EA Levels from DTAG EA Meta-model 1.0

In designing solution for cloud service delivery two main options were discussed:

- delivery of cloud services from central cloud through central marketplace,
- distributed delivery of cloud services in peer to peer mode between clouds without central hub.

First option requires less integration effort to bring new service to the market, but brings dependency on central cloud. Second option take into account local telecom provider needs, flexibility and consistent customer experience, but require initial high integration effort.

After evaluation second options were chosen. In this option each cloud could use service from any other cloud without need for central hub.

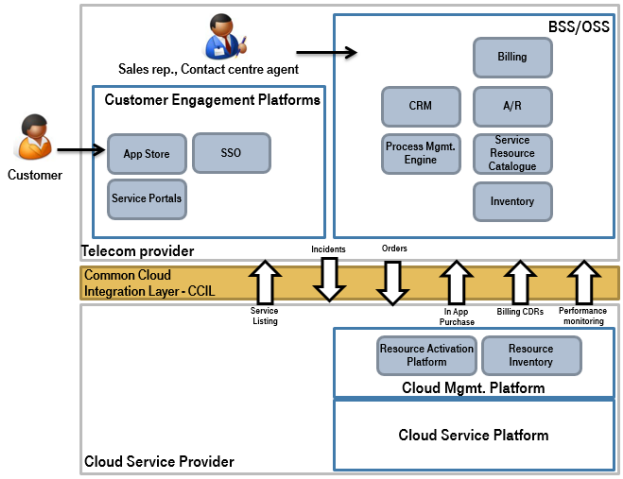
In this option all communications toward customer, customer support, providing application marketplace and customer billing remains responsibility of local provider.

Local provider finds interesting services offered by other providers of cloud services, contract service delivery and integrate it into own processes and system stacks.

In defining the solution architecture following architecture design principles were set:

- **Peer to peer cloud services providers**: application could be hosted anywhere (locally, in other telecom provider, centrally, 3rd party)
- **Easy integration into standard telecom architecture**: multiple channel support, support for standard telecom processes, one integrated invoice with telecom and local/global cloud products
- **Seamless customer experience**: customer should not notice difference between local and global cloud products
- **Easy replicable architecture**: the same architecture should be easily replicated in different environment (today telecom providers has different internal IT architecture with different systems in place)
- **Optimization of cost structure**: economy of scale, global contracts.

The idea is to connect telecom provider's clouds through standardized set of interfaces called Common Cloud Integration Layer (CCIL) – shown in brown on Picture 2. This set of interfaces will be implemented by each telecom provider. Through this set of interfaces telecom provider will be able to connect their existing BSS/OSS systems to other telecom providers in standardized way. Once initial integration is done, cloud service provider will be able to easily provide mass amount of services to other providers.



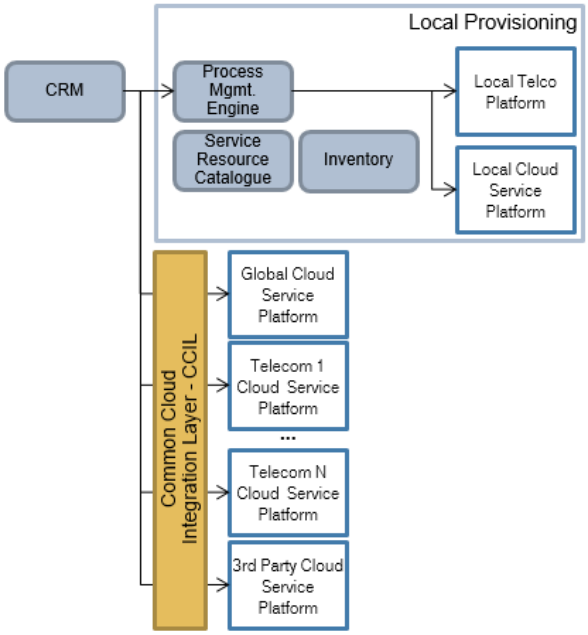
Picture 2. Common Cloud Integration Layer

Telecom provider business processes are described in standard frameworks like Frameworx from TM Forum [10] with main processes in fulfillment, assurance and billing area. Processes for cloud services has to be aligned with standard telecom processes to enable bundling with existing telecom products and using existing organization and infrastructure.

Although eventually all processes concerning cloud services could be automated, stepped approach could be defined that start with automation of fulfillment process, and in later phases automate assurance and product/service lifecycle management.

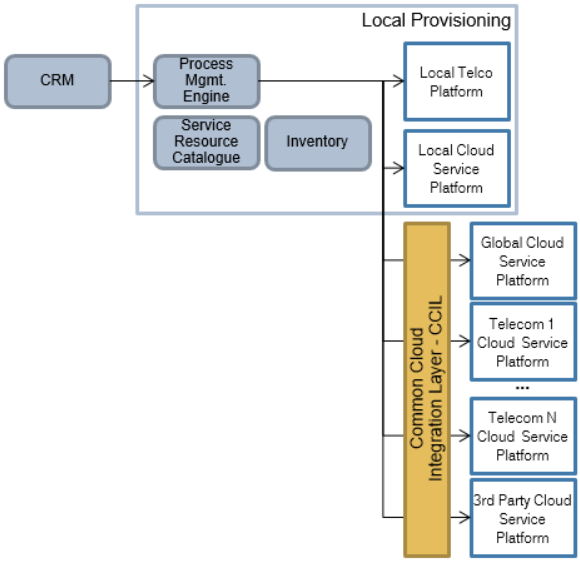
CCIL supports different architectural styles for integration with local BSS/OSS (Business Support Systems/Operating Support Systems). Common Cloud Integration Layer could be connected to local CRM as additional provisioning platform or could be connected to local OSS as an additional service platform.

Connecting CCIL to local CRM as additional provisioning platform (see Picture 3) results in faster cloud service provisioning because it bypasses the local provisioning layer. However, this approach lack service bundling and orchestration abilities that brings the local provisioning platform and requires from CRM to orchestrate order provisioning through several provisioning platforms.

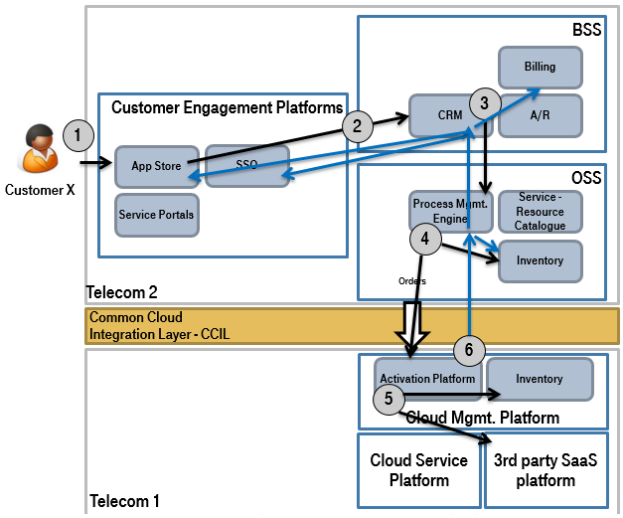


Picture 3. CCIL connected to CRM

Connecting CCIL to local OSS as additional service platform (see Picture 4), enables service bundling (for example ADSL service with cloud storage service) and using provisioning platform orchestration capabilities. However, this approach prolongs order provisioning time due to additional layer involved and also requires more configuration when a new product is introduced because product has to be configured in CRM and OSS.



Picture 4. CCIL connected to OSS



Picture 5. Use case for new cloud service fulfillment

III. PILOT IMPLEMENTATION

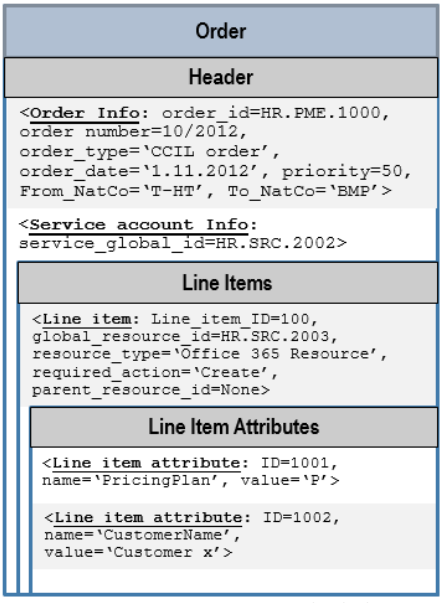
For pilot implementation of Common Cloud Integration Layer a scenario is defined in which SaaS application provided by independent software vendor to Telecom 1 is published through CCIL to Telecom 2. Only fulfilment process is covered by CCIL in the pilot implementation.

CCIL is implemented on Telecom 1 existing application marketplace and connected to Telecom 2 OSS system stack through middleware platform. To enable provisioning process, new product is configured on Telecom 2 local application marketplace, CRM and OSS systems.

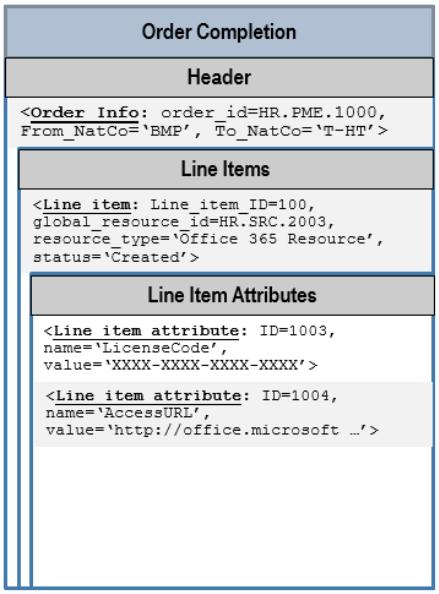
Fulfillment process for cloud service is done in the following steps (see on Picture 5):

1. Customer order SaaS application in App Store
2. App Store send product order with specific tariff option product to CRM
3. CRM decompose product order to service order and send service order to OSS Process Management Engine (OSS PME)
4. OSS PME decompose services to resources using Service/Resource Catalogue and create new SaaS application service in S/R Inventory. New resource order for creation of SaaS application resource is created and sent through CCIL to Telecom 1 Cloud Activation Platform
5. Activation platform provision SaaS application on ISV platform and store resource information in Telecom 1 cloud inventory
6. Information about provisioned resource is returned back to Telecom 2 and propagated to S/R Inventory, CRM, Billing, SSO and App Store

Interface for fulfillment process is built in such way that it is agnostic to type of cloud services ordered through this interface. Basic object sent through the interface is an order in form of XML message which an example can be seen on Pictures 6 and 7 respectively. Each order contains one or more line items with resource description, action required on the resource and resource attributes (see Picture 6). Order completion object (see Picture 7) which is sent as a response after finished provisioning of resource contains information about resource status after provisioning and resource attributes.



Picture 6. Example order message for fulfillment



Picture 7. Example message for order completion

IV. CONCLUSION

In this work we presented high level solution architecture for integrating clouds services into telecom provider environment based on Common Cloud Integration Layer. Based on this solution architecture initial pilot implementation on simplified scenario was done to prove validity of proposed models and concepts. After successful pilot implementation the work has been started on production implementation.

Although, assurance and contracting of service delivery are covered in high level through the solution architecture at this stage, they have not worked out in detail and automated, and it remains for the future phases.

Competence Transfer through Enterprise Mobile Application Development

Saša Vojvodić*, Matteo Zović*, Veselin Režić*, Hrvoje Maračić** and Mario Kušek**
* Ericsson Nikola Tesla, Zagreb, Croatia
** University of Zagreb / Faculty of Electrical Engineering and Computing, Zagreb, Croatia
{sasa.vojvodic, matteo.zovic, veselin.rezic}@ericsson.com, {hrvoje.maracic, mario.kusek}@fer.hr

Abstract - Large world corporations need corresponding information technology (IT) support as well as constant improvement of software tools, which should enable further business development and more efficient work to operational organizations. The main interest of IT support organizations is currently more and more connected with mobile IT equipment of the employees. Specific business mobile applications improve the efficiency and result in new operating possibilities.

The cooperation between Ericsson Nikola Tesla (ENT) and Faculty of Electrical Engineering and Computing (FER) of the Zagreb University, has enabled a fast development of competencies in ENT, necessary for mobile application development and quality realization of innovative solution for platforms iOS and Android. In this cooperation at the project realization the methodology of application development was defined, the corresponding competencies were developed, the system architecture was designed together with the communication of mobile application and back-end IT systems.

In the project the iterative development approach, tools for software code versioning and project control have been used thus enabling continuous insight in project progressing. At any moment it was possible to determine priorities of functional development and solution elements, as well as to realize the necessary additional transfer of knowledge.

The project has resulted in an enterprise mobile application for iOS and Android platforms, which had been implemented and tested in several countries. The complete solution enables data management by means of the portal, thus decreasing the frequent changes of users' mobile application and significantly accelerating the process of new functionalities introduction.

I. INTRODUCTION

The growing variety of devices, computing styles, user contexts and interaction paradigms, consequences of bring your own device (BYOD) programs that are significantly increasing the size of the mobile workforce is placing tremendous strain on Information Technology (IT) organizations [1]. Mobility is the megatrend in enterprise networking.

Reach mobility possibilities are demanding the new IT knowledge on creating expanded user interface models that can connect people and information in new and different ways. Mobility and BOYD create both efficiency and challenges. When employees have information and communication tools on the move and at their fingertips, enterprises can make decisions more quickly, communicate more effectively, and interface more closely with their partners and customers.

BYOD and mobility drive demand for more pervasive networks, multi-mode devices, and more sophisticated applications and user interfaces.

The worldwide tablets and smartphones shipment significantly outpaced the PC shipments numbers. In 2014, the worldwide tablet market is forecasted to grow 47 percent [2]. Sales results in Croatia in the first half of 2013 show tremendous growth: 349.000 smartphones and 172.089 tablets or 61% and 780% sales growth compared to the first half of the previous year [3]. Worldwide combined shipments of devices (PCs, tablets, ultramobiles and mobile phones) are projected to reach 2.5 billion units in 2014 (Figure 1.

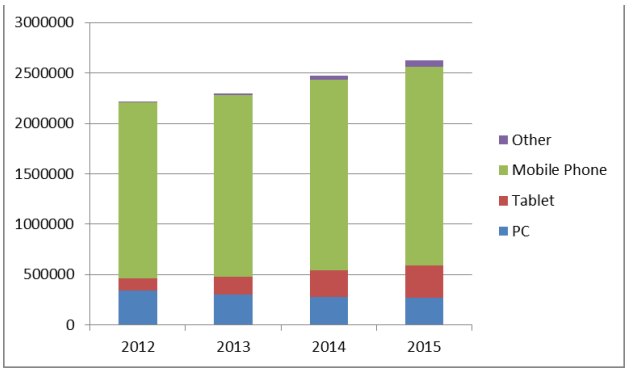

Figure 1. Worldwide Device Shipments by Segment (Thousands of Units)

Enterprise IT organizations have to act. Evolutions by means of internal transformations are needed in three different directions:

- New knowledge; focus towards mobile applications,
- New way of working; service oriented approach,
- True business partner in operational development and business excellence; savings and revenue focused innovations.

New knowledge is necessary to develop and provide enterprise mobile application that takes center stage as

mobility adoption increases. The mobile apps development lifecycle is unlike the traditional application development lifecycle, so there is a need for new management tools, and existing skills do not transfer from desktop application development to mobile app development because the patterns for building efficiency, performance, and security into mobile devices are different [4]. The new released apps should consider the application lifecycle management, application distributions, performance management, monitoring and analytics, version management, security, etc. – and this is all new for traditional enterprise IT.

To speed up the required evolution, Ericsson Nikola Tesla (ENT) decided to engage external qualified partner in know-how for knowledge transfer. The choice fell on University of Zagreb, Faculty of Electrical Engineering and Computing (FER), and cooperation in boosting mobile application development knowledge through concrete project execution has started.

II. COOPERATION

The cooperation goals were to gather information, best practices on mobile development approach and to create a new mobile application development initial team across the existing organization unit structure. Final delivered apps were supposed to be implemented on global corporate scale, so cooperation with colleagues from USA, Sweden and other test countries were established.

The knowledge management system plays a vital role in supporting the organization to increase its level of innovation by facilitating access to knowledge, encouraging the free flow of ideas, and by supporting and accelerating the learning processes within the organization. This was all achieved through this cooperation. Figure 2. describes 5-phase organizational knowledge development serving as innovation founder [5].

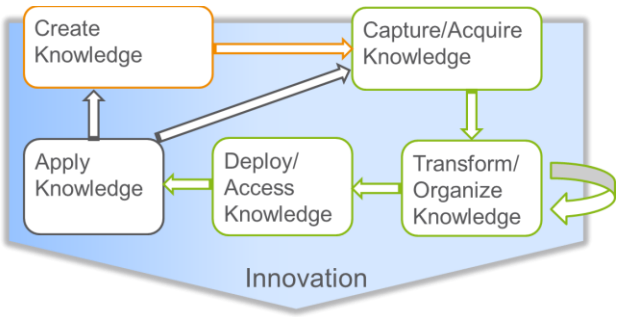

Figure 2. 5-phase organisational knowledge development

Core and non-core specific competence found inside the company and assigned to the project are the following:

- System development, software design, test and verification,
- Graphical user interfaces design,
- IP network design,
- Application and database servers design,
- Security and
- Specific application requirements competence.

In a broader perspective, the cooperation should establish overall framework to improve company competence building, mobility, administration, efficiency and productivity by deploying new innovative mobile enterprise applications. Knowledge management system is critical to get this done; hence phase approach shown in Figure 3. was established.

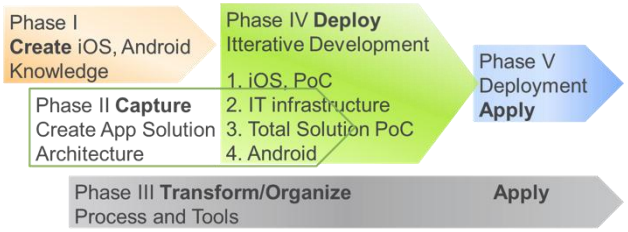

Figure 3. Cooperation phase approach

iOS [8] and Android [9] knowledge were built as starting step (Phase I) thus corresponding to Create Knowledge in 5-phase approach. Solution architecture, functional and non-functional requirements were defined and designed (Phase II) and correspond to Capture/Acquire Knowledge. Adjusting corporate ecosystem by applying tools and processes were used in Phase III in parallel with other activities. This phase is covered with Apply Knowledge from 5-phase approach. Iterative development (Phase IV) was used and each iteration was resulting with set of deployable functionalities which corresponded to Deploy/Access Knowledge in 5-phase approach. Each iteration (except the first one) was followed by deployment phase (Phase V), which corresponds to Apply Knowledge.

III. MOBILE PLATFORM

A number of different mobile platforms exist. Two of the most widely used are Android and iOS. Together, they account for more than 65% of all mobile phones [10].

The Android Open Source Project is a project initiated by the Open Handset Alliance, led and developed by Google. It is open source and manufacturer independent [11]. Different manufacturers, e.g. Samsung, HTC, Motorola, port Android to their devices, mostly by implementing drivers and other device-specific features. The operating system itself remains the same, allowing the same application to be used on all Android devices, regardless of their manufacturer. There is an Android Compatibility Program designed to ensure this. Each manufacturer needs to comply with the Android Compatibility Definition Document (CDD) and pass the Compatibility Test Suite (CTS) [12]. Android itself is written mostly in C and C++, while user interface elements are written in Java. Due to Android's use of the Dalvik Virtual Machine instead of the regular Java Virtual Machine, applications for Android are written in the Java programming language and compiled specifically for Android.

iOS, on the other hand, is a closed system, developed and used exclusively by Apple for their mobile devices, including iPhone, iPad and iPod Touch. Applications for iOS are written in ObjectiveC.

Both platforms have their respective application stores. Developers of consumer applications submit their applications to the store. The application is then reviewed for compliance with the store's terms and requirements and published. Since corporate applications can be distributed internally, there are fewer requirements since there is no store review.

New versions of both iOS and Android are published regularly. Android is currently in version 4.4, Application Programming Interface (API) level 19. When deciding which versions to support, we decided to go with version 2.1, API level 7 and newer ones. This is done because all needed features were already available in that version, there are no phones in our corporate environment with older Android versions and global use of older versions is also negligible [13]. iOS is currently in version 7, but at the time of development was in version 6. We decided to support versions 6 and 7 because all iPhones since version 3GS are capable of running those versions, all devices in our corporate environment have at least version 6, and share of these two versions is 96% [14].

Unlike iOS, which runs on only two different screen sizes on phones, Android phones have numerous different screen sizes and screen resolutions. Drivers and core services on Android phones are usually implemented by manufacturers, which means that sometimes, due to either bugs or differences in implementations, same services behave differently on different Android phones of the same operating system version. As an example, we discovered that one of our users had a phone which did not handle a certain feature properly, unlike all other manufacturers which we tried, for the same Android version. It also means that an application has to be scalable to support different screen sizes.

One of the challenges on iOS was detecting whether the user is currently in roaming. Although the iOS has this information, it is not accessible by applications, probably due to privacy concerns.

Also due to the decision to support iOS version 6 and 7, we had to switch to the new Xcode, Apple's Integrated Development Environment (IDE) for developing iOS applications. Unfortunately with the new IDE there was a change in the User Interface (UI) of the IDE and development team had to spend more time to adapt to the new version changes. In addition to the changes of the IDE, there was a change in the iOS itself. The new iOS has brought enhancements in graphical elements behavior which consequently automatically fixed graphical outstanding issues on iOS 6 that had been preventing a proper implementation of customer graphic requirements.

IV. METHODOLOGY

A. Tools

When working in a team, one of the important aspects is how to enable efficient code synchronization and sharing between team members. To facilitate this, a number of different version control systems exist, e.g. CVS, SVN, Git [15]. We decided to choose Git due to its performance and built-in support in Xcode, Apple's Integrated Development Environment (IDE) and in Eclipse, used for Android development. Online services for Git hosting are available, both paid and free, but we decided to set up our own server based on the Gitblit stack [16] considering the commercial and internal nature of the project.

Another challenge when working in a team on a project is project management. We decided to use ChiliProject, an open source, web based project management system [17]. It provides support for the complete project lifecycle, including setting up, tracking the issues and reporting work progress. It allowed us to keep track of who is working on what, and the progress of that work. It was a very important tool in tracking everyone's work and ensuring on-time deliveries.

From technical perspective, mobile development strategy with frameworks automates a large amount of the plumbing necessary to build mobile applications allowing developers to focus on the user interface, experience and integration into business processes.

On iOS we use a number of open source frameworks for different functionalities. For logging we use the Lumberjack framework [18]. It is an almost drop-in replacement for the built in logging facility i.e. uses the same syntax with a different object, but offers a variety of output devices unlike the built in facility. It enables the developer to specify one or more logging destinations, including console, debug window of the IDE, file system or a custom log processor. Single log message is then written to all these locations simultaneously.

For crash reporting in iOS, we use the QuincyKit framework [19]. It consists of the client part running on the customer's phone and the server part running on the developer's server. On every application restart after a crash the framework detects the crash and uploads all the relevant crash information to its server. This information includes the code which was currently executing at the time of the crash.

iOS already has a data persistence framework, Core Data, which enables the developer to store objects [20]. To further simplify the use of this feature, we decided to use the MagicalRecord framework [21]. It builds on top of the Core Data framework allowing clear and simple one-line fetches.

Although iOS has different kinds of progress indicators and user alerts, it is not possible to use or customize them using a public API. To address this, we used the MBProgressHUD framework which provides iOS-style progress indicators, user alerts and messages [22].

On Android we used in most cases frameworks built into the Android API.

B. Process

For the application development, we used agile approach [6] with iterative development. Daily monitoring of the progress and a scrum like framework [7] is used for

the project management. The team members were not fully assigned to this project so we defined few days in week as days for this project only. This rule was in most cases applied.

The project has been divided in four major iterations, with a cycle of two to three weeks. At the beginning of each iteration, we had a meeting to define the goals we should achieve in the current iteration. Depending on the objective of the iteration we also planned the competence development.

On a daily bases we have a short meetings analyzing current iteration tasks progress. Since team-members were on different locations, teleconference or videoconference with screen sharing has been used. Depending of gaps between existing and required knowledge to complete development tasks, additional consultations for further competence development were prepared and executed.

The above operation can be defined as scrum-like since each iteration has been divided in smaller individual tasks sorted by priorities. Each development iteration cycle can be considered as a sprint in which development team develops the application.

C. Testing

Because of the iterative application development method, short deadlines for application completions and large amount of UI element, the development was not based on the Test Driven Development (TDD) process. A unit test is created just for checking work that doesn't require UI, while other tests were performed during the development of the application and at the end of every iteration.

After completion of the integration testing of all components, we began beta testing that we conduct in several countries. User guides for all supported iPhone and Android devices were also created. These guides are divided into three parts:

- An introduction to mobile app (detailing pre-requisites),
- A guide to the app on specific mobile platform and
- A description of how to get more help, a list of procedures to perform and detail instructions how to provide feedback and get in contact with Operations and development team.

The problem with beta testing with users is how to get feedback from them and their phones. That is the reason we have integrated feedback option in both versions of application. Usage of integrated feedback, log mechanism are a preferred way of communication with development team because we get additional info about the operating system and type of device in use.

Users can send comments for improvements, malfunction reports and can send logs or crash reports. Logs and crash reports are primarily assistance for developers bug finding. Sent data logs include various information about Android phone versions of OS and phone models and skins.

Feedback is received through Representational State Transfer (REST) service and dispatched to all support team members from mail daemon running on the server.

V. BUILDING SOLUTION

Some of the important requirements for the application were as follows:

- Location independent and
- Easy to use interface.

The above requirements have been successfully implemented with the proper architecture and design solutions, and using well-known ergonomic elements.

Application is based on the Model-View-Controller (MVC) architecture. Benefits of this architecture are to have a separate Model (data, business logic), View (application screens) and Controller (input elements on screen). This model is facilitating team development, maintenance existing functionality and testing new functionality solutions.

The application design is based on a client-server communication model and the MVC architecture. Choosing this design solutions ensure that the data obtained through the server communications and stored in the model are specific for the chosen location. This design allows us to add new location, specific function for existing location or to correct data that affect the proper operation of the application without the need to change the application itself. On the server side developed App Portal enables building of location specific configuration by responsible persons through controllable access permissions.

As stated before, communication between the application and the server is based on Representational State Transfer (REST) architecture. By implementing REST architecture we have achieved faster development time, simple configurable interface and easier download or send data to the server.

A. Deployment

Delivery of the application is done in two ways.

- Enterprise application store (EAS) and
- Web page.

Enterprise application store (EAS) is a distribution channel for mobile applications where end user can download and update specific enterprise applications. It is like App Store or Google Play for enterprise.

It also provides a mechanism of remote administration and management of the client phone that allows an Enterprise more controllable and secure way to allow BYOD possibilities, and to have an efficient way to maintain company specific applications. On the other hand, if mobile device is stolen or lost, wipe out of all data on device and reset to factory settings can be executed remotely.

The second mechanism is web page distribution. Selected Ericsson corporate users for beta testing got installation instructions for iOS and Android on a web page together with mobile application installation files.

VI. CONCLUSION

Project success was measured through five different perspectives. Ordinary project perspectives: time, cost and scope plus two additional and in this project the most interesting perspectives: knowledge transfer effectiveness and impact on organization. Project valuation perspectives are shown in figure 3. With the latest iteration and final mobile apps delivery and development phase completion, the knowledge transfer effectiveness was evaluated considering factors shown in Table 1.

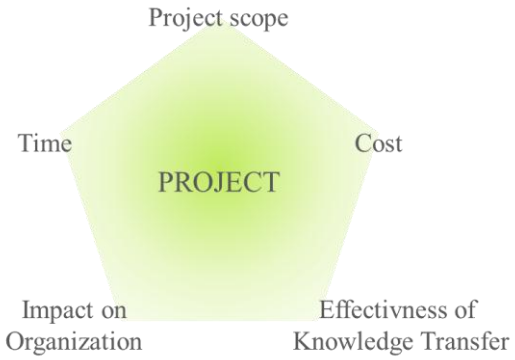

Figure 4. Project valuation perspectives

Table I. Knowledge transfer effectiveness evaluation

Mobile Apps Development – Knowledge Transfer Effectiveness Assessment of factors fulfillment in knowledge transfer	
Factor:	**Assessment:**
Cooperation readiness	Completely fulfilled
Knowledge transfer organized as a project	Completely fulfilled
Cultural differences	Not existing; no impact on knowledge transfer
Knowledge transfer complexity	In majority fulfilled(*)
Time constraints	Apps were delivered with slight delay
Budget constraints	The budget was slightly exceeded
Previous domain knowledge	There were no previous mobile apps development experience
Previous tools knowledge	Some project members were familiar with used tools
Previous methods knowledge	Some project member were familiar with scrum methodology

(*) Transfer of knowledge for this specific project scope was realized completely. Fundamentals for mobile apps development were established. However, with new and different mobile apps requirements there will be need for further competence development.

The project was successful. Joint cooperation between FER and ENT assured ENT the new IT strategic knowledge and starting capability that will be utilized as new demands from evolving corporate mobility eco-systems are coming. The whole cycle (Figure 2) for specific delivery project was closed but further cycles with continual knowledge creation, effective growth and new innovation should come.

An Empirical Study of Factors Affecting the Adoption of Self-Service Checkout Terminals in Slovenia

Boštjan Šumak*, Maja Pušnik* and Marjan Heričko*
* University of Maribor, Faculty of Electrical Engineering and Computer Science, Maribor, Slovenia
bostjan.sumak@um.si, maja.pusnik@um.si and marjan.hericko@um.si

Abstract - Few years ago, retailers started to employ self-service checkout terminals providing customers a choice to scan the barcodes on their own items and complete the purchase process without an interaction with retailer's staff. This study aimed to investigate factors which can have a significant impact on user's decision about how and when they will use the self-checkout unit. To understand customers' perceptions about using self-checkout terminals, the Technology Acceptance Model (TAM) was used to develop the research model. In this study, several external factors with direct or indirect impact on user's behavioral intentions are proposed: anxiety, perceived service quality, attitude toward innovation, self-efficacy and anonymousness. Empirical data was conducted using an online survey. The proposed relationships were empirically tested using the structural equation modelling approach. The implications and limitation of the study are also discussed.

I. INTRODUCTION

Merchants invest significant time and money to optimize the checkout process. The checkout process must be expedient and secure and has to offer sufficient customer service to leave the customer with a positive impression. In Slovenia in the past few years, Mercator and SPAR merchants have started implementing self-service checkout terminal (SSCT) solutions in their major stores. The need for improving in-store traffic flows, speeding up the checkout process and increasing customer service and loyalty has led merchants implement innovative solutions.

SSCT provides an alternative to the traditional checkout and enables customers to pay for purchase from a retailer without an interaction with retailer's staff. There are cases however, where the completion of the purchasing process demands attendance of the staff. For example, when buying alcohol, the purchaser has to prove the appropriate age in order to be able to buy alcohol, tobacco products, etc. Because there are cases, where the customer can't really complete the purchasing process on his or her own, these self-service terminals can also be called semi attended customer activated terminals (SACAT).

In the self-service checkout process, customers scan the barcodes of their items in order to identify items they want to purchase. The scanned items are displayed on the monitor, where customers can check for possible errors. After scanning, items are put in a special bag where these items are weighted. Customer is permitted to proceed scanning after the scanned/identified item was put into the bag and weighted and whether the observed and expected weights match [2]. The weight observed in the bagging area provides a control for ensuring that the items in the bag are items which were scanned or identified. Figure 1 shows an example of SSCT introduced in Mercator shop in Slovenia.

It is very common to see in Slovenian stores that customers don't chose to use SSCT terminals on their way out. It happens very often that customers rather step into the long line with human cashier and wait even if they have just a small amount of items in their shopping bag. Although SSCT makes possible to avoid waiting in long lines, customers don't choose this option. Such observations that can be seen every day inspired this study, which aimed to investigate the factors that can affect customer's decision when he or she will use SSCT

Figure 1. IBM's self-checkout terminal in Mercator retail shop (Slovenia) [1]

in order to complete the purchase process.

The paper is organized as follows: in the next section, theoretical backgrounds about acceptance theories are given. In section three, the research model and a list of research hypotheses are proposed. In section four, the research methodology is described, where the development of a measurement instrument is explained and the data collection and statistical analysis processes are described. In section five, data analysis and results are given. Last section concludes the paper including discussion about the implications and limitations of the study.

II. THEORETICAL BACKGROUNDS

Studies, dealing with identification of factors and assessment of their impact on user's decision whether he or she will accept and use a certain technology, are usually based on a technology acceptance theory. Table 1 provides the list of most common technology acceptance theories being used in existing acceptance research studies. In technology acceptance studies researchers are mostly interested in the structural relationships among constructs in the research model that help explain an individual's acceptance of a technology. The empirical data is usually statistically analyzed using structural equation modeling (SEM).

Davis [3] proposed TAM to explain the potential user's behavioral intentions of using a technological innovation. TAM is based on the theory of reasoned action – TRA [4], which is a psychological theory that can be used to explain behavior. The Motivational Model (MM) is another psychological theory that is often being employed in studies dealing with the factors that have an impact on the end user's motivation in the use of an information technology.

TABLE I. ACCEPTANCE THEORIES

Theory	***Factors***
Theory of Reasoned Action (TRA)	attitude toward behavior, subjective norm, behavioral intentions, actual use
Technology Acceptance Model (TAM)	perceived usefulness, perceived ease of use, attitude toward use, behavioral intentions, use
Motivational Model (MM)	intrinsic motivation, extrinsic motivation, behavioral intentions
Theory of Planned Behaviour (TPB)	attitude toward behavior, subjective norm, perceived behavioral control, behavioral intentions, actual use
Model of PC Utilization (MPCU)	facilitating conditions, social factors, perceived consequences, long-term consequences, behavioral intentions, actual use
Innovation Diffusion Theory (IDT)	relative advantage, ease of use, image, visibility, compatibility, results demonstrability, voluntariness of use, behavioral intentions
Social Cognitive Theory (SCT)	computer self-efficacy, perceived outcomes, affect, anxiety, use
Unified Theory of Acceptance and Use of Technology (UTAUT)	performance expectancy, social influence, effort expectancy, facilitating conditions, behavioral intentions, actual use

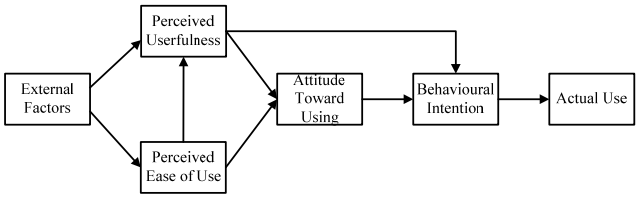

Figure 2. Technology Acceptance Model

TAM is one of the most widely used theoretical models in IT/IS acceptance research because of its understandability and simplicity [5] and is applicable to different information technologies. TAM involves two main independent factors which have a direct or indirect influence on users' behavioral intentions (see Figure 2):

1. *Perceived usefulness* is the degree to which a person believes that using a particular system would enhance his or her job performance.
2. *Perceived ease of use* stands for the degree to which a person believes that using a particular system would be free of effort.

The TAM model has one dependent variable – behavioral intention, which is the degree to which a person has formulated conscious plans to perform or not perform some specified future behavior.

Several existing systematic literature reviews and meta-analysis [5]–[7] show that TAM is the most common theory being used as a ground theory for designing the research in the field of acceptance and use of technology. This is why the TAM model was chosen as a ground theory in this study.

Research about acceptance and use of an information technology can be divided into two types of studies: (1) an empirical validation of the theory (e.g. the TAM theory) in the context of a specific information technology, and (2) an extension of the theoretical model (e.g. the TAM model) with user specific factors. The main objective of this study was not only to evaluate the TAM research model in the context of acceptance and use of self-service checkout terminals, but also to identify external factors, which may have a significant impact on TAM related factors.

III. RESEARCH MODEL AND HYPOTHESES

In this study, we proposed extending the TAM research model with following external factors: (1) anxiety, (2) perceived service quality, (3) attitude toward innovation, (4) self-efficacy and (5) anonymousness. Figure 3 presents the extended TAM research model with hypothesized relationships between constructs. According to the research model, following hypotheses were proposed:

H1: Anxiety will have a significant (negative) impact on user's intention to use SSCT.

H2: Perceived Service Quality will have a significant influence on user's perception about usefulness of SSCT.

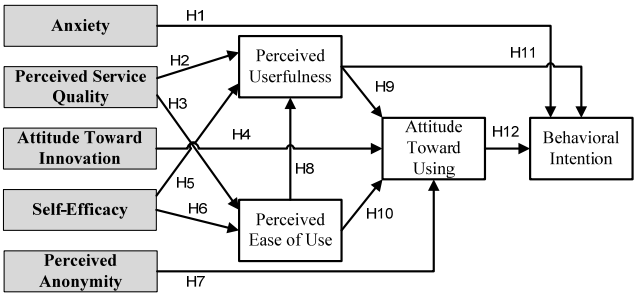

Figure 3. The research model

H3: Perceived Service Quality will have a significant impact on user's perception about ease of use of SSCT.

H4: Attitude toward innovation will have significant influence on user's attitude toward using SSCT.

H5: Self-efficacy will have significant influence on user's perception about usefulness of SSCT.

H6: Self-efficacy will have significant influence on user's perception about ease of use of SSCT.

There are cases, when a customer could be too embarrassed to buy certain products. Customer could be afraid that the cashier will for example mock or condemn or have some negative comprehension during the scanning of his or her items. Traditional checkout process involves the face-to-face interaction between the customer and the cashier and can cause a low level of anonymity. Therefore, one of the reasons for which customers would choose SSCT is because they seek for anonymity [8]. We therefore propose following hypothesis:

H7: Perceived anonymity will have significant influence on user's attitude toward using SSCT.

Hypotheses that follow were proposed according to the original TAM theoretical model and are adapted to the context of usage of SSCT.

H8: Perceived ease of use will have a significant influence on user's perception about usefulness of SSCT.

H9: Perceived usefulness will have a significant influence on user's attitude toward using SSCT.

H10: Perceived ease of use will have a significant impact on user's attitude toward using SSCT.

H11: Perceived usefulness will have a significant influence on SSCT usage intention.

Attitude toward using technology is an individual's overall affective reaction to using a system. It stands for an individual's liking, enjoyment, joy and pleasure associated with technology use. The attitude toward using a system has been shown as a determinant of behavioral intention in different studies. We therefore suggest the following hypothesis:

H12: Attitudes toward use is related to behavioral intention.

IV. RESEARCH METHODOLGY

Quantitative research in the form of an online questionnaire based survey was performed to test the hypotheses, stated in previous section. The questions were organized into two groups: (1) demographic questions about the respondents' gender, age, frequency of use of SSCT, the purchase value, for which users choose to use SSCT, rather than internet experience, Moodle experience, voluntariness, etc. (see Table 2 for the characteristics list); and (2) measures for the TAM constructs and external factors.

The TAM constructs and external factors were adapted into the context of use of SSCT. The measuring items were assessed by a seven-point Likert-type scale from "strongly agree" to "strongly disagree", where the respondents gave the extent to which they agreed or disagreed with each statement of the constructs.

To reduce measurement error, a pre-test of the questionnaire was performed in order to improve the content of the measuring items. In the pre-test, colleagues at the faculty were asked to examine the questionnaire for meaningfulness, relevance and clarity. With remarks and propositions, the measurement items were improved.

After the pilot test, the request form for participation in the online survey was sent to random students and staff at the faculty. They were also asked to forward the request to their friends. 212 online surveys were started, of which 170 were successfully finished and 42 returned incomplete. Thus, the usable response rate was 80%.

TABLE II. SAMPLE CHARACTERISTICS

Demographic characteristics	***Freq.***	***%***
Gender		
Male	134	78.8
Female	36	21.2
Age		
less than 16 years	1	0.6
16 – 20 years	31	18.2
21 – 25 years	79	46.5
26 – 30 years	24	14.1
31 – 35 years	18	10.6
36 – 40 years	5	2.9
41 – 45 years	2	1.2
46 – 50 years	1	.6
more than 50 years	9	5.3
Frequency of use		
allways, when shopping	14	8.2
almost always when shopping	55	32.4
halftime, when shopping	39	22.9
sometimes	56	32.9
never	6	3.5
Using SSCT when value of the purchase is		
10€ or less	52	30.6
up to 50€	49	28.8
up to 100€	2	1.2
the purchase value is not important	67	39.4
Using SSCT when buying up to		
3 items	7	4.1
5 items	26	15.3
8 items	35	20.6
10 items	40	23.5
number of items is not important	62	36.5
Using also other self-service terminals (self-service check-in at airport, etc.)		
Yes	106	62.4
No	64	37.6

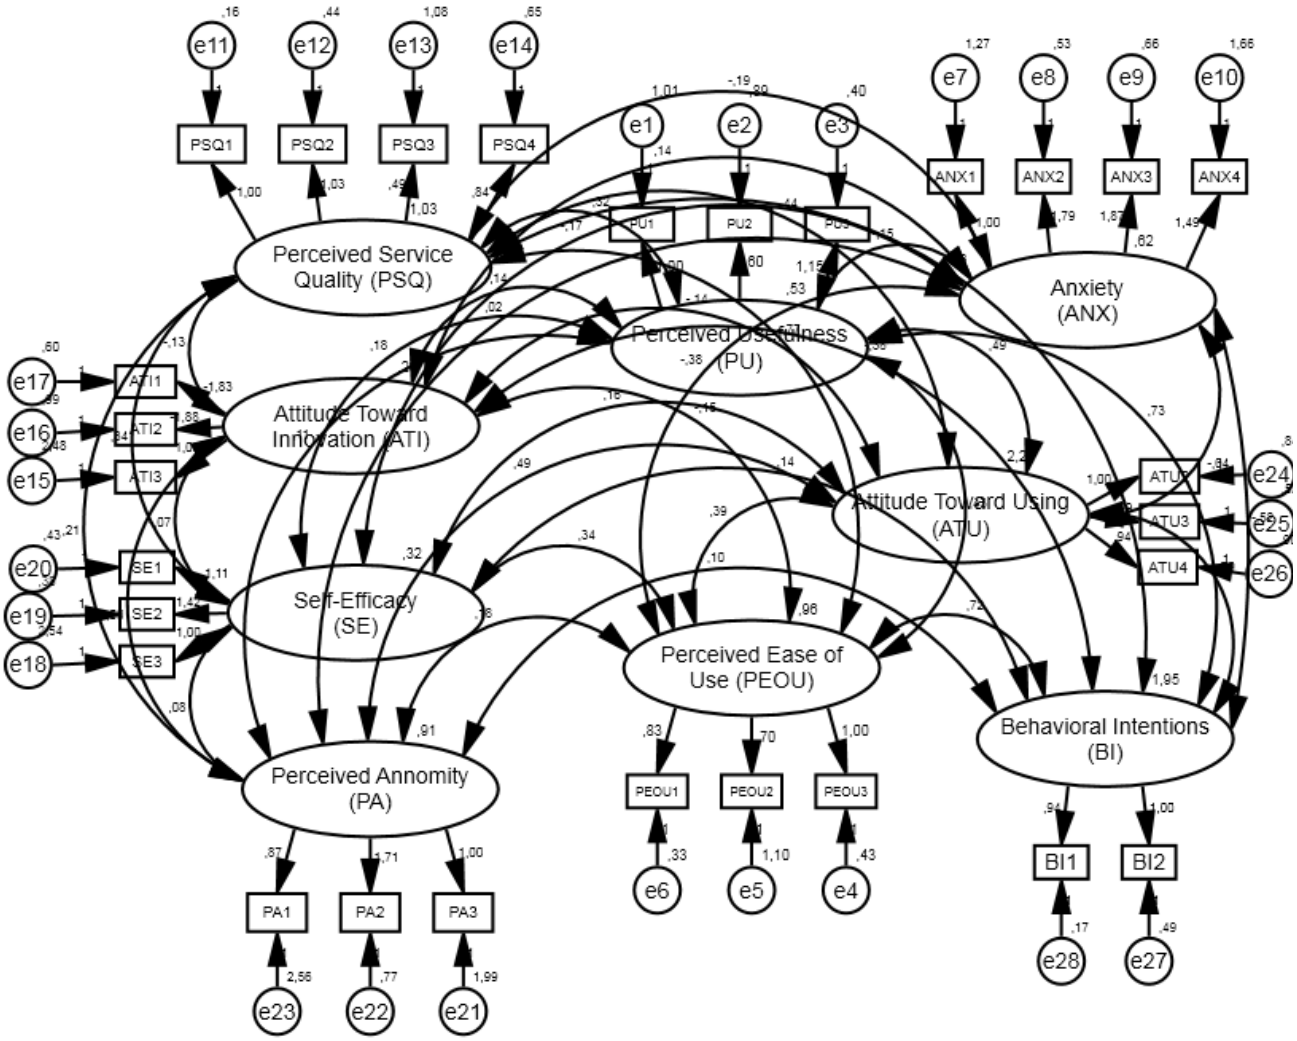

Figure 4. The measurement model

To describe the main features of an average participant in this study, descriptive statistics was used on the respondents' characteristics data. To understand user's perceptions about using SSCT, the extended TAM research model and hypothesized relationships between constructs were empirically tested using the structural equation modelling (SEM) approach. SEM was used to test the fit of the proposed theoretical model with empirical data. The measurement model (see Figure 4) was estimated using confirmatory factor analysis to test whether the proposed constructs possessed sufficient validation and reliability. After the final measurement model passed the goodness-of-fit tests, the structural part of the research model was estimated using SEM on the structural model. The structural model (see Figure 5) was also tested for a data fit with appropriate goodness-of-fit indices. A statistical analysis was performed using the SPSS 22 statistical package together with AMOS 22 software.

TABLE III. HYPOTHESIS TESTING RESULTS

Hypothesis	*Effect*	*Path coefficient*	*Remarks*
H1	ANX→BI	-0.327^{***}	Supported
H2	PSQ→PU	-0.058^{NS}	Not Supported
H3	PSQ→PEOU	0.581^{***}	Supported
H4	ATI→ATU	-0.022^{NS}	Not Supported
H5	SE→PU	-0.028^{NS}	Not Supported
H6	SE→PEOU	0.316^{**}	Supported
H7	PA→ATU	0.298^{***}	Supported
H8	PEOU→PU	0.651^{***}	Supported
H9	PU→ATU	0.396^{***}	Supported
H10	PEOU→ATU	-0.013^{NS}	Not Supported
H11	PU→BI	0.574^{***}	Supported
H12	ATU→BI	0.123^{NS}	Not Supported

V. DATA ANALYSIS AND RESULTS

The characteristics of the respondents are presented in Table 2. The typical respondent is a 21-25 year old male that uses SSCT sometimes or halftime when shopping. The respondent choice to use SSCT is not related to the number of items he is buying. The purchase value is also not the main factor upon which the purchaser would chose to self-checkout. The respondent is also using other self-service terminals (e.g. self-service check-in terminals at the airport).

The results of the final structural model are shown in Figure 6 and the summary of hypothesis testing is presented in Table 3. The analytical results show that anxiety has a negative impact (β=-0.327, $p<0.001$) and perceived usefulness a strong positive impact (β=0.574, $p<0.001$) on user's intention to use SSCT. These results provide support for hypotheses H1 and H11. However,

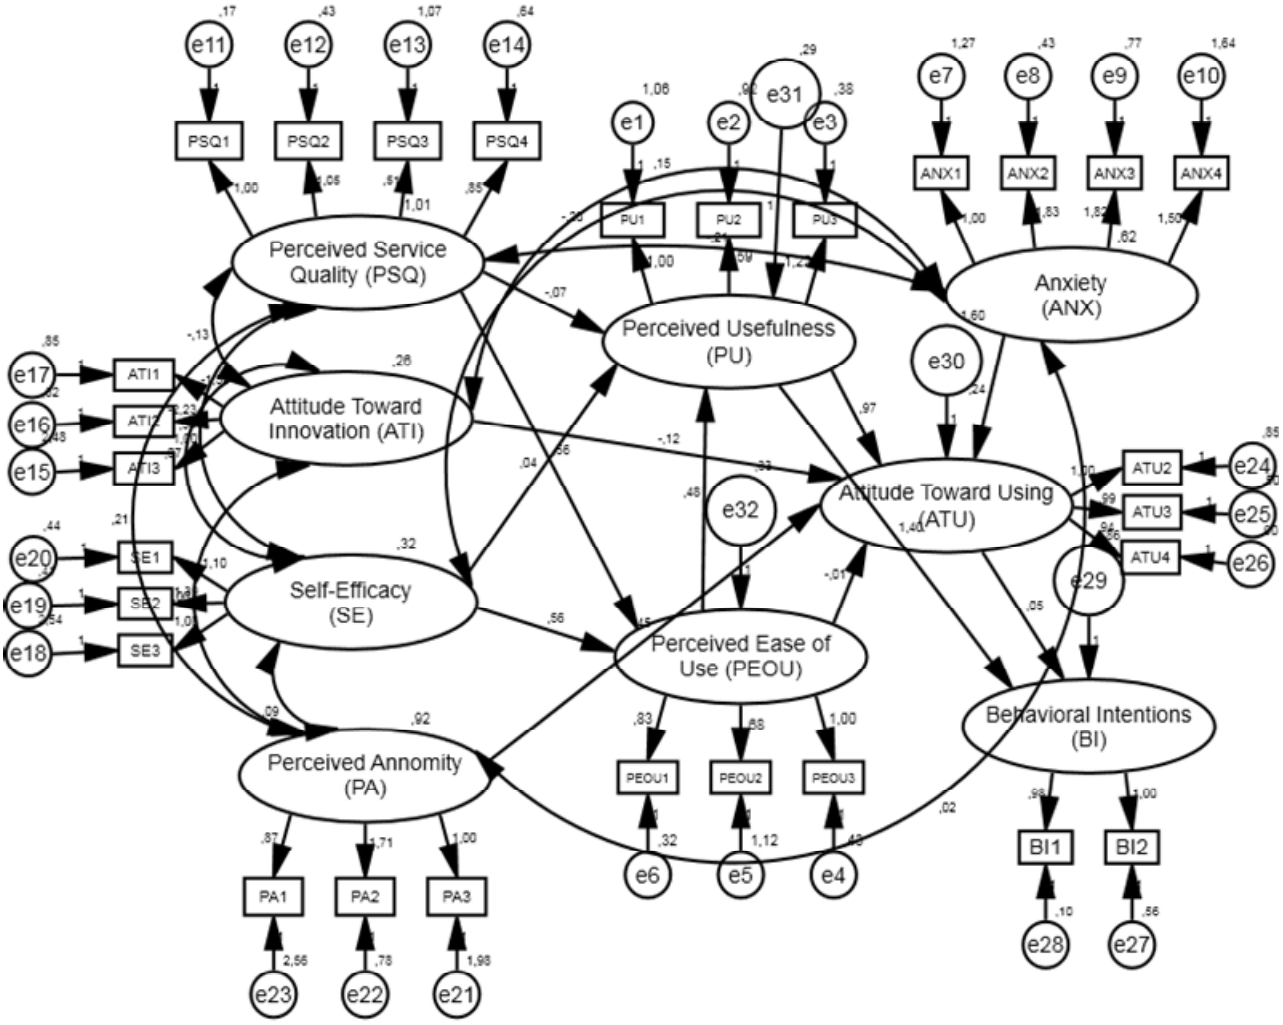

Figure 5. The structural model

there was no significant relationship found between attitude toward using SSCT and user's intention to use SSCT. Therefore, the hypothesis H12 was rejected.

Perceived ease of use of SSCT has a significant impact on perceived usefulness (β=0. 651, p<0.001), therefore the hypothesis H8 was accepted. However, proposed external factors perceived service quality and self-efficacy didn't have a significant impact on user's perceptions about usefulness of SSCT. Therefore hypotheses H2 and H5 were rejected.

A strong significant relationship was found between perceived service quality (β=0.581, p<0.001) and perceived ease of use. Self-efficacy also had a significant impact on user's perceptions about ease of use of SSCT (β=0.316, p<0.05). Therefore, hypotheses H3 and H6 were accepted. User's attitude toward using SSCT was also affected by perceived anonymity (β=0.298, p<0.001) and perceived usefulness (β=0.396, p<0.001). Thus, hypotheses H7 and H9 were supported. However, there was no statistically evidence regarding the impact of attitude toward innovations and perceived ease of use on user's attitude toward using SSCT. This means that in this study, the analysis did not support hypotheses H4 and H10. Therefore, hypotheses H4 and H10 were rejected.

VI. CONCLUSION

The main purpose of this study was to identify external factors which may have a significant influence on user's decision whether he or she will use the SSCT to finish the purchase. According to the literature review, this study is one of the few attempts to investigate user's perceptions about acceptance and use of an SSCT.

The results of this study showed that perceived usefulness and perceived anonymity have had a significant direct effect on attitudes toward using SSCT. However, perceived ease of use and attitude toward innovation don't influence customer's attitude toward using SSCT. There was no prof for significant influence of attitude toward using on customer's behavioral intention. However, customer's behavioral intention is predicted by perceived usefulness and anxiety, where for the latter factor a strong negative relationship was found. User's perceptions about ease of use of SSCT are influenced by self-efficacy and perceived service quality, where perceived service quality was the strongest indicator of perceived ease of use. Perceived usefulness was determined by user's perceptions about ease of use of SSCT.

The implications of the results of this study are important especially to retailers who employ SSCTs in

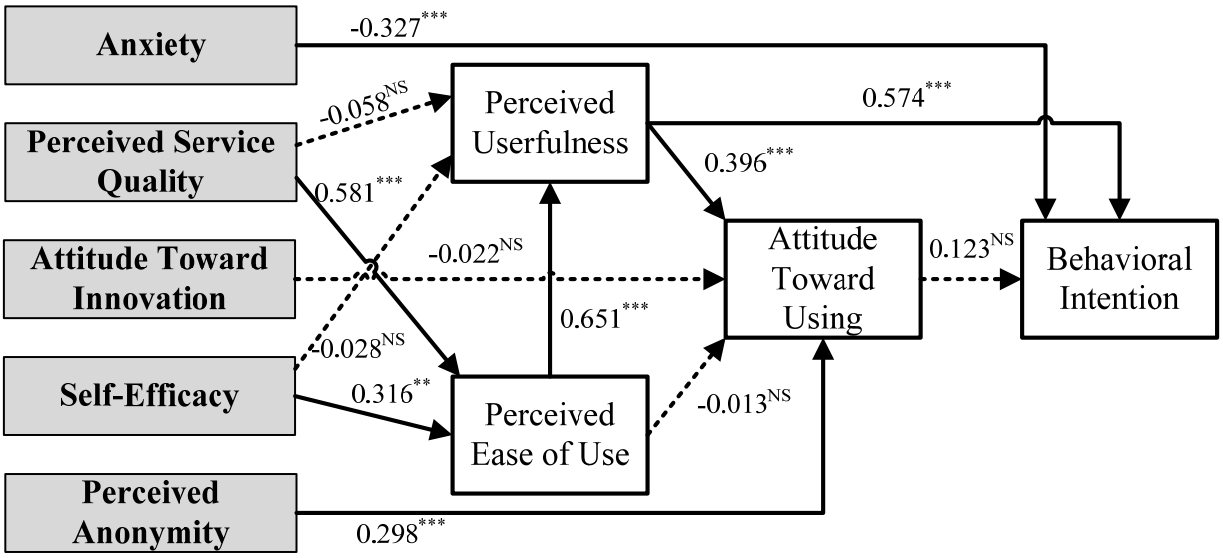

Figure 6. The research model results

their stores. Customers don't use SSCT because it is easy to use, but rather because it is useful and because it provides a certain level of anonymity when finishing the purchase process. It is also important that SSCT providers assure sufficient quality level in SSCT checkout application, because customers will have a better understanding of the application and will thus find it more useful. The customer must also have a strong belief that he or she is self-sufficient and doesn't need assistance in the checkout process when using SSCT.

As in all empirical research, this study has some limitations that need to be identified and discussed. First, the sample is limited to Slovenian customers that use self-service checkout terminals in major stores from Mercator and SPAR. Although the results from this study are useful for describing the characteristics of a large population of customers, the generalizations of the results are limited.

Cash Register Lines Optimization System Using RFID Technology

D.Budić, Ž. Martinović, D. Šimunić
Faculty of Electrical Engineering and Computing / Department of Wireless Communications
Unska 3, 10000 Zagreb, Croatia
E-mail: dora.budic@fer.hr, zeljko.martinovic@fer.hr, dina.simunic@fer.hr

By doing business the old way, retail chains don't use all the potential of developed technologies in order to increase their efficiency. Cash register lines optimization system uses RFID (Radio Frequency Identification) technology to follow the number of shopping carts and baskets in front of cash register. Developed system consists of RFID reader and passive RFID tags with assigned ID. System works on ultra-high frequency (UHF, 868 MHz) with long range (up to 15m) which enables development of protocols using simultaneous communication between reader and tags. One reader can collect data from 8 antennas at the same time. Concept of following shopping carts and baskets using RFID is based on backscatter coupling which enables powering RFID tags with energy from magnetic field of the reader. System uses SQLite3 database and Python 2.7 programming language. Web application is written using JavaScript jQuery framework and HTML/CSS Twitter Bootstrap framework. Also, for sending SMS, mail2sms technology is used. JSON via HTTP protocol is used for communication between reader and server and between server and web application. In order to inform the store manager, SMS is generated. Web application is used for tracking the whole system. Statistics integrated in web application enable store managers to organize employees in advance considering observations from past periods.

I. INTRODUCTION

More and more retail chains today have the need for automated monitoring of the number of customers in cash register lines in real time. Previously developed systems have proved to be insufficiently effective because they involved additional and unpleasant interaction between customers and employees or monitoring in the way that threatens the privacy of customers. To avoid such problems, it was necessary to design different solution which would implement new technologies.

There are many different jobs that employees can do: working in bakery department, cash register, placing the products on the shelves etc. Store managers have the task to distribute employees in the most efficient way. The decision about distribution can be made on the basis of real-time status analysis, statistical analysis and combination of the two methods. Real-time distribution means that the store manager has the data based on the real-time status of the store, and statistical analysis can assume what the distribution should be based on the previous observations. Combination of the two methods provides better precision because it considers previous observations and real-time status analysis.

System has the task to collect and analyze data that can be used for concluding how many customers wait in the cash register lines. In case where system concludes that there are more customers that it can be handled in optionally given time frame, it is necessary to warn the store manager that conditions are met where it is needed to redistribute workers in the way that more people work on cash registers. Also, store manager is warned when too few customers are in the lines so some cash registers should be closed and extra workers redistributed on other jobs. All collected data is permanently stored in the database. In every moment it can be used to offer insight into real-time status and statistical analysis status [1].

Technology that makes development of system like this possible is RFID.

II. SYSTEM CONCEPT

RFID is the wireless non-contact use of radio-frequency electromagnetic fields to transfer data, for the purposes of automatically identifying and tracking tags attached to objects. Every RFID system consists of several basic elements:

- Reader

Figure 1: RFID reader Motorola FX9500

- Antenna and tags

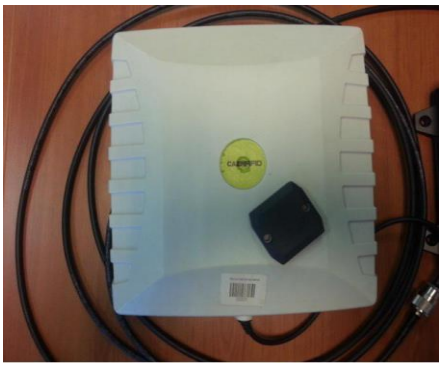

Figure 2: RFID antenna and tag

RFID systems differ in operating frequency, coupling, range, memory type and battery presence in the tag.

Operating frequency is the one that reader uses for impulsion. The different transmission frequencies are classified into the three basic ranges:

- Low frequency (LF) from 30 to 300 kHz
- High frequency / radio frequency (HF/RF) from 3 to 30 MHz
- Ultra-high frequency (UHF) from 300 MHz to 3 GHz / microwave > 3 GHz

A further subdivision of RFID systems according to range allows us to differentiate between close-coupling (0-1 cm), remote-coupling (0-1 m) and long-range (>1 m) systems.

Close-coupling systems are coupled using both electric and magnetic fields and does not rely upon the radiation of fields because of closeness of the tag. Close-coupling systems are primarily used in applications that are subject to strict security requirements, but do not require a large range.

Almost all remote coupled systems are based upon an inductive (magnetic) coupling between reader and transponder. These systems are therefore also known as inductive radio systems.

All long-range systems operate using electromagnetic waves in the UHF and microwave range. The vast majority of such systems are also known as backscatter systems due to their physical operating principle. In addition, there are also long-range systems using surface acoustic wave transponders in the microwave range. Ranges of 15 m and above can be achieved using active (battery-supported) backscatter transponders.

Tags can be passive or active considering the battery presence. Passive tags don't have any power source (battery). Electromagnetic field of the reader provides all the energy necessary for tag to work via tag antenna. This means that the emitted energy of the reader is used to transfer data from reader to tag and from tag to reader. Active tags have their own power source (battery or solar cell) which is used for powering the chip. This means that electromagnetic field of the reader isn't necessary for powering like it is necessary with the passive tags. This feature enables using the reader with weaker field to transfer data. Tags also vary in memory capacity. 1-bit tags have only one bit of memory that stores 1 if the tag is in the field and 0 if tag isn't in the field. Other tag type is the one with ID stored in the memory by the factory. Third type is the one that has enough memory for storing ID and extra data (by the user). Tags are produced in plastic and glass housing in shape of coin, sticker, capsule, little box and card [2].
RFID uses the low-end of the electromagnetic spectrum and signal strenght is limited

The RFID UHF signal strenght is defined under ISO/IEC 18000-6:2004standards. Signal strenght can be in range mW up to several mW and therefor can not represent danger for human health.

III. SYSTEM ARCHITECTURE

The idea is to put readers and antennas on cash registers and tags on shopping carts and baskets. When a tag on the shopping cart or basket is read as present for a certain period of time in front of cash register, system recognizes that the customer is standing in that line. This way it can be determined how long is the line in front of cash register and in case that it is too long, system sends SMS to store manager that more cash registers should be open. Also, if the lines are too short, store manager gets information that some case registers should be closed.

We wanted to make the system as simple as possible to modify for additional demands and to integrate in existing store system. Because of that, the whole system is divided into three separate entities:

- *Pinkie* – part of the system in charge of reading ID from tags
- *Brain* – part of the system that stores collected data into database and processes them to become data useful to store manager
- *Protocol* – part of the system that enables communication between Pinkie and Brain parts

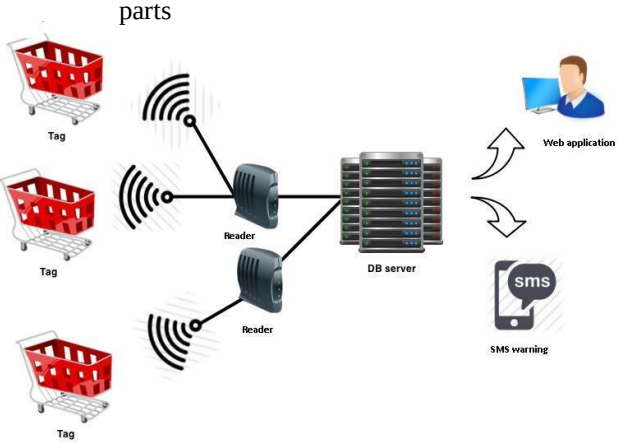

Figure 3: Shema of the system

A. Pinkie

Pinkie presents part of the system in charge of RFID technology. When a cash register is opened, antenna reading is automatically turned on in front of that cash register. Every reading first comes to the reader that has embedded software. That software enables data manipulation using modified built-in functions that are required for correct data reading.

Reader can be configured to send signals to the tags at specified time intervals. Constant reading ensures greater accuracy, but creates data redundancy. For this reason, reader functions can be modified in the way that the rest of the system gets an update only if there is a change in the system. Eg., a particular tag enters the antenna field so the reader reads its ID and sends the information to the rest of the system because the change in the system occurred. Since we do not want to read data every second of the time that tag remains in the field of antenna, a modified function sends an alert only if the tag gets out of the field of the antenna. Additional functionality is reading multiple tags at the same time and ignoring tag readings that are in the antenna field too short.

For the purpose of testing the developed software solution for optimization of cash register lines using RFID technology, we used Motorola FX9500 fixed RFID reader (868 MHz) that supports .NET and C as API support [3]. Also, passive tags in thicker plastic housing that have ID memory have been chosen (due to better work with metal surfaces). Used antenna is circularly polarized (dimension 24.5x23.5 cm).

B. Brain

Brain is in charge of storing, processing and displaying of received data. Data sent by Pinkie is stored in the database. Used database is Open Source SQLite3. To make collected data visible to store managers, we developed web application that can run on mobile phone, computer and tablet. Web application enables a graphical representation of the real-time status and status in selected period of time (so the statistical analysis can be performed). Also, web application (whose interface has automatic update every few minutes) sends SMS to store manager in the need for redistribution of employees. Data processing is written in Python 2.7 programming language. Web application is created using JavaScript jQuery and HTML/CSS Twitter Bootstrap framework that gives functionality like buttons or drop-down menu to the application. Sending of SMS is implemented using mail2sms technology.

C. Protocol

To make parts of the system communicate with each other, it is necessary to implement communication protocol. For this system we used sending of JSON (JavaScript Object Notation) through HTTP protocol. JSON is an open standard format that uses human-readable text to transmit data objects consisting of attribute-value pairs. It is used primarily to transmit data between a server and web application.

HTTP protocol is an application protocol that defines format (JSON in this case) and the way of message transportation between client and server.

D. Results and additional functionalities

Figures 4, 5 and 6 show results of developed system:

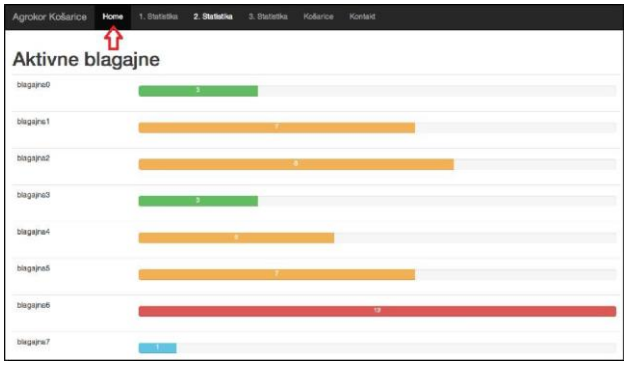

Figure 4: Web application

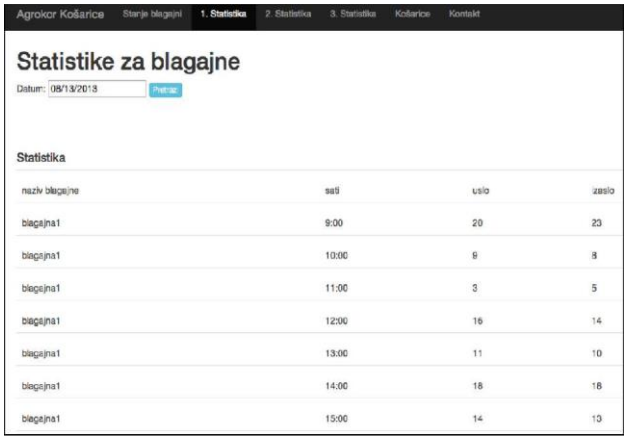

Figure 5: Cash register statistics

Figure 6: Real-time cash register state

Additional implemented functionality is basket counter. In front of every cash register stands a place where used baskets are collected. System offers automated monitoring of number of baskets to warn a store manager that collected baskets have to be removed. Functionality is developed the same way as the rest of the system.

IV. CONCLUSION

Cash register lines optimization system using RFID offers automated monitoring of number of customers in cash register lines without uncomfortable interaction between customers and employees of the store and also without threatening customers privacy. The whole system is designed to be easily upgradable with many additional features and integrated with already existing solutions in stores. All the newest technologies in the field of RFID wireless communications and also web applications have been used.

For further development, we recommend using active tags to reach an optimal range of 12 m. Also, for better communication between tag and the reader, we recommend using narrow radiation pattern antenna.

Pozicija BH Telecoma d.d. Sarajevo prema Adižesovoj teoriji životnih ciklusa preduzeća

Adnan Gabela*, Lejla Pamuk ** i Jasmin Gabela***
* BH Telecom d.d. Sarajevo, Bosna i Hercegovina
** BH Telecom d.d. Sarajevo, Bosna i Hercegovina
***USAID, Sarajevo, Bosna i Hercegovina

I. UVOD

Jedan od vodećih eksperata iz oblasti menadžmenta i ekonomije **dr. Isak Adižes** svoju teoriju "Životnog ciklusa preduzeća" i principe kako upravljati promjenama u kompaniji razvija i sprovodi posljednjih trideset godina. Njegova teorija i principi daju objašnjenje zašto kompanije rastu, stare i umiru, i šta se povodom toga može uraditi. On opisuje i analizira uobičajen put kojim kompanije prolaze dok rastu i optimalan put kojim bi trebalo da idu, da bi izbjegle probleme karakteristične za rast i starenje.[1]

Kao i kod živih organizama, rast i starenje privrednih društava se manifestuje u međusobnom odnosu dva faktora – **fleksibilnosti** i mogućnosti **kontrolisanja** procesa. Kad su organizacije mlade, one su veoma fleksibilne, ali se ne mogu uvijek kontrolirati. Kako organizacije stare, odnos se mijenja. Mogućnost kontrole raste, a fleksibilnost opada. Veličina i vrijeme nisu uzroci rasta i starenja, pa ne možemo reći da su velike kompanije sa dugom tradicijom po pravilu stare, a male kompanije bez tradicije mlade. Postoje stogodišnje mylade kompanije i petogodišnje stare (treba li ovo?).

Nijedan sistem - ljudski, organizacioni, tehnički - ne može istovremeno biti i maksimalno **fleksibilan** i maksimalno sposoban da održava kontrolu nad procesima. Stadijum kada organizacija ima istovremeno najveću moguću **fleksibilnost** i sposobnost **kontrole** nazivamo **„top forma“** i to je stanje koje bi svaka organizacija trebala nastojati postići. U svakoj fazi organizacija je suočena sa normalnim i patološkim problemima, karakterističnim za tu fazu. Organizacija **„top formu“** može postići tipičnim putem - put rasta i starenja - popraćen svim standardnim problemima u pojedinim fazama ili optimalan putem – bržim i putem bez problema karakterističnih za tipični put.

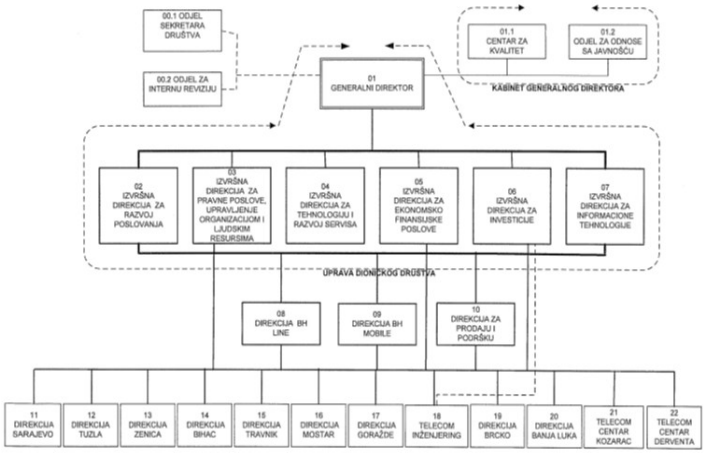
[1]

II. ORGANIZACIJA BH TELECOMA

A. *Osnovni podaci i organizacija BH Telecoma*

BH Telecom d.d. Sarajevo će ostati vodeći telekom operator u Bosni i Hercegovini koji će stalnim razvojem novih usluga i kvalitetom istih odgovoriti na zahtjeve tržišta, te udovoljiti potrebama korisnika i više od njihovog očekivanja.

Organizaciona shema BH Telecoma



B. *Pozicija BH Telecoma prema teoriji životnih ciklusa privrednog društva*

Prema navedenoj teoriji, stanje BH Telecoma je **„aristokratija“**, **fleksibilnost** 44/100, **kontrolisanost** 83/100 (graf na stranici ispod). Ovu fazu karakteriše relativno nizak stepen **fleksibilnosti**, a relativno visok stepen **kontrolisanosti** kompanije. Karakteristike ove faze životnog ciklusa, koje se konkretno mogu primjetiti u BH Telecomu su:

- Sve manja očekivanja za rast;
- Pažnja se usmjeravaja na dostignuća iz prošlosti;
- Sumnjičavost na promjene;

- Nagrađuju se oni koji rade ono što im se kaže;
- Novac se troši na kontrolne sisteme, nagrade i uređenje prostorija;
- Veća briga o tome kako se radi nego o tome šta i zašto se radi;
- Zapošljavaju se pojedinci koji brinu o vitalnosti kompanije, ali radni moto je: "ne talasaj";
- Zanemarljivo malo unutrašnjih inovacija – Kupuju se tuđa rješenja da bi se došlo do novih proizvoda, tržišta i ideja;
- Mnogo gotovine, potencijalna meta za nove vlasnike;
- Komuniciranje – pismena forma, niko otvoreno ne govori o problemima;
- Zaposleni žele što manje sukoba i što manje promjena;
- Promjene se svode na najmanju moguću mjeru;
- Opada proces reagovanja na kratkoročne potrebe, jer se zanemaruju dugoroče mogućnosti;
- Organizaciona klima je ustajala;
- Ne priznaje se stvarnost;
- Gubi se tržište i sve je teže održati konkurentnost sa svojim proizvodima i uslugama;
- „Dividende se moraju raspodjeliti";
- U organizaciji preovladava osjećaj sveopšteg zadovoljstva.

C. *Opis trenutnog stanja i obrazloženje zašto se BH Telecom nalazi u fazi **aristokratije***

Postoji više razloga za navedenu situaciju, a jedan od najizraženijih je prevelika administracija i jako duboka linija odlučivanja i na horizontalnom i na vertikalnom nivou. Osim toga BH Telecom je kao javno preduzeće dužan poslovati u skladu sa Zakonom o javnim nabavkama BiH, čime se ionako veliki i komplikovani način nabavke i odlučivanja dodatno usložnjava. Samim time se BH Telecom stavlja u nepovoljniji položaj u odnosu na konkurente koji ne podliježu zakonu. BH Telecom je predmet konstatnih kontrola poslovanja od strane Regulatorne agencije za komunkacije (RAK), Uprave za indiraktno oporezivanje, Ombdusmana, Federalne inspekcije, eksterne revizije, interne revizije, internog audita i drugih. Zbog svoje specifičnosti i činjenice da je gotovo neprekidno predmet kontrola po raznim osnovama BH Telecom je ograničen da djeluje brzo i dužan je pratiti gotovo beskonačan broj pravila i procedura. Prateći trendove u svijetu RAK konstantno nastoji da tržište telekomunikacija učini konkurentnijim, pružajući alternativnim operatorima povoljnije uslove u odnosu na dominante, što dodatno otežava poslovanje BH Telecoma. Ipak i pored brojnih navedenih kontrola i inspekcija, jako je teško u organizaciji od skoro 3.500 zaposlenih izmjeriti produktivnost zaposlenika i izvršiti adekvatnu evaluaciju složenosti radnog mjesta, zbog čega se javljaju problemi u motivisanosti, manjak produktivnosti, te činjenica da neki zaposlenici odrađuju mnogo, a neki vrlo malo posla.

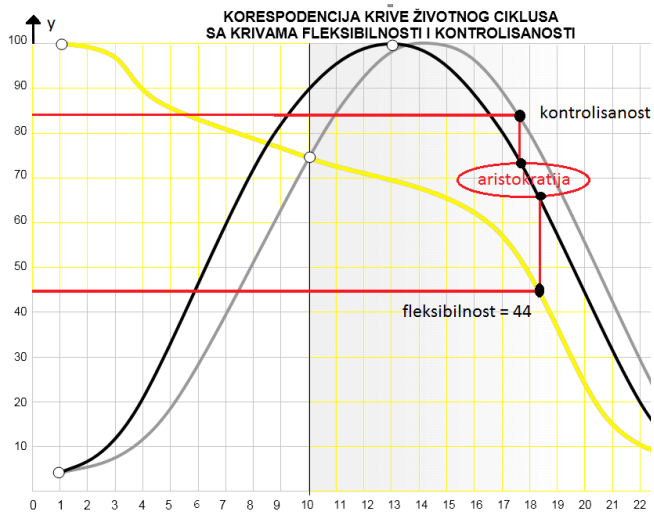
Drugi razlog za sporost u odlučivanju i provođenju odluka je sama fizička odvojenost organizacionih djelova koji moraju da sarađuju u velikom broju projekata. Trenutnom organizacijom ID za razvoj poslovanja, FD za prodaju i podršku i ID za informacione tehnologije se nalaze u jednoj zgradi, ID za ekonomsko finansijske poslove i ID za pravne poslove, upravljanje organizaciom i ljudskim resursima u drugoj, a ID za tehnologiju i razvoj servisa i ID za investicije u trećoj. Zbog činjenice da svi dokumenti u BH Telecomu cirkulišu u hard copy (papirnatoj) formi, sam protok dokumenata između različitih organizacionih jedinica oduzima jako puno vremena. Kada se na sve to doda i nejasan raspored odgovornosti i ovlaštenja između direkcije, te generalne klime bježanja od istih, očito je da zbog svojih internih problema, tačnije prevelikog i tromog administrativnog aparata organizacija ne djeluje na optimalnom nivou produktivnosti.

Kao primjer navedene problema sa prevelikom adiminstracijom prikazujemo put fakture za proviziju posrednicima koji vrše prodaju eDopuna BH Telecoma. Od momenta prijema fakture na protokolu, faktura prolazi 27 koraka u različitim organizacionim jedinicama do momenta plaćanja:

Faktura se prima na protokolu
Faktura se šalje generalnom direktoru na signaturu
Faktura se vraća na protokol
Saradnik/operator iz Službe za platni promet vrši prijem i parkiranje fakture
Saradnik iz Službe za kontrolu prihoda vrši preuzimanje fakture i provjeru ispravnosti
Faxom se faktura šalje u F Direkciju za prodaju i podršku
Saradnik iz Službe za UP pri FD PiP preuzima fakturu i sačinjava obrazac 6.
Obrazac 6. potpisuje šef Službe za upravljanje plasmanom RK
Obrazac 6. potpisuje rukovodilac Sektora za prodaju
Obrazac 6. potpisuje direktor Direkcije za prodaju i podršku
Obrazac 6. se šalje redovnom poštom prema ID za EFP
Obrazac 6. se prima na protokolu
Obrazac 6. ide na signaturu kod izvršnog direktora ID za EFP
Obrazac 6. ide na signaturu kod rukovodioca Sektora za finansijske poslove
Obrazac 6. ide na signaturu kod šefa Službe za kontrolu prihoda
Saradnik iz Službe za kontrolu prihoda vrši prijem obrasca
Saradnik iz Službe za kontrolu prihoda šalje fakturu na plaćanje
Šef Službe za kontrolu prihoda potpisuje fakturu da je saglasan da se šalje na plaćanje
Saradnik/oprator iz Službe za platni promet vrši prijem i likvidaturu fakture
Fakturu, da je saglasan da ide na plaćanje, potpisuje šef Službe za platni promet
Fakturu, da je saglasan da ide na plaćanje, potpisuje rukovodilac Sektora za finansijske poslove
Fakturu, da je saglasan da ide na plaćanje, potpisuje izvršni direktor ID za EFP
Faktura se vraća saradniku/operatoru iz Službe za platni promet
Original fakture se šalje prema Sektoru za ekonomske poslove, knjigovodstvo i kontroling
Saradnik/operator iz Službe za računovodstvo preuzima fakturu
Saradnik/operator iz Službe za računovodstvo vrši uknjiženje fakture u SAP
Saradnik/oprator iz Službe za platni promet vrši plaćanje fakture

Osim gore pomenutih ograničenja, telekomunikacioni operateri generalno su suočeni sa novim konkurentima, kao naprimer sve većim rastom, i masovnom upotrebom alternativnih načina komunikacije i prenosa podataka (Facebook, Twitter, Viber, WhatsApp, Skype), te nametnutim smanjenjima cijena saobraćaja. Iz gore navedenih razloga je očita nemogućnost brzog djelovanja na tržištu i prilagođavanja promjenama, čime kompanije

ubrzano gube efikasnost i efektivnost, te ubrzano stare po **Adižesu**.



D. *Znakovi da kompanija ide u korak sa vremenom i trendovima*

Uprkos gore navedenom očiti su pokazatelji da kompanija prati trendove oblasti TK industrije.

Godine 2009., BH Telecom je pružao osnovne telekomunkacione usluge, uz mogućnost kupovine telefona na rate za pretplatnike. Jedini način naplate tih računa je bio u JP BH Pošta i bankama.

Samo u zadnje četiri godine, kompanija je uvela ili je u fazi uvođenja sljedećih projekata: naplata računa u vlastitim Telecom centrima, putem POS terminala, SMSom, online, dostava računa online. Pored prodaje telefona na rate, u istom periodu je omogućena ili će uskoro biti prodaja laptopa, tableta, televizora, igračkih konzola i dodataka za sve navedene uređaje. Trenutno je pokrenut projekat i za razvoj m2m rješenja sa partnerima.

Pokrenut je proces bolje saradnje sa bankama, čime je omogućeno plaćanje računa u prostorijama BH Telecoma putem POS aparata, putem SMSa i za neke usluge i online (planirano je da se omogući i plaćanje svih računa onlina). Ovim inovacijama BH Telecom je značajno smanjio troškove vezane za naplatu računa i omogućio veći komoditet svojim pretplatnicima (mogućnost preferiranog izbora naplate, eliminisanje čekanja u redovima i sl.)

BH Telecom je omogućio i dostavu računa korisnicima elektronskim putem (e-mailom), što se radi za sada samo na zahtjev korisnika. Dostava računa ovim putem značajno smanjuje troškove dostave, ali zbog nesprovođenja Zakona o elektronskom potpisu, BH Telecom nema mogućnost prelaska dostave svih računa na ovaj način, nego to može provesti isključivo na zahtjev korisnika.

U toku je i projekat izdavanja jedinstvenog računa za sve usluge BH Telecoma, čime bi se još više smanjili troškovi BH Telecoma, a povećalo zadovoljstvo korisnika.

BH Telecom nastoji iskoristiti svoju široku prodajnu mrežu i veliki broj korisnika te u saradnji sa partnerima plasirati prodaju tk i srodnih uređaja. BH Telecom veliki broj aparata nastoji plasirati komisionom prodajom, čime se koriste kanali distribucije partnera, njegova skladišta, a BH Telecom unosi široku prodajnu mrežu, veliki broj korisnika i dobre mehanizme fakturisanja i naplate.

Trenutno je u fazi projekat za razvoj m2m (Machine to machine) rješenja sa partnerima u oblastima: javni prevoz, zdravstvo, nadzor vozila, nadzor ljudi, sigurnost i metering javnih usluga. Ovaj projekat predstavlja ulazak BH Telecoma u potpuno nove oblasti, gdje sa svojim specifičnim karakteristikama postoji mogućnost za zauzimanje novog segmenta tržišta. Implementacijom navedenih m2m rješenja, te planiranim razvojem nfc rješenja (Near Field Communication) BH Telecom prati trendove u oblasti telekomunikacione industrije i pozicionira se kao lider u domenu pružanja novih usluga.

E. *Prijedlozi i rješenja za povratak kompanije u stanje **„top forme“***

- Rad u timovima sa posebnim naglaskom na nove tehnologije

Najveći dio navedenih projekata je uveden od strane stručnih timova, koji su imenovani od svojih organizacionih jedinica i imali su zadatak da osmisle, razviju i implementiraju konkretno rješenje. Članovi tima su na osnovu svoje kompetentnosti dobili određen stepen autonomije za svoj rad i zajedničko djelovanje u cilju ostvarenja zadatka. Svaki član je definisao i sproveo zadatke ispred svoje organizacione jedinice, ali kao dio tima imao je ovlasti da u nekim segmentima djeluje i van svoje organizacione jedinice u cilju implementacije zadatka.

U skladu sa **Adižesovom** metodologijom, rad u komplementarnim PAEI timovima i predstavlja najbolje rješenje za djelovanje i u konkretnoj situaciji predstavlja jedan od preduslova za povratak kompanije u **„top formu“**. Budući da BH Telecom djeluje u oblastima koje su konstatno podložne promjenama i inovacijama, potrebno je povećati stepen **fleksibilnosti**, a smanjiti stepen **kontrolisanosti**, kako bi se kompanije pozicionirala i održala u stadiju **„top forme“**. [2]

Rad ovih timova svakako treba podsticati, ali je jako bitno izabrati članove koji imaju znanje, volju za radom i sticanjem novih znanja i spremnost na rad u timu. U idealnim uslovima članovi tima bi trebali da formiraju komplementaran PAEI tim, ali zbog činjenice da svi aspekti poslovanja moraju biti prisutni, kao i nastojanja da timovi nemaju pretjeran broj članova (zbog gubitka produktivnosti), komplementarnost ne može uvijek nužno biti ispunjena. Po prirodi svog posla, predstavnici ID za

RP osmišljavaju uslugu i daju koncept (E), tehnika (BH Line, BH Mobile) i prodaja (FD za PiP) pružaju uslugu (P), a ID za EFP, ID za PPUOiLJR i ID za IT sistematizuju i institucionališu uslugu (A), a Uprava BH Telecoma u saradnji sa ID za RP integriše tim (I).

- Pojednostavljenje administrativnog aprata i eliminisanje internih ograničenja

BH Telecom je u prvoj polovini 2014. godine planirao preseljenje u novu zgradu, gdje bi se na istom mjestu nalazile organizacione jedinice koje direktno određuju strategiju, čime bi se značajno izvršila ušteda na vremenu. Još jedan dobar način uštede na vremenu je uvođenje novog sistema protokola, kojim bi se svi dokumenti zavodili elektronski u jedinstven registar, a dalje cirkulisali unutar organizacije elektronskim putem.

- Povećati motivaciju zaposlenih

Zbog prirode svoje djelatnosti, BH Telecom je primoran konstantno kupovati i poboljšavati svoju infrastrukturu i softwarsku podršku. Definitivno postoji opravdanost kupivine velikog broja platformi, stanica, licenci, programa i aplikacija, ali postoje i brojna rješenja koja se trenutno kupuju od strane softwareskih kuća, iako BH Telecom zapošljava veliki broj informatičara i TK inžinjera koji su u stanju razviti određene aplikacije. Tako je naprimjer BH Telecom kao jedan od prvih u Bosni i Hercegovini kupio knjigovodstveni program SAP, koji je dokazan kao najbolji u svijetu i opravdanost takve kupovine ne može biti dovedena u pitanje. S druge strane kupljena su brojna rješenja za aplikacije koje su mogle biti razvijene interno. Razvoj programa i mogućnost poboljšanja kompanije iznutra, može se ostvariti uvid u znanje i sposobnosti svojih vlastitih kadrova čime bi se značajno poboljšala motivisanost zaposlenih.[3]

Osim toga primjetna je činjenica da u većini timova za razvoj novih usluga i tehnologija učestvuju skoro isti ljudi. Članstvo u ovim timovima, samo po sebi dokazuje kompetentnost i sposobnost, te budi motivisanost zaposlenika, ali budući da se radi o krucijalnim projektima BH Telecoma, potrebno je izvršiti detaljniju selekciju članova po projektima i program motivacije i nagrađivanja u ovisnosti o uspjehu projekta.

- Vršiti konstatne obuke zaposlenika koji su u direktnom kontaktu sa kupcima

U svakoj kompaniji, posebna pažnja se treba posvetiti zaposlenim koji ostvarju direktne kontakte sa kupcima. U BH Telecom bi se to posebno odnosilo na prodajno osoblje i podršku korisnicima (call centri, monteri). S obzirom da se često slika o organizaciji i percepcija o proizvodi i kvaliteti kreira putem odnosa sa osobljem, potrebno je konsatno provoditi posebne treninge, radionice i seminare za navedene zaposlenike.

- Poboljšanje „last mile“ infrastrukture

Bakarne parice, na osnovu kojih maloprodajni pretplatnici ostvaruju povezanost sa tk infrastrukturom su u Bosni i Hercegovini često u jako lošem stanju, najčešće zbog starosti i istrošenosti. Sve brzine koje BH Telecom garantuje (po osnovu ADSL, VOIP, IPTV...) se odnose na brzinu do pristupnih tačaka, i u glavnom dijelu infrastrukture te brzine su na zadovoljavajućem nivou. Problem se međutim javlja u „last mile“ infrastrukturi, koja vodi do pretplatnikovog doma.[4] Ovaj dio infrastrukture nije u vlasništvu BH Telecoma, nego krajnjih pretplatnika (vlasnika zgrada i sl.), ali s obzirom da kvalitet „last mile“ infrastrukture direktno utiče na kvalitet usluga potrebno je učiniti više napora i iznaći rješenja za popravak ovog dijela infrastrukture za sve pretplatnike.

III. Zaključak

Na osnovu navedenog, zaključuje se da postoji mogućnost povratka kompanije u stanje **„top forme”**, ali da je za realizaciju tog cilja neophodan angažman zaposlenih, kako na strateškom tako i na operativnom nivou. S obzirom na specifičnosti industrije telekomunikacija i veliki broj inovacija i promjena u ovom području, sljedećih nekoliko godina bi moglo biti ključno za razvoj i održivost kompanije. Povećanjem **fleksibilnosti**, a smanjivanjem **kontrolisanosti**, kompanija bi uspjela da se pozicionira na željeno mjesto, uz pretpostavku da se provođenje procesa provodi uz visok nivo posvećenosti i kompetentnosti, što je optimlano realizovati kroz rad komplementarnih timova, te poštivanje ostalih tačaka navedenih ovim radom.

E-mail: darko.markulin@t.ht.hr, kristina.musa@t.ht.hr

Sažetak - Potrebne akcije na strani pristupne mreže telekomunikacijskog operatora tijekom realizacije usluga u velikoj mjeri utječu na ukupne troškove operatora potrebne za realizaciju usluge te isto tako imaju veliki utjecaj na ispunjavanje postavljenih ciljeva u vidu KPI-ova (ključnih pokazatelja uspješnosti). U velikoj mjeri akcije na strani pristupne mreže izvršavaju zaposlenici operatora ili vanjskih izvođača. Upravo zbog toga postupak automatske dodjele zadataka za realizaciju ovih akcija može znatno doprinijeti uštedama i efikasnijoj realizaciji usluga.

U sklopu automatske dodjele zadataka potrebno je osigurati optimalan put zaposlenika koji izvršavaju akcije, osigurati zadovoljavanje definiranih poslovnih uvjeta s vanjskim izvođačima, osigurati realizaciju usluga unutar zadanih KPI-ova te osigurati realizaciju usluga u vremenskim rokovima dogovorenim s korisnicima.

U radu su prikazani osnovni principi i postavke koje treba zadovoljiti automatska dodjela zadataka u sklopu dodjele zadataka na području pristupne mreže koje se primjenjuje u HT-u. Ne ulazi se u opis samog algoritma dodjele zadataka.

Ključne riječi: automatsko dodjeljavanje zadataka, poslovni procesi, usluga, resursi, sustavi podrške

I. UVOD

Dvije su osnovne komponente koje u znatnoj mjeri utječu na uspješnu realizaciju telekomunikacijske usluge i optimalne troškove. To su tijek poslova (workflow) i dodjela zadataka (workforce).

Tijek poslova definira potrebne akcije vezane uz konfiguraciju mrežnih elemenata i definiranje potrebnih zadataka za akcije koje akteri poslovnog procesa trebaju poduzeti u cilju realizacije usluga. Ispravnim i optimalnim kreiranjem tijeka akcija osigurava se uspješna realizacija usluga što je vrlo bitno kod složene realizacije više usluga ili poslovnih procesa. Veliki utjecaj na uspješnost realizacije i smanjenje troškova u ovoj komponenti poslovnog procesa ima automatizacija akcija vezanih uz konfiguraciju mrežnih elemenata i sustava za podršku [1], [2].

S druge strane određene akcije tijekom poslovnog procesa ne mogu se automatizirati i njih moraju izvršavati akteri poslovnog procesa. Primjeri za to su ožičenje na razdjelniku na kojem se pristupna mreža spaja s mrežnim elementima telekomunikacijske mreže te konfiguracija usluge na strani korisnika. Za realizaciju tih usluga akter poslovnog procesa treba utrošiti određeni dio svog radnog vremena na putovanje i realizaciju usluge. Ovo znatno utječe na ukupne troškove realizacije usluge. S druge strane potrebno je paziti na vrijeme realizacije usluge. Različiti zadaci imaju i različitu važnost u odnosu na realizaciju usluge. Pravovremena realizacija najvažnijih zadataka mogu također znatno utjecati na ukupne troškove telekomunikacijskog operatora vezano uz procese realizacije usluga. Primjer za to su realizacije reguliranih usluga gdje kašnjenje u realizaciji može uzrokovati znatne troškove kroz različite penale koje operator zbog kašnjenja mora plaćati.

Stoga se zbog svega navedenog nameće potreba za automatskom dodjelom zadataka kojom će se osigurati optimalna dodjela zadataka. Na taj se način žele smanjiti troškovi realizacije usluga, povećati efikasnost aktera poslovnog procesa i povećati zadovoljstvo korisnika. Sve to zajedno doprinosi poboljšanju poslovnog procesa realizacije telekomunikacijskih usluga.

U nastavku rada opisani su osnovni principi i postavke automatske dodjele zadataka čijom se primjenom u poslovnim procesima realizacije usluga u HT-u želi znatno doprinijeti poboljšanju realizacije usluga i smanjenju ukupnih troškova realizacije. Opis i definicija samog algoritma dodjele zadataka na temelju kojeg se stvoreni zadaci dodjeljuju na aktere poslovnog procesa ne razmatra se u ovom radu. U radu se ne razmatra niti način prikazivanja dodijeljenih zadataka. Ipak, važno je napomenuti da mogućnost pregleda i dodjele zadataka kroz kartu područja na kojem se dodjeljuju zadaci dodatno doprinosi uspješnoj dodjeli zadataka i njezinom praćenju.

II. OSNOVNI PRINCIPI AUTOMATSKE DODJELE (DISPEČIRANJA) ZADATAKA

Prilikom specifikacije automatske dodjele zadataka nameće se potreba za definiranjem početnih uvjeta koje je potrebno zadovoljiti prilikom dodjele zadataka. Ti uvjeti ovise o poslovnim pravilima koja vrijede kod operatora za kojeg se specificira automatska dodjela zadataka i zapravo znače dodatne parametre koje je potrebno uzeti u obzir prilikom automatske dodjele zadataka. Kod primjene automatske dodjele zadataka u pristupnoj mreži HT-a potrebno je osigurati:

A. Dodjela zadataka na vanjske izvođače

Prilikom dodjele zadataka na vanjskog izvođača potrebno je više pravila. Neka od tih pravila su:

- Na određenim područjima svi se zadaci dodjeljuju na vanjskog izvođača (npr. otoci),
- Na ostalim područjima definiran je postotak zadataka koji se dnevno dodjeljuje na vanjske izvođače,
- Potrebno je zadovoljiti uvjete dogovorenih poslovnih pravila s vanjskim izvođačima koje se tiču predviđenog vremenskog roka za pojedini vrstu realizacije. Prilikom automatske dodjele zadataka potrebno je voditi računa o količini naloga s određenom vrstom realizacije jer se ona razlikuju po iznosu plaćanja, pa je tu moguć velik utjecaj na ukupne troškove realizacije usluge,
- Definira se određeni postotak naloga koji se dodjeljuje na vanjskog izvođača, a ostatak se dodjeljuje na interne izvođače operatora,
- Određeni se zadaci odmah dodjeljuju na vanjskog izvođača bez utjecaja kriterija koje odnosi algoritam. Primjer za to je usluga koju s korisnikom ugovara vanjski izvođač,
- Ukoliko realizacija zadatka zahtjeva ulazak u prostorije operatora, a vanjski izvođač nema dozvolu samostalnog ulaska u nju zadatak se ne može automatski dodijeliti na vanjskog izvođača.

B. Utjecaj željenog vremena

U slučaju kada je potrebno uslugu realizirati u određenom vremenskom periodu (period od nekoliko sati ili jedan dan) vrlo je bitno zadatak dodijeliti točno u vremenskom periodu kada ga je potrebno odraditi. Takve zadatke je potrebno dodjeljivati s visokim prioritetom i točno unutar vremenskog razdoblja kada ga je potrebno odraditi.

C. Utjecaj dogovorenog vremena realizacije s korisnikom

Kod operatora koji koriste mogućnost dogovora realizacije uključenja ili otklanjanja smetnje s korisnikom vrlo je važno to i osigurati kroz automatsko dodjeljivanje. Kao i kod zadataka koje je potrebno odraditi u željeno vrijeme zadacima za čiju je realizaciju dogovoreno vrijeme potrebno je dodijeliti visoki prioritet dodjele, a u isto vrijeme potrebno je voditi računa da se ti zadaci dodjele točno u periodu kada je i dogovorena realizacija.

D. Utjecaj definiranog KPI-a

Vrlo bitan faktor koji utječe na uspješnost automatskog dodjeljivanja je realizacija zadataka unutar definiranih rokova kroz KPI. Tim je zadacima potrebno postaviti takve prioritete koji mu osiguravaju dodjelu na vrijeme. Vrlo je bitno istaknuti da akteri poslovnog procesa odrađuju i zadatke koji su preduvjeti za konačnu realizaciju usluge. Primjere je ožičenje na razdjelniku koji je preduvjet za realizaciju usluge, ali i kojeg je potrebno realizirati u vrijeme koje omogućava dodjelu konačnog zadataka za realizaciju usluge u predviđenom roku. Ovo je bitno za zadatke s dogovorenom realizacijom usluge s korisnikom, zadatke sa željenim vremenom realizacije usluge i zadatke s definiranim KPI-om. To algoritam automatske dodjele zadataka treba osigurati.

E. Utjecaj na dodjelu slijedećeg zadatka

Moguće je definiranje više različitih faktora koji utječu na automatsku dodjelu zadataka. To mogu biti lokacija zadnjeg izvršenog zadatka, pozicija aktera poslovnog procesa te prioritet odrade zadatka.

F. Mogućnost da se zadatak ne realizira, a automatska dodjela zadataka se može nastaviti

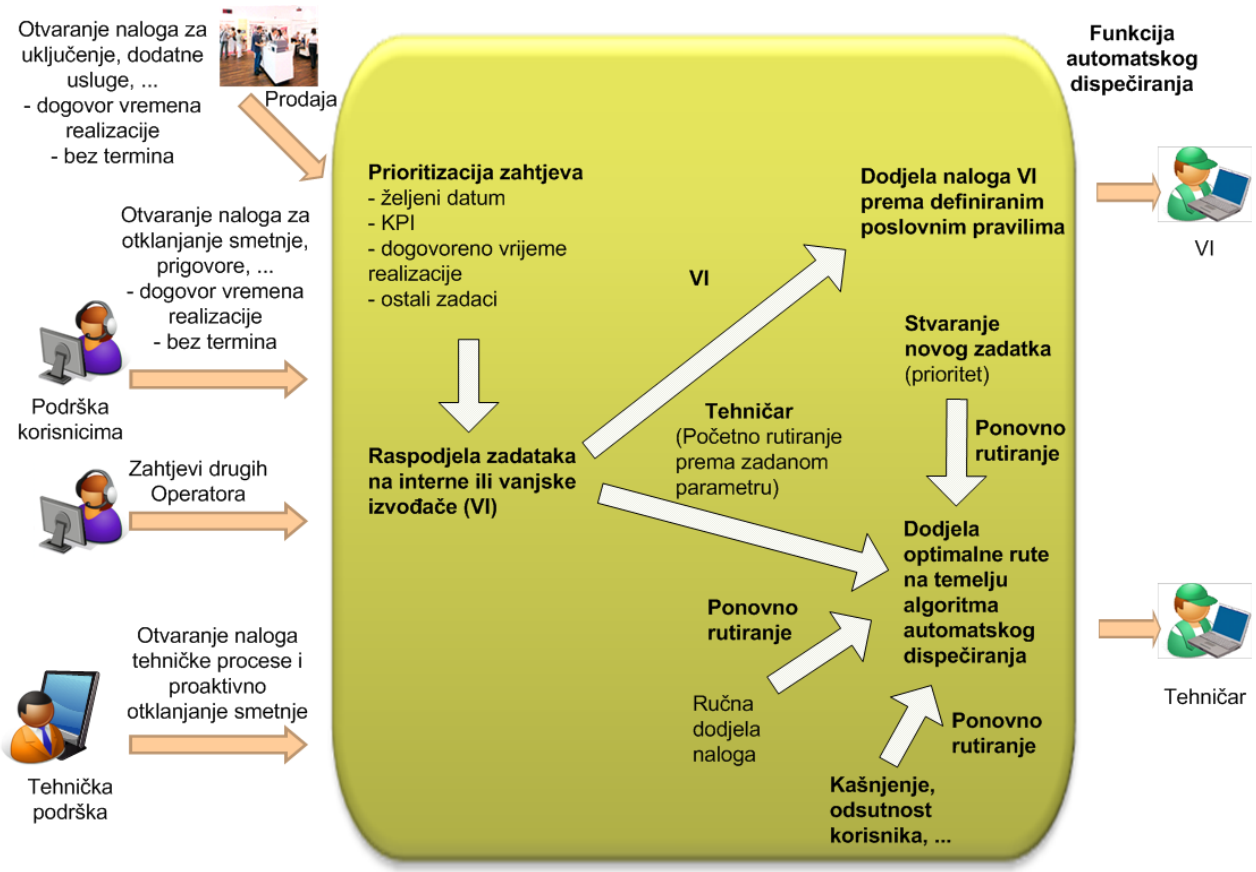
Postoje situacija kada akter poslovnog procesa ne može do kraja realizirati zadatak odmah, već nakon nekog vremena. U tim situacijama potrebno je omogućiti automatsku dodjelu zadataka bez daljnjeg utjecaja ovog zadatka. Taj će se zadatak odraditi kroz neki od ostalih predviđenih postupaka dodjele zadataka.

G. Dodjelu zadataka mimo utjecaja algoritma automatske dodjele zadataka

Ukoliko je potrebno hitno odraditi neki zadatak bez utjecaja algoritma automatskog dodjeljivanja potrebno je omogućiti dodjeljivanje takvih zadataka. Nakon realizacije takvog zadatka uzima se njegova lokacija u proračun slijedećeg zadatka koji se dodjeljuje kroz automatsku dodjelu.

Kako telekomunikacijski operatori koriste vrlo veliki broj poslovnih procesa kao posljedica vrlo složenog djelovanja vrlo je teško uklopiti sve poslovne procese u postupak automatskog dodjeljivanja i predvidjeti sve moguće situacije prilikom realizacije telekomunikacijske usluge. Stoga je potrebno ostaviti mogućnost ručnog dodjeljivanja zadataka čija realizacije direktno ne utječe u rad algoritma automatskog dodjeljivanja. No posredno ovo može značajno utjecati na efikasnost algoritma. Stoga je tu potrebno osigurati kontrolu u vidu mogućnosti ručnog dodjeljivanja zadataka koji se nalaze unutar unaprijed definirane udaljenosti od zadnjeg realiziranog zadatka kroz automatsko dodjeljivanje. Također se može definirati maksimalni broj zadataka koji se može dodijeliti kroz ručno dodjeljivanje.

Vrlo važna karakteristika automatskog dodjeljivanja zadataka je mogućnost definiranja različitog utjecaja određenih parametara na rad algoritma dodjele. Definiranjem težinskih vrijednosti mogu de definirati različiti utjecaji na rad algoritma s obzirom na udaljenost između lokacija zadnjeg i slijedećeg realiziranog zadatka, pridodanog prioriteta zadatku s obzirom na njegovu važnost te početne pozicije internih izvođača s koje započinje svoj radni dan. Na slici 1 prikazan je osnovni princip rada primijenjene automatske dodjele zadataka.



Slika 1. Prikaz principa primijenjene automatske dodjele zadataka

Može se izdvojiti nekoliko osnovnih koraka u postupku automatske dodjele zadataka.

A. *Kreiranje naloga na osnovu kojih se pokreću poslovni procesi*

Vrsta i način otvaranja naloga utječe na način i važnost dodjele zadataka unutar poslovnog procesa koji se primjenjuje na području telekomunikacijske pristupne mreže. Ukoliko je to nalog koji se otvara na zahtjev drugih operatora izvršavanje zadataka u sklopu odgovarajućih poslovnih procesa najvećeg je prioriteta. Vrlo velikog prioriteta su nalozi u sklopu kojih je s korisnikom dogovoreno vrijeme realizacije. Najmanjeg prioriteta su nalozi koji ne pripadaju jednoj od nabrojanih skupina te za koje nije definiran KPI.

B. *Dodjela zadataka vanjskim izvođačima*

Kako vanjski izvođači svoje zadatke trebaju dobiti na vrijeme koje je osigurano kroz dogovorena poslovna pravila automatska dodjela zadataka zasniva se na nešto drugačijim principima od dodjele zadataka internim izvođačima. Automatska dodjela zadataka vanjskim izvođačima pokreće se odmah nakon kreiranja zadatka koji se dodjeljuje prema prethodno nabrojanim principima.

C. *Dodjela zadataka internim izvođačima*

Konačno, automatska dodjela zadataka pokreće se na način da se zadovolje principi kojima se osigurava realizacija usluge na optimalan i efikasan način. To uključuje realizaciju u traženo ili dogovoreno vrijeme, zadovoljavanje postavljenih KPI-ova te optimalan put tehničara tijekom svog radnog vremena.

S obzirom na različite karakteristike područja na kojima djeluju interni izvođači i poslovne jedinice unutar kojih djeluju potrebno je omogućiti različita poslovna pravila koja vrijede unutar tih poslovnih područja. Tako se može definirati da se na određene djelatnike mogu dodjeljivati određeni zadaci s obzirom na područje djelovanja, vrstu procesa, vrstu zadatka i doba dana. Isto tako interni izvođač treba imati odgovarajuće znanje za odrađivanje određenog zadatka.

Kako su principi automatske dodjela zadataka vrlo složeni posljedica su vrlo složene forme kroz koje se uvode poslovna pravila i način djelovanja algoritma automatske dodjele. Njihovo popunjavanje i ažuriranje zahtjeva vrlo dobro poznavanje poslovnih procesa i načina rada prilikom realizacije telekomunikacijskih usluga.

III. ZAKLJUČAK

Dodjela zadataka akterima poslovnog procesa vrlo je složen postupak jer je istovremeno potrebno zadovoljiti više čimbenika koji utječu na uspješnu i efikasnu dodjelu zadataka, a samim time i uspješnu realizaciju usluga. Uspješan rad algoritma automatske dodjele zadataka nije sam po sebi dovoljan ukoliko se pri tome ne zadovolje svi postavljeni preduvjeti koji uvelike utječu na postupak automatske dodjele zadataka. Preduvjeti se znatno mogu razlikovati između operatora i stoga je prilikom njihove definicije potrebno dobro poznavanje poslovnih procesa i poslovnih pravila koji se koriste kod operatora koji će koristiti automatsku dodjelu zadataka.

Mehanizam automatske dodjele zadataka vrlo je složen i stoga je definicija svih potrebnih parametara za njegovu uspješnu primjenu vrlo složen postupak. I tu je potrebno vrlo dobro poznavanje svih mogućih prilika i događaja prilikom dodjele zadataka akterima poslovnog procesa.

Primjena automatske dodjele zadataka na području pristupne mreže u HT-u na samom je začetku i njezin daljnji tijek pokazat će u kojoj mjeri postavljeni principi i rad automatske dodjele zadataka pridonose efikasnosti rada aktera poslovnih procesa i koliko pridonose uštedi u sklopu ukupnih troškova realizacije uključenja telekomunikacijskih usluga i ostalih poslovnih procesa koji se primjenjuju u HT-u.

Iako su princip rada i funkcionalnosti automatske dodjele zadataka prilagođeni uvjetima i načinu rada na području pristupne mreže u HT-u, planiraju se dobiveni rezultati usporediti i s iskustvima ostalih telekomunikacijskih operatera te na taj način definirati daljnja moguća poboljšanja rada automatske dodjele zadataka.

Predprodajna reklamna aplikacija telekomunikacijskih usluga

Jasna Mulabegović, Halil Šabanović, Adisa Arslanagić
BH TELECOM d.d.
Obala Kulina Bana 8 71000 Sarajevo
E-mail: halil.sabanovic@bhtelecom.ba, jasna.mulabegovic@bhtelecom.ba, adisa.arslanagic@bhtelecom.ba

Sažetak - Prodajne mogućnosti koje telekom operatori nude svojim korisnicima nužno moraju biti interaktivne prirode kako bi korisnik mogao birati opcije koje odgovaraju njihovim željama i potrebama. Uzimajući u obzir prodajna iskustva koja se temelje na prodajnim rezultatima ostvarenim kroz tradicionalne kanale prodaje jasno je da korisnički zahtjevi idu ka opcijama prodajne ponude koja nudi mogućnost odabira telekomunikacijskih usluga najprije putem e-prodajnog kanala. Kreiranje prodajnog pristupnog kanala za ovu namjenu temeljenu na modelu „Predprodajne reklamne aplikacije“ je jedan od mogućih načina unaprijeđenja prodajnog procesa sa ciljem omogućavanja ostvarenja individualnih zahtjeva korisnika. Cilj ovog rada je pokazati mogućnosti integracije i distribucije korisničkih znanja u predprodajnu reklamnu aplikaciju telekomunikacijskih usluga sa svrhom primjene individualnih korisničkih zahtjeva kako bi se proizvela dodatna vrijednost u smislu pozitivnih korisničkih iskustava tokom procesa prodaje te kako bi se temeljem ovakvog pristupa prodajnom procesu ostvarili pozitivni efekti u povećanju prihoda.

I. UVOD

U skladu sa prodajnom strategijom telekom operatora koja se temelji na konceptu zadržavanja postojeće baze korisnika te potom njenog uvećavanja, osim dobro osmišljene ponude telekomunikacijskih usluga temeljenih na različitim tehnologijama neophodno je omogućiti korisnicima jednostavan pristup takvoj ponudi te odabir paketa usluga sa odgovarajućim opcijama prema individualnim korisničkim zahtjevima i potrebama.

Široka paleta usluga koje telekom operatori nude je osnov na kojem je moguće temeljiti cilj zadržavanja korisnika te eventualno dodatnog rasta, a mogućnost jasnog i jednostavnog odabira odgovarajuće usluge za korisnika je važan aspekt na temelju kojeg daje svoje povjerenje telekom operatoru. U ovom smislu od presudne važnosti su profili prodajnih kanala i njihova efikasnost u predprodajnoj podršci potencijalnim korisnicima usluga. S obzirom na kompleksnost i različitost opcija ukupne ponude usluga jednog savremenog telekom operatora, za uspješnu prodaju usluga zaposlenicima u prodaji je neophodna adekvatna pomoć u vidu aplikacije ili nekog drugog informatičkog alata (baza znanja, pretraživač, savjetnik i sl.).

II. CRM I ISKUSTVO KORISNIKA

Primjena CRM sustava u upravljanju iskustvom korisnika prema istraživanjima provedenim u različitim industrijama u kojima je ovakav pristup korišten, pokazala se vrlo ovisnom o okolnostima pod kojima se takav sustav koristi [1]. Uspješnost primjene CRM sustava u velikoj mjeri je u ovisnosti od stupnja integracije znanja temeljenih na informacijama prikupljenim od strane samih korisnika unutar određenog tržišta te potom integriranja takvih znanja u pojedine razine CRM sustava [2]. Svrha primjene CRM sustava je povećanje zadovoljstva korisnika kod isporuke željene usluge pri čemu fokus telekom operatora postaje sam kupac, te tako iskustva kupaca u procesu prodaje i isporuke usluga postaju relevantni za poslovanje. Kvalitet usluga koje telekom operator nudi, potom komunikacija u prodaji i isporuci usluga i na koncu cijena usluge bi trebali odgovarati ili premašiti očekivanja kupaca te za rezultat imati pozitivan utjecaj na lojalnost korisnika.

Djelotvorni i učinkoviti komunikacijski kanali u kontaktima „licem u lice“, putem telefona, interneta ili putem drugih interaktivnih medija omogućavaju telekom operatoru bolju dostupnost korisnicima te na taj način stvaraju povoljne okolnosti za razumijevanje njihovih potreba i želja. Logički slijed aktivnosti koji korisnicima olakšavaju izbor optimalne telekomunikacijske usluge, stvara preduvjete za pozitivna korisnička iskustva u kupovini i korištenju usluga telekom operatora. U tom smislu definiranje i kreiranje e-predprodajne reklamne aplikacije kao logičkog koraka nakon analiziranja korisničkih iskustava te integriranje ovog rješenja u potencijalni CRM sustav i WEB portal je dodatna mogućnost podizanja kvaliteta brige za korisnička iskustva od strane telekom operatora.

CRM procesi trebaju promjene na način da telekom operatori mogu prepoznati individualne korisnike te ih predstaviti u vidu informacija: ko su ti korisnici i što žele. Telekom operatori trebaju biti u poziciji stvaranja dodatnih vrijednosti u predprodajnom i prodajnom

procesu na način da prilagođavaju ponude svojih usluga korisničkim zahtjevima. Na koncu takav pristup se ogleda i u razvoju interaktivnih prodajnih kanala korisnik-telekom operator-korisnik.

III. E- PRODAJNI KANAL

A. *Razlozi kreiranja predprodajne reklamne aplikacije*

Telekom operatori koji imaju mogućnost korisnicima ponuditi različite vrste usluga ili iste vrste usluga ali preko različitih tehnologija, što je vezano i sa različitim cjenovnim pragovima za takve usluge, primjenom predprodajnih reklamnih aktivnosti olakšavaju korisniku optimalan izbor seta usluga u skladu sa njegovim trenutnim potrebama i mogućnostima. Cilj kreiranja i definiranja predprodajne reklamne aplikacije je da stvori poslovnu vrijednost kroz povećanje zadovoljstva korisnika čime je stvorena pretpostavka korisničke lojalnosti svom operatoru.

B. *Principi primjene predprodajne reklamne aplikacije*

Osnovi principi predprodajne reklamne aplikacije su zasnovani na grupama upita koje korisnici popunjavaju i na koncu ovog slijeda upita u ovisnosti od odabranih odgovora korisniku se nudi set usluga prema njegovim zahtjevima. Ovakav pristup prodaji usluga predstavlja u izvjesnom smislu evoluciju od pristupa upravljanja telekomunikacijskim uslugama kao proizvodom (Product Managament) prema upravljanju korisnikovim iskustvom (Costumer Experience Managament).

Izbor potrebne telekomunikacijske usluge, pri čemu je taj odabir u skladu sa korisnikovim trenutnim potrebama i mogućnostima, iz veoma široke ponude telekomunikacijskih usluga, korisnicima stvara nedoumice oko toga što odabrati i često predstavlja cilj do kojeg je korisnicima prilično komplicirano doći. Ključni uvjeti za uspješan proces prodaje sa stajališta prve linije prodaje i isporuke usluga korisnicima su:

- Visoka razina obučenosti i kompetentnosti prodajnog osoblja da korisniku preporuči optimalno rješenje za njegove potrebe, pri čemu su te kompetencije i znanja usklađena sa dinamikom isporuke novih rješenja telekomunikacijskih usluga
- Velika dinamika kreiranja novih telekomunikacijskih usluga u ponudi telekom operatora, praćena efikasnom dinamikom same isporuke novih usluga korisnicima
- Visoka prodajna iskorištenost usluga kao posljedica usklađenosti termina isporuke usluga sa prodajnim akcijama
- Brza isporuka usluga usklađena sa korisničkim očekivanjima.

Telekom operatori koji svoju razvojnu strategiju baziraju na pružanju usluga korisnicima po različitim tehnologijama imaju za potrebu napraviti kvalitetnu sponu između korisnikovih zahtjeva i tehnoloških rješenja telekomunikacijskih usluga iz svoje ponude. Ovakvi telekom operatori često jednu vrstu usluge mogu pružiti preko različitih tehničkih rješenja, koji kao svoje komponente sadrže različite cjenovne rangove.

Cilj ovog rada je prikazati principe i metodologiju moguće praktične primjene „Predprodajne reklamne aplikacije“ sa ciljem da se što jednostavnije omogući korisniku uspješan odabir optimalne telekomunikacijske usluge. Dodatni cilj je istražiti i analizirati druge mogućnosti aplikacije kao što je postizanje pozitivnog iskustva kod korisnika i zaposlenika u prodaji usluga, te procijeniti moguće efekte primjene ovog tipa predprodajne reklamne aplikacije na proces prodaje usluga kod telekom operatora.

IV. PRINCIPI I METODOLOGIJA PRIMJENE PREDPRODAJNE REKLAMNE APLIKACIJE

Efikasna predprodajna reklamna aplikacija treba ispuniti sljedeće pretpostavke:

- WEB bazirana aplikacija lako dostupna neovisno o lokaciji korisnika aplikacije;
- Aplikacija daje mogućnost izbora optimalnog seta usluga korisniku kroz jednostavan izbor lako razumljivih parametara;
- Aplikacija daje mogućnost pristupa korisniku svim dodatnim informacijama o svakom paketu usluga na jednostavan i razumljiv način, čime je korisniku omogućen lakši izbor optimalne usluge prema korisničkim potrebama i zahtjevima;
- Aplikacija omogućava prikupljanje vrijednih informacija telekom operatoru o korisničkim željama, potrebama i sugestijama na aktualnu ponudu usluga.

Rješenje „Predprodajne reklamne aplikacije“ je implementirano u testno okruženje kod telekom operatora gdje su analizirani efekti primjene aplikacije. Razvoj aplikacije i njena integracija u testno okruženje kod telekom operatora je trajao dva mjeseca. Proces integracije rješenja bio je prilagođen postojećem informacijskom sistemu te bitnih prepreka za okončanje integracije nije bilo. Za praktičnu implementaciju predprodajne reklamne aplikacije izabrana je grupa lako razumljivih parametara za definiranje optimalnog seta usluga:

- način plaćanja (putem računa, bez računa)
- mobilnost (na jednoj lokaciji, u pokretu)
- kategorija korisnika (fizičko lice, pravno lice)
- uključeni servisi (govor, prijenos podataka, IP TV, pristup internetu).

Parametar „način plaćanja“ definira profil usluga sa dvije mogućnosti, postpaid profil usluga- plaćanje putem računa ili prepaid profil usluga- bez računa (plaćanje unaprijed npr. e-vaucher). Parametar „mobilnost“ određuje tehnologiju, „u pokretu“- mobilna mreža ili „na jednoj lokaciji“- fiksna mreža. Parametar „kategorija korisnika“ određuje dvije grupe usluga namjenjene za fizička ili pravna lica, te parametar „uključeni servisi“

(govor, prijenos podataka, IPTV i pristup internetu) bliže određuju pakete usluga.

A. Primjer scenarija rada sa aplikacijom

Korisnik bi nakon pristupa aplikaciji putem web portala birao uslugu npr. pristupa internetu. Pri tome bi odabrao parametre:

- Način plaćanja- putem računa
- Mobilnost- na jednoj lokaciji
- Kategorija korisnika- fizičko lice
- Uključeni servisi- Govorni pozivi- Ne, Prenos podataka- Da, IP TV- Ne, Pristup internetu- Da.

Nakon završenog odabira parametara korisnik ima pristup ponudi paketa usluga prema zadanim kriterijima:

- 1. BH Line CLL (10 KM/mjesec)
- 2. BH Line L.Net (15 KM/mjesec)
- 3. BH Line WLL (18 KM/mjesec)
- 4. BH Line ADSL (20 KM/mjesec).

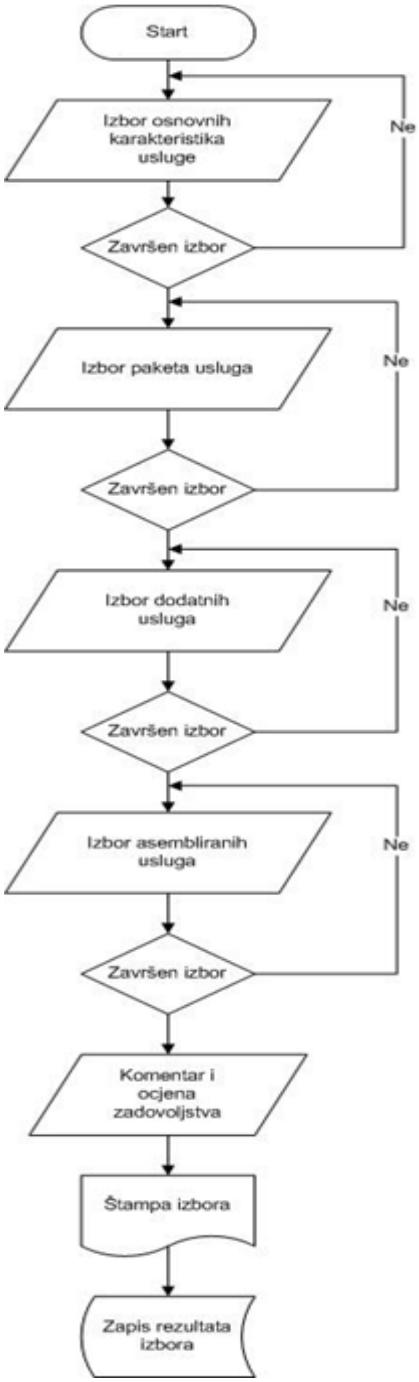
Nakon osnovnog seta upita korisnik ima mogućnost izbora jednog od četiri ponuđena paketa usluga. Drugi set upita dodatno daje mogućnost korisniku odabrati opciju dodatnih usluga kao i uređaja iz ponude telekom operatora koja mu najviše odgovara.

Uvid u detaljni opis svake od ponuđenih usluga korisniku daje mogućnost da odabere uslugu po svom izboru npr. korisnik može odabrati „L.Net“ uslugu koja je korisniku na raspolaganju i isporučiva od strane telekom operatora a zadovoljava korisnikove zahtjeve. Predprodajna reklamna aplikacija korisniku omogućava i dodatni uvid u cjenovnik za dati paket usluga kao i uvid u ponudu dodatnih usluga predviđenih za odabrani paket. Kao još jednu mogućnost osim izbora dodatnih usluga na odabrani paket, korisnik ima mogućnost odabira uređaja iz liste asembliranih uređaja za odabrani paket usluga, za ovaj primjer ponuđena je opcija prodaje USB modema za „L.Net“ paket.

Dodatna vrijednost korištenja predprodajne reklamne aplikacije se svakako nalazi u dostupnosti ovog tipa aplikacije samim korisnicima putem web pristupa ovakvom tipu prodajnog kanala. Takvim pristupom korisnik ima mogućnost odvojiti vremena koliko je potrebno da bi analizirao i uspoređivao ponuđene opcije usluga prema traženim zahtjevima i na koncu samostalno odlučivao o izboru optimalne usluge.

V. LOGIKA PREDPRODAJNE APLIKACIJE

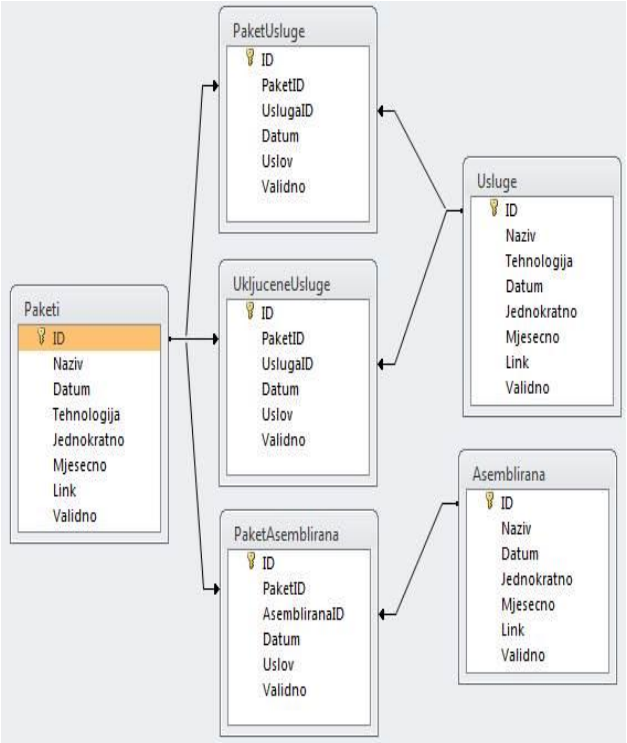
Istraživanja su pokazala da jedan od nedostataka koji dovodi u pitanje uspješnost CRM procesa jeste sam način prikupljanja i obrade podataka o klijentima [4]. CRM procesi, tehnologije i CRM informacije se nužno razvijaju u uskoj uzajamnoj sprezi. Kompanije kojima je kupac fokus poslovanja moraju preispitivati svoje procese, posebno u području prikupljanja podataka o klijentima, njihovoj obradi kao i analizi takvih podataka . Primjena efikasne metrike u korištenju prikupljenih podataka o korisnicima utječe na povećanje zadovoljstva i lojalnosti kod korisnika te omogućuje smanjenje troškova i povećanje prihoda kod telekom operatora.



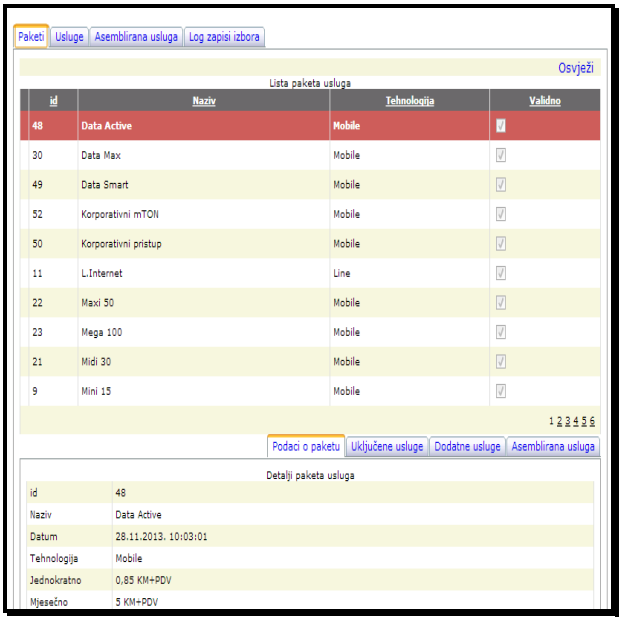
Slika 1. Logička struktura predprodajne-reklamne aplikacije

Logička struktura predprodajne reklamne aplikacije (Slika 1. i Slika 2.) treba osigurati prikaz obimne ponude usluga telekom operatora. Ujedno se sa pravilno definiranim relacijama među podacima može pojednostaviti algoritam same aplikacije, čime se ubrzava njen rad i pojednostavljuje održavanje.

Za održavanje podataka o ponudi usluga koristi se administratorska aplikacija (Slika 3.) putem koje se ažuriraju izmjene, dopune i nove usluge, te uređuju relacije između paketa usluga i samih usluga.

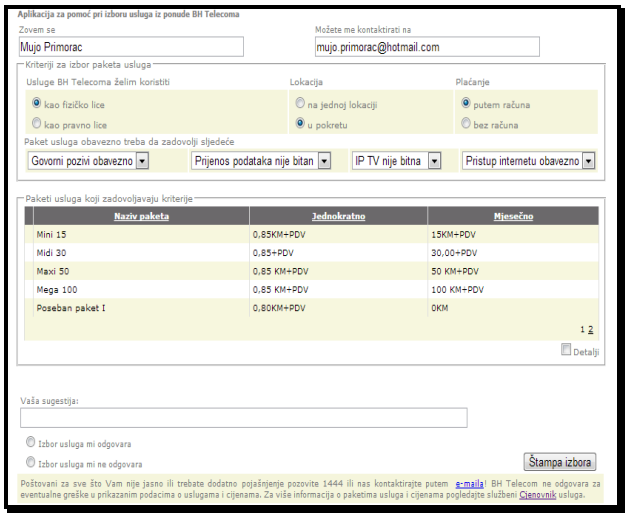


Slika 2. Struktura podataka predprodajne reklamne aplikacije

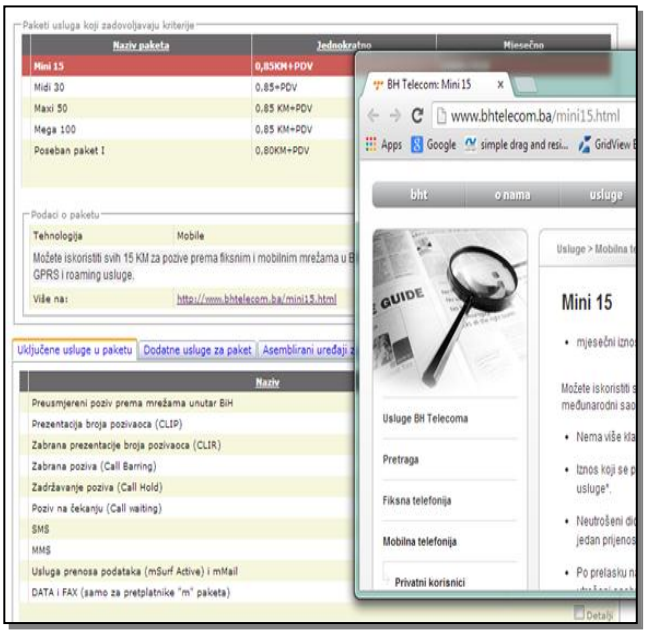


Slika 3. Administratorski dio predprodajne reklamne aplikacije

Korisnička aplikacija (Slika 4.) svojim sučeljem prilagođena je upotrebi korisnicima sa „prosječnim“ tehničkim znanjima na način da je dovoljno imati relativno malo znanja o telekomunikacijskim tehnologijama. Fokus aplikacijske logike je na sužavanju ponude paketa usluga prema postavljenim zahtjevima od strane korisnika te omogućavanju korisniku izbora optimalnog paketa usluga koji mu odgovara prema cijeni korištenja i njegovim realnim potrebama u trenutku korištenja aplikacije. Na osnovu odabira opcija jasno definiranih paketa usluga moguće je imati potpun uvid u ponudu paketa usluga za pojedine tipove usluga.



Slika 4. Korisnički dio predprodajne reklamne aplikacije

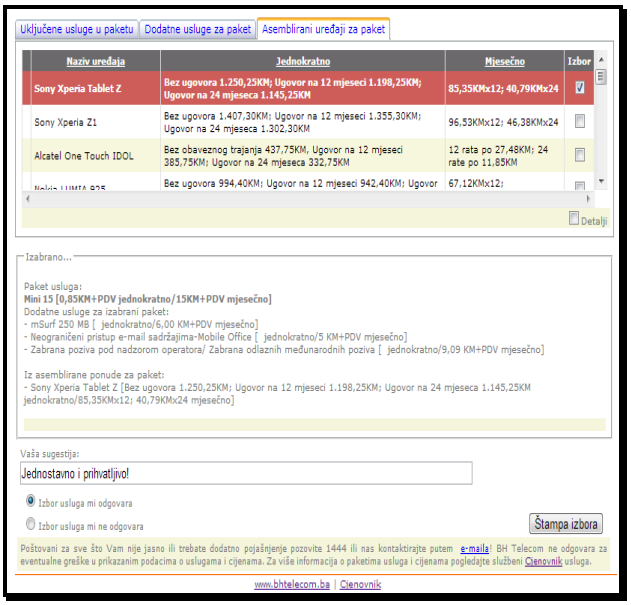


Slika br. 5 Izbor seta usluga na osnovu dodatnih informacija

Za svaku pojedinu uslugu na raspolaganju je skup osnovnih podataka i link na druge web stranice koje sadrže dodatne podatke o uslugama, za one korisnike aplikacije koji se ne mogu lako odlučiti (Slika 5.).

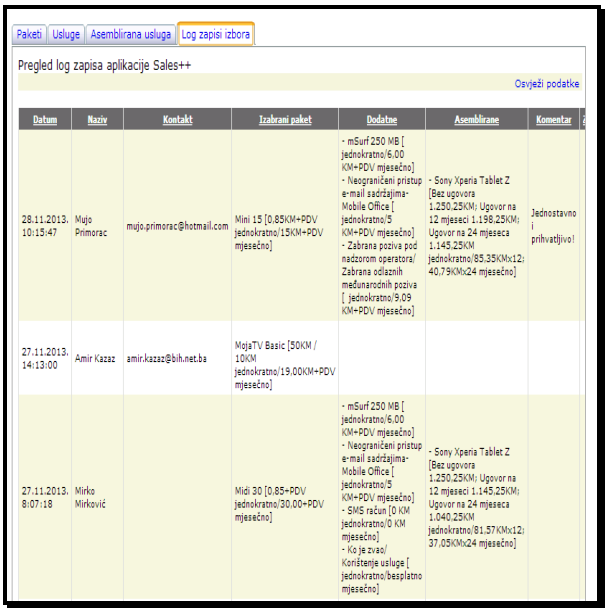
Korisnička aplikacija obezbjeđuje povratnu vezu sa telekom operatorom na način da korisnik može dodati svoju sugestiju/ preporuku/ prigovor na ponudu usluga, te može izraziti svoje zadovoljstvo izborom usluga (Slika 6.). Aplikacija nudi mogućnost izjašnjavanja korisnika o zadovoljstvu izborom usluga (Izbor usluga (ne)

odgovara), odnosno štampom stranice (Štampa izbora) zapisuje podatke o izabranim uslugama zajedno sa povratnim podacima korisnika (Slika 7.).



Slika 6. Podaci o izabranim uslugama i povratne informacije korisnika

Prikupljeni podaci iz predprodajne reklamne aplikacije mogu biti veoma korisni za analizu potreba korisnika, njihovo viđenje ponude usluga, te kao takvi mogu poslužiti i za proaktivnu ponudu na osnovu iskazanog interesovanja korisnika.



Slika 7. Podaci o korisnicima, izboru usluga i povratne informacije korisnika aplikacije

Dakle, moguće je zaključiti da prodajni kanal temeljen na „predprodajnoj reklamnoj aplikaciji“ telekomunikacijskih usluga korisnicima nudi mogućnosti odabira odgovarajuće usluge pri čemu korisnik u interakciji sa opcijama aplikacije dobija potpuniji uvid u ukupnu ponudu telekom operatora, sa svim opcijama usluga, opis tehničkih karakteristika i cijene korištenja. Istovremeno telekom operator dobija na jednostavan način vrlo vrijedne informacije o interesovanjima korisnika i eventualnim nedostacima svoje ponude.

Primjenom rješenja „Predprodajne reklamne aplikacije telekomunikacijskih usluga“ ponuda telekom operatora postaje posve transparentna za korisnike čime odabir željene usluge postaje jednostavan. Bitno se povećava dostupnost za odabir širokog spektra dodatnih telekomunikacijskih usluga sa kojima korisnici vrlo često nisu bili upoznati zbog činjenice da su takve usluge vrlo brojne. Dodatno, korisnicima je omogućen jednostavan odabir uređaja za kupovinu kao vrlo važan aspekt korisničkih zahtjeva, što prema prodajnim iskustvima kod telekom operatora povećava zadovoljstvo korisnika. Za telekom operatora se primjenom ovakvog rješenja otvara prostor brže i efikasnije prodaje, povećanja prodajnih rezultata, kreiranja različitih prodajnih akcija kojima bi se efikasno moglo upravljati te na taj način ostvarivati bolje prodajne rezultate. Poseban efekat ovakvog rješenja je moguć u segmentu povećanja prodajnih rezultata za nove usluge koje su na ovaj način dostupne za kupovinu odmah, pri čemu je za telekom operatora iznimno važno smanjenje vremena upoznavanja korisnika sa novom uslugom.

VI. ZAKLJUČAK

Strateško opredjeljenje kod telekom operatora koje se ogleda u poticanju sposobnosti za razvoj poslovne prakse u kojoj se kupac stavlja u fokus poslovnih procesa, obavezno podrazumjeva i to da se informacije o mišljenju korisnika prikupljaju, analiziraju i prevode u bolju vrijednost i pozitivno iskustvo za kupca. Predstavljeni model predprodajne reklamne aplikacije pokazao je samo neke od mogućnosti putem kojih su dostupna aktualna znanja o korisničkim navikama i potrebama temeljem kojih je omogućeno definiranje razvojne strategije kao i redefiniranje poslovnih procesa prema aktuelnim okolnostima. Prilagođenost ponude jedne kompanije stvarnim potrebama kupca posebno na tržištu kakvo je telekomunikacijsko tržište, čine telekom operatore sposobnijim zadržati postojećeg kupca ali i privući novog. Krajnji rezultat uspješne ponude su povećanje kupovne orijentacije korisnika i bolje upravljanje iskustvom kupca. CRM kao složeni sustav za upoznavanje korisnika i upravljanje njihovim iskustvom ne može se kupiti kao ad-hoc rješenje. Ovakav sustav se gradi od brojnih komponenti kao što je i opisana predprodajna reklamna aplikacija, a u takve komponente se postepeno ugrađuje nakupljeno iskustvo zaposlenika kompanije, te prikupljena znanja o korisnicima kao i najbolje prakse drugih uspješnih kompanija. Široka paleta ponude usluga telekom operatora je preduvjet za uspješan rad na dinamičnom telekomunikacijskom tržištu. Izbor usluge ili seta usluga a posebice optimalan izbor prema potrebama i zahtjevima korisnika je trenutno veoma zahtjevan posao, kako za prodajno osoblje tako i za potencijalne korisnike usluga. Iz tog razloga cilj prikazanog rješenja predprodajne reklamne aplikacije za telekomunikacijske usluge predstavlja mogući iskorak ka olakšavanju i pojednostavljenju izbora optimalne usluge prema zahtjevima korisnika telekom operatora.

Abstract - Nowadays, using touch applications is almost ubiquitous. It is appealing to different age groups, including very young generations who have just started their education. This paper describes development of a product that implements existing web applications into environment that enables multiple users to simultaneously interact with multi-touch device. Web application is developed for children to help them solve various tasks encountered for the first time. This paper analyzes web application requirements and implementation of required functionalities. The main requirement is to provide multi-user environment. Another important requirement is the ability to adjust game representation to child's position at the table. This is why the web application enables users to drag, rotate and resize each instance of the game. This paper also describes how the above mentioned content management is implemented. The other possible ways of implementation will also be mentioned, even though they are not used in the final product. Considering the fact that some children might have mobility difficulties, both gesture and button controls are implemented and can be used, depending on the preferences of a single child. In addition, this paper describes limitations, problems and solutions that have arisen during the web application development process.

I. INTRODUCTION

Nowadays, multi-touch devices are well accepted in the global population. With multi-touch foil padded on, almost any device with display can perform as interactive multi-touch device. Touch screen technology is increasingly popular in all age groups, including the youngest that are just starting their education. Usage of multi-touch devices brings a whole new dimension in solving mathematical tasks, helping children to learn faster by combining education and fun.

This paper describes the development of web application which enables simultaneous use of different types of web applications (e.g. educational games) in a multi-touch and multi-user environment. It initially includes two educational games, Mathematical Carousel and Mathematical Playroom, developed as part of ICT-AAC project at University of Zagreb, Faculty of Electrical Engineering and Computing.

Developed web application is primarily intended for preschool children to help them in coping with various tasks which they face for the first time. For this reason the application is primarily intended for use on large multi-touch tables, but it can also be used on other appropriate multi-touch devices.

One of the main goals in development of this web application was ensuring stable multi-user environment. Therefore, each child can use a web application instance of their choice at the same time and in any part of the same web browser. Because of planned use with multi-touch tables, each instance should be independently adjustable in size, position and rotation according to needs of each child and their position at the table. Therefore, controls for dragging, rotation and resizing should be implemented. Taking into account the fact that some of the children might have motoric difficulties, it is important to support different ways of managing instances – using both simple button controls and multi-touch gestures. Thus each child can choose which way of managing their instance they prefer.

Next section gives an overview of related work in using multi-touch tables and multi-touch and multi-user gesture detection. The third section describes application design and structure, implemented button controls and gesture detection. Article ends with conclusion and references sections.

II. RELATED WORK

Recently, there has been a significant amount of both software and hardware oriented work related to multi-touch devices and applications. In this section, some of the work that relates closely to this research will be described.

Paper [1] describes a set of interaction techniques which enables the usage of gestures in interactive multiuser direct-touch tabletop environments. It provides a variety of interesting functionalities including drag, rotate and resize gestures. Second paper [2] describes an adaptation of a single-user desktop application DigiQuilt into DigiTile, a multi-user multi-touch tabletop application. An example which includes both hardware and software development is presented in the third paper [3]. The work designs and implements a smart dining table which fits the requirements of the open-plan kitchen living room. Presented solution includes interactive entertainment games.

As part of this research, a number of multi-touch gesture detection libraries, offering certain capabilities

necessary for development of the application, were encountered.

The most interesting among observed was Hammer.js, which is a JavaScript library for multi-touch gestures. Hammer.js supports a variety of one-finger and two-finger gestures, namely drag, rotate, tap, double-tap and pinch zoom (resize). Library can be effectively used for detection and control over user gestures on multi-touch devices which was suitable for the purpose of this research. However, although it provides most of the needed functionalities, Hammer.js does not provide multi-user support which, for us, was of upmost importance. Therefore, it was used only for development of demo versions of the application which were mostly used for testing purposes, but not for the development of the final version.

Another library considered was SwinxyTouch which is a JavaScript library for multi-user gesture detection. SwinxyTouch provides a set of cross platform and cross device touch events. However, library is a commercial software and therefore wasn't appropriate for the purposes of this research.

Related work mentioned in this section represents a collection of interesting solutions which, when combined, support all of functionalities needed for development of the core application. However, none of the solutions fully fit the requirements mainly because they aren't web-oriented or exhibit a lack of multiuser support. The goal of this project was to develop an application which would satisfy both requirements mentioned above. Although this project shares a lot of qualities with presented examples of related work, it stands out by implementing those qualities into web-oriented environment which offers a new platform for various multi-touch and multi-user intended applications, as well as a new and simple access point for end-users.

III. SYSTEM DESIGN

A. *Application structure*

Developed application is implementation of existing web applications into the multi-user framework that supports multi-touch. Multi-user framework gives possibility to run multiple instances of web applications (e.g. educational games) and every user can interact with their instance independently and simultaneously, on the same multi-touch device. Every instance runs in its own separate container. Except the games that are available in the current solution version, developed application is very easy to upgrade by adding new web applications.

The user interface is presented in Figure 1.

Figure 1. User interface

Figure 2 presents the application structure with its key HTML elements mapped with corresponding JavaScript script on which particular HTML element relies on.

Application consists of a toolbar and main container. There are three controls within toolbar: "New game" button for starting a new game, "Settings" button and "Info" button for review of user manual. New instance containers for web applications are instantiated in the main application container. Every instance container has two sub-elements with controls for managing game instance and sub-element in which the game is loaded.

When loading the new instance in the browser window, it is necessary to set initial size of the instance

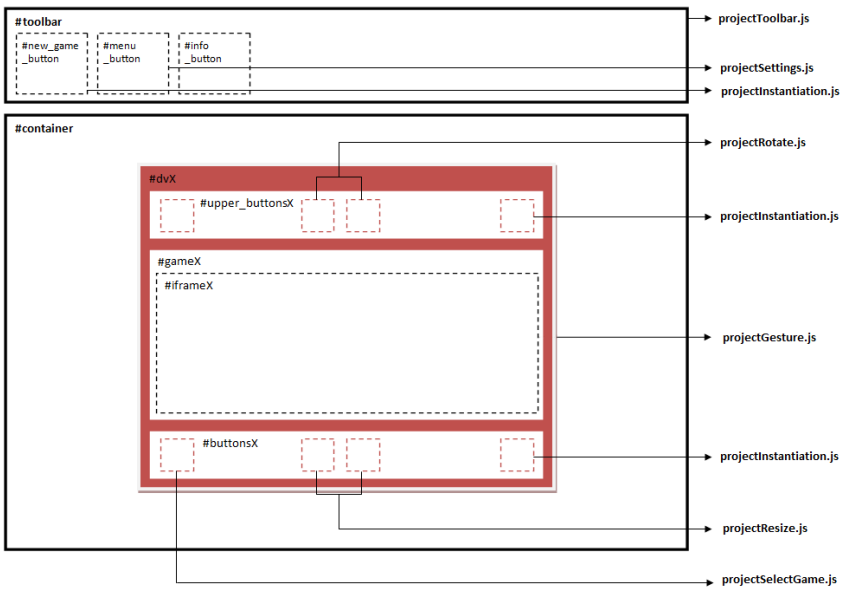

Figure 2. Application structure

and its position in the browser window. Initial size depends on the size of the screen – or more accurate, on the size of the browser window. This enables the scalability of the application on different devices, from mobile phones to large-sized screens. Besides the initial size, there is also the minimal and the maximal size to be set, dependently on the browser window size as well. Every new game is initially positioned in the middle of the screen.

B. *Application controls*

The most important part of the developed application is the user's ability to adapt instance containers according to their preferences by managing size, position, and viewing angle. The main goal was to create the user interface that suits the needs and preferences of users with different psycho-physical qualities, age groups and technology knowledge. Users can adjust instance containers either by well-known multi touch gestures or by using simple button controls. Every instance can be controlled independently and users can combine these two control methods.

By using button controls, as seen in Figure 2, users can change the size of their game instance, up scaling or down scaling the original container by clicking the buttons. Also, there is the ability to reposition (drag) the container anywhere inside the browser window. Finally, users can adapt every container to their viewing angle by changing the angle of the container using the buttons. Every button click rotates the container by 45 degrees in clockwise and counterclockwise directions, respectively.

C. *Multi-touch and multi-user gesture detection*

Another way to manage instance containers is by using multi-touch gestures. As noted in the previous section, there are gesture detection libraries available, but they don't fulfill all the necessary requirements – most importantly, multi-user support. For this reason, during this project, a custom gesture detection algorithm was built. It focuses mainly on detecting one-finger and two-finger gestures (i.e. drag, rotate, and resize). Detection of these gestures is separately and simultaneously available for each instance container.

Implemented algorithm uses a set of low-level web browser events described in [4], a W3C Recommendation. The prerequisite for activating basic touch events is the existence of one or more touch points (e.g. fingers) on multi-touch surface. Algorithm uses data stored in Touch objects, namely the target HTML element and coordinates of touch point within the browser window. Implementation also uses the TouchEvent interface and associated events (i.e. *touchmove* and *touchend*).

Touchmove event is used as the main event for detecting drag and transform (i.e. rotate and resize) gestures over a generic container. When such an event is detected, the algorithm counts the number of touch points over each instance container, and thus determines whether a drag or a transform gesture was performed. If a single touch point was recorded over the instance container, event is processed as a drag gesture, and if two touch points were recorded, it is processed as a transform gesture.

Simultaneously, a list of previous recorded touch points over each instance container is maintained. This enables the calculations necessary for determining the scaling factors and rotation angles that are to be applied on target instance container in case of performing a transform gesture. On the other hand, if a *touchend* event – which signals the release of a touch point, and thus the termination of a multi-touch gesture – is detected, the list of previous recorded touch points for the specific instance container is to be revised. The specific instance which lost a touch point is determined by comparing *touches* and *changedTouches* list provided by the TouchEvent interface.

After the multi-touch gesture is successfully detected and all the necessary parameters are dynamically calculated, same logic is applied as when using button controls.

D. *Implementation*

Web application has been implemented in HTML, CSS and JavaScript. JavaScript code is used primarily for detecting touches and dynamically adjusting CSS of target instances in order to control their shape, size, and position. Having reusability in mind, the functionality of JavaScript library jQuery, which is rich in essential functions on which this application relies on, was used.

IV. CONLUSION

Developed application enables multi-user usage of web applications using multi-touch devices. It is primarily developed for bigger multi-touch devices such as multi-touch tables. Multiple users can simultaneously use different instances of applications on a single multi-touch device.

Solution includes two different applications that users are able to choose from, however the nature of solution enables it to easily add numerous different applications to choose from. Users can use gestures and buttons to manipulate their instance of application. One of the biggest problems that we faced during the development of the application was the lack of libraries for simultaneous multi-user gesture detection.

Further improvements can be made by improving the gesture detection algorithm, namely making it more precise. Also, it is possible to implement an automatic positioning of application instances depending on number of instances that are used. Automatic positioning will automatically calculate the best position for each instance so there will be no need for users to manually manipulate the instances as much.

In the future, application can be used mostly in kindergartens and different educational institutions, since it can offer a fun experience while learning.

Abstract - With the evolution of the internet the loading speed of the web pages has become a vital factor for their success. A few hundred milliseconds difference in the response time are enough for visitors to choose one page instead of its competitors. This paper describes the increasing demand for faster loading webpages and the need of methods for optimization of the web code in order to increase their speed. It describes the process of loading webpages in browser and lists several methods for front-end performance optimization. The understanding of the loading process allows the correct identification of the parts that can be affected and improved. It also helps for understanding the effect of these methods and the cases when they can be applied. Although the total effect of the optimization depends on the specific webpage the appliance of these rules does not only reduce the page loading speed but it also affects the total bandwidth and load of the web server.

Keywords: front-end, optimization, web, performance, speed, optimization methods

1. INTRODUCTION

In the last few years we are witnessing the increasing usage of internet sites and web based applications. They have become an essential part of our lives and daily schedule. Unnoticed by the regular users together with the increased number of websites there is a huge increase of the number of resources used by these webpages. The increased load on the webservers, forces the hosting companies to add new webservers, to handle it, which leads to increased expenses for the business. The increased number of resources not only adds load to the servers hosting the websites and applications but also to the users. In addition to this the loading speed of the websites has become a major factor determining the user experience and one of the criteria used by search engines for positioning in the search results. The loading time and bandwidth for the websites can be decreased by applying different front-end optimization methods. As a side effect these methods decrease the load of the web servers as a result of the decreased bandwidth and number of established connections.

Section two presented the change of webpage size covering a period of 17 years together with the current state of the web pages. The sections analyzes the effect of the constant growth of the page's size on both the server and client side and marks the basic areas that optimization should target.

Section three starts with description of the webpage loading process followed by presentation of several different methods for front-end optimization of web pages with explanation of their target and effect.

Sections four contains the data of an experiment measuring the webpage size and loading time before and after the appliance of optimization methods. It also shows the difference of the server response time before and after the optimization.

2. HISTORY AND CHANGE OF THE WEBPAGE SIZE

History of the web page size

The evolution of the computer technologies in the last few years resulted in rapid increase of the internet connection speed and also the size of the web pages. According to a research published by websiteoptimization.com in November, 2012 the average size of the webpages has more than tripled for the period 2008 - 2012[1].

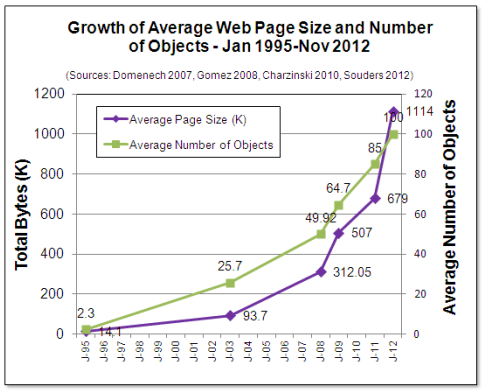

Fig.1 Average webpage size growth 1995 - 2012

As shown on fig.1 together with the growth of the average size there is also a significant growth in the average number of resources per page. From 2.3 up to 100 - this number has increased almost 50 times.

According to HTTP Archive for the period between November 2012 and November 2013 the average webpage size has raised from 1.25MB to 1.7MB, resulting in 40% growth for the last year[2].

Together with the growth of the page size there is also a constant increase of the end user bandwidth. A research made by Jakob Nielsen that covers the period from 1983 to 2013 shows a 50% growth of the connection speed per year[3]. The increase of the connection speed also raises the demand of the customers for faster loading and highly available websites.

The result of page size growth

The growth of the webpages has 2 major effects – on one side it increases the loading time for the end client and on other it increases the load of the server. The second of which is caused by the higher number of resources per page and the increased bandwidth.

For example if the total size of a webpage including its resources is 1.5MB, the total number of concurrent connections that a server can handle is 100 and the average connections speed is 1.5MB/s, which means that for 1 minute the server can serve the page up to 6000 times. This example ignores the fact that modern web browsers can open multiple simultaneous connections to the server to fetch page resources which adds additional load because of the process of establishing and closing connections.

The higher number of concurrent connections and their duration affects directly the total number of clients that the website host can serve. In order to lower the server load and increase the maximum number of users that the server can handle is necessary to either decrease the bandwidth or the number of connections per page.

3. WEBPAGE LOADING PROCESS AND FRONT-END OPTIMIZATION

Webpage loading process

The understanding of the webpage loading process is essential for the understanding of the effect of the front-end optimization methods.

The loading of the website starts by entering an URL in the address bar of the browser or clicking on a link. Then the browser parses the URL and determines the correct protocol, mainly HTTP or HTTPS, the domain, port resource address and request arguments if provided. Once the browser has determined the domain it makes a DNS lookup in order to find the IP address of the server hosting the page. Then a network connection is established between the server and the browser and the browser requests the specified page. The server generates a response and returns it to the browser. The response can be either a static resource or it can be generated by an application.

After the browser has received the response and if it is an HTML document it starts parsing it. In case of incorrect syntax the browser suppresses the error and tries to generate a structure as close as possible to the markup. Then a Document Object Model (DOM) is created. It is a hierarchical structure where every tag and attribute is represented as a separate node. Once the DOM is completely loaded the browser starts to load the additional resources specified in the code – styles, images and scripts.

After the load of each style resource the browser parses it and starts to apply the defined styles to the nodes in the DOM tree. The styles do not amend the DOM tree and as a result the browser can continue loading other resources simultaneously with their processing.

Due to the fact the scripts may cause changes in the DOM tree, during their loading, parsing and execution all other processes are halted. An exception here is the fact that some browsers as Mozilla and Safari continue loading other resources during the execution of the script using separate threads. In this case the DOM manipulations are still placed only in the main thread of the browser. Once the DOM tree is generated and the base resources are loaded and the browser starts rendering the webpage.

The front-end optimization methods primary target the process of page resources loading, their order and the usage of caching techniques.

The effect of front-end optimization

According to Steve Souders' "Performance Golden Rule" average of 80-90% of the user response time, while loading a webpage is spent in the front-end[4]. This time is spent mainly downloading resources and processing them. It is additionally increased by the fact that most browsers pause all other processes while downloading and executing script resources. Based on this fact Souders recommends to the developers to start optimizing the front-end parts of the websites and applications before focusing on back-end optimization[5].

The main goal of the frontend optimization methods is to reduce the loading time by lowering the generated traffic; respectively the time spent downloading resources. Another part of the optimization process is to reduce the number of resources required by the page, again in order to optimize the loading time for the end client. The second main goal is to allow the browser to load the page and its resources progressively and display a rendered page as fast as possible leaving the user with the feeling for quickly loading webpage. Here are described some of these methods and how they affect the loading process and the server performance.

CSS/JavaScript minification – this is the process of removing obsolete characters like blank lines and comments from the code in order to lower its size. The process of minifying JavaScript also includes a code obfuscation that replaces the names of the variables and methods with shorter ones. This process is also known as compression and can combine different scripts or styles into a single resource. As a result not only the size of the resources is lowered but also their number is decreased which leads to lower number of connections opened per page load.

Using Expires and Cache-Control headers – these headers are used to instruct the browsers whether a specific resource can be cached or not. The Cache-Control header was introduced in HTTP/1.1 in order to overload some of the limitations of the Expires header, for example while Expires value is specific date the Cache-Control max-age directive can set a time interval since the request has been served e.g. "X days after the resource has been served". Although the Cache-Control header is actually a replacement of the Expires one, it is recommended to use both of them together in order to ensure compatibility with browsers not supporting HTTP/1.1.

The main benefit of the use of Expires and Cache-Control headers is that once the resource has been cached the browser will make no more requests to fetch it from the server until the resource is considered an expired. This way once the page is loaded and the resources are cached they would not be requested again if the page is reloaded or during navigation inside the website.

Using GZip compression – this method is controversial because on one side it reduces the

bandwidth but on other the process of compressing the resources adds an additional load to the server. However, combining this method with proper caching techniques leads to lower number of requests i.e. lower number of executions of the compression algorithm. This method has good effect on text based resources like HTML documents, styles and scripts but has poor effect on images and other documents. In version 1.1 of the HTTP protocol the capabilities of the Accept-Encoding header are have been extended in order to allow the browsers to send additional data to the web servers regarding the supported compression methods and their preference order.

Using a Content Delivery Network – with this method the task of serving static resources is delegated to different network of servers. The Content Delivery Network (CDN) is a large geographically distributed network of servers aimed to serve content to end-users with high speed and availability. The distribution is made in order to serve the user request from the closest and fastest location. Such networks are widely used in the modern web sites to serve static content, downloadable resources, media and other.

In the CDN networks the servers are split into two groups – edge and origin servers. The end-user communicates with the edge servers and asks them for the needed resources. If the edge server does not possess the required resource it makes a request to an origin server for it. Once the resource is retrieved from the origin server the edge serves it to the user and also stores a copy of it for future uses. This way the end-users can retrieve the static resources of the webpages much faster because of the closer location of the server.

When using a CDN the application server should handle only the request to dynamic pages, e.g. those for which data calculating and preparation is required. In this case, the server hosting the application should not static resources.

Using only external JavaScript and CSS files is another method that can reduce the traffic generated to load the page. If measured directly, loading a page with internal JavaScript and CSS files is faster than using external ones, which is caused by the reduced number of requests.

However this way the end-user cannot benefit from the caching capabilities of the browser because the styles and scripts will be served as part of the HTML code for each page. This way, the traffic generated when navigating inside the website is increased and so is the loading time of the webpages. Vice versa putting all scripts and styles into external resources allows the browser to cache them and this way reduce the traffic and loading time for the page.

All methods presented this far are related to the bandwidth and number of requests made in order to completely load a webpage. The following methods affect the process of progressive loading of the page and the moment when the browser starts rendering the content.

Placing the styles at the top of the page – this way the styles are among the first resources that the browser starts to load after the HTML document has been processed. As a result the declared styles are applied to the DOM tree before the loading and execution of other resources and the browser can start rendering the webpage while waiting for other resources to be loaded. This is the reason why the style tags should be placed as higher as possible in the "head" section of the HTML document.

Placing the styles at the bottom of the page is another method for speeding up the loading of resource and progressive rendering. As described above during the loading and execution of the script resources the browsers halt all other processes. This also affects parallel downloads. Although browsers can download multiple resources simultaneously, most of them stop the downloading process when executing scripts, even if the resources are coming from different hosts. To avoid this blockage the script tags should be placed at the bottom of the page, usually before the closing body-tag.

Removing the duplicate scripts is another essential part of the front-end optimization. Having duplicate scripts has two major drawbacks. First of them is the increased loading time as a result of the repeated parsing and execution of the script. The second drawback is caused by the fact that frequently duplicate scripts lead to unexpected behavior in the front-end and may also lead to errors breaking the whole page.

In modern website quite often some visual elements like images, menus or even sidebars are removed when displaying the page in mobile devices. These changes are focused in two directions – lowering the bandwidth and the loading time due to the lower number of resources to load and also providing better experience for users by better utilization of the smaller screen. However such techniques are usually part of the design and user experience so they are only mentioned in this paper without being described thoroughly.

4. MEASURING THE EFFECT

The total effect of these optimization methods strongly depends on the specifics of the web page – the number of resources that can be cached and that are reused between the different pages of the site, the percent of bouncing users i.e. the ones that visit only a single page and then leave the website and others. However, testing a sample HTML template can show the general effect of the frontend optimization on both the server and the client.

In this case the following optimization methods are applied:

- CSS/JavaScript minification and compression
- Use of Expires and Cache-control headers
- Use of only external styles and scripts
- Placing styles at the top
- Placing scripts at the bottom

As shown on table 1 after the optimization the size of the webpage is reduced by 13.5% for initial load and up to 99.7% while reloading. The cause of the small reduce of the initial size of the pages is the heavy usage of images that represent a significant part of the webpage size and cannot be compressed.

The much lower traffic when reloading the page is due to the heavy use of caching for the resources on the webpage. In this case all resources except the HTML page are cached, and the page itself is served after GZip compression.

TABLE I. FRONT END OPTIMIZATION EFFECT

	First Load		**Reload**	
	Size(KB)	***Loading time(s)***	***Size (KB)***	***Loading time(s)***
Before	790.5	1.82	790.5	1.82
After	683.5	1.28	1.1	1.24
Difference (%)	13,5	29,7	99,7	31,9

The loading time of the page is reduced by 29.7% for the initial load and by 31.9% for the consecutive ones. This decrease shows the effect of the reduced size of the page and mainly the reduced number of requests made for loading external resources. The small difference in the loading time between the initial and the consecutive load results from the fact that the major part of the loading time of the page is spent while processing and executing scripts and not downloading resources.

The response time of the webserver before and after the optimization can be easily measured with the Apache JMeter tool. The test settings used for the test are as follows:

- Test duration: 600 seconds
- Number of threads: 50
- Ramp-up period: 50 seconds

The number of threads means the total number of concurrent users of the webpage and the ramp-up period is the time for starting all threads. The usage of the ramp-up period is for avoiding the extreme load of the webserver at the beginning of the test.

The test case is also set to imitate browser behavior i.e. to use the caching mechanisms used by the browsers and to reuse the connections with "keep-alive". The results of the test are shown in table 2.

TABLE II. SERVER RESPONSE TIME

	Number of samples	Response time (ms)		
		Average	*Minimal*	*Maximal*
1	10041	33	9	10091
2	10049	0	0	159

Row 1 of the table shows the data for the page before optimization and row 2 after the optimization process. The 0 values for the response time after the optimization are result of using caching techniques for the static resources. This way only the main page is loaded on consecutive loads and the time for its retrieval from the server is close to zero due to the fact that the testing tool and the server reside on the same machine.

In production environments, users are rarely in the same network with the hosting servers, so the time required to download the HTML page will increase, but still it will be much lower if the static resources are cached.

Although for sites and applications in production caching all of the static resources required by the webpages is not always possible the test results still show a valid example of the effect of the optimization. The much lower response time is a strong indicator of the reduced server load and proves the two-side effect of the front end optimization.

5. CONCLUSION

Undoubtedly in the last two decades the web has evolved from a small system for information exchange between scientists to a network connecting billion of users. In the context of this evolution the loading speed of the web pages has become a major factor for the success of websites and applications.

The methods presented in this paper cover the basic and most effective steps for front-end optimization. Their effect is mostly based on the reduced traffic as a result of the usage of compression and resource caching.

As stated above caching all resources is rarely possible but still a major improvement of the bandwidth when navigating between the pages of the website. This, combined with the correct placement of styles and scripts, allows the browser to start rendering the page earlier than for non-optimized pages, giving the user a faster response and progressive loading which improves the user experience and the satisfaction from the usage of the site. In addition to the effect on the browser the server load is reduced due to the lower number of connections and traffic.

The wide usage of mobile devices not only opens additional opportunities for bandwidth and loading speed optimization but also requires it due to the lower connection speed and more expensive bandwidth for mobile traffic.

To summarize these methods improve both the response time of the webpage and the loading speed and also reduce the web server load. Having in mind the fact that the number of internet users is constantly increasing applying these techniques will allow website owners to serve more users without changes of the existing hosting equipment.

The reduced number of requests lowers the load of the server processors so the main load remains on the storage. The reduced expenses for bandwidth and processing power can be invested in faster storage – SSD disks and/or more RAM for even faster resource delivery.

Finally, on the business side this improvement means lowering the expenses for servers and bandwidth, or keeping them the same while increasing the number of users. Even in the case of using a CDN which may add an additional cost to the expenses, the result of increased user satisfaction, respectively conversion rates will diminish the increased expenses.

We are yet to see the new opportunities for optimization that technologies as SPDY[6] and the second version of the HTTP protocol – HTTP 2.0[7] will provide in the area of webpage optimization but the path is clearly set. The effort is focused in the creation of better transport protocols, providing lower latency, better compression and reduced page load time.

Comparative analysis of Google and Bing SEO on leading Croatian News portals

Ivan Britvić, Jurica Đurić, Dalibor Bužić
Visoka škola za informacijske tehnologije, Klaićeva 7, Zagreb, Croatia
ivan.britvic@vsite.hr, jurica.duric@vsite.hr, dalibor.buzic@vsite.hr

Search engine optimization is a important task in professional web site design. Google dominates the search engine market but there are others, namely Bing, Yahoo, etc. How well are web sites optimized for other search engines and is it worth a trouble? What are the main differences between search engine algorithms?

This research paper tend to answer these questions by comparing Google and Bing. Research includes example study of Croatian news portals, analyzing their SEO parameters and results they get on a Google and its primary contender, Microsoft Bing.

I. INTRODUCTION

Enormous quantity of content on World Wide Web is not well organized. A web search engine is complex software which enables user to easily find required information on Web. Search engine basically acts as answering machine. Delivering relevant results to user's query is it's critical success factor – user who found information with one search engine will most likely use it again.

Search engines like Google, Bing, Yandex, etc. have developed different algorithms to rank results and present them to a user. Ranking algorithms are business secret, so knowledge about them are in fact assumptions based on literature. Google algorithm is complex, and it includes more than 200 elements which influence on relevance (and consequently position in result) of web pages which content is closest to user's queries [1]. First position on Google's search engine result pages (SERP) brings 32,5% while second position brings 17,6% of all clicks from SERP [1][2]. That means, if 40.000 queries in Croatia for term 'sport' are submitted in one month, first ranked result could receive about 13.000 of all clicks from users. So, natural tendency for website content publishers is to have their web page as higher as possible on SERP. Better positioning means more visitors to their website.

Based upon [3][4][5], search engine optimization (SEO) can be considered as continuous process which helps web pages to be better positioned on SERP. One class of SEO techniques can be applied directly on particular web page (so it is called on-page SEO). The second class is performed out of web page (it is called off-page SEO). But first of all, it is necessary to emphasize high importance of quality web page content. Quality content means unique, informative and/or interesting content from visitor's perspective. According to [6][7][8][9] quality content could hold visitor for longer time on website, and sometimes user will share that content with his friends on social networks – and that is exactly a part of off-page SEO. Part of off-page optimization can be made by user – with no cost. On the other hand, poor content can decrease visitor's interest, so he can leave from website quickly.. Search engines learn from user experience, and if many visitors leave website from first page they entered within short time period, that page could fall down on SERP. Creating better content decreases efforts in SEO. If more publishers create equally good content, better SEO could help in better positioning.

II. SEO PHASES

Based upon [10][11][12][13] four main phases in SEO process can be differentiated: search term analysis, on-page SEO, off-page SEO and, finally, measuring results. If measuring results shows weak success, returning to previous phases with redefined tactics is necessary.

A. Search term analysis

Starting point in SEO is developing search terms strategy. Search term is word (or words) which user types into search box. Special online services known as keyword tools help analyst to find out appropriate synonyms, variations and phrases for specific keyword. Some of them provide search volume estimation on monthly basis. Important part of analysis is competitor identification. Trying to get top ranking with one generic single-word term can be unreachable goal for new website if many established competitors exists. With terms compound of two, three or even four words it can be easier to get in top ten ranking in SERP (having in mind that longer search terms have smaller search volume).

B. On-page SEO

Some of most important on-page optimization elements are [4][5][11]: title and description tags, headings, link structure, keywords density and consistency. Results of search term analysis (in further text: keywords) will be applied in on-page elements. Title tag is web page descriptor which is, besides in browser, shown to user in SERP. It is desirable to create eye-catching, not too long (up to 80 characters) title tag which contains exact match or variation of user's query. Meta description tag often (but not always) shows up in SERP, so effort to create concise description on page content can be rewarded by gaining more visitors. HTML header tags contribute to readability of longer text. Using clean URLs (URLs easily read by humans, not containing query strings or parameters) makes search engine easier to crawl pages on website. URL containing important keywords is descriptive to user who can see it in SERP and in shared content on social networks.

Preferred keywords should appear in title, headings, description, URL and, of course, in page content. Myth is that keywords need to be an exact match, or there is an ideal keyword density in page. It just should be used in a reasonably manner [14]. High keyword density could have negative impact on ranking.

Page load time is also one of important on-page SEO element which influences on user experience. Smaller load time is better, and can be achieved by using caching method, gzip compression, minifying CSS, HTML and JavaScript, prioritizing visible content etc.

C. *Off-page SEO*

Search engines count link to a page from another website as vote for that page [3]. More external links (or backlinks) does not automatically mean better ranking. Key is value of backlink. Search engines have ways to determine values of links. Backlinks from reliable or popular sites have greater value [6]. More value for sport page has link from sport shoes related website than from jewellery related website. Search engines prefer links from more authoritative and trusting sites because such links are harder to get.

Recently anchor text (visible text in hyperlink) was highly appreciated by search engines, but now things have changed [15].SEO masters used same anchor texts excessively in links from other websites, but it was indicator to search engine that such links could be made by professionals [16]. There is an opinion in SEO community that search engines now like more imperfectly structured links (variations in anchor text, using 'click here' in anchor text, links without anchor text) [17]. That could mean non-professional user put link to web page, and such user usually does not know anything about anchor text. Mix of two above mentioned types of inbound links is considered as the best for SEO at this moment [18].

Social media links are unavoidable part of off-page SEO. Social media activity helps search engines to determine page relevancy. Higher social network activity increases authority of website and it also directly brings visitors to website.

D. *Measuring results*

Performance measurement activities are necessary in efficient SEO. Keyword rank monitoring, traffic tracking, link tracking and cost of SEO (time and money) are inputs for adaptation, improvement and planning a new SEO cycle.

III. BING VS. GOOGLE SEO

Search engines publish guidelines to webmasters for optimizing web pages. Some of general Bing recommendations are [19]:

- clear, deep, easy to find, rich and engaging content which provides visitors information they need
- inbound links as signal of popularity
- social sharing as impact on organical rank (unpaid position on SERP)
- technical part such as using sitemaps, robots.txt files, fast page load time, redirects and canonical tags
- using title, description and header tags

Some of Google guidelines are [20]:

- create useful, information-rich site with clear hierarchy and text links
- include words users would type to find a page in page content
- create pages primarily for users, not for search engines
- use sitemaps, robots.txt, optimize load times
- reasonable number of links on a page

Search engines emphasize avoiding techniques which try to deceive users and search engine (known as black hat SEO) such as:

- cloaking (showing one content to search engine and another content to visitor),
- link buying, link spamming, participating in link schemas
- duplicate content
- meta refresh redirects
- automatically generated content
- hidden text and links
- sending automated queries to search engine.

Differences between Google and Bing SEO ranking factors which make search engines unique are not easy to determine. Comparing various resources on Web, some findings however can be obtained [21][22][23] as shown in Table 1.

Table 1. Differences between Bing and Google SEO ranking factors

	Bing	Google
Caching	caches first 100 KB of most pages	has no problem with larger pages
Indexing	discards pages with no ranking authority	indexes every file
Keywords in title	heavier emphasize on keywords, doesn't consider position of keyword in the title of page	lighter emphasize on keywords, considers keyword in the title of page as ranking factor
Natural links	less emphasize	more emphasize
Flash	more friendly	less friendly
Fresh content	less important	more important
Exact matching keywords	necessary	not necessary thanks to better understanding of synonyms
Domain age	more important	less important

Google is dominant search engine. According to [24] Google is used by 97.49%, Bing by 0.95% and Yahoo by 0.48% users in Croatia in 2013. Most of Croatian SEO efforts are aimed toward Google. But Bing US market share is 18.2% [25]. Since US market determines worldwide trends it is clear that Bing is not irrelevant.

IV. SEO ANALYSIS

In order to determine how are Croatian sites optimized for search engines and what results they achieve on two major search engines we selected five leading news portals in Croatia: www.index.hr, www.jutarnji.hr, www.vecernji.hr, www.net.hr and www.tportal.hr. List is kept only five sites short in order not to lose focus by analysing too much similar sites. Criteria for selection was site popularity, but also a differences in site designs and SEO approach. News portals are selected because they should rank rather high in search results in Croatian language.

Basic SEO parameters that are taken in account are: Woorank grade, Google PageRank, number of indexed pages, backlinks, Facebook likes, Twitter backlinks and load time. Tools used in all analysis are Woorank and Webrank.

A. *Woorank grade*

Woorank grade is dynamic grade on a 100 point scale that represents internet marketing effectiveness at given time. Many parameters are considered in Woorank grade, so it's a relevant global grade for SEO.

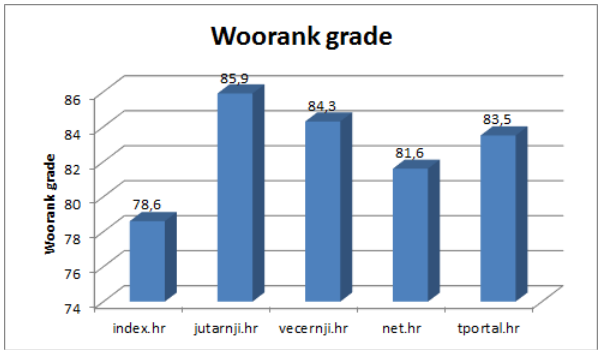

Figure 1. Woorank grade

Jutarnji.hr had the highest score and index.hr the lowest, but that grade is dynamic so results may vary in future.

B. *Google PageRank*

PageRank is an algorithm used by Google Search to rank the relevance of websites in their search engine results. According to Google: PageRank works by counting the number and quality of links to a page to determine a rough estimate of how important the website is. The underlying assumption is that more important websites are likely to receive more links from other websites [26]. PageRank goes from 1 to 10, 1 is the worst and 10 is the best PageRank.

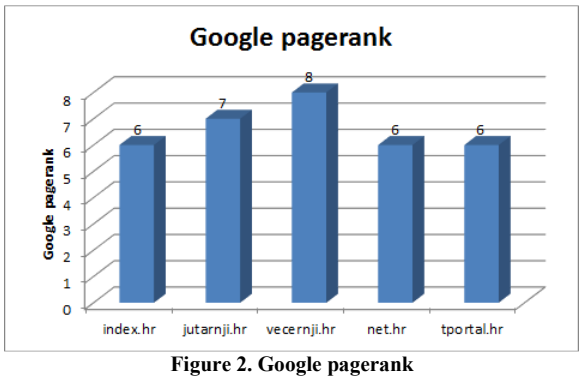

Figure 2. Google pagerank

The highest PageRank has vecernji.hr, followed by jutarnji.hr, remaining three news portals are equally leveled.

C. *Indexed pages*

Every search engine has its crawler engine that scans all web pages on single site and index them. Number of pages changes regularly, but it is very important factor in search engines ranking. Generally more is better. Here are the results for our portals:

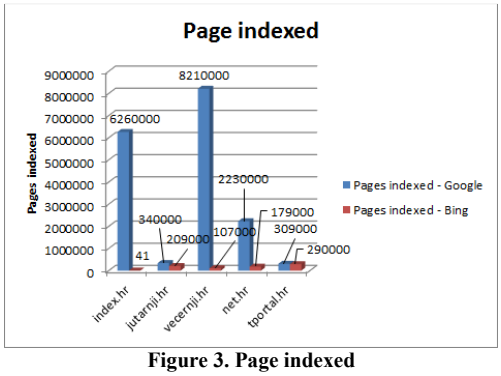

Figure 3. Page indexed

D. *Backlinks*

Backlinks, also known as incoming links, inbound links, inlinks and inward links, are incoming links to a website or web page. In basic link terminology, a backlink is any link received by a web node (web page, directory, website, or top level domain) from another web node [27].

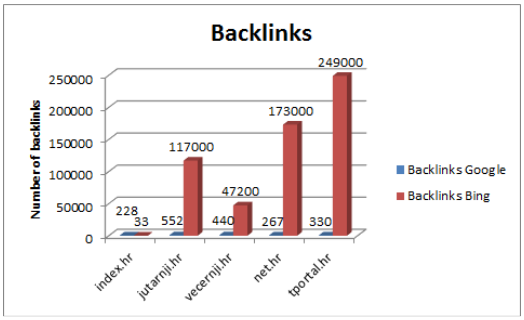

Figure 4. Backlinks

There is noticeable difference, Google has far less backlinks then Bing. It is consequence of very strict polices of Google to remove all links that are considered unimportant. This way Google ignores all marginal or

fraudulent links. Bing is at this point less advanced and can be easily misled by fake links.

E. Social

Social networks mentioning (likes, shares, etc.) have a huge influence in SEO. Two major social networks Facebook and Twitter are considered in this analysis.

I. Facebook

Importance of Facebook in todays web cannot be overstated. But here Bing has advantage, as Facebook data is pretty much inaccessible for Google which is one of the greatest problems that Google faces in order to keep market dominance. Here are the Facebook likes for our sites:

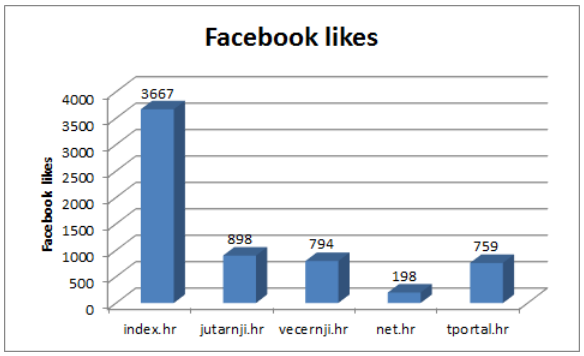

Figure 5. Facebook likes

It is clear that index.hr dominates in this segment which is clear indication of better integration of this site with social media sites.

II. Twitter

Twitter data are accessible as paid service to both of search engines and is considered as important factor in search results.

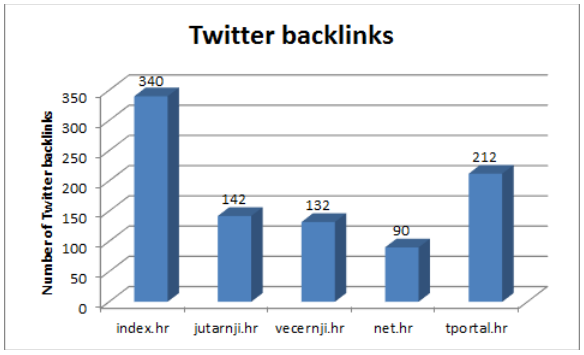

Figure 6. Twitter backlinks

Twitter backlinks are evenly distributed but index.hr has slight lead even here.

F. Load time

Load time describes amount of time needed to present requested page to the end user. Higher load times often indicate not just more multimedia content but poorly designed sites. Naturally, sites that have inadequate structure, unclean design and HTML and JavaScript errors score noticeable lower in search results. It is general opinion that Google put much more accent on this parameter.

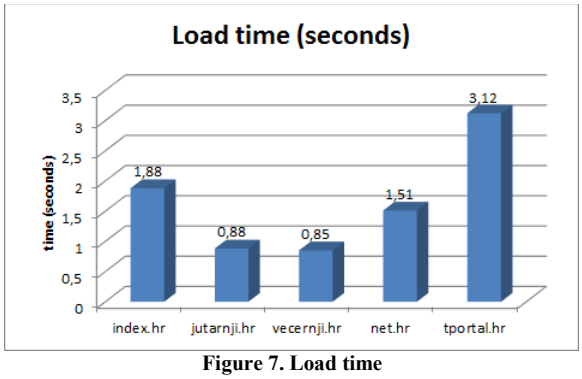

Figure 7. Load time

Tportal.hr has highest load time which should indirectly result in worse search rankings.

V. Search Engine Results Analysis

Search results ranking for selected news portals is tested for typical daily news search phrases in Croatian. Having in mind sites relevance, they all should rank rather high in observed searches, definitely in top one hundred. However, this wasn't always the case in performed analysis. Also there are sometimes significant differences in Google and Bing rankings. Achieved results are shown in following table (0 indicates site is not listed in top hundred results):

Table 2. Search phrase analysis

Search Phrase	index.hr		vecernji.hr		jutarnji.hr		net.hr		tportal.hr	
	Google	Bing	Google	Bing	Google	Bing	Google	Bing	Google	Bing
novosti	92	0	77	0	5	7	0	86	0	0
vijesti	1	8	4	51	2	10	7	46	8	76
najnovije vijesti	1	1	3	7	4	12	6	9	34	59
vijesti iz hrvatske	1	3	6	4	2	2	4	17	9	0
novosti iz inozemstva	75	0	9	20	4	45	0	18	85	0
hrvatska	18	41	37	0	0	0	47	0	12	51
svijet	8	0	3	2	4	8	25	32	6	51
sportski rezultati	53	0	0	0	15	0	2	8	50	0
vremenska prognoza	21	95	23	0	17	0	23	32	19	83
ljepota i zdravlje	2	33	57	0	42	0	16	18	0	0
dnevni horoskop	0	0	11	36	5	10	6	57	2	43

VI. CONCLUSION

Presented results clearly show that targeted sites usually rank lower than they should in search results. Search term "novosti" is common also for Serbian, Bosnian and similar languages so ranking here is a bit lower but still, "not in first 100", is not acceptable result for any of selected sites. One factor, not initially considered, emerged as truly important: clean URL's (uniform resource locators) [26]. Well defined URL's that include search phrase words were ranked high, even when they

originated for not so relevant sites. Also, in search results from Table 2, URL structure that didn't comply to the clean URL standards resulted in lower rankings.

When we compare Google and Bing results, it is clear that selected sites are usually ranked far worse on Bing. This is partially proof of superiority of Google search engine but also a strong indicator that sites didn't took Bing in consideration, maybe even didn't created XML site maps for Bing. It should be possible to greatly improve search results with dedicated Bing SEO effort. Having in mind recent iOS Bing integration, it is clear that although Bing is distant second in market share, it cannot simply be ignored in SEO process. Generally, Bing SEO should bring more visitors and enhance profitability for specific news sites.

Altogether, we can assess that SEO is done only partially on selected sites and have potential of further improvement. At this point, all observed sites are losing potential visitors due to unsolved SEO issues. There is definitely potential for improvement in SEO process for researched Croatian news portals.

***Abstract*—IPTV is an essential new technology in ICT, which changes the perspective of the way end users consume TV services, but also serves as a platform for new ideas and concepts in other areas, such as medicine, science and industry. It is considered as a technology that brings significant contribution in different scientific areas, as well as medicine and industry, besides the development of information and communication technology itself. This paper gives an overview of recent state of the art research and technology development, appropriate architectures, design issues, upgrades and hot topic features. The analysis of recent relevant IPTV research papers and the comparison of the novelties they bring to the IPTV technology itself has led to the conclusion about the existence of three main approaches to state of the art IPTV research: IPTV Channel Control and Management, P2P IPTV systems and Technology Assisted Living. These approaches are further observed and discussed as an attempt to prove the importance of IPTV as a technology.**

***Index Terms*—IPTV; Full-duplex EAS; P2P TV; UMB Smart-TV**

I. Introduction

The ubiquitous growth of broadband Internet connections, characterized with enhanced data transmission rates and minimized overall losses, arises many different opportunities for exploiting the advantages of the IPTV technology. Since the future in ICT largely relies on the advancement of IPTV, its overall quality must be significantly improved. Thus, numerous researches are being undertaken in order to discover the ways in which IPTV can be enhanced not only as a technology, but also as a service platform used in different areas (economy, politics, industry etc.). The motivation for this paper is identifying and classifying the opportunities for improving the IPTV technology so that human society can take a step forward and fully benefit from this essential service platform.

Mainly, this paper elaborates on the existence of three different approaches to IPTV technology research: system and technology functionality upgrade (contextualized IPTV monitoring, IPTV channel control algorithm, reducing energy consumption in IPTV networks, IPTV channel control algorithm, reducing channel zapping time by creating adjacent multicast groups, the mesh-pull P2P streaming approach), performance analysis (Measuring Bit-torrent and large-scale P2P IPTV systems) and creating or improving technology-assisted living (Full-duplex emergency IPTV alert system, An IPTV platform for Integrating Multimodal Technologies, IPTV in health telemonitoring as well as education).

In Section II we explain the definition of IPTV as a term, the most popular interactive IPTV applications, as well as an overview of IPTV system architecture. An overview of recent related research papers is given in Section III. We believe that they represent state of the art exploitation of IPTV as a technology. Section IV explains the differences between some of today's most popular STB implementations. Finally, the discussion and conclusions presented in Section V will elaborate on future intentions and trends in the explained area of interest.

II. Background

A. Defining IPTV

According to O' Driscoll [1], IPTV is a technology that aims at securely delivering high quality broadcast television and/or on-demand video and audio content over a broadband network. Being based on the Internet Protocol, IPTV has a number of features which include:

- *Support for interactive TV*. The two-way capabilities of IPTV systems allow service providers to deliver interactive TV applications (standard live TV, HDTV, interactive games, high speed Internet browsing).
- *Time shifting*. A mechanism for recording and storing IPTV content for later viewing, along with a digital video recorder
- *Personalization*. The bidirectional communications with the IPTV system allow users to decide what they want to watch and when they want to watch it.
- *Low bandwidth requirements*. Service providers only stream the channel that the end user has requested instead of delivering every channel to every end user, thus conserving more bandwidth.
- *Accessible on multiple devices*. Consumers can use not only televisions, but also their PCs and mobile devices to access the IPTV content.

It is also important to state that IPTV and Internet TV differ in terms of their approaches in delivering IP based video, even though they share the same core base of technologies. Their main differences are shown in Table I [1].

B. Interactive IPTV applications

Although the key IPTV services are broadcast digital TV and Video on Demand (VoD), IP based technologies also allow service providers to offer a range of advanced interactive TV (iTV) applications. O' Driscoll [1] states that iTV changes

TABLE I: Differences between Internet TV and IPTV [1]

Features	Internet TV	IPTV
Platform for delivering video services	Leveraging the public Internet	Secure dedicated private networks managed by the SP
Geographical reach	No geographical limitations	Located in fixed areas
Network infrastructure ownership	QoS is not guarantied	QoS is guarantied
Access medium	STB device	PC
Costs	Mainly free	monthly subscription
Content generation methodologies	User generated content	Traditional shows and movies

the TV set from being the source of one-way, passive entertainment to two-way active entertainment, infotainment and communication. iTV applications can be embedded, network centric or server centric. These applications are listed as follows.

By bringing web-like interactivity to the traditional TV viewing experience, IPTV allows the end users to view hundreds of channels, simultaneously record TV material and access a range of interactive TV services by offering at least the following interactive IPTV applications:

- *EPG*. The Electronic Program Guide informs the subscribers about the available program channels. Subscribers can also personalize their EPGs to meet their own needs.
- *On-demand video content*. Subscribers access video content on their own schedule by using their IPTVCD.
- *IPTV browsing*. The IPTV STB browser adjusts existing Web pages for presentation on a TV.
- *IPTV e-mail*. Subscribers access their e-mail accounts by using an advanced digital IPTVCD with a keyboard.
- *Digital video recording*. Recording and storage of video content, made possible by adding a hard diet to the IPTVCD.
- *Walled garden portal*. Emulating a Web portal, whose interface is branded with the logo of the IPTV host.
- *Instant IPTV messaging*. Integration of IM with a number of commercially available IPTV networking platforms.
- *IPTV commerce*. Delivery of electronic commerce applications on a TV.
- *On-screen caller ID*. A combination of video content and telephony services.
- *Targeted interactive TV advertising*. Advertisers as well as service providers generate additional revenue by inserting adverts into their IP based video channels.
- *Gaming on demand*. A result of the combination of the TV medium and the two- way capabilities of broadband.
- *Parental control*. Parents managing the type of content viewed by their children.
- *IP based emergency alert systems*. Notifying residents of emergency situations (severe weather storms and terrorist attacks). A proposed system for emergency alerts [2] will be explained in the next section.
- *IPTV program related interaction*. Presentation of additional information on the screen while the viewer is watching the video content.

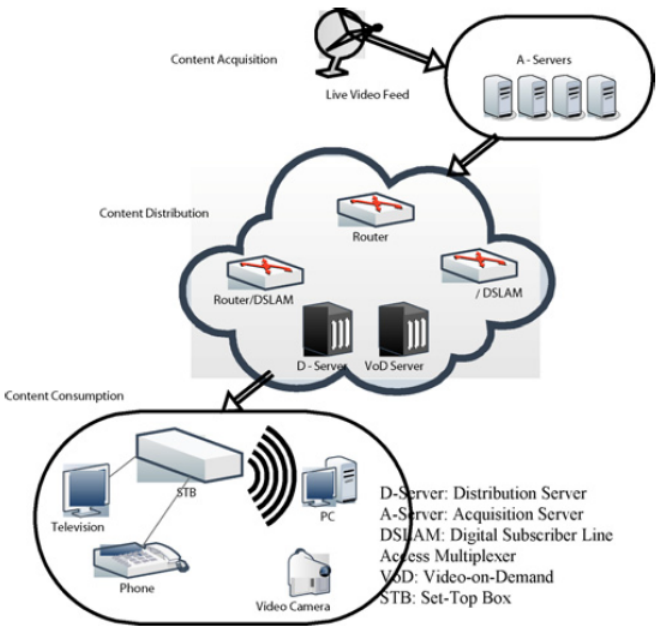

Fig. 1: A basic IPTV system [3]

C. IPTV Architecture

Leaving any technological differences aside, a typical IPTV infrastructure is comprised of three conceptual domains: content acquisition, content distribution, and content consumption [3], as shown in Fig 1.

The comprising entities of each domain are explained as follows.

- Acquisition servers (A-servers): They encode video and add DRM metadata.
- Distribution servers (D-servers): They provide caching and QoS control.
- VoD creators and servers: They retain a library of encoded VoD content to provide VoD services.
- IP routers: They route IP packets and provide fast reroute in case of routing failures.
- Residential gateways: IP routers for bundled services at home.
- STBs: A STB is a device on the customer side that interfaces with the user terminal (e.g., TV, PC, laptop, and others) with a DSL or cable wiring. [3]. As technology evolves, this device has become more than just a means for the typical user to receive their IPTV provider's predefined subscription content. That is, major ICT companies have created their own STB products with many advantages over the 'standard' ones. The following

section gives a list of some of today's hottest STB brands. Furthermore, [4] discusses the option of delivering IPTV services in the absence of an STB device.

III. Overview of Research Topics

In this section we will present an overview of recent research papers which aim at fully exploitation of the IPTV potential in various domains or at improving its quality as a service.

A. Optimizing the bandwidth

Optimizing the channel bandwidth, improving the QoS/QoE as well as energy savings are the goals of IPTV channel control. Some research on this topic will be presented as follows. An effective channel control algorithm is described in [5]. This research paper focuses on effectively designing the IPTV service system in terms of optimal management of the channels' bandwidth [5]. Joo et al. state that despite the STB device immediately displaying the selected channel, it still receives all of the channels regardless of whether they are used or not. However, due to the lack of bandwidth, the IPTV service cannot transmit all the channels at the same time.

Furthermore, the channel zapping time term as an essential parameter [5]. Channel zapping time is defined as the time difference (i.e. delay) between the moment a channel becomes available at the STB, and the one when the user watches the display of that selected channel on their IPTV watching device. This occurrence exists due to the computational overhead at the router when the number of broadcasting channels increases as a result of the IP multicast technology which is used to reduce the duplicate data transmission over the network. Thus, the proposed algorithm concurrently considers both the broadcasting channel distribution state, as well as the video encoding structure as control variables to effectively guarantee channel zapping time.

The same goal is being achieved in [6]. In this research, Cho et al. intend to improve the channel zapping time by making adjacent multicast groups of a current channel come to the home gateway in advance. Therefore, multicast streams for the adjacent channels of the one that is currently watched are always available to the home gateway. When the STB requests join to an adjacent channel, the home gateway can forward the corresponding multicast stream immediately, thus reducing the channel zapping time.

The similar goal of optimizing the channel bandwidth is being achieved with the OptiBand FP7 project [7] which we have previously observed in [8]. These two researches differ in the part of the IPTV network which they intend to improve. [7] focuses on improving the the access line rates (predominately ADSL) for the delivery of multiple HD streams over a single ADSL line, and by that enabling multiple HD channels per household, while [5] aims at effectively guaranteeing channel zapping time by an algorithm that takes both broadcasting channels' distribution state as well as the video encoding structure.

Despite bandwidth savings, according to Ramos et al. reducing the energy consumption can be done by a dynamic power consumption model scheme that pre-joins only a selection of TV channels instead of multicasting all TV channels at all times to everywhere, also aimed at achieving a very small number of TV channel switching requests. As stated above, the final result is comprised of bandwidth, energy and cost savings [9].

Finally, we will mention the opportunity for contextualized IPTV monitoring executed by the design of a scalable system for monitoring the state of an IPTV network, which will not only capture and analyze network traffic at key network points, but also provide granularity associated with hundreds of subscribers [10].

The presented solution [10] is a loosely coupled system with a server side and a large number of dedicated software agents running on distributed IPTV STBs across the IPTV network. The server side is responsible for receiving, storing and processing messages in real time, while each IPTV STB acts as an IPTV quality sensor node by capturing quality and telemetry related data, which then sends to the server side of the system.

B. P2P systems

One of the ways of effective bandwidth usage and providing an IPTV service with service guarantees, aimed towards the users' Quality-of-Experience (QoE) is by implementing the P2P (peer-to-peer) method of content delivery. This helps the Internet backbone and access networks which are constantly being overwhelmed by the ever-increasing IPTV video traffic. Also, according to Hei et al. [11], the most successful IPTV deployments have employed mesh-pull P2P streaming architectures. A lot of research exists about the structure and measurements of IPTV P2P systems.

[12] explains the mesh-pull P2P streaming approach. Hei et al. state that the operation of the mesh-pull system rely on the bandwidth contribution from each peer, even though they may have different upload capacity due to different types of access links. Furthermore, [11] was aimed towards developing a large-scale P2P IPTV system. The global view of user behaviors includes modifying the peer tracking methodology, which was followed by investigating the evolution of participating users, as well as the connections and traffic characteristics. The final results were achieving shorter star-up delay, higher rate streaming, smaller peer lags and better NAT traversal [11].

On the other hand, Biernacki [13] describes the implementation of an OMNeT++ based P2P TV simulation which enables to observe how the internal structure and the rules describing the interactions between the comprising elements influence the macroscopic behavior of the system. The goal is creating a common simulation framework for rapid P2P TV systems. Typically, the four main components are: a source (broadcaster), peers, superpeers and a tracker. The results describe how the upload to download ratio, the number of maximum allowed connections, and the number of sources and super- peers' influence on the system performance [13].

Similarly, as we discussed in [8], the NAPA-WINE project [14] aims at providing suggestions for P2P developments and Internet providers regarding the design of systems that minimize the impact on the underlying transport network, and the cost actions that can be taken in order to better exploit the network bandwidth This was achieved by creating a software library with the studied algorithms, as well as releasing a P2P-TV application.

Furthermore, one way to reduce startup delays which occur in channel switchings due to bandwidth limitations and the employment of buffers and overlay structures in today's P2P IPTV systems is shown in [15]. Manzato et al. propose four novel schemes for providing fast channel switching that reduce the occurrence of latency: Linear, Fast, Slow and Immediate schemes. The idea behind the proposed schemes is that users do not need to receive streams in full quality to verify the content being broadcast on a channel, instead they can receive streams at their minimum quality in order to do so [15].

C. IPTV and Internet TV in Technology-Assisted Living

As we already mentioned, IPTV as a technology provides endless opportunities for implementing different technology-assisted living systems. We will discuss this opportunity as follows.

Thang et al. [2] explore the possibility of using IPTV in the users' homes for disaster scenarios. The focus of their research is a two-way emergency alert system (EAS) with very high availability. The main goal of the system is to maintain a high availability of service, which can be achieved by applying the following solutions: redundancy of devices, multiple means of alert notification, as well as scalability and prioritization of data. The architecture of the system contains four conceptual parts- gateways, in-house gateways, outside networks and a database [2].

Mlakar et al. [16] present UMB-SmartTV, a novel platform that combines traditional IPTV services with multimodal-based non-IPTV services (automatic speech synthesis, speech recognition ambience control). It is important to note that any service within IPTV in this platform can be operated by using speech. The core of this platform is IMS, which is combined with a distributed DATA architecture in order to merge IPTV services and other non-IPTV services into a novel and highly modular solution. The first block, named Content core, represents an application server for content production and presentation. The second block is named IMS core. In the context of IPTV system, IMS represents multimedia service platform architecture. The third block is named Multimodal services. It actually represents the novel contribution of this platform- a distributed system intended for providing non-web speech-based multimodal services (automatic speech recognition, automatic text-to-speech synthesis, virtual assistants, home automation, personalization, etc.). Finally, the fourth block is named Environment controller, which controls several devices in the household (either by using TV remote, keyboard, mobile device, or speech)[16].

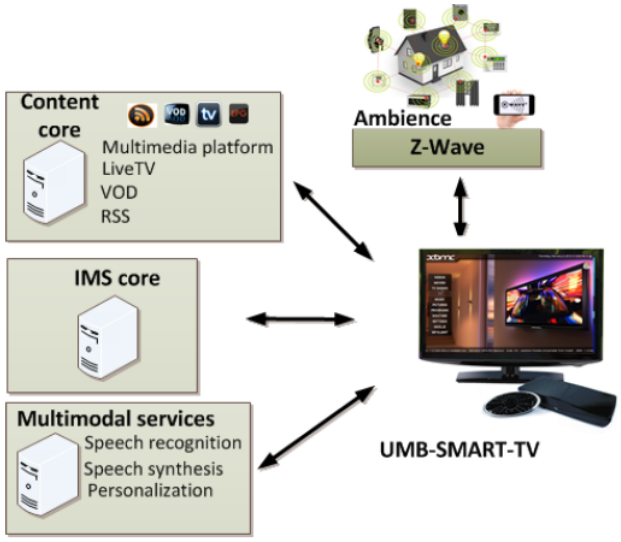

Fig. 2: The UMB-SmartTV environment [16]

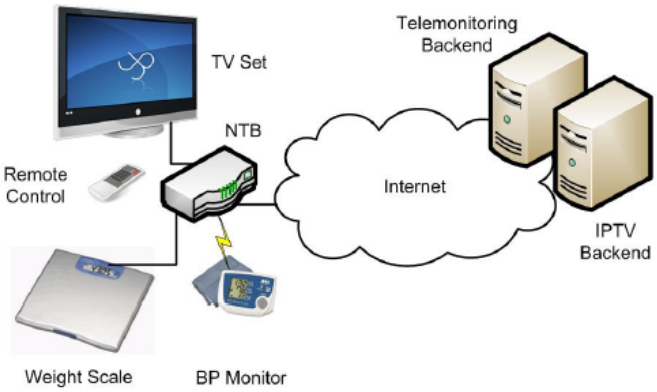

Fig. 3: Health monitoring system architecture [17]

An example of exploiting the benefits of IPTV as a technology in designing personalized health care systems is given in [17]. This research focuses on the development of a personal health telemonitoring application integrated into the IPTV home communication environment. The application enables monitoring of blood pressure and body weight, with rather common sensors and weight scales that have built-in communication interfaces, thus taking medicine to a whole new level. The application also supports on-line medical interviews. The user interface is manageable by a simple TV remote-control. The proposed system architecture is given in 3 [17].

Another example of using the IPTV technology for enhancing advancement in the field of medicine is the Vital Mind project [18], [8]. Here, instead of improving the diagnostics (remote measurement of blood pressure and weight), the goal is increasing the lifespan of the elderly by enabling them to actively participate in mind fitness exercises while watching TV by using a combination of cognitive psychology, the TV medium and advanced interactive ICT. This is done by

TABLE II: IPTV research papers comparison

Research	State of the art contribution
Functionality Upgrades	
[10]	scalable monitoring system which captures and analyzes network traffic, provides granularity (hundreds of subscribers) and pinpoints the source of errors
[5]	a channel control algorithm which effectively guarantees channel zapping time
[9]	bandwidth, energy and cost savings by creating a dynamic power consumption model scheme
[15]	Reducing latency in channel switchings within P2P IPTV systems with four novel fast channel switching schemes
[6]	improving the channel zapping time by making adjacent multicast groups of a current channel
[12]	increasing bandwidth savings with the mesh-pull P2P streaming approach
System Performance Analysis	
[13]	common simulation framework for rapid P2P TV systems
[11]	achieving shorter star-up delay, higher rate streaming, smaller peer lags and better NAT traversal in large-scale P2P mesh-pull IPTV systems
Technology-Assisted Living	
[2]	a highly available two-way EAS with redundancy of devices, multiple means of alert notification, scalability and prioritization of data
[16]	improving user's interactivity by a distributed system of non-web speech-based multimodal services (automatic speech recognition, text-to-speech synthesis, virtual assistants, etc.)
[17]	blood pressure, body weight and on-line medical interviews provided by a personal health telemonitoring application integrated into the IPTV service at home
[19]	IPTV in tertiary education, continuing professional development (CPD), and personally tailored education services

new methods for users control, production of Authoring and Production tools for IDTV STB and the development of usage of USB Flash-Device-UFD as an alternative to a broadcast delivery system [8].

Furthermore, IPTV easily finds its role in education. This is discussed in [19]. The purpose of this article is to provide examples of the IPTV technology being used in a variety of situations across the educational spectrum, including tertiary education, continuing professional development (CPD), and personally tailored education services in the home for the wider community. IPTV's efficacy in an educational setting has been proved by introducing 'Uni TV' at the The Melbourne Dental School because of its many video-content creation avenues [19].

D. Comparison of related research papers

In this subsection we give a comparison of the researches we analyzed. We have observed three different approaches to IPTV technology research: system and technology functionality upgrade, system performance analysis, and creating or improving technology- assisted living. This is presented in Table II.

IV. Comparison of different STB implemenations

This section gives an overview of some of the contemporary STB devices coming from different vendors, such as Apple TV, Google Chromecast, HBO Roku, Netgear NeoTV, Sony Bravia Smart Stick, which are yet to be proved as efficient enough to replace the existing 'standard' STBs that only deliver the service provider's predefined content to which a user has previously subscribed. It is important to note that STBs can be used both in IPTV and Internet TV, since their role is decoding the video downstream. However, given the main difference between these two technologies being the QoS support, STBs are mainly used in IPTV, while PCs, smartphones or laptops are usually used to access Internet TV.

Apple TV is Apple's popular streaming device runs on 512MB memory, 8 GB NAND Flash for Cache, and requires a Wi-Fi (802.11a/b/g/n) or 10/100 Ethernet connectivity. Its operating system is consisted of Apple TV Software 6.0 (based on iOS 7) [20]. It allows users to access more than two dozen channels, including free channels [21]. Supported Internet media services [20] include: iTunes Store, iCloud or Flickr photos, Netflix and Hulu streaming, sport channels including NBA, MLB, WatchESPN, than HBO Go, Sky News, Disney channels, Weather etc.

Google Chromecast is a digital media player that plays audio/video content on a high-definition television by streaming it via Wi-Fi from the Internet or local network. Users select the media to play on their television from the Google Chrome web browser on a personal computer or from a supported app on their mobile device [22]. Although it is by far the cheapest streaming video device, it has the weakest lineup of viewing channels.

Nevertheless, third-party monthly service is attempting to deliver more channels. Furthermore, ChromeCast requires users to select videos with a smartphone or tablet, via Android operating device. intended only for users with Android phones [21].

Roku is the streaming device sold by the Roku consumer electronic company offering a handful of upgrades and can stream more than 1,000 channels, including HBO Go. With low prices, Roku attempts to offer a set-top box for everyone. It is also one of the few companies that integrates a USB port for hard drive extensions, a headphone jack and a motion-controlled remote for gaming [21].

Netgear offers a series of set-top boxes: NeoTV, NeoTV Pro and NeoTV Max with the ability to stream a wide array of channels. The actual number of streaming channels is roughly 100 including Hulu, Netflix, YouTube, CinemaNow and Vudu.

Bravia Smart Stick is Sony's latest USB connected streaming device. Designed as the company's next Google TV device, it only works with Sony TVs. Hulu and other Bravia apps will be available even though they are not currently supported by the Google TV format. WIth its price being a bit higher than Apple TV's and Chromecast's, this device might become the least popular one [21].

In terms of having the aforementioned IPTV features in Section II, these STB devices have support for interactive

TV, time shifting, personalization of available TV channels, low bandwidth requirements and are accessible on multiple devices. However, this access is limited by the operating system. For example, Chromecast can only be accessed by devices that work with Android. Unfortunately, when it comes to IPTV applications, not all of those listed above are available to the users, such as IPTV e-mail, walled garden portal, instant IPTV messaging, a combination of video content and telephony services, gaming on demand as well as IP based emergency alert systems. Thus, the vendors of STBs should consider the implementation of some (if not all) of these missing IPTV applications which the technology itself can host, so that they can offer the users a more attractive product and increase their popularity on the market.

A. IPTV in the abscence of a STB

Recent research in the area has led to a new opportunity for delivering IPTV services, which excludes the usage of an STB device. This is made possible by the implementation of DVB-CI plus standard, whose 1.4 version was introduced in September 2013. As stated in [4], this DVB Common Interface (DVB-CI) plus standard is a result of resolving a security loophole of the firstly DVB-CI standard presented in 1997. It described the interface between a Conditional Access Module (CAiptvM) and the host, which is typically a TV set. When the IPTV customer inserts the SmarDTV CI Plus 1.4 CAM into an IP-connected TV set, an automatic discovery process starts to find the location and type of the available IPTV Channels, The application is launched and the first IPTV channel is displayed. The QoE has proven to be the same as in TV consumtion from other sources.

This standard has benefits for both consumers and IPTV service providers. Consumers would no longer have to make space for a STB and cables in their homes, and would save on their electricity bill, while the providers would save on equipment handling and cost by using a standards-based solution [4].

V. Conclusion and Future Work

The analysis of the IPTV state of the art has lead us to a conclusion that IPTV is an new emerging technology that represents a possible direction of future ICT ubiquitous and pervasive computing solutions. We have presented basic IPTV features and interactive applications, as well as the analysis of the impact of current research.

While in [8] we give an overview of recent research and technology development of appropriate architectures and design issues, as well as features and functionalities concerning IPTV as a technology in FP7 projects, this paper mainly focuses on the advancements in IPTV technology made in scientific research papers.

The fact that IPTV can easily be provided at alternative venues such as libraries, health centres, and other public places, such as the relatively inexpensive STB makes IPTV a useful technology in education, medicine and other scientific areas via sophisticated entertainment.

Having learned that IPTV can rise many opportunities for overall ICT growth, and technology assisted living, our future work will be aimed towards implementing the functionalities in new concepts and application areas enabling game oriented sophisticated concept of realizing continuous education, systems that support better living, etc.

ABSTRACT: Video conferencing is a quickly growing market. Suppliers are enhancing their services in order to get more functionality beyond the traditional video services. Such add-on functionality is the presenter tracking system. This solution can operate with any videoconferencing system or other video capture device. It allows complete room freedom and adds movement flexibility utilizing smooth continuous tracking.
In this paper, a kinect-based presenter tracking system for video conferencing systems is introduced. The prototype is validated with Ericsson's Visual Communication system. Ericsson Visual Communication (VisualCom) offers an operator hosted, enriched video communication experience to enterprises and professionals, enabling the operators to evolve their communications. VisualCom was originally made for holding video conferences in smaller rooms. Presenter Tracking System expands VisualCom's capabilities by adding a moving HD camera (also known as a pan tilt zoom camera) that focuses a single presenter, and can be controlled both automatically and manually.

KEY WORDS

1. Kinect, 2. Videoconferencing, 3. Presenter tracking, 4. Visual communication

I. INTRODUCTION

As video conferencing services become more focused on supporting user activity, a growing need for presenter's location and activity is recognized. To support such videoconferencing systems, a tracking application and algorithms are required.

In this paper, we present a Presenter Tracking System which consists of Kinect Sensor, which is used for tracking the presenter. Kinect is a cost-efficient device which contains multiple sensors (skeletal tracking, voice recognition, infrared, stereoscopic), as well as a powerful API for tracking human movement. In this project Kinect for Windows was used, although the application can be run with Kinect for Xbox, but with lower performance. Note that the Xbox version does not support all features, such as the near-mode tracking. Other part of the solution is HD PTZ camera which is used to follow presenter movements around the predefined space.

II. PRESENTER TRACKING SYSTEMS

Generally, tracking is the observing of people or objects on the move and supplying a timely ordered sequence of respective location data to a model e.g. capable to serve for depicting the motion on a display capability. In virtual space technology, a tracking system is generally a system capable of rendering virtual space to a human observer while tracking the observer's body coordinates. For instance, in dynamic virtual auditory space simulations, a real-time head tracker provides feedback to the central processor, allowing for selection of appropriate head-related transfer functions at the estimated current position of the observer relative to the environment [1].

As stated earlier, PTS is a solution which consists of Kinect Sensor, which is used for tracking the presenter, and PTZ camera. The Kinect sensor provides head coordinates of the presenter to the application, that turns them into appropriate camera pan and tilt values (Fig 1).

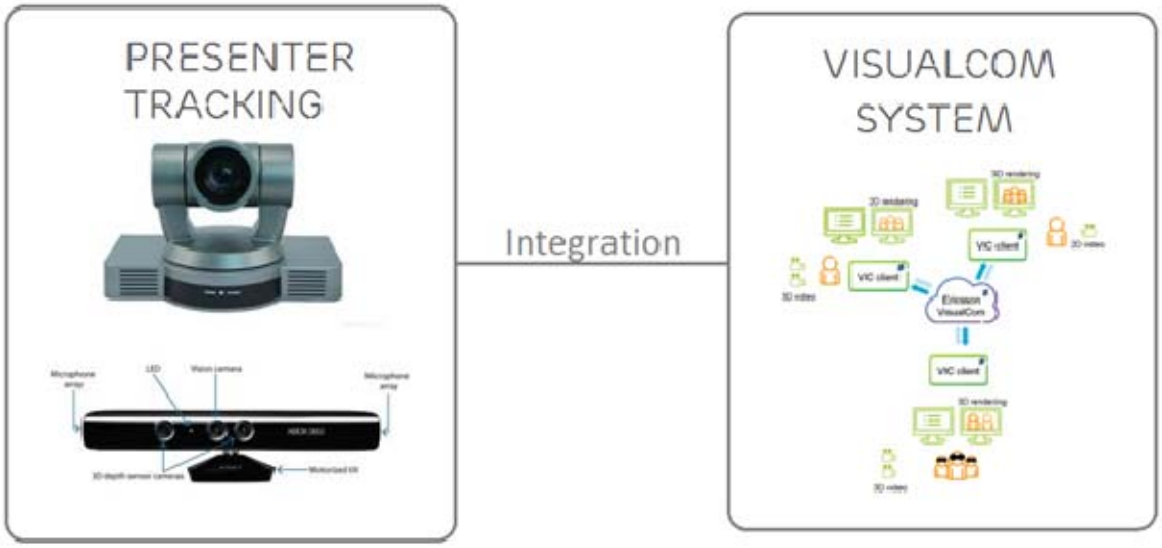

Fig 1 Kinect-based Presenter Tracking System solution overview

III. ERICSSON VISUAL COMMUNICATION (VISUALCOM)

The Ericsson Visual Communication solution is aimed at allowing operators to provide their business and consumer customers with easy to use, interconnected, and interoperable high quality video conferencing experiences globally. It offers an operator hosted, enriched video communication experience to enterprises and professionals, enabling the operators to evolve their communications offering in the quickly growing video conferencing market (Fig 3). VisualCom solution is an implementation based on the Ericsson IMS System with enhancements for high quality and high definition video communication. The solution brings together multiple nodes that employ standardized entities and interfaces [2].

Ericsson Visual Communication shows how high quality video communication can be realized with Ericsson and optional third party products. It is a complete network solution, bringing together multiple nodes that are based on standardized entities and interfaces.

Standard VisualCom Solution is based on Ericsson VisualCom Client HW, VisualCom Client SW, consumer electronics and standard VisualCom stand. VisualCom was originally made for holding video conferences in smaller rooms (Fig 2).

Fig 2 Visualcom Hardware Client for end-users

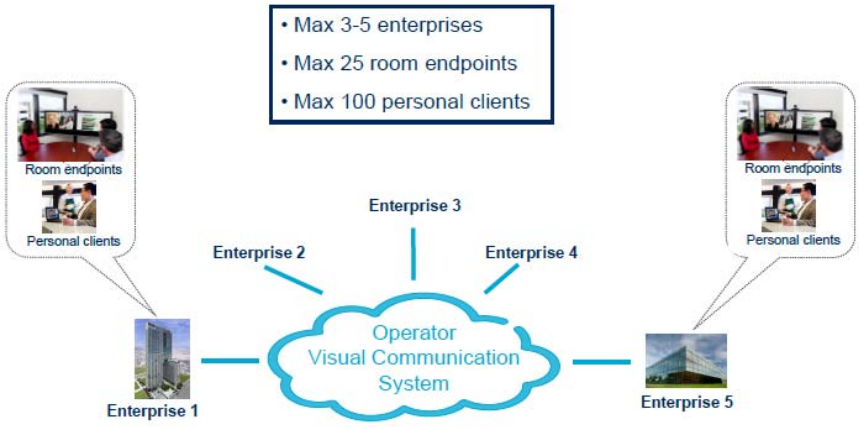

Fig 3 Ericsson Visual Communication Service

IV. SYSTEM ARCHITECTURE

Presenter Tracking System expands VisualCom's capabilities by adding a moving HD camera (also known as a pan tilt zoom camera) that focuses a single presenter, and can be controlled both automatically and manually. Manual control can be useful for focusing the camera vision on the product being currently presented or even, people in the audience. The HD camera can use up to 18x zoom, making it possible to install the camera far away from the presenter. Visualcom combined with the presenter tracking system adds support for much larger rooms, with 16 to 100 people inside, as well as stages. Visualcom & PTS can be used for educational purposes, promoting eLearning.

Presenter tracking system is a solution that uses a PTZ camera to follow a presenter over a medium sized area (3.5x4m). It is compatible with the VisualCom video conferencing system, allowing the user to walk around on stage, giving his presentation to the audience located in the room, while the camera is automatically following his movement. A moving camera adds a much larger viewing angle for the remotely connected audience and the automatic zoom function also gives a more enjoyable video conferencing experience.

The presented prototype consists of following components:

1. Kinect Senzor

A Kinect sensor (also called a Kinect) is a physical device that contains cameras, a microphone array, and an accelerometer as well as a software pipeline that processes color, depth, and skeleton data. The physical device is displayed on the picture bellow.

Figure 4 Kinect sensor

2. Kinect for windows SDK

The Kinect for Windows SDK provides a sophisticated software library and tools to help developers use the rich form of Kinect-based natural input, which senses and reacts to real-world events [5]. The Kinect and the software library interact with the developed application.

The needed components of SDK are following

a) Kinect hardware - The hardware components, including the Kinect sensor and the USB hub through which the Kinect sensor is connected to the computer.
b) Kinect drivers - The Windows drivers for the Kinect, which are installed as part of the SDK setup process as described in this document. The Kinect drivers support:
   - The Kinect microphone array as a kernel-mode audio device that you can access through the standard audio APIs in Windows.
   - Audio and video streaming controls for streaming audio and video (color, depth, and skeleton).
   - Device enumeration functions that enable an application to use more than one Kinect.
c) Audio and Video Components
   - Kinect natural user interface for skeleton tracking, audio, and color and depth imaging
d) DirectX Media Object (DMO) for microphone array beam forming and audio source localization.
e) Windows 7 standard APIs - The audio, speech, and media APIs in Windows 7, as described in the Windows 7 SDK and the Microsoft Speech SDK. These APIs are also available to desktop applications in Windows 8.

3. PTZ camera

For this project, PTZ Camera KT-HD60 was used. It is a high resolution, 18x zoom video capturing device. It outputs the HD signal through a HDMI out. Camera acquires commands via serial port and supports multiple pan tilt zoom camera protocols, such as Pelco D/P, and VISCA. In this solution, we have used VISCA protocol to communicate with the camera. Note that the camera doesn't follow Pelco D/P standards closely, so some commands will not function when using Pelco protocols. To use the camera in the upside down mode, you must flip the jumper that is located on the bottom side of the camera. Camera commands such as moving the motor left and right are automatically flipped, meaning any software adjustments are not necessary [3].

V Concept Validation

As mentioned before In this project we have used Kinect for Windows, although the application can be run with Kinect for Xbox, but with lower performance. Other part of the solution is HD PTZ camera which is used to follow presenter movements around the predefined space. the concept validation consisted of following goals:

1. Integration of Kinect with PTZ camera,
2. Developing Graphical User Interface (GUI),
3. Concept validation on existing videoconferencing system.

The integration was done in C#, .NET framework 4.0 and the Kinect SDK. Concept validation was done on Ericsson Visual Communication System. Presenter tracking system was tested using the Ericsson Visual Communication Hardware Client in small and large rooms. The system is very mobile, and can be quickly reconfigured to work in different rooms. The benchmarks proved that Presenter tracking system is a useful upgrade for the Ericsson Communication System.

User interface consists of two parts. The first part is image data received from the Kinect sensor, it represents the visual field of the Kinect sensor, and its application is for the presenter to know if he is locked down by the sensor. The second part of the interface are camera and Kinect controls and Kinect and camera data, such as 3D coordinates, presenter velocity, camera pan and tilt angle (See Figure 5). Kinect has limited tilting capabilities [6]. The user can change the sensor tilt angle by moving the tilt slider. User interface also provides a way to take over manual control of the camera. This function can be used to focus the camera vision onto a product that is being presented. Manual controls are started by pressing the Tracking ON button. While the manual controls are active, automatic tracking will be disabled, and vice versa. Camera movements are controlled with keypad arrow buttons (up, down, left, right). Camera zoom is controlled with keypad + for zooming in, and keypad – is for zooming out. It is also possible to force stop zoom by pressing the * key. Above the Tracking ON/OFF button there are 2 sliders.

In this project, customized Fzbin Kinect Gesture library [4] was used for Gesture implementation. System possibilities such like adding new gestures, using gestures with skeleton data and presenter gestures (lock-on and unlock gestures) were developed and implemented.

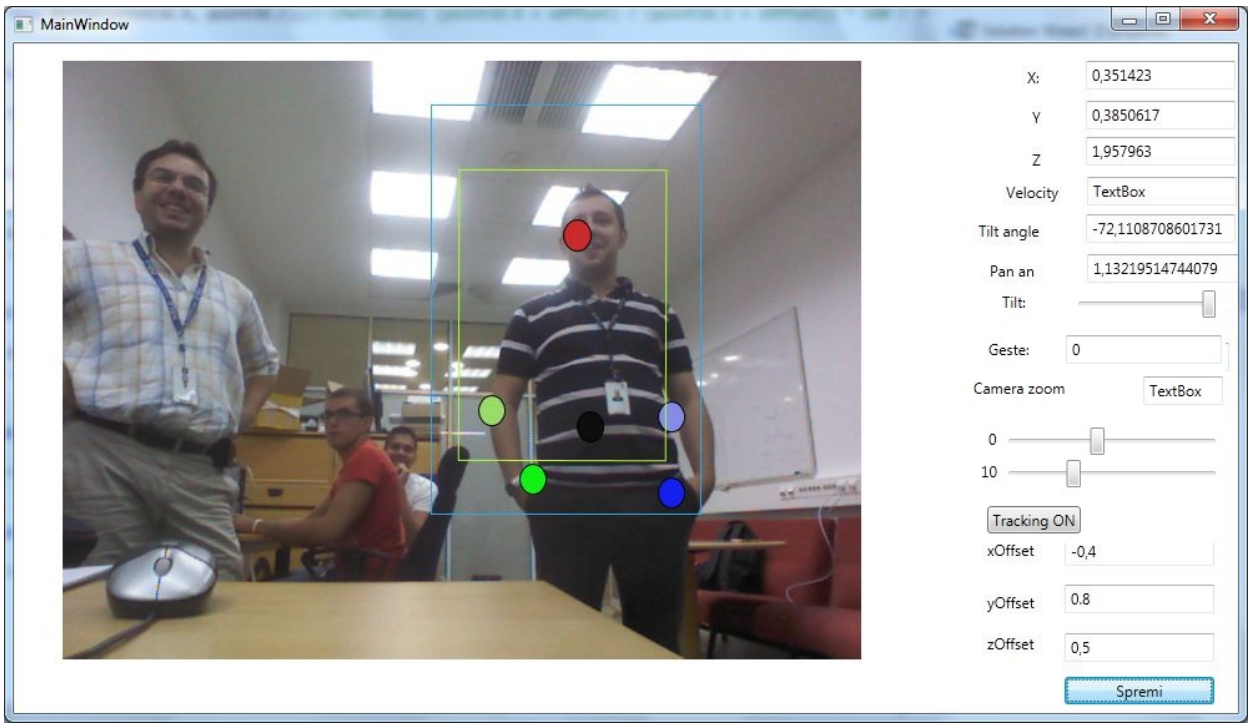

Figure 5 Hardware and Software Interaction with an Application

VI. Future work and development

Presenter Tracking system is visually stunning solution for halls and big rooms. Solution can be expanded in several different ways. Currently, the biggest problem for PTS is space for the presenter to move. One of the possible solutions for this problem is adding multiple Kinect sensors to cover more space. Future development can also include implementing new presenter gestures, such as swipe left and swipe right which can be used for controlling the presentation. For example, swipe left could mean next slide, while swipe right can mean previous slide. Current solution has gesture support system, so adding new gestures can be described as a task of medium difficulty.

Main direction for future development should be integration with VisualCom user client interface. This way, no additional processes would be needed, and PTS could be automatically started with the video conference. This could be described as a task of medium difficulty. PTS could also be expanded by adding an option for a second presenter, and move the camera depending on which of the presenters is currently speaking. Kinect API already has voice direction recognition, but the logic of camera movement depending on which of the presenter is speaking would be a problem. This could be described as a task of high difficulty.

Another suggested feature includes tracking members of the audience with an additional PTZ camera. Using Kinect's sound sensors, it is possible to determine the approximate direction the voice is coming from and then pinpoint it using facial recognition algorithms to determine which person is opening its mouth. The person in the audience who is talking would also appear on the screen, showing the dialogue between the presenter and the person in the audience, rather than just presenter talking to an unknown voice. This would work especially well for recording university classes, where a lot of questions are asked during the lecture. It's worth noting that many famous universities such as Stanford, UCLA are starting to offer online lectures.

VI. CONCLUSION AND FUTURE WORK

Audio and video communications are a current world trend. This trend produces a certain market, not only for end users customers, but for large companies as customers. VisualCom is one of the products that can help Ericsson conquer the market of HD visual and audio communication. It targets larger companies as end users. It is mainly designed for small conference rooms, but to expand the market this project was created and implemented.

Presenter Tracking System helps expand quality of

service for VisualCom serving as a plugin for video conferences and presentations in bigger rooms. This way, Ericsson can expand its offer to companies. In a sense, presenter is interacting with the camera using gestures, while the Kinect serves as a user-interface.
Implementation of Presenter Tracking System is complete; however some of the components in the solution could be replaced with higher quality products. For example, PTZ camera has a very slow auto focus, unstandardized values for VISCA protocol, low quality image stabilization at higher speeds. Regardless, PTS is a solid solution for economic expansion of Ericsson product portfolio.

Iterative Receiver for Qc-LDPC Coded Underwater Acoustic Communication Systems

Liang Zhao*
* Xi'an Research Institute of Navigation Technology, Xi'an, P.R.China
xdyjs204@hotmail.com

Abstract - Quasi Cyclic-Low Density Parity Check (QC-LDPC) codes are easy to construct and provide the considerable coding gain, which is suitable for underwater acoustic communication (UWAC). Single-carrier (SC) transmission with frequency-domain equalization (FDE) is today recognized as an attractive alternative to orthogonal frequency-division multiplexing (OFDM) for communication application with the inter-symbol interference (ISI) caused by multi-path propagation, especially in shallow water channel. In this paper, the turbo theory is applied on the QC-LDPC codes and minimum mean square error (MMSE) decision feedback equalizer (DFE) to design iterative data processing for underwater acoustic communication system. In the proposed iterative structure, the MMSE based FD-DFE and QC-LDPC decoder exchange soft information through an iterative manner so that the performance of underwater acoustic communication system can be improved greatly. Based on sound speed profiles (SSP) measured in the lake and finite-element ray tracking method, the shallow water channel is constructed to verify the validity of the proposed system structure.

I. INTRODUCTION

The major cause of performance degrade in underwater acoustic communication system is the inter-symbol interference (ISI) introduced by multi-path propagation [1]. Multi-channel adaptive decision feedback equalizer (ADFE), as in [2-4], has been certified as effective approach to eliminate the ISI for the underwater acoustic multi-path channel. Meanwhile, channel coding is an effective technology to ensure reliable data transmission. Low-density parity-check (LDPC) code, firstly presented by Gallager [5], is the one most close to the Shannon limit of a class of error-correcting codes. From the point of view of modern coding theory, Mackay [6-7] proved that LDPC codes are capable of performance close to the Shannon limit. LDPC code has become the hot point in current error-correcting code field. Quasi Cyclic-Low Density Parity Check (QC-LDPC) codes [8] exhibit excellent decoding performance, simple encoding structure, lower encoding complexity and easily to implement with hardware.

For channels with severe delay spread, such as underwater acoustic channel, frequency domain equalization (FDE) is computationally simpler than corresponding time domain equalization because an efficient FFT operation is involved. A single carrier (SC) system with FDE (SC-FDE) has essentially the same performance and low complexity as an orthogonal frequency division multiplexing (OFDM) system when combined with FFT processes and the use of a cyclic prefix (CP) or zero padding (ZP) [9-10].

But, single technique, such as equalization or coding technique, is difficult to obtain satisfied data transmission because of the complexity of UWA channel, especially in shallow water channel. So, in this paper, an iterative receiver is developed combining MMSE based FD-DFE and Qc-LDPC decoder. In the proposed iterative receiver, the Qc-LDPC decoder and FD-DFE iteratively exchange soft information. And thus, the performance of equalizer can be improved utilizing decoding gain provided by decoder such that the performance of communication system is improved.

II. SYSTEM DSCRIPTION

For MPSK, let's define $m = \log_2 M$, where, M is number of phases. Irregular Qc-LDPC code is characterized by a $M \times N$ parity-check matrix $H(M, N)$ with variant column weight and variant row weight. The code rate can be calculated by $R = 1 - M / N$. In this paper, irregular Qc-LDPC codes with code rate *R=1/2* and *2/3*, are adopted in the proposed communication system.

In receiver, the received signal is firstly transformed into baseband by multiplying the local carrier frequency. And then, iterative data processing is performed. The structure of iterative receiver is shown in Fig.1. The concrete algorithm will be given in Section III.

III. ITIRATIVE RECEIVER

The block diagram of the proposed iterative receiver is illustrated in Fig.1. In its *l*th iteration, the frequency domain received vector feeds to the FD-DFE. This produces the vector feeding to a Qc-LDPC decoder producing *a posteriori probability* (APPs) of data, which are exploited to generate the extrinsic information. This is then processed to produce a soft estimate of the ISI in the received signal samples, and feedback to the feedback filter of FD-DFE for the next iteration.

In this section, we first derive FD-DFE algorithm. And then, an iterative receiver based on equalization and decoder is developed. As shown in Fig.1, the space diversity technology is adopted.

A. Fast Encoding of Qc-LDPC

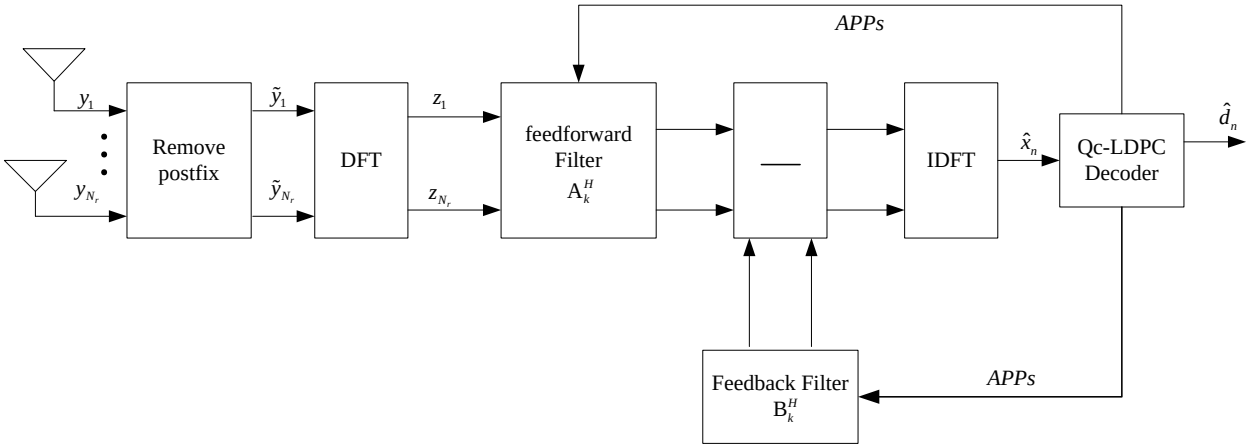

Fig.1 Block diagram of the proposed iterative receiver

Parity-check matrix H*(M,N)* can be divided into six sub-matrixes, that is

$$H = \begin{bmatrix} A & B & T \\ C & D & E \end{bmatrix} \tag{1}$$

where, the size of matrixes A, B and T are $(m-z)\times k$, $(m-z)\times z$ and $(m-z)\times(m-z)$, the size of matrixes C, D and E are $z\times k$, $z\times z$ and $z\times(m-z)$.

The encoded symbols can be divided into two parts: information bits S and parity bits $P=[P_1;P_2]$. The length of P_1 and P_2 are z and $m-z$ respectively, which can be calculated as follows:

$$P_1^T = \left(ET^{-1}A+C\right)S^T \tag{2}$$

$$P_2^T = T^{-1}\left(AS^T + BP_1^T\right) \tag{3}$$

So, the outputs of Qc-LDPC encoder are $[S;P_1;P_2]$.

B. MMSE Based Frequency Domain Decision Feedback Equalization (FD-DFE)

After performing *K* point discrete Fourier transform (DFT), the received symbols in frequency domain (FD) $\mathrm{Z}=\left[Z_0,Z_1,...,Z_{K-1}\right]^T$ are produced

$$\mathrm{Z}_k = \mathrm{H}_k S_k + \mathrm{V}_k \tag{4}$$

Where, $H_k(f)=H(k/KT)=\sum_{l=0}^{L-1}\hbar_l e^{-j2\pi k\tau_l/KT}$ is the frequency response of $h(n)$, and V_k is complex additive white Gaussian noise (AWGN) in FD. S_k is the *k*th component of the vector $\mathrm{S}_K=\left[S_0,S_1,...,S_{K-1}\right]^T$,which is the DFT of x_K, that is $\mathrm{S}_K=F_K\mathrm{x}_\mathrm{K}$, where, F_K is the *K*-point DFT matrix with the $(p+1,q+1)^{st}$ entry as $\left(1/\sqrt{K}\right)e^{-j2\pi pq/K}$.

The corresponding error in frequency domain (FD) is

$$\mathrm{E}_{DFE} = S_k - \hat{S}_k = S_k - A_k^H\mathrm{Z}_k + B_k^H\tilde{S}_{k'} \tag{5}$$

Appling MMSE criteria on eq.(5), and after mathematic derivation, we can get the optimal forward filter and feedback filter as

$$A_k = \mathrm{cov}(S_k,S_k)(\sigma_v^2 I + H_k\,\mathrm{cov}(S_k,S_k)H_k^H)^{-1}H_k^H \tag{6}$$

$$B_k = A_k H_k^H E(\tilde{S}_{k'},S_k^H) - E(\tilde{S}_{k'},S_k^H) \tag{7}$$

where σ_v^2 is the noise variance.

In iterative FD-DFE, the soft symbol estimations at last iteration $\tilde{S}_{k'}$, are used as the input of feedback filter. Thus, the $E(\tilde{S}_{k'},S_k^H)$ is equal to the correlation between transmitted and detected data sequences.

In order to estimate the parameters in eqs. (6) and (7), we introduce the mean, power, and variance of S_k in FD:

$$E(S_k) = \frac{1}{K}\sum_{i=0}^{K-1}E(x_k)\times\exp\left(-j\frac{2\pi ki}{K}\right) \tag{8}$$

$$E\left(|S_k|^2\right) = \frac{1}{K}\sum_{i=0}^{K-1}E\left(|\hat{x}_k|^2\right)\times\exp\left(-j\frac{2\pi ki}{K}\right) \tag{9}$$

$$\sigma_S^2 \triangleq \mathrm{cov}(S_k,S_k) = E\left(|S_k|^2\right) - |E(S_k)|^2 \tag{10}$$

The correlation $E(\tilde{S}_{k'},S_k^H)$ in eq.(7) can be expressed as

$$\begin{aligned}\gamma_{\tilde{S},S} &\triangleq E(\tilde{S}_{k'},S_k^H)\\ &= \frac{1}{K}\sum_{i=0}^{K-1}E(\tilde{x}_i,x_i^H)\exp\left[-j\frac{2\pi(k-k')i}{k}\right]\\ &= \frac{1}{K}\sum_{i=0}^{K-1}\rho_s\delta(k-k')\exp\left[-j\frac{2\pi(k-k')i}{k}\right]\end{aligned} \tag{11}$$

Where, $E(\tilde{x}_i,x_i^H)$ is the correlation in TD. $\tilde{x}_i$ is the estimation of the x_i in TD at the last iteration. So, in eq.(11), the ρ_s describes the reliability in the quality of the estimate $\tilde{x}_i$.

If $\tilde{x}_i$ is an excellent estimate of x_i, then $\rho_s \approx 1$, and nearly all of the interference is subtracted from the received symbols.

During the course of iterative processing, the APP $P(\hat{x}_k = \alpha_i)$ delivered by Qc-LDPC decoder is used to estimate the transmitted symbols. So, we can use it to approach the ρ_s :

$$\rho_s \cong \max_{i \in \mathbb{S}} (P(\hat{x}_k = \alpha_i)) \tag{12}$$

which means $\tilde{x}_k$ equal to x_k with the maximum probability.

Thus, using eq.(12), eq.(11) can be simplified to

$$\gamma_{\tilde{s},s} \triangleq E(\tilde{S}_{k'}, S_k^H) \cong \frac{1}{K} \sum_{k=0}^{K-1} \max_{i \in \mathbb{S}} (P(\hat{x}_k = \alpha_i)) \tag{13}$$

So, the optimal forward filter and feedback filter can rewrite as

$$A_k = \sigma_s^2 (\sigma_v^2 I + H_k \sigma_s^2 H_k^H)^{-1} H_k^H \tag{14}$$

$$B_k = A_k \hat{H}_k^H \gamma_{\tilde{s},s} - \gamma_{\tilde{s},s} \tag{15}$$

After IDFT, we can get TD transmitted symbol $\hat{x}_k$, which will be send to the decoder to generate the final bits decision $\hat{d}_k$ and the APPs of transmitted symbols for next iteration. As mentioned above, the output vector after IDFT is applied to a Qc-LDPC decoder producing the APPs of data, which are exploited to generate the extrinsic information. This is then processed to produce a soft estimate of the ISI in the received signal samples, and to adjust the iterative FD-DFE for the next iteration.

In this paper, Qc-LDPC decoder adopts min-sum algorithm (MSA) [11] as the decoding algorithm, which has the linearly complexity.

IV. Simulation Results

In this section, based on sound speed profile (SSP) measured in the lake and finite-element ray tracking method, underwater acoustic channel is constructed to evaluate the performance of the proposed iterative receiver.

A. Channel Model and System Parameters

The sound speed profile (SSP) measured in the lake is shown in Fig.2. The water with mixed gradient is about 33m depth. Based on the SSP, the shallow water channel with multipath propagation is constructed using ray tracking method.

Before data symbols are transmitted, the preamble symbol is transmitted to detect the channel impulse response (CIR). The LFM signal is used as preamble in our system. In Fig.3, we can see that there are two receiving elements are deployed (Ch1 and Ch2).

The system parameters of computer simulation are shown in Table 1. The transmitted signal with QPSK modulation is adopted.

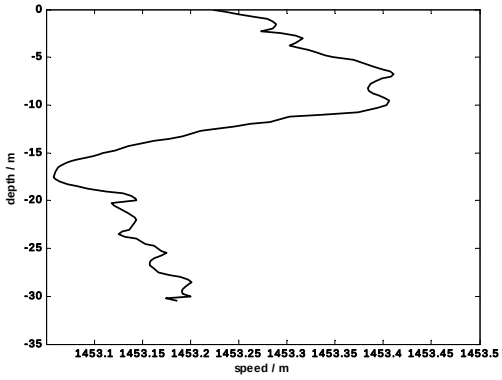

Fig.2 Sound speed profile (SSP)

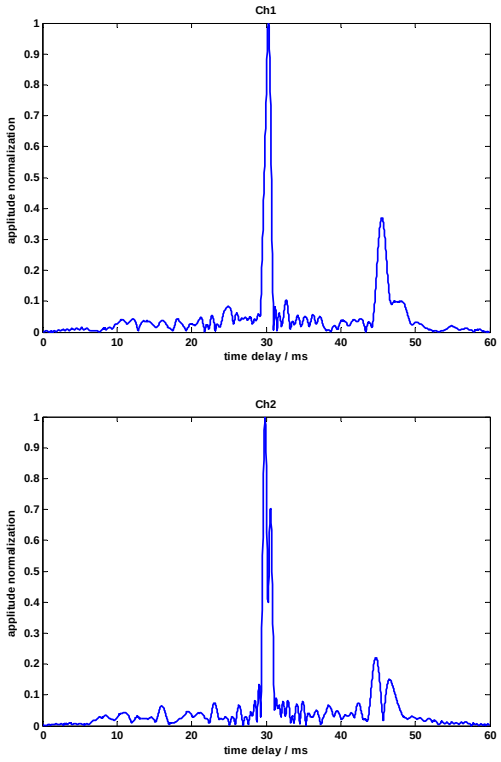

Fig.3 Channel impulse response (Ch1 and Ch2)

TABLE I. System Parameters

Parameters Name	***Values***
Carrier frequency	10 *KHz*
Symbol rate	5 *Ksps*
Sample rate	40 *KHz*
Transmission distance	2000 *m*
DFT length (*K*)	600
Code rate	1/2 ; 2/3
Receiving elements	2

B. *Performance of Iterative Receiver*

Fig.4 and Fig.5 show the bit error rate (BER) curves of the proposed iterative receiver using two receiving antennas with variant numbers of iterative equalization and decoding (marked with "IED" in Fig.4 and 5) and iterative Qc-LDPC decoding (marked with "Qc-LDPC decoding" in Fig.4 and 5). We can see that the proposed iterative receiver can sufficient utilize the decoding gain provided by decoder to improve the system performance. Thus, the data transmission with lower BER can be obtained. What's more, more Qc-LDPC iterations can obtain better performance under the condition of the same IED iterations.

Comparing Fig.4 with Fig.5, we can find that the system performance will reduce as the code rate rose. That is because there are more parity bits for lower code rate such that the more error will be corrected.

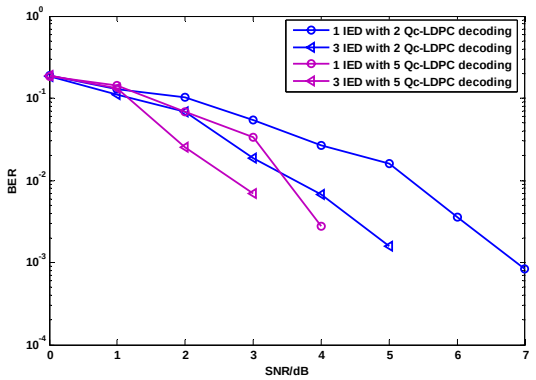

Fig.4 The performance of the iterative receiver with 1/2 code rate

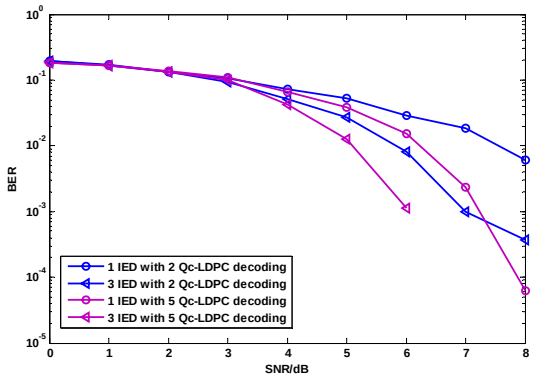

Fig.5 The performance of the iterative receiver with 2/3 code rate

V. CONLUSION

In this paper, according to the characteristics of underwater acoustic channel, an iterative receiver based on frequency domain decision feedback equalization (FD-DFE) and Qc-LDPC decoder is investigated to overcome Inter-symbol interference (ISI) caused by multi-path propagation. Based on SSP measured in the lake and finite-element ray tracking model, the shallow water channel is constructed to evaluate the performance of the proposed iterative receiver. The results suggest that the proposed iterative receiver can significantly improve the performance utilizing decoding gain provided by decoder and obtain better data transmission. Moreover, the proposed FD-DFE algorithm is developed for multi-channel receiver. So, it can easily extend to MIMO system.

SOFTWARE PLATFORM FOR WIRELESS INDOOR LOCALIZATION PLANNING BASED ON THE STRENGTH OF RECEIVED RADIO SIGNAL

Igor Vitas, Bojan Lukovac, Dina Šimunić

Faculty of Electrical Engineering and Computing, University of Zagreb, Croatia

ABSTRACT

Abstract – Radiofrequency positioning problem within indoor space becomes significant with respect to the specific area for which the radiolocation is required. The area of interest may be an apartment, shop or storage area of any shape and size. The specificity of the space defines various requirements on the radiolocation system and the need for software that would facilitate the planning of such a system is obvious. Using well-known empirical and deterministic models for propagation of electromagnetic waves in enclosed spaces and precise analysis of specific closed areas, localization based on the RSS (Received Signal Strength) method should give good positioning results in any enclosed space. Software solution that was developed in this work allows you to determine the optimal position of the receiver on the walls of any space that is selected as an area in which implementation of a system of RSS indoor localization is required. The optimal position of the receiver provides precise and reliable localization within the indoor enclosure. The software can be used to optimize the indoor localization of people or objects, with the requirement that special radio frequency tags or radio frequency transmitters are mounted on them. The software supports the ability to import an arbitrary layout of indoor space over which optimization will be carried out from AutoCAD or a CAD tool.

Keywords **–** radiofrequency indoor positioning, software tool, received radio signal strength

1. INTRODUCTION

Wireless positioning has been an issue of high research interest in the last two decades [1]. Numerous systems for wireless positioning are already in use, most of them are global systems used for positioning of people or objects (e.g.. cars, trains, planes) on the surface of the Earth. The most popular system used for such a purpose is definitely GPS – the Global Positioning System. Positioning of people and objects is an efficiently solved problem in open space areas (Earth surface), because satellite positioning systems are advanced systems built for the specific application of positioning. A significant problem with that kind of system is that they do not work in areas that cannot be covered with the radio signal from a satellite, such as indoor spaces, tunnels, Earth surface areas with high forest density and so on. The strength of the radio signal required for normal work of the GPS system is usually too weak in indoor environments, so specific indoor positioning systems are being developed[2][3][4].

Similarly to outdoor positioning systems, indoor positioning systems also work on three fundamental principles of radiolocation:

1. Received radio signal strength
2. Time of flight of the radio signal
    a) Time of arrival
    b) Time difference of arrival
    c) Phase of arrival
3. Angle of arrival of the radio signal

The indoor propagation environment is much more complicated than an outdoor propagation environment like free space. It is, for example, hard to precisely predict a relationship between distance and received radio signal strength because of the unpredictability of the indoor propagation environment. Indoor propagation is very space-dependent because the number of indoor spaces that can be used as a propagation scenario is infinite. Also, indoor spaces can contain very different kinds of materials that effect propagation such as a walls, furniture or any kind of in-house equipment (e.g. electrical equipment with metal housing).

Propagation in indoor environments can be described easily with a modified Friis equation (1). Indoor path loss (or path gain) for a given distance d will be a random variable that will vary around some expected value.

$$PG_{dB} = 10n \log\left(\frac{\lambda}{4\pi d}\right) + X_\sigma \quad (1)$$

X_σ is a random variable with standard deviation. Parameters for the varible X_σ regarding various indoor spaces can be seen in Table 1.

In the case where equation (1) is not used for the calculation of path loss in indoor space, some empirical equations that determine path loss in specific indoor space can be used. Most popular empirical equations and models used for determination of path loss in indoor space are COST 231 Multi Wall, COST Average Wall and Motley-Keenan model [5].

Table 1 Comparison of standard deviation of random variable X_σ and propagation exponent for various indoor spaces and frequencies.

Propagation space	Frequency (MHz)	Propagation exponent	Variable deviation (σ)
Supermarket	914	2.2	8.7
Office, frequency 1	1500	3.0	7.0
Office, frequency 2	900	2.4	9.6
Factory	1900	2.6	14.1

Performance of radio technologies in indoor environments is restricted, so many systems for indoor positioning are hybrid systems that use radio technologies coupled with other technologies such as infrared, ultrasound or optical systems [6][7][8] . Another very popular option is also a combination of radio technologies coupled with electronic accelerometers that can be used for determination of motion. Motion detection with use of an electronic accelerometer provides good results in various indoor localization systems.

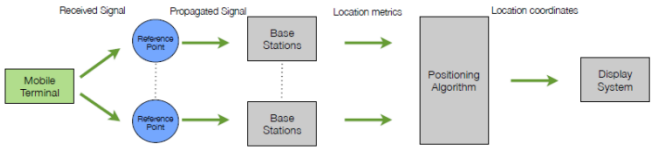

Figure 1 Architecture of typical wireless positioning system.

Because all commercial wireless technologies that are used in indoor space such as Bluetooth, WLAN (IEEE 802.11), ZigBee (IEEE 802.15.4) have the possibility to measure the received signal strength of an incoming radio signal [9], the easiest way to implement an indoor positioning system is to measure the received signal strength from multiple access points on one mobile node. In that case, the mobile node needs to calculate its own position using signal strength measurement and known location (coordinates) of all access points in indoor space [10]. The minimal number of access points needed for this unilateral measurement procedure is three. The process of finding the position of a mobile node in a network that is made of three wireless access points and one mobile node is called trilateration. Trilateration is calculated using equations (2), (3) and (4).

$$(x_1 - x)^2 + (y_1 - y)^2 + (z_1 - y)^2 = D_1^2 \quad (2)$$
$$(x_2 - x)^2 + (y_2 - y)^2 + (z_1 - y)^2 = D_2^2 \quad (3)$$
$$(x_3 - x)^2 + (y_3 - y)^2 + (y_1 - y)^2 = D_3^2 \quad (4)$$

$D_1, D_2, D_3 \rightarrow distance\ between\ access\ point\ and\ mobile\ node$

$(x_n, y_n) \rightarrow\ access\ points\ coordinates$

$(x, y) \rightarrow mobile\ node\ coordinates$

The localization algorithm that is used in a received signal strenght localization system needs to minimize function (5) quickly and accurately. Minimizing the equation F, the system can calculate position coordinates of a mobile node in indoor space.

$$F = \sum_{i=1}^{M} (\sqrt{(x_i - x_e)^2 + (y_i - y_e)^2} - D_i)^2 \quad (5)$$

$M \rightarrow number\ of\ system\ access\ ponts$

For systems that work with a received signal strength localization algorithm, it is very important to make a good prediction of path loss in the envirnonment in which the system is located. The path loss model will be used by the positionig system to determine values D_i in equation (5) and because of that, it will directly affect positioning system precision.

Choosing the correct path loss model for a specific indoor space scenario is not an easy task. The propagation exponent and deviation shown in Table 1 will theoretically be differenet for every indoor space and they will highly depend on the current situation in that space, such as the type of the building walls, presence of people, furniture, position of wireless access points on walls of the space and so on. The most accurate way to choose a path loss model for specific indoor space is the method of radiofingerprintig. Radiofingerptinting can use a finite number of measurements inside a specific indoor space (e.g. measurement of path loss between a raster of points in the space and every acces point in the space) to determine the average propagation exponent and variable deviation for that space. With the calculated average propagation exponent and variable deviation found by radiofingerprinting, it is possible to most accurately calculate values of D_i , and mobile node position. If we consider that the number of radiofingerprinting measurements for a specific indoor space is N, we can calculate propagation exponent for every point of measurement i in indoor space as shown in equation (6).

$$prop_exponent(i) = \sqrt{G_T G_R \frac{P_T}{P_{R(i)}} \frac{\lambda^2}{16\pi^2}} \quad (7)$$

Average propagation exponent that is used to describe the entire indoor space is then calculated as (7).

$$prop_exponent_space = \frac{1}{N} \sum_{i=1}^{N} prop_exponent(i) \quad (7)$$

$N \rightarrow number\ of\ measurement\ points\ in\ indoor\ space$

2. SOFTWARE PLATFORM

The goal of our developed software is to optimize a specific indoor space in terms of indoor radiofrequency-based positioning. An imported AutoCAD file(.dwg format) represents an architectural visualisation of indoor space (e.g. an apartment, house, warehouse, factory, shopping center). Processing is done over the AutoCAD file to produce a geometric model of the indoor space over which calculations will be taken. The software uses propagation models of

electromagnetic waves that can accurately simulate propagation conditions in any indoor space that is imported from the AutoCAD tool to our software. With those propagation models, the software can suggest cooridantes of ponts in the indoor space in which installation of wireless access points is required to cover the entire area with sufficient radio signal strength for normal operating of a specific wireless system (e.g. WLAN).

Positions of wireless access points are choosen with two conditions:

1. Optimal coverage of the entire indoor space with sufficient strength of radio signal – first access point is set in the geometric middle of the indoor space, every next access point is placed in the point with the minimal level of radio signal strength and so on, until every surface is covered with sufficient signal for at least three access points. In this example,the chosen threshold for determing minimal possible allowed radio signal strength in any point of the space is -89 dBm (IEEE 802.11 system with 8% PER and 11 Mbps transmission speed).

2. Positioning of access points in space so they can be efficiently used in the trilateration algorithm for indoor localization using received radio signal strenght – in the ideal case, trilateration would be most precise if transmitters of the system would form an equilateral triangle as shown in figure 2. A special algorithm is used to place access points of the system (wireless transmitters) in space so the three access points form three vertices of a geometrical shape that is as close as possible to an equilateral triangle.

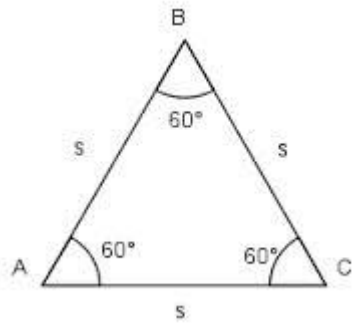

Figure 2 Equilateral triangle with wireless transmitters A, B and C in its vertices.

Virtual radiofingerprinting of the indoor space is also calculated in a resolution that the user can input (ideally it would be $\frac{\lambda}{10}$ meters for radio signal with a wavelenght of λ). Figure 3 shows the indoor space (apartment) that is imported to our software with the purpose of optimization, the selected resolution in this example is 0.5 meters. Higher resolution of space also means a higher computation time for the software to determine indoor space optimization.

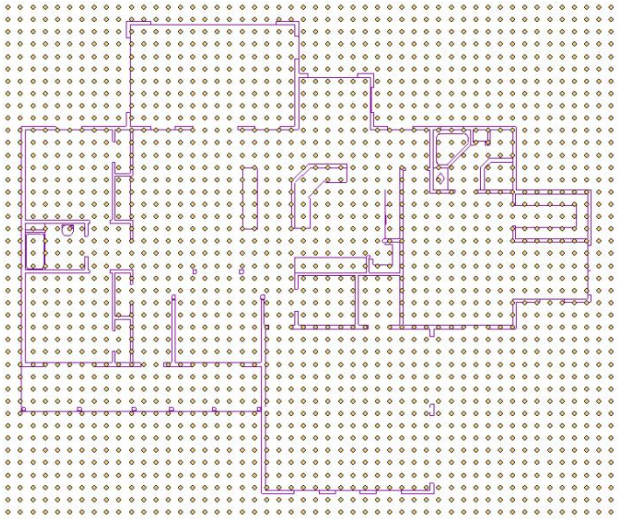

Figure 3 Flat with 0.5 meter resolution of calculation domain.

When radiofingerprinting of the whole space is completed and when the average propagation exponent is calculated with equation (7), that information is used to make the indoor localization system path loss model. This model will be adapted to fit the specific indoor space that is imported to the software so that the localization with that model in a real system that would be implemented in actual indoor space would be as accurate as possible.

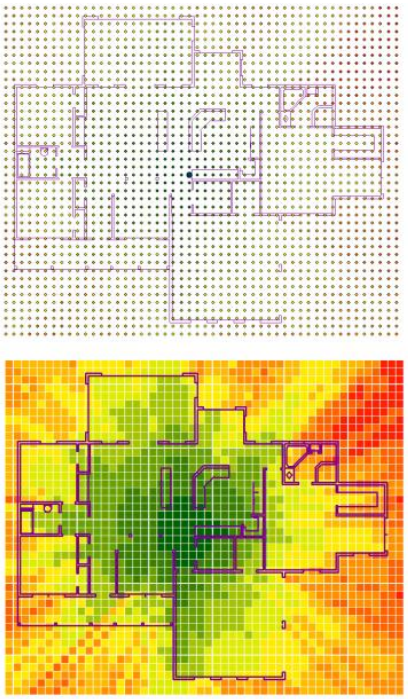

Figure 4 Radio coverage of the indoor space with first transmitter in the middle of the apartment (blue point on the first picture).

Figure 3 shows the placement of the first transmitter in the geometric middle of the flat. The second and third transmitter are set on the positions determined by the software regarding conditions 1 and 2. The placement of the second transmitter is shown on figure 4 and the placement of the third

transmitter with respective radio coverage of the flat is shown in figure 5.

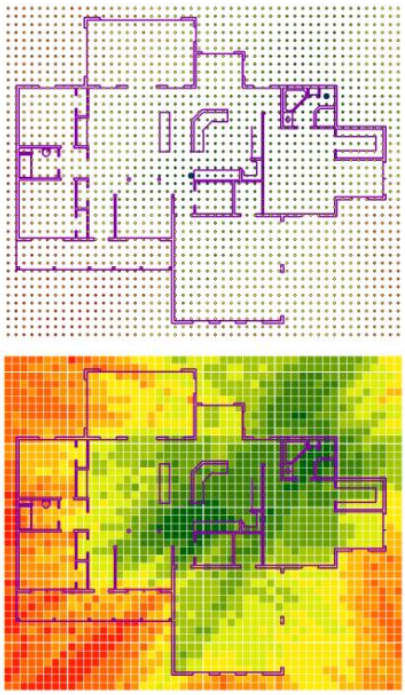

Figure 5 Radio coverage of the indoor space with first two transmitters in the apartment (two blue points on the first picture).

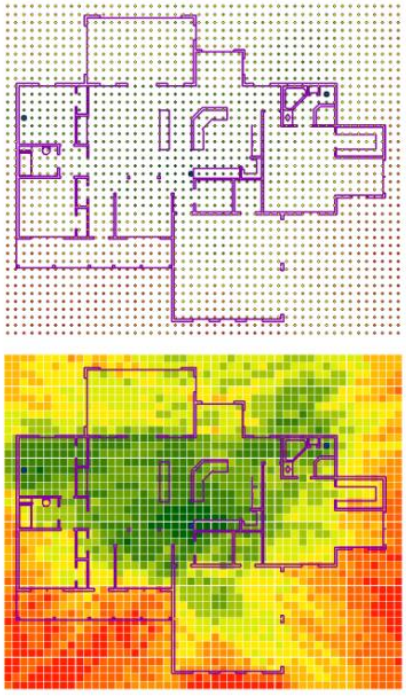

Figure 6 Radio coverage of the indoor space with three transmitters in the apartment (three blue points on the first picture).

In the used example for indoor the layout showed in figure 3, the software calculated $prop_exponent_space$ parameter to be 2.7568. The transmitter power used in this example was 20 dBm which is the typical strength of a WLAN 802.11 transmitter. The propagation model that was used to simulate real world propagation was the COST Average Wall model (8).

$$L(dB) = L_0 + 20\log d + k_w L_w \quad (8)$$

$k_w \rightarrow number\ of\ walls$
$L_w \rightarrow attenuation\ of\ average\ wall$

When software is over with calculations for specific space that is being optimized, all informations for indoor positioning system implementation are ready. Mobile node that is being tracked by three access points set by the software needs to pass initialization before it is put in use. Initialization consists of memorizing the indoor space map, coordinates of three access points and the $prop_exponent_space$ parameter. When the initialization of mobile tracked node is completed, the node can be moved freely in space and trilateration can be done on the mobile node device for the application of determing mobile node position.

Figure 7 shows scale that can be used to read radio signal strength (dBm) for every radio coverage map example in this work.

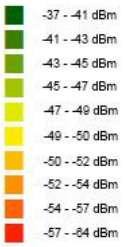

Figure 7 Radio signal strength values.

3. POSSIBLE ERRORS IN MEASUREMENT OF RADIO SIGNAL STRENGTH WITH COMMERICAL WIRELESS TECHNOLOGIES

Received signal strength indicator (RSSI) in some wireless technologies, (for e.g. WLAN, Bluetooth, ZigBee) is primarily used to set the output power of the transmitter with respect to the estimated distance of the second wireless module. Indicator of the received radio signal strength usually does not show its measured radio signal power in dBm, it actually shows a voltage which would ideally be increased linearly with the logarithmic change of the radio power at the entrance of radio signal strength measuremnt circuit. The output of the signal strength indicator is in linear scale, but the input is shown in a logarithmic scale because of the large variation in the strength of the received radio signal which may occur in the radiofrequency receiver circuit of wireless access point.

Implementation of the wireless localization system with some wireless technology (e.g. Bluetooth, WLAN, ZigBee)

technology depends largely on the implementation of the RSSI circuit. Transmission characteristics of the RSSI circuit [9] that is presented in Figure 9 shows typical transmission characteristic of the RSSI circuit implemented in CMOS technology, the error in the RSSI measurement of this circuit for the worst case is around 7.5 dB. Design of a typical RSSI microelectronic circuit which is implemented in CMOS technology and incorporated into commerical chips is shown in Figure 8 [9]. The circuit consists of a cascade of limiting amplifiers, full wave current rectifiers and low-pass filters.

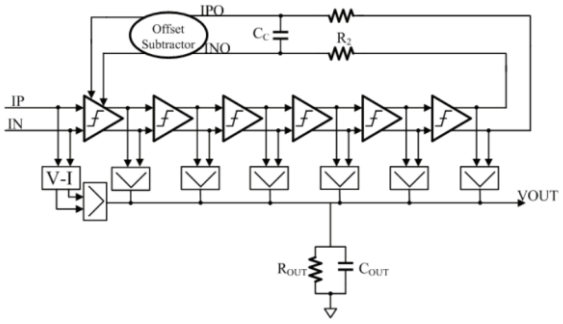

Figure 8 Typical microelectronic design of RSSI circuit [11].

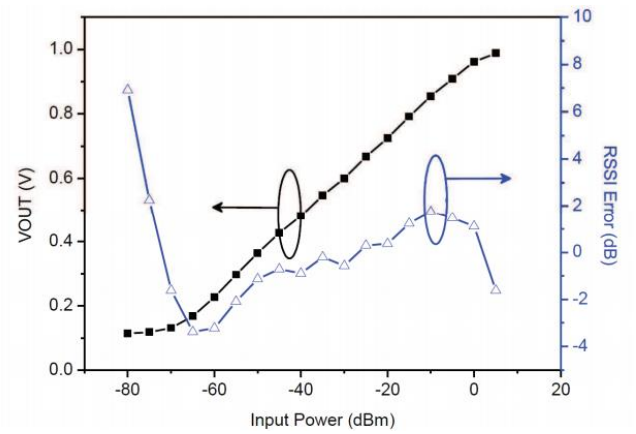

Figure 9 Transfer characteristic of the RSSI circuit [11].

RSSI circuits that are implemented, for example, in commercial Bluetooth devices are not equal because of their non-ideal manufacturing process. In Figure 10 deviation of RSSI circuit transfer characteristic for three Bluetooth devices can be seen. All three compared Bluetooth devices from Figure 10 were bought as the components with equal technical characteristics.

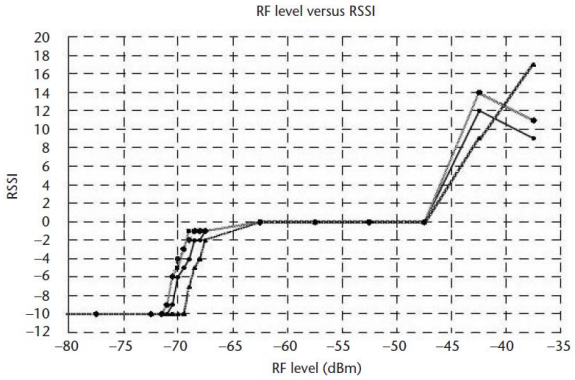

Figure 10 Example of RSSI characteristic for three randomly chosen Bluetooth devices.

4. CONCLUSION

This work presents developed software that is used for the optimization of various indoor spaces in terms of radiofrequency positioning and radio coverage. This software can be used to implement radiolocation services in indoor spaces with cheap, "off the shelf" wireless technologies that possess the ability to measure received radio signal strength. To make this software more accurate and reliable, a more complex 3D propagation model such as an indoor ray-tracing model needs to be implemented as a model that represents real world propagation in a particular environment. Errors that are introduced in the measurement of radio signal strength by various wireless technologies such as WLAN, Bluetooth and ZigBee will also be introduced in the next version of our software.

Management in M2M networks

V. Cackovic, Ž. Popovic
Ericsson Nikola Tesla d.d., Zagreb, Croatia
vanesa.cackovic@ericsson.com
zeljko.popovic@ericsson.com

Abstract - The vision of future networks usually depicts huge amount of different type of devices connected through heterogeneous networks. All those devices do not act alone, but many devices act together to achieve some goal. Although distributed processing is critical to achieve the mass deployment of systems for Machine-to-Machine (M2M) communication, centralized decision making and centralized management of billons of devices will become the key challenge for achieving the global mass market.

Unlike management of traditional telecom network, M2M networks have some characteristics specific to M2M communication that need to be considered while designing efficient M2M network management. Examples of those characteristics would be networks including sleeping devices, low power lossy area networks, heterogeneous networks and device intelligence. Certain characteristics like mobility, time sensitivity of data and data volume differ from application to application but also need to be considered since they put requirements for efficient end to end management.

The paper will focus on identifying the minimum requirements needed for M2M network management, propose mechanisms for efficient management in M2M networks as well as describe the relevant standardization activities for network management in M2M systems.

I. INTRODUCTION

The market for Machine-to-Machine (M2M) communication services is not new, but is rapidly developing, with a predicted yearly growth of more than 30%. Challenges in the space include a multitude of business models, ecosystems and a huge diversity in services, protocols and devices. Ten predictions for M2M and Internet of Things (IoT) in 2014 identified by global researchers and analysts [1] on M2M are:

1. Dawning realization of the evolution from M2M to IoT. There has been a lot of buzz around IoT in 2013. This year is when that becomes a reality. The old "stove-pipe" M2M application approach is giving way to a more integrated approach to application development which draws from a wider range of data sources (including M2M connected devices of different types and also corporate and other IT systems) and stitches these together with more sophisticated applications. This evolution presents massive opportunities but also threatens to sideline any company in the M2M ecosystem that does not evolve.

2. More traffic and more average revenue per user (ARPU). The old days when M2M was only about low volume low ARPU sensor networks is passing. There will be more high bandwidth applications, generating higher ARPU.

3. Fears over 2G re-farming will continue to interfere with the growth of M2M. Buyers of M2M are struggling with how to cope with mobile network operators (MNO) plans for 2G switch off and the impact it will have on their technology choices. This will inhibit growth in some geographies in some sectors in 2014.

4. Low power wide area networks will see much more widespread deployment. There will be much more substantial deployments of low power wide area radio access technologies such as SigFox and Weightless. These networks are very good fit for many M2M applications and a number of announcements of network deployments are expected during 2014.

5. Customers will move away from roaming-based services, towards localized connectivity using remote provisioning (and mobile network operators/service providers will resolve associated commercial issues). In December 2013 the GSM Association published its specifications for Over-The-Air (OTA) provisioning of M2M SIMs. This is on the back of pre-standard solutions available from vendors such as Giesecke&Devrient [2] and Gemalto [3]. Customers and operators alike will recognize the benefits of multi-national (i.e. relationships with facilities-based operators) in each territory, rather than relying on roaming SIMs. The service providers and operators offering these localization options will resolve the commercial arrangements necessary to let it happen.

6. Those selling to the M2M market will find their focus, and smaller operators will find their feet. Today almost everyone in the M2M value chain is attempting to address all customers: MNOs, service providers, module vendors, systems integrators, and everyone in between, are trying to sell to the same set of M2M to customers. As a result they are spreading themselves too thinly trying to be all things to all potential customers. There will be a settling down in the value chain in 2014 as players find their position and the customers to which they should most appropriately be addressing themselves. Smaller, national MNOs will begin to assert their position in the M2M market as they come to better understand their optimum strategy and key market segments.

7. The big data analytics segment will rise...and fall. The value of data is in having a monopoly on the right kind of data or in being able to use it in some clever way. But the market will come to realize that there isn't

much value in the actual analytic part of big data analytics.

8. More merges and acquisitions are going to happen. The M2M industry is evolving very rapidly and with changing dynamics we would expect more consolidation, as all major players gear up to become full service providers. The consolidation will cut across all sectors, including device vendors, service providers and software/cloud platforms.

9. The ratio of products revenue to services revenue will sort the big players from smaller ones. With huge growth expected across all of M2M, it will be those players best able to productize their offerings that will win through. The cost of service provision tracks service revenues, only products scale allowing products-focused companies to outcompete services-focused companies in the same domain.

10. Connected homes finally arrive. They have been promising so much for so long, but 2014 looks like it will be the year when it actually gains some momentum.

To summarize, the world of M2M communications is continuing to grow steadily as predicted few years ago. Operators and service providers that build M2M solutions in a smart and efficient way, solutions that are based on relevant standards [4], [5], [6], [7], [8] will be better in the game of getting the M2M market lead than ones building vertical isolated solutions.

Unfortunately there is still a lot of misunderstanding regarding the complexity and impact on existing networks when talking about end-to-end M2M solutions. Similar situation happened in the past with IMS (IP Multimedia Subsystem) when IMS was firstly perceived as one single platform that will easily enable launching "killer applications". The fact is that IMS solutions similar to M2M solutions consists of several nodes responsible for different functionalities, that integration with supporting systems like charging, provisioning and similar is not trivial and that holistic approach which takes into account clients, network, services and so on is needed when designing network.

Reducing complexity and enabling cost efficient management of devices by enabling one horizontal device management solution instead of a multitude of vertical management solutions will be one of the key components of M2M communication solutions and it will be explained in more details in the following chapters.

II. Overview of M2M Architecture

M2M system is a combination of various heterogeneous electronic, communication, and software technologies. The general architecture of M2M networks such as those being specified in ETSI TC (technical committee) [5] M2M is shown in Figure 1 below.

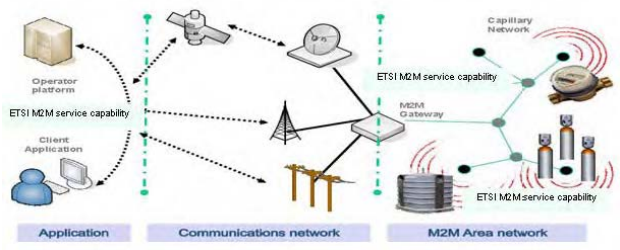

Figure 1 ETSI M2M architecture

In reference to this architecture, M2M devices (intelligent and communication enabled) form an M2M area network; this could be from a small-scale home environment to a bigger environment such as company. The M2M area network is connected to the communication network such as cellular base stations through the M2M gateway. Through the communication networks, they are connected to the M2M management server on the M2M service platform and subsequently reaching the M2M applications on the other side of the M2M management server.

Data in M2M systems travel from an area network to a communication core network. When data leaves the area network and arrives to communication core network, its first destination is usually a gateway. The gateway is a device which decides the communication protocols and converts the incoming data into legacy system format. A middleware layer that routes data and converts the format of the data could also be part of the communication core network. Middleware layer could also perform network management tasks such as logging, notification, auto-configurations, etc. Some parts of the business logics could also be applied in these middleware's and gateways.

Communication network can be of any type including wireless LAN, telephone lines, Ethernet, satellite or cellular networks. Finally, the data gets integrated into a business process at the M2M application layer such as smart metering, fleet management, eHealth etc. The data flow explained above is not always exactly the same; it varies from application to application. Some components will merge with others as time passes and M2M systems mature.

III. Standards for M2M Network Management

Since standards for M2M communications are written relatively recently, M2M network management is also a new area of investigation. In this section, the main standards related to M2M network management will be explained.

ETSI defined in M2M Functional architecture document [5] the overall end to end M2M functional architecture, including descriptions of the functional entities, the related reference points and the service capabilities; M2M identifiers, information model; procedures for bootstrapping, security, and management; charging; and implementation guidance. Besides its other functionalities, the Service capability layer (see Figure1) supports remote management of gateways, devices and

area network, including performance management, configuration management, fault management and software and firmware upgrading management [5]. In the functional architecture management resources are described as MgmtObj. The resources are handled with the RESTful style of data exchange. The four basic methods in the RESTful architecture are Create, Retrieve, Update and Delete.

ETSI "Machine-to-Machine communications (M2M); BBF TR-069 compatible Management Objects for ETSI M2M" The document [11] defines the corresponding BBF-TR-069 compatible Data Model. In its TR-069 the BroadBand Forum (BBF) specifies a protocol for communication between a CPE (Customer Premises Equipment) and an ACS (Auto-Configuration Server). ETSI M2M defines a Device Management function that allows to remotely configure the M2M Devices by using already existing Device Management protocols (e.g. BBF-TR-069, OMA-DM, etc.). Due to the RESTful nature of the interface with the M2M Applications, some ETSI Management Objects are specified and modelled as REST resources in [5]. Some of these ETSI resources may be mapped on already existing Data Models / Management Objects as defined by BBF or/and OMA. The corresponding mapping rules are specified in [6]. Some other resources do not correspond to any existing Data Models/Management Objects as defined by BBF or/and OMA.

Similar to the previous technical specification, ETSI published also ETSI TS 103 092 for OMA DM compatible Management Objects [12].

Open Mobile Alliance (OMA) on the other side, sharing the same idea as ETSI, has responded to market demand in the M2M area, understanding that a common set of standards for managing light weight and low capability devices on a variety of networks is not just a nice option, but a mandatory approach. Considering the billions of devices expected to be connected to networks in homes, as well as smart metering and medical devices to name a few, the ability to monitor, provision and manage these billions of connections becomes absolutely essential. Facing the new challenges offered by the market, the OMA DM Working Group with its expertise in remote management addressed the M2M environment with OMA Lightweight M2M protocol, which focuses on constrained cellular and sensor network M2M devices.

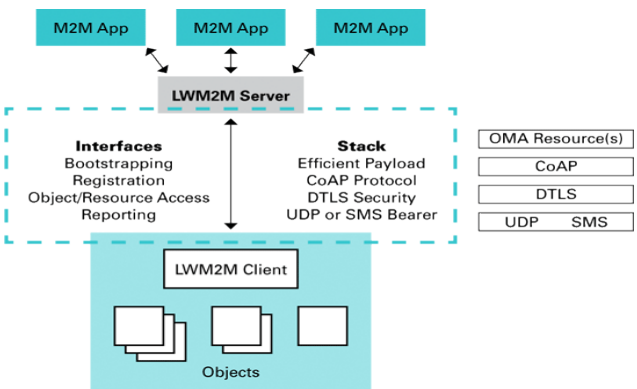

Figure 2 OMA Lightweight M2M protocol

The OMA lightweight specifies simple management interfaces based on IETF standards (CoAP and DTLS with UDP and SMS bindings), with plain text, TLV and JSON serialization for data payload and an Object Model based on manageable Resources (accessible via URI) and Instances concepts (borrowed by OMA DM technology).

OMA LightweightM2M 1.0 is targeted for release in 3Q 2013.

The Telecommunications Industry Association (TIA) Smart Device Communications Engineering Committee TR-50 is responsible for the development and maintenance of access agnostic interface standards for monitoring and bi-directional communication of events and information between machine-to-machine (M2M) systems and smart devices, applications or networks. These standards development efforts pertain to but are not limited to the functional areas as noted: Reference Architecture, Informational Models and Standard Objects, Protocol Aspects, Software Aspects, Conformance and Testing, and Security. TR-50 is developing an M2M Smart Device Communications framework that can operate over different underlying transport networks (wireless, wired, etc.) and can be adapted to a given transport network by means of an adaptation/convergence layer. The TR-50 framework will make its functionality available to applications through a well-defined Application Programming Interface (API) that is agnostic to the vertical application domain (eHealth, Smart Grid, Industrial Automation, etc.). TR-50 works with international standards organizations to ensure end-to-end functionality and interoperability, to avoid overlap or duplication of work, and to foster collaboration and coordination among organizations addressing various components of Smart Device Communication Systems [13].

IP for Smart Objects (IPSO) supports IP for smart objects. This alliance was formed to promote IEEE and IETF standardization bodies. Standards established by the 6lowpan, Roll and CoRE working groups under IETF can provide complete M2M solutions. 6lowpan provides an adaption layer for IPv6 over IEEE 802.15.4. Their technique includes packet fragmentation, reassembling, header compression and optimized neighbor discovery for Low power and Lossy Networks (L2Ns). The Roll working group defines the routing solutions for L2Ns. The first draft of the Roll group's IPv6 Routing Protocol for L2N (RPL) is almost stable. The CoRE working group specifies a framework to monitor and control smart objects intended to run on L2N. They will define a RESTFul style of API and specify the proxy handling mapping between CoAP and REST APIs. CoAP will also support cashing for sleepy devices [14].

Since the M2M industry is fragmented and spread across many different sectors (telecommunications, energy, health, automotive and so on) the current situation is that industry verticals are solving their M2M needs on their own depending on dominant technologies in their sector. Many organizations are working on standardization. These efforts need both leadership and consolidation. There is an opportunity for telecoms companies to take the lead here and convene the world's

experts in the field to work together on this important issue.

IV. Requirements for M2M Network Management

In this section we will elaborate the network management functionalities required for M2M networks and applications.

1) Fault Management (FM) is the set of functions that detect, isolate, and correct malfunctions in the network. FM also compensates for environmental changes, and include maintaining and examining error logs, accepting and acting on error detection notifications, tracing and identifying faults, carrying out sequences of diagnostics tests, correcting faults, reporting error conditions, and localizing and tracing faults by examining and manipulating database information. FM is essential part of all types of M2M networks and applications. Fault management could be periodic, on demand or event driven and M2M network management shall support reporting of faults with specific parameters (i.e. time, date and fault data). Apart from general event driven faults, accidental, environmental and theft related context information can also be triggered as an event in fault management of M2M.

2) Configuration Management (CM) - For a device to be operational several parts need to be configured. This includes the following functionalities:

- Periodic inform - Configuration for how often and in which timeframes a device must contact the management system
- Management server - Configuration for which management system to contact and what authentication method to use
- Connection request - Configuration for which username and password the management system must use when sending connection requests to a specific device
- If managing devices behind a NAT gateway the STUN server information must be provisioned.

In addition to the things needed for device management the service parameters needed for the different services to work is of course possible to configure. This can be e.g. parameters for VoIP service as specified in TR-104 or presence service as specified in presence MO.

3) Mobility Management - is critical requirement in M2M applications with high mobility (such as fleet management or good tracking). Mobility management will include location awareness, navigation support, vertical-horizontal handoff and roaming facilities depending on the application needs.

4) Service Assurance - The service assurance function shall support the service provider in the following use cases:

- Assurance/trouble shooting - Performing tests on individual devices in case of problems reported
- Activation - Performing tests on individual devices after installation at the customer premises in order to make sure that the offered bandwidth etc. is fulfilled.
- SLA tests - proactive and continuous tests towards several devices in order to make sure that agreed SLA is fulfilled

5) Account management – Charging scheme for M2M service usage can be prepaid or postpaid. M2M account management shall provide support for both type of charging schemes.

6) Security - Hackers and malware are finding tempting targets in connected devices across all vertical markets, from consumer electronics and automobiles to medical equipment and military hardware. One of the key elements for a successful deployment and adoption of M2M systems is to ensure trustworthiness, authenticity, and privacy of data being communicated.

V. Management in M2M Solutions – Implementation Considerations

To achieve the mass market, M2M solutions will need to operate in very lean and effective ways. It is therefore essential that management and support functions are well thought out and integrated from the beginning.

Furthermore, M2M solutions cover a broad spectrum of solution spaces that might have quite different business requirements. In the M2M solution space an “off-the-shelf” solution is seldom good enough. There are, however, many management and support functions that fit well across solutions. From experience around 80% of the functionality is common between verticals and thus existing functionality can be reused which allows cost efficiencies to be reached, the remaining 20% of the functionality is unique per vertical.

It has been shown from the implementation experience that horizontal platforms for managing the end devices are the best option. Example of the management platform would look like shown in Figure 3:

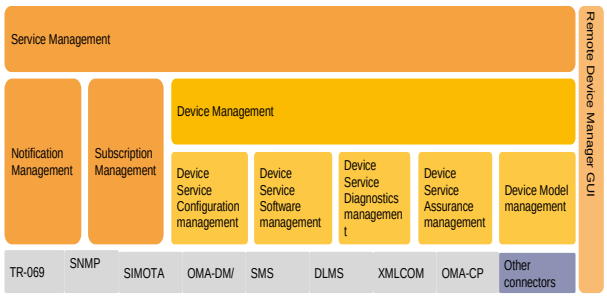

Figure 3 Internal Management Platform Structure

The Management provides a graphical user interface for administration and customer care. The Remote Device Manager GUI uses the services interface exposed by each component. These services are also exposed as external web services interfaces and can be used for integration towards other systems and end user portals.

- Every component owns its data and is storing persistent data in the resource layer (database layer)
- Every component exposes a public web services API which can be used to integrate with external systems
- The protocol connectors are handling the sessions with the managed devices and SIM cards. The protocol connectors are abstracting the differences in the protocols to the upper layers. Examples of connectors shown in the picture are currently implemented protocol connectors are:
  - TR-069 connector
  - OMA-DM connector
  - SNMP connector
  - XMLCOM connector
  - OMA-CP connector
  - Proprietary SMS connector
  - SIMOTA connector
  - DLMS connector

In this way, the platform is modular and can be expanded with additional connector for supporting required technologies. The common functionalities like configuration management or diagnostics reside atop of specific connectors and can be reused regardless of underlying technologies. Benefits of this approach are in simplified integration, creating a one to many (in place of a costly many-to-many) interface to support multiple devices and technologies with a single northbound API that supports all device management functions.

Common functionalities support all device-related use cases for implementation of the complete M2M system, ie. Smart metering application:

- Device Configuration Management – ensure correct settings; continuously update; lock or reboot; apply automatic firmware/software updates
- Network Provisioning – provide device information; initiate provisioning upon device events
- Device Lifecycle Management: device installation, substitution, software update, configuration, removal, termination, (re)activation
- Data & Event Collection – scheduled or on-demand retrieval of device data; cleanse device data; publish device data for multiple uses
- Diagnostics – verify and resolve device software and configuration settings
- Fault Management – detect device alarms and forward to external systems
- Monitoring – collect and forward vital device KPIs; support quality of service, optimize campaigns and maintain SLAs

The Management platform will enable reuse of the device data it collects. In this way, the operator, for example, can use this to improve processes for supply, market planning and customer relationships.

With fewer, shorter and more efficient customer care calls, the overall service experience becomes more positive, leading to happier customers and increased profits for the service.

VI. CONCLUSION

When deploying a new service that is aimed for thousands or even millions of consumers, the operator and service provider face a number of challenges. Many of these are related to equipment handling, and the time and skill needed to cope with manufacturing, installation and configuration. In addition there are challenges once the equipment is in service; to keep the software up to date at all times, assure the equipment is functional.

There is a logistic challenge to manufacture M2M devices that will be deployed globally. The software version may differ from market to market and the data connectivity e.g. access points will differ from the selected service provider.

One answer to this challenge is late configuration of an M2M device. By integration with the mobile network it is possible for Management platform to act upon a network attach of an M2M device, and automatically initiate configuration of the device (e.g. by setting the APN) and/or by installing the latest firmware and software onto the device. This enables a full automated process to bring the device into service.

Depending on the area an M2M device may have a very long lifetime. During this lifetime the software has a need to be updated (with bug fixes or even software enabling new services). Management platform is a tool to enable remote update of the device firmware and software.

If a device is deemed as malfunctioning, e.g. noticed by the M2M Enterprise by gaps in its data collection, or via the Management platform monitoring feature then analyses of what might be wrong is desired. Sending out a service technician is of course costly and thus remote troubleshooting is desired. Some M2M devices do support remote trouble shooting and diagnostics and thus Management platform can be the tool to perform these tasks, thus saving time and money in the process.

M2M devices may also collect and store service KPI's which Management platform can collect using the monitoring functionality as well as to forward data to backend systems. This way the quality of the M2M service can efficiently be assured which is a huge value for the M2M service operations.

In summary, device management is a very important and essential part in order to secure cost efficiency in managing the vast amount of devices soon deployed.

Rolling out M2M services can be complex, as different industries can have diverse requirements and deployment characteristics. The described M2M device management platform is oriented around ETSI M2M standards, which

provides a simplified functional architecture fir addressing the M2M needs of multiple industries. This is key for operators and service providers that want to extract value from a single platform serving multiple customers on millions of endpoints concurrently.

ABSTRACT: Utilities today are being challenged as never before. We are witnessing the creation of Next Generation Utilities, which differ from the old utilities in their massive use of extremely sophisticated ICT equipment and processes. In particular the introduction of Smart Grid Communications and Smart Metering requires the ability to deal with ICT projects of a scale and complexity that are beyond the experience and resources of most utilities. There is a need for utilities to make use of partners with advanced ICT skills regarding deployment of systems based on machine-to-machine communication and development of new services like electric vehicle charging.

In this paper, a mobile electric vehicle charging station is being introduced. As plug-in hybrid electric vehicles and battery electric vehicle ownership is expanding, there is a growing need for widely distributed publicly accessible charging stations, some of which support faster charging at higher voltages and currents than those available from domestic supplies. Many charging stations are on-street facilities provided by electric utility companies. Mobile charging stations have been recently introduced. Presented proof-of-concept provides a complete solution for remote control of electric vehicle charging stations, for both customers and owners using web clients.

KEY WORDS

1. Utilities, 2. M2M communication, 3. Electric Vehicle Charging

I. INTRODUCTION

As an electric vehicle charging (EVC) station, also called EV charging station, electric recharging point, charging point and EVSE (Electric Vehicle Supply Equipment), is an element in an infrastructure that supplies electric energy for the recharging of plug-in electric vehicles, including all-electric cars, neighborhood electric vehicles and plug-in hybrids.
Some charging stations support faster charging at higher voltages and currents than those available from domestic supplies. Many charging stations are on-street facilities provided by electric utility companies. Mobile charging stations have been recently introduced. Some of these special charging stations provide one or range of heavy duty or special connectors and/or charging without a physical connection using parking places equipped with inductive charging mats.

Figure 1 Ericsson Electric Vehicle (EVC) charging Station [4]

Machine to Machine (M2M) communication is communication between two or more entities that do not necessarily need any direct human intervention. M2M services intend to automate decision and communication processes. M2M uses a device (such as charging station) to capture an event (such as start of charging, voltage, etc.), which is transferred through a network to an application, that translates the captured event into meaningful information [1].
There are many benefits regarding integrating EVC system with M2M Data Management (M2M DM) platforms like Ericsson MDM DM. Ericsson M2M DM is capable to receive the data measurements on the southbound interface and store the data but also to provide data visualization capabilities on northbound interface. M2M DM is excellent with dealing and processing thousands of requests. Security is another big advantage. With intelligent M2M data management system, customers and available devices can always be tracked [2] [3].

II. STANDARDS FOR ELECTRIC VEHICLE CHARGING SYSTEMS

T in SAE (Society of Automotive Engineers) International, 240 volt AC charging is known as level 2 charging, and 500 volt DC high-current charging is known as DC Fast Charge. Owners can install level 2 charging station at home, while businesses and local government provide level 2 and DC Fast Charge public charging stations that supply electricity for a fee or free [5]. The International Electro technical Commission (IEC) modes definition:

- **Slow** - slow charging from a regular electrical socket (1- or 3-phase)
- **Semi-fast** - slow charging from a regular socket equipped with some EV specific protection arrangement (e.g., the Park & Charge or the PARVE systems)
- **Fast** - slow or fast charging using a specific EV multi-pin socket with control and protection functions

There are three connection cases:

A. Case A is any charger connected to the mains (the mains supply cable is usually attached to the charger) - usually associated with modes 1 or 2

B. Case B is an on-board vehicle charger with a mains supply cable which can be detached from both the supply and the vehicle - usually mode 3

C. Case C is a dedicated charging station with DC supply to the vehicle. The mains supply cable may be permanently attached to the charge-station such as in mode 4.

III. SYSTEM ARCHITECTURE

User connects to EVC web application from any device with internet browser. The browser is used to access the end-user service portal. Service portal is an web application with EVC application. Web application communicates with server that delivers all of the functionality displayed in pictures below. Once web server receives request for charging to start, it assigns logged in user in M2M to selected gateway (Charging station) and sends confirmation SMS message. Every 5 seconds EVC charging station sends its status to M2M southbound interface. Web server pulls data from northbound and shows them on user's device as shown on Figure 2.

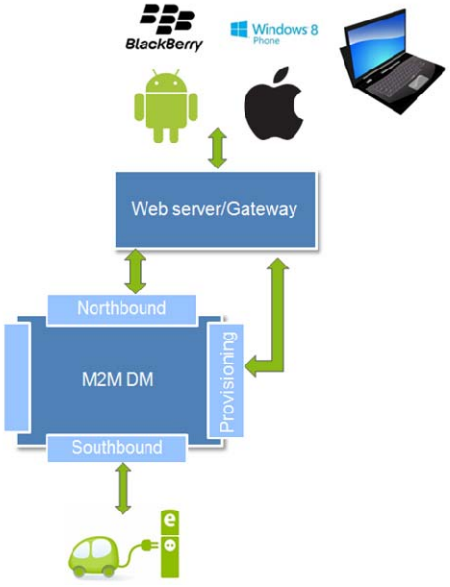

Figure 2 Electric Vehicle Charging – generic system architecture

Sequence diagram on Figure 3 shows successful charging scenario:

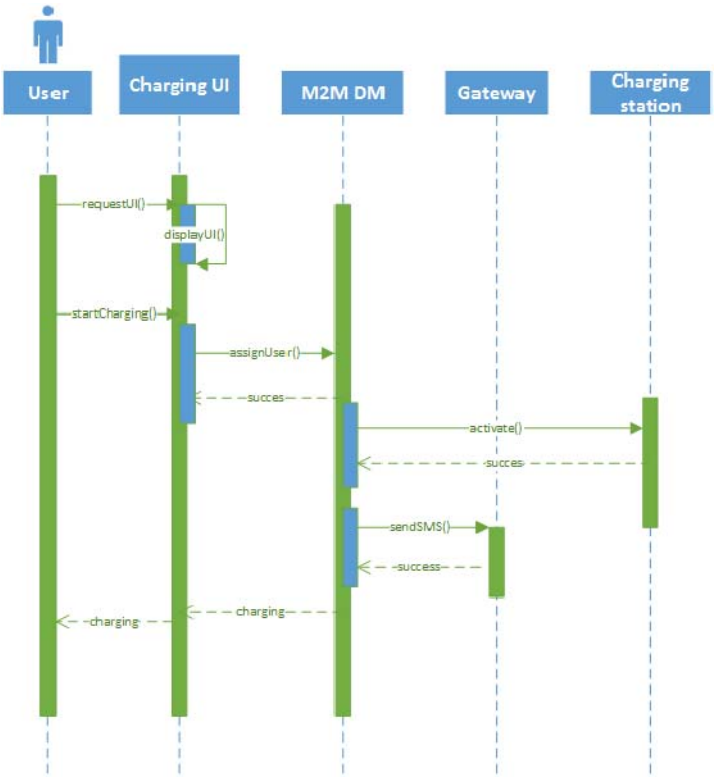

Figure 3 Sequence diagram for EVC using M2M DM

- User sends „requestUI()“ message to Charging UI to display user interface.
- Charging UI executes „displayUI()“ message and displays the user interface to user.
- Users sends „startCharging()“ message to ChargingUI.
- ChargingUI sends „assignUser()“ message to M2M DM node.
- M2M DM assigns current user to gateway instance and sends confirmation message „success“ to Charging UI.
- Presenter M2M DM then sends „activate()“ message to the Charging station to start the charging.
- Charging station turns the light bulb on and responds with „success“ message back to M2M DM node.
- M2M DM sends „sendSMS()“ message to SMS gateway. Gateway sends SMS message to designated cellphone number and responds with „success“ message back to M2M DM node.
- M2M DM responds with „charging“ message back to Charging UI which forwards the message back to User.

This is a critical point of the system because M2M DM plays the role of the data collector, while devices (Charging station) play the role of data providers. In this form of distributed architecture, the data providers connect to the data collector and post the measured data from the devices sensors.

As Gateway shown in Figure 3, Ozeki SMS gateway was used. SMS Gateway enables sending the applications to send/receive SMS messages to mobile devices the battery status information. Also in order to reserve, start and stop the charging process the gateway was needed and used.

IV. CONCEPT VALIDATION

As part of our project, we have developed a service portal, which communicates with the M2M through northbound interface and through provisioning interface. The communication is being done with standard HTTP protocol. The northbound interface is used for querying the M2M and for receiving the data provided by the M2M. All sensors are connected to M2M through the southbound interface. This interface is used for inputting the data from the sensor devices and it is based on REST principles. The protocol for communication is also standard HTTP in combination with DIGEST authentication. Important thing to mention is that the communication is done both ways, from the charging station (EVC) to M2M DM, and from M2M DM to EVC.

The validated concept has the following hardware and software solution components:

- Ericsson Vehicle Charging station
- ZyXEL power line communication device
- M2M DM for capturing and processing the events
- EVC end-user and administrator web application.

End-user web application has following pages and functionalities:

- Welcome page
- User registration page
- Car battery status page
- Charging station map and reservation page
- Start & Stop charging page
- Charging history page

Administrator web application has following pages and functionalies:

- Sign in page
- Overview of available charging points
- Adding / removing charging points
- Overview of utilization by individual charging points

In welcome screen user has option to choose application language. Also they have a choice to sign in if they have EVC account or register for a new one as show on Figure 4.

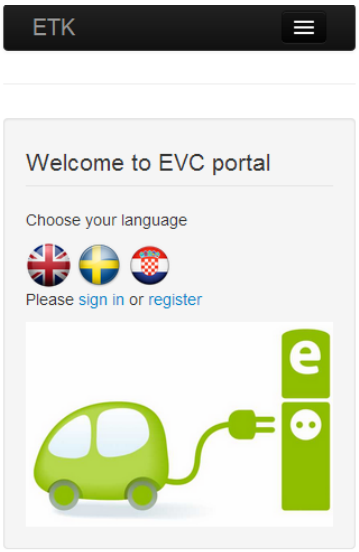

Figure 4 End-user welcome screen

User has to fill out some personal information. Username, email and password are necessary fields while others are optional (on demand that can change in future). Term of Services is yet to be determined and filled out. If all entered information is correct user is going to see success message, otherwise error message with list of invalid fields is going to show up.

Under locations tab user can see maps with marked positions of all EVC charging stations. All green markers indicate that EVC charging station is currently available. Red markers indicate that EVC charging station in unavailable.

When user clicks on green marker (available) they get pop-up box with option “Charge here”. When clicked on “Charge here” user gets redirected to charging page where they have option to start charging as shown on Figure 5.

Charging page allows you to customize charging of

your car. First option is to select charging point from dropdown menu. Second you can choose type of charging, three default values are slow, semi fast and fast. And optional you can define time period for charging. Start charging button initiates charging, sends customer SMS message with start time and all following activities as shown on 6, 7 and 8.

The administrator can see average power consumption during the day for selected charging station. Every column represents a 24 hour day. Under each column administrator can see daily use percentage of charging station. Red fields represent the time of day when the charging station was inactive (not charging) and green fields represent the time of day when the charging station was active (charging) (Figure 9).

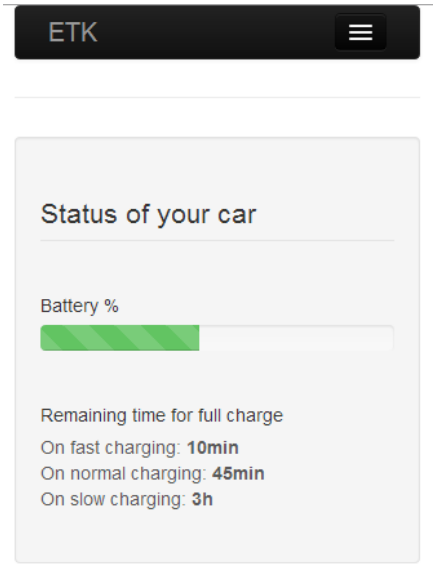

Figure 5 Car battery status

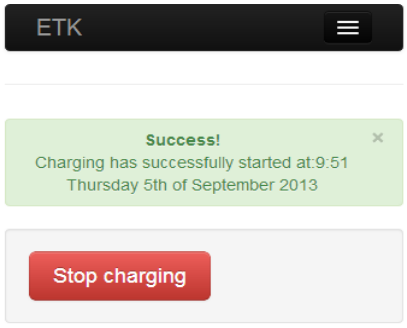

Figure 6 Stop charging process functionality

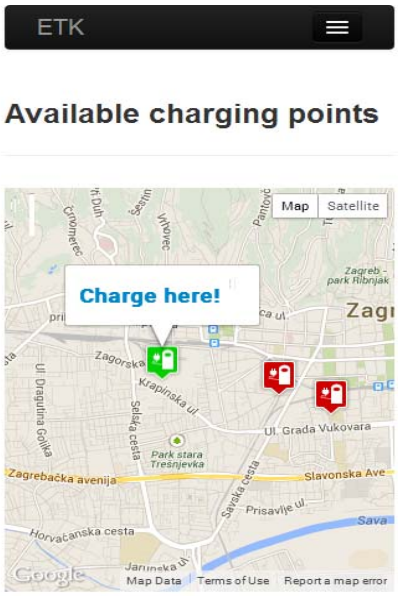

Figure 7 Available charging station points

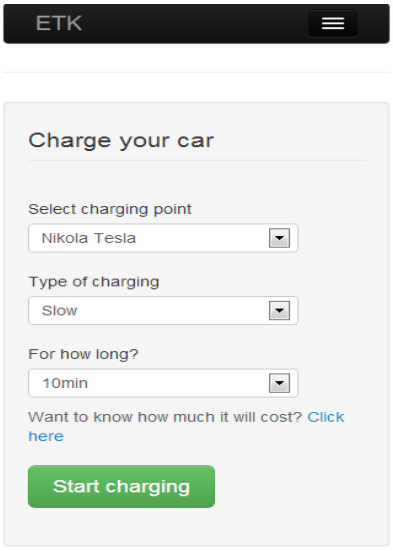

Figure 8 Start charging process functionality

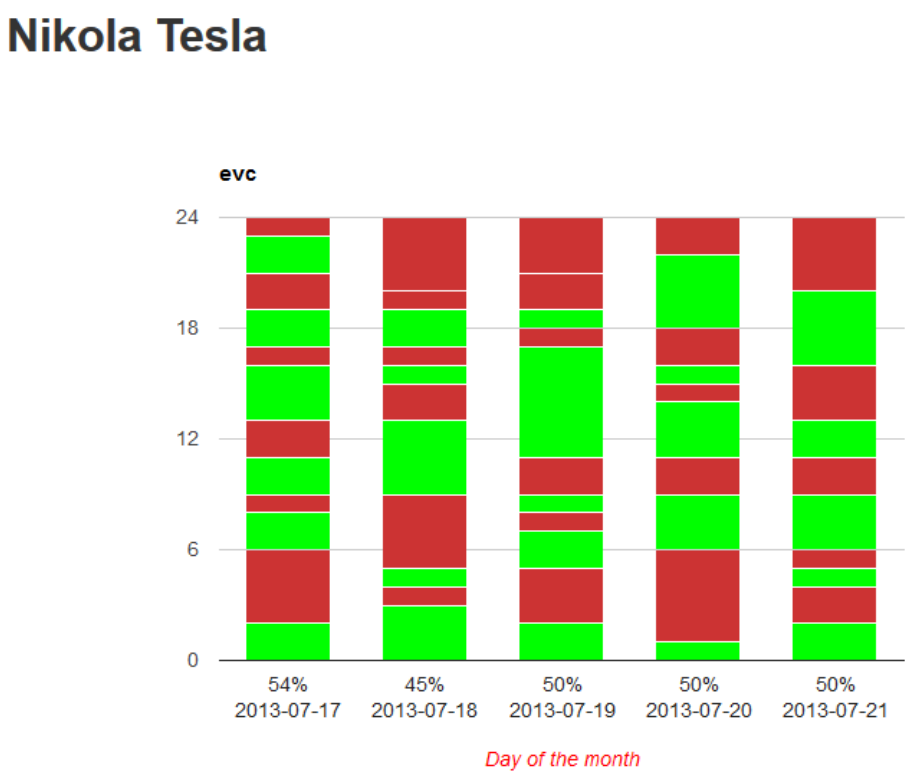

Figure 9 Charging point utilization overview

VI. FUTURE WORK AND DEVELOPMENT

Even though the whole system has been developed, a few points exist in which the system could be upgraded in the near future.

- One major upgrade is to integrate the system with Ericsson Service Portal in order to get user profile provisioning
- Integration with services from smart grid area.
- Other possibility for further development is to implement more features to our EVC application:
- Develop location services so that, based on your location, application can determine nearest charging station and give you directions to it
- Read current battery status of plugged in car

That upgrade has to be enabled on car as well on the charging station side. With information provided from battery we can determine estimated time of remaining charging time.

VI. CONCLUSION

Complete system for remote control of electric vehicle charging stations, for both customers and owners was developed as a result of this project. System consists of frontend web application and backend scheduler application on M2M electric vehicle charging station.

The system is able to collect availability data from M2M electric vehicle charging stations using scheduler application which communicates with M2M DM. Web application can pull that data from M2M DM and control the charging process by sending on/off signals to charging stations.
Light bulb was connected to charging station representing electric vehicle. When the bulb lights up, it represents charging process is on. When the bulb is turned off, it represents charging process is off.

Web application works on any computer or smartphone capable of internet access. It utilizes

administrator and user interface. M2M service enablement data and charging statistics are presented in web application interface. Administrator has additional features for managing and checking charging stations availability presented on both Google Maps and separate status tab in web application.

Goal of the project was to show that variety of devices can communicate using M2M DM..

ACKNOWLEDGEMENT

The authors thank M2M SE team members for help provided in regards to M2M SE Node and especially to Marko Mrkus for help provided in integrating described prototype system with M2M SE.

Applications methods of the objects, and suitability for universal applications in computer graphics context

Nderim Zeqiri*

* Faculty of Applied Sciences– State University of Tetova, 1200 Tetovo, R. Macedonia, office, Mechatronics
nderimzeqiri@gmail.com

Abstract – The use of the primitive objects, can be modified and adapted for universal applications in computer graphics context. The present paper addresses some access and research in the field of computer graphics. The program code present the basics step to increase the study and to explore differently level by describing each of them by math formulas and graphical representations. Also, here is explained the methods how we can use all these recourses to implement to any system, where can be find the better solution in the context of universal applications and solutions.

So, to solve all from above questions, are given some characteristics objects and program code for respective representations. Also is given a direct approach for ADC (analog-digital conversion), by use the fundamental steps followed by this topics: sampling rate, quantization. Also is given statistical results by creating the respective images and respective view in the context of the statistical analyses.

Keywords: Computer graphics, motion, adaptations, program code, generation, ADC converter, samples

I. INTRODUCTION

To make a good system that must be a functional and well structured system is required basic knowledge of a relevant programming languages and communications systems. Depending on the application, one or another measure might be more relevant [1].

The present paper addresses some access, research and implementation for computer graphics and image processing.

The two major components in a high-speed digitizer's are the analog input path and the analog-to-digital converter (ADC) as presented in Figure 1.

The analog input path such as: attenuates, amplifies, filters, and/or couples give us an opportunity to optimize the digitization by the ADC converter or transformation [1] [12] [13].

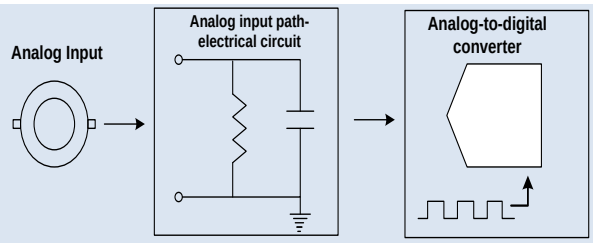

Figure.1. Analog input path and ADC converter.

The Analog to digital (ADC) converter, converts the analog input waveform to digital data. Here is used the sampling rate as a first step to obtain a discrete values on the basis of the Nyquist theorem [2][3][15]. The Nyquist Theorem explains the relationship between the sample rate and the frequency of the measured signal.

In the paper has been decribed how we can do the better solution in the way of implementations, and how we can make a system flexible to use in differently applications.

Also here is described and is given the adequate math formula for values generations, which are very important for fast generations. Using respective sampling rate can be obtained statistical result. The quantization method is a second aim of the paper. Also, in the paper is given how can do and realize the quantization process and statistics for signal to noise ratio.

II. PROGRAM CODE AND MATRIX TRANSFORM DETERMINATION

In the below step is given the code, where is described the manner and the way, how we can generate a primitive object in the windows form applications,

```
Graphics g = e.Graphics;
GraphicsState State = g.Save();
g.PageUnit = GraphicsUnit.Pixel;
Matrix matrixTransformes = new Matrix (1, 0, 0, -1, 0,
0);
matrixTransformes.Translate(this.ClientRectangle.Widt
h / 2, -this.ClientRectangle.Height / 2);
g.Transform = matrixTransformes;
g.DrawLine(new Pen(Color.FromArgb(255, 0, 0), 3), 0,
0, 100, 100);
g.Restore(StateBefore);
g.DrawLine(new Pen(Color.FromArgb(0, 255, 0), 3), 0,
0, 100, 100);
```

The given code can practically serve as a good basis of simulation for graphics context by uses the primitive objects, which are very important to create a good basis and solution for matrix transformer and translation [5][6]. A large number of simulations and projects, in terms of computer graphics can be used in educational institutions, and companies. The main code (given above), creates the possibility of expanding it at the request of users. Application software products have to be developed on the basis of the algorithm, from where we can create a software product, which is relevant and appropriate that finds wide application in the context of computer graphics [7][8].

III. IMAGE PROCESSING SYSTEMS ANALYSES AND VISUAL INFORMATION

Visual information is analyzed according to some research, which represents nearly 80% of all information we receive.
This is not just for the audience that human senses are efficient, but also from the fact that electromagnetic radiation, as well as their part and light are the main carriers of information about objects and processes found in nature [9][10].
Movement of visual information can be presented with the following scheme:

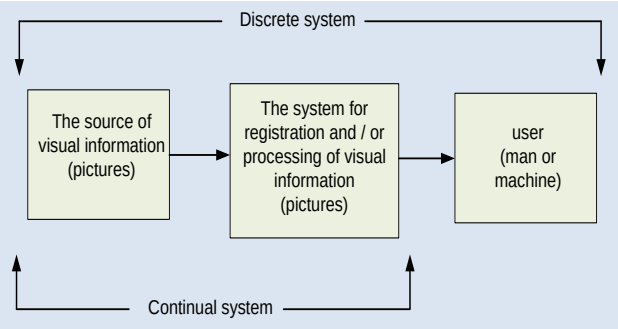

Figure.2. Control flow of visual information

In mostly of the differently system can be incorporated sensors systems which can be an intelligent sensor, for directly implementations to the computer control system, for respective visualizations scene [8] [10].
Received information the user may use in two ways.

- Directly: to control any process (for reaching a decision and take appropriate action).
- Indirectly: for observation, i.e. accumulation of visual information, in order that they will later be processed along with some other information.

Scene, meant limited two-dimensional fields:
Where each point (x, y) at any point of broadcasts (as primary or secondary source) electromagnetic radiation, power spectral density [12][13].

$$P(x, y, \lambda, t) \quad (1)$$

$$0 \leq P(x, y, \lambda, t) \leq A \quad (2)$$

Distribution of load accumulation in the field of cumulative interval T is:

$$\frac{dQ(x,y,t)}{dt} = k \int_{\lambda 1}^{\lambda 2} P(x, y, \lambda, t)\varepsilon(\lambda) \quad (3)$$

This is an analogue aspect, and the goal of researchers in recent years has been the transition to digital system because analog systems needs report definitions S/N (signal/noise), the band and especially the creation of issuing high stability of these characteristics. Therefore processing of digital image processing goes on, especially with the development of advanced computer system.
Transfer of analog monochrome figure – in digital image, called digitalization and includes three procedures [9]:

- Discretization or 2D (sampling) of analog figure.
- Discretization of luminance samples (samples) or quantization.
- Coding

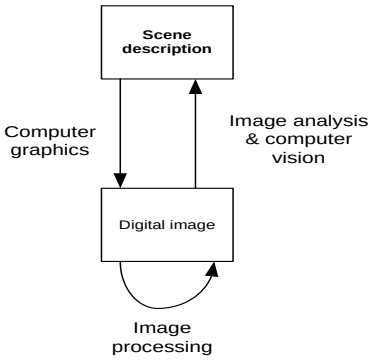

Figure.3. Computer graphics and Image Processing

IV. THE SAMPLING RATE AND RELEVANT VALUES

Sample rate is not directly related to the bandwidth specifications of a high-speed digitizer. Sample rate is the speed at which the digitizer's ADC converts the input signal, after the signal has passed through the analog input path, to digital values that represent the voltage level. This means that the digitizer will sample the signal after any attenuation, gain, and/or filtering has been applied by the analog input path, and converts the resulting waveform to digital representation [13]. The sample rate of a high-speed digitizer is based on the sample clock that tells the ADC when to convert the instantaneous analog voltage to the digital values, Figure 4. National Instruments high-speed digitizers support a variable effective sample rate derived from the maximum sample rate of the device. For example, the NI 5112 has a maximum sample rate of 100 Megasamples/second (MS/s) and can be set to rates of (100MS/s)/n, where n = 1,2,3,4,.... [2][14]

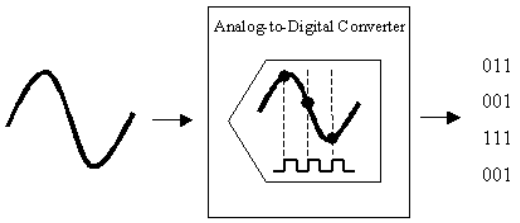

Figure.4. Nyquist theorem, sample rate and ADC

It is recommended that the bandwidth of our digitizer be 3 to 5 times the highest frequency component of interest in the measured signal to capture the signal with minimal amplitude error (bandwidth required = (3 to 5)*frequency of interest). The theoretical amplitude error of a measured signal can be calculated from the ratio of the digitizer's bandwidth in relation to the input signal frequency (R). A complete simulation system must model all components of a computer system. However, only a few components play a determining factor in the speed of the simulation etc [5][8][9].

V. THE QUANTIZATIONS AND STATISTICS FOR SNR (SIGNAL TO NOISE RATIO)

For digital signal processing, continuous-amplitude samples from the sample-and-hold are quantized and mapped into n-bit binary digits. For quantization to n bits, the amplitude range of the signal is divided into $M = 2^n$ discrete levels, and each sample is quantized to the nearest quantization level, and then mapped to the binary code assigned to that level [2].

The quantization of the signal into 4 discrete levels [4][15]. Quantization is a many-to-one mapping, in that all the values that falls within the continuum of a quantization band are mapped to the centre of the band. The mapping between an analog sample xa(m) and its quantized value x(m) can be expressed as,

$$x(m) = Q[x_a(m)] \quad (4)$$

Where $Q[x_a(m)]$ - is quantizing function. The performance of a quantized is measured by signal to quantization noise ratio SQNR per bit. The quantization noise is defined as,

$$e(m) = x(m) - x_a(m) \quad (5)$$

Now consider an n-bit quantized with an amplitude range of ±V volts. The quantization step size is, $\Delta = 2V/2^n$. Assuming that the quantization noise is a zero-mean uniform process with an amplitude range of ±Δ/2 we can express the noise power as,

$$E[e^2(m)] = \int_{-\Delta/2}^{\Delta/2} f_{E(e(m))}\, de(m) = \frac{1}{\Delta}\int_{-\Delta/2}^{\Delta/2} e^2(m)de(m) = \frac{1}{\Delta}\cdot\frac{V^2 2^{-2n}}{3} \quad (6)$$

Sampling and Analog–to–Digital Conversion where $f_{E(e(m))}$=1/ Δ is the uniform probability density function of the noise. Using Equation (6) signal–to–quantization noise ratio is given by,

$$SQNR(n) = 10Log_{10}\left(\frac{E[x^2(m)]}{E[e^2(m)]}\right) = 10Log_{10}\left(\frac{P_{Signal}}{V^2 2^{-2n}/3}\right) = 10log_{10}\ \ 3\text{-}10\ \ log_{10}\left(\frac{V^2}{P_{Signal}}\right) + 10log_{10}2^{2n} = 4.77 - \alpha + 6n \quad (7)$$

Where Psignal is the mean signal power, and α is the ratio in decibels of the peak signal power V^2 to the mean signal power Psignal.

After the sampling we have a sequence of numbers which can theoretically still take any value on a continuous range of values. Because this range in continuous, there are infinitely many possible values for each number, in fact even uncountable infinitely many. In order to be able to represent each number from such a continuous range, we would need an infinite number of digits - something we don't have. Instead, we must represent our numbers with a finite number of digits, that is: after discrediting the time-variable, we now have to discredit the amplitude-variable as well. This discretization of the amplitude values is called quantization. Assume, our sequence takes on values in the range between −1... + 1. Now assume that we must represent each number from this range with just two decimal digits: one before and one after the point. Our possible amplitude values are therefore: −1.0, −0.9, . . . , −0.1, 0.0, 0.1, . . . , 0.9, 1.0. These are exactly 21 distinct levels for the amplitude and we will denote this number of quantization levels with each level is a step of 0.1 higher than its predecessor and we will denote this quantization step size as q. Now we assign to each number from our continuous range that quantization level which is closest to our actual amplitude: the range −0.05... + 0.05 maps to quantization level 0.0, the range 0.05...0.15 maps to 0.1 and so on. That mapping can be viewed as a piecewise constant function acting on our continuous amplitude variable x. In the Table 1 is given the statistics for signal to quantization noise ratio - where Psignal is the mean signal power, and α is the ratio in decibels of the peak signal power V^2 to the mean signal power Psignal. Therefore, from Equation (7) every additional bit in an analog to digital converter results in 6 dB improvement in signal–to–quantization noise ratio.

Number-Examples	$\boldsymbol{\alpha = \left(\frac{V^2}{P_{Signal}}\right)}$ **is the ratio in decibels**	**n**	**The ratio in decibels of the peak signal power to the mean signal power Psignal** $\boldsymbol{10log_{10}\left(\frac{V^2}{P_{Signal}}\right)}$	$\boldsymbol{10log_{10}2^{2n}}$	**Signal to quantization noise ratio** $\boldsymbol{SQNR(n) = 4.77 - \alpha + 6n}$
1	1	2	0.00	12.04	16.81
2	2	3	3.01	18.06	19.82
3	3	4	4.77	24.08	24.08
4	4	5	6.02	30.10	28.85
5	5	6	6.99	36.12	33.90
6	6	7	7.78	42.14	39.13
7	7	8	8.45	48.16	44.48
8	8	9	9.03	54.19	49.92
9	9	10	9.54	60.21	55.43
10	10	11	10.00	66.23	61.00
...	...	…	…	…	…

Table.1. The quantization and statistics for signal to noise ratio.

Note, that this mapping also includes a clipping operation at ±1: values larger than 0.95 are mapped to quantization level 1, no matter how large, and analogous for negative values.

Each intensity value is a number, for digital storage the intensity values must be quantized [14][16]. The quantization can limit the number of different intensities that can be stored, can limit the brightest intensity that can be stored, how many intensity levels are needed for human consumption [2] [3]:

- 8 bits usually sufficient
- some applications use 10 or 12 bits

VI. DIGITAL IMAGE DEFINITIONS

A digital image a[m,n] described in a 2D discrete space is derived from an analog image a(x,y) in a 2D continuous space through a sampling process that is frequently referred to as digitization. The 2D continuous image a(x,y) is divided into N rows and M columns. The intersection of a row and a column is termed a pixel. The value assigned to the integer coordinates [m,n] with {m=0,1,2,…,M–1} and {n=0,1,2,…,N–1} is a[m,n] [13]. In fact, in most cases a(x,y) – which we might consider to be the physical signal that impinges on the face of a 2D sensor – is actually a function of many variables including depth (z), color (λ), and time (t) [15][16].

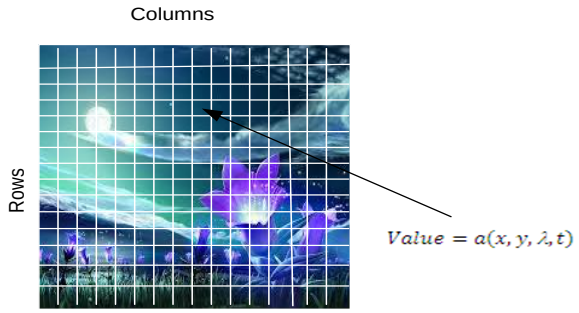

Figure.5. Digitalization of a continuous image. The pixel at coordinates [m=10, n=3] has the integer brightness value 110

The image shown in Figure 5 has been divided into N = 16 rows and M = 16 columns. The value assigned to every pixel is the average brightness in the pixel rounded to the nearest integer value. The process of representing the amplitude of the 2D signal at a given coordinate as an integer value with L different gray levels is usually referred to as amplitude quantization or simply quantization.

There are standard values for the various parameters encountered in digital image processing. These values can be caused by video standards, by algorithmic requirements, or by the desire to keep digital circuitry simple. Table 2 gives some commonly encountered values.

Parameter	Symbol	Typical values
Rows	N	256,512,525,625,1024,1080
Columns	M	256,512,768,1024,1920
Gray Levels	L	2,64,256,1024,4096,16384

Table.2. The standard values for the various parameters encountered in digital image processing.

On the basis of the Table 1 - as Author's own generations, we see quite frequently cases of $M = N = 2^K$ where {K = 8,9,10,11,12}. This can be motivated by digital circuitry or by the use of certain algorithms such as the (fast) Fourier transform [16] [17].

The number of distinct gray levels is usually a power of 2, that is, $l = 2^B$, where B is the number of bits in the binary representation of the brightness levels. When B>1 we speak of a gray-level image; when B=1 we speak of a binary image. In a binary image there are just two gray levels which can be referred to, for example, as "black" and "white" or "0" and "1".

VII. COLOUR VISION ANALYZE

Exist three types of cone, each responds to a different spectrum, roughly can be defined as red, green, and blue; each has a response function r(λ), g(λ), b(λ); different sensitivities to the different colors, roughly 40:20:1, so cannot see fine detail in blue, overall intensity response of the eye can be calculated:

$$y(\lambda) = r(\lambda) + g(\lambda) + b(\lambda) \qquad (8)$$

$y = k \int P(\lambda)\, y(\lambda) d\lambda$ - is the perceived luminance many different spectra will induce the same response in our cones the values of the three perceived values can be calculated as:

$$r = k \int P(\lambda) r(\lambda) d\lambda \,, g = k \int P(\lambda)\, g(\lambda) d\lambda$$
$$b = k \int P(\lambda)\, b(\lambda) d\lambda \qquad (9)$$

k is constant, P(λ) is the spectrum of the light incident on the retina; two different spectra (e.g. P1(λ) and P2(λ)) can give the same values of r, g, b; can thus fool the eye into seeing (almost) any color by mixing correct proportions of some small number of lights.

Implications of vision on quantization humans can distinguish, at best, about a 2% change in intensity not so good at distinguishing color differences

For TV - 10 bits of intensity information, 8 bits is usually sufficient. Why use only 8 bits? Why is it usually acceptable? This is adequately for movie film – which is 14 bits of intensity information [14][15].

VIII. STORING IMAGES IN MEMORY

To store image in memory is the main aims, because, after sampling rate, and diskretization, all the imgaes converted into binary number, respecitvely can be stored in memory. So, for example, on the basis of the Figure 6, 8 bits has become as a standard for greyscale images, 8 bits = 1 byte, an image of size *WxH* can therefore be

stored in a block of *WxH* bytes, one way to do this is to store pixel[x][y] at memory location *base + x +W x y* base; memory is 1D, images are 2D. [11][12][15]

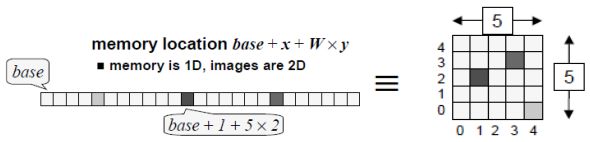

Figure.6. Storing images in memory

IX. CONLUSION

The present paper addresses some access, research and management, implementation of computer graphics. Also in the paper is treated the image processing, sampling rate, quantization and coding process. By creating programming codes as a starting point and visual access methods for generating a certain values, which can be used to advantage parts and segments of any object, image, and to a certain body dimensions. Mobility of primitive and others complex objects forms requires the idea and development of the interpolation method. After the sampling we have a sequence of numbers which theoretically can take any value on a continuous range of values. The conversion from analog to digital values, give us the opportunity to consider this transformations as better solution in the context of performance and as fast solution, because by use formula (7) is optimal range in the aspects to obtain discrete value. Quantization is a many-to-one mapping, in that all the values that falls within the continuum of a quantization band are mapped to the centre of the band.

In the context of color vision analyze- is emphases that exist three types of cone, each responds to a different spectrum, roughly can be defined as red, green, and blue; each has a response function r(λ), g(λ), b(λ); different sensitivities to the different colors, roughly 40:20:1. Also, is described one way how we can memorize any image into memory; adequately is described memory locations and its bases.

These values are practical because they may soon be generated through the respective program and differently programs can be incorporated to establish respectively connection with software components.

Adaptation is about the ways of communication and connection of external equipment. By using this system can be managed the communications system, because this process can be a part of processing, all these values are converted into discreet value, and they are ready for computer processing systems [16][17]. In the section, Waveforms, quantization & and signal to noise ration and statistics are given the solution to consider an n-bit quantizer with an amplitude range of ±V volts. The quantization step size is $\Delta = 2V/2^n$. Assuming that the quantisation noise is a zero-mean uniform process with an amplitude range of ±Δ/2 we can express the noise power, the formula and calculated statistics are very flexible, and extremely convenient for different systems.

** Medical Center VIKOM/Immunologist, Kremenchuk, Ukraine
gasta1@yandex.ru

Modern information technology and the existing rapid (express) diagnostics method allow you to monitor the state of health. The method is based on the thermovision diagnostics and enables determining the human immune status. The designed software implements this method. At the time of the diagnosis the system generates recommendations for eliminating an immune deficiency. These recommendations are made based on the results of the calculations of the integral temperature indicator used in the expert module.

The system consists of the web and desktop applications, local and global databases, which use Sqlite and MSSql technologies. The access to the global database is realized by the web-service with the help of a ServiceAdapter mediator, which implements the data storage interface and encapsulates the web-service behavior. The designed program of the express diagnostics of the immune status can be easily scaled as a local application, on web, or cloud.

Results of statistical data analysis from the data warehouse can be presented in the form of diagrams, graphs, tables and allow a qualified health professional to evaluate the health status of the population of the city, region, etc.

The developed software system is accessible on-line to everyone.

I. INTRODUCTION

Immunity is responsible for protecting a human health, and immune deficiency is a signal that health is at risk, and the necessary measures should be taken immediately. Diagnostics of the immune status will allow an early detection of any abnormalities. It will allow to restore vital functions of the human body and prevent developing serious diseases. Prevention of the immune deficiency is important for reduction of the overall morbidity, reducing chances of developing chronic diseases, and decreasing the number of incidences of atypical courses of the diseases. It would also lead to a more of efficient immunization routine, and reduce a number of adverse reactions to vaccinations. Additionally, it would improve reparative function of the human body, lengthen the life of AIDS patients, improve a maternal and child health, and the overall population dynamics.

Currently, there are two ways to diagnose immune deficiency - a laboratory diagnostics and express diagnostics. The first method requires an immunology laboratory, time, and experienced personnel, which make it difficult to use it for prevention of the immune deficiency among the population. The second method is based on thermovision diagnostics, which was developed by Professor Michael Vogralik. According to his data, sensitivity and level of reliability of the thermovision diagnostics, were 84% - 90% [1].

The Vogralik method is as follows. There is a verified link between the immune deficiency and the heat production of the immunity organs (thymus gland and spleen). In order to determine the status of the metabolic and functional activity, the level of the heat production of the immunity organs needs to be measured. The IR thermometer – pyrometer with a measuring accuracy up to 0.1 degrees of Celsius - is needed for such measurement. For a thymus gland, a deep temperature is measured in the organ projection. For a spleen, a temperature in the remote locations that reflexively related to the spleen is measured. It is possible to determine the activity of immunity organs by taking into account both quantitative and qualitative immune system parameters. One of the easily controllable parameters of the immune response is a measure of lymphocytes, which may be obtained from the total blood analysis.

One of the methods that allows to make an immunocorrection without any side effects is the use of the physical therapy that uses reflex mechanisms of action on immunocompetent organs. The duration of the immune status normalization is up to 6 months, and this term satisfies the rules of the clinical supervision, the practice of anti-recurrence treatment, and disease prevention. Taking into consideration the indicators of lymphocytes and leukocytes, it is possible to rationalize the choice of the physical impact factor to eliminate immune deficiency.

In 1995 a special device for express diagnostics was created in Russia based on the Vogralik method. In 2004 a local version of a software was developed for the out-patient clinic in the Automobile Plant KrAZ and Medical Center VIKOM using the same method. During more than 9 years of practical experience of using express method (a metabolic control of the immune status) in the Medical Center VIKOM the number of clinical visits was reduced by 1.8 - 2.4 times [1]. After few years the method of the software operation was improved, namely, changes in the heat production level calculations were introduced. As a result, it became necessary to create an

information system of the express diagnostics of human immune status with the support of local, web and cloud applications [2]. This system provides an opportunity to use express diagnostics applying two methods - by a specialist during a clinical visit (local application) or self-diagnostics using the public access to the system through Internet resources.

II. Approaches and Program Development Phase

Information model is represented by the following information entities:

- Users working with the system are divided into two categories - a qualified health professional and the end user who wants to take the express diagnostics independently in the on-line mode.
- Input data for both types of users remain unchanged.
- The output results are formed based on the input data and predetermined system rules. The results may be presented in different document formats (MSWord or HTML).
- The statistical data stored in the data warehouse are represented in the form of charts, graphs, and tables, so a qualified health care provider can assess the health status of the population of the city, region, etc.

A generalized model of the express diagnostics information system has been developed (1). It consists of the off-line applications that work with the local databases, the on-line application that works with the support of a global database, and a system kernel. The model includes an expert system module, a statistics module, an output documents module, a data access module, and a kernel configuration module.

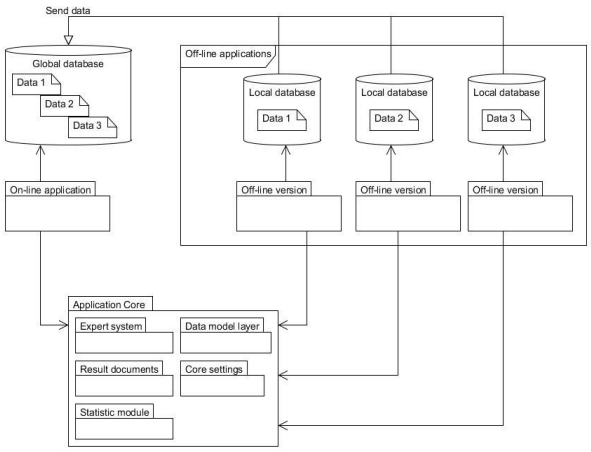

Figure 1 - Model of the information system

Information system architecture (2) combines a multi-level architecture of the distributed application (a service oriented application with respect to access to data warehouses for both local and distributed applications). It is built on a single system kernel, which supports the operation of the basic system functions.

A component - oriented approach was used to develop the program [3].

An important practical result of applying the component approach concept is an ability to improve the strategy of reusing the code and reduce the cost of designing and implementing the software. The code with a higher level of abstraction does not require a substantial modification in adapting to the changing conditions or new data types.

The main advantage of the chosen concept is a unification of the different categories of objects. Abstract classes and methods allow an uniform handling of the heterogeneous data, and it is not required to develop an additional code to adapt to new classes and data types. The development of the system can be performed using interfaces by adding new components and replacing some of the old components without rebuilding the entire system. To expand the system, you can create new components that provide additional services.

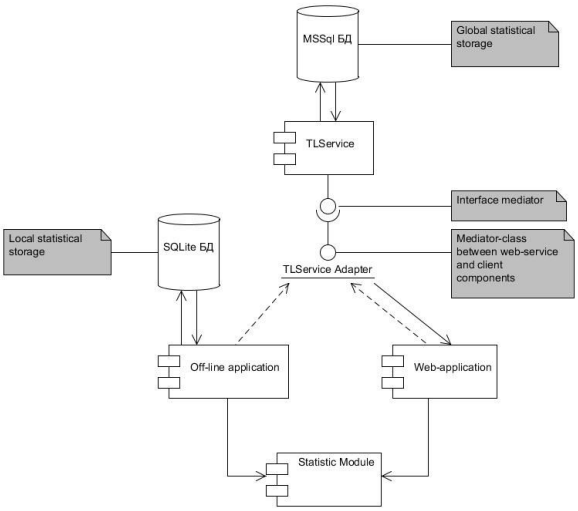

Figure 2 - Architecture of the information system of rapid diagnostics

The developed implementation model presented in the form of a component diagram (3) simulates the physical aspects of the information system of express diagnostics.

The implementation model of the information system of express diagnostics consists of the following components:

- The software kernel. It is responsible for the model levels and their interfaces, expert system, resulting documents, and statistical data processing system.
- Resource library. It includes additional choices of language (English, Ukrainian, etc.), images, and all other resources. Library allows to change graphics, string and file application data dynamically - without recompiling the program.
- Web-service. It plays a role of a global data repository and is used for the statistical data collection (for local and on-line versions).

- On-line version of the system. It provides the ability to pass the express-testing without installing a local version. It serves as an interface for the administration tasks including viewing statistics. On-line version has a research module, a statistics module, data validation, and program localization.
- Local version. It has the widest variation of settings, the ability to save a document in different formats, the licensing system, and other functions.
- Licensing system. It is responsible for the state of the product according to the status of the license. It serves to protect against unlicensed use of the product.
- Generator license. It uses a licensing system to generate license keys.
- Library of localization. It depends on the technology chosen. Typically it is used by external libraries for localization of local applications.

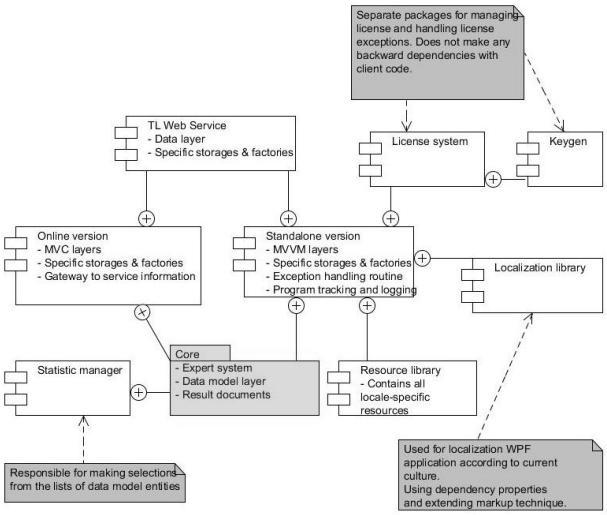

Figure 3 - Component Diagram

The project was implemented using Microsoft.Net technology [4].

The designed system works with two databases - local and global, and each of them uses a separate technology (Sqlite and MSSql). Web-service is the entry point to the global database [5]. It is accessed through a mediator ServiceAdapter that implements an express diagnostics results data storage interface and encapsulates the logic of working with the web-service. Both types of applications use the data storage to send and receive data from a global data repository.

Interfaces and general base classes are included in the kernel without reference to the platform and the component type. Setup classes are also in the kernel, and they can be used to configure the kernel to work with local or web-application.

For less connectedness of the system the kernel was distributed to the following atomic parts:

- data model and interfaces;
- system settings;
- system of document creation;
- expert system;
- statistics system;
- extend functions of Net Framework [6].

Given that the kernel supports both the off-line and on-line applications, it was not possible to use the built-in settings of the Net [6]. To maintain such a function, it was necessary to realize a settings mechanism that saves its state between software runs.

Expert system architecture directly depends on the data model, since it is necessary to operate data entities during the express diagnostics.

The rules are formed by immunology specialist and are loaded into the program model in the interactive mode. The expert system is initialized by storage of these rules (XML for both versions), and corresponding objects are created. Thereafter, the expert system is ready for the express diagnostics. This mechanism allows achieving the following goals:

- an ability to change the rules in the runtime;
- an ability to localize the rules and, as a result, the entire source document;
- a possibility of using a unit-testing to ensure the correctness of code writing.

It should be noted that some rules may lead to the emergency completion of the express diagnostics, and some - to results cleanup. Activity diagram (4) describes this behavior.

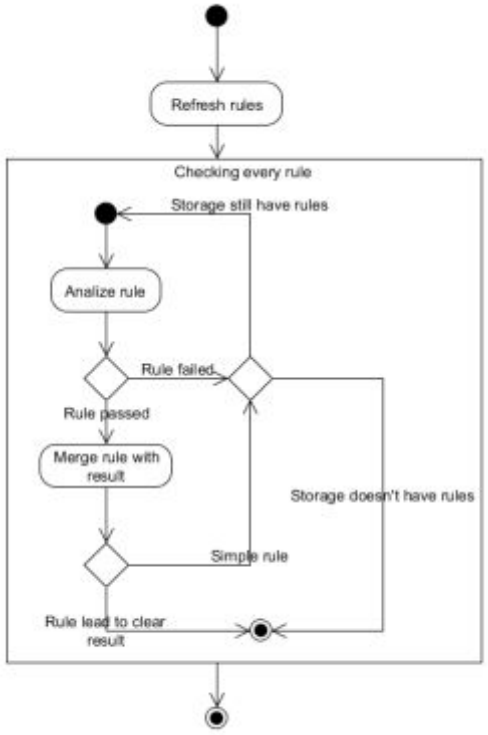

Figure 4 - Activity diagram of the expert system

The system uses a resource library, which includes a mechanism for localization of other languages, images, and all other resources. It allows dynamically change the graphics, string and file data used by the program.

When designing a document creation system, it was taken into account that it can display both the resulting express diagnostics documents and statistical documents. The option to save documents in various formats is provided in the documents interface.

Full specific business logic is applicable only to the off-line version and completely detached from the software kernel, or simply extends it. For example, the licensing system is used only in the off-line version. It has been implemented in order to protect the product from unauthorized use without the knowledge of the customer.

The express diagnostic results and the results of the statistical data analysis can be output in two formats - MS Word and HTML.

Some of the interfaces require a step by step data input. Given this, it is expedient to organize a wizard that encapsulates the logic that relates to the incremental data input. During the design and implementation phase the following have been taken into consideration: the need for the input data validation, editing of the Wizard's steps, and changing an algorithm of the express diagnostic completion. These needs were met by designing an architecture that allows transmitting a controller interface into Wizard object. Two controllers have been created - for the first launch Wizard and Wizard for the express diagnostics.

Geographic Information System web-service of Yandex is used (5) to visualize the distribution of the immune status parameters of the population by country, region, city, etc. Polygons were used to enable the selection of the individual regions on the map. They are located on a server as XML documents.

Figure 5 - Geodistribution indicator of immune status by regions of Ukraine (1 - hyperfunction, 2 - norm, 3 - hypofunction, 4 - limit of normal)

Research module is a part of the kernel that is common for both off-line and on-line applications. It includes expert system and system of the temperature and blood test analysis indicators. These systems are used for obtaining a qualitative and quantitative immunity results. In the system of the temperature indicators analysis the calculations of the integrated temperature indicator used by expert system were modified. To verify data entry, a mechanism of client and server validation is used. The application allows keeping a history of the express diagnostics that makes it possible to see the dynamics of the human immune system for any length of time. The system has a choice of various settings, ranging from the visual settings (for an average user) to the configuration of the expert system (for immunology specialist). A global database collects anonymous information from the on-line application and transmits it from local databases and off-line applications over the Internet.

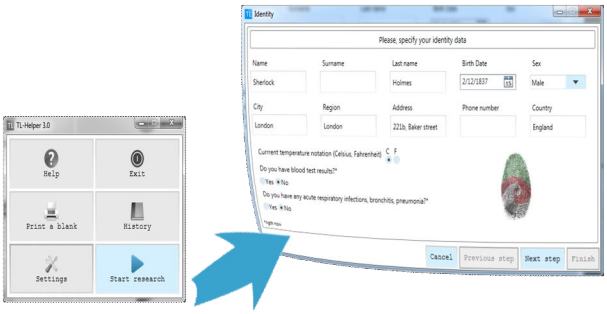

Figure 6 – Program menu and input data window

There are seven global commands (6) for the whole application - Show history, Show settings, Display help, Show local statistics, Start research, Print a blank, and Exit the application. They are available in any application window.

III. CONLUSION

The program of the express diagnostics of the immune status designed by authors can be easily scaled as a local application, on web, or on cloud. It has a flexible architecture and solves a wide spectrum of problems with minimal connectivity between components.

An approach to the design and implementation of an information system is based on the component-oriented programming technique. This approach makes it possible to implement a combining software architecture in a base of common kernel for different types of applications. The idea is to select the components in software kernel that do not depend on the type of application and deployment platform. This kernel can be initialized and configured by the client code according to the needs of the target platform. Therefore, the proposed approach can be used in projects with similar architecture.

The developed software system realized an express method of the self-diagnostics of the immune deficiency and its prevention. A medical health provider can work with the off-line version of the system where he or she can use the local database with the patient's diagnostics results to monitor the patient's immune status during the course of

the treatment. A global database is available on-line only to the health care authorities that registered in the system with administrator rights. A global database contains the anonymous diagnostics data for all people who used the on-line system for diagnostics, and these data can be used for monitoring the immune status of the population on the level of city, region, or country.

A limitation of the presented method of the express diagnostics is in that it cannot replace the full immunology laboratory results since it only provides an information on the immunity status of the patient - the presence or absence of the immune deficit.

The product is successfully operated in the establishment of the practical health care Medical Center VIKOM in the city of Kremenchug, Ukraine and is available on-line at www.tl-helper.com.

Information system infrastructure planning - threshold setting based on risk analysis

I. Golub and B. Radojević*
* Croatian Academic and Research Network (CARNet), Zagreb, Croatia
Ivana.Golub@CARNet.hr, Branko.Radojevic@CARNet.hr

Abstract - Information systems infrastructure planning performed based on the data collected from network monitoring and asset management systems can be developed further to include risk assessment and analysis as an input to the threshold setting methods in the two-dimensional load-age balance graph. The two-dimensional load-age balance graph is used to present generic value for network devices load gathered as measured values through the network managements system, and age - gathered from the asset management system. Threshold lines are defined in such graph to present areas of different interest from the perspective of low-high age, low-high load, or some other selection criteria. This paper explores how the threshold values can be set to reflect risk assessment methodology of the owner/maintainer/user.

The position of each networking device in the graph is unique, disregarding the threshold values. However, the total score for the system, determined based on the position of a device in the graph area, depends on the defined threshold. The paper analyzes the impact of the threshold change based on the risk assessment criteria to the total score for a system. The total score can then be used to compare different systems, or to compare the same system in time.

I. INTRODUCTION

Information systems infrastructure planning has to be based on the information about the current state of the system received from the system itself (e.g. via monitoring system), and information about the plans for further development of services and users needs. It is usually not in the domain of the system maintainers to have information about neither the future services development nor the users growth. The only data that can be gathered and examined are those from the system itself.

Risk in a general sense represent "a probability or threat of damage" or "loss or any other negative occurrence" "caused by external or internal vulnerabilities, that may be avoided through preemptive action" [1] or the possibility that something bad or unpleasant will happen [2]. In the sense of an information system, a risk can be seen in the degraded level of service, or as the total unavailability of the service offered to users (customers).

Risk assessment has its two dimensions - the probability for an event to happen and the level of danger that the event can cause to the system. In addition, as explained in [3], [4], the risk has its objective and subjective side, and both determine the assessment of a risk in a system. While the "risk as analysis" (as defined in [4] starts from the information gained through measurement systems of the current state of an information system, the "risk as feelings" [4] has its final decision in the determination of the risk levels and categories.

The model for the determination of the current stage for an information system is presented in [5] and is re-printed in the Figure 1.

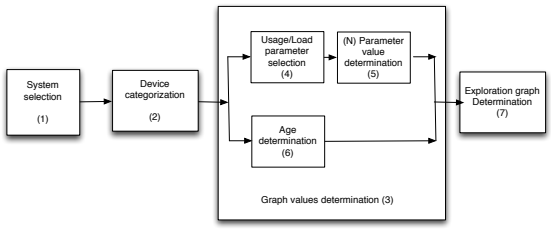

Figure 1. Exploration Determination Model (Source [5])

Based on that model, using the data from a monitoring system, and as explained in the [5] it is easy to design two-dimensional load-age graph with the current status of each observed device represented with one dot in the graph. X axis will contain generic value for the load of the system-relevant components (e.g. CPU and memory load and the number of used ports for networking equipment, average CPU and memory load for servers) expressed in percent of the maximum load and represented as the sum of values for each measured parameters. Y-axis contains the age calculated as the current year minus year of the equipment acquisition. Thus created graph represents current state of the observed system. However, in order to be able to interpret the data and use it for the purpose of system development and planning, it is necessary to put this data into the relevant context for the system.

II. RISK ASSESSMENT AND THRESHOLD DEFINITION

Each information system can be seen differently from different user groups - the system owner's view does not necessarily have to be the same as the view of a user or a view of a service owner or the information system

maintainer. Such different views on the requirements and the levels of service will also reflect the definition of risk. A general interpretation, in accordance with the definitions found in on-line dictionaries can be summarized to the probability that the service will be degraded or unavailable. Transferring that expression into the view of a system maintainer, the risk can be seen through the system performance degradation, or system unavailability. The first from the two parameters for risk determination - the probability for an event to occur - can be learned through the system observation, understanding, as well as the previous knowledge of the system, based on the system behavior analysis. The second parameter - the potential loss produced with an event has to be determined for an individual system. For example, the same system can be established in one scenario for a small number of users (e.g. as an redundant system) with a small number of non-vital services, and in another scenario for several times more users with vital business-critical services. In those two cases, even if the same risk indicator is identified for both systems, the potential loss in the case of system degradation will not be the same.

For an information system and the presented exploration determination model, the risk assessment is determined based on the reached level of individual parameters at which there is a higher probability that a system degradation of malfunctioning can happen.

For example, in an information system, the failure may occur when there is a high CPU or memory load. In addition, in the networking part of the system, the possibility for future development and growth is reduced with the decreased number of available interfaces.

Which level of CPU/memory load is critical for which system, and especially potential loss that can thus be caused to the system owner or user - cannot be seen directly from the graphs or current status of the system, but is based on the knowledge of the system and attached services.

The risk can be expressed using Boolean (bipolar) representation or a range representation. In the Boolean representation, values are expressed for each field either is there is NO risk (the state is "good"), or there is a risk (the state is "bad"). In the later case, existence of risk is a message to the maintainer to perform an action to determine the cause of the potential risk and undertake actions to reduce the recognized risk to the minimum.

Range representation of a risk would allow an analyst to define more then two risk levels. For example, levels can be defined as in the Table 1, or there could be even more levels defined for risk assessment used for the range representation.

TABLE I. RISK LEVELS IN THE RANGE REPRESENTATIONS

Risk level	Risk Level Description
0	No risk
1	Small
2	Medium
3	High

For the analysis of the two provided approaches, the same example data will be used as presented in [5]. In this paper, a part of a data center was analyzed from the perspective of load and age for each relevant device. The analysis was separated for servers and networking equipment since those two device categories have different set of parameters relevant for the determination of the current state. Average CPU and memory load was observed versus equipment age for server farm and results represented in the two-dimensional graph where maximum load range reaches the level of 200%. In the case of networking equipment, together with the load of CPU and memory, the percentage of used network interfaces was also examined as a third parameter versus the equipment age, and data presented at the graph with max x axis value of 300% (total sum of load percentage for all three observed parameters).

Starting graphs as presented in [5] are provided in Figures 2 and 3.

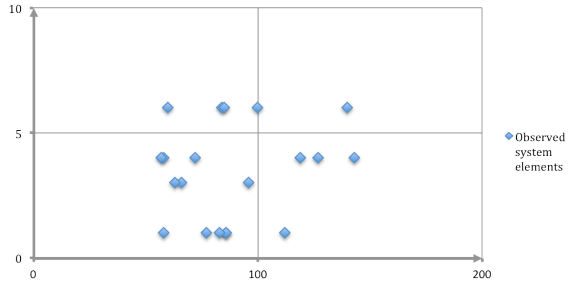

Figure 2. Exploration graph for the servers

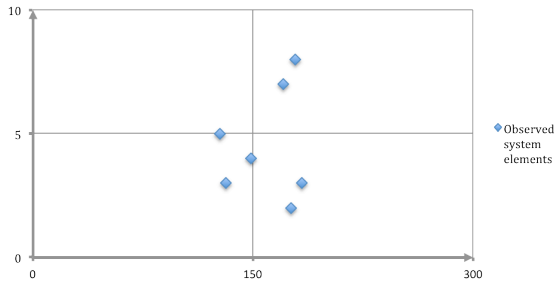

Figure 3. Exploration graph for the networking equipment

Both figures are taken from the same test case and presents also thresholds as initially defined at the 50% of the load scale and at the 5 years of custom amortization value. In order to focus on the risk assessment, the definition of thresholds and the interpretation of data in thus yielded graph, it is sufficient to follow just one of the two presented examples - either for server or for the networking equipment. Therefore, all further analysis will be demonstrated using data from Figure 3.

When the thresholds are used to represent the risk assessment, then the risk level is defined for each axis separately. The threshold levels are drawn at the graph to present the risk level, dividing the graph into several fields.

III. RISK ASSESSMENT FROM THE EXPLORATION GRAPH

In the case of Boolean representation, there will be two values for each axis. Such case is already represented at Figures 2 and 3. At X axis, field in the range [0-150) is field with NO risk, and the field [150-300] is the field that contains the risk. At Y axis, filed [0-5) is NO risk field, and [5-10] brings the risk. Looking at the whole graph, only the lower left field near the coordination system origin is a NO RISK field. At Figure 3, there is only one device that completely belongs to that field. For any other of the remaining three fields there is at least some level of risk assigned to it. The further from the coordination system origin a point is - the bigger is the risk for the maintainer and system owner. In praxis, that means that for each of the points (devices) that are outside of the NO RISK area additional examination should be started in order to determine the risk cause, and to define the techniques that could be applied in order for the risk to be minimized or removed. The final goal should be to "move" the state for each individual device as close to the coordinating system origin as possible. The Figure 4 presents the NO_RISK/RISK definition for the devices in the graph from Figure 3, based on the Boolean representation of the risk.

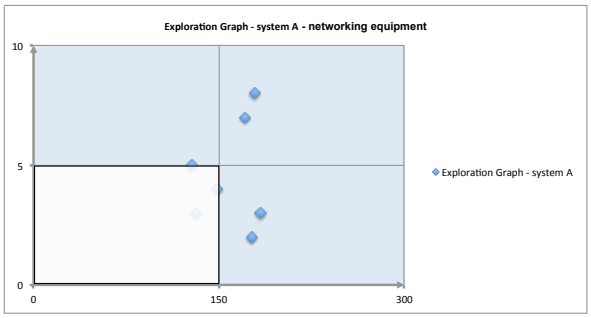

Figure 4. Exploration graph for the networking equipment with white NO-RISK area and blue RISK areas

In the four-fields representation of young/old and low/high loaded devices it was easy to recognize for each device, which risk its position in the graph it might carry. For the old equipment, there is a risk of absence of maintenance, no spare parts, lack of support for new features or new technologies. In the field of high load, there is a risk that a small increase of load might cause system instability or unavailability. With this risk representation in the same graph, it is even easier to recognize all the devices that can potentially be a cause of problem for the system.

In the case with range risk representation, as exampled in Table 1, such granulation should again be applied to each axis separately. In addition, the risk assessment has to be performed separately for each observed parameter that determines the overall load. The values can differ for each of those parameters, to reflect the correct status and development of the system.

As an easier example, consider that the ranges for X-axis parameter will be the same for each parameter at the each risk level, as presented at the table 2.

TABLE II. RISK LEVELS IN THE RANGE REPRESENTATIONS

Risk level	Risk Level Description	Age	Load level for 1 parameter	Load for 3 parameters
0	No risk	0-3	0-30 %	0-90
1	Small	3-5	30-50 %	90 - 150
2	Medium	5-7	50-70 %	150 - 210
3	Large	>=7	>=70 %	>=210

It is important to emphasize that the numbers in the Table 2 are examples of values that could be selected for each risk level for each parameter. For a selected system, the values have to be defined in accordance with the system use policy and taking into considerations development plans from the perspective of users as well as the system owners.

Values for thresholds for Y axis are given in column 3 and for X axis in column 5, and the graph with corresponding multiple thresholds is provided in Figure 5..

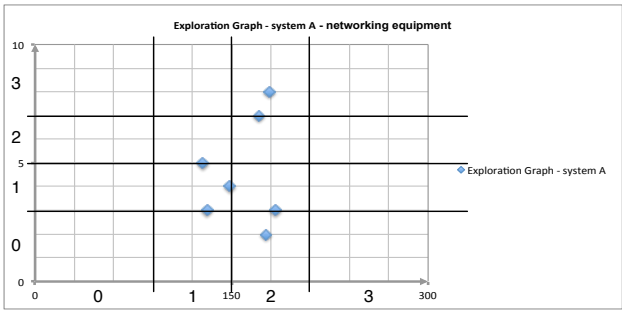

Figure 5. Exploration graph for the networking equipment with several thresholds corresponding to range risk representation

At X and Y-axis each field is presented with the corresponding risk level. Again, it can be seen that only lower left field closest to the coordinating system origin is risk free area, while all the other fields carry some risk level associated with it. Only the devices that will be in the NO RISK field will not require any action at the moment, based on the time of the analysis. (It is possible though that at the very next analysis period a device will change its place based on the load/age values and that might require additional analysis and actions.) All the other devices in all other areas of the graph will require additional analysis to determine the cause for the potential risk and possible actions that could be taken in order to bring each device status closer to the coordinate system origin. For the upper example NO RISK and risky areas are presented at Figure 6.

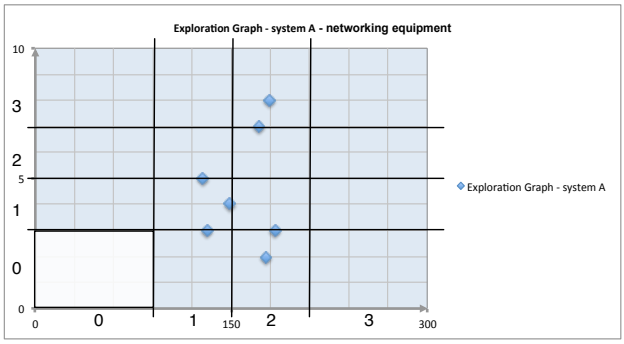

Figure 6. Exploration graph with white NO RISK area and blue risk areas for the networking equipment with several thresholds corresponding to range risk representation

In the case when the risk range values are different for each parameter, for the same risk range (0, 1, 2 or 3) the range where this risk applies for an observed parameter has to be defined, and the upper level for the threshold range is determined by summing the values for all observed parameters. With the Y axis the situation is clear since age is the only parameter observed.

Additionally, for each field in such multiple thresholds graph, the risk value can be calculated as the sum of the X-axis risk and the Y-axis risk. On this way, for the graph presented in Figure 6 there will be up to six different risk categories, as presented at Figure 7. Despite the different values, the conclusion can again be simply expressed that the risk is higher for the points in the graph that are more distant from the coordinate system origin.

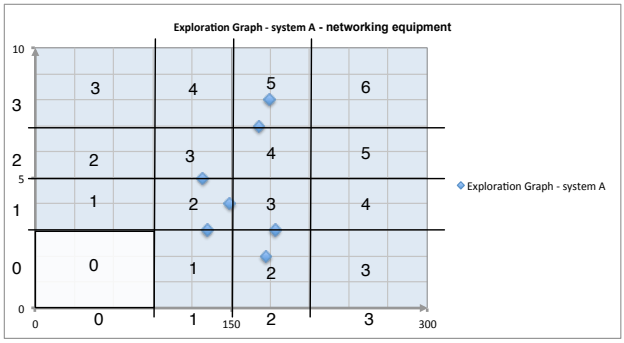

Figure 7. Exploration graph with white NO RISK area and six categories of blue risk areas based on the risk calculation

Although there were four different categories of risk (no risk, low, medium and high) calculated for each parameter, and different thresholds defined in each of those risk groups, risk recognition is at the end categorized only at two levels - is there a risk for a devices or not. Lack of risk means that at the time when the analysis is performed there is no need for individual devices in the NO RISK area to be analyzed further based on its load and current age. Devices with its points in the risk area - no matter in which one of the individual multiple threshold fields - will require additional analysis.

So, instead of multiple thresholds per axis and multiple risk levels, it is sufficient to define only one level per axis that will represent the point where there might be a possibility for an event occurrence that might jeopardize current status of the system so that the system will no longer be available to provide a service, either at the acceptable level (so that the service will be degraded) or at all (so that the service will not be available).

IV. Related work

The research presented in this paper is continued work from [5], based at the same model for the information system infrastructure planning. This model relies on the data from the network/data infrastructure monitoring system, present in each network/service provider system, as those presented in [6]. The representation at two levels - Boolean or range representation, used for the categorization of risk representation - is used in [7] for the representation of link quality. Analog tomography used for individual links is similarly used for the representation of individual parameters that combined influence the total load for a device. Presented model can as well be used as a part of a decision support system, like the one presented in [8].

V. Conclusion

Presented model for the information system infrastructure planning can very easily and successfully be used to graphically indicate elements in the system whose current status represents a potential risk for the system owner or maintainer. Data are gathered from the monitoring and asset management system(s), and presented at a time when the analysis is performed. Since data are gathered from a live system that can be a subject of a constant change, the results are is valid for the time when the analysis is performed, with a possible extension depending on the dynamics of the system. Risk levels are calculated and determined based on the knowledge of the system and cannot be determined statically and uniquely for any generic system, since it depends on the number and activity of users, number and importance of services, as well as the development plans. Therefore, a risk levels for each system and for each parameter has to be carefully determined.

The results presented in this paper has shown that it is more important to define correct risk levels for a two-level (Boolean) risk representation, then to introduce multiple levels of risk, because the main decision is the system at risk or not will again be just a two-choices answer that will split the graph into just two fields - one containing the devices without recognized risk status and the other with the devices whose status brings certain risk into the current system.

For all devices whose risk level is above the NO RISK status (above zero risk) will require additional analysis in order to define the risk cause and possible actions that could be taken in order to reduce the potential risk and move the device-representing point closed to the origin in the coordinating system of the exploration graph.

All the analysis was presented at the graph for the networking equipment (from the sample case from [5]). However, the logic with two or multiple risk levels per axis can equally be applied for the servers example with two load parameters.

This analysis has again proven the simplicity of the two-dimensional graph representation of the system status, and the information about the potential risk can easily be seen by any viewer, for different levels of the technical knowledge of the system, and management hierarchy.

Interactive application in service of popularizing architectural heritage

M. Jozić, T. Oštarčević, M. Šalković, D.Šimunić
Fakultet elektrotehnike i računarstva/Zavod za radiokomunikacije, Zagreb, Hrvatska
matej.jozić@fer.hr

The main aim of this paper is making connections between modern technologies, architecture and art, i.e. how to increase the interest for cultural sights and facilitate the retrieval of desirable information with use of modern technologies. Smart phones dominate worldwide mobile phone market and they are mainly used for display and information retrieval. Furthermore, not only that smartphones offer information accessibility at any moment, they also demand interaction with user, so the aspiration for information's is increasing. As a solution, an android application the Story of Zagreb was chosen, which allows display of information, photographs and locations of cultural sights in Zagreb. Desirable data can be reached with choosing certain cultural sight from the list or by sensing QR code, two dimensional code, which describes that cultural sight, with the camera of smartphone.

I. INTRODUCTION

Story of Zagreb is a project, which has purpose of promoting cultural sights of Zagreb.

Its database contains number of sights for various purposes the catedral, many churches, stadiums, museums, libraries, theaters and other attractive buildings in Zagreb.

Application allows user to get familiar with a particular building or to improve existing knowledge of it, so it's useful for tourists, but also for the residents of Zagreb aswell. It includes descripitons of development of construction, its function both historically and today, special features, a variety of anecdotes, legends, etc. There are also some other interesting features that make the building attractive.

In addition, it is possible to go through the photographs of selected buildings which include representations from various perspectives, view inside and out, view the details (various images, altars, monuments, etc.), important events (inaugurations, anniversaries, etc.) Each image contains a brief description of display.

Application also offers user an option of locating buildings on a map of Zagreb, which allows easier reach to the desired destination.

To search for available sites, it is not necessary to know their names, it is sufficent to choose a picture of current interest. Each sight is available to search and contain generated unique QR code that it describes. That allows user who is already on the point of his interest to simply read the QR code within the application and the application will automatically connect the user with the chosen sight.

A. *Implementation*

The application is developed for portable devices (mobile phones and tablets) which use the Android operating system.

Since this is a very popular operating system, the application is therefore available to a large number of users.

The system is available in several versions, and application is based on version 2.2 (called Froyo) which is compatible with the majority (96% to be more accurate) of Android portable devices.

Within the application, ZbarScanner is also available. It is a library which is integrated in application, whose role is reading QR codes. With that, user doesn't need to install a special application on his device to read QR codes, and it becomes automatically available when you install the application 'StoryOfZagreb'.

All sights, which are available by searching the application, are located in the database that can be further expanded, if it is necessary, regardless of whether it is a complete adding of new sights or partial modification of existing information specific sites.

II. DEMONSTRATION

A. *Home Screen*

During the launch of appliaction, the application opens the home screen, shown in Figure 1, which enables the function described below.

Figure 1 - The layout of the home screen when launching application StoryOfZagreb

- Language selection – currently there are two available languages: Croatian and English. Depending on the choice, all the options, as well as the content and available descriptions will be displayed in the chosen language.
- Reading QR code – an option that allows you to search available sights that are contained in the application, by reading (scanning) QR codes and attractions. While chososing this method of search, the camera is turning on, on the portable device of the user, and after focusing QR code in the center of the camera, the application automatically detects sights and shows the user, informations associated with it.
- Search – another way of searching the available sights that are contained in the application. While choosing this method of search, the images and names of all available sights are opening. After choosing the sight, the application show informations related to that chosen sight.

B. *Additional features*

In Figure 2, it is seen the display of the selected sights containing text description. For example, Croatian National Theater is chosen, and on the home screen, the language will be Croatian.

Application allows user returning to the previous, home screen or to continue searching, or on the other hand, selecting additional options related to the current selection.

Additional features include:

- Picture Gallery – display of images of sights in whole or detailed view of some of its parts, as well as images that are in some way connected with it. Each image contains a further description of what it shows (in the language selected on the home screen). Part of the picture galleries for the Croatian National Theatre building, is shown in Figure 3. In the example, the chosen langauge is Croatian.
- Show on map – this option opens map of Zagreb in the browser you use, in which location of the chosen sights is marked. This option is intended for users who search on the basis of the available sights, rather than through QR code, and users who are not currently located in front of thesights. Display on the map for the building of Croatian National Theathre, is shown in Figure 4.

C. *Display of design of the application*

Figure 2 - Layout of textual description of Croatian National Theatre and offered additional opportunities

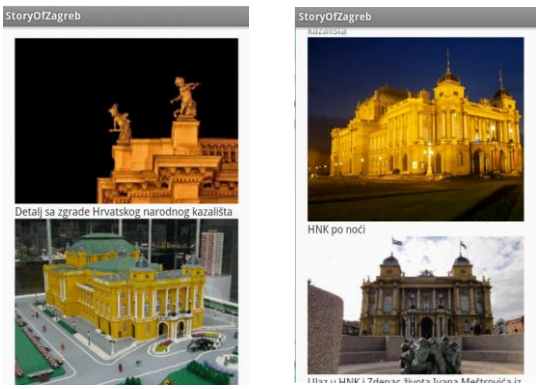

Figure 3 - Part of picture gallery for Croatian National Theatre

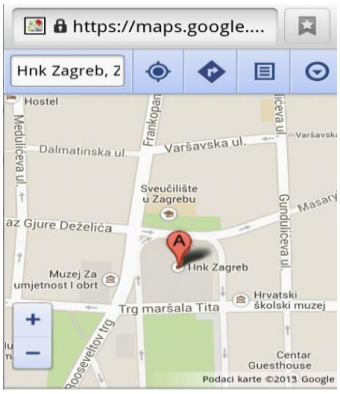

III. CONCLUSION

This paper has shown how art and technology, despite popular opinion, may very well cohabitate. The interweaving of art and modern technology lately, is experiencing bigger attention and delivers interesting and useful gain.

With use of new tehcnologies in terms of this project, it enables the fast and efficent retrieval of information and popularization of destinations.

This application, except the fact that promotes tourism industry, also plays an important role in preserving the heritage of the urn and its opening up to the rest of the world.

Sažetak – Elektroničko poslovanje je izvršavanje svih elemenata poslovnih aktivnosti ekonomskog procesa elektroničkim putem, odnosno stvaranje dodatnih vrijednosti koristeći se ICT tehnologijama. Informacijski posrednik je fizička ili pravna osoba koja u ime drugih obavlja otpremu, prijem i prijenos elektroničkih dokumenata.

U radu se predlaže generička arhitektura sustava informacijskog posrednika pod utjecajem normi i smjernica za adresiranje i usmjeravanje u kontekstu poslovnih funkcija upravljanja odnosima s kupcem i upravljanja uslugama i operacijama. Opisan je i prijedlog strukture interne poruke prilikom obrade u sustavu informacijskog posrednika. Isporuka dokumenata zahtijeva uspostavu dodatne strukture, tzv. omotnice oko dokumenta. U omotnici se pohranjuju informacije iz poslovnog konteksta pošiljatelja potrebne za adresiranje i usmjeravanje dokumenta prema krajnjem odredištu. Adresiranje i usmjeravanje u sustavu informacijskog posrednika koristi prilagođene podatkovne strukture temeljene na normama OASIS ebXML Messaging (ebMS), OASIS UBL 2.1, te CEN CWA smjernicama što omogućuje informacijskom posredniku uspostavu različitih scenarija razmjene poruka.

I. UVOD

Elektroničko poslovanje je oblik poslovanja koji prilikom razmjena informacija između poslovnih partnera koristi informacijske i komunikacijske tehnologije. Cilj je elektroničkog poslovanja što više automatizirati poslovne procese radi povećavanja efikasnosti i efektivnosti, te smanjenja troškova poslovanja.

Elektronički računi i ostali poslovni dokumenti u elektroničkom poslovanju razmjenjuju se putem poruka (eng. messages). Poruka je informacijski paket koji se koristi prilikom razmjene, a sastoji se od zaglavlja (eng. header) u kojem se nalaze informacije potrebne za dostavu poruke na krajnje odredište (eng. Addressing and Routing information) i sadržaja (eng. Payload) koji uključuje jedan ili više elektroničkih dokumenata [9].

Adresiranje u elektroničkom poslovanju je upravljanje logičkim identifikatorima sudionika u razmjeni poruka te identifikacija informacija potrebnih za dostavu poruke na krajnje odredište.

Da bi poruka bila isporučena na krajnje odredište potrebno je identificirati put, tzv. rutu kojim mora putovati prema krajnjem odredištu. Usmjeravanje je identifikacija puta poruke. Prilikom usmjeravanja koriste se procesi adresiranja s ciljem određivanja svih potrebnih jedinstvenih identifikatora primatelja i pošiljatelja, njihovih adresa za prijem i dostavu, ali i identifikatora međuodredišta u situacijama kada se na ruti nalazi više od jednog informacijskih posrednika.

U elektroničkom poslovanju koje se operativno temelji na razmjeni elektroničkih dokumenata, procesi adresiranja i usmjeravanja su neophodni. Adresiranje će jedinstveno identificirati primatelja i pošiljatelja elektroničkog dokumenta, a usmjeravanje poruka omogućuje razrješenje gdje i kako je potrebno isporučiti poslovni dokument. Adresiranje i usmjeravanje poruka je naročito važno u visokoautomatiziranim procesima razmjene.

Za pouzdanu i efikasnu elektroničku komunikaciju poslovni partneri moraju definirati i razmijeniti skupove identifikatora potrebnih za uspostavu elektroničke komunikacije te iste implementirati u svoje informacijske sustave. Prije implementacije identifikatora poslovni i pravni zahtjev je da isti postaju dio poslovnog odnosa, a s time i dio formalnog ugovora između dvije poslovne strane. U tom kontekstu ugovoreni identifikatori između dvije strane se teško mogu propagirati u ostatak poslovnog okruženja.

Bilateralno ugovaranje prema svim poslovnim partnerima je dugotrajan proces. Radi olakšavanja ugovaranja elektroničkog poslovanja samo ugovaranje kao poslovni proces se prepušta trećima tj. informacijskim posrednicima. Uloga informacijskog posrednika postaje olakšavanje i skraćivanje procesa ugovaranja [10] elektroničke razmjene dokumenata.

Prilikom adresiranja informacijski posrednik mora imati mogućnost upotrebe različitih identifikacijskih shema i identifikatora. Proces adresiranja informacijskog posrednika nije ograničen na upotrebu jedne identifikacijske sheme.

Upotreba različitih identifikacijskih shema dovodi do izazova u implementaciji općenitog sustava adresiranja koji će efikasno i pouzdano identificirati sudionike razmjene i omogućiti određivanje rute puta elektroničkog dokumenta kroz mrežu.

Izazovi na koje je potrebno odgovoriti su:

- koje identifikatore koristiti za adresiranje i kako specificirati njihove identifikacijske sheme,
- kako mapirati identifikatore na odredišne adrese na koje je potrebno isporučiti elektronički dokument,
- kako implementirati procese adresiranja i usmjeravanja poruka u sustav informacijskog posrednika.

Kao odgovor na ove izazove prilikom implementacije sustava informacijskog posrednika potrebno je definirati zajedničko zaglavlje koje pruža konzistentno sučelje i neophodno je za operativnu uspostavu pravne, organizacijske, semantičke i tehničke interoperabilnosti među sudionicima razmjene.

Na stručnom skupu o registru korisnika e-računa održanom 16. studenog 2012. godine na Fakultetu elektrotehnike i računarstva u Zagrebu, tim koji radio na pilotskom projektu „FER e-račun“ [15] je u svrhu jednostavnijeg preslikavanja identifikatora na odredišne adrese predložio uvođenje središnjeg nacionalnog registra korisnika e-računa. Kako nije došlo do značajnijeg napretka u implementaciji središnjeg registra, u ovom radu neće se razmatrati scenariji adresiranja i usmjeravanja koji uključuju takav registar.

U ovom radu je iznesena upotreba i utjecaj normi za adresiranje i usmjeravanje elektroničkih dokumenata na arhitekturu sustavu informacijskog posrednika. Prikazan je proces razmjene elektroničkih dokumenata prema modelu 4-strane. U poglavlju III. opisana je generička arhitektura sustava informacijskog posrednika te funkcija adresiranja i usmjeravanja. U poglavlju IV. predložena je struktura poruke, opisano zaglavlje poruke koje omogućava adresiranje i usmjeravanje unutar sustava informacijskog posrednika. Nakon toga je opisana uloga kanonskog oblika e-dokumenta unutar sustava informacijskog posrednika.

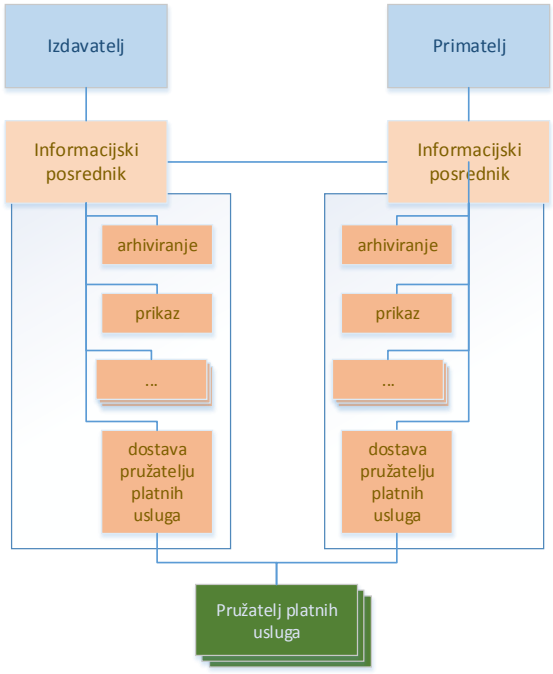
II. ZAHTJEVI NA ARHITEKTURU INFORMACIJSKOG POSREDNIKA

Informacijski posrednik će preuzeti aktivnosti ugovaranja razmjene elektroničkih dokumenata. Primatelj i pošiljatelj sklapaju bilateralne ugovore [10] [11] za uslugu razmjene elektroničkih dokumenata pojedinačno s informacijskom posrednikom. Usluga razmjene mora biti dostupna različitim profilima korisnika, npr. pravne ili fizičke osobe, velike ili male organizacije, organizacije visokog, srednjeg ili niskog stupnja informatizacije i sl. Zavisno od profila korisnika korisnici osim usluge razmjene elektroničkih dokumenata imaju potrebu za dodatnim uslugama čije funkcionalnosti nemaju realizirane u vlastitim IT sustavima, npr. arhiviranje elektroničkih dokumenata, dostava naloga za plaćanje pružatelju platnih usluga, mjesto za zaprimanje i slanje elektroničkih dokumenata (elektronički sandučić) i ostalo.

Kompleksnost se povećava ako korisnici ugovaraju razmjenu svaki sa svojim informacijskim posrednikom. Informacijski posrednici moraju ugovarati interkonekciju što će omogućiti dostavu elektroničkog dokumenata prema korisnicima koji se nalaze kod drugog informacijskog posrednika i obrnuto. Informacijski korisnik operativno radi po dva modela [4] [9] u odnosu na ishodište i krajnje odredište:

- Model 3-strane – u ovome modelu pošiljatelj i primatelj imaju ugovor s istim informacijskim posrednikom. Informacijski posrednik funkcionira u isto vrijeme s jedne strane u ime pošiljatelja, a s druge strane u ime primatelja.
- Model 4-strane – je model u kojem i pošiljatelj i primatelj imaju različite informacijske posrednike koji u njihovo ime razmjenjuju elektroničke dokumente.

Prijem i dostava elektroničkih dokumenata prema korisnicima različitih profila odvijat će se upotrebom različitih komunikacijskih kanala i protokola [3]. Svaki korisnik ugovara s informacijskim posrednikom komunikacijski kanal, protokol i tipove elektroničkih dokumenata, formate poruka, logičke identifikatore i ostalo.



Slika 1. Model 4-strane za razmjenu elektroničkih dokumenata.

III. GENERIČKA ARHITEKTURA SUSTAVA INFORMACIJSKOG POSREDNIKA

Sustav informacijskog posrednika potrebno je minimalno promatrati kroz nekoliko pogleda:

- Procesni pogled – koje je poslovne procese potrebno uspostaviti za isporuku usluge korisniku.
- Funkcionalni pogled – koje funkcije je potrebno osigurati za podršku uspostavljenim poslovnim procesima.

Ovdje identificirajte konkretne sponzore. Ako nema sponzora, izbrišite ovaj tekstualni okvir. (sponzori)

- Podatkovni pogled – kako i u kojim strukturama omogućiti pohranu podataka i informacija potrebnih za realizaciju neophodnih funkcija.

Svaki pogled će rezultirati uspostavom jedne od arhitektura i to procesne arhitekture, funkcionalne arhitekture i podatkovne arhitekture.

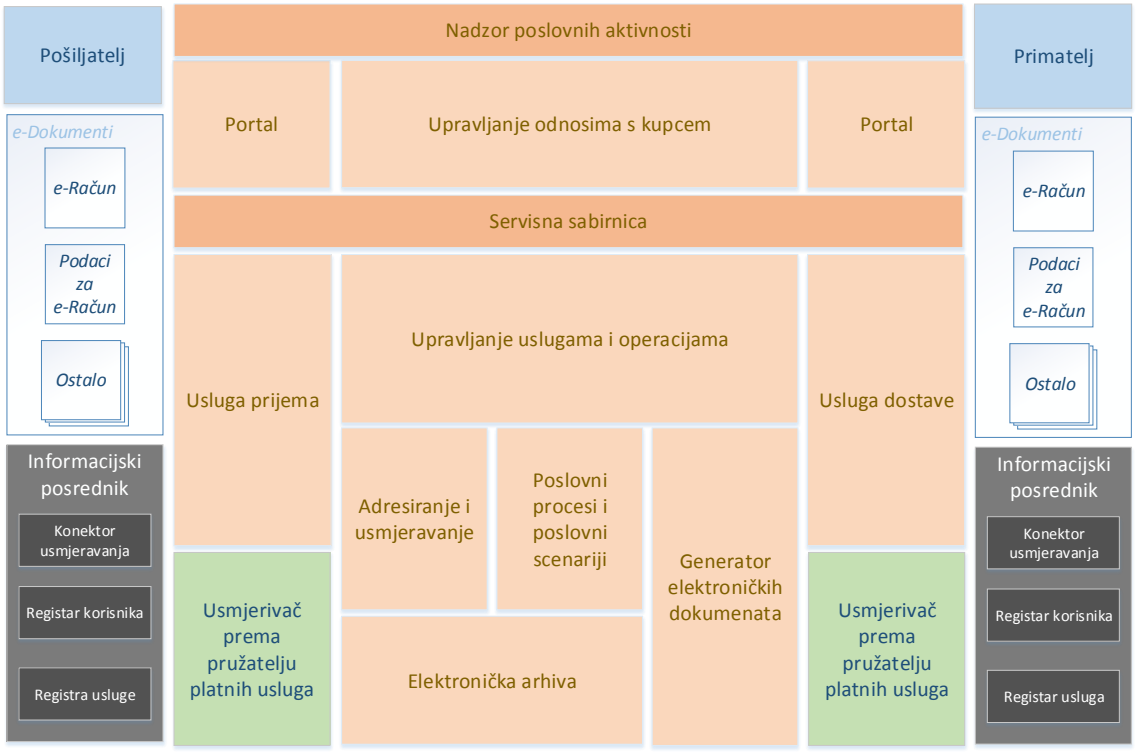
Procesna arhitektura informacijskog posrednika mora minimalno sadržavati ključne poslovne procese za uspostavu poslovanja usmjerenog na isporuku usluga. Uz poslovnu arhitekturu kao potporu izvršavanju poslovnih procesa potrebno je osigurati adekvatnu funkcionalnu i podatkovnu arhitekturu. Funkcionalna arhitektura definirat će potrebne funkcije za realizaciju poslovnih procesa. a podatkovna arhitektura smanjuje složenosti prilikom uspostave sustava, integracije s drugim informacijskim sustava, samog razvoja sustava i naknadnih prilagodbi.

Poslovanje informacijskih posrednika zasniva se na isporuci elektroničkih usluga korisnicima. Slično kao u telekomunikacijskoj industriji informacijski posrednik grupira usluge u proizvode, proizvode u kataloge proizvoda te uspostavlja tarifne modele nad katalogom proizvoda. Procesna arhitektura sustava informacijskog posrednika mora podržavati poslovne procese iz domene odnosa s kupcima (eng. Customer relationship management) i upravljanja uslugama i operacijama (eng. Service management and operations).

Kao ključna komponenta za uspostavu procesne arhitekture može se koristiti Business Process Framework (eTOM) [12], koji kao podatkovnu arhitekturu koristi Information Framework (SID) [13], što je dobro polazište za izgradnju podatkovne arhitekture informacijskog posrednika. SID osigurava referentni model i zajednički rječnik podataka.

Generička funkcionalna arhitektura (Slika 1.) implementira minimalni skup potrebnih funkcija za realizaciju poslovnih procesa iz domene odnosa s kupcem i upravljanja uslugama i operacijama. Glavne funkcionalne komponente su:

- Portal – dio sustava čija je uloga pošiljateljima i primateljima omogućiti pristup informacijama vezanim uz proces isporuke, statusu predanih elektroničkih dokumenata, pregledu ugovorenih usluga i servisa. Funkcionalnost portala mora implementirati različite funkcije zavisno o profilu korisnika. Npr. privatni i poslovni korisnici, izdavatelji i primatelji i sl.
- Upravljanje odnosima s kupcem (eng. Customer Relationship Management) – implementira funkcionalnosti potrebne za upravljanje odnosima s korisnicima, pokriva ugovaranje, osiguravanje nivoa kvalitete isporuke usluga (eng. Customer QoS i SLA management), kataloga produkata, registra korisnika, te naplate korištenja usluge.
- Upravljanje uslugama i operacijama (eng. Service Management & Operations) – funkcija koja implementira katalog servisa, konfigurira i aktivira servise, sakuplja informacije o upotrebi servisa (proces medijacije). Kao potporu operativnom radu minimalno mora uspostaviti funkcije potpore procesima rješavanja problema, te osiguravanja zadovoljavajućeg nivoa isporuke usluge.
- Usluga prijema, usluga dostave (eng. Receiver Services, Delivery Serivces) – uspostavlja različite vrste komunikacijskih kanala i protokola. Svaki kanal i protokol inkapsulira se u tzv.



Slika 2. Generička arhitektura informacijskog posrednika

konektor, npr. ERP konektor, Peppol konektor, konektor za informacijske posrednike.

- Adresiranje i usmjeravanje (eng. Addressing & Routing) – funkcija adresiranja će jedinstveno identificirati primatelja i pošiljatelja elektroničkog dokumenta, a usmjeravanja poruka će identificirati gdje i kako je potrebno elektronički dokument isporučiti. Usmjeravanje će razriješiti rutu kroz koju je potrebno poslati poruka na konačno odredište.
- Poslovni procesi i poslovni scenariji (eng. Business Processes &, Scenarios) – zavisno od ugovorenih proizvoda od strane korisnika sustav informacijskog posrednika omogućava izvršavanje različitih poslovnih scenarija korištenjem dostupnih servisa. Uspostavlja repozitorij i konfigurator poslovnih procesa.
- Ostale funkcionalne komponente: Elektronička arhiva (eng. e-archive) ,Servisna sabirnica (eng. Enterprise Service bus), Nadzor poslovnih aktivnosti (eng. Business activity monitoring), Generator elektroničkih dokumenata (eng. Eletronic Document Generator), Usmjerivač prema pružatelju platnih usluga (eng. Payment Service Provider gateway).

A. Funkcija Adresiranje i usmjeravanje

Prilikom isporuke do konačnog odredišta moguć je scenarij u kojem se na putu poruke nalazi jedan ili više drugih informacijskih posrednika

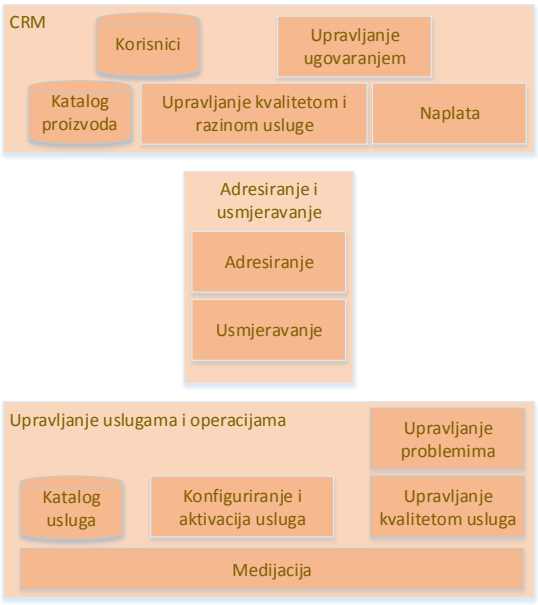
Adresiranje i usmjeravanje je poveznica između dva funkcionalna bloka sustava. Jedan je Upravljanje odnosima s korisnikom a drugi je Upravljanje uslugama i operacijama.

Upravljanje odnosima s korisnicima implementira Registar korisnika u kojem su pohranjeni identifikatori korisnika po različitim identifikacijskim shemama. Upravljanje uslugama i operacijama implementira Katalog Usluga, te konfiguraciju svih usluga koje pojedinog korisnik, kao i procese aktivacije pojedinih usluga.

Adresiranje koristi podatke iz Registra korisnika. Registar korisnika omogućava identifikaciju korisnika identifikatorom po jednoj shemi, dohvat svih podataka o korisniku, te preslikavanje identifikatora korisnika na drugu identifikacijsku shemu, npr. identifikacija korisnika po OIB-u, te dohvat njegovog GLN-a po GS1 identifikacijskoj shemi.

Usmjeravanje koristi podatke iz Konfiguratora usluga. U Konfiguratoru usluga su pohranjene instance pojedine definirane usluge iz Kataloga usluga. Instanca usluge kao objekt pohranjuje sve potrebne konfiguracijske vrijednost koje se odnose za pojedinog korisnika. Temeljem vrijednosti instanca Usluga pronalazi se ruta za isporuku elektroničkog dokumenta od pošiljatelja prema primatelju.

Npr. u jednostavnom scenariju kada i pošiljatelj, Korisnik A, i primatelj, Korisnik B, imaju ugovoren odnos s istim informacijskim posrednikom Korisnik A će imati ugovorenu uslugu slanje elektroničkog dokumenta. Instanca Usluge slanja će sadržavati podatke o



Slika 3. Pozicioniranje adresiranja i usmjeravanja u arhitekturi informacijskog posrednika

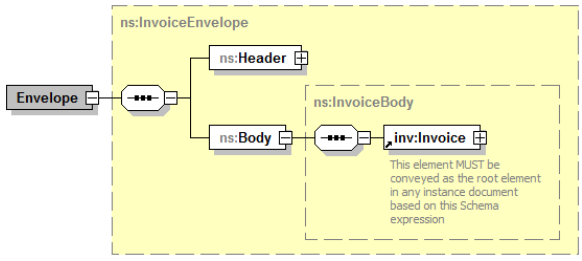
komunikacijskom kanalu i protokolu, prijemnoj lokaciji, formatu poruke i druge. Korisnik B će imati ugovorenu uslugu primanja. Instanca Usluge primanje će sadržavati informacije o komunikacijskom kanalu i protokolu, prijemnoj lokaciji, formatima poruke koju može zaprimiti i drugo. Adresiranje će temeljem identifikatora u zaprimljenoj poruci u Registru korisnika a temeljem identifikacijske sheme dohvatiti potrebne informacije o Korisniku B. Informacije će omogućiti ispravno usmjeravanje poruke prema prijemnoj lokaciji Korisnika B.

IV. ZAHTJEVI NA IMPLEMENTACIJU ADRESIRANJA I USMJERAVANJA

Jedan od kritičnih zahtjeva na adresiranje i usmjeravanje je podržavanje modela 4-strane [11]. U ovom modelu poruka od pošiljatelja putuje prema njegovom informacijskom posredniku koji je usmjerava prema informacijskom posredniku primatelja koji je prosljeđuje na krajnje odredište, tj. samom primatelju. Sve sudionike razmjene je potrebno jedinstveno identificirati. Problem je kompleksniji ako je potrebno preusmjeravati poruke zavisno o vrsti sadržaja koji se s njima prenosi.

Prilikom adresiranja različiti sustavi koriste različite identifikacijske sheme. Kao što je navedeno u [6] u različitim zemljama implementirani su različite identifikacijske sheme. Npr. Norveška, Nizozemska i Švedska koriste službeni porezni broj i upotrebu meta identifikatora sukladno ISO/IEC 6523. ePRIOR sustav podržava upotrebu internacionalnog identifikatora GLN od GS1 organizacije. Njemačka koristi identifikatore informacijskog posrednika čija je struktura sukladna ISO 3166 standardu [14]. Za Republiku Hrvatsku je u [6] specificirana identifikacijska shema prema poreznom broju (OIB-u). Prema identifikacijskoj shemi porezni broj za Republiku Hrvatsku ima kod 9934.

Implementacija adresiranja osim identifikacije po nekoj od identifikacijskih shema omogućuje i



Slika 4. Struktura poruke [7]

preslikavanje vrijednosti iz skupa vrijednosti jedne identifikacijske sheme na vrijednosti iz skupa vrijednosti druge identifikacijske sheme. Preslikavanje će dohvatiti jedan ili više dodatnih identifikatora po različitim identifikacijskim shemama. Norma [5] specificira formalni mehanizam za identifikaciju poslovnih subjekata u poslovnim XML dokumentima. Mehanizam adresiranja minimalno bi morao implementirati ISO 6523 [14], ISO 9735 [14] i ISO 20022 [14] kataloge shema za imenovanje identifikacijskih domena. Specifikacija [5] definira formalni mehanizam za referenciranje identifikacijskih shema korištenjem URN notacije.

U slučaju da je identifikacijska shema registrirana u ISO 6523, ISO 9735 ili ISO 20022 koristi URN format:

*urn:oasis:tc:*ebcore*:partyid-type:catalog-identifier:scheme-in-catalog:scheme-specific-identifier*

U ostalim slučajevima koristi URN format:

*urn:oasis:names:tc:*ebcore*:partyid-type:unregistered:mycatalog:myscheme*

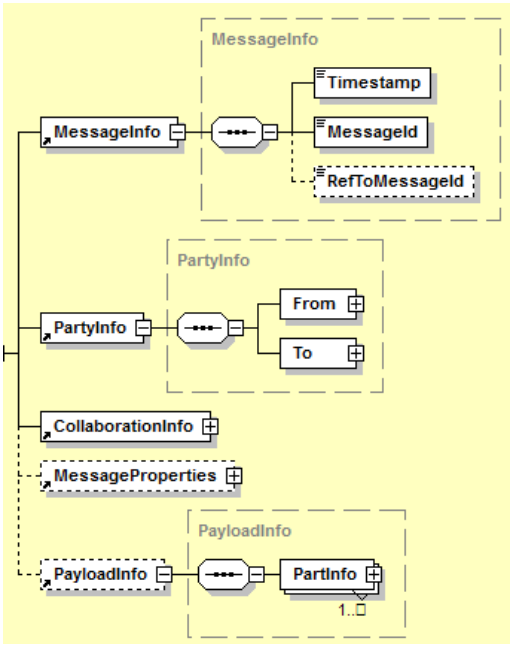
Usmjeravanje, na temelju vrijednosti identifikatora iz zaprimljene poruke, određuje odredište ili odredišta na koja zaprimljena poruka biti treba dostavljena. Prilikom određivanja odredišta usmjeravanje koristi funkcionalnosti adresiranja u svrhu preslikavanja identifikatora iz zaprimljene poruke na identifikatore odredišta. U zaglavlje poruke dodaju se novi identifikatori i poruka se prosljeđuje prema odredištu. Unutar sustava informacijskog posrednika za elektronički račun e-dokumenti imaju ovojnicu. Slika 4 prikazuje strukturu ovojnice. Ovojnica sadrži zaglavlje (Header) i tijelo poruke (Body). Zaglavlje poruke sadrži podatke o poruci, podatke usmjeravanja, opis tijela poruke itd. Slika 5 prikazuje strukturu zaglavlja poruke. Tijelo poruke sadrži kanonski oblik zaprimljene poruke ili e-dokument.

Zaglavlje poruke opisano u [7] ima sljedeće elemente:

- MessageInfo sadrži podatke o poruci: vremensku oznaku kreiranja zaglavlja (Timestamp), jedinstveni identifikator poruke (MessageId) i identifikator povezane poruke (RefToMessageId).
- PartyInfo sadrži podatke kreatora i primatelja poruke: identifikator organizacije (PartyId) i ulogu organizacije (Role).
- CollaborationInfo sadrži podatke o suradnji između stranaka: poveznica na ugovor (AgreementRef), usluga koja djeluje na poruku (Service), operacija ili aktivnost unutar usluge (Action) i identifikator konverzacije (ConversationId).
- MessageProperties sadrži svojstva poruke. Kao dijelovi zaglavlja svojstva sadrže informacije koje kvalificiraju podatke poruke ili omogućavaju povezivanje poruke s nekim poslovnim procesom. Time se može omogućiti učinkovitije praćenje, korelacija, usmjeravanje ili validacija podataka poruke bez pristupa sadržaju poruke.
- PayloadInfo identificira nosive podatke povezane s porukom. PayloadInfo može identificirati podatke unutar poruke ili podatke dostupne preko URL-a.

Primjer korištenja različitih informacijskih shema u elementima From i To iz zaglavlja poruke:

```
<eb3:PartyInfo >
  <eb3:From>
    <eb3:PartyId
type="urn:oasis:names:tc:ebcore:partyid-
type:unregistered:x2xplatformid:0001">3DF5848-85D5-
48FB-831F-A4DF30C7A128
    </eb3:PartyId>
    <eb3:Role>Supplier</eb3:Role>
  </eb3:From>
  <eb3:To>
    <eb3:PartyId
type="urn:oasis:names:tc:ebcore:partyid-
type:iso6523:9934">47475070790</eb3:PartyId>
    <eb3:PartyId
type="urn:oasis:names:tc:ebcore:partyid-
type:unregistered:x2xplatformid:0003">
          5006346999
              </eb3:PartyId>
    <eb3:Role>Buyer</eb3:Role>
  </eb3:To>
</eb3:PartyInfo>
```



Slika 5. Struktura zaglavlja poruke [7]

V. KANONSKI OBLIK ELEKTRONIČKOG DOKUMENTA

Sadržaj koji se razmjenjuje može biti u različitim formatima. U upotrebi su različite norme po kojima se generiraju dokumenti, npr. UN/CEFACT ASTMA, OAGi, UBL i druge. Potrebno je omogućiti standardni način razmjene sadržaja. Zbog optimizacije različiti tipovi dokumenata, npr. račun, narudžbenica, pisma, podnesci, akti i drugo, unutar sustava informacijskog posrednika bi trebali imati vlastiti standardni format, tj. kanonsku formu. Npr. preporuka za standardni format za e-Račun može biti zasnovana na normi UBL 2.1 [1]. Ovakav pristup rezultira optimizacijom pri transformacijama dokumenata iz jednog u drugi format te pojednostavljuje ukupnu implementaciju ostalih funkcionalnih komponenti sustava informacijskog posrednika. Informacije koje se pohranjuju u zaglavlje poruke prilikom zaprimanja dolaze iz poslovnog konteksta pošiljatelja. Poslovni kontekst pošiljatelja može biti zapisan u sadržaj poslanog dokumenta ili kao skup dodatnih podataka izvan sadržaja. Identifikatori iz sadržaja e-dokumenta ne trebaju biti osnova za usmjeravanja zbog nekoliko razloga. Ako je e-dokument kriptiran informacijskom posredniku identifikatori mogu biti nerazumljivi. Ukoliko informacijski posrednik ne čita sadržaj poruke neće moći dostaviti poruku prema identifikatorima iz same poruke. Za slučaj kada se podaci nalaze izvan sadržaja dokumenta prilikom razmjene potrebno je implementirati Business Document Header [2] strukturu. Iz Business Document Headera podaci poslovnog konteksta se preslikavaju u zaglavlje poruke, a u sadržaj poruke postavlja se sam dokument ali i Busines document Header. Zaglavlje poruke se koristi kao objekt koji nosi sve potrebne informacije za daljnje procesiranje.

VI. ZAKLJUČAK

Prilikom razmjene elektroničkih dokumenata potrebno je implementirati različite identifikacijske sheme u procesima adresiranja i usmjeravanja poruka. U internim procesima potrebna je čak i implementacija dodatnih internih identifikatora. Uspostava standardiziranog oblika poruke za internu obradu postaje obavezan zahtjev u sustavima informacijskih posrednika. Struktura interne poruke mora omogućiti jednostavna preslikavanja u ili iz eksternih struktura u kojima je pohranjen poslovni kontekst i elektronički dokument. Na taj način se osigurava prilikom razmjene jedinstven kontejner za različite elektroničke dokumente bez obzira na njihov format. S druge strane standardiziranje eksterne strukture omogućuje izvoru i konačnom odredištu automatizaciju obrade u njihovim poslovnim aplikacijskim sustavima.

U radu je predložena generička arhitektura sustava informacijskog posrednika pod utjecajem normi i smjernica za adresiranje i usmjeravanje u kontekstu poslovnih funkcija upravljanja odnosima s kupcem i upravljanja uslugama i operacijama. Predložena je struktura interne poruke prilikom obrade u sustavu informacijskog posrednika i zahtjevi na adresiranja i usmjeravanje, te preslikavanje različitih identifikatora.

[3]GEOprem d.o.o. Osijek, Hrvatska
franjo.ambros@geoprem.hr

Sažetak - Digitalnom agendom Europa 2020 definiran je način provedbe širokopojasnog pristupa. Hrvatska vlada je 2011. godine usvojila strategiju i provedbeni program iz tog područja. Novina u pristupu pri realizaciji ovih dokumenata je uvođenje lokalne samouprava kao mogućeg aktivnog subjekta pri planiranju i izgradnji širokopojasne infrastrukture za koju su predviđeni fondovi EU iz područja infrastrukture koji u velikom postotku investicije sudjeluju u realizaciji takovih projekata. Kako bi se osigurale sve pretpostavke za racionalno ulaganje, potrebno je analizirati potrebe korisnika, opisati postojeću telekomunikacijsku infrastrukturu kroz katastar vodova te njen potencijal za realizaciju širokopojasnog pristupa. Osim toga, prostorne planove treba adekvatno pripremiti za rezervaciju infrastrukturnih koridora, a postupkom imovinsko pravnog uređenja osigurati vlasničke pretpostavke za realizaciju ove zadaće. Bez adekvatne informatičke podrške, koja će dati sveobuhvatni pregled problema, nije moguće potpuno definirati i izraditi projektni zadatak. U radu je izložen koncept ulaznih parametara potrebnih za bazu podataka temeljem koje se donose odluke o prioritetima ulaganja u širokopojasni pristup, te prikaz web pristupa podacima.

I. UVOD

Europska komisija je u okviru Strategije Europa 2020 sredinom 2010. inicirala Digitalni plan za Europu (engl. *Digitalna Agenda for Europe*) kao jednu od sedam ključnih inicijativa predviđenih tim strateškim programom. Hrvatska Vlada krajem 2011. godine donosi dokument: „Strategija razvoja širokopojasnog pristupa u Republici Hrvatskoj u razdoblju od 2012. do 2015. godine“ i „Provedbeni program Strategije razvoja širokopojasnog pristupa u Republici Hrvatskoj za razdoblje od 2012. do 2013.“[1].

U Osijeku je početkom 2012. godine na Elektrotehničkom fakultetu Osijek održan stručni skup uz sudjelovanje Ministra graditeljstva i prostornog uređenja i Hrvatske agencije za poštu i elektroničke komunikacije (HAKOM), s ciljem pripreme lokalne zajednice za provođenje ovog strateškog dokumenta koji, prema ocjenama svih, daje tehnološki iskorak usporediv s elektrifikacijom koja je provedena u prošlom stoljeću.

Na skupu je navedeno kako ovaj tehnološki iskorak ima i neke specifičnosti karakteristične za Hrvatsku. Naime, pravna regulativa iz područja elektroničke komunikacijske infrastrukture (EKI) nije predviđala da, investitor u ovu infrastrukturu, može biti lokalna samouprava što proizlazi iz duha ove Agende. U međuvremenu je HAKOM predložio, a Vlada donijela: „Uredbu o mjerilima razvoja elektroničke komunikacijske infrastrukture i druge povezane opreme“ [2] te time otklonila ovu dilemu. Drugi uočen problem je neadekvatna prostorno planska dokumentacija temeljem koje se planira izgradnja lokalne infrastrukture. Treći mogući usporivač procesa je neuređeno imovinsko pravno stanje na nekretninama na kojima se planira gradnja EKI. Uočeno je kako ne postoje aktualni strateški dokumenti razvoja lokalne sredine temeljem kojih planiramo buduće potrebe.

Tim koji je tada formiran pri Elektrotehničkom fakultetu Osijek, odmah je započeo sa pripremom dokumenata temeljenih na strategiji širokopojasnog pristupa. Napravljen je idejni projekt „Slavonska mreža“ koji će se, u vidu pilot projekta, realizirati na području 5 županija istočne Hrvatske (Osječko-baranjska, Vukovarsko-srijemska, Brodsko-posavska, Požeško-slavonska i Virovitičko-podravska). One predstavljaju 22,1% teritorija Hrvatske na kojem živi preko 800 tisuća stanovnika u 998 naselja, teritorijalno organiziranih u 22 grada i 105 općina. Veličina početne investicije je procijenjena na 21.5 milijuna €.

Projektna ideja je kandidirana na natječaj raspisan u okviru Programa pripreme i provedbe razvojnih projekata prihvatljivih za financiranje iz fondova Europske unije u 2013 godini – potprogrami Priprema regionalnih razvojnih projekata. Ministarstvo regionalnog razvoja i

fondova Europske unije je krajem 2013. godine donijelo odluku kojom se projektu odobrava tehnička pomoć u pripremi.

Kako bi se projekt racionalno vodio potrebno je izraditi informacijski sustav podataka sa svim parametrima koji utječu na poslovne odluke. Bitne karakteristike takovog sustava su modularnost i 24-satni pristup informacijama. Modularnost uključuje podatke razvrstane u bazama davatelja informacija koje se koriste pri izradi detaljnih projekata. Ovakvu logiku imaju geografsko informacijski sustavi (GIS) dok 24-satni pristup osigurava web servis. Autori ovog rada, sa suradnicima, razvijaju informacijsku potporu temeljenu na web pristupu kojom će se omogućiti racionalnije planiranje i planiranje izgradnje elektroničke komunikacijske infrastrukture, nastojeći iskoristiti dostupne javne baze podataka direktnim uvidom, ili uz prilagodbu.

II. INFORMACIJE NA KOJIMA SE TEMELJI PROJEKT

Realizacija Strategije širokopojasnog pristupa temelji se na prikupljanju raznih podataka o prostoru, imovinsko pravnim odnosima na trasama budućih koridora infrastrukture, stanju prostorno planske dokumentacije, lokacijama potencijalnih korisnika usluga, podataka o postojećoj infrastrukturi, razini dostupnih brzina širokopojasnog pristupa kako za fiksnu tako i za mobilnu mrežu i podataka o potencijalnoj izgradnji ostale infrastrukture. Važno je napomenuti da sve podatke prate i tzv. Metapodatci koji opisuju kvalitetu i strukturu podataka bez kojih često dolazi do krivog tumačenja ulaznih parametara, što se u konačnici odražava na kvaliteti realizane ideje.

A. Koordinatni sustavi

Prije nego detaljnije analiziramo izvore podatke potrebno je ukazati na potrebu vezanja svih podataka na određenu lokaciju/adresu. Pretpostavke za to su definirani koordinatni sustavi koji imaju matematičku osnovu preslikavanja geometrijskih oblika sa zemljine površine na ravninu. Napominjemo da koordinatni sustavi imaju svoju praktičnu svrhu te da je poznata matematička osnova velikog broja koordinatnih sustava. Samo podaci prikupljeni u jednom koordinatnom sustavu mogu se jednoznačno povezati s lokacijom. Ukoliko želimo koristiti podatke u jednom a prikupljeni su u drugom koordinatnom sustavu, neophodna je transformacija podataka. U Hrvatskoj postoje podaci o prostoru prikupljeni u više koordinatnih sustava (geodetski datumi). To je naša stvarnost o kojoj moramo i te kako voditi računa. Specifičnosti pojedinog koordinatnog sustava nije predmet ovog rada nego upozorenje da je od 1. 1. 2010. godine službeni koordinatni sustav (geodetski datum) Hrvatski terestički referentni sustav/trans Mercator, čija skraćenica glasi: HTRS96/TM [3]. Obveza upotrebe ove projekcije je pri izradi topografskih karata i katastarskih planova. Kako su od 1929. do 2010. godine na našim prostorima bila u primjeni 2 koordinatna sustava Gauss-Krügerove projekcije (5. i 6.), velik broj podataka treba transformirati u novi koordinatni sustav. Pri toj transformaciji, uz veliko povećanje karte, na ekranu računala se uočavaju značajna vizualna odstupanja do kojih dolazi zbog karaktera same transformacije. Pri ocjeni tih odstupanja mora se voditi računa o ekonomičnosti. Ponekad su odstupanja od nekoliko metara u granicama tolerancije, dok u nekim slučajevima tražimo centimetarsku točnost.

B. Karte, izvori podataka o prostoru

Izvori podataka za planiranje zahvata u prostoru su kartografski prikazi u raznim mjerilima (sl. 1). Izrada karte je složen i dugotrajan postupak te je potrebno ocijeniti aktualnost svake dostupne karte. Informacije za procjenu uporabne vrijednosti karte, ukoliko se radi o tiskanim primjercima, obično se nalaze na obodu karte. Potrebno je obrati pozornost na mjerilo jer ono određuje stupanj uopćavanja, vrijeme prikupljanja podataka, jer je ono indikator zastarijevanja, podatke koji ukazuju na vezu s kartama sitnijeg mjerila i dr. Kako je list karte prikaz (isječak) određenog područja koje se u odabranom mjerilu može prikazati u nekom standardnom formatu, potrebno je obratiti pozornost i na međusobnu vezu listova. Radi lakše dostupnosti i korištenja, karte se prevode u digitalni oblik. Najčešći oblici konverzije su skeniranje, geokodiranje i vektorizacija. Geokodiranje je postupak kojim se slikovni oblik karte smješta u prostor te time nastaje hibridni model koji je pogodan kao podloga za prikaz tematskih sadržaja. Vektorizacija je rastavljanje karte u elementarne dijelove, a potom spajanje u digitalni oblik. Smatramo da se o karti kao proizvodu mora posvetiti više pozornosti. Korištenjem karte u digitalnom obliku, ona se vraća u realan prostor. Međutim, podaci o „realnom prostoru“, konverzijom analogne u digitalnu kartu, nisu prikupljeni točnošću koja se očekuje (koju pruža računalo). Za razliku od analogne karte, gdje su dostupni podaci za svaki list karte temeljem kojih se procjenjuje upotrebljivost karte, korištenjem digitalnih prikaza prethodi ocjena upotrebljivosti temeljem Metapodataka.

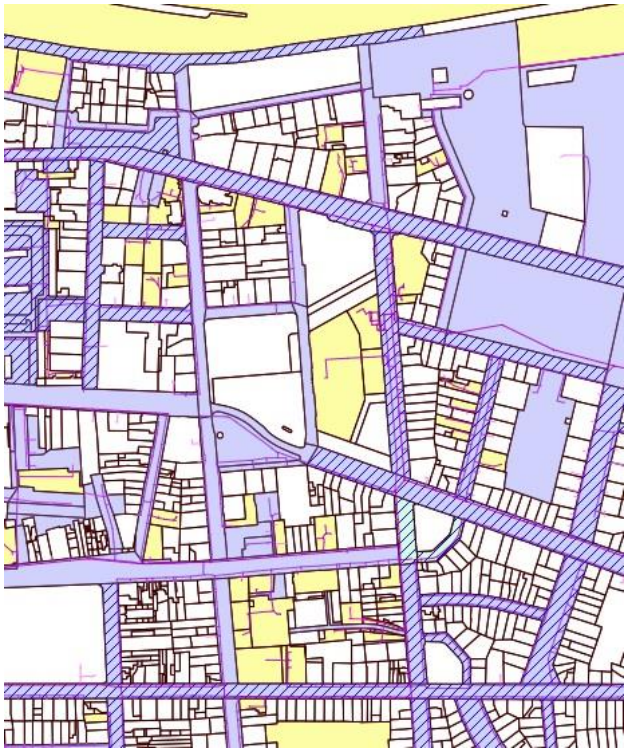
C. *Katastarski planovi - izvori o podacima pravnih režima na nekretninama*

Katastarski planovi, za razliku od drugih kartografskih prikaza, težište usmjeravaju na granice raznih pravnih režima. Najčešće govorimo o granicama vlasništva. Katastarski planovi prikazuju katastarske čestice kao dijelove prostora čiji je vlasnik jedna (samovlasništvo) ili više osoba (suvlasništvo). Pri planiranju EKI, moraju se urediti imovinsko pravni odnosi s vlasnikom nekretnine, pri čemu su to najčešće fizičke osobe, tvrtke, lokalna ili regionalna samouprava odnosno država. Karakteristika uređivanja imovinsko pravnih odnosa za potrebe infrastrukture je kompleksnost odnosa zbog velikog broja katastarskih čestica na kojima se linijska infrastruktura gradi, neusklađeni podaci o posjednicima i vlasnicima koji se vode u javnim evidencijama (Katastar/ Zemljišna knjiga) sa stanjem na terenu. Hrvatska ima preko 14 milijuna katastarskih čestica, a dosadašnja elektronička komunikacijska infrastruktura je izgrađena na 8.72% katastarskih čestica, od kojih je 66% u privatnom vlasništvu. Na česticama u privatnom vlasništvu je oko 25% duljina svih trasa EKI. [4]. Koridori za infrastrukturu zaslužuju daleko veću pozornost nego što im se do sada poklanjala. Ukoliko se želi racionalnije i brže graditi mora se pojednostaviti pravna regulativu po pitanju prostornog planiranja i gradnje infrastrukture. [5].
Zbog potrebe uvida u imovinskopravno stanje razrađen je model provjere usklađenosti javnih evidencija i budućih planova izgradnje (sl. 2). Ulazni podaci, za ovu provjeru, su javni podaci katastra dostupni kao e-posjedovni list, digitalni katastarski planovi, čija je dostupnost uz plaćanje moguća preko Državne geodetske uprave, baza



Slika 2. Sklopljeni ugovori za upis služnosti

Ministarstva pravosuđa: e-zemljišno-knjižni izvadak te podaci iz katastra vodova upravitelja voda. Za ovu je analizu razvijen program koji vizualizira neusklađenosti ili potencijalno problematične upise koji bi mogli biti prepreka pri kandidiranju projekta za financiranje iz EU fondova. Ovom se analizom otkrivaju i neka upisana prava (pravo služnosti) koje je prednik vlasnika infrastrukture stekao u prošlosti (sl. 3 i 4.).
Detaljnije o aktivnostima oko uređivanja imovinsko pravnih odnosa na infrastrukturi u radu [6]

D. Prostorno planska dokumentacija

Planiranje infrastrukture na nekom području podrazumijeva osiguranje koridora ili lokacije za izgradnju na kome će se graditi infrastruktura ili objekt u funkciji infrastrukture. Za potrebe mobilne mreže, lokacije baznih stanica su dogovorno planirane u sklopu županijskih prostornih planova (sl. 5), koridori infrastrukture su obično rezervirani u planovima nižeg reda, izuzetak su magistralni pravci koji prelaze granice lokalne ili regionalne samouprave (sl. 6).

Istraživanja o troškovima izgradnje podzemne infrastrukture [7] ukazuju da je udio troškova kopanja oko 70% kod gotovo svakog voda. Ovo upućuje na moguću uštedu ukoliko se sinkronizira izgradnja više tipova infrastrukture istovremeno. O toj činjenici bi trebalo voditi računa već pri izradi prostorno planske dokumentacije. Informacijski sustav bi trebao signalizirati da su počele pripreme za projektiranje infrastrukture na određenom području. Zakoni Republike Hrvatske predviđaju različite investitore za svaku infrastrukturu. Procjenjujemo da postojeći kaos: kopanje – zatrpavanje – asfaltiranje pa ponovo kopanje treba prekinuti jer on osim neracionalnosti nepotrebno iritira građane. Transparentno planiranje (uvid preko weba), doprinijeti će većoj koordinaciji pri planiranju i izgradnji infrastrukture.

Slika 6. Prostorni plan pošte i telekomunikacija Osječko-baranjske županije

E. Podaci o postojećoj infrastrukturi

Za realizaciju strategije širokopojasnog pristupa prostor kao resurs može ograničavati izgradnju potpuno nove infrastrukture, zbog toga je neophodno da se analiziraju postojeći kapaciteti koji su izgrađeni za potrebe telekomunikacija. Prije svega tu je telefonska kanalizacija koja se u gradovima počela graditi prije više od 70 godina. Zatim je tu distributivna telefonska kanalizacija (DTK) koja se gradi više od 20 godina (sl. 7). Osim toga tu su i optički kabeli raznih infrastrukturnih operatera ili vlasnika.

Kroz cijelo razdoblje izgradnje i eksploatacije telekomunikacijske mreže dokumentacija o položaju i kapacitetima se odvojeno vodila, što zbog praktičnosti a što zbog zaštite tajnosti. Tako je ustrojavanjem katastra vodova samo prostorni položaj infrastrukture bio predmet katastarske evidencije dok je tehnička dokumentacija koja je prikazivala kapacitete bila samo kod upravitelja voda. Za osmišljavanje projekta širokopojasnog pristupa interesantan je kapacitet kanalizacije i DTK te optički kabeli koji su u toj kanalizaciji.

Od 1969. godine postoji obveza osnivanja i vođenja katastra vodova [8] temelj kojega je geodetska izmjera vodova. Od 1973. ovo područje je regulirano Zakonom o katastru vodova [9]. Sjeverni dio Hrvatske ovu je zakonsku obvezu ozbiljnije shvatio od južnog dijela Hrvatske. Ova bi činjenica mogla sjevernom dijelu Hrvatske pomoći u realnijem osmišljavanju realizacije strategije širokopojasnog pristupa.

Slika 7. Distributivna telefonska kanalizacija

Promjenom tehnologije s „bakra na optiku“ promijenili su se tehnološki zahtjevi prema DTK kao infrastrukturi. Uz tehnologiju mikro-cijevi kapaciteti se mogu višestruko povećati tako da taj resurs treba staviti na raspolaganje svim ostalim operaterima pa i davateljima digitalnih usluga koje nemaju javni karakter, ali mogu značajno unaprijediti kvalitetu života (umrežavanje raznih senzora onečišćenja zraka, buke, usluga učenja, e-doktor i dr.). To u budućnosti implicira na mijenjanje odnosa koji proizlaze iz prava puta, u odnos partnerstva lokalne zajednice, infrastrukturnih operatera, davatelja i korisnika usluga.

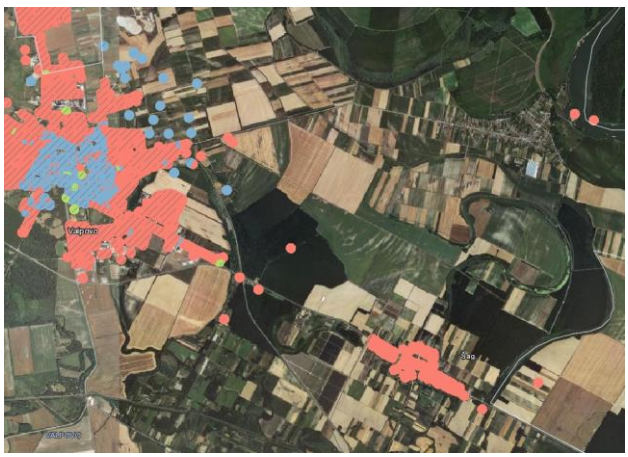
Posebno je interesantna činjenica da je najveći infrastrukturni operater HT Hrvatski telekom od 2009. godine investirao preko milijardu kuna u optičke kabele (FTTH) koji su danas „mrtvi kapitali“.

Još jedan segment koji utječe na uobličavanje svih elemenata digitalne usluge je kućna instalacija zgrade. Ukoliko se u proces ulaska u digitalno doba ne uključe vlasnici zgrada, upitna je realizacija strategije širokopojasnog pristupa. Tu lokalna zajednica mora preuzeti aktivnu ulogu izgradnje kućne instalacije po svim zgradama prema važećim propisima i standardima. Podaci o zgradama i vlasničkoj strukturi zgrade bitni su za osmišljavanje koncepta obnove kućne instalacije. Važno je napomenuti da dopunama Zakona o vlasništvu i drugim stvarnim pravima [10] od 2008. godine montaža i održavanje elektroničke komunikacijske infrastrukture i povezane opreme, spada u redovnu uporabu zgrade, što omogućava da 51% vlasnika donosi odluku o radovima na zgradi.

F. Dostupnost korisnika maksimalnim brzina

Kako je podatak o dostupnosti određenoj brzini širokopojasne usluge podatak koji mijenja prioritete kod investiranja u ovu infrastrukturu iz fondova EU potrebno to prokomentirati HAKOM ovu kartu.

Karta Područja dostupnosti širokopojasnog pristupa (sl.8) dostupna je na stranicama HAKOM-a [11] uz ogradu od prezentiranih podataka. Kako na brzinu preko postojeće bakrene infrastrukture utiče više elemenata: udaljenost od digitalnog čvora (centrale), kvaliteta spojeva u kabelu,



Slika 8. Karta Područja dostupnosti širokopojasnog pristupa

broj istovremenih korisnika to ukazuje da bez mjerenja na određenom području ne postoji realna slika o dostupnim brzinama. Ugovori kojima operateri ugovaraju pakete usluga s korisnicima teško bi prošli detaljniju provjeru udruge potrošača. Što znači brzina koja u periodu mjesec dana korištenja nije prešla 10% maksimalne ugovorene brzine.

Na karti su podaci dostupnosti i za fiksnu i za mobilnu mrežu. Nije potpuno jasno da li se u ocjeni područja koje se priprema za izgradnju infrastrukture za širokopojasni pristup smatra da postoje dva operatera fiksni i mobilni. Ukoliko se radi u dva komercijalna operatera područje spada u područje koje nema pravo na potporu iz fondova Europske unije.

III. MOBILNA MREŽA

Uloga mobilne mreže zaslužuje analizu njene dostupnosti i potencijala za digitalnim uslugama u ruralnom području. Nažalost potencijal ove usluge nije u Hrvatskoj korišten za razvoj privrede nego se koristi za zabavu i društvene mreže. Pokrivanje signalom je usmjereno prema koncentraciji korisnika a ne na pokrivanje teritorija. Rezultat čega je da su neki servisi ostali bez adekvatne telekomunikacijske logistike. Tako je u radu [12] iznijeta analiza rada mobilnog interneta preko kojeg servis CROPOS prima korekcijske parametre za određivanje pozicije u realnom vremenu s centimetarskom točnošću. Servis CROPOS je u službenu upotrebu pustila Državna geodetska uprava 9.12.2008. Ovaj servis je osim geodetima namijenjen i drugim korisnicima. Njegov potencijal u „preciznoj poljoprivredi“ nije prepoznat jer je mobilni Internet u ruralnom području često nedostupan. Usluga je usmjerena na govornu komunikaciju, tako da nedostaje kapaciteta za podatkovnim uslugama. Doradu ove mreže treba razmotriti za kandidiranje iz fondova EU u sklopu širokopojasnog pristupa.

Lokacije baznih stanica svih mobilnih operatera s podacima o usmjerenjima antena trebaju činiti bazu podataka temeljem koje će se praviti procjena realizacije strategije širokopojasnog pristupa.

IV. INFORMACIJSKA PODRŠKA ZA REALIZACIJU STRATEGIJE ŠIROKOPOJASNOG PRISTUPA

U posljednje vrijeme je mrežni pristup GIS-u sve popularniji. Prikaz dinamičkih mapa preko Interneta postaje rastući izazov. Vlada RH i lokalne samouprave sve češće postavljaju digitalne mape kao javne servise na svoje Web stranice. Trgovačka društva žele zemljopisnim podacima informirati svoje potencijalne kupce o mjestima trgovina.

Pri stvaranju GIS mapa teži se, nedovoljno obučenim korisnicima, pojednostaviti usluga dostupa podataka preko GIS okruženja. Jednostavnim označavanjem željenih procesa, korisnici aktivno sudjeluju u prikazivanju i istraživanju podataka korištenjem interaktivnih mapa preko pogodnosti korištenih web preglednika.

U GIS programe se ulažu velika sredstva za njihovo istraživanje i razvoj kako bi se tržištu ponudile nove, napredne mogućnosti. Ovdje se prvenstveno misli na obradu 3-D zemljopisnih podataka te na web prikaz temeljen na georeferenciranim podacima. Ovo se posebno odnosi na razvoj distribuiranih tehnoloških sustava obrade velikih količina podataka kao i obrade zemljopisnih podataka u realnom vremenu.

A. Primjena web prikaza podataka

Opredjeljujući se za 24 satni pristup podacima i istovremenom potrebom da se uključuje što veći broj korisnika, nameće se kao rješenje web pristup tipa: „geoportala otvorenog koda“ koji podržava MapGuide Open Source. Aktualnost karata i katastarskih planova moguće je provjeriti uvidom u digitalni ortofoto plan (DOF5). Isto koristi i HAKOM za karte područja dostupnosti širokopojasnog pristupa. Moguće je uključiti Google Maps i Street View. Preveliki zahtjevi prema informatičkim tehnologijama mogu dovesti do nerealnih očekivanja i usmjeravanja prema interpretaciji, a ne prema kvaliteti prikazanih podataka. Vizualizacija podataka može ukazati na moguće nelogičnosti podataka unutar baze, tako da o tome trebamo posebno voditi računa. Dosadašnja praksa svjedoči o neusklađenosti slike i zbilje. Ovo je uobičajena zabluda kod GIS tehnologija. Korisnik često odustaje prije moguće prilagodbe prikazanih podataka jer želi savršeno prezentirani traženi podatak. Zato je informacijska podrška u ovoj fazi namijenjena krugu stručnjaka koji će osmišljavati strategiju i na osnovu prezentiranih podataka određivati prioritete.

V. ZAKLJUČAK

Provedba Strategija razvoja širokopojasnog pristupa u RH od 2012. do 2015. godine je na području istočne Hrvatske započela projektom „Slavonska mreža“ – kojeg je 2013. g. pokrenuo Elektrotehnički fakultet Osijek u suradnji s pet županija regije Slavonija i Baranja. U pripremnim etapama ovog projekta uočen je niz problema i organizacijskih prepreka koje treba riješiti na nacionalnom planu. To su:

- Izrada informacijskog sustava kojim će se utvrditi standardi korištenja postojećih podataka i meta podataka kako bi se dobio realan uvid u stanje prostora i koridora.
- Utvrđivanje modela i organizacijske razine katastra vodova; ne samo širokopojasnog pristupa već svih infrastrukturnih instalacija u prostoru)
- Izgradnja informacijske podrške koja će biti kompatibilna s postojećim sustavima u jedinicama lokalne samouprave
- Izgradnja baze podataka o prostoru i elektroničkoj komunikacijskoj infrastrukturi kojom će se koristiti svi ovlašteni subjekti

Zahvati u prostoru koji iziskuju toliko ulaznih parametara kao što je izgradnja infrastrukture za širokopojasni pristup - ne mogu biti osmišljeni i realizirani bez informatičke podrške. Ovim se pristupom mogu paralelno prikupljati i analizirati podaci te modelirati postupci provedbe uz manje troškove i primjerene rokove izgradnje.

Uz tradicionalne isporučitelje telekomunikacijskih sustava: elektroničke komunikacijske infrastrukture (EKI) i usluga pojavljuju se u posljednje vrijeme i posve novi tip ponuditelja telekomunikacijske infrastrukture. To su jedinice lokalne samouprave (JLS): gradovi i općine koji investiraju u gradnju nove komunalne infrastrukture EKI.

Liberalizacijom telekomunikacijskog tržišta došlo je do promjene vlasništva nad javnom telekomunikacijskom infrastrukturom – privatnopravni gospodarski subjekti koji su postali vlasnici, prvenstveno vode brigu o ekonomskim interesima svojih tvrtki. No razvoj i gradnja elektroničke komunikacijske infrastrukture javni je interes koji država i JLS moraju poticati, promicati i zaštititi osobito radi osiguranja istih uvjeta i ravnomjernog razvoja na svim nastanjenim područjima vodeći se pri tome načelima održivog razvoja, te zaštiti drugih javnih i privatnih interesa.

Gradovi i općine koji namjeravaju pokrenuti projekte nove EKI imaju mnogobrojne izazove – traže se novi izvori financiranja potrebni za daljnji razvoj zajednice, ali i bolju kontrolu i naplatu stavki koje im po zakonu pripadaju. Potencijalno velika sredstva iz budžeta Europske Unije (EU) su na raspolaganju, no pitanje je imaju li JLS dovoljno kapaciteta i znanja za pripremu i realizaciju takvih novih projekata? Malo je vremena preostalo za projektiranje infrastrukture ukoliko se želi smanjiti zaostatak za sumjerljivim zemljama iz Europske Unije. Manji gradovi nemaju vlastitu IT infrastrukturu i dovoljno stručnih kadrova za efikasno upravljanje životnim ciklusom izgrađene infrastrukture.

Koristeći svoja značajna iskustva u procesu izgradnje komunikacijskih sustava odnosno mrežne infrastrukture, te dobro definirane poslovne procese, Ericsson Nikola Tesla (ENT) predlaže „industrijalizaciju" procesa kreiranja projekata i aplikacija za EU fondove.

I. UVOD

Liberalizacijama telekomunikacijskih tržišta i postupcima privatizacije došlo je do promjene vlasništva nad javnom telekomunikacijskim infrastrukturama – privatnopravni gospodarski subjekti koji su postali vlasnici prvenstveno vode brigu o svojim korporativnim privatnim ekonomskim interesima, te objektivno zapostavljaju razvoj širokopojasne infrastrukture u ruralnim ili ekonomski neatraktivnim područjima gdje je povrat uloženog kapitala predug ili ne zadovoljava financijske kriterije privatne korporacije. No razvoj i gradnja javne elektroničke infrastrukture od javnog je interesa koji država i JLS moraju poticati, promicati i zaštititi osobito radi osiguranja istih uvjeta i ravnomjernog razvoja na svim nastanjenim područjima vodeći se pri tome načelima održivog razvoja, te zaštiti drugih javnih i privatnih interesa.

Telekom operateri odnosno davatelji usluga trebaju pouzdanu infrastrukturu da bi bili konkurentni, profitabilni, da bi odgovarali potrebama klijenata – ne samo danas - već i pri ispunjavanju budućih zahtjeva tržišta i poslovnih ciljeva. Sposobnost davatelja usluga da integrira vlastitu telekomunikacijsku infrastrukturu s aplikacijskim alatima sustavima operativne podrške (Operation Support Systems – OSS) u širem smislu, određuje koliko su dobro dostupne informacije usvojene, korisne, upravljane i sačuvane. Stoga za učinkovito i pravovremeno donošenje odluka informacije iz brojnih sustava moraju biti dostupne svim nadležnim osobama.

No, uz već tradicionalne korisnike OSS sustava pojavljuje se u posljednje vrijeme i posve novi tip korisnika – JLS. One su prepoznale važnost osiguranja nove elektroničke komunikacijske infrastrukture koja će svim stanovnicima zajednice omogućiti nove razvojne potencijale korištenjem inovativnih informacijsko komunikacijskih tehnologija (ICT). Nova širokopojasna informacijska infrastruktura postala je u zadnjim revizijama prostornih planova jednakovrijedna drugim infrastrukturama (energetskim, vodoopskrbnim, prometnim, itd.) čime se konačno zahtijeva da uz vodu, električnu energiju i prometnice, građanima treba osigurati i širokopojasni pristup na Internet.

Evolucija ponašanja privatnih i javnih korisnika komunikacijskih usluga podržana je eksponencijalnim razvojem sofisticiranih korisničkih uređaja i pripadajućih multimedijskih aplikacija. Isporuka ili razmjena audio-video sadržaja visokih i super visokih rezolucija putem EKI, zahtjeva osiguranje vrlo brzih **simetričnih**, minimalno 100 Megabita u sekundi (Mbps) komunikacijskih infrastruktura koje će osigurati odgovarajuću kvalitetu i korisničko iskustvo. Nažalost,

postojeća bakrena kabelska infrastruktura ima svoja tehnološka ograničenja i ne može osigurati tražene brzine i kvalitetu.

Trenutne digitalne (Digital Subcsriber Line, DSL) i kabelske (Data Over Cable Service Interface Specification, DOCSIS) linijske tehnologije, ovisno o kvaliteti bakrenih i kabelskih mreža, dosežu maksimalne brzine u prijemu od 50 Mbps, što nije dovoljno već sada, a kamoli za buduće potrebe razvitka društva. Potrebne simetrične brzine omogućava svjetlovodno vlakno, pa se ono treba planirati, vezati i ugrađivati kao integralni dio cjelokupne komunalne infrastrukture (struja, voda, kanalizacija, plin, prometnice).

II. POSLOVNI MODELI

Postoje različiti poslovni modeli za tržište komunalnih širokopojasnih mreža [1], tj. ne postoji jedinstveni poslovni model koji bi bio pogodan za sve JLS.

U pravilu, u poslovnom modelu postoje tri osnovne razine:

- prva razina određuje tko eksploatira pasivnu infrastrukturu (distribucijska telekomunikacijska kanalizacija, zdenci, šahtovi, svjetlovodni kabeli i dr.)
- druga razina određuje tko osigurava i eksploatira aktivnu mrežnu infrastrukturu (usmjernici, komutatori, prijenosni svjetlovodni komutatori i sl.)
- treća razina određuje tko nudi pristup mreži, usluge i sadržaj.

Mrežni operator osigurava pasivnu infrastrukturu, najčešće svjetlovodnu kabelsku mrežu. Tipičan mrežni operator je komunalna tvrtka u vlasništvu JLS.

Komunikacijski operator osigurava aktivnu infrastrukturu (komutacije, usmjernike, svjetlovodne mreže, i dr.). Komunikacijski operator iznajmljuje fizičke kapacitete od mrežnog operatora.

Davatelj usluga, osigurava usluge na mreži. Davatelj usluga plaća komunikacijskom operatoru pristup krajnjem korisniku i ima prihod od krajnjeg korisnika.

Dodjela različitih odgovornosti jednoj od razina u poslovnom modelu proizvodi različite poslovne scenarije koji pokazuju kako javne organizacije, gradska uprava, komunikacijski operatori i davatelji usluga međusobno surađuju na dobrobit krajnjih korisnika, građana i zajednice.

Posve je jasno da bez obzira na odabrani model JLS rade iskorak u, za njih, posve novo i nepoznato područje i da će trebati efikasno i ekonomski održivo rješenje za upravljanje životnim ciklusom infrastrukture. Bez obzira na nedostatak sredstava u JLS, otvaranje mogućnosti za financiranje širokopojasne infrastrukture iz sredstava EU strukturnih fondova daje nade da će se očekivane investicije u narednom razdoblju ipak realizirati.

Važno je napomenuti da usmjeravanje sredstava EU strukturnih fondova za financiranje telekomunikacijske infrastrukture omogućava kompenziranje značajnog financijskog jaza kada je riječ o prvoj razini poslovnog modela, odnosno pasivnoj infrastrukturi. Dio troškova pasivne infrastrukture koje treba nadoknaditi JLS može se financirati na temelju prihoda iz druge i treće razine poslovnog modela, odnosno iz prihoda od komunikacijskog operatora te davatelja usluga.

Zahvaljujući činjenici da telekomunikacijska infrastruktura može ostvariti određenu razinu vlastitih (komercijalnih) prihoda ovakvi sustavi idealni su za uspostavljanje odgovarajućeg modela javno-privatnog partnerstva (JPP) [2], [3]. Naime, zbog neutralizacije financijskog jaza sredstvima EU značajno se smanjuju rokovi povrata na vlastita ulaganja JLS u ovim projektima. U situaciji ekonomsko-financijske krize, u kojoj nema raspoloživih proračunskih sredstava, JLS mogu putem JPP modela financiranja prenijeti trošak nepokrivenog dijela financiranja pasivne infrastrukture na privatnog partnera. Na taj način zaokružuje se poslovni model u kojem se financira javna telekomunikacijska infrastruktura (u vlasništvu JLS) bez korištenja ograničenih proračunskih sredstava. Naravno, stupanj samofinanciranja ovisit će o visini donacije EU te mogućnostima komercijalnog iskorištenja druge i treće razine infrastrukture.

III. SITUACIJA

A. Izazovi lokalne zajednice

Kako smo vidjeli, potencijalno velika EU sredstva su na raspolaganju, no pitanje je su li JLS dovoljno stručno i organizacijski sposobne za pripremanje, apliciranje i realizaciju novih projekata vezanih uz širokopojasne distribucijske mreže? Malo je vremena preostalo za projektiranje infrastrukture ukoliko se želi smanjiti zaostatak za sumjerljivim zemljama iz Europske Unije. Manji gradovi nemaju vlastitu IT infrastrukturu i dovoljno stručnih kadrova za efikasnu pripremu i upravljanje životnim ciklusom novo izgrađene infrastrukture.

Mnoge JLS (županije, Grad Zagreb, gradovi i općine) kao nositelji planiranja vlastitih komunalnih infrastruktura trebaju projektante obvezati na kvalitetno razvojno planiranje EKI odnosno same preuzeti odgovornost za unaprjeđivanje širokopojasne infrastrukture na svojim područjima.

Dodatni argument za veći angažman JLS jest nepostojanje jedinstvene baze postojećeg stanja EKI i povezane opreme što je temelj svakog kvalitetnog planiranja. Podaci neophodno potrebni za planiranje razvoja sporadično se prikupljaju od telekom operatora, postojećih raznolikih podatkovnih izvora u JLS (npr. katastar, komunalna poduzeća, itd.). Tako prikupljeni podaci dobiveni u različitim formama i formatima često nisu konzistentni, ne odražavaju stvarno stanje na terenu i bitno usporavaju bilo kakve zahvate u prostoru te poskupljuje sve aktivnosti.

B. Strategija i ciljevi Europske Unije

Europa 2020 strategija je rasta EU-a za sljedeće desetljeće. U svijetu koji se stalno mijenja želimo da EU ima pametno, održivo i inkluzivno gospodarstvo. Navedena tri prioriteta, koja se međusobno jačaju, trebala bi pomoći Europskoj uniji i državama članicama ostvariti

visoke razine u području zapošljavanja, produktivnosti i kohezije.

Unija je, konkretno, postavila pet ambicioznih ciljeva: u području zapošljavanja, inovacija, obrazovanja, socijalnog uključivanja i klime/energije koje je potrebno ostvariti do 2020. godine. Svaka je država članica prihvatila vlastite nacionalne ciljeve u svakom od navedenih područja. Strategiju određuju konkretne aktivnosti na razini EU-a i pojedinih država članica.

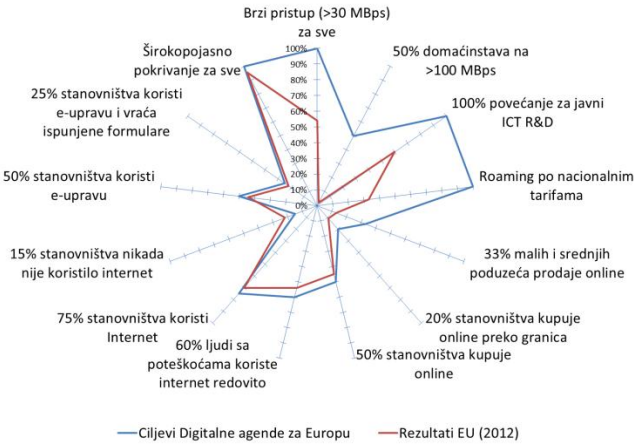
Na temeljima strategije razvoja Europe [4], a kroz program Digitalne agende za Europu (DAE) unaprjeđuje se razvoj digitalnih tehnologija koje će pomoći ostvarenju ciljeva strategije Europa 2020 [4][5]. Digitalna ekonomija raste sedam puta brže od ostale ekonomije, te je od strateške važnosti razvoja pojedine članice EU ispuniti ciljeve definirane DAE programom, prikazane Slika 1.

Hrvatska gotovo u svim parametrima mjerenja uspješnosti razvoja digitalne industrijalizacije zaostaje za prosjekom Europske Unije. Za dosezanje razina razvoja naših susjeda potrebno je uložiti značajno veći napor i angažirati značajnija financijska sredstva. Ipak, najvažnija karika brzih i kvalitetnih pomaka razvoja je efikasna organizacija cjelokupnog procesa od priprema projekata, natječaja, izgradnje i konačnog upravljanja novim infrastrukturama temeljem državne i regionalne strategije razvoja [6][7]. Uz novu infrastrukturu potrebno je osigurati i razvoj novih digitalnih e-usluga paralelnim programima.

Kako bi se spomenute ambicije pretvorile u stvarnost Europska komisija aktivno radi na uklanjanju barijera. Spomenut ćemo samo neke, našem radu, interesantne akcije.

Najznačajnija aktivnost je sufinanciranje izgradnje širokopojasnih mreža velikih brzina kroz instrumente EU i privlačenje kapitala za ulaganja u širokopojasnu infrastrukturu. Razlog fokusa na područje sufinanciranja leži u činjeničnom stanju slabog razvoja EKI (Slika 1. uzrokovana percipiranim visokim rizicima javno-privatnih modela, dugim povratima investicija, nedovoljnim iskustvom javnog partnera, te još uvijek nedostatnim dokazima koji opravdavaju novi poslovni model kojim širokopojasna infrastruktura postaje nova državna imovina.

Nadalje, države članice trebaju poduzeti mjere, uključujući i zakonske odredbe, kako bi se olakšalo ulaganje u širokopojasnu infrastrukturu. Sustavno uključivanje potencijalnih investitora prilikom izgradnja komunalnih infrastruktura (voda, plin, kanalizacija i sl.), jasna regulativa prava puta, te dostupnost podataka o postojećoj infrastrukturi značajno će smanjiti trošak gradnje.



Slika 1. Ciljevi i rezultati (2012 g.) Digitalne agende za Europu

C. EU fondovi i koristi za lokalnu zajednicu

U svrhu potpore ostvarivanja ciljeva Digitalne agende Europska komisija je:

- usvojila revidirane smjernice za primjenu EU pravila o državnim potporama u sektoru širokopojasnog pristupa [4], posebno dijela koji sadrži jačanje obaveza otvorenog pristupa i unaprjeđenje pravila transparentnosti.
- usvojila prijedlog Uredbe o smanjenju troškova za građevinske radove, koji čine do 80% troškova izgradnje širokopojasne mreže. Izbjegavanje nepotrebnih kopanja prema prijedlogu Uredbe Komisije, može se uštedjeti između 40 i 60 milijardi eura ili do 30% ukupnih investicijskih troškova.

Važna nova komponenta koja se pojavljuje kao prilika za jedinice lokalne samouprave da osiguraju sredstva subvencioniranja izgradnje putem državnih potpora, ali i putem Europskih strukturnih fondova: Europskog poljoprivrednog fonda za ruralni razvoj (*Agricultural Fund for Rural Development*, EAFRD) i Europskog fonda za regionalni razvoj (*European Regional Development Fund*, ERDF). ERDF je namijenjen financiranju projekata za smanjivanje razlika u razvoju pojedinih zemljopisnih područja koja uključuju postavljanje nove elektroničke komunikacijske infrastrukture.

Budžet fonda je oko 50 milijardi eura godišnje temeljen na sufinanciranju (50-85% - ovisi najviše o socioekonomskim parametrima države) i namijenjen regijama čiji je BDP po stanovniku manji od 75% prosjeka EU. Sam fond ima 6-godišnji ciklus sa sljedećim bitnim miljokazima:

- Europska Komisija (European Commission, EC) definira prioritete fondova na razini EU kroz Community Strategic Guidelines dokument
- Države članice na temelju tok dokumenta transformiraju prioritete u nacionalne prioritete kroz National Strategic Reference Framework (NSRF) dokument
- Države članice na temelju NSRF izrađuju Operativne Planove (OP) za svaku svoju regiju

- EC mora odobriti NSRF i OP prije bilo kakve implementacije

Aplikacija za sredstva ERDF slijedi sličan proces kao i za IPA: nakon što su odobreni OP, operativno tijelo Republike Hrvatske (npr. ministarstvo) otvara natječaj za prijavu projekata. Budući korisnici predaju projektni sažetak koji se nakon prve selekcije pozitivno ocjenjuje ili odbacuje. Ako je projekt pozitivno ocijenjen, onda se od predlagatelja traži potpuni prijedlog projekta sa svim financijskim i operativnim detaljima. Operativno tijelo daje konačnu ocjenu, te se pristupa potpisivanju ugovora. Za svaku godinu države članice potpisuju ugovor s EC o sufinanciranju odobrenih projekta u narednoj proračunskoj godini.

D. Ključne koristi za JLS

Investiranje u širokopojasne mreže donosi brojne koristi za JLS primarno u domeni razvoja gospodarstva, otvaranje novih poslovnih prilika i novih radnih mjesta. Utjecaj izgradnje širokopojasne infrastrukture na porast bruto društvenog proizvoda (BDP) u JLS je nedvojben pri čemu upravo sredstva EU pomažu da se infrastruktura uopće izgradi. Glavne direktne, indirektne i inducirane koristi koje donosi nova infrastruktura za zajednicu su:

- novi izvor prihoda lokalnim zajednicama od prodaje kapaciteta i najma infrastrukture
- e-građanin u uređenoj e-zajednici: e-uprava, e-zdravstvo, socijalna skrb, sigurnost, e-obrazovanje, transport, turizam: dostupnost svih tijela gradske i ostalih razina vlasti potrebnih za realizaciju usluga potrebnih građanima i poslovnim korisnicima
- nove mogućnosti poslovanja i trgovanja putem novih e-poslovnih mogućnosti
- otvaranje novih radnih mjesta, omogućavanje i povećanje inovativnosti i konkurentnosti.
- povećanje kvalitete i standarda života
- zaustavljanje i okretanje negativnih depopulacijskih trendova

E. Izazovi projektiranja i izgradnje nove širokopojasne infrastrukture

Za uspješan završetak svakog projekta, pa tako i izgradnje širokopojasne infrastrukture, potrebno je odlučiti o metodama, procesima i alatima koji će se koristiti. Neophodno je u samom početku izabrati tehnološko i topološko rješenje nove infrastrukture ne zaboravljajući na činjenicu da projekt ne smije biti tretiran izolirano, te da je on samo djelić veće geografske i komunalne cjeline. Kompatibilnost metoda, procesa i alata u tom širem kontekstu i van okvira JLS mogla bi donijeti korist cijeloj zajednici.

Dizajniranje mreža može biti usko grlo i usporiti ostale povezane procese. Bez centraliziranog pristupa dizajnu mreža, koji bi trebao biti stalno dostupan i korišten tijekom cjelokupnog procesa implementacije od projektiranja preko izgradnje do prodaja i upravljanja instaliranih kapaciteta, bitno će biti otežano dovršavanje pojedinih radnih segmenata ili zadataka. Slobodni decentralizirani pristupi nužno sa sobom donose problematiku različitosti formata, dokumentacija, teškog pristupa informacijama partnera na projektima te eventualnu potrebu usklađivanja ili integracija između JLS i županija na državnoj razini. Problematika takvog pristupa zahtijevat će puno iteracija i usklađivanja kako bi se pojedini zadaci mogli izvršiti.

Pogledajmo izazove koje donosi projektiranje širokopojasnih mreža za JLS. Tradicionalni procesi su prespori, zahtijevaju veliku količinu manualnog rada, izvori podataka su nesinkronizirani odnosno neažurni te su moguće brojne pogreške:

- Novodizajnirana topologija mreža nije usklađena sa postojećom infrastrukturom (voda, struja, kanalizacija, ceste, plin, postojeća EKI) ili socioekonomskom situacijom u JLS
- Dizajn i stvarno izgrađena mreža i pripadajuća dokumentacija nisu usklađeni najboljom praksom te sa standardima i smjernicama koje propisuju EU i nadležna tijela države
- Informacije iz projekta mreže teško su dostupne ili čitljive svim sudionicima projekta, te je vrlo visoka mogućnost pogrešaka tijekom izgradnje
- Ne postoji konzistentan proces upravljanja projektom što rezultira probijanjima rokova izgradnje i troškovnika
- Loši ili nedostupni podaci zahtijevaju češće nadzore i više ponekad potpuno nepotrebnih izlazaka na teren
- Različiti alati i pristupi dizajniranju otežavaju međuprojektnu suradnju (posebice na razini regija ili klastera), a dugoročno su neodrživi
- Ne postoji nesmetani protok informacija između projektanata, izgradnje, upravljanja i održavanja mreže što zahtjeva velike količine manualnog rada, a time i česte pogreške u interpretaciji informacija.

Navedeni izazovi mogu se riješiti unificiranim pristupom. Primjenom zajedničkih metoda, procesa i alata tijekom svih segmenata projekta ali i na svim sličnim projektima moguće je smanjiti ili potpuno ukloniti navedene izazove, te ubrzati pripremu i izgradnju novih mreža.

GIS baziranim alatom za projektiranje i upravljanje mrežama pozitivno će se utjecati na kvalitetu i troškove projekta: boljim načinom uvida u stvarnu situaciju na terenu, ujednačavanjem dizajna, boljim načinom dostave planova izgradnje tehničarima na terenu, mogućnost uvida u blizinu postojećih infrastruktura, te brze procjene troškova izgradnje.

Geografski informacijski sustav (GIS) je sustav za upravljanje prostornim podacima i osobinama pridruženih njima. U najstrožem smislu to je računalni sustav sposoban za integriranje, spremanje, uređivanje, analiziranje i prikazivanje geografskih informacija.

Ključ industrijalizacije leži u upravljanju podacima koje treba prikupiti, konfigurirati i koristiti. Zapitajmo se

koje podatke treba spremiti, kako i u kojem sustavu, te kako ćemo osigurati njihovu dostupnost partnerima u projektima i drugim korištenim sustavima? U zajedničkom GIS sustavu informacije o tome gdje je planirana ili se nalazi oprema, kakvih kapaciteta i zauzeća, kako je povezana, koji je trošak gradnje, te kada će biti spremna dostupne su u svakom trenutku.

Specijaliziranim GIS alatom namijenjenim za upravljanje životnim ciklusom telekomunikacijske infrastrukture automatizirat će se pojedini specifični zahtjevi procesa dizajna, izgradnje i upravljanja. Definiranje vlastitih pravila izgradnje automatizirati će planiranje i dizajn novih mreža, shematski prikazi osigurat će kvalitetnije snalaženje u planiranju i rješavanju problema, a alat za terenske ekipe osigurat će lakši i sigurniji rad, te stalnu konzistenciju podataka. Nakon izgradnje proširenje funkcionalnosti na upravljanje instaliranom imovinom smanjiti će i ubrzati donošenje odluka smanjujući trošak održavanja.

IV. NACIONALNI PROGRAM

Ministarstvo pomorstva, prometa i infrastrukture (MPPI) pokrenulo je niz aktivnosti usmjerenih prema razvoju širokopojasne infrastrukture u Hrvatskoj. Krajem 2013. godine objavljena je javna rasprava na temu o okvirnom nacionalnom programu za razvoj infrastrukture širokopojasnog pristupa u područjima u kojima ne postoji dostatan komercijalni interes za ulaganja. Okvirnim programom predviđeno je imenovanje jednog tijela javne vlasti nositeljem Okvirnog programa (NOP), koji će koordinirati provedbu Okvirnog programa na nacionalnoj razini te nadzirati sukladnost pojedinačnih projekata s Okvirnim programom, kao odobrenim programom državnih potpora. Pojedinačne projekte koji će slijediti iz Okvirnog programa u većini slučajeva će voditi tijela javne vlasti na lokalnoj ili područnoj (regionalnoj) razini (općine, gradovi i županije) kao nositelji pojedinačnih projekata (NP-ovi). Osim toga, uz koordinativnu ulogu NOP-a, u ključnim provedbenim aktivnostima projekata predviđena je i podrška HAKOM-a, kao nacionalnog regulatornog tijela za sektor elektroničkih komunikacija.

V. METODOLOGIJA UNIFICIRANOG PRISTUPA

Koristeći svoja značajna iskustva u procesu izgradnje komunikacijskih sustava odnosno mrežne infrastrukture, te dobro definirane poslovne procese Ericsson predlaže „industrijalizaciju“ procesa kreiranja projekata i aplikacija za EU fondove.

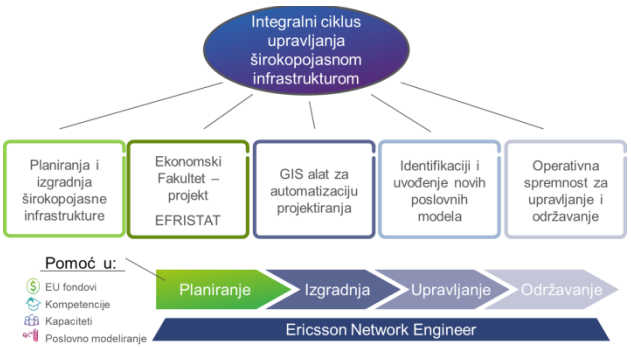
Predloženo rješenje ne prejudicira konkretan alat ili kompaniju nego praktično vizualizira prednosti unificiranog pristupa na projektiranju i upravljanju mrežama, te pripremi natječajne dokumentacije. Posve je jasno da odabir konkretnog tehničkog rješenja za predloženi sustav (softveri i implementacija) u cijelosti mora biti odrađen u skladu sa EU pravilima i pravilima javne nabave.

Analizom problema i prepreka koje smo ranije adresirali nužno je JLS pomoći u sljedećim segmentima:

- Kompetencija – za planiranje i dizajn mreža
- Kapacitet – za izgradnju i održavanje
- Poslovno modeliranje – za odabir optimalnog modela korištenja izgrađene infrastrukture
- Prikupljanje i održavanje potrebnih podataka

Osim toga nužno je predložiti rješenja koja će biti repetitivnog tipa odnosno replikabilna za sve JLS bez obzira na veličinu.

Konceptualno rješenje uz primjenu komercijalnih proizvoda je prikazano na Slika 2. Dvije su ključne pretpostavke – unifikacija ulaznih podataka uz pomoć sustava EFRISTAT Ekonomskog fakulteta u Rijeci [9] te korištenje Ericsson Network Engineera kao sustava za projektiranje i optimizaciju svjetlovodne infrastrukture, čime će se realizirati unifikacija procesa na razini svih jedinica lokalne samouprave i dobiti konzistentni rezultati.



Slika 2. Uvođenje „industrijskog“ principa u koncept upravljanja mrežnom infrastrukturom kao funkcija primijenjenog polja.

Projekt EFRISTAT je baza podataka gradova i općina u RH koja objedinjuje znanstvene te stručne potencijale domaćeg gospodarstva te unaprjeđuje upravljanje lokalnim javnim sektorom. Osnovnu podlogu predstavlja formiranje baze podataka, i izračuni pokazatelja o gradovima i općinama, koja sadržava sljedeće:

- ekonomski podaci
- fiskalni podaci (kategorije prihoda, kategorije rashoda, zaduženost, pokazatelji efikasnosti i djelotvornosti)
- socijalni podaci (siromaštvo, demografski podaci, kriminalitet)
- organizacijsko-administrativni podaci (kvaliteta administracije, podrška lokalnom poduzetništvu i sl.)
- svi ostali podaci i pokazatelji relevantni za lokalne jedinice.

Svrha ovakvog tipa baze podataka je potencijalnim ulagačima osigurati detaljan uvid u mogućnosti ulaganja unutar pojedinih gradova i općina, a jedinicama lokalne uprave i samouprave podršku za učinkovitije upravljanje vlastitim ekonomskim razvojem.

Korištenjem EFRISTAT-a uz tehnološka rješenja, također je moguće ubrzati proces izrada predstudija o izvedivosti, koja se izrađuje tijekom faze identificiranja, osigurava utvrđivanje svih problema te ocjenu svih mogućih rješenja, kao i toga da je odabrano najbolje rješenje na temelju faktora kvalitete. Studijom i Europska

komisija i zemlja korisnica dobivaju dovoljno informacija na kojima će se temeljiti njihovo prihvaćanje, izmjena ili odbijanje predloženog projekta.

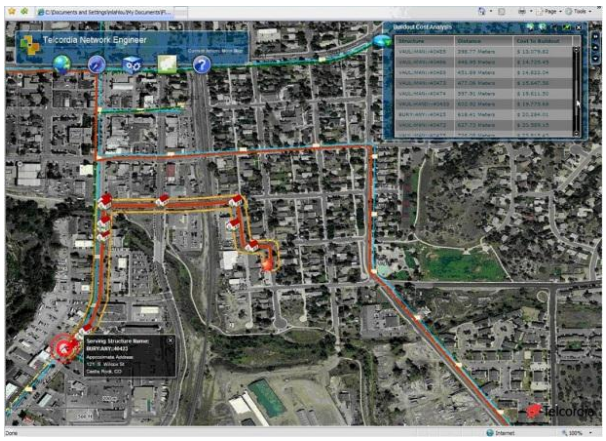
Iz EFRISTAT-a se pripremaju ulazni podaci za Ericsson Network Engineer odnosno za proces projektiranja i optimizacija. Podaci uključuju generalne informacije o korištenju prostora u JLS (radne zone, turistička područja) te detaljne informacije o pozicijama tzv. Demand Pointova odnosno točaka koje je potrebno povezati na svjetlovodnu infrastrukturu. Osim rezidencijalnih korisnika u fokusu su sljedeće lokacije od posebnog interesa:

- Objekti samih JLS
- Obrazovnih i odgojnih ustanova (fakulteti, škole, vrtići, domovi)
- Knjižnice svih razina
- Bolnice, ambulante, privatne ordinacije
- Vatrogasci, policijske postaje
- Komunalna društva
- Lučke uprave, kapetanije
- Nadzor prometa

Nakon odabira tehnologije pristupa se izradi idejnog rješenja u Ericsson Network Engineeru i inicijalnog troškovnika potrebnog za budžetiranje i izradu studija isplativosti.

VI. JAVNA DOSTUPNOST I TRANSPARENTNOST IDEJNIH RJEŠENJA NAPRAVLJNEIH ZA POTREBE JLS

Kao logičan nastavak prethodnih aktivnosti i primjer praktične implementacije koncepta je i računarstvo u oblaku u kontekstu aplikacija e-uprave putem koje će sve do sada navedene aktivnosti biti transparentno prezentirane široj društvenoj zajednici i na raspolaganju širem krugu potencijalnih korisnika.



Slika 3. WEB prikaz podataka JLS

Kako su korištene GIS tehnologije već odavno sposobne prikazivati rezultate na WEB-u (primjer Slika 3.) a danas je koncept pružanja informacija kroz oblak postao prevladavajuća forma i poželjan način konzumacije ponuđenih informacija. Prednost rješenja u oblaku je što se sustav može ponuditi većem broju raznih korisnika u vrlo kratkom vremenu i na konzistentan način čime se optimiziraju troškovi i na strani davatelja usluge i na strani korisnika.

JLS prije svega ne moraju imati vlastitu opremu i stručne kadrove za održavanje aplikacija – oni se pojavljuju samo kao korisnici sustava. Ukoliko sve JLS koriste isti sustav omogućeno je vrlo jednostavno i koherentno praćenje svih projekata, a posebice važno – uvođenje ključnih indikatora efikasnosti korištenja sredstava iz EU te praćenje napretka i izvođenja projekata.

VII. ZAKLJUČAK

Iskorak državne uprave, županija i JLS, a pogotovo u smislu uvođenja vrhunskih OSS tehnologija, iz tradicionalnog telekom segmenta u domenu podrške JLS predstavlja značajnu pomoć lokalnoj upravi i samoupravi na putu ka efikasnijem korištenju sredstava iz strukturnih fondova EU te ne predstavlja „nemoguću misiju“. U kriznim vremenima kakva su danas posebno je važno za cijelu društvenu zajednicu korištenje ekonomski optimalnih tehničkih rješenja i alata, pri čemu se pokazuje da najmodernije OSS tehnologije, ako su pravilno koncepcijski iskorištene i implementirane, ne moraju biti nedostupne čak i vrlo malim korisnicima koji nemaju posebno domensko znanje.

Rješenje je u korištenju jedinstvenog procesa i zajedničke baze projekata u geografskom informacijskom sustavu dostupne svim dionicima i u svim fazama razvoja, od idejnih do realiziranih rješenja.

QUALITY MANAGEMENT

Real Time Assuring QoE in the Lowest OSI/ISO Layers During Delivering of IPTV Services

Abstract - this paper compares the values of data link layer QoS (Quality of Service) indicators of several access lines, which can serve as a measure of the physical link quality or QoPh (Quality of Physical Layer), in real environment without reference video signal (No Reference), during the delivering of IPTV (Internet Protocol Television) multicast services to multiple users. It also focuses on the fact that an increase in channel capacity reduces the number of signal degradation indicators in the data link layer, because it increases the resistance of useful information on the interference. The paper proves the fact that at the same time, improving the physical layer conditions, the values of network QoS indicators, such as packet loss or delay, is reduced which affects the final grade at the end-user QoE (Quality of Experience) of IPTV (Internet Protocol Television) services.

***Keywords* — Access network; Quality of Service; Quality of Experience; Quality of Physical Layer; Channel estimation;**

I. INTRODUCTION AND RELATED WORK

Functional dependency between QoS (Quality of Service) parameters and QoE (Quality of Experience) is a challenge while defining the simplest system of prediction of a service QoE level evaluation with no reference original signal. The authors consider analytical dependence in the [1] and [2], and emphasize that MOS is a typical user oriented evaluation of any service which can be determined with a subjective evaluation given by individual users or with an objective measure of service features delivered along with the service. They also claim that the appearance of basic QoS indicators, such as packet loss, delays, delay variations, wrong packet order and traffic limits, implies the appearance of problems in application layer, e.g. the appearance of video artifacts, different video signal degradations or in some cases, waiting for a service, which is reflected to the awaited QoE level. They have discovered that the relation between QoE and QoS parameters can be presented as certain function dependence. The relating function is called IQX (exponential interdependency of quality of experience and quality of service) hypothesis and has been successfully tested on QoS network parameters. The authors in [3] have developed a slightly different correlation model of QoS and QoE which numerically estimates IPTV (Internet Protocol Television) QoE with usage of survey results. They have classified the traffic towards IP QoS classes [4] and determined how big is the impact of IP QoS parameters on IPTV service for every class. They have used weighting factors to estimate total QoS, and then, based on the modified IQX hypothesis, the QoE values have been obtained. The authors in [5] also claim that the main question to be solved at quality QoS/QoE correlation is deep packet inspection. The authors in [6] have examined the layer QoE through defining integral relation between QoE and observed network and application layer parameters, not as independent entity. This relation is defined as the function dependent on a joint factor AQoS (Application QoS*)* and NQoS (Network QoS) in a new QoE evaluation frame. AQoS parameters, especially during the delivery of video content, have also been considered by the authors in [7-9]. Testing of quality of experience of IPTV service in relation to NQoS parameters as well as different types of testing scenarios are presented in [10]. The authors in [11] see the solution to this problem in modified design of QoS, while on the other hand [12] and [13] present cross-layer design solutions which, from physical layer of the media and QoS demands of certain applications, take into account rate calculations, strength, physical media coding and their adjustments to application demands at a given channel and given network conditions. The authors in [14] see the solution to this gap towards optimization of the relation between QoS and QoE in correlating the physical layer with QoS parameters of the application layer. They used VoIP over LTE technology as an experimental service, and in their work they correlated parameters of the first and second layer of LTE radio configuration with IP performance parameters. The connection with QoE has been realized by MOS results with the use of PESQ algorithm. However, the authors haven't given a unique analytical solution for the mentioned relation and they also haven't put the correlation between physical layer parameters and the QoE level evaluation. In the report [15], certain demands have been formed for IPTV service delivered over DSL in a form of technological improvements based on DSM, vectoring, improved protection from impulse noise, SRA, AL-FEC and measurements. The authors in [16] have worked on the influence of impulse noise on QoS parameters as well as appearance of error seconds caused by impulse noise. Although end-to-end QoE in ITU recommendation implies monitoring these values to the user, very few authors, e.g. in [16] and [17], deal with home and access networks. In other words, the authors emphasized that in order to fulfil the above mentioned demands, it is necessary to observe each technological segment that contributes proper QoE evaluation. Therefore models that correlate these segments have great importance in end-to-

end QoS insurance. Considering a particular technology and some type of protective coding, the physical link quality or QoPh can be discussed. The basis of this paper is the novel method and analyzing the physical layer influence on a service quality performance and quality of experience of a service delivered to the user, at the same time. Technology, as well as usage of certain type of media for information transfer, is being developed, but in order to consider service quality at access network domain, it is highly important to consider the physical channel which connects the user with the first point in telecommunication system. The evaluation of total QoS is emphasized in this paper, but the focus is on the correlation between parameters of physical layer and appearance of packet loss at network layer as a QoS indicator and as a basic parameter of QoS/QoE correlation.

II. MATHEMATICAL OBSERVATIONS

In order to determine quantitative influence of physical channel on quality of service delivery in access network domain i.e. from the customer to the first point of a telecommunication system it is necessary to define and discover physical layer parameters as well as data link layer parameters that represent reflection of occurrences in the channel. This is a very important determination of total customer QoE estimation, because after this it is possible to estimate delivered QoE, indirectly with measurable QoS indicators, now available from the calculated electrical channel characteristics. The mentioned indicators relating to jitter, delay and packet loss are changeable depending on the channel conditions, therefore there is the function:

$$\mathrm{QoE} = f_1\left(\mathrm{AQoS}, \mathrm{NQoS}, \mathrm{DQoS}, \mathrm{QoPh}\right) \qquad (1)$$

Not one system has been defined which can completely control the QoS parameters for service delivery. Therefore it is necessary to provide an overview of deep packet inspection of bottom up OSI/ISO layers. In other words, the solution must involve estimation of occurrences in the last mile which is, in its biggest part, subject to disturbances of different sources in form of stationary and non-stationary noise, so it is necessary to identify the parameters which have to be modelled with higher OSI/ISO layers, in order to provide more precise QoE estimation. Quality of IPTV service delivery to end users depends on timing of transport stream that passes through numerous routers, compression technics in higher OSI/ISO layers and psychological and psychophysical possibilities of users. However, we want to discover and consider influence of the last mile on QoE. That can be done only by considering optimal line rate on physical layer that can be accomplished only with good channel conditions. Also considering appearance of bit errors, caused by stationary and non-stationary noise especially in OFDM channel, and error control system can help in quality evaluation of physical layer [18]. Undoubtedly, while evaluation the quality of physical layer, it is necessary to consider the relation between signal and noise (SNR), needed energy or bit power, bandwidth and transfer function of observed channel. It is obvious from all the things mentioned that, considering the above parameters, it is necessary to accomplish the maximization of needed line bit rate of a service. Besides that, the choice of error-correcting code defines the quality of packet loss correction. During the transmission of DMT signal in DSL systems, channel capacity can be presented by the following equation:

$$Rc = \frac{1}{2N}\log_2\left(\prod_{n=1}^{N}\left[1+\frac{SNR_n}{\Gamma \bullet mar_n}\right]\right) \qquad (2)$$

Main significance of this formula is that it provides a high-level way of thinking about how SNR as the performance of a communication system depends on the basic resources available in the channel, without going into the details of specific modulation and coding schemes used. Maximum bit rate can be accomplished by minimization of average SNR, because low values of that relation generate appearance of symbol errors. At the same time low SNR values lead to reduction of SNR margin that is necessary to provide symbol error probability less than 10e-6. Error probability rises if SNR margin falls below 6 dB. If there is bigger depth of SNR margin variation, increase of symbol errors will occur. Error control system will not succeed in recovering all wrong bits and that will lead to indicators appearance of that phenomenon in form of CRC (Cyclic Redundancy Check) bits. Every code violation (CV) or CRC in DSL super frames will cause packet loss in higher OSI/ISO layers. At the same time, system will try to solve the originated problem with increasing of interleaving, but that will raise delay. From all above mentioned, we can conclude that there is functional dependency between indicator of QoS and SNR or SNR margin, i.e. we can write:

$$\mathrm{QoS}_{pack_loss} = f_2\left(mar, \mathrm{CV}\right) \qquad (3)$$

In case of extremely low SNR margin, the coded system cannot improve error probability values. In case of Gaussian noise, the coded system can achieve maximum value of channel capacity, but it cannot if signal fades with changing of coupled transfer function, especially in long lines. Therefore, if huge variations of SNR margin appear, it can cause typical bit error when we use coded systems as well as uncoded systems. One major challenge for researchers is observing IPTV delivery in real time and timeframe for consuming that service from customer side. Considering [15], existing of an error second in one hour of IPTV service consummation can be allowed for ordinary users. An error second will appear only if one or more code violations appear. The number of error seconds increases with the number of code violations. This phenomenon depends on depth of negative changes of SNR or SNR margin as well as actual Ra and maximum possible rate in channel Rc. So, there is a function:

$$ES = f_3\left(mar, \mathrm{CV}, \mathrm{R}_a / \mathrm{R}_c\right) \quad (4)$$

These violations, in DSL case, are correlated to packet loss, because they appear in superframes. Every 68 DSL frame has one CRC indicator. That superframe carries on IP packets that contain MPEG-2 TS packets. Depending on actual rate and transferred service, that super frame can carry on 10 to 20 IP packets and at the same time 70 to 140 video packets. This can be a linear indicator of quantitative measure of disturbances in physical channel. It also introduces a reflex of data link layer when SNR margin changes dramatically. As we mentioned earlier, packet loss, especially in UDP cases, can indicate one important QoS parameter that can help in QoE evaluation. The most known correlation that defines dependency of QoE from QoS is IQX hypothesis. It is exponential interdependency of quality of experience and quality of service and it can be depicted as:

$$\mathrm{QoE} = \alpha \cdot e^{-\beta \cdot \mathrm{QoS}} + \gamma \quad (5)$$

Authors have got parameters α, β and γ, by nonlinear regression analysis and they also have been arguing good correlation with real values. This correlation was being checked, as we say in the introduction, for different network cases as testing of audio, Web, video and data packets. Considering packet loss, IQX hypothesis in network layer can be shown as follows:

$$\mathrm{QoE} = 3,01 \cdot e^{-4,473 \cdot \text{packet loss}} + 1,065 \quad (6)$$

As there is linear interdependency between appearance of CRC and packet loss, IQX hypothesis can be identified in data link layer. In that case next equation is given:

$$\mathrm{QoE} = 3,01 \cdot e^{-\frac{\mathrm{CV}}{\mathrm{CV}_{tot}} \cdot t} + 1,065 \quad (7)$$

It can be noticed, considering the quantity of CRC, that QoE level can be evaluated in real time, but only in DSL domain, i.e. in access network domain. Certainly, this is not total QoE value because packets travel through a huge number of routers as well as different head-end and super head-end systems.

III. Test Environments

In order to validate the above equations, we have chosen an experimental method in which the IPTV service delivery is observed in real time on three independent DSL lines. SDTV IP service has been delivered via MPEG-2 transport stream, UDP transport protocol, IP network protocol, ATM and ADSL2+ data link and physical layers. Three slightly longer lines have been disturbed by stationary and non-stationary noise and their values of SNR and maximum attainable rate have been compared. Stationary noise was caused by neighboring DSL lines in L0 state, while non-stationary noise was generated by neighboring DSL lines which changed their states from L0 to L2. We measured SNR margin, actual rate and attainable rate in physical layer. In data link layer, we also observed the appearance of CRC code violation of DSL super frames. In network layer, packet loss was observed and correlated with all the mentioned data.

IV. Results

Overview of the results of the mentioned measurements, from test environment is given in the Table 1. SNR_margin determines average variability of SNR margin of all subcarriers that caused the code violation appearance; CV determines the number of code violations and CV_{tot} total number of potential CVs. At the same time, IQX hypothesis determines the value obtained in the equation result (6) and IQX_DLL the value of equation (7). In order to compare the obtained results, it is necessary to construct a graph presented in Figure 1

TABLE I. Measured Values

SNR_margin	3,26	2,9	2,1
CV	249	449	4711
CV_{tot}	211764,7	211764,7	211764,7
$\mathrm{CV}/\mathrm{CV}_{tot}$	0,0012	0,0021	0,0222
Packet loss	0,12%	0,21%	2,24%
IQX hypothesis	3,73	3,50	1,39
IQX_DLL	3,56	2,08	1,065

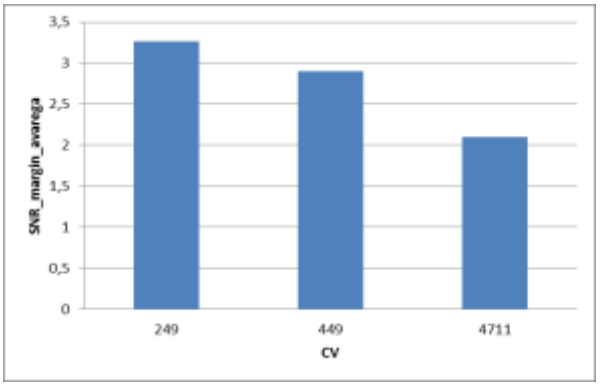

Figure 1. Relation between SNR_margin and CV

which determines the relation between the appearance of code violation and average noise margin in observed period. Each appearance of the error caused a packet loss with an average value of given in Table 1. Figure 2 presents the relation between the appearance of average packet loss and QoE calculated by IQX hypothesis. The relation between measured value CRC (i.e. CV) and total number of potential errors (i.e. in every superframe there are code violations) is presented with $\mathrm{CV}/\mathrm{CV}_{tot}$. Figure 3 presents the same relation and anticipated QoE calculated by modified IQX hypothesis in data link layer. If Figure 2 and 3 are compared, it can be confirmed that, with the help of modeling of physical and data link layer

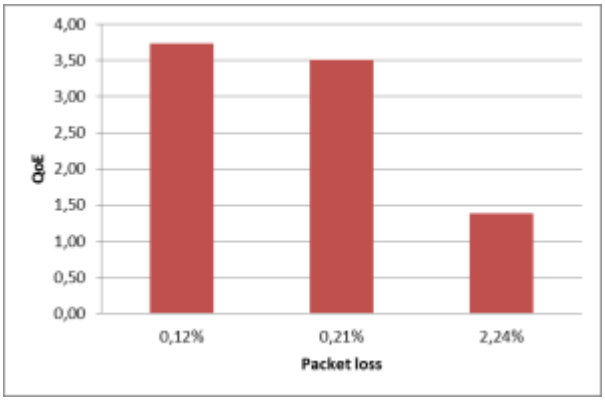

Figure 2. QoE dependency on packet loss

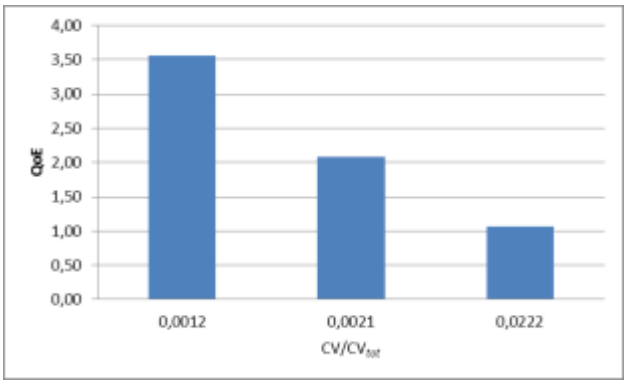

Figure 3. QoE dependency on CV/CV$_{tot}$

parameters, it is possible to evaluate QoE in domain of access network more precisely than in the case of IQX hypothesis in network layer.

V. CONCLUSION

Without considering physical layer, we cannot get complete and accurate model that can serve for QoE evaluation process, especially, if total QoE has to be evaluated in E2E (end-to-end) solutions. In this case, access network domain, from user terminal equipment to operator's CO, cannot be avoided. Channel capacity, SNR, bit power, modulation and coding have huge importance in defining possible rate in access network that is needed for a service. Variations of SNR and changing of actual and maximum possible rate relation can be used for evaluation of stability of conditions that is necessary for IPTV service delivery. In this paper we have described the way for evaluation that can show the amount of influence of physical layer parameters. These results can be used by a monitoring system for decreasing necessary time for maintenance of particular lines. For future work we plan to get precise function between all parameters of physical and data link layer needed for determination of bit error propagation through OSI/ISO layers.

Abstract - Quality measurements of XML schemas are difficult to perform objectively, providing all aspects of quality demands. However, an approximate evaluation of XML schema's quality and validation, whether a higher version of an XML schema standard is in fact an improvement, is useful information for XML schema users. The paper addresses who are the users of XML schemas, what aspects of XML schemas are vital to its quality and how to measure those aspects. We present 3 quality aspects in more detail: (1) structure type, (2) re-use possibilities and (3) balance of building blocks. A table of all included variables, that were measured, is provided. Based on results of over 200 XML schemas, quality assessment are given, including data standardization methods. Measurement results of XML schema's versions are compared, providing insight into quality growth (or decline) through versioning.

I. INTRODUCTION

Quality measurements of XML schemas are difficult to perform objectively, providing all aspects of quality demands. Since the XML schemas constantly change, the quality has to be consistent through newer versions, preferably higher than the quality of the previous XML schema.

The primary role of XML schemas is the definition of XML data and supporting rules regarding the use of constantly changing XML data, an important part of information technologies. XML schemas and related technologies present an important part of IT solutions [2]. Using XML has spread from the field of e-business and data exchange to data presentation into various levels of contemporary information solution architectures. The quality of XML schema is visible within its structure and also in the contents of elements and attributes.

By definition, XML schemas are extensible, flexible and reusable in all kinds of environments, representing a foundation to the complex infrastructure of e-business, which is concealed to the end-user. If done properly, their quality reflects on time and cost reduction, creating lower-cost services, improving user experience, creating more flexibility, shorter time to market and many other features, which play an important role in enabling high performance of the end product, operating with the XML document and consecutively the XML schema [8][9].

Due to the widespread use of XML schemas and its constant change, the question of its quality is often open, particularly from the aspect of structure (and content) of XML schemas, which indirectly influence the quality of data that XML schema describes. Therefore measuring XML schemas quality as it is growing is one of the basic research challenges in our paper.

TABLE I. VARIABLES WITHIN METRICS

N	*Abbreviation*	*Explanation*
1	NE	number of elements
2	Nat	number of all attributes
3	Nt	number of all data types
4	Nr	number of restrictions
5	Ng	number of all groups
6	Nan	XML schema document size
7	Nt_s	number of simple data types
8	Nt_c	number of complex data types
9	Nt_i	number of derived data types
10	NE_U	number of unbounded elements
11	Nre_all	number of references on elements
12	Nra_all	number of attribute references
13	Nrt_all	number of all used data types
14	Nrg_all	number of group references
15	Nri_all	number of external XML schemas
16	LOC	lines of code

This paper is organized in 5 chapters. The first two introduce the research area and related work, exposing the lack of research in the field of measuring quality of XML schemas and its versions. The third chapter presents the research model and explains the definition of XML schema quality aspects, as well as a set of three hypotheses. The fourth chapter explains the quality change through versioning. Conclusions and future work are given in chapter five.

II. LITERATURE REVIEW

There have been several attempts to evaluate and measure XML schemas. Few of them are summed in [1]; however none of them includes measurements of the same XML schema through versions. Significantly related work was also done in [4] and [6], where attempts to measure XML schemas and software in general were made. The

subject was addressed in other papers, not included in this overview, however the background are mainly software metrics, which do not necessary always apply to needs of XML schema quality (and complexity) measurements.

Dynamic creation and adaptation of XML schemas schedules and presents an additional research challenge that requires the use of new approaches and solutions, universal and specific according to a domain. The aim of this paper is definition of an approach for evaluating the quality of XML Schema, based on a new set of metrics and comparing its results through versions. The formulas are derived from research work made in [11].

III. RESEARCH MODEL

An evaluation of XML schema's quality and validation, whether a higher version of an XML schema standard is in fact an improvement, is very useful information for XML schema users. The paper addresses what aspects of XML schemas are vital to its quality and how to measure those aspects.

We present 3 quality aspects in more detail: (1) structure type, (2) re-use possibilities and (3) balance of building blocks. A table of all included variables, that were measured, is provided in TABLE I. Based on results of over 200 XML schemas, quality assessment are given, including data standardization methods.

A. *Quality aspects*

The results of a systematic review of literature in the field of measuring XML schemas showed that several metrics were applied to XML schema evaluation, extracted mainly from the methods of software engineering measurements, focusing mostly on the complexity of XML Schemas. To include a variety of parameters addressing complexity and quality, we searched different fields on quality measurement and defined the following three, shown in Figure 1.

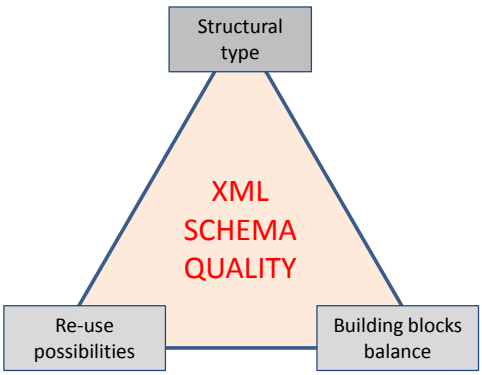

Figure 1. Quality aspects of XML schemas

Structure type: Other authors have researched measuring the structure of XML schemes for calculating the complexity and quality in [4] and [5]. The authors present a number of metrics, taken mainly from "quality model" ISO standard and link them into a single formula. Each variable is further multiplied, however the factors are not justified, values are not on the same scale, so the formula cannot be applied, but we have analyzed and partly used it in our calculation formula of quality. Within the complexity calculations a conclusion can be made that the higher the value of the individual variable, the greater the complexity. According to XML schema needs we redefined metrics into the following composite metric (1) with the following parameters:

$$Q1 = N_{ri_all} + \frac{N_E}{N_{at}} + \frac{N_r}{N_{t_s}} + \frac{N_{t_s}}{N_{t_c}} + \frac{N_{An} + N_{t_i} + N_{E_U}}{N_E} \quad (1)$$

Re-use possibilities: The equation was inspired by [7]; summing up existing results and defining a set of metrics for measuring re-use of software. The metric includes parameters that allow the re-use and are inherently global (2).

$$Q2 = \frac{N_{re_{all}} + N_{ra_all} + N_{rg_all} + N_{ri_all} + N_{rt_all} + N_{t_i}}{N_E + N_{At} + N_g + N_t} \quad (2)$$

Balance of building blocks: In this metric we combine the parameters indicating the minimum XML schemas building blocks, where the concept of minimalism is defined as the level, where one can anticipate that there is no other set of less building blocks, however still descriptive full (3).

$$Q_3 = \frac{N_{An} + N_E + N_{At}}{LOC} + \frac{N_{rt_all}}{N_t} \quad (3)$$

The XML schema **quality index** combined all three aspects equally (4). Each included XML schema was evaluated individually by each metric and a combined quality index was calculated. Versions of the same XML schemas were compared.

$$Q_i = \frac{1}{3}(Q_1 + Q_2 + Q_3) \quad (4)$$

The proposed parameters and metrics are relatively non-complicated to obtain and calculate, however no such tool was found available within our support tools survey. Therefore a personalized web application "XML schema metrics" was implemented (under supervision of Institute of informatics Maribor), measuring and reporting all vital XML schema variables, enabling a much faster gathering of data, hindering hand-made mistakes.

B. *Hypothesis*

In this study, we addressed the following research question: The newer version of XML schemas is of higher quality as the previous one. We addressed the research question with the following hypothesis:

H1 –The quality of structural view is higher in case of a higher version.

H2 – The quality of re-use possibilities is higher in case of a higher version.

H3 - The quality of building blocks balance is higher in case of a higher version.

C. *Standardization methods*

The calculated parameter values included several value spans, from zero to over 1000. So that individual

metrics could be compared, standardization of variables was conducted. All the variable results that were used within metrics were transformed to a scale of 0 to 1, where 0 represented the least desirable value for each parameter and 1 the most desirable value. The transformations were based on linear programming, assuming that the growth relationship is without exception linear. Each of the parameters underwent a resize process with the help of one of the three scaling techniques (Figure 2, Figure 3, Figure 4).

If the most desirable outcome of the parameter is as maximal as possible, the maximal value holds the estimation 1 and it linearly drops to 0 (Figure 2).

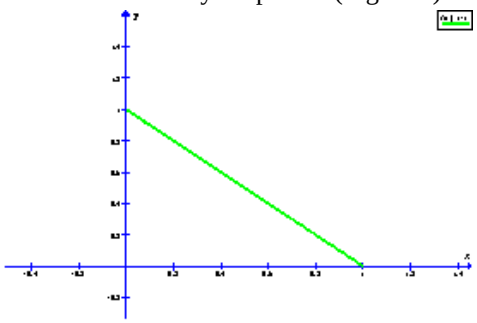

Figure 2. Maximum value best option

If the most desirable outcome of the parameter is as minimal as possible, the minimal value holds the estimation 1 and it linear goes to 0 (Figure 3).

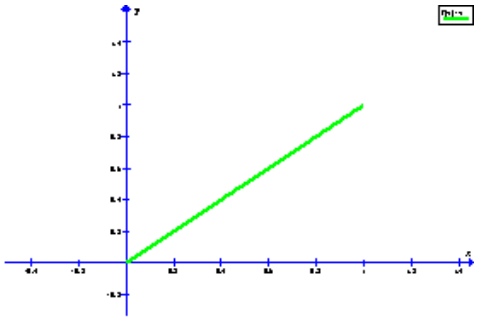

Figure 3. Minimum value best option

If the most desirable outcome is of average value then the average value holds 1; the extreme minimal and maximal values hold value 0 (Figure 4).

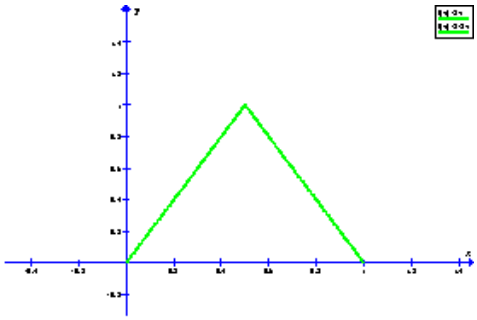

Figure 4. Average value best option

IV. QUALITY CHANGE THROUGH VERSIONING

Measurement results of XML schema's versions were compared, providing insight into quality growth (or decline) through versioning. We overviewed several types of versioning notation in order to compare the right XML schemas.

A. *Definition of versions*

In [10] the author explains the possible XML schema versioning techniques: (1) changing the internal schema version attribute, (2) changing the schema's target namespace, (3) changing the name of the schema or (4) changing the location of the schema. Each technique has its advantages and disadvantages:

- **Changing the schema version attribute**; although an easy task the validator often ignores the attribute field and can be used only as a cue to the human user (Technique 1).
- **Changing the schema's target namespace** demands a suitable change in instance documents, which will not validate until they are changed to designate new target namespace, attribute, even if the change to the schema would not impact the instance. The problems occur with included XML schemas (Technique 2).
- **Changing the (file) name of xml schema;** is the most often case of versioning, however additionally demanding a change in instance documents, facing with identical problems as in technique 2 (Technique 3).
- **Changing the location of the schema** is used in conjunction with case 3 (Technique 4).

XML schemas, included in our research, mostly used technique 3, in combination with technique 1 or technique 2.

B. *Comparission of XML schema versions*

The formulas were tested on 250 XML schemas; regression analysis was conducted in order to verify significance of included variables [11]. However, comparing versions of included XML schemas was reduced to 10% of all XML schemas, due to the lack of availability of more than one version of XML schemas

All three quality aspects as well as joint quality index were compared among the found XML schema pairs. In average, the newer version improved the structural aspect for 2%. The aspect of re-use was reduced for 1% and optimality of building blocks was improved by 2%. In average a newer version of XML schema was improved by no more than 1%.

C. *Hypothesis answers*

Although the average quality of XML schemas with newer version was higher (Figure 5), all hypotheses could not be confirmed.

H1 – The quality of structural view was in fact averagely higher by 2% in some cases even as high as 21%. Hypothesis ACCEPTED.

H2 - The quality of re-use possibilities is higher in case of a higher version was averagely not correct. Averagely the newer version had a lower quality evaluation by 1%, in some cases even as low as 33% lower. Hypothesis REJECTED.

H3 - The quality of balance of building blocks is higher in case of a higher version was true averagely by 2%; however several newer versions had a significantly lower quality level as low as to 70%. Therefore the hypothesis can be only PARTIALLY ACCEPTED.

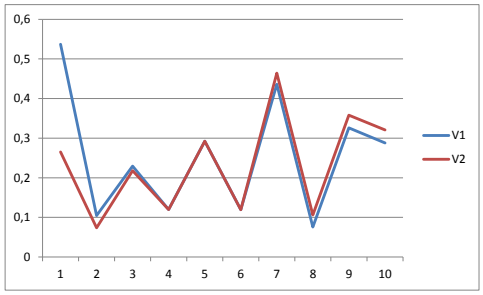

Figure 5. Quality of two successive XML schema versions

In average, the newer version had a 1% improvement on its quality evaluation (TABLE II). Several newer versions had a poorer quality evaluation by 27%, maximum evaluation of quality index was better by 3%, pointing out that newer XML schemas are at best only slightly higher than the older versions; most of them in fact have a poorer quality evaluation.

TABLE II. RESULT IMPROVEMENT IN NEWER VERSION

Aspect	***Min***	***Average***	***Max***
Structure	-2%	2%	21%
Re-use	-33%	-1%	8%
Balance	-70%	2%	12%
Average	-27%	1%	3%

V. CONLUSION

A comparison of two version of the same XML schema was made for several schema pairs. The newer XML schema was averagely slightly improved compared to the previous XML schema, however only by 1 %. The largest improvement was in the structure quality aspect and the balance of the building blocks aspect. The lowest improvement was in re-use of XML schema elements. The results show, the newer versions focus mainly on adding new content or changing older content; improving their structure or enhancing re-use of its building block is not a priority while re-shaping XML schemas.

Since XML schemas develop and change through their life cycle, quality of each newer addition to XML schema is an important aspect, influencing not only XML documents but also higher levels of IT development. The versioning process should be created with greater care, providing improvement not only in its up-to-date contents, but more so in a consistent structure. Each newer version should be tested for its quality before released to achieve at least the same level of quality as its predecessor. As results showed, this is not always the case, opening a concern in the future of XML schema versioning.

The study has also limitations. The first limitation is a small set of XML schema version pairs. Once a new version is released, the older is often no more available. The study should be repeated on a larger set of latest XML schemas, in order to enhance its relevance. Additionally, we compared only two versions. A research should be extended to comparing all versions of one XML schema and monitoring its growth or decline in quality index.

In our future work we will address the deficiencies described as limitation of this study. A larger set of XML schemas will be collected, including all available versions. Quality comparison will be made among all XML schema versions, enabling a more precise evaluation of quality change within XML schema life cycle. Metrics will also be expanded with other approaches such as entropy as a measure of quality and abstract data type structuring.

***Abstract*- IEEE 802.11 standard primarily utilizes Distributed Coordination Function (DCF) which is based on carrier sense multiple access with collision avoidance (CSMA/CA). IN DCF, when a collision occurs, then a backoff algorithm will take place to randomize medium access for the nodes. The default backoff mechanism used in 802.11 is the binary exponential backoff (BEB) algorithm. In this paper, we analyze the behavior of various backoff algorithms used in IEEE802.11 standard: BEB, I-BEB, and E-BEB, then we propose the New Binary Exponential Backoff (N-BEB) algorithm to improve channel access fairness while preserving the channel throughput. Our N-BEB algorithm improves the selection process of the contention window CW, based on the number of successful and unsuccessful transmissions. Simulation results confirm fairness improvement, power consumption enhancement, reduction of dropped packets and high delivery ratio for proposed proptocol over BEB, I-BEB, and E-BEB protocols.**

***Keywords:* IEEE802.11 back off, BEB, QoS, chancel fairness, wireless MAC.**

I. INTRODUCTION

Much research literature and several algorithms address the problem of fairness among senders in wireless networks. Some of these algorithms, despite solving the fairness problem, suffer a significant reduction of the channel throughput, increase delay or reduce packet delivery ratio. In this paper, we proposed a novel approach to solve the fairness problem in wireless networks without degrading other metrics. Throughput and fairness in wireless channels are inversely related, for instance, some research maximizes the throughput [1] but keeps the CW constant, while other research modifies the CW with respect to the size of the region and the state of the channel. Yet, others modify the CW with respect to the conditions of the network load.

The quality of service (QoS) of the IEEE 802.11 protocol is a critical issue for some applications such as multimedia. Therefore, a key element is that we preserve the bandwidth, packet loss rate, and delay for such applications to achieve an acceptable performance in wirless networks.

II. RELATED WORK

Wireless medium access control (MAC) protocol suffers from several problems such as hidden terminal, exposed terminal, as well as fairness problem. The sharing of the channel causes hidden and exposed terminal problems while the fairness problem is a result of using ill-suited backoff algorithm. In binary exponential backoff (BEB) algorithm [2], the CW is used to determine the value of the backoff time (BT) for each node, whereas CW value is changed in BEB as follows:

- When a node sends a packet successfully, the value of the CW will return to CW_{min}:

$$CW = CW_{min} \quad (1)$$

- When a node sends a packet and a collision occurs, CW will be doubled:

$$CW = 2 * CW \quad (2)$$

- When a node sends a packet unsuccessfully for seven times, the packet will be dropped.

BEB algorithm is the main cause of the fairness problem in IEEE802.11, when a node in BEB sends its packet successfully, it will choose a random number in the range of (0, 31), knowing that unsuccessful transmission will double its CW to reach a large value such as 64, 128, 256….and so on. These values are considered very large with respect to CW_{min}. Hence, the chosen random number will probably be larger than the one chosen earlier, in other words, each node with a small CW will have a higher probability to access the channel and vice versa [2], that is to say, the node that accesses the channel for the first time has a higher probability in accessing the channel in the next trial. Conversely, the node,with a large value for the CW, has a lower probability to access the channel and send its packets.

Improved binary exponential backoff (I-BEB) algorithm [3] is an adaptive algorithm which improves the QoS of IEEE 802.11 protocol. This adaptive algorithm is dependent on a dynamic operation to modify the value of the CW based on the number of successful sending times. In I-BEB, when the node sends a packet successfully, it will execute the function *rst_cw_I_BEB()*. In this function, if the amount of successful transmissions is less than a predefind threshold quantity *c*, the CW value of those nodes which send data packet successfully is divided by the parameter *d*. When the CW is less than another predefined threshold quantity *G* (CW<*G*), their protocol sets CW value equals to *G* (i.e $G = 0.125 \times CW_min$)[3].

If the amount of successful transmissions is greater than *c*, this algorithm will increment CW to a large value (i.e., CW+e×CW_min), giving other nodes the opportunity to use the channel. Both processes are repeated in a continual manner, giving a more evenly distributed opportunity to each node for channel access. They proposed the best values for the parameters in this algorithm as: *e*=8, *d*=4, *c*=12 [3].

To compaire with our approach, we implemented and tested I-BEB algorithm against multiple scenarios using NS2 simulator. After analyzing the results, we found that I-BEB achieves high fairness but suffers the highest number of dropped packets among all studied algorithms (BEB, E-BEB, N-BEB), and this leads to channel overhead increase and network utilization reduction, since a large number of packets will be lost.

Enhanced binary exponential backoff (E-BEB) algorithm[4] uses a distinct tactic when successful transmission occurs. In this algorithm, a new variable is added which differentiates it from BEB and I-BEB. This variable is called "*BT_TH*" and used to calculate the backoff time. Unlike the traditional technique that calculates the backoff time by *BT=CW*Slot time*, the *BT_TH* in E-BEB algorithm, is calculated as:

$$BT_TH = \frac{CW_{min}}{\sqrt{CW_{max}}} \times CW \times slot\ time \qquad (3)$$

We also implemented and tested E-BEB under NS2 against varios scenarios, and we found that E-BEB achieves low fairness with high processing, in addition to power dissipation increase, which is a crucial factor in the wireless network lifetime.

III. PROPOSED ALGORITHM

In our proposed algorithm, which is based on the original BEB algorithm and its generations, a new procedure is followed. Our algorithm enhances the opportunity for any given node intending to send packets to access the channel. In the instance, when the node cannot access the channel, our proposed algorithm allows the CW to increase its value two times consecutively. However, these increments depend on specified parameters were calculated by intensive simulationexperiments to achieve the best results. After two unsuccessful transmissions, the node starts decreasing the value of the CW.

When a transmission is successful as shown in Fig. 1, the CW is calculated by CW=CW / ($\sqrt{2} \cong 1.4$).This operation is repeated during the first nine successful transmissions. Afterwards, we reset the number of successful transmission to 1 and CW is set to CW×1.5. The value of 1.5 is selected based on extensive simulation results, which gives opportunity to other nodes to use the channel specially those nodes that collide more than two times. This step introduces an efficient fairness between the nodes.

In case of an unsuccessful transmission as explained in Fig. 2, the CW is calculated by CW=CW×($\sqrt{2}$). This operation will be repeated during the first two unsuccessful transmissions. Thereafter, the number of unsuccessful transmission is set to 1 and CW to CW/1.5. This reduction in CW value allows this node to retransmit its data successfully.

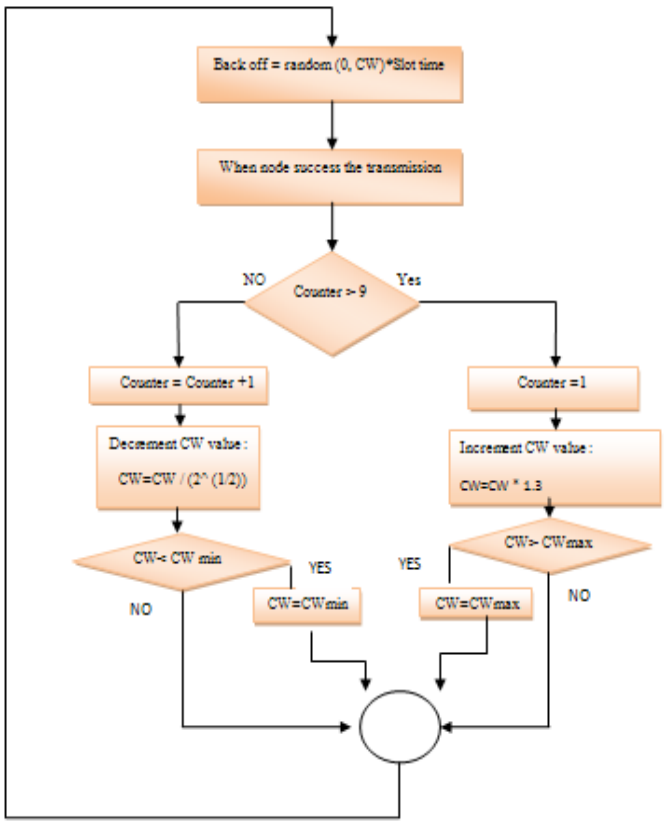

Fig.1 Proposed algorithm (Successful case)

IV. SIMULATION AND RESULTS

We used NS2 [5] simulator to implement and test our proposed algorithm using parameters in Table 1, and the same scenarios mentioned in I-BEB and E-BEB papers:

Scenario (1) : there are 10 nodes distributed on the 500×500 planar domains at random; the maximum connections are 4, the transport layer adopts the UDP protocol. In the application layer, CBR (Constant Bit Rate) is adopted as flows, the top node's speed is 10m/s, residence time is 10 Sec, the simulation time is 100 Sec [3].

Table 1 Simulation parameters

Simulation parameters	
Transport Protocol	UDP
Max-speed	10m/s
Slot time	20 µs
ACK	20 bytes
RTS	25 bytes
CTS	20 bytes
Packet size	1000 bytes
DIFS	40 µs
SIFS	10 µs
CW_{min}	31
CW_{max}	1023
Bandwidth	2 Mbits/s

We implement BEB, I-BEB, and E-BEB as a baseline comparison with our proposed algorithm (N-BEB), using scenario(1) as mentioned in I-BEB paper [3]. As demonstrated in the simulation results figures, we notice that our proposed algorithm achieved the lowest number of dropped packets during the simulation, reduced the channel overhead and increased the packet delivery ratio (PDR). Additionally, N-BEB achieved the least end-to-end delay.

Our algorithm is a bit more complex than I-BEB and BEB, since the original BEB has two cases: successful, where CW is reset to $CW_{min,}$ so the node can access the channel as soon as possible, and unsuccessful, whereby the BEB algorithm simply duplicates the CW, while the I-BEB algorithm focuses primarily on success, and the algorithm assesses the number of successful transmissions to determine whether to increase or decrease the CW; however, in the cases where transmission did not attain success consecutive manner, the CW is reset to minimum, making both of these algorithms simpler than our algorithm.

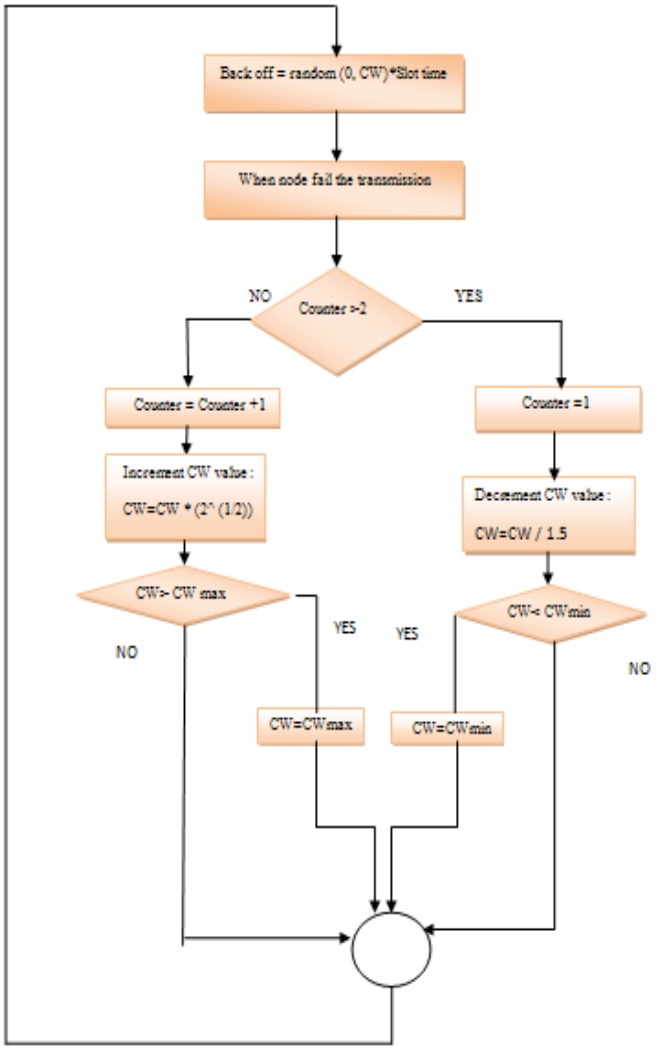

Fig. 2Proposed algorithm (Unsuccessful case)

In our algorithm, we considered both cases of successful and unsuccessful transmissions.We take into consideration the number of unsuccessful and successful transmissions and adjust the value of CW accordingly, thus, N-BEB is considered a little more complex than BEB and I-BEB.

In E-BEB algorithm, we note that its higher complexity stems from taking into account the value of the backoff time, which is then used to recalculate the value of the CW. By doing so, this algorithm adds a new computational complexity, this computational complexity increases power consumption which is critical issue in ad hoc network. Our algorithm considers power consumptionof nodes and tries to save power by condensing the calculation needed to perform the task but it still requires more computation than BEB and I-BEB.

Fairness index can be quantified by fairness index (FI) using the following formula:

$$fairness\ index\ (FI) = \frac{(\sum_{i=1}^{n} x_i)^2}{n \times \sum_{i=1}^{n} (x_i)^2} \qquad (4)$$

where *n* is the number of the same priority flows and *Xi* is the throughput of flow *i*.

Scenario (2): 8 nodes share same channel. Distance between neighbor nodes is 50m; the nodes are static, at 1.0 Sec simulation time, nodes (0, 2, 4 and 6) start simultaneously sending data to its neighboring nodes (1, 3, 5 and 7) respectively[4].

The result we obtained was 98% fairness, the reason behind this high result is that the node is static and each node can connect to only its neighbor node, for this reason we make a new scenario based on mobile nodes as shown in Fig (3), the result is shown in Fig (9) and this scenario is explained next.

Scenario (3): in this scenario 8 nodes share one channel at the same time, all nodes are single-hop, we assume that all nodes are mobile and fall within the range of each other. At time 1.0 Sec, nodes (1, 4, 6, 8) start simultaneously sending data to their neighboring nodes (2, 5, 7, 9) respectively.

We test this scenario on the four algorithms: BEB, I-BEB, E-BEB, and our N-BEB. In the two cases of static and mobile nodes, we can see from the result that our proposed algorithm has higher value of fairness than other algorithms as shown in Fig (9).

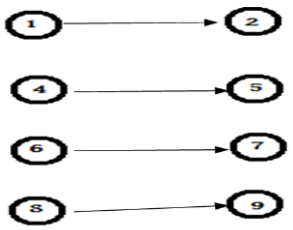

Fig.3 scenario(2)

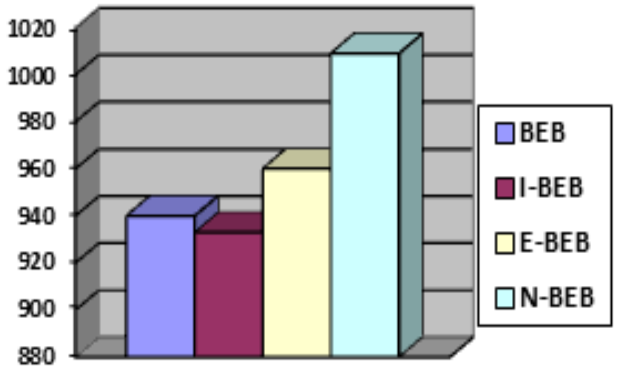
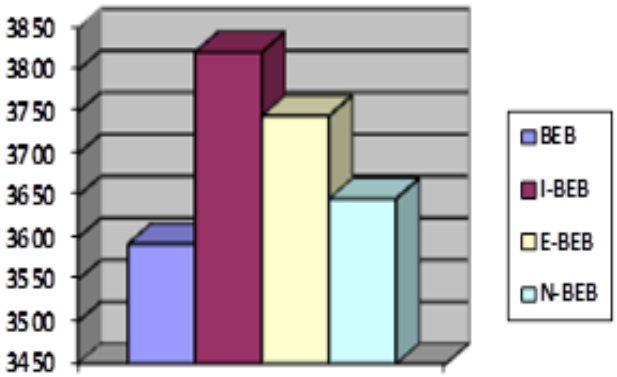


(A)



(B)

Fig. 4: (A) Number of successful sent packets
(B) Number of overall sent packets

Fig. 4(A) shows the number of successfulsent packets for N-BEB algorithm along with the other mentioned algorithms. It is clear that the number of successfulsent packets in our prposed algorithm is the largest among all mentioned algorithms.

Fig. 4(B) shows the overall sent packets for N-BEB along with the other mentioned algorithms. It is noticeable that the number of sent packets in our proposed algorithm is less than I-BEB and E-BEB, because the number of dropped packets (shown in Fig. 5) is reduced and retransmissions are not needed, which also implies a reduction in power consumption. The number of sent packet in the proposed algorithm is greater than the original BEB, knowing that our algorithm reduces the end-to-end delay, allowing more packets to be sent and received during the same network period of time.

Fig. 5 compares the dropped packets for N-BEB algorithm with the other described algorithms. The proposed algorithm N-BEB, has the least number of dropped packets when compared to the other algorithms and as a result, the channel overhead is reduced significantly, thus, a higher network utilization is accomplished, since a lower number of packets will be lost and consequently retransmitted.

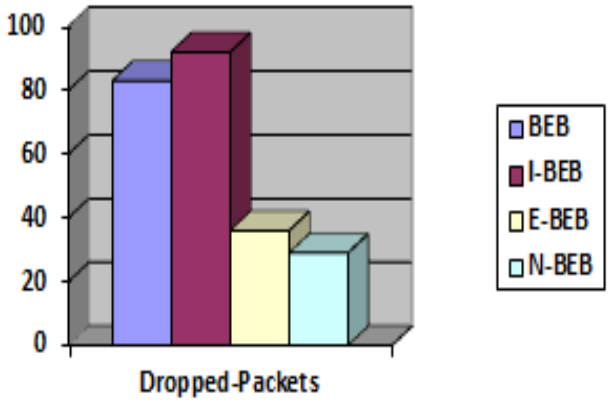


Fig. 5 Dropped packets

To make sure that N-BEB is scalable, we applied N-BEB on a network with different number of nodes (10 to 60 nodes). Here, we see that our algorithm is scalable and can be applied to networks with various numbers of nodes as shown in Fig. 6.

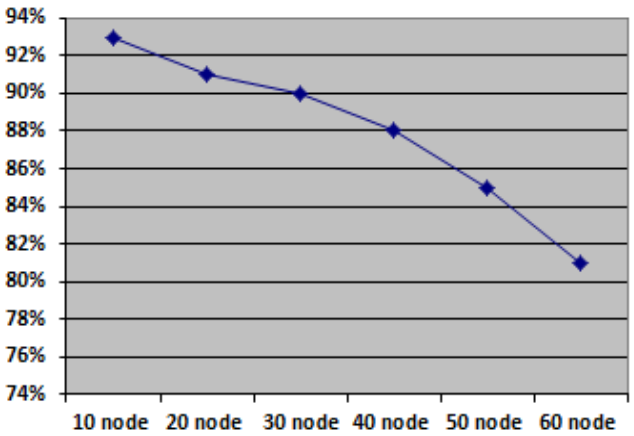

Fig.6 N-BEB scalability with respect to PDR

Fig. 7 shows the delivery ratio for the proposed algorithm, N-BEB, when being compared to the other algorithms. It is obevious that the proposed algorithm has the highest delivery ratio due to the higher channel availability for the sender than the other algorithm as a result of retransmissions reduction.

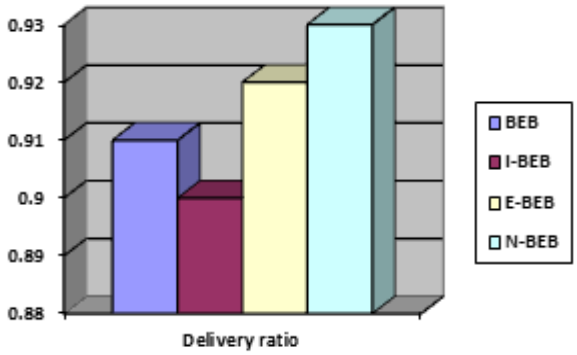

Fig. 7 Packet delivery ratio

End-to-end delay for N-BEB and the other mentioned algorithm is shown in Fig. 8. Among all algorithms, N-BEB has the least delay because the opportunity to access the channel is significantly increased.

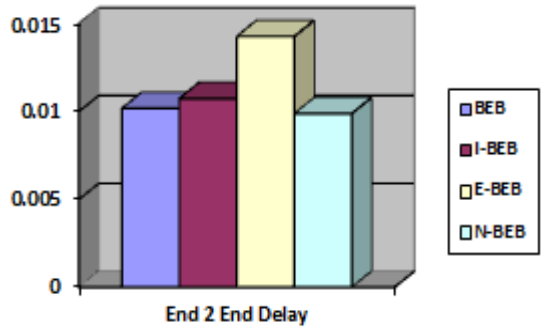

Fig. 8 End-to-end delay

Fig. 9 shows the value Fairness index of N-BEB along with the other mentioned algorithms according to scenario(3). It is clear that the value fairness index for our proposed algorithm is the highest among other algorithms..

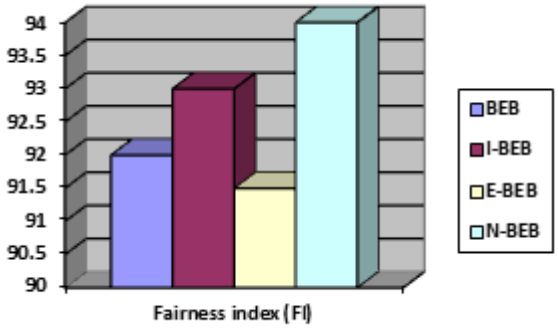

Fig. 9 Fairness index

V. CONCLUSION

In this paper, we proposed a new binary exponential backoff (N-BEB) algorithm that mainly aims to solve the problem of fairness without neglecting the improvement of the throughput. In addition to attaining the best fairness among other tested and relevant algorithms, the N-BEB achieved the highest packet delivery ratio and least number of dropped packets. It deserves pointing out that our proposed algorithm manages a massive improvement in the end-to-end delay, which found to be the least among comparative algorithms. When making a comprehensive evaluation and as far as the complexity is concerned, we found that N-BEB complexity is greater than I-BEB and BEB, but lower than E-BEB.

***Abstract*—In the process of design of protocols for medium access control in wireless sensor networks, it is necessary to find a compromise between energy saving, time sensitivity, scalability, adaptability and complexity. In this research, as an object of optimization S-MAC protocol is chosen. The main advantage of the S-MAC protocol is a state of sleep, which significantly reduces power consumption. Although the S-MAC protocol is described with a large number of parameters, in this paper we have selected three parameters that directly affect the time frame protocol: the duty cycle, the duration of the synchronization interval, and duration of the data interval. To assess the quality of the selected parameters, three measures were selected: total electricity consumption in the network, delay in the delivery of packets to the application layer, and the total achieved bandwidth. Using ns-2 network simulator, a model for testing the influence of parameters of S-MAC protocol on network performance has been developed. The parameters values are selected using the NSGA-II algorithm implemented in MATLAB software package, and the whole process of finding of non-dominated solution set is fully automated. In addition to multi-objective optimization of parameters, an experiment with single-objective optimization using aggregated utility function and the standard GA is performed. Finally, the analysis of the obtained set of non-dominated solutions is performed and a comparison with the results of the single-objective optimization is done.**

Keywords — S-MAC, WSN, multi-objective, single-objective, NSGA, optimization, ns-2, protocol.

I. Introduction

The performance of communications networks depends on various factors at all layers of the OSI/ISO reference model (physical layer, data link layer, network layer, transport layer, session layer, presentation layer and application layer). Although the OSI/ISO reference model provides separate views on different network layers, overall behaviour of the network can not be inferred looking at single layer, because as there is interaction between peer layers and between adjacent layers in OSI/ISO hierarchy. When optimizing the performance of communication networks, the problem is usually solved in two ways (or in two directions, i.e. cross-layer) from the lowest to the highest layer, or vice versa. Direction of optimization is selected depending on which layer has the most impact on the overall network performance.

Cross-layer design approaches presented in [1] can be classified depending on layer interactions (e.g. interaction between Medium Access Control (MAC) layer and Network layer, Physical layer and MAC, etc.). One example of these approaches in design, Energy Aware Routing Protocol, proposed in [2] has the disadvantage in that it only regards one parameter as the performance measure.

When it comes to optimize the performance of wireless sensor networks (WSN), where they perform relatively simple applications, lower layers of the OSI/ISO reference model have the greatest impact on the overall network performance. Since the physical layer is largely standardized (conventional modulation technique, coding, pre-defined radio channels, etc.), the logical choice to start the optimization is the data link layer. The task of the data link layer is to control medium access and establishing a logical connection between two nodes in the network. The behaviour of this layer is defined by the design of MAC protocol. Important factors in the design of MAC protocols in wireless sensor networks are:

- Energy saving - the main goal of the design of the MAC of protocols for wireless sensor networks is energy saving in the wireless sensor nodes which increases the lifetime of the network [3]. An important factor is also the QoS in the network, which is manifested through measures such as throughput, delay, fairness, bandwidth utilization etc. To fulfil the mentioned objectives it is necessary to design an efficient MAC protocol.
- Time sensitivity - another important requirement in the design of the MAC WSN is to ensure the real-time transmission for applications that require it [4].
- Scalability and flexibility - the MAC protocol of wireless sensor networks must be highly scalable due to the large number of sensor nodes and the different functionalities that the network can support. Also, the MAC protocol must be adaptable to changes in topology that occur due to failure or node mobility. The network should be self-organizing and capable of functioning normally regardless of unreliability of individual nodes. To make the network more reliable, decentralized network architecture is desirable [4].
- Complexity - refers to the power consumption in the execution of complex algorithms and protocols. One of the most important requirements in the design of WSN MAC is the simplicity [5].

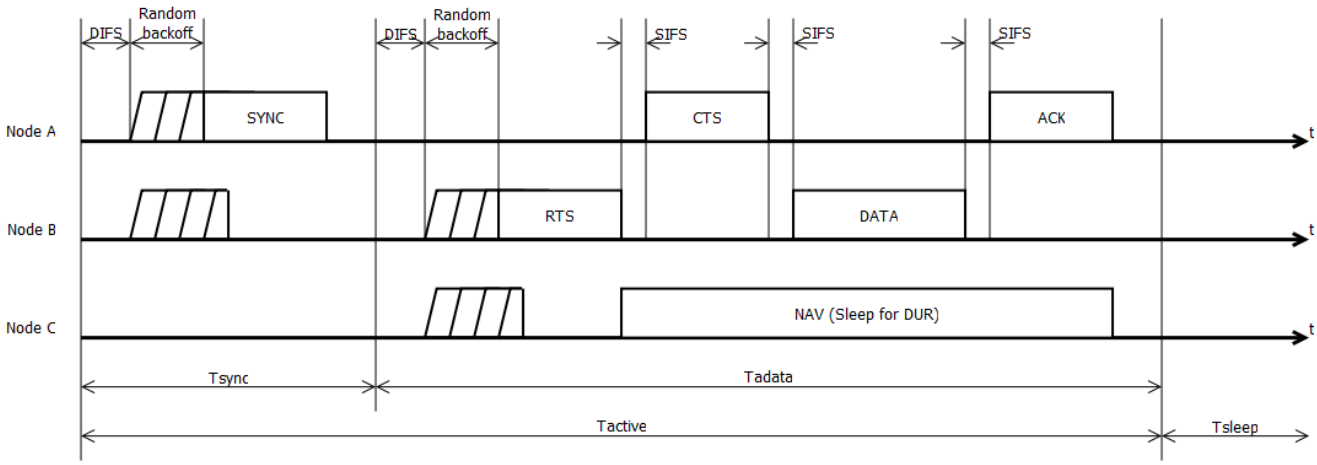

Fig. 1. Timeframe of S-MAC protocol

In the process of design of the MAC protocols it is necessary to find a compromise between the above set of requirements, since some of them are in opposition to each other.

The protocols used within the data link layer of a WSN in the general case are classified into two categories: protocol based on contention for medium and Time Division Multiple Access (TDMA) protocols. Although the IEEE 802.11-based protocols are mainly used for simplicity and resistance to the problem of hidden nodes they are energy inefficient because they do not solve the problems of constant listening to the media and listening to media in the IDLE state. Details about the disadvantages that eliminates certain protocols from the above categories in compared to S-MAC protocol are described in [6]. An overview of all existing MAC protocols for WSN along with their pros and cons is also given in [7]. The main advantage of the S-MAC protocol is the SLEEP state which significantly reduces power consumption. S-MAC also easily adapts to changes in topology. In addition, there is no need for a central node or strictly precise synchronization [8].

In the S-MAC protocol (Fig. 1), one cycle of network operation is divided into two intervals: interval of activity (T_{active}) and sleep interval (T_{sleep}). These periods alternate and have the same time of occurrence for all nodes in a virtual cluster (nodes are fully synchronized). The network can consist of multiple virtual clusters. The active period is divided into two sub-periods consisting of time slots in which the first is used to exchange messages to synchronize the cluster (T_{async}), and the other is used for data transfer (T_{adata}). In both sub-periods nodes access the medium using CSMA/CA mechanism with random counters that each node internally runs if the medium is free. To avoid the problem of hidden nodes in the network are used RTS/CTS control packets by which a particular node informs the other nodes about the duration of its transmission. The nodes that receive the RTS packet, update their Network Allocation Vector (NAV) counters on the duration of transmission of the node that transmits and go to sleep. In this way the energy saving is achieved.

Although the S-MAC protocol is described with a large number of parameters, in this paper three parameters were chosen which have a direct impact on the time frame of the protocol: duty cycle (i.e. the ratio of the interval of activity T_{active} and the total period $T_{active}+T_{sleep}$), duration of T_{sync} and the duration of the interval T_{data}. To assess the quality of the selected parameters three measures were chosen: total energy consumption in the network, average delay in delivery of packages at the application layer, and the total achieved bandwidth at the application layer.

In [9], the effect of duty cycle on network performance is investigated. However, impacts on delay and energy consumption are evaluated seperately. Furthermore, impact of contention window sizes is neglected.

Therefore, this paper will give a much broader look at problem that has been studied earlier, but with multi-objective approach.

II. A FORMAL MODEL OF THE PROBLEM SITUATION

In this paper, the problem situation is the optimization of the parameters of the S-MAC protocol. Problem situation can be formally presented with a set of alternatives in three-dimensional problem space:

$$\mathbf{x} = \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix} \in E^3 \tag{1}$$

where x_i are alternative elements (with the given constraints based on empirical assumptions) which correspond to the following parameters of the S-MAC protocol:

- $x_1 \in [1, 99]$ - Duty cycle.
- $x_2 \in [7, 127]$ - Window size for contention during media access in SYNC phase ($SYNC_CW$). This parameter linearly affects the duration of the interval T_{sync}.
- $x_3 \in [7, 127]$ - Window size for contention when accessing the media in the DATA phase ($DATA_CW$). This parameter linearly affects the duration of the interval T_{adata}.

The objectives of the problem situation can be expressed using three objectives:

- $q_1 \simeq E$ - The total energy consumption in the network.
- $q_2 \simeq T$ - Mean end-to-end delay in the delivery of packets of the application layer.
- $q_3 \simeq B$ - Total achieved bandwidth at application layer.

Total energy consumption in the network is calculated as:

$$E = \sum_{i=1}^{N} E_i \tag{2}$$

where E_i is the power consumption of the i-th node in the network and N is the number of nodes in the network, and is calculated as:

$$\begin{aligned} E_i =& P_{IDLE} \cdot T_i^{IDLE} + P_{TX} \cdot T_i^{TX} \\ &+ P_{RX} \cdot T_i^{RX} + P_{SLEEP} \cdot T_i^{SLEEP} \end{aligned} \tag{3}$$

Constants P_{IDLE}, P_{TX}, P_{RX} and P_{SLEEP} represent power dissipation in idle mode (listening to the media), when sending packets, when receiving packets and in a state of sleep, and variables T_{IDLE}, T_{TX}, T_{RX} and T_{SLEEP} time the i-th node spent in the corresponding mode.

Mean end-to-end delay is calculated as the average of delay of all packets:

$$T = \frac{1}{M} \sum_{i=1}^{M} (t_i^R - t_i^S) \tag{4}$$

where M is the number of sent and received packets, t_i^R the time of receipt of the i-th packet, and t_i^S is the sending time of the i-th packet.

Achieved bandwidth is calculated as:

$$B = \frac{\sum_{i=1}^{M} P_i}{T_{sim}} \tag{5}$$

where M is the number of received packet, P_i is the size of the i-th packet and T_{sim} duration of the simulation, i.e. time of the activity of traffic generator.

Aspiration level can be defined for each objective:

- Achieve the minimum of energy consumption ($\max_{x \in \Omega}\{q_1\}$).
- Achieve the minimum of end-to-end delay ($\max_{\mathbf{x} \in \mathbf{\Omega}}\{q_2\}$).
- Achieve the maximum of bandwidth ($\max_{\mathbf{x} \in \mathbf{\Omega}}\{q_3\}$), or achieve the minimum of unused bandwidth ($\max_{\mathbf{x} \in \mathbf{\Omega}}\{\frac{q_3^{max} - q_3}{q_3^{max}}\}$).

For multi-objective problem can be defined vector function $\mathbf{Q} : E^3 \rightarrow V^3$ that point of problem space $\mathbf{x} \in E^3$ maps to point of value space $\mathbf{v} \in V^3$, where:

$$\mathbf{Q} = \begin{bmatrix} q_1 \\ q_2 \\ q_3 \end{bmatrix}, \mathbf{x} = \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix} \in \mathbf{\Omega} \subset E^3, \mathbf{v} = \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} \in V^3. \tag{6}$$

If we want to solve the multi-objective problem as a single-objective, then one of the methods is using the aggregate utility function. Aggregate utility function (AUF) performs the mapping three objective functions into a single function as follows:

$$\begin{aligned} U(x_1, x_2, x_3) &= w_1 q_1(x_1, x_2, x_3) \\ &+ w_2 q_2(x_1, x_2, x_3) + w_3 q_3(x_1, x_2, x_3) \end{aligned} \tag{7}$$

where w_1, w_2 and w_3 are weights which determine the preference of each of the objectives. Now the optimization problem is reduced to search for the minimum/maximum of aggregate utility function.

III. Parameters optimization

Fig. 2 shows the software architecture of the system for optimization of parameters. For the realization of the simulation model of the S-MAC protocol, the network simulator NS-2, which is written in C++ programming language with OTcl API was used. To create a simulation model scripting language Tcl was used which represents the interface between the user and OTcl API. In this paper, for the purpose of the S-MAC protocol optimization, a simple simulation model was realized, in which eight of wireless sensor nodes generate traffic at a constant rate and send it to a wireless access point (i.e. a node which performs the function of the receiver).

For the analysis of trace file that is produced by NS-2, a tool designed to analyse large text files AWK was used. The tool is controlled with AWK scripting language with syntax similar to C language. Based on the proposed formal model of the problem situation, three AWK scripts for calculation of energy consumption, end-to-end delay and achieved bandwidth were written. By executing these scripts, three files containing the evaluated measures of performance are generated.

In MATLAB, algorithms for a multi-objective and single-objective optimization of parameters based on genetic algorithm (GA) are implemented. In phase of fitness evaluation for selected individual from the population, MATLAB runs the NS-2 simulator with the parameters encoded within the individual and the result, obtained after the execution of the simulation and AWK scripts, is returned as a value of fitness. Upon completion of the NSGA-II, individuals from the last generation represent the estimated Pareto front.

A. Multi-objective approach using NSGA-II

MATLAB supports GA-based multi-objective optimization using the tool *gamultiobj* which implements a variant of the algorithm NSGA-II with controlled elitism. NSGA-II is described in detail in [10]. Elitist GA favours individuals with better fitness function value (i.e. better rank). GA with controlled elitism favours individuals that enhance the spread of the population, even if these individuals have a lower value of the fitness function. It is very important to maintain a spread of population to converge to Pareto front. The spread is maintained by controlling the elite members of the population during the execution of the algorithm.

B. Single-objective approach using AUF

To demonstrate the main advantage of multi-objective approach, the problem is also solved as a single-objective using

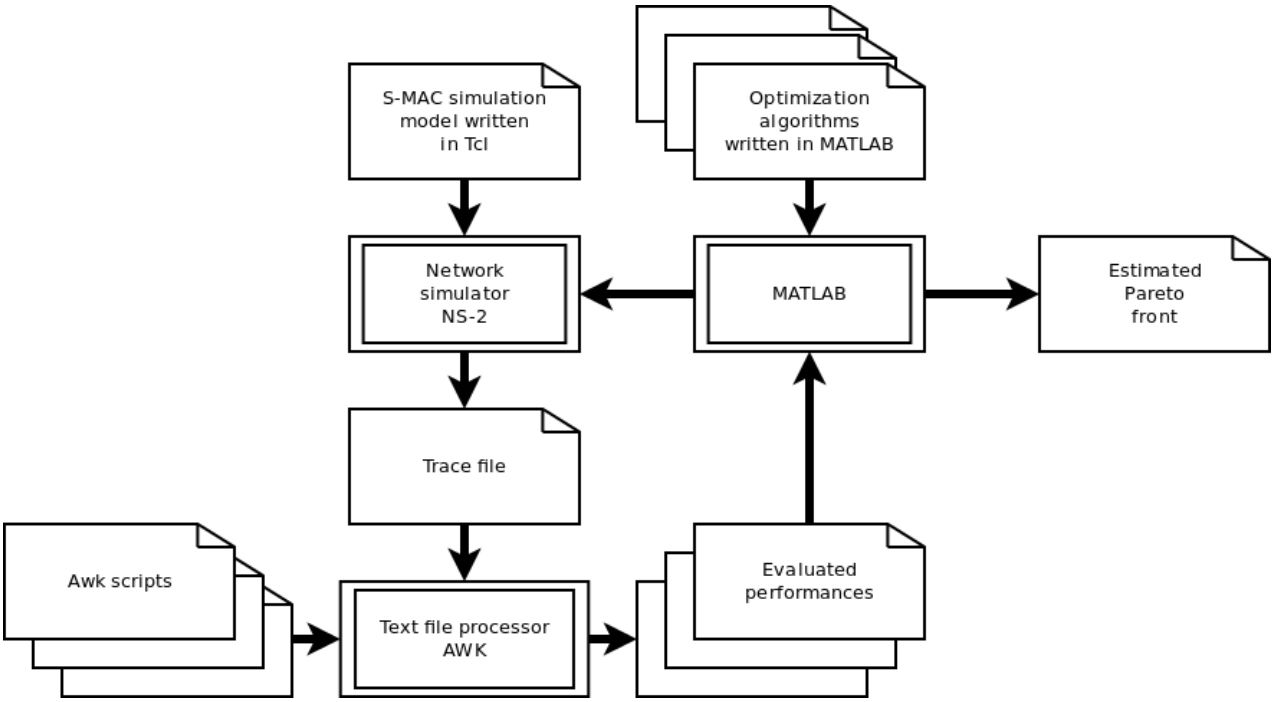

Fig. 2. Software architecture of the optimization system

aggregated utility function. Taking into account the values obtained by all three objectives in multi-objective approach, weight ratios, which also normalize objective functions, are determined, and the following function is obtained:

$$U(x_1, x_2, x_3) = q_1(x_1, x_2, x_3) + 100 \cdot q_2(x_1, x_2, x_3) + q_3(x_1, x_2, x_3) \quad (8)$$

With this mapping one thing is clear - part of the information is lost, because the three-dimensional problem is reduced to one-dimensional. The impact on results will be discussed in next section. As already mentioned before, now the optimization problem is reduced to search for the minimum/maximum of aggregate utility function. With regard to the objective set so that the aspiration level represents a minimum for each of the objectives, in single-objective optimization it is necessary to find a minimum of aggregate utility function.

IV. Results

In the following results obtained using both mentioned approaches will be presented and discussed.

A. Multi-objective approach using NSGA-II

During the execution of NSGA-II algorithm it is possible to monitor parameters such as the average spread of individuals on the Pareto front (Fig. 3) and the average distance between individuals. These two parameters provide information about the distribution and proximity of solutions to the Pareto front. The average spread can be used as a stopping objective of the algorithm. When this value converges to a small value (ideally zero), the solutions are uniformly distributed on the Pareto front.

Taking into account the distribution of non-dominated solutions, layout of Pareto fronts can be guessed, and the using of linear interpolation even shown (Fig. 4). Fig. 5 shows the non-dominated solutions in the problem space. Elements of alternatives in the problem space do not take the full range of possible values.

Table I shows several chosen solutions based on different objectives.

The first solution has a minimum value at the first objective (energy consumption). In the problem space, this solution has a pretty large duration of duty cycle (approximately 84%), while the ration of sizes of the windows: to exchange SYNC, and to exchange DATA packet is approximately 1:2. At first glance, it can be concluded that the high value of the duty cycle could ensures low energy consumption. This is reasonable if we take into account that nodes that do not transmit information go to sleep, ie power save mode, even if the active phase is in progress (due to the mechanism of the NAV of the counter).

The second solution has a minimum value at the second objective (delay). In the problem space, this solution has a larger window sizes for the exchange of SYNC and DATA packets. By increasing the contention window size, the more nodes have a greater chance to send a packet, so the delay is reduced. However, too large windows lead to the frequent occurrence of collisions, and it reflects on energy consumption.

The third solution has the minimum value of the third objective (unused bandwidth). In the problem space, this solution has a moderate duty cycle (approximately 43%), and the ratio of sizes of the windows similar to second solution.

Fourth chosen solution has a moderate value by all three objectives (neither objective does dominate). In the problem

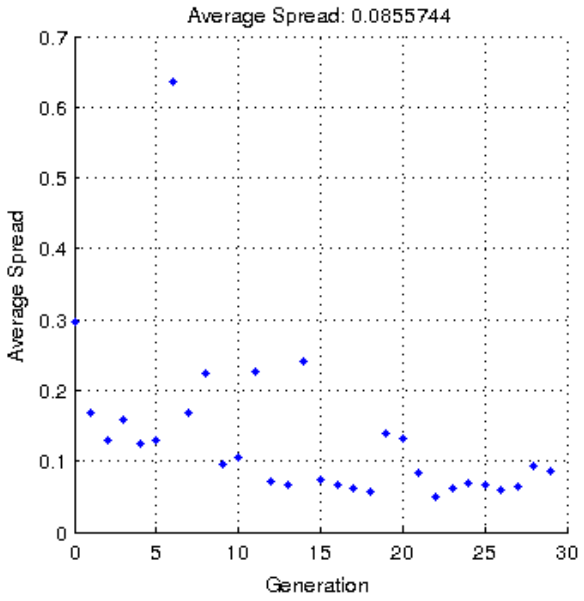

Fig. 3. Average spread

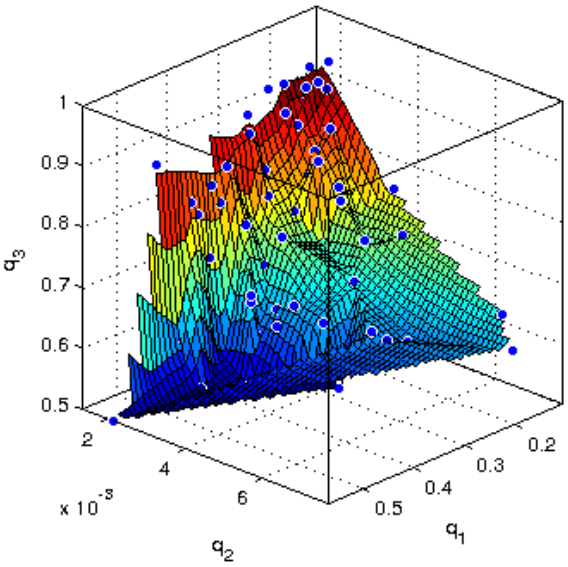

Fig. 4. Linear interpolated Pareto Front (NSGA-II)

space, this solution also gives moderate values for all three parameters. If we take into account that wireless sensor networks do not transfer a large amount of information, when choosing a concrete solution third objective can be neglected. Then selection of solution is reduced to a compromise between energy consumption and delay.

B. Single-objective approach using AUF

After optimization by a single objective, the GA has generated population of solutions that are close to minimum of aggregate utility function. The minimum value of the aggregate utility function is 1.2139, the average value of 1.7035, and the

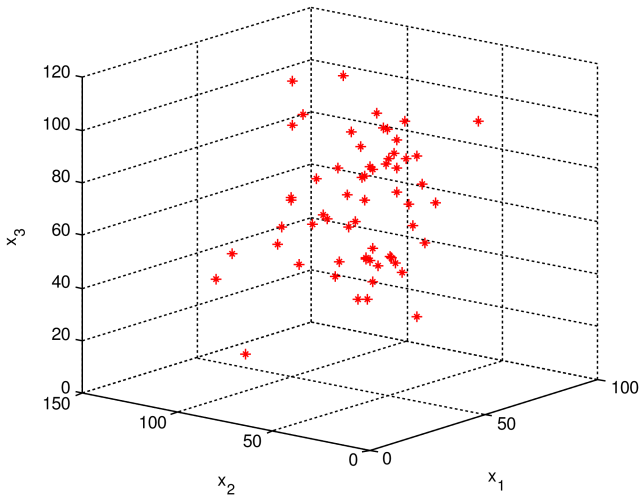

Fig. 5. Non-dominated solutions in problem space (NSGA)

TABLE I
CHOSEN SOLUTIONS (NSGA-II)

Selection objective	x_1	x_2	x_3	q_1	q_2	q_3
$min_{\mathbf{x}\in\mathbf{\Omega}}\{q_1\}$	84.3495	44	96	0.1076	0.0017	0.9185
$min_{\mathbf{x}\in\mathbf{\Omega}}\{q_2\}$	69.2336	123	104	0.2033	0.0014	0.8994
$min_{\mathbf{x}\in\mathbf{\Omega}}\{q_3\}$	43.3275	82	62	0.5648	0.0021	0.5003
Mean by all	55.4211	68	48	0.2627	0.0025	0.7041

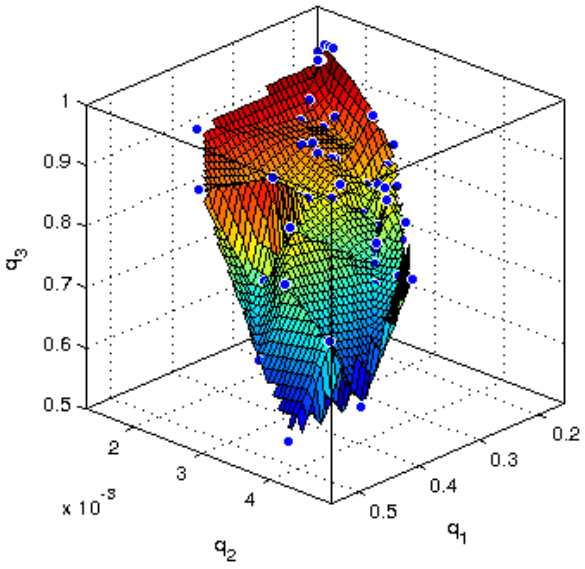

Fig. 6. Linear interpolated Pareto Front (AUF)

standard deviation is 1.3965. From this we can conclude that a large number of particular solutions lie close to minimum of aggregate utility function.

For easier comparison of the solutions obtained by solving the multiple-objective problem, for the each individual, value of each objective is determined and shown in the space of values (Fig. 6). By linear interpolation of points in the space

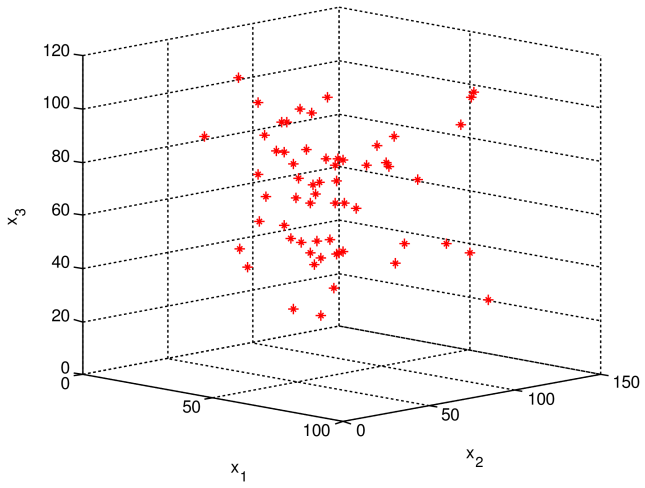

Fig. 7. Non-dominated solutions in problem space (AUF)

TABLE II
CHOSEN SOLUTIONS (AUF)

Objective	x_1	x_2	x_3	q_1	q_2	q_3	U
$\min_{x\in\Omega}\{U\}$	42.46	35	52	0.1591	0.0013	0.9238	1.21
$\min_{x\in\Omega}\{q_1\}$	42.69	35	52	0.1590	0.0014	0.9412	1.24
$\min_{x\in\Omega}\{q_2\}$	42.46	35	52	0.1519	0.0013	0.9238	1.21
$\min_{x\in\Omega}\{q_3\}$	42.44	35	67	0.5426	0.0043	0.5732	1.54
Mean	98.53	35	15	0.2818	0.0032	0.7312	1.46

of values, surface on which points lie is generated.

Fig. 7 shows the non-dominated solutions in the problem space. Elements of alternatives in the problem space do not take the full range of possible values.

Table II shows several chosen solutions. When selecting different objectives were used. The first solution achieves a minimum of aggregate utility function. Second, third and fourth solution, a minimum by the first, second and third objective, respectively. The fifth solution has moderate values for each objective. Low spread of obtained solutions proves the assumption about the loss of information when mapping multi-objective problem in single-objective.

The solutions of single-objective problem are more concentrated than the solutions of multi-objective problem. In the solution set of single-objective problem, there are points in the problem space that do not exist in the set of solutions of multi-objective problem. Due to the small elitism of the single-objective GA it can be assumed that these solutions do not lie near the Pareto front (dominated solutions).

V. CONCLUSION

In this paper we dealt with the problem situation relating to the choice the parameters S-MAC protocol to meet various objectives. The duty cycle and the size of contention window are selected as parameters. Energy consumption, delay, total achieved / unused bandwidth were chosen as the objectives. Aspiration level of multi-objective problem is the minimum for each objective. Using the NS-2 network simulator, model was developed to test the influence of the S-MAC protocol parameters on the network performance. Estimation of network performance is obtained by using the three selected measures. Optimization is performed in two ways: solution of multi-objective problem using NSGA-II, and solution of single-objective problem using AUF.

The entire process of finding a set of non-dominated solution is fully automated. Finally, the analysis of the obtained set of non-dominated solutions is performed and a comparison with the results of single-objective optimization is done. The analysis of results has led to some interesting conclusions:

- In both approaches, the obtained solutions in the problem area are covering 60-70% of the scope of allowed values of the elements of the problem situation.
- It is shown that the resulting solutions are a compromise between the chosen objective, which legitimate multi-objective approach to solving problems.
- It is shown that the mapping of multi-objective problem in single-objective leads to the loss of part of the information, which is reflected in the diversity of the obtained solutions (less coverage of Pareto front).
- By solving the single-objective problem, part of the obtained solutions does not lies in near the Pareto front.

Primjena FMEA metode u upravljanju kvalitetom telekomunikacijskih usluga

Mr.sc. Nermin Karahmetović
BH Telecom d.d. Sarajevo - RD Tuzla, Tuzla, Bosna i Hercegovina
nermin.karahmetovic@bih.net.ba

Sažetak - U implementaciji sistema za upravljanje kvalitetom (QMS, TQM i sl.) neophodna je primjena adekvatnih kombinacija metoda i alata. Kao jedna od metoda koja kompanijama stoji na raspolaganju je i FMEA metoda. Iako je prvobitno bila namjenjena za upravljanje kvalitetom u proizvodnim djelatnostima, u zadnje vrijeme se nerijetko primjenjuje i u uslužnim kompanijama. U ovom radu prezentirat će se mogućnost primjene ove metode u unapređenju telekomunikacijskih usluga i procesa koji prethode pružanju usluga. Svrha FMEA metode jeste poduzimanje akcija za eliminisanje ili smanjivanje broja grešaka ili nedostataka, počevši od onih koji imaju najveći značaj i prioritet. Dobiveni rezultati pružaju smjernice pri rangiranju grešaka na način da ukazuju koji problem treba prvo rješavati. Prema dobivenim rezultatima pristupa se prvo rješavanju grešaka s najvećim rizikom. U istraživanju FMEA metoda je primjenjena na procese koji učestvuju u isporuci paket usluga, na način da je izvršena analiza ključnih procesa i aktivnosti. Cilj analize procesa i aktivnosti uključenih u stvaranje paket usluge je povećanje njihove efikasnosti i efektivnosti, te maksimiziranje vrijednosti (kvaliteta) koja se paket usluzi dodaje u svakom procesu i njegovim aktivnostima. Rezultati dobiveni primjenom metode ukazuju na konkretne mjere i mjerljive pokazatelje uočenih nedostataka te u konačnici pokazuju da je moguće značajno povećati efikasnost posmatranih procesa.

I. UVOD

FMEA metoda (*eng. Failure Mode and Effect Analysis*) omogućava identifikaciju i sprječavanje problema na proizvodu/usluzi ili u procesu prije nego što i nastanu, a fokusirana je na prevenciju grešaka, odnosno smanjivanje mogućnosti da se greška dogodi, a u konačnici ima pozitivan uticaj na povećanje zadovoljstva korisnika.
Postoje četiri osnovne vrste analize utjecaja i posljedica grešaka: FMEA sistema, FMEA dizajna, FMEA procesa i FMEA usluga.

Neki autori spominju samo dvije vrste, i to: FMEA dizajna (DFMEA- Design Failure Mode and effect Analysis) i FMEA procesa (PFMEA-Process Failure Mode and effect Analysis) [1].

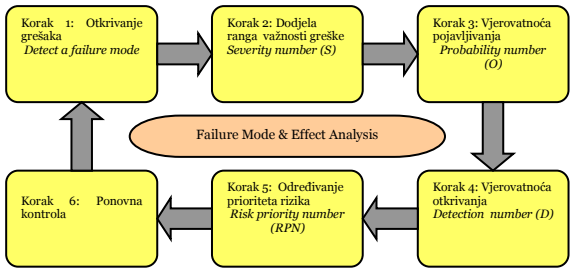
Metoda je prepoznatljiva po jednostavnosti i terminologiji kojom se koristi prilikom primjene, kao što su: greška, posljedica, rizik, uzrok greške, važnost, vjerovatnoća ponavljanja, vjerovatnoća otkrivanja i pojam faktora rizika.

U fazi dizajna usluge, procesa i sl. FMEA se koristi da bi se spriječile moguće greške, a u kasnijim fazama se koristi za sprovođenje kontrole.

FMEA je specifična metoda koja omogućava ocjenjivanje sistema, dizajna, procesa ili usluge svim mogućim oblicima u kojima se potencijalne greške mogu dogoditi. Za svaku uočenu ili prepoznatu grešku (bez obzira je li ona već uočena ili je potencijalna), radi se procjena vjerovatnoće pojavljivanja, važnosti i vjerovatnoće otkrivanja [2].

Analiza mogućih grešaka i njihovih posljedica predstavlja sistemski način osiguranja da sve moguće greške u dizajnu, procesu ili one koje prethode pružanju usluge budu uzete u obzir.

U suštini, FMEA je metoda kojom se maksimizira zadovoljstvo korisnika kroz potpuno eliminiranje ili djelimično smanjivanje uzroka problema koji se mogu pojaviti. Sa aspekta primjene (FMEA metode) izrazito je važno definisati da korisnik nije samo krajnji potrošač/kupac, već to može biti i naredni proces ili naredna operacija u istom procesu. Za optimalne rezultate u primjeni FMEA metode potrebno je da se započinje u najranijim fazama dizajna i sprovodi se kroz cijeli životni vijek usluge.



Slika 1. FMEA ciklus

Analiza mogućih grešaka i njihovih posljedica koristi se [3]:

- U toku dizajna ili redizajna procesa, proizvoda ili usluge, nakon provođenja QFD (Quality Function Development) metode, a prije nego li je dizajn finaliziran.
- Kada se postojeći proces, proizvod ili usluga primjenjuje na novi način.
- Prije razvoja planova kontrole novih ili modificiranih procesa.
- Kada se planiraju ciljevi unaprjeđivanja za postojeće procese, proizvode ili usluge.
- Kada se analiziraju greške u postojećim procesima, proizvodima ili uslugama.
- Povremeno kroz životni vijek procesa, proizvoda ili usluga.

FMEA usluga primjenjuje se za analizu usluge prije nego što usluga bude pružena korisniku. Budući da su osnovne

karakteristike usluge neopipljivost, nedjeljivost, nemogućnost uskladištenja, heterogenost i sl., kod primjene FMEA usluga treba posebnu pažnju posvetiti upravo ovim karakteristikama.
Primjenom ove metode za upravljanje kvalitetom usluga, najviše dolazi do izražaja raznolikost shvatanja pojma kvaliteta od strane korisnika kao krajnjeg potrošača, izražena kroz subjektivan osjećaj zadovoljstva ili nezadovoljstva pruženom uslugom.

II. OSNOVNI ELEMENTI PRIMJENE METODE

Shodno rečenome, cilj primjene FMEA metode je minimiziranje vjerovatnoće pojavljivanja grešaka. Slika 1. prikazuje korake koji su prisutni u primjeni metode. Kako bi se navedeni cilj adekvatno i sveobuhvatno realizirao, kroz različite faze internog i eksternog istraživanja prikupljaju se neophodni podaci, te se njihovom detaljnom analizom i obradom definišu određeni zaključci, te se predlažu mjere za unapređenje zadovoljstva korisnika paket usluge.
U teoriji i praksi implementacija FMEA metode neznatno varira zavisno od specifičnosti svake organizacije/kompanije. Ona u svom prvom koraku podrazumjeva formiranje jednog šireg tima, sastavljenog od stručnih ljudi različitih funkcija i znanja o procesima, uslugama, potrebama kupaca. Uključene funkcije su: dizajn, proizvodnja, testiranje, održavanje, nabava, prodaja, marketing i dr. Naredni korak je određivanje područja za primjenu FMEA. Primjenjuje li se na cjelokupni poslovni sistem, dizajn, proces ili samo na uslugu. Vrlo je važno da svi uključeni uposlenici koji provode primjenu metode poznaju područje svog djelovanja i da primjenjuju iste mjerne instrumente. Nakon toga se pristupa popunjavanju FMEA obrasca (Tabela 1.), kojeg svaka kompanija može prilagoditi svojim potrebama i specifičnostima. Naredni koraci se sastoje od prikupljanja informacija koje se unose u odgovarajuće kolone navedenog obrasca.
Za svaki od navednih uzroka se identifikuju, opisuju i unose postojeće kotrolne tačke ili procesi kontrole (kolona 7.). To mogu biti testovi, procedure ili mehanizmi koji se trenutno koriste da bi se izbjegle ili na vrijeme uočile pogreške i kako one nebi stigle do korisnika.

Za svaku od identifikovanih kontrola određuje se rang otkrivanja „D“ (*eng. detecting rating – D*).

Pomenutim rangom (kolona 8.) se procjenjuje koliko dobra može biti kontrola, odnosno koliko efikasna može biti u otkrivanju uzroka grešaka ili samih grešaka nakon što se pojavila a prije nego je stigla do korisnika. Vjerovatnoća otkrivanja se isto tako rangira na skali od 1 do 10, gdje 1 označava u potpunosti pouzdanu kontrolu, a 10 u potpunosti nepouzdanu kontrolu ili da kontrola uopšte ne postoji. Rang vjerovatnoće otkrivanja unosi se za svaki uzrok greške pojedinačno.

Nakon utvrđivanja ranga važnosti (S), ranga vjerovatnoće pojavljivanja (O) i ranga vjerovatnoće otkrivanja (D) uzroka greške, slijedi izračunavanje RPN faktora (kolona 9.) za svaku potencijalnu grešku pojedinačno. RPN (*eng. Risk Priority Number*) predstavlja faktor prioriteta rizika, i izračunava se po sljedećoj formuli:

$$RPN=S \times O \times D \quad (1)$$

Nakon izračunavanja RPN faktora, pristupa se izračunavanju CRIT faktora (*eng. Critical Factor* – tabela 1. kolona 10.) koji predstavlja faktor kritičnosti, a prema sljedećoj formuli:

$$CRIT=S \times O \quad (2)$$

Dobiveni rezultati pružaju smjernice pri rangiranju grešaka na način da ukazuju koji problem treba prvo rješavati. Prema dobivenim rezultatima pristupa se prvo rješavanju grešaka s najvećim rizikom. Nakon izračunavanja RPN faktora za svaku potencijalnu grešku, dobivene vrijednosti mogu se sabirati, te na taj način dobiti ukupni RPN faktor za cijeli posmatrani proces, uslugu ili sistem.

Nakon izračunavanja RPN faktora i faktora kritičnosti, rangiranja mogućih pogrešaka i njihovih posljedica, identifikuju se preporučene mjere (kolona 11.) tj. koraci za njihovo otklanjanje ili smanjenje ranga RPN i CRIT faktora. Ove mjere mogu biti promjene u procesu ili dizajnu usluge, uvođenje kontrolnih tačaka tamo gdje ih nije bilo i sl. Poduzete mjere imaju za cilj da u budućnosti izbjegnu pojavljivanje grešaka, smanjenje troškova, uštede u vremenu, povećanje zadovoljstva korisnika, te povećanje konkurentnosti.

Prijem i kontrola prijema terminalne opreme (mobilinih telefona) od dobavljača	Mogućnost prijema neispravnih ili uređaja sa skrivenim nedostacima te puštanje takvog uređaja u prodaju	Nepotrebno velik broj reklamacija na prodate uređaje i kroz to nezadovoljstvo korisnika.	8	Tvornička greška na uređaju, neadekvatno skladištenje i rukovanje u transportu ili skladištu, neadekvatna kontrola kod dobavljača i sl.	7	Uzorkovanje i kontrola po ugovoru sa 3 ili 1% zavisno od dobavljača,kontrol a nakon otkrivanja grešaka.	7	392	56	Kontrola prijema i uzorkovanje po sistemu ANSI/ASQC Z1.4.(jednostruko uzorkovanje). Vođenje evidencije i zapisa o kontroli, vođenje evidencije i zapisa o izmjerenim vrijednostima vlage na ambalaži i samom uređaju.	Rukovodioc i u prodaji, komisija za prijem, magacinsko osoblje i dr.	Kontrola prijema i uzorkovanje po sistemu ANSI/ASQC Z1.4.(jednostruko uzorkovanje). Vođenje evidencije i zapisa o kontroli, vođenje evidencije i zapisa o izmjerenim vrijednostima vlage na ambalaži i samom uređaju.	4	5	6	120

Također je vrlo važno da se evidentira tko je odgovoran za provođenje tih mjera kao i krajnji datum realizacije predviđenih mjera (kolona 12.).
Prilikom određivanja rizika i prioriteta pojedinih mjera odnosno akcija, nije dovoljno samo oslanjati se na RPN i faktor kritičnosti, već je potrebno uključiti i ličnu procjenu i sud svih članova tima. Nakon što se završi sa provođenjem predloženih mjera, rezultati se evidentiraju u FMEA obrazac (kolona 13.). Ukoliko su preduzete mjere uspješno sprovedene, one rezultiraju nižim rangom važnosti (S), nižim rangom vjerovatnoće pojavljivanja (O) te nižim rangom vjerovatnoće otkrivanja (D), što u konačnici rezultira nižim RPN faktorom.
Na kraju se u Obrazac unose i te nove vrijednosti S, O, D, RPN (kolona 14, 15, 16, 17).
U svakom procesu definiraju se ulazni i izlazni zahtjevi, kontrolne mjere i potrebni resursi za uspješnu realizaciju svih operacija u procesu. U primjeni procesne FMEA metode definicija korisnika/potrošača nije jedina pretpostavka, već se kao potencijalni „korisnik“ može posmatrati i naredni procesni korak, odnosno operacija.
Bez jasne definicije procesa i procesnih operacija nije moguće ostvariti maksimalne koristi od primjene FMEA metode, s obzirom da postoji mogućnost zanemarivanja bitnih dijelova procesa i fokusiranja na područja koja ne zahtjevaju veliku pažnju. Iz tog razloga, poželjno bi bilo da uz opis procesa bude i grafički prikaz radi boljeg razumjevanja.
Analiza uticaja i posljedica grešaka može se posmatrati i kao analiza rizika sa osnovnim ciljem dobijanja odgovora na dva osnovna pitanja:

- koja su sva moguća odstupanja (greške) od propisanog zahtjeva, odnosno šta sve može poći pogrešnim pravcem i tako prouzrokovati potencijalne gubitke i nepotrebno trošenje resursa, i
- ukoliko postoji mogućnost nastanka grešaka, koja je vjerovatnoća nihovog pojavljivanja i koje posljedice donose u odnosu na uslugu, proces ili cjelokupan sistem.

U tom smislu vrši se detaljna analiza pritužbi korisnika u svim slučajevima koji su zabilježeni i radi se kvalitativna procjena važnosti za korisnika i kompaniju da se te greške izbjegnu u budućem radu. Za ovaj segment moguće je koristiti sve interne resurse, baze podataka i ankete uposlenika i korisnika. Dodatno, ukoliko je detektovano da se neka greška počela pojavljivati pristupa se procjeni vjerovatnoće njenog pojavljivanja, te se u taj podatak kvantificira sa posljedicama koje ta greška sa sobom donosi. Za procjenu vjerovatnoće pojavljivanja koriste se izvještaji i svi dosadašnji zabilježeni slučajevi otkrivanja, matematičke procjene i sl.

U tom smislu kao osnovna prednost ove metode je njena preventivna komponenta izražena kroz utjecaj na probleme prije nego se oni i pojave ili nakon već prvih pojavljivanja, jer se na taj način može smanjiti vjerovatnoća njihova pojavljivanja u budućnosti, a ako uzmemo u obzir činjenicu da je problem već poznat i sigurno je da će nastati, moguće je i minimizirati njegove posljedice. Na taj način, funkcija praćenja troškova nadopunjava se mogućnostima njihovog smanjivanja, a princip rješavanja problema, ustupa mjesto pronalaženju načina da se oni nikada i ne dogode.

III. METODOLOGIJA ISTRAŽIVANJA

Upravljanje kvalitetom telekomunikacijskih usluga primjenom FMEA metodologije u ovom istraživanju ima za cilj da se testiraju mogućnosti uključivanja uposlenika u procesima prodaje usluga pri unapređenju tih procesa, te da se u budućnosti ova metodologija uključi kao formalni alat u cjelokupno implementiranom QMS (Quality Management Sistem) sistemu BH Telecoma.

U istraživanju su obuhvaćeni procesi u prodaji paket usluge kod čijih je outputa postojalo najviše pritužbi krajnjih korisnika ili narednog korisnika tog procesa. Naime, radi se o usluzi kojom se GSM korisnicima pružaju usluge govora, prenosa podataka, i terminalne opreme.

Za potrebe istraživanja u primjeni FMEA metodologije angažovano je i obučeno 16 zaposlenika iz procesa prodaje i postprodajne podrške. Također, u procesu davanja prijedloga i procjene uspješnosti provođenja datih prijedloga učestvovali su i rukovodioci organizacionih cjelina u kojim se odvijaju posmatrani procesi.

Usaglašena je metodologija vrijednovanja kriterija i faktora u FMEA obrascima te ostavljena sloboda svim uljučenim za definisanje prijedloga mjera za poboljšanje.

Nakon unesenih podataka u FMEA obrasce i dostavljanja istih, izvršeno je kvantitativno vrednovanje unesenih podataka (S, O, D, RPN i CRIT) te je potom izvršeno usaglašavanje i konačno definisanje onih prijedloga i mjera koji su imali učestalost veću od 75%. Za kvantitativno vrednovanje korišteni su interni izvori podataka, statistički izvještaji te komparacija različitih internih baza podataka i mjesečnih izvještaja.

Za potrebe utvrđivanja ranga važnosti, vjerovatnoće pojavljivanja i vjerovatnoće otkrivanja mnoge kompanije i organizacije koriste razvijene kriterije (Tabela 2.) [4].

Analiza aktivnosti koje se realiziraju u procesima prodaje i podrške paket usluge treba da odgovore na osnovna pitanja efikasnosti tih procesa i njihovim efektima kod krajnjih korisnika. Analiza će obuhvatiti sve aktivnosti koje se direktno odnose na procese u koje su uključeni organizacioni dijelovi prodaje i podrške paket usluge a za koje je analizom potvrđena mogućnost unapređenja. Iako se određene aktivnosti vezane za paket usluge obavljaju i u drugim organizacionim dijelovima, tj. van okvira djelovanja cjelina prodaje i podrške, njihovo uključivanje koristit će se samo u slučajevima gdje su uposlenici iz prodaje i podrške naredni korisnici u lancu realizacije paket usluge.

U radu će se primjenom FMEA metodologije pokušati ukazati na mogućnosti unaprjeđenja procesa i aktivnosti za koje je praćenjem i analizom uočena potreba za unaprijeđenje, a sve s ciljem povećanja sveukupnog kvaliteta paket usluga.

Proces osmišljavanja paket usluga, različitih profila i sadržaja unutar ove usluge jedna je od bitnih faza stvaranja i prodaje paket usluge. Uključenost svih resursa (znanje, tehnologija, organizacija i dr.) preduslov je za uspješnost ove faze. U tom kontekstu rezultati istraživanja treba da posluže kao ulazni parametri u procesu kreiranja novih i unaprjeđenja postojećih usluga i servisa, a sve kako bi usluga bila što atraktivnija i pouzdanija. Dodatno, rezultati istraživanja i provedenih posmatranja poslužiti će kod definisanja potrebnih podataka i informacija u internim bazama podataka. Ažuriranje baza podataka kroz poboljšanje ažurnosti, za vanjske i interne korisnike preduslov je normalnog odvijanja procesa prodaje paket usluge.

Prijem i kontrola terminalne opreme koja ulazi u sastav paket usluge, aktivnost je koja mora biti u stanju da, pored kvantitativnog, obezbjedi i kvalitativni aspekt kontrole isporučene opreme. Osiguranju potrebnog kvaliteta, pored kontrole terminalne opreme, doprinosi i njeno adekvatno skladištenje, te će i ova aktivnost biti predmetom analize.

Upravljanje distribucijom terminalne opreme i ostalih komponenti potrebnih za pružanje cjelovite paket usluge, također, su značajne aktivnosti u cjelokupnom toku realizacije paket usluge. Optimalna iskorištenost raspoloživih kapaciteta (ljudskih, materijalnih i dr.) u stanju je da efikasno upravlja zalihama u cilju njihove raspoloživosti u skladu sa potražnjom.

Analizom svih prikupljenih podataka o reklamiranim slučajevima, obavljenih razgovora sa zaposlenicima zaduženim za različite aktivnosti unutar više odvojenih procesa, obilaskom svih prostorija za skladištenje, prostorija za prijem i otpremu terminalne opreme u procesu distribucije, pregledom transportnih sredstava, analizom procesa i samog čina prodaje terminalne opreme u sklopu paketa i dr., moguće je izolovati slabe tačke u svakom od odvojenih procesa a koji su u funkciji konačne isporuke terminalne opreme korisniku zajedno sa pripadajućom uslugom.

Način i mjere za otklanjanje nedostataka koji mogu direktno ili indirektno umanjiti kvalitet i funkcionalnost terminalne opreme, a samim time i kvalitet i funkcionalnost cjelokupnog paketa prikazati će se kroz FMEA metodologiju upravljanja kvalitetom, zajedno sa svim ostalim aspektima upravljanja kvalitetom.
Smanjenje RPN i CRIT faktora ostvaruju se kroz korekcije na izolovana procesa i više pratećih aktivnosti unutar procesa, a koji su uključeni u plasman paket usluge. Ti procesi su:

1. Prijem i kontrola prijema terminalne opreme,
2. Distribucija terminalne opreme u sklopu paket usluge,
3. Prodaja paket usluge,
4. Reklamacije i žalbe na kvalitet paket usluge.

Nakon opisa procesa koji su uključeni zaposlenici analizirali, u FMEA obrazac evidentirane su sve varijacije potencijalnih neuspjeha, a potom i efekti i učinci svakog neuspjeha. Nakon ovoga, pristupilo se izdvajanju i nabrajanju mogućih uzroka neuspjeha procesa, te mjere kontrole koje se trenutno obavljaju nad procesom ili aktivnostima unutar procesa. U skladu sa opisanom metodologijom određenim kategorijama dodjeljene su vrijednosti na osnovu kojih su izračunati RPN i CRIT faktor. U procjeni i kvantitativnom vrednovanju kriterija S, O i D uposlnici su se koristili izvještajima o reklamacijama, interim evidencijama o prijavama nedostataka i grešaka, izvještajima od strane komisije za kontrolu prijema terminalne opreme, anketama učesnika posmatranih procesa i njhovim kvantitativno/kvalitativnim procjenama i projekcijama. Izbor i preporuka korektivnih akcija i odgovornih zaposlenika treba da rezultira poboljšanjem kvaliteta kako samog procesa/aktivnosti, tako i njegovog *outputa.* Nakon što su

TABLICA II. KRITERIJI ZA ODREĐIVANJE RANGA VAŽNOSTI, VJEROVATNOĆE POJAVLJIVANJA I OTKRIVANJA

Rang	Kriterij		
	Važnost (S)	Vjerovatnoća pojavljivanja (O)	Vjerovatnoća otkrivanja (D)
1	Korisnici ne uočavaju grešku	Vrlo nevjerovatna. greška se pojavljuje manje od jednom u milion i pol slučajeva.	Gotovo sigurno otkrivanje greške.
2	Neki korisnici primjećuju grešku. Vrlo mali uticaj na uslugu ili proces.	Izuzetno rijetka. Jednom u 150.000 slučajeva.	Odlične prilike za otkrivanje greške: 99,99%
3	Većina kupaca primječuje grešku. Mali uticaj na uslugu ili proces.	Rijetko. Jednom u 15.000 slučajeva.	Vrlo viska vjerovatnoća otkrivanja greške: 99,9%
4	Korisnici blago uznemireni. Usluga ili proces pokazuje male nedostatke.	Nekoliko. Jednom u 2.000 slučajeva.	Visoka vjerovatnoća otkrivanja greške: 95%
5	Korisnici uznemireni. Nekritične komponente usluge ili procesa neadekvatne.	Povremeno. Jednom u 500 slučajeva.	Umjerena vjerovatnoća otkrivanja greške: 80%
6	Korisnici doživljavaju neugodnosti. Nekritične komponente usluge ili procesa neadekvatne.	Često. Jednom u 100 slučajeva.	Moguće je otkriti grešku: 50%
7	Korisnici prilično nezadovoljni. Djelimična nefunkcionalnost nekritičnih komponenti usluge ili procesa.	Vrlo često. Jednom u 20 slučajeva.	Mala vjerovatnoća otkrivanja greške: 20%
8	Korisnici vrlo nezadovoljni. Usluga ili proces nije u skladu sa očekivanjima.	Ponavljano. Jednom u 10 slučajeva.	Vrlo nevjerovatno otkrivanje greške: 10%
9	Sigurnost korisnika i usklađenost sa regulativom ugrožena, sa upozorenjem.	Uobičajeno. Jednom u 3 slučaja	Izrazito niska vjerovatnoća otkrivanja greške: 5%
10	Katastrofalni rezultati. Sigurnost korisnika ili usklađenost sa regulativom ugrožena, bez upozorenja.	Gotovo sigurno. Više od jednom u dva slučaja.	Gotovo sigurno da greška neće biti otkrivena ili ne postoje kontrolni mehanizmi koji mogu identifikovati grešku.

stepenu važnosti (S), vjerovatnoći pojavljivanja (O) i vjerovatnoći otkrivanja (D).

IV. REZULTATI ISTRAŽIVANJA

Na osnovu rezultata dobivenih tokom provedenog istraživanja i unesenih parametara u FMEA obrasce, odabrani su procesi kod kojih su uočene greške i nedostaci sa najvećim rizikom. Shodno rečenome, rezultati obavljenog istraživanja i primjene FMEA metodologije odredili su procese i aktivnosti koji trebaju biti predmetom unaprjeđenja i poboljšanja. Radi se o četiri evidentirane sve nabrojane mjere vrijednosti, izvršen je izračun ili procjena novih vrijednosti RPN i CRIT faktora.

Detaljnim posmatranjem i analizom toka realizacije prijema i transporta mobilnih uređaja, uočeni su brojni nedostaci čije otklanjanje ili minimiziranje može uticati na značajno smanjenje broja reklamacija na prodate mobilne uređaje i ostalu terminalnu opremu. Izmjerene vrijednosti su prikazane u Tabeli broj 3.

Nakon provedenih posmatranja i analiza, od strane zaposlenika koji su učestvovali u istraživanju, dati su prijedlozi mjera i urađena je procjena rezultata i očekivanja od primjene

predloženih mjera. Rezultati proračuna tih procjena i očekivanja dati su u Tabeli broj 4.

TABLICA III. IZMJERENE VRIJEDNOSTI POSMATRANIH PROCESA

Proces redni broj:	**1.**	**2.**	**3.**	**4.**
Važnost (S)	8	6	5	8
Vjerovatnoća pojavljivanja (O)	7	4	8	6
Vjerovatnoća otkrivanja (D)	7	7	6	7
RPN	392	168	240	336
CRIT	56	24	40	48

TABLICA IV. IZRAČUN VRIJEDNOSTI PREDLOŽENIH MJERA

Proces redni broj:	**1.**	**2.**	**3.**	**4.**
Važnost (S)	4	4	2	4
Vjerovatnoća pojavljivanja (O)	5	2	4	4
Vjerovatnoća otkrivanja (D)	6	4	4	5
RPN	120	32	32	80
CRIT	20	8	8	16

Analiza uočenih nedostataka u procesima i prijedlozi mjera za unaprjeđenje prikazanih numeričkim vrijednostima u tabelama 3. i 4. u svom opisnom dijelu rezimirana su kroz opisna opažanja, koja iznosimo u nastavku rada.

Prijem i kontrola prijema terminalne opreme - Kontrolom procesa i analizom prikupljenih podataka konstatovano je sljedeće:

- Potencijalni neuspjeh procesa ogleda se u mogućnosti prijema neispravnih ili uređaja sa skrivenim nedostacima te puštanje takvog uređaja u prodaju,
- Potencijalni učinci neuspjeha ogledaju se u nepotrebno velikom broju reklamacija na prodate uređaje i kroz to nezadovoljstvo korisnika,
- Mogući uzroci su tvornička greška na uređaju, neadekvatno skladištenje i rukovanje u transportu ili skladištu, neadekvatna kontrola kod dobavljača i sl.,
- Trenutne kontrole procesa se vrše na način da se uzorkovanje i kontrola po ugovoru sa 3 ili 1% zavisno od dobavljača, te kontrolom nakon otkrivanja grešaka,
- Preporučene akcije su kontrola prijema i uzorkovanje po sistemu ANSI/ASQC Z1.4.(jednostruko uzorkovanje). Vođenje evidencije i zapisa o kontroli, vođenje evidencije i zapisa o izmjerenim vrijednostima vlage na ambalaži i samom uređaju,
- Odgovorni uposlenici za provođenje preporučenih mjera su rukovodioci u prodaji, komisija za prijem, magacinsko osoblje i ostali uposlenici po potrebi.

Distribucija terminalne opreme u sklopu paket usluge - Kontrolom procesa i analizom prikupljenih podataka konstatovano je sljedeće:

- Potencijalni neuspjeh procesa ogleda se u mogućnosti nastanaka oštećenja na terminalnoj opremi u procesu distribucije, sporoj i neefikasnoj distribuciji i redistribuciji terminalne opreme, neefikasnom korištenju ljudskih i materijalno-tehničkih sredstava,
- Potencijalni učinci neuspjeha ogledaju se u oštećenjima i nastajanju kvarova na terminalnoj opremi, kašnjenju sa isporukom terminalne opreme, nepotrebno i neopravdano visokim troškovima distribucije i redistribucije,
- Kao mogući uzroci su otkriveni neadekvatan utovar i istovar, neprilagođena i neadekvatna transportna sredstva, postojeća organizacija poslova disrtibucije, angažman nepotrebnog broja uposlenika i odvajanje tih zaposlenika od redovnih radnih zadataka, troškovi putovanja (dnevnice i dr.), amortizacija vozila, troškovi goriva i sl.,
- Trenutne kontrole procesa se vrše na način da se vrši kvantitativna kontrola prijema/predaje distribuiranih asortimana, organizacija i upravljanje procesom distribucije vrši se na nivou Direkcije za prodaju i podršku i Regionalnih direkcija,
- Preporučene akcije realizovati kroz obezbjeđenje adekvatnih transportnih sredstava, da se lokacija utovara i istovara terminalne opreme obezbjedi u zatvorenim prostorijama bez direktnog atmosferskog uticaja (kiša, snijeg i sl.), organizaciju centralizovane distribucije iz Centralnog skladišta do priručnih sladišta regionalnih direkcija i istovremenu redistribuciju te obezbjediti aktivno upravljanje distribucijom,
- Odgovorni uposlenici za provođenje preporučenih mjera su rukovodioci u prodaji i distribuciji te magacinsko osoblje.

Prodaja paket usluge - Kontrolom procesa i analizom prikupljenih podataka konstatovano je sljedeće:

- Potencijalni neuspjeh procesa ogleda se u tome što se prodaja asemblirane usluge uglavnom odvija na način da korisnik ne dobije dovoljno informacija, kao i da korisniku nije prikladno i u potpunosti prezentirana terminalna oprema koja mu se prodaje,
- Potencijalni učinci neuspjeha ogledaju se u čestim prigovorima i žalbama korisnika da nisu dobili sve ili neke od informacija vezanih za terminalnu opremu,
- Mogući uzrok je da su šalterski radnici nedovoljno stručni i obučeni da daju sve informacije koje korisnici očekuju a odnose se na specifikaciju i funkcionalne karakteristike TO, da šalterska radna mjesta u tradicionalnim (poštanskim) šalter salama ne obezbjeđuju uslove za kvalitetnu prezentaciju terminalne opreme, da je starosna struktura zaposlenih u prodaji neadekvatna, te da je prisutan nesistematičan i nedovoljno definisan sistem obuke prodajnog osoblja po pitanju upoznavanja sa traženim specifikacijama terminalne opreme,
- Trenutne kontrole procesa se vrše kroz povremene i izolovane pojedinačne kontrole na prodajnim mjestima,
- Preporučene akcije podrazumjevaju intezivniju i obaveznu obuku zaposlenika sa ciljem upoznavanja osnova korištenja naprednih GSM servisa i aplikacija, inteziviranjem koncepta prodaje putem Telekom centara kao ambijenta koji omogućava i adekvatnu prodaju TO, obavezno propisanu konačnu kontrolu terminalne opreme i njenu kompatibilnost sa korisničkim paketom u momentu prodaje paketa i prije samog uručenja iste korisniku,
- Odgovorni uposlenici za provođenje preporučenih mjera su Top menadžment, menadžment prodaje i podrške, rukovodioci i zaposlenici u prodaji.

Reklamacije i žalbe na kvalitet paket usluge - Kontrolom procesa i analizom prikupljenih podataka konstatovano je sljedeće:

- Potencijalni neuspjeh procesa ogleda se u nepotrebnom i, za korisnika, dugom periodu rješavanja reklamacija, ne rješavanje reklamacije u skladu sa očekivanjima korisnika, višestruko pojavljivanje istih kvarova na TO, poništenje garancija na terminalnu opremu i sl.,
- Potencijalni učinci neuspjeha ogledaju se u nezadovoljstvu korisnika, neizvjesnoj ponovnoj kupovini, troškovima reklamacija, sudskim troškovima, gubitcima kroz izostalo korištenje GSM usluga za vrijeme trajanje reklamacije,

- Mogući uzroci su nekvalitetan prijem i obrada reklamacija, nepostojanje fleksibilnih i alternativnih rješenja i opcija, nekvalitetna servisna podrška, neadekvatan pritisak na servisne centre da kvalitetnije pristupaju rješavanju reklamacija, neupitna i bezuslovna konačna ocjena i nalaz servisnog centra a koja je uzrokovana neusklađenošću interesa telekom operatora i servisnih centara,
- Trenutne kontrole procesa se vrše po proceduri za rješavanje reklamacija TO, kontrolu kroz aplikaciju za reklamacije TO, te kontrolu obavljenu u servisnim centrima,
- Preporučene akcije podrazumjevaju obezbjeđenje mehanizama koji će omogućiti zamjenu ili popravak terminalne opreme o trošku telekom operatora tamo gdje ima interesa i gdje postoji opravdana dilema da korisnik nije kriv za nastali kvar, istrajavanje na konstantnom pritisku na servisne centre da otklanjanju kvarova na TO posvete više pažnje, integrisanje aplikacije za reklamacije u jedinstveni aplikativni sistem (korisnička baza - produkti),
- Odgovorni uposlenici za provođenje preporučenih mjera su menadžment za razvoj poslovanja, menadžment prodaje i podrške, menadžment EFP-a, i drugi po potrebi.

V. ZAKLJUČNA RAZMATRANJA

Upravljanje kvalitetom telekomunikacijskih usluga treba da obezbjedi brojne koristi, a njihov uticaj se, prije svega, treba posmatrati kroz uticaj kvaliteta na zadovoljstvo korisnika. Za razliku od upravljanja kvalitetom u procesima proizvodnje materijalnih dobara (proizvoda i roba), upravljanje kvalitetom usluga je mnogo suptilnije i zahtjeva intezivan monitoring svih procesa/aktivnosti integralno.

Praksa je pokazala da niti jedan implementirani QMS sistem nije održiv dugoročno i da zahtjeva stalnu nadogradnju kroz kritičko preispitivanje postojećeg sistema rada. Ukoliko se uzme u obzir jasno izražena dinamika promjena koja je prisutna u telekomunikacijskom sektoru, onda je jasno da je neminovna i intezivna primjena različitih metoda, modela i alata za upravljanje kvalitetom, sve šireg spektra, usluga.

Prezentirani primjer upravljanja kvalitetom telekomunikacijskih usluga primjenom FMEA metodologije pokazuje da je on itekako primjenjiv i u domenu usluga. Prisutni su brojni primjeri primjene ove metode u uslužnim i trgovinskim kompanijama [6]. Ono bitno što se izdvaja nakon primjene ove metodologije jeste to da se pokazalo da zaposlenici koji su aktivni učesnici i izvršioci procesa mogu biti izvrsni analitičari koji su sposobni da, ukoliko im se u ruke da adekvatan alat, prepoznaju manjkavosti procesa i značajno unaprijede procese u kojima učestvuju.

Kao konkretne zaključke izdvojit ćemo i sljedeća opažanja i mjere za unaprjeđenje, i to kako slijedi:

- Prijem i kontrolu prijema terminalne opreme potrebno je organizovati na način koji obezbjeđuje veću pouzdanost kod otkrivanja aparata sa greškom. Prijedlog za kontrolu je organizacija iste po sistemu ANSI/ASQC Z1.4. po principu jednostrukog uzorkovanja, normalnog nivoa kontrole kvaliteta. Izmjenom postojećih ugovora, predvidjeti kontrolu u skladištima primaoca opreme a ne u skladištima dobavljača.
- Disrtibuciju i redistribuciju terminalne opreme organizovati centralizovano, tj. na nivou cjelokupnog telekom operatora, gdje bi se sva distribucija i redistribucija obavljala iz jedne polazne tačke tj. od centralnog skladišta prema svim regionalnim i priručnim skladištima.
- Prodaju terminalne opreme u sklopu paket usluge organizovati na način da se aplikativna finalizacija prodaje obavlja tek nakon što je korisnik odabrao, pregledao i isprobao željeni aparat, te na otpremnici predvidjeti formu kojom korisnik i potvrđuje da je to tim redoslijedom izvršeno. Tek nakon ovih radnji i potpisivanja dokumentacije korisniku uručivati aparat uz ovjeru garancije. Na takav način u značajnoj mjeri bi se obezbjedilo: dodatna (prijeko potrebna finalna) kontrola terminalne opreme prije uručivanja iste korisniku, smanjenje broja slučajeva u kojima korisnik nakon završene prodaje (potpisivanja dokumenacije i ovjere garancije) traži povrat aparata sa obrazloženjem da nije želio taj model i sl.
- Putem nadležnih organizacionih dijelova telekom operatora potrebno je jasno definisati programe obuka i edukacija prodajnog i osoblja u podršci paket usluge, kako bi se i u tom segmentu smanjile mogućnosti za nastanak situacija u kojem navedeno osoblje nije u mogućnosti da na zahtjev korisnika ponudi potpunu i kvalitetnu informaciju ili još važnije, da ne ponudi netačnu informaciju korisniku što direktno proizvodi nezadovoljstvo kod korisnika paket usluge.
- Obezbjediti sistem podnošenja i evidentiranja svih vrsta pritužbi korisnika na način da sam proces prijave i evidencije pritužbe bude stimulirajući i lagodan za korisnika, a sve kako bi se obezbjedile dragocjene informacije o potencijalnim propustima i manjkavostima unutar procesa u pružanju paket usluga.
- Podršku za monitoring reklamacija na terminalnu opremu ostvariti integracijom postojećih aplikativnih rješenja za evidenciju i praćenje reklamacije u jedinstven aplikatini sistem, a koji će obezbjeđivati sve neophodne informacije za adekvatno upravljanje procesom reklamacija korisnika.
- Prije konačne implementacije predloženih mjera za poboljšanje kvaliteta paket usluge potrebno je formirati radni tim za izradu i testiranje svih funkcionalnosti procesa i njihovih *outputa*. Tek nakon tih aktivnosti pristupiti donošenju konačne odluke za njihovu primjenu.
- Detaljno razmotriti mogućnost implementacije garancije prodavca na isporučenu terminalnu opremu, tj. garancije koju bi telekom operatori nudili svojim korisnicima, a u skladu sa iskustvima kompanije *Asurion* iz SAD-a. Naravno, tačni uslovi pod kojima bi se vršilo osiguranje i reosiguranje trebaju biti predmetom opsežnih razgovora i pregovora sa osiguravajućim kompanijama.
- Ukrupnjavanjem pojedinačnih procesa, te jasnim definisanjem vlasnika svakog procesa (ime i prezime zaposlenika) omogućiti efikasniji monitoring, kontrolu i realizaciju svih aktivnosti i zadataka cjelokupnog niza procesa u prodaji paket usluge.

SOFTWARE ENGINEERING & TOOLS

Experiences from building a EUD business portal

Abstract - End user development (EUD) is the idea of providing end users, professionals outside computer science community, means to develop their own software. This idea has received special attention by domain experts who would like to easily modify software applications to their needs, without intervention of technical professionals and without learning conventional programming languages. The end user development is in fact a system property, closely related to system adaptability that should be built into a system to enable number of modifications at different system levels securing powerful expressions that would satisfy the end user needs. This is a challenging requirement for every software provider. There are a number of identified system perspectives, critical to EUD, and general guiding principles that should be addressed. However, in reality, building these properties into the concrete system, a number of complex and interrelated issues have to be solved. In this paper we report challenges that we addressed while implementing end user development capability into a software system within business domain.

I. INTRODUCTION

End User Development is focused around concept of providing means and tools for non-professional developers to participate in software development. Lieberman at el. give the following definition [1]: "End-User Development can be defined as a set of methods, techniques, and tools that allow user of software systems, who are acting as non-professional software developers, at some point to create, modify or extend a software artifact."

Spreadsheet is the most popular and well-known EUD tool, but there is an increase in the number of solutions such as scripting programming languages or graphical mashup tools that combine existing functionality into composite applications. The main reason for the popularity of EUD is the cost and time expense in traditional on-demand software development that many organizations face. The downside is the lack of quality in terms of reliability and security, especially in mission critical computing.

Our motivation for building a EUD business portal is to enable our customers with a tool for creating applications that implement simple business processes yet uncovered by their existing IS solutions. Such implementations are commonly non-critical with lower return of investment. This decision was made after a decade of software development experience in business domain designing and delivering various customer requests.

Building an end-user development system from technical perspective means combining and applying numerous existing software engineering concepts that are offered to improve the software lifecycle process. Usually the ideas behind these concepts are clear however their implementation is full of traps and obstacles.

Here we will elaborate on one particular case study how some of the most famous software engineering concepts are implemented and we elaborate the problems that have to be solved. The following concepts are addressed: automated customization of products to customers, automated production process, automatized delivery process and web oriented end user development process.

II. CONTEXT OF THE STUDY

We illustrate the concepts of this paper based on an example of software development in the supply chain management (SCM) domain. More precisely, the focus of this paper will be the software for supporting the continuous control of trading contracts. Trading companies are businesses usually selling different kinds of products to consumers. The products are ordered from different producers, offered in a retail stores and resold to buyers. One typical example is food shop. The relation between trading company and producer is defined by trading agreement. This contract includes metrics such as minimal number of products to be exposed on shelves, product positioning inside shop or minimum stock per product to be ensured. Contracts are subjects of control and future management that is performed by field agents dispatched by producers themselves. They ensure that for each of their products being sold, metrics agreed in contracts are being fulfilled across retail stores. In sequel, the software for supporting agents at managing trading contracts will be referred as Manage Trade software.

The company that is developing the Manage Trade software has long tradition and numerous customers. Our customers are before mentioned producers and distributors of goods. The core software system has been evolving for more than 10 years. A numerous improvements have been introduced in the software system. Here we will mention just few that have implications for our future elaborations.

1. When contract is signed between a producer and trading company, a number of agents are engaged to control and manage the contract execution. For that purpose, a number of software applications - one per agent - are developed for the purpose of one specific contract. Each software application has implemented one smaller derivation from the contract. For that purpose we introduced a feature of automated customization in our Manage Trade software system. That feature enables to automatically derive a number of customized software applications for every different contract.

2. Since we have many customers we have identified similarities in the agreements and contract management processes. A logical step was to automate software production with maximal reuse of existing software. Therefore, we developed our Domain Specific Language (DSL), a script language that describes the differences introduced with each contract by inheriting from common predefined constructs. That way all the specifics in applications for different customers are expressed easily.

3. We developed a Web based system coordinating and supplying data to applications from all agents by using a single server database instance for multiple contracts and producers.

4. Further step in improving our business was to automate the software delivery process. In that aim we implemented a Web based system that enabled Web based delivery of software applications to the agents of specific contract.

5. Our next step in improving our business is empowering our customers to develop their contract support system and thus reuse the concepts of the End user development (EUD) paradigm. A specific feature would be introduced in our Web based system to enable end user development. This feature we will refer as EUD portal.

III. EUD PORTAL – CONCEPT AND DEFINITIONS

EUD portal is a Web based system for definition, automatic construction and delivery of software applications in a certain domain of business. We observe and describe EUD portal use cases from different perspectives:

1) From *application development perspective* it is a web platform for modeling software applications using a provided DSL language. Resulting software applications

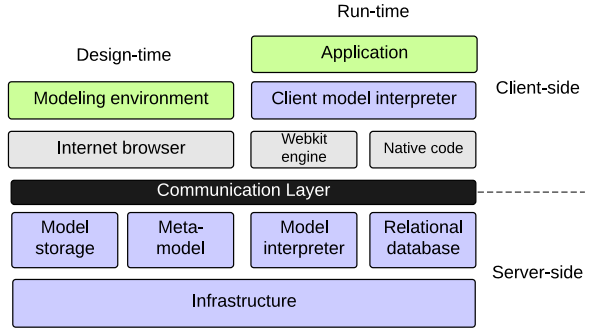

Figure 1. EUD portal by layers

are limited to elements and expressive level of DSL provided. In our case, we provide adequate DSL for Manage Trade domain where producers create applications to support their agents at work. The targeted end-user for this use case is a business expert who usually has some experience and expertise in simple programming such as creating Excel documents or scripting simple programs. Description of end-user programming interface used is out of the scope for this study and is still in development stage. We address only technical underlying challenges of building a portal with these properties.

2) From *runtime perspective*, the execution of Manage Trade applications, EUD portal leverages Software as a Service (SaaS) delivery model [2]. Each agent uses an application delivered and managed by EUD portal.

A. Application development perspective

Contracts between producers and retail shops vary in content. Agreements in these contracts evolve over time meaning that agent applications change. In addition, some producers also required additional functionality such as sales order creation or collecting additional data for their business intelligence systems. Given all that, our portal needs a lot of expressive power. To satisfy such a large variety of requirements, we pursued a model-driven approach, and defined a common AGM Meta-model typical for our tenants requirements presented at [3]. AGM meta-model possesses expressive power to model applications that can process a variety of structured data, business processes and validation rules to minimize data collection errors. AGM was defined from years of experience in SME business domains such as Manage Trade. The guidelines for defining a solid meta-model are provided at [4].

Figure 1 illustrates that design-time, or sometimes referred to as modeling-time, together with run-time environments reside on the same web infrastructure. Model storage is a specialized graph database Neo4J[1] containing end-user defined models. It is used by EUD portal as a central model repository of every modeled application, and for storing meta-model elements and definitions. Models are constructed using before mentioned DSL language for Manage Trade domain inside modeling environment provided by portal. This web-based environment is at a very basic and early stage, providing only a simple DSL editor to input or modify application definition. This area is a subject to future improvement with introduction of graphical modeling environment for a more user friendlier approach [5].

[1] Neo4J – open-source graph database, available at http://www.neo4j.org

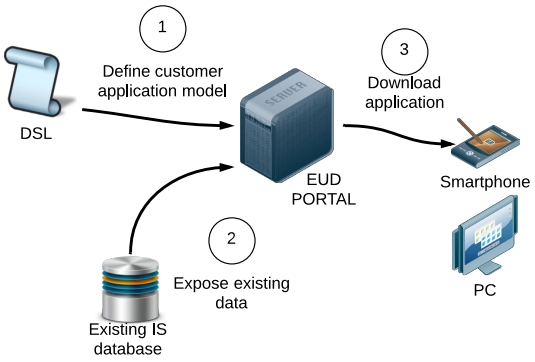

Figure 2. Basic steps involved in creating application

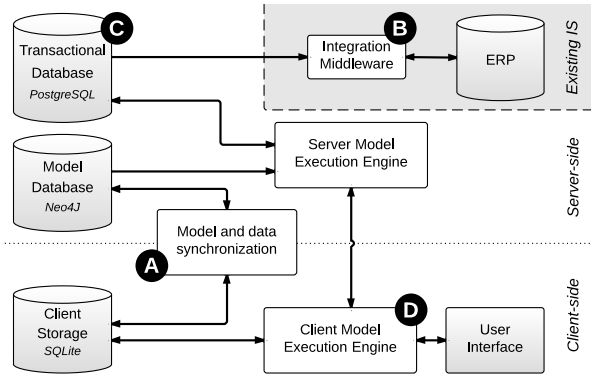

Figure 3. EUD portal architecture

Overview of complete application creation scenario is shown in Figure 2. Steps are simplified omitting ones like tenant registration or management of users. It gives the high-level picture of three-step application development:

1) In first step business expert in the role of end-user programmer models the application using the interface provided from EUD portal. This modeling step includes definition of data structure, data transactions that will be carried by agents, and a model of user interface. Transactions are modeled as a set of data collection forms. In Manage Trade domain agents use these forms to collect information that is analyzed to see if contracts are being met. Therefore, these forms are modeled according to contract contents.

2) Each organization exposes data from their existing IS through an ODBC [2] database connector or uses connectors to SAP ERP[3] or Microsoft Dynamics NAV[4] systems. The tools are provided by portal. This step is often completed with some help of professional developer or system integrator who has a deeper knowledge of SQL[5] language and database procedural languages. The structure of exported data in this step must conform to data structure defined in previous step.

3) Final application is automatically assembled and downloaded to each of agent devices. Manual download is required, but future updates are automatic and seamless.

EUD portal does not assemble each application as different executable specific to each agent, but rather provides a common executable for every agent, which is capable of interpreting provided model at runtime. We refer to this executable as a *client engine*. Model is synchronized to each client engine upon first usage and updated as necessary. Model interpretation in favor of generating end applications makes this an interpretative MDD approach. Differences between MDD approaches and benefits of each, together with rationale for choosing interpretative approach are described in [6].

B. *Runtime perspective*

1) From runtime perspective, EUD portal is a distributed software system composed of server and client components. Server-side components provide data storage services for assembled applications. Each agent continually collects information at retail stores that is stored in portal. This is achieved using a relational database. Single database instance is shared between agents and data is isolated accross companies.

To support data storage for multiple agents and organizations in a single database, we used a multi-tenancy design of the portal and underlying relational database. This means that each customer shares hardware and software resources leading to better resource utilization. A *shared-table design* [7], [8] is used to isolate data inside relational database instance. In our implementation, a single tenant correlates to single customer – producer or distribution organization.

EUD portal also possesses Web services and tools that provide integration with existing IS. In our business case, agents require immediate access to different information contained within existing Customer Relationship Management (CRM) and Material Management (MM) systems. Such information includes details about retail shops and products. Each agent also receives daily work schedules provided from these existing systems. They define a list of retail stores to visit and ensure contracts are being followed correctly. This work schedules are synchronized from outer systems to EUD portals central database and then further passed to each agent application.

Client side components are packaged as a hybrid mobile and desktop application [9]. Hybrid application composing means that applications are built using web technologies: JavaScript and HTML, combined with native modules developed separately for each platform we provide: PC, Android and iPhone. These native modules

[2] ODBC – stardadized middleware for accessing database management systems, originally developed by Microsoft

[3] SAP – SAP AG's Enterprise Resource Planning software, available at http://www.sap.com

[4] Dynamics NAV – ERP software product from Microsoft, available at http://www.microsoft.com/en-us/dynamics

[5] SQL – special domain specific language for managing data contoained in database management systems

are referred as *native wrappers*. They use Webkit[6] open-source engine to display HTML and JavaScript contents. That way we obtain functionality specific to native applications and still benefit from web technologies that facilitate software delivery and multiplatform execution [10]. Native functionality includes: access to file-system, photo camera, gyroscope, GPS module, device information and phone address book, depending on platform.

IV. CHALLENGES AND FUTURE DIRECTIONS

Many technical challenges arose during implementation phase. Those will be described in following subsections, each section covering different technical aspect of EUD portal. To position each problem according to EUD portal layer or component, we relate to Figure 1, which provides an overview on portal run-time and design-time layers, and Figure 3, which shows the main components used.

A. Communication between server and clients

As shown in Figure 3, labeled (A), data synchronization between portal and end applications is achieved with a distributed synchronization module residing both on server and client side. This empowers each client application to conduct computation over data independently, which unburdens server infrastructure resources. This is also very useful for supporting *offline* data processing, meaning that agent applications can process transactions on smartphones without data network, and postpone synchronization of completed transaction back to server after connection is reestablished. Modeling language provides expressions to filter data that is to be synchronized on each agent application.

It was quite difficult to achieve a stable synchronization mechanism given that resulting applications were designed by end-users so the synchronized data volume was often unpredictably large. This problem is even more present when data is sent over old generation mobile networks.

To resolve this issue, we are researching a mechanism that will predict the volume of data at run-time and warn the developers when such volume hits a certain threshold. That way, end-users can decide to lower the volume of data by filtering some less important data.

B. Integration

A key part of any business system is interoperability - efficient cooperation with existing systems. This is in our experience one of the greatest barriers for using EUD in business organizations. Many existing, on-premises IT systems are inaccessible or difficult to integrate with. A most common method of integration in our experience is by using intermediate tools to connect to their database systems. In Figure 3 this tools are noted (B). It can be observed that relational transactional database is connected with *integration middleware* for connecting to existing IS databases. These tools are configurable applications provided to be installed inside existing IS environments. The reason for on-premises installation is to evade strict firewall policies many of our customer posses and their inability to provide web services. Although SOA architectures are getting more common, our customers do not posses such solutions, so data is synchronized with their databases through ODBC drivers and a configurable set of SQL commands.

We already stated that for a stable integration, assistance from professional developer is required and this is quite a drawback for end-user development due to unpredictable costs and time factors when engaging professional help. After the transition to service-oriented architecture this problem will be easier to tackle, as there is many research on integrating web services with EUD principles. Dörner et al. [11] are researching end-user development integration with Service-Oriented Architectures (SOA) by making web services more understandable to end-users. Similar pattern can be applied here. However, our customers are from small and medium business (SMB) sector, and are still just considering migrating to SOA. Direct integration with their databases is still the most flexible and common solution.

C. Persistence Layer

Data persistence, marked (C) in Figure 3 is the most important part of any business transaction processing system and this was where we faced many challenges. When we did our research for choosing the right database to store EUD portal customers data, we had several main requirements:

- ACID properties,
- An open-source solution is preferred,
- Schema-less database is preferred; as it makes storing end-user designed data objects easier to implement.

We have chosen a relational open-source PostgreSQL[7] database. PostgreSQL, like any ordinary relational database, requires schema to be defined prior to usage. We gave up on this aspect in favor of ACID properties and reliability, as schema-less NoSQL[8] databases are still mainly not mature enough for business production usage, like storing important and sensitive data. Main deciding factors for PostgreSQL were durability, robustness and open-source code.

To achieve best hardware resources utilization, we implemented a row level multi-tenancy meaning that

[6] Webkit – open source layout component designed to render web pages, available at http://www.webkit.org/

[7] PostgreSQL – open-source object-relational database management system released under PostgreSQL license, available at http://www.postgresql.org

[8] NoSQL – common names for databases that store data in forms other than tabular relation used in relational databases, many of which do not require a schema to be defined

tenants share same tables with each row having tenant identification.

Since tenants had different schema structures, we had to share tables and columns across tenants. For that reason each column had the same universal variable length string type. This table and column abstraction on database side brought a small performance drawback because the benefits of relational schema were not fully utilized. To satisfy data isolation between tenants, we implemented a layer between the portal application code and database that does the mapping between user-defined schema and real database schema. This layer also brought a small degradation of data access performance. Similar approach has been implemented by the Force.com Salesforce1 solution [12] on top of Oracle relational database. We have not applied enough attention to properly address this issue and further research is required in this area. More research towards implementation of this feature natively inside databases is required, such as [13].

Another big issue was database scaling, ability operate effectively regarding to database size. We did not automatically track each tenant metrics on table sizes nor implement a mechanism for automatic index creation to rectify slow queries. Instead, we performed database optimization and administration manually. Taught by this production experience, we defined a set of characteristics that a fully automated EUD business system persistence layer should have:

1) Mechanism for keeping track of per-tenant meta-data and metrics: slow queries, overall data size, data fragmentation, and index efficiency. Basic solution is provided at Figure 4 where execution time is monitored together with requested query. Collected data is analyzed for decision such as automatic creation of additional indexes, data sharding and partitioning. Similar approach is applied at [14] on cost-driven basis.

2) Data sharding should take care not to divide data inside common tenant and to divide shards evenly. Such mechanism should track fastest growing tenants and reserve enough storage for further growth. If a single tenant gets larger than a single shard (database) it should be further split by relocating less accessed data.

Modern Platform-as-a-Service (PaaS) solutions offer APIs for managing hardware infrastructure. This could also be used for automatic new creation of additional database instances when total capacity is close to being exceeded with automatic data reallocation. An example of such solution is Amazon Auto Scaling[9] but it is limited in terms that it allows only predefined set of rules like defining peek times, or CPU usage thresholds when a scaling should occur. Scaling API should be combined with analysis of existing tenant meta-data and metrics for optimal resource allocation. Combined with a database that easily scales should provide a solid ground point towards building a database layer capable of handling large quantities of different tenant schemes. A good

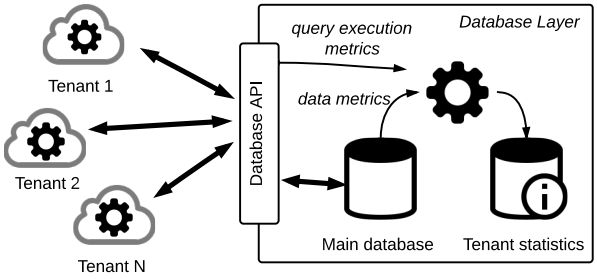

Figure 4. Mechanism for collection tenant data size and query performance metrics

database engines categorization with a special review to scaling is given in [15]. This work shows a promising future for NoSQL schema-less database solutions once they become more reliable.

D. Extending modeling capabilities

Certain transactions conducted by agents' required additional functionality that could not be expressed with our DSL language. Therefore, we provided means for writing simple JavaScript[10] functions extending provided modeling capabilities e.g. specific tax calculations, custom advanced validation controls or other types of more complex algorithms. They were executed on agent applications and can be modeled to execute on certain application events like startup of the application, beginning or end of transaction, periodically, and on different user interface actions.

Using these extension scripts in practice revealed a few additional problems:

1) *Security concerns* – client side JavaScript code is not safe from manipulation, so an additional JavaScript interpreter located at portal should revalidate those client-side calculations upon successful synchronization of data back into the portal database.

2) *Inefficiency* – certain scripts can perform much better on server side, e.g. manipulating a larger set of data. This requires more resources than client side computing can offer.

3) *Poor usability* – to write an extension, one needs some sort of assistance from professional developer who knows JavaScript. This was not suited for an end-user.

To resolve performance issues, an algorithm based on heuristics could predict functions to be executed on server side e.g. function with frequent access to large amount of data.

V. CONCLUSIONS

Implementing EUD portal in the web environment where technology is still not specialized enough for such dynamic use cases offers several technical challenges to surpass. Main concerns are infrastructure barriers, integration issues and scalability.

[9] AAS – Amazon Auto Scaling solution, available at http:// http://aws.amazon.com/autoscaling/

[10] JavaScript

Computational and network infrastructure is limited, but end-users do not possess understanding of those limitations which results in unstable and underperforming applications. Integrating EUD systems with existing solutions is another key barrier for end-users because it is often very complicated even for professional developers to understand and find a way to integrate with closed systems.

Regarding data persistence layer, greatest challenge is achieving multiple schema multi-tenant data storage on classical database management solutions. Having a user-defined data structure imposes a need for higher flexibility to change data structures in runtime. We proposed using a schema-less database or an abstraction layer over relational databases. A mechanism that would gather meta-data and usage statistics for each tenant is also needed to tackle self-optimization. Such mechanism should take decisions and actions over data partitioning, sharding and indexing.

To enable automatic scaling, platforms could be built on IaaS solutions that enable API's for dynamically creating new worker and storage nodes to take on extra traffic. Figure 5 shows an overview on key portal architecture characteristics: 1) multiplatform execution, 2) web-based WYSIWYG modeling environment, and 3) execution engine with ability to use infrastructure APIs for automatic scaling. Self-adaptivity in forms of carefully configured algorithms should take decision to scale by managing storage and computation resources from IaaS provider during runtime. This is crucial for EUD solutions where application resource footprints are highly dynamic and unpredictable.

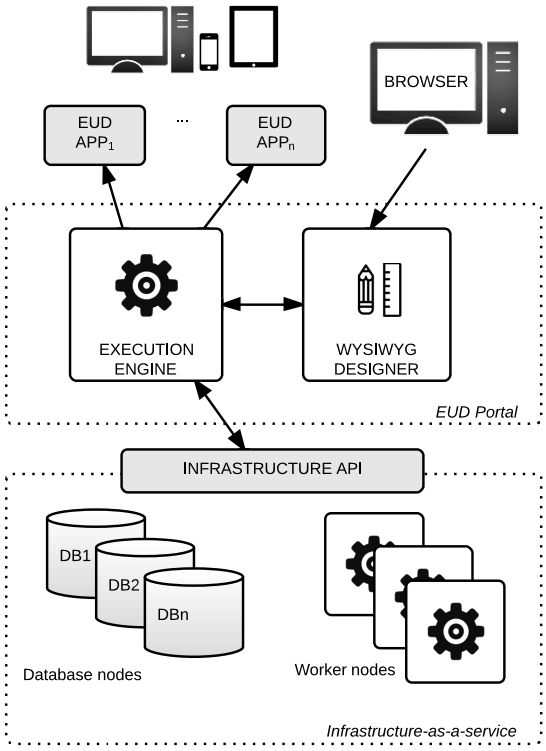

Figure 5. Proposed EUD portal architecture

Modeling of software failure cost in ERP systems

Frane Urem *, Krešimir Fertalj **, Ivan Livaja *

** Faculty of Electrical Engineering and Computing/Department of Applied Computing, Zagreb, Croatia
e-mail: frane.urem@compco.hr, kresimir.fertalj@fer.hr, ivan.livaja@vus.hr

Abstract - Enterprise resource planning (ERP) systems are the most important software for many types of businesses. Software defects inserted on working ERP system can cause significant cost to their users. Existing software reliability models usually don't consider any financial impact at all. A model proposed in this paper links the ERP application layer with critical business operations and proposes cost calculation. The described modeling also encourages users to easily quantify the consequences of software failures that will always appear in ERP system. The proposed methods are illustrated by a case study.

I. INTRODUCTION

In certain way ERP vendors and their customers have different perspective of software failure costs. It is relatively easy to determine failure costs to be borne by the ERP vendors during failure fixes. They will investigate reported problems, identify and remove software defects that have caused failures. That process defines the main costs for ERP vendor because it includes certain experts costs (developers, business domain experts, consultants etc.) for solution search and rework spent in defect removing from the current software release. Most of these costs ERP vendor can predict and charge users before (installation, configuration, training) or after (maintenance contract) an ERP implementation. Of course, the ERP vendor may suffer certain indirect costs connected with user dissatisfaction, legal contracts etc. but that is hard to capture and it is out of scope of software reliability modeling anyway.

User's perspective is different and more complex to define because every failure is linked with business and failure cost is dependent on affected business process. Existing business that is closely related to the installed ERP system can be seriously compromised in case of untimely failure fixes.

Therefore, in this paper proposed model links the ERP application layer with critical business operations and propose cost calculation from user's perspective. Described model is directly linked with ERP software failure cost for the customer but proposed procedures can be also useful for ERP vendors in order to focus on the customer's needs and know true risks of using their product.

II. DEFINITIONS

Standards as IEEE 1044 [1] are well-defined in classification of software anomalies such as problem in software, failure, defect and fault. These definitions are used in this paper and their interrelation is illustrated in Figure 1.

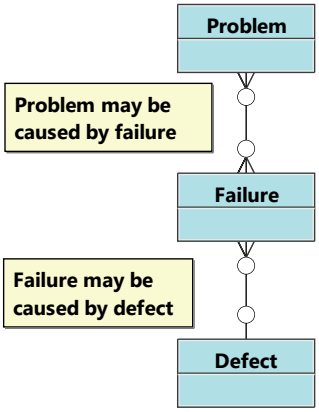

Figure 1 Relationship Problem – Model – Defect as an ER diagram

According to Figure 1, in every installed ERP system user can suffer various problems during the execution of different business operations. Problems may be caused in ERP system by software failure but it is not a rule because sometimes the cause may be something else such as insufficient training of users to work. According to definition from [1] failure is termination of the ability of an ERP system to perform required function or to perform it in previously specified limits. Defect is a source of software failures but sometimes user will not experience failures because defect is built in some functionality that is not actually used on existing ERP installation. In the past (as an example earlier version of IEEE 1044 standard published in 1993.) it was presumed that defect is a fault (error in software) but in complex software systems like ERP, defect term is more appropriate because defect can be something else like wrong configuration of ERP module. Software defect was initially defined by IBM [2], [3] but in IEEE 1044 standard defect attributes are more fully described.

III. MODEL

An adapted model from [4] is presented in Figure 2 and can be used to determine various ERP failure cost information. Initial model linked business layer to hardware/software system (called IT layer) deployed in a plant. Relevant business processes cost is linked with software function call with specific failure probability. Software reliability prediction is combined with financial calculations and software failure cost prediction is determined as a result.

In a Figure 2, original model is simplified because failure probability of ERP function call is not considered. Critical business operation is mapped with ERP function through software failure severity (caused by defect inserted in certain ERP function) which is later displayed in Table 1.

System is observed from user's perspective on two layers: business and ERP and some business process steps are assigned to corresponding functions implemented in ERP system. In case of success next optimal business process B will be executed. In case of failure another business process C will be executed with additional costs.

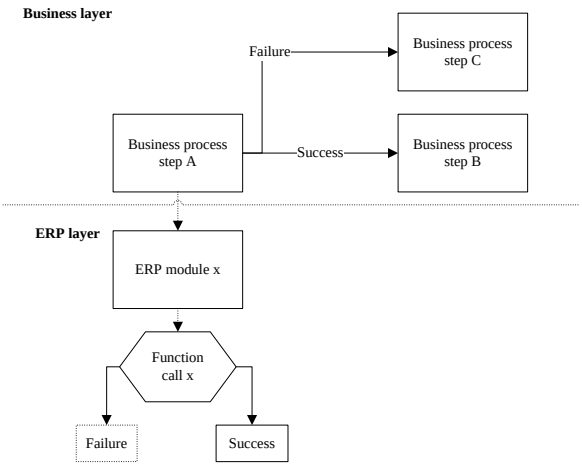

Figure 2 Connection between business layer and ERP system

Defect tracking system must be implemented as important prerequisite to apply presented model. Every failure is reported on defect tracking system with attributes detailed described at [1]. For failure cost analysis the following key attributes for reported failure must be available:

- Date/time when failure is observed
- Date/time when final disposition is assigned
- Defect reference

Referenced defects should be described with key attributes such as:

- Severity (the highest failure impact)
- Effect (the class of requirement that is impacted)
- Insertion activity (the activity during witch defect was inserted)

Severity can be simply correlated with expected frequency of failure. IEEE classification for defect severity [1] can be used as:

- Blocking (impossible to work on certain ERP module)
- Critical (certain critical business operation is disrupted)
- Major (certain critical business operation is affected but can proceed)
- Minor (nonessential business operations are disrupted)
- Inconsequential (no significant impact on business operations)

ERP module failure costs can be calculated according to (1) as:

$$CT = (ALC + DC) \times RT \times N \quad (1)$$

- CT - total failure cost
- ALC - additional labor costs caused by failure
- DC - downtime induced costs
- RT - resolution time
- N - the number of affected workplaces

Every failure is affecting a particular business operation and business domain experts define the financial costs according to referenced failure severity.

As a result, Table 1 can be made for every ERP module.

TABLE I. USER ASSESSMENT OF POSSIBLE COSTS FOR SPECIFIC ERP MODULE FAILURES WITH CERTAIN SEVERITY

COST DESCRIPTION:	*lost labor hours, downtime induced costs*			
MODULE:	*ERP module name*			
	CRITICAL BUSINESS OPERATIONS			
FAILURE SEVERITY	*Operation 1*	*Operation 2*	*...*	*Operation N*
Blocking				
Critical				
Major				
Minor				
Inconsequential				

Resolution time is calculating from failure report as the difference between dates when failure is observed and final disposition is assigned. Insertion activity can be used as a parameter for the case when user wants to assess the total cost in situation when failure is observed and corrective actions are in progress. For these cases Table 2 can be used. By contractual relations between the ERP vendor and customer it is usually possible to define and predict the response time when failures will occur during coding, configuration and documentation insertion activities. It is difficult to predict the time for corrective actions needed for removing of defects that were inserted

during requirements or design phase. Quite certainly the occurrence of such defects will seriously jeopardize business operations because their removal requires much more time.

TABLE II. USER ASSESSMENT OF POSSIBLE COSTS FOR SPECIFIC ERP MODULE FAILURES WITH CERTAIN SEVERITY

MODULE:	*ERP module name*	
DEFECT INSERTION ACTIVITY		
VALUE	**Definition (with examples)**	**Expected time for corrective action**
Requirements	Defect is inserted during requirements definition (incomplete use case specification, incorrect performance specification, incorrect security specification, incorrectly specified function etc.)	difficult to predict- business is at risk
Design	Defect is inserted during design activities (incorrect interface specification, incapable design etc.)	difficult to predict- business is at risk
Coding	Defect is inserted during coding or similar activities (incorrect data initialization on interface form, module interface does not work correctly, wrong reporting etc.)	contractually defined- controlled losses
Configuration	Defect is inserted during ERP module configuration (wrong interface to other ERP modules, incorrect interface to other software systems etc.)	contractually defined- controlled losses
Documentation	Defect is inserted in documentation for installation and operation	contractually defined- controlled losses

IV. CASE STUDY

The following case study illustrates proposed model for software failure cost on already implemented ERP system. One ERP module upgrade is analyzed on existing ERP system made by one Croatian ERP vendor. The user wanted to replace existing POS (Point Of Sale) module with the new one from the same vendor. Basically, it was an existing module upgrade with the following improvements:

- new user interface design optimized for use on the touch screen
- more detailed user roles
- better reporting integrated in a new interface

Nothing has changed on existing technology (.NET, Microsoft SQL Server) or equipment (only new touch screens were installed). The specified user was one of the first who decided to replace the old POS module but the new one has already been shipped to several smaller sites and there were no reported problems.

After installation the user has reported failures described in Table 3. All failures were categorized by ERP vendor and reported on vendor's helpdesk system.

TABLE III. REPORTED FAILURES

ID	**Title**	**Severity**	**Date observed**	**Date closed**	**Business operation**	**Referenced defect**	**Defect insertion activity**
1	Fiscalization service is working slower than in old module	Major	2.9.2013	4.9.2013	**Sales**	G2-TSPRM-006	Coding
2	Discount based on user role does not work correctly	Minor	2.9.2013	4.9.2013	**Sales**	G2-TSPRM-007	Coding
3	Cash register report does not print cash deposit amount correctly on POS printer (on screen report is working correctly)	Inconsequential	5.9.2013	9.9.2013	**Sales**	G2-TSPRM-008	Coding
4	After upgrade bar-code reader does not work correctly for Coca Cola products	Major	9.9.2013	10.9.2013	**Sales**	G2-TSPRM-009	Coding
5	After upgrade document replication from central location to POS does not work	Critical	10.9.2013	11.9.2013	**Replication**	G2-TSPRM-010	Coding

The user did not have serious problems with the observed module after the failures described in Table 3. According to Table 3 all defects were inserted during coding and every defect caused single failure. There were lot of problems caused by some reported failures but it was impossible to report all problems in a real time. As a result, it was impossible to objectively assess the costs incurred.

After an interview with the user, Table 4 and Table 5 were formed according to Table 1 and calibrated with available information about real costs that are incurred during failures from Table 3. Thus some costs were linked to lost labor hours according to the records of overtime hours caused by reported failures and some downtime costs were calculated as reduced earnings compared to regular working days. Some type of failures (like failures with blocking severity) was not reported and costs were estimated with worst case scenario. At the end, the resulting Tables 4 and 5 represent a projection of future costs that may be expected when certain types of failures will occur.

TABLE IV. USER ASSESSMENT OF LOST LABOR HOURS FOR SPECIFIC ERP MODULE FAILURES WITH CERTAIN SEVERITY

COST DESCRIPTION:	lost labor hours at one workplace, during one working day			
MODULE:	Point of sale			
CRITICAL BUSINESS OPERATIONS				
FAILURE SEVERITY	Sales/Returns	Replication (new products, prices, cash register ...)	Version upgrade	Loyalty programs
Blocking	16	2	1	2
Critical	16	2	1	2
Major	2	1	0	1
Minor	0,5	0,5	0	0,5
Inconsequential	0	0	0	0

TABLE V. USER ASSESSMENT OF DOWNTIME INDUCED COSTS FOR SPECIFIC ERP MODULE FAILURES WITH CERTAIN SEVERITY

COST DESCRIPTION:	downtime induced costs at one workplace, during one working day (EUR)			
MODULE:	Point of sale			
CRITICAL BUSINESS OPERATIONS				
FAILURE SEVERITY	Sales/Returns	Replication (new products, prices, cash register ...)	Version upgrade	Loyalty programs
Blocking	1.000,00	250,00	125,00	250,00
Critical	1.000,00	250,00	125,00	250,00
Major	250,00	125,00	0,00	125,00
Minor	50,00	50,00	0,00	50,00
Inconsequential	0,00	0,00	0,00	0,00

For an example, expected failure cost with major severity that affects sales operations for one day is calculating from (1) and Tables 4 and 5 (in this calculation salesperson work time corresponds to 7 EUR per hour) as:

CT = (2x7 EUR+250 EUR) x 1 x 10 = 2.640,00 EUR

The total costs of all reported failures from Table 3 are calculated in Table 6.

TABLE VI. TOTAL COST OF ALL REPORTED FAILURES FROM TABLE 3

Failure ID	**Cost**
1	2.640,00
2	505,00
3	0,00
4	2.640,00
5	2.640,00
TOTAL	**8.425,00**

Total estimated costs were amounted to more than 30% of planned upgrade investment. However, such costs are still within the limits expected. A newer POS version has introduced new features and added values so total investment was paid back soon after installation. Response time from ERP vendor in situations when failures are occurred was under contract limits so there was no reason to charge vendor for failure costs. In all ERP implementations or bigger upgrades failure cost can be expected but also prevented with stronger system testing. In described case study all defects were inserted during coding activities so failure costs were acceptable because repairs were made relatively fast.

It is also interesting to analyze worst case scenarios when blocking failures can be occurred during upgrade

according to Tables 4 and 5. For an example, the failure cost for one blocking failure in described ERP installation is more than 10.000,00 EUR per day. It seems impossible that issue will happen but failure number 4 from Table 3 occurred only because during system testing bar code function was not tested with Coca Cola products (QA tester used different products from other suppliers). In described case study some defects have simply resulted in failures although it has not happened to other users because they use the same ERP module in a different way. Therefore it is very important for user to provide a detailed system test on his location before any kind of ERP upgrade. This is particularly important when it comes to ERP module that can directly affect the business as in described case study.

V. CONCLUSION

Described modeling can be useful as a simple assessment of software failure costs that could occur in installed ERP system. In this model the critical business processes are linked to the severity of observed failures through the user assessment. In this way, ERP users can compare expected failure costs and investments required for their prevention. The initial failure cost estimation can be updated with the new failure records and the associated costs. The proposed model will be extended in future research with failure cost prediction according to previous failure occurrences.

Sažetak - Jedinstvena platforma na kojoj se spremaju svi elementi projekta nove i/ili postojeće telekomunikacijske infrastrukture pojednostavljuje i ubrzava realizaciju novih projekata. Softverski alat baziran na GIS podacima, nedvosmisleno precizira trase i vizualizira administrativne pretpostavke za realizaciju projekta (npr. građevinske dozvole ili pravo puta).

Za kvalitetnu realizaciju projekata neophodni su ažurni GIS podaci. Prilikom izrade projekta svjetlovodne infrastrukture to su svi objekti od interesa kao što su namjena i korištenje prostora, kućanstva, ceste, zemljišne čestice te dostupnost postojeće telekomunikacijske i druge infrastrukture.

Alat za projektiranje mreže automatski izračunava potrebne količine materijala i trasa za realizaciju projekta te rezultate pohranjuje u GIS bazu. Iz baze se lako izračunava ukupna potrebna investicija, te se dodatnim funkcionalnostima lako upravlja i prati realizacija projekta na terenu.

Time je omogućena ključna komponenta uvođenja konzistentnosti u sve poslovne procese a posredno i u podatke, a to je implementacija upravljanja životnim ciklusom mrežne infrastrukture. Najveći izazov pri izradi ovakve vrsta projekata je osiguranje kvalitetnih ulaznih podataka.

Uređivanje i harmonizacija svih relevantnih podataka kroz izgradnju kvalitetno dizajnirane GIS baze omogućit će našem društvu efikasnije planiranje razvoja i izgradnje širokopojasnih mreža, lakše povlačenje sredstava iz EU fondova, pomoć pri donošenju odluka vezanih uz prostor, te transparentnu dostupnost društveno značajnih informacija.

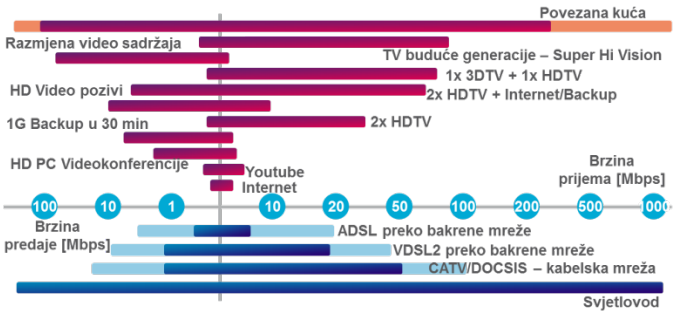
I. UVOD

A. *Potrebe*

Današnji način života okružen digitalnim sadržajima širi se u svim područjima društva povezujući svakoga i sve. Novo umreženo društvo omogućuje ljudima napredniju suradnju, otvara nove mogućnosti inovacija, potiče edukaciju, unaprijeđuje javni servis, a sudionici u umreženom društvu djeluju na načine za koje još prije nekoliko godina nismo mislili da će ikada biti mogući.

Da bi se ostvario potencijal umreženog društva, potrebna je nova, brža telekomunikacijska infrastruktura na osnovama jednostavnih, pametnih i skalabilnih rješenja fleksibilnih mreža i mreža spremnih za budućnost. To su mreže i mrežne tehnologije koje se razvijaju u svojim performansama od nekadašnjeg dial-up pristupa, ISDN-a (engl. Integrated Services Digital Network), preko danas raširenog ADSL-a (engl. Asymmetric Digital Subscriber Line) do sutrašnjeg sveprisutnog pristupa svjetlovodnim vlaknom.

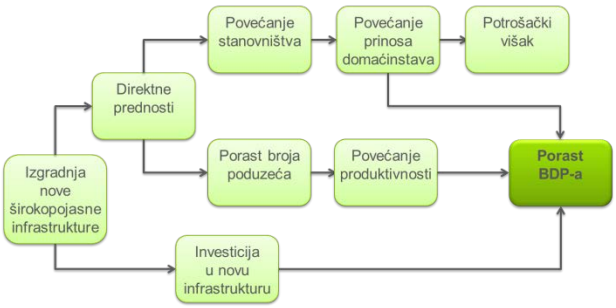
Promjene u mogućnostima, a time i ponašanju krajnjih korisnika digitalnih i sve obimijih video sadržaja zahtjevaju veće brzine i kvalitetu usluga koja je već sada dovela postojeću bakrenu telekomunikacijsku infrastrukturu do svojih limita. Postojeća digitalna DSL tehnologija doseže maksimalne brzine do 50 Megabita u sekundi (Mbps) u predaju, i jako je ovisna o kvaliteti bakrene veze. Ova brzina nije dovoljna za mnoge nove aplikacije, pa je potrebno planiranje i izgradnja novih svjetlovodnih mreža. Primjeri prijemnih i predajnih brzina ovsnih o tehnologijama i aplikacijama prikazani su slikom 1.



Slika 1. Brzine prijenosa u odnosu na tehnlogiju i uslugu

B. *Utjecaj nove infrastrukture na društvo*

Investicije u razvoj nove širokopojasne infrastrukture utječu na bruto domaći proizvod (BDP) direktnim angažmanom kapitala u izgradnji, te dugoročnim utjecajem promijenjenih ekonomskih i socijalnih aspekata (edukacija, zdravlje, uprava), te pozitivnog utjecaja na okoliš (promet, CO2), slika 2 [1].



Slika 2. Utjecaj nove infrastrukture na BDP

Mogućnosti koje pruža nova radna okolina pozitivno utječu na mogućnosti kreiranja novih radnih mjesta. Također ne zaboravimo na pozitivan efekt smanjenja emisije CO2, slika 3 [1].

Slika 3. Utjecaj nove infrastrukture na zapošljavanje

II. TEHNOLOGIJA I TOPLOGIJA SVJETLOVODNIH PRISTUPNIH MREŽA

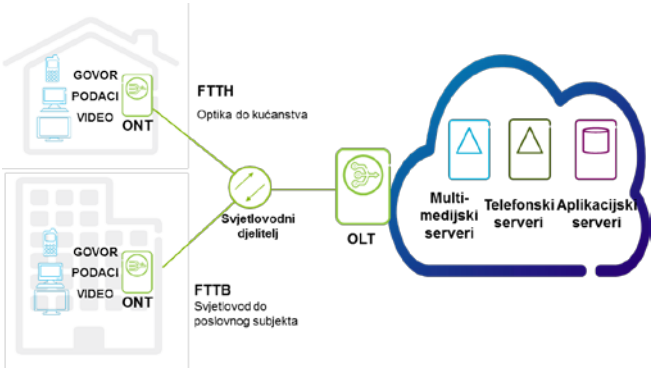
A. *Očekivanja od nove mreže – zašto projektiramo?*

Potrošačka potražnja za IPTV i drugim naprednim uslugama danas stvara potrebu za konvergentne, u potpunosti IP (engl. all-IP) bazirane svjetlovodne mreže visokog kapaciteta. Obećanje koje daje sve-svjetlovodna IP mreža uključuje i visoku učinkovitost i uštedu troškova te znatno veću propusnost. Tako ne treba čuditi da je većina telekomunikacijskih operatora već odabrala gigabitne pasivne svjetlovodne mreže (engl. Gigabit Passive Optical Network, GPON) [2] točka-do-više točaka (engl. Point-to-Multipoint, P2MP) sustava koji dijele jedno svjetlovodno vlakno za povezivanje više korisnika bez potrebe za aktivnom opremom u vanjskom postrojenju. GPON, Ethernet i ITU (engl. The International Telecommunication Union) standard, nudi isplativo rješenje koje osigurava visoku brzinu prijenosa podataka i napredne funkcionalnosti. Pasivne komponente instalirane izvan telekomunikacijskog središta ne zahtijevaju dodatno napajanje za rad. Kako više korisnika dijeli dio distribucijske mreže, potrebno je manje mjesta za aktivna sučelja i svjetlovodne distribucijske okvire u ormarima u telekomunikacijskom središtu. GPON pruža migracijski put prema all-IP mrežama i nudi potrebnu propusnost za isporuku nove napredne glasovne, video i podatkovne usluge.

B. *Pametna arhitektura mreže omogućuje trenutne usluge i usluge sljedeće generacije*

Umreženo društvo predviđa velike zahtjeve na kapacitet medija korištenjem velikog broja uređaja. Nova mreža treba biti svjesna uređaja, sadržaja, položaja korisnika i toka podataka, a takvu arhitekturu podržavaju GPON mrežna rješenja. Dedicirani prometni upravljači u PON arhitekturi omogućavaju nuđenje fleksibilnih paketa krajnjim korisnicima te na taj način koriste minimalni broj konekcija na najučinkovitiji način.

Slika 4. prikazuje osnovnu arhitekturu GPON tehnologije i način spajanja krajnih korisnika. Može se vidjeti da od GPON optičkog linijskog terminala (engl. Optical Line Terminala, OLT) koji se nalazi u telekomunikacijskom središtu ide samo jedno vlakno do pasivnog razdjelnika koji onda dijeli to isto vlakno na više krajnjih korisnika. Tako između telekomunikacijskog središta i krajnjih korisnika nema potreba za aktivnom opremom i napajanjem opreme električnom energijom, već je sva oprema pasivna.



Slika 4. Osnovna arhitektura GPON mreže

Neke od prednosti GPON tehnologije [3] i arhitekture mreže su:

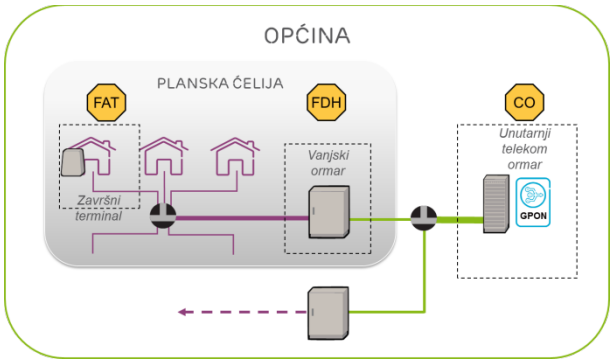
- Ušteda svjetlovodnih niti između telekomunikacijskog središta, tj. centralnog distribucijskog mjesta (engl. Central Office, CO) i djelitelja (engl. splitter)
- Samo se pasivna oprema (svjetlovodne niti i djelitelji) instalira izvan CO, dok je sva aktivna oprema smještena u CO ili kod krajnjeg korisnika
- Pouzdanje mreža s obzirom na potencijalne ispade elektroenergetskog sustava
- Kako se koristi struktura točka-do-više točaka iskorištava se manje portova na aktivnoj opremi u odnosu na točka-do-točka strukturu
- Podrška za scenarij plati kad je potrebno proširenje (engl. pay as you grow scenario)
- GPON tehnologija je tehnologija sa otvorenim standardima i spremna je za budućnost te nadogradnju tehnologije kao takve

C. *Dimenzioniranje*

Izabrana tehnologija i topologija nove mreže određuje arhitekturalno rješenje, te time utječe na izradu nominalnih planova distribucijskih i agregacijskih dijelova mreža. Razmotrimo dimenzioniranje distribucijske mreže na razini jedinice lokalne samouprave, to jest općine.

Područje općine ili aglomeracije dijeli se na planske ćelije čija se područja određuju gustoćom naseljenosti, sadašnjih i budućih potreba, te parametrima izabrane tehnologije. Unutar svake planske ćelije instalira se vanjski svjetlovodni distribucijski ormar (engl. Fiber Distribution Hub - FDH) kao središnje mjesto koncentracije svjetlovodne distribucijske mreže za pojedinu plansku ćeliju. Unutar FDH čvora instalira se svjetlovodni djelitelji tako da je svjetlovodna distribucijska mreža od FDH do krajnjeg korisnika izvedena u zvjezdastoj topologiji.

Svaki FDH spaja se na centralno distribucijsko mjesto pojedine općine na kojem će biti smješteni unutarnja telekomunikacijska oprema. Centralno distribucijsko mjesto (CO) se sa svakim FDH spaja direktnom vezom koja je izvedena sa svjetlovodnim kabelom odgovarajućeg kapaciteta.



Slika 5. Logička shema povezivanja na nivou općine

Distribucijski čvorovi (FDH) dimenzioniraju se za proračunati kapacitet uz minimalno +20% kapaciteta u rezervi za buduća proširenja i/ili nove korisnike. Svjetlovodna distribucijska mreža između FDH i krajnjeg korisnika u pravilu je maksimalne dužine do 1000 m po trasi sa ciljem što manje potrebe za varenjem svjetlovodnih vlakana. Svaki krajnji korisnik spaja se s jednom cjevčicom u koju se potom upuhuje svjetlovodno vlakno.

Općenito, korisnici se mogu podijeliti u dvije kategorije:

- Rezidencijalni/mali (engl. single dwelling unit, SDU) -> 1 svjetlovodno vlakno s 2 niti
- Poslovni/veliki (engl. multi dwelling unit, MDU) -> 1 svjetlovodno vlakno s 8 niti

Od toga se jedna nit terminira u korisničkom pristupnom terminalu i u distributivnom čvoru, dok ostale niti služe za buduće potrebe.

III. PROBLEM ULAZNIH PODATAKA

Dostupnost i kvaliteta ulaznih podataka značajno utječu na rezultate projektiranja mreže. Primjerice, manja cijena izgradnje i što jednostavnija pravna procedura može se osigurati imamo li dostupan podatak koje su parcele u vlasništvu jedinice lokalne samouprave, a dimenzioniranje rezervnog kapaciteta može se preciznije odabrati ukoliko je dostupan prostorni plan i strategija razvoja.

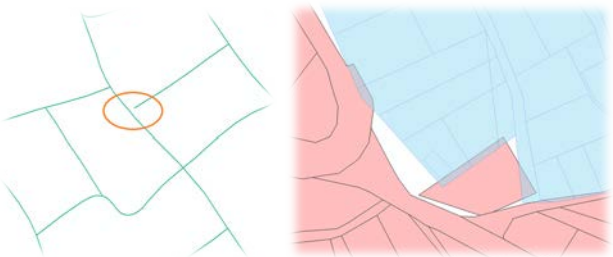
Poželjno je primijeniti GIS pristup gdje su ulazni podaci organizirani u prostornoj bazi podataka kako bi se moglo izvršiti prostornu analizu i dobiti što bolje rezultate. Većina podataka koji su bili na raspolaganju u dosadašnjim projektima a odnosili su se na kartografsku vizualizaciju (karte i planovi) nije bila dovoljne kvalitete za automatizaciju procesa projektiranja uz pomoć GIS sustava prikazano slikom 6.

Slika 6. Proces dizajna svjetlovodne mreže

Ishodište problema leži u činjenici da je naglasak kod postojećeg procesa prikupljanja podataka bio na „crtanju“ a nije se vodilo računa o konzistentnosti nego samo o njihovoj vizualnoj reprezentaciji. Stoga je prvi korak u planiranju analiza, razvrstavanje, konverzija i uređivanje ulaznih prostornih i tabličnih podataka korištenjem GIS i ETL alata (Extract-Transform-Load).

Poligonski i linijski podaci moraju biti topološki ispravni, ne smije biti preklapanja poligona (overlap) niti „rupa“ između susjednih poligona (gaps). Linije moraju biti zaljepljene (snap) jedna na drugu, pojedina linija ne smije zatvarati petlje (self-intersect) sama sa sobom. Mora biti osigurana povezivost alfanumeričkih podataka (preko jedinstvenih identifikatora) s prostornim podacima.

Na slici 7. vidljive su topološke greške gdje linije cesta nisu zaljepljene jedna na drugu u čvorovima, te preklapanja i praznine na sloju katastarskih čestica



Slika 7. Topološke pogreške

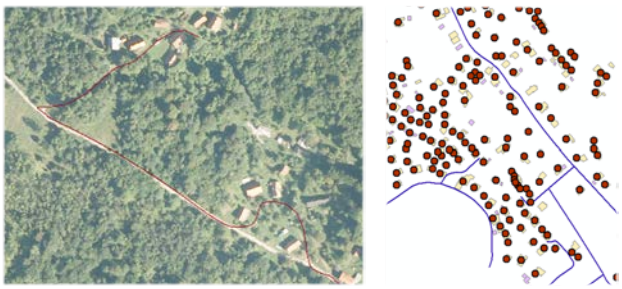
U sljedećem primjeru, slika 8., adresa je upisana crnim tekstom a broj stanara na pojedinoj adresi crvenim tekstom. Situacija broj 1 (zaokruženo na slici) ukazuje na pogrešan unos naziva ulice (Splitska 1 umjesto Osječka 1). U situaciji broj 2 vidljiva je greška nastala prilikom unosa broja stanara (22 stanara u privatnoj kući tlocrtne površine 60m2). U planiranju bi se do te adrese dovelo 8 (MDU) umjesto 2 (SDU) niti ako greška ne bi bila

ispravljena. Situacija broj 3 pokazuje neupisanu adresu na stambenoj zgradi. Potrebno je izvršiti provjeru na terenu, upisati podatke u bazu i tek tada planirati mrežu.

Slika 8. Primjer netočnih adresa i broja stanara

Prilikom sređivanja podataka tipični problemi na koje se nailazi su starost podataka od deset i više godina, neažurne evidencije, nečitka slova hrvatske abecede (korištena stara kodna stranica 437). Vrlo često se prostorni podaci nalaze u „starom“ koordinatnom sustavu, 5. i 6. zoni Gauss Krugerove projekcije te ih je potrebno preprojicirati koristeći prikladne transformacijske parametre.

Problem uzrokuje i prostorna netočnost podataka s pogreškom koja iznosi i do desetak metara, neažurnost ili nepostojanje pojedinih podataka u bazi kao što je vidljivo na slici 9. Sloj cesta preklopljen sa snimkom iz zraka ukazuje na starost i netočnost podataka. U sljedećem primjeru vidljiv je velik broj adresa (crvene točke) ali ceste nisu ucrtane u bazi te ih treba dodatno unijeti.



Slika 9. Netočne i neucrtane ceste u bazi

IV. PROJEKTIRANJE UZ POMOĆ GIS ALATA

Dosadašnje metode projektiranja u kojima se nije koristio GIS bazirani alat, potrebno je zamijeniti sistemskim GIS rješenjima, transparentnom dostupnošću svih potrebnih ulaznih parametara koji će osigurati kvalitetu projekta i njegovu dugoročnu konzistenciju.

A. Neophodni ulazni podaci i koordinatni sustav

Za kvalitetan proces planiranja mreža potrebno je više vrsta informacija. Generalno se mogu podijeliti u poligonske, linijske, točkaste i alfanumeričke vrste podataka. Ulazni geoprostorni podaci trebaju biti pohranjeni u nekom od standardiziranih GIS formata (npr. kao *.shp datoteka). Ako se koristi ESRI ArcGIS platforma [4], dobro je da podaci budu konsolidirani u *.gdb prostornu bazu podataka (engl. File Geodatabase).

Odlukom Vlade RH definiran je koordinatni sustav kartografske projekcije HTRS96/TM kao referentni i od 2010. godine je ušao u službenu primjenu. HTRS96/TM sustav koristi se i za projektiranje svjetlovodne infrastrukture u GIS alatu.

Kao podloge za izradu projekata mogu se također iskoristiti podaci dostupni na javnim servisima DGU (URL: *http://geoportal.dgu.hr/wms*). Nakon uspješnog spajanja može se iz popisa slojeva odabrati željeni sloj čime se može provjeriti da su dostavljeni podaci i korištene podloge ažurni i u korektnoj projekciji.

Tematski slojevi koji se koriste pri planiranju su katastarske čestice i objekti u vlasništvu JLS, lokacije poduzetničkih zona, odnosno prostora buduće izgradnje - sadašnji i budući prostorni planovi (UPU, DPU i sl.) te lokacije potencijalnih prepreka (groblja, jezera, zaštićeni krajobraz).

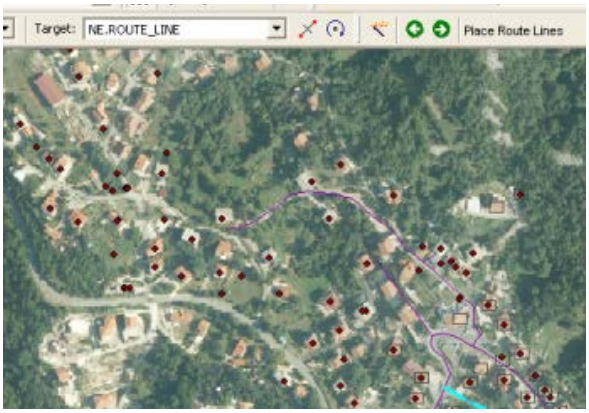
Neophodno je poznavati trase postojeće i planirane infrastrukture (prometnice, kanalizacije, vodovodi, plinovodi, javna rasvjeta) i lokacije objekata koji su u vlasništvu JLS, a mogu poslužiti kao preferirane ishodišne točke za planiranje optičke mreže.

Adresni model sa koordinatama kućnih brojeva koristi se za geokodiranje agregiranih statističkih podataka o potencijalnim korisnicima sustava, informacija o broju i tipu poduzeća u pojedinoj zgradi, broj zaposlenika i vrsta djelatnosti.

B. Softverski alat baziranim na geografskom informacijskom sustavu

Za bolje sagledavanje važnosti spomenutih prostornih i statističkih informacija u procesu automatiziranog projektiranja donosimo kao primjer kratak pregled procesa projektiranja FTTx mreža uz pomoć sustava Ericsson Network Engineer (ENE).

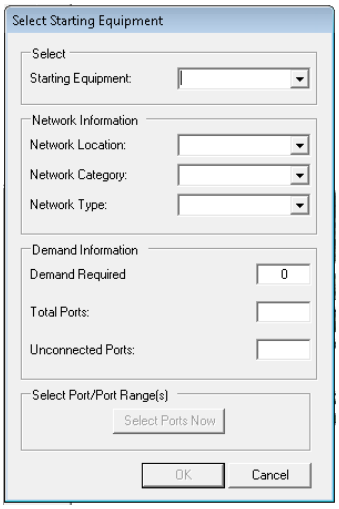
Nakon pripreme dostavljenih podataka (eventualne konverzije ili dorade, statističke obrade), pristupa se njihovom učitavanju u Ericsson Network Engineer te pokretanje procesa projektiranja mreže.



Slika 10. Prikaz radnog prozora Ericsson Network Engineer alata

Kako je prikazano na slici 10. . vidljive su točke od interesa za FTTx projekt te cesta koja u konkretnom slučaju služi kao ruta prema kojoj će sustav izvršiti optimizaciju elektroničke komunikacijske infrastrukture (EKI). Uobičajeno je da se kao ruta koristi postojeća komunalna infrastruktura čime se pojednostavljuje imovinsko pravna problematika i minimiziraju troškovi gradnje. Otvaranjem novog radnog naloga u aplikaciji, započinjemo proces projektiranja nove mreže na osnovu prikazanih ulaznih podataka.

Sami proces projektiranja uvelike je ubrzan uz pomoć čarobnjaka (eng. Design Assistant) kojemu je potrebno definirati sve potrebne parametre (opremu, rute i označiti koje interesne točke koristimo) i daljnje projektiranje je u potpunosti automatizirano (slika 11. , slika 12.).

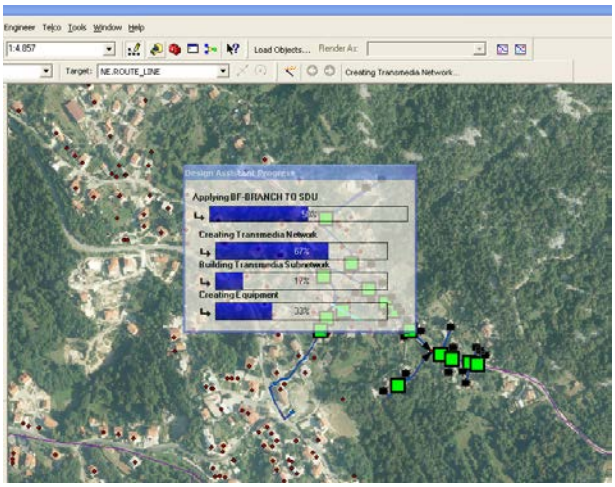


Slika 11. Jedan od prozora čarobnjaka za automatizaciju procesa (Design Assistant)

Time se značajno smanjuju potencijalne ljudske pogreške, povećava brzina samog projektiranja i pojednostavnjuje pronalazak optimalne varijante projekta.

Tijekom automatiziranog procesa projektiranja mreže na grafičkom sučelju sustava za projektiranje pratimo tijek procesa. U realnom vremenu prikazuje se izgenerirana topologija mreže (slika 11.) čiji se detalji u bilo kojem trenutku mogu izmjeniti i sa izmjenjenim detaljima nastaviti automatizirani proces.

Provjerom i usporedbom dobivenih tehničkih rješenja, projektant odabire optimalnu varijanu koja se onda završno obrađuje.



Slika 12. Dimenzioniranje svjetlovodne infrastrukture u ENE alatu

Konačni rezultat je optimalna topologija planirane mreže te kompletan troškovnik u skladu sa tehničkim rješenjem a što je prikazano slikom 13. .

Red. broj	Naziv produkta	Količina	Jedinica
1. Oprema

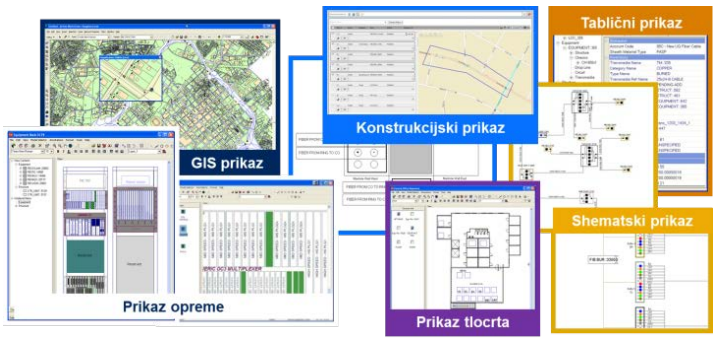
Slika 13. Primjer troškovnika za jednu plansku ćeliju

Ovako dobiveno rješenje predstavlja optimalan idejni projekt i predstavlja kvalitetno ishodište za zadovoljenje brojnih potreba JLS (strateško planiranje i budžetiranje, priprema materijala za natječaje, katastar vodova, itd.).



Slika 14. Višedimenzionalno korištenje alata za projektiranje

Upravo korištenje GIS baziranog alata za projektiranje znatno ubrzava proces planiranja (slika 6.) i omogućava uspostavu kvalitetnog mehanizma (slika 14.) za

upravljanje životnim ciklusom mrežne infrastrukture (od planiranja preko izgradnje i eksploatacije te konačno održavanja).

V. ZAKLJUČAK

Prije neposrednog planiranja mreže potrebno je izraditi ažurnu GIS prostornu bazu podataka i uspostaviti mehanizme održavanja sustava. Time JLS dobiva kvalitetni sustav za podršku odlučivanju kojeg može koristiti ne samo u planiranju i izgradnji telekomunikacijske infrastrukture nego i u drugim projektima. Smjernice za implementaciju takvog sustava su:

1. Napraviti kvalitetni pregled stanja svih postojećih prostornih i alfanumeričkih podataka zasnovan na stručnom pristupu kontrole podataka (topologija, popunjenost atributa, jedinstvenost i usklađenost identifikatora).
2. Popisati potrebe korisnika za prostornim informacijama (informacijski proizvodi) prema trenutnim saznanjima, administrativnim i zakonskim obvezama i pravilima, te korištenjem metode intervjua dionika.
3. Izraditi model GIS baze podataka, u službenom koordinatnom sustavu HTRS96/TM, zasnovan na identificiranim potrebama korisnika.
4. Konvertirati postojeće podatke, provesti kontrolu kvalitete i unijeti podatke u GIS bazu.
5. Načiniti plan upravljanja podacima za određeno vremensko razdoblje, opisati procese prikupljanja i uređivanja podataka s jasnim ulogama pojedinih dionika.

Tako pripremljen GIS sustav omogućava da se uopće može pristupiti projektiranju mreža uz pomoć naprednih alata za projektiranje.

Time se značajno smanjuju troškovi te se olakšava dugoročna održivost cjelokupne komunalne infrastrukture.

Upotreba alata za mjerenja na radijskom sučelju u nastavi mobilnih komunikacija

Leonard Novosel
Sveučilište u Zagrebu, Fakultet elektrotehnike i računarstva
Zavod za radiokomunikacije
Unska 3, 10 000 Zagreb, Hrvatska
leonard.novosel@fer.hr

Sažetak – Moderni su radijski komunikacijski sustavi složeni te zahtijevaju od studenata, budućih inženjera, opsežno poznavanje teorije. Nažalost, često puta se zanemaruje praktičan rad na stvarnim radijskim komunikacijskim mrežama što zbog objektivnih, a ponekad i subjektivnih razloga. Razvoj profesionalnih alata za mjerenje na radijskom sučelju u sustavima mobilnih komunikacija omogućuje razvijanje novih metoda u nastavi. Nove metode teže aktivnijem sudjelovanju studenata i usvajanju novih praktičnih znanja primjenjivih u profesionalnom telekomunikacijskom okruženju. Postojanje alata za mjerenja na radijskom sučelju koje svakodnevno koriste telekomunikacijski inženjeri za terenska mjerenja i optimizaciju odlična je prilika za korištenje tih alata u nastavnom procesu sa svrhom boljeg razumijevanja sustava mobilnih komunikacija. U ovom će se radu predstaviti korištenje jednog od dostupnih profesionalnih alata za mjerenje parametara radijskog sučelja Anite Nemo Handy s naglaskom na aktivnom sudjelovanju studenata u mjerenjima, analizi podataka te donošenju zaključaka vezanih uz performanse sustava mobilnih komunikacija.

Abstract - Modern wireless communication systems are complex and require from students, future engineers, extensive theoretical knowledge. Unfortunately, practical work on real wireless communication networks is often neglected because of objective, and sometimes subjective reasons. Development of professional mobile communications radio interface measurement tools allows the development of new teaching methods with active student participation. Students learn new practical knowledge applicable in professional telecommunication environment. The existence of radio interface measurement tools that telecommunication engineers use every day for field measurements and optimization is an excellent opportunity to reuse these tools in the educational process with the aim of better understanding the mobile communication systems. This paper will introduce the use of one of the available professional mobile communications radio interface measurement tools Anite's Nemo Handy with an emphasis on the active student participation in measurements, data analysis and drawing conclusions on the performance of mobile communications system.

I. UVOD

Današnja nastava mobilnih komunikacija zahtijeva od studenta da shvati mnoge apstraktne pojmove što predstavlja problem u njihovom vjernom i jednostavnom prikazu. Teorijski dio u nastavi mobilnih komunikacija dobro je obrađen i objašnjen dok je praktični dio najčešće zanemaren. Glavni razlog manjeg udjela praktičnog rada je cijena kao i sam format opreme koji ne dopušta korištenje izvan laboratorija, odnosno ne omogućuje studentima da samostalno provode mjerenja, analiziraju rezultate i izvode zaključke.

Studenti, odnosno budući inženjeri, tijekom studija ne dolaze u doticaj s mjernim uređajima i sustavima koje koriste profesionalni telekomunikacijski inženjeri te im je potrebno određeno vrijeme da prouče priručnike i odaberu način mjerenja pri prvom susretu s takvom opremom. Problem je i sama analiza rezultata i izvođenje zaključaka koje zahtijeva određeno predznanje i proučavanje opsežne literature kako bi se shvatilo međudjelovanje svih elemenata sustava mobilnih komunikacija [1]. Primjena analizatora spektra uobičajena je pomoć u nastavi mobilnih komunikacija [2], no javlja se problem mjerenja izvan laboratorija zbog veličine opreme. Korištenjem alata za terensko mjerenje na radijskom sučelju vrlo se jednostavno mogu izmjeriti i proučiti parametri mobilnih mreža. Mjerenjem na stvarnim sustavima proširuje i upotpunjuje se teorijsko znanje dobiveno kroz nastavu na predmetima koji su tematsko vezani uz sustave mobilnih komunikacija.

Ovaj rad će pokušati predstaviti neke primjere primjene alata za testiranje mreža mobilnih komunikacija u objašnjavaju fenomena koji se javljaju u stvarnim sustavima. Rad je organiziran na način da se u II. poglavlju uvode pojmovi koji se podučavaju u nastavi mobilnih komunikacija i objašnjavaju osnovni fenomeni koji bi se mogli provjeriti mjerenjem. U III. poglavlju objašnjavaju se mogućnosti Nemo Handy sustava te uvodi u način mjerenja pomoću alata Nemo Handy. U IV. poglavlju razmatra se upotreba mjerenja i mjerenih vrijednosti za objašnjavanje utjecaja radijskog kanala te povezuje s teorijskim znanjima koje bi studenti trebali posjedovati. Poglavljem V. zaključuje se rad.

II. NASTAVA IZ RADIJSKIH KOMUNIKACIJA

Tijekom studija studenti se podučavaju osnovama propagacije elektromagnetskih valova, utjecaju radijskog kanala na elektromagnetski val, osnovnom arhitekturom i načinom rada sustava mobilnih komunikacija. Osnovni cilj ovog teoretskog uvoda jest upoznati studente s mogućnostima i ograničenjima sustava mobilnih komunikacija. Detaljno se izučavaju sustavi mobilnih komunikacija koje studenti mogu svakodnevno sresti, a na

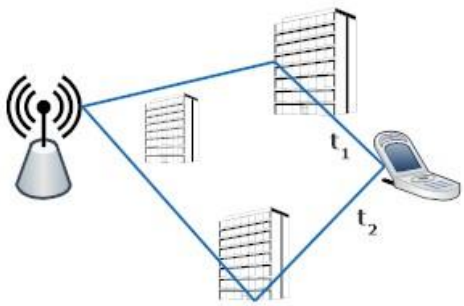
kojima će raditi kao budući inženjeri. Primjeri su sustavi druge i treće generacije mobilnih komunikacija (GSM, UMTS) te sustavi lokalnih radijskih mreža (IEEE 802.11).

Poseban osvrt daje se na ćelijski raspored u sustavima druge i treće generacije kroz teme kapaciteta ćelijskog sustava, raspodjele kanala te međudjelovanja susjednih ćelija na kvalitetu prijenosa. Zanimljiva je i tema utjecaja veličine ćelije na prostiranje elektromagnetskog vala kao i sam tip ćelije. Razmatraju se makro (1- 30 km), mikro (200 – 2000 m), te u posljednje vrijeme i nano i piko (4 – 200 m) ćelije kojima se povećava kapacitet ćelijskog sustava. Smanjenje opsega pokrivanja ćelije rezultira manjim kašnjenjem te povećanjem propusnosti, no povećava se interferencija među susjednim ćelijama kao i broj prijelaza mobilnog uređaja iz jedne ćelije u drugu.

Mehanizmi širenja elektromagnetskog val, a i njihov utjecaj na primljeni signal još je jedna od dobro obrađenih tema kroz pojmove prigušenja slobodnog prostora te proračuna prigušenja pomoću Frissovog zakona. Teme refleksije od tla i prepreka, ogiba, raspršenja vala na objektima koji su reda veličine valne duljine te apsorpcije vala pri prolazu kroz prepreke poučavaju se kroz primjere i simulacije kako bi se dobio vizualni prikaz prostiranja vala u takvom okruženju [3].

Posebno je zanimljiv pojam višestaznog širenja koji se obrađuje kroz teme sporo promjenjivog i brzo promjenjivog fedinga pomoću statističke analize primljenih signala te rezultantnog konstruktivnog ili destruktivnog zbrajanja signala na prijamu [3]. Sporo promjenjivi feding ili sjenjenje javlja se u slučaju postojanja jedne izravne zrake ili uz prisustvo slabe refleksije dok se brzo promjenjivi feding javlja u slučaju pojave mnogo zraka koje najčešće imaju slučajno raspodijeljene faze. Utjecaj brzo promjenjivog fedinga na primljeni signal očituje se kroz nagle i učestale propade primljenog signala dok se pojava sporo promjenjivog fedinga primjećuje kao spora promjena srednje vrijednosti primljenog signala [3].

Kroz teme ćelijskog rasporeda te višestaznog širenja elektromagnetskog vala studenti upoznaju utjecaj radijskog kanala na rasprostiranje valova i efekte na signal na prijamnoj strani. Utjecaji se sinteziraju i proučavaju kroz različite modele kanala koji su dobiveni mjerenjima te naknadnom obradom ili empirijski razradom osnovne teorije. Veličina, tip i raspored objekata u ćeliji utječu na elektromagnetski val, a taj se utjecaj očituje kroz promjene i kašnjenje signala na prijamu.



Slika 1. Višestazno širenje

Teorijski dio modela kanala dobro je razrađen i proučava se kroz sve stupnjeve studija, no praktični odnosno mjerni dio loše je zastupljen u nastavi. U laboratorijskim se uvjetima može vrlo jednostavno mjeriti signal na prijamu pomoću analizatora spektra [2], osciloskopa ili drugih specijaliziranih uređaja te vršiti potrebna obrada i analiza te izvesti zaključci, no u takvim se uvjetima ne mogu promotriti utjecaji različitih okolina na rasprostiranje vala te provesti identifikacija okoline. Terenska se mjerenja mogu provesti i provode se takvim mjernim uređajima no ona se redovito vrše pomoću automobila ili drugog prijevoznog sredstva što, zbog veličine opreme i potrebe za napajanjem, nije prihvatljivo za mjerenja koja bi trebali provoditi studenti u sklopu nastave.

Umjesto korištenjem analizatora, terenska mjerenja studenti mogu jednostavno provesti pomoću profesionalnih alata za mjerenje na radijskom sučelju kakve koriste telekomunikacijski inženjeri. Nedostatak tih alata jest nedovoljna vremenska razlučivost i gruba podjela u mjerenju snage, no za promatranje osnovnih fenomena propagacije u raznim okruženjima, odnosno modelima kanala, ta je razlučivost sasvim dovoljna.

Upoznavanjem mjerne opreme te programske podrške studenti proširuju svoje praktično znanje, a samim mjerenjima i obradom podataka dobivaju uvid u stvarne fenomene koji se odvijaju u radijskom kanalu. Analizom rezultata uz proučavanje literature i usporedbom s teorijom produbljuju svoje znanje o utjecaju kanala na signal na prijamu i kompleksnom međudjelovanju dijelova sustava. Jedan takav alat kojeg svakodnevno koriste telekomunikacijski inženjeri u terenskim mjerenjima, a može se koristiti i u nastavi, jest Nemo Handy tvrtke Anite.

III. MJERENJA POMOĆU NEMO HANDY SUSTAVA

A. Nemo Handy mjerni sustav

Nemo Handy je aplikacija s grafičkim korisničkim sučeljem koja sadrži više različitih stranica prilagođenih za različite zadatke koje uređaj može izvršavati, a instalira se na mobilni telefon. U paketu koji se koristi u ovom radu nalazi se mobilni telefon Nokia C7-00 sa Symbian operativnim sustavom. Navedeni mobilni uređaj je standardni mobilni telefon bez dodatnih funkcija dok mobilna aplikacija Nemo Handy pruža mogućnost pregleda signalizacijskih parametara koji se razmjenjuju između bazne stanice i mobilnog uređaja pri standardnom načinu rada. Mjerenja je moguće provoditi u aktivnom stanju (*dedicated mode*) ili stanju mirovanja (*idle mode*) [4].

Testiranje mobilnih mreža moguće je provesti korištenjem skripti kojima se definiraju aktivnosti mobilne stanice prilikom mjerenja, na primjer broj i trajanje poziva, slanje SMS i MMS poruka, količina prenesenih podataka, slanje elektroničke pošte te protokol za prijenos. Spajanjem mobilnog uređaja na baznu stanicu inicijalizira se spremanje svih dostupnih signalizacijskih podataka, a mobilni uređaj prelazi u aktivno stanje. Sam postupak mjerenja vrlo je jednostavan: na lokaciji predviđenoj za mjerenje pokreće se program Nemo Handy, a rezultati se

zapisuju u zasebnu datoteku koja se kasnije otvara i obrađuje u aplikaciji Nemo Outdoor.

Nemo Outdoor je računalna aplikacija koja se nalazi u istom programskom paketu kao i Nemo Handy. Njena svrha je analiza i pregled mjerenja u jednostavnom grafičkom okruženju koja su ostvarena mobilnim uređajem i Handy aplikacijom.

B. Mjerenja na mrežama druge generacije

Spajanjem na mrežu druge generacije (GSM) u aktivnom stanju osnovni su mjerni parametri razina prijamne snage (*RX level*) i kvaliteta veze (*RX quality*) te odnos signal/interferencija. Za prikaz prijamne snage koristi se njezina vrijednost u rasponu od -120 do -20 dBm (u praksi od -110 do -48 dBm), dok se kvaliteta prikazuje u razinama od 0 do 7. Kvaliteta signala odnosi se na broj krivo prenesenih bitova u 4 uzastopna okvira. Uz navedene podatke prikazani su i broj kanala, smjer prijenosa informacije, poruka i vrsta poruke pojedinog sloja te vrsta korištenog logičkog kanala. Ovime je omogućeno promatranje ponašanja mreže pri upućivanju poziva ili prijenosu informacija.

C. Mjerenja na mrežama treće generacije

Mjerni uređaj Nemo Handy omogućuje detaljna mjerenja na mrežama treće generacije kojima se dobiva uvid u rad zračnog sustava. Nabrojeni su samo neki parametri koji se mogu upotrijebiti za analizu i otkrivanje uvjeta u kanalu [4]:

- HSDPA propusnost (*HSDPA Throughput*) je parametar kojim pokazuje izmjerenu brzina prijenosa podataka (propusnost), kako na aplikacijskom (korisničkom) sloju, tako i na fizičkom MAC (*Medium Access Control*) sloju;
- Procjena snage primljenog signala (*Received Signal Strength Indication*, RSSI);
- Postotak pogrešaka u prijenosu na MAC sloju (*MAC Block Error Rate*) prikazuje parametar *BLER*, a dobiva se kao omjer pogrešno prenesenih blokova i ukupnog broja prenesenih blokova;
- Postotak ponovno poslanih blokova prvi put na MAC sloju (*MAC 1st retransmission rate*) je mjera ponovno prenesenih paketa dobiven omjerom ponovno prenesenih blokova i ukupnog broja blokova koji se promatra pri mjerenju;
- Omjer energije podimpulsa i spektralne gustoće šuma (E_c/N_0) jedan je od bitnijih parametara kvalitete, definira se kao omjer primljene snage korisnog signala (*Received Signal Code Power*, RSCP) i ukupno primljenog signala sumiranog u svim ćelijama (*Received Signal Strength Indication*, RSSI) [5];
- Procjena kvalitete kanala (*HSDPA Channel Quality Indication*) je broj u rasponu [0, 30] koji definira kvalitetu kanala, a samo mjerenje tog parametra ovisi o uređaju koji se koristi. Ako je *CQI* = 30, kvaliteta prijenosa u kanalu je najviša, dok je za *CQI* = 0 najniža [6];
- QoS parametri (*QoS Parameters*) su parametri kvalitete usluge koji su dogovoreni između mobilne stanice i bazne stanice prije samog početka prijenosa.

IV. KORIŠTENJE HANDY MJERNOG SUSTAVA U NASTAVI

Uvođenjem Nemo Handy sustava u nastavu prvenstveno se želi postići veća uključenost studenata u samostalnom istraživanju i mjerenjima. Na Zavodu za radiokomunikacije Fakulteta elektrotehnike i računarstva Sveučilišta u Zagrebu aktivno se koristi Anite Nemo mjerni alat u nastavi na nekoliko predmeta preddiplomskog i diplomskog studija. Uvođenjem mjernih alata u nastavu pokušava se studente potaknuti na samostalan rad. Samostalan rad je često stran studentima koji su navikli na učenje teorije i rješavanje zadataka iz pripremljene literature. Tijekom studija, na zasebnom predmetu ili u sklopu laboratorijskih vježbi, studentima je zadan neki inženjerski zadatak koji moraju samostalno riješiti. Studenti se pokaznim vježbama prvo upoznaju s mogućnostima mjernog sustava, osnovama korištenja i instalacijom potrebne programske podrške. Drugi korak je ustupanje mjernog sustava na korištenje studentima. Kao pripremni zadatak studenti su dužni napraviti okvirni plan mjerenja s planiranim lokacijama mjerenja, parametrima koje će mjeriti kao i očekivanim rezultatima mjerenja. Pripremni zadatak je važan zbog pripreme studenata za mjerenja kroz samostalno proučavanje korisničkih priručnika mjernog sustava te identifikaciji potrebnih parametara za mjerenje. Korisnički priručnici prikazuju mogućnosti sustava, a studenti odabiru koje mogućnosti, odnosno parametre za mjerenje, žele iskoristiti u rješavanju problema. Studentima se daje i literatura iz područja radijskih komunikacijskih sustava kako bi mogli proučiti teoriju na kojoj se baziraju parametri koje će mjeriti. Dodatna literatura pomaže i proširivanju i upotpunjavanju postojećih znanja iz radijskih komunikacijskih sustava uvođenjem i objašnjavanjem novih termina, a koji su važni za rad stvarnog sustava radijskih komunikacija. Proučavanjem literature i korisničkih priručnika dobiva se teorijsko znanje o međudjelovanju elemenata radijskog sustava kao i međusobnom utjecaju mjernih parametara. Planiranjem mjerenja primjenjuje se teorijsko znanje kako bi se dobili dosljedni mjerni rezultati te pokazalo razumijevanje utjecaja i ograničenja sustava.

Provođenjem planiranih mjerenja studenti se upoznaju s upotrebom mjernog sustava na terenu te načinom pohrane podataka. Mjerni se podatci mogu provjeriti odmah nakon mjerenja na samom mobilnom uređaju kako bi se osigurala točnost i dosljednost mjerenih vrijednosti. Sljedeći je korak obrada mjerenja pomoću dostupnih programskih alata. Nemo mjerni sustav dolazi s Nemo Outdoor aplikacijom za obradu i prikazivanje podataka. Pomoću aplikacije odabiru se parametri koji se odnose na rješenje zadanog problema, dok se ostali mogu prikazati informativno. Podatci se mogu usporedno prikazati u Outdoor aplikaciji ili pretvoriti u drugi format. Pretvorbom u drugi format podatci su dostupni za obradu u drugim programskim alatima poput Matlaba ili Mathematice. Korištenje tih alata posebno je korisno pri obradi velike količine podataka te upotrebe statističkih

funkcija za analizu. Studenti su dobro upoznati s tim alatima što im omogućava brzu obradu podataka i njihov kvalitetan prikaz.

Nakon obrade i analize podataka pristupa se izradi dokumentacije gdje se sinteziraju teorijska i praktična znanja. Studenti u izrađenoj dokumentaciji opisuju upotrebljene mjerne metode, prikazuju mjerene parametre, komentiraju rezultate te izvode zaključke. Zaključivanje je proces spajanja teorijskog znanja prikupljenog iz literature te uočavanja utjecaja koji su dobiveni kao rezultati analize mjerenih vrijednosti. Izradom dokumentacije studente se navodi na diskusiju kako bi razmjenjivali ideje i prepoznali uzroke dobivenih rezultata. U nastavku su navedeni neki primjeri mogućih zadataka koje bi studenti mogli riješiti mjerenjem pomoću Nemo sustava.

Pokretanjem korisničke skripte za mjerenje u aktivnom stanju započinje se postupak mjerenja i spremanja vrijednosti. Primjerice, moguće je mjeriti i spremati podatke o ukupnom kašnjenju (*Round-Trip Delay Time*, RTT). RTT je vrijeme koje je potrebno da primatelj primi signal (podatak) i potvrdu o primitku vrati pošiljaocu [4]. RTT je podatak koji pokazuje utjecaj svih elemenata sustava, tipa ćelije, smještaja mobilnog uređaja unutar ćelije kao i interferencije na ukupno kašnjenje i kvalitetu veze. Usporedbom mjerenih vrijednosti RTT i srednje izmjerene propusnosti na MAC sloju kao u tablici I., može se primijetiti trend smanjenja propusnosti s povećanjem kašnjenja. Mjerenjem i prikazom ovisnosti brzine prijenosa o kašnjenju, studenti mogu dobiti prikaz utjecaja svih povezanih elemenata sustava kao i raznih propagacijskih mehanizama na parametre veze.

Posebno je zanimljiva upotreba aplikacije Nemo Outdoor za prikaz nekoliko povezanih parametara što omogućuje bolje razumijevanje povezanosti fenomena u kanalu te posljedice na kvalitetu prijama. Na primjer, vrlo se lako može promatrati utjecaj promjene razine snage na kvalitetu kanala te brzinu prijenosa podataka kao na slici 2 gdje se na horizontalnoj osi nalazi točno vrijeme mjerenja, a na vertikalnoj vrijednosti u ovisnosti o odabranom parametru. Studenti mogu vrlo lako izmjeriti i prikazati usporedno više parametara te komentirati utjecaj raznih fenomena u kanalu na određeni parametar što omogućuje primjenu teorijskih znanja na stvarnim sustavima [7]. Mjerenjem se može dobiti ovisnost brzine prijenosa o indikaciji kvalitete (CQI) kanala te RSSI. Mjerenjem u aktivnom stanju te obradom u Nemo Outdoor aplikaciji dobiva se odnos brzine prijenosa u odnosnu na RSCP. RSCP se koristi za odluke o prekapčanju, proračunu prigušenja staze kao i mjera primljene snage [8].

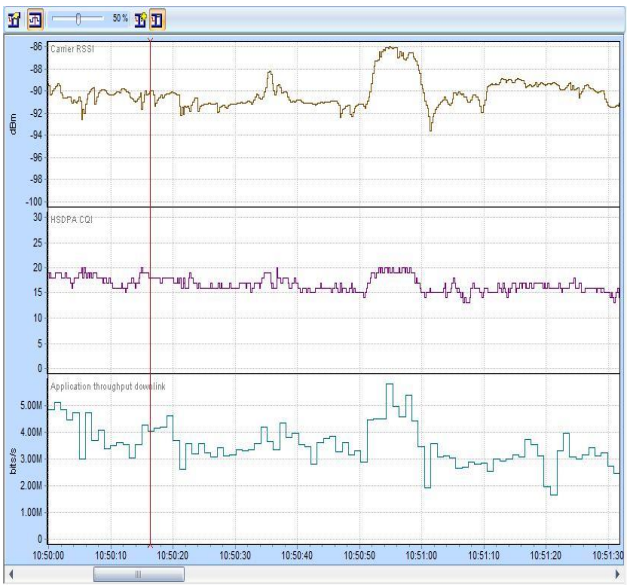
TABLICA I. OVISNOST PROPUSNOSTI O KAŠNJENJU

RTT [ms]	Propusnost na MAC sloju [Mbit/s]
128	4.18
144	4.52
265	4.03
278	4.23
293	3.69
309	3.16
318	3.17
334	2.40
384	3.25
414	2.48
500	2.06
547	1.23
749	1.82
4097	0.003

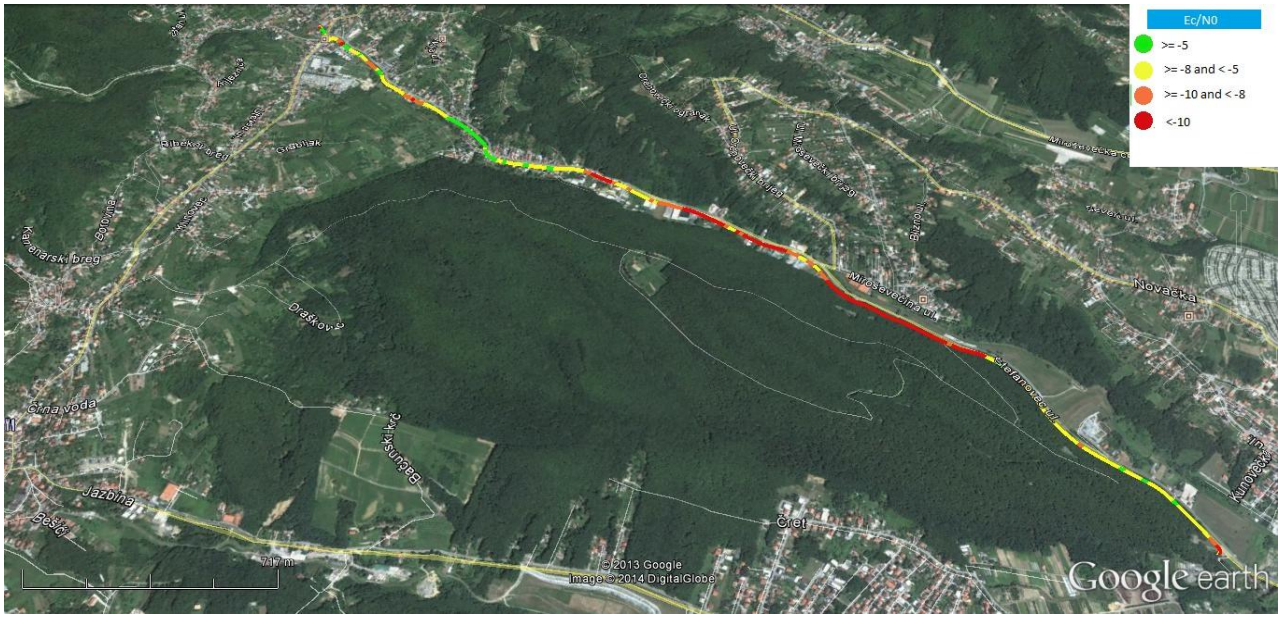
Iscrtavanjem izmjerenih vrijednosti E_c/N_0 na karti kao na slici 3. vrlo se jednostavno mogu uočiti promjene parametra u odnosu na razne objekte koji se pojave u radijskom kanalu kretanjem mobilnog uređaja. Mjerni uređaj mjeri i sprema svoju poziciju, brzinu kretanja i nadmorsku visinu pomoću GPS-a. Tako se na slici 3. vidi smanjenje E_c/N_0 prilikom prolaska mobilnog uređaja kroz brdovito područje uslijed sjenjenja prirodnim zaprekom. Općenito E_c/N_0 pokazuje pokrivanje i kapacitet ćelije jer uzima u obzir pokrivanje ćelije preko RSCP vrijednosti te razinu interferencije preko RSSI vrijednosti. E_c/N_0 može se iskazati preko RSCI i RSSI kao [8]:

$$\frac{E_c}{N_0} = \frac{RSCP}{RSSI} \tag{1}$$

Promjene E_c/N_0, zbog povezanosti s RSSI, pokazuju promjene razine šuma u mjernoj trasi kao na slici 3. Promjene šuma mogu se pojaviti zbog utjecaja okoline ili promjene opterećenja ćelije [8]. Studenti mogu izmjerene vrijednosti E_c/N_0, kao i izmjerena kašnjenja iskoristiti za identifikaciju raznih vrsta *fedinga* te proučiti utjecaj okoline na stvarni komunikacijski sustav kao i utjecaje opterećenja u raznim tipovima ćelija s različitom gustoćom korisnika. Zanimljiva je upotreba opcije zaključavanja Nemo Handy mobilnog uređaja na jednu baznu stanicu za mjerenje pokrivanja bazne stanice i promatranje utjecaja objekata u ćeliji na promjene izmjerenih vrijednosti.

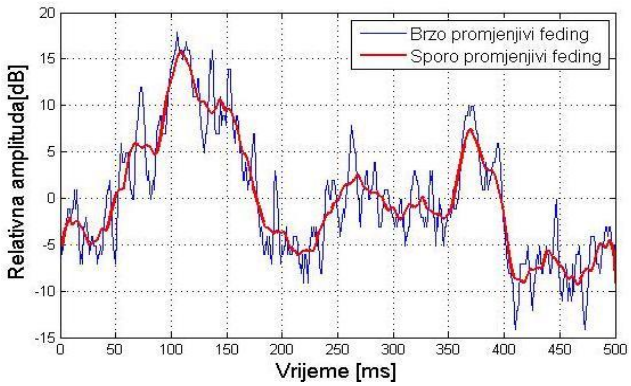


Slika 2. Usporedni prikaz parametara u Nemo Outdoor aplikaciji



Slika 3. Prikaz promjene E_c/N_0 na mjernoj trasi

Mjerenjem primljene snage signala na mreži druge generacije u stanju mirovanja u jednoj urbanoj makro ćeliji te naknadnom obradom može se dobiti prikaz brzo i sporo promjenjivog fedinga kao na slici 3. Rezultati mjerenja preuzeti su iz [9], dokumenta koji je nastao kroz studentski projekt diplomskog studija. Iako vrijeme uzorkovanja od 1 ms nema dovoljnu razlučivost za fino mjerenje brzog fedinga, on je ipak vidljiv kao nagle i značajne promjene amplitude signala na prijamu.



Slika 4. Brzo i sporo promjenjiv feding

V. ZAKLJUČAK

Cijena i kompleksnost opreme koja se koristi za mjerenja u bežičnim komunikacijama često puta je ograničavajući faktor pri samostalnom radu studenta na mjerenjima. Postoje mjerni alati kojima se koriste inženjeri u telekomunikacijama, a koji vrlo učinkovito mogu zamijeniti skupe i glomazne mjerne uređaje u terenskom mjerenju no uz cijenu smanjenje osjetljivosti mjerenja. Posebno je korisna opcija takvih alata mogućnost usporednog prikaza nekoliko izmjerenih parametara kako bi se povezalo znanje o utjecaju kanala na izmjerene vrijednosti.

Alati poput Nemo Handy mjernog sustava posebno su zanimljivi za razne studentske projekte kao i u nastavi upravo zbog jednostavnosti mjerne opreme i mogućnosti prikaza rezultata. Korištenjem takvih alata studenti imaju priliku praktično se upoznati s opremom i programskom podrškom koju će koristi kao telekomunikacijski inženjeri. Tijekom studija studenti dobiveno praktično iskustvo mogu vrlo lako povezati s teorijskom podlogom korištenjem literature ili kroz diskusiju sa svojim mentorima i profesorima.

NETWORKS & ENVIRONMENT

Reselection of base station in TETRA network

Saša Punčikar
Visoka škola za informacijske tehnologije, Zagreb, Croatia
spucikar@vsite.hr

Abstract – TETRA (Terrestrial Trunked Radio) is ETSI defined standard for professional digital mobile radio network. It is mission critical system and one of most important parameter is reliability. Mobile functionality is of great importance for end users and special attention should be given to reselection parameters. The article gives a detailed explanation of the process of reselection, it is explained what are slow reselect threshold and fast reselect threshold, list of adjacent base station that are sent from serving base station to terminal and their influence to smooth transition from serving cell to adjacent cell. Examples of parameters will be shown and practice guides and tools to discover problems of reselection.

I. INTRODUCTION

TETRA (Terrestrial Trunked Radio) is digital mobile system developed with primary function to operate for police department, fire brigades, ambulance, and military purposes but because of rough construction and reliable functionality it was adopted also by electricity and oil companies, airports, mines and it is used for many other applications. TETRA first goal was to offer voice communication and using TDMA, it was possible to deliver opportunity for 4 different users to communicate at same time on same radio channel. Talkgroups were defined and many talkgroups can passively connected on one base radio (one base radio use one radio channel) but only 4 at same time. Also possibility of deploying dynamic allocation of resources was great breakthrough comparing TETRA to analog system where one channel has been used for one group of users and no possibility of dynamic allocation of resources.

Data communication trough TETRA at first was using only SDM (Short Data Messages) trough control channel and without affecting voice communication. Available bitrates trough control channel are sufficient system for control and management for SCADA and similar systems.

Cell reselection of MS can influence both voice and data communication but since data traffic is much shorter and has implemented mechanism for retransmission reselection influence to data traffic is negligible. Also considering fact that in SCADA system probes are mainly mounted on one position and doesn't change position cell reselection is perform rarely, mostly because of equipment malfunction.

On the other hand Mobile Station (MS) primary used for voice communication are constantly changing positions and cell reselection happens very frequently, it should be done as smooth as possible. It is very important for reselection is done quickly; best possible result is for customer not to know about any this.

Special attention should be consider to take into count transmit power balance from BS and transmit power from TETRA terminal. In most TETRA system BS can provide 60-80 W (48-49 dBm) per each base radio that means TX power at antenna connector can be up to 20 W (43 dBm). Typical TX power of handheld terminal is 1W (30 dBm) and mobile terminal (intended to be mounted in vehicle) is 3W (35 dBm). TX power figures are depending on manufacturer but those are typical values that can be seen on practically all systems. Transmit power balance must be achieved to accomplish network quality and lowering power consumption.

Power disbalance of complete system can strongly influence cell reselection, especially if some base stations are set to maximum power because Mobile Station (BS) measuring *RSSI* and calculating *CX* parameter base on *RSSI* from Base Station.

II. RECEIVED SIGNAL STRENGTH

Important difference between TETRA system and most of other commercial mobile network is that in TETRA mobile subscriber unit initiate reselection of Base Station (BS). MS is constantly measuring receiving signal strength indicator (*RSSI*) from serving cell and from adjacent base stations. Using *RSSI* mobile station is calculating *CX* parameter which is basically fade margin for mobile station. *CX* figure defines amount of available additional attenuation before *RSSI* falls below minimum defined value.

For serving cell *C1* parameter is calculated and for adjacent site *C2* parameter is calculated but calculation is done using same formula:

$$CX = RSSI - Rx_Min_Access_level - max(0, Max_MS_Tx_Power - Power_MS) \quad (1)$$

Rx_Min_Access_level is minimum received signal strength value from BS measured on MS that is permitted MS to operate on. If *RSSI* decrease below this value MS will not be able to communicate on this BS. This parameter must be higher than RX sensitivity of base station (BS) and it is defined trough system software. In Motorola Dimetra system this parameter is configured in Zone Configuration Manager separately for each BS and can be used to decrease cell covering area and decrease number of MS that will be connected to BS.

Parameter *max(0, Max_MS_Tx_Power - Power_MS*) is needed to modify *CX* parameter depending on difference of maximum transmit power of MS that can be

used in system and transmit power of specific MS that is in use since two way communication must be achieved. Most manufactures of TETRA terminals produce handheld terminals with 1W (30 dBm) TX power and mobile terminals for installation in vehicles with 3W (35 dBm).

For example *Rx_Min_Access_level* is set to -110 dBm and measured *RSSI* is -82 dBm *C1* would be:

- -82 – (-110) -5= 23 dBm for handheld terminal and (2)
- -82 – (-110) -0= 28 dBm for mobile terminal. (3)

III. RESELECT PARAMETERS

Most important parameters that are determing reselection of BS are fast reselect threshold, slow reselect threshold, fast reselection hysteresis and slow reselection hysteresis:

A. *fast reselect threshold (FRT)* is the maximum level above C1 = '0' for a radio relinquishable link,

B. *fast reselect hysteresis (FRH)* is the hysteresis for a radio relinquishable link

C. slow *reselect threshold (SRT)* is the maximum level above fast reselect threshold for a radio improvable link *and*

D. *slow reselect hysteresis (SRH)* is the hysteresis for a radio improvable link.

Slow and fast hysteresis parameters are in use for defining hysteresis for reselection to occur while slow and fast reselect thresholds are defining minimal conditions for reselection to occur.

Fast reselect parameters are generally in use for relinquishable link. To make the site switching smoother, it is needed to increase the fast threshold and reduce the fast hysteresis parameters. With this set-up the site switching will occur earlier, more often and with less hysteresis.

For site switching in areas of weak coverage, fast hysteresis should be set to 2 dB or 4 dB and slow hysteresis always need to be set to greater value than the fast hysteresis.

Through the Zone Configuration Manager (ZCM) in Motorola TETRA system adjacent sites (eg. Adjacent base stations) must be defined for any base station BS. List of adjacent sites and other parameters (*FRT, SRT, FRH SRH*) are transmitted to mobile station (MS) trough Broadcast Network Channel (BNCH) and Broadcast Control Channel (BCCH). Since every base station should be working on different frequency channel Zone Configuration Manager is sending ID and frequency channel number of adjacent base stations to mobile station (MS). MS is measuring *RSSI* for serving cell and all of adjacent sites and calculating *CX* parameter. Any mistake in defining adjacent site can be critical in process of reselection.

For instance if near base station BS1 is not defined as adjacent site mobile station (MS) is not measuring its signal because it did not received information that this site exist in network. This is the reason why it is not possible to use BS1 if receive signal from active base station is lost. Mobile Station will try to connect to BS2 with lower receiving signal strength. If BS1 is configured as adjacent site for BS2 then it will connect to BS1. Every reselection need some time to take place and problems in communication will probably appear. This kind of behavior is very confusing for end users and most probably they will not be able to describe what is problem.

IV. SERVING CELL STATUSES

Five possible statuses for serving cell are defined through TETRA standard:

A. Exclusive - *RSSI* from serving cell is higher than

Fast Reselect Threshold + Slow Reselect Threshold above Fast + Start Monitoring Threshold Delta. (4)

In Exclusive mode MS is not scanning for adjacent sites since it has excellent signal from serving cell and this saving battery energy,

B. Superior mode - enable MS to start scanning for adjacent sites but it is not possible to start reselection process in this mode,

C. Usable – MS is scanning for adjacent sites and reselection process is possible in this mode but rarely happens because *RSSI* from serving cell is still high,

D. Improvable - MS is scanning for adjacent sites and reselection process is possible and

E. Relinquishable – *RSSI* is low and it is near *RX sensitivity* of MS, MS is scanning for adjacent sites and reselection will take place as soon as possible.

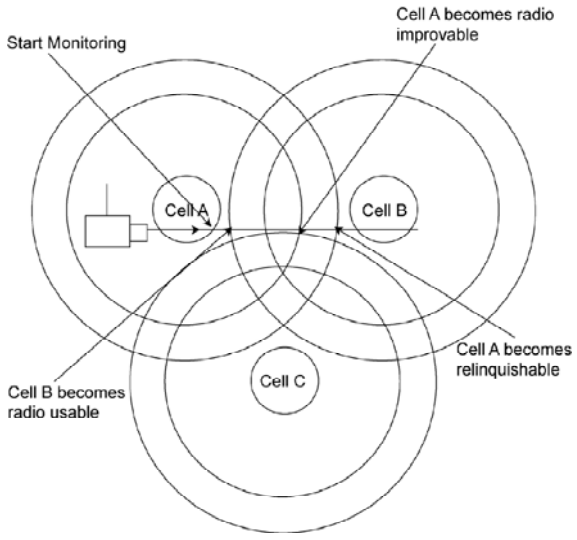

Figure 1. Statuses of serving and neighbor cell

V. NEIGBOR CELL STATUS

Three possible statuses for neighbor cell are defined through TETRA standard. Moving Mobile Station trough TETRA network is shown in figure 1 and boundaries different thresholds for each status.

Statuses for neighbor cell are:

A. Usable – reselection to Usable cell is not allowed if serving cell and neighbor cell have same service level since in this case there is no benefit of reselection. Reselection is possible only if usable cell provide higher service level (higher subscriber class, home location area, cell load or similar). Reselection to usable cell happens very rarely.

B. Improvable – *RSSI* of neighbor cell becomes better than *RSSI* of serving cell so MS is trying to register on neighbor cell. Following criteria must be accepted for reselection to take place:

- *RSSI* of neighbor cell must be for value of *SRH* higher then *RSSI* of serving cell BS and
- *RSSI* of serving cell must lower than *Rx_Min_Access_level* + *FRT* + *SRT*.

C. Relinquishable – *RSSI* of serving cell is lowering and MS is trying to register on neighbor cell as soon as possible. Following criteria must be accepted for reselection to improvable cell to take place:

- *RSSI* of neighbor cell must be for value of *FRH* higher then *RSSI* of serving cell BS
- *RSSI* of serving cell must lower than *Rx_Min_Access_level* + *FRT*

VI. EXAMPLES FOR RESELECTION TO NEIGHBOR CELL

Following parameter on ZCM are configured for all base stations:

Rx_Min_Access_level: -105 dBm

Slow reselect threshold (SRT): 8 dB

Fast reselect threshold (FRT): 12 dB

Slow reselect hysteresis (SRH): 6 dB

Fast reselect hysteresis (FRH): 10 dB

Example 1:

Serving cell *RSSI*: - 76 dBm

Neighbor cell *RSSI*: - 68 dBm

First criteria for neighbor cell to be improvable state is achieved (-68+6>-76 dBm) but second criteria is not achieved (-76>-105+12+8) and reselection will not take place.

Example 2:

Serving cell *RSSI*: - 86 dBm

Neighbor cell *RSSI*: - 78 dBm

First criteria for neighbor cell to be improvable state is achieved (-78+6>-86 dBm). Second criteria is also achieved (-86<-105+12+8) so reselection will take place since neighbor cell is defined as improvable.

VII. TOOLS FOR RESELECTION TEST

Mobile handheld devices and mobile terminals provide service menu (Figure 2.) where it is possible to see *RSSI* and calculated *C1* for serving cell. Also *RSSI* and *C1* can be shown for sites that are defined as adjacent sites for that serving cell.

Entering service menu for Motorola MTH800 is available using combination of four keys: *, #, MENU and RIGHT ARROW. Service menu for Sepura STP8000 is available using combination of four keys: *477.

Figure 2. Motorola MTH800 and Sepura STP8000 terminals in service menu

Basic information about *RSSI* and *CX* from serving cell and adjacent site that are available from service mode can be very useful for basic troubleshooting and it is possible to get information from nontechnical person. Service mode is implemented in all mobile station and it is free tool, network operator can easily guide end users to enter this menu. Trough Zone Configuration Manager (ZCM) it is possible to define profile for Mobile Station to constantly use same serving cell and to determine cell coverage. After determing of coverage for serving cell and for adjacent site together with information about *RSSI* reselection parameters can be set properly.

Motorola Scout is full solution for air interface monitoring and it can be used for testing of TETRA system reselection. Mobile terminal is connected to PC running Scout software using serial RS232 connection. Scout software tool can be used only using USB key with HASP software licensing.

Using Scout information that Mobile station (MS) is receiving trough Broadcast Network Channel (BNCH) and Broadcast Control Channel (BCCH) can be seen. Serving Cell Data window provide information about serving cell reselection parameters, operating channel *RSSI*, *C1* and status of serving cell.

Adjacent Sites Data window provide basic information about adjacent sites that are defined trough Zone Configuration Manager, *RSSI*, *CX* and operating Channel. Any mistake during adjacent site configuration in Zone Configuration manager will be seen on this display.

Scout software can obtain geographic coordinates from Mobile station or using external GPS receiver and it is possible to show on map position of terminal and position of serving cell and adjacent cells.

Microsoft MapPoint maps are used and if database with information about base stations in TETRA network is implemented also symbols and labels for Base Stations will be displayed. Distance to the sites can be shown and GPS track in different colors depending on *RSSI* measured at Mobile Station (MS). Special marks are placed when cell reselection occurs.

RSSI graph for serving cell and monitored adjacent cells is drawn that can provide useful information.

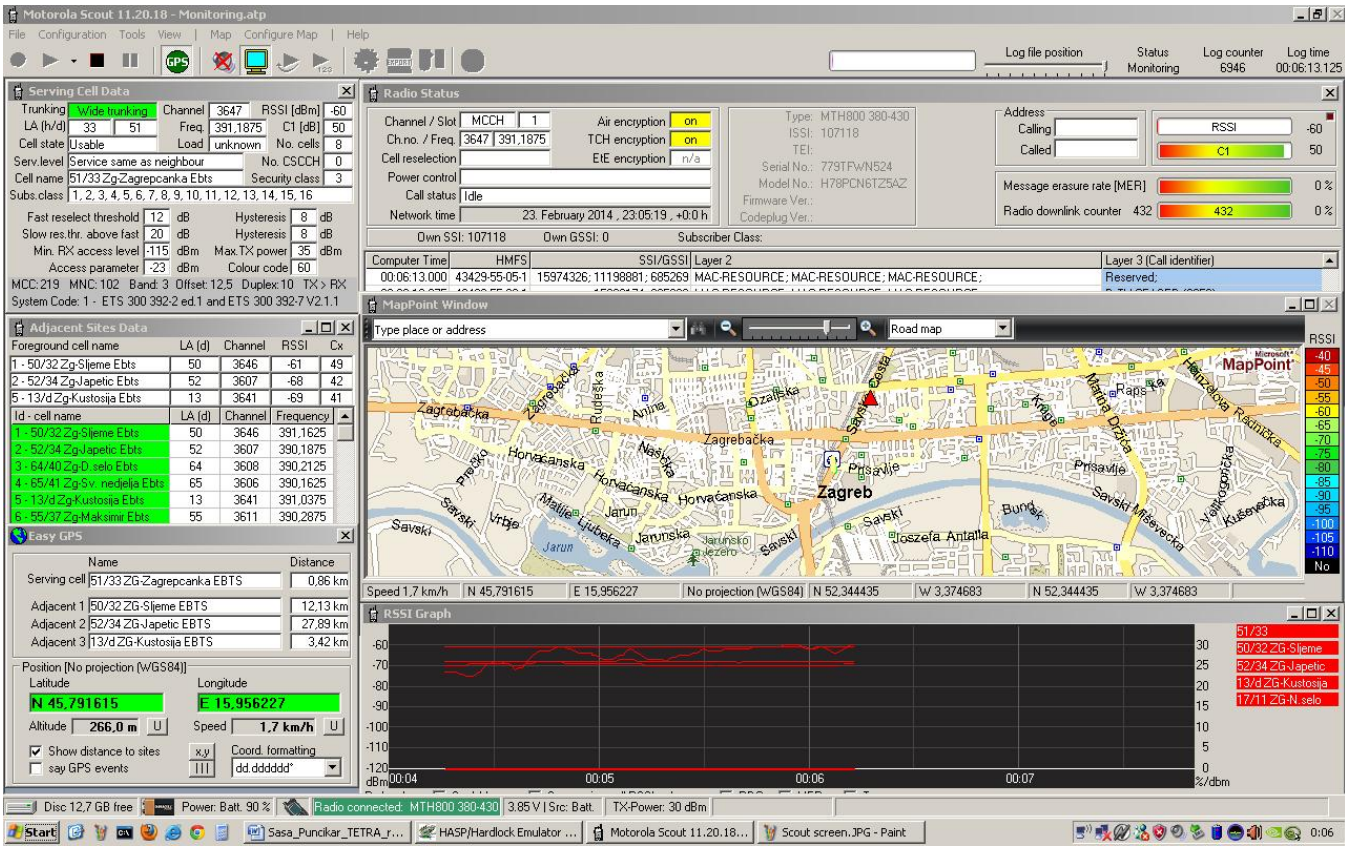

Figure 3. Motorola Scout software

Force channel menu delivers possibility to lock Mobile Station to specific radio channel (specific Base Station).

It is possible to lock MT to specific cell to determine coverage area for any specific cell much easier and much faster way then by Zone Configuration Manager.

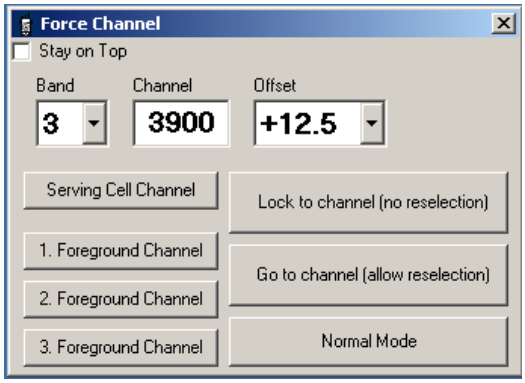

Figure 4. Force Channel menu in Scout software

VIII. CONCLUSION

When configuring TETRA system or adding additional base station in existing system special attention should be dedicated to reselection parameter and defining adjacent sites to enable smooth cell reselection.

After installation empirical field measurement should be done using appropriate tool to verify that all parameters are set properly. During exploitation period using same tools it is possible to determine possible coverage problems due to malfunctioning of base stations, antennas or other parts of system.

Most important parameters for reselection process, *Slow reselect threshold* (*SRT*), *Fast reselect threshold* (*FRT*), *Slow reselect hysteresis* (*SRH*) and *Fast reselect hysteresis* (*FRH*) should be set according to manufacturer specification. After installation and verification at field specific modification should be done for each Base Station since coverage and signal propagation depend on geographic profile and user density.

Inventory management system for water supply network

O. Jukić, I. Heđi
Virovitica College, Virovitica, Republic of Croatia
{oliver.jukic | ivan.hedi}@vsmti.hr

Abstract - In this paper, inventory management system for water supply network is presented. Considering the existing experience in telecommunications network management area, we have made comparison between basic aspects of telecommunications network management and water supply network management. As a first step, we have detected the need for developing water supply network inventory system, covering configuration management functional area. The main goal of this system is to collect, process and store inventory data through graphical user interface, to be presented to network operating personnel. Related work is researched and briefly presented. After that, the inventory management system solution is presented. Complete network structure is modelled as information model in Data Warehouse. Graphical user interface, developed in web technology with Google maps as background, with basic knowledge integrated, is presented. Some basic functions of GUI (graphical user interface) are discussed, such as: logging of network maintenance and repair actions, network planning support and reporting. Finally, we have tried to define future steps for evolution of this inventory management system in complete water supply network solution. Hence, we have made basic discussion related to technical aspects of real-time data collecting in water supply networks, introducing performance and fault management functional areas in water supply network management.

Keywords: Water supply network, network management, leak detection

I. INTRODUCTION

A. Telecommunication and water supply network

Services provided by network operators rely on operator's network infrastructure. Network infrastructure capacity (read: "cost") should be optimized, but service level from the customer's point of view must not be degraded. Because of that, every network operator has some kind of centralized network and/or service operation and maintenance center (official names vary, such as "Operation and Maintenance Center", "Network/Service Operation Center", etc.), tracing current network status and triggering appropriate restoring actions in case of network problems.

Originally, above text was published in [3] within the context of telecommunications network. However, it can be applied to any other network type, such as water supply network. Indeed, there is a network, as a structured collection of nodes (vertices) joined by edges (links); there is a specific network infrastructure (pipes, valves, etc.), there is a service provided; there is measurable service quantity (cubic meters of water delivered); and finally, there is measurable service quality (i.e. chemical content of water, network down-time in seconds, average water pressure in specific network link, etc.).

TABLE I: COMPARISON OF NETWORK ELEMENTS IN TELECOMMUNICATION AND WATER SUPPLY NETWORK

Network elements and terms	
Telecommunication network	***Water supply network***
Optical link; airwave link; UTP link, etc.	Pipe
Router, switch, telephone exchange	i.e. T- valve
Firewall	Valve
Data flow (bit/s)	Water flow (l or m^3/s)
Information flow source – e.g. Video on demand server	Water flow source – e.g. water wellhead

In network theory, there are four general classes of networks: technological networks, social networks, information networks and biological networks. The division into classes is a useful one, since networks in the same class are often treated using similar techniques, ideas and algorithms [4]. Both telecommunication and water supply network belong to the class of technological networks. Terminology and brief network elements comparison is shown in table 1.

B. Inventory (configuration) management

In telecommunication management network concept, there are five main system management functional areas (SMFA). Those system management functional areas are:

- Configuration management
- Fault management
- Performance management

This paper is result of project "Knowledge-based water supply system management" sponsored by company Komrad d.o.o., Slatina

- Accounting management
- Security management

Configuration management is used to locate resources, and to keep track of the resources and their details. Fault management primarily covers detection, isolation and correction of any unusual network operational behavior. Performance management covers performance data collection, analysis, presentation and reporting. Accounting management covers the usage of resources, including charges for this usage. Finally, security management covers detection of security violation [2].

All of those areas are also of great importance in management of water supply networks. Basic functional area is configuration management, which is the basis for all other functional areas. Hence, we have started our research and development activities related to that area.

In water supply network almost all network elements are invisible, located in the ground. In most cases, network elements are not accessible through any communication infrastructure, and they are "software-free" elements. Hence, there is no possibility to implement self-detection or auto-discovery features. Hence, it is rather important to implement and maintain network configuration database. Water supply network operators usually have "database" as a collection of different type documents describing network, even in the electronic form. However, that is not enough for maintenance and management activities. There is very strong need for information system for network configuration management, which we call "inventory" management (in water supply network we use term "network inventory" for all elements building water supply network). As a first step in our research we have focused on related work and developing of our own water supply inventory management system.

C. *Related work*

Vienna Waterwork's approach to network maintenance and rehabilitation is described in [1]. Network information system of Vienna Waterwork is briefly presented. System is primarily used to provide assistance platform for planning process. For predicting pipe failures the proportional hazards model (PHM) is used.

GIS-based water supply information system for an urban area is described in [7]. The basic aim of that water supply information system is to serve as a decision support tool for Waterwork's management by helping maintain records of leaks and repairs.

Both systems are focused on inventory management, but currently without GPS coordinates. Real-time data integration is also not considered.

In [8] system using telemetry for obtaining real-time data from water-supply network is described. However, all data are propagated to SCADA application; inventory management is not considered.

All facts mentioned above have encouraged us to continue research and development activities leading to the integration of real-time collected data with network inventory system based on GPS coordinates.

II. INVENTORY MANAGEMENT SYSTEM ARCHITECTURE

A. *Database layer*

System core is located at database layer. There are three main databases: network inventory database, repairing action database and real-time performance database. Central database in the context of network inventory system is network inventory database. It can be assumed as configuration database. Inventory management system architecture for water supply network is shown on figure 1.

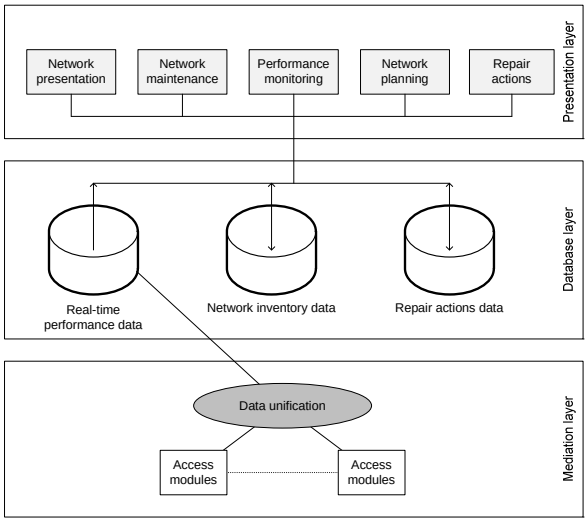

Figure 1. Inventory management system architecture

Since there are no auto-discovery or self-detection features in a "software-free" network, network inventory data must be imported into the database through graphical network presentation interface. Data collection process includes consolidation of all possible sources within the company, such as: network schemas, network descriptions, project plans, repairing logs, internal human knowledge, informal notes etc. Generally, there are two types of network elements: basic elements, such as valves or pipes, that cannot be divided into the smaller parts; compound elements, such as manhole, are compound of number of basic elements. UML class diagram shown on figure 2 presents one compound element containing basic elements such as pipes or valves.

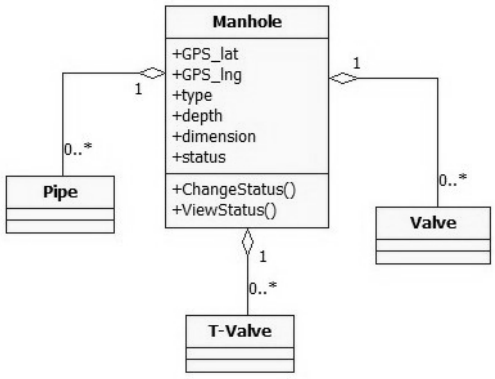

Figure 2. UML class diagram of network element types

GPS coordinates are a very important part of network inventory data model, since they allow network presentation on any GPS supporting platform (figure 3).

Network inventory database is the foundation for all other network-related data and network maintenance and management actions. Repair actions database represents some kind of "log" or "network diary", where all data about network repairing actions are stored and paired with an appropriate network element. Repairing actions data are usable for prediction of future pipe failures using appropriate prediction models. By knowing the number of failures in the past, it is possible to predict time of the next failure with a certain probability. Research and development of suitable models will be subject of the future work, while one possible approach (proportional hazards model - PHM) is described in [5]. All mentioned information are an important part of network planning process.

When water-supply network information model is stored in database, it can be used as foundation for performance management. Every single network element is allowed to become performance measurement point, where specific key performance indicators can be measured. All measurements should be collected in real-time manner from the water-supply network.

Figure 3. Network inventory data presentation on GPS supporting platform

B. *Mediation layer*

Main functions of mediation layer are:

- data collection from water-supply network
- unification of all data formats
- aggregation of collected data on low level, preparing it for storage in real-time performance data warehouse

All data are collected by specific applications called access modules. Every access module uses specific techniques and performs specific actions in order to obtain data from the water-supply network. For instance, data can be collected through any kind of communication protocol (usually using GPRS for data transport), from existing databases or industrial measurement solutions.

All collected measurements are stored into a real-time performance data warehouse. Every measurement is related to some specific performance measurement point, which is defined in a water-supply network information model. This is the basis for data unification. Namely, every measurement is tuple containing:

- performance measurement point (where was it measured?)
- performance measurement indicator name (what was measured?)
- performance measurement value (which value was measured?)

Following the data unification, aggregation of collected data can be performed. Data can be aggregated by any mathematical function, such as sum, average or count. Aggregation can be grouped by performance measurement points or performance measurement indicator names.

C. *Presentation layer*

Network presentation GUI is web interface located on the top of database layer. There are five main modules within network presentation layer:

- Network presentation
- Network maintenance
- Performance monitoring
- Network planning
- Repair actions

Network presentation is aimed to present data about network inventory to the user. However, it is possible to include some other data sources into the graphical presentation. For instance, some very important performance measurement values can be placed on the main screen. This graphical interface is layered, with zooming feature included. Furthermore, compound elements can be "drilled-down", showing its content (figure 4).

Performance monitoring graphical interface serves as "performance cockpit" where all relevant performance measurement indicators can be monitored. Also, some performance measurement configuration data can be set here.

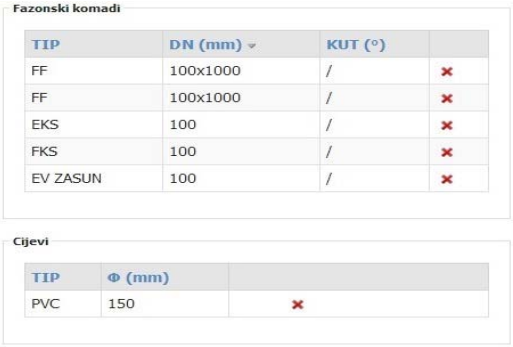

Figure 4. Content of the compound element

Network planning is used for performing different algorithms on network pipes and node elements, in order to predict failures in the future. Input of this process is number of repair actions per network element, which is then processed by algorithm. As a candidate for algorithm arises proportional hazards model (PHM) [6]. This part of the system is still under construction.

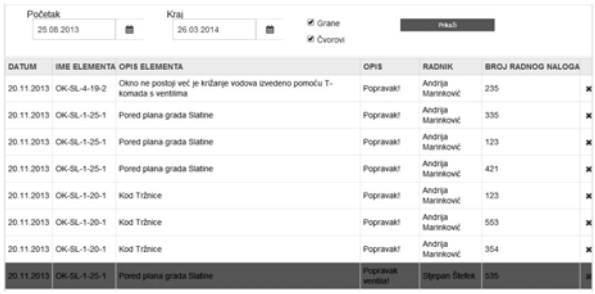

Figure 5. Repairing actions graphical user interface

In order to obtain data about past repairing actions, repair action GUI is developed (figure 5). This is where all data related to some specific repairing action are "logged". Activities during repair are shown on figure 6 using UML activity diagram.

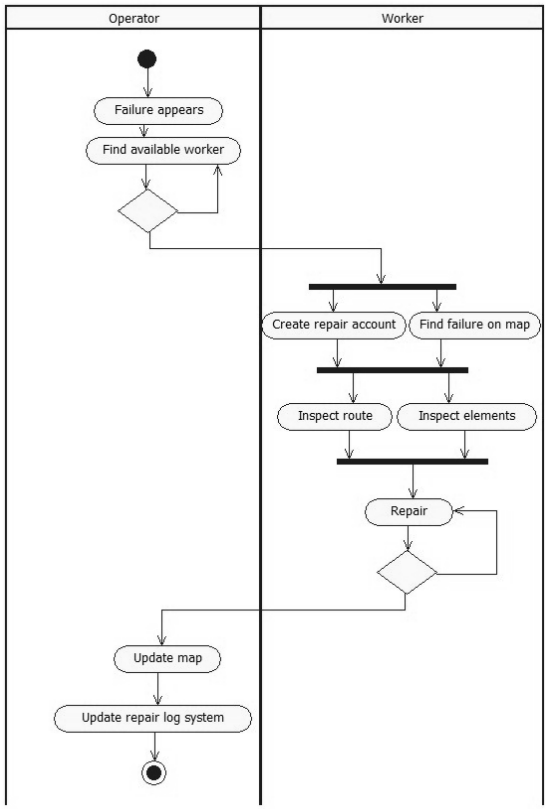

Figure 6. UML activity diagram for repair actions

Since every repair action is followed by number of official records, internal to organization, repairing actions database is typically connected to some internal data sources, for instance working orders database in some ERP (enterprise resource planning) system.

III. CONCLUSION

In this paper we have presented information system for inventory management in water-supply network. Based on existing experience in telecommunications management area, we have compared basic aspects of management in water-supply and telecommunication networks. Encouraged by the results, we have developed inventory management system for water-supply network.

Complete network structure is modelled as information model in Data Warehouse. Graphical user interface, developed in web technology with Google maps as background, with basic knowledge integrated, is presented.

The system was developed and launched during the project "Knowledge-based water supply management" sponsored by company "Komrad d.o.o.", Slatina. It is used during network management, maintenance and repairing process. Some of system components are still subject of research efforts; it will be subject of future work and will be presented in future papers. It is primarily related to real-time data collecting functionality, which will enable performance data integration into the network planning process and network presentation graphical user interface.

mira@etf.rs

Sažetak - Dnevno izlaganje elektromagnetskim poljima GSM/UMTS baznih stanica, iz godine u godinu, povećava javnu zabrinutost o mogućim negativnim efektima po zdravlje ljudi koji žive i rade u njihovoj blizini, a koje danas predstavljaju najrasprostranjeniji izvor nejonizujućeg zračenja. Međunarodni standardi i smjernice ustanovljeni za ograničavanje izloženosti ljudi EM poljima podjeljeni su u dvije kategorije: Osnovna ograničenja (SAR - *Specific Absorption Rate*, indukovana gustina struje i indukovana gustina snage) i Referentni nivoi (jačina električnog polja, jačina magnetskog polja i gustina snage u slobodnom prostoru). Da bi se provjerilo slaganje sa obje ove kategorije, u radu su predstavljena mjerenja jačine el. polja i gustine snage, te su dobijeni rezultati iskorišteni za numeričku predikciju SAR. Mjerenja su izvršena u urbanoj zoni u periodu vršnog (*peak*) saobraćaja. Rezultati su upoređeni sa ICNIPR, IEEE i CENELEC standardima.

I. UVOD

Povećana upotreba mobilnih komunikacija dovela je do postavljanja GSM/UMTS baznih stanica, čak i u blizini kuća, škola, itd, odnosno u gusto naseljenim područjima (zone povećane osjetljivosti). Ovo podiže zabrinutost javnosti u pogledu sigurnosti stanovništva u odnosu na elektromagnetsko (EM) zračenje iz takvih izvora. Uradjene su mnoge studije o potencijalnim biološkim i termičkim efektima EM polja iz GSM/UMTS opsega, ali jasnog stava o mogućoj štetnosti za sada jos uvijek nema. Interakcija GSM/UMTS EM polja i ljudskog organizma treba da obuhvati više aspekata, [1]:

- „Materijal“ (ljudsko telo) ima veoma neobične elektromagnetske osobine i svojstva: električna permitivnost, električna provodljivost;
- Ove osobine nisu sasvim poznate i zavise od aktivnosti osobe;
- Ovaj „materijal“ je aktivan materijal na ćelijskom nivou;
- U većini slučajeva, problem je zapravo spregnut: termički efekat je jedan od glavnih efekta i u zavisnosti je od cirkulacije krvi u organizmu;
- Geometrija i orijentacija ljudskog tijela takođe utiču na apsorpciju elektromagnetske energije u tkivima;
- Raspodjela elektromagnetskog polja je veoma složena i mora se uzeti u obzir aproksimacija ravanskim talasima u dalekoj zoni zračenja.

S druge strane, nadležne organizacije su uspostavile smjernice za ograničavanje izlaganju EM poljima. Međunarodni standardi i smjernice su date u dvije kategorije: (a) Osnovne ograničenja - ograničenja o izlaganju vremenski promjenljivim EM poljima direktno zasnovanim na ustanovljenim zdravstvenim efektima (opsegu GSM/UMTS frekvencija fizička količina koja se koristi da se izračuna ovo ograničenje je SAR) i (b) Referentni nivoi - obezbjeđuju praktičnu procjenu izloženosti u cilju provjere da li su prekoračena osnovna ograničenja. Osnovni cilj provjere usklađenosti za vrijeme ljudske izloženosti EM polju je da data osnovna ograničenja budu zadovoljena. Iz tog razloga sve smjernice i preporučena ograničenja za izlaganje ljudi EM poljima u GSM/UMTS opsegu dati u pogledu SAR (*Specific Absorption Rate*) vrijednosti.

II. SPECIFIČNA BRZINA APSORPCIJE (SAR)

Polja iz opsega radiofrekvencija koja prodiru u tijelo opadaju sa porastom frekvencije. U cilju razumijevanja efekata koje ovo prodiranje može da ima na ljudsko tijelo, potrebno je utvrditi veličinu polja u različitim dijelovima tijela koji su izloženi polju. Ovo zahtijeva poznavanje električnih svojstava različitih vrsta tkiva. Kada se odrede ova svojstva, moguće je proračunati vektore E i H za svaki dio tijela koji je izložen određenoj vrsti izvora. SAR se definiše kao:

$$SAR = \frac{\sigma \left| E^2 \right|}{\rho_m} \left[\frac{\mathrm{W}}{\mathrm{kg}} \right] \qquad (1)$$

gdje je: σ - provodljivost tjelesnog tkiva, E - jačina el. polja u posmatranoj tački, ρ_m - gustina mase tkiva u toj tački. Pošto je SAR, promjena apsorbovane RF energije u jedinici vremena po jedinici mase, veoma teško i složeno mjeriti u biološkim tkivima, standardi dozvoljavaju upotrebu referentnih nivoa gustine snage (W/m^2) u slobodnom prostoru. IEEE standardi ustanovili su osnovna ograničenja za efektivne (*rms*) vrijednosti jačine električnog i magnetskog polja, E i H, tzv. maksimalnu dozvoljenu izloženost (MPE, *Maximum Permisible*

Exposure) i slično kao i ICNIRP standard definišu referentne granice za jačine polja u slobodnom prostoru. Zadovoljavanjem ovih ograničenja osigurano je poštovanje SAR vrijednosti. Dakle, umjesto kompleksnih SAR mjerenja, za usklađenost procjene, gore pomenuti standardi nam omogućavaju jednostavnije mjerenje jačine električnog polja (*rms*). Kao što je spomenuto u uvodu, vrijednost SAR-a zavisi od nekoliko faktora, [2,3]:

- Parametara incidentnog (upadnog) polja, kao što je npr. frekvencija, intenzitet, polarizacija i konfiguracija izvor – objekat (da li se radi o bliskom ili dalekom polju),
- karakteristika izloženog tijela, kao što su veličina tijela, interna i eksterna geometrija, kao i dielektrična svojstva raznih tkiva,
- uticaja ostalih objekata koji se nalaze u polju u blizini izloženog tijela.

Kada je vektor *E* paralelan sa osom koja prolazi kroz centar ljudskog tijela i kada se to tijelo nalazi u dalekom polju, SAR za cijelo tijelo dostiže svoj maksimum. Količina apsorbovane energije zavisi od mnogo faktora, uključujući i veličinu tijela. Za "čovjeka prosječne veličine", koji nije uzemljen, rezonantna apsorpciona frekvencija (frekvencija na kojoj se apsorbuje najviše energije) je 70 MHz, dok ista može varirati kod osoba nestandardnih dimenzija, viših, nižih, djece i osoba koje sjede. Kod osoba koje su uzemljene vrijednost ove frekvencije je manja dva puta. S druge strane, kada imamo uslove izlaganja koji odgovaraju bliskom polju, onda treba napomenuti da se ove frekvencije, kao i uopšte procjena SAR-a potpuno razlikuje. U ovom slučaju, prilikom izlaganja može doći do velikih vrijednosti lokalnog SAR-a, a ta vrijednost, kao i vrijednost SAR-a za cijelo tijelo je jako zavisna od rastojanja čovjeka od izvora visokih frekvencija. Iz (1) vidi se da vrijednost SAR-a zavisi od provodnosti i gustine tkiva. S obzirom na to da se provodnost mijenja u različitim dijelovima tijela, postoji i zavisnost SAR-a od položaja tijela, što je i jedan od razloga zbog kojeg se SAR nekada računa za cijelo tijelo, a nekada za lokalne dijelove tijela (kao što su glava, vrat, trup i ekstremiteti). Gustina tkiva je poprilično konstantna duž tijela, tako da promjena SAR-a ne zavisi od njene vrijednosti. Postojanje drugih objekata u polju može da utiče na samo polje preko intenziteta, polarizacije, i na taj način da promijeni vrijednosti za SAR. SAR se proračunava na osnovu eksperimentalnih podataka iz laboratorije ili određenim numeričkim metodama. To znači da prilikom provjere kompatibilnosti sa nekim graničnim nivoom iz standarda nisu česti slučajevi u kojima će se to provjeravati direktno iz vrijednosti SAR-a. Zbog toga su date tzv. Referentne vrijednosti koje su izražene nekim veličinama koje se lako mogu izmjeriti (npr. vektori *E* i *H*), a koje odgovaraju određenim vrijednostima SAR-a. Inače, SAR pored toga što se nalazi u standardima kao granična vrijednost, takođe se daje kao aproksimacija količine apsorbovane energije koja potiče od nekog uređaja u vidu podatka za taj uređaj, kao što je to slučaj npr. sa mobilnim telefonima. U odnosu na apsorpciju energije u tijelu EM polja se mogu podijeliti u četiri opsega, [2, 3]:

- Frekvencije od približno 100 kHz do vrijednosti malo manje od 20 MHz, na kojima apsorpcija u trupu opada brzo sa opadanjem frekvencije, a značajna apsorpcija može da se pojavi u vratu i nogama,
- frekvencije u opsegu od 20 MHz do 300 MHz, na kojima relativno visoke apsorpcije mogu da se pojave u cijelom tijelu, a ukoliko su dostignute rezonantne frekvencije mogu biti još veće,
- frekvencije u opsegu od 300 MHz do nekoliko GHz, kod kojih imamo lokalnu i neuniformnu apsorpciju i
- frekvencije preko 10 GHz, kod kojih se apsorpcija energije dešava primarno na površini tijela.

Koncept SAR ima smisla samo u opsegu od 100 kHz do 10 GHz, jer je u tom području dubina penetracije veća od 1 cm, [2,3]. Gustina indukovane struje je važan parametar na frekvencijama ispod 100 kHz, dok se na frekvencijama iznad 6 GHz energija apsorbuje površinski, pa je važna gustina upadne snage. Postoji opsežna literatura o procjeni srednje vrijednosti SAR za cijelo tijelo i prostornoj raspodjeli SAR za različite modele životinja, pa čak i za model čovjeka. Neke ranije procjene bazirale su se na prostim sferičnim ili elipsoidnim modelima, npr. Durnijev, [4]. Međutim, u novijim istraživanjima koriste se numeričke simulacije anatomski korektnijih modela odraslog čovjeka. SAR je ključni koncept u planiranju i analizi eksperimenata, kako onih *in vivo*, tako i *in vitro* i služi kao osnova savremenim standardima za zaštitu ljudi od RF/MT zračenja. Pri tom treba istaći da podjednaku važnost imaju i prosječna vrijednost za SAR za cijelo tijelo, kao i lokalni maksimumi prostorno usrednjene vrijednosti za SAR, [5].

III. PRORAČUN SAR VRIJEDNOSTI

U zoni dalekog polja izloženost opšte populacije zračenju baznih stanica može se smatrati kao izloženost ravanskim elektromagnetskim talasima. Na frekvenciji GSM 900 MHz, prosječna provodljivost ljudskog tijela je $\sigma = 0{,}97$ S/m, dok je relativna permitivnost $\varepsilon_r = 47{,}4$. Na frekvencijama GSM 1800 MHz, te UMTS 2100 MHz, ove vrijednosti su približno: ($\sigma = 1{,}35$ S/m, $\varepsilon_r = 45{,}21$) i ($\sigma = 1{,}5$ S/m, $\varepsilon_r = 45{,}2$), u skladu sa srednjom vrijednosti, računatom za cijelo tijelo prema [6]. Relativna magnetska permeabilnost ljudskog tijela, prema [7], približno iznosi $\mu_r = 0{,}99$, dok je prosječna gustina ljudskog tijela, prema [8], 1062 kg/m^3. Imajući u obzir gore navedene činjenice, SAR se može izračunati u funkciji incidentnog električnog ili magnetskog polja koristeći (1):

$$SAR = \frac{\sigma}{\rho} \cdot \frac{\mu\omega}{\sqrt{\sigma^2 + \varepsilon^2\omega^2}} \left(1+\gamma_r\right)^2 \left|H\right|^2, \qquad (2)$$

$$\gamma_r = \frac{2\left|\sqrt{\varepsilon'}\right|}{\left|\sqrt{\varepsilon'} + \sqrt{\varepsilon_0}\right|} - 1, \qquad (3)$$

$$\varepsilon' = \varepsilon + j\frac{\sigma}{\omega}, \qquad (4)$$

$$H = \frac{E}{Z_0}, \tag{5}$$

$$SAR = \frac{\sigma}{\rho} \cdot \frac{\mu\omega}{\sqrt{\sigma^2 + \varepsilon^2\omega^2}} (1+\gamma_r)^2 \frac{|E|^2}{Z_0^2}, \tag{6}$$

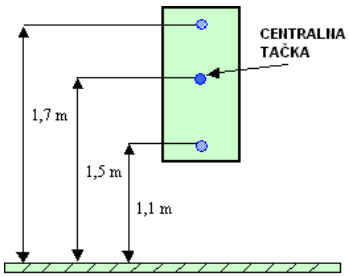
pri čemu su: γ_r – odgovarajući koeficijent refleksije, ε' – kompleksna permitivnost sredine, H i E – efektivne (*rms*) vrijednosti magnetskog i električnog polja, respektivno.

U ovom radu su predstavljeni rezultati mjerenja jačine el. polja i gustine snage u blizini bazne stanice u urbanom okruženju. Procjena izloženosti se vršila u cilju provjere nivoa izloženosti elektromagnetskom zračenju, te poređenju istih sa odgovarajućim standardima. Na osnovu dobijenih rezultata, koristeći izraz (6), prikazane su i SAR vrijednosti.

IV. MJERENJE JAČINE ELEKTRIČNOG POLJA I GUSTINE SNAGE U BLIZINI BAZNE STANICE

Precizno mjerenje jačine el. polja i gustine snage u složenom i dinamičnom okruženju je težak zadatak. To je uglavnom zbog refleksije, apsorpcije i interferencije EM talasa. Stoga, različita mjerenja mogu dovesti do vrlo različitih rezultata zbog ovakvih uslova [9]. Mjerenja EM zračenja baznih stanica (BS) mobilne telefonije izvršena u ovom radu su samo jedan od segmenata iz oblasti mjerenja zračenja radiofrekventnih EM polja, u skladu sa [10, 11]. U nastavku je ukratko opisan postupak mjerenja u skladu sa Slučajem 2 (skeniranje promjenljivog frekventnog opsega po određenim frekvencijama u dalekoj zoni zračenja) Pravila 37/2008. Ovaj tip mjerenja je najbolje raditi koristeći lagane, baterijski napajane analizatore spektra (AS). Analizator spektra bi trebao da ima mogućnost softverske kontrole, koja je neophodna zbog velike količine frekventnih i amplitudskih podataka koji se moraju prikupiti tokom ispitivanja, a da bi se zadržala konzistentnost rezultata dobijenih od većeg broja kompleta mjerne opreme kojom rukuje više ljudi. Softver treba da ima mogućnost programiranja faktora pojačanja antene i gubitaka na konektorima kablova. Ovo će dozvoliti sistemu za ispitivanje da koristi različite antene i kablove dozvoljavajući veći stepen prilagođavanja za svaki opseg. Na ovaj način mogucnost greške ljudskog faktora se svodi na minimum. Analizatori spektra će povremeno raditi u opstruirajućem RF okruženju (*hostile RF environments*). Stoga, dobar dinamički opseg i intermodulacione preformanse će biti od najveće važnosti za vjerodostojne i ponovljive rezultate. Antene za ispitivanje trebaju biti lagane i robusne, a trebaju se koristiti i napojni kablovi dobrog kvaliteta. Antene koje se preporučuju za korištenje su: (a) Magnetna petlja za HF područje; (b) Širokopojasna dipol antena ili (zatvorena) *log* periodic antena; (c) Bi-konična antena; (d) Direkciona antena za druge emisione tipove (korištenje ovih antenna se preporučuje kada postoji glavno zračenje, dok je sekundarno zračenje zanemarljivo); (e) Izotropna, trosna antena. Sva mjerna oprema treba biti kalibrisana (u skladu sa preporukama proizvođača ili prema postupcima za izvođenje kontrole kvaliteta). RF instalacije (kablovi, konektori, talasovodi...) se trebaju, svaki pojedinacno, odrediti i provjeriti prije upotrebe zbog mogućih mehaničkih oštećenja. Svaka promjena pojačanja faktora antene i gubici na kablovima trebaju se programirati u mjerni prijemnik/softver. Postupak mjerenja se treba odvijati u sljedećim koracima:

a) **Mjerna tačka.** Mjerenja treba obaviti u jednoj jedinstvenoj tački na visini od 1,5 m od nivoa zemlje (ili nivoa poda).



Slika 1. Centralna mjerna tačaka u zoni dalekog polja

b) **Frekventni opseg.** Mjerni postupak iz Slučaja 2 se koristi za frekventni opseg „9 kHz – 3 GHz".

c) **Podešavanje analizatora spektra (AS).** Usljed različitih RF izvora u radio spektru, mjerna širina opsega trebala bi biti kompromisna veličina. Unutar spektra postoji mješavina širokih/uskih, analognih/digitalnih i kontinualnih/diskontinualnih izvora zračenja. Preporučuje se za analizatore spektra da koriste sljedeću širinu opsega/vrijeme ispitivanja (konkretno za posmatrani opseg u Slučaju 2, 9 kHz – 3 GHz): RBW = 100 kHz, VBW = 300 kHz sa vremenom ispitivanja od 700 ms – 1 s ili prema preporukama proizvođača. Prag osjetljivosti od –40 dB (može do -70 dB) se odnosi na usvojeni nivo iz smjernica. Antena treba biti korištena u oba, horizontalnom i vertikalnom položaju. Takodje, trebaju biti korišteni "*Max-hold*" i "*Peak*" način rada (za detektor).

d) **Obrada podataka.** Imajući u vidu da se razmatra slučaj mjerenja u dalekoj zoni zračenja, mag. polje H ili gustina snage S mogu se, u odnosu na prostiranje u slobodnom prostoru (impedansa vazduha $Z_0 = 377\ \Omega$), prema poznatoj vrijednosti el. polja, izračunati prema (7):

$$S = EH = E^2 / Z_0 = H^2 Z_0. \tag{7}$$

Da bi se izračunala ukupna gustina snage u podesivom frekventnom opsegu, za AS korišten u ovom radu, neophodno je bilo znati faktor pojačanja antene u tom opsegu, prema [12]. Za ovu konverziju se koristi izraz (8):

$$S = \frac{10^{\left(\frac{p-G}{10}\right)}}{1000} \cdot \frac{4\pi}{\lambda^2} \tag{8}$$

gdje je S gustina snage (u W/m^2), p je izmjerena snaga (u dBm), G je faktor pojačanja antene u odnosu na izotropni radijator (u dBi) i λ je talasna dužina izvora (u metrima).

e) **Provjera koeficijenta ukupne izloženosti.** Za frekvencije iznad 100 kHz sljedeći zahtjevi bi

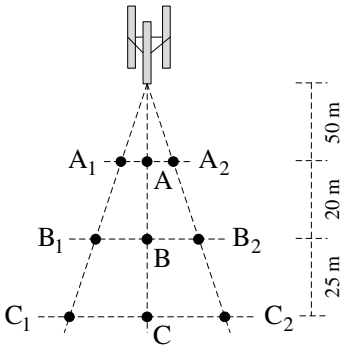
trebali da budu ispunjeni za vrijednosti el. i mag. polja, te srednju gustinu snage EM zračenja:

$$\sum_{i=100kHz}^{1MHz}\left(\frac{E_i}{c}\right)^2+\sum_{i>1MHz}^{300GHz}\left(\frac{E_i}{E_{L,i}}\right)^2\le 1 \qquad (9)$$

$$\sum_{j=100kHz}^{1MHz}\left(\frac{H_j}{d}\right)^2+\sum_{j>1MHz}^{300GHz}\left(\frac{H_j}{H_{L,j}}\right)^2\le 1 \qquad (10)$$

$$\sum_{i=1}^{N}\frac{S_i^{meas}}{S_i^{guid}}=\frac{S_1^{meas}}{S_1^{guid}}+\frac{S_2^{meas}}{S_2^{guid}}+\ldots+\frac{S_N^{meas}}{S_N^{guid}}<1. \qquad (11)$$

gdje su: E_i intenzitet električnog polja na frekvenciji i, $E_{L,i}$ referentni nivo električnog polja dat u Tabeli II u odnosu na ICNIRP standard, H_j intenzitet magnetskog polja na frekvenciji j, $H_{L,j}$ referentni nivo magnetskog polja prema [13], $c = 87/f$ V/m i $d = 0{,}73/f$ A/m za izlaganje opšte populacije, S_i^{meas} izmjerena gustina snage na frekvenciji i, te S_i^{guid} referentni nivo gustine snage dat Tabeli II u odnosu na ICNIRP standard.



Slika 2. Raspored mjernih tačaka u zoni dalekog polja

Slika 3. (a) Spectran HF-4040; (b) HyperLOG 7040, Aaronia

Slika 4. EME SPY 140, Satimo

Mjerenja u ovom radu su obavljena u više tačaka u pristupačnoj zoni dalekog polja na platou Elektrotehničkog fakulteta Istočno Sarajevo. Sve mjerne tačke su odabrane kao najbolji reprezenti raspodjele i maksimalnih nivoa EM polja, tako da je većina njih bila u osi glavnih snopova usmjerenih dijagrama zračenja antena. Slika 2 prikazuje raspored mjernih tačaka u odnosu na lokaciju bazne stanice smještene na krovu Elektrotehničkog fakulteta u Istošnom Sarajevu. U ovoj zoni, jačinu el. polja i srednju gustinu snage čine komponente upadnog polja (LOS – *Line of Sight*), te komponente polja nastale usljed refleksije, rasijavanja, itd. [1, 2]. U cilju preciznijih rezultata mjerenja istovremeno su korištena dva mjerna uredjaja u dalekoj zoni zračenja: (a) širokopojasni, frekventno-selektivni, programabilni analizator spektra Aaronia HF4040 (sa HyperLog 7040 antenom u opsegu 700 MHz - 4GHz) u sva tri ortogonalna smjera, u kombinaciji sa računarom uključujući softver *MCS Spectrum Analyzer* i (b) izotropski dozimetar Satimo EME Spy 140, koji je mjerio jačinu el. polja nezavisno od polarizacije emitovanih talasa, Slike 3 i 4, respektivno. Detaljnije specifikacije mjerne opreme date su u [12,14].

V. REZULTATI MJERENJA I SAR VRIJEDNOSTI

U Tabeli I prikazani su rezultati mjerenja jačine el. polja i gustine snage u opsegu frekvencija GSM900, GSM1800 i UMTS2100, u rasponu (SPAN) od 35 MHz, 75 MHz i 60 MHz, respektivno. Mjerenja su izvršena u periodu vršnog (*peak*) saobraćaja. Vremenski interval mjerenja u svakoj mjernoj tački iznosio je 6 minuta. U radu su prikazani i dijagrami promjene signala u vremenu iz UMTS opsega snimljeni pomoću analizatora spektra (AS) Spectran HF-4040 i EME SPY 140, Slike 5 i 6, respektivno. Dobijeno rezultantno el. polje pomoću AS Spectran HF-4040, Tabela I, izračunato je prema zbiru jačina komponenti vektora el. polja E na više zabilježenih frekvencija unutar posmatranog frekvencijskog opsega. Vrijednosti polja dozimetra EME SPY 140 predstavljaju usrednjene vrijednosti unutar posmatranog opsega. Podešavanja za RBW izabrana su po preporuci proizvođača, a u skladu sa izabranim opsegom i vrstom mjerenog signala. Kod svih rezultata dobijenih u programu *MCS Spectrum Analyzer*, Tabela I, u obzir je uzeta mjerna netačnost instrumenta od ±3 dB, pojačanje antene, kao i slabljenje kalibrisanog kabla. Cijelo vrijeme tokom mjerenja, u programu je bila korištena opcija „*Trace Maximum*“, jer bi bez nje procedura mjerenja bila neizvodljiva, kako zbog promjena amplitude EM talasa u vremenu, tako i zbog dugog vremena mjerenja. Ako izvor signala na određenoj frekvenciji nije bio operativan prilikom skeniranja tog opsega, onda on nije bio uključen u procjenu izlaganja. Slično tome, ako su signali bili emitovani povremeno ili sa promjenljivim snagama, samo su maksimalni nivoi snage, tokom vremena skeniranja, bili zabilježeni, pa je, za određene frekvencije signala, izlaganje moglo biti precjenjeno. Stoga, ovi rezultati predstavljaju maksimalno izlaganje, koje se povremeno dešava na mjestu mjerenja. U Tabeli I su prikazane i SAR vrijednosti izračunate primjenom izraza (6) za procjenu SAR u funkciji izmjerene jačine el. polja. Izračunate vrijednosti su date za visinu od 1,5 m od nivoa tla, prema Slici 1. Dobijeni rezultati su upoređeni sa referentnim nivoima [11, 13, 15], te pokazuju da su gustine snage EM

polja, u trenutku mjerenja, bile daleko ispod ovih vrijednosti, što je i u skladu sa [16]. Granične vrijednosti el. polja i gustine snage, te SAR vrijednosti, prikazane su i u Tabelama II i III, respektivno. Rezultati mjerenja pomoću dozimetra EME SPY 140 pokazuju odredjenu razliku u odnosu na vrijednosti izmjerene pomoću AS Spectran HF-4040, koja se mogu objasniti akumulacijom greške tačnosti Spectrana HF-4040 i dozimetra EME SPY 140. Drugi uzrok ovih razlika može biti vremenski aspekt. Ukupna gustina snage je veoma promjenljiva u vremenu. Takođe, prilikom mjerenja, bila je prisutna interferencija signala usljed smetnji od nekih drugih izvora (najčešće DECT telefona), što se ogleda u većem odstupanju izmjerene frekvencije u odnosu na centralnu ARFCN pojedinih kanala. Razlike su i u mogućnostima podešavanja samih parametara unutar mjernih uređaja (parametre za RBW i SPAN, širinu frekventnog opsega, kao i mjerenje jačine el. polja i gustine snage po kanalima u GSM/UMTS mreži nije moguće podešavati kod dozimetra EME SPY 140). Razlikuje se i vrijeme uzorkovanja signala tj. vrijeme prebrisavanja frekventnog opsega ova dva uređaja. Konačno, AS Spectran HF-4040, za razliku od dozimetra EME SPY 140, nema mogućnost izračunavanja ukupne gustine snage u posmatranom frekvencijskom opsegu.

TABELA I. REZULTATI MJERENJA ELEKTRIČNOG POLJA I GUSTINE SNAGE U GSM I UMTS OPSEGU

Koordinate MT		Opseg (MHz)	E_{HF4040} (V/m)	E_{EMESPY} (V/m)	Devijacija (V/m)	S_{HF4040} (μW/m^2)	S_{EMESPY} (μW/m^2)	SAR_{HF4040} (μW/kg)	SAR_{EMESPY} (μW/kg)	$SAR_{DEVIJACIJA}$ (μW/kg)

VI. ZAKLJUČAK

BS mobilne telefonije su danas veoma interesantne sa aspekta procjene intenziteta EM zračenja. Razlog za to je što veliki procenat zračenja, kome je čovjek danas izložen, potiče upravo od njih. Ta procjena nije jednostavan zadatak, jer zavisi od relativnog položaja čovjeka i BS, karakteristika emitovanog signala, konfiguracije terena i antenskog sistema, stepena urbanizacije sredine, itd. U okviru mobilnih komunikacionih sistema, jedan od parametara koji se koristi za procjenu izloženosti ljudske populacije EM poljima je SAR. Korištenjem izraza za predikciju SAR mogu se odrediti indukovane SAR vrijednosti za osobe koje se nalaze u neposrednoj blizini BS. Analizirajući rezultate praktičnih mjerenja koja su izvršena na ograničenom broju mjesta u zoni u kojoj je uobičajno prisustvo opšte populacije, na visini od 1,5 m u odnosu na nivo tla, jačina el. polja i gustina snage koju su emitovale posmatrane antene GSM/UMTS opsega, te SAR vrijednosti u dalekoj zoni zračenja, nikada nisu prešle referentne nivoe po ICNIRP, IEEE i CENELEC standardu, kao ni prema važećem Pravilniku 37/2008 Regulatorne agencije za komunikacije BiH. Pošto su svi dijelovi ljudskog tijela izloženi EM zračenju, paznja je najvećim dijelom usmjerena na prosječnu izlozenost SAR cijelog tijela. Konačno, numerička predikcija SAR vrijednosti, takođe, zadovoljava osnovna ograničenja.

Utjecaj LTE tehnologije na razine elektromagnetskih polja u mobilnim mrežama Hrvatskog Telekoma

Ružica Gajić *, Ksenija Janaček*
* Hrvatski Telekom, Roberta Frangeša Mihanovića 9, Zagreb, Hrvatska
ruzica.gajic@t.ht.hr; ksenija.janacek@t.ht.hr

U području pokretnih komunikacija u Hrvatskoj su prisutni izvori elektromagnetskog polja tehnologija GSM, UMTS, DCS i LTE. Mreža pokretnih komunikacija tehnologije LTE je u komercijalni rad u Hrvatskoj puštena u ožujku 2013. godine, od strane dvaju telekomunikacijskih operatera. S obzirom da su elektromagnetska polja emitirana od strane visokofrekvencijskih izvora u mobilnim mrežama stalni predmet interesa javnosti, u radu se razmatraju izmjerene razine elektromagnetskih polja i njihova usporedba s dozvoljenim razinama. Analizirane su izmjerene vrijednosti električnog polja u mobilnim mrežama Hrvatskog Telekoma: 882 mjerenja izvora tehnologije GSM, 987 mjerenja izvora tehnologije UMTS, 130 mjerenja izvora tehnologije DCS i 22 mjerenja izvora tehnologije LTE. Utvrđeno je da su sve izmjerene vrijednosti unutar razina propisanih Pravilnikom o zaštiti od elektromagnetskih polja, kao i istodobni utjecaj više polja koja djeluju na istom mjestu.

I. UVOD

Mreža pokretnih komunikacija tehnologije LTE (eng. Long Term Evolution) je u komercijalni rad u Hrvatskoj puštena u ožujku 2013. godine, od strane dvaju telekomunikacijskih operatera. Uz LTE, u Hrvatskoj su prisutne i ostale tehnologije: GSM (eng. Global System for Mobile Communications), UMTS (eng. Universal Mobile Telecommunications System) i DCS (eng. Digital Cellular System). Razloga za uvođenje sustava LTE je više: rast usluga koje zahtijevaju pristup širokopojasnom mobilnom pristupu Internetu, kapacitivna ograničenja sustava UMTS iz tehnologije 3G (tehnologija treće generacije, eng. 3G, 3rd generation), povećanje učinkovitosti korištenih radijskih resursa. Neminovno je da su u mobilnim mrežama tehnologije LTE postignute veće brzine prijenosa podataka te da će već sama ta činjenica omogućiti kvalitetnije korištenje usluga, kao i razvoj novih usluga.

S druge strane se postavlja pitanje razina elektromagnetskih polja emitiranih u mobilnim mrežama i njihov utjecaj na zdravlje. Javnost je vrlo senzibilizirana utjecajem elektromagnetskih polja a uočava se i manjak objektivnih činjenica, bilo o poznavanju zakonodavnog okvira, bilo o stvarnim razinama elektromagnetskih polja koje se javljaju u praksi. Još jedna tehnologija mobilnih komunikacija postavlja u prvi plan sljedeće teme: Zadovoljavaju li razine elektromagnetskih polja tehnologije LTE zakonom propisane granice? Jesu li zadovoljeni uvjeti istovremenog rada polja više frekvencija? Kolike su razine elektromagnetskih polja emitiranih od već uvedenih tehnologija GSM, DCS i UMTS?

S obzirom da su elektromagnetska polja emitirana od strane visokofrekvencijskih izvora u mobilnim mrežama stalni predmet interesa javnosti, u radu se razmatraju izmjerene razine elektromagnetskih polja i njihova usporedba s dozvoljenim razinama. Mjerenja su obavljale isključivo tvrtke koje posjeduju ovlaštenje Ministarstva zdravlja, sukladno odredbama Pravilnika o zaštiti od elektromagnetskih polja. U Republici Hrvatskoj su dozvoljene razine referentnih veličina definirane u Pravilniku o zaštiti od elektromagnetskih polja. Cilj rada je utvrditi zadovoljavaju li izmjerene referentne veličine granične razine propisane u Republici Hrvatskoj, u slučaju rada jednog izvora te u slučaju istodobnog rada više izvora elektromagnetskih polja. Analizirane su izmjerene vrijednosti električnog polja, referentne veličine u mobilnim mrežama Hrvatskog Telekoma. Razmatrane su bazne postaje tehnologija GSM, DCS, UMTS i LTE. Izmjerene vrijednosti u okolini izvora elektromagnetskih polja su uspoređene sa propisanim graničnim razinama iz Pravilnika o zaštiti od elektromagnetskog polja.

II. REGULATIVA U VEZI ZAŠTITE OD ELEKTROMAGNETSKIH POLJA U REPUBLICI HRVATSKOJ

U Republici Hrvatskoj na snazi je Pravilnik o zaštiti od elektromagnetskih polja, izdan od strane Ministarstva zdravlja [1]. Pravilnik opisuje temeljna i referentna ograničenja. Prema članku 2. stavak 3 Pravilnika o zaštiti od elektromagnetskih polja, zbog mogućih znanstveno još nepotvrđenih štetnih zdravstvenih utjecaja elektromagnetskih polja, primjenom načela predostrožnosti, granične razine referentnih razina su smanjene u odnosu na pripadna temeljna ograničenja.

Kako se iz jedne referentne veličine mogu računski izračunati sve ostale referentne veličine, u radu se analiziraju rezultati mjerenja električnog polja, koje pripada u referenta ograničenja, i to isključivo u području povećane osjetljivosti, radi interesa javnosti. Područja povećane osjetljivosti su zgrade namijenjene boravku ljudi, čestice na kojima su izgrađene zgrade stambene namjene, škole, vrtići, rodilišta, bolnice, smještajni turistički objekti, dječja igrališta te površine neizgrađenih

čestica koje su prema urbanističkom planu namijenjene navedenoj uporabi. Referentna ograničenja su značajna u praktičnoj primjeni jer se odnose na mjerljive veličine. Ostale referentne veličine su gustoća snage, jakost magnetskog polje i gustoća magnetskog toka. U uvjetima mjerenja u slobodnom prostoru, u dalekoj zoni izvora, gustoća snage iznosi:

$$S = E \cdot H \tag{1}$$

Ovdje su E i H efektivne vrijednosti električnog i magnetskog polja. U slobodnom prostoru, u dalekoj zoni izvora, iznosi električnog i magnetskog polja povezani su izrazom:

$$\eta = \frac{E}{H} \tag{2}$$

gdje je η valna impedancija slobodnog prostora i iznosi 377 Ω. Iz navedena dva izraza, gustoća snage u dalekom polju može se izraziti i kao:

$$S = \frac{E^2}{\eta} = H^2 \cdot \eta \tag{3}$$

Na temelju ove jednadžbe je vidljivo da se mjerenjem jedne referentne veličine mogu dobiti i ostale veličine pa je analiza, zbog obujma podataka, napravljena samo za električno polje.

Tablica I. podrobnije opisuje granične razine referentnih veličina u području povećane osjetljivosti.

U odnosu na preporuke Međunarodne komisije za zaštitu od neionizirajućeg zračenja (ICNIRP – International Commission on Non-Ionizing Radiation Protection) [2], na referentne veličine u navedenim frekvencijskim područjima primijenjen je faktor umanjenja koji za područje povećane osjetljivosti iznosi 2,5 – 6,25, ovisno o referentnoj veličini. Za jakost električnog polja primijenjen je faktor umanjenja od 2,5. Ovu činjenicu je potrebno naglasiti radi eventualnih usporedbi rezultata ovog rada s međunarodnim preporukama.

TABLICA I. GRANIČNE REFERENTNE VELIČINE ZA PODRUČJE POVEĆANE OSJETLJIVOSTI PREMA PRAVILNIKU O ZAŠTITI OD ELEKTROMAGNETSKIH POLJA

Referentna veličina	***Pravilnik o zaštiti od elektromagnetskih polja***
Jakost električnog polja E (V/m)	400-2000 MHz: 0,55 $f^{1/2}$
	2-300 GHz: 24,4
Jakost magnetskog polja H (A/m)	400-2000 MHz: 0,00148 $f^{1/2}$
	2-300 GHz: 0,064
Gustoća magnetskog toka B (μT)	400-2000 MHz: 0,00184 $f^{1/2}$
	2-300 GHz: 0,08
Gustoća snage (ekvivalentnog ravnog vala) Sekv (W/m2)	400-2000 MHz: f/1250
	2-300 GHz: 1,6

Pravilnik o zaštiti od elektromagnetskih polja definira i pojam značajnog izvora. Sukladno članku 2. Pravilnika o zaštiti od elektromagnetskih polja, značajan izvor elektromagnetskog polja pojedine frekvencije jest onaj stacionarni izvor čije elektromagnetsko polje u području povećane osjetljivosti, ili u području profesionalne izloženosti, doseže barem 10% iznosa granične razine zadane za tu frekvenciju. U radu se analizira broj značajnih izvora prema tehnologiji.

Pravilnik o zaštiti od elektromagnetskih polja definira i uvjete koji moraju biti zadovoljeni u slučaju istodobnog (tzv. kolociranog) djelovanja izvora elektromagnetskih polja više frekvencija. Na takvim lokacijama svaki od izvora elektromagnetskog polja mora udovoljavati graničnim razinama, a dodatno treba provjeriti i njihov zajednički učinak prema zahtjevima članka 13. Pravilnika o zaštiti od elektromagnetskih polja, prema izrazu:

$$\sum_{>1MHz}^{300GHz} \left(\frac{E_f}{E_{g,f}} \right)^2 \leq 1 \tag{4}$$

gdje je :

E_f = efektivna vrijednost jakosti električnog polja u V/m na frekvenciji f

$E_{g,f}$ = efektivna vrijednost jakosti granične razine električnog polja u V/m na frekvenciji f

Ovaj uvjet postaje posebno interesantan s razvojem raznih tehnologija u području pokretnih komunikacija, jer je na jednoj lokaciji danas moguće imati izvore elektromagnetskih polja iz područja tehnologija GSM, UMTS, DSC i LTE.

III. ANALIZA MJERNIH IZVJEŠĆA

U radu su korištena mjerna izvješća koja su izradile isključivo tvrtke ovlaštene za provođenje mjerenja od strane Ministarstva zdravlja, radi objektivnosti. Razmatrano je isključivo područje povećane osjetljivosti, zbog strožih granica i izloženosti građana. Pregled tehnologija i broja izvršenih mjerenja prema tehnologijama dan je u Tablici II.

TABLICA II. BROJ IZMJERENIH IZVORA PREMA TEHNOLOGIJAMA

Mjereni izvori po sustavima	***Broj izmjerenih izvora***
GSM 900 MHz	882
DCS 1800 MHz	130
UMTS 900 MHz	553
UMTS 2100 MHz	434
LTE 800 MHz	8
LTE 1800 MHz	14

Izvješća su obrađena na način da su pregledom izvješća za pojedinu lokaciju (baznu postaju) izdvojeni rezultati najvećih izmjerenih vrijednosti jakosti elektromagnetskog polja u pojedinim točkama u području povećane osjetljivosti. Za potrebe obrade, razmatrani su rezultati s uračunatim mjernim nesigurnostima pojedinog izvođača mjerenja na kojeg se rezultati odnose. Obrada rezultata obavlja se na način da se analizira dobivena vrijednost jakosti električnog polja za svaku pojedinačnu frekvenciju u području pojedinog sustava (GSM, DCS, UMTS, LTE) usporedbom s dozvoljenim vrijednostima za danu frekvenciju prema Pravilniku o zaštiti od elektromagnetskih polja.

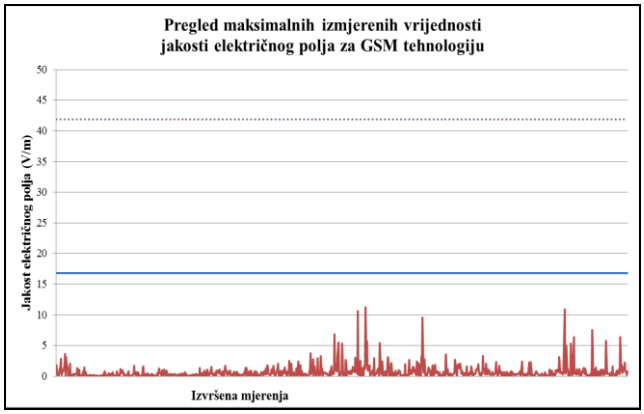
Glavni cilj rada je utvrditi udovoljavaju li postavljeni izvori elektromagnetskog polja ograničenja iz Pravilnika o zaštiti od elektromagnetskih polja za područje povećane osjetljivosti. Razmatrano je električno polje (referentna veličina), a prema Pravilniku, dozvoljena vrijednost električnog polja izražena u V/m u području povećane osjetljivosti definirana je u odnosu na frekvencije te iznosi:

- u rasponu od 400-2000 MHz: 0,55 $f^{1/2}$
- u rasponu od 2-300 GHz: 24,4

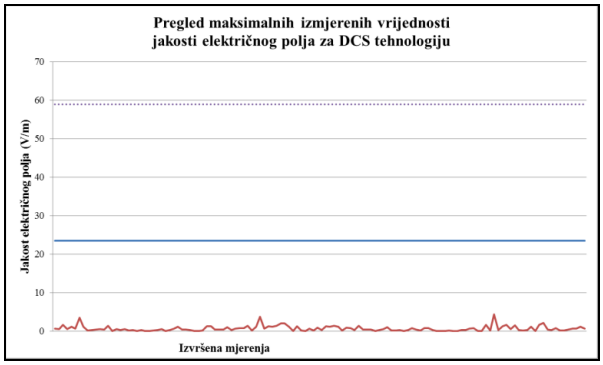
Upravo zbog frekvencijske ovisnosti, analize su provedene za svaku tehnologiju zasebno. U grafovima je napravljena analiza mjernih rezultata, koji su uspoređeni s maksimalnom dozvoljenom vrijednosti prema preporuci ICNIRP-a te maksimalnom dozvoljenom vrijednosti prema Pravilniku o zaštiti od elektromagnetskih polja.

Na slici 1. prikazani su rezultati mjerenja električnog polja tehnologije GSM i uspoređeni s dozvoljenim razinama. Isprekidana linija označava dozvoljenu razinu električnog polja prema preporuci ICNIRP-a, dok puna linija označava dozvoljenu razinu električnog polja prema Pravilniku o zaštiti od elektromagnetskih polja, za frekvencije na kojima je obavljeno mjerenje. Crvenom bojom je označena vrijednost stvarno izmjerenog električnog polja u ukupno 882 lokacije tj. mjerne točke s najvišom vrijednošću električnog polja u pojedinom mjerenju. Najviša izmjerena vrijednost električnog polja iznosi 11,253 V/m, što iznosi 67,06 % od dozvoljene vrijednosti.

Na slici 2. prikazani su rezultati mjerenja električnog polja tehnologije DCS i uspoređeni s dozvoljenim razinama. Isprekidana linija označava dozvoljenu razinu



Slika 1. Pregled maksimalnih izmjerenih vrijednosti jakosti električnog polja za tehnologiju GSM



Slika 2. Pregled maksimalnih izmjerenih vrijednosti jakosti električnog polja za tehnologiju DCS

električnog polja prema preporuci ICNIRP-a, dok puna linija označava dozvoljenu razinu električnog polja prema Pravilniku o zaštiti od elektromagnetskih polja, za frekvencije na kojima je obavljeno mjerenje. Crvenom bojom je označena vrijednost stvarno izmjerenog električnog polja u ukupno 130 lokacija tj. mjernih točaka s najvišom vrijednošću električnog polja u pojedinom mjerenju. Najviša izmjerena vrijednost električnog polja iznosi 4,44 V/m, što iznosi 18,85 % od dozvoljene vrijednosti.

Na slici 3. prikazani su rezultati mjerenja električnog polja tehnologije UMTS 900 i uspoređeni s dozvoljenim razinama. Isprekidana linija označava dozvoljenu razinu električnog polja prema preporuci ICNIRP-a, dok puna linija označava dozvoljenu razinu električnog polja prema Pravilniku o zaštiti od elektromagnetskih polja, za frekvencije na kojima je obavljeno mjerenje. Crvenom bojom je označena vrijednost stvarno izmjerenog električnog polja u ukupno 553 lokacija tj. mjernih točaka s najvišom vrijednošću električnog polja u pojedinom mjerenju. Najviša izmjerena vrijednost električnog polja iznosi 2,06 V/m, što iznosi 12,19 % od dozvoljene vrijednosti.

Na slici 4. prikazani su rezultati mjerenja električnog polja tehnologije UMTS 2100 i uspoređeni s dozvoljenim razinama. Isprekidana linija označava dozvoljenu razinu električnog polja prema preporuci ICNIRP-a, dok puna linija označava dozvoljenu razinu električnog polja prema

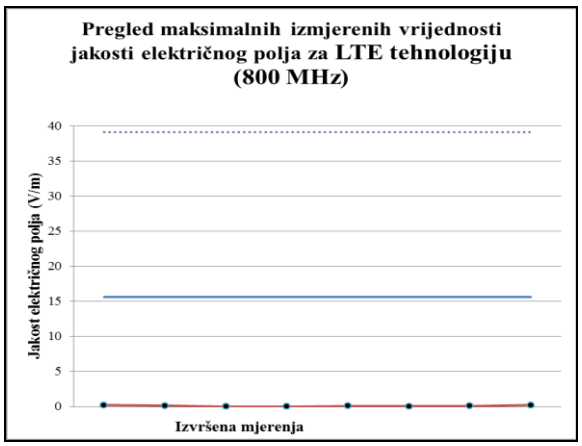
Pravilniku o zaštiti od elektromagnetskih polja, za frekvencije na kojima je obavljeno mjerenje. Crvenom bojom je označena vrijednost stvarno izmjerenog električnog polja u ukupno 434 lokacija tj. mjernih točaka s najvišom vrijednošću električnog polja u pojedinom mjerenju. Najviša izmjerena vrijednost električnog polja iznosi 12,14 V/m, što iznosi 49,77 % od dozvoljene vrijednosti.

Na slici 5. prikazani su rezultati mjerenja električnog polja tehnologije LTE 800 i uspoređeni s dozvoljenim razinama. Isprekidana linija označava dozvoljenu razinu električnog polja prema preporuci ICNIRP-a, dok puna linija označava dozvoljenu razinu električnog polja prema Pravilniku o zaštiti od elektromagnetskih polja, za frekvencije na kojima je obavljeno mjerenje. Crvenom bojom je označena vrijednost stvarno izmjerenog električnog polja u ukupno 8 lokacija tj. mjernih točaka s najvišom vrijednošću električnog polja u pojedinom mjerenju. Najviša izmjerena vrijednost električnog polja iznosi 0,25 V/m, što iznosi 1,57 % od dozvoljene vrijednosti.

Na slici 6. prikazani su rezultati mjerenja električnog polja tehnologije LTE 1800 i uspoređeni s dozvoljenim razinama. Isprekidana linija označava dozvoljenu razinu električnog polja prema preporuci ICNIRP-a, dok puna linija označava dozvoljenu razinu električnog polja prema



Slika 5. Pregled maksimalnih izmjerenih vrijednosti jakosti električnog polja za tehnologiju LTE 800

Pravilniku o zaštiti od elektromagnetskih polja, za frekvencije na kojima je obavljeno mjerenje. Crvenom bojom je označena vrijednost stvarno izmjerenog električnog polja u ukupno 14 lokacija tj. mjernih točaka s najvišom vrijednošću električnog polja u pojedinom mjerenju. Najviša izmjerena vrijednost električnog polja iznosi 1,6 V/m, što iznosi 6,81 % od dozvoljene vrijednosti.

Analiza rezultata mjerenja pokazala je da izmjerene razine elektromagnetskog polja u svim mjernim točkama udovoljavaju graničnim razinama za područja povećane osjetljivosti prema zahtjevima Pravilnika o zaštiti od elektromagnetskih polja. Vidljivo je da se izmjerene razine kreću u velikom rasponu, što je i razumljivo s obzirom da su obavljena mjerenja sustava različitih snaga, na različitim visinama i udaljenostima. Važno je istaknuti da su u svim slučajevima izmjerene vrijednosti jakosti polja unutar dozvoljenih vrijednosti.

I prethodno izvršena analiza razina polja za 1778 izvora tehnologija GSM, UMTS i DCS te njihova usporedba s dozvoljenim razinama [4] pokazala je isti rezultat, tj. da su sve izmjerene vrijednosti, jednako kao i istodobni (kolocirani) utjecaj više polja koja djeluju na istom mjestu, unutar razina propisanih Pravilnikom o zaštiti od elektromagnetskih polja.

IV. ZNAČAJNI IZVORI

Pravilnik o zaštiti od elektromagnetskih polja definira pojam značajnog izvora. Sukladno članku 2. Pravilnika o zaštiti od elektromagnetskih polja, značajan izvor elektromagnetskog polja pojedine frekvencije jest onaj stacionarni izvor čije elektromagnetsko polje u području povećane osjetljivosti, ili u području profesionalne izloženosti, doseže barem 10% iznosa granične razine zadane za tu frekvenciju.

Na temelju analize mjerenja, utvrđen je broj značajnih izvora u mjernom uzorku (Tablica III.).

Na temelju analize je vidljivo da je postotak značajnih izvora mali, pogotovo u tehnologijama UMTS i DCS, čak i uz strogo postavljenu granicu za značajne izvore (10% od dozvoljene vrijednosti). Očekivano je najveći broj značajnih izvora u tehnologiji GSM.

TABLICA III. BROJ ZNAČAJNIH IZVORA U MJERNOM UZORKU

Mjereni izvori po sustavima	*Svi izmjereni izvori*	*Broj značajnih izvora*	*Postotak značajnih izvora*
GSM 900 MHz	882	77	8,73%
DCS 1800 MHz	130	3	2,31%
UMTS 900 MHz	553	1	0,18%
UMTS 2100 MHz	434	24	5,53%
LTE 800 MHz	8	0	0,00%
LTE 1800 MHz	14	0	0,00%

Značajnih izvora u tehnologiji LTE nema, što se može objasniti malim brojem postavljenih i izmjerenih izvora ove tehnologije.

V. KOLOCIRANI IZVORI

S obzirom da su gotovo na svim lokacijama Hrvatskog Telekoma postavljeni kolocirani izvori, obavljena je i analiza učinka zajedničkog rada sustava GSM, DCS, UMTS i LTE na lokacijama na kojima je instalirana tehnologija LTE. Svi rezultati pokazuju da je uvjet Pravilnika o zaštiti od elektromagnetskih polja vezan za zajednički učinak svih kombinacija sustava Hrvatskog Telekoma ispunjen na svim izmjerenim lokacijama.

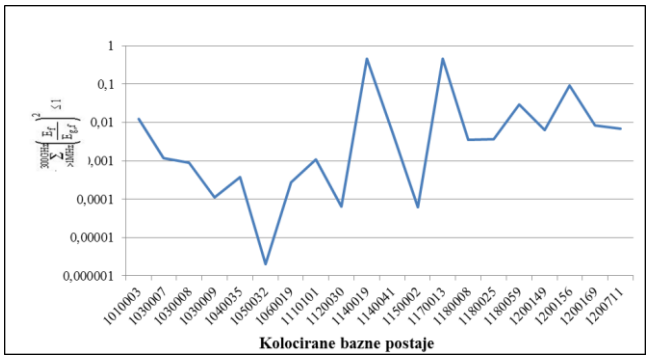
Na slici 7. dan je primjer izračuna za nekoliko kolociranih baznih postaja sustava GSM, DCS, UMTS i LTE. Ordinata pokazuje vrijednost izračuna uvjeta Pravilnika o zaštiti od elektromagnetskog polja prema (4), a na apscisi su dane identifikacijske oznake kolociranih baznih postaja.

Ukoliko bi za neki izvor izmjerena vrijednost električnog polja bila veća od granične vrijednosti dozvoljene prema Pravilniku o zaštiti od elektromagnetskih polja (što ovdje nije slučaj), brojnik u (4) bio bi veći od nazivnika, te bi njihov kvadrat a time i ukupni zbroj svih članova niza bio veći od 1, čime uvjet iz Pravilnika ne bi bio ispunjen. Nadalje, budući da je za sve tehnologije većina izmjerenih vrijednosti unutar 10% granične vrijednosti dozvoljene Pravilnikom (svega je 5,2% značajnih izvora u ukupnom mjernom uzorku za sve sustave), tako su i kvadrati odnosa izmjerene i granične dozvoljene vrijednosti brojke još manjih vrijednosti (tj. bliže nuli). Iz tog su razloga vrijednosti na slici 7. prikazane u logaritamskom mjerilu.

Vidljivo je da su izračunate vrijednosti manje od vrijednosti dozvoljene prema zahtjevima Pravilnika o zaštiti od elektromagnetskih polja. Kolociranost s ostalim tehnologijama koje se nalaze u istom frekvencijskom spektru nije promatrana.

VI. ZAKLJUČAK

U području pokretnih komunikacija u Hrvatskoj su prisutni izvori elektromagnetskog polja tehnologija GSM,



Slika 7. Grafički prikaz rezultata kolociranih sustava GSM, DCS, UMTS i LTE

UMTS, DCS i LTE. Pravilnik o zaštiti od elektromagnetskih polja, koji se primjenjuje u Republici Hrvatskoj, postavlja granice referentnih veličina za frekvencijska područja u kojima emitiraju izvori elektromagnetskih polja u mobilnim komunikacijama (400-2000 MHz, 2-300 GHz). S obzirom na vrlo stroge granice, koje su određene visokim faktorom umanjenja u odnosu na preporuku Međunarodne komisije za zaštitu od neionizirajućeg zračenja, u radu se analiziraju rezultati mjerenja referentnih veličina u okolini izvora elektromagnetskog polja u mobilnim mrežama Hrvatskog Telekoma za tehnologije GSM, DCS, UMTS i LTE. Posebno le razmatran istodobni rad svih izvora elektromagnetskih polja na pojedinim mjestima (istodobni rad izvora GSM, UMTS, DCS i LTE tehnologija).

Nakon analize 882 izvora sustava GSM, 987 izvora sustava UMTS (od toga 434 za UMTS 2100 MHz i 553 za UMTS 900 MHz), 130 izvora sustava DCS i 22 izvora sustava LTE (od toga 8 za LTE 800 MHz i 14 za LTE 1800 MHz), utvrđeno je da su svi izmjereni rezultati unutar granica propisanih Pravilnikom o zaštiti od elektromagnetskih polja.

Na lokacijama na kojima dolazi do istovremenog rada više izvora elektromagnetskih polja različitih frekvencija izvršena je analiza zadovoljenja uvjeta iz Pravilnika o zaštiti od elektromagnetskih polja (njihov zajednički učinak). Promatrano je 20 lokacija na kojima istodobno djeluju izvori tehnologija GSM, DCS, UMTS i LTE. Analizom je utvrđeno da sve lokacije udovoljavaju zahtjevima članka 13. Pravilnika o zaštiti od elektromagnetskih polja koji se odnosi na zajednički učinak više izvora koji istodobno rade.

amhayajneh11@eng.just.edu.jo, makhodeir@just.edu.jo, mistarihi@just.edu.jo

***Abstract*— A new incremental-relaying cooperative-diversity technique with a simple dual transmit diversity, decode-and-forward and best relay selection scheme is presented. Closed-form expressions for the the bit error rate, the signal to noise ratio outage probability, and average achievable rate are derived using binary phase shift keying modulation scheme over independent non-identical Rayleigh fading channels. The results show that the simple space time block coding scheme with the incremental-relaying cooperative diversity and best relay selection outperforms the regular incremental fixed cooperative diversity and saves resources.**

***Index Terms*—Rayleigh fading, adaptive relaying, incremental-relaying, maximal ratio combining, error performance, outage probability, space time block coding.**

I. INTRODUCTION

In the last few years the incremental-relaying cooperative-diversity networks has become one promising technique which is proposed widely in wireless communication systems. The motivation in the technique is the better utilization of the resources and the great saving in power consumption for relaying. This can be achieved by allowing the relay to operate in very specific cases (i.e., when the received *signal to noise ratio* (SNR) at the destination is below a pre-defined threshold value). Here, the relay should send another copy of the transmitted signal (i.e., already saved at the relay) to the receiver. The authors in [1] and [2] discussed the performance of the regular cooperative-diversity networks, where they derived a closed-form expressions for both the average *bit error rate* (BER) and SNR *outage probability* (P_{out}). Next, the authors in [3] derived a closed-form expressions for the same metrics for incremental-relaying cooperative-networks based on the results of [1] and [2]. The results were shown assuming a *single input single output* (SISO) transmission model is used and exploiting both *amplify-and-forward* (AF) and *decode-and-forward* (DF) relaying schemes. In particular, the results showed that the regular incremental cooperative-diversity achieved superior channel utilization as compared with the regular cooperative-diversity. For more generalization on the incremental relaying technique, the authors in [4] derived a closed-form expressions for both the BER and SNR outage probability assuming a simple transmit diversity based on the simple *space time block coding* (STBC) for Alamouti and DF relaying scheme [5].

Finally, the motivation of this study is to capture the effect of using the adaptive best relay selection with the incremental cooperative-diversity utilizing a simple dual transmit diversity technique. This will add more diversity orders to the achieved virtual diversity gain in [3]. Thus, the transmitter in the proposed model is equipped with two antennas with a minimum required separation to achieve independent fading channels and transmitting due to the simple transmit diversity scheme [5], [6]. Fig. 1 below shows the configuration of the antennas and the geometry of the network, where the *relay* (R) is between the *source* (S) and the *destination* (D) assuming asymmetric network geometry (i.e., variable relay location). Moreover, the DF relaying scheme (i.e., regenerative relays) is used, where the transmitted signals from the source are fully decoded then retransmitted to the destination when the received SNR is below the pre-defined threshold as a response to a request from the destination. Here, using the simple transmit diversity does not require a perfect *channel state information at transmitter* (CSIT).

Overall, the rest of this paper is organized as follows. In Section II, a closed-form expression for the average BER of the incremental cooperative-diversity is derived, where a BPSK modulation scheme is assumed over independent non-identical Rayleigh fading channels with a dual transmit diversity. Then a closed-form expression for the SNR outage probability analysis is presented in Section III. Next, Section IV shows the average achievable rate performance. Furthermore, Section V analytical and numerical results analysis. Finally, Section VI presents the conclusion and future work.

II. SYSTEM MODEL

A new scheme of relaying in incremental-relaying is assumed, where the network has multiple relays to assist in the relaying phase by selecting the relay that has the best performance as shown in Figure 1. Here, we have *L* relays cooperating in the network and all the relays are assumed to operate using DF scheme (i.e., re-generative relaying). By utilizing the dual transmit diversity, then every relay must has the ability to decouple the Alamouti received signals, decode

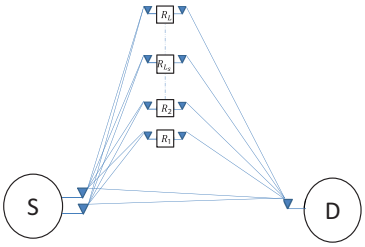

Fig. 1. Illustration of the incremental-relaying cooperative-diversity networks using dual transmit diversity and best relay selection.

and re-encode these signals, and then re-transmit them to the destination. Moreover, the destination will request a signal retransmission from the best relay (i.e., selected among the L relays) if the received SNR coming from the direct path $S \rightarrow D$ is below the pre-defined SNR threshold. Due to this request, the selected relay will retransmit the encoded signals to the destination. This will add virtual diversity gain to the gain achieved in the aforementioned relaying schemes.

In general, the received signal at any of the cooperating relays, which is originally coming from the source can be expressed as follows:

$$y_{S,R,i} = h_{S,R,i}\sqrt{E_s/2}\,x(t) + n_i \quad , i = 1, 2, 3, ..., L \quad (1)$$

where L is the number of the cooperating relays, $y_{S,R,i}$ is the received signal at the relay from the source, $h_{S,R,i}$ is the source relay channel coefficient, $x(t)$ is the transmitted symbol from the source with unity energy, and n_i is the AWGN terms. Then the received signal coming from any relay at the destination can be written as follows:

$$y_{R,D,i} = h_{R,D,i}\sqrt{E_s}x_r(t) + n_i \quad , i = 1, 2, 3, ..., L \quad (2)$$

where $y_{R,D,i}$ is the received signal at the destination coming from the *i-th* relay, $h_{R,D,i}$ is the relay destination channel coefficient, $x_r(t)$ is the retransmitted signal from the relay.

Actually, the selection of the best relay is a routing protocol problem. In particular, in order to get the total instantaneous received SNR from the best relay, one can get the SNR coming from the best relay as follows:

$$\gamma^*_{R,D} = \underset{i=1,2,3,...,L}{max}\{\gamma_{R,D,i}\} \quad (3)$$

where $\gamma^*_{R,D}$ denote the received SNR coming from the best relay at the destination. Finally, all the the channel coefficients are assumed to have non-identical Rayleigh fading channels.

Due to best relays selection, the knowledge of ordered statistics of the received signals is a must. In particular, ordered statistics means that the the routing protocol has the capability to order the received signals realizations due to the backward channels due to their SNR values. Here, ordered statistics deal with the PDFs of the received signals. The authors in [7],[8], and [9] developed unified approaches to determine the PDF of the ordered statistics of independent and identically distributed random variables with a common PDF and CDF. Here the protocol that is utilized ranks the realizations beginning from the one with the largest received SNR to the one with the smallest SNR (i.e., $\gamma_{1:L} \geq \gamma_{2:L} \geq ... \geq \gamma_{L-1:L} \geq \gamma_{L:L}$). Furthermore, the relay with the best SNR value is denoted by $\gamma_{1:L}$ and for simplicity assume $\gamma^*_{R,D} = \gamma_{1:L} = \gamma^*$. Therefore, to write the PDF of $\gamma^*_{R,D}$ assuming that all the received SNR PDFs from the relays have a common mean, one can write,$f_{\gamma^*_{R,D}}(\gamma) = 2Lf_{\gamma_{R,D}}(\gamma)[1-F_{\gamma_{R,D}}(\gamma)][2F_{\gamma_{R,D}}(\gamma) - (F_{\gamma_{R,D}}(\gamma))^2]^{L-1}$ For Rayleigh fading channels, then the PDF of $\gamma_{R,D,i}$ follows the exponential distribution as follows:

$$f_{\gamma_{R,D,i}}(\gamma) = \frac{1}{\overline{\gamma}_{R,D,i}} e^{-\frac{\gamma}{\overline{\gamma}_{R,D,i}}} \quad (4)$$

Next, with the common mean assumption:

$$f_{\gamma_{R,D}}(\gamma) = \frac{1}{\overline{\gamma}_{R,D}} e^{-\frac{\gamma}{\overline{\gamma}_{R,D}}} \quad (5)$$

Now, the the received signal from the best relay has the following PDF [7]:

$$f_{\gamma^*_{R,D}}(\gamma) = \sum_{i=1}^{L}(-1)^{i-1}\binom{L}{i}\frac{2i}{\overline{\gamma}_{R,D}} e^{-i\frac{2\gamma}{\overline{\gamma}_{R,D}}} \quad (6)$$

Moreover, in order to capture the effect of the path loss on the performance of the proposed model, one can define the statistical average operators as in [10] such that $\mathbf{E}\left(h^2_{S,D}\right) = 1, \mathbf{E}\left(h^2_{S,R,i}\right) = \left(\frac{d_{S,D}}{d_{S,R}}\right)^{\alpha}, \mathbf{E}\left(h^2_{R,D,i}\right) = \left(\frac{d_{S,D}}{d_{R,D}}\right)^{\alpha}$, where $\mathbf{E}(\cdot)$ is the statistical average operator, α is the path loss, and $d_{k,m}$ is the distance between terminals k and m

III. Error Performance Analysis

In order to analyze the error performance of the proposed system, one needs to determine the error probability of the combined signal at the receiver using the following [3]:

$$\begin{aligned} P(e) &= P_r(\gamma_{S,D,\Sigma} \leq \gamma_o) \times P_{div}(e) \\ &+ (1 - P_r(\gamma_{S,D,\Sigma} \leq \gamma_o)) \times P_{direct}(e) \end{aligned} \quad (7)$$

However, the total SNR due to the received signal at the receivers is the sum of the SNR from the signal coming from the direct path, and the SNR due to the signal received from the best relay. Thus, the total SNR for the total received signal can be written as follows:

$$\gamma_{tot} = \gamma^*_{R,D} + \gamma_{S,D,\Sigma} = Z \quad (8)$$

Moreover, the PDF of the total received signal can be written as the convolution of the two random variables $f_{\gamma^*_{R,D}}(\gamma)$ and $f_{\gamma_{S,D,\Sigma}}(\gamma)$ which can be written as follows [11]:

$$\begin{aligned} f_{\gamma_{tot}}(z) = \frac{1}{\overline{\gamma}^2_{S,D}} \int_0^{\infty} \sum_{i=1}^{L}(-1)^{i-1}\binom{L}{i}\lambda_i \\ \times e^{-\lambda_i\gamma}(z-\gamma)e^{-\frac{z-\gamma}{\overline{\gamma}_{S,D}}}d\gamma \end{aligned} \quad (9)$$

where $\lambda_i = \frac{2i}{\overline{\gamma}_{R,D}}$. Then, after some manipulations, one can write the above equation as in Eqn. (10), which can be further simplified to Eqn. (11). Finally, to find the average BER assuming a BPSK, one must find ,$P_{div}(e)$, which is the error due to the combined signal at the destination as follows:

$$P_{div}(e) = P^*_{S,R,\Sigma}(e) \times P_x(e) + (1 - P^*_{S,R,\Sigma}(e)) \times P_{tot}(e) \quad (12)$$

$$f_{\gamma_{tot}}(z)=\begin{cases}\dfrac{1}{\overline{\gamma}^2_{S,D}}\displaystyle\int_0^z\sum_{i=1}^{L}(-1)^{i-1}\binom{L}{i}\lambda_i e^{-\lambda_i\gamma}(z-\gamma)e^{-\frac{z-\gamma}{\overline{\gamma}_{S,D}}}d\gamma & \text{if } z\le\gamma_o.\\ \dfrac{1}{\overline{\gamma}^2_{S,D}}\displaystyle\int_{z-\gamma_o}^z\sum_{i=1}^{L}(-1)^{i-1}\binom{L}{i}\lambda_i e^{-\lambda_i\gamma}(z-\gamma)e^{-\frac{z-\gamma}{\overline{\gamma}_{S,D}}}d\gamma & \text{if } z>\gamma_o.\end{cases} \tag{10}$$

$$f_{\gamma_{tot}}(z)=\begin{cases}\dfrac{1}{\overline{\gamma}^2_{S,D}}\displaystyle\sum_{i=1}^{L}\frac{(-1)^{i-1}\binom{L}{i}\lambda_i}{\left(\lambda_i\overline{\gamma}_{S,D}-1\right)^2}\\ \times\left[\overline{\gamma}^2_{S,D}e^{-\lambda_i z}+\overline{\gamma}^2_{S,D}\lambda_i z e^{-\frac{z}{\overline{\gamma}_{S,D}}}-\overline{\gamma}^2_{S,D}e^{-\frac{z}{\overline{\gamma}_{S,D}}}-\overline{\gamma}_{S,D}z e^{-\frac{z}{\overline{\gamma}_{S,D}}}\right] & \text{if } z\le\gamma_o.\\ \dfrac{1}{\overline{\gamma}^2_{S,D}}\displaystyle\sum_{i=1}^{L}\frac{(-1)^{i-1}\binom{L}{i}\lambda_i}{\left(\lambda_i\overline{\gamma}_{S,D}-1\right)^2}\times\left[\overline{\gamma}^2_{S,D}e^{\lambda_i\gamma_o}\lambda_i\gamma_o e^{-\frac{\gamma_o}{\overline{\gamma}_{S,D}}}e^{-\lambda_i z}\right.\\ \left.+\overline{\gamma}^2_{S,D}e^{-\lambda_i z}-\overline{\gamma}^2_{S,D}e^{\lambda_i\gamma_o}e^{-\frac{\gamma_o}{\overline{\gamma}_{S,D}}}e^{-\lambda_i z}-\overline{\gamma}_{S,D}e^{\lambda_i\gamma_o}\gamma_o e^{-\frac{\gamma_o}{\overline{\gamma}_{S,D}}}e^{-\lambda_i z}\right] & \text{if } z>\gamma_o.\end{cases} \tag{11}$$

where $P_{tot}(e)$ is the BER in the combined signal (i.e., the direct path signal and the best relay signal), and $P^*_{S,R,\Sigma}(e)$ is the probability of a desision error at the best relay. Thus, to complete the study of the best relays selection with the OSTBC scheme, one can write $P_{tot}(e)$ as follows:

$$P_{tot}\left(e\right)=\frac{1}{2}\int_0^\infty f_{\gamma_{tot}}\left(z/\gamma_{S,D,\Sigma}\le\gamma_o\right)erfc(\sqrt{z})dz \tag{13}$$

Next, the conditional PDF of γ_{tot} has the following distribution:

$$f_{\gamma_{tot}}\left(z/\gamma_{S,D,\Sigma}\le\gamma_o\right)=\frac{f_{\gamma_{tot}}\left(z\right)}{1-\left(\frac{\gamma_o}{\overline{\gamma}_{S,D}}+1\right)exp\left(-\frac{\gamma_o}{\overline{\gamma}_{S,D}}\right)} \tag{14}$$

Thus, by substituting Eqn. (11) in the above equation one can find a closed-form expression for $f_{\gamma_{tot}}\left(z/\gamma_{S,D,\Sigma}\le\gamma_o\right)$ Here, after solving Eqn. (13) and after some manipulations one can write $P_{tot}(e)$ as follows:

$$\begin{aligned}P_{tot}(e)=&\frac{1}{2\overline{\gamma}^2_{S,D}\left(1-\left(\frac{\gamma_o}{\overline{\gamma}_{S,D}}+1\right)exp\left(-\frac{\gamma_o}{\overline{\gamma}_{S,D}}\right)\right)}\\ &\times\sum_{i=1}^{L}\frac{(-1)^{i-1}\binom{L}{i}\lambda_i}{\left(\lambda_i\overline{\gamma}_{S,D}-1\right)^2}\left[\Theta(0,\gamma_o\overline{\gamma}^2_{S,D},\lambda_i)\right.\\ &+\Phi(0,\gamma_o,\overline{\gamma}^2_{S,D}\lambda_i,\frac{1}{\overline{\gamma}_{S,D}})-\Theta(0,\gamma_o,\overline{\gamma}^2_{S,D},\frac{z}{\overline{\gamma}_{S,D}})\\ &\left.-\Phi(0,\gamma_o,\overline{\gamma}_{S,D},\frac{z}{\overline{\gamma}_{S,D}})+\Theta(\gamma_o,\infty,\eta,\lambda_i)\right]\end{aligned} \tag{15}$$

where $\eta=\overline{\gamma}^2_{S,D}+\overline{\gamma}^2_{S,D}e^{\lambda_i\gamma_o}\lambda_i\gamma_o e^{-\frac{\gamma_o}{\overline{\gamma}_{S,D}}}-\overline{\gamma}^2_{S,D}e^{\lambda_i\gamma_o}e^{-\frac{\gamma_o}{\overline{\gamma}_{S,D}}}-\overline{\gamma}_{S,D}e^{\lambda_i\gamma_o}\gamma_o e^{-\frac{\gamma_o}{\overline{\gamma}_{S,D}}}$, and $\Phi(A,B,\omega,\lambda)$ and $\Theta(A,B,\omega,\lambda)$ are auxiliary functions that are defined in the appendix (A).

Now, assuming the dual transmit diversity with BPSK modulation scheme is used under Rayleigh fading channels, the expression for the probability of decision error at the best relay in decoding the Alamouti signals,$P^*_{S,R,\Sigma}(e)$, can be written as follows:

$$\begin{aligned}P^*_{S,R,\Sigma}(e)&=\int_0^\infty f_{S,R,\Sigma}(\gamma)\times P\left(e/\gamma\right)d\gamma\\ &=\frac{\left[1-\left(1+\frac{3}{2\overline{\gamma}_{\mathrm{S,R}}}\right)^{-3/2}\sqrt{1+\frac{1}{\overline{\gamma}_{\mathrm{S,R}}}}\right]}{2}\end{aligned} \tag{16}$$

Finally, by substituting the above equation and Eqn. (13) in Eqn. (12) and substituting the result in Eqn. (7) one can find a closed-form expression for the total average BER for the incremental relaying with best relay selection and simple STBC scheme.

IV. Outage Probability

In this section, the performance of the SNR outage probability is analyzed as extension to the analysis of error probabilities. Here, the total SNR outage probability for the total received signals from the best relay assuming the DF scheme is employed. For the whole bunch of the relays, one can write the total probability of outage as follows [3]:

$$\begin{aligned}P_{out}&=P^*_r\left(\gamma_{S,R,\Sigma}\le\gamma_o\right)P_r\left(\gamma_{S,D,\Sigma}\le\gamma_o\right)\\ &+\left(1-P^*_r\left(\gamma_{S,R,\Sigma}\le\gamma_o\right)\right)P_r\left(\gamma_{tot}\le\gamma_o\right)\end{aligned} \tag{17}$$

where $P^*_r\left(\gamma_{S,R,\Sigma}\le\gamma_o\right)$ is the outage probability at the best relay. $P_r\left(\gamma_{S,D,\Sigma}\le\gamma_o\right)$ is the outage probability if the direct path is used only, and $P_r\left(\gamma_{tot}\le\gamma_o\right)$ is the outage probability when the direct path signal and the relayed signal are combined at the destination. In particular, Eqn. (17) is valid for evaluating the outage probability for the regular incremental relaying with the OSTBC scheme derived in [4].

Furthermore, by using the previous definitions, to evaluate Eqn. (17), one can write $P_r^*\left(\gamma_{S,R,\Sigma} \leq \gamma_o\right)$ as follows:

$$\begin{aligned} P_r^*\left(\gamma_{S,R,\Sigma} \leq \gamma_o\right) &= \int_0^{\gamma_o} \frac{1}{\overline{\gamma}_{S,R}^2} \gamma e^{-\frac{\gamma}{\overline{\gamma}_{S,R}}} d\gamma \\ &= 1 - \left(1 + \frac{\gamma_o}{\overline{\gamma}_{S,R}}\right) e^{-\frac{\gamma_o}{\overline{\gamma}_{S,R}}} \end{aligned} \quad (18)$$

As a result, the SNR outage probability at the combined signal at the destination can be written as in Eqn. (19). Finally, by substituting Eqns. (19) and (18) in Eqn. (17) one can find a closed form expression for the SNR outage probability for the incremental relaying with the best relay selection and simple STBC scheme.

V. Average Achievable Rate

Now, the average achievable rate in the Shannon sense is analyzed in order to evaluate the system performance under which errors are recoverable. In particular, to find the total average achievable rate for the proposed best relay selection scheme, one can write the following:

$$\begin{aligned} C_{avg} &= P_r\left(\gamma_{S,D,\Sigma} \leq \gamma_o\right) \times C_{tot} \\ &+ \left(1 - P_r(\gamma_{S,D,\Sigma} \leq \gamma_o)\right) \times C_{direct} \end{aligned} \quad (20)$$

where C_{tot} is the average achievable rate for the combined signal from the best selected relay and the direct path transmission and C_{direct} is the average achievable rate achieved by the direct path only (i.e., the relay has no role in transmission). In particular, to evaluate the above equation, one have to write C_{direct} as follows:

$$\begin{aligned} C_{direct} &= BW \int_0^{\infty} log_2(1+\gamma) \\ &\times f_{\gamma_{S,D,\Sigma}}(\gamma/\gamma_{S,D,\Sigma} > \gamma_o\ ) d\gamma \end{aligned} \quad (21)$$

Next, after some manipulations on can write C_{direct} as in Eqn. (22), where $E_1(\bullet)$ is the exponential integral. Now, to complete Eqn. (20), one can write the average achievable rate for the combined signals, C_{tot}, as follows:

$$C_{tot} = \frac{BW}{2} \int_0^{\infty} log_2(1+z) \times f_{\gamma_{tot}}(z|\gamma_{\mathrm{S,D},\Sigma} \leq \gamma_o\ ) dz \quad (23)$$

Now, after some manipulation for the above integral one can write C_{tot} as follows: weher $\Phi_c(A,B,\omega,\lambda)$ and $\Theta_c(A,B,\omega,\lambda)$ are auxiliary functions that are defined in the appendix (B). Finally, by substituting Eqn. (24) and (22) in Eqn. (20) one can find the closed-form expression for the total average achievable rate for the incremental best relay selection when the simple OSTBC scheme is used.

VI. Numerical Results

In this section the numerical results for the incremental best relay selection are presented. In particular, average BER, SNR outage probability, and the average achievable rate versus the transmitted signal (E_s/N_o dB) are calculated. Furthermore, in order to capture the effect of the number of relays and the geometry of the network in the sense of the distance from S and R, many figures are shown to view the relationships between the performance metrics and different arguments of the whole system.

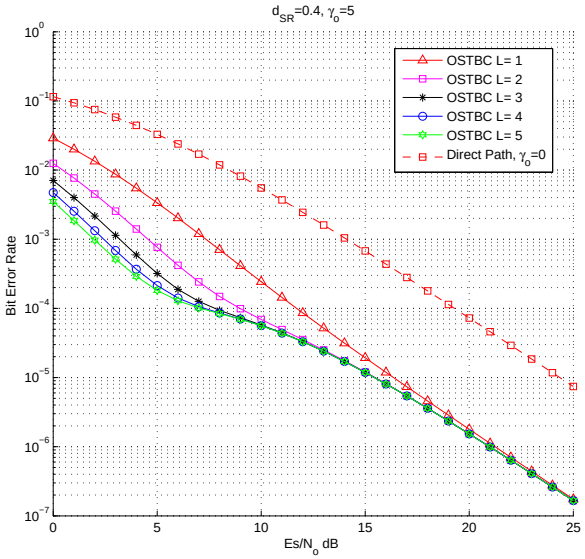

Fig. 2. Average BER versus the SNR of the transmitted signal ($E_s/N_o\,dB$) for the best relay selection with $\gamma_o = 5$.

Now, Figure 2 shows the BER versus the transmitted signal (E_s/N_o dB) for the proposed model and for multiple number of relays. Here, assuming that the relative distance between the source and the relay is denoted by $d = d_{S,R} = 0.4$ which is the optimal relative distance to achieve the best BER performance and the SNR threshold is denoted by γ_o. Moreover, the path loss exponent, α, is assumed to be 3. Obviously, the incremental best selection relaying with dual transmit diversity outperforms both of the fixed incremental relaying scheme as well as the one-hop transmission (i.e., $\gamma_o \to 0$). For example, for $d_{SR} = 0.4$, $\gamma_o = 8$ dB and L=2 relays, the incremental best relay selection with a simple OSTBC requires a 4 dB less SNR than that for the fixed incremental relaying (i.e., L=1) scheme to achieve the same value of the $BER = 10^{-6}$. However, the incremental best relay selection outperforms the fixed relaying schemes for low values of (E_s/N_o) and this depends on the value of γ_o and the proposed model will require more assistant from the relays. In fact, involving more relays in the relaying phase will add more diversity order and the BER will be enhanced to some extent. Hence, selection amongst more than 3 relays will not add a perceptible enhancement (i.e., this resembles the conventional selection mechanisms in the one-hop receive diversity). Furthermore, Figure 3 shows the P_{out} versus the SNR for the proposed model. The results show that the incremental best relay selection outperforms the fixed incremental relaying and achieves higher virtual diversity array gain and transmit diversity gain, as well as giving better SNR outage probability performance. In particular, for $d_{SR} = .4$, $\gamma_o = 5$ dB and $L = 2$ relays the incremental best relay selection with a simple OSTBC requires 6 dB less SNR than that for the fixed incremental relaying scheme to achieve the same outage probability (i.e., $P_{out} = 10^{-6}$). Moreover,

$$
\begin{aligned}
P_r\left(\gamma_{tot} \le \gamma_o\right) &= \int_0^{\gamma_o} f_{\gamma_{tot}}(\gamma) d\gamma \\
&= \frac{1}{\overline{\gamma}_{S,D}^2} \sum_{i=1}^{L} \frac{(-1)^{i-1}\binom{L}{i}\lambda_i}{\left(\lambda_i \overline{\gamma}_{S,D} - 1\right)^2} \\
&\quad \times \Bigg[\left(\overline{\gamma}_{S,D}^2 \gamma_o - \overline{\gamma}_{S,D}^3 \lambda_i \gamma_o - \overline{\gamma}_{S,D}^4 \lambda_i + 2\,\overline{\gamma}_{S,D}^3\right) e^{-\frac{\gamma_o}{\overline{\gamma}_{S,D}}} \\
&\qquad - \frac{\overline{\gamma}_{S,D}^2}{\lambda_i e^{\lambda_i \gamma_o}} + \frac{\overline{\gamma}_{S,D}^2}{\lambda_i} + \overline{\gamma}_{S,D}^4 \lambda_i - 2\,\overline{\gamma}_{S,D}^3 \Bigg]
\end{aligned} \tag{19}
$$

$$
\begin{aligned}
C_{direct} = \frac{BW}{ln(2)\left(1 + \frac{\gamma_o}{\overline{\gamma}_{S,D}}\right) exp\left(-\frac{\gamma_o}{\overline{\gamma}_{S,D}}\right)} \Bigg[& \ln\left(\gamma_o + 1\right) e^{\frac{-\gamma_o}{\overline{\gamma}_{S,D}}} + \frac{\gamma_o}{\overline{\gamma}_{S,D}} \ln\left(\gamma_o + 1\right) e^{\frac{-\gamma_o}{\overline{\gamma}_{S,D}}} \\
& + e^{\frac{1}{\overline{\gamma}_{S,D}}} E_1\left(\frac{\gamma_o}{\overline{\gamma}_{S,D}} + {\overline{\gamma}_{S,D}}^{-1}\right) + e^{\frac{-\gamma_o}{\overline{\gamma}_{S,D}}} - \frac{e^{{\overline{\gamma}_{S,D}}^{-1}}}{\overline{\gamma}_{S,D}} E_1\left(\frac{\gamma_o}{\overline{\gamma}_{S,D}} + {\overline{\gamma}_{S,D}}^{-1}\right) \Bigg]
\end{aligned} \tag{22}
$$

$$
\begin{aligned}
C_{tot} = & \frac{BW}{2\overline{\gamma}_{S,D}^2\left(1 - \left(\frac{\gamma_o}{\overline{\gamma}_{S,D}} + 1\right) exp\left(-\frac{\gamma_o}{\overline{\gamma}_{S,D}}\right)\right)} \\
& \times \sum_{i=1}^{L} \frac{(-1)^{i-1}\binom{L}{i}\lambda_i}{\left(\lambda_i \overline{\gamma}_{S,D} - 1\right)^2} \Bigg[\Theta_c(0, \gamma_o \overline{\gamma}_{S,D}^2, \lambda_i) + \Phi_c(0, \gamma_o, \overline{\gamma}_{S,D}^2 \lambda_i, \frac{1}{\overline{\gamma}_{S,D}}) \\
& - \Theta_c(0, \gamma_o, \overline{\gamma}_{S,D}^2, \frac{z}{\overline{\gamma}_{S,D}}) - \Phi_c(0, \gamma_o, \overline{\gamma}_{S,D}, \frac{z}{\overline{\gamma}_{S,D}}) + \Theta_c(\gamma_o, \infty, \eta, \lambda_i) \Bigg]
\end{aligned} \tag{24}
$$

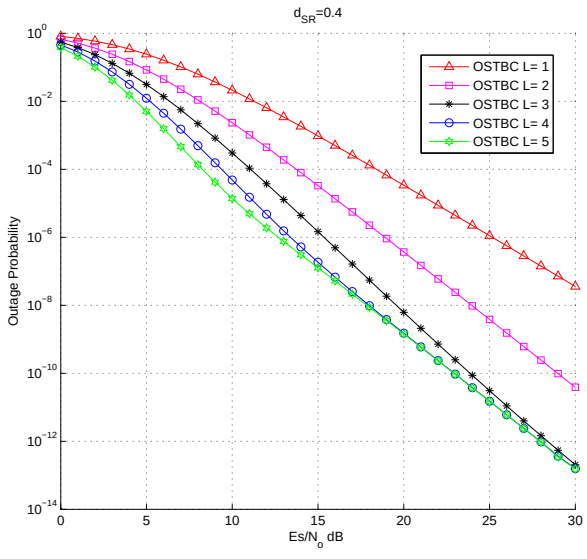

Fig. 3. Outage probability versus the SNR of the transmitted signal (E_s/N_o) for the best relay selection with $\gamma_o = 5$ dB.

one can notice that by increasing, L the outage probability, P_{out}, will be decreased and a better overall performance will be achieved. Furthermore, increasing L will result in an improvement in the outage performance to some extent whereas a slight improvement will be achieved when $L > 3$.

Finally, Figure 4 shows the performance of the average achievable rate versus the SNR of the transmitted signal for both the incremental cooperative diversity with best relay selection utilizing dual transmit diversity and the regular cooperative diversity OSTBC for different number of the participating relay nodes. The result shows that utilizing the OSTBC scheme with the incremental relaying best relay selection scheme saves channel resources (i.e., spectral efficiency improved) in the sense of the average channel capacity as compared to the regular cooperative scheme of relaying (i.e., $\gamma_o \to \infty$). However, increasing the number of the involved relaying nodes yields to a slight channel utilization (i.e., slight increase in the overall average achievable rate). However, a remarkable improvement in the the sense of the BER and the SNR outage probability with approximately the same average achievable rate performance.

VII. Conclusion

In paper, an incremental best relay cooperative diversity with a dual transmit diversity is studied. Closed-form expressions for the average bit error rate, average achievable rate, and signal to noise ratio outage probability are derived. Here, a

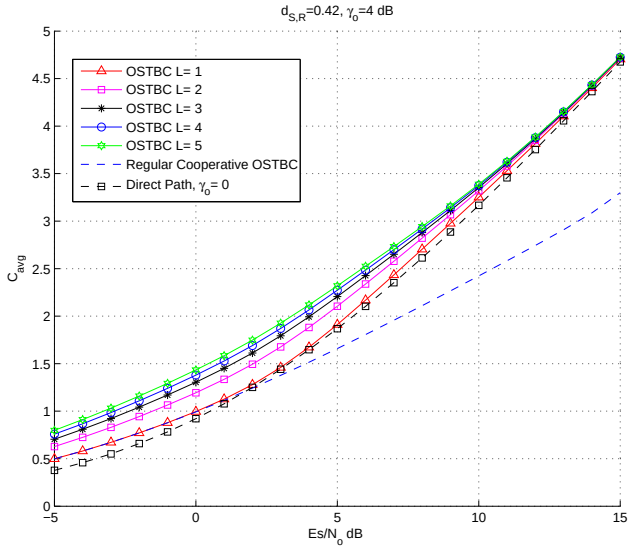

Fig. 4. Average achievable rate versus the SNR of the transmitted signal (E_s/N_o) for best relay selection with $(d = 0.42)$.

binary phase shift keying modulation scheme over independent and identically distributed Rayleigh fading channels is used. The results show that the best relay selection scheme with multiple input single output incremental-relaying outperforms the regular incremental cooperative diversity and can achieve full diversity orders with the same transmitted energy, which is the sum energy of the two transmit antenna.

APPENDIX A

For simplicity and to reduce the number of terms used in the integrals, the following auxiliary functions $\Phi(A, B, \omega, \lambda)$ and $\Theta(A, B, \omega, \lambda)$ are defined as follows:

$$\Phi(\ A\ , B, \omega, \lambda) = \int_A^B \omega\, z e^{-\lambda\, z} erfc\left(\sqrt{z}\right) dz$$
$$= \frac{\omega}{\sqrt{\pi}\lambda^2\,(1+\lambda)^{3/2}}\Bigg[\left(-3/2\,\lambda - 1\right)\sqrt{\pi} erf\left(\sqrt{1+\lambda}\sqrt{z}\right)$$
$$+ \sqrt{1+\lambda}\Bigg(e^{-\lambda\, z}\sqrt{\pi}\left(-1 + erf\left(\sqrt{z}\right)\right)(1+\lambda)\,(\lambda\, z + 1)\Bigg)$$
$$+ \lambda\sqrt{z} e^{-(1+\lambda)z}\Bigg]_A^B \qquad \text{(A-1)}$$

$$\Theta\ (A, B, \omega, \lambda) = \int_A^B \omega e^{-\lambda\, z} erfc\left(\sqrt{z}\right) dz$$
$$= \omega\left[-\frac{e^{-\lambda\, z}}{\lambda} + \frac{erf\left(\sqrt{z}\right)}{\lambda e^{\lambda\, z}} - \frac{erf\left(\sqrt{1+\lambda}\sqrt{z}\right)}{\lambda\sqrt{1+\lambda}}\right]_A^B \qquad \text{(A-2)}$$

APPENDIX B

For the average achievable rate evaluation, the integrals involving the *log* function are widely appearing. Next, we introduced some auxiliary functions used in this paper.

$$\Phi_c(A, B, \omega, \lambda) = \int_A^B \omega\, z e^{-\lambda\, z} log_2\,(z+1)\, dz$$
$$= \Bigg[-\frac{\omega\ (1+\lambda\, z)\, \mathrm{e}^{-\lambda\, z}\ln(1+z)}{\ln(2)\,\lambda^2}$$
$$- \frac{\omega\, \mathrm{e}^{-\lambda\, z}}{\ln(2)\,\lambda^2} + \frac{\omega\, \mathrm{e}^{\lambda} E_1\,(\lambda + \lambda\, z)}{\ln(2)\,\lambda}$$
$$- \frac{\omega\, \mathrm{e}^{\lambda} E_1\,(\lambda + \lambda\, z)}{\ln(2)\,\lambda^2}\Bigg]_A^B \qquad \text{(A-3)}$$

$$\Theta_c(A, B, \omega, \lambda) = \int_A^B \omega e^{-\lambda\, z} log_2\,(z+1)\, dz$$
$$= \Bigg[-\frac{\omega\, \mathrm{e}^{-\lambda\, z}\ln(1+z)}{\ln(2)\,\lambda} - \frac{\omega\, \mathrm{e}^{\lambda} E_1\,(\lambda + \lambda\, z)}{\ln(2)\,\lambda}\Bigg]_A^B \qquad \text{(A-4)}$$

where $E_1(.)$ is the exponential integral.

Abstract - **Incremental relaying, which is a form of the adaptive cooperative wireless networks, has been recently introduced to compensate for the channel resources utilization deficiencies associated with the fixed relaying schemes. Incremental relaying operates by exploiting a feedback from the destination to both the source and the relay that inform them about usability of the source-destination direct channel and by this, the channel resources will be saved since the relay will be used only when needed. This paper discusses the performance, namely the outage probability, of the decode-and-forward incremental relaying scheme over Nakagami-m fading channel and incorporates the effects of the multiple L interferers near the destination that will degrade the overall system performance. Numerical results are provided to validate our derivations.**

Keywords: Cooperative Diversity, Incremental Relaying, Fixed Relaying, Outage Probability, Signal to Noise Ratio, Signal to Interference Ratio, Decode-and-Forward, Maximal Ratio Combiner (MRC).

I. INTRODUCTION

The newly adopted form of the cooperative diversity is deployed by placing an intermediate relays between the source and the destination in order to relay the source signal to the destination. And by this, the spatial diversity gain will be achieved at the destination without placing the actual multiple antennas on both the source and the destination as in the Multiple Input Multiple Output systems (MIMO) [1].

Cooperative wireless networks is further splitted into regular or fixed relaying schemes and adaptive relaying schemes, and their functions is dependent, among many other factor, on the usability of the channel resources allocations between the source and the relay. In other words, in the fixed cooperative schemes the relay(s) is/are used to relay the source signal in a deterministic manner without taking into account the status of the direct channel from the source to the destination which in turn will lead to an improper utilization of the channel resources [2-3]. These schemes have been thoroughly analyzed and discussed as in [4-5] where a closed form expressions were obtained for the amplify-and-forward fixed relaying systems over Rayleigh fading channels.

A new form of the cooperative wireless networks is introduced in order to compensate for the deficiencies associated with the fixed cooperative schemes. The adaptive wireless networks are implemented in an opportunistic manner. In other words, the relay path(s) will be used only when needed and more precisely, when the direct path is in outage, by this, the channel resources will be saved effectively and properly used [6].

The incremental relaying scheme is a form of the adaptive cooperative networks in which a feedback from the destination is sent to both the relay and the source in each time slot to inform them about the usability of the direct channel. For instance if the direct transmission was successful, then a single bit will be sent from the destination informing the source and the relay about the successfulness of the transmission of the first time slot and requesting a new signal from the source within the second time slot. Otherwise, a negative feedback will inform the relay to resend the source signal within second time slot after which the destination will combine the two received signal from both the source and the relay by the maximal ration combiner (MRC) [7]. This system is thoroughly analyzed as in [8] where a closed form expression of the outage probability and the BER were obtained for the decode-and-forward incremental relaying over Rayleigh fading channels with no interferers introduced in the system.

In this paper, a closed form expression for the outage probability of the Decode-and-Forward Incremental Relaying over Nakagami-m fading channels with the presence of the multiple interferers near the destination that cause a Co-channel interference is derived. Numerical results are provided to show the effects on the system performance when changing the Nakagami-m order, the number of the interferers near the destination and the minimal threshold γ_o, below which the destination would request the assistance of the relay in sending the source signal.

This paper is further presented as follows; Section II provides the system model. Section III provides the performance analysis and derived tight closed form expression of outage probability. Results and discussion are presented in section IV. We concluded this paper in section V.

II. SYSTEM MODEL

Fig.1 shows the incremental relaying system where the source and the relay communicate with the destination over a channel whose channel coefficients, $h_{S,D}$, $h_{S,R}$ and $h_{R,D}$ which follow the Nakagami-m distribution. The noise terms at the destination are all assumed to be additive white Gaussian noise (AWGN) with zero mean and a unity variance N_0. The multiple access technique used to send the source signal can be any orthogonal access technique such as Frequency Division Multiple Access (FDMA) or the Time Division Multiple Access (TDMA), in our system, we adopted the TDMA. All the communicating nodes are equipped with only one single antenna. The channels from the interferers to the destination are assumed to be identically and independently distributed Rayleigh random variables. If the relay path is used, then upon the reception of the two signals from the source and the relay, the destination will combine these two signals by the maximal ratio combiner (MRC).

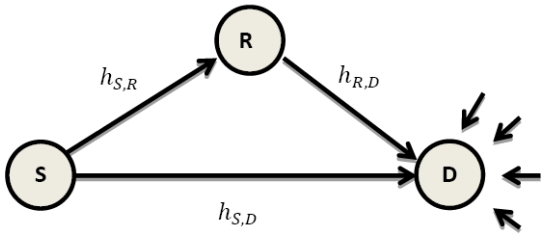

Fig. 1 Cooperative Diversity Network with Multiple L Interferers Located near the Destination.

Upon the reception of the source signal within the first time slot by the destination, the destination will decide whether or not the relay should participate in the transmission of the source signal by sending a feedback to both the source and the relay informing them about the usefulness of the direct path. For instance, if the direct path is in outage then the destination will send a negative feedback requesting the relay to send the source signal to the destination within the second time slot. Otherwise, a positive feedback will be sent to inform the source to send a new signal within the second time slot.

The received signals at the destination from both the source and the relay within the first time slot are as follows:

$$y_{S,D}(t_1) = h_{S,D}\sqrt{E_s}\, x(t_1) + n_1(t_1) + I(t_1) \tag{1}$$

$$y_{S,R}(t_1) = h_{S,R}\sqrt{E_s}\, x(t_1) + n_2(t_1) \tag{2}$$

where $x(t)$ is the source signal and E_s is the energy of the source signal. The interferers effects near the destination within the first time slot is represented by $I(t_1)$. $n_i(t_1)$ where $i \in \{1,2\}$, represent the noise effects at the destination from the source and the relay within the first time slot.

If the relay participates in the transmission, then the received signal at the destination within the second time slot will be:

$$y_{R,D}(t_2) = h_{R,D}\sqrt{E_s}x_r(t_2) + n_3(t_2) + I(t_2) \tag{3}$$

where $x_r(t_2)$ is the regenerated signal at the relay, $I(t_2)$ represents the effects of the Co-channel interference near the destination in the second time slot.

The quality assessment measure of the direct path by the destination is determined by comparing the signal to noise ratio (SNR) of the direct path against γ_o which is the minimal SNR beyond which the destination can receive the source signal without the help of the relay which is also an application dependent parameter. An important observation is that as γ_o increases, the relay path will be used more often which in turn will enhance the spatial diversity benefits in the expense of the deficiency of using the channel resource properly since the relay path will be used more often.

III. PERFORMANCE ANALYSIS

The corner stones in the derivations of the performance metrics of any communication system are by providing the probability density function (PDF) and the cumulative distribution function (CDF) of both the signal to interference ratio (SIR) at the destination from the direct and the relay paths. Since the effect of the noise at the destination is not comparable to the Co-channel interference, we will bypass the noise effects by working only on the SIR at the destination where interference limited environment is a common practice in the literature.

In the following subsections we will derive the PDFs and the CDFs of the SIRs ($\eta_{S,D}$, $\eta_{R,D}$) from both the source and the relay to the destination and the SNR ($\gamma_{S,R}$) from the source to the relay respectively.

A. Probability Density Function of SIR's $\boldsymbol{\eta_{S,D}}$ and $\boldsymbol{\eta_{R,D}}$

The PDF of the SIR ($\boldsymbol{\eta_{S,D}}$) at the destination from the source path is given as follows:

$$f_{\eta_{S,D}}(\eta_{S,D}) = \zeta_{S,D}\left(\frac{(\eta_{S,D})^{m-1}}{(\eta_{S,D}+\lambda_{S,D})^{L+m}}\right) \tag{4}$$

where $\zeta_{S,D} = \frac{(L+m-1)!}{m^L\Gamma(m)(L-1)!}(m\,\lambda_{S,D})^L$, $\lambda_{S,D} = \frac{\overline{\gamma_{S,D}}}{m\overline{\gamma_C}}$

The PDF of the SIR **($\boldsymbol{\eta_{R,D}}$)** at the destination from the relay path is given as follows**:**

$$f_{\eta_{R,D}}(\eta_{R,D}) = \zeta_{R,D}\left(\frac{(\eta_{R,D})^{m-1}}{(\eta_{R,D}+\lambda_{R,D})^{L+m}}\right) \tag{5}$$

where $\zeta_{R,D} = \frac{(L+m-1)!}{m^L\Gamma(m)(L-1)!}(m\,\lambda_{R,D})^L$, $\lambda_{R,D} = \frac{\overline{\gamma_{R,D}}}{m\overline{\gamma_C}}$

Proof:

Given that the SNR of the direct path $\gamma_{S,D}$ and the relay path $\gamma_{R,D}$ at the destination from both the source and the relay, respectively, follow the Nakagami-m distribution and the fading channels from the interferers to the destination ($\gamma_b = \sum_1^L \gamma_k$) is assumed to be a sum of identically and independently distributed exponential random variables. The PDF of the SIR ($\boldsymbol{\eta_{S,D}}$) can be calculated as [10]:

$$f_{\eta_{S,D}}(\eta_{S,D}) = \int_0^\infty \gamma_b f_{\gamma_{S,D}}(\gamma_b \eta_{S,D}) f_{\gamma_b}(\gamma_b) d\gamma_b \quad (6)$$

And the PDF of the SIR $(\boldsymbol{\eta_{R,D}})$ can be calculated as:

$$f_{\eta_{R,D}}(\eta_{R,D}) = \int_0^\infty \gamma_b f_{\gamma_{R,D}}(\gamma_b \eta_{R,D}) f_{\gamma_b}(\gamma_b) d\gamma_b \quad (7)$$

The PDFs of $\gamma_{S,D}$, $\gamma_{R,D}$ and γ_b are denoted as [9]:

$$f_{\gamma_{S,D}}(\gamma_{S,D}) = \frac{m^m {\gamma_{S,D}}^{m-1}}{\overline{\gamma_{S,D}}^m \Gamma(m)} exp\left(-\frac{m\gamma_{S,D}}{\overline{\gamma_{S,D}}}\right), \gamma_{S,D} > 0 \quad (8)$$

$$f_{\gamma_{R,D}}(\gamma_{R,D}) = \frac{m^m {\gamma_{R,D}}^{m-1}}{\overline{\gamma_{R,D}}^m \Gamma(m)} exp\left(-\frac{m\gamma_{R,D}}{\overline{\gamma_{R,D}}}\right), \gamma_{R,D} > 0 \quad (9)$$

$$f_{\gamma_b}(\gamma_b) = \frac{{\gamma_b}^{L-1}}{\overline{\gamma_c}^L (L-1)!} \exp\left(\frac{-\gamma_b}{\overline{\gamma_c}}\right) \quad (10)$$

where $\overline{\gamma_c} = \frac{\mathcal{E}}{N_o} E({\alpha_k}^2)$ is the average SNR per channel which is assumed to be independent and identical for all the channels, and $\mathcal{E}$ is the signal energy and:

$$\gamma_b = \frac{\mathcal{E}}{N_o} \sum_{k=1}^{L} {\alpha_k}^2 = \sum_{k=1}^{L} \gamma_k \quad (11)$$

γ_k is being the instantaneous SNR of the $k-th$ channel and L is the number of the interfering channels near the destination. And since the fading channels are mutually and statistically independent, then $\gamma_k's$ are statistically independent.

Solving the integrals in (6) and (7) to get the compact form of the SIR's PDF at the destination from the direct path as in (4) and from the relay path as in (5) using [11,(3.351.1)].

B. The Cumulative Distribution Function of SIR's $\boldsymbol{\eta_{S,D}, \eta_{R,D}}$

The CDF of the SIR $(\boldsymbol{\eta_{S,D}})$ at the destination from the source path is given as follows:

$$F_{\eta_{S,D}}(\eta_{S,D}) = \frac{\zeta_{S,D}}{(\lambda_{S,D})^{L+m}} \frac{{\eta_{S,D}}^m}{m} \, {}_2F_1\left(L+m, m; 1+m; -\frac{\eta_{S,D}}{\lambda_{S,D}}\right) \quad (12)$$

The CDF of the SIR $(\boldsymbol{\eta_{R,D}})$ at the destination from the relay path is given as follows:

$$F_{\eta_{R,D}}(\eta_{R,D}) = \frac{\zeta_{R,D}}{(\lambda_{R,D})^{L+m}} \frac{{\eta_{R,D}}^m}{m} \, {}_2F_1\left(L+m, m; 1+m; -\frac{\eta_{R,D}}{\lambda_{R,D}}\right) \quad (13)$$

where ${}_2F_1(a, b; c; z)$ is the Gaussian Hyper geometric function [11].

Proof:

The CDF of $\eta_{S,D}$ can be calculated as [10]:

$$F_{\eta_{S,D}}(\eta_{S,D}) = \int_0^{\eta_{S,D}} f_{\eta_{S,D}}(y) dy \quad (14)$$

where $f_{\eta_{S,D}}(y)$ is given as in (4).

The CDF of $\eta_{R,D}$ is found by integrating the PDF of $\eta_{R,D}$ given in (5) as follows:

$$F_{\eta_{R,D}}(\eta_{R,D}) = \int_0^{\eta_{R,D}} f_{\eta_{R,D}}(y) dy \quad (15)$$

Solving the integrals in (14) and (15) using [11,(2.117.2)], the compact form of the CDF of $\eta_{S,D}$ will be as in (12) and that of $\eta_{R,D}$ will be as in (13).

The CDF of the SNR $(\boldsymbol{\gamma_{S,R}})$ at the relay from the source path is given as follows:

$$F_{\gamma_{S,R}}(\gamma_{S,R}) = \frac{\gamma\left(m, m\frac{\gamma_{S,R}}{\overline{\gamma_{S,R}}}\right)}{\Gamma(m)} \quad (16)$$

where $\gamma(a, b)$ is the Incomplete Gamma function [11] and $\Gamma(m)$ is the gamma function.

Proof:

The CDF of $\boldsymbol{\gamma_{S,R}}$ is found by integrating the PDF of $\boldsymbol{\gamma_{S,R}}$ as follows [10]:

$$F_{\gamma_{S,R}}(\gamma_{S,R}) = \int_0^{\gamma_{S,R}} f_{\gamma_{S,R}}(y) dy \quad (17)$$

where $f_{\gamma_{S,R}}(y)$ is given as [9]:

$$f_{\gamma_{S,R}}(\gamma_{S,R}) = \frac{m^m {\gamma_{S,R}}^{m-1}}{\overline{\gamma_{S,R}}^m \Gamma(m)} exp\left(-\frac{m\gamma_{S,R}}{\overline{\gamma_{S,R}}}\right), \gamma_{S,R} \geq 0 \quad (18)$$

Solving the integral in (17) using [11,(3.381.1)], the compact form of the CDF of $\boldsymbol{\gamma_{S,R}}$ will be as in (16).

C. Outage Probability Analysis

The outage probability events of the incremental relaying are characterized in two events; basically, when the direct path is in outage, the destination will inform the relay to send the source signal in an attempt to enhance the reception of the signal by combining them using the MRC. The second event when the SNR of the MRC's two combined signals at the destination fall below the pre-specified threshold γ_o.

Representing the two cases of the decode-and-forward incremental relaying outage probability events, p_{out} is given as:

$$p_{out} = P_r(\eta_{S,D} \leq \gamma_o) \times P_r[\min(\gamma_{S,R}, \eta_{S,D} + \eta_{R,D} \leq \gamma_O | \eta_{S,D} \leq \gamma_o)]$$

$$p_{out} = P_r(\eta_{S,D} \leq \gamma_o)\left[1 - P_r(\eta_{S,D} + \eta_{R,D} > \gamma_o | \eta_{S,D} \leq \gamma_o)\right] \times P_r(\gamma_{S,R} > \gamma_o | \eta_{S,D} \leq \gamma_o)$$

$$p_{out} = P_r(\eta_{S,D} \leq \gamma_o)\left[1 - \frac{P_r(\eta_{S,D} \leq \gamma_o) - P_r(\eta_{S,D} + \eta_{R,D} \leq \gamma_o)}{P_r(\eta_{S,D} \leq \gamma_o)} P_r(\gamma_{S,R} > \gamma_o)\right] \quad (19)$$

It is worth to mention that the operator min(•|•) encompasses the two outage events, in other words, the first argument within the operator is the outage at the relay whereas the second one represents the outage at the destination .

Further simplifications on the above expression yields:

$$p_{out} = P_r(\gamma_{S,R} \leq \gamma_o) P_r(\eta_{S,D} \leq \gamma_o) + P_r(\gamma_{S,R} > \gamma_o) P_r(\eta_{S,D} + \eta_{R,D} \leq \gamma_o) \quad (20)$$

$$p_{out} \approx \frac{\zeta_{S,D}}{m(\lambda_{S,D})^{L+m}} \frac{\gamma\left(m, m\frac{\gamma_o}{\gamma_{S,R}}\right)}{\Gamma(m)} (\gamma_o)^m \; {}_2F_1\left(L+m, m; 1+m; -\frac{\gamma_o}{\lambda_{S,D}}\right) + \frac{\zeta_{R,D}}{m(\lambda_{R,D})^{L+m}} \left[1 - \frac{\gamma\left(m, m\frac{\gamma_o}{\gamma_{S,R}}\right)}{\Gamma(m)}\right] (\gamma_o)^m \; {}_2F_1\left(L+m, m; 1+m; -\frac{\gamma_o}{\lambda_{R,D}}\right) \quad (21)$$

When using the MRC, the value of $\eta_{S,D}$ is not comparable to $\eta_{R,D}$ since we used the relay path in the first place to compensate for the deficiency of the direct transmission. And hence, it will be intuitive to omit $\eta_{S,D}$ from the argument to get the approximated outage probability expression as given in (21).

The detailed mathematical derivations of (4), (5), (12), (13), (16), and (21) will be submitted to a journal for publication.

IV. NUMERICAL RESULTS

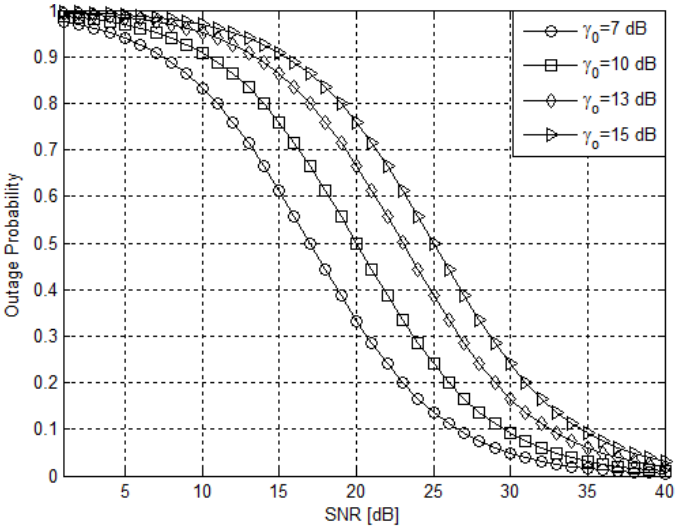

Fig. 2 Outage probability for different values of γ_o, (γ_o=7 dB, 10 dB, 13 dB and 15 dB), the Nakagmi-m order (m= 1) and only one interferer near the destination.

Fig.2 depicts the system performance when there is only one interferer and the Nakagmi-m order is one (m=1) and various values of γ_o. From the figure, one can see that as we increase γ_o, the system performance in terms of the oytage probability will be degraded. As an example, for a system with (γ_o =15 dB) to have the same performance as that with (γ_o=7 dB), an increment of about 8 dB is required given that the outage probability is 0.5.

Fig.3 shows the effects of changing the Nakagni-m order on the outage probability performance when there is only one interferer near the destination and (γ_o= 10 dB). As can be seen from the figure, as the Nakagami-m order increases, the system performance will be enhanced. For example, for an outage probability of 0.1, an increment of about 5 dB is required for a system with (m=1) to have the same performance as that with (m=3).

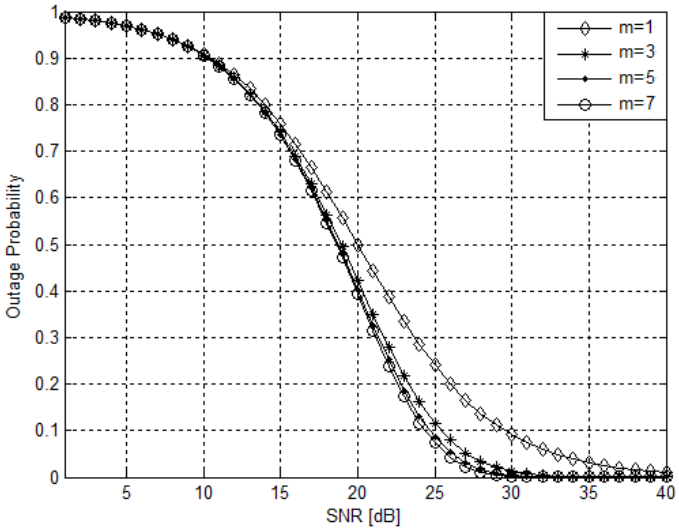

Fig. 3 Outage Probability for different values of the Nakagmi-m order (m=1,3,5,7), (γ_o=10dB) and only one interferer.

Fig.4 combines the impact of changing γ_o and the Co-channel effects caused by the interferers near the destination on the system outage probability. As shown from the figure, the impact of increasing γ_o on the system performance is more apparent than changing the number of interferers. For example, a system with (γ_o=10 dB) and (L=2+3) will behave much better than a system with (γ_o=15 dB) and (L=1).

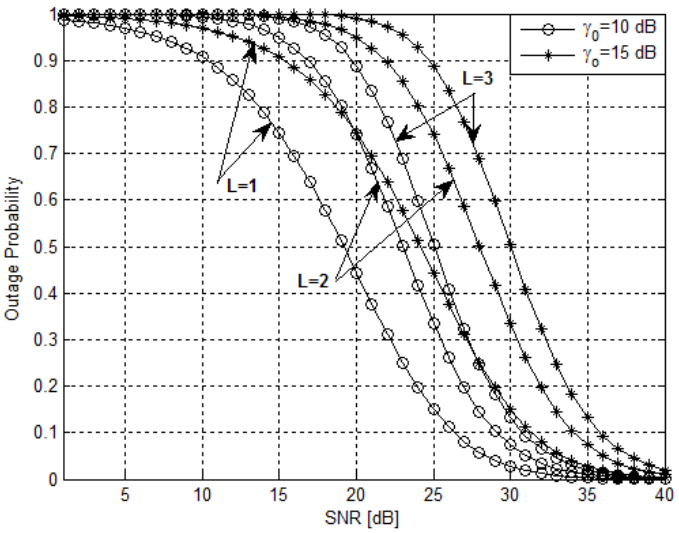

Fig. 4 Outage Probability for different numbers of interferers (L=1,2,3), different values of γ_o (γ_o=10 dB, 15 dB) and the Nakagami-m order (m=1).

Fig.5 depicts the outage probability behavior when changing the number of interferers and the Nakagami-m order for a system with γ_o=13 dB. and this is obvious especially in the high SNR region. From the figure, as we increase the Nakagami-m order and decrease the number of interferers a considerable enhancement will be achieved especially in the high SNR region. Also, the effects of changing the Nakagami-m order on the system performance is more influential on the outage probability than changing the number of the interferers. For example, given that (L=1), then for a system with (m=1) to behave as that with (m=4), an increment of about 5 dB is required to have the same performance for an outage probability of 0.1. To illustrate the effect of the interference, for an outage probability of 0.2 and Nakagami-m order of one (m=1), an increment of 5 dB is required for a system with (L=3) to behave the same as the one with (L=1).

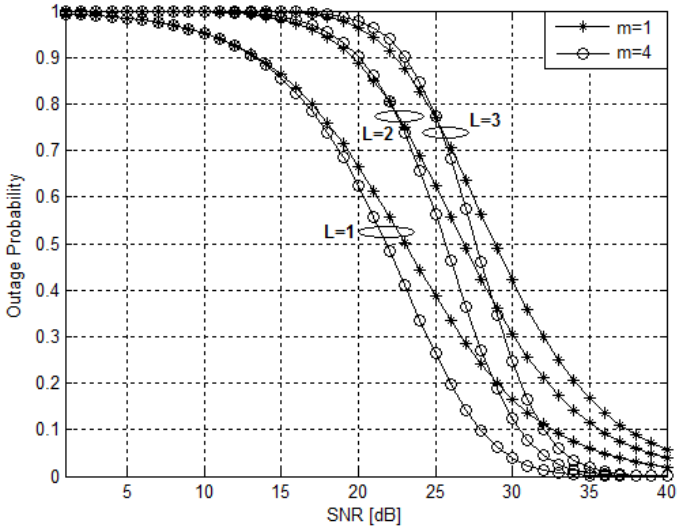

Fig. 5 Outage Probability for different numbers of interferers (L=1,2,3), different values of the Nakagami-m order (m=1,4) when (γ_o=13 dB).

V. CONCLUSION

In this paper, we analyzed the effects of the Co-channel interference on the decode-and-forward incremental relaying scheme over Nakagmi-m fading channel caused by the multiple L interferers near the destination which in turn will degrade the overall system performance. Closed form expression of the outage probability is derived. It is apparent that as we increase the Nakagmi-m order and decrease the number of the interferers near the destination and γ_o, the system will get a considerable enhancement regarding the outage probability performance.

On practical solutions of AQM queues with large buffers

Pawel Mrozowski and Andrzej Chydzinski
Faculty of Automatic Control, Electronics and Computer Science, Silesian University of Technology, Gliwice, Poland
andrzej.chydzinski@polsl.pl

***Abstract*—In a router equipped with the active queue management (AQM), the arriving packets may be rejected even if the buffer is not full. This is supposed to reduce the queue size, while maintaining a high link utilization. The simplest approach to AQM is rejecting arriving packets with the probability that is a function of the queue length. The recently developed mathematical models of such systems present numerical difficulties that are not trivial to overcome, especially in systems of large sizes. In this paper we first overview the analytical solutions of these models, which contain both Markovian (Poisson) and non-Markovian (general renewal) traffic models. Then we discuss the computational techniques that enable solving and designing of such AQM queues with buffers for thousands of packets. Finally, we demonstrate computational examples with such buffers.**

***Index Terms*—active queue management, Internet routers, dropping function, numerical solutions**

I. Introduction

It is known that FIFO tail-drop queues used for packets in Internet routers have several disadvantages. In particular, they induce large queueing delays, flow synchronization and unfairness between flows, to name only three of them. When these (and other) problems with FIFO tail-drop queues were noticed, the active queue management (AQM) for Internet routers was proposed. The idea is that the router can drop incoming packets even if the buffer is not full yet, thus preventing the queue from building up. Additionally, if random dropping is involved, the flow synchronization is reduced and the fairness improved. The first proposed AQM algorithms were the Random Early Detection gateway (RED) [1] and its modifications e.g. [2], [3], [4], [5], [6]. To date many other AQM algorithms were proposed, including the well-known solutions like REM [7], PI [8], [9], BLUE [10], GREEN [11], AVQ [12], and newest propositions [13], [14], [15], [16].

The simplest approach to AQM is rejecting arriving packets with the probability that is a function of the queue size observed upon packet arrival. The function assigning the dropping probability to the queue size is called a *dropping function*. Intuitively, the dropping function should be monotonic (non-decreasing). In RED for instance, the dropping function is linear.

Recently, two important models of the queueing systems with dropping functions have been solved analytically, namely the model with Poisson arrivals [17], and the model with exponential service distribution, [18]. These models are equivalent to the classic $M/G/1/N$ and $G/M/1/N$ finite-buffer queues, but with added dropping function mechanism.

Unfortunately, for the reasons discussed in details in Section V, the analytical results presented in [17], [18] cannot be used directly to obtain numerical results when the buffer size is large. In fact, they are even hard to use for moderate buffers. (In papers [17], [18] only examples with very small buffers are presented – for 10 and 6 packets, respectively).

Naturally, in practice we need solutions for much larger buffers. The routers' manufacturers use the bandwidth-delay product when dimensioning the buffers [19]. Typically, the buffer is supposed to accommodate 100ms (or 200ms) of the traffic. For instance, if the output link capacity is 1Gb/s and the average packet size equals 1000 bytes, then the buffer for this link should accommodate 12500 packets (1Gb/s $\cdot$ 100ms). The active queue management should reduce the average queue (and the necessary buffer size) by an order of magnitude. Thus in practice we have to solve models with buffers for 1000-2000 packets.

Therefore, the purpose of this paper is to present and discuss computational techniques that enable solving and designing of AQM queues with buffers for a few thousands of packets, basing on the analytical results of [17], [18].

The remaining part of the paper is structured as follows. In Section II, the formal description of the queueing model with the dropping function is recalled. Then, in Sections III and IV, the analytical solutions of the model with renewal (G) and Poisson (M) arrivals are reviewed, respectively. In Section V, the computational issues connected with large buffers are reviewed first. Then, for each of them a proposition of the solution is presented. In Section VI, several numerical examples with buffers for 2000 packets and different traffic and service types are presented and discussed. Finally, remarks concluding the paper are gathered in Section VII.

II. Queueing model

The following model of the queue of packets at the routers output interface will be considered.

Packets arrive to the queue according to a renewal process with the interarrival time distribution given by distribution function $F(t)$. The distribution of the service (transmission) time of a packet is given by distribution function $G(t)$. The packet buffer (waiting room) has size b (including the service position). Therefore, a packet incoming when already b packets

are present in the buffer is rejected. Additionally, even if the buffer is not full yet, every arriving packet can be dropped with probability d_n, where n is the queue size observed upon this packet arrival. The function d_n is called a dropping function and is not further specified - it can assume any form. By $\mathbb{P}$ we will denote the probability, by $X(t)$ the queue size at time t (including the service position), by X_k – the queue size left by the k-th departing packet, while by $f(s)$ – the Laplace transform of the interarrival time distribution, i.e:

$$f(s) = \int_0^\infty e^{-st} dF(t).$$

Finally, we denote:

$$P_m(t,n) = \mathbb{P}(X(t) = m | X(0) = n),$$

and

$$P_m = \lim_{t\to\infty} \mathbb{P}(X(t) = m).$$

In the following two sections we will recall the analytical results, which allow computation of P_m, obtained in [17], [18].

III. General arrivals and exponential service

In this section we assume that the service time is exponentially distributed with parameter μ, i.e.

$$G(t) = 1 - e^{-\mu t}, \tag{1}$$

while the interarrival time distribution can assume any form. Denote

$$p_m(s,n) = \int_0^\infty e^{-st} P_m(t,n) dt, \tag{2}$$

$$\mathbf{p}_m(s) = \left[p_m(s,0), p_m(s,1), ..., p_m(s,b)\right]^T. \tag{3}$$

In [18] it was proven that:

$$\mathbf{p}_m(s) = \mathbf{A}^{-1}(s)\mathbf{B}_m(s), \tag{4}$$

where $\mathbf{B}_m(s)$ is a vector of size $b+1$ defined as:

$$\mathbf{B}_m(s) = \left[I(m=0)\frac{1-f(s)}{s}, -\gamma_m(s,1), \ldots, -\gamma_m(s,b)\right]^T, \tag{5}$$

with

$$\gamma_m(s,n) = \int_0^\infty e^{-(s+\mu)t}\big(1-F(t)\big)\left[I(n \geq m \geq 1)\frac{(\mu t)^{n-m}}{(n-m)!} + I(m=0)\sum_{k=n}^{\infty}\frac{(\mu t)^k}{k!}\right] dt, \tag{6}$$

$$I(A) = \begin{cases} 1, & \text{if } A \text{ is true,} \\ 0, & \text{otherwise,} \end{cases} \tag{7}$$

while $\mathbf{A}(s)$ is a $(b+1)\times(b+1)$ matrix with the following elements:

$$a_{0,0}(s) = 1 - d_0 f(s), \tag{8}$$
$$a_{0,1}(s) = (d_0 - 1) f(s), \tag{9}$$
$$a_{0,j}(s) = 0, \quad 2 \leq j \leq b, \tag{10}$$
$$a_{i,0}(s) = d_0 \sum_{k=i}^{\infty} \alpha_k(s), \;\; 1 \leq i \leq b, \tag{11}$$
$$a_{i,1}(s) = d_1 \alpha_{i-1}(s) + (1-d_0)\sum_{k=i}^{\infty}\alpha_k(s) - I(i=1), \quad 1 \leq i \leq b, \tag{12}$$
$$a_{i,j}(s) = (1-d_{j-1})\alpha_{i-j+1}(s) + d_j \alpha_{i-j}(s) - I(i=j), \quad 1 \leq i \leq b, \;\; 2 \leq j \leq \min\{i, b-1\}, \tag{13}$$
$$a_{i,i+1}(s) = (1-d_i)\alpha_0(s), \;\; 1 \leq i \leq b-1, \tag{14}$$
$$a_{b,b}(s) = (1-d_{b-1})\alpha_1(s) + f(s+\mu) - 1, \tag{15}$$
$$a_{i,j}(s) = 0, \quad \text{otherwise,} \tag{16}$$

and

$$\alpha_k(s) = \int_0^\infty e^{-(s+\mu)t}\frac{(\mu t)^k}{k!} dF(t). \tag{17}$$

IV. Poisson arrivals and general service

In this section we assume that the interarrival time distribution is exponential with parameter λ, i.e.

$$F(t) = 1 - e^{-\lambda t}, \tag{18}$$

while the service time distribution may assume any form.

In [17] it was proven that the steady-state distribution of the queue size has the form:

$$P_b = 1 - \frac{\sum_{i=0}^{b-1}\pi_i/(1-d_i)}{\pi_0/(1-d_0)+\rho}, \tag{19}$$

$$P_m = \frac{\pi_m/(1-d_m)}{\pi_0/(1-d_0)+\rho}, \quad 0 \leq m \leq b-1, \tag{20}$$

where π_m is the distribution of the queue length left behind by departing packets, i.e.:

$$\pi_m = \lim_{n\to\infty}\mathbb{P}(X_n = m), \tag{21}$$

while ρ is the offered load:

$$\rho = \lambda \int_0^\infty t dG(t). \tag{22}$$

The numbers π_m can be computed by means of the system of equations:

$$\begin{cases} \pi_k = \sum_{j=0}^{b-1}\pi_j p_{j,k}, & 0 \leq k \leq b-1, \\ \sum_{j=0}^{b-1}\pi_j = 1, \end{cases} \tag{23}$$

with

$$p_{j,k} = \begin{cases} a_{1,k}, & \text{if} \quad j=0, \; 0 \leq k \leq b–1, \\ a_{j,k-j+1} & \text{if} \quad 1 \leq j \leq b–1, \; j-1 \leq k \leq b–1, \\ 0 & \text{otherwise,} \end{cases} \tag{24}$$

$$a_{n,k} = \int_0^\infty Q_{n,k}(u) dF(u), \tag{25}$$

where the function $Q_{n,k}(u)$ denotes the conditional probability that the first departure time is later than u and k packets are accepted in $(0, u]$, assuming $X(0) = n$. The values of $Q_{n,k}(u)$ can be obtained using its Laplace transform, i.e.:

$$q_{n,k}(s) = \int_0^\infty e^{-su} Q_{n,k}(u) du. \tag{26}$$

In [17] it was proven that

$$q_{n,k}(s) = \frac{\prod_{i=0}^{k-1} \lambda(1 - d(n+i))}{\prod_{i=0}^{k}(s + \lambda(1 - d(n+i)))}, \qquad n \geq 0, \quad k \geq 0. \tag{27}$$

V. Practical solutions

Although the analytical results presented in sections III and IV can be used in unaltered form to obtain numerical results, such approach may result in extensive, time-consuming computations, even in cases with moderate buffer sizes.

The numerical difficulties have several sources.

Firstly, the results are presented in terms of the Laplace transform. As demonstrated in [17], transform (27) is a rational function which can be inverted symbolically. In practice, however, it is achievable only for small values of b, therefore a numerical inversion have to be used. Formula (4) does not need an inversion, as the limit $\lim_{s\to 0+} s\mathbf{p}_m(s)$ can be used instead, but requires a proper choice of s for the limiting distribution – too small s may produce large errors connected with range overflows during computation. Secondly, there are integrals (e.g. in (6), (17)) that have to be computed either symbolically or numerically. Thirdly, infinite summations appear in formulas (6), (11) and (12). Finally, in (4) an inversion of a matrix of size $(b+1) \times (b+1)$ is needed. For a very large b this also may be computationally demanding.

In the remaining part of this section we address all the aforementioned issues.

A. Infinite sums

The infinite sums in formulas (6), (11) and (12) can be easily replaced by finite sums using the identity $e^x = \sum_{k=0}^\infty x^k/k!$. In particular, from (6) we obtain:

$$\gamma_m(s,n) = \int_0^\infty e^{-(s+\mu)t}\big(1 - F(t)\big)\left[I(n \geq m \geq 1) \frac{(\mu t)^{n-m}}{(n-m)!} + I(m=0)\left(e^{\mu k} - \sum_{k=0}^{n-1} \frac{(\mu t)^k}{k!}\right)\right] dt, \tag{28}$$

while (11) and (12) give:

$$a_{i,0}(s) = d_0\big[f(s) - \sum_{k=0}^{i-1} \alpha_k(s)\big], \;\; 1 \leq i \leq b, \tag{29}$$

$$a_{i,1}(s) = d_1 \alpha_{i-1}(s) + (1 - d_0)\big[f(s) - \sum_{k=0}^{i-1} \alpha_k(s)\big] - I(i=1), \quad 1 \leq i \leq b. \tag{30}$$

B. Integrals

The integrals in (6) and (17) can be computed symbolically for many types of distribution $F(t)$. Below we present ready-to-use results for four popular distributions.

1) Exponential distribution with parameter λ. We have

$$F(t) = 1 - e^{-\lambda t}, \qquad f(s) = \frac{\lambda}{s+\lambda}. \tag{31}$$

In this case, from (17) and (28) we obtain:

$$\alpha_k(s) = \frac{\lambda \mu^k}{(s + \lambda + \mu)^{k+1}}, \tag{32}$$

$$\gamma_n(s,m) = I(n \geq m \geq 1) \frac{\mu^{n-m}}{(s+\lambda+\mu)^{n-m+1}} + I(m=0)\left(\frac{1}{s+\lambda} - \sum_{k=0}^{n-1} \frac{\mu^k}{(s+\lambda+\mu)^{k+1}}\right). \tag{33}$$

2) Erlang distribution with parameters K and λ. We have

$$F(t) = 1 - \sum_{i=0}^{K-1} \frac{(\lambda t)^i}{i!} e^{-\lambda t}, \quad f(s) = \left(\frac{\lambda}{s+\lambda}\right)^K. \tag{34}$$

From (17) and (28) we obtain:

$$\alpha_k(s) = \frac{\lambda^K \mu^k (k+K-1)!}{(s+\lambda+\mu)^{k+K} k!(K-1)!}, \tag{35}$$

$$\gamma_n(s,m) = I(n \geq m \geq 1) \sum_{i=0}^{K-1} \frac{\lambda^i \mu^{m-n}(i+n-m)!}{(s+\lambda+\mu)^{n-m+1+i} i!(n-m)!} + I(m=0)\left(\sum_{i=0}^{K-1} \frac{\lambda^i}{(s+\lambda)^{i+1}} - \sum_{k=0}^{n-1}\sum_{i=0}^{K-1} \frac{\lambda^i \mu^k (i+k)!}{(s+\lambda+\mu)^{i+k+1} i! k!}\right). \tag{36}$$

3) Uniform distribution on interval $(0, v)$. We have

$$F(t) = \frac{1}{v} t, \qquad f(s) = \frac{1 - e^{-sv}}{sv}. \tag{37}$$

Now from (17) and (28) we obtain:

$$\alpha_k(s) = \mu^k \frac{k! - \Gamma(k+1, v(s+\mu))}{v k! (s+\mu)^{k+1}}, \tag{38}$$

$$\gamma_n(s,m) = I(n \geq m \geq 1)\frac{\mu^{n-m}(s+\mu)^{m-n-2}}{v(n-m)!}$$
$$\cdot \Big[-(n-m+1)!$$
$$+ v(s+\mu)\big((n-m)! - \Gamma(n-m+1, v(s+\mu))\big)$$
$$+ \Gamma(n-m+2, v(s+\mu))\Big] + I(m=0)\Big[\frac{e^{-sv}+sv-1}{s^2v}$$
$$- \sum_{k=0}^{n-1} \frac{\mu^k(s+\mu)^{-2-k}}{vk!}\Big(-(k+1)! + v(s+\mu)\big(k!$$
$$- \Gamma(k+1, v(s+\mu))\big) + \Gamma(k+2, v(s+\mu))\Big)\Big], \quad (39)$$

where $\Gamma(k,t)$ denotes the incomplete gamma function.

4) Constant interarrival time equal to c. W have

$$f(s) = e^{-cs}, \quad (40)$$

and

$$\alpha_k(s) = e^{-(s+\mu)c}\frac{(\mu c)^k}{k!}, \quad (41)$$

$$\gamma_n(s,m) = I(n \geq m \geq 1)\Big[\frac{\mu^{n-m}(s+\mu)^{m-n-1}}{(n-m)!}$$
$$\cdot \big((n-m)! - \Gamma(n-m+1, c(s+\mu))\big)\Big]$$
$$+ I(m=0)\Big[\frac{1-e^{-cs}}{s} - \sum_{k=0}^{n-1}\frac{\mu^k(s+\mu)^{-k-1}}{k!}\big(k!$$
$$- \Gamma(k+1, c(s+\mu))\big)\Big]. \quad (42)$$

C. Choice of s and n

In the case of the exponential service time, the steady-state queue size distribution can be computed from (4) using the well-known properties of the Laplace transform around $s = 0$. Namely, we have

$$P_m = \lim_{s \to 0+} sp_m(s,n), \quad (43)$$

for any n. Therefore, in numerical calculations we have to choose a proper, small value of s. Theoretically, the smaller s, the better. However, if s is very small, $p_m(s,n)$ and other intermediate results may become large, what may cause numerical errors, depending on the precision of numbers used in computations. We observed that in typical computations satisfactory results are obtained for $s = 10^{-10}$.

As for the choice of the initial queue size n (i.e. the element of vector (3)), theoretically any n is good. However, in typical cases the average queue size in the steady state is somewhere between 0 and b rather than close to 0 or b. Therefore, in order to exploit a quicker convergence rate to the steady state in (43), it is reasonable to choose e.g. $n = \frac{b}{2}$ rather than 0 or b.

D. Transform inversion

In the case of the exponential interarrival time, the Laplace transform given in (27) has to be inverted. When the buffer is large, this has to be done numerically. For this purpose, in [20] we checked several methods for numerical transform inversion, including the methods by Gaver and Stehfest [21], Talbot [22], Zakian [23], Weeks [24], Piessens [25], Dubner and Abate [26], Abate and Choudhury and Whitt [27]. We came to the conclusion that the Zakian method offers the best tradeoff between the computation time and accuracy of the results. This method is very fast, while in typical cases offering not worse accuracy than the most computationally demanding method [27] (see [28], [29] for examples of usage of the method).

If $H(t)$ is an original function and $h(s)$ is its Laplace transform, then the Zakian inversion formula has the form:

$$H(t) \approx \frac{2}{t}\sum_{k=0}^{n} \mathrm{Re}\big[\omega_k h\left(\frac{\alpha_k}{t}\right)\big]. \quad (44)$$

where n, α_k, ω_k are specially chosen parameters (α_k, ω_k are complex numbers). Commonly used values are $n = 4$ and the following values of α_k and ω_k.

k	α_k	ω_k
0	12.83767675 + i 1.666063445	-36902.08210 + i 196990.4257
1	12.22613209 + i 5.012718792	61277.02524 - i 95408.62551
2	10.93430308 + i 8.409673116	-28916.56288 + i 18169.18531
3	8.776434715 + i 11.92185389	4655.361138 - i 1.901528642
4	5.225453361 + i 15.72952905	-118.7414011 - i 141.3036911

E. Matrix inversion

In (4) we have to invert a matrix of size $(b+1) \times (b+1)$. In the case of a buffer for a few thousands of packets, this can be easily done, even using an average PC and the classic (Gaussian) method of matrix inversion, whose time complexity is of $O(b^3)$. For larger buffers, advanced methods of matrix inversion can be considered, for instance the Coppersmith & Winograd method, whose time complexity is of $O(b^{2.376})$.

VI. Examples

To perform sample numerical calculations, we assumed that the router output link of 1Gb/s capacity serves the arriving traffic of 1.1Gb/s bitrate. The buffer size was $b = 2000$ and the following dropping function was used:

$$d_n = \begin{cases} 0, & \text{if} \quad n \leq 500, \\ 0.0001201602n - 0.06008011, & \text{if} \quad 500 < n < 2000, \\ 1, & \text{if} \quad n \geq 2000. \end{cases}$$

As we can see, this is a linear dropping function of the RED type [1]. This particular form of the dropping function has been chosen so that the average queue size would be roughly 1250 packets.

The following six examples, with different types of traffic and service time distribution were computed. (All the distributions were scaled so that the average interarrival time is 1.)

1) The interarrival time is exponential, $\lambda = 1$, the service time is exponential, $\mu = 0.9090909$.

TABLE I
QUEUEING CHARACTERISTICS IN EXAMPLE 1)

	computation	simulation
mean queue size	1256.56	1256.83
std. dev. queue size	86.99	86.95
$\mathbb{P}(1000 \leq queue < 1200)$	0.252	0.252
$\mathbb{P}(1200 \leq queue < 1300)$	0.432	0.432
$\mathbb{P}(1300 \leq queue < 1500)$	0.311	0.311

2) The interarrival time is exponential, $\lambda = 1$, the service time is constant and equal to 1.1.
3) The interarrival time has Erlang distribution with parameters $K = 3$ and $\lambda = 3$, the service time is exponential, $\mu = 0.9090909$.
4) The interarrival time has Erlang distribution with parameters $K = 9$ and $\lambda = 9$, the service time is exponential, $\mu = 0.9090909$.
5) The interarrival time is constant and equal to 1 (CBR traffic), the service is exponential, $\mu = 0.9090909$.
6) The interarrival time is uniformly distributed on interval $(0, 2)$, the service is exponential, $\mu = 0.9090909$.

The computation results are presented in Tables I-VI. Each table contains also results of a long-run simulation (about 10^9 packets) of the queueing system, performed using OMNeT++ simulator, [30]. For computation we used an Intel Quad Core i7 (3GHz) machine with hyperthreading and an application written in Java 1.7 64bit. In most cases calculations were done using double precision numbers, with exceptions for Examples 6 and 5. These two examples caused range overflow, when double precision numbers were used. Therefore, in these examples the BigInteger and BigDecimal classes from standard Java math library and from Java JAS Project library [31] were used.

As we can see, in all the examples the computed queueing characteristics agree pretty well (though not perfectly) with the simulation results. This indicates that P_m's are overestimated a little for small m. To further illustrate this, in Figs. 1 and 2 we present distributions of the queue size in Example 2) and Example 6), respectively. In Fig. 1 the computed distribution agrees very well with the simulated one. However, in Fig. 2 the two distributions are apart for queue sizes below 1100. As both figures are plotted in logarithmic scale, the errors concern rather small probabilities and do not have a deep impact on the practical applicability of the computational method (in the worst case, they change the average queue size by 0.2 percent only). At this moment it is unclear what is the reason of these errors.

Finally, in Tab. VII the computation times of the considered examples are gathered. As we can see, they vary from a few minutes to a few hours, so they are not prohibitive for practical purposes. The significantly longer computation times of Examples 5 and 6 are connected with the usage of the BigInteger and BigDecimal classes during computation.

INVITED PAPERS

Children as co-creators of video stories: mobile videos for learning

Jari Multisilta, Hannele Niemi
University of Helsinki, Cicero Learning, Helsinki, Finland
jari.multisilta@helsinki.fi, hannele.niemi@helsinki.fi

Abstract – In this paper we describe the MoViE mobile video storytelling platform, related Global Sharing Pedagogy framework and present examples of their use in learning and education. MoViE, the Mobile Video Experience platform, is a research platform for studying how learners create mobile video stories and how they share and learn with mobile social media. MoViE supports collaborative video creation, as people can use video clips of the same event made by others in their own mobile video stories because they are sharing the same experience. Currently, MoViE and GSP have been used in several international research projects, and there are over 1200 users and 1500 videos from 5 countries. In this paper, the research results and experiences from MoViE and GSP as tools for cross-cultural co-creation of learning related videos are presented.

I. INTRODUCTION

The use of videos on the internet has grown significantly in the last few years. For example, Khan Academy has a large collection of educational videos, especially on STEM subjects, available for free on the internet. It is also relatively easy to produce technically high-quality videos almost by anybody since the most new smartphones have high-quality media capture features. The growth of Internet video coupled with trends in social networking and participatory media, provide exciting new opportunities for video storytelling to become an integral component of distributed creative learning environments.

A growing number of education and research communities have started to use video in learning activities in new ways. According [1], the uses of "video are expanding from teachers simply showing videos to students to approaches where learners interact with, create, or comment on video resources as part of their knowledge-building activities."

The use of internet videos can be classified into three types, namely A) consuming videos from the internet, B) producing videos and uploading them to the internet, or C) remixing and enriching existing internet videos and their metadata.

Although the most popular videos in the internet are related to entertainment, web videos can have many educational uses. Khan Academy is an example of a type A web video service that has a large collection of educational videos, especially on STEM subjects. Khan Academy supports the traditional recorded lecture model. According to [2], "Khan Academy is a collection of video lectures that give demonstrations of mechanical processes." Much debate has taken place about the pedagogical model behind Khan Academy [2, 3, 4]. The main criticism is that Khan Academy is not supporting a constructivist model where learners actively create knowledge using activities that support knowledge construction. Our mobile video storytelling platform MoViE supports co-creation of mobile video stories and its use for learning can be designed and analyzed using the Global Sharing Pedagogy (GPS) model.

This paper reviews the use of video storytelling for learning. After the review the paper describes briefly the GSP model and the MoViE platform. Two examples of using GSP and MoViE will be presented. Finally, we discuss the lessons learned, and outline the need for the future research.

II. BACKGROUND

A. Video storytelling for learning

Instead of passive watching, the creation of video stories by the learners themselves seems to be a more efficient way of using video in learning. Mobile video storytelling is considered to be a new form of user participation and communication [5]. According to [5], "the ability to have constant access through mobile devices allows a new way of doing cinematographic narratives that can enhance the participants' experience in a significant way."

Isomursu et al. [6] summarized four ways that video clips can be used in a design process: the co-authoring of video materials, video as reflective material, the collaborative designing and editing of a video documentary, and collaborative sense-making. These four steps can also be applied to the educational uses of video storytelling.

Digital stories can be fictional or non-fictional. Non-fictional stories may originate from the author's own experience or document a specific event. Video stories can be scripted before shooting, or they can be ad-hoc stories. In many cases, digital video stories require editing or remixing. The life cycle of a web video is typically difficult to define. In many cases it may be impossible to control the video after it has been uploaded to a service. However, some of the recent internet video services support videos that can have a very short life. For example in Snapchat, the author of the video can set a life time of just a few seconds for a video. The video would be viewable only for that period, and afterwards be deleted permanently from the service.

Video stories can be interactive [7] or generated in real-time with scripting [8]. Storytelling platforms can also support automatic story creation [9, 10]. Multisilta and his research group created a mobile social media service for community created videos [9, 11]. MoViE has been used for example at Kasavuori Dream School in Kauniainen, Finland [12] and with university students at Tampere University of Technology, Finland [13].

Digital stories have also been used to preserve, reflect on, and share the life experiences of people who do not have access to personal computers and who are living in rural areas in South Africa [14]. Based on the classification in [6] it can be said that the video in this case is used as reflective material. Digital story creation may also be able to provide a means of exploring self-identity through the sharing and group construction of digital video stories [8].

Mobile video storytelling has also been used in user experience studies [6]. The users were testing a location-based mobile application, but collecting the data by observing users in real life contexts proved to be challenging. The solution was to recruit test persons in pairs, where one used the location application and the other recorded user experience material using their mobile phone camera. According to [6], by using mobile video, researchers received "richer emotional material and more versatile usage situations than with traditional observation methods". In this case the video were used as a way to collaborative design and edit of a video documentary.

The users' video clips were also used in the research interview as a starting point for a deeper discussion of the test situation. In this case, the video clips were used as a tool to document the situation. In addition, some test users not only documented the test situations, but "created, acted out and recorded mini dramas and mini comedies around use situations to make their point clear" [6]. Finally, the video stories were found to be an important tool in design and in communicating about design between stakeholders in the design process.

In designing digital storytelling systems, ethnographic studies have been used to understand the storytelling mechanisms and story structures [7, 14, 15].

B. Global Sharing Pedagogy

Niemi and Multisilta [16, 17, 18] have developed a Global Sharing Pedagogy (GSP) framework for designing and analyzing the learning activities and the learning process involving co-creation of video stories. The GSP is based on socio-cultural theories of learning. In GSP learning is seen as a result of dialogical interactions between people, substances, and artefacts [19, 20, 21, 22]. The primary objective is to strengthen student engagement in learning and mediate them to become active learners and knowledge creators. Engagement is seen as a motivational component that consists of the emotional states of students, such as joy and fun experienced in learning, as well as qualities that are typical in self-regulated learning. It includes commitment to learning tasks and a willingness to make efforts to achieve an objective [23, 24]. The GSP framework has four components, that are are called the mediators of learning: 1) learner-driven knowledge creation and skills development, 2) collaboration, 3) networking, and 4) digital media competencies and literacies. The GSP model has been applied to mobile video storytelling projects described below in Chapter III.

C. MoViE - Mobile Video Experience platform

MoViE (Mobile Video Experience) platform is used to create and share mobile videos. MoVIE enables users to record video clips using their mobile devices (phones, tablets, digital cameras, etc.), upload videos to the MoViE web site, and create video stories using all the clips they and their collaborators have taken [9, 25, 11, 12]. Existing video clips can also be remixed to new video stories. The content of the videos is not limited by the MoViE. Teachers and students can create videos that fit their needs and support learning both in and outside the classroom.

In the classroom, the teacher initiates the video project by providing the guidelines for using MoViE and agreeing the topic of the project with the learners. After that, the learners record short video clips of the topic and upload the clips to MoViE. They can record video clips at school or outside school on their free time. After uploading their video to MoViE, the users can add a description, tags and comments to the video. Next, the learners are asked to watch the videos others have produced and add comments to the videos. MoViE includes a commenting feature where the comments appear as a list after the video. Commenting videos and responding to the comments is an important phase where students give feedback, ask questions and answer questions others have asked. It is also possible to add links to other web pages or to other MoViE videos. Finally, the video clips, comments, and links represent the structure of the knowledge that the learners have collaboratively processed.

III. CASE EXAMPLES

A. Cross-cultural video sharing

In the Boundless Classroom project mobile video storytelling was used for experimenting with cross-cultural video sharing among schools in Finland, Greece and California in 2012-2013. The researchers requited several classes from these countries on voluntary basis. The researchers also facilitated the communication between the participating schools and teachers. They had the freedom to choose whatever topic they wanted for their mobile video storytelling project. In addition, they could do the project either by themselves or in collaboration with another class in another country. The teachers were provided training on using the MoViE platform in their teaching before the classroom projects started.

Students in Finland (n = 192), Greece (n = 111), and California (n = 16) created video stories and shared them with their peers locally and, in some cases, globally with their partner class in another country. The purpose was that each class would have an international partner class with whom they could share their videos and receive comments and feedback from their international peers. However, not all teachers and classes had the resources to

collaborate internationally; since working with videos was a new classroom activity to many teachers, they preferred to collaborate locally. The students who collaborated with a class in another country were excited and motivated to share their video stories with them.

The project took from one to six weeks depending on how it was integrated with other activities in schools. In the beginning of the classroom video projects, the students were brainstorming the topic of their video project and drafted a manuscript for their video. Often they had to seek additional knowledge on their topic from different sources. They recorded small captures on the theme of they story and uploaded them to the MoViE platform. A joint video repository was created for all group members.

Students produced their videos on a variety of themes, in some classes closely related to curriculum, in some classes more freely. The aim was that students would work actively, create knowledge collaboratively, learn to use digital devices and environments as tools for learning, and also become 'networked' while making connections with peers in other countries.

The main results from the Boundless classroom experiment indicate that students can become highly engaged through digital storytelling. The engagement seems to combine both an emotional aspect like fun and a commitment with hard work. During the project the students learned several 21st century skills when producing their own video stories. In addition, group work and co-creation were important for the motivation and enthusiasm. The MoViE platform itself supported both engagement and learning outcomes [16, 17, 18].

B. Video Inquiry Method in STEM

Video Inquiry Project [26] was a joint research project with Stanford University and University of Helsinki in 2013-2014. Learning "how to see" scientific and mathematical aspects of real world phenomena and raise real questions that foster engagement in inquiries is a key education problem for the STEM disciplines (Science, Technology, Engineering and Mathematics). The main research question in the VIP project was: what if learning across formal and informal environments could be bridged and enhanced by learners using mobile smartphones for capturing videos of STEM-rich worldly events and phenomena, raising questions about them that can anchor sense-making inquiries and discussions in classrooms and online forums?

The pilot phase was realized in fall 2013 and spring 2014 both in Finland and in California. In Finland, two 5th grade classes from an urban school and two classes from a rural area school participated to the pilot. In these classes there were around 80 learners. In the urban school learners used iPads that were offered by the school, whereas in the other school learners' own devices like tablets, smartphones, mobile phones, video cameras, or system cameras were used. An ability to shoot videos was the only technical requirement for those devices. In California there were two classes of students, total number of 59 sixth grade students (age 11–12). During the pilot phase students were learning to use the MoViE platform, get used to do video recordings with mobile devices and get familiar with online commenting. The topics of the videos were related to motion, air and water (Finland) and dissolving (California).

The study was based on both design research and intervention research in which the goal is to research how pupils' own mobile videos affect on learning and how they affect on interest/engagement in natural sciences.

The two pilot schools in Finland differed very much from each other. Pupils in the rural area school concentrated better on learning and seemed to be more interested about MoViE and learning itself. Interestingly, also the teachers in these two schools acted in the similar way: the teachers in the rural area school were more interested and involved in the project, whereas in the urban area schools the teachers usually withdrew from the activities during the editing lessons.

In California, both groups of the students were keen to use the tablets. Group A was more technologically intuitive regarding the use of the tablets. They were able to ask many technical questions and understand how tablets can be used in various situations. The students from Group B were intuitive toward the technology at the beginning, but more verbal instruction and explanation were needed in order to conduct the session. Toward the end of the seventh session, however, we found both groups of students were able to film the experiment, save the video, and upload it to the MoViE.

There were some technical problems that may have had an influence on the eagerness of the students to carry out the learning tasks involving video editing. The students both in the urban area school in Finland and in California expressed frustration because of the slowness of MoViE server while uploading and remixing their videos. Other problems included forgetting how to upload in certain situations, the length of the film, the sign-in passwords, and remembering how to search for their own video with the software.

Although the students were able to see the potential of using the videos and tablets as a way to develop their scientific exploration, the technical issues delayed their further engagement with the topic. Especially in California, due to the long uploading time, the students were not able to look at other videos or write comments during the classroom time — the inquiry process on the video was not able to take place. Despite the technical issues during the upload, we found that the students were able to start asking question as they conducted and filmed the experiment.

As a part of the design research, in Finland we also tested different teaching approaches for digital storytelling. Firstly, the task for the students was to remix together videos recorded during the lessons. They were also asked to add some comments to the videos others had uploaded to the service. However, because the students did not seem to progress enough, the researchers and the teachers came up special frame story for supporting the storytelling [26]. The purpose of the frame story was to give students an idea to follow in remixing their video clips. In the next phase at the rural area school the process of storytelling was supported by giving the students

detailed instructions on storyboarding and recording. This resulted in stories that resemble more natural learning process than in the first school. In these video stories learning natural sciences can be seen e.g. in the progress of videos, presenting of them, and also in the comments added to the videos.

IV. CONLUSION

Based on our studies, working with mobile videos both in a classroom and outside the classroom can be seen engaging. The engagement seems to combine both an emotional aspect like fun and a commitment with hard work. In addition, group work, co-creation and the MoViE platform were important factors for motivating students to learn and work with video stories.

The lousy user experience can however significantly lower the engagement. Students are used to very high quality commercial web services, and the same response time and quality is expected from the services the school is providing. Commenting adds an engaging feature to the learning process. It was also possible to add the engagement by creating a framework story to help students to create their videos. Despite the technical issues during the pilot projects, we found that the students were able to start asking question as they conducted and filmed the experiment.

Many videos (the outcomes of the pilot projects) had an important message aiming to influence other viewers' opinions (in other countries) in topics like recycling, water, homelessness, and animal testing. The student's own voice could clearly be seen in the videos. Based on our data, we think that the creation of mobile video stories and sharing support the learning of global awareness and 21st Century Skills, such as problem solving, collaboration, networking, and cultural understanding.

ACKNOWLEDGMENT

The author would like to thank Tekes – the Finnish Funding Agency for Innovation, Academy of Finland, and all the partners in the Finnable 2020 –project and the SAVI Innovations in Education –programme for supporting the research described in this paper. The author would also like to thank the Stanford University H-STAR Institute for an inspiring environment while being there as a Visiting Scholar.

Children's safety on the Internet - development of the school curriculum

Lidija Kralj*
* Osnovna škola Veliki Bukovec, Veliki Bukovec, Croatia
lidija.kralj@skole.hr

Abstract - Generations that are currently receiving their education and those yet to come should get prepared for everyday interaction with information and communication technology. European Parliament and the Council of the European Union included digital competence in key competencies which each person needs to possess in order to adapt to the rapidly changing world. Their definition of digital competence, along with knowledge and skills, include critical attitude toward the responsible use of ICT. At the moment, Croatia does not have a national strategy for the internet safety and not even the minimum of children's knowledge about appropriate and safe use of internet is obligatory in school curriculum.

OŠ Veliki Bukovec together with partners OŠ Popovača, OŠ "Mladost", OŠ "Gripe" and OŠ "Mato Lovrak", is running a 16-month European Union-funded project " Children's safety on the Internet " developing new school curriculum area for children's safety on the Internet for students aged 7 -14, their parents, teachers and local community. Curriculum will consist of pedagogical-didactical model, acceptable use policies, multimedia resources, textbooks and guides. The project aims to improve students' digital competences and encourage children to assume responsibility for their own safety with a focus on empowerment, emphasizing responsible behavior and digital citizenship and to raise student teacher, parents and general public awareness and understanding of issues relating to children's safety online in synergy with the EU policies.

I. INTRODUCTION

Generations that are currently receiving their education and those yet to come should get prepared for everyday interaction with information and communication technology (ICT). This was recognized by the European Parliament and the Council of the European Union [1] which included digital competence in key competencies which each person needs to possess in order to adapt to the rapidly changing world. Their definition of digital competence, along with knowledge and skills, include critical attitude toward the responsible use of ICT.

Currently, students in compulsory schools in Croatia have a chance to obtain ICT related skills and knowledge only if they choose an elective subject - Informatics in grades 5 to 8, or if similar extra-curriculum activity is enabled for grades 1 to 4 [2]. Therefore not even the minimum of children's knowledge about appropriate and safe use of internet is obligatory at the time and none of Croatian schools has developed an acceptable use policy regarding the use of ICT and mobile devices in schools.

Education Sector Development Plan 2005-2010 [3] considers equipping people with the skills to use information and communication technology in everyday life as one of the prerequisites for active involvement in an information-based society. In National Curriculum Framework [4] the use of ICT is transversal theme the aim of which is to develop information literacy skills as part of competences for lifelong learning.

All children should reach minimum standard and gain experience and practices regarding risky and safe use of the Internet and new online technologies. Children should be prepared to use computers and the Internet, get advice appropriate to their age, with emphasis on visibility and public availability of their personal information on the Internet, various nasty, malicious and harmful effects which happen in online communication while encouraging creativity and lifelong learning through the exploration and learning through the Internet.

According to the latest UNICEF's survey in Croatia [5], 85% of children have Internet access at home, their favorite activities on the Internet are seeking entertainment, communication with friends, and use of social networking sites while using the internet for research and learning are less frequent. The same survey showed that 34% of children experienced some form of electronic violence and that usual teachers' reaction when faced with such cases is asking for advice from an expert. Therefore, teachers need further professional development in that area to prevent electronic violence and successfully deal with children's safety on the Internet.

EU Kids Online research "Risks and safety on the internet" encompassing 25 countries in 2011 [6] showed that the average age of first internet use is seven, that 93% of children aged 9 - 16 use internet daily or several times a week and that 55% of them have public profiles with personal information published on social networks. 12% of European children say that they have been bothered or upset by something on the internet. The research findings suggest that digital skills training needs continued emphasis and updating in terms of training, safety features and applications operation to ensure that all children reach a minimum basic standard and to prevent digitally isolated and unskilled children. All policy actors have the responsibility to ensure greater availability of age-

appropriate positive content for children, especially in small language communities such as Croatia.

EU Safer Internet programme recommend using programs that include children, parents and teachers to develop effective models of support for children using the internet for learning and research. Such model of targeted initiatives is especially important for countries in Eastern Europe, where there is a major difference between child and parental knowledge of the capabilities of the Internet.

Those demonstrate the importance of incorporating courses and learning objects about children's safety on the Internet into the school curriculum of compulsory education in Croatia.

II. PROJECT AIMS

Project Children's safety on the Internet is a 16-month European Union-funded project developed by OŠ Veliki Bukovec, together with partners OŠ Popovača, OŠ "Mladost", OŠ "Gripe" and OŠ "Mato Lovrak", Croatia, financed from grant scheme Further development and implementation of the Croatian Qualifications Framework (Europeaid/131254/ M/ACT/HR). The project is taking place in Croatia from 19th August 2013 till 19th December 2014. Project associates include Education and Teacher training agency (Agencija za odgoj i obrazovanje), Croatian academic and Research net (Hrvatska akademska i istraživačka mreža CARNet), Croatian personal data protection agency (Agencija za zaštitu osobnih podataka), Association "Partners in learning (udruga "Suradnici u učenju"), municipality of Veliki Bukovec (Općina Veliki Bukovec), municipality of Mali Bukovec (Općina Mali Bukovec), Brodsko-posavska county, City and Univesity library Osijek, City of Nova Gradiška and Tourism office Nova Gradiška.

The project has been designed after consultations with the Education and Teacher Training Agency, public institution responsible for teachers' training, CARNet and the NGO Suradnici u učenju as Safer Internet Committee for Croatia. Partner schools get support from their Counties who consider this project to be a great potential for county development. All consulted organizations highly recommend this project and will be involved in project realization and dissemination.

The project objectives are:

- to develop, according to principles of the Croatian Qualifications Framework (CROQF), learning outcome-based school curriculum area for children's safety on the Internet which will enable holistic approach involving students, parents and teachers on the same goal;
- to develop and implement appropriate pedagogical and didactical model for student centered learning which will make the most of teachers' potentials and new technology strength;
- to improve primary school teachers' educational skills and expertise so they could apply the new methodologies for student centered learning and principles of CROQF in their work;
- to improve students' digital competences and encourage children to assume responsibility for their own safety as much as possible with focus on empowerment, emphasizing responsible behavior and digital citizenship;
- to raise students, teachers, parents and general public awareness and understanding of issues relating to the children's safety online in synergy with the EU policies.

Project facilitates cooperation and experience exchange as well as sharing best practice between Croatian and EU schools on issues relating to children's safety online and thus ensure European added value.

Furthermore, project promotes gender equality and equal opportunities through carefully chosen characters and their roles in all forms of learning materials. Digital materials have options for modification for use by disabled people. Project also gives equal opportunities to all students to reach standard learning outcomes in area of safe, legal and ethical behavior on the Internet and to prevent digitally isolated and unskilled children.

III. PROJECT ACTIVITIES

The project is going to last for 16 months with activities organized in four phases during which the school capacity for implementation of student centered learning will be improved and modernized.

First 6 months were the Research phase - pedagogical team of teachers individually and during 2 study visits (Belgium and United Kingdom) explored the existing school curriculum and examples of good practice in the area of online child safety in EU. First study visit was Insafe and European Schoolnet, which works in the area of Internet safety and has continuous experience in professional development for teachers. Second study visit was to the United Kingdom, to schools which have perennial experience in development of school curriculum and implementation of topics about e-safety in teaching ICT and other subjects and acceptable use policies implemented.

The pedagogical team was trained in 2 workshops (Plitvička jezera and Đurđevac) related to e-safety, EU policies and strategies, curriculum development, determining learning outcomes and learner-centered educational methods and then prepared a report and planned strategies for curriculum development.

Next 6 months is the Development phase - all teachers are trained in 5 workshops where colleagues who have attended study visits and workshops will share their experience and knowledge (cascade training). Pedagogical team will work on development and publishing of school curriculum area (compound of 4 courses & sets of materials for students, teachers and parents) for children's safety on the Internet with specified learning outcomes according to the principles of CROQ. During this phase all partner schools are equipped with mobile learning environment with modern tablets, interactive board and wireless access to internet.

Two months of Testing and improvement phase follows - developed school curriculum area will be tested, evaluated and improved according to students, parents and teachers feedbacks. Research regarding students digital competences and parental knowledge of the capabilities of the Internet will be carried out as part of the pilot project. New versions of curriculum and learning object will be published and made freely available.

Last 2 months will be the Dissemination phase - devoted entirely to dissemination of project results, reporting and evaluation. Final conference and exhibition of students' works resulting from the pilot project will be held.

IV. CURRICULUM

School curriculum will consist of four courses addressing one of four age groups in primary schools (students aged 7-8, 9-10, 11-12 and 13-14). That level of curriculum structure is chosen to enable the creation of age appropriate contents and methods in balance with available resources for this project.

One set of teaching/learning materials would include textbooks for students, multimedia resources, teachers' guides and guides for parents. Learning objects within teaching/learning materials will be created in form of text, hypertext, pictures, animated stories, videos, audios, computer games, social games, coloring pages, photos, interactive quizzes, learning quests. Colorful characters have been created and will be used in all learning resources so curriculum will have unique and recognizable multimedia representations. Special attention will be paid to the flexibility of learning objects so students with disabilities can use them more easily. Every course will be described in terms of learning outcomes, as well as knowledge, skills and competences. That description will include theoretical knowledge, practical and technical skills and social competences needed for responsible, safe and appropriate use of the Internet. Evaluation methods, associating self-assessment, feedback mechanisms and procedures for improvement will be planned in each course. Acceptable Use Policy for ICT in schools will be created.

School curriculum area for children's safety on the Internet is vertically adjusted in five units: information, communication, content creation, safety and problem solving as recommended in EU Framework for Developing and Understanding Digital Competence in Europe [7]. Some of the topics covered in curriculum are; personal data protection, e-mail phishing and scams, netiquette, online communication and collaboration, risks on social networks, responsible use of mobile devices, sharing and authoring rights, identity theft, digital footprints, e-portfolios and online presence, evaluation of information on the Internet, how to protect computer and family, prevention of cyberbullying.

School curriculum would be tested and evaluated by two sides - schools which take part in project and external advisors. To be sure that school curriculum area is well planned and all resources well created, pilot testing will be performed with 220 students and 220 parents - 2 classes from each participating schools.

After feedback and recommendations, school curriculum would be adjusted and prepared for publication and further implementation

V. IMPACT

The proposed action is directly targeting the following target groups: teachers, students and parents.

Teachers in Croatian primary schools have the basic level of ICT competencies but usually poor knowledge about capabilities of the Internet, possible risks, safety measures and prevention of electronic violence. They have only general information about CROQF, learning outcomes and student-oriented approaches. During the project 15 teachers attended 2 study visits, 25 teachers participated in 2 five-day workshops, and 218 teachers (all teachers and principals from partner schools) will be trained in the area of e-safety. The project will be disseminated among approximately 2500 teachers participating in 50 County Teacher Councils in different subjects in 5 counties where partner schools are situated.

Today, students grow up surrounded by a variety of digital and electronic devices and online tools. They often misuse those devices and embrace potentially risky behavior on the Internet. Students need guidance in how to behave in a safe, legal and ethical way and protect themselves on the Internet. 220 students aged 7-14 will be involved in a pilot project of implementation of developed school curriculum area. During the pilot testing participating students will create at least one practical work in which they present the knowledge they have gained, and give advice to peers about responsible, appropriate and safe use of Internet. Students' works will be showcased on the project web and at the final conference as an exhibition of works resulting from the implementation of new curriculum. Approximately 2700 students will be involved in awareness raising campaign and school curriculum implementation during this and next school year.

Parents often have poor knowledge about opportunities and risks related to the use of the Internet and children usually know more than parents. Therefore parents' awareness about the internet safety issues have to be raised and they need to be educated in order to support their children. 220 parents of the students involved in the pilot project will also take part in the project and give feedback. Approximately 2700 parents will be reached after the project results are implemented in all classes of the partner schools.

Local community and general public will be positively influenced through raising awareness about internet safety. To accompany school curriculum and establish stronger connection between educational institutions and local community, awareness raising campaign was created. Awareness raising campaign includes workshops, exhibitions, lectures, interactive round tables, articles, radio and TV shows targeting on local, regional and national level. Project publicity and dissemination

activities will be synchronized with that campaign so every event will serve both causes - raising awareness and project dissemination.

VI. CONCLUSION

At the moment, Croatia does not have a national strategy towards the internet safety so our project could be used as a reference or case study for future prevention programme or national strategy and all project results may easily be available for future use on the national level.

School curriculum with four courses and all associated teaching/learning materials will be published in digital form online and made freely available on project web page **petzanet.HR** for all interested schools.

The long-term project objective is to reach every single primary school in Croatia through different national seminars and online publication. Awareness raising campaign will set model to help other schools in establishing connection between school and local community on common goal of protecting children on the Internet.

Abstract - This paper gives theoretical insight into importance of introducing customer relationship management (CRM) into libraries. CRM is defined as system or software for storage or analysis of data, but also as strategy oriented to customer and change of organizational culture. One of reasons for CRM implementation is that companies sometimes more care for their products and services than for customers. E-CRM can help libraries to sophisticate their e-services which is an imperative for libraries as leading educational institutions. Namely, libraries have mission to gather, process, store and make access to information and that's why they must make their e-services better to attract new users and to keep existing users. Working hypothesis in this paper is that level of readiness of Croatian academic libraries for e-CRM is low. According to research results this hypothesis is confirmed, namely discrepancy between possibilities and needs for introducing e-CRM into academic libraries is rather high.

I. INTRODUCTION

Libraries in 21. century are characterized by constant changes due to development of information and communication technology. Expanding libraries' e - services and their sophistication becomes an imperative in libraries and a way how libraries can stay leading educational institutions. The concept of customer relationship management (CRM) is exactly that business system or tool which can help libraries to keep existing users and attract new users.

CRM system is very important option in libraries. Namely, libraries as educational institutions have mission to gather, process, store and make access to information and that's why they must make their services better and attract new customers as well as keep existing users. CRM implementation can contribute to development of better libraries' e-services according to many studies as for example is research conducted in academic library in Taiwan [10]. Namely, the main advantage of CRM implementation in libraries can be seen in their efficiency [6].

Customer relationship management (CRM) is business strategy which includes selection and customer relationship management with a goal to optimize their long term loyalty. The term CRM is used from early 60-ies. Namely, the acronym CRM was defined as customer relationship management but also customer relationship marketing [3]. Theodore Levitt, an expert in marketing, stated that the main goal in business is to recruit and keep the customer. He interceded for fact that companies should see the whole business process which consists of discovering, creating, challenging and fulfilling customer needs. In addition to that, recent marketing studies have shown that CRM software implementation would be increased for 700% from that time [4]. CRM can be observed as continuation of so called precise marketing which implies art of merging product or service with customer's need to provide safe sale. CRM also implies use of contact centers for cohesive and unique view of customer but also driver of investments in data warehouse systems. CRM is defined as technology, system or software package for storage of data or analysis of data, but also as strategy oriented to customer and change of organizational culture [1]. One of reasons for this kind of strategy is that companies sometimes more care for their products and services than for customers. It should be accentuated that CRM has its roots in relationship marketing which goal was to conquer new customers. Namely, it differs from today's marketing which tends to keep existing customers [5]. The birth of CRM was strongly influenced by high concurrence among companies in all fields. That's why CRM motto could be "know your customer and you will know what he/she buys" [9].

CRM systems are extremely growing field of investments into IT solutions. CRM systems differ in a function which system covers and which solution would choose a particular company depends upon its needs and business strategy. The fact is that implementation of typical CRM lasts minimally two years and that in 60 - 70% cases completes with failure [9]. The main reason for CRM system failure lies in a fact that companies' top management don't understand the meaning of CRM. Lots of researches shown that a lot of people think that CRM software manages customer relationships instead that it is an instrument which helps in customer relationship management [9]. Namely, whole CRM solution consists of three parts: analytical, collaborative and operative. Operative and analytical parts are fundamental elements of system. Operative system is in charge for everyday communication with customers and analytical system, the brain of whole CRM system, is in charge for analysis of data gathered from operative part and for generating strategies and adequate decisions based on results of analysis. On the contrary, collaborative system is based on external organization namely customer sees that system in communication with company. Collaborative

system encompasses all CRM functions that provide interactions with customers, partners and suppliers. In this way operative data are generated and these data are the base for analytical part of CRM which gathers, stores, processes, extracts, interprets and informs about customers. That's why analytical part can be seen as business intelligence of CRM system unlike operative part which gives options for data exchange and integration with information systems [9]. CRM implementation is a very demanding process. An imperative for successful CRM implementation lies in clear communication between CRM strategy at all organizational levels and employers involvement into its implementation. Some problems which occur before CRM implementation are: identification of customers' needs, understanding customers, giving feedback etc. [8]. CRM system does not provide quick success, namely long period of time is necessary for CRM implementation and to make customer happy which is a safe way for keeping customer's loyalty.

For the purpose of conducting content analysis of Croatian academic libraries' web sites in regards to exploring needs and possibilities for introducing e-CRM the working hypothesis is stated. Namely, working hypothesis in this paper is that level of readiness of Croatian academic libraries for e-CRM implementation is low.

II. METHOD

For the purpose of conducting research in this paper scientific method of content analysis was selected. Content analysis is flexible research method and it can be qualitative or quantitative but also within it can be used combination of these two methods. Namely, in this paper was used quantitative content analysis of text within Croatian academic libraries' web sites according the list in appendix.

Content analysis is research method which objectively and systematically describes written, verbal or visual communication [2]. Krippendorff describes content analysis as research method for derivation of repeatable and valid conclusions from text within its context [7]. Content analysis helps to determine presence of certain words, phrases or concepts within text or collections of texts. Texts can be from books, speeches, interviews, essays, historical documents, scientific articles, pictures, web pages etc.

Content analysis can be implemented to any written or other form of human communication and that's why in recent decade it is often used in marketing, cultural studies, journalism, sociology, politics, phycology, cognitive science, economy, information sciences etc.

III. INTERPRETATION OF RESULTS

Croatian academic libraries' web sites according to the list in appendix were analysed in purpose to explore needs and possibilities for introducing e-CRM. E-options considered as preconditions for introducing e-CRM into academic libraries were grouped into following eight categories obtained by the method of content analysis: (1) communication with users, (2) design of user-friendly system, (3) information about library and public relationships, (4) affective engineering, (5) promoting content of library, (6) expanding and enhancing e-services, (7) superior service quality and (8) contacts with potential future users.

A. Communication with users

Fig. 1 shows that majority of libraries have e-mail (73) and newsletters (50) but only few of them have surveys options (8) and webinars (5).

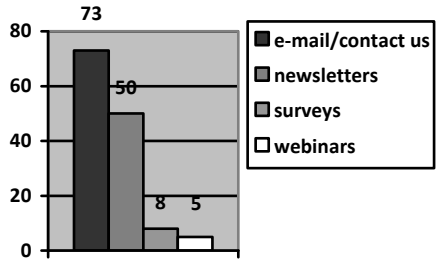

Fig. 1. Communication with users

B. Design of user-friendly system

The majority of libraries (50) have drop-down menus as part of design of user-friendly interface and almost half of libraries take care about presenting legal matters on their web sites (34) as it is shown at Fig. 2. Instructions for use of web site (9) and site map (13) are rare options. Only four libraries have an option FAQ (frequently asked questions).

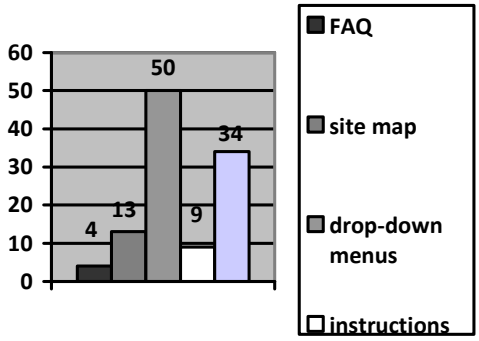

Fig. 2. Design of user-friendly system

C. Information about library and public relationships

Almost all libraries' web sites consist of information about library (65), library location (60), history of library (55) and annual reports give 21 libraries shown on Fig. 3.

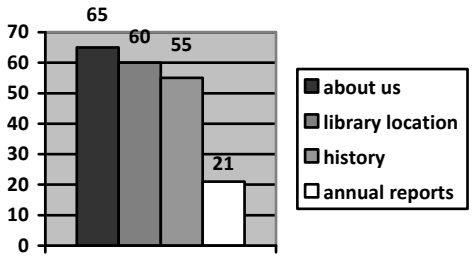

Fig. 3. Information about library and public relationships

D. Affective engineering

In regards to libraries' affective engineering, Fig. 4 shows that 46 libraries offer useful textual materials and materials for download (20). Charitable activities (6) and ideas for products' use (3) like for example *Bookcrossing* are very rare.

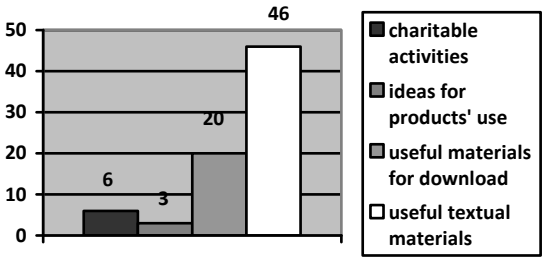

Fig. 4. Affective engineering

E. Promoting content of library

Fig. 5 shows that 64 libraries promote their content through catalogs and 26 libraries points out prices of their services.

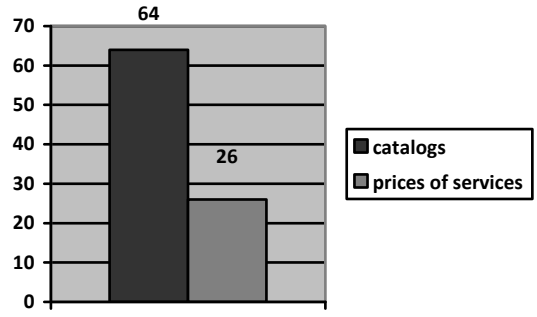

Fig. 5. Promoting content of library

F. Expanding and enhancing e-services

Fig. 6 shows some of ways through which libraries try to expand and enhance their e-services like for example 63 libraries offer educational material dealing different databases, online dictionaries etc. Great number of libraries offer information about e-services (45), innovative and exclusive e-services (30), users' forum (25) and few of them e-entertainment (8).

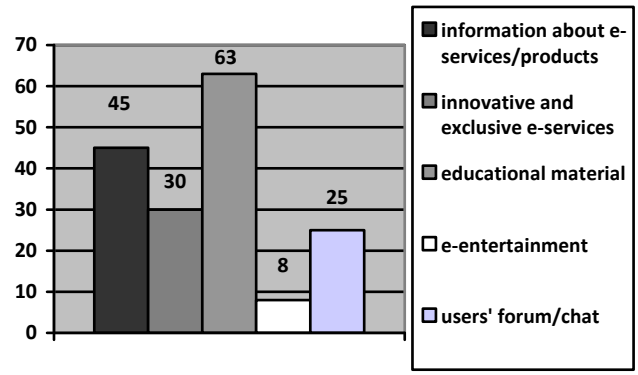

Fig. 6. Expanding and enhancing e-services

G. Superior service quality

Very small number of libraries have attractive visual design of users' interface (19), remind users about new content/services (18), seek for feedback (13) and conduct e-surveys about users' satisfaction (3) which is shown on Fig. 7.

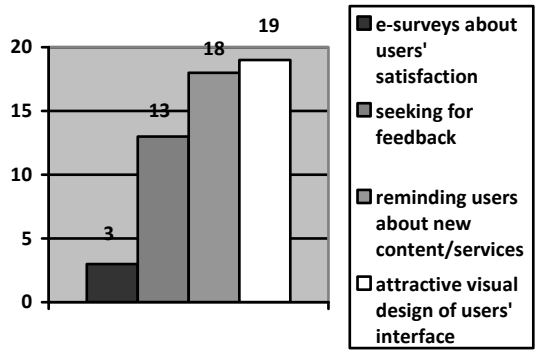

Fig. 7. Superior service quality

H. Contacts with potential future users

Fig. 8 shows that only 10 libraries try to contact with potential future users through noncommercial e-content or access to users outside the traditional library. Five libraries try to recruit users with new needs.

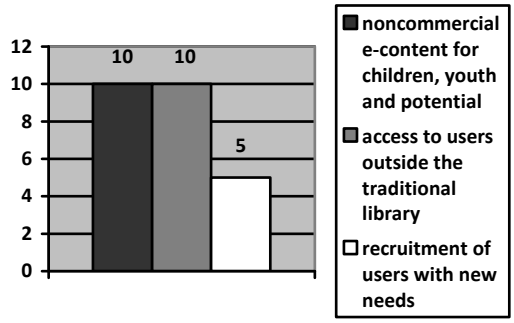

Fig. 8. Contacts with potential future users

IV. CONCLUSION

CRM is defined as system or software for storage or analysis of data, but also as strategy oriented to customer and change of organizational culture. One of reasons for CRM implementation is that companies sometimes more care for their products and services than for customers. E-CRM can help libraries to sophisticate their e-services which is an imperative for libraries as leading educational institutions. Namely, libraries have mission to gather, process, store and make access to information and that's why they must make their e-services better to attract new users and to keep existing users. Working hypothesis in this paper was that level of readiness of Croatian academic libraries for e-CRM is low.

Croatian academic libraries' web sites according to the list in appendix were analyzed in purpose to explore needs and possibilities for introducing e-CRM. E-options considered as preconditions for introducing e-CRM into academic libraries were grouped into following eight categories obtained by the method of content analysis: (1) communication with users, (2) design of user-friendly system, (3) information about library and public relationships, (4) affective engineering, (5) promoting content of library, (6) expanding and enhancing e-services, (7) superior service quality and (8) contacts with potential future users.

According to research results the hypothesis is confirmed, namely discrepancy between possibilities and needs for introducing e-CRM into academic libraries is rather high.

Virtual Machines in Education

Vladimir Mateljan, Vedran Juričić, Marko Moguljak
Faculty of humanities and social sciences, Zagreb, Croatia
Department of information and communication sciences
vladimir.mateljan@gmail.com, vedran.juricic@gmail.com, marko.moguljak@gmail.com

Virtualization finds wide application in information and communication technology. Some of these applications can be used in education, to simplify the administration and teaching performance while saving money. In the last few years, computer technology has progressed sufficiently thus facilitate the development of virtual machines that provide a completely new method of using computers and their resources.

The virtual machine is a software implementation of a machine that executes programs like a physical machine. There are several types of virtualization, span from partial to complete, and most of them could find a useful application in education. Setting up test environments, virtualization of classroom for a particular course, remote connection, and use of existing computer without any hardware upgrades, faster backup, and easier maintenance are some of the benefits of implementing virtual machines in education.

I. INTRODUCTION

Information and communication technologies have significantly changed and improved business practices, thus created a process in which companies stimulate the further development of these technologies. Among these trends virtualization finds wide application, and the requirements of information technology and the market situation are creating the tendency for further development.

II. VIRTUALIZATION

Although the concept of virtualization is relatively new, scientists have used virtual machines for decades on mainframe computers. Only in the last few years computer technology has advanced enough for virtualization to have wider application. Some of these applications could be useful in education, to simplify administration and teaching performance while saving money.

The term "virtualization" traces its roots to 1960's mainframes, during which it was a method of logically dividing the mainframe's resources for different applications. The usual goal of virtualization is to centralize administrative tasks while improving scalability and overall hardware-resource utilization.

A. Virtual computer

A virtual computer is a logical representation of a computer in software. By decoupling the physical hardware from the operating system, virtualization provides more operational flexibility and increases the utilization rate of the underlying physical hardware. ("Wikipedia, 2014)

Although virtualization is implemented primarily in software, many modern microprocessors now include hardware features explicitly designed to improve the efficiency of the virtualization process. In a traditional physical computer, one instance of the operating system supports one or more application programs. In a virtualization environment, a single physical computer runs software that abstracts the physical computer's resources so that they may be shared between multiple "virtual computers." Each virtual computer may be running a different operating system from all of the other virtual machines on the physical machine. A crash or other program error on any of the virtual machines leaves all of the other virtual machines unaffected. (IBM Corporation, 2007)

III. VIRTUALIZATION IN EDUCATION

Virtualization technology comes in several different varieties. It represents an abstraction from physical resources. All uses of virtualization are based on this concept. There are three major types of virtualization; server virtualization, desktop (client) virtualization and storage virtualization. All three major types can be useful in education by improving operational efficiency while reducing hardware and space requirements, energy consumption, and maintenance. It can also provide a layer of security because the virtualization applications run independently of each other so that a problem with one server can be confined to that server, and will not spread to others.

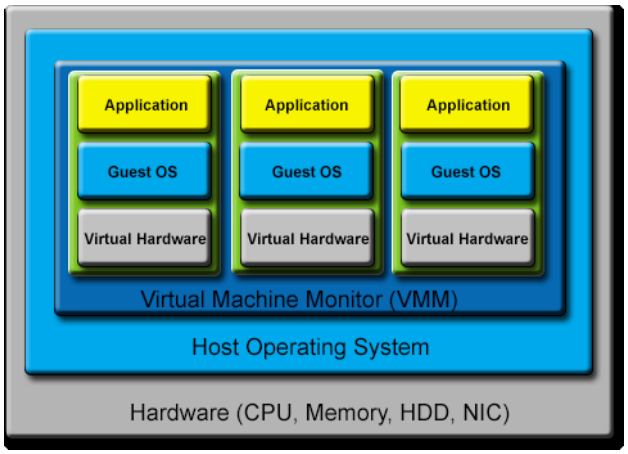

Figure 1. Virtual Computer diagram
Source: National instruments "Virtualization Technology Under the Hood", 2009,

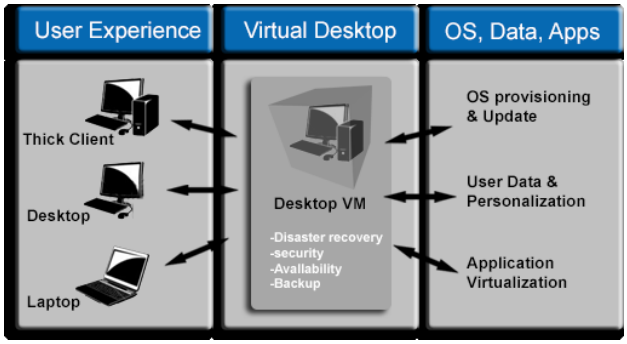

Figure 2. Desktop Virtualization
Source: Larry Dignan, "VMware: Desktop virtualization tipping point in 2011?" 2010.

A. *Desktop virtualization*

Desktop virtualization is the concept of separating the logical desktop from the physical machine. This type of virtualization moves the operating system and the applications it supports from the student desktop to a virtual computer running in a server. Each user can customize the desktop environment depending on the extent permitted by school policies.

This approach provides great advantage over working on a single assigned PC. When the student moves to a different location, such as from the classroom to a lab or library, the student's entire workspace appears on whichever workstation or device the student is currently using. If workstation hardware fails, the student's entire workspace is instantly available on any other workstation on the network. Software licenses for applications the student uses may be available for use by other students when the student's virtual desktop is not actually in use.

B. *Server virtualization*

Server virtualization lets one server do the job of multiple servers by sharing the resources of a single server across multiple environments. Each server typically serves one function (i.e., mail server, file server, Internet server, etc.), with each server using only a fraction of its true processing power, server virtualization breaks through the "one application, one server" barrier and facilitates the consolidation of numerous servers into one physical server. This equates to less physical servers required, and 70 to 80 percent or higher utilization of existing hardware as opposed to the previous 10 to 15 percent. (Bill Johonnesson, 2010,)

If the resource requirements of one of the server-based products running in a virtual server grows, because of increased usage for example, moving that virtual server to a different physical server with more available resources is as simple as copying a file. This ease of replication of virtual servers also means that it's simple to maintain snapshots of virtual servers as file back-ups and quickly restore complex systems to operation in the event of physical server hardware failures. This increased resilience results in more efficient use of existing physical server resources, lower operating costs, reduced power consumption and greater overall reliability. (IBM Corporation, 2007)

C. *Storage virtualization*

Storage virtualization technology separates virtual storage partitions from physical storage devices (storage devices that hold, spin, read and write magnetic or optical disks such as CD, DVD, or even a hard disk drive, etc.).

The virtualization software presents users with a logical storage area for storing their data, and itself handles the process of mapping it to the actual physical location. Virtualizing storage gives administrators greater control over storage resources and allocation of storage space for applications and users that need it most. Data migration is also made easier through storage virtualization. Data can be moved to another storage device without disrupting computer operations. It's also easier to expand storage space when the physical location is full.

IV. THE BENEFITS OF VIRTUALIZATION FOR *EDUCATION*

A. *Hardware life span savings*

Most student workstation computers are acquired over an extended period. Most schools are faced with the dilemma of whether to spend scarce technology budget money to expand the number of student workstations toward one per student or to replace the oldest machines with newer models that will better support current operating systems and desktop applications. Desktop virtualization provides a way to increase the useful life of existing older PCs while at the same time reducing the cost-per-seat of new student workstations. This is done by running virtual desktop software on older PCs and purchasing less expensive thin client workstations rather than full desktop computers to add additional workstation seats to the school. Even older PCs that cannot run current versions of new operating systems and resource demanding desktop applications can do so when used as thin clients running virtualized desktop software. There are no specific minimum requirements, the PC only needs

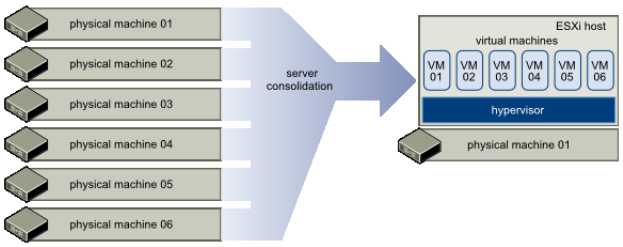

Figure 3. Virtual Server
Source: WMware, "Aspects of Virtualization" 2014.

to be able to run the application for virtual desktop software, which access the resources on the host computer. Working performance depends on many different factors, most important are the number of client computers, server's hardware resources, network bandwidth, type of virtualization, and virtualization software. (IBM Corporation, 2007)

B. *Hardware efficiency*

Any virtual machine can be run on any server in the data center because the virtualization layer abstracts the resources of the underlying computer and presents them in a standardized way to the virtual machine's operating system and applications. Older, smaller servers will support fewer virtual machines than newer, larger servers. However, the management interfaces to all of the virtual machines will be uniform and will result in lower administration costs.

Virtualization provides a way to deliver a uniform student experience for desktop workstations regardless of PC age. A lab equipped with PCs with different processors and memory will provide a uniform student user experience because the virtualized desktop environment exists on the network servers rather than individual PCs. The students' personalized workspaces will follow them from classroom to lab to library, and, where connectivity is available, the workspaces will even follow students home. (IBM Corporation, 2007)

C. *Remote connectivity*

As connected devices are becoming more ubiquitous, schools will be faced with the problem of supporting not only their devices, but also a growing range of devices owned by students. More and more students now own personal network capable devices. Some, such as cell phones, smart phones, tablets, laptops, etc. students already bring to school. Others, such as game consoles and personal computers, could be used to extend the school day by providing access to curriculum content from home. Virtualization technologies provide a way to abstract the workspace environment in such a way as to be able to present educationally valid content on a broad range of devices (IBM Corporation, 2007)

The additional network security provided by virtualization makes it possible for school networks to allow connection of student-owned devices to the school network without compromising the security, which is essential to maintain the reliability of the network. With client virtualization, it is no longer a problem that all of the devices on the network are not similar. It is possible to deliver curriculum content to students regardless of where they are or what sort of device they are using.

D. *Licencing utilization*

With virtual desktop workstations, purchase of software licenses is needed only for the peak instantaneous usage of any given product. Because licensed software runs in virtual PC clients on the server rather than on individual machines, it's easier to control. Limiting usage of a particular program to the number of licenses on hand becomes a manageable task. Just as virtual servers maximize utilization of physical server resources, virtual PC clients maximize utilization of software licenses. (IBM Corporation, 2007)

E. *Security improvement*

In a virtual desktop environment, software, data and most of the hardware elements that comprise the desktop workstation are in the data center and not on the desktop. This makes virtual PC clients inherently more secure since all of the data resides on servers in a secure data center rather than spread over desktops throughout the school. The inherent security provided by virtualizing client machines lets you open the network to outside connections without compromising security. (IBM Corporation, 2007)

Allowing students to connect from home has a beneficial effect on student performance, the network security issues and lack of standardized equipment in homes has made this difficult until now. Client virtualization addresses both issues. Students connecting to virtual PC clients on the school server can use a broad range of workstation devices ranging from game consoles to the family PC. The school network is protected because the virtual client connection interface is inherently secure

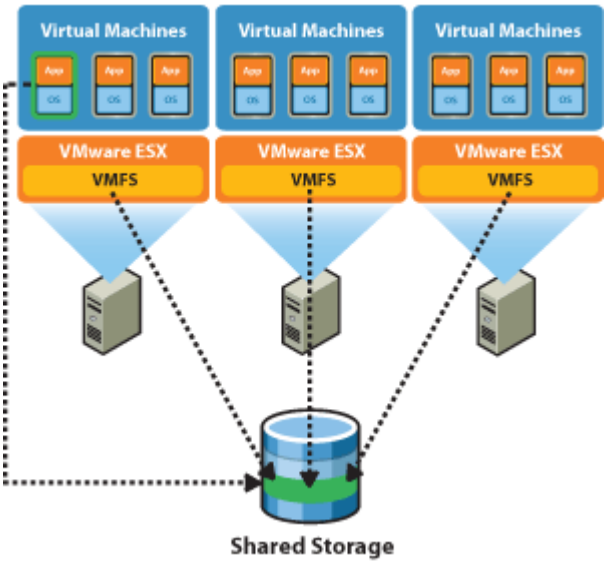

Figure 4. Storage Virtualization, VMFS_diagram
source: Eric Horschman, Virtual Reality, 2008.

and protects the school network from malicious content on the students' physical devices. (IBM Corporation, 2007)

F. *Easy lab enviorment settup*

Labs are set up to provide environments where the students can learn and solve problems. Entire rooms are often allocated for this purpose and contain different software and hardware as well as a number of machines. These labs are usually difficult to manage successfully. The different courses and the number of machines they might need lead to conflicting requirements. Shortages of available space and finances are a concern and limits the number of students in a lab and the amount of available equipment. Virtual lab can solve most of this problems and improve user experience. A significant savings can be realized when the whole virtual lab runs on a single machine. This machine can stand in the college's server room and won't take up much space. There is no need for student access to the main server in order to recover from problems. The use possibilities of the virtual laboratory are practically unlimited; it can be a base for any studies, course or training program. It is assumed that projects of the laboratory are fully multimedial. The participants of this laboratory can e.g. investigate training experiments from the definite field of material engineering, ask questions, pass tests, make contact with lecturers and the different users of the laboratory, and participate in development of its design and content. (IBM Corporation, 2007)

V. VIRTUAL MACHINES IN DIFFERENT ENVIORMENT

Most of the educational institutions in Croatia use Windows operating system as a main platform for classes. Although windows has wide support for applications, it is not always the best solution, and another operating system is required to perform tasks.

Virtualization offers a way of dealing with that problem in a simple manner, by installing a virtual machine software that contains operating system different from the one on a physical computer. There are many virtual machine software to choose from, and it depends on a computer hardware and installed software how well

Figure 5. Configuration

it works. To test virtual machines in different environments, a research needs to be done.

A. *The research*

Virtual machine used in research is VirtualBox, chosen because it is free, and is most frequently used among freeware. Operating systems used are; Windows7 ultimate and Linux mint 15. On a personal computer (see configuration reference figure 5.) are installed Windows7, and VirtualBox with Linux mint 15, which are given 1024MB RAM and 25GB of hard disk space. Benchmark tool used for testing is Geekbench 3, which measures integer performance, floating point performance and memory performance The process is repeated three more times in all other combinations of Windows and Linux as host OS and virtual machines, with same parameters. Results are then compared and ranked.

B. *VirtualBox*

Oracle VM VirtualBox is a virtualization software package for x86 and AMD64/Intel64-based computers from Oracle Corporation as part of its family of virtualization products. It was created by innotek GmbH, purchased in 2008 by Sun Microsystems, and now developed by Oracle. It is installed on an existing host operating system as an application; this host application allows additional guest operating systems, each known as a Guest OS, to be loaded and run, each with its own virtual environment.

C. *Geekbench 3*

Geekbench 3 is a cross platform benchmark tool. Scores are calibrated using a Mac mini (Mid 2011) with an Intel Core i5-2520M @ 2.50 GHz processor as a baseline with a score of 2,500 points. Higher scores are better, with double the score indicating double the performance. Geekbench 3 uses a number of different tests, or workloads, to measure performance. The workloads are divided into four different sections:" (Primate Labs, 2013,)

- "Integer performance: Integer workloads measure the integer instruction performance of your computer by performing processor-intensive tasks that make heavy use of integer instructions. All software makes heavy use of integer instructions, meaning a high integer scores indicates good overall performance." (Primate Labs, 2013)

- "Floating point performance: Floating point workloads measure floating point performance by performing a variety of processor-intensive tasks that make heavy use of floating-point operations. While almost all software makes use of floating point instructions, floating point performance is

TABLE I. TEST SCORES

OVERALL INTEGER PERFORMANCE				
	OS: Windows VM: Linux	OS: Linux VM: Linux	OS: Windows VM: Windows	OS: Linux VM: Linux
Single-core	1306	1099	1167	1099
Multi-core	1294	1106	1154	1106
OVERALL FLOATING POINT PERFORMANCE				
	OS: Windows VM: Linux	OS: Linux VM: Linux	OS: Windows VM: Windows	OS: Linux VM: Linux
Single-core	1237	1221	1154	1221
Multi-core	1231	1229	1161	1229
OVERALL MEMORY PERFORMANCE				
	OS: Windows VM: Linux	OS: Linux VM: Linux	OS: Windows VM: Windows	OS: Linux VM: Linux
Single-core	619	733	572	733
Multi-core	258	724	99	724

- especially important in video games, digital content creation, and high-performance computing applications." (Primate Labs, 2013)

- "Memory performance: Memory workloads measure memory bandwidth. Geekbench 3 uses tests based on the STREAM benchmarks developed by John D. McCalpin. Software working with large amounts of data (e.g., digital content creation) relies on good memory bandwidth performance to keep the processor busy." (Primate Labs, 2013)

D. *Results*

Tests has shown that there is a difference in performance in every combination of host OS and virtual OS. As shown in overall score (see Figure 6.) even single-core and multi-core scores differs in a single test. From a user experience these differences are negligible and virtual machine can work properly in any given combination. This is simple and free solution that offers many possibilities, and it is educator's choice of which of the operating system will be used for their class.

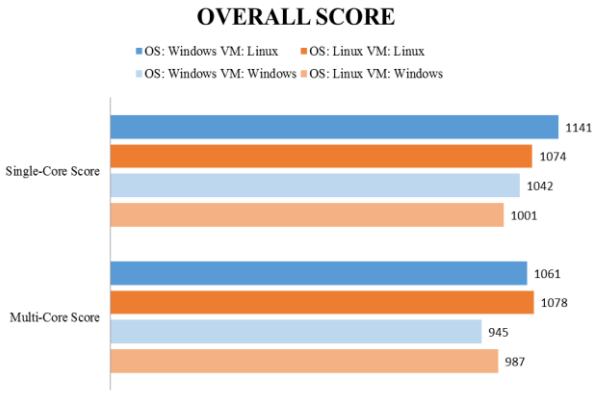

Figure 6. Overall Score

VI. SUMMARY

Virtualization is a powerful technology trend that is happening now. The trend is already underway and the outlook is that it will grow very rapidly. Educators should examine the opportunity very closely and see when and how they can start taking advantage of this capability. Virtualization provides better experience for students and teachers at lower cost and with greater security and reliability.

Abstract - One of the key issues in the current information society is the easy and open availability of required resources. The concept of "openness" covers several resource categories, such as data, software sources, services, innovation and education. Open Data is seen as a promising source of new business. The concept of open innovation is based on the idea of distributing "useless" innovations for beneficial use in a new context. The role of open education has grown quickly at different education levels – especially university level. Open social networks are important platforms both for information distribution and as a source of information. There is a bidirectional influence between the availability of open resources and applications based on them: On the one hand, new applications create trends that demand open availability of resources, while on the other hand, the availability of resources creates opportunities for new applications. From the technology perspective, important change factors include mobility, big data technologies, digitalization, and context recognition. At the beginning of our paper we build a "big picture" of the important phenomena in the modern information society; open resources are seen in the role of enabler. National (Finland) and regional (AVARAS Project) initiatives are used to concretize the overall discussion.

.

I. INTRODUCTION

A. Towards an open information society

The importance of information as a factor of The importance of information as a factor of production has grown and information itself has a high commercial value. The Internet transfers enormous amounts of data in a reasonably open format. The skills for acquiring, marshalling and analyzing raw data to build utilizable knowledge and its visualization has a rapidly increasing value. Traditionally, these skills are used inside closed organizations like companies. *Business intelligence (BI*) is a technology that transforms raw data into knowledge to help decision makers in business management. BI software tools are able to handle large amounts of data, in most cases produced by the information systems of the company. However, nowadays *external data sources* are becoming more and more important sources of raw data – either combined with the company's internal data or also as such. The Internet makes enormous amounts of data sources available to all Internet users. Simultaneously it provides the means for *tracking users' Internet activities*; elements of which are scattered in an unmanaged way in several repositories. The term *Big Data* is connected to processing very large (usually public) data sets. The goal is – as in BI – to collect, organize, structure and publish individual data chunks in a form applicable for the users. The technologies used both by BI and Big Data tools apply a wide variety of Knowledge Engineering (KE) technologies. One important new source of data for analysis is Open Data; it is worth differentiating this term from *openly available data*. *Open data* refers to the idea that certain data should be freely available for use and re-use [1]. In general discussion, data sources are most often connected to the data produced, collected or paid for by public bodies. Examples of such data sources are geographical information (map data), statistics and weather data. However, an increasing amount of data is produced by autonomous sources (machines), like CCTV cameras, real time sensors, microphones, RFI readers, and information sensing mobile devices. Openly available data has a wider scope – it covers all data that can be accessed without meaningful restrictions, e.g. Facebook stream, public web pages, Twitter tweets, RSS feeds.

B. ICT Based Incremental and Radical Changes, New Paradigms and Phenomena

There are accelerating changes in current (modern) societies. In innovation theory, the changes are classified into four categories: incremental innovations, radical innovations, changes in technological systems, and changes in techno-economic paradigms [2]. This approach is applied in Figure 1 to classify some current phenomena.

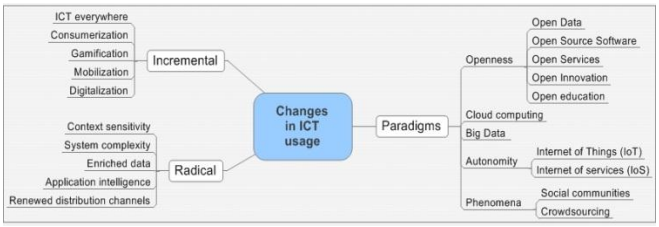

Figure 1. Changes in ICT usage Openness in figure above

Although the topic of this paper is focused on the role of open data – or openness at a general level – we wish to start by building a big picture of the detectable information technology phenomena having openness – especially open data as a driving force. We are trying to clarify the importance of the changes by using the categorization derived from innovation theory. *Incremental changes* appear continuously in existing products and services (continuing the existing trend). *Radical changes* appear when new research findings are applied in products to transfer their properties or

performance to a new step or cycle (movement to a new trend). *Changes in technological systems* are caused by combinations of several incremental and radical innovations in societal and organizational systems. *Changes in paradigms* are revolutionary and lead to pervasive effects throughout the target system under discussion (in our case the information society). The classification is used (in Fig. 1) in a quite broad way, which provides a means for criticism. Our aim is, however, to point out the importance of some existing phenomena and dependencies between them. The detailed aspects included in Figure 1 are discussed in Sections 2 and 3 of this paper.

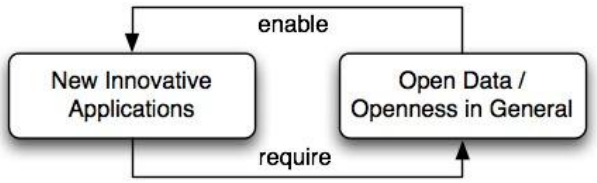

Figure 2. Bidirectional dependency between Openness and Innovative Applications

There is a bidirectional influence between the "paradigms" in the role of "enablers" on the right side of the figure and the phenomena on the left side in the role of incremental and radical changes (Figure 2): On the one hand, the changes recognized create demand for information resources, and on the other hand the availability of these resources creates a platform for new kinds of applications and use of information (Figure 2).

C. Structure of the paper

The aim of this paper is to point out the importance of open access to resources – especially to open data – as one of the driving forces of the current society and changes in it; the manifestations of changes are new services and applications and improvements in them. Sections 2 and 3 of this paper discuss the topics introduced in Fig. 1 more extensively. The aim is to introduce the key concepts related to openness and their role as an enabler of currently recognizable phenomena. Section 4 returns to the role of Open and Openly available Data as a key resource of improved and innovative products / services. It includes a general analysis and reports some experiences of Open Data in Finland. Section 5 covers a short introduction to the role of Open Data in education as one of its important and fast growing application areas. Section 6 introduces our regional Open Data project AVARAS (AVoimista tietovARAnnoista liiketoimintaa Satakuntaan –New Business for the Region of Satakunta From Open Data) by introducing its goals set and some preliminary results. Section 7 concludes the paper.

II. PARADIGMS AS ENABLERS

There is a common trend towards *cloud*-based service structures that provide a wide variety of scalable computing resources through the Internet [3;4]. For the software business, cloud architecture provides a standardized platform for application development and distribution. From the user point of view, cloud-based software solutions (SaaS – Software as a Service) provide easy location and device independent access to applications – data and services – in a symmetrical (device and platform independent) way.

The ability to apply openly available data resources is based on two factors: the ability to find the applicable resources (data mining) and the technology to apply intelligent data handling methods [5] *Big data* (discussed above) technologies are under active development; new algorithms and tools are being developed to provide data with high relevance in fulfilling the goals of the data mining requests [6]. The components of data mining technologies cover e.g. access technologies, methods used to understand the meaning of data items, methods for combining different data items to create understanding (knowledge), and technologies to publish and visualize the findings. In their study of the "Digital Universe," IDC [7] reported fast growth in Big Data: the amount of data applicable for open analytics is expected to grow from 130 EB (ExaBytes = 10^{18} Bytes) in 2005 to 40,000 EB in 2020. According to the report, the utilization level of available data is reasonably low: in 2013 only 0.5% of data was utilized in analysis, whereas 25% would be utilizable (33% in 2020). Additionally, the proportion of data that requires protection (because of privacy issues) is growing faster than the digital universe (from 30% to 45% of all data in ten years); only half of the data that needs protection is protected. Security and privacy are important issues when processing open data[8].

The source of data is also changing dramatically in the period covered by the report's analysis: 11% of data in 2005 was produced by *autonomous devices*; in 2020 this percentage is expected to grow to the level of 20%. Consequently, Big Data technologies have the opportunity to combine data from traditional data sources into real time data produced by cameras, sensors and other technical devices connected to the Internet. The term *Internet of Things (IoT)* refers to a collaborative structure in which the Internet or an Internet-like structure provides a platform for these connections. In addition to the source of data, IoT provides a means for the collaborative work of separate devices. In the service context, the term *Internet of Services (IoS)* is used to describe the service activity based on collaborating independent services. In connection with IoT, data technologies are used to find and analyze "sensor" type data that is combined with data from other open sources in an intelligent way.

At the human level, there is a great deal of evidence of the importance and power of collaborating individuals as members of social networks – *social communities*. Facebook provides a social networking platform for 1.4 billion users, Twitter for 646 million and LinkedIn for 261 million users [9; 10; 11]. These are only examples of the best-known collaboration platforms, which also have different usage profiles. LinkedIn has become an important source of data in recruiting, and Facebook and Twitter in experience-sharing and social communication. Simultaneously, the *data streams* of all these networks are important sources of data mined by big data technologies (social analytics) for commercial and profiling purposes. Active social network members are easy targets for social gesture building – the value of a network user is the value of its social gesture. The traffic is monitored by the service providers (like Facebook) for "quality

improvement purposes"; the reality is more or less related to the improvement of their business. In addition, this kind of open Internet traffic is also vulnerable to social analytics made by other parties in an uncontrolled way.

A special form of social networking is *crowdsourcing*, in which tasks are distributed to an undefined public group of people (crowd) for execution. There are different variations of the basic idea, e.g. *crowdfunding*, collective creativity, cloud labor, collective knowledge, community building, and open innovation [12]. There are several examples of successful crowdsourcing services: Duolingo (http://www.duolingo.com/) is a foreign language learning portal that is simultaneously used for crowd translations of texts as a commercial service; Kickstarter (http://www.kickstarter.com/) is a portal for the crowdfunding of innovations, which is aimed at providing a platform for startups to find funding for their product development.

Common to all of the above-mentioned "paradigms" is *openness* – openly available (data) resources provide a means for their successful implementation. *Open source software* combines in a way both the ideas of crowd labor and open innovation (software development in collaboration with loosely connected teams) and free (taking into account the licensing rules) exploitation of the final product without license fees. *Open Innovation* refers to the idea that the (internal) innovations (of organizations) are provided for open use, as well as existing (external) innovations being utilized beneficially. The idea is opposite to the tight licensing policy and careful protection of Intellectual Property Rights (IPR).

Open Education implements the idea of the open innovation principle in education. *Massive Open Online Courses (MOOC)* are provided to gain access to educational courses. *Open services* refer to service interfaces that provide a means for collaborative service implementation.

Open Data is freely available for everyone to use and republish without restrictions from copyright, patents, or other control mechanisms. The "Open Data" movement originates in the USA, but also the European Union (2003; Amendment 2013) was active as early as 2003 by creating a directive that encourages member countries to open public data sources for free business use; several member countries have passed laws or regulations to follow this recommendation.

III. FROM PARADIGMS TO CHANGES

As discussed above, the open availability of data and the ability to use the data in a beneficial way is one of the key factors of success in the utilization of Information and Communication Technology (ICT). ICT is more or less invisibly embedded in daily activities, processes, and products (*ICT everywhere*). Its utilization is bidirectional: on the one hand, it is used as an interface to services and, on the other hand, it is an important source of information.

Mobilization (the growing importance of mobile devices) provides a means for time and location independent service usage in a symmetrical way (the same service for different platforms and devices, scalable according to the network quality and type of user interface). The functionality (a wide variety of inbuilt sensors) of mobile devices provides a means for a growing amount of versatile data to be used by applications based on data transferred in a network. Mobile devices also have a richer context than workstations connected to a fixed network. In addition to the mobile terminal role, these devices also have the role of *information provider*. Their capability to collect user and usage dependent information is high. As a network connected device, a mobile terminal also has the capability to combine this information with other (openly available) information in the network as well as to send it to application developers (for analysis purposes) and interested external sources (e.g. intelligence agencies). The location and usage profile as well as the mobile terminal content are of high value, especially when connected to other user profile information (e.g. in a Facebook profile, Twitter profile, e-shopping profile).

Digitalization refers to the automatization of applications, digital marketing, and e-commerce – in general to technologies that are based on the handling of digital content. It is worth noting that even in situations where the original content is analog (like a video camera stream), in many cases it is transferred into and handled in digital format. An interesting application of digitalization is the virtual currency Bitcoin (https://bitcoin.org/en/) initiated in 2008 by Satoshi Nakamoto (a pseudonym). It uses peer-to-peer technology with no central authorities. It manages transactions and the issuing of Bitcoins is carried out collectively by the network. Bitcoin is also an example of an open-source product; its design is public, nobody owns or controls it. At the moment (February 2014) the amount of Bitcoin currency is 12 million and the p2p protocol allows its growth up to the level of 21 million (which will be reached in the next few years). Its current exchange rate is 1 Bitcoin to 700 EUR; the lowest rate has been 35 and this virtual currency suffers from fast changes.

Context sensitivity – the ability of an application to adapt to the context of its usage – enables the enrichment of applications. Although in connection with mobile terminals the term "context sensitivity" is most often seen as a synonym for the term "location sensitivity", the new applications are able to handle versatile context data in an organized way. *Lifeline* provides a *time* dimension for versatile context data items covering information items about *location*, *user* (e.g. health data, movement), *physical situation* (temperature, air pressure), *social environment*, *user preferences*, *presence and status*, etc. taking into account the capabilities built in to the device used. Context sensitivity is also the main source for growing *application intelligence* – the application's ability to create better quality knowledge based on complex handling and combining of data resources.

Adding "intelligence" to the data itself - *Enriched data* - provides new opportunities to use the same data for different purposes and to support more intelligent use of the data. In practice it is a question of combining different data formats in one visible / manageable data item. Examples of enriched data are embedded www-links in images, (reading the image automatically directs the device to the web page having the embedded address), QR codes directing the reader to the real information

connected to the code, embedded meta information in images, and applications used to extend the original information (e.g. taking a photo of an advertisement in a newspaper opens information related to it in a browser (see e.g. http://shortcut.karkimedia.fi).

The terms consumerization and gamification describe the characteristics of modern applications from several points of view. *Consumerization* is the product and service designs approach, in which the individual consumer (user value) is the primary driver. Such phenomena like the growing importance of social networks in marketing (you have to go where the consumers are) and BYOD (Bring Your Own Device) are typical manifestations of this, as well as the transfer of application development from experts to enthusiasts (crowd; a large share of mobile applications are developed by "non-professionals"). The users are also used to buying applications from platform providers' software online stores instead of special software shops or companies, at reasonably low prices. This *overhaul/restructuring of distribution channels* and the growing importance of cloud-based applications is changing the ICT business dramatically. *Gamification* describes users' expectations of usability; the same user experience and attractive look-and-feel that is available in games software is expected from serious applications. Consumerization and gamification can also be interpreted as an *attitude*: users tend to use ICT as a consumer product instead of a special product – as a part of everyday life, without any threats.

System complexity growth is actually a paraxial concept. Modern applications are designed for use in reasonably low performance devices (like mobile phones and tablets), but in a symmetrical way also in more powerful equipment. This application scalability can be implemented by distributing some part of the processing needed in (more) powerful (cloud) servers. As a consequence, complex monolithic systems are being replaced with less complex collaborating components. From the software development point of view, the complexity of a single component has decreased, but collaboration has increased the complexity of interfacing solutions. In general, we can also see that to an increasing extent applications are no longer stand-alone but a part of a complex environment. Barry Boehm [15] has described this using the term "*complex system of systems*" indicating that the current information systems are collaborating, independent systems.

IV. OPEN DATA

A. Sources of Open and Openly Available Data

Sections 2 and 3 painted the big picture related to the role of openly available data covering different points of view. This "big picture" covers both *Open Data* in its traditional meaning and *Openly Available Data*. The latter covers such data sources that are connected to a public network and (due to a lack of or insufficient security) provide a means for monitoring its content. The latter sources have a growing value in Big Data analytics. These include data sources opened purposely for public use (like the road cameras of some weather stations) but also such sources that are available but without the data owners' permission (like data collected by mobile phones, social network discussion streams, e-shopping data, private communication, etc.). Somewhere between these two types is open www-data, which is easy to use for data mining and analytics using text and image analysis. The rest of this paper concentrates on open data in line with the definition of the European Union [1;13; 14; 16]: "Open data refers to the idea that certain data should be freely available for use and re-use."

Open data is seen as a meaningful source of new business, especially for small and medium-sized companies; the importance of public sector information - government data - is considered important. Examples are geographical information (maps), statistics, weather data, data from publicly funded research projects, and digitized books. The Commission lists the following reasons to open governmental data[1]:

- Public data has significant potential for re-use in new products and services. Overall economic gains from opening up this resource could amount to € 40 billion a year in the EU direct business volume (and € 140 billion indirect).
- Addressing societal challenges – having more data openly available will help us discover new and innovative solutions;
- Achieving efficiency gains through sharing data inside and between public administrations;
- Fostering participation of citizens in political and social life and increasing transparency of government.

The Gartner group has positioned Open Data on the Emerging Technologies Hype Slope [17] in the category of potential breakthrough in 2-5 years, locating it in the curve position of the "Trough of Disillusionment" – passing through the Valley of Death!

It is worth noting that, in addition to governmental data, several private bodies (e.g. companies, private individuals, and private associations) and non-governmental public bodies (like cities, regional administration, publicly owned companies) have valuable information that would be beneficial for open use. Examples include applications using bus timetables, flight radar, city maps, and measurements from public sensors.

B. Challenges related to open data

In spite of the positive expected future of open data, there are several related challenges:

- problems in the capability of users and application developers to recognize the opportunities related to open data;
- unfamiliar business idea – how to use data to create new business;
- lack of technical readiness to use data sources because of complex data format or interfaces;

- inability to find suitable data sources for application purposes;
- insufficient availability of regional data sources for developing applications for local services;
- unclear licensing: in spite of openness there are rules limiting the rights of usage (as in open source software);
- legal issues – rules and limitations to republish data that is available in public sources (e.g. web pages) are unclear when processing open data [18] or when securely accessing it [19];
- technical limitations related to data publishing platforms;
- guarantee of maintenance and updatedness of data is missing;
- variation in data quality and reliability, etc.

In this paper we have no opportunity to handle these topics in detail; therefore we will satisfy ourselves with giving a short list of the challenges and reference to our future work on the AVARAS project introduced in Section 6 of this paper.

C. Open Data in Finland

At national level, Open Data has been noticed in several countries – we use Finland as our example. The Finnish government has followed the EU directives and regulated laws that demand that governmental data be opened for public use. In spite of having a positive attitude on the topic itself earlier, the real activities took place in the 2010s. Here are some important milestones worth recognizing:

- The first steps in the area of open data were taken by the National Land Survey of Finland in 2012 (geographical and map data) and the Finnish Meteorological Institute in 2013 (weather data); at the same time, Statistics Finland opened its statistical data.
- The report of the Ministry of Employment and Economy (TEM) [20] "Analysis of success paths for the future" reports the ability to apply information technology and information resources as one of the future success factors; in the Finnish economy this means the transfer from successful ICT producer role to the role of innovative adapter of data resources as a source of new business.
- At the same time, and based on the above-mentioned report, the Government of Finland published an "Open Data Programme" (http://www.vm.fi/vm/fi/05_hankkeet/02381_avoin_tieto/index.jsp) for the period 2013-2015; this program includes a list of operative actions to promote and coordinate open data related activities.

The Government Internet service portal *Suomi.fi* includes a special section dedicated to Open Data sources (http://www.suomi.fi/suomifi/tyohuone/yhteiset_palvelut/avoin_data/).

Some regions were faster than the government. Helsinki (the capital of Finland) started its project *Helsinki Region Infoshare* (http://www.hri.fi/fi/hri-projekti/) as early as 2010, and after the project the local open data portal has been developed and maintained as a normal part of the operative activities of the organizations involved. The *Tampere region* (http://www.hermia.fi/opendatatre/) was one of the pioneers in opening regional data sources for free use. Our project AVARAS ("Open Satakunta") also belongs to the group of pioneers with the goal of supporting application developers to find and apply open data sources in their business, encouraging developers to develop regional services in the form of open data based applications, and encouraging data owners to open their data sources for open access. One of the manifestations of open data related activities is the annual "Open Data Contest" Apps4Finland (http://www.apps4finland.fi/) that has been organized at national level annually since 2010. There is also a regional contest in the Pirkanmaa - Tampere region (http://apps4pirkanmaa.fi/). The contests provide a nice overview of the application base and also the types of data sources used in the applications. An analysis is discussed in Section 6 of this paper.

V. OPEN EDUCATION

Openly available education in the form of MOOCs is a fast growing opportunity to organize educational activities at different levels. At the moment this is seen as opportunity with big potential, but also drawbacks. In most cases it is a question of the availability of single courses for wide distribution and their official acceptance as a part of the curriculum; there are also cases where a full university degree is built on MOOCs as a "low-budget" alternative to more expensive traditional implementations of the curriculum. The popularity of MOOCs is explained by easy availability and in most cases also free access to lectures by the "world's leading specialists" available everywhere on the Internet. However, the motivation to participate in courses varies: sometimes it relates to the need to pass the course as part of the curriculum, sometimes it is at the level of general interest only. There are no reliable statistics available of the participants' behavioral patterns, but there are some case studies that report very low percentages of students passing the final examinations compared to the number of registrations, which is in the hundreds of thousands.

The most commonly known and globally used MOOC platforms are Coursera, Udacity, EdX, NovoEd and Khan Academy; in addition there are national level MOOC platforms, like that of the University of Helsinki (http://mooc.cs.helsinki.fi/). *Coursera* (https://www.coursera.org/) has its roots in Stanford University. It is a for-profit educational technology company, currently having 2.7 million users and partnership with 62 universities. Its offering covers courses in physics, engineering, humanities, medicine, biology, social sciences, mathematics, business, computer science, and other areas. Like Coursera, Udacity (https://www.udacity.com/) is also a for-profit educational organization having its roots in the free computer science classes offered in 2011 through Stanford University. Udacity has 25 (as of 30 September 2013) active Stanford University courses (source:

http://en.wikipedia.org/wiki/Udacity). EdX (EdX https://www.edx.org/) was founded by the Massachusetts Institute of Technology and Harvard University in May 2012. Its purpose was to provide university-level courses in several disciplines for worldwide distribution at no charge. It also conducts research in the area of learning. EdX has nearly 1.6 million users (http://en.wikipedia.org/wiki/EdX). Khan Academy (https://www.khanacademy.org/) is a non-profit educational website created in 2006 by educator Salman Khan, who has close connections to MIT and Harvard Business School. Its mission is to provide 'a free world-class education for anyone anywhere' for free, forever. Khan Academy provides thousands of educational resources, including a personalized learning dashboard, over 100,000 exercise problems, and over 4000 micro lectures via video tutorials stored on YouTube. The scope of study topics covers mathematics, history, healthcare, medicine, finance, physics, general chemistry, biology, astronomy, economics, cosmology, organic chemistry, American civics, art history, macroeconomics, microeconomics, and computer science. (http://en.wikipedia.org/wiki/Khan_Academy). NovoEd (https://novoed.com/) is another Stanford university spin-off in MOOC supply. There are also two recently new efforts in the area of open MOOC platforms: Stanford University has developed OpenEdX (http://code.edx.org/) and Google mooc.org (http://mooc.org/) as a OSS solution for establishing own MOOC platform.

MOOC based education provides the opportunity to reorganize (part of) education at all levels. The traditional approach in the form of distance learning has already been accepted as a part of the education system; videoconferencing, video recordings of lectures, and self-study based network courses have been widely adopted by educational institutes. What is new in MOOC? Maybe nothing other than wide geographical coverage and a platform that supports network based learning and an idea of a new type of learning. For partner organizations, MOOCs provide an alternative to self-organized courses. Instead of lecturing on the same topic that is available as a MOOC, the user institutes would use the same resources in student support activities at individual or small group level. This topic has been discussed in more detail by Henno et al. in their conference papers [21; 22].

Open Data – in general - also provides opportunities for use as a study material for teaching, studying and research work. The added value compared to the raw data available in www-pages is the opportunity to handle it in analysis, to combine and compare several sources of data and to illustrate the results of analysis.

VI. Regional Initiative to Reveal the Opportunities of Open Data

In autumn 2013, the Pori Department of Tampere University of Technology initiated a regional project to reveal the opportunities offered by open data. The one-and-a-half-year project is conducted in co-operation with the City of Pori and eight SME-sized software development companies from the Satakunta region in western Finland. The role of the partners is to direct and give guidance to project activities forming the interest group of the project. The acronym of the initiative, AVARAS, comes from its Finnish name "Avoimista tietoVARAnnoista liiketoimintaa Satakuntaan" which is "New Business for the Region of Satakunta from Open Data" in English. The project is funded by the European Union Regional Fund (ERDF), as part of the Satakunta Regional Centre for Economic Development, Traffic and Environment funding program.

The overall goal of the AVARAS project is to provide software companies with information on how to apply open data sources in their businesses. The project is expected to answer the following three questions: 1) what kind of business opportunities do open data offer? 2) What sort of open data sources exist? 3) How can open data be utilized technically? The questions were the basis for the three main work packages of the project: WP1 Open Data in Business, WP2 Meta-portal and Reviews, and WP3 Applications and Technologies. An additional target of the project is to encourage the public organizations of the region to open their data sources for open public use.

The first work package of the project (WP1) is composed of questionnaire studies, public seminars, and workshops with the interest group. It also includes tasks clarifying open data in context and the phenomenon of openness in general. This paper is one of the outcomes of the tasks. The first questionnaire-based study targeted the business and public sector in Satakunta. 166 respondents received the web-based survey, the results of which are being analyzed. The aim is to find out how well the basics of open data are known, and how its opportunities in business are seen. At first glance, it seems that awareness of the topics is not very high among the respondents.

The second work package (WP2) is intended to discover relevant sources of open data, resulting in an open data portal (www.tut.fi/avaras), which is called a meta-portal, because, instead of listing individual open data sources, the aim is to offer links to such portals. Thus, the outcome of the work package is for the most part a portal of open data portals. The portal is used also to deliver all the results of the project.

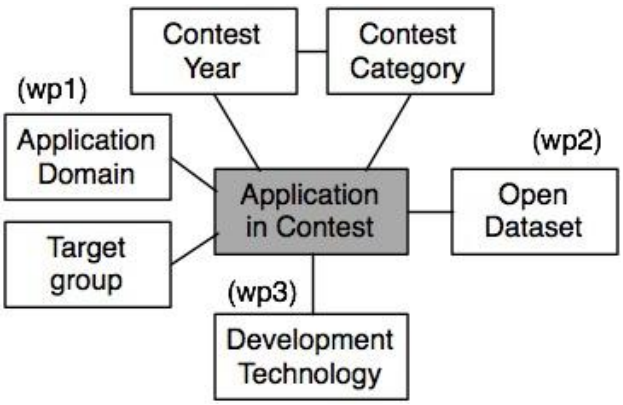

Figure 3. The dimensions to be used in the analysis and synthesis of applications, and their connections to the work packets of the project

The third work package (WP3) a) builds pilot applications using open data and b) examines existing software. During the development of the pilots, the technologies and tools needed in application development

are evaluated. The pilot applications will be openly available via the portal for public use. Their purpose is especially to bring out interfacing technologies and interface specifications for re-use in new applications. One of the pilots is discussed in [23]. The input of task group (b) is applications which have participated in the open data contests in Finland. There are nearly 400 contest applications from the period 2010-2013 to examine. The result of the study will also contribute to the other two work packages. The analysis and synthesis will be done from several dimensions as depicted in Fig 3. In addition to *development technologies*, there are dimensions for *application domains*, *target groups* (WP1), and *open datasets* (WP2).

In addition to the three initial work packages, two further topics for review have come to the fore during the project: a) Opportunities for companies to employ open education offered by several universities in the form of Massive Open Online Courses (MOOC), and b) NoSQL databases as a means to deliver open data. From the point of view of data models, there are several approaches for NoSQL solutions, such as key value, document, columnar, and graph. This sort of data models seems to be more flexible and straightforward to use than traditional relations. Commonly, the systems also offer e.g. ready-made REST interfaces and inherent replication. The steering committee of the project has just confirmed the inclusion of these topics in the work packages.

VII. CONLUSION

The paper discusses topics related to Open and Openly available Data at a general level. The approach is based on the hypothesis that open resources (data) are enablers for new innovative applications and new innovative applications create a demand for the availability of new resources. We have analyzed some visible phenomena in the modern information society; some of these are seen to have an "incremental" character and some to have more importance in the role of radical changes. Availability and opening of resources for public use is seen as a new paradigm in ICT; it provides new opportunities that will cause remarkable changes. In addition to the opportunities, there are also threats which are discussed briefly in the paper. Open Education – the fast growing availability of MOOCs is an opportunity to change education, or it can also be seen as a threat to the current state. Our case report (related to one European country) lists activities that have manifested the beneficial use of Open Data as a consequence of the European Union Directive to encourage its member countries to open the data resources owned by governmental organizations for free business use by application developers. On this continuum, a regional initiative (AVARAS) is introduced. The project is still in its "embryonic" phase and the results of the studies related to it are not available yet. The aim is to continue this introductory paper with more detailed reports of our project results at a later date.

ACKNOWLEDGMENT

The AVARAS project is funded by the European Union Regional Fund (ERDF), as part of the Satakunta Regional Centre for Economic Development, Traffic and Environment funding program.

Abstract – Need for Higher Education is growing rapidly - by 2020 two thirds of all jobs will require postsecondary education [1]. The current higher education system cannot satisfy this need in many fields, e.g. Gartner predicts, that already in 2015 only a third of jobs for big data analysts can be filled [2].

The rapid development of Information and Communication Technology (ITC, IT) has changed many aspects of teaching and learning. Educational materials are moving into cloud(s) and degrees are given on-line ('Master's Degree Online Directory' lists over 90,000 programs [3]), old-fashioned Colleges and Universities with large campus, staff and high costs are getting more and more competition from numerous educational entrepreneurs, who start massive open online courses (MOOC) with millions of users/students from all around the world; they establish new on-line universities where costs of obtaining a degree are marginal compared to 'brick-and-mortal' universities and which are open to nearly everyone independent of user geographical location. Until now MOOC have not yet proved their value - less than 4% of enrollees complete the courses [4] and they do not receive (yet) university diploma. But the World most prestigious technical university, MIT, has already set up a certification system - students who can master the subjects taught in MOOC receive an official certificate of completion [5]. Although these certificates will not carry the weight of a traditional MIT diploma (they will be issued by started by MIT online learning initiative called MITx), but the word 'MIT' alone carries a weight.

When speaking about possibilities of IT in education most speakers/writers are excitedly discussing technology - servers, communication lines, bandwidth, security (preferably all in thick cloud of technical jargon). Nearly nobody presents practical experience, suggestions and/or theories about how to teach with this new technology in order best to utilize its possibilities. The 'education in the cloud' mainly consists of video clips trying to repeat the classroom experience: recorded before the old-fashioned blackboard (only nowadays it is white), where professor is presenting the same lecture what he presented in lecture hall, only now lectures are cut into 5-10 min video clips - the 'mobile approach'. Is this why the old lecture halls are still needed?

Rapidly increasing costs of University Education, increasing competition of educational entrepreneurs and constant increase of population of working students have made clear, that both sides of University education - teaching/learning and accrediting, giving diplomas need changes. University Education should more take into account students informal and non-formal learning, their participation in professional work - both in organization of study and in certification.

In the following are considered several aspects of current situation, presented practices which authors use when teaching IT students and examined possible changes in universities teaching and certification methods.

I. INTRODUCTION

Advancements in technology are constantly reshaping our teaching/learning/training practices.

In last 10..15 years, the biggest influence for educational practice have had computers and Internet Technologies (IT) and their role is increasing, especially for delivering training. The impact of IT to education was characterized in developed countries already in 15 years from now as the 'e-Learning Revolution' [6],[7]. Currently the E-learning revolution has started or is starting even in rural Africa [8], while developed countries have already embraced the M-learning revolution [9], our classrooms have become cloudy [10], [11] and some are moving classrooms into boxes ('the classroom in a box') [12], [13].

Technology and buzz-words around it have changed rapidly. But disparity between what goes into higher education and what many get out of it are not always encouraging.

Greek writer Aristophanes complained already more than 2,000 years ago in his comedy 'The Clouds' [14], that universities ('Thinkeries with quacks') left students heavily indebted and without practical skills. Clouds, the 'patron goddesses of thinkers and other layabouts' arrives in the comedy singing majestically and promising with teachings from professor 'Inferior Argument' earthly 'summum bonum' and a life of ease and pleasure, typical of men who know how to talk their way out of trouble.

Headings indicate, that little has changed during the last 2000 years, except that youth less and less believes that professors can lead them to life of ease and pleasure : "*Student Loan Problems: One Third Of Millennials Regret Going To College*" [15], "*Graduate data reveal England's lost and indebted generation* " [16], "*Today's College Graduates: In Debt and Unable to Find a Job*" [17].

The forerunner of the computer revolution in education has been USA - very innovative country, the very birthplace of computers, PC, the iPad and also initiator of application of computers in education

[18],[19]. Creativity and innovation have always been in USA highly valued [20]. But recent research indicates, that creativity of American children is on decline [21].

Has something gone wrong with rapid advance from learning to e-leaning to m-learning to c-learning (c- cloud, [22]) to ... - and if, then what ?

II. LEARNING

Education is the most complex area of production. Schools take in young human beings and try to develop their minds - create an 'added value' - and charge either society or directly the customer, student. But at the same time those minds, their ways of life are also rapidly changing and these changes happen quicker than changes in big systems - in universities, in the whole European Higher Education Area [23].

Learning occurs constantly, “from cradle to grave”. In 1996 the Organization for Economic Co-operation and Development (OECD) member states agreed to develop lifelong learning strategy, which includes formal, non-formal and informal learning [24], [25].

The formal learning is highly structured and implemented by specialized organizations - schools. Formal learning is intentional, schools and learners have explicit objectives covering knowledge, skills and competences, what learner should get.

Informal learning is learning from life experience - language acquisition, accepting cultural norms and social behavior. This is happening all the time, everywhere and is not intentional nor organized.

With development of society everything becomes more organized, thus also learning which happens not in schools tends to be organized. An example are Massive Open On-Line Courses (MOOC), which are rapidly gaining popularity, e.g. the Khan Academy [26] provides every month online lessons for more than 10 million visitors from about 200 countries. Organized 'outside school' learning is by OECD terminology non-formal learning. This kind of learning is very accessible - lessons/videos can be followed even on iPhone, iPad or Android phones [27]. While the first MOOC (Udacity, Codeacademy, Khan Academy) were focused on math, computer programming and computer science, currently MOOC are providing very broad selection of courses and new providers appear constantly. Even the World Economic Forum (WEF) announced at its last meeting about launch of its Forum Academy, where the huge network of industry leaders and opinion-makers of WEF will make their expertise and visions available to the global audience [28].

All these 'educational entrepreneurs' are directly moving into universities playground - several already provide accreditations. Currently they are mostly just for participation. But this is comparable with universities - participating, 'seat time' is in universities also often considered as something that gives students 'deeper understanding' (whatever this is), thus as a base for passing a course, although a correct mark were "Great Listener - constantly gave a nod of assent!")

Many university apparatchik's are doing everything in their power to make sure that universities continue to function the way they have. The notable difference is steady increase in the number of universities non-teaching staff, e.g. in the flagship Stanford University, USA - 3-5% every year [29]) - the first 'Thinkerie with quacks', Socrates, managed to shepherd his disciples to 'earthly summum bonum' alone.

And the academic staff should produce more and more 'bubbls' ('bubblications' - many are very soft inside).

Universities consider the formal learning as the only 'real' learning and want to continue in traditions of the Bologna university dating back to 1088. But students learn more and more in spheres of non-formal, informal learning, acquire skills and appreciation in many (professional) social networks. Universities should find a way to consider all these tendencies.

III. STUDENTS

Today's students are different from what they were five years ago and in the next year they will be even more different. Young people accept changes, especially new technology, much easier than their peers in universities. Today's students are multitasking and collaborative; they're constantly connected and use multiple devices for being connected. They're highly visual and experiential; they're action- and just-in-time-oriented.

They value highly their time, since most of them work, often full-time.

Students are worldwide increasingly participating in work life, e.g. the U.S. Census report indicated that 71 percent of college undergraduates and 82 percent of graduate students were working in 2011 [30]. In Estonia and in Finland, more than two-thirds of students are employed. The official statistics possibly do not indicate the real percentage, since e.g. for an IT student it is very easy to work (e.g. create www-sites) from home or even from computer class at university and not to indicate (for taxation) all sources of income. When the first author asked students in Feb 2014 his group (83 IT specialty first -year students) in the opening lecture, all students indicated, that they work. Even the academic time-tables have been already for several years adjusted for working students - some weekdays are free, but on some days lectures/exercises end at 21.00

Research results indicate, that working does not reduce academic achievements [31],[32], even contrary, working students are more organized, value their time and manage to achieve good results in their studies. This clearly shows in their behavior in lectures and exercises - they never just sit there, they are very active and want to get maximum what teacher can provide. Besides Facebook and Google+ accounts they have accounts in LinkedIn, StackOverflow, Quora, Scribd and in many other professional, topic-oriented social networks.

If they want to solve a problem, learn something, then they ask in on-line professional forums. Some are already answering professional questions posed by others and thus earning the appreciation. And for courses which they just want to pass, they share their essays, presentations,

laboratory exercises, answers to test questions etc in online databases like "Ucionica.hr je banka znanja na internetu" [33] or [34] (the Estonian version).

In these professional social networks they learn a lot and their knowledge in some areas connected with their work exceeds that of their professors in the university.

The generations X (the “lost” generation, some of them still study) and Y (Millennials) [35],[36] grow with Internet and have developed different techniques for solving their problems:

- *googling* .The first thing they do in computer class - they start Google and whatever problem with e.g. programming languages syntax - they google, and usually get necessary piece of knowledge already from the Google's page of results, without opening any page from there. This is a very useful habit and allows them quickly start using new applications - nowadays everything changes very quickly and it is pointless to try to memorize all UI/syntax details.
- *hacking*. They read program code much quicker than older generations (their peers) and grasp instantly the general structure, the information flow of a program - what is imported/input, what is exported/output and understanding of the structure allows them make modifications without even reading the whole text of the program - another very useful technique in our quickly changing world

Role of every kind of non-formal and informal learning and non-academic techniques is increasing and universities have not yet found adequate responses. As a result the millennials increasingly question the value of university education. A PhD students of the first author complained after successful defense, that in employment interviews several reviewers suggested him to remove mention of his PhD degree from his Curriculum Vitae - he looked 'over-educated'. His interests and practice before entering doctorate was management of IT projects. But there were no IT projects waiting for managers - all IT projects were invented (with financial help from the Ministry of Economy or crowd sourcing) to be managed by similarly desperate project managers (and most failed).

IV. Can Technology Replace Teachers ?

Education is a rather expensive sector in every government budget. In Finland expenses for education during the last ten years have been over 13%; in Estonia - around 12% [37]. So it is understandable, that governments want to reduce this item of expenses, suggesting use of more technology in schools, which should make teachers more effective or replace them.

Attempts of using technology for educating masses have long history. Already in 1920's started in USA educational radio broadcasts; later appeared educational TV, the PLATO - Programmed Logic for Automatic Teaching Operations (Automatic Teaching!) and currently MOOC. But all these ventures show very low course completion rates, e.g. the study from University of Pennsylvania revealed, that in average MOOC courses complete only 4% of users [38].

The number of on-line educational materials is growing exponentially. Most of them are short (5-10min) videos.

Most of these videos try to repeat the classroom experience and have been created in traditional style of university lectures - a 'speaking head'- style video, where professor reads chapters from his own textbook, occasionally jotting some hard to understand handwritten characters/figures/schemas on the blackboard (modern professors have already whiteboard).

Video is far less interactive than printed book. With book user can slip pages, look for references, skip uninteresting sections, with video one has to follow everything with video's speed. This breaks the fundamental principle of UI (User Interface) design: user, not the computer, should always have control. Videos cannot have links to outside materials and user can not copy-paste formulae or data from a video.

Video clips exploit very little of human's audio-visual capabilities. Bandwidth of human eye's is ca 10 Mbps (million bits per second) [39], ears - 1.4 Mbps, i.e. we receive every second ca 11.4 Mb of information. Bandwidth of educational video clips e.g. in YouTube is on average only 4500 kbps (everyone can check - right-click on clip and select 'Stats for nerds'), thus these clips engage only a quarter of our input capacity. But a weaker signal creates also weaker perceptions [40].

Figure 1. Sensory (visual+audio) signals are in classroom lecture many times stronger than in educational video from WWW.

Video lectures are for many more difficult to comprehend than the actual textbook which has been used, if there are formulae or data which user should write down, there are references to topics which are not covered in this particular lecture - from video user can not copy-paste and video does not support links. The widely used by universities simultaneous reading the slide text with voice ('speaking head') is useful only for users with reading disabilities, for other users it makes text comprehension more difficult [41], although some research claims (for different age group) the opposite [42].

Figure 2. 'Speaking head' reading the text of 20 slides. User should watch for 10min 47sec, in order to get the data and formulae, user

should pause the video and manually wrote everything down (no copy-paste, no links).

A good on-line study material should be self-contained - it is easy to open another paragraph from book, but rather troublesome to find another video clip explaining missing issues. And the aim should be to explain the topic, not to show the professor.

However, some video clips are really excellent - self-contained, with content menu and using the best features of digital media - animations, sound/voice; examples are e.g. the Introduction to Modern Information Theory [43] from Khan Academy or the winners of the Medical College Admission Test (MCAT) Video Competition, a collaboration between Khan Academy, the Robert Wood Johnson Foundation, and the Association of American Medical Colleges AAMC [44]. As this last example shows, students can make better educational materials than professors - students know, what their fellow students need.

There are many educational tutorials on WWW about nearly everything. They have been created without considering traditions of university lecture, but considering audience - to whom this may be useful - and maximally utilizing latest technical possibilities of modern browsers, e.g. allow to demonstrate interaction of different parts of www-page - html code, JavaScript, CSS [45]. And IT students already use these for learning far more than university lectures - lectures are for many only for getting diploma.

V. Best Practices

The technology is not the lesson presented by a live teacher. The competition in (higher) education is all the time becoming stronger and under the pressure of it, all teachers are seeking better practices in their teaching. The following are suggestions following from our everyday practices.

A. Activate, engage students

Getting students and professors together in a lecture room is an effort which has a cost - both students and professor's time, the lecture room etc. This time should not be wasted to make students passive listeners of oracle, who is (often) reading passages from his own book and who (often) has never tried to implement his recipes in some real business enterprise.

The advancement in communication technology have made such sessions of passive listening utterly senseless. Students could listen/watch these sermons online. The precious time when the whole group and professor are face-to-face should be used actively.

Many studies have shown, that learning is effective only when students are actively engaged in the learning process. Thus the first what lecturer should do is *Engage, activate students, make them active participants, make a lecture/practice active dialog instead of one-sided sermon!*

B. The Flipped classroom

University education is a rare (probably only) field of social activity which has nearly not changed from the times when first universities appeared in 11th..12th centuries - many of them are still active [46].

Proud of longevity and academic traditions professors continue to deliver lectures nearly the same way as did their predecessors during centuries: top-down, deductively - first the lecture explaining theory and then some examples and exercises illustrating the theory. This is the test-oriented method of teaching - tell students exactly what students need to know for the test, nothing more, nothing less.

In order to acquire knowledge and not simply to pass tests gives the inductive, problem-based learning, discovery learning, inquiry learning much better results than deductive [47]. Learning should start from a case, a problem, a story what students can understand. This is the Scahnk's story-based teaching method [48].

An often used tradition is to assign at the end of a lecture readings for home. But usually teachers discover at the start of the next lecture, that nobody has done their readings. Thus instead of continuous crying "How to get them to Do the Readings ?" maybe it is time to ask, whether this tradition should be changed. The essential knowledge, which earlier was assigned as home readings after a lection, should be discussed in class, but in order the discussion to be successful, students should first do some exercises from on-line tutorials, where are assigned on-line materials which present theory.

C. Use on-line materials and video clips

Teachers should use the best examples of the vast and rapidly growing pool of freely (still!) available materials. It has no sense to invent the bicycle or to sit a long evening trying to compile an animation for your next lecture, which will run in couple of seconds. There are already lot of ready material on-line - use it!

D. Hackers style

The most influential figures in modern computing world - Bill Gates, Steve Jobbs, Mark Zuckerberg and others where college drop-outs. Instead of theories they wanted to 'see how this thing works'.

Understanding the general, 'top-down' structure, flow of information in a program or a system is a very valuable ability, which allows quickly to understand new systems and programs (and currently they appear nearly every day). Many students already possess this ability - they see instantly, where is a closing bracket of a block or function, which lines have syntax errors etc. For instance, when the first author showed in class program lines which caused the recent Apple's SSL/TLS bug [49], several students quickly indicated the erroneous line. Many university teachers consider such 'top-down' style as 'non-serious' and even dangerous, but rapid increase of new systems and technologies makes this approach inevitable everyone want first to see how it works, how it can be used and only (if it can be used) - what are the details. The quick advancement of HTML5 is due just to its openness - everyone can investigate, 'how this works'.

E. Give students more choise

In his commencement speech Steve Jobbs described his decision to drop out from college: "... it was one of the

best decisions I ever made. The minute I dropped out I could stop taking the required classes that didn't interest me, and begin dropping in on the ones that looked interesting."

Students, especially working students, are well aware of developments in their field, since companies follow all the time, what is happening in their field - this determines their success or failure. They should have more freedom in selecting courses, for visiting or not visiting lectures and presenting their projects for credits. The rigid division to semesters and sessions is very questionable, e.g. why can teacher assess the achievements of a student only in pre-determined time, during the examination session? The marks go to university's database (the Studies Information System); this system runs like all server databases 7/24, so should also be accessible 7/24. Some universities are already experimenting with more flexible practices, e.g. the Rio Salado College in Arizona allows for a semester 48 start times in a year [50].

VI. Example Case

Some of relevant practices are illustrated in the following with a brief overview of first author's exercise class in theme "3D communication" in spring 2014. Participants were first year bachelor students, this was the semester's first exercise and the exercise was the first step for creating 3D web shop window, where customers could freely manipulate 3D objects.

A. Story

In 2008 appeared in Apple on-line store for iOS applications an app, which showed on screen a glowing gem with some lines of verse ("I'm rich...); the application was described as "a work of art with no hidden function at all" (i.e. just a picture), prize - 999.99 USD. During the first day eight people bought it, then Apple removed the app [51].

The story noticeably enlivened students and they started to create an enormous (1m x 1m x 1m) 3D diamond, which they could expose rotating on their www-sites using the html5/WebGL (the result: [52]).

B. Using on-line tutorials

The 3d model was created with Sketchup; students followed the YouTube tutorial [53].

C. Gamification

The indicated tutorial (and the following steps) could be improved, thus students were encouraged to propose improvements. The 3D model was improved with creating an additional upper bevel with author's initials (not part of on-line tutorial).

Figure 3. Upper bevel and author's initials

Those, who could propose improvements to the tutorial, could implement the additional bevel and remove unnecessary hidden surfaces earned credits - +-points, which will be considered in course final assessment.

D. Hacking

The 3D- model was transformed in Collada format to html5 document. For this was quickly (3-5 minutes) introduced the Javascript WebGl package three.js [54]. The whole package is > 200 MB, therefore students copied to assigned to them hard disk area only some files, first the examples/webgl_loader_collada.html and all files needed to run them in browser (they had to investigate the Javascript import clauses and create a corresponding directory structure). When the monster from webgl_loader_collada.html become alive, they had to create a directory parallel with monster's directory, export there from Sketchup their precious stone in Collada format and replace the monster's import with import of their Collada object. For additional points they had first to replace rotation of the world with rotation of the stone only; better students could also add camera control hacking the file , examples/misc_controls_orbit.html.

After 90 min (end of the class) all students succeeded in creating the rotating stone in html5 page. Those, who did not understand everything, had to consider at home everything from the www-tutorial (the 'flipped' classroom).

VII. Future of Technologies

It is very difficult to predict - changes are all the time accelerating. However, most technologies have up to now followed the Gartner's Technology Hype development stadiums, which illustrates utilization of emerging technologies [55]:

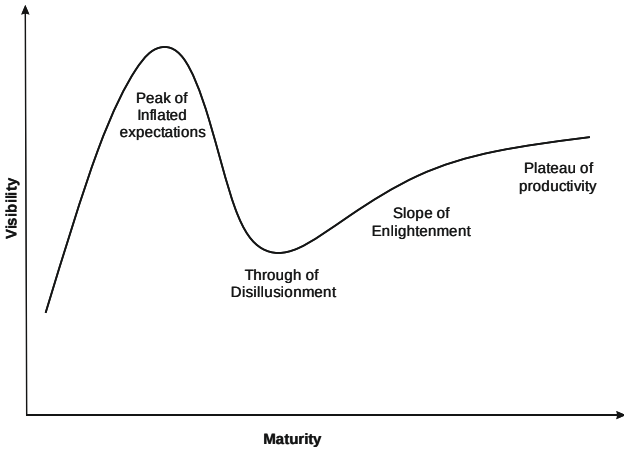

Figure 4. The Technology Hype curve (Gartner [55])

Some of education-connected technologies are currently in the following stadiums(for the full list check [56]):

- **On the Rise**:

  Open Microcredits - free or low-cost way to demonstrate competency in some area; some number of them could be used to obtain a certificate or diploma [57], [58];

  Student Retention CRM - relationship management software, which helps to identify at-risk students

before retention and predicts and reports student behavior to faculty members and administrators; replacing a drop-out student costs twice;

Affective Computing - procedures to influence our emotions and other affective phenomena (could become a part of the previous);

- **At the Peak** (beginning to drift down):

MOOC - the initial enthusiasm around MOOC is cooling down [59], since on university level participants of MOOC courses (even with on-line mentors to interact with students, 1:100) showed much weaker results compared to equivalent live classes on campus [4], thus currently their main application area seems to be professional training for enterprises, but many universities still believe in the bright future of MOOC [60];

BYOD - allowing employees, business partners and other users to use personal devices - laptops, tablets, mobile phones - to execute enterprise applications and access data is inevitable trend, but brings along several dangers: the personal devices are usually connected with social networks, so " by 2017, 40 percent of enterprise contact information will have leaked into Facebook" and in average 20% of personal devices are compromised by malware ;

Big Data - used e.g. for analyzing MOOC performance issues

- **Sliding Into the Trough** :

Social Learning Platform for Education;
Mobile-Learning Smartphones;
Virtual Environments/Virtual Worlds;

- **Climbing the Slope:**

Open-Source Learning Repositories.

VIII. CONCLUSIONS

Universities have two contradictory roles in the world of learning: distributing knowledge, teaching and evaluating their own work with diplomas. Both of these roles - teaching and certificating - got their established forms long time ago, when world was small and closed; in our open, connected world both these functions have lot of pressure for modifications.

The university teaching should embrace all existing tendencies for non-formal, informal education and the new skills of students:

googling - ability to find quickly relevant information from the World biggest data resource - Internet;

hacking - understanding the information flows, the essential structure of a system - an enterprise, (local) government;

multitasking - simultaneous handling of several tasks;

being all the time connected etc

University teaching, distributing new knowledge should better use the rich and constantly renewing source of knowledge - Internet. Physical, i.e. publishing on paper is all the time becoming more expensive and the published materials are always first prepared in digital form - why to bother publishing on paper ? All materials are much easier to distribute and access on Internet. Scientific reports and journals, conference proceedings etc increasingly appear on-line.

People like to teach - creating a tutorial is the best way to understand a topic and new tutorials on newest IT application areas appear in Internet constantly. Most of them are free - the Wikipedia has been created for free. Wikipedia is referential, not designed for learning, but there are already many pedagogically well-designed tutorials covering many areas of IT.

Certification (giving diplomas) may disappear altogether. When diploma is not any more a guarantee for earthly 'summum bonum' and government ministers obtain their diplomas giving them 'a life of ease and pleasure' with copy-paste techniques [61], then - why to bother, spend 4-6 years under extreme strain and then when receiving the diploma discover that (at least) half of your hardly obtained knowledge is already obsolete [62], [63] ?

Microcredentials - digital “badges” [64] - are increasingly respected as a representation of a credential and accepted proof of knowledge, skills or achievements [65]. They digital, thus much more foolproof than classical paper diplomas. Contrary to diplomas, which reflect only the state of (academic) knowledge of the owner at the time of issuing, the microcredentials evolve with e.g. every proper answer in SourceForege or LinkedIn. They are open and public, everyone can support or disprove them.

Some creative minds, self-proclaimed “most experienced organization in professional licensure and certification services” [66] or "Institute for Credentialing Excellence" [67] already claim that they are the "only true source of this kind of information". It is difficult to believe, that this additional item of expenses for obtaining credentials can live long - diplomas are already too expensive. Everything is becoming open. The achievements obtained in open professional networks are easy to check and hard to forge - who needs additional (costly) 'certification services' ?

dina.vrkic@gmail.com, mpavlovs1987@gmail.com

Abstract - One of the basic needs of contemporary engineering students is to, evoke their individual ability for creative and critical thinking in science, professional or research and development (R&D) field. This ability descends from an individual's level of information competency that, as the basis of lifelong learning, poses several distinctions compared to the level of one's skills in the fields of electrical engineering, computing and information and communication technology (ICT).

Previous researches show that the quality of those skills in the students' practices is markedly high, but the lack of information competencies is still notable.

The aim of this paper is to present the results of the information behavior and information competencies survey conducted among students of the Faculty of Electrical Engineering and Computing (FER) at all undergraduate and graduate levels. The results of the study will be processed to determine the skill level of information competencies and behavior of engineering students.

The outcome will be beneficial in the planning process for information providing strategies in academic libraries in the electrical engineering, computing, information, and communication technology (ICT) fields.

I. INTRODUCTION

Computer and information competence of students of technical disciplines is a component of information literacy. Computer competencies mean that students developed knowledge of information and computer and technical skills connected to their usage. But information competence means understanding necessity of actual and significant information, skills to find the information sources, using the most effective search strategy, estimate information critically and competently, to differ facts from opinions, to estimate the found information creatively, to use received habits on information search for personal purposes and professional activity, understanding information meaning in the development of democratic society, knowledge and following ethical standards in the sphere of information technologies, to operate in search and use of information and finally the skill to share results of one's activity [1].

II. LITERATURE REVIEW

Information behavior is the totality of human behavior in relation to sources and channels of information, including both active and passive information-seeking, and information use [2] or simply: how people need, seek, give and use information in different contexts [3].

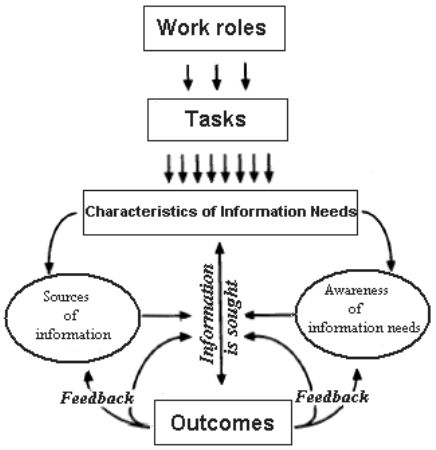
In other way, creativity is connected to engineers who possess a more thorough knowledge of information retrieval strategies and information sources, therefore they should be more efficient in educating themselves and should develop more creative solutions to problems, will practice more efficiently, and will be more competitive in the global economy [4].

Leckie and Fullerton study show that engineering students, as engineers in the academic area, tend to begin to develop serious information retrieval skills later in their program of study [5].

Previous research shows [6], [7] that students do not always examine the citation of the content found to evaluate information accuracy, which indicates that students don't validate the content through the citation given, as long as the information found answers the given academic question [7].

Kerin, Madden and Fulton examined the information-seeking patterns of final year undergraduate engineering students split evenly between two engineering institutes in Irish universities. It was reported that engineering students seem to have a preference for channels that require the least effort, such as the Internet. They explained that the result was due to the fact that student engineers viewed the Internet as a speedy, current information source which fed initial information needs quickly [8].

TABLE I. THE INFORMATION SEEKING OF PROFESSIONALS MODEL[9]



Awareness of information sources, including accessibility, quality, timeliness, trustworthiness, familiarity and previous success, has a direct impact on approaches taken in information seeking. For instance, engineers tend to rely heavily on informal sources of information, such as colleagues [10], [11], [12], and [13].

As Lasić-Lazić et. al. [6] said in a research that current educational systems thrive for student-centered, active, flexible and problem-based learning, which emphasizes the students' independent information seeking.

III. METHODOLOGY

The research method was an online survey (via GoogleForm/GoogleDrive) consisted of thirteen questions. The survey structure was inspired by a survey instrument of research carried out in Project information literacy (PIL) [14] but adjusted to the engineering students and oriented to the previous research conducted in the paper of Lasić-Lazić et. al. [6]. Questionnaire was published on the intranet pages of the News for students of the Faculty of Electrical Engineering and Computing (FER), University of Zagreb in the period from January 27, 2014 until February 7, 2014. The intranet page was selected because it is an instrument to connect information with students via push notification to their official e-mail with the content of the news for the 3516 students at the undergraduate and graduate levels.

The survey was approved by the Faculty Commission for quality management.

The survey was divided into four parts with the structure of the thirteen questions survey. The first, introductory part consisted of multiple-choice questions about types of research assignments they had for the courses they took last year. The second part was about information sources composed by several question types: two 5-array point choice, two close (with one open sub question), one 7-array point choice and one multiple-choice question. The third part was about research approaches with two 7-array point choice and one multiple-choice question. At last, the fourth part was about demographic information.

IV. RESULTS

The response rate includes sample of 75 voluntary students (2.13% students) of which 37 (1.84%) undergraduate, 31 (3.01%) graduate and 7 (2.17%) post-graduate students. The low response rate was due to the setup of the push notification (connected to e-mail) and lack of monitoring notifications on the News for students.

The first question asked concerned the insight on student activity in course-related research. The 46 (26%) of students already wrote seminar papers, 26 (15%) BSc thesis, 27 (15%) some kind of reports, 24 (13%) laboratory notebook, 12 (7%) essay and professional article 10 (6%) students. These results demonstrate the representation of the seminar and professional papers (except the BSc thesis at the undergraduate level). Seminar papers and essays are specific to (higher) education, but the students will continue to produce reports and laboratory notebooks in professional purposes after formal education.

The question related how often did they consult information resources during course-related research process, authors established that undergraduate and graduate students almost always use search engines as their primary source of information. Undergraduate and graduate students equally use encyclopedias, Wikipedia, personal collection of materials, or find their course-related source of information from colleagues. The usage of the library for graduate students is on fifth place and for undergraduate and postgraduate students at sixth.

In the previous question, authors did not include the use of databases because they wanted to evaluate the difference within the results of the previous research [6] conducted on the information competencies of FER students. Therefore, authors proposed it as a separate question. The total number of students who declare to use databases was 27 (36%) and the total number of students that declared they do not use databases was 48 (64%) students. From this large percentage of students at the undergraduate and graduate levels that do not use databases, authors can conclude that students at those levels are not aware of the usefulness of databases.

The problem can be found in the fact that a large number of students, especially at the beginning of their study, rely on textbooks in which they can find the information they need systematically written and have no need to look for sources that broaden the base knowledge for their courses. On the other hand, postgraduate students' results showed increased database use. The curriculum of undergraduate studies represents no courses on the topic of information competencies, while on the graduate level there are several courses that include instruction in the scientific information search, including a course designed from the perspective of library science: „Research, publications and responsibility in science". At the postgraduate level, professors at FER hold the course „Searching scientific information and publication of research results".

TABLE II. USE OF SCHOLARLY PEER-REVIEWED DATABASES

Students	Yes	No
Undergraduate	10 (27,03%)	27 (72,97%)
Graduate	12 (38,71%)	19 (61,29%)
PhD	5 (71,43%)	2 (28,57%)

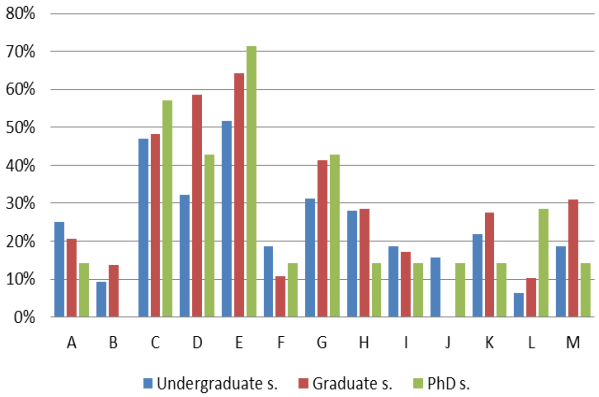
Furthermore, according to the research [6], authors set up a sub-question on a pre-positively answered question, requesting the students to list the options what they use while searching databases. They responded that they usually use advanced search options, search by uncontrolled expression (author-supplied keywords), Boolean operators, thesaurus, ISBN/ISSN, truncation symbols and wildcard characters and at last place DOI. The results form year 2007 and today are almost equal, except for usage of DOI.

In order to further evaluate the problem of students not using databases, authors asked students (of all study levels) if they had difficulties in finding the necessary information sources on the Web. The results indicate that 58 (77%) students do have difficulties, while 17 (23%) students responded that they do not have problems with information search. Students' stated in sub-question regarding the peer-review database search problems that their common problems are related with formatting information queries, determining the relevance and trustworthy of search results. Unfortunately they are not conscious, since the databases are relevant-trusted information source. They also mentioned that they are not familiar with the representation of databases at Faculty and the ways to reach articles (e.g. they do not know that FER has secured access to the IEEE/IET Electronic Library (IEL)).

The evaluation of library sources (books or articles from peer-reviewed databases) varies between the student levels. Undergraduate students almost always consider whether authors have vital information in the charts (e.g. not just attractive graphics), but rarely they consider whether the author/s give credit for someone else's ideas (e.g. footnotes). Graduate students almost always evaluate how current the library source is and also consider whether they have used the library source before. On the other hand, students rarely evaluate whether the library source has a bibliography and who is the publisher. Postgraduate students almost always consider the evaluation of library sources author's credential (e.g. where he/she is faculty or works) and whether the author gives credit for using someone else's ideas. They rarely consider using the library source mentioned by librarian, and whether they have ever heard of it or used it before.

With a notable lack in the use of information competencies, the issue arises: to whom students address for the evaluation of information sources? Undergraduate and graduate students most frequently consult among themselves, while postgraduate students equally ask help from professors and professionals (engineers). Undergraduate and postgraduate students rarely ask librarians for help in evaluating sources, while graduate students sometimes do ask librarians. In the last place, they all have in common demanding evaluation of information sources from friends and family.

TABLE III. COURSE-RELATED ASSIGMENTS (N=32 UNDERGRADUATE STUDENTS, N=29 GRADUATE STUDENTS, N=7 PHD STUDENTS)



A – Start over with new topic, after couple of searches w/out results

B – End research after finding number of citations required

C – Add in own perspective to assignment

D – Create thesis statement early on

E – Develop an outline (draft of paper)

F – Sit down and write, with no plan at all

G – One of the first things I do is to figure out search terms

H – Develop an overall research plan

I – Use system for organizing sources retrieved

J – Use Interlibrary Loan (ILL) for sources

K – Use same set of resources for different assignments

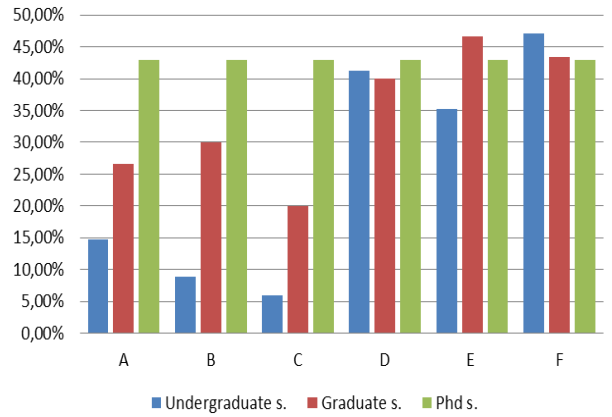
L – Use same topic for different assignments

M – Spend same amount of time on assignments

During course-related assignments, students show that most of them first develop an outline (draft of paper) and work their own perspective into the assignment, so the instructor/professor knows what they think. The results so far did not show significant growth of information competencies, so it is interesting that on the fourth place of the list of habits is that 'one of the first thing they do is to figure out search terms to use'. Undergraduate and graduate students tend to use same set of resources for different assignments, while postgraduate students tend to do it rarely. Students from all three levels of study are not inclined to give up, for example, if they do not find the necessary literature in one or two searches they will not begin with a brand new topic. They do not tend to write about the same topic from one assignment to the next. Undergraduate students rarely use interlibrary loan,

graduates do not use it, while postgraduate students use it sometimes.

TABLE IV. DIFFICULTY SEGMENTS IN COURSE-RELATED RESEARCH RESPONSES OF ″STRONGLY AGREE″ AND ″SOMEWHAT AGREE″ HAVE BEEN COMBINED INTO CATEGORY GENERAL IMPORTANCE. N=32 UNDERGRADUATE STUDENTS, N=29 GRADUATE STUDENTS, N=7 PHD STUDENTS)



A – Creating search terms

B – Finding articles in library databases

C – Finding Web sources

D – Determining credibility of sources

E –Figuring out where to find sources

F – Evaluating sources

As shown in table IV, in course-related research the most difficult tasks for all student levels are to evaluate information sources, finding up-to-date materials and determine credibility of sources. While, on the other hand, students of the undergraduate and graduate levels stated that they do not agree that is difficult to finding Web sources, finding articles in library databases and creating search terms. Postgraduate students are aware of the difficulty, better said, uncertainly of the overall information competencies because they are in a position to use above-mentioned skills on a daily basis.

TABLE V. USAGE OF P RODUCTIVITY TOOLS (N=65) (FROM MOST TO LESS USED)

Rank	Productivity tools
1	Document sharing Web application (e. g. Google Drive)
2	VoIP (e. g. Skype)
3	Highlighting feature on software program
	Digital “sticky notes”
	Forum
4	Wikis
5	Photo sharing sites (e. g. Flickr, Photobucket)
6	Virtual Research Environments
7	Reference manager software (e. g. RefWorks, EndNote, Mendeley)
	Web alerts (e. g. Google Alerts)
	Microblogs (e. g. Twitter)
	Online time management program (e. g. Google Notebook)
8	Social bookmarking (e. g. dig, Delicious)
	Blog (e. g. LiveJournal)
	Other

In the multiple-choice question about usage of productivity tools that students use in course-related research they marked that the most useful tools are the ones for document sharing Web applications (e. g. Google Drive) and VoIP (e. g. Skype), therefore, communication tools. Then, tools for helping them in the better processing of the research papers. Students rarely use tools regarding the reference management, probably, because they are not informed about the existence, offered opportunities and they're widespread of usage in professional and scientific (social) community.

Social Web component (Web 2.0) is the least used among students for course-related assignments.

V. CONCLUSION

Students at all levels of study show that they adjust their information behavior to contemporary media/research setting. For example, after they develop an overall research plan, they search for information sources out on the Web, not in the relevant information sources, e.g. peer-reviewed databases or in library sources. The results showed that the importance of information awareness (information competence) is developing exponentially with each additional level of education.

The library will have to be incorporated into contemporary concepts of supporting the learning process and supporting teachers through curriculum (interdisciplinary/cross-curricular segments). The study indicated that though behaviors can be changed through course design, values linked to learning tend to be much difficult to change.

Key sources for course related information are Google, Wikipedia, and personal collection of printed materials, rarely the library and almost never peer-reviewed databases. Authors can confirm the existence of disproportional usage of evaluating and consulting about information sources: almost never with librarians but usually with colleagues. To overlap the information gap, the library needs to pursue, as authors said above, the implementation of information literacy into the curriculum.

By providing timely information and customized education at each student level, they can gain necessarily required information skills that could extend the time for development of creativity either in information retrieval strategies and information sources either in a professional way.

Application of Modern Teaching Techniques in the Educational Process

M. Filipović Tretinjak*, A. Bednjanec* and M. Tretinjak*
*School of Electrical Engineering (Elektrotehnička škola), Zagreb, Croatia
martinafilipovic.tretinjak@gmail.com; andrea.bednjanec@gmail.com; mario.tretinjak@gmail.com

Abstract – Today students are using computers, cell phones and other electronic devices to communicate and to access information. New technologies fundamentally changed the way they interact with knowledge so the traditional approach to learning and teaching is no longer sufficient. In order to make the learning environment more interactive and enable students to learn easier and faster, modern teaching techniques need to be applied. There are many different teaching techniques that have emerged from the integration of technology in education such as: flipped teaching, whole brain teaching, gamification, social media, etc. Flipped teaching encourages students to study the course material before class by using readings, pre-recorded video lectures or research assignments. Class time is reserved for active learning strategies. Whole brain teaching helps stimulate both sides of the brain and emphasizes active learning in which students repeat core information and practice basic skills through humor and games. Gamification is a game-based learning technique that allows students learning through the use of games. Nowadays students are always connected to some social network. These students are easily motivated to engage with social media in the classroom. Experience from the School of Electrical Engineering in Zagreb shows that the use of different modern teaching techniques is making learning interesting and teaching more effective.

I. INTRODUCTION

Today students are using computers, cell phones and other electronic devices to communicate and obtain information. The use of technology in the classroom allows students to interact with knowledge in a new way and provided teachers with various online platforms for developing different learning materials and virtual classrooms.

Traditional teaching techniques were based mainly on a teacher explaining a topic and students taking notes. Teaching techniques in today's education should revolve around enhancing students' intrinsic motivation.

In our research we explored whether different modern teaching techniques can help students achieve better exam results and will students become more interested in course topics. Most mentioned methods require computers with access to internet in the classroom. Therefore we have based our research on courses that already have in-class computer-based activities such as: system software, technical documentation, computer networking and internet technologies.

II. FLIPPED TEACHING

Flipped teaching (or flipped classroom), also known as backwards classroom, reverse instruction, flipping the classroom and reverse teaching is a teaching technique in which students are encouraged to study course material online before class using readings, pre-recorded video lectures or research assignments. Class time is reserved for interactive activities, exercises, illustrating concepts, projects, discussions, etc.

Instead of lecturing, teachers offer students personalized guidance through learning materials and more interaction with course topics.

The main objective for implementing a flipped classroom is a change from a passive to an active learning model. Basic differences between traditional and flipped teaching are given in Table 1.

TABLE I. TRADITIONAL VERSUS FLIPPED TEACHING

	Traditional teaching		**Flipped teaching**	
	Teacher	Students	Teacher	Students
Before class	prepares lecture	mostly do no work	prepares reflective web-based lecture materials such as videos, content- rich websites, blogs, quizzes, etc.	complete interactive learning materials, prepare to participate in class activites, gain necessary knowledge or skills
During class	tries to get through all the lecture material, repeats what was in the lecture	listen to a lecture, follow guided instruction, take notes	guides the learning process, gives students support as needed	verify their understanding, extend their learning, practice skills
After class	grades past work	memorize notes, try to do homework	posts additional resources and explanations as necessary	continue applying their knowledge and skills, extend learning to more complex tasks

Four steps to successful flipped classroom implementation:

A. Identify what course content can be reversed

The flipped classroom can be used for flipping parts of each unit or an entire course. Our research has shown that reverse teaching is very useful for courses that already have in-class computer-based activities, such as system software, technical documentation, computer networking and internet technologies.

B. Create engaging class environment

To create an engaging class environment, use different instructional approaches such as peer instruction, team-based learning (TBL), case-based learning (CBL) and process-oriented guided inquiry learning (POGIL). Engage students in learning activities with an assessment. Evaluation tasks will provide feedback for students and teachers about mastered learning outcomes.

Peer instruction is a method by which students prepare for class by doing pre-class reading and answering questions. Answered questions give the teacher feedback about what students found confusing or difficult. For the next lesson, the teacher prepares questions based on the students' responses. During class the students discuss their answers, giving the teacher opportunity to evaluate their progress and to determine whether more explanation is needed before moving on to the next teaching unit.

Team-based learning (TBL) is an instructional approach in which students prepare before class by doing pre-class reading. At the beginning of the lesson students individually and as a team take a quiz or a test about the class topic they prepared for. The teacher estimates the students' comprehensions of the topic; gaps in understanding can be explained through mini-lectures (10 to 15 minutes long videos, presentation, etc.). Then teams engage in various assignments.

Case-based Learning (CBL) is an instructional design model that is quite similar to project-oriented learning. Students work together in small groups (3 or 4 students) analyzing a specific case study provided by the teacher. Case study is a complex, real-life scenario for the social sciences, natural sciences, computer sciences and other disciplines. The students through discussions analyze the given case study and evaluate the given course of action or determine an appropriate course of action on their own. The case study analysis develops the students' analytical thinking.

Process-oriented guided inquiry learning (POGIL) is a student-centered instructional technique in which students work together in small groups (3 or 4 students) on activities that are designed around a learning cycle (exploration, concept invention and application). Students are given a piece of data (graph, map, or image) or information and questions. Students use the questions to explore the given data and generate a conclusion, and then they apply these conclusions in new situations.

The POGIL activities develop the students' critical thinking, problem solving, information processing and team collaboration.

C. Developed and organized course materials

To create a dynamic environment within the flipped classroom, students need to come prepared for class. Define knowledge and skills that students need to acquire during class and then determine what they will need to read or view in advance of the lesson.

Students can prepare for class using traditional materials such as reading materials (textbook chapters or relevant articles) or using online video content (online lectures, simulations or demonstrations of specific procedures).

In order to manage the gathered and created course materials easily, organize them into three groups according to what students need to experience before, during and after the class.

Find the existing online content using websites such as TEDEd, YouTube, Vimeo, SchoolTube, KhanAcademy and OpenCulture. In our research, these websites served as an inspiration for creating our own course material. To create video lectures we used programs like Screencast-O-Matic, Photo Story 3 for Windows and Windows Movie Maker. Course material was shared with students through platforms such as Edmodo, Facebook and Moodle (CARNet).

D. Extend learning after class

In the flipped classroom, students apply course content during the class. In order to help students achieve the expected learning outcomes, teachers assign additional problem tasks (on the blackboard, course website or from the textbook). Also, the teacher can assign additional readings (from the textbook, particular article from a website or newspaper) to further expand concepts discussed in the class.

Our research has shown that flipped teaching offers many advantages and disadvantages like any other teaching technique. The advantages and disadvantages of the flipped classroom are given in Table 2 below.

TABLE II. THE ADVANTAGES AND DISADVANTAGES OF THE FLIPPED CLASSROOM

		Advantages		Disadvantages
Flipped classroom	**Teacher**	can devote more time to helping students, can easily identify students incomprehension	**Teacher**	needs to have access to the required technology, needs to motivate students for completing the pre-class assignment, needs time to collect and create the necessary learning materials
	Students	are able to access learning materials at home, learn and examine course material at their own speed, comprehend better, develop critical thinking	**Students**	need to have access to a computer and internet, spend more time on the computer

III. WHOLE BRAIN TEACHING

Students perceive and assimilate information in different ways. Whole brain teaching is a teaching technique that stimulates both sides of the brain and emphasizes active learning in which students repeat core information and practice basic skills through humor and games.

Seven methods on how to implement the whole brain teaching technique into the classroom:

A. Attention getter: Class-Yes

Class yes is an attention getter that the teacher uses to focus students on what they are going to say next. At the beginning of the class the teacher says "Class!" any way he/she likes and the students imitate the teacher's voice by responding "Yes!". Class-yes is also used during entire class to get students' attention to another short lesson.

B. Classroom Rules

Before teaching a specific topic, the teacher repeats the classroom rules with the entire class to ensure that students understand them.

There are five classroom rules supported by gestures [4]:

- Follow directions quickly! (Make your hand move forward like a fish.)
- Raise your hand for permission to speak. (Raise hand, make a talking motion).
- Raise your hand to leave your seat. (Raise hand; make a walking motion with fingers.)
- Make smart choices! (Tap one finger to your temple as you say each word.)
- Keep your dear teacher happy! (Hold up each thumb and index finger out like an "L" framing your face and smile really big!)

C. Whole brain developer: Teach-OK

At the beginning of each class, the teacher needs to divide the students into pairs. Then he/she presents a short lesson and the students turn to each other to teach the demonstrated short lesson. The teacher observes the students' comprehension and if necessary repeats the lesson. To begin this process the teacher says "Teach!" and the students respond with "OK!". If the students understood subject matter, the teacher moves on to the rule "Class-Yes" and begins another short lesson.

D. Scoreboard Game

In our research we used a scoreboard game based on the Teacher vs Student model.

Students receive a point when they perform the demonstrated short lesson well. The teacher wins a point if the students do not perform well. To avoid the students' disinterest, the difference in scores between the students and the teacher should not be greater than three points.

E. Focuser: Hands and Eyes

Hand and eyes is a focuser that can be used during the lesson. When the teacher wants students to pay special attention on what he/she is saying/doing, he/she needs to say "Hands and Eyes!". Students then fold their hands and closely monitor the teacher.

F. Mirror

In addition to using the focuser Hands and Eyes, the teacher can gain control of the classroom and get students to imitate his/her words and motions using another method called the mirror. When the teacher says "Teach", students respond "OK" and then mimic the teacher's' speech and motions.

G. The whole class involver: Switch!

Switch needs to be used with the teach-ok method. When the teacher says "Switch!", students respond "Switch!" and then change places in teaching each other. This technique ensures that every student in the class is equally engaged in speaking and listening.

Our research has shown that students of all ages wanted to learn and follow the listed techniques. The main problem was that we did not have enough time for implementing the learned methods. We mainly used the whole brain teaching for repeating the subject's topics.

IV. GAMIFICATION

Gamification is a game-based learning technique that allows learning through the use of games. Games can be used along with other teaching techniques and have a great potential in the educational process.

Incorporating game elements into non-game settings makes learning more interactive, increases motivation through engagement, transfers knowledge into skills, allows teachers to track the students' progress easily and to create a more dynamic lesson structure.

Examples of gamification:

A. Add points to assignments and tests

Students collect points through each assignment (homework, project) and test. Here is an example on how to gamify assignments and tests:

- One point for turning in the homework assignment.
- Ten points for turning in the project assignment before the given time limit.
- Two points for every passing grade on the test.
- Five points for every excellent grade on the test.
- Twenty points for every test that was solved without mistakes.

Students' grades depend on the amount of points they have accumulated at the end of the course.

B. *Award students with badges*

Award students with badges for each completed assignment (homework, project) and class attendance.

Example of assigning badges:

- Badge "Perfect attendance" for students that are always present in the class.
- Badge "Participant" for students that actively participate in the class activities.
- Badge "Hard worker" for students that have completed every assignment.
- Badge "Star performer" for students that have earned three excellent grades in a row or solved at least three tests without mistakes.

To assign various badges, websites such as ClassBadges, OpenBadges and Edmodo can be used. To show the best students in the class, teachers can create a leaderboard using a website like Leaderboarded.

Students have quickly accepted this evaluation method. As our research has shown they liked it because they could monitor their learning progress in a visual way.

C. *Organize a class tournament*

In our research we have found that class tournaments stimulate students to learn the course material and practice skills. Students gladly demonstrated their mastered skills; they were excited about seeing themselves on a leaderboard. TopHat and PurposeGames platforms can be used to organize a class tournament.

D. *Integrate educational games in the classroom*

Students can practice learned skills through the use of games. There are a lot of different websites that offer tools for creating various games that can be used in the classroom, such as interactive crossword puzzles, word searches, word scrambles, quizzes and other educational games.

Platforms that can be used as games creation tools are: ProProfs Brain games, PurposeGames, HotPotatoes and SuperTeacherTools.

V. SOCIAL MEDIA

Social media include different number of online technology tools that enable users to create and share information and resources or to communicate easily. Social media can include text, audio, video, images and other multimedia contents.

Here are the most popular social media platforms used in the educational process: Facebook, Twitter, LinkedIn, Google Plus+, Instagram, Pinterest, Wikispaces Classroom, Edmodo, Edublogs, YouTube, TeacherTube, SchoolTube, etc.

There are lots of ways to use social media as a teaching technique considering there are hundreds of social networks available.

Several ways to use social media platforms that have been applied in our research are given below:

A. *Create a virtual classroom*

In our research we have created a virtual classroom on Edmodo. Edmodo is a free website designed for teachers, students and parents. Through Edmodo teachers can share content, educational applications and important information. Students can connect to the classroom, access homework, learning materials and submit assignments even after the school day is over.

In order to observe their child's progress or to discuss with his/her teachers, parents can access the Edmodo website either under their child's username or they may create their own account. Parents can also receive alerts from teachers about school events, missed assignments and other important messages.

Edmodo is an easy to use learning management system similar to Facebook. After creating an Edmodo account, classes for students can be created.

Currently we are using Edmodo for class discussions, placing and viewing students' assignments, uploading digital learning materials and tracking progress of more than two hundred students from 13 to 18 years of age.

Edmodo is very suitable for sharing files and links. For example, the teacher uploads homework or an assignment and sends it to the class and all the students who are in that class automatically have access to the tasks. Students do not have the option to exchange files with each other. Students can send a file directly to the teacher or anyone in the class (including the teacher).

This platform is extremely useful in subjects that teach students to work in specific programs such as Microsoft Office, CADdy++ Electrical, Dev-C++, Photo Story 3 for Windows because teacher has the option to upload videos that explain program features.

Also, Edmodo can be used in all other subjects, so that students from home can review submitted learning materials. Our research has shown that students like to use Edmodo at home and in the classroom.

B. *Create a class account*

Allow students to choose a social media platform such as Facebook, Twitter, Myspace or Instagram and encourage them to create a class account for communication and sharing learning materials.

For example, students can easily upload homework assignments and other tasks, exchange learning materials such as links to videos, blogs, websites and other resources for a particular subject. Absent students can quickly obtain the necessary information. Students learn to find and manage information, create an online community, collaboration and develop skills that prepare them for the use of social media in the workplace.

C. *Provide access to resources*

As our research has shown, students like to have online access to different learning materials. Course materials were available to them through several social

media platforms like Facebook, Edmodo and Moodle (CARNet). Students were accessing materials even after classes, posted their comments and links and explored lessons that they have not learned yet.

By using YouTube and other similar platforms such as TeacherTube and SchoolTube, students can watch videos, discuss content or share created videos with others. If a video demonstrates a procedure that the student should learn (for example create and format a table in Microsoft Word) the student can review it countless number of times until they learn the required skill. These social media sites offer a lot of free resources that can be used for lesson ideas as well as to supplement a lecture during the class.

D. Create your personal learning network (PLN)

Each teacher should create their own personal learning network (PLN) using for example LinkedIn social networking website. Connections with other like-minded teachers can help find required resources for creating course content.

E. Gather content with Pinterest

Pinterest is a social media platform that offers collecting and organizing gathered information through pin boards. With Pinterest you can plan class projects, collect information on a specific class topic, organize collected learning materials and share ideas for the classroom with other teachers.

VI. SEARCH RESULTS

Our research was conducted in the last three years on two hundred randomly selected students from 13 to 18 years of age. Participants were students who attended system software, technical documentation, computer networking and internet technologies classes.

In teaching students we used both traditional and modern teaching techniques. Figure 1 shows the research results. Most of the interviewed students (76%) enjoyed learning in a new way. Students claimed that modern teaching techniques made learning fun and interesting, helped them achieve better results on exams, increased student-teacher interaction, etc.

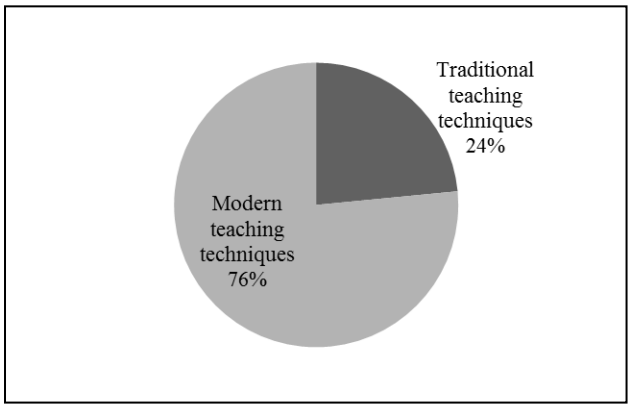

Figure 1: Research on traditional versus modern teaching techniques

Only 24% of the interviewed students claimed that they prefer traditional teaching techniques. When asked, they explain that is because they need to devote more time to completing various assignments during and after class, spend more time in front of the computer, etc. However, they agreed that doing different tasks helped them in acquiring the learning outcomes more quickly.

VII. CONCLUSION

Experience from the School of Electrical Engineering in Zagreb shows that the use of different modern teaching techniques such as flipped teaching, whole brain teaching, gamification and social media are making learning interesting, improve the students' comprehension, enhance the student-teacher interaction and improve critical thinking.

Open access initiative and its impact on use of digital information resources for research and teaching in higher education institutions in Croatia

Radovan Vrana
Faculty of Humanities and Social Sciences,
Department for Information and Communication Sciences,
University of Zagreb, Croatia
rvrana@ffzg.hr

Abstract – Digital information resources have become popular in academic community around the world as their quantity available on the internet increases. This is particularly evident in the case of open access information resources. The idea of open access to scientific information resources promotes use of mostly free of charge scientific information resources thus substituting use of fee based access to scientific information resources. Open access has both advantages and disadvantages. Main advantages would be greater visibility of published research, greater accessibility of scientific content in general, higher rates of citations etc. and disadvantages would be questionable quality of peer review, absence of peer review in some cases, charging authors for publishing their articles, lack of long term preservation policy etc. This paper also presents results of a study of use of digital information resources by students enrolled in two university courses at the Faculty of Humanities and Social Sciences in Zagreb over period of three years. The results showed that students prefer digital over printed information resources in researched two courses and that they are oriented more towards use of different types of free information resources for writing their term papers instead use of fee based information resources.

I. INTRODUCTION

The ongoing technological and information revolution presents us new challenges on a number of fronts on a daily basis. Two such fronts are educational process and research at higher education institutions. It is generally expected that higher education institutions benefit from the implementation of information and communication technology (ICT) in all their activities, especially in teaching and research and that ICT will help us all build a new information society. To achieve this goal, higher education institutions and academic community in general need support in form of quality information resources accessible without limitations i.e. open access information resources. The concept of open access to scientific information resources is related to modern science and its public, collective character as well as its commitment to cooperative inquiry and free sharing of knowledge [1]. Since part of the modern science is publicly funded, the results of the publicly funded research should also be freely available. As universities around the world are currently facing financial problems, they are changing their orientation from use of fee (subscription) based information resources towards open access information resources to provide the desired levels of availability and access of information resources to its users [2] thus helping the idea of open access to scientific information resources to become widely accepted. Without open access, new research would become more difficult to begin and, at the same time, it would introduce inequality in education between students who can afford paying the access to the educational material and those who can't. In the first part, this paper will discuss the idea of open access to scientific information resources and benefits and downsides of their use. In its second part, this paper will present results of the study of use of different categories of information resources in students' term papers in two university courses (one undergraduate course and one graduate course) at the Department of information and communication sciences at the Faculty of Humanities and Social Sciences in Zagreb. The next section of the paper focuses on the development of scholarly communication system which, eventually, led to the advent of open access.

II. DEVELOPMENT OF SCHOLARLY COMMUNICATION SYSTEM

Communication is integral part of science and it is present at all stages of the research process [3]. For centuries, scientific community and universities around the world have been depending on scientific journals for publishing the results of their research i.e. "(...) the diffusion of research results and the public documentation of copyright" [2]. In his article on digital distribution of academic journals and its impact on scholarly communication, Solomon [4] described briefly the history of development of the system of publishing of scientific journals. In the beginning of their existence, scientific journals belonged to scientific societies; they had small circulations and were funded by subsidies and page charges to authors (similarly to current efforts of some

commercial publishers which offer authors to pay a substantial fee to make their articles available in open access). Over time, commercial publishers started taking over scientific journals from scientific societies and increased journal subscription fees to maximise their profit (average journal annual fee has increased at a rate of more than 10% annually [5]) while the development of journals slowed down. During the same period, in the second part of the 20th century governments invested substantial money in research which resulted in growth of number of research articles and scientific journals as well as in increase of their subscription costs which led to scientific publishing crisis of the late 20th century when universities couldn't pay the increased journal subscription fees anymore. Consequently, the diminishing budgets of universities and university libraries initiated the cut backs in number of subscriptions to scientific journals [3] and, at approximately same time, universities initiated search for a solution of the this problem in form of a new scientific publishing paradigm. The next step in history of scientific publishing system development was invention of electronic and later on online journals. With the fast growth of the internet in 1990s the idea of open access as a scientific content publishing and distribution paradigm was born.

III. OPEN ACCESS INFORMATION RESOURCES AND BENEFITS OF THEIR USE

The most cited definition of open access is the one created by the Budapest Open Access Initiative: "By "open access" to this literature, we mean its free availability on the public internet, permitting any users to read, download, copy, distribute, print, search, or link to the full texts of these articles, crawl them for indexing, pass them as data to software, or use them for any other lawful purpose, without financial, legal, or technical barriers other than those inseparable from gaining access to the internet itself. The only constraint on reproduction and distribution, and the only role for copyright in this domain, should be to give authors control over the integrity of their work and the right to be properly acknowledged and cited" [6]. In last two decades of their existence, open access publications have gained popularity [7] because they are "(...) free to read or use via the Internet and is supported by new technologies and databases" [8]. For Antelman [4] open access information resources could be potentially cited more by other scientists in comparison to fee based information resources. However, some authors like Anderson [10] claims that in case of journal articles "closed articles will be cited more often – simply because they are assumed to be of higher worth, given the older and more prestigious publications in which they appear". Although the use of open access journals has increased in numbers and in quality [10],[11] they are still not universally accepted. Liesegang [5] points out that open access will be finally accepted in scientific community when it becomes stable, when it produces sustainable and fair online business model which will preserve the scientific record and permits ease of exploration.

The goal of open access is to make the content of scientific journals freely available and that the cost of publication is funded via means other than subscription fees [4]. According to Mittell [12] open access should replace exclusive, limited-access, high-priced resources necessary for research and teaching. Gasparyan, Ayvazyan and Kitas [13] suggest that "for academics, broad access to periodicals, theses, books, and presentations is an indispensable tool for upgrading knowledge base and translating it into the skills of their trainees". For Goetsch [14] "open access helps achieve the fundamental mission of the academy - to disseminate knowledge. Users of that research can apply and build on it, and the public can reap the benefits of critical research more quickly".

Funders of academic institutions and research are especially interested in advancement of open access. They "(…) invest in research in order to accelerate the pace of scientific discovery, encourage innovation, enrich education, and stimulate the economy – to improve the public good"[15]. Open access brings academic institutions greater visibility and clearer management information [16]. The result of acceptance of open access could be not only greater accessibility of research but it could also help in attracting new research, new students and help kick-start new collaborations [17].

In education in general, open access brings the following advantages: contribution to core mission of advancing knowledge; democratization of access across all institutions – regardless of size or budget; provision of access to crucial educational materials; increase of competitiveness of academic institutions; enrichment of the quality of students' education; ensuring access to all that students need to know, rather what they (or their school) can afford and contributes to a better-educated workforce [15].

Students can directly benefit from open access because it facilitates unrestricted access to educational material and enables enriched education [16]. Furthermore, open access can ensure students getting the best possible education and these students are not artificially limited by the selection of information resources (they get access to the latest research findings throughout the world [18]). Open access is used by students for writing their term papers and final theses and they can access open access information resources regardless of their social status. Finally, after student finishes his / hers studying open access information resources will remain available [19] unlike fee based information resources. Open access is important for professors who must access to the latest research, so students' education isn't outdated.

Scientists can benefit from open access in a number of ways. First of all, open access can induce "(...) immediate visibility for research output and thus increased visibility and usage of their results" [16]. In addition to sharing the results of their work in form of published journal articles or books, they can share the research data to „(...) make genuine data accessible and preserve it in the long term" [20]. The research data are then often used in new research as well as in education after publication. Some universities in USA such as Harvard, MIT and Stanford recommended or even required deposit of researchers' works in campus digital repositories [14] making this type

of digital information resources more attractive to scientists for publication of their work and for its long term preservation. By helping scientists to disseminate and preserve scientific knowledge, open access information resources accelerate the rate of scientific progress [21].

Science (in general) and the general public can benefit from open access in the following ways [22]: all articles will become freely and universally accessible online - so an author's work can be read by anyone at no cost; the authors hold copyright for their work and grant anyone the right to reproduce and disseminate the article, provided that it is correctly cited; a copy of the full text of each open access article is permanently archived in digital repositories; authors are assured that their work is disseminated to the widest possible audience; the information available to researchers will not be limited by their library's budget, and the widespread availability of articles will enhance literature searching; the results of publicly funded research will be accessible to all interested readers and not just those with access to a library with a subscription; a country's economy will not influence its scientists' ability to access articles because resource-poor countries (and institutions) will be able to read the same material as wealthier ones, although creating access to the internet is another matter. Open access helps in enhancing and accelerating research cycle [16].

Open access has its downsides too. Some publishers have started to take advantage of open access and have become so called predatory publishers. These are publishers which ask hefty fee from authors to publish their paper after the paper is accepted and published [23]. Warlock [24] also discussed criticism of open access for charging authors or their institutions article processing charges which, then "(...) could create conflicts of interest and have a negative impact on the perceived neutrality of peer review, as there would be a financial incentive for journals to publish more articles". Additionally, some open access journals have a low article acceptance threshold so they accept as many papers as they can to collect money (from authors); they lie about peer review process thus ruining the credibility and reputation of the journal once author discover that there was no real peer review; such journals don't care much about digital preservation [23] and they even accept fake scientific papers [25] which can also destroy confidence in open access journals in general.

Despite these downsides, open access presents an important initiative and so far global academic community has benefited from it significantly mostly because works of countless scientists have become more accessible to wider readership. As these information resources are important to students in writing their term papers and final theses, a study was initiated to find out whether or not group of students at the Department of information and communication sciences at the Faculty of Humanities and Social Sciences in Zagreb (FHSS) are using different types of information resources including open access information resources in two courses they attend (one as a part of the undergraduate study and one as a part of the graduate study of information sciences).

IV. USE OF DIGITAL INFORMATION RESOURCES AT THE FACULTY OF HUMANITIES AND SOCIAL SCIENCES IN ZAGREB

The FHSS is one of the largest academic institutions in Croatia so its policies towards use of digital information resources and its position on open access initiative could accelerate the acceptance of this important initiative in other academic institutions in Croatia. The FHSS has one of the few operational digital repositories in Croatia which stores works written by researchers and students at the FHSS [26]. To help development of this and other open access digital repositories, special attention should be given to students' attitudes towards use of digital information resources in general and open access information resources in particular. The basis for the study in this papers are two researchers done in 2012 and 2013 [27][28] at the FHSS about attitudes of students at towards use of digital information resources and modes of use and preservation of digital information. The first research done in 2012 indicated that the students at this faculty are still oriented towards use of printed information resources in the Faculty's library. However, the same research also showed that students at the FHSS do search for digital versions of scientific information resources both in the FHSS library and on the internet [27] as an addition to use of printed information resources. Another research about use of digital information resources done in 2013 showed that students at the FHSS seek unlimited accessibility and availability of digital content that could be used on a number of different electronic devices they own and use. The same research confirmed that students would love to use digital content without any obstacles but they need someone else (a library) to take care of the long term preservation of the digital content they create during their years of studying [28]. The results of these two researches indicated a slow but definitive shift from use of printed towards digital information resources. Wide implementation of open access in Croatia would certainly help students in their studying as well as development of strategies for support to research in higher education institutions in Croatia. This is especially important in the present time of economic crisis when universities have less money for library acquisitions.

V. STUDY OF USE OF DIGITAL INFORMATION RESOURCES IN TWO UNIVERSITY COURSES

This part of the paper is dedicated to the study of use of digital information resources by students of information sciences at the Department of information and communication sciences at the FHSS in Zagreb enrolled in two courses from 2011 to 2013. The purpose of this study is to establish how many different types of digital information resources are used by students free of charge or for fee (full text databases paid by the Croatian government for use by the members the whole Croatian academic community). Such studies help university teachers to determine trends in use of digital information resources by students in a particular course or a program

of study in order to modify and update reading lists for their university courses. Content analysis was used as the method for analysis of students' term papers. The analyzed content was divided into several categories: journal articles (printed), journal articles (available in full text databases), journal articles (open access journals and freely available journals on the Web (which didn't declare explicitly themselves as open access), content on Web pages of academic institutions, content on Web pages of commercial companies, content on Web pages of newspapers and popular magazines, content on Web pages of Web portals, content on Web pages of miscellaneous organizations, content on private Web pages of the internet users, content on Web pages of private organizations, content on Web pages of government organizations, content on Web pages of encyclopaedias, books (printed), books (online), conference proceedings, university lecture materials and MSc and PhD theses. The study was carried out by analysis of the content of lists of references at the end of students' term papers written in courses "Digital collections" and "Internet culture" from 2011 to 2013 (during three consecutive academic years) and each information resource in the each individual list was categorized. The following number of term papers was analyzed in the course "Digital collections": 18 term papers in 2011/2012, 21 term papers in 2012/2013 and 26 term papers in 2012./2013. The following number of term papers was analyzed in the course "Internet culture": 29 term papers in 2011/2012, 23 term papers in 2012/2013 and 23 term papers in 2013/2014. The next part of the paper presents results of this analysis.

Students in both courses were encouraged to use fee based full text databases which offer peer reviewed scientific and professional content in digital format (access to these full text databases is paid by the Croatian government). Access is possible on computers in the library of the FHSS and its Web page.

The first two tables present the total number of term papers per year in the courses "Digital collections" and "Internet culture"; total number of references in one academic year in all term papers in these two courses and average number of references per term paper in each academic year in these two courses.

TABLE I. NUMBER OF REFERENCES IN TERM PAPERS IN COURSE "DIGITAL COLLECTIONS"

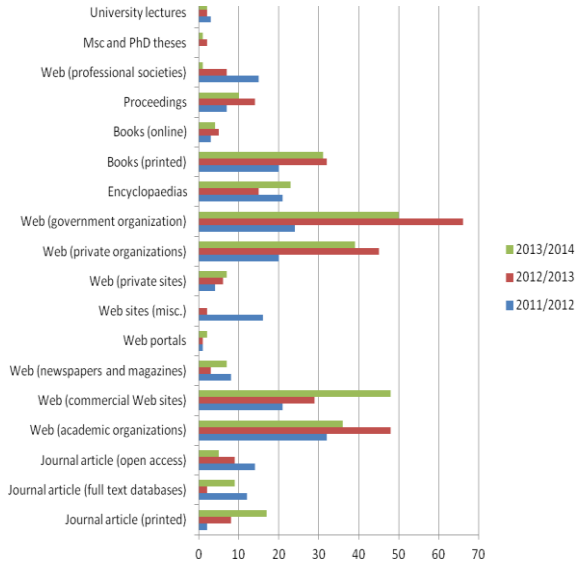
	2011./2012.	2012./2013.	2013./2014.
Total number of term papers per year	18	21	26
Total number of references in all term papers per year	223	296	292
Average number of references per term paper per year	12,38	14,09	11,23

TABLE II. NUMBER OF REFERENCES IN TERM PAPERS IN COURSE "INTERNET CULTURE"

	2011./2012.	2012./2013.	2013./2014.
Total number of term papers per year	29	23	23
Total number of references in all term papers per year	296	205	211
Average number of references per term paper per year	10,20	8,91	9,17

The following two figures present results of analysis of types of information resources listed at the end of each term paper.

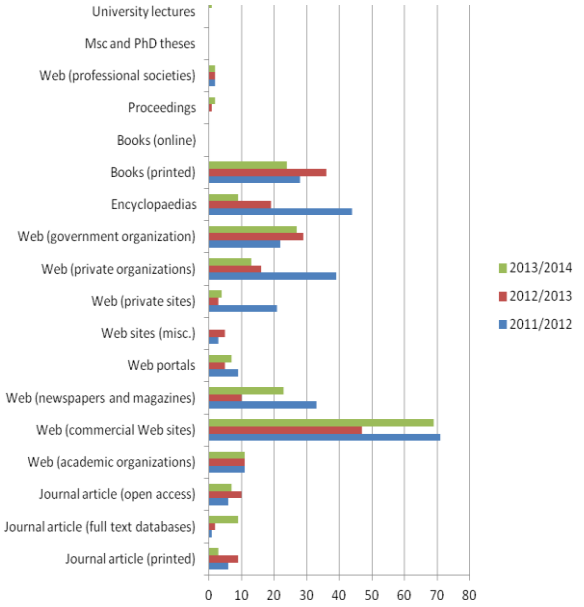
FIGURE I. TYPES OF INFORMATION RESOURCES USED IN COURSE "DIGITAL COLLECTIONS" FROM 2011/2012 TO 2013/2014.



The first figure presents results of use of different information resources in the course "Digital collections". It must be pointed out that the very nature of the course is to teach students different aspects of development, use and management of digital collections and that a significant quantity of content today is published only in digital format. Students are taught to pay attention to the digital nature of the (recently) created human knowledge and its preservation and significant portion of the information resources used in teaching in this course are also in digital format. In this course the following types of information resources were used most frequently by students for writing term papers: Web sites created by different governments (not just the Croatian government), academic institutions, private organizations and commercial Web sites followed by other types. Unlike expected infrequent use of printed journal articles, students in this course use printed books for writing their term papers (books listed in the course reading lists are available in the FHSS library). Additionally, students in this course use online encyclopaedias for writing their term papers which are popular among students [28], however, they are not encouraged to use encyclopaedias

too extensively as they contain abbreviated information and they should read and analyze primary information resources instead.

FIGURE II. TYPES OF INFORMATION RESOURCES USED IN COURSE "INTERNET CULTURE" FROM 2011/2012 TO 2013/2014.



The second figure presents results of use of different types of information resources in the course "Internet culture". In this course, the commercial Web sites are most frequently used as sources of information for writing term papers. Other popular information resources in this course are printed books which are available in the FHSS library, Other popular information resources are Web sites of government organization, followed by encyclopaedias and Web sites of private organizations. Other information resources including printed scientific journal articles and journal article available in full text databases are used less. Journal articles are apostrophized because of their importance in research and teaching and their subscription price. These two types of information resources are published more slowly than articles in online newspapers, popular magazine, on private Web pages etc. and are less attractive for students in this university course. Furthermore, not all of these information resources are scientific; some of them articles in popular magazines and articles newspapers which are simply freely available on the internet.

The analysis showed that students of two university courses has used predominantly digital information in the process of writing term papers while printed information resources were used significantly less during the analyzed period of three consecutive years. The analysis also showed clearly infrequent use of fee based information resources such as journal articles in full text databases. This paper didn't research specific aspects of use of digital informatin resources by students of study of information sciences at the FHSS (like motives for use of specific Web resources) as this will be part of the future reasearch. Nevertheless, it is rather disappointing to see such a low use of this category of digital information resources by students although these resources are highly recommended to them for use in their learning.

VI. CONCLUSION

Today, when digital information resources are essential for research and teaching, one of the biggest problems is access and their unlimited use because a large quantity of these information resources are accessible only on a basis of a paid fee. The fee for a single scientific journal article could be very high if a person paid from his or hers own pocket, so scientific journals are usually made accessible to scientists and students by university libraries. Since universities around the world started to cut back on funds for journal subscription, libraries started to look for other non fee based information resources they could offer to researchers and students. The solution to this problem came in form of open access to information resources, mainly of scientific nature. Academic community was given a number of information resources for use in teaching and research free of charge. However, vast number of journals and books are still unavailable freely and the number of open access information resources has still not grown big enough to replace the fee based resources. As a result, academic community uses both categories of information resources as needed. To see whether students of two university courses (one undergraduate and one graduate course) use open access information resources and to what extent, a study was initiated. The results showed low use of fee based information resources and extensive use of digital information resources available on the internet for free. Some of these information resources are marked as open access and majority is not but still fall under broad definition of open access. The results of the study clearly indicate orientation of students in two analyzed courses towards use of digital information resources and towards free information resources. Additional research would be needed to find out to what extent students at the FHSS are using open access information resources, with what motives and to find out their good and bad experiences in access to free of charge information resources on the internet. Such results would help teaching staff in creating new reading lists for their courses and the FHSS library to select information resources on the internet for use by students. Positive experiences at the FHSS could be shared by other faculties in Croatia in order to enrich teaching and research in their institutions.

The organization of classes and assessment system using Moodle

T. Alajbeg, T. Horvat, T. Novak
Polytechnic of Zagreb, Department of Electrical Engineering, Zagreb, Croatia
trpimir.alajbeg@tvz.hr; thorvat3@tvz.hr; tnovak@tvz.hr

Abstract - The organization of classes and assessment system on the Personal Computer Applications (PCA) course, in the professional study of electrical engineering at the Polytechnic of Zagreb, is based on the Moodle system. Moodle is widely used open source application designed for e-learning. This system enables students to prepare for lectures and exercises, while emphasis is placed on their independent and individual work. Students have access to all the necessary teaching materials, applications, tasks and direct communication with the teacher even outside the class schedule. The aim of the PCA course is to point out the wide range of possible applications of personal computers, but still having in mind specific needs for a study of electrical engineering. This paper presents the organization scheme and content of the course lab exercises with the system of assessment, all based on the mentioned objectives and the use of e- learning system, Moodle.

I. INTRODUCTION

E-learning systems are in many aspects different from the traditional way of teaching both – for the teacher, learning – for the students and assessment –for both the teacher and students. They vary in the availability and transfer of learning (teaching) materials and information, method and time of interaction - communication with the teacher. The manner and speed of assessment and the impact of subjective parameters in the evaluation are also significantly different.

However, through the e-learning system, it is not possible to fully detect the sphere of interest of the students and their motivation. It is very difficult to distinguish and identify the sources of problems encountered in learning, use of instruments and computer applications. Missing component of empathy in communication makes inspiring and motivating students virtually impossible. In these segments direct contact between students and teachers is irreplaceable.

Combining the advantages of both methods of teaching / learning (e-learning and person to person), both modes of interaction and communication between students and teachers in the teaching process, it is possible to achieve a better effect for the mutual benefit.

The system of the teaching and assessment for the Personal Computer Applications (PCA) course, in the professional study of electrical engineering at the Polytechnic of Zagreb, is based on that ideas. Moodle, licensed and free open source application, is used as a e-learning system on the PCA course. Since the aim of the PCA course is to point out the wide range of possible applications of personal computers, the use of Moodle itself, since it is implemented in the course, may be considered as a part of the teaching course.

Laboratory (and construction) exercises are the practical and individual work of each student and make a total of half hourly rate of the course. As the course is at the beginning of the study, the laboratory exercises include the set of general computer applications a future engineer might need. Certainly, laboratory exercises are a complex form of teaching because, in addition to the readiness of students for the subject of a single exercise, their independent work and understanding of the results are expected. Students preparation for each topic is required.

However, availability of computer applications for work / exercise at home has to be considered. This may be achieved by allowing free applications to students, open source applications or demonstration versions of commercial software packages. Thus, wherever possible, the option of choosing an alternative, free tools is given. PCA laboratory exercises are designed with respect to the above requirements and needs. It requires a certain level of teachers' productivity within a predetermined time, therefore automated evaluation is preferred.

II. MANAGING ATTENDANCE RECORDS AND STUDENT'S ACHIEVEMENTS OVERVIEW

Administration tasks related to teaching are a necessity, although time consuming. Also, there is a need for reducing possible errors if not to the zero level, then certainly to a minimum. Administration tasks imply keeping record of each student's attendance during exercises as well as keeping track of the necessary conditions that need to be fulfilled so that a student could enter for an exam. The same refers to students' assessment. Since about 230 students enroll the course each year, this automated management administration shows its importance and advantages. Total time required to execute these types of tasks is reduced and the possibility of oversights, omissions and errors of the teachers are minimized. The ultimate goal of this kind of administration is to have an overview of the achievements, whether cumulative or individual for each student.

The particularity of attendance recording is that some students do not join their group. They attend exercises in one of the other groups, usually with another teacher. With the traditional „pen and paper" method of keeping

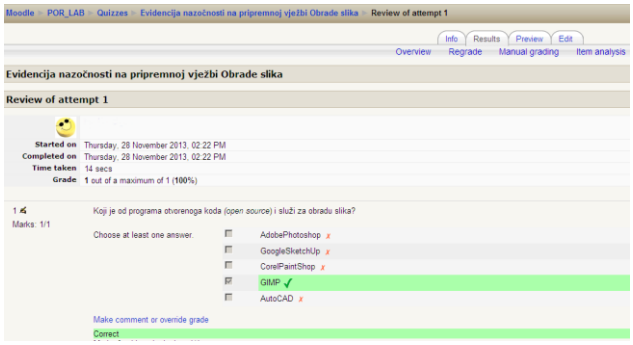

Figure 1 Example of attendance quiz question

records, that would represent additional work and thus an additional waste of time increasing the possibility of error due to a larger number of intermediate steps. Using Moodle capabilities with respect to the particularities mentioned above, records in the laboratory are made in the form of a quiz. All students present during the lab exercise receive a one-time password from the teacher in order to access the attendance quiz. The quiz is a multiple choice test with just one correct answer. Students have up to 2 minutes to submit their answers. When the test is finished, the password is changed to prevent possible distributing passwords and cheating. The only purpose of the quiz is keeping track of students' attendance, without any influence on the assessment issue. The question is simple so the students can easily and quickly choose the correct answer. If the student chooses the right answer, they get 1 point for attendance. Figure 1 shows an example of such a question.

Students answers are stored in the database. At the end of the exercise cycle, the review score clearly shows the attendance records (Figure 2). Of course, there is the possibility that a student has chosen a wrong answer. In that case the test shows 'zero' points, as shown in Figure 2., the teacher can delete that student's attempt from the database and give the student another chance. However, this is not the best solution. A better way for the teacher is to correct the answer manually. If the 'zero' grade is detected later, by the time the test was taken it can be checked i f the student had actually attended. Moodle offers several ways of verification when attendance is concerned, but this method proved to be the most effective.

Given that the administration of students' achievements in laboratory requires a plain and unique review in one place, all the relevant parameters are classified as 'Grades'. Selecting 'Grade' for each student displays the interface shown in Figure 3. The way of assessment of student's work during laboratory exercises will be presented in another chapter. It is possible to export this review in Excel or OpenOffice spreadsheet.

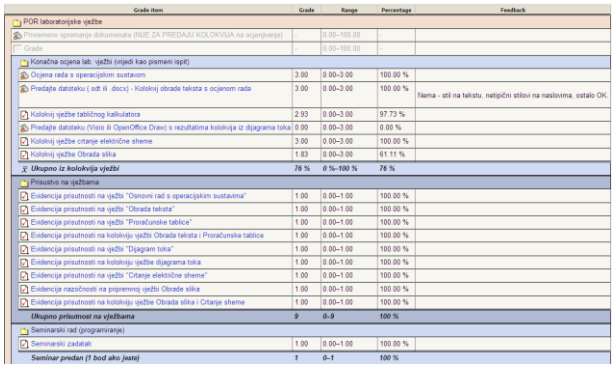

Figure 3 Unique (cumulative) overview of the achievements for each student

III. TOPICS AND PREPARATION

According to the Bologna process, each ECTS credit which a student receives when they pass, the exam includes a certain number of hours of work at home. Students need to master the use of general computer applications at the beginning of the study because they will probably use them in their private and professional lives, regardless of specific applications important in electrical engineering and will be addressed in special courses throughout the study. Taking these facts in account provides students access to those applications on their computers and at home. They can use them to attend lab exercises, practice after the exercises for exams and later in study or at work, preferably without additional investment in buying the commercial software packages. That is enabled by using open source applications or demonstration versions of commercial software packages.

Moodle allows opening a specific topic in advance, making it visible to students. All topics do not have to be visible in advance. Usually visibility is set in a way that students can see earlier themes, current topic and the first next topic. Information concerning the purpose of the exercise with activities and skills that should be mastered, as well as materials are included. Material required for the preparation of exercises can be found in 'Resources'. Materials usually consist of an Internet link to the literature and basic notes on the application software that will be used in the exercises. Informations on how and where a student can download it legally and free of charge, are also included. An example of the above-mentioned for two topics is shown in Figure 4.

Combining the above-mentioned principles and features, laboratory exercises enable students to work with applications that cover the following areas, some of them in a couple of exercises:

A. Basic use of operating system

The operating system used is Microsoft Windows 7. It is free and legally available for students through MS DreamSpark program for members of academic institutions. This exercise places an emphasis on working with files and folders and their organization and retrieval, installation and starting user and system applications, uninstalling programs and Windows components and managing peripherals.

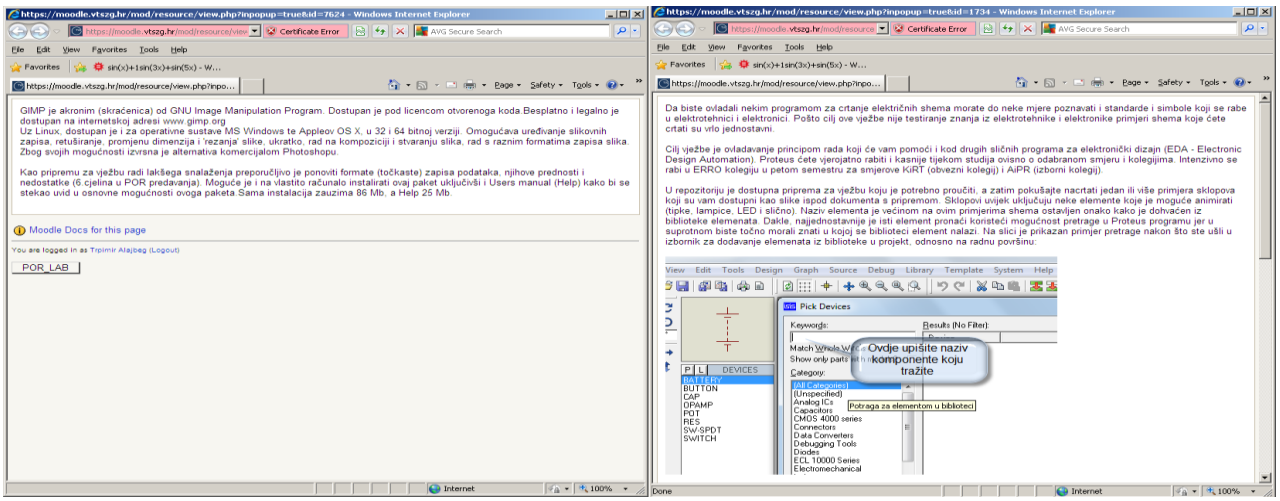

Figure 4 Access to the application and materials for the preparation

B. *Office Suite*

Word and Excel, from MS Office 2013 package, are used. Since this is not a free software package available to students, as an alternative possibility is offered work in the open source Apache OpenOffice package, which also includes word processing and work with spreadsheets. The aim of the text processing exercise is to master basic procedures which includes working with the application and adapting it to the user, creating documents, text entry and search, text formatting and working with objects and preparation for printing. In addition to the basic operation and the adaptation to the user, the goal of working with spreadsheets is to master cells and worksheets, formatting content, working with formulas, functions and graphs.

C. *Flowcharts*

This exercise includes working with Visio, form MS Office 2013 package. It is free and legally available for students through MS DreamSpark program for members of academic institutions. The aim of this exercise is to understand what flowcharts are and how to approach to a task or to solve a problem by using flowcharts.

D. *EDA (Electronic Design Automation) program*

Proteus ISIS package is used. Students can free and legally download demonstration version of the program. The main restriction, in comparison to a full version, is that the clip can not be saved. Of course, there are several more restrictions, but in this course, they are irrelevant. The aim of the exercise is to master the operating principle that can help with later use of other programs for electronic design or with simulation of circuits work.

E. *Image processing*

GIMP application, available under open source licenses, is used. The aim is to become familiar with the basic operations with the computer processing of images (photos). The exercise covers setting the working environment, retrieving, creating and saving documents, sizing images, work with different formats of images, their features and capabilities as well as the most suitable application. The purpose and the opportunity to work with layers and masks, is also included.

IV. ASSESSMENT – TESTS OF KNOWLEDGE AND SKILLS

In this segment are valid starting points listed in Section II. (reducing the number of intermediate steps and the amount of time spent, reducing the possibilities of teachers omissions to a minimum...). An additional requirement is reducing the potential teachers subjectivity in assessing students' works. In near future this influence should be reduced to zero. One possible way is the use of fully automated assessment. Of course, automated assessment is not in all cases the most appropriate and does not appropriately reflect student's level of skill working with a PC application. No less important in the verification of knowledge is to reduce and ultimately prevent the eventual inappropriate actions like copying. Proceeding from the above, the following options are applied on laboratory exercises:

A. *Demonstration*

The traditional method of verification is the students demonstration of work on a computer. This method is applied in Basic operating system exercise. Students present their skills of operating a computer to the teacher. The teacher manually enters the grade in Moodle.

B. *Evaluating submitted works*

For some exercises it's the most appropriate for a student to submit his work to Moodle and the teacher later reviews and evaluates it. This method of assessment is used in the text processing and flowcharts exercises. A module is opened for file submission in Moodle. Students, upon completion of work, submit their documents. The teacher, besides entering the grade (assessment), can enter a comment that will be visible to the student with the grade. Usually, as a comment are entered some notes and observations. This, along with criteria known in advance, makes the grading process more transparent. The student sees what was done well or omitted and can immediately respond in case of teachers oversight.

In this mode of assessment is not possible to use the Safe Exam Browser (details in the following paragraphs) because other (e.g. Word) applications should be opened along with the test. However, inappropriate actions can be made difficult by requiring the understanding of given informations rather than merely stating the facts. Another way is creating a sufficiently large base of questions that are randomly selected, changing the sequence of questions and responses (shuffle within questions, shuffle within answers).

C. Automated assessment

In addition to the significantly reducing the time spent evaluating and the possibility of erroneous results , another benefit is the reduction of the possibility of inappropriate actions during the test. This is made possible by using the Safe Exam Browser from which students access the tests. The window of that web browser opens over the entire screen without any navigational elements. Only permitted actions are solving the test, using calculator and logging off from the computer. Use of this browser disables, among other things, switching to another application, use of copy / paste, use of e-mail client and visiting other Internet sites, such as sites and objects with references to relevant materials.

In this mode of assessment Moodle offers more ways of answering the questions, one of which is in between the other tests used : Multiple Choice (single or multiple answer); Short Answer, Numerical answer (students write in response word, symbols or numbers); Matching (pairing of terms and their meaning or use). After the submission of the test , or when the time expires, students immediately see their score. The score is stored in the database and displayed in an overview as shown in Figure 3.

In this mode of assessment it is possible to analyze students' scores on tests in a manner that identifies which questions were too difficult or too easy. Questions can then be either reformulated or simply removed - deleted from the database without re- creating an existing test. Figure 5, in the lower right part, displays the analysis of the success in answering each question within a test for the current group of students (students of the academic year 2013/2014). There is also a display of successful answering a question that involves students and other groups (previous years).

Figure 5 Average number of points for a particular question

V. CONCLUSION

Basic use of computers is not easy to present to the participants who come from different backgrounds. They had different availability of information technology and the Internet, thus varying degrees of knowledge. Their previous interest in the subject can not be ignored as well. The use of a personal computer can not be reduced only to the use of electronic mail, social networking and sharing photos and video content. These are the reasons why the laboratory exercises of this course were designed in the manner described in the paper. ,

Moodle in being used in PCA lab exercises during the last six years, and the student's feedbacks are very positive. General impression is that using Moodle in combination with direct teacher - student contact is a good method and it is easy to identify where further focus is needed, on what topics and which students. This approach to the organization of teaching requires a good and thorough preparation materials in Moodle, but it constantly improves exercises, making them better for each succeeding generation.

Abstract – Verificator is an educational tool meant for learning syntax and semantics of the C++ programming language at the introductory programming courses. With an objective to explore quality of Verificator from students' perspective, a pilot study was carried out. Data were collected by means of an online post-use questionnaire. The analysis of collected data uncovered pros and cons of Verificator perceived by novice programmers. Empirical findings are presented and discussed.

I. INTRODUCTION

Drawing on our teaching experiences at different programming courses, an initial version of an educational tool meant for writing code in C++ programming language named as Verificator was developed [1]. The idea behind the development of Verificator emerged from the observations of teachers. Students often tend to adopt some bad programming habits in their attempt to pass the exam. For instance, some students have learned even big fragments of program code by heart, almost without any understanding. There were also cases when students have written large amounts of program code without any syntax or logical testing. The set forth has resulted in a huge number of errors, discouraging students from learning programming. The use of Verificator prevents such bad practice and motivates students to adopt good programming habits.

The evaluation of the quality is an integral part of the life cycle of every software product. According to ISO/IEC 25000 [4], quality is a "degree to which a software product satisfies stated and implied needs when used under specified conditions". In the Software Product Quality Requirements and Evaluation (SQuaRE) series of the international standards [5][6] the quality evaluation framework consists of three models: the product quality model, the quality in use model, and the data quality model. Each of the aforementioned models offers a set of quality characteristics relevant to various groups of stakeholders.

This paper deals with the assessment of the perceived quality of Verificator from students' perspective. The remainder of the paper is structured as follows. Next section provides a brief overview of theories and models that form the background to our research. Features of Verificator are described in the third section. Findings of the pilot study are presented in the fourth section. Conclusions and future research directions are contained in the last section.

II. LITERATURE REVIEW

A. Theoretical background

The constructs that were used and examined in our research are based on several models: Technology Acceptance Model (TAM), Information System Success Model (ISSM), Unified Theory of Acceptance and Use of Technology (UTAUT), Expectation Confirmation Theory (ECT) and Theory of Flow (TOF).

TAM is a theoretical framework which provides insight into the determinants of the adoption and use of the information technology. From its latest version [7], we adopted four different constructs. Perceived ease of use is the degree of ease associated with the use of Verificator. Perceived usefulness represents the extent to which a student believes that using the Verificator will enhance his or hers performance in assignment performance. Self-efficacy denotes the degree to which a student believes that he or she has the ability to perform specific assignment by means of Verificator. Relevance refers to student's perception regarding the degree to which Verificator is suitable for the task at hand.

ISSM was developed as a framework and model for measuring the complex-dependant variable in IS research. For our study, we adapted one construct from its ten-year update [8]. System quality is the extent to which a student perceives the quality of specific aspects of interaction with Verificator.

UTAUT represents a synthesis of eight technology acceptance studies. From its recent extension [9] we adapted one construct. Performance expectancy (in our study added value) is the degree to which the use of Verificator will provide benefits to students.

ECT [10] examines cognitive beliefs and affects influencing one's intention to continue using information systems. Two constructs were adopted from this theory. Confirmation is the degree of fulfilled expectation when student was using the Verificator. Satisfaction refers to a pleasurable or positive emotional state resulting from the use of Verificator.

TOF [14] is a model which examines mental state, involvement and enjoyment of a person in the process of some activity. One construct was adopted from this model. Flow denotes the extent to which a student is fully immersed and enjoys interacting with Verificator.

Apart from the aforementioned, we added three additional constructs that are specific for our research. Helpfulness is the degree to which Verificator helps in better understanding of programming concepts. Good programming habits refer to the extent to which a student can utilize better his or hers programming skills and develop good programming habits when using the Verificator. Feedback represents the degree to which Verificator notifies users about the progress or status of the task at hand through appropriate messages.

B. *Related work*

There are many tools that were developed to help students' education process of computer programming. A brief overview of these tools is offered in [3]. Lane and VanLehn [18] found that tools developed for learning programming can positively influence on students' perception and motivation.

TAM is the most popular model for technology acceptance in the online learning domain [19]. There are a few studies that deal with constructs of TAM in the field of computer programming but they are not specific to a certain learning tool. Orehovački et al. [2] uncovered that perceived usefulness and perceived ease of use have influential role weather students will accept the learning tool and future behaviours towards its use. According to Ramalingam et al. [13], self-efficacy and mental models significantly affect the process of learning programming. Webster et al. [20] emphasize that flow plays a significant role in human-computer interactions. Results of the study conducted by Potosky [17] showed that there is a link between flow and post-training programming efficacy. Previous programming experience can also have significant role in programming education and acceptance of supporting learning tools [12][16]. Finally, findings of several studies indicate that computer anxiety correlates with the students' prediction of their final grade and with perception of their own programming skills and habits [11][15].

The lack of research on the acceptance of tools aimed for teaching programming together with the set forth findings motivated us to initiate a study on the assessment of selected aspects of the perceived quality in the context of the educational software named as Verificator.

III. VERIFICATOR

Verificator[1] is an educational tool developed with the aim to improve the process of teaching programming at the university beginners' level thus helping students to acquire programming skills more easily [1]. The user interface of Verificator is displayed in Figure 1.

After introducing some basic functionalities like preventing copy/paste of program code and obligatory syntax checks within given intervals, over years, Verificator has been enriched with several novel features such as program testing mode, tutor, time control, program structure analysis, etc. The aforementioned functionalities will be explained in more detail in the following sub-sections.

A. *Personalization of programs*

Students are asked to fill out the welcome form with some general information about themselves and the assignment (e.g. name, id, program name and description). These data are included into the program code in the form of comments together with a checksum by means of which it can be examined whether the program code was completely written in Verificator or not.

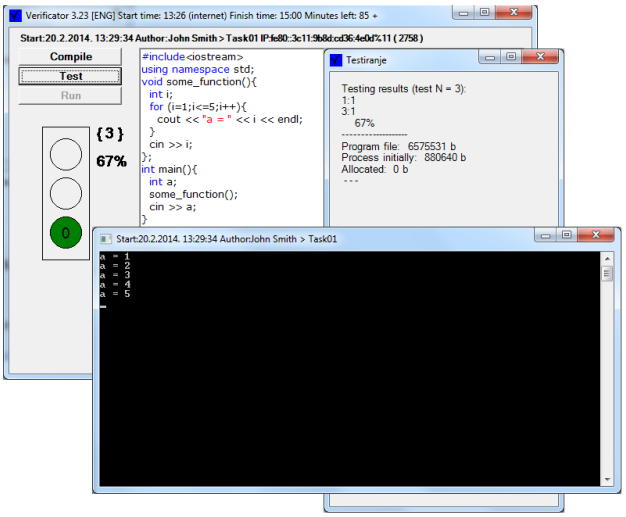

Figure 1. User interface of Verificator

B. *Time limitation for solving the assignment*

Students should solve the assignment within a predefined time interval. To avoid the problem with various system time at different computers, the time is controlled with the use of time servers on the Internet. After the time runs out, a student can still run the program, but he or she cannot modify it.

C. *Prevention of copying programs from colleagues*

Verificator prevents copying program code from external sources. In that respect, the overall code, apart from the given library, must be entered by the student. This feature is connected with obligatory intervals of syntax and logical program testing. Therefore, it is not possible to retype the program code. Instead, it has to be verified within the specified intervals.

D. *Adoption of good programming habits*

Findings of prior studies [1][3] indicate that students who employ standard programming environments to some extent tend to adopt bad programming habits such as learning programming code by heart, programming without syntax and logical checks, etc. Verificator requires from students to check the syntax of their programs after every 10 new lines of code which is graphically illustrated with traffic lights (e.g. red light indicates that is no longer possible to compile the program). Furthermore, program has to be checked logically within the given intervals (expressed in the number of program blocks) in a way that all program blocks have to be reached during the execution.

[1] http://gpml.foi.hr/teaching_tools.html

E. Help for easier detection of syntax and logic errors

Apart from the standard errors and warnings provided by the compiler, Verificator offers further explanation of possible causes of these errors (e.g. unmatched curly brackets or parentheses, incorrect use of certain operators, etc.). In addition, Verificator also contains a tool for the analysis of the program structure as well as the debugging tool.

IV. Pilot Study

A. Procedure and Apparatus

During the winter semester of the academic year 2013/2014 the study participants employed Verificator to solve fifteen diverse lab-based programming assignments. Students also had the opportunity to use Verificator in order to prepare themselves for the lab-based exercises which took place once a week. At the end of the semester, students were asked to complete the post-use questionnaire consisted of 7 items related to their demographic characteristics as well as 50 items meant for evaluating twelve different facets of the perceived quality of Verificator in the context of teaching programming. The responses to the items referring to specific aspects of the perceived quality were modulated on a five-point Likert scale (1 – strongly agree, 5 – strongly disagree).

B. Participants

A total of 121 respondents ranging in age from 19 to 28 years (M = 20.89, SD = 1.315) took part in the study. The sample was composed of 83.47% male and 16.53% female second-year undergraduate students enrolled in the Information Systems study programme. The majority of students (43.80%) perceived their programming skills as good. Similarly, most of the respondents (56.20%) had good knowledge of C++ programming language syntax. Considering the frequency of using the Verificator, 83.47% of students employed it between once and twice a week while 63.64% of them used the aforementioned tool between one and three hours per week. Finally, the majority of participants (84.30%) had up to four years of programming experience.

C. Findings

Responses to the post-use questionnaire items related to the perceived quality of Verificator in teaching programming are presented in Table 1 (see Appendix). Items marked with asterisk are reverse coded. Results of data analysis indicate that majority of pilot study subjects (61.49%) believe that the employment of Verificator contributes to the development of good programming habits. For instance, 63.64% of students reported that Verificator motivates them to be more disciplined while solving the problem-based assignments (M = 2.40, SD = 1.158). In addition, 59.50% of participants stated that Verificator encourages them to write their program solutions more clearly (M = 2.62, SD = 1.349).

The collected data also imply that 54.88% of students perceive Verificator as a helpful tool in the context of teaching programming. While 63.64% of respondents reported that Verificator is advantageous in the interpretation of syntax errors (M = 2.46, SD = 1.133), merely 44.63% of them believe that Verificator explains messages provided by the interpreter in a more intuitive manner (M = 2.74, SD = 1.061).

As can be observed from the responses to questionnaire items, 64.30% of study participants think that messages provided by Verificator are of high quality. Namely, majority of them (73.55%, 62.81%, 62.81%, 62.81%, and 59.80%, respectively) agree that messages displayed by Verificator are useful (M = 2.17, SD = 0.898), understandable (M = 2.42, SD = 0.955), accurate (M = 2.30, SD = 0.823), trustworthy (M = 2.28, SD = 0.839), and clear (M = 2.45, SD = 0.939).

The data gathered from study participants also indicate that 46.28% of students believe that Verificator has sufficient level of system quality. Namely, 69.42% of the respondents are pleased with the responsiveness of Verificator (M = 2.32, SD = 0.896). On the other hand, only 29.75% of them agree that Verificator is stable and reliable in its operation (M = 3.25. SD = 1.113).

Furthermore, the findings of the pilot study imply that Verificator made an impression on only one third (33.33%) of students. More specifically, 40.50% of participants reported that interaction with Verificator was a frustrating experience for them (M = 2.93, SD = 1.209). On contrary, 31.40% of study subjects were satisfied with using the Verificator (M = 3.13, SD = 1.072).

According to the results of data analysis, only 41.05% of students agree that the interaction with Verificator was as they expected. While 48.76% of participants reported that majority of their expectations related to interaction with Verificator were confirmed (M = 2.68, SD = 1.035), 34.71% of them stated that the employment of Verificator has not met their expectations (M = 3.03, SD = 1.016).

As can be observed from the responses to questionnaire items, 30.74% of study participants believe that frequent use of Verificator improves their programming skills. For instance, 45.45% of students think that there is a positive correlation between frequency of using the Verificator and number of points obtained during lab-based sessions (M = 2.93, SD = 1.219). On contrary, 36.36% of participants reported that frequency of using the Verificator has nothing with their efficiency in learning programming concepts (M = 2.78, SD = 1.092).

Considering the results of data analysis, Verificator is a relevant tool for teaching programming. Namely, 46.28% of students think that Verificator is convenient tool for learning programming concepts (M = 2.85, SD = 1.188).

Data displayed in Table 1 imply that 44.30% of study participants perceived Verificator as useful tool for teaching programming. More specifically, 50.41% of students agree that employment of Verificator improves their effectiveness in understanding both syntax and semantics of the C++ programming language (M = 2.78, SD = 1.165). Moreover, 38.02% of respondents believe that they can learn programming concepts more efficiently when they use Verificator than when they employ teaching materials (e.g. textbooks, educational artefacts deployed on LMS, etc.) for the same purpose (M = 2.93, SD = 1.146).

Results of the data analysis also indicate that majority of respondents (66.94%) believe that using the Verificator

does not require a lot of effort. Namely, 76.03% of students reported that is easy to learn to operate the Verificator (M = 2.03, SD = 0.921). Similarly, 60.33% of them stated that is easy to become skilful at using the Verificator (M = 2.33, SD = 1.028).

As can be observed from students' responses, 42.81% of them think that Verificator successfully focuses and holds their attention while making the solution of the problem-based assignment. More specifically, 53.72% of study participants reported that they are completely focused on solving the assignment while they are using the Verificator (M = 2.71, SD = 1.294). Furthermore, 30.58% of them stated that nothing can distract them while they are writing the program code in the Verificator (M = 3.16, SD = 1.162).

Finally, data presented in Table 1 indicate that majority of respondents perceived themselves as self-efficient in the context of using the Verificator. For instance, 8.26% of students believe that they could use Verificator only when someone would instruct them what to do (M = 4.07, SD = 0.941). In addition, 47.93% of study participants think that they could use Verificator even if they had not employed similar tools before (M = 2.73, SD = 1.162).

V. Discussion and Conlusion

The objective of this paper was to explore diverse facets of the perceived quality in use of the educational tool Verificator. For that purpose a pilot study was carried out during which the post-use questionnaire was developed and administered among information systems students. An analysis of collected data revealed strengths and weaknesses of Verificator. The high quality of the displayed messages, the effortlessness in use and the effect on the development of good programming habits are the main Verificator's advantages. For instance, 64.30% of students believe that messages displayed by Verificator are beneficial and constructive. In addition, 61.71% of respondents find Verificator easy to use. Finally, 61.49% of study participants think that Verificator significantly contributes to the development of good programming habits. On the other hand, the low level of the perceived satisfaction, relevance in the context of teaching programming, and confirmation of expectation are major disadvantages of Verificator. More specifically, only 33.33% of students finds the interaction with Verificator pleasant. Besides, 35.26% of study participants think that Verificator is appropriate tool for learning programming. Finally, 36.09% of respondents believe that the use of Verificator has met their expectations.

Considering all the aforementioned, the introduced questionnaire can be employed for measuring the quality of educational tools meant for teaching programming. Moreover, the proposed quality attributes can be used as a background for future research advances in the field. Given that the work presented in this paper is a part of an ongoing research, our future research efforts will be focused on modelling interrelations among determined quality attributes.

APPENDIX

TABLE I. RESPONSES OF STUDENTS TO QUESTIONNAIRE ITEMS RELATED TO THE PERCEIVED QUALITY OF THE VERIFICATOR

Items	Strongly Agree	Agree	Neutral	Disagree	Strongly Disagree
Good Programming Habits					
Verificator encourages me to prepare myself better for the lab-based exercises.	18.18%	43.80%	19.83%	9.09%	9.09%
Verificator stimulates me to write a program code more clearly.	20.66%	38.84%	14.05%	10.74%	15.70%
Verificator encourages me to be more disciplined while writing a program code.	22.31%	41.32%	17.36%	12.40%	6.61%
Verificator stimulates me to better manage my time during the lab-based exercises.	23.14%	37.19%	21.49%	8.26%	9.92%
Verificator encourages me to think more while solving the problem-based assignment.	15.70%	46.28%	19.83%	10.74%	7.44%
Helpfulness					
Verificator is helping me in the interpretation of syntax errors that occur in the program.	16.53%	47.11%	18.18%	9.92%	8.26%
Verificator is helping me find logical errors that occur in the program.	7.44%	51.24%	16.53%	16.53%	8.26%
Verificator enables me a better insight into the structure of the program.	13.22%	40.50%	23.14%	13.22%	9.92%
Verificator clarifies messages of the interpreter in a more intuitive way.	9.09%	35.54%	36.36%	9.92%	9.09%
Verificator is helping me in debugging the program.	11.57%	42.15%	23.97%	14.88%	7.44%
Feedback					
The messages displayed by Verificator are clear.	12.40%	47.11%	26.45%	11.57%	2.48%
The messages displayed by Verificator are understandable.	12.40%	50.41%	23.14%	10.74%	3.31%
The messages displayed by Verificator are useful.	20.66%	52.89%	17.36%	7.44%	1.65%
The messages displayed by Verificator are accurate.	14.88%	47.93%	30.58%	5.79%	0.83%
The messages displayed by Verificator are trustworthy.	16.53%	46.28%	30.58%	5.79%	0.83%
System Quality					
Verificator has all the necessary functionalities.	8.26%	34.71%	25.62%	22.31%	9.09%
Verificator is stable and reliable in operation.	4.13%	25.62%	25.62%	30.58%	14.05%
Verificator contains various forms of user help.	4.13%	31.40%	35.54%	22.31%	6.61%
The response time of Verificator is acceptable.	12.40%	57.02%	19.01%	9.09%	2.48%
Verificator contains mechanisms that prevent users to make mistakes during the use.	16.53%	37.19%	23.97%	15.70%	6.61%
Satisfaction					
I am pleased with using the Verificator.	3.31%	28.10%	33.88%	21.49%	13.22%
Using the Verificator was a frustrating experience for me.*	13.22%	27.27%	21.49%	28.93%	9.09%
I think that Verificator is an excellent tool for teaching programming.	5.79%	24.79%	34.71%	19.01%	15.70%
Confirmation					
Most of my expectations related to the use of Verificator were confirmed.	9.92%	38.84%	30.58%	14.88%	5.79%
The interaction with Verificator has not met my expectations.*	8.26%	19.83%	37.19%	29.75%	4.96%
I expected the benefits from using the Verificator would be higher than they actually were.*	9.09%	30.58%	35.54%	21.49%	3.31%

* reverse coded items

TABLE I. CONTINUED

Items	Strongly Agree	Agree	Neutral	Disagree	Strongly Disagree
Added Value					
The students who employ the Verificator more often get higher scores than those who use it infrequently.	8.26%	37.19%	23.97%	14.88%	15.70%
The students who employ the Verificator on a regular basis pass the course earlier than those who use it less frequently.	7.44%	27.27%	35.54%	16.53%	13.22%
The frequency of using the Verificator does not have significant effect on students' efficiency in learning programming concepts.	15.70%	20.66%	38.84%	19.83%	4.96%
The frequency of using the Verificator has significant effect on students' effectiveness in gaining programming competence.	3.31%	23.14%	42.98%	18.18%	12.40%
The frequency of using the Verificator does not have significant effect on students' productivity in solving problem-based assignments.	14.05%	26.45%	37.19%	18.18%	4.13%
Relevance					
Verificator plays an important role in learning programming.	6.61%	18.18%	42.98%	19.83%	12.40%
Verificator is appropriate for solving various problem-based assignments.	5.79%	28.93%	28.93%	23.14%	13.22%
Verificator is suitable for learning programming concepts.	9.92%	36.36%	24.79%	16.53%	12.40%
Perceived Usefulness					
Using the Verificator improves students' efficiency in understanding the programming concepts.	6.61%	38.02%	28.10%	17.36%	9.92%
Using the Verificator enhances students' effectiveness in understanding the syntax and semantics of the programming language.	9.92%	40.50%	22.31%	16.53%	10.74%
Using the Verificator, students can learn programming concepts much faster than when employing teaching materials for the same purpose.	8.26%	29.75%	25.62%	22.31%	14.05%
Using the Verificator, students can understand the syntax and semantics of the programming language much easier than during lectures.	7.44%	34.71%	26.45%	19.83%	11.57%
Verificator is useful for learning programming.	9.92%	36.36%	23.14%	19.01%	11.57%
Perceived Ease of Use					
Learning to operate the Verificator is easy.	29.75%	46.28%	16.53%	5.79%	1.65%

Abstract – Physicists research numerous interesting physics problems, among them the behaviour of liquid crystals. These problems can be very useful for illustrating general principles of physics, and so we worked to include them in our natural science program. In the frame of a project entitled "Introduction of current research interdisciplinary topic into education - liquid crystals" we prepared static and dynamic components for e-learning materials to highlight some of the key properties of typical liquid crystalline phases and some structures that appear in different geometrical boundaries or in bulk systems. The materials produced, and an analysis of the appropriateness of different types of e-learning materials for different levels of education (including primary education, secondary education, and physics courses for educational and engineering studies) are described in this article.

I. INTRODUCTION

Physics in primary and secondary school is far from being a popular subject. Several reasons influence its popularity but at least one of them is an insufficient number of examples of the applicability of physics. In Slovenia, the physics major topics in the current curriculum are at least a hundred years old and they are not interesting from the point of view of many students. Yet, they need to be a part of curriculum, because without them, contemporary Physics cannot be understood. The integration of modern topics into the physics curriculum in primary and secondary schools can increase students' interest. One of the fundamental motivational factors is the perception of students that the topics they study are contemporary and relevant, and in physics we should pay more attention to these factors. It would be unwise, however, to put topics beyond the comprehension level of the students on the curriculum; therefore, contemporary topics should be carefully chosen.

Liquid crystals are a modern topic that is very suitable for the teaching of physics [1-4]. Students are exposed to numerous applications of liquid crystals in every-day life. When teaching the principles of liquid crystals, it is essential to explain the liquid crystals' phases. Liquid crystals can be demonstrated using mechanical models or with e-learning materials. We can create many different static and dynamic components for e-learning materials about liquid crystals. For this purpose, e-learning materials were constructed to help students visualize the main liquid crystal phases (nematic, smectic-A, smectic-C) and phase transitions. By using suitable arrangements of the dynamic components of e-learning materials, we succeeded in simulating the phase transitions of liquid crystals.

In this article, our E-learning materials dealing with different static and dynamic components are presented. The efficiency of different types of components is discussed, based on our observations. The intended users of our e-learning materials on liquid crystals [5-7] are primary and secondary school students. A large part of the materials presented were developed in the frame of a project entitled Development of Natural Science Competences [8].

II. DIDACTIC ASPECT OF E-LEARNING MATERIALS

For our purpose, we divided e-learning materials concerning liquid crystals into static and dynamic categories, based on the type of components used in the e-learning materials. Static e-learning material contains mostly text in two languages: around 3300 characters of text in the Slovenian language and 4300 characters of text in English. Static e-learning materials also contain graphic elements, for example, figures and equations [5]. The static e-learning material is composed of 5 screens. The first screen gives a short summary of liquid crystals. The second to fourth screens contain theory and mathematics equations pertaining to liquid crystals. The last one is reserved for conclusions and references.

We prepared two types of dynamic e-learning materials. The first type [6] contains around 2000 characters of text, which is around half the amount of text in the static e-learning materials. It also contains graphic materials and audio-visual elements, including video and animations. On the main page we can choose between (1) the theory of liquid crystals, which includes text or animations and (2), video of the main phases of liquid crystals. The second type [7] contains only VRML (Virtual Reality Modelling Language) simulations with short descriptions of the main liquid crystal phases (isotropic, nematic, smectic-A, and smectic-C) and liquid crystal defects.

III. KEY PROPERTIES OF TYPICAL LIQUID CRYSTALS

Liquid crystals (LC) are special a state of matter that has some properties of conventional liquids and others of solid crystals. For instance, a liquid crystal may flow like a liquid, but its molecules may be oriented in a crystal-like way.

LC phases are often referred to as a fourth state of

matter. LC phases are an intermediate state between ordinary liquids and crystals. At low temperatures, a typical LC material forms a solid state in which the centers of mass of the molecules lie on a lattice, and the molecular axes point in certain fixed directions. This solid state is said to have long-range positional and orientational order. At high enough temperatures, the material enters a liquid (isotropic) phase in which molecules have no order. There is some short-range clustering of molecules, but the molecular centers of mass diffuse freely and the molecular axes point in random directions. At intermediate temperatures, several different LC phases can become stable, characterized by orientational, and possibly some partial, degree of positional long-range order. These LC phases can be broadly classified as nematic, cholesteric and smectic (Fig 1).[9]

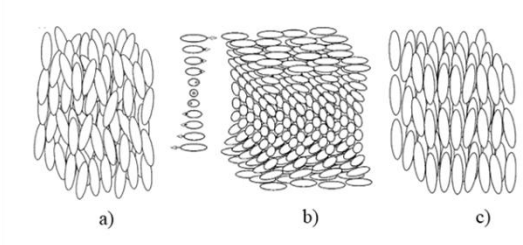

Figure 1: (a) Nematic, (b) cholesteric and (c) "smectic-A" liquid crystalline phases. In the nematic phase molecules tend to be aligned in parallel along a symmetry breaking direction. In the cholesteric phase, the planes with nematic-like ordering (the local nematic director field is marked by arrows on the left side of the figure Fig 1(b)) are twisted with respect to each other and form a helical structure. In smectic phases, molecules are arranged in layers. The various smectic phases differ according to the molecular arrangement within the layers. In the smectic A phase, the molecules tend to be aligned perpendicular to the layer [9].

In the nematic phase, LC molecules tend to be oriented locally in one direction, but they fluctuate around this direction. The local average orientation of molecules is traditionally described by a unit vector field $\vec{n}(\vec{r})$, called the director field. A molecule at the site $\vec{r}$ has its long axis in the average along $\vec{n}(\vec{r})$. Note that in the nematic phase the molecules display what is called "head to tail" invariance. A rotation of an angle π about the axis perpendicular to $\vec{n}(\vec{r})$ (i.e. the transformation $\vec{n}(\vec{r}) \rightarrow -\vec{n}(\vec{r})$) does not influence the physics of the problem. How intensive molecules fluctuate around the average direction is described with the nematic order parameter S:

$$S(\vec{r}) = \left\langle \frac{1}{2}(3(\vec{a}(\vec{r},t)\cdot\vec{n}(\vec{r}))^2 - 1) \right\rangle. \qquad (1)$$

Here $\langle ... \rangle$ indicates the spatial average over a small volume assigned to a "point" $\vec{r}$ in the continuum description and the time average over the "fast time-scales" of the system. An average temporal orientation of a molecule`s axis within the volume is described by the unit vector $\vec{a}(\vec{r},t)$. For randomly fluctuating molecules on fast time-scales, one gets $S(\vec{r}) = 0$. Conversely, $S(\vec{r}) = 1$ reflects perfectly aligned molecules along $\vec{n}(\vec{r})$ [9].

The classification of defects is based on group-theoretical theorems. In fact, group found its first impressive performance in physics in the area of defects. The essential group-theoretical quantity assigned to a defect is the integer topological charge q. This is defined in terms of the molecular orientational ordering enclosing the defect. To predict the potential cancellation of interacting defects, one introduces the winding number, noted as M. This reveals the rotation of $\vec{n}$ on encircling the defect counter-clockwise. Point defects are characterized by integer M, i.e. $M = \pm 1, \pm 2, \pm 3....$ For line defects half-integer values are also allowed $(M = \pm 1/2, \pm 3/2...)$ because of the head to tail invariance. Defects of opposite winding number may annihilate each other. One conventionally refers to the singularities with plus/minus winding signs as defect/anti-defect. [9].

IV. E-LEARNING MATERIALS FOR TEACHING THE PHYSICS OF LIQUID CRYSTALS

An example of static e-learning materials on the topic of liquid crystals is shown in Fig. 2. This e-learning lesson contains a large quantity of text about the theory of liquid crystals and a few pictures of the main liquid crystal phases and liquid crystal defects. It is suitable to give a student with a high level of knowledge of physics a broad perspective. It does not show the typical choice of color combinations because it is written in black and white.

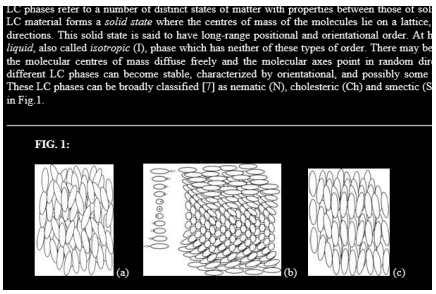

Figure 2: An example of static e-learning material on liquid crystals.

An example of dynamic e-learning material on the topic of liquid crystals, which contains a text about liquid crystals and video records and animations, is shown in Fig. 3. This e-learning lesson contains only a limited amount of text about the theory of liquid crystals and several video recordings and animations about liquid crystal defects. It is suitable for a pupil in secondary school. In these video records and animations, we can choose between different presentations of liquid crystal defects.

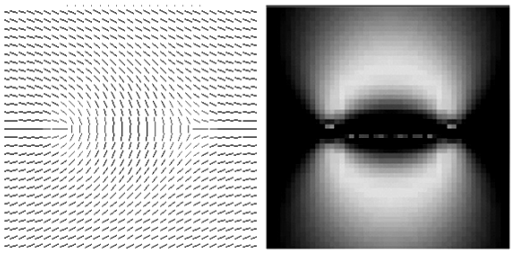

Figure 3: An example of dynamic e-learning material of liquid crystals which contains a video records and animations.

An example of a dynamic e-learning lesson on the topic of liquid crystals that contains VRML simulations of liquid crystals is shown in Fig. 4. This e-learning material contains some text about the theory of liquid crystals and many simulations of phases and defects of liquid crystals. These simulations are suitable for all levels of learning because they allow the student to better imagine the phases and defects of liquid crystals it in three dimensions (3D).

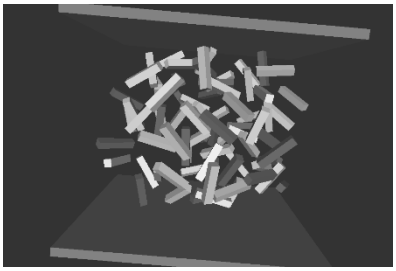

Figure 4: An example of dynamic e-learning material of liquid crystals which contains VRML simulations.

V. Analysis of the Appropriateness of E-Learning Liquid Crystals Materials

Our comparison of static and dynamic components in e-learning materials on the topic of liquid crystals was made with a particular focus on the learning effectiveness of two dimensional (2D) and 3D presentations [10]. The main finding was that a 2D representation (using different cross-sections) of a physical 3D system is preferable for experts in the field since the proper 2D visualization gives more concise information than the 3D view. On the other hand, a 3D active representation (in particular using VRML files) of the system is more appropriate for beginners. Another investigation [11] showed that the combination of frontal work with Information Communication Technology (where the use of VRML files and other visualization tools described in this paper is included) is especially useful for introducing some contemporary physics topics, such as the use of LC, in primary schools.

VI. Conclusion

To ensure the achievement of qualitative, applicative and sustained knowledge, it is important to find efficient ways of teaching, including research into the effectiveness of different teaching tools. Understanding physical phenomena often requires a comprehensive imagination of the course [11]. Visualization software uses two main approaches for presenting three-dimensional (3D) physical systems in two dimensions (2D): 3D virtual simulation (3D view - dynamic E-materials) or 2D cross-sections (2D view - static or dynamic E-materials). We focused on analyzing the appropriateness of E-learning materials for presenting topics related to liquid crystals at different levels of education: for primary and secondary schools and for students of physics in educational and engineering study programs. We found in our comparative study of comprehension of both approaches for two groups of students, those unfamiliar and familiar with LCs, that students with experience in this field prefer the use of 2D views, while other students are significantly worse in interpreting 2D views [10]. In our opinion, there is neither an advantage or disadvantage to using 2D static (web pages with a large amount of information: mostly text, images, formulae etc.) or dynamic E-materials (small amounts of text, more cross-polarizer-simulation videos, cross-section time development videos, etc.). Our experience shows that teaching the topic of liquid crystals at different educational levels is appropriate, modern, and motivational. We have to be careful, however; for students with experience in the field of liquid crystals, the use of 2D static presentations is more appropriate. Dynamic presentations, such as VRML simulations, are more appropriate for students with less or no such experience.

Abstract - **Distance learning using innovative use of technologies is becoming a good way in the last ten years to obtain knowledge separate from the traditional attending in the classrooms. The goal of this type of education is to provide maximum possible outcome for students. For developing societies and people who are in specific conditions, this method is a fastest growing form of education.**
The aim of this paper is to talk about recent remote education methods, their challenges and propose a new method to use offline distance learning. Nowadays internet is being widely used all over the world but for some territories the speed of internet is very slow or people don't have access to internet. Satellite communications are the main ways of interconnecting people all around the world. Distance education in terms of satellite communication can be done in two online and offline modes. Online method requires installing and buying special devices and services in which regarding different factors they are not cheap. In this paper we propose of using DVB-S devices to use offline remote learning. Using the proposed method is very useful especially for the regions that there is no good infrastructure for internet.

I. INTRODUCTION

Distance learning or distance education is not a new concept. They are different definitions for distance education. All of them have one thing in common: facilitating learning.

Based on Nipper [1][2] they are 3 generations of distance learning. Print technology is the first generation where the technology of printing press along with postal services is widely used for hundreds of years and known as correspondence learning.

In the second generation, broadcasting power of radio and television is playing an important role. Of course they are some bottlenecks in this way. For example the interaction between instructors and students remains minimal.

Computer and network communications are main elements of third generation. Rapid growth of computer networks and increasing the speed of communications among people especially in terms of internet and other digital technologies shows reduced response times to individual requests for information.

Typically, an activity can be considered as distance learning regarding the following features [2][3]:

- Distance: There is physical distance between the student and the instructor.
- Content: The content of program is provided and managed by an organization.
- Requirements: All requirements of system are well defined.
- Metrics: Measuring of learning output for improving its performance.

Media is an important factor for teaching in distance learning.

They are some basic comprehensions that the instructors collaborating in distance learning should aware of them. This includes the knowledge of using new instructional and communication technologies [10].

Distance learning makes it possible to learn without attending in classrooms. In this way individuals have opportunity to learn without considering boundaries include geography, time and other factors that finally will result in enthusiasm, hope and avoiding skepticism to continue education.

They are variety types of distance learning include [3][4][5]:

- Synchronous: training at the same time in different places. For example: Online chat, forums.
- Asynchronous: transferring information at different times for instance sending an email and replying.
- One-way: broadcasting information to other points, like TV and radio programs and.
- Two-way: Two sides can communicate together.
- Multi-point: many places can receive information at the same time. For example: video conferencing among different points.
- Multi-cast: delivery of information to a group of destination learners in a single transmission from the source at the same time [6].

Good aspects of distance learning are including [7][8]:

- It's a fast and effective way for global training.
- It provides the chance to use the best instructors and high-quality education.

- Information used for training is always up to date.
- Trainees are in charge of their personal success.
- Investment productivity will be increased. Is our society collectively getting the best bang for the bucks we are spending on education? If we can increase productivity we can educate more students to a higher level for the same investment.
- Reducing travel costs instead having more time for learning.
- Scheduling and managing distance learning sessions are easier.
- Adding new learners and instructors can be done easily.
- Learning resources and materials are easy access.

Some negative considerations of distance learning are [4][9]:

- Initial costs for implementation of distance learning courses are high.
- Generally, administrative services are more complex in contrast to live courses.
- Socialization may be reduced due to the reduction of interaction among students and instructors.
- All trainees learning the same, maybe there is only one educational package, lower chance for making mutual dialogue between student and instructor.
- Attending the maximum number of students may provoke numerous abandon because lack of good concomitance of the learning process.

II. REQUIREMENTS

Distance learning can be done by state or private organizations but generally we need the following considerations especially for web based training inside the system:

Administration: for example: unique identification numbers for students, managing databases, tracking trainee's participation.

Course design: using communication tools to share materials, work collaboratively among qualified instructors.

Development of materials: using multimedia along with sharing classic learning methods like e-books can increase the interactivity of materials.

Course delivery: Internet and other communication technologies are good way to distribute materials.

Student support: sending email, designing negotiation forums and availability of online chat to address learner's particular issues.

Assessment: online tests.

Evaluation: interactive communication tools like questionnaire and online feedback [8][10].

III. BASIC IDEA

The main idea behind this plan is to use satellite communications using Digital Video Broadcasting-satellite, second generation or DVB-S2. Satellite communications can be used to broadcast large amounts of data directly to user groups. With the latest advances of high-powered direct broadcast satellites and the changing traffic and usage patterns in the Internet, satellite communications are new ways of delivering data directly to the end user in which become viable alternatives especially to the territories that suffer from lacking of modern technologies like Africa or the speed of exchanging data is low due to different reasons. Figure 1 shows an instance of such networks for sending and receiving purposes.

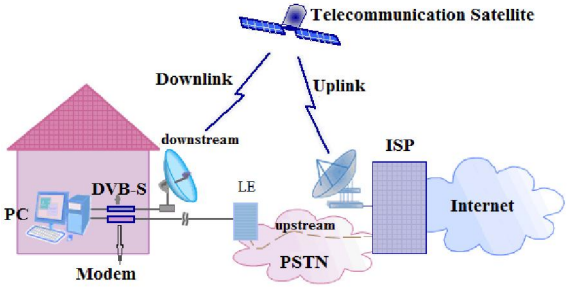

Figure 1. General schema of using satellite internet using DVB-S card (send & receive)

The goal was to deploy this satellite-based caching service for measurements and investigations into its benefits and disadvantages and to develop recommendations for the optimum usage of this technology. Protocols and connection issues were studied to develop an assessment as to the usefulness of incorporating caching into service delivery networks for to enhance their access to information resources available on the Internet.

The primary operational mode of the network augments the school's existing Internet access by providing a mechanism to update all caches within the satellite network with "popular" web objects. The main function of this mode is to inform the gateway cache of every request for web site content coming from any of the schools connected to the test network.

During normal school hours any request from any web browser was first be directed to the cache. The cache will immediately respond by sending the requested objects to the requesting computer. Requests for objects

not found in the cache are forwarded to the main server over the Internet connection, and then responses are stored in the cache and also sent to the requesting computer. These activities are logged in the cache.

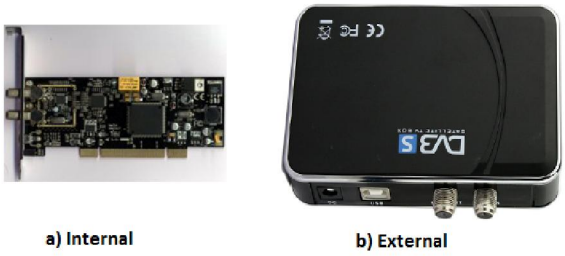

Figure 2. Internal DVB-S vs (b) External DVB-S

All log files are transmitted at regular intervals by phone line or Internet connection to the gateway cache and stored in a "master log" file for analysis. An algorithm called the "intelligence engine" evaluates all files in the master log file, and filters out the "popular objects." The gateway cache then retrieves these objects from the Internet, and adds them to the "popular objects" file. All objects appearing in this file are broadcast at regular intervals over chose satellite to all the receivers and caches in the network [11]. The secondary mode of operation for this network permits teachers to request whole web sites. Each cache has a graphical user interface, which is accessible from any computer in the system with a standard web browser. This graphical user interface (GUI) allows teachers and administrators to directly interface with the cache, to request satellite delivery of in a specific web site pages. The instructor simply types in a list of desired sites. Once a day, this list of sites is sent back to the gateway along with the regular cache log files. The web pages from these sites are treated as high priority items by the gateway intelligence engine, and they bypass the regular filtering process. All these items are simply retrieved from the Internet and added to the list of objects to be transmitted to all that night. This mechanism permits teachers to plan ahead and share information with other teachers in the network [12].

IV. PROPOSED PLAN

As mentioned before using DVB-S2 devices are fundamental of proposed plan. DVB-S2 devices are in two forms of internal and external as shown in Figure 2. Internal cards can be installed on computer main board. External DVB-S devices can connect to computer using usb ports. Generally internal DVB-S cards are cheaper and popular. No especial devices are required to use this method, one dish and LNB, one DVB-S2 and a computer are enough to gain remote education.

The main goal of using DVB-S2 is to watch television and listen to Radio channels, store favorite programs in computer. Along with watching television programs, the user is able to receive offline data from the satellite. They are different software types on the market that installing them will allow user receive offline satellite data like Skynet [13]. The mechanism of receiving data has been explained in prior part and based on the data cached in satellite.

The most important aspect of this method is to managing received data. The user is able to filter types of information that he or she is receiving by adjusting some sample settings in software installed in the computer. As mentioned before using this method there is no need to pay any tuition to gain satellite services since the mentioned services are expensive regarding some factors like bandwidth and etc.

They are several education channels or programs in each communication satellite. Administration is the most important criteria in this method. Several scenarios have been represented in Figure 3.

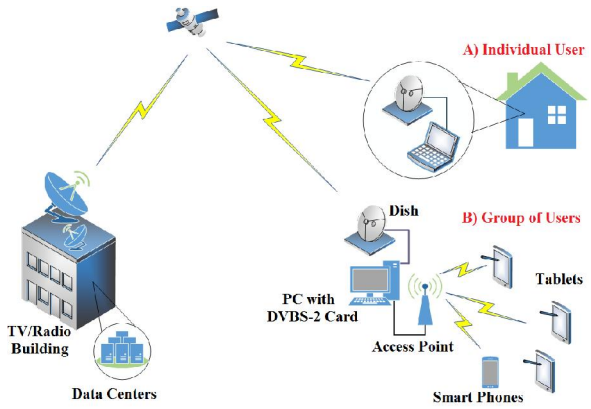

Figure 3. General schema of using DVB-S for distance education

As you can see in Figure 3, accessing to TV/Radio and offline date can be as individual or group of users. Typically in single scenarios, the trainee is able to watch training programs and record them inside computer. If he/she loses the some programs then he/she is able to receive the mentioned programs as multimedia sent and organized by TV/Radio channel through satellite. Other materials can be sent in the same way. For instance pdf's, training PowerPoints and other resources will be sent through satellite link.

In the second scenario there is only one PC equipped with DVB-S device. As it has been shown in Figure 3, this scenario is especially good for campuses, student dorms or rural areas. In this way the pc can be act as server and other devices include tablets, cell phones or any other devices that can receive wireless Wi-Fi signals can gain online education through TV signals or accessing to the materials store on server to study further. If number of trainees is increased or there is delay for receiving data from server, there is probability to install more access points or repeaters to cover more users.

Figure 4, shows another application of DVB-S. This scenario specifically is good for schools or classrooms. In this way students can watch online training programs through big LCD or projector. At the other hand since the data is stored in school server, students are able to watch and review multimedia data's.

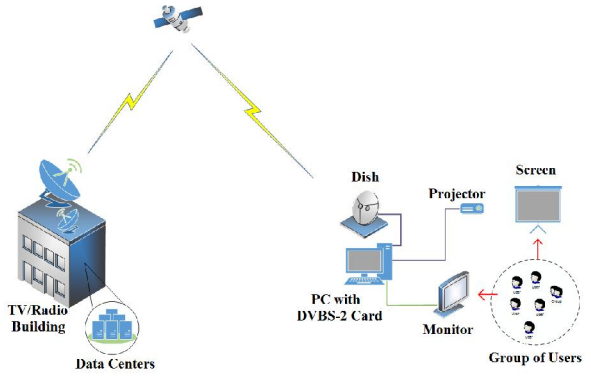

Figure 4. Using DVB-S for group of students

Using DVB-S has a lot of advantages like the act of installing these devices is simple, there is no need to pay for expensive satellite services, receiving dish and LNB's can be found everywhere, the user can chooses the required material but they are negative aspects using this device like communication is single way so the user can not send any request to satellite, large volume of data can be stored in computer therefore filtering and choosing file types is mandatory. However considering all cons and pros for these devices, DVB-S can be a good solution for remote education especially for territories like Africa or developing countries.

V. CONLUSION

The main goal of distance learning is to providing facilities to whom that can't attend in traditional classrooms for different reasons. For example because of financial matters the individual is working and cannot participate in typical educational environment or there are many rural places that are excluded from basic education equipment. Nowadays satellite communications are the most pervasive shape of exchanging data and information in the world. The plan represented here able trainees to get online training as watching TV and storing and receiving offline materials in order to study more using DVB-S devices.

Online vs. Paper-Based Testing: A Comparison of Test Results

Sanja Čandrlić, Martina Ašenbrener Katić and Martina Holenko Dlab
Department of Informatics, University of Rijeka, Rijeka, Croatia
sanjac@inf.uniri.hr, masenbrener@inf.uniri.hr, mholenko@inf.uniri.hr

Abstract - This paper presents the results of a comparative research of paper-based testing versus online testing using MudRi. The research was conducted on three courses at the Department of Informatics, University of Rijeka, and included 1231 tests. In observed courses, online tests have largely replaced traditional paper-based tests in the last few years. Therefore, the aim of this research was to determine whether the online testing results differ from the results of traditional paper-based tests. The research results showed that, for the observed courses, the median values of the results achieved during MudRi online tests and traditional paper based tests are not significantly different when online tests include certain percentage of subjective test questions.

I. INTRODUCTION

An important aspect of the educational process is knowledge assessment. Knowledge assessment is required to determine the extent to which learning outcomes are achieved. The goal of knowledge assessment is not only to rate or rank students, but also to provide feedback. Therefore, in the educational process it is important to feature formative assessment as well as summative assessment. While summative assessment seeks to evaluate students' knowledge with a grade, the goal of formative assessment is to provide feedback to students about their learning in order to positively influence their learning motivation and help them to take control of their own learning [1].

Along with the development of information and communication technology (ICT), which is increasingly used in education, teachers today have computer-based testing (CBT) tools at their disposal. The popularity of such tools, especially in the sphere of higher education, stems from the fact that with the use of CBT it is possible to assess more students in less time because the computer program reviews and evaluates tests [2]. The advantages of using ICT in education have been recognized in a much broader context than just for the assessment process since the use of ICT makes possible to replace traditional classroom instructions with e-learning. Although courses could be realized entirely online by the use of web-based learning environments, a mixed or hybrid approach to e-learning is being used in practice, also called blended learning. This approach combines online learning with traditional face-to-face learning [3].

Learning Managements Systems (LMS) play a major role in the realization of e-courses. These systems enable teachers to deliver educational materials and implement collaborative activities online by the use of tools such as forums, chats and wikis. An essential part of every LMS is a subsystem that enables online testing. An online test is a test (a series of questions used to assess students' knowledge) that students solve using a computer rather than writing their responses on paper. Standard LMS systems provide various options that make the process of creating tests or quizzes very flexible. Test created in this way can be used for formative or summative assessment [4], [5]. By the use of LMS systems such as Moodle [6], Sakai [7], Dokeos [8] and Blackboard [9] it is possible to develop tests that feature different types of questions, randomly generate tests from question banks, allow students to solve the test several times, etc.

A big advantage of online testing is automated correction that makes the job easier for teachers. But, that is not the case with objective types of questions, the correction of which mainly requires teacher's involvement. In order to overcome this problem specialized modules have been developed. For example, the knowledge assessment subsystem AHyCo LMS [3], along with standard assessment provides automated correction of programming tasks. It is possible to evaluate responses automatically for questions the answer to which is code written in one of the following programming languages: C, C++, C# and SQL [10]. Tools that can be used for the evaluation of descriptive answers are being developed, e.g. Automatic Essay Assessor [11] and Intelligent Essay Assessor [12], but their use is rather complex and language-dependent.

Although assessing student's answers in case of subjective questions can be time consuming for teachers, this type of questions should not be neglected in the process of creating tests. By using subjective questions type like Essay it is possible to measure understanding of subject matter, but also students' skills in solving some types of problems and expressing ideas in written form [13].

This paper presents the analysis and comparison of results of traditional paper-based tests and online tests that students solve on a computer. The aim of the research was to determine if and what kind of online tests can replace traditional tests that students solve on paper. Based on the results, we propose a model for transition from paper-based to online testing. The paper is organized as follows. The second chapter lists the features of the system MudRi for online testing. The third chapter describes the research methodology, including the process of preparing questions

and creating tests that were used in the scope of this research. The fourth chapter presents the research results. The last, fifth chapter, presents conclusions and plans for future work.

II. TESTING WITH MUDRI

The academic community at the University of Rijeka (teachers, students and other University employees) uses the MudRi system [14]. MudRi is a customized solution for the realization of e-courses based on the open source product Moodle. The system is extensively used with the courses of the Department of Informatics. Since it offers many features in the context of online testing, MudRi has been chosen for this study. The following sections of this paper present the types of questions and features that are available while creating online tests.

A. Types of questions

MudRi offers a whole range of question types that can be present in online tests. For the purpose of this research, questions of objective type (*Multiple choices* questions, *Connection* and *True/false* questions) and questions of subjective type (*Essay* and *Short answers*) were used and are described in the remaining of this section.

The *Multiple choices* question type offers several answers of which one or more answers are accurate. It is possible to mix the order of offered answers and define the percentage of points that will be assigned for each correct answer. The *True/false* question type has only two possible answers – true and false – of which one is the correct answer and the other is the wrong answer. It is possible to define the percentage of points that each answer carries. In *Connection* questions students are supposed to connect questions or concepts on one side with answers or concepts on the other side. It is possible to mix the order of these concepts.

The *Essay* question type is used for questions that require a longer answer and that cannot be automatically evaluated through the system but the teacher must review and evaluate the response. In *Short answer* question type students enter a word or a phrase in the answer field, which is then compared with the correct answer (or more correct answers) that were entered by the teacher. It is also possible to subsequently award points for a correct answer.

When creating questions it is necessary to define a standard number of points awarded for a correct answer and a penalty factor for wrong answers. The penalty factor is an option for adaptive tests – tests that can be taken several times. The penalty factor enables the subtraction of a portion of points when the student is allowed to offer an answer to a question that was previously answered incorrectly. For each question, the teacher can enter the desired feedback that will be displayed to the student in case of correct or incorrect answers. For some question types, it is possible to define feedback for each possible answer and in this way, for example, provide detailed explanation for incorrect answers.

B. MudRi online tests

A test consists of selected questions that are stored in a question bank. Each question can be used in multiple tests. When choosing the questions that will be used in a test, the teacher can define a fixed set of questions, let the system randomly pick questions from a category or use a combined approach. In order to allow random selection of questions, it is convenient that questions are grouped by chapter, by question difficulty or by other criteria. The number of predefined points that a question carries can be modified in the process of creating a test. This means that the same questions can carry a different number of points in different tests.

When creating tests, it is possible to define a period of time during which the test is available, limit the time available for writing the test (in minutes), set the number of questions displayed on a page and set the access password. It is also possible to configure the system to shuffle the questions or answers thus reducing the possibility that a student can copy correct answers from other students during examination. The teacher can also decide whether to add a penalty for incorrect answers in order to discourage the students from guessing the correct answer. In order to prevent opening other web pages during the examination, it is possible to set up the test to be solved in a so-called 'safe window'.

Upon completion of each test, their own test results are available to students, while the teacher has access to the test results of all students. Information about each taken test is visible, such as test start and end time, time spent, number of points achieved and number of points per question. In addition, the total average of the test is calculated and the results are displayed graphically so that teachers can analyze the test as a whole and by specific questions.

III. RESEARCH METHODOLOGY

The aim of this research was to determine whether online tests can replace traditional paper-based tests and what types of questions should online tests contain. This includes an analysis of whether the online tests consisting exclusively of objective type questions can completely replace the paper-based ones, or the online test should include a certain percentage of subjective type that will be manually graded by teachers. The main hypothesis of the research is: *There is no significant difference in median values of the results achieved during MudRi online tests and traditional paper-based tests.*

The research analysed results for the tests taken on three courses at the Department of Informatics, University of Rijeka: *Data Modeling*, *Process Modeling* and *Information Systems*. These three courses offer fundamental knowledge in the field of information systems development and are suggested as important for the education of future practitioners in the field [15]. The transition to the online test was conducted in three phases performed by two teachers. The first phase included the adjustment of questions to an online test format and their insertion into the MudRi system (creating a question bank). The second phase included creation of online tests where a special attention was devoted to the composition

of the test (i.e. the ratio of subjective and objective questions type). The final, third phase refers to conducting the tests in a real environment.

A. *Creating the Question bank*

The study used questions from classic paper-based tests that were adapted to the MudRi testing environment.

Set of questions used in paper-based tests for observed courses had been created over a longer period of time. Questions used in paper-based tests were mostly *Essay* type which included description, model or picture description and listings. Questions that require a short answer or those that require to draw or describe a picture or a model were used less often. Questions of objective types were used rarely. The number of different questions used during paper-based testing for *Data Modeling*, *Process Modeling* and *Information Systems* course was 137, 62 and 149 respectively.

The transformation of questions from the previously used written format to available objective types included transformation of the question itself and the creation of possible answers. Question bank was also supplemented with certain number of subjective questions - existing *Essay* and *Short answer* questions were also translated into online form.

Table I shows the number of created questions in the online question bank, grouped by type and course. When compared to the number of questions used in paper-based tests, as stated earlier in this section, the number of different questions in online tests is significantly bigger. Besides that, the ratio between question types used in paper-based tests comparing to those created for online testing has significantly changed: in paper-based tests questions were mostly of *Essay* type while in online question bank *True/false* and *Multiple choice* questions prevail.

Questions in online tests are designed to be clear and unambiguous, not too easy and not too hard. For example, in *Multiple choice* questions it is necessary to write the question text and offer a few (one or more) correct and a few incorrect answers [13]. We tried to ensure that incorrect answers are not too easy i.e. that their identification and elimination as incorrect is not too obvious. Sometimes, it was not easy to do so. The same applies to *True/false* question type.

Compared to conventional paper-based tests, online tests are restricted when it comes to the use of questions that need to be answered by a drawing (e.g. drawing a diagram, graph or model). This type of questions is not supported by online tests. Therefore, apart from online tests, other assessment activities were used to estimate students' knowledge.

TABLE I. ONLINE TESTS QUESTION BANK

Category of questions	Data Modeling	Process Modeling	Information Systems
Essay	25	26	0
Short answer	3	0	0
Connection	31	9	50
Other: True /false, Multiple choice	159	184	540
Sum	218	219	590

Since inserting questions and answers into the MudRi system is a time-consuming task, we considered automatic import from a file offered by the system. MudRi offers the ability to import questions that were created in other solutions such as Blackboard and Hot Potatoes and import of files of the following formats [14]: Aiken, GIFT, Moodle XML, etc.

We prepared questions for each chapter in a textual document, and therefore chosen the Aiken format [16] to import them into the MudRi system. The format allows the creation of *True/false* and *Multiple choice* questions and these two types of questions were the most common in our question bank. The Aiken format is quite simple. The question is formulated in the first paragraph, and every subsequent paragraph provides a response. The proposed answers begin with a letter which is followed by a dot '.' or a bracket ')', and space ' '. The list of answers is followed by a paragraph that begins with the keyword "ANSWER:" and this is followed by a letter that indicates the correct answer. In case that a single file contains several questions, they have to be separated by an empty paragraph.

Essay, *Connection* and *Short answer* types were manually inserted.

During test grading, the points assigned to student's correct answers are summed up. For the process of grading *Multiple choice* questions that have multiple correct answers, we used the rule that an incorrect answer nullifies a correct answer in order to discourage students from guessing the correct answer. For example, if we have a task with five answers from which two are correct, each of the correct answers carries 50% of the question points (the sum is 100%), and each of the incorrect answers - 33.33% (the sum is 100%). This system ensures that in case that a student picks all answers, the sum will be 0% (i.e. no points will be awarded).

B. *Creating the tests*

Online tests were set up to be solved within a 'safe window' and in a specific timeframe. Each test had an access password defined which was given to students just before the test begins. Tests consist of 15 – 25 questions from different categories. For every online test a part of questions was predetermined and a part was randomly chosen by the system from specified categories in order to cover all course lessons.

Traditional paper-based tests included *Essay* type of questions, questions for which it was required to draw a sketch, and *Short answer* questions.

For the purpose of this study, tests for different courses were designed differently, in respect to the question types used. In the *Data Modeling* course and the *Process Modeling* course online tests one third of questions was subjective (*Essay* and *Short answer* types) and two thirds were objective (*Multiple choice*, *True/false*

TABLE II. TEST PROPERTIES

	Classic paper-based tests	Online tests	Online tests
	All three courses	Data Modeling, Process Modeling	Information Systems
Question type	Essay type of questions, short essays and listings, image drawing, short answer questions	Multiple choice, true/false questions, connection; essay and short answer	Multiple choice, true/false questions, connection;
Duration	60 minutes (paper-based)	20 minutes (computer-based)	20 minutes (computer-based)
Number of questions	15 (on average)	20 (on average)	25 (on average)
Number of tests	753	310	168

questions, *Connection* question types). Objective questions carried fewer points than *Essay* or *Short answer* type of questions. For the *Data Modeling* and the *Process Modeling* course points based on answers for objective type of questions was 50%, i.e. almost 70% of objective type questions carried 50% of points and 30% of subjective type questions carried 50% of points. Questions in online tests for the *Information Systems* course were only objective. Test properties are compared in Table II.

After students hand in the test for evaluation, they are presented with their test results, correct answers, feedback related to particular questions and overall feedback related to the whole test and scoring. *Essay* and *Short answer* questions are graded later manually by the teacher. After closing the test, points and overall feedback is visible to the student.

C. Participants and online testing properties

The research was held at the Department of Informatics, University of Rijeka, so the participants were students of Single major and Double major program of informatics at the Department (second and third year of undergraduate study).

We have started with online testing in 2009 in the *Data modeling* and the *Process modeling* course, using tests created as described in previous section. After two years of using online tests with combination of subjective and objective question types, our intention was to ease the correction of tests and therefore use only objective question types in the *Information systems* course. The motivation for such approach arises from the fact that in recent years the number of students, and consequently teachers' teaching load, has increased. This is especially the case when teachers hold several courses with two or three test planed.

Both, online and paper-based tests were solved in the classroom under controlled conditions. In order to solve the traditional test students had 60 minutes, and in this time, they had to solve about 15 questions. Although online tests had more questions than paper-based tests, less time was needed to solve them due to different questions types.

Grading traditional paper-based tests required significantly more time than grading online tests. Online tests were graded automatically by the system immediately after students submitted them. Teachers manually graded *Essay* type questions (if present in the test) and given points are automatically added to the total sum of points.

All the tests carried through the study were used as part of the summative assessment. Minimum of 50% test points was necessary for passing the test. Apart from online and paper-based tests, teachers used other activities in order to assess students' knowledge in mentioned courses.

IV. COMPARISON OF TEST RESULTS AND DISCUSSION

The goal of the research was to determine whether there was a significant difference between median values of the results achieved during MudRi online tests and traditional paper-based tests. The study included 753 paper-based and 478 online tests. In the *Data modeling* and in the *Process modeling* course used tests included both, subjective and objective types of question, while those for the *Information systems* course consisted only of objective ones. Descriptive statistical analysis for all three courses was performed. The results are presented in Table III.

High variance coefficient for paper-based test results shows that arithmetic mean cannot be considered as representative central tendency indicator. Rather low value of quartile deviation coefficient refers to median as better indicator of central tendency.

It is also important to notice that measures of variance are significantly lower for online tests. Based on the Levene's test for equality of variances, in all three cases the hypothesis of equality of variances can be rejected with extremely high significance ($p<0.0001$), i.e. we can conclude that variances for online tests and paper-based ones significantly differ.

The tests results for *Data Modeling, Process Modeling* and *Information Systems* courses are shown using the Box-Plot graph in Fig. 1, 2 and 3 respectively. In each figure the results for online test are shown in the left part of the graph, and for paper-based test in the right part of the graph.

TABLE III. DESCRIPTIVE STATISTICAL ANALYSIS

	Data Modeling		Process Modeling		Information Systems	
	Online tests	Paper-based tests	Online tests	Paper-based tests	Online tests	Paper-based tests
N	162	226	148	254	168	273
Arithmetic mean	0.6475401	0.6025221	0.5643795	0.5626378	0.6349981	0.5535165
Range	0.2415-0.9635	0-1	0.221-0.8915	0-1	0.33-0.93042	0-1
Standard deviation	0.140849	0.240482	0.135689	0.249787	0.136961	0.262828
Variation coefficient	0.2175147	0.3991249	0.2404207	0.4439565	0.2156873	0.4748339
Median	0.65875	0.63	0.56275	0.58	0.634095	0.57
Interquartile range	0.2125	0.27	0.1625	0.32	0.202145	0.36
Quartile deviation coefficient	0.164674	0.212598	0.146961	0.283843	0.160266	0.321586

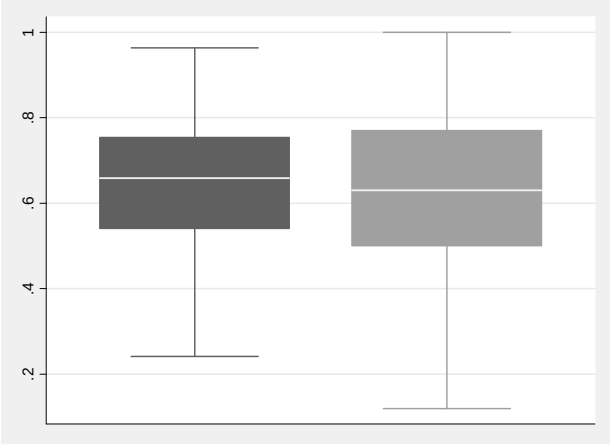

Figure 1. Box-plot diagrams for Data Modeling course (left online tests, right paper-based tests)

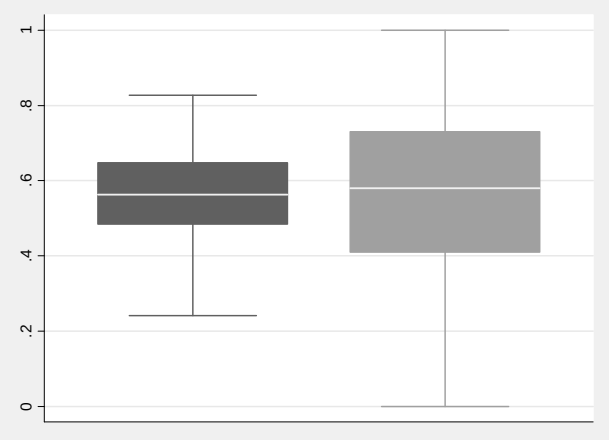

Figure 2. Box-plot diagrams for Process Modeling course (left online tests, right paper-based tests)

Figure 3. Box-plot diagrams for Information Systems course (left online tests, right paper-based tests)

Online tests, in which the majority of questions are of the *Multiple choice* or *True/false* type exclude the impact of subjective factors related to the teacher as the evaluator, which were potentially present while correcting *Essay* type of questions in paper-based tests.

Normality analysis (Table IV) indicated the use of nonparametric statistic methods for hypothesis testing. By using Mann-Whitney test it is stated that for the *Data Modeling* course and the *Process Modeling* course there is no significant statistic difference in median values (p=0.2401 and p= 0.3777, respectively) between online and paper-based tests. For the *Information Systems* course the difference is extremely significant (p=0.0066).

TABLE IV. NORMALITY ANAYSIS

	Data Modeling		Process Modeling		Information Systems	
	Online tests	Paper-based tests	Online tests	Paper-based tests	Online tests	Paper-based tests
Shapiro-Francia W'	0.98905	0.94746	0.99238	0.97006	0.99270	0.96782
P	0.20769	0.00001	0.53225	0.00009	0.47966	0.00002

Therefore, for the *Data Modeling* and the *Process Modeling* the hypothesis is confirmed – median values do not differ significantly. For the course *Information Systems* whose tests consist only of *Multiple choice*, *True/false* and *Connection question* types (i.e. objective questions), the difference in median values between online and paper-based test results is significant. Better results on online tests in the case of the *Information Systems* course can be explained by the fact that *True/false* and *Multiple-choice* questions can be answered even with lower levels of knowledge and based on recognition.

A large difference in the maximum number of points achieved in paper-based tests and in online tests can be noted. We conclude that the subjective factor of the examiner plays an important role in the assessment of descriptive answers, since the examiner has the possibility to assess the answer as partially correct, or to assess the "hidden knowledge" in the given answer. Differences can also be observed for the minimum number of achieved points in paper-based tests and online tests. On written tests, students will very often give up from finishing the test if they estimate that they will not be able to achieve the enough number of points. This is the reason why we recorded the minimum score of 0 in the analysis of paper-based tests.

Based on the result of the study, we conclude that online tests can replace traditional paper-based tests for student' knowledge assessment, but special attention should be paid to its composition. Therefore, we propose a following model for transition to the online testing.

In the phase of questions creating, existing question bank needs to be adapted to the online testing environment. The certain number of existing *Essay* type questions could be transformed to the questions of objective type (e.g. *Multiple-Choice*, *Connection*), while some of them could be just imported in online system as they are. Depending on the course domain, question types offered by the chosen system can or can not be adequate. In case there is no adequate question type (like drawing questions in our case), additional assessment activities can be performed [17]. When creating *Multiple-Choice* questions with multiple answers, we suggest to use the rule that an incorrect answer in certain percentage nullifies a correct answer. In addition, we highly recommend entering questions into the system using the Aiken or similar format because it is faster than entering questions

manually. Only minor modifications and manual input of questions that the format does not support are necessary.

Concerning the test creating phase, we consider that it is best to use a combination of online tests and other methods of knowledge assessment. In order to prove that they have adopted the course material, students have be able to explain what they learned, which is possible with the *Essay* type of questions. Therefore, instead of online tests in which the questions are posed in the *True/false* or *Multiple choice* types, we propose that online tests have around 30% of subjective questions (*Essay, Short Answer*). Although it is not possible to correct them automatically, this ratio does not represent great time workload for the teacher (it's about 2-3 questions per test).

V. CONCLUSION AND FUTURE WORK

This paper presents the results of a research that included 1231 paper-based and online tests. If the results are compared with the results of online tests, we can conclude that it is possible to replace paper-based tests with online tests in order to assess student knowledge. The biggest advantage of paper-based on the other hand is the short time in which it is possible to prepare the test and the possibility to ask questions that require a drawn response.

Based on students' comments that we received during the testing activities, we conclude that they prefer to use the keyboard rather than a pencil so they would rather take online tests than paper-based tests.

Due to above-mentioned, we plan to use them in the future in the scope of observed courses. Our future work will include efforts to further improve methods for online assessment. This includes revising the question bank. Students responses will be analyzed in order to identify to easy questions (the questions with 100% correct answers), as well as questions for which there are no correct answers (the questions that are potentially unclearly stated and therefore incomprehensible to the students). We also plan to update the question bank with sets of different types of questions for formative assessment. Students will be able to solve a self-assessment test after completing each course unit. This will enable them to test their knowledge, in the process of preparation for the tests that follow.

VI. ACKNOWLEDGEMENTS

The research has been conducted under the project "Extending the information system development methodology with artificial intelligence methods" (reference number 13.13.1.2.01) supported by University of Rijeka (Croatia).

Abstract – The use of Learning Management Systems (LMS) and the web-based formative and summative assessments during the traditional teaching in classroom provides the huge amount of data on students' behavior and results at the point of time when the course is still in progress. This data could be used for the final exam performance prediction so that the excellent as well as the students requiring help could be detected. The data on 302 students enrolled into the first year Physics course of a biomedical university study program in 2011/2012 have been used. The data were preprocessed by dividing Croatian grading system which comprises 5 grades (range 1-5; 1=fail, 5=excellent) into 2 categorical classes in one version of the experiment and into 3 categorical classes in the second version. Several up to date algorithms for classification were applied without and with attributes optimization by a genetic algorithm. Also, since students have 4 chances at 5 exam terms during an academic year, 3 different dependent variables were constructed. In order to evaluate the performance that each of the classification models had the following performance criteria were used: accuracy for all models and sensitivity and area under curve (AUC) for binary classifier systems.

I. Introduction

The hybrid learning as the form of learning environment in which the traditional teaching in classroom is mixed with the computer mediated interaction [1] is spreading rapidly in higher education in Croatia and worldwide. Students use some form of Learning Management System (LMS) on the regular basis during the course and also in some cases an additional web-assessment tool as well as the classical pen-and paper mid-term exams. This provides a vast number of data on students' behavior and results.

The goal of classification as a data mining type is to accurately predict the target class for each case in the data. During the process of a model building i.e. training process, a classification algorithm finds relationships between the values of the attributes and the values of the target class. Classification algorithms use different techniques for finding relationships. These relationships represent a model, which can then be applied to a different data set in which the class assignments are unknown. The historical data for a classification is divided into two data sets: one for building the model and the other for testing the model. Classification models are tested by comparing the predicted values to known target values in a set of test data.

The aim of this paper is comparing different classification models, which could not only differ by the classification algorithm but also by attribute selection (optimized or not by a genetic algorithm) and also by the selection and construction of the class label (definition of success classes in respect to grade and time of passing the exam).

The paper will be structured in the following way: the overview of the recent work in this field will be followed by the presentation of the used methodology and the obtained results with discussion. At the end, the conclusions with limitations and directions for the future research will be presented.

II. Literature Review

Educational data mining (EDM) is a relatively new research area which pursues the development of methods and computational approaches for exploring data originating from an educational context [2].

According to Baker and Yacef [3], during the period 1995-2005 the most prominent type of EDM research was the relationship mining and the prediction was the second most prominent research area. During 2008-2009, a shift occurred moving the prediction to the first place and discovery with models as a new type of research was moved to the second most frequently used type of EDM. The appearance of the discovery with models is explained by the integration of psychometrics and student modeling researches into the EDM community. In discovery with models, a model of a phenomenon is developed and then used as a component in another analysis, such as prediction or relationship mining.

A number of papers have been published elaborating the issue of predicting student performance using machine learning techniques and the majority refers to distance learning environment [4, 5, 6] or even intelligent tutoring

systems [7]. The papers referring to blended learning environment are not so frequent and not necessarily using DM [8, 9, 10, 11, 12]. Blended learning environment usually does not provide so many automatically available data as distance learning and especially intelligent tutoring systems but in Croatia blended learning represents the prevailing higher education environment also emphasized in Croatian universities mission statements.

Based on data from strictly e-learning environment Lykourentzou et al. [4] proposed a method for a dropout prediction. The authors used following machine learning techniques: feed-forward neural networks, support vector machines and probabilistic ensemble simplified ARTMAP. The decision schemes which combine the results of those three techniques were also proposed.

Jovanović et al. [5] described the application of a variety of classification algorithms as well as clustering students on grounds of their cognitive style. The data set was acquired from a completely distance learning environment.

Kotsianis et al. [6] deployed in distance learning environment several classification algorithms for predicting the students' performance and also assessed the relevance of the attributes involved (demographic data, face-to face meeting data, written assignments data). The data came from distance learning environment. The Naive Bayes was found to be the most appropriate for eventual construction of a software support tool.

De Nui at al. [10] used data from hybrid learning environment and investigated the relationship between LMS usage and student performance.

W. Dekkar et al. [9] used different modeling techniques on the data sets of students' past education as well as university grades and related data collected from the electrical engineering department to test their impact on students' performance.

Delgado et al. [8] used artificial neural networks for predicting students' marks from the logs to Moodle [13]. Thai-Nghe et al.[11] compared the accuracy of Decision Tree and Bayesian Network algorithms for predicting the academic performance of undergraduate and postgraduate students at two academic institutes.

Divjak and Oreški [12] used discriminante analysis for analyzing the effect of 30 attributes (the data collected by a questionnaire hybrid learning environment) upon the student success.

III. METHODOLOGY

A. Dataset preprocessing

Data on 302 students enrolled in the first year Physics course of a biomedical university study program in the year 2011/2012 have been used in this paper. Out of 302 students 121 (40,07%) are men and 181 (59,93%) are women.

As attributes we have used the data collected by Moodle [13] Learning Management System and a previously developed web-based formative assessment tool named *Pitalica* as well as 3 mid-term exam results. The application of *Pitalica* during seminars was extensively described in Gamulin et al. [14] and the application during laboratory teaching in [15]. The idea of *Pitalica* is to allow the teacher to assess a large student group during seminars and through their answers to detect the level of their former knowledge of the subject and understanding of the seminar topic and adjust the course of lecture accordingly. It is strictly formative assessment. In lab *Pitalica* allows the teacher to quickly assess students at the beginning of each laboratory exercise. The idea is to motivate students to prepare for their lab exercises and the result achieved at *Pitalica* has a mild summative component.

Using Moodle a student has the access to self-assessment test which could be taken only once, web-laboratory, simulations, video laboratory (short videos describing specific exercises), interactive exercises and PowerPoint presentations. After the course is over a student has 4 chances to take the final exam at 5 exam terms. Grading system in Croatia consists of 5 grades (range 1-5; 5=excellent, 4=very good, 3=good, 2=sufficient, 1=fail). This opens a variety of possibilities for constructing the class label (it is final oral exam grade, in further text FOEG) in a classification model. In this paper we investigated 12 different class labels. We used data discretization which is dividing the numerical data into categorical classes in order to increase interpretation and comprehensibility [16]. The 5 grades system is discretizated into 2-classes system in two different ways depending on whether we observe excellent and fair students or good and poor students in 2 classes (grades 5,4→class Excellent; grades 3,2,1→class Fair) or in 2 classes* (grades 5,4,3→class Good; grades 2,1→class Poor). We formed 3-classes system also in two different ways depending on whether we observe distinction students, very good and poor in 3 classes (grade 5→class Distinction; grades 4,3→class Very Good; grades 2,1→class Poor) or very good, standard and poor students in 3 classes* (grades 5,4→class Very Good; grade 3→class Standard; grades 2,1→class Poor).

Also, it is not all the same whether a student has passed an exam in his/hers first trial or fourth. Students have 4 chances at 5 exam terms during an academic year. Taking an exam repeatedly causes the exhaustion with students and also makes the heavy workload to teachers. In Table I there is an overview of all attributes and class labels.

TABLE I. DESCRIPTION OF THE ATTRIBUTES AND CLASS LABELS

Attribute	Description		Values
x_1	total scores of midterm exams (written).	integer	=[0 – 5]
x_2	scores of web-based formative assessment during seminars (*Pitalica* – seminars)	integer	=[11 – 42]
x_3	scores of web-based formative assessment during seminars and laboratory teaching (*Pitalica* – total)	integer	=[19 – 77]
x_4	scores of web-based formative assessment during laboratory teaching (*Pitalica* – laboratory)	integer	=[6 – 38]
x_5	number of logins to Moodle (learning material + general information about the course)	integer	=[15 – 869]
x_6	ability [17] calculated according scores of midterm exams	numeric	=[-4.184 – 405]
x_7	number of logins to Moodle learning material	integer	=[5 – 623]
x_8	number of login to Moodle general information about course	numeric	=[0 – 348]
x_9	ability [17] calculated according to scores of self-assessment test on Moodle	numeric	=[-2.673 – 4.102]
x_{10}	time used for self-assessment test on Moodle	numeric	=[0 – 5]
Class label			
y_1	FOEG, 1stT, 3 classes	polynominal	=[Distinction, Quite Good, Poor]
y_2	FOEG, 1stT, 3 classes*	polynominal	=[Very Good, Standard, Poor]
y_3	FOEG, 1stT, 2 classes	binominal	=[Excellent, Fair]
y_4	FOEG, 1stT, 2 classes*	binominal	=[Good, Poor]
y_5	FOEG, 3rdT, 3 classes	polynominal	=[Distinction, Quite Good, Poor]
y_6	FOEG, 3rdT, 3 classes*	polynominal	=[Very Good, Standard, Poor]
y_7	FOEG, 3rdT, 2 classes	binominal	=[Excellent, Fair]
y_8	FOEG, 3rdT, 2 classes*	binominal	=[Good, Poor]
y_9	FOEG, 5thT, 3 classes	polynominal	=[Distinction, Quite Good, Poor]
y_{10}	FOEG, 5thT, 3 classes*	polynominal	=[Very Good, Standard, Poor]
y_{11}	FOEG, 5thT, 2 classes	binominal	=[Excellent, Fair]
y_{12}	FOEG, 5thT, 2 classes*	binominal	=[Good, Poor]

Here we proposed three different ways of capturing the best image of final exam success when failures at some of the terms are possible:

1stT= the first term, final oral exam grade at the1st term calculated as the average of four questions' grades

3rdT=the third term, final oral exam grade calculated as the average of first three terms, failures are also registered

5thT= the fifth term, final oral exam grade calculated as the average of all five terms, failures are also registered

Tables with results accumulated by means of *Pitalica* during web-based formative assessment on seminars and laboratory teaching as well as data collected by Moodle (logs number, log date, type of accessed material, results from self-assessment test), and mid-term and final exam results were stored in a database. The data were exported to the format which can be processed by Rapid Miner 5.3 tool [18].

B. Modelling

In this paper we used 5 state of the art algorithms.

Logistic regression analysis (LogReg) which was also used by [5, 6, 7, 19] is a type of probabilistic statistical classification model used in research situations where predicting the outcome of a categorical class label is based on one or more predictor variables (attributes). The relationship between the classifier and attributes is a non linear function.

Neural Networks (NN) which was also applied by [5, 6, 8, 19, 20], are computational models inspired by neuropsychology where a nerve cell functioning principle has been used [21]. A multi-layer neural network consists of large number of units (neurons) joined together in a pattern of connections. Input units receive information to be processed, output units present the results of the processing and units in between are called hidden units.

Random Forests (RF), also employed in work of [5], operates by fitting a number of decision tree classifiers on various sub-samples of the dataset and use averaging to improve the predictive accuracy and control over-fitting.

The Support Vector Machines technique (SVM), also applied in paper by [6, 22], maps the data to a higher dimensional space in order to separate the positive from the negative instances in the training set.

K-nearest neighbor (kNN), also used by [6], operates on the principal that the instances within a data set will generally exist in close proximity with other instances that have similar properties. If the instances are tagged with a classification label, then the value of the label of an unclassified instance can be determined by observing the class of its nearest neighbors.

In Rapid Miner we generated 2 processes. In the first process, the split validation with stratified sampling was performed meaning that one set of data was used for model building (70%) and the other for validation of the model (30%). In the second process the proposed attributes were optimized by the genetic algorithm (GA) and then the model was built on grounds of the optimized selection of attributes and validated it as described in the first process.

The overall accuracy criterion is used to measure the number of positive and negative instances correctly classified in proportion to all the instances. In Table II it is shown that the accuracy is evidently higher in models where the attributes were optimized by the genetic algorithm and we achieved the same result for all class labels. That is why in further discussion we focused on the models with the GA optimization only.

TABLE II. ACCURACY FOR SELECTED CLASS LABELS

accur %	y_9	y_{10}	y_{11}	y_{12}
LogReg			72,09	72,09
LogRegGA			87,21	88,37
NN	52,14	62,79	77,91	80,23
NNGA	74,42	76,74	83,72	90,7
RF	52,33	51,16	75,58	67,44
RFGA	58,14	76,74	83,72	83,72
SVM			76,74	76,74
SVMGA			87,21	90,7
kNN	52,33	52,33	69,77	66,28
kNNGA	68,6	76,74	87,21	86,05

IV. RESULTS

In Table III there is an overview of accuracy indicators calculated by different algorithms.

Confusion matrix is the visualization of efficiency of an algorithm since it provides the overview of whether the actual and predicted classes are confused. Accuracy as a predictor could be misleading especially when the two classes are numerically unbalanced.

The precision criterion is used to determine the proportion of true positive instances versus the total number of true positives and false positive instances.

To measure the efficiency that each technique demonstrates in correctly identifying the positive instances, the sensitivity (recall, hit) criterion is used. This criterion measures the proportion of the number of positive instances correctly classified versus the total number of positive instances correctly classified and instances misclassified as negative.

Confusion matrices have been calculated for all class labels and out of that it could be concluded that discretisation into 3 classes (grade 5→class Distinction; grades 4,3→class Very Good; grades 2,1→class Poor) gives better performance than 3 classes* (grades 5,4→class Very Good; grade 3→class Standard; grades 2,1→class Poor), while 2 classes (grades 5,4→class Excellent; grades 3,2,1→class Fair) give better result than 2 classes* (grades 5,4,3→class Good; grades 2,1→class Poor) and in general, the best results are achieved by 2 classes (grades 5,4→class Excellent; grades 3,2,1→class Fair) when the stability of class recall and class precision for all the observed classes are considered. The only exception is noticed with NNGA where 2 class* gave better results. As an example, in Table IV and V, there are shown the confusion matrices for y_5 and y_{12} when RFGA and NNGA applied.

TABLE IV. CONFUSION MATRIX FOR Y_5 WHEN RFGA IS APPLIED

Accuracy 66,28	true Distinction	true Poor	true Quite Good	class precision
pred. Distinction	9	0	2	81,82%
pred. Poor	1	25	14	62,50%
pred. Quite Good	6	6	23	65,71%
class recall	56,25%	80,65%	58,97%	

TABLE V. CONFUSION MATRIX FOR Y_{12} WHEN NNGA IS APPLIED

Accuracy 90,7	true Good	true Poor	class precision
pred. Good	54	6	90,00%
pred. Poor	2	24	92,31%
class recall	96,43%	80,00%	

Area Under Curve (AUC) could be interpreted as the probability that a classifier will assign a higher score to a randomly chosen positive instance than to a randomly chosen negative instance under the assumption that positive ranks higher than negative [23] i.e. it is displaying the tradeoff between true positive rate and false positive rate.

The specificity indicator is used to determine the

TABLE III. ACCURACY FOR ALL CLASS LABELS, ATTRIBUTES OPTIMIZED BY THE GENETIC ALGORITHM

	1stT				3rdT				5thT			
accur %	**y_1** 3 classes	**y_2** 3 classes*	**y_3** 2 classes	**y_4** 2 classes*	**y_5** 3 classes	**y_6** 3 classes*	**y_7** 2 classes	**y_8** 2 classes*	**y_9** 3 classes	**y_{10}** 3 classes*	**y_{11}** 2 classes	**y_{12}** 2 classes*
LogRegGA			86,05	84,88			**87,21**	82,56			87,21	88,37
NNGA	68,6	75,58	80,23	87,21	70,93	80,23	83,72	81,4	**74,42**	76,74	83,72	**90,7**
RFGA	63,95	76,74	81,4	86,05	**66,28**	77,91	**83,72**	86,05	58,14	76,74	83,72	83,72
SVM GA			83,7	87,21			**87,21**	86,05			87,21	90,7
kNN GA	63,95	70,93	77,91	86,05	66,28	73,26	**87,21**	83,27	**68,6**	76,74	87,21	86,05

proportion of the number of negative instances correctly classified versus the total number of negative instances correctly classified and the number of negative instances misclassified as positive.

In Table VI there are presented AUC, sensitivity and specificity indicators for binary classifier systems.

When applying LogRegGA Class 2 comparing to Class 2* gives high accuracy, better confusion matrix and high AUC, sensitivity and specificity (y_7 and y_{11}). Employing NNGA with Class 2* gives better accuracy and confusion matrices for the first and fifth term data (y_4 and y_{12}). RFGA achieves better accuracy for Class 2* but confusion matrices are poor, so, it should be taken Class 2 as more reliable, especially since the accuracy is still high and the confusion matrices are better and AUC, sensitivity and specificity are high. SVMGA and kNNGA have the same picture as RFGA meaning that Class 2 is sorted out as more representative.

For 3 classes models we compared NNGA, RFGA and kNNGA. NNGA gave better accuracy for Class 3* model but the confusion matrices are better for Class 3 models. RFGA gave the same result as NNGA with remark that only confusion matrix for the Class 3 at the third term gave good score. kNN algorithm returned better accuracy for Class 3* but the confusion matrices implied that Class 3 is more reliable.

TABLE VI. AUC, SENSITIVITY AND SPECIFICITY INDICATORS FOR BINARY CLASSIFIER SYSTEMS

	1stT		3rdT		5thT	
AUC	y_3	y_4	y_7	y_8	y_{11}	y_{12}
LogRegGA	0,885	0,895	0,938	0,856	0,938	0,899
NNGA	0,87	0,901	0,893	0,837	0,893	0,938
RFGA	0,886	0,812	0,934	0,859	0,934	0,893
SVM GA	0,892	0,915	0,92	0,897	0,92	0,927
kNN GA	0,849	0,917	0,908	0,886	0,908	0,894
Sens in %	y_3	y_4	y_7	y_8	y_{11}	y_{12}
LogRegGA	89,47	81,67	89,47	80,95	89,47	91,30
NNGA	83,87	92,73	78,95	83,82	78,95	90,00
RFGA	89,19	84,00	88,00	85,14	88,00	81,82
SVM GA	83,72	88,14	88,57	87,93	88,57	91,43
kNN GA	75,00	89,06	86,11	88,52	86,11	86,36
Spec in %	y_3	y_4	y_7	y_8	y_{11}	y_{12}
LogRegGA	83,33	92,31	85,42	86,96	85,42	76,47
NNGA	78,18	77,42	87,50	72,22	87,50	92,31
RFGA	75,51	100,00	81,97	91,67	81,97	100,00
SVM GA	83,72	85,19	86,27	82,14	86,27	87,50
kNN GA	80,43	77,27	88,00	72,00	88,00	85,00

Starting from the observation that Class 2 gives better results than Class 2*, with exception of NNGA, we compared results for specific exam terms.

LogRegGA, RFGA, SVMGA and kNNGA produced the equally good results for the third and the fifth term and only NNGA produced the best results for the fifth term data. All this leads to the conclusion that the third term data is a good enough representative to build the model which has significant practical implications since the third term is still in summer and there is some time to remedy the possible issues before the academic year ends.

Similarly, if we take the starting point that Class 3 enables better results than Class 3*, we can see from Table III that NNGA and kNNGA give the highest accuracy (accuracy 74,42% and 68,60%) at the fifth term and RFGA at the third term (y_5, accuracy 66,28%).

When we take into account class construction, exam term, accuracy, confusion matrices, sensitivity, specificity and AUC, the best results were achieved for two classes by LogRegGA, SVMGA and kNNGA (y_7, accuracy 87,21%), and by NNGA (y_{12}, accuracy 90,70%) and RFGA (y_7, accuracy 83,72%). For three classes model the best results were achieved by RFGA (y_5, accuracy 66,28%) NNGA (y_9, accuracy 74,42%) and kNNGA (y_9, accuracy 68,60%).

V. CONCLUSION

Success of a prediction model depends not only on the attribute selection (genetic algorithm), algorithm selection, but also on class label construction and selection. In the specific case described in this paper we showed that the models with two classes have better prediction indicators but also have some flaws and a researcher has to decide about the trade-off between better prediction performance and other information that the three-class model brings (information concerning risk students and potentially good students).

For the future work the authors plan to take as attributes for the model also the LMS activity of students refined according to various LMS contents (simulations, videos, interactive exercises, PowerPoint presentations and self assessment tests).

Also, authors are planning to provide an algorithm that could follow the procedure of selecting the most appropriate combination of attributes, algorithms and class labels as described here, that would fit the desired option.

Abstract - With a view to facilitate personal development and achievement of goals by means of career development planning, an organization facilitates the realization of personal goals aimed at achieving organizational goals. In this way, the career has both a subjective and an objective dimension. Subjective dimension refers to the attitudes, interests and motives of individuals, whereas the objective dimension refers to the organization's conditions, the structure of work posts, job promotion criteria, etc. It is essential to develop strategies for personal career development in order to eliminate the identified shortcomings and take advantages in achieving one's goals. The research results show the distribution of opinions on the role of an organization in an individual's career development.

I. Introduction

Nowadays there are four generations present in the labour market: traditionalists, big generation – Baby Boomers, Generation X and Generation Y. Generation Y replaces their parents Baby Boomers and they will almost certainly have great social and economic influence in the coming years. Different perspectives, motivation, attitudes, and needs of those four generations have changed the workforce dynamics. [4]

Generation Y, people born in 1980s are just arriving in the labour market. They spent their formative teenage years in a society in which post-war social security was not only questionable, but it was completely destroyed.

Internet and third generation of mobile telephony transform ways in which the ideas are exchanged and their creative contribution while social and economic innovations profit greatly from them.

However, in many countries small and medium companies work with obsolete technology, low-skilled human resources, weak management systems and entrepreneurial abilities, unavailability of appropriate and timely information, insufficient usage of information technology, low quality of products all of which contributes to low productivity. Hence, it is necessary to develop additional knowledge and skills on the individual level that will enable the individual to establish himself in today's labour market.

II. Career Development Phases

In different periods of their life people have specific relationship to career. During career development people constantly change, especially in view of attitudes towards values and life, goals, ambitions, possibilities and needs. First situation is at the beginning, second situation is in the middle and the third situation is at the end of a career. In simplest terms, people aged 15 and people aged 50 want different things from life as well as in career. Most authors have determined four key career development phases. Even though they are often connected with certain life phases and are determined on the basis of duration, their beginning and their length depend on the nature and the complexity of an occupation, length of the education process, length of the preparation for the occupation and the occupation itself. [11]

Popular way to analyze the career is to observe it as a sequence of phases. There are five-phase models that can be referred to the majority of people during their working life. Five-phase model includes:

1. Investigation - when individuals analyze possible career options and when they make key choices
2. Establishment - when individuals start with job search and when they get their first job
3. Middle career - when individual is no longer perceived as a "pupil"
4. Late career - when individual can share his knowledge with the others within organisation
5. Withdrawal - when individual officially stops to work (retirement)

III. Crisis as the Chance

Ability to recognize the chances in the environment is a characteristic of top-line managers. Current economic crisis is a source of numerous chances for the development of personal knowledge and abilities in order to be more competitive in the labour market. On the basis of the analysis of the data available from web page http://www.ekonomskiportal.com [1] it is visible that time of crisis and high unemployment initiates the search for specific data and knowledge.

Because Figure 1. below is very small in size due to the two-column paper format and path of the sub-pages is written in Croatian the authors have prepared their translations in English as shown:

Figure 1. Keywords according to the interest of webpage visitors
Rank of the visited sub-pages in comparison to total webpage visits

On the basis of the analysis of the available data authors conclude that the visitors of the web page search for two main types of knowledge/skills:

1. primarily necessary knowledge
2. other knowledge and skills

Consequently and on the basis of the conducted survey it is possible to identify individual's needs and his perception of necessary steps for career development.

IV. Career Management on a Business System Level

Career development includes career planning, treading of the possible career paths, development and training activities, formal staff policies, promotion criteria, estimating, counselling and promotion of mentoring. Besides career planning as a process in which there is a dominance of the individual, a business system is primarily associated with a term career management. That is a process of forming and implementing goals, plans and strategies that enables managers and human resources professionals to meet the needs for those resources, but it also enables individuals to reach personal career goals (Figure 2.).

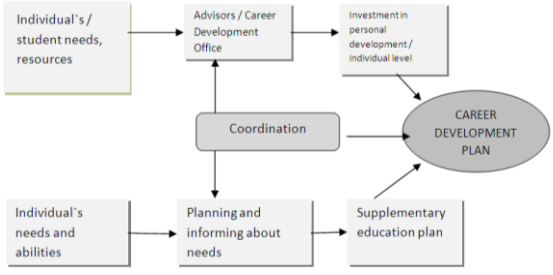

Figure 2. Career planning process [9]

Career management assumes great coordination and collaboration of managers, employees and human resources department. At the same time organizational unit human resources department should have the coordination role and the role of the one who provides the necessary professional help to managers and employees.

Individuals should be managing their careers like entrepreneurs manage their companies (Figure 3.). They must perceive themselves as self-employed even if they are employed in a big business system. For successful career management it is important to know yourself, to understand your potential and abilities as well as to correctly set yourself personal goals and to learn how to make right decisions.

TABLE I. Career Management in a Business System

CAREER MANAGEMENT		
INDIVIDUAL	MANAGER	ORGANIZATION
- determining personal preferences, interests and abilities - planning life and work - information on occupations - choosing organization - determining development and career options - work and professional preferences - introducing management with personal development preferences - activity planning for career development - self steering - developing abilities, knowledge and skills - tracing internal and external possibilities for career development	- catalyst and motivator for employee's development - estimating and tracing performance - determining abilities and talents - assessing the reality of goals and development needs - counselling for and supporting career development - providing information on organizational needs and possibilities for career development - steering - training - providing information on employee's development potential - matching individual and organizational needs	- estimating individual potentials and preferences - matching individual and work needs - performance grade - linking human resources planning with career development - establishing career ladder - professional steering - educating and developing employee - information system for human resources and needs - information on possibilities for careers development - counselling for career development - tracing, evaluating

Figure 3. Career management in a business system

Career management is a process that does not happen on a one-time basis, rather it is continuous and repetitive in a cycle of individual development. It is very hard for the individual to determine the ultimate career goal during the establishment of career goals. It is much more appropriate to establish career goals for a period of 10 to 15 years that can be even shorter because career goals are specific for every individual.

V. Case Study - Career Management On a Level of Higher Learning Institution: Faculty of Economics in Osijek

According to the curriculum in academic year 2013/2014, Faculty of Economics in Osijek at J.J. Strossmayer University of Osijek there are five courses of Graduate Studies: Financial Management, Marketing, Entrepreneurship, Management and Business Informatics.

Topic of empirical research in this paper is observation of the nature of relationship between career development and expectations about future job that was analyzed through career planning for the students of final year of graduate study (4th semester) from the courses Financial management and Marketing.

From a total number of enrolled students (106) there were 70 participants in the online survey.

Through general students' attitude towards career planning and career development options as well as thorough estimation of individual needs and expectations, the cognitive, behavioural and emotional aspects attributes of students have been observed. The majority of participants will, in a course of 2014 when they gain their Graduate study diplomas (mag.oec., eng. Master), find themselves in a labour market and/or in a business entity. In the course of online survey analysis the most frequent answers have been extracted presented.

. Consequently, with the realistic snapshot of participants' gender demographics it is confirmed once more that females are more dominant in the participants' sample and in the total student population that study economics. Above-mentioned matches the data about gender structure of Croatian students from Croatian Bureau of Statistics in which female students constitute 56% of total student body population and male students constitute 44%.

Figure 4. Gender structure of survey participants

Readiness for spatial and professional mobility is one of the very important factors to reduce unemployment. Promotion of workforce mobility within EU is treated as the one of new, important characteristics of the labour market. Creation of new jobs and rapid changes in labour demand generate the need for increased workforce mobility. [8]

Possibility of professional development is something that 79% of participants see as the most desirable form of advancement even though it was ranked as sixth in the ranking of desirable workplace characteristics. It can be assumed that the large portion of participants does not see possibility of professional development as an integrative part of career development, but as a form of reward for job well done and career advancement.

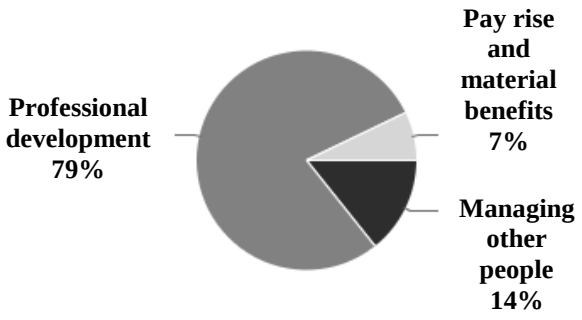

Figure 5. What career advancement means to survey participants

As opposed to male participants, female participants see professional development, in 63% of answers, as a desirable form of career advancement. From the presented results it can be concluded that there is a big difference between male and female participants in the terms of choosing "Professional development" as the desirable form of career advancement, while there is a small difference in their attitudes towards management positions and material satisfactions.

Members of Generation Y believe that technology will play the important role in their future work and they emphasize the need for organizations to keep up with technology. They wish to share knowledge on social networks through examples of good practice and collaboration with colleagues.

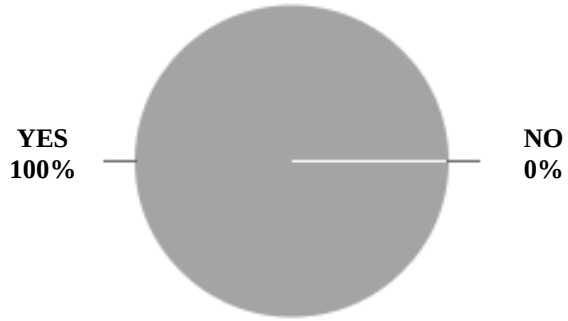

Figure 6. Social networks inclusion of survey participants

As per gender differences of participants there are no significant deviations and both genders are evenly represented in the utilization of social networks.

Which of the given possibilities do you use in order to gather data on potential jobs that you are interested in?

One of the reasons why presented results for personal contacts are so high is because of the inclusion in social networks.

TABLE II. POSSIBILITIES THAT ARE USED IN ORDER TO GATHER DATA ON POTENTIAL JOBS

Online job portals	18%
Employment agencies	5%
Job fairs	4%
Work experience in a company	7%
Career centre at the university	4%
Searching through companies' web pages, pages regarding employments/careers	14%
University mailing lists	0%
Job advertisements in press and media	4%
Company presentations at the university	7%
Professional collaboration with universities	0%
Employment services and offices	12%
Personal contacts	19%
Online news portals	7%

Youth's attitude towards lifelong learning and development is tested by various questions and grades on a scale from 1 (I do not value it) to 5 (I do value it). Data shows that the answer for which the most participants have awarded the highest grade is (with over 40%) "Mentor work". It is followed by "Formal education in scientific academic institutions with 35,9%. On the bottom of the list there is "E-learning, various short business courses" with only 23,2%.

TABLE III. THE MOST DESIRABLE FORM LIFELONG LEARNING – MENTOR WORK

1 (I do not value it)	7%
2	7%
3	7%
4	36%
5 (I do value it)	43%

In comparison, the answers that were given by the participants in a research on a world level (PwC, 3907 participants) have graded the E-learning much better (62%). [10] Youth from the other parts of the world, similar to the Croatian participants, have graded mentor work as the desired format. Such answers confirm the theories about Generation Y that state the importance of mentor's role in the young employees' career development, namely much more than the E-learning through technology that is very close to them.

VI. FINAL CONSIDERATIONS AND SUGGESTIONS FOR IMPROVEMENT

Research goal manifests in the attempt to, on the basis of research results analysis, provide appropriate guidelines and models that would act as a support with career planning and career development to young people during their education.

That also implies the importance of the increasing awareness of lifelong career development for every individual that will arrive in the labour market after education, but also the employer's awareness of the importance of employee's career and the realization of quality human resources in his business system.

Conducted research represents a kind of foundation for a pilot project whose target groups (users) would be:

- students in the final year of their graduate study
- young entrepreneurs without sufficient formal education who are wishing to improve their business by learning
- popularization of the entrepreneurship in target groups.

On the basis of presented research results analysis project activities can be defined even further with an aim to derive direct and indirect benefits from the project.

Direct benefits relate to competitiveness in labour market, additional practical knowledge as well as new approach to knowledge, technologies and information.

Indirect benefits imply decline of unemployment rate, increase of self-employment rate and recognition of the situation in the environment through the interaction with the attendees.

Throughout mentioned project activities and constant mentoring of the attendees the more quality promising professional future for the economists that are arriving in the labour market is foreseen.

E-learning next step – learning materials for students

Marjan Krašna, Matjaž Duh, Tomaž Bratina
University of Maribor, Faculty of Arts, Department of Pedagogy, Maribor, Slovenia
marjan.krasna@um.si; matjaz.duh@uni-mb.si; tomaz.bratina@uni-mb.si

Abstract: E-learning materials were first introduced at the university level education in last years of previous century in Slovenia. From the initial steps and pilot projects we learned the trade and participate in many e-learning material developments for primary and secondary schools. But in the recent years we regretful discovered that the university's e-learning materials are not in the same league as lower level education e-learning materials. It is true that students' population is different from kids but "*digi-kids*" have grown up and become students and they are familiar with the e-learning materials. It is the fundamental difference between lower level education and university level education. Lower levels education e-learning materials were funded by the government but university does not have funds for e-learning materials production. Up until now lecturers used LCMS for communication and documents sharing. But it is become evident that this is not enough and upgrade of e-learning material is required. It is evident that this process will take time and should be efficient from all perspective (didactically suitable, cheap, and fast). In the last year e-learning materials was prepared for students to test what suits them most. A lecture for a whole course was prepared with the different composition of text, sound and video. In forthcoming semester we are going to test our e-learning materials and receive feedback from the students. Article presents the learning materials specification, expected didactical results, aesthetical considerations, individual preferences (visual, audio, kinaesthetic), and client's browser's limitations. It is still not clear if university level students require more elaborate learning materials than PDF which was their favourite type up to now.

Keywords: distance education, e-learning, learning materials, design, verification and validation

I. INTRODUCTION

Since 1998 when we first prepare web study materials for a whole course Multimedia for teachers [1] many years and many projects have passed. These initial steps were the first glimpse to the future of learning materials preparation. For a decade we have upgraded materials according to the advancement in the software technology and IT infrastructure. We were always one step ahead in the anticipation what are going to be the technologically feasible and acceptable by students. In all these years we have again and again witnessed the students' ICT paradox [2]. Older the students less they were familiar with the technology and more are conservative in their preferences. Even today we still have students that print their web materials and learn from paper.

From initial web textbooks we advanced to the more elaborate learning materials where we used animation (made of successive images) to shorten the learning process of certain skills. As the infrastructure advanced and computer processing power increased we started experimenting with video in education [3] [4] [5] [6]. In the beginning videos were post stamp size but it gives us valuable experiences with video editing. We experienced and studied the information overflow [7]. In those early years the aesthetic of e-learning materials was not an issue. The existence of e-learning materials was inherent aesthetic achievements.

In 2006 projects for better cooperation of educational institutions started [8]. In course of this project different e-learning materials were made (from distance learning didactics to support for teachers practical training in schools). These e-learning materials were the blueprints for later production of e-learning materials.

In 2008 projects for development of e-learning materials for primary and secondary schools were funded by European Social Fund and Ministry of Education and Sport of Slovenia [9]. What was started as an enthusiastic pilot project was now expand into the high quality production. The team was established and project started with tight schedule and different technological constraints. We have managed to prepare e-learning materials for primary and secondary schools and learn many pitfalls of distance education. Learning material was not enough for successful distance learning. Two years later (2010) the productions of e-learning materials were refined and more suitable for all participants in the educational processes – especially for teachers [10].

Whatever experiences we gained were for lower levels of education. In the same time we did not survey ours students. Information we get was just from the informal interview with the students. At that time we were happy to see more and more of lecturer using courses in Moodle than pay particular attention to the e-learning materials attributes. Moodle was mainly used for communication and file repository [11]. After lecturers have acquired basic knowledge they start to use Moodle for students' report submission too. Lecturers have acquired different styles for their materials structuring and some classes the structure was really opaque and annoying for students. Too many topics spread in too many divisions and

submission in different topics with practically the same names proves to be unsuccessful. Clear structure of the course is definitely successful approach and favoured by any users.

II. STUDENTS' PREFERENCES

Students' generation changes in different perspective [12]. Digital natives have come to the faculties. If it was a rare sight around five years to see students using laptops at the faculties then now it is a common sight. Students have laptops in our halls and corridors during their free time. They browse the web; read learning materials; or just watch YouTube videos. Current Wi-Fi architecture becomes congested and prevents users from accessing web on some occasions. Students generally occupy two connection one for laptop and the other for smart-phone. Inside the classroom we discovered that students generally do not use computer but they also write less notes as few years ago. Some of the students admit that they type faster than they write text by hand but our classroom equipment did not follow new needs. Especially electrical connections are insufficient and unavailable to the students therefore they preserve battery for other more needed tasks. Implicitly they only listen the lecturers and access learning materials on the web later. In our practice we have deep insight to the different students' groups. Observations of students from general pedagogy, art education and elementary education are presented in this topic.

In the winter semester of 2013/2014 we have a course of "*Didactics strategies information support*". This course enables us to work with postgraduate students of general pedagogy and acquire information about their preferences in studying and learning materials usage. Their future job will be understanding and organizing the educational activities and help students and teachers to perform better in the educational systems. Many of those graduates are later employed outside the educational system and works for different companies to organize in-house education or work on public relations or human resource management. In general they are specialist for learning. During their years of education they express that they acquire *spatially specific learning methods.*

1. In the classroom they listen to the lecturer and rarely actively participate. They could not explain their general passive behaviour in the discussion but from the lecturer perspective there are multiple reasons for their passiveness. Students in Slovenia are more or less shy in the classroom. They do not want to be regarded as silly if they ask something what others may already know. Unless they are explicitly instructed to do something they rather stay in the anonymity. The second reason is that students are focused on acquiring the data during the lecture and they do not process the data at the same time. This corresponds with the traditional structure of the courses where lectures are for knowledge acquisition, laboratory work or seminar is for discussion. Any deviation from "tradition" is new to the students. They are not accustomed to public improvisation and creative problem solving in the classroom therefore they are rather "*safely passive*".
2. During the laboratory work student prefer the detailed instructions what to do and how to do. Student often do not like open problems with multiple solutions. If we give students assignment to make a report of their research work about how can they use production of promotion materials in education, they generally ask what kind of promotion and how many pages should report have. Even if we give them option that they could use any type of promotion, they would generally all pick the same type and the creativity in their work is very limited. From students perspective they often express that they have a lot of work and they would like to know exactly: what to do; how to do; and it should not take them more than 2 hours of their precious time.
3. Their home or dormitory is for deep study; mental reasoning; and creative work. Most of them require their own study workspace (like protective cocoon where everything is at hand) and if they are not there they are often less effective and sometimes even incapable to do the required tasks. They often express that they need a certain time span to start the work. It they know they have less than three hours' time they rather not start the work at all.

Feedback from the student of art education is a bit different. They generally use laptops, tablets computers are still rare, but most of them use smart-phones regularly. Art students use ICT in multilevel approach:

1. On the **primary level** students use their ICT for communication and social networking. Both positive and negative impact can be observed. We do not approve their attempts to cheat on written exams and other types of knowledge assessments.
2. On the **second level** they use ICT in study processes. Some academic content in the professional and artistic courses require knowledge and creative use of computer tools for processing images and video materials. Freeware software is used for this purpose because they faculty does not provide licensed programs to improve the quality of their visual content creation on both technical and artistic level. Student acquire their basic knowledge to use these software tools on the web pages; specialised forums; and YouTube. The course Information and communication technology is scheduled in the 9th semester of study. This is too late and huge disadvantage for them because in the previous courses they have already acquired most of their professional and pedagogical content. Regarding the objectives of ICT course, which states that the student will achieve information literacy; understand and know the basics of computer science and digital technologies; and know how to use computer applications, we see that this course definitely scheduled too late. ICT skills are need at the beginning. Students should use them during their studies to see usefulness and effectiveness of ICT in education. To continue in the objectives of the ICT course curriculum we can read that the student will be able to electronically communicate with synchronous and asynchronous tools; known e-learning

technologies; be familiar with computer graphics; digital recording; media formats and possibilities of interactivity and multimedia. All these topics are required preconditions before they study them in details in other processional courses [13]. Despite the general ICT literacy of students they acquire in previous education, we see that they could perform better during their studies and professional and didactical assignments.

3. On the **tertiary level** use of ICT in didactical practical training (lectures in schools and pedagogical practice). ICT in education is mandatory and art education students should use them in full extend. Data sources for visualization of art assignments are available on the web. Contemporary information can be recorded on mobile phones or other recording devices. Images, video and web are building blocks for multimedia learning materials that are used in the classrooms. PowerPoint as a tool of choice can be used for static or dynamic presentations. In art education it is very important dynamic building of the visual presentation to highlight the graphics elements (central perspective lines, layers of colouristic perspective, contrasts presentations, colour lessons, etc). Animations in this occasion are not ornamental add-ons but fundamental necessity to teach the artistic expression. Students are aware of importance of multiple communication channels but beside images, video, animations and occasionally text they rarely use sound. Sound component of their presentation is included as their speech and explanation during presentation. It should be know to students that ICT is actually limited in the art education. It does not provide stimuli for all valuable modalities (sight, hear, touch, smell and taste) jet we know that students achieve better results in data processing and comprehensive information acquisition using multiple concurrent modalities. In their pedagogical practice the production and use of such materials prove to be highly motivational in the classroom; enhance the quality of content acquisition; and contribute to the deeper understanding of artistic phenomena. All this is the good basis for the practical art exercise solving and understanding the theoretical and history of art facts. Students prepare their own presentation for the pedagogical practice and no use of already prepared materials was observed.

Students of art pedagogy are sufficiently ICT literate for their own communicational and social. The less skilled are when they use ICT for education. No gender difference or social status difference was observed regarding the use of ICT. Only students' personal preferences make the differences.

Student for elementary school teachers study do not use tablets but they extensively use smart-phones. Observations show that less than half of them use laptops. Interestingly they do not use smart-phones for access to the LMS and they work exclusively with computers or laptops. Geographically they access the e-learning materials mainly from home or dormitories, and rarely between breaks on faculty.

During the laboratory work in computer room they do access the learning materials because they have to. The amount of access to the LMS increases before the exam and seminar work submission deadlines. Interestingly we have discovered from the log files on the LMS Moodle that students excessively visit the same topics again and again despite they should already acquired them during the lecture and lab-work.

Students use computers for word processing and communication. Social networking is ranked high in their computer activities where significant number of students started using smart-phones. Much less computers are used for preparation of multimedia elements for their study and pedagogical practice.

Life long students (part-time study) show different behaviour. They access the LMS even outside regular pedagogical activities. Their acquired knowledge is more effective used. Reasons are different and one is the limited ability to communicate with the lecturers face-to-face. Therefore electronic communication has higher value in their study process.

For formal communication with the lecturers e-mails are used. Informal communication between colleagues and other acquaintances is done in social networks and mobile communication (phone calls or SMS).

III. E-LEARNING MATERIALS PREPARATION

Our students are accustomed to the use of LMS Moodle and different types of learning materials. But those materials are generally all in separate files. We want to break this tradition and prepare learning materials differently. From the review of courses in our Moodle it is clear that courses mainly have learning materials in PDF, Word and PowerPoint files. Much less often additional types of learning materials are used (Excel, SPSS, images, and animations outside PowerPoint). Even rarely lecturers use video learning materials and video lectures. Video in education may be didactically controversial. A link to the YouTube video that last for an hour where important part of video for the students is only five minutes somewhere in between is not favourable between our students. Right composition and volume of data is crucial. In the past we discovered that we need to use different types of e-learning materials to boost the retention level but we need carefully orchestrated environment not to trigger information overflow [7].

Most of students start their study from the PowerPoint presentations and some students even stay there. PowerPoint should be used as a reminder and table of content of the lecture. The knowledge behind the slides is presented by the lecturer and/or can be found in the textbooks. But some lecturers prepare their PowerPoint presentation with the full text. Despite the bad taste of such presentations students actually like them. To pass the exam they often need no additional literature; web sources; journals; and textbooks. From aesthetic perspective such presentations are rubbish and bad didactical practice. From practical viewpoint it should be banned because some students actually think that is the way to produce presentations. This bad influence can be seen at the diploma theses presentations.

Our task was therefore not only to prepare learning material that is suitable for students but also present the good practice how to prepare e-learning materials and slides. We know who will use our learning materials therefore we could make a mental thinking (modelling?) about the intended users. From our previous researches we discovered that there is statistically significant difference between students who attend the lectures and those who study by themselves. Even 10% difference in grades can be observed. We have decided to prepare learning materials in blended learning paradigm. Blended learning materials is good for those who attended the lectures and wants additional explanations. In some occasion they can be used for self-study but little less successful without additional learning materials.

One would argue that with the better learning materials we make students even more passive they already are but the efficiency is the only thing that counts. If it is hard for students to switch from one learning material to another due to different reasons why not to ease this step. Regarding the research that shows increased efficiency in working with larger monitor or two monitors [14] due to more visible information on the screen; we therefore decide to prepare *integrated learning materials*.

In the preparation of integrated e-learning materials we wanted to address the different aspects: technical, practical, didactical and aesthetical.

Simple procedure and use of known tools were desired because we would need to support a lot of courses.

A. *Technical aspect*

In recent year there are shifts in the computer market. Number of sold PC declines and number of different tablets sale raises. We don't have enough funds to customize e-learning materials for different hardware therefore our product should be available for computers, tablets and smart phones. It is not going to be an application but a web page and it should look good and work in all browsers.

We already have experience with the production of e-learning materials for primary and secondary school that still works like a charm. It was produced using Adobe Flash technology that has many benefits over other technology but also some drawbacks. In general flash technology is not supported on new version of Android, iOS and Windows mobile. Therefore whatever we know and learned about the flash production it is out-dated. But in the recent years we have get almost working HTML5 browsers. We still have to figure out how to made resizable viewport for equal presentation of content on different screen sizes.

From technical viewpoint we need common encoding the diacritical characters present in the text which is solved with UTF-8 encoding, we need images in JPG or PNG encoding, we need support for MP3 audio encoding and MP4 video encoding. Text and image is supported in all browsers but the MP3 and MP4 are not. Though Firefox browser support MP4 from the version 23 upward (now version 26 is available) this is true in Windows and MacOS operating systems. In Linux this is not true by the default and additional settings that are a bit beyond the abilities of normal computer users are needed. All our requirements are covered with the Chrome browser that is available for practically every operating system.

B. *Practical aspect*

From the practical aspect we would like to reuse a large amount of already produced learning materials. Since we have no authoring tool available some things have to be done manually and we would like to minimize that. Authoring tools are generally limited but they enable authors to focus on content and not on the technology. In previous developments we were able to transform PowerPoint presentation to the FLASH. We have not tried commercial PPT to HTML5 conversion tools. Trial version and free conversion tools are not really what we want. Conversion is packed in the predefined layouts and these are not what we want. We did try the commercial product Hype authoring tool for HTML5 but it works on MacOS only and the produced HTML5 is hard to change.

Since we found from the feedback from the students that they are satisfied with the PDF files of presentations we do not need too much attention to the animated effects of the PowerPoint's presentations. If in general static image of presentation is enough then we can use free tools to do much of our work and only specific post processing are added later. This compromise enables us to reuse already made learning materials. Authors upgrade their existing PowerPoint presentations with the notes text. This PowerPoint can later be exported as HTML; include into the desired layout; and upgraded with HTML5 components. We managed to prepare the two hours blended learning materials in less than 2 hours if all multimedia components were available.

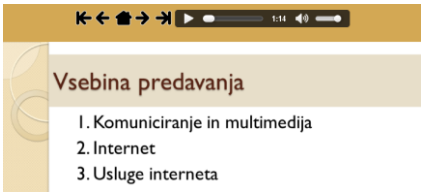

Figure 1: Sound narrated slides

Figure 2: Video narrated slides

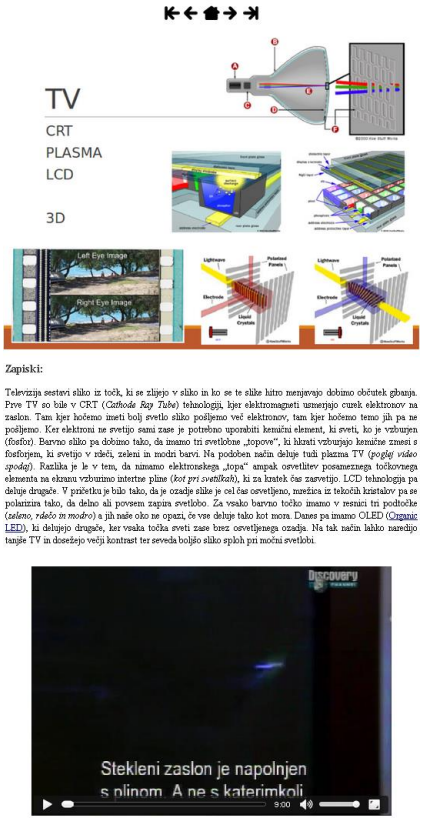

Figure 3: Integrated learning materials

C. *Didactical aspect*

Graduate level didactics is a bit different than those in primary and secondary schools. It is not even the part of general andragogy (learning of adults). We deal with the students who already have highly developed learning processes. We do not need to teach them how to study. In the preparation of e-learning materials we need to consider time constraint – topics should not require more than 15 min to process and we need to provide clear and unambiguous explanations. We can add outside sources and links to additional materials but for the time management it is still desired to include most important components into the package.

From the feedback of the students about the learning materials we discovered they do not care much about distractions which are necessary during the lectures. They are happy with PDF files but switch to additional materials is distracting. Either they skip the additional materials when reading the text and study it later or they do go visit other materials and have return problems. Even if they are using web daily they still have problems with browsing. By design the author can open link in the same window or in the new window. Browsers in general do not allow opening new window they open new tab instead. In the process of high concentration users too often close the window after reading the content of the tab and not only the current tab. In these occasions they cannot get back to the text they supposed to study further. Finding the e-learning materials takes time and additional effort is required to ascertain the position where to continue study. Such unwanted pauses lower the efficiency of study process.

Though we have not jet tested the new e-learning materials we have tested the components. We know that video is good for teaching skills. Sound is quite effective because it can be used where other types of learning materials are less appropriate (busses and walking). Text can be read on mobile phones. But on the other hand we discovered that even if we record the lecturer in the classroom and upload the video on the web students rarely watch such video. From the Moodle log file analysis we discovered that half of the students never even start playing the video. Around three quarter of students that start the video stops watching the video after 5 min. Only handful of students watch video for 15 min and no one watch entire video – except the lecturer. Therefore if we use video in the e-learning materials it should be short (no more than 5 minutes).

Data gathered from the faculty library shows that students rarely use audio books. Mainly students with special needs use audio books. Even on overcrowded buses or during their walks they rather listen to the music.

For the purpose of better communication between students we have bulletin board software. Analysing the posts we discovered that there is a huge free market for student's notes. In general we could not see the content of the notes but in some rare occasions someone have made the electronic version of the notes where we could analyse the content. Despite we do not know the content of the notes we can assume what is written from students' questions. From those sources we have highly confident insight that students sometimes makes a factual mistakes in the notes and those mistakes are not corrected and they live through multiple students' generations. Study literature and lecturer are available to the students' questions but students rarely use them.

D. *Aesthetical aspect*

In the e-learning materials each screen need to be designed according to the multiple parameters: technical, didactical, and aesthetical. Creatively designed e-learning materials must have following characteristics:

- *Applicable value* – assessed in pedagogical and didactical review;
- *Novelty* – new fresh idea, rarity, unusual and positive motivational impact
- *Appropriateness* – material must meet the problem based teaching [15]

High quality visualization is not important only for aesthetic pleasure. It gives the integrity of materials and learning for better processing of knowledge from e-learning materials. Contemporary upbringing and education build on the concept that activates auditory, haptic and visual perception. Those concepts therefore need to be fundamental part of e-learning materials. Through long observations we perceived preference shift toward visual perception. It is known that processing of same amount of information delivered through verbal messages takes more time than delivered through visual messages [16]. Therefore it is reasonable that authors extensively use visual perception activation concept in their e-learning materials design. The use of e-learning materials attracts visual capabilities. It requires an

organized observation, mental, emotional and other activities for processing the visual stimuli. The text takes much more time for processing and visuals are therefore more effective [17]. E-learning materials should be designed so that the introductory or intermediate sequence confronts the student with aesthetically ordered textual and visualized data to accept the content. "*The happiness regarding the transparent and organized screen with new content leads to the intrinsic motivation that positively affects the content acceptance*" [15]. Transparency and orderliness of screen can be achieved if elements (text, images, interactive elements, etc.) are positioned into the virtual orthogonal grid. Such perpendicular arrangement gives the required static and designed psychological simplicity and highlights isolation [18]. Unfortunately this arrangement also causes optical burden, inactivity and stiffness of composition. Important elements should therefore be positioned outside the grid. Such new composition achieves the correlation between content, importance, aesthetical attractiveness, and versatility.

Some authors [19] recommend that designers of e-learning materials should prepare the answers to the following questions before they set the design concept:

1. What is the overall structure of the e-learning materials?
2. Are the contents didactically appropriate and sufficiently reasonable?
3. How the information flows between screens from user perspective?
4. Can e-learning materials be used intuitively?
5. Which media elements are going to be used for visualization of individual content?

Additional multimedia elements have broad cognitive, educational, cultural, technical and social functions. With these we achieve a higher educational effectiveness in both educational directions wideness of knowledge and depth of knowledge [20]. It is therefore evident that for quality information transmission both aspects are important: learning content aspect and the presentation technique aspect. Didactically suitable structured e-learning materials have to be technically flawless and aesthetically pleased in order to achieve pedagogical objectives.

IV. RESEARCH

E-learning materials for course of 15 ECTS was made (15 hours lectures and 15 hours laboratory work). Apart of the lectures and laboratory work we also provide Moodle quizzes for self-assessment. Due to huge workload we did not provide the same topics in different composition but we prepare different topics in different composition (text, audio, video and integrated learning materials). Different compositions allow us to test the differences in human preferences on learning materials. It is known for a long time that people have different preferences in learning style (visual, audio or kinaesthetic) and some research shows that there are possible to get equal effectiveness in face to face as in online education [21].

Because we prepared learning material for blended learning we are going to allow access to the specific materials only after corresponding lecture. Students' performance will be tested with the quizzes and after that they will grade the materials according to different aspects.

A. *Presentation and narrative text*

Two types of presentation and narrative text are available to the students:

- Flash presentation where narrative text is displayed on demand, and
- PDF where each slide is accompanied with the narrative text.

In these two types of e-learning materials we would like to text students preference toward PDF files.

Figure 4: Presentation and narrative text – Flash technology

Čeprav danes veliko govorimo o prostorskem zvoku je zanimivo to, da lahko zelo dober prostorski učinek dosežemo že s pomočjo stereo zvoka. Seveda moramo v takšnem primeru snemati tako kot bi slišali – s pomočjo umetne glave. Posnetek je neverjetno dober, doživeti pa ga je mogoče le z uporabo slušalk.
V prostoru namenjenem za več ljudi je potrebno posvetiti pozornost ozvočenju. Odvisno od velikosti prostora in števila poslušalcev je potrebno razmišljati o geometriji postavitve zvočnikov in jakosti zvoka posameznih zvočnikov.

Figure 5: Presentation and narrative text – PDF file

B. *Presentation and audio*

Each slide in this presentation is accompanied with the audio that narrates the slide. To emphasise the value of audio we prepared slides with text only. This type of presentation has some advantage because everything is on one screen and no scrolling is needed. Students get feedback about the length of audio on the audio control slider.

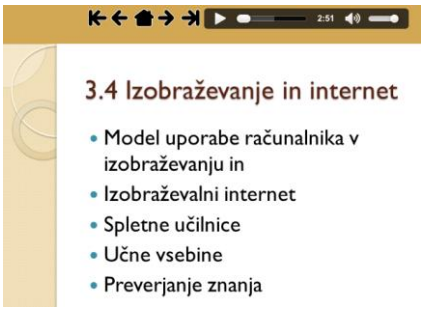

Figure 6: Presentation and audio narration

C. *Presentation and video*

Video was added to each slide to narrate slide. Since video occupy space and covers the part of the slide we add the control to hide the video. Hidden video still plays sound and enables students to hear the narrated voice of the slide. We have prepared this type of presentation according to observation of students' behaviour. They would never watch the whole video but in this occasion it is cut to the smaller chunks that covers only one slide. All video are in the time span of less than 5 minutes.

Figure 7: Presentation and video narration

D. *Presentation and text, images, links, video (integrated learning materials)*

This is probably the most favoured type of learning materials. It has drawbacks in the scrolling. Reviewers who have experience with the design and development or e-learning materials give higher score. Such materials are probably easier to implement since we do not need to record (sound or video) of lecturer. The only think we need is the narrated text and additional elements. But we need to check this finding with the students' preferences.

Figure 8: Integrated learning materials

E. *Research questions and intended users*

The research is going to go in two distinct directions: appropriateness and effectiveness. The first direction can be achieved easily in one generation but the second needs more time and search of trends through many generations of students.

Research questions:

- Number of perceived informations and layout.
- Ease of navigation.
- Personal preference to the tested type of e-learning materials.
- E-learning materials' building blocks preferences.
- How useful are controls on the e-learning materials (sound level control, hide/show video, pause, etc.)?
- How e-learning materials influence their understanding and knowledge acquisition?
- What devices were used for e-learning materials viewing?

In the summer semester of 2013/2014 we are going to test these materials for two distinct groups of students: natural science students and social sciences students.

V. CONCLUSION

University level student population is different than other students. They are highly skilled learners with established preferences in learning. Today's students are known as digital natives. This can be seen in different levels. They type better than write and they use ICT throughout whole day for different purposes. They are accustomed to different type of learning materials and only the lack of handy portable devices still bound them to the paper. During past years a lot of effort and funds were assigned to the production of e-learning materials for primary and secondary schools. University level education was not part of these projects and no funds were given to the e-learning materials production. E-learning materials were therefore limited to most common types of files (PDF, Word, and PowerPoint). Students therefore rarely make their notes and they study from PowerPoint slides. In the past we would fail such students but in recent years we see that this is not an option since we would need to fail almost all of them. Students therefore have huge width but at the same time very shallow knowledge. It becomes hard for them to search learning materials on different locations.

In an effort to enhance e-learning material and provide students with easier study we prepare different type of e-learning materials. To test their preferences we combine presentation and different narration types (text, audio and video) and prepare the integrated e-learning materials. According to their feedback we will provide support for e-learning materials production in other courses and gradually change all learning materials. We hope that this will positively influence the knowledge retention and provide good practice for further e-learning materials development.

Configurable Image-Processing System for Education in Automotive Applications

C. Madritsch, T. Klinger
Carinthia University of Applied Sciences/Engineering and IT, Villach, Austria
c.madritsch@cuas.at, t.klinger@cuas.at

Abstract - This paper describes the overall image-processing system, which has been developed for the use in education and at various industrial projects. The added value for the students is the tight link between computer-based education in image processing and the real-world relevance. Complex and changing quality control demands of safety critical components for automotive applications require an innovative graphical systems design, which can be effortlessly reconfigured by the user. The quality control challenge claimed us to detect imperfections on the backside of brake shoes. These imperfections can cause safety related problems and therefore, the affected brake shoes need to be sorted out. From an engineering point of view, this was a technically challenging image-processing application. The surface of the brake shoe is highly reflective; the contrast between the imperfections and remaining areas is very low, the selection criteria are complex (depending on the size, number, and location of the imperfection). Due the fact that every car manufacturer and almost every car model needs different brake shoes, the most demanding requirement was, that the shape of the brake shoe needs to be freely configurable by the user.

I. Introduction

The Carinthia University of Applied Sciences (CUAS) offers R&D support to companies on a wide range of topics. Waldraff Technologies, a Germany based, well-known manufacturer of production equipment for the automotive industry, requested us to solve a quality control challenge for the inspection of brake shoes. Since other famous providers of image-processing solutions like KEYENCE have not come up with a suitable solution, we at CUAS were able to satisfy all needs and requirements of Waldraff Technologies.

The quality control challenge claimed us to detect imperfections on the backside of brake shoes. These imperfections can cause safety related problems and therefore, the affected brake shoes need to be sorted out. Figure 1 gives an example of such imperfections on the backside of a brake shoe. The glue, which was applied during the previous manufacturing step, is partly damaged. If during the next production step an aluminum plate is fixed to the backside, these imperfections will cause an uneven connection between those parts. The result can be that during the braking process of the car, the brake shoe will start vibrating. In the best case, only a high frequency audible noise will be present, the worst case is that the braking force can be influenced in a negative way.

Figure 1. Brake shoe with imperfections

II. Algorithmic Solution

From an engineering point of view, this was a technically challenging image-processing application. The surface of the brake shoe is highly reflective, the contrast between the imperfections and remaining areas is very low, the selection criteria are complex (depending on the size, number, and location of the imperfection). Due the fact that every car manufacturer and almost every car model needs different brake shoes, the most demanding requirement was, that the shape of the brake shoe needs to be freely configurable by the customer, Waldraff Technologies.

Figure 2 depicts the first part of the developed innovative image-processing algorithm. The acquisition of an image is triggered by a magnetic sensor of a light barrier, which is mounted to the conveyor belt of the manufacturing equipment. The first challenge is to detect the shape of the brake shoe. This is done using a contour

algorithm [1]. In parallel, a particle algorithm is used in order to detect reflective pixels, which represent the faulty areas on the brake shoe. Finally, both images are combined using a binary AND operation.

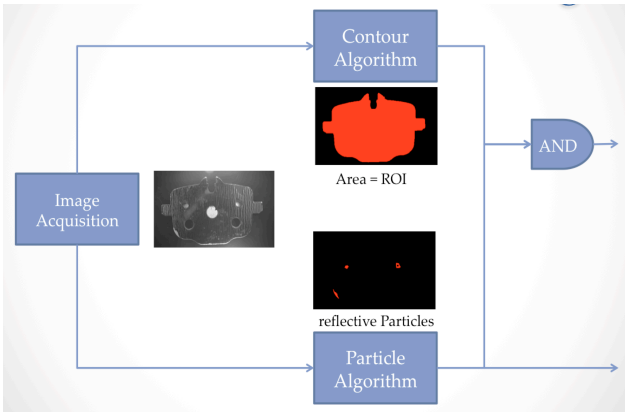

Figure 2. Image-processing algorithm Part 1

In Figure 3, the second part of the image-processing algorithm is shown. The resulting image from the contour and particle algorithm is the input into an Inverted Distance (Danielsson) Function. The Danielsson function [2] returns a distance map of the image. Here, the distance from the border of the object is computed and the result is a gradient, which allows for the classification of the faulty areas. The closer the faulty area is to the border of the object, the higher is its relevance in the quality assessment process, indicated by the grayscale value of the faulty area and shown as bright areas in Figure 3.

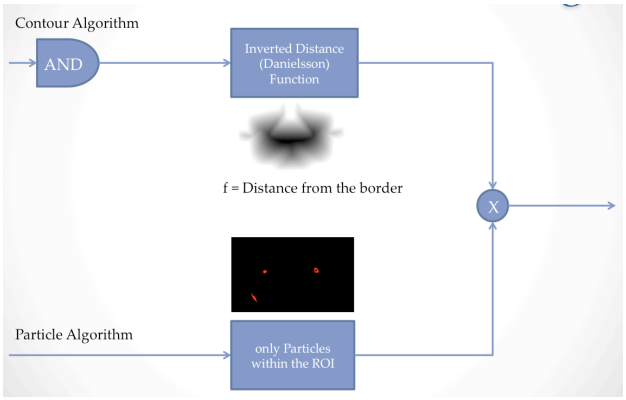

Figure 3. Image-processing algorithm Part 2

Figure 4 shows the last step of the image processing algorithm. The brightness of the resulting pixels is an inverse proportional function to the distance from the border of the object. Finally, using classification functions, the overall brake shoe is analyzed. The size, the position, and the number of faulty areas are used to compute a total impact number. If this number exceeds a given maximum value, the corresponding brake shoe is sorted out and removed from the conveyor belt. Otherwise, this brake shoe passes the quality inspection and proceeds to the next production step.

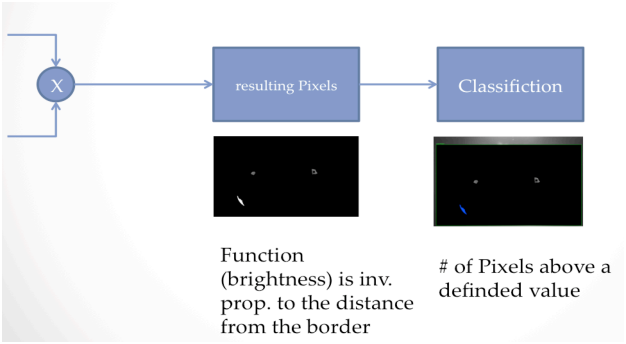

Figure 4. Image-processing algorithm Part 3

Some advantages of the developed image processing algorithm are that

- teaching of the contour of a brake shoe is not necessary, and
- assessment of the border areas of the brake shoe due to the Danielsson function is simple.

Although this algorithm is quite usable, there are some disadvantages, like

- high sensitivity against small deviations in the lighting conditions,
- the background needs to be homogeneous dark, and
- specific brake shoe elements, like holes, need to be taught manually.

An alternative algorithm to the previously depicted innovative solution is the use of a conventional image-processing mechanism. Both, the high sensitivity to changing lighting conditions and the homogeneous black background, become mostly obsolete. The teaching of the contour of brake shoes is now necessary. Since almost all brake shoes have some specific design characteristics (holes, pins, etc.), teaching might also be necessary using the innovative approach.

In Figure 5, this alternative algorithm is sketched. After the acquisition of the image, the first step is to filter ambient noise. This eliminates negligible small imperfections on the brake shoe´s image.

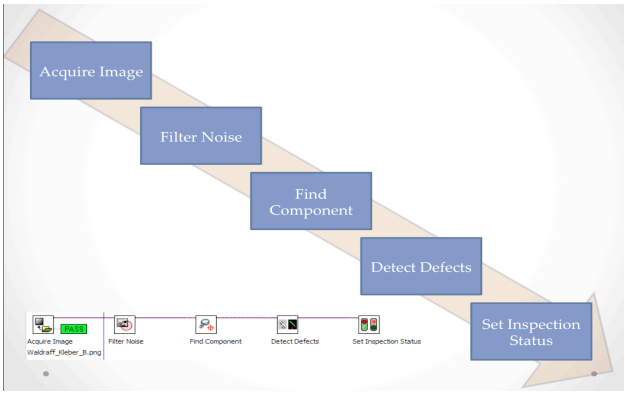

Figure 5. Classic Image-Processing Approach

After this step, a Find Component function is performed. The key to this function is Pattern Matching. Pattern Matching uses a previously thought image of the

brake shoe (see Figure 6). This function is insensitive to the rotation of the brake shoe on the conveyor belt; it can also introduce some minor perspective corrections [3].

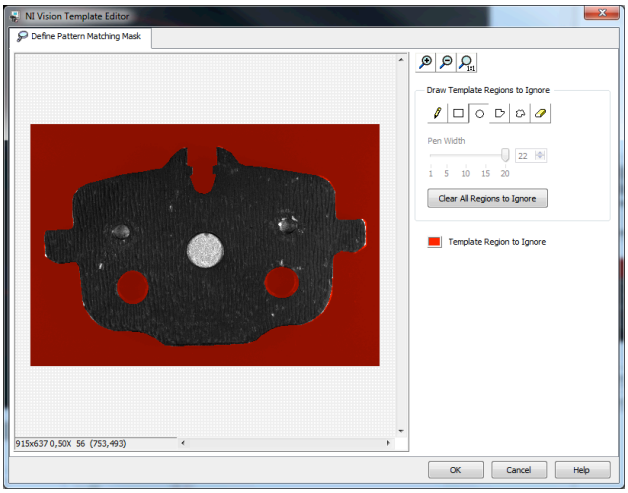

Figure 6. Pattern Matching Setup

The following step, Detect defects (Figure 7), highlights imperfections and faulty areas on the surface of the brake shoe. Here, a previously thought image of the brake shoe is used to eliminate holes and pins.

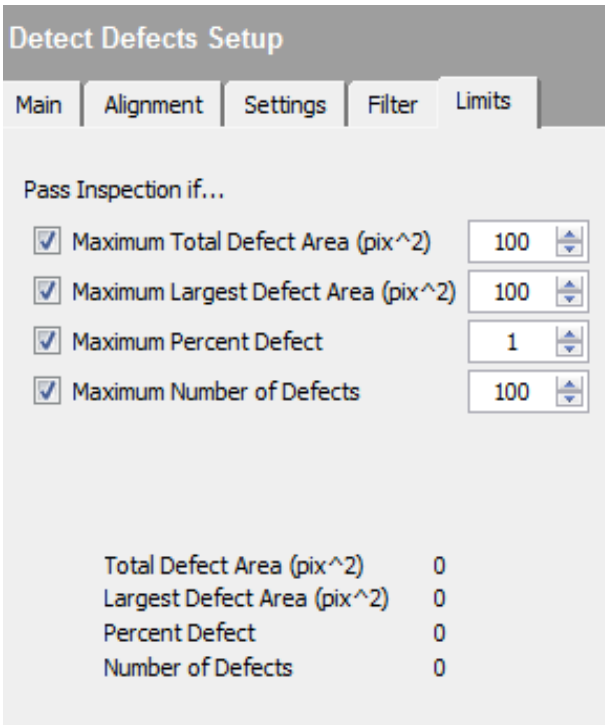

Figure 7. Classic Image-Processing Approach

The final step assesses the results from Detect defects and sets, if necessary, the inspection status of the current part to faulty which will result in the removal of this component from the conveyor belt.

The overall inspection time using an average PC is less than 50ms. This allows for a fast moving conveyor belt with an acceptable number of parts to be inspected per minute.

III. System Overview

The overall image-processing solution consists of hardware, software, and mechanical components. After the brake shoes leave the coating plant, they are transported to the sorting unit using a conveyor belt.

Due to difficult surface conditions of the brake shoes (their high reflectiveness and poor contrast between imperfections and remaining areas) the lighting unit is constituted of a big dimension light dome with four external high-power LED lamps [4] using a color temperature similar to daylight (see Figure 8).

A circular hole on the top of the light dome allows an industrial camera (Basler scA1390-17fm, 1392x1040 pixels resolutions) to capture images of the brake shoes, triggered by an external light barrier.

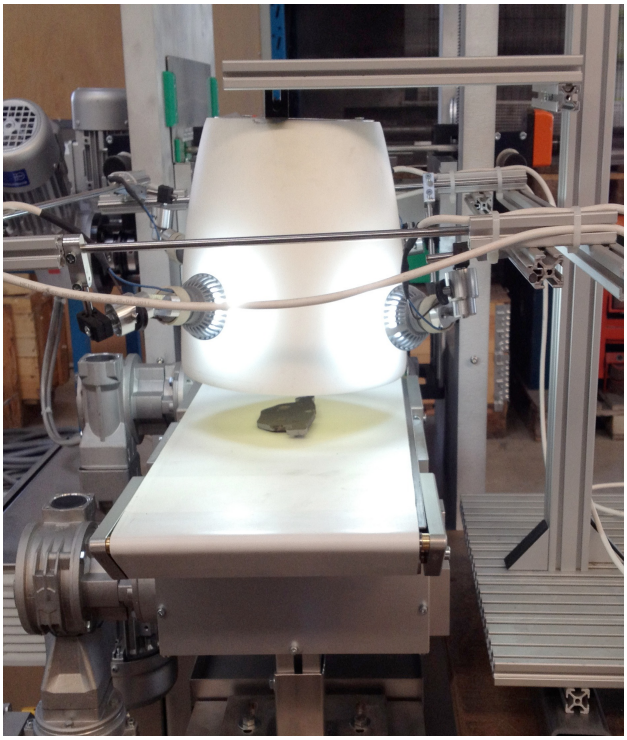

Figure 8. Light dome and brake shoe

A durable and powerful dual-core NI PXIe system, which can withstand the rough industrial environment, equipped with an NI PXI-8252 IEEE1394 interface, controls the triggering unit, the camera as well as the sorting mechanism using PROFIBUS/PA.

IV. Graphical System Design Approach

First, we developed a solution for the image-processing challenge together with students from the Systems Engineering (Bachelor level) and Systems Design (Master level) course in our labs. Then the prototype was tested with the customer's real manufacturing equipment. The most challenging requirement was, that the shape of the brake shoes varied. Our first approach was to develop a self-configuring solution, which would have automatically learned the shape of a new brake shoe. This approach leads to conflicting image-processing demands. Reliably detecting

the shape and inspecting the surface cannot be done with only one lighting setup.

The next and final approach was the one, where the customer would teach the image-processing system the shape and specialties (position of holes, cavities) of a new brake shoe with minimum effort.

CUAS has a long history of using LabVIEW for both educating our students and developing successful solutions for industrial partners. CUAS members, who are advanced LabVIEW Graphical Systems Designers on CLA, CLD, and CLAD level, attend trainings and certifications including classroom, online, or on-site custom training on a regular basis.

Without question, a Graphical Systems Design Approach was needed in order to satisfy all requirements. We have tested a variety of different configurations, for instance a LabVIEW standalone solution as well as a Vision Builder AI stand-alone solution. After intensive testing, a combination of both has been implemented. Now, the only tool the customer needs to use is NI Vision Builder AI [5]. There, we predefine the inspection process for quality control of brake shoes in general. More advanced test-steps, which cannot be accomplished using the build-in functionality of the Vision Builder AI, have been added using the NI Vision Builder AI Development Toolkit with LabVIEW.

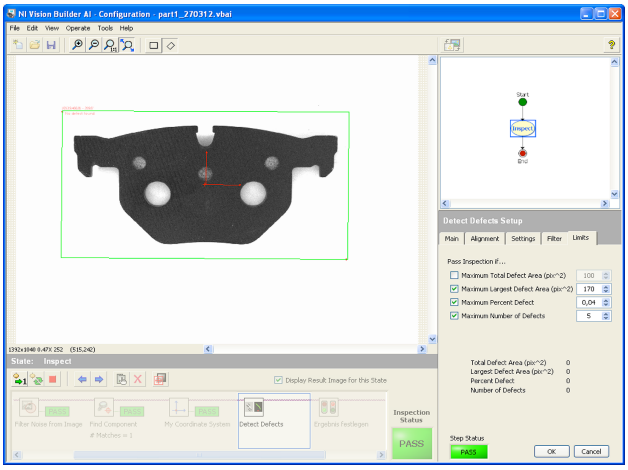

Figure 9. Custom Waldraff Technologies User Interface

The teaching of any new brake shoe requires the customer to configure two steps. The first step is the primary Find Component step, which needs to know about the shape of the part. The second step is the Detect Defects step, where holes or cavities need to be specified. The overall configuration time for a new component now is less than 20 minutes; the previous solution at the customer required a service call to the image-processing provider in order to redevelop the application; which costs a substantial amount of time and resources. During normal operation, a simplified custom user interface (see Figure 9) is used.

V. CONCLUSION

The developed image-processing solution shows that conflicting requirements can be combined into a successful application using NI software and hardware components. The chosen Graphical Systems Design approach can easily be configured by the customer; saving time and money. Furthermore, the quality control process for the production of brake shoes has been significantly improved.

Future requirements will be implemented using LabVIEW VIs which are incorporated into the NI Vision Builder AI testing sequence. Currently, Waldraff Technologies uses the prototype implementation as a demo plant for their customers. CUAS is currently developing extensions to the original challenge, implementing new types of quality control mechanisms for other types of production faults. These extensions can be seamlessly integrated into the existing solution without affecting the operating system.

Students from various courses of study like Systems Engineering (Bachelor course), Systems Design and Electrical Energy and Mobility Systems (both Master degree courses), are taking part together with lecturers and professionals from industry, in the process of specifying, implementing, testing, and installing manufacturing-ready solutions in the image-processing lab and bring them to the customer site. This unchallenged experience offers both, a great opportunity for direct contact to real-world projects and a relevant, useful and challenging image-processing platform for computer based education in automotive applications. Since this form of cooperation between industry and academia generates win-win situations on both side, it will of course be continued in future, possibly using other application domains.

Using hybrid mobile applications for adaptive multimedia content delivery

Aleksandar Karadimce*, Dijana Capeska Bogatinoska*
*Faculty of Computer Science and Engineering
University of Information Science and Technology "St. Paul the Apostle" Ohrid Republic of Macedonia
aleksandar.karadimce@uist.edu.mk, dijana.c.bogatinoska@uist.edu.mk

Abstract - Increasingly more people are using smart mobile devices for delivering multimedia content such as text, video, images and audio in everyday communication. Therefore, there is an increased interest for developing mobile applications that will be supported by different mobile devices. The hybrid mobile applications are built using HTML5 and JavaScript native container that provide access to native platform features, such as built-in camera, accelerometers, GPS and gyroscopic sensors for navigation. This way application can extensively use the mobile device features in order to provide multimedia content that is adapted to learners in m-learning environment. The research focuses on methods and concepts for adaptive multimedia content delivery systems that are considering real-time multimedia delivery to hybrid mobile devices. The adaptive process requires considering the influence from interactive functionality and technical capabilities of mobile devices in m-learning environment. We will conclude the paper with a case study based on the hybrid mobile application used in mobile learning environment.

Keywords: hybrid mobile applications, adaptive multimedia content, m-learning

I. INTRODUCTION

In 2013, the number of mobile-cellular subscriptions had reached 6.8 billion that correspond to a global penetration of 96%, according to the latest report on global mobile-cellular subscriptions by ITU Statistics [1]. This increased revenue from smartphones and tablets sale and fast data connections provided by the mobile operators has created an explosion of mobile applications. Previously, using the web on mobile device with the limitations in screen size and processing capability was a fairly unsatisfactory and frustrating one. With the introduction of the *responsive web design* the website became flexible enough to work well at variating resolutions that can be controlled and fit to the screen, being viewed on phone or tablet or laptop. Considering today smartphones that are getting larger and faster with big displays and quad-core processors, they are also beating many of the desktop PCs used in education, business and home used ten years ago [2].

Besides all of this processing hardware the mobile devices, because of their mobility, have number of built-in sensors for orientation, location and capturing images or video. The sensor technology for smart mobile devices includes the accelerometers to detect the orientation of the device, Global Positioning System (GPS) capabilities and gyroscopic sensors for navigation. Embedding all of this technology into a single mobile device makes it perfect instrument for social networking, travelling, electronic payment, distance learning and etc. However, these built-in sensors can be used only with mobile applications provided by the smartphone vendor or developers that can create application for the specific mobile device as well as use them. If the owners of other type of mobile devices want to use the same application, which consumes the built-in sensors, the developers have to redevelop the mobile application using a different one. These applications can extensively use the mobile device features in order to provide multimedia content that is adapted to learners in m-learning environment. Therefore, today we can see increased interest for hybrid mobile applications, which are built using HTML5 and JavaScript native container that provide access to native platform features. We are proposing an effective adaptive multimedia content delivery for mobile devices by using the hybrid mobile application development platform. This research will provide proof of concept how it is easy to create hybrid mobile applications for different mobile OS vendors in the process of m-learning.

This paper is organized as following: Section II gives overview of the related work for the similar research. Section III discusses the difference between the native mobile applications and mobile web applications. Section IV presents the benefit of using the hybrid mobile applications for m-learning. Section V presents the results of considering the case study for mobile application development platform. Finally, Section VI concludes the paper and proposes future work.

II. RELATED WORK

Mobile applications can be generally classified into three categories: native mobile applications, mobile web-based applications and hybrid mobile applications [2]. Considering the differences in their underlying technology, each approach has characteristic benefits and disadvantages. The native mobile applications, as the name suggests, are built specifically for a particular mobile devices and its operating system. These applications can take advantage of the latest technology accessible on mobile device and can integrate with on-board core applications such as the calendar, contacts, and email or on-board hardware (such as GPS, camera, and

graphics) and software (such as email, calendar, contacts, picture/video gallery, file manager, and home screen widget areas) [3]. Native mobile applications are able to work across multiple devices, separate versions of the application required. On the other side, a mobile web application is normally downloaded from a central web server each time it is run, although applications built using HTML5 can also be run on the mobile device for offline use [3]. Major advantage of mobile web applications over native mobile apps is cross-platform compatibility, which allows reaching the widest audience for the least effort [3]. Unlike a web application that is accessed over the internet, a native application is downloaded from a web store and installed on the device [3]. The process of mobile web application development is relatively cheap, easy, and fast to build, while some device-specific customization is usually essential.

Another major paradigm of the hybrid mobile applications that they can save time by using web-based technologies to design nice user interface and the native shell to access mobile native functionality. These hybrid frameworks allow the use of web technologies for applications development with native access to device's resources [4]. These frameworks are based on open web-standards which mean that the application can be run and tested on common web browsers [2]. It is a cross-platform mobile application development framework which through the use of HTML5, CSS and JavaScript allows the development of applications for iOS, Android, Blackberry, Symbian, Windows, WebOS, Bada and Palm devices [2]. The hybrid mobile application, from the user interface, looks like browser based, with a native application wrapped around it providing access to device native functionality. The developers can feel an enormous difference, as they do not have to rewrite the entire application for each mobile platform, they simply write code in HTML, CSS, and JavaScript, and reuse it across different mobile devices [3].

The mobile learning (m-learning) has been defined as any sort of leaning that happens when the learner is not at a fixed, pre-determined location or learning that happens when the learner takes advantage of learning opportunities offered by mobile technologies [12]. Based on the paper review, given by the Nagella and Govindarajulu in [12], the process of adaptation is achieved in terms of the learner context, the learner's knowledge levels, by the content that is been presented, the learner's style which may vary from learner to learner and adaptation to the device's context. This process leads to personalized learning content adaptation, which becomes increasingly important to meet the diverse needs imposed by devices, users, usage contexts, and infrastructure. The proposed Personalized Learning Content Adaptation Mechanism (PLCAM) is using variety of data mining techniques, including clustering and decision tree approaches, to efficiently manage a large number of historical learners' requests in order that the adaptation engines provide the adapted mobile educational content for the learners [13]. The significance of the adaptive content delivery is a driver for new and competitive multimedia services that are based on hybrid mobile applications for end user learning services.

III. NATIVE MOBILE APPLICATIONS VS. MOBILE WEB APPLICATIONS

One of the main challenges for creating mobile solution is software development in a high-competitive and highly fragmented and rapidly evolving business market. Mobile applications developing require a fair amount of customization to run on various mobile devices and keep a continued stream of new hardware, OS versions and browsers. Therefore, due to differences in the underlying technology of native and web applications, each approach has inherent advantages and drawbacks.

A. Native mobile applications

A native mobile application (native app) is an application program that has been developed for use on a particular platform or device. Native applications are specific to a given mobile platform (iOS or Android) using the development tools and language that the respective platform supports (e.g., Xcode and Objective-C with iOS, Eclipse and Java with Android). It is "Native" because the code is essentially written for that platform and it is built for the native architecture of that device. The user can install the native applications through an application store (such as Google Play or Apple's App Store). Native applications have binary executable files that are downloaded directly to the device and stored locally. Once the application has been installed on the device, the user launches it like any other service the device offers. They provide fast performance and a high degree of reliability.

The native application is free to access all APIs that are made available by the OS vendor, they have the ability to use device-specific hardware and software, which means native applications, can take advantage of the latest technology available on mobile devices. According [5], there are two levels of APIs: low-level APIs and high-level APIs. Through *low-level* APIs calls the application can interact directly with the touch screen or keyboard, render graphics, connect to networks, process audio received from the microphone, play sounds through the speaker or headphones, or receive images and videos from the camera [5]. It can access the Global Positioning System (GPS), receive orientation information and, read and write files on the solid-state disk or access any other hardware element available today or in the future. *High-level* APIs include processes like browsing the web, managing the calendar, contacts, photo album and, the ability to make phone calls or send and receive text messages [5].

The portability of the code to other platforms always requires some level of rewriting which means that code written for one mobile platform cannot be used on another, making the development and maintenance of native applications very long and expensive process for multiple OSs. Native applications provide richer user experience and stronger engagement, but can cost significantly more because they've been developed only for certain OS vendor. The native approach is the best suited when you look for the best performance and maximum capability for a mobile application. However, while native mobile applications can be very powerful with rich feature offerings that have access to all device

capabilities and run seamlessly using the processing power of the devices, developing native applications can be a costly and resource-heavy approach due to each ecosystem using different native code development and separate deployment to each platform [6]. This means if you want as many users as possible to be able to use your mobile application then you have to build multiple versions to cover the variety of platforms.

B. *Mobile web applications*

A mobile web application is a web based application designed for smartphone and tablet use, and accessed through the mobile device's web browser. It combines the versatility of the web with the functionality of touch-enabled devices. The core technologies that are used to build mobile web applications are: HTML (for structuring content), CSS (for applying all visual styles) and JavaScript (for (almost) all interactive functionality). In addition, JavaScript toolkits have been created, such as jQuery Mobile or dojox.mobile or Wakanda, which generate user interfaces that are comparable in appearance to native applications. Mobile web applications are device agnostic and accessed at a standard URL through the device's web browser. The content is searchable (it is visible in search engine results), making it easy in delivering to a large mobile audience than which is available through the app store alone.

Since web applications are browser-based, they're intended to be platform and device independent, able to run on any web-enabled smartphone or tablet. They're relatively cheap to be hosted and deployed (we can host the app on our own web server - no approval processes and no added cost), fast to build - although some device-specific customization is usually required, and easy to support. Mobile web applications can reach the widest range of devices that are cross-platform compatible. Web applications generally cannot access the on-board hardware and software on a mobile device. Requirements such as camera control, direct GPS control (there is limited access to current location), or heavy/complex custom graphics like gaming cannot be supported.

The universal application that can run across any device, on any operating system, simply by using the web browser is the emergently thrilling promise behind HTML5. Inasmuch, HTML5 standard presents new semantic elements such as <nav>, <header> and <article> [6]. However, when it comes to mobile applications the most powerful thing it gives us is browser native media using the new elements tags for <audio> and <video> [6]. It provides possibility for local storage using the localStorage API in order to store their data locally on the user's mobile device. It provides location services by using the Geolocation API and enhances the user's interaction with your service by identifying exact position using the GPS sensors built into the mobile device. The Multi-threaded JavaScript provides the ability to use scripts that run in the background without interacting with users. The main power for developing mobile web-based applications comes with the combination of HTML5, with the presentation tricks delivered via CSS3 and behaviors and functionality through JavaScript [6].

IV. HYBRID APPLICATIONS

We define hybrid as a web mobile application that is wrapped inside a thin native container that provides access to native platform features. Hybrid applications are part native applications, part web applications. Like native applications, they live in an app store and can take advantage of the many device features available. Like web applications, they rely on HTML being rendered in a browser, with the caveat that the browser is embedded within the applications. To the user, a well-designed hybrid mobile application looks very similar to a native app: it is downloaded from an app store, stored on the mobile device, and launched just like a native mobile application.

The comparison of the mobile application is given in Figure 1, where we can clearly see that the position of the hybrid mobile application is between native and web based mobile application.

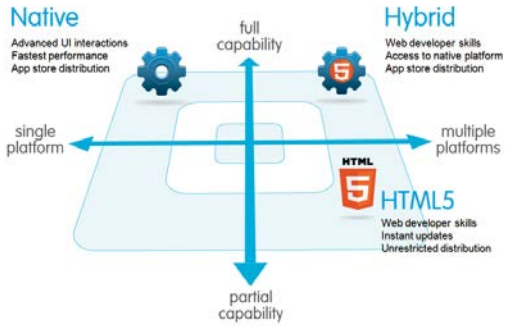

Figure 1. Native, web-based and hybrid mobile applications [7]

For the developers there is a huge difference, because they write at least some of the code in HTML, CSS and JavaScript, and reuse it across different devices rather than rewriting the entire mobile application for each mobile platform. Developers want to code less and accomplish more, to reuse and recycle across multiple platforms as much as possible, and they don't have to start from scratch for each OS. Hybrid applications combine the best of both the native and web worlds. They create a "bridge" between the browser and the device APIs, so the hybrid mobile application takes full advantage of all the features that smartphones and tablets have to offer.

There are few containers for creating hybrid mobile applications. Some of the most popular are PhoneGap [8], Appcelerator Titanium [9] or Intel XDK [10]. PhoneGap [8] is a widespread choice for developers of hybrid mobile applications, because it is a standards-based, open source development framework, free to download, with community-built development tools and plugins. Another popular solution, Titanium offers their SDK and basic mobile APIs for free, with add-on subscription packages for more advanced APIs and tools for Enterprise [9]. Benefit of hybrid mobile applications is that it can save time by using web technologies to develop the UI and the native shell to access lower-level functionality. For the purpose of this paper, we will introduce the tool Intel XDK. According its documentation, the Intel® XDK provides a comprehensive cross-platform development environment for building hybrid HTML5 applications for

mobile phone and tablet devices [10]. HTML5 applications are not limited to smart web pages viewed in a browser, we can also package our HTML5 code and deploy it directly on a mobile device as locally installed hybrid mobile applications. This development tool provides single development lifecycle to be used to create application compatible for multiple mobile devices. Using Intel XDK [10] we can code, debug, test and build mobile web applications and hybrid HTML5 applications for multiple target platforms. We can create an HTML5 project from scratch, or import existing HTML5 applications or modify any of the included sample applications. When a project is created or imported, the Intel XDK creates a special <project-name>.xdk file and locates it in the same directory as the project's index.html file. After the full project is finished, Intel XDK allows us to test our mobile application on a real device. Our mobile application is loaded into a container app on the real device that is representative of the native wrapper included with our mobile application when we build it.

Using this process we can evaluate how it behaves on a real device, and remotely debug it while it runs on the real device. The last step, in order to deploy our application as a hybrid mobile app, is to build it. The build process packs our app into a format that can be submitted to a mobile app store and, ultimately, downloaded and installed on customer's mobile device. All of the popular mobile platforms (Android, iOS, Windows 8, Amazon and Nook) are supported by the Intel XDK.

This great new tool is available for free and runs on Windows, OS X, and Linux. Abbreviated summary of features included in the Intel XDK[10]:

- Editor, Device Emulator and Debugger
- App for On-device Testing
- JavaScript UI library optimized for mobile
- APIs for game developers with accelerated canvas
- Prototype GUI quick-start wizard
- Intel cloud-based build system for most app stores
- No need to download Native Platform SDKs
- Tool to convert iOS applications to HTML5

With this research we were able to create context-aware and comfortable hybrid mobile application for discovering and learning the cave churches at the coast of the Ohrid Lake.

V. CASE STUDY

Cave churches are difficult to detect without careful examination of the environment, therefore we have created hybrid mobile application for m-learning. There are no written sources about occurrence of cave churches on the shore of the lake, presumably beginning emerged in the middle of the IX century with the spread of Christianity [11]. They were built in the recesses and cracks that have made nature at the foot of mountains or large rocks [11]. Cave churches are important because they continue to cherish the tradition of rewriting the Church Slavonic books and allow spreading education and culture. Bearing in mind that worldwide talk about common European cultural heritage, cave churches will be recognized on a wider level through this project. Creating m-learning application that can be used on a variety of mobile devices will mean fast widespread of the application between the learners. Giving the mobile application possibility to use the mobile device built-in sensors capabilities will provide adaptive learning capability. In order to achieve the following goals we propose to use the Intel XDK development platform to create hybrid mobile application. This application provides visual and textual presentation of each of cave churches, and their precise location.

The developed hybrid mobile application has been tested with HTC Desire X mobile device, which has display 4.0 inches (480 x 800 pixels), with camera 5 MP (2592 x 1944 pixels), Android OS (v4.0), CPU Dual-core 1 GHz and 768 MB RAM. The case study included testing of the hybrid mobile application for cave churches on site. At the location of the cave church of the Presentation this is located in the rocky slopes of the south side of the main temple in Caneo, near to the St. Johan Monastery Church in Ohrid. The first testing of the hybrid mobile application started without using Internet connection, which can be seen on screen capture of the application (see Figure 2).

The testing continued by getting closer to the cave church of the Presentation in Caneo, we were able to capture couple of images using the built-in camera. The screenshots of using the camera where made on the HTC mobile device (see Figure 3).

Using the camera from the mobile device we are able to capture the moment of visiting the cave church of the Presentation in Caneo. The image given in Figure 4 shows the cave church very near. Using this feature we were able to store the images in the image gallery for visited cave churches or the HTC phone gallery.

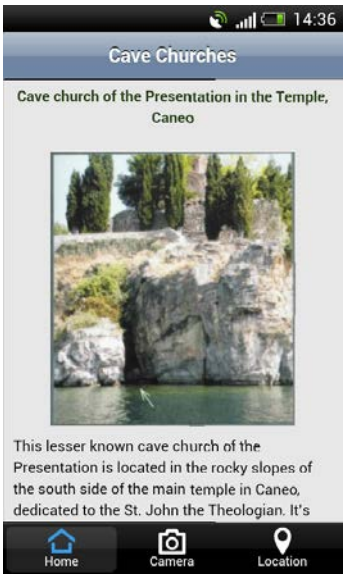

Figure 2. First look at the hybrid mobile application (no Internet).

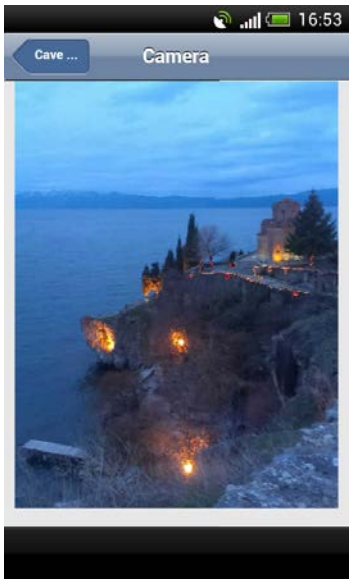

Figure 3. Using the camera from hybrid mobile application on site (no Internet connection).

Figure 4. Using of the camera from hybrid mobile application on site closer to the object (no Internet connection).

The location of the cave church of the Presentation in Caneo is determined using the geo-location plugin API. During our second visit to the site we were able to test the hybrid mobile application using the available 3G mobile data network connection. In order to increase the user interaction with the hybrid mobile application we have added location service. This service is provided by geo-location API, which uses simple JavaScript API and this provides the exact position using the GPS sensors built into mobile device. Therefore, we have created other two screen captures of the hybrid mobile application. The second testing of the hybrid mobile application was done using the HSDPA network, which allows us to have Internet connection on site. This can be seen on screen capture of the application, indicated with the symbol H (HSDPA) and two arrows (see Figure 5 and 6).

Figure 5. Using the location on hybrid mobile application on site.

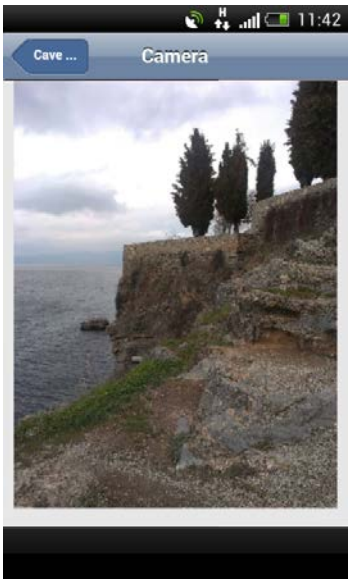

Figure 6. Using the camera from hybrid mobile application on site (with Internet connection).

The Figure 5 provides information for our current location on site, near the cave church of the Presentation in Caneo. Our current location is near the cave church of the Presentation in Caneo is marked with red circle. Whereas, in the Figure 6 is given screen capture of the use of built-in camera on site.

With this case study we have provided validation on use of the mobile device built-in sensors with the use of hybrid mobile application. This way the students using the benefit of hybrid mobile application development platform can easily create mobile app that can be distributed and used by variety of mobile devices. The creation of hybrid mobile applications in the same time this will increase the attention and provide better user experience in the process of m-learning.

VI. CONLUSION AND FUTURE WORK

This proposed model for adaptive multimedia content delivery is utilizing the benefit of hybrid mobile applications for m-learning. These mobile applications support the use of built-in functions on multiple OS vendors using the JavaScript wrap-up containers to enable the hybrid application to work on variety of devices. The main benefit of creating m-learning mobile application is the promotion of cave churches on the shore of the lake will include visual and textual presentation of each of cave churches, and their precise location. The continuation of the project will enable and contribute to the protection and promotion of cultural heritage of Ohrid-Struga region into an area not sufficiently made actual. In the future we plan to start covering the cave churches of the territory of the Republic of Macedonia, therefore we will ask for support from the Ministry of Culture of the Republic of Macedonia.

***Abstract*—Google has enabled the use of interactive image technologies for development of Google maps. The technology is based on presenting only a part of the image, which has sufficient details. This part is selected by appropriate zoom level or navigation through the image. The complete technology pre-processes the image in such a way to enable navigation and zooming and transferring of relatively small files over Internet, instead of transferring the complete high-resolution picture.**

In this paper we present several ideas how to use this technology in the learning process. We present how this technology can be used in analysis of medical images, and in realization of an adaptive e-Learning environment realized by e-Testing features. ADELE (ADaptive E-LEarning) is the name of the concept we propose in this paper to enable this integration. The realized applications are at least the following: 1) realization of a test with an interactive image, 2) opinion image, 3) collaborative learning with interactive images, and 4) voting image for collaborative learning. Each of these application areas will be described with functional description and analysis.

***Keywords*-e-Learning, Interactive Images, e-Testing, Cloud Computing, Medical Images**

I. Introduction

Learning refers to a cognitive process of acquiring knowledge and skills. Adaptive learning is a specific learning process adapted to the current learner's knowledge and skills. Adaptive learning can be efficiently implemented by e-Learning tools. According to Clark and Meyers [1] definition of e-Learning types, adaptive learning maps to *knowledge construction* method e-Learning type with perform-principle goals.

The realization of the adaptive learning as e-Learning may have various implementations, but we use our own approach by a system of online learning with interactive testing [2], based on a well known Socrates and Aristotle's methods, who educated students by continuously asking them questions. This process stimulates critical thinking, and illuminates ideas [3], [4] and finally leads towards knowledge construction with knowledge discovery technology. The students think that they have discovered the solutions, although it was the professor who led them towards careful analysis and deductive conclusions. Our approach uses the computer instead of a professor and acts as an adaptive software agent or a kind of intelligent agent, which will continuously ask the questions and react based on the answers provided.

The background to enable adaptive learning was the establishment of a sophisticated e-Testing system that was recently upgraded to a cloud based solution [5] and Assessment as a Service solution [6].

Recently we have realized an e-Testing systems that uses interactive images, called e-Testing with interactive images (eTii) [7]. The technology to realize interactive images is initially proposed by Google for their Google maps and its application in education [8]. Although, Google refers only to maps using this technology, we find that it can be efficiently used for various interactive images [9], such as medical images or images found in similar scientific areas.

In this paper we propose a new system for adaptive e-Learning based on e-testing with interactive images, called ADELE. The idea is to integrate the new concept of testing with interactive images into an adaptive e-Learning system.

The rest of the paper is organized as follows. The concept model of the ADELE system is presented with explanation of users and functions, interactions and functional description in Section II. Section III presents the main architecture model, along with intelligent software agent concepts and the adaptive e-Learning realization. Related work is presented in Section IV and discussion in Section V, along with presentation of obstacles, advantages and benefits of a such system. Finally, Section VI gives the conclusion and overview of future work.

II. Concept Model of ADELE

The main idea behind the ADELE concept is in realization of an intelligent software agent that acts as a professor in the learning process. The agent particularly has a professor role to evaluate the current student's knowledge and skills and lead him/her towards higher learning goals.

To present the ADELE concept model we will describe the actors in the learning process, and their interaction in the environment.

A. Users and functions

Stakeholders in the ADELE concept are instructors, students, external experts and interested parties, as presented in Figure 1.

Instructors are the users that are setting the e-Learning environment, by performing several functions: uploading samples, labeling characteristic points, lines, contours, identifying appearance of relevant knowledge items and learning objects, developing questions and learning materials. In addition to

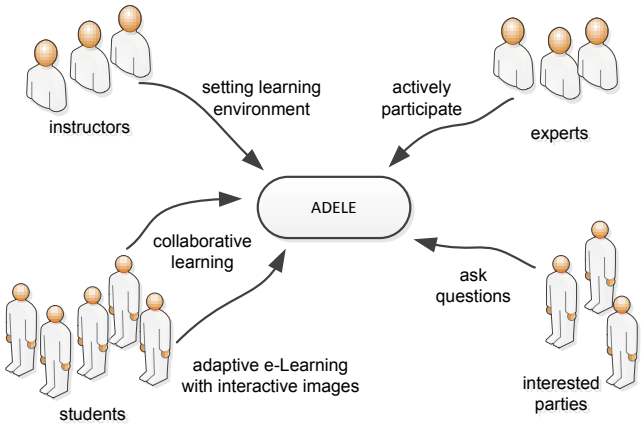

Fig. 1. Users and main ADELE functions.

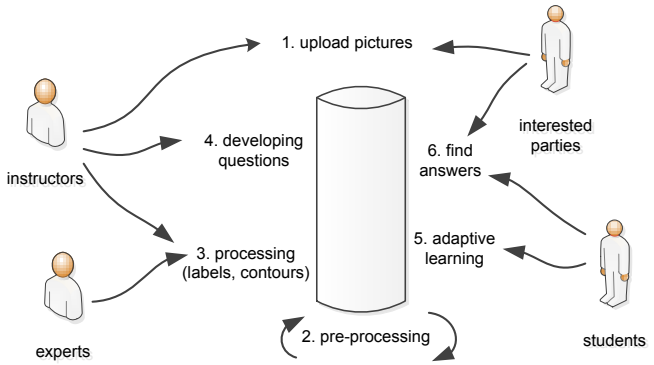

Fig. 2. Sequence of interactions of main ADELE functionalities.

this, they are capable to view and administer the progress of students, with functions that modern Learning Management Systems (LMSs) have.

Students use the system as an adaptive learning environment with interactive images. In this system, besides the learning materials with static samples, and basic textbook explanations, there are questions with interactive images, where they can analyze the question, and point or mark a contour where the knowledge item has to be identified on the interactive image. The adaptive system returns true or false responses for given answers, and the student is motivated to identify the appropriate region that is requested by the given question. In addition students may use collaborative learning approach and discuss with other colleagues about particular questions and answers.

External experts in the system can actively participate on a commercial basis, by giving their opinion for a specific uploaded sample. They can also contribute in the e-Learning system by setting new research results and discovered knowledge items.

Interested parties are those users that can use the system to analyze the latest research results. This is especially important for realization of the life-long learning concept. There is also another group of interested parties, a case when they would like to uploading images and ask for experts' opinion, and use the system with the conventional search tools.

B. Interactions

Interactions among users in the ADELE concept present how the users use the system in the adaptive e-Learning environment. A sequence of interactions that provide the main ADELE functionalities is shown in Figure 2. The following essential activities and functions are identified to be:

1) *upload pictures*, performed by instructors and interested parties;
2) *pre-processing*, realized by the automated system to enable realization of navigation and zooming of pictures;
3) *processing*, realized by experts and instructors, by setting labels and identifying contours for given knowledge items;
4) *developing questions*, realized by instructors, by setting questions using processed samples and enabling an interactive image for a given learning objective;
5) *adaptive learning*, realized by registered students for a given course, where the learning material with interactive images is accessed and used within the adaptive environment that adjusts to a given knowledge of a student; and
6) *find answers*, used by interested parties and students in the life-long learning concept, by enabling search functions and also opportunity to ask the expert for an opinion about a particular uploaded picture.

A more detailed functional description of these activities is presented in the next section.

C. Functional description

To realize the ADELE interactive system means to design and model a platform where text, images and other interactive multimedia elements can combine and integrate in a sophisticated learning environment. The idea is to include rich and intuitive interfaces for teachers and students and simulations and representations for teaching, learning and communicating about a topic.

Technology for interactive images includes upload of huge sized high resolution photos, their pre-processing to be used in web environment for different zoom levels and positioning, setting multimedia labels to certain points, establishing on-line quizzes based on point and click, or click and drag actions, use of multi touch pads etc.

Compact, mobile, primarily touch-based electronic devices could be used, but must be significantly improved for highly interactive medical e-learning. (Multimedia Messaging Service) MMS will research and develop novel user interfaces for e-learning on mobile devices, which may include touch, video or audio based interactions with medical training modules to maximize the user experience.

Interactive images and multimedia technology includes at least the following functionalities:

- *Small resolution pictures* offered via web to enable fast communication and response times, even if Internet speed is not fully broadband;
- *Human Computer Interface with input devices for pointing and sliding*, like point, click, drag, slide and other multi-touch pad interactions;
- *Picture navigation* technologies enabled by zooming and navigating though details in the image, even on multi-touch screen tablets;
- *Pointing and line (contour) drawing* functions realized by clicking, drag and drop or sliding actions, offering a possibility to point and mark picture regions;
- *Labeling and line identification* as technology to enable an environment with learning materials - descriptions of a certain point, region or picture object;
- *Multimedia interaction through sound and video* in addition to text annotations defined with corresponding protocols; and
- *Various picture processing components*, such as blurring, fading, etc.

D. Human Computer Interface

E-Learning human computer user interfaces for advanced image processing includes at least introduction of the following:

- *Touch screens*. The idea behind interactive images needs a pointing device that moves relatively fast over the screen surface. It is used for pointing, line drawing, and similar actions.
- *Multi-touch technology*. This technology is necessity to enable zooming, scaling and similar effects in image processing.
- *Portable cloud enabled devices*. Devices that are small enough and equipped with Internet access are desired to enable full outdoor access 24 hours a day.

Graphical user interface between users and the system can be realized by mouse, keyboard or touch pads. The system responds with presentation of textual and graphical objects. The expected input entered by the users in realization of tests is mostly click by a pointing device (mouse or touch pad) or entered value by a keyboard or selection object accessed by a pointing device (mouse or touch pad).

GUI model to realize the e-Testing with interactive images (eTii system) includes navigation and zooming [9]. For this purpose the system carefully administers the XY position and the size of the visible image part, and loads appropriate image parts stored on the server to present a figure with sufficient resolution. Interaction with image includes at least: object selection, region marking, setting a pin, commenting the pin, and selecting multiple objects.

E. Question Types for Interactive Images

Recently, we have introduced [7] three new question types intended for interactive images:

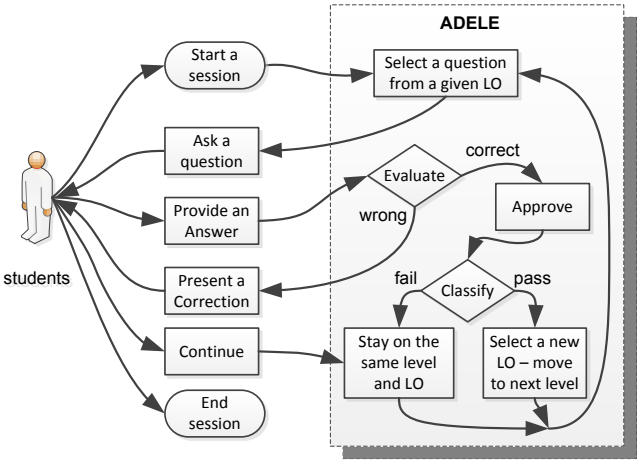

Fig. 3. Algorithms in ADELE adaptive e-Learning concept.

- *Single Graphic Choice (SGC)* question, which corresponds to a graphical variant of a classical multiple choice question with a single answer, but with enormous possibilities to include answer options, presented by dots in the image.
- *Opinion Map (OM)* question, which can be used to collect opinion about certain objects in the image. This is ideal for collaborative learning, where users can set a pin and write a comment on a specific graphical object.
- *Multiple Graphic Choice (MGC)* question, which is similar to the SGC, but the answer is constructed not on a single click on the image but on a selection of several objects.

The research realized afterwards showed possibility of new question types that are already built in our eTii prototype:

- *Voting Question (VQ)*, which corresponds to a graphical variant of a textual voting, where one can click on a specific object that is required by the question, in order to express the opinion with votes instead of comments.
- *Matching Question (MQ)* intended to enable matching among different graphical objects by assigning a line among these objects. Only pairs of objects can be matched.

III. ADELE Architecture Model

The architecture model will be presented by description of the realization of the adaptive e-Learning concept, the intelligent software agent approach and the ADELE main building modules.

A. Adaptive e-Learning

The concept behind establishment of an adaptive e-Learning environment is presented in Figure 3. A student starts the learning session and the ADELE system selects a question from a given Learning Objective (LO). Then the e-Testing engine is started and the question is presented to the student. The student provides an answer on the interactive image via

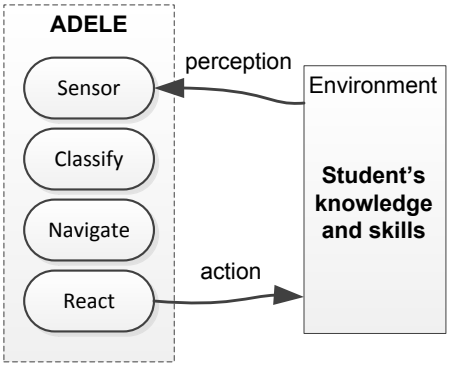

Fig. 4. ADELE adaptive e-Learning as an intelligent software agent.

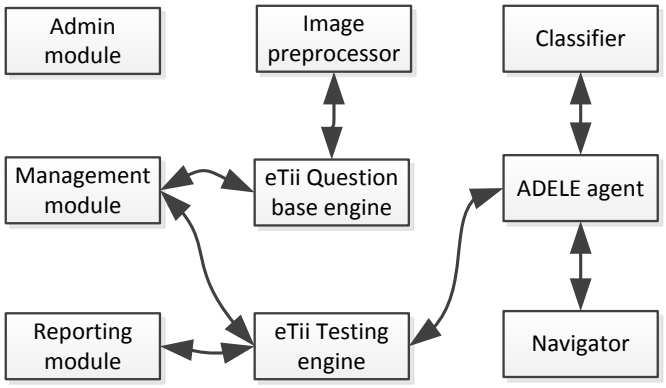

Fig. 5. Overall architecture of the ADELE model.

the graphical user interface, as presented in previous sections. The e-Testing engine is responsible to evaluate the answer and responds with wrong or correct options. In case of the wrong answer the e-Testing engine provides a corrective measure by displaying the correct answer and suppying explanation.

All previous functions and interactions were realized by the e-Testing engine, as described in the eTii prototype. It acts as a sensor part of the agent which makes the perception of the environment - presented by the evaluated level of provided answer.

In case of approval or when the student continues the session, ADELE starts with classification of the student's knowledge and skills. The classification algorithm responds with pass or fail as an estimation if the student has learned the corresponding LO.

The next part is realization of the navigation algorithm, which determines the level and LO adapted to the current student's level. It continues with the same level and LO, or in case of conclusion that the student has passed the corresponding LO, it moves to the next, usually higher level, with selection of a new LO.

B. Intelligent Software Agent

The intelligent software agent concept is presented in Figure 4. The environment is presented by the evaluated student's knowledge and skills. The sensor is realized by the eTii testing engine to realize the perception of current knowledge presented by the student answer. Later, another module realizes the classification of overall student's knowledge for the given LO and makes a decision. The next module realizes the navigation in the pool of LO presented by corresponding levels. This finishes with reaction, presented by asking the next question from a selected LO, and realized by the eTii engine.

A comprehensive explanation about classification strategy and navigation algorithm can be found in our recent publication [2]. We have analyzed several classification strategies to evaluate student's knowledge with pass or fail, by asking a subset of questions from a given pool of questions in the LO. The conclusion is that the strategy three correct answers in-a-row was the best alternative, when analyzing several criteria, such as avoiding boring repetition of the same question within a given LO, having sufficient probability of correctness if all questions were asked, analyzing user satisfaction, and analyzing results from provided experiments.

The navigation algorithm through levels was realized according to the already known tree traversal algorithm, particularly the preorder traversal algorithm for visiting all nodes in a given level before moving to a higher level (LRO preorder is visiting first the left beaches, then the right and at the end the node itself).

C. The ADELE architecture

The basic architecture is based on the eTii testing solution [7]. The overall architecture model is presented in Figure 5, presenting the 9 essential modules and some of the essential workflow communications among modules.

The architecture of the adaptive e-Learning concept of the ADELE system is using the following three modules:

- *ADELE agent*, which provides intelligent agent software functionality, communicating with sensor, classifier, navigator and finally reacts upon fulfillment of certain conditions;
- *Classifier*, which realizes the classification algorithm and makes decision about pass or fail; and
- *Navigator*, which realizes navigation in the knowledge levels and LOs, enabling staying in the same LO, or moving to the next levee and LO, and also selection of appropriate question from a given LO.

The overall architecture of background activities that support the ADELE system is using the following three modules:

- *eTii Testing engine*, which provides e-Testing functionality with interactive images and realizes the graphical user interface with the students, including functionalities, such as question asking, students answering, evaluation, presenting corrective measures, approval, etc;
- *eTii question base engine*, which provides functionality to fill the question base with interactive images, including functionalities, such as question developing, question processing, level organization, LO organization, etc;

- *Image pre-processor*, which processes images for exploitation as interactive images;
- *Reporting module*, which prepares and presents reports, statistics and analytics;
- *Management module*, which is responsible for management of classes, learning sessions, and overall system realization of a course; and
- *Admin module*, which realizes the administration of courses, users, authentication, authorization, and security.

IV. Related work

Two categories of adaptation are identified in learning environments [10]. The first is about *Adaptive Interaction* and refers to interface adaptations that facilitate the process of user's interaction. The second targets the *Adaptive Collaboration Support* intended to capture adaptive learning involving collaboration towards common objectives.

There are currently numerous organizations, like the Dublin Core Metadata Initiative, the IEEE, the IMS Global Learning Consortium, the Alliance of Remote Instructional Authoring and Distribution Networks for Europe, the Aviation Industry CBT Committee, the Advanced Distributed Learning Initiative, etc., that are dedicated to, or have committees and working groups active in the establishment of eLearning standards. It should be noted that the core standards are the various specifications of IMS1, ADL SCORM2, and the AICC specifications [11].

Having an intelligent (adaptive and interactive) online system is very important both for the students and teachers since the students gained knowledge and skills more easily when an interactive and adaptive environment for online learning is used [12]. Such a system should also recognize the students' motivation, emotion and mood condition since disengaged students usually gain less from learning than more motivated and engaged students. Several relevant attributes identified by Cocea and Weibelzahl [13] can be used to predict the students' disengagement. They even improved the prediction by analyzing the log-data of the system (the time of reading pages) [14]. Moridis and Economides [15] use the previously students' correctly answered questions to determine their mood during the assessment. They even improved their method by including the latest correct or incorrect answer [16]. An adaptive Learning Management System is proposed by Yaghmaie and Bahreininejad [17] by using link-level and content-level levels of adaptation to the learners' needs.

Several authors benefit of applying formative assessment in learning environments [18], [19]. Hwang and Chang [20] proposed an approach based on a formative assessment in order to improve the learning outcomes of students in a mobile learning environment.

However, although all these previous solutions, models and frameworks improve the learning in one or another way, all of them are using multimedia only as a support to the knowledge base. Revolutionary, in this paper we propose an adaptive e-testing system based on interactive images.

Browser technology to enable the required navigation and zooming depends on existing Google APIs [21]. Although the API was originally intended for maps only, we found that this technology is well suited for other scientific images, including astral images, medical images, etc. These are high resolution and huge size images and the only way to make a detailed analysis is by using the navigation and zooming features. Especially this is the case when the images are loaded from Internet. Current zooming enabled in the API allows up to 10 levels, which enables sufficient details. Storing the image in all zoom levels usually uses up to 10 times more storage capacity, than the original size, but the average load size of each image in a single session is at least 100 times less, as our experiments prove.

V. Discussion

The main obstacles in enabling a high resolution image presentation and manipulation of graphical objects is the size and enormous communication times to transfer the whole image from a server to the web browser that required it. Knowing that only a selected image part should be presented with sufficient details, the idea behind presenting the global figure with low resolution, enable navigation and zoom only the selected part saves a lot of time.

The application domain is not limited in only specific areas, such as, astral images or medical images. To realize the proof of concept for the eTii system, which is intended for e-Testing with interactive images, we have developed a set of 200 images for the course of Computer Networks [7]. The questions asked included typos of:

- Click where can you find an occurrence of a typical object or a concept on the figure!
- Mark a region with specific characteristics on a figure!
- Comment specific characteristics of each object!

For example, a figure contained a complex network with a lot of devices and the student had to identify which device is a router, or switch, or mark a subnet region. To realize this, the student has to navigate and zoom enough to read all details, including IP and MAC addresses assigned to each device. Another example is analysis of a sequence of signal levels and application of a specific data encoding scheme, such as biphase Manchester, NRZ or similar encoding techniques. There were several mistakes on purpose and the student has to click on all mistakes.

The motivation to include interactive images instead of classical multiple choice questions is based on several criteria, including extended domain of search options, extended answering possibilities, favoring creativity and solution discovery instead of memorizing, decreased cheating etc. We have already published a more detailed analysis of these advantages and analyzed in details in [9].

Combining the advantages of applying interactive images with the adaptive e-Learning concept tends to have even a more precise evaluation of current student's knowledge and skills, from one side and from the other side, to enable a better

learning platform, which initiates a higher degree of curiosity and establishment of a collaborative learning principles. Interactive images offered via an adaptive learning environment increase the overall understanding of learned material, avoiding memorization in multiple choice questions. Having a visual presentation instead of textual phrases is always a better concept to understand the corresponding concepts and analyze their relations. The system also provokes knowledge discovery instead of guessing in multiple choice questions. These concepts support the overall goal for knowledge construction method of the ADELE system.

VI. Conclusion and Future Work

In this paper we have presented the ADELE concept of an e-Learning adaptive environment that exploits interactive images. The work on building a prototype has already started and we expect that it will be realized in 2014.

The complete ADELE architecture consists of several modules, such as the eTii question base engine, image preprocessor, management module, reporting module, admin module and adaptive e-Learning module. Our solution for realization of the adaptive e-Learning module uses the already developed eTii engine for e-Testing with interactive images and on top of it, it builds the classifier and navigator modules. It acts as an intelligent software agent by sensing the student's knowledge and skills from the answer given, making a decision on how to proceed with corresponding classification and navigation algorithms and then reacting by asking a new question.

As future work we plan to test which strategy suites the best when nteractive images are applied, since we have used the three correct answers in-a-row strategy, mostly as a conclusion from realization of a conventional adaptive environment that uses multiple choice questions. The experiments will cover student's behavior and enable better estimation about classifying strategy to decide whether the student has learned an appropriate knowledge item or LO. We plan to realize experiments about the realization of the navigation algorithm, also. The user satisfaction and usability of the applied system are also foreseen to be realized as soon as the prototype is build and used. Development of a strategy to realize relevant learning content and development of a sustainability strategy are also planned.

We plan to continue with development of questions for other courses from computer science and create an extensive database of questions. Our experience shows that these type of questions are more difficult than the standard multiple choice questions, and that the students need a lot of concentration to solve the test. In addition, these questions actually present those analytical skills to understand the concepts and analyze complex figures, in comparison to the multiple choice questions which can correlate to memorizing capabilities of the student. We plan to report these findings in details after the finalization of the course and analysis of obtained results.

***Abstract*—In this paper, we report a survey that gathered the opinions on electronic student services by implementing the iKnow system. The methodology to evaluate user satisfaction was based on realization of questionnaires, and surveys with students, as well as interviews with the teaching and administration staff. We have realized several surveys and questionnaires, not just during the development cycle, but also during first two years of exploitation.**

The results show that most respondents have a positive attitude towards the iKnow software system. A very interesting fact is the one about swing of the attitude towards better recognition of the system, mostly due to the understanding of iKnow possibilities at all. Overall, our findings imply that iKnow has alleviated much of the basic and long-range problems that have challenged students in the past. Additionally, the study also reveals some shortcomings of iKnow, and lays ground for defining and building an even better user experience with the iKnow system.

***Index Terms*—*user interface design*; *software verification*; *software validation*.**

I. Introduction

iKnow [1] is an E-Student Services System developed as a delivery of an EU financed Tempus Project. It realizes the vision of a paperless university management and electronic workflow of student activities. Both students and staff use iKnow as a web-based application to automate the entire system of student programs, courses, the relationships among courses, courses with programs, mapping of teachers with courses, etc. The processes of studying, enrollment of students in semesters, enlisting in courses, exams passed, ECTS credits earned are also managed in this way. Members of faculty, classrooms, laboratories and all resources can be be administered with this module. Using iKnow, a total of 76 different workflow activities previously done by administration personnel are now automated and only a few clicks away.

Yet, the question whether iKnow will fully replace the outdated Student Services Desk largely depends on good user experience and acceptance by the users. iKnow is intended as an essential and indispensable component of daily university administration, collaboration and communication. In fact, users need to spend a significant amount of time daily interacting with iKnow. It encompasses a wide set of functionalities and presents a huge amount of data. For these reasons, it is evident that a seamless and pleasant user experience is of crucial importance and may have drastic consequences. Nielsen [2] identifies that usability has multiple components and is traditionally associated with five usability attributes: learnability, efficiency, memorability, errors and satisfaction. In this paper we are tackling only the user satisfaction. A user-friendly and user-centered design has become an increasingly important feature of all modern information technology systems.

User satisfaction refers to a domain, where the users do not have the relevant software development documentation that expresses the user requirements and software design, but can help in evaluation if the realized system corresponds to their expectations. In this paper we target the end users to find out how much they accept the system and to evaluate their attitude. We use a methodology with realization of questionnaires, surveys and interviews, realized immediately after deployment and also after two years of exploitation. This approach will show if there is a change in general attitude and if the software has been improved to meet the user expectations.

User experience (UX) shows a growing interest within the HCI (Human-Computer Interaction) community, both in academia and industry. Recently HCI researchers and practitioners have recognized that products are not merely means to achieve goals; they fulfill our need for stimulation [3], they evoke memories [4], and they provoke emotional reactions [5]. Products need not only to succeed in gaining initial acceptance, but also to become objects of increased emotional value over prolonged use.

In this regard, the traditional user satisfaction testing framework has its limitations. It focuses primarily on user cognition and user performance, In contrast, UX addresses human needs that go beyond the instrumental. In fact, UX highlights non-utilitarian aspects of human-computer interactions, shifting the focus to user affect, sensation, and emotion. As [6] observes, UX is associated with a broad range of fuzzy and dynamic concepts, including emotional, affective, experiential, hedonic, and aesthetic variables.

The rest of the paper is organized as follows. The iKnow system is briefly described in Section II. In Section III we present the used methodology and elaborate on implementation decisions. The results are presented and discussed in Section IV. Finally, relevant conclusions and future work is specified in Section V.

II. Description of the iKnow System

The eStudent Information System iKnow is designed to store and administer student's records and personal files, as well as related university data. It is developed using innovative approach and knowledge management techniques. The system provides exchange of electronic information among all stakeholders: students, professors, administration, university management and the Ministry of Education [1].

The system consists of two main components: the new students Enrollment Student Services (ESS) and the Core Student Services (CSS). Both components consist of modules and special software modules have been developed for data migration from legacy software applications into iKnow using Excel template files.

The ESS component consists of the candidate's enrollment wizard, the enrollment forms for manual entry of candidate's data, candidate's data processing, ranking module and the enrollment results publishing.

A total of 15 smaller modules define the CSS component, including the following:

- Module for administration (university and faculties), which encompasses users management, exams sessions, semesters and the integration with the learning management system Moodle;
- Module for study programs, which encompasses schedules, study programs management, courses management, equivalency of courses, connections between courses and programs, etc; and
- Module for academic records with goal to administer evaluation of academic activities that students perform while following the course, including laboratory assignments, homework, projects, partial and final exam results.

28 roles have been defined in the CSS component, including 6 different roles of technical, resource, IT and overall administrators on university, faculty or computing center level. Several roles have been assigned to university management administration, including HR department, student services, financial officer, ECTS coordinator, rector, deans, academic vice-rectors and vice-deans, and professors. The main intended role are the students, but the set is extended to tutors, evaluators, and other similar correlated roles.

76 workflow processes have been realized within the iKnow system, including enrollment in particular course subject, applying for exam, administration of academic records, repotting etc.

Overall the electronic student information system iKnow is a complex software solution used by more than 30.000 students and 3.000 staff at the Sts Cyril and Methodius University.

In the context of our study we tested both the CSS and ESS components.

III. Methodlogy

The goal of the methodology is to evaluate the user satisfaction with iKnow. According to Nielsen [2], from a usability perspective, questionnaires and interviews are indirect methods, since they do not study the user interface itself but only users' opinions about the user interface, and are direct methods when it comes to measuring user satisfaction. We have used questionnaire, survey, and interview methods to test the user experience and enable sufficient base for delving conclusions about user satisfaction evaluation.

A. Metrics

In the context of user satisfaction assessment, methods include focus groups, interviews, questionnaires, and surveys [7].

Interviews and focus groups are structured methods of inquiry, which are used to gather information about users' experiences and preferences. While surveys and questionnaires may also be used to gather such information, interviews and focus groups allow for more interaction with the users and for immediate answers to questions raised during the interview or focus group. In addition, focus groups consist of multiple users whose interaction may raise additional issues of interest [8]. Interviews and focus groups are generally conducted at early stages of product development, while surveys and questionnaires are generally used later in the product's life cycle. In an effort to incorporate the strengths and avoid the weakness of each method, we decided on a survey style with open-ended questions.

Regarding the survey design, it has been proven repeatedly that the way a survey question is asked can have influence on the answer. For instance, it is how political campaigns can generate opinion polls saying the exact opposite of what their opponent's poll revealed. It is evident, therefore, that the survey must be as neutral as possible, in order to yield an accurate, unbiased picture. Aside from the fact that the mere asking for their opinion will change the users' opinion of the product, a survey shouldn't in itself be considered a marketing tool. For this reason, the survey questions were asked in a plain, matter-of-fact way, and not in an advertising tone. In fact, much care was taken in designing the questions. For example:

- *NOT:* The iKnow team takes every attempt to please the students in regard to technical support. How would you rate our success in these efforts?
- *BUT:* How would you rate iKnow's technical support?

Another point requiring great care is designing the rating scale used. Lickert's scale [9] is used as a method of constructing an attitude with values from 1 to 5. The used system actually corresponds to the grading system used for the students in primary and and secondary schools, and the students are well used to it.

Specifically, giving an odd number of response options favors a 'neutral' response. In contrast, an even number of response options, without that comfortable middle ground will force a respondent to choose one or another of the extremes. To avoid similar traps, we decided to ask open-ended questions, and then evaluate the answers we received. Thus, the users' opinions were coded as:

- *(5) Strongly satisfied (strongly approve)*, flagged whenever a respondent expressed the most positive attitude,

the user is aware of, and strongly approves the statement;
- *(4) Satisfied (approve)*, flagged whenever a respondent expressed a positive attitude and approves the statement;
- *(3) Neutral (undecided)*, flagged whenever a respondent is neutral to express a positive or negative attitude, and had no particular comment or had no remarks;
- *(2) Not Satisfied (disapprove)*, flagged whenever a respondent had one or more remarks or stated problems encountered and disapproves the statement; and
- *(1) Strongly Not Satisfied (strongly disapprove)*, flagged whenever a respondent expressed the most negative attitude, the user is aware of, and had a lot of remarks or stated problems encountered and strongly disapproves the statement.

B. Designing the Surveys

User satisfaction questionnaires can be quite sophisticated [2]. For example, the QUIS (Questionnaire for User Interface Satisfaction) method reported by Chin et al. [10] rates 27 system attributes on 10-point scales, followed by a factor analysis. Furthermore [11], the provided factor analysis of a subset of subjective satisfaction questionnaire consisting of 18 questions shows importance of three underlying factors: system usefulness, information quality, and interface quality. It should be possible to assess these three factors with a reasonably small number of questions.

Another study provided by Bailey and Pearson [12] introduced 39 factors in the Computer User Satisfaction (CUS) questionnaire. Their conclusion based on rating of each factor, found that the users rated as most important: accuracy, reliability, timeliness, relevancy and confidence in the system. A lot of various studies also concluded that a simpler version of user satisfaction measurement instrument is necessary and sufficient to make relevant conclusions.

We developed a framework of questions (see Table I) during the project as a part of a collective team development of a corresponding control quality work package. The project participants including Technical University of Dortmund, Germany, London South Bank University, UK, University in Ljubljana, Slovenia, and University Ss Cyril and Methodius, Skopje, Macedonia, have actively participated in planing and developing the survey. A more detailed elaboration [13] shows the essential objectives of the survey, with target to evaluate the user satisfaction of the iKnow system. The focus was set on employees and students in development phase of the iKnow system, and after deployment on students as end users in the exploitation phase.

The final goal is to measure the user satisfaction with different aspects of iKnow. The used communication medium is digital (electronic) questionnaires, on line survey and personal interview. The techniques included closed questions defined as simple and clear statements using the already explained evaluation metrics Lickert's scale from 1 to 5. The sample size is 400 students in 2012 and 300 students in 2013. The questionnaire survey was conducted in a one week period during the semester as anonymous survey.

TABLE I: The content of the closed questioned survey

ID	Question
Q1	What is your general satisfaction from the iKnow system?
Q2	How do you evaluate the support that the system gives you as a student?
Q3	Do you support future usage of this system with enhanced functionalities?
Q4	The browser you are using displays all information in a correct way?
Q5	The loading time and the response time of the system correspond to the content which is displayed?
Q6	The system has a consistent look and feel?
Q7	The messages the system communicates are clear and descriptive?
Q8	There is an easy channel available to communicate with an administrator?
Q9	The content is understandable and up to date?

The planning process included analyses of several general user satisfaction criteria:

- Accuracy;
- Layout;
- Navigation;
- Exception and status handling; and
- User guidelines and online help.

The quality and information structure criteria included questions about content and efficiency.

Initially the draft survey consisted of more than 23 questions in the software development phase, when the survey was intended as customer response in the agile development. A careful analysis in the software exploitation phase after software deployment has recommended to reduce the number of questions to 9 essential questions. This was also necessary to make the survey as small as possible and applicable for greater number of students taking approximately 5-10 minutes on average for answering the survey. These nine questions showed to be the most essential for selected criteria in making final conclusions to realize the main objectives stated in this paper.

Finally, the realized survey consisted of those questions presented in Table I. The first four questions refer to the functionality criteria, the next three to the layout, and the last two to the navigation, user guidelines and online help criteria. We have reduced the questions that express the content and efficiency criteria, due to the fact that the software development phase is finished. This was also the reason to reduce the questions in the overall assessment criteria and also for exception and stats handling.

In addition to the closed question survey realized with relatively huge number of participants, we have realized also an open question survey for a smaller group of students, where they can express their comments for their user satisfaction. In addition we have added new criteria:

- New approaches; and
- Quality assessment.

The new approaches criteria were chosen mainly to include new sophisticated trends in realization of the software. It includes the user interface, which changes and improves

TABLE II: The content of the open questioned survey

New Approaches	
Q1	Could you share the application on Facebook using the iKnow system?
Q2	What do you think, what is that something that Facebook has, the iKnow system is missing as user interface?
Q3	What do you think, during the application, what information should be given, such as pictures, like on Facebook?
Q4	What do you think if your Facebook profile should be connected with your iKnow profile?
Q5	What do you think, if there should be an option for "Like" or "Comment" on the iKnow system, like there is on Facebook, to express yourself better?
Quality Assessment	
Q1	What do you think about the process of enrollment?
Q2	What remarks do you have about the steps of the enrollment application?
Q3	What do you think about the iKnow system?
Q4	What would you change in order to make the iKnow system better?

with new technologies to enable better user experience. Our intention was to include Facebook as the most popular social network and used application by the students (more than 95% students actively use Facebook).

The second criteria includes quality assessment of the both the ESS and CSS modules.

The survey presented in Table II included also total 9 questions, as the closed questioned survey. However, it was realized as interview and not as electronic version of a questionnaire, since most of the participants do not like to spend a lot of time on an electronic survey, while on interview will be able to provide more attention.

C. Conducting the Surveys

At the onset of the surveys, in September 2013, iKnow was well beyond the deployment stage, actually two years in exploitation and further improvement. The software has been officially accepted in October 2012, and in the last year several improvements have been realized (mostly in developing new reports, and improving some procedures). The process of re-design of workflow procedures for administration related to student services and academic records was finalized by September 2012 after alms a full year of meetings, presentations, and trainings. Probably the most difficult issue was persuading the university management to use the new system, although it had not yet been tested and rolled out. Luckily, all the processes were finalized and the system is officially used. The user satisfaction survey helps the university management to improve the system.

The interview method was conducted for a total of 32 participants randomly chosen among prospective students at the university who applied for enrollment. These users face the iKnow system for first time, in contrast to the students who provided answers for the closed questioned survey, who have been experienced in using the iKnow system. Statistically, this sample size yields still significant results intending to provide quality analysis of the used user interface technology, although there were more than 8000 prospective students applying for the enrollment at the university.

TABLE III: Statistics for the closed questioned survey

Question	avg. 2012	avg. 2013	st.dev 2012	st.dev 2013
Q1	3.10	3.68	13.81	12.65
Q2	3.18	3.52	16.07	11.27
Q3	3.72	3.90	12.22	14.72
Q4	3.18	4.32	17.82	23.93
Q5	3.18	3.56	17.82	13.52
Q6	3.35	3.75	21.71	13.23
Q7	3.32	3.70	16.99	13.17
Q8	3.16	2.77	21.45	07.79
Q9	2.92	3.33	13.86	09.80
Average	**3.23**	**3.61**	**16.86**	**13.35**

We have satisfied the selection criteria for socio-demographic characteristics, and also to cover various faculties the students were applying for. The sample included 16 males and 16 females and the origin town for half of them was the town where the University is situated.

Conducting the surveys was a relatively straight-forward task. We realized the survey by making interview, not in an electronic way with higher number of participants. This enabled to analyze open-ended answers and also ask questions in context to the discussions. Interpretation of this survey gave a set of suggested improvements and ideas.

To make the survey more attractive, an innovative method of organizing a lottery was included, where the interviewers draw a lucky question and were awarded with a small present (chocolate). Bearing in mind that the survey should take no more than 10 minutes, not all questions were asked of all respondents.

IV. Results and Discussion

The results include descriptive statistics including textual description and visual impressions, followed by discussion of trends and establishing conclusions about typical behavior. Finally the recommendations are given as a consequence of detailed analysis of the results, observed trends and typical behavior in the conclusions.

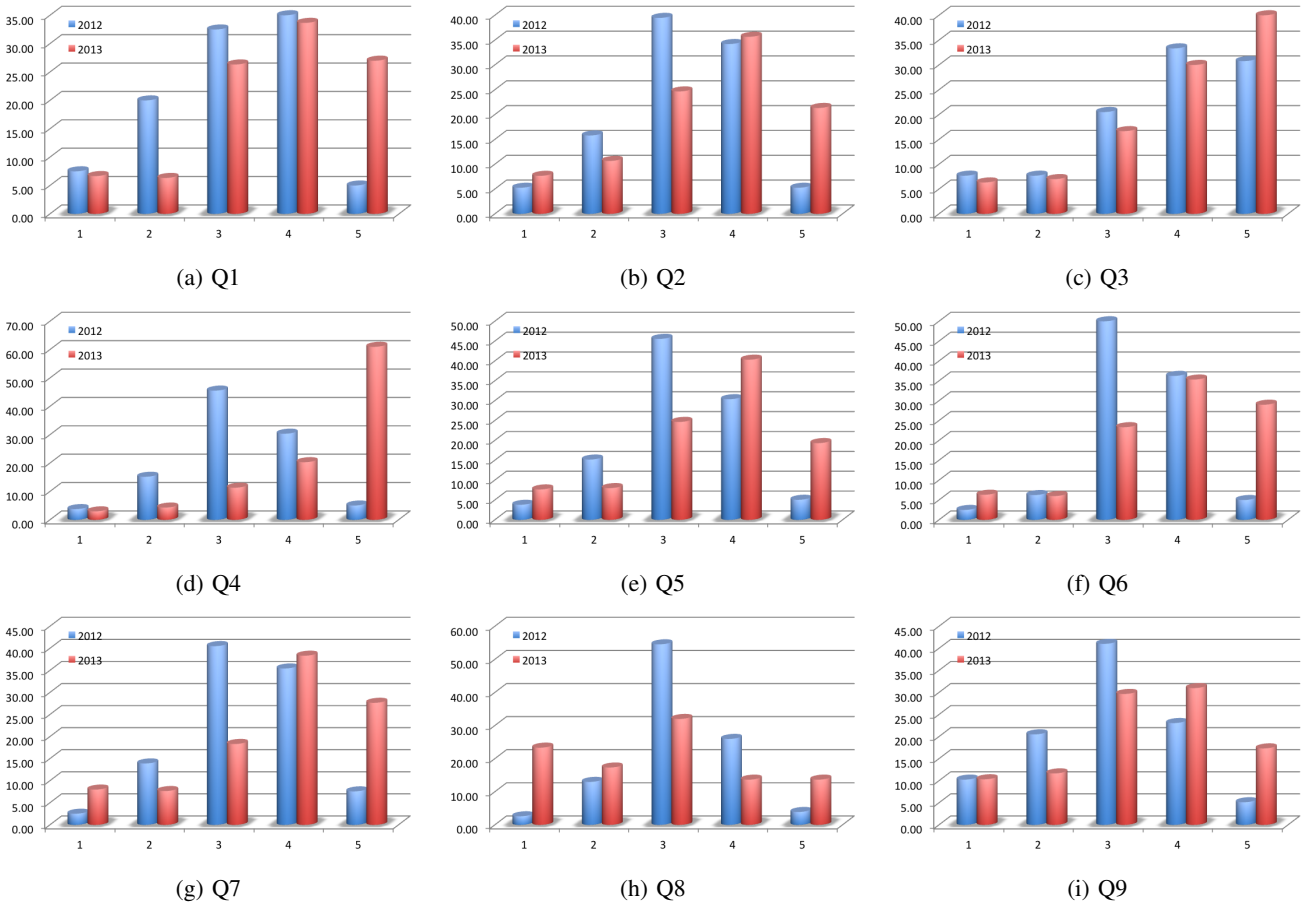
A. Discussion about results from closed questioned survey

A total of 400 students participated in the survey in 2012 and 300 students in 2013. Visual representation includes relative presentation of answers to avoid the difference of the number of students that answered a particular question and enable comparison of results in the two consecutive years.

We have compared the results from a survey conducted in 2012 [13] and a survey we have conducted in 2013. The relative responses are charted in Figure 1.

Statistical calculation of the average and standard deviation are presented in Table III. In the avg. columns we present the average grade calculated from provided discrete value answers, and in the st.dev we present the calculated standard deviation.

An interesting aspect of iKnow's UX evaluation is that of temporality, i.e. how the quality of users' experience develops over time. For this reason we compare our survey results conducted in 2013 with those conducted in 2012 [13].



(a) Q1 (b) Q2 (c) Q3

(d) Q4 (e) Q5 (f) Q6

(g) Q7 (h) Q8 (i) Q9

Fig. 1: Survey Results

One might immediately conclude that the results in 2013 are better than those in 2012, meaning that the small add-ons and improvements of the deployed software were successful and user satisfaction is increased from 3.23 to 3.61 on average.

Improvement is also concluded to the standard deviation as it gets smaller values, meaning that answers were convergent to the mean value and there were no huge discrepancies in provided answers. Relatively small values of the the standard deviation show that the curves follow the normal distribution, as it can also be seen in Figure 1.

A careful analysis shows a shift from *neutral* to *positive* attitude. This leads to a conclusion that in 2013 there are more satisfied students than those that were neutral in their answers. The charts undoubtedly confirm that the students have a positive attitude toward iKnow.

Normal distribution with average above neutral (middle) point is evident for most of the questions in both measurements, especially for Q1, Q2, Q5, Q6, Q7, and Q9. Raising trend of user satisfaction is obtained for Q3 for both measurements, meaning that there were more satisfied students than those unsatisfied. While Q4 had normal distribution in 2012, in 2013 it shows raising trend, meaning that great majority of students is completely satisfied.

Q8 shows discrepancy in answers for 2013 and normal distribution for 2012. We can conclude that there were no good channels for online help and direct communication with the administrators, i.e. the raised number of unsatisfied students showed that there were cases of students who were trying to reach the administrator, who, obviously had not responded. This is the only case of decreased average user satisfaction for value of 12%. However, this issue is not directly connected with the iKnow system, but with the administrators.

In all cases different from Q8, there is a positive shift of the user satisfaction of average 12% with minimum of 5% for Q3 up to 36% for Q4. The highest discrepancy in provided answers is recorded for Q4 in 2013 measurements and for Q6 and Q8 for 2012.

B. Discussion about results from open questioned survey

Most of the provided answers expressed satisfaction from the applying process and expressed what is missing by setting accent on paper forms with content same as the electronic form, some expected more graphics but were satisfied with the basic functionalities. A great majority expressed satisfaction that the system uses most of technology for user interface present at the FaceBook social network they are used to. Smaller system malfunctions were also reported to the software provider. Some provided answers are quoted as follows:

- "... All in all I'm satisfied with this tool, although personally I'd change few things. ..."
- "It's a very useful and effective website, which makes the university application process much easier. Furthermore it is a student-friendly tool and it's accessible ..."
- "... personally think that the aesthetic part of the system is overwhelming..."
- "... It's a bad idea to include pictures in the electronic application. The most impressive thing was the ranking of the student programs. ... "
- "I do not really have any remark about how to make the iKnow system any better. It is good as it is. And also I think it would be a great idea to connect it to Facebook since the youth, now, spends a lot of time on it. ..."
- "...I really like this system because I could fetch all the information I needed online, and there was no need for me to go to my university, which is great for the students who live far away. ..."
- "Personally I find the iKnow system useless, it just wastes my time when I am obligated to write the application on hand again. And also, the design on the site should be enriched. ..."

Judging by the realized analysis, we conclude that the students benefit by using this system, not only in the application for enrollment, but also in provision of overall electronic services for students.

V. Conclusion and Future Work

iKnow system is a delivery of an EU TEMPUS project to introduce electronic student services at universities. The project introduced change of university management workflow procedures, not by just changing the paper based activities with electronic, but changing the procedures themselves, to make usage of software more efficiently. Introduction of such a system included soft management skills to persuade the university management to believe that the new system will work more efficiently, even though the system was not tested in the moment of deployment.

Comparing this system with previous three attempts at the university for introducing automated student services information system, we conclude that iKnow has survived the initial roll out and is now in exploitation phase (second year), while the others were abandoned after its deployment due to software malfunctions, not trained staff to use the system and most importantly the high level of university management was not confirmed that it will successfully work. User satisfaction is an important part of a successful system, since it gives back a positive feedback on what and how to improve the system to satisfy the user needs. We are glad that iKnow resulted with a successful implementation, although, worldwide, there is a low successful rate of implementation of complex systems such as this one.

Nielsen [2] finds that the entire purpose of having a subjective satisfaction usability attribute is to assess whether users like the system, and therefore it seems highly appropriate to measure it by asking the users. Judging by realized empirical measurements of the user satisfaction, the students have positive or neutral attitudes about the system. Having in mind the critical approach by the students, especially since all of them were highly IT-literate and keen on using FaceBook social network at least 3 hours per day on average, we argue that the system is well adopted by the students and that they see the benefits in using the system further.

Thus, it can be concluded that iKnow will fully replace the outdated Student Service Desk. Not only the students, but also the general population will benefit from a change in the application method for university. We asked the students for their opinions, to which, most of them replied that they would like to apply for university via the internet. This will result in a massive reduction to the student queues during the applications process.

Moreover, more the students use, and new improved software versions are deployed, we witness the swing from *neutral* in 2012 to *satisfied* in 2013. All in all, electronic services build with the iKnow system has become an integral part of the university management and fulfilled the mission of the initial project setup.

We will continue to realize user satisfaction measurements and suggest software improvements of the iKnow system, and also realize a more comprehensive evaluation.

Keywords-Macedonian sign language; Education; Games; Deaf and hard of hearing

Abstract - In Macedonia there are around 6000 deaf people [4] and according to the National association of deaf and hard of hearing of Macedonia, this represents only 0.3% of the population. Because of this low percentage the community of deaf and hard of hearing feels very isolated and stigmatized. Only one television channel (the national channel) offers once a day a Macedonian Sign Language (MSL) interpreted news. Moreover, there are only two schools in Macedonia that offer education to deaf children. For that reason, when a new deaf child is born by non-deaf parents, the learning of the sign language represents a real challenge that affects the whole family. This is the reason why we created the sign tutor - to help this community and to introduce the whole family (the deaf children and the non-deaf parents) with the Macedonian sign language in an easy and entertaining way, with interesting animations and games.

This paper will give an overview of the MSL and the general recommendation for using IT tools in sign language learning. The project created as a result of the research – the Sign tutor will be resented, along with the results and comments received after promoting this project. The paper also elaborates on current upgrades and optimizations to this project, in order to make it more available.

I. INTRODUCTION

According to the World Health Organization statistics updated in 2013, there are around 360 million people worldwide that have disabling hearing loss (Disabling hearing loss refers to hearing loss greater than 40dB in the better hearing ear in adults and a hearing loss greater than 30dB in the better hearing ear in children) [1]. That represents over 5% of the world's population. According to the World Federation of Deaf there are about 70 million deaf people who use sign language as their first language or mother tongue [2]. However, they live isolated from the rest of the world. The reason for this is the inability for communication with the non-hard of hearing world. Regular world has little knowledge of the challenges that heard of hearing or deaf people experience in everyday activities. For a long time it has been generally accepted that the deaf and hard of hearing people are unintelligent, so that's why the offensive term "deaf and dumb" has been used. The terms deaf and hard of hearing are voted as an official designation in 1991 by the World Federation of the Deaf (WFD) [2] [3].

The language of the deaf and hard of hearing people is called Sign Language (SL). This language can be signed with usage not only of the hands and arms, but also the head, lips or the torso. This is not universal language and the languages differ from country to country, although there are universal features in sign languages. Also the signed languages are not based on the spoken language of the region.

Figure 1. Signs conserning human relations in the MSL dictionary [5]

In Macedonia there are around 6000 deaf people [4] and according to the National association of deaf and hard of hearing of Macedonia, this represents only 0.3% of the population. Because of this low percentage the community of deaf and hard of hearing feels very isolated and stigmatized. Macedonian Sign Language (MSL) dictionary exist only in printed form [5]. Fig. 1 depicts some signs about human relations included in the dictionary. Only one television channel (the national channel) offers once a day a MSL interpreted news, a weekly show called "The world of silence" and few MSL interpreted shows. All the other national programs and TV channels don't offer even subtitles to their contents in Macedonian language. Moreover, there are only two schools in Macedonia that offer education to deaf children: the primary school "Kocho Racin" in Bitola and the high school "Partenija Zografski" in Skopje. For that reason, when a new deaf child is born by non-deaf parents, the learning of the sign language represents a real challenge that affects the whole family. This is the reason why we created the sign tutor - to help this community and to introduce the whole family (the deaf children and the non-deaf parents) with the Macedonian

sign language in an easy and entertaining way, with interesting animations and games.

This paper will give an overview of the MSL and the general recommendation for using IT tools in sign language learning. The project created as a result of the research – the Sign tutor will be resented, along with the results and comments received after promoting this project. The paper also elaborates on current upgrades and optimizations to this project, in order to make it more available.

II. Related Work

Many have shown that the deaf children don't acquire sufficient lip-reading skills and that many deaf and hard of hearing individuals have difficulty with reading. In a large study conducted by Conrad [6] it has been discovered that deaf and hard of hearing children attending schools using an oral approach rarely acquire sufficient lip-reading skills. The children with hearing loss greater than 85 dB could only comprehend about 25% to 28% of the words through lip-reading that they could comprehend through reading. The children with hearing loss less than 65 dB could only comprehend about 36% of the words through lip-reading that they could comprehend through reading. Also it has been shown that the deaf are not truly acquainted to words and the writings are based on the spoken language [7]. Another study on deaf and hard-of-hearing children shows that there is a moderate association between the finger-spelling comprehension and reading comprehension [8].

A most efficient way to introduce the sign language to a deaf person is with the help of the visual perception. In that direction the IT tools that exploit the today's visual technologies are most efficient in the process of learning the sign language.

A lot of researches concentrate on the learning process of the sign languages. One research presents a HCI conceptual meta-environment framework to construct computational Intellectual Artifacts in SL to promote bilingualism (Libras-Brazilian SL/Portuguese) in order to increase family bonding activities and effective bilingualism for Deaf children and non-Deaf parents. This framework combines the SL with the cognitive theories (Sense Making, Common Sense, and Concept Maps). Its goal it is to give directions to design of bilingual artifacts in various genres like games, educational objects, storytelling environments etc. [9]. According to another of these studies a pedagogical (teaching and learning) architecture should have strong pedagogical conception, a methodological systematization and should provide a virtual learning environment [10]. Some results of researches that also exploit the visual technologies for learning the sign language are: the System for Sign Language Tutoring [11] which evaluates users' signing and gives multimodal feedback to help improve signing, the 3D Animation Editor and Display Sign Language System for Thai Sign Language [12], that exploits the XNA framework in order to train the general person and Deaf person with Thai Sign Language for ability to communicate to each other, and SignOn, which is a Model for Teaching Written Language to Deaf People [13].

Most popular commercial products on the market are the Vcom3D Sign Smith products which use avatar for signing the American SL. They offer the products like Illustrated Dictionary, Studio, ASL and Signing Science Dictionary. [14].

III. Macedonian Sign Language (MSL)

According to the National association of deaf and hard of hearing of Macedonia there are only 12 licensed interpreters of the Macedonian Sign Language (MSL) [15]. The signs of the alphabet along with the terms for mother, father and some basic colors were the only information about MSL that could be, until recently, found online. Since then the National association upgraded their web page and published this information online. Unlike the bigger countries that promote their national sign language, there are no e-books, videos or any other type of online content that can help learning the MSL.

The Macedonian sign language is based on hand gestures and body gestures, as all the other sign languages. The hands are the basic communication means. The signs are performed with predefined movement and location using one or both hands. Not every hand movement has meaning. There are additional elements that enable more efficient and understandable communication, like head movement, facial expression, mouth or body movement. MSL vocabulary is limited and it contains around 2800 terms (signs).

The Macedonian sign alphabet consists of 31 signs, the same number of letters in Macedonian alphabet. There are two versions of the alphabet: one version is signed using only one hand and the other is using both hands.

IV. Raising awerness among ICT students

ICT industry mat have big impact in providing a great help for persons with some kind of disability. Being ICT educator gives an opportunity to raise awareness about specific target groups, like the deaf and hard of hearing target group, to ICT students. In the University st. Cyril and Methodius, in the Faculty of Computer Science and Engineering, this is incorporated within the course Human-computer interaction (HCI).

In this course the students learn how to use the state-of-the-art technologies and create different kind of useful software products. It introduces the students to the basics of the complex interaction between the computer and the user. The students grasp the principles for building interfaces that compound the interests of the humans and the possibilities of the technology. During this course, the students understand that the humans are the main component of the computer systems and they learn how to develop the software and the hardware for utilizing different groups of users.

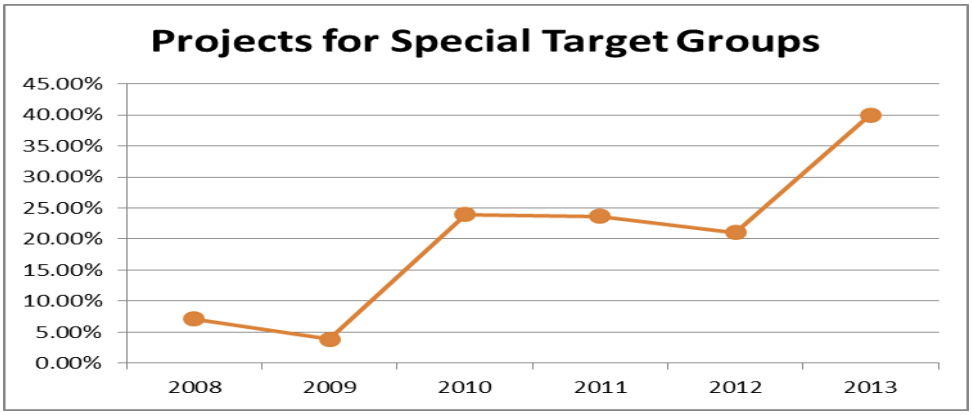

Figure 2. Percentage of projects intended for specific target groups per year

This course offers special experience and provides different perspective from other courses because it introduces knowledge about different kinds of target groups. It offers perspective of the challenges and opportunities for creating ICT projects for people with disabilities, when they are included as target groups. Since the software and hardware products for these clients come with special limitations, the students are thought recommendations how to build applications, working under strict constraints. This is challenging, but the experience shows that the students are very interested in creating such applications. As a result, out of 200 projects that were created in this course in the past 6 years, many were dedicated to special target groups. Some of the researches that students conducted for their projects were intense, since it's not common for computer engineers to gather knowledge that borders medicine, ergonomics, social sciences and psychology, especially not in the Computer Science curricula. It was shown that the students are interested to learn more, about the specific target group as well as about the technologies that enabled better application development. The interest for working with special target groups rises every year and the students show willingness to input extra effort, especially since these projects require additional knowledge in mathematics, optimization techniques, algorithms, special dedicated hardware etc. The trend of increased interest for working special target groups can be noticed from the following statistics: The first year (2008) only 7% of the student projects were intended for specific target group. The interest started to rise in 2010 and resulted with 24%, while in 2013 raised up to 40%. Fig. 2 depicts how the interest rises over the years. Furthermore, 33 projects were evolved to a diploma thesis, and are now fully functional applications for a specific target group or application domain.

Sign Language Tutor was such an example project. It started as a project in this HCI course, continued as a graduate work and at this moment a group of six students are working on the upgrade of this project.

V. SIGN LANGUAGE TUTOR

Sign Language Tutor is an interactive platform for MSL learning that is easily extendible. It represents a collection of games and modules that will ease the learning and increase the mental and memory skills of the deaf and hard of hearing children. The central part of this project consists of 3D animations of a girl that signs the chosen alphabet character or some objects. Fig. 3 shows our character performing signing.

The application consists of several modules, shortly described below.

3D simulation – this module provides signing of alphabet letters and words. The user chooses the letter or the object and the 3D animation illustrates the chosen sign. The user can rotate the animation in all directions and enables different views to better capture the signing. This is of outmost importance, since the signs and words are actually expressed in 3D, usually with more than just fingers and hands. The animation can be paused and started again.

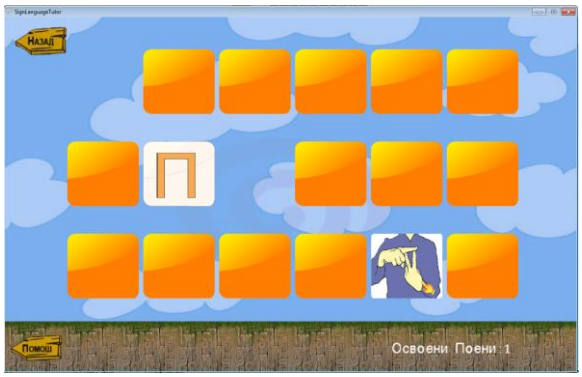
Memory – this module represent a standard memory game where the goal is to merge an alphabet letter with the appropriate sign.

Explore – this module is a 2D game where our hero goes in an adventure against monsters and collects objects. Each of the collected objects is an award – an animated 3D sign of that object in MSL. The game doesn't require special skills and it is adapted for children.

Fig. 4 (a) shows the Memory module and (b) shows the first level of the Explore module.

The application enables the children to learn while having fun. However, the educational modules are interesting even for the other, possibly non-deaf members of the family, or the friends. The wider circle of people to a deaf or hard of hearing child can benefit from learning sign language in a fun and interesting way. This is especially true for the non-deaf children.

Figure 3. 3D animation of the girl signing



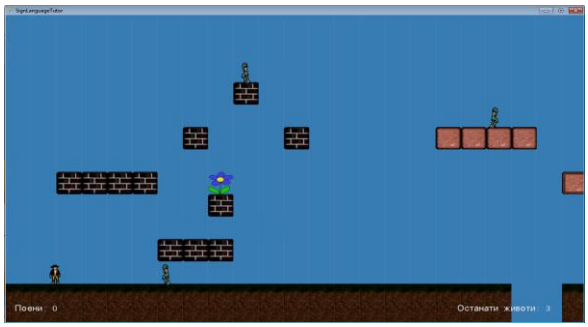


Figure 4. The Memory module (b) The first level of the Explore module

A. Sign Language Tutor Architecture

The Sign Language tutor is built from several software modules that are interconnected. This enables easier manipulation and expandability of the project. Fig. 5 depicts the architecture of the project.

The architecture is built of the following modules (and their descriptions):

- SignLanguageTutor - This module along with the core part is the central part of the software solution and depends of all the other modules. It represents a Windows Game type of project that work on XNA 4.0 framework. It contains the concrete implementations of the games, and respectively the entire user interfaces.
- SignLanguageTutorContent - This module is responsible for the management of the resources. It represents a ContentProject type of project and it is used for resources compilation, storage and preparation for use during the execution. It is divided in parts responsible for management of models, backgrounds, textures, maps etc…
- SignLanguageTutor.AnimationPipeline - This module is compiled to a dynamic link library. It contains the AnimationProcessor class that extends ModelProcessor. The processor contains two parts needed for texture processing: skeleton processing and animation processing part. This actions are called through the function Process that is inherited and replaced from the ModelProcessor.
- SignLanguageTutor.AnimationAux - The AnimationAux is an auxiliary module that includes animation processor con-nection. It contains entities for animation model storage, helpers for animation and models' binary formats loading directly in the source code.
- SignLanguageTutor.TileEngine, LevelEditor and LevelEditorContent - This TileEngine module is used in the 2D game Explore. It represents a framework that

defines all the basic 2D game functionalities like movement physics, game map and view. This is also popularly called game engine. The LevelEditor and LevelEditorContent modules are in charge for game maps creation and storage. The map editor is also XNA Windows Game application

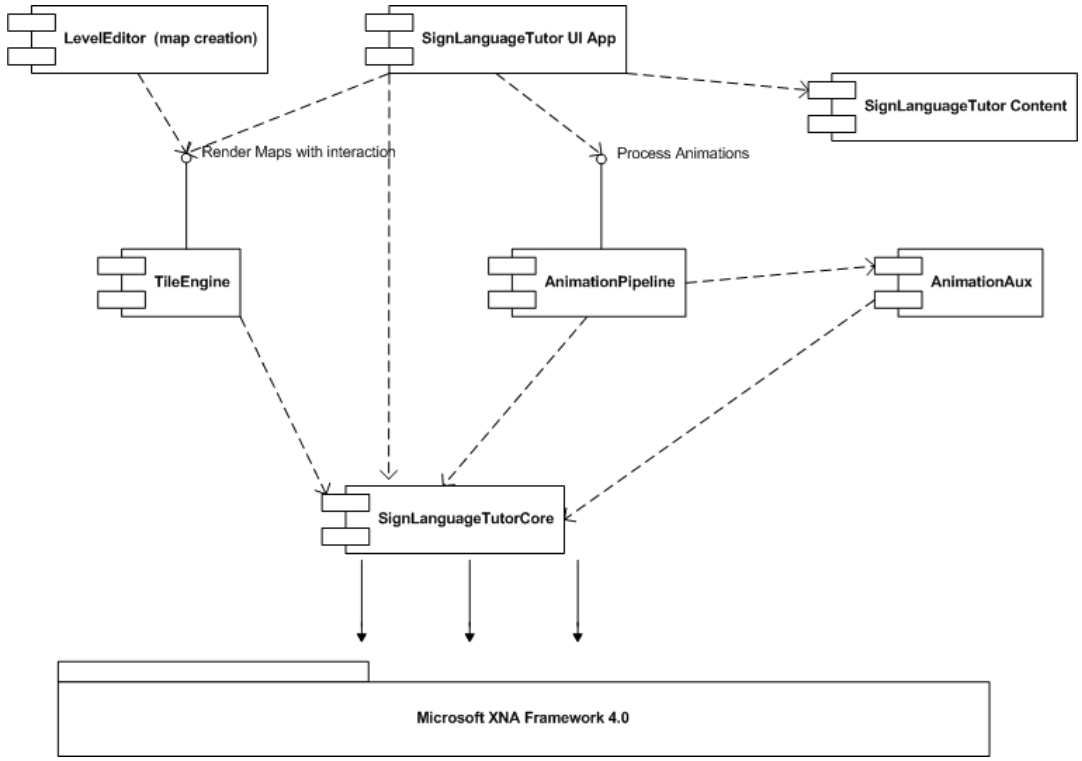

Figure 5. Sign Language Tutor architecture

VI. RESULTS AND CURRENT WORK

The first version of the Sign Tutor was presented to the final workshop of AEIF (Alumni Engagement Innovation Fund) Project - Equal Access through Service Learning for Persons with Disabilities, in front of persons with disabilities and especially people who work with deaf children. The project raised big interest and was approved and warmly welcomed by these people. They offered their help in the future extension of this project. Also, the interest resulted in filming an article about this project by the national television.

As expected, since the application has educational, but also entertaining components, the explore game module was found as one of the most interesting feature. At the moment of publishing the first version it consisted only of two levels. However, presently two additional levels are being created.

Since the initial project was a desktop application, it was very difficult to make appropriate upgrades. This was found to be limiting and less available to the user. For that purpose the project is rebuilt to a web platform. The new platform represents a type of content management system, where the content is easily manageable. It is expected that this new platform will allow adding new signs and terms in user-friendly manner, but will also allow leaving comments by the users. Another challenge that was faced during the migration was the size of the animations – they were large. For that reason a transformation process is currently taking place, and the animations are converted to gif files with good quality.

VII. CONCLUSION

Raising awareness about the needs of different target groups should be a goal to many ICT educators. ICT students welcome new knowledge about people they don't know much about, such as people struggling with disabilities and special conditions that limit their everyday activities. This was the case in building the Sign language tutor, an application for deaf and hard of hearing children, developed by ICT students in Macedonia.

The sign tutor offers an easy and entertaining way of learning of the Macedonian sign language, and it is the first application of this type in Macedonia. It is accepted by the deaf and hard of hearing community in Macedonia and it is precious tools for the deaf children and especially the non-deaf parents and friends, enabling them to learn through games and animations. This project also offers bigger inclusion and increases the awareness of this social group by helping the deaf and hearing people to learn MSL.

The project follows the recommendations given by human-computer interaction research concerning deaf children [16] [17] about deaf children psychology and abilities. It offers deaf and hard of hearing children, as well as their parents, an environment to learn through fun and games. The new, web based platform is expected to make this project even more accessible to the wider public.

Interoperability Challenges Among University Electronic Services Systems

Magdalena Kostoska, Marjan Gusev and Sasko Ristov
University Ss. Cyril and Methodius, Faculty of Computer Sciences and Engineering,
1000 Skopje, Macedonia
{magdalena.kostoska, marjan.gushev, sashko.ristov}@finki.ukim.mk

***Abstract*—This paper analyzes the interoperability issues of the information exchange among essential software applications that enable University electronic services. The analysis of the existing standards shows that there is no fully defined compatibility for these software solutions, which motivated us to conduct a research in order to detect and describe the interoperability challenges of creating a fully automated interaction.**

In this paper we present several case studies of challenges faced at our University, while integrating three existing different systems: iKnow as a custom developed university management system, a customized version of an open source Moodle learning management system and e-Testing as a custom developed e-assessment system. Although these systems operate independently, still there are many interactions among them; keeping the system consistent and tightly connected at the same time. Keeping the software development compliant with the elaborated standards and enabling a push or scheduled synchronization modules will eliminate a big maintenance effort to enabling interoperability with new software versions or when migrating to another type of service provider.

Keywords—Learning system platforms; eAssessment; University Management Systems; Inteoperability issues.

I. Introduction

A typical software solution to provide University electronic services uses at least three different software products for University Management Systems (UMS), Learning Management Systems (LMS) and eventually e-Assessment systems (EAS). These systems are usually developed by different vendors and are implemented separately, which means that they lack interoperability [1]. An additional challenge for the university is imposed by the new upgrades or changes of these softwares.

In this paper we give an overview of possible collaborations between LMS [2], EAS and UMS software solutions as well as existing standards that apply for them, in order to detect and describe the challenges of creating fully automated interactions between all of these systems in a manner of interoperability [3]. The main goal is to tackle the interoperability issues and to analyze if it is possible to go even further, to establish an interoperable environment, so the University can change the service type provider, or software provider, or both, without any loss or damage. Our idea is to explore the possibility of automated interaction and data exchange between these systems, as well as between general types of systems, in order to create a fully integrated environment.

Three systems used at our University will be analyzed in this paper: iKnow UMS (custom developed university management system) [4], Moodle LMS [5] and e-Testing EAS (custom developed e-assessment system upgraded as adaptive online learning [6]). All of these systems operate independently, limiting to only few interactions among them; while at the same time they are tightly connected. The reason why we use a dedicated EAS, rather than Moodle LMS assessment options, is the fact that it represents a safe assessment environment which imposes automated assessment, without access to any learning materials or any other software, randomized questions offering, prevents cheating, etc.

The rest of the paper is organized as follows. Related work about interoperability analysis of similar systems is presented in Section II. Section III gives a description of each of the system types and the idea of collaboration between these systems, where we define the possible data flows. These flows are used to identify the use cases for interactions between systems, which are presented in Section IV. Section V describes the possibility of using existing standards for each of these use cases, or the lack of standards, followed by identification and analysis of the interoperability challenges. Finally, in Section VI we evaluate the significance of each of the found interaction challenges and address the source of these challenges.

II. Related Work

Each of the analyzed systems needs a good specification and definition to provide integration of the University electronic services. Although most of the functionalities, specified data, authorization and authentication are standardized for each system, we can say that the LMS systems have been best defined and standardized [7], [8], [9].

The standardization of EAS is in process since the functionalities of these systems vary and initial standards are created [10]. Unlike LMS and EAS, UMS are neither well defined nor standardized, so integration of these systems is left to creating personal solutions. Only some parts of this system are included in IMS standards, like e-Portfolios [11].

Most of current research papers analyze the possibility of integration between two of the explored systems. For example, Maican targets the interoperability between LMS and Content Management Systems (CMS) like the open source tools Moodle Learning System and DotNetNuke framework [12]. Armenski explores the usage of SCORM, IMS Content Packaging and IMS Learning Design standards in order to create Service Oriented Architecture that will enable interoperability between LMS and AES [1].

Kudrass tackles the problem of integration of all three systems (UMS, LMS and EAS) as proposal of a high-level

architecture for coupling of existing systems [13]. However, this solution is not applicable to a variety of systems.

III. Overview of LMS, EAS and UMS

This section contains relevant definitions and gives an overview of the functionalities, the systems use to enable better understanding of the interoperability issues.

A. Learning Systems

LMS is a system that enables an environment where the teachers interact with students in the delivery of learning materials, assessments, homework assignments, and other relevant activities. It keeps track of all related activities for the learning process. It also enables discussion, forums, etc. The functionalities of these types of systems vary and may include many elements. One comprehensive example of the functionalities that these systems can have is the E-Learning Framework, shown in Fig. 1. This framework is developed through coordinated efforts of U.K Joint Information Services Committee (JISC) and Australia Department of Education, Science and Training (DEST) [14]. This Framework recognizes 59 distinct functionalities divided into three main groups: Sample User Agents, Learning Domain Services and Common Services.

One of the relevant standards in this area is developed by the Aviation Industry CBT (Computer-Based Training) Committee (AICC), which is an international association of technology-based training professionals. They have developed nine AICC Guidelines and Recommendations (AGR's) and in order to be "AICC Compliant" the training product should complies with one or more of these AGR's. They offer formal certification testing procedures for AGR-006 (File-based CMI Systems) or AGR-010 (Web-based CMI Systems) [15].

The most popular standard for LMS is the Sharable Content Object Reference Model (SCORM). It represents a set of technical standards and specifications for, as the name indicates, creating units of online training material that can be shared across systems [16]. It is developed by the Department of Defense's Advanced Distributed Learning (ADL), a research group sponsored by the United States Department of Defense. SCORM generally references existing standards and elements of the Institute of Electrical and Electronics Engineers (IEEE), AICC, and Information Management Standard (IMS) specifications.

At our University we use a customized Moodle installation. Moodle is a robust open-source learning platform and it includes most of the standard LMS functionalities and some additional features. It is compliant with most of the well-known international standards like IMS LTI, SCORM and IMS Question & Test Interoperability (QTI) [5].

B. E-Assessment Systems

E-Assessment systems are separated from the LMS, offering a possibility for question definition and administration, test creation, test delivery, test execution, evaluation, assessment and management of users and results [17].

A well-defined standard for EAS is the IMS QTI specification, which enables the exchange of item, test and results data between authoring tools, item banks, test constructional tools, learning systems and assessment delivery systems [18]. It is created by the IMS Global Consortium. EAS describes a data model for the representation of question and test data and their corresponding results reports. The specification is spread over a number of documents: Implementation Guide, Assessment Test, Section and Item Information Model, Metadata and Usage Data, Results Reporting, Integration Guide, XML Binding and Migration Guide.

Most of the LMS systems would like to upgrade their systems with all e-Assessment features, but the implementation are with limited perimeter and scope. Most popular EAS comprehensive systems are produced as stand-alone products, but still these products lack of interoperability with other LMS, or lack some other basic features, like adaptability according to learner characteristics and possibilities for content reuse. There is no evidence of sophisticated integrated LMS and EAS software [19] [20]. Although Moodle has a possibility for assessing the students' knowledge through different question types and grading scores, it builds only a small subset of the EAS functionalities.

A custom built EAS system is in use at our University since 1999 [6]. This solution has been upgraded with several newer versions. One of the latest upgrades of the system includes an adaptive testing realized via information and communication technologies, as well as on computer based assessment.

All versions support at least the following question types: multiple choice questions and single value input questions. Essay types of question or others are avoided since they require additional assessment by a human. The goal is to simplify the evaluation process and make it more efficient. In addition, the implementation of a single choice answer question is a subset of multiple choice answer questions. Single value input questions are those where the student is expected to provide a single answer that may be a number or a word. It has to be exactly the same as the expected answer, and different formats of writing the numbers or synonyms are not accepted by the system. This system also implements a negative grading schema. During the process of testing the instructor generates a strategy to create the test and sets a date when the test will be generated and valid for execution. The strategy is realized by selecting which knowledge items or learning objectives (LO) will form a test and the numbers of question of each selected knowledge item. If the number of available questions for the item is bigger than the number the instructor chooses, this system will generate different tests for each student. In addition beside the random selection of questions, this system also provides random positing of multiple choice answers. The test is available to the students that enrolled the course and that are present in the faculty laboratories.

Recent version of the e-Assessment system includes interactive images, where the users can navigate and zoom the image, and realize several actions on the image, such as answering by clicking on an appropriate graphical object, marking a region, annotating, setting an answer/comment on a given position, etc. A new set of question types has been developed, including Single Graphic Choice (SGC) which provides a single answer on a map sensitive figure; Opinion Map (OP) where a figure is presented to intended users and they can click on the map and enter their opinion; and Multiple

Graphic Choice (MGC) which allows the user to enter multiple answers on a map sensitive figure [21].

C. University Management Systems

In this paper we refer to academic University management system as a subset of a complete UMS providing student services and academic records, meaning a system that keeps track of all student relevant information, including their records and files, and even financial and other administrative workflows involved among students and University.

Our University uses a custom developed solution as a delivery of an EU funded project Innovation and Knowledge Management towards eStudent Information System - iKnow. This system is designed to store and administer student's records and personal files, as well as related university data. This system is developed in order to enable conditions for realization of eStudent Information System for: Enrollment process; Identity management, with authorization and access control; Management of university services and resources usage (accounting); Administration of Europass CV, ECTS, diploma supplement and other certification issuing; Administration of student activities; Administration of registration and schedules of classes and assignments; and Administration of academic results, including course, exam and study results [4].

The system provides exchange of electronic information among all stakeholders: students, professors, administration, university management and the Ministry of Education. The system consists of two main components, each consisting of modules: the new students Enrollment Student Services (ESS) and the Core Student Services (CSS). The ESS component consists of the candidate's enrollment wizard, the enrollment forms for manual entry of candidate's data, candidate's data processing, ranking module and the enrollment results publishing. The CSS component includes: Module for administration on University and faculty levels, Module for study programs and schedules, Student activities module, Module for personal identification and access control, Module for electronic payment and use of resources and Module for migration of old data and interfaces to other systems [22]. The architecture of this system is shown in Fig. 2.

D. Interactions

The need for information exchange may vary, depending of the corresponding implementations and functionalities of the

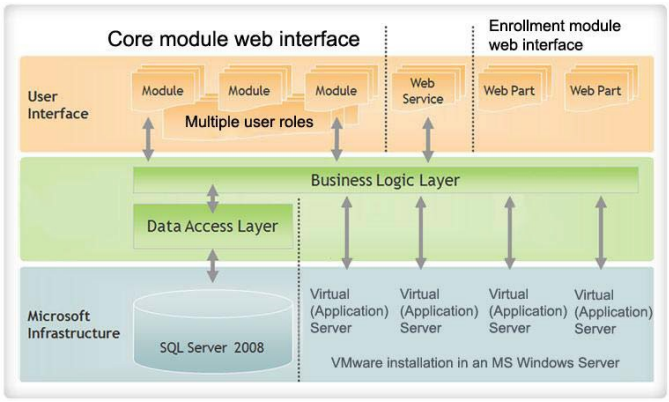

Fig. 2. iKnow Software Architecture [22]

described systems. Fig. 3 presents a possible interaction scenario for information and data exchange between the systems.

The interaction from LMS to EAS is to transfer the information about curricula, learning objectives, and students. In reverse direction, EAS sends assessment results of conducted exams and various reports used to improve the learning and teaching part of the course.

The LMS and UMS interaction is described next. The UMS sends information about relations of students and courses determined with the enrollment process, so the LMS can realize a proper authorization. In the opposite direction, the LMS sends academic records to the UMS about grades and obtained scores, along with various reports needed for the University Management.

There is no direct interaction between EAS and UMS, since the required interaction is performed via the LMS.

The central authentication system (single sign-on) is usually a part of the UMS. Its purpose is to authenticate the users and to inform the other analyzed systems for successful authentication, thus enabling the three systems with a possibility for authorization management.

IV. Interaction Use Cases

In this section we represent several use cases of interactions between the analyzed systems.

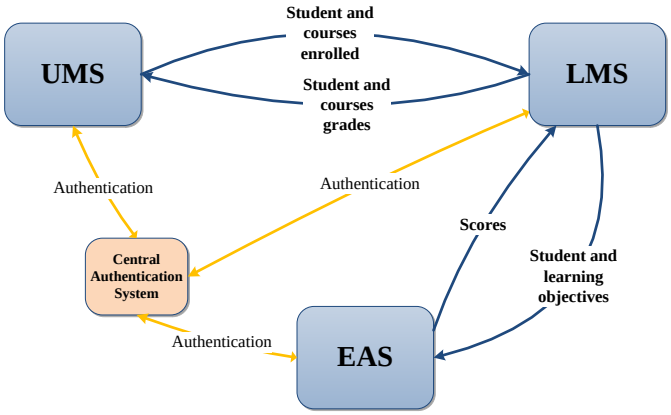

Fig. 3. Interaction among LMS, EAS and UMS systems

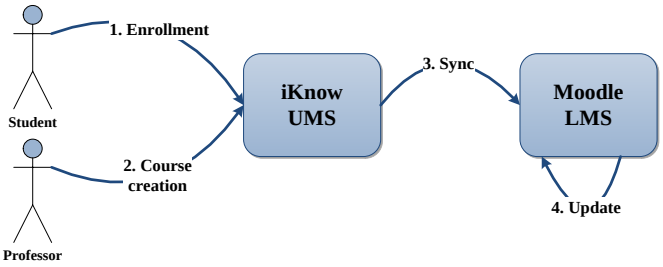

Fig. 4. UseCase: Transfer of student information for course enrolment

A. *Transfer of student information for course enrollment*

A special software module was developed and implemented at our University to enable transfer of student information. This module aims to enable a transfer functionality to the Moodle LMS filtering only those students that enrolled a particular course as registered by the iKnow UMS. This module relies on the Moodle enrollment functionality using an external database (in this case the iKnow database is the external database). This package uses synchronization to insert/update data in regular time periods. iKnow provides the relevant data for courses and students enrolled in these courses, as well as professors/instructors assigned to the course.

This interaction use case consists of at least the following steps, as presented in Fig. 4:

1) At the beginning of each semester, a student enrolls courses in the iKnow UMS;
2) When the enrollment period is over, every professor has an option (built in the iKnow UMS) to automatically create a Moodle course if he was assigned to or to create one Moodle course for multiple similar or same courses in iKnow (defined separately for different reasons);
3) A synchronization activity is started each hour on the Moodle LMS side; and
4) The Moodle course is automatically created and all the students that have enrolled the course are added, as well as the professor, with the appropriate permissions.

The current interaction is not standardized, so if the LMS is changed, it would require adaptations, which is not desirable. An improvement to this communication would be using IMS Enterprise standard [23]. The IMS Enterprise Information Model is designed to support interoperability of the following business process components: Personal Profile Data Maintenance, Group Management, Enrollment Management and Final Result Processing. Potential problem may occur if a new LMS system is introduced and that system does not offer all the functionalities that Moodle offers or doesn't support the IMS Enterprise standard.

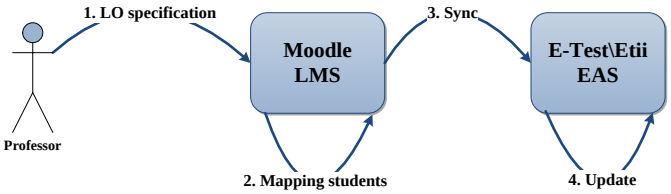

Fig. 5. UseCase: Transfer of information from LMS to EAS

Another possible improvement of this process would be creating SCORM learning packages for each course and import them in Moodle along with the creation of the course.

B. *Transfer of information from LMS to EAS*

Test creation process needs specification of learning objectives that have to be included in the test. The idea of this interaction use case scenario is to transfer the required specification from the LMS whenever an assessment activity is required. Created tests are delivered only to the students enrolled in the course to test their knowledge. The evaluation of results and assessment may be designed in a way that includes only some of the course topics or only students that satisfy some prerequisite to be able to take a test.

This interaction use case scenario for transfer consists of at least the following steps, shown in Fig. 5:

1) At the begging of each semester, the professor specifies the learning objectives for each course in the Moodle LMS;
2) The Moodle LMS keeps track of all relations between enrolled students and available courses;
3) A synchronization activity is started each hour on the Moodle LMS side to send the information about learning objectives and enrolled students with the EAS side; and
4) The EAS updates the learning objectives and list of enrolled students in the activated courses.

This interaction use case scenario is generally difficult to realize since it requires automated creation of questions. One possibility is to use semantics and ontology for each learning objective and to use them to create questions. But this would suggest that ontology is already created and available. Jovanov and Gusev [24] already explored this subject and created an initial model.

This use case has not been fully implemented in our systems yet and it is in development and testing phase, since it requires add-ons on the existing software.

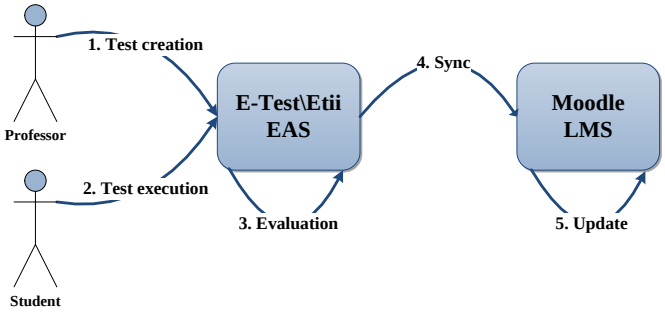

Fig. 6. UseCase: Transfer of assessment results from EAS to LMS

C. Transfer of assessment results from EAS to LMS

The goal of this use case is to enable automatic transfer of student scores from e-Test to Moodle for every assessment (test). This interaction use case scenario realizes the following steps, presented in Fig. 6:

1) The instructor creates the strategy and schedules test;
2) The student answers the test and EAS automatically evaluates and updates the results;
3) A synchronization activity is started as push activity on the EAS and corresponding results are sent to the Moodle LMS side,
4) A synchronization activity is started each hour each hour on the Moodle LMS to update the information received;

Initially this problem was solved by creating a dedicated Moodle activity for results import from the custom built EAS. This Moodle activity requires the testing id to enable the result import. This component had to be adapted with each Moodle upgrade since they appear frequently. This requires a permanent maintenance for the Moodle LMS and another solution is in effect at this moment. The alternative solution is based on exporting the results in a standard spreadsheet format, such as excel CSV or tab delimited data.

This interaction is not standardized, although it uses standard data representation. A better choice is to use the QTI standard. A problem may arise if the LMS system doesn't offer automatic results import or doesn't supports QTI standards. Another general problem of this interaction use case is defining how each test will influence the student's grade and how many points (in the course grading system) can be obtained through that test.

D. Transfer of student's academic records from LMS to UMS

The idea of this use case is to enable automatic transfer of grades upon course completion from Moodle LMS to the iKnow UMS. For this option to be possible, the professor has to define a criteria and relevant grading conditions in each course, as well as all the results (of any activity) to be available in Moodle. Another administrative issue is that the students in our University have to submit exam application for each course which will allow them to take the exam in given exams sessions and a grade can be set only for students that have submitted the application.

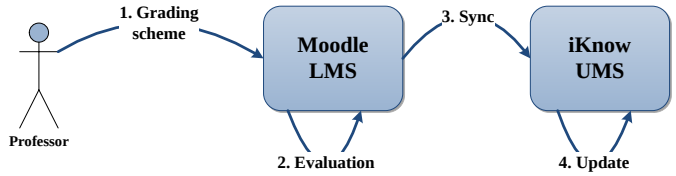

Fig. 7. UseCase: Transfer of student's academic records from LMS to UMS

This interaction use case scenario for communication from LMS to UMS consists of the following steps, shown in Fig. 7:

1) The professor defines the academic activities, grading criteria and passing conditions in the Moodle LMS;
2) The Moodle LMS has updated status of academic results for each student's activity and calculates the grade according to the defined criteria and conditions;
3) A synchronization activity is started each hour on the Moodle LMS to send the relevant information to the iKnow UMS; and
4) The synchronization module on the iKnow UMS updates the relevant academic records for the students.

Similarly to the previous use cases, due to the lack of sufficient maintenance for the LMS, this interaction is realized by using an alternative method. The results are exported in a standard spreadsheet format, such as excel CSV and later they are imported into iKnow.

This interaction can be improved and standardized by using the IMS Enterprise standard.

V. Results and Challenges

The presented interaction use cases are part of a possible scenario and do not include all the possible interaction details and data exchange information. For some of the use cases there are no applicable standards and some of the proposed standards may not be enough to complete the use case.

A formal specification of exchanged information between LMS and EAS includes various parameters, such as student information, course information, specification of learning objectives, test results, evaluation and assessment reports, etc. QTI standard specifies questions and test interoperability, but does not conform to challenges defined previously. SCORM is used as a standard to exchange learning materials, but does not cover all mentioned challenges.

The exchange between LMS and UMS includes at least the enrollment information, course identification, student information and academic results (grades). A possible usage of IMS Enterprise can be applied. Most of the efforts are done by developing specialized software solutions.

In order to enable partial interoperability among systems for the described interaction scenario, every system should support certain standards. Table I shows at least which standards the systems should support. It does not cover all relevant issues, but it covers the essential ones for exchange of learning related information.

Keeping compatibility with these standards will enable interoperability of solutions and new versions of the software, avoiding big maintenance efforts.

TABLE I. RECOMMENDED STANDARDS FOR SYSTEMS TO ENSURE PARTIAL INTEROPERABILITY FOR E-LEARNING RELATED CONTENT

System / Standard	SCORM	QTI	IMS Enterprise
UMS	X		X
LMS	X	X	X
EAS	X	X	

Another issue is the realization of a synchronization as a push-pull mechanism or as a scheduled activity. All software development should enable synchronized input and output of relevant information.

VI. CONCLUSION AND FUTURE WORK

The area of e-Learning offers a lot of well-established standards, while the area of assessment is still developing. In this paper we present our approach in defining interoperability challenges among LMS, EAS and UMS systems. As an example we comment on how we have faced and solved some of these challenges at our University. We also give recommendations on which standards may be used in order to provide partial interoperability. Yet all of the interactions among these systems can be delicated to orchestrate and very little number of available systems support all of the stated standards and standards are not always applicable.

A new challenge in this area which stresses the need for interoperability is service migration to the cloud. Problems arise when a university decides to migrate some features onto a cloud. Although the cloud offers good resources flexibility and scalability, storage, computational requirements and network access, and most important, lower cost [25], sometimes, this process is a nightmare, as the complex migration might cost time and information lost. We already started to migrate parts of the EAS system to the cloud [26] and faced a lot of interoperability obstacles.

Formal specification of these challenges will initiate recommendations for a possible standard and recommendations for interoperability framework and enable existence of independent cloud solutions, where information and services can be exchanged among various cloud providers and software solution providers without loss and damages.

ACKNOWLEDGMENT

This work was partially financed by the Faculty of Computer Science and Engineering at the "Ss. Cyril and Methodius University", Skopje, Macedonia through the project XaaSin-Cloud. The iKnow project has been developed as a part of the Tempus JPGR 511342 Project.

***Abstract*—Today's dynamic life has changed the traditional teaching from the classroom and laboratory based classical learning to an approach using online and distance e-Learning. Universities usually follow this trend and enable their resources as online utilities for the students. There are several ways to offer these facilities online and cloud is the most promising one when analyzing several criteria. The cloud technology provides many benefits reducing the overall cost and improving the business continuity. In this paper we present an idea how to transfer the traditional computer laboratory into a cloud based utility using open source cloud frameworks. This transformation creates a dynamic, flexible, elastic, reliable and modern laboratory that can serve the students as a tool for distance learning for many courses simultaneously. It acts on a "Lab as a Service" principle.**

***Index Terms*—Education, Cloud Computing, Online laboratory**

I. Introduction

Universities are faced with a huge problem when they design their data centers and laboratories. The hardware equipment's life-cycle is usually three to five years and the managers must be smart enough to choose appropriate hardware, that is, to choose the most powerful equipment within a given limited budget. However, the experience shows that most of the time the resources will be either over-utilized (for example, during assignment deadlines, assessments or enrollments), or underutilized (during holidays or weekends).

Another problem, which maybe the worst, is to choose a sufficient and appropriate laboratory equipment. That is, different courses require equipment with specific technical characteristics. For example, multimedia-based courses require computing power and available storage space, parallel programming and algorithms need multi-core CPUs and a lot of RAM memory, while some courses demand only a high-bandwidth Internet connection, regardless of the equipment's power.

Apart of the hardware equipment, the various courses require different system and application software. A diversity of operating systems limit the use of learning tools, some might need Unix or Linux, while others Windows or Mac operating systems. Even more, 16-bit programs are not supported, and many 32 bit programs do not work properly on 64 bit operating systems since they run in an emulator [1]. Another problem arises when installing a program for one course damages already installed programs for other courses. There are file version conflicts, registry value conflicts, and their unnecessary duplication.

University laboratories are deployed to allow the students to learn the material more practically. However, there are many part-time students, which are part-time employed and cannot attend the hands-on laboratory in specific hours. They demand a distance learning environment available 24h per day. European Credit Transfer and Accumulation System (ECTS) on the other hand, gives a recommendation to the universities to evaluate the students' homework assignments and projects, which usually are developed at home, and the regular students also need some distance learning environment.

A possible solution for all these challenges is to use the emerging technologies, such as virtualization and cloud computing. Virtualization allows a creation of separated virtual machine images for each course and instantiating arbitrary number of active instances with customized virtualized hardware resources (CPU, RAM, I/O, HDD). By using the cloud computing paradigm, the universities can either build their own private clouds in their data centers, or rent resources from some commercial public cloud service provider, or both. A para-virtual laboratory can even improve the students' performance [2].

Our idea is to realize the laboratory based on a service principle offered by the cloud technology. In this paper, we present an idea how to develop a cloud based laboratory for distance learning by using the emerging techniques without or with a little additional cost. This online laboratory acting as a service is intended to be used by the arbitrary number of students of several courses simultaneously, 24 hours per day, 7 days in a week, instead of university working hours only.

The rest of the paper is organized as follows. Section II presents the related work in the area of distance education based on cloud. In Section III, we describe the architecture of our cloud based laboratory for distance learning. The usage of the laboratory is presented in Section IV. Section V discusses about further development of the laboratory for distance learning and self assessment, apart of classical online laboratory. Finally, we conclude our work and present our plans for future work in Section VI.

II. Related Work

This section presents the state of the art in the area of distance learning, especially the cloud based.

Many online courses exist that offer distance learning. Udacity offers free and chargeable online courses, which

can be started at arbitrary time [3]. Putting the Stanford's Introduction to Artificial Intelligence course online, Thrun got an enrollment of 160,000 students from all over the world [4]. StarHPC [5] (the Software Tools for Academics and Researchers) is one of the first projects where the cloud is used in distance learning, which "brings" arbitrary Amazon's EC2 (Elastic Computing Cloud) resources into the students' laboratory. StarCluster [6] is a similar project where the students can create a cluster computing environment in the cloud for parallel and distributed computing applications and systems. For more than 10 years, Cisco has a learning environment, which is migrated on the cloud [7].

Platform as a Service (PaaS) cloud service layer can be also useful in education, since it allows the students to focus in the tasks, rather than on spending a lot of time to set up the necessary software for course activities [8]. Tian's framework [9] manages PaaS in a virtual cloud laboratory and manages the users, resources and their access rights. Yin et al. [10] built a multimedia courseware sharing platform, which is based on Google App Engine. NVLab is another tool, which uses virtualization. It is a web-based laboratory for management of network designs [11].

Gusev et al. [12] developed an e-Learning and benchmarking platform for distance learning of the Parallel and Distributed Processing course. They proposed a cloud model for the platform, as well as [13]. Bastidas [14] proposed the implementation of the computer networking laboratory infrastructure to distance students in order to extend the learning.

III. The Online Laboratory Architecture

In this section we present our model of a distance learning lab working as a service on a cloud. The architecture consists of two open source cloud frameworks, which are dedicated with arbitrary number of physical cloud server nodes.

A. The Physical Equipment

The laboratory is based of the existing 20 workstations, one router and one switch, as depicted in Figure III-A. All workstations are grouped in several VLANs connected by a switch. A router is used to enable an access to the university internal network.

B. The Architecture

We have a lot of experience during the last several years with various open source cloud frameworks, such as OpenStack, Eucalyptus, OpenNebula and CloudStack. Realizing various cloud deployments we have faced several challenges, such as Java incompatibility with applications in the cloud, or interaction with the cloud interfaces. Therefore, our recommendation is to implement two cloud frameworks, i.e., OpenStack and Eucalyptus, as most appropriate to deploy our online laboratory. This provides a sufficient redundancy, as well as extension for research options.

Figure III-B depicts the architecture of this online laboratory offered as a service. Two workstations are used as Eucalyptus

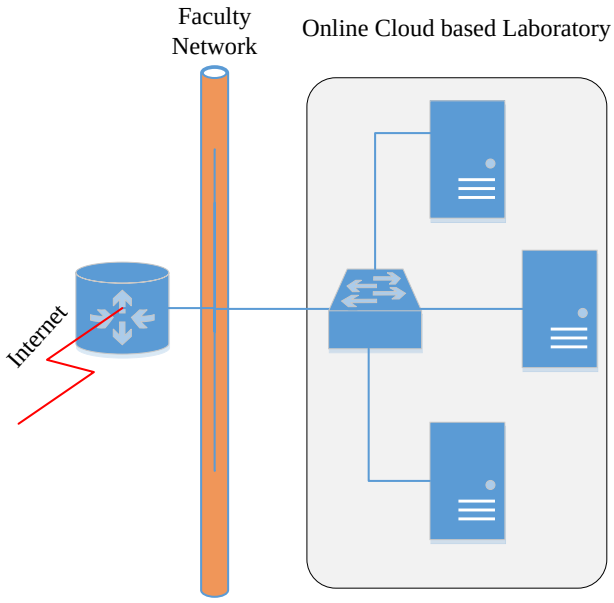

Fig. 1. The online laboratory equipment

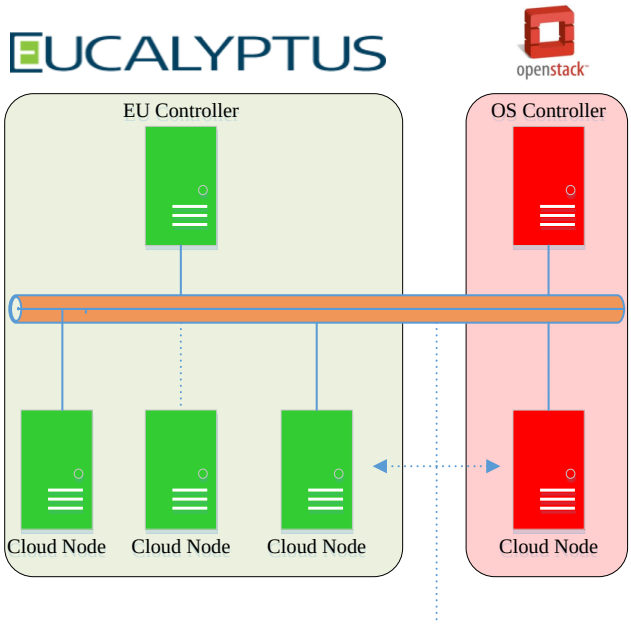

Fig. 2. The online laboratory architecture

cloud and cluster controllers, and one workstation for OpenStack. All others are used as cloud node controllers.

In normal mode, the Eucalyptus cloud uses all other workstation to instantiate virtual machines, while all OpenStack's services are disabled. When necessary, the OpenStack's services will be enabled, while the Eucalyptus' services will be disabled on several cloud nodes.

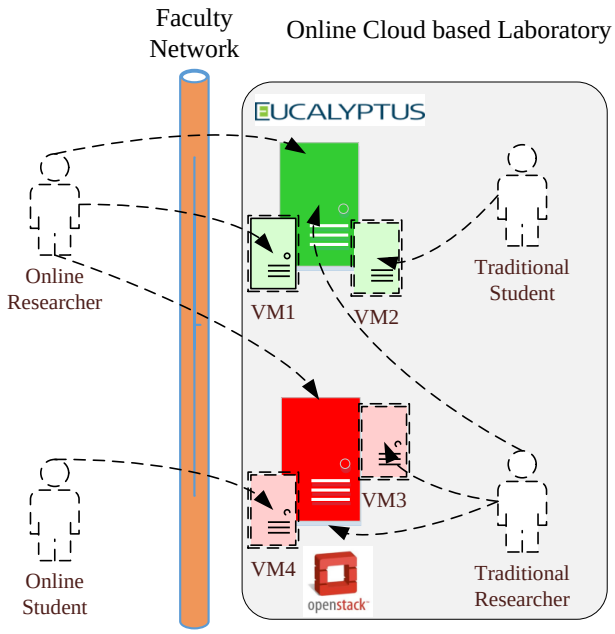

Fig. 3. The usage scenario

IV. Functional Description

This section describes the usage of our deployed cloud based online laboratory realized as a service. Figure IV depicts its three main purposes:

- *Traditional Physical Laboratory* opened for the students only in working hours;
- *Distance Learning Laboratory* available for the students 24/7/365; and
- *Research laboratory* [15], available both for the students and researchers.

A. Using as a Traditional Physical Laboratory

Since each workstation is installed with Linux with GUI (Graphical User Interface), the whole laboratory can be used as a traditional physical laboratory in the faculty's working hours. The students use the host operating system for those courses that require Linux operating system, while they can still run the virtual machine instance of the cloud for a particular course that requires Windows based applications.

B. Using as a Distance Learning Laboratory

Our currently prepared image with Windows operating system has 124 installed applications, which includes several IDEs (Integrated Development Environments) for various programming languages, simulators, network and database tools, etc. Each of the laboratory workstations is installed from this image. Although this is a huge list of installed applications, it is only a Windows platform, and something else is always missing, such as some plug-in or some configuration file is changed by other application.

Update of the image is conducted each semester, which limits the flexibility of the traditional laboratories. Therefore, we migrated one laboratory in the cloud to become a distance learning laboratory. We developed several images, each for a particular course. For example, the Computer Networks image is Windows based, which contains Cisco's learning materials, several network tools and simulators, etc, while the image for the High Performance Computing course is Linux based, which contains C++ compiler, OpenMP, MPI and BLAS libraries.

Since most of the regular students are at the faculty and work on the host operating systems, while the other busy students are at work, the laboratory is used mostly as a traditional physical laboratory in the working hours. Just in case, the administrator can limit the number of available virtualized resources through the cloud according to the requirements of the laboratory exercises of the current course. For example, if the current course requires two CPUs of four core cloud server nodes, the administrator can limit the cloud scheduler to instantiate virtual machine instances with maximum two CPU cores per physical server.

C. Using as a Research Laboratory

Additionally, apart of the already prepared customized virtual machine images for several courses, we prepared "blank" virtual machines for the master and PhD students to realize research, or for the undergraduate students to realize a team-oriented project. These virtual machines are allowed to interact with the cloud controllers in order to develop the elastic and scalable applications as a service on the top of the cloud, according to the model for e-Assessment cloud solutions [16].

V. Discussion

This section discusses details of current and further lab development to realize the overall goal as a distance education lab providing its resources as a service to the students, teachers and researchers. The benefits of migrating the traditional laboratories in the cloud are elaborated along with description of possible challenges.

A. The Benefits

The university can achieve many benefits if it migrates some or all of its laboratories in the cloud and offer it on a service based approach. In this section we present the most important ones.

1) Isolated Course Applications: The online laboratory is used for several courses: Computer Networks, High Performance Computing, Parallel Programming, Teamwork, Computer Network Design, Microprocessor Systems, etc. Each virtual machine instance is independent of others and works isolated when it is instantiated. This improves the performance of the guest operating system because it has less system files, rather than our image with 124 installed programs.

2) Balanced Load of the Equipment: Since different courses require various hardware resources and cloud based online laboratory allows the students to work in the arbitrary time, the utilization of the laboratory equipment will be balanced instead of either over-utilized or underutilized. Even more, the laboratory can serve much more online students rather than a maximum of 20 if it is used as traditional laboratory only. That is, usually less than a maximum of 20 students are enrolled in the exercises, and not all of them attend all exercises.

3) Reducing the Cost: Migrating the laboratory in the cloud can reduce the costs in several ways.

E-Learning should be developed towards open access to learning, open source software, open standards, and OER [18]. The additional software that our pilot cloud based laboratory uses is open source, that is, OpenStack and Eucalyptus. Although the expert's assistance is required to setup a fully operational, open source workbench [19], the cost for man hours for the initial efforts for installing and configuring the clouds is much smaller than the cost for formating and configuring each computer at the beginning of each semester, and the administering during the semester (viruses, no storage place, deleted files, etc).

The reduced number of students in the laboratory will also reduce the cost for laboratory maintenance. The cost for electricity can be reduced because all physical machines (except the cloud controllers) can be started or deactivated dynamically, according to the students requirements.

B. Further Challenges

Despite the benefits, there are additional challenges for the online cloud based laboratory, such as security or availability.

All cloud based environments are more exposed than being on-premise due to virtualization and multi-tenancy [20]. However, the student exercises' data are less sensitive.

Another challenge is the laboratory availability. That is, the laboratory room is neither dedicated for mission critical services, nor its room has sophisticated climate and redundant power supply. Still, our design with two clouds and many server nodes offer good availability.

Maybe the most important challenge is the usage of the online laboratory for hardware based courses, which requires working on real equipment, rather than on simulators. However, the remote engineering is a new trend to share the lab equipment, which will allow the students with more time for learning, instead of traveling to the University [21].

C. Further Extensions and Improvements

Our pilot project is a huge step forward, both for the university and the students. However, we are not going to stop at this level, instead we are going to further improve and enhance our cloud based online laboratory. Our intention is to develop the laboratory not only for distance learning, but more wider, that is, for distance education.

Applying formative assessment in learning environments increase the benefits [22], [23]. The learning outcomes of students can be improved in a mobile learning environment [24].

Recently, we have developed a scalable and elastic cloud solution for e-Assessment based on OpenStack cloud framework [17] and E-Assessment system with interactive images [25]. Both of them will be hosted in our cloud based online laboratory in order to allow the students to learn through e-Testing. The following sections briefly describe them.

1) Scalable and Elastic e-Assessment Cloud Solution: The e-Assessment cloud system is deployed on OpenStack cloud, which allows to dynamically instantiate and deactivate the virtual machine instances. Figure 4 presents its architecture. The implementation creates an instance of already prepared virtual machine for assessment with particular size according to the number of assessed students, which is deactivated after the assessment is finished.

2) E-Assessment System with Interactive Images: This system uses sophisticated technologies for interactive images, such as Google Maps Engine. Interactive image technology offers a web based environment where the images are sent to the students. After loading the image, the students can navigate and zoom to an appropriate level to analyze the image details. The students answer by setting up one or more marks on some regions of the image. This system enriches the e-Assessment environment, enables more correct evaluation and prevents several methods of cheating and unfair grading.

VI. Conclusion and Future Work

This paper presents the architecture and the usage of the multi purpose cloud based distance education laboratory. It is deployed by migrating the existing traditional laboratory in the cloud by using the open source cloud frameworks. It is offered as a service free of charge for enrolled students and University researchers that demand more hardware resources. It acts as an extended Platform as a Service, since it offers more than standard platforms the conventional cloud providers offer. It is not a fully Software as a Service offer for the students, since it offers a limited set of software tools and hardware in comparison to the full software the conventional cloud providers offer. Finally, the students are expected to develop the final application code or realize experiments with the available tools and hardware.

The laboratory can be used in three manners. The students still can work on-site when they have hands on exercises, such as hardware based courses, which require working on equipment. Apart of being the traditional on-site laboratory, it allows the students to work remotely from home whenever they can and want, for each course. Finally, it is also used by the young researchers, such as master or PhD students.

The usage of the laboratory can be also extended in distance education, that is, it can host faculty's online learning and online self assessment systems. We will migrate our interactive e-Assessment and e-Learning systems in the laboratory in order to make them scalable and elastic capable to handle arbitrary number of assessed students.

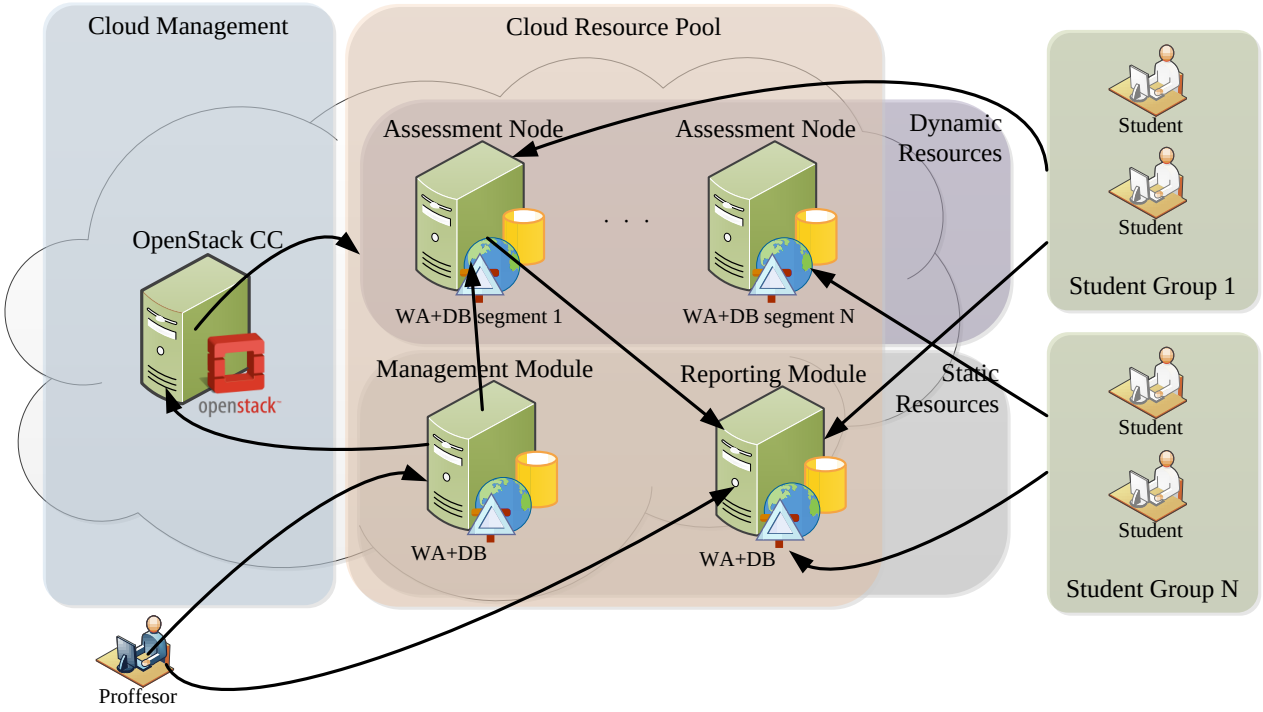

Fig. 4. e-Assessment cloud system [17]

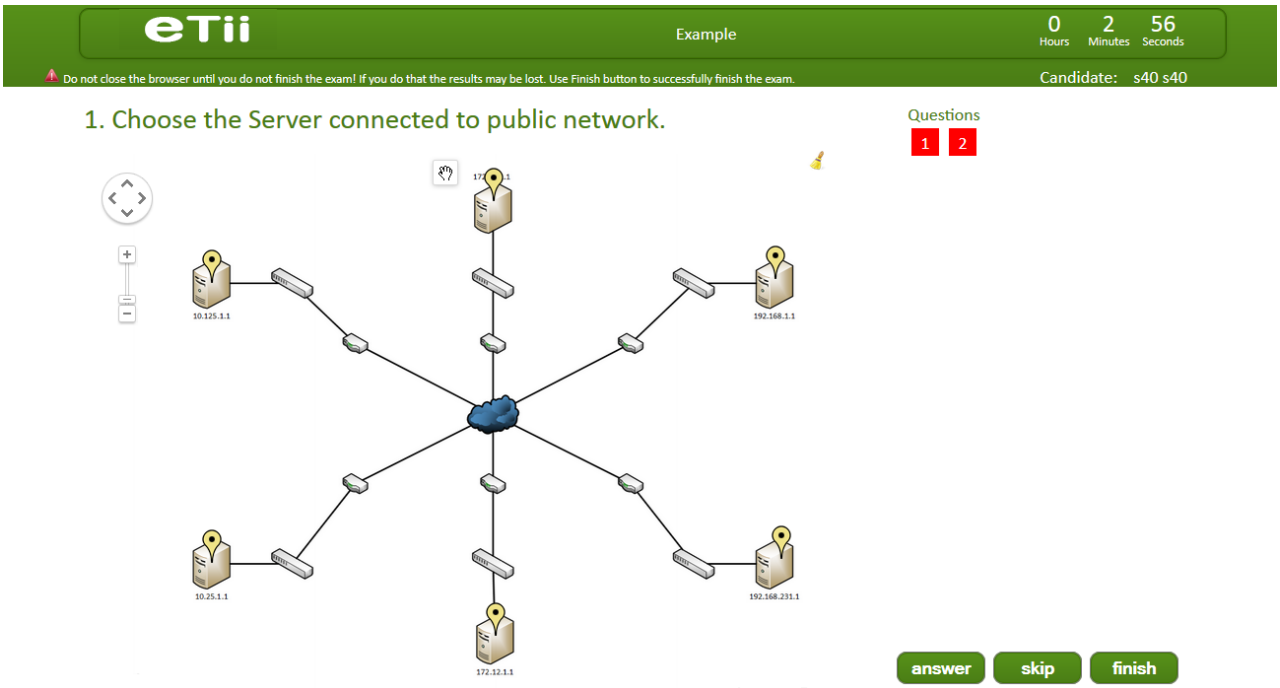

Fig. 5. An example of a MGC question for e-Assessment system with interactive images [25]

Our pilot laboratory will be extended and improved in several directions. We will develop and implement virtual machine images for more courses and we will test the performance of the increased number of the users. Also, we are challenged to integrate several distributed laboratories on several locations into one huge virtual online laboratory for distance education.

Mediated Heritage Learning in Formal and Informal Contexts: Antiquity CyberEd

G. Zlodi*, Ž. Miklošević*
* Faculty of Humanities and Social Sciences, University of Zagreb/
Department of Information and Communication Science, Zagreb, Croatia
E-mail: gzlodi@ffzg.hr, zmiklose@ffzg.hr

This article explores the ways a physical educational resource is transformed by ICT into a virtual learning material on the example of Ancient Greek sculptures at Zagreb's Faculty of Humanities and Social Sciences. The sculptures, acquired as casts from the originals in the British Museum and Louvre, serve as a learning resource in teaching museum study courses, while the results of this formal education provide a new learning material for an online environment. The theoretical framework is based on Laurillard's classification of educational media that facilitate participative learning in formal education and consequently in informal online heritage education.

I. INTRODUCTION

Cultural institutions, including museums have in the past several decades been oriented to users and the ways users themselves construct meaning communicated through heritage objects and sites. This trend corresponds well with contemporary educational theories, which replace transmissive approach in which the body of knowledge is conveyed to learners, with the approach that gives the central importance in the learner and his ways of constructing knowledge. In other words, learner becomes more important than the body of knowledge.

A. Cultural Heritage in Contemporary Theories of Learning – new media-enhanced education

Priority is given primarily to individual experience and social context in which learning takes place. Self-exploration, participation, experience, social interaction, personalization are only some of the terms which comprise contemporary view on learning in museums and heritage sector and have been used in literature dealing with informal learning, in museums and in general [1], [2] [3], [4], [5]. Presented cultural heritage exerts influence on users and their cognitive and perceptual characteristics change only if they come from the familiar cultural and social contexts and have previously known experiences related to the topic [6].

Furthermore, museums and interpretation centres are expected to provide users with opportunity to establish personal links with heritage items, topics and experiences, to enable participation in activities which go beyond mere observation, and finally, offer possibility of sharing experiences and opinions of people belonging to certain groups.

As one of the currently most used concept in heritage sector which is heavily oriented to communication, heritage interpretation has developed in the last thirty years, and especially with the introduction of the internet, into functional framework. Online heritage interpretation started with web pages that resemble an electronic brochure, end continued with the pages whose content is more of a digital database of museum objects, which turned into complex sites offering information related to different heritage contexts and preferences of online users instead of exclusively to museum objects [7], [8].

B. Museum Object in the Virtual Environment

The influence of new media on heritage or museum objects can be seen, on the one hand, as a threat to professionally created knowledge, and on the other hand as an opportunity to broaden the impact heritage can have on people if it becomes more accessible, both in terms of space and time, which is somewhat the internet provides, and in terms of understanding which can be achieved by inclusion of different contexts and perspectives on heritage.

The principles of numerical representation, modularity, automation, variability and transcoding [9] enable limitless copying, appropriation and modification of digital heritage objects by a network of wide varieties and groups of users. Digital objects are qualitatively and materially different from their "physical" counterparts. While the physical objects are relatively stable (Figure 1 and 2) entities in space and time, digital ones are mobile

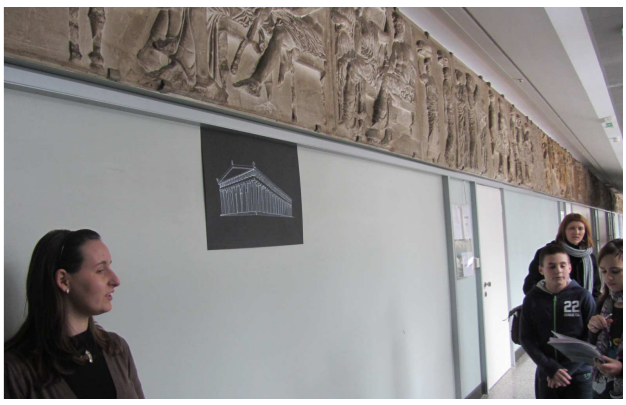

Figure 1. Casts of original sculptures from Parthenon - guided tour for 5th grade of elementary schoool

and volatile. Perry, however, observes changes in the comprehension of the "static" museum object in the virtual environment. The definition and value of the object became scaled and distanced from the issues of materiality and immediate physical presence, characteristic for the industrial period, and more in tune with the post-industrial perception of material culture in a wide sense – as units of human experience which witness the individual and collective epistemology and ontology [10]. In the institutional context, the use of digital integrated multimedia enables distancing from the limited information distribution and better representation of a wide range of contexts pertaining to certain information [11]. As far as users are concerned, access to digital objects forms continuous stimulation in creating new interpretation and knowledge.

Affordances offered by new technology design can easily be used as advantages for multiple interpretation and contextualisation of objects in virtual environment. Additionally, these online environments can help in overcoming certain limitations imposed by traditional methods of organisation and presentation of information and can contribute to the use of multiple levels, various aspects and quantity of information about particular topics.

Narratives which emerge around objects, created by various users, entice much more discussion than objects themselves since stories are the main thing that brings close users by encouraging knowledge acquisition [12], [13] and identification with heritage [14].

Still, materiality of heritage items and their auratic characteristics will always be important for experience. However, as opposed to the physical encounter with objects which is strongly supported by the desired visual, and more narrowly defined aesthetic experience, the physical world could (and should?) be extended by virtual spaces in terms of quality of heritage communication. The use of new media in heritage context should be taken as a positive direction towards digital practices in which elements of greater significance include connectedness, access, fortuity, network, collaboration, participation, freedom of expression, and cultural and social empowerment of users. These "key words" have served as guidelines for the project Antiquity CyberEd which comprises a virtual museum as an environment of informal education for a wide range of users and created by students within university courses in museum studies as part of their formal education.

II. ANTIQUITY CYBERED PROJECT

Antiquity CyberEd project is ongoing cultural heritage project launched at the Department of Information and Communication Sciences at the Faculty of Humanities and Social Sciences, Zagreb University. It envisages collaborative work of various faculty departments on the protection and communication of a collection of Ancient Greek and Roman sculptures. The Antiquity CyberEd forms only one part of the project and focuses on the educational process revolving around the collection, in terms of both formal learning within several courses in museum studies programme and informal learning in the form of virtual museum which results from the formal educational process.

Figure 2. Students of museology taking notes and discussing about damages on the sculptures

A. *Collection of casts of antiquity artworks located in Zagreb's Faculty of Humanities and Social Sciences*

The collection was formed in 1892 through acquisition of casts of ancient Greek sculptures housed in European museums. The biggest number of works belongs to the Parthenon frieze (Athens, Greece, ca 438-432 BC) and was cast in the British Museum in London. The man most responsible for the acquisition was Isidor Kršnjavi whose intention was to use the collection to bring awareness and aesthetic sensitivities to the general public [15].

Every few years, the collection moved from one institution to another, without the much needed care and museological interpretation and presentation. Recently, Zagreb's Faculty of Humanities and Social Sciences has made investments in conservation of several most damaged works. Still, objects are not equipped with labels and there is no theme panels providing contextual information to the collection as a whole. Furthermore, there is no navigation inside the faculty building which would direct people's attention to the collection.

This all has consequences on general visibility of the collection. Students know very little or nothing about it and a lot of individual artefacts have been damaged by carvings, graffiti and other kinds of devastation. After introducing students with the value and status of the collection, they showed high motivation and interest in the topic.

B. *Productive educational framework - from formal to informal learning contexts*

The theoretical framework of the project relies on the theory of experiential learning [16], [17] and embraces both the sense of institution-sponsored learning (i.e. university) in that it involves a direct encounter with the studied phenomena (in this case the physical collection), and the type of learning which occurs as a direct participation of individual in his or her life (i.e. informal learning or self-directed learning). The formal learning, emphasizing both process and product is made possible by the content management module which enables the

creation of digital "heritage content" for the virtual environment that facilitates informal learning.

The focus in both of these types of learning is placed on the technology-enhanced production and organization of knowledge which supports at the same time content and process intelligence and employs acquisition and contribution learning forms.

The framework presented in this paper (Table I.) comprises the following categories:

- learning resources (physical collection in the center of formal, and virtual collection as the core of informal learning)
- learning process supported by ICT tools which require students' participation and their individual creation, adaptation, structuring and organization of information related to the collection
- learning process results (Collection documentation and virtual catalogue and web site as an informal education resource)

TABLE I. PRODUCTIVE EDUCATIONAL FRAMEWORK

Productive educational framework - from formal to informal learning contexts		
Resources	***Learning process via ICT tools***	***Results***
Physical collection	Collection management and documentation	Collection documentation and virtual catalogue
Literature and related audio-visual material	Content management and adjustment	Web site (as an informal education resource)

User segmentation has been done in order to determine the tasks and goals of each group in the process of content creation and organisation, since they are all at different levels of knowledge about and relatedness to the collection in question. Museology students, as the primary group in formal education, have a task of creating and structuring a cultural heritage content, first from the perspective of museum research and documentation and then from the perspective of museum and heritage communication. Other students of the faculty who are envisaged to be a potential source of contribution as authorized online users with their expert knowledge about the sculptures, historical period, ancient languages, myths as well as personal stories from their everyday encounters with the collection at the faculty. In addition to these two groups of participants, there are also all other online users which will be able to visit the site and engage in informal learning about the collection in the virtual environment in their own pace, space and time.

C. Museum documentation database as a tools for productive education

At the beginning of the project museology students have to enter information about the collection from the already existing published museum catalogues, the information which can be obtained directly from the casts (measures, colour, damages etc.), and create links to audio-visual documentation which they also have to either create or include in the database. For this purpose they use M++ museum documentation database where each object is represented with multiple records about the origin, condition, related references etc.

This sort of information is highly formalized and structured by international standards and guidelines for data structure and data values. For example, students have used ICONCLASS classification system for vocabulary control for mythology and other subject information.

D. Content management module as a tool for productive education

After finishing the first main objective – to document the collection, students have to reuse digital content used in the collection documentation process and then adjust this content for communication purposes and publish it via content management system. Students use the content management module of M++ database (Figure 3) which enables developing of virtual collections and exhibitions.

This module enables following key features: development of thematic structure with related texts and visuals and linking of associated information about objects form the collection. It is important to stress at this point that catalogue items are integrated into already defined and structured topics which contain cultural, social and historical stories which are then supported, or better yet, evidenced by deliberately chosen and most suitable objects. The module is also characterized by a feature that enables flexibility of the created information (i.e. student-created knowledge). Since the main purpose is to develop a website as an informal learning resource the module facilitates modification and adjustment of the linked information in order to make the online communication easier, more comprehensive and effective.

Another very interesting functionality of content management module is the possibility to choose terms from controlled vocabularies that will be visible on the end user interface. That enables a fine adjustment of the complexity of terms and hierarchical structures on the

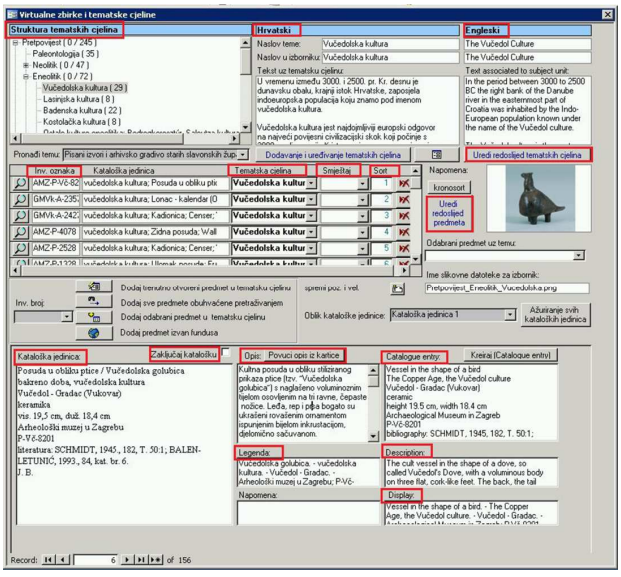

Figure 3. Content management module of M++ museum collection management database

website. It is also possible to map items (i.e. terms) from hierarchically structured vocabularies to visual controls such as timelines or ground plans.

E. Website as an informal education resource

In this ongoing project the website would be a continuously growing resource where final results of formal learning process would be presented for many generations of students. The projects' long term goal is to communicate continuous care for physical collection via web pages whose content will be constantly updated and new functionalities implemented.

Students who decide to continue their contribution to the project after their formal obligations in museology courses would be able to update web site segments such as stories and interesting facts related to the collection in informal context as website users.

A virtual catalogue, as the central part of the website, provides multiple points of access to information about the heritage objects and associated contextual information through timelines, interactive maps and thematic structures, and allows the inevitable search through the entire database. Interactive ground plans would be a very effective way to give directions from the virtual environment to a specific position in the physical environment [18]. Visitor experience in physical environment could also be enriched by interactive video projection mapping on sculptures. Simulation of colors in which marble originals at the Parthenon were painted has been projected, as you can see on Figure 4.

To ensure communication in the opposite way, from the physical to virtual environment, to find additional information about the objects and collection, QR codes would be included as an integral part of object labels.

Technology-mediated creativity and research done by museology students thus forms the basis of a further development of the heritage content by virtual users, which can further stimulate the development of new solutions in both technological and content-based aspects of the framework. This approach therefore makes students/users not only participants in the creation of heritage content but also co-creators of learning resources through the use ICT. This knowledge-making process reflects also on the learning outcomes for students in the formal aspects of education which is beneficial not only to the quality of their academic achievement but to their personal intellectual and social growth. Or, as Jarvis says: "Experiential learning is the process by which individuals, as whole persons, are consciously aware of a situation and make sense, or try to make sense of what they perceive, and then seek to reproduce or transform it and integrate the outcomes into their own biography." [17]

From the point of practical contribution of the project particularly, and museology courses in general, one of the most important though implied goal is to provide students with an insight into a part of the custodian work, which comprises a wide range of procedures, from collection care and documentation to different ways of communicating heritage – from exhibitions in the physical or virtual spaces, narrative development and the like.

Figure 4. Projection of simulation of colors in which marble originals was painted at the Parthenon

III. CONCLUSION

Experiences and results of the work on the presented project show that it is possible to narrow the gap between a documentary approach, as a set of traditionally rigid procedures of fixating identities of cultural heritage objects in controlled documentation media, and heritage communication in the virtual environment, which by definition involves a flexible approach based on interactivity, multimedia and open access.

This project, relying in its goals on the productive educational framework and the described content management module, promotes knowledge construction and organization through the use of physical and digital heritage artifacts. It also helps students and online users to capture the totality of learning experience which is based on participation and contribution of individually created content.

Abstract – At the University of Rijeka the theoretical knowledge is mainly transferred by the traditional model consisting of professor explaining material to a group of students in front of a blackboard. We believe that this model dates from the period of the industrial revolution when it was necessary to educate large number of people to work on new machines, but there was no technology for more efficient knowledge transfer. Nowadays, such a model cannot keep up with the speed of generating new knowledge and technology. A larger number of participants cannot be educated due to time and space constraints, and the knowledge usually becomes obsolete by the end of studies. The result of this model are students with skills unadapted to the labor market requirements. We believe this is an extremely important issue for our university. One of the possible solutions might be digitizing theoretical parts of courses. Using web technologies, theoretical lectures can be held online and in that way more efficient methods of teaching on campus can be used. In this paper, the process of digitizing the university course Introduction to Psychology is presented, as well as the benefits that can be achieved by creating and using multimedia online courses.

I. PROBLEM DESCRIPTION

A. *Outdated model of knowledge transfer in Croatia*

At the University of Rijeka the theoretical knowledge is mainly transferred by the traditional model consisting of professor explaining material to a group of students in front of a blackboard or using power point slides. We believe this model is outmoded and dates from the time when there was no technology for more efficient knowledge transfer. Nowadays, such a model cannot keep up with the speed of generating new knowledge and technology. A larger number of participants cannot be educated due to time and space constraints, and the knowledge usually becomes obsolete by the end of studies. The result of this model are students with skills unadapted to the labor market requirements. We believe this is an extremely important issue for our university.

B. *Practical problems*

Students are faced with a number of problems in mastering course content. Inadequate, outdated and sometimes raw literature, the lack of literature, badly maintained course websites, no playback of lectures, and the lack of interaction during the class are some of these problems. Students who wish to choose and design their own curriculum, by attending only those courses that interest them, are forced to make compromises in their work week, due to the spatial and temporal limitations such as overlapping classes. Hence, the maximum capacity of their learning is not utilized [1]. Teachers, on the other hand, are overloaded by teaching and by bureaucratic obligations, which greatly inhibits their scientific productivity.

C. *Saving resources*

The University of Rijeka organizes a large number of courses each academic year - about half of the teaching workload comprises theoretical lectures. For example, the Department of Informatics offers 41 course at the undergraduate level, which is approximately 1125 hours of theoretical lectures [2]. When these theoretical parts of the courses could be mastered over the Internet by watching multimedia video lessons, the University could redirect significant resources in research and scientific projects. By using computer technology, universities can reduce the number of classrooms, staff and hard copies of teaching materials which are required if the number of students is to be increased [3]. Payne and Stergioulas argue that technology enhanced learning could be a significant driver for progressive change and economic growth, which can assist in the economic recovery, as well as in the democratization of education [4]. Teachers would not need to spend time in teaching and preparing the content year in year out, and students would be able to adapt the learning process to themselves so that they learn where and when they want and at a pace that suits them [3]. Moreover, such an approach would evidently solve the problem of overlapping courses.

II. TECHNOLOGY AND EDUCATION

Using technology in education can enhance the process of learning; therefore it is called Technology Enhanced Learning (TEL). It can make the process of learning more effective, efficient and flexible for students and it can improve teaching quality and add more value [3, 5, 6]. Technology evolved to the level that it can support individualized and collaborative learning [7, 8, 9]. There are even reports that students prefer TEL to the traditional face-to-face learning methods [1]. Some people in academia fear that TEL can never be as effective as face-to-face teaching, but one might argue

that this held true in the past, due to the negative experience with poorly designed content or inappropriate use of technology [4]. With education becoming more and more personalized, and enriched with multimedia and social media, that should not be the case anymore.

A. *Democratization of knowledge*

Until recently, access to the most advanced knowledge, created by leading experts, has been reserved for a small number of students who passed a rigorous and financially very demanding process of enrolling in one of the prestigious universities. All that changed with the open curriculum initiatives, which began to spread across prestigious universities. Since 2012, many online platforms have emerged with the goal of providing top quality education for free. Some of them are Coursera, edX, Udacity, Venture Lab, Udemy in USA or OpenupEd and Iversity in Europe. Since the courses are open to the general mass, they are called Massive open online courses or abbreviated MOOC. One might ask why institutions and educators would give their knowledge for free. Bonk argues that by doing it they promote their talent and enhance their reputation, they potentially help faculties with recruitment and retention, and they create connections with life long learners [10]. They can also build business models around this free content, like charging for knowledge certification or charging other institutions for material usage.

B. *MOOCs*

MOOCs are online courses with no formal entry requirements, and usually no participation limit. They can be enrolled free of charge and they do not earn credits. [11]. According to Siemens, there are 2 different categories of MOOCs [3, 12]. By adopting a connectivist philosophy, cMOOC, where c stands for connectivity, emphasizes creation, creativity, autonomy, and social networking learning. xMOOC is based on the traditional learning approach, and comprises of lecture recordings and short quizzes and tests. Lisa Lane suggests that MOOCs can be grouped into three types: network-, task-, and content-based [17].

C. *Big data in education*

More and more activities are carried out via the Internet. This results in an increasing amount of data to be analyzed in order to develop intelligent tools for improving the decision-making process. The same applies to the process of learning. With the development of MOOCs, the educational process began blending with the Internet in much higher rate. Users interact with LMS systems (Learning Management System) in different ways, and thus generate enormous amounts of data. These data should be analyzed to better understand the process of learning over the Internet and thus improve the LMS systems and the design of the courses themselves.

Learning analytics "is the measurement, collection, analysis and reporting of data about learners and their contexts, for purposes of understanding and optimizing learning and the environments in which it occurs" [13]. By building predictive models based on learning data, researchers can answer questions like: "What sequence of topics is most effective for a specific student? What student actions are associated with more learning (e.g., higher course grades)? What student actions indicate satisfaction, engagement, learning progress? What features of an online learning environment lead to better learning? What will predict student success [14]?" Long and Siemens argue that by using learning analytics we can innovate and transform university systems and pedagogical approaches, so its biggest value is in reforming activities in higher education and assisting educators in improving teaching [15].

III. COURSE DEVELOPMENT

The course Introduction to Psychology from the Faculty of Humanities and Social Sciences at the University of Rijeka is digitized for the purpose of this paper. The course is offered at the undergraduate level and intended as an elective course for the students of the entire university.

By enrolling in a course at the university, a student is expected to adopt certain theoretical concepts and develop specific skills. Since the purpose of this course is to provide a basic overview of the entire scientific field of psychology, most of the course loads are theoretical lectures and it is, therefore, not possible to go into the depths of matter or to develop certain skills. The course is digitized with the aim of making students learn theoretical concepts before coming to class, and thus a content-based xMOOC is created.

To create this online course, a web application for distributing the content needed to be developed, and the course content needed to be digitized.

A. *Web application development*

For the development of the web application, the "Lean Startup" philosophy is used [18]. Since this approach is based on fast and agile development, technology which enables developing a fast, dynamic and flexible application needed to be chosen. The back end part of the application is developed in Python programming language and Django web development framework driven by MySQL database. The front end is developed using HTML language and jQuery Javascript library. An important criterion for choosing these technologies was the fact that they are free and available to everyone.

B. *Course digitization*

The course is divided into 12 thematic sections, each divided into concepts that are shown in the form of video lessons with the average duration of two minutes. Recent research suggests that the format of short videos provides learning outcomes comparable to the traditional on-campus lectures [19]. To keep the users engaged, a fast exchange of short videos and short single choice questions with immediate feedback is employed. The

purpose of the questions is not evaluating users' knowledge, but rather pointing out key points and helping with memorizing them.

The course is available to the general public since one of the goals is the popularization of psychology. To make the course materials interesting and fun to watch, video lectures are made in the form of comics and drawings in the making. In order to improve users' memory, mnemonics is used, a strategy that helps in storing information in long term memory and recalling it when needed [20]. Fig. 1 shows an example of mnemonics which describes the role of glial cells inside our brain.

The whole digitization process, as shown in Fig 2, is conducted in 5 steps. The first step consists of preparing the course content in the form of narrative, and the questions that go with video lectures. Thereafter, two processes take place in parallel. While the illustrator creates graphics using the drawing tablet, the lecturer is recorded in a specially prepared studio. These steps are then followed by the assembly of video in a video editing software. The final step is the publication of the content on the web platform.

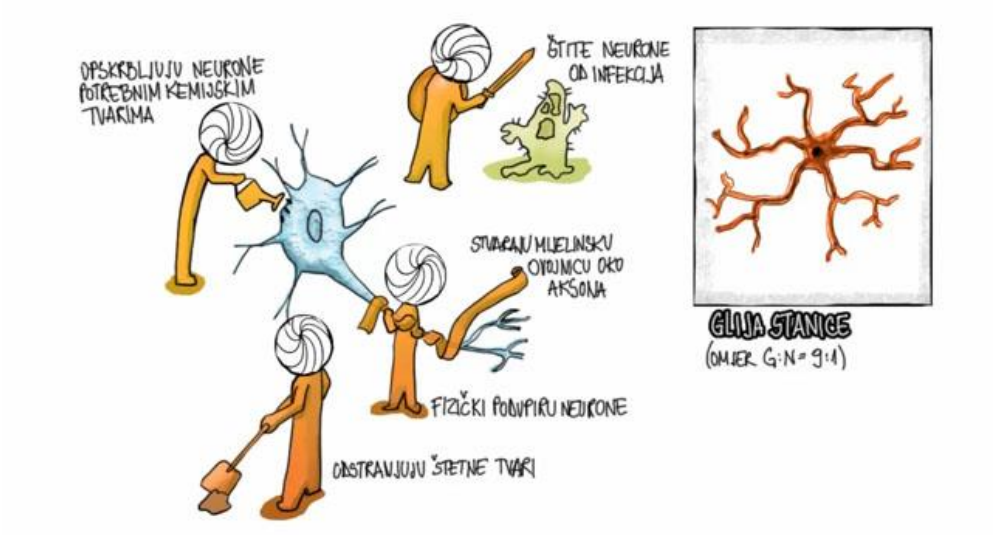

Figure 1. Using mnemonics in describing function of glial cells

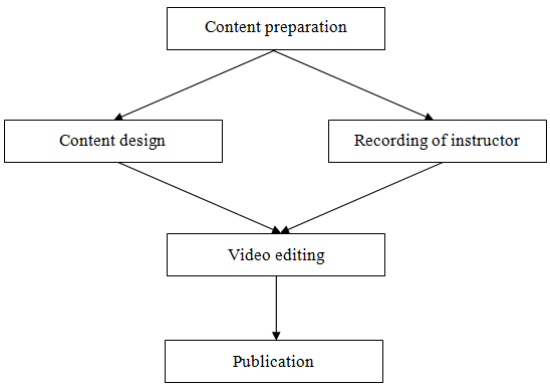

Figure 2. Course digitization process

IV. PRACTICAL RESULTS

Following the example of developing platforms for MOOCs mentioned in this paper, we opt for a similar approach. A standardized platform is made, enabling all courses to have the same structure. User interface currently consists of two main parts: a promotional page and a virtual classroom.

The main element of the promotional page is a motivational video, in which the course instructor is trying to motivate visitors to enroll in the course. This page also provides information about the course instructor, description, thematic segments and literature. Once participants enroll in the course, they get access to the classroom where they can watch video lectures and answer lecture questions, as shown in Fig 3 and Fig 4.

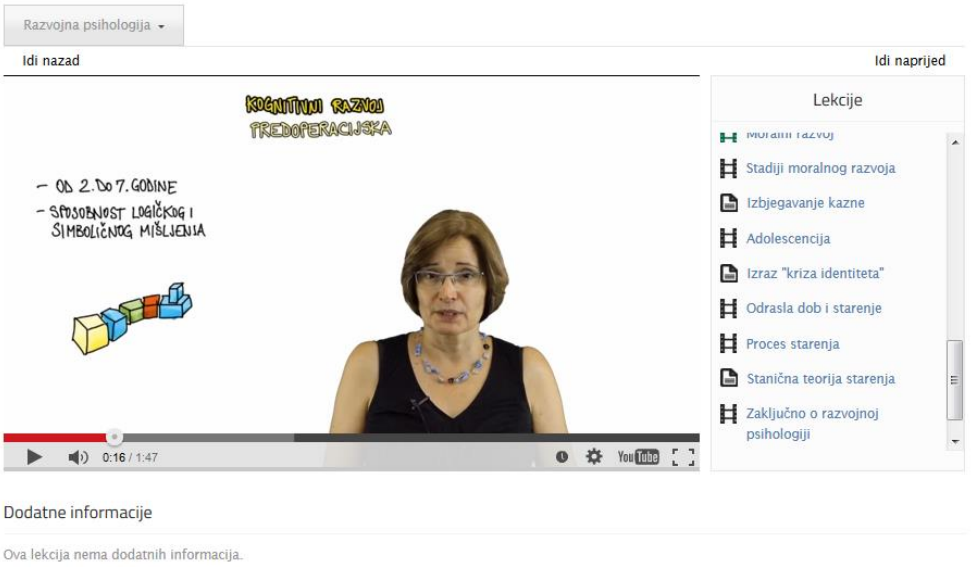

Figure 3. Watching video lessons inside virtual classroom

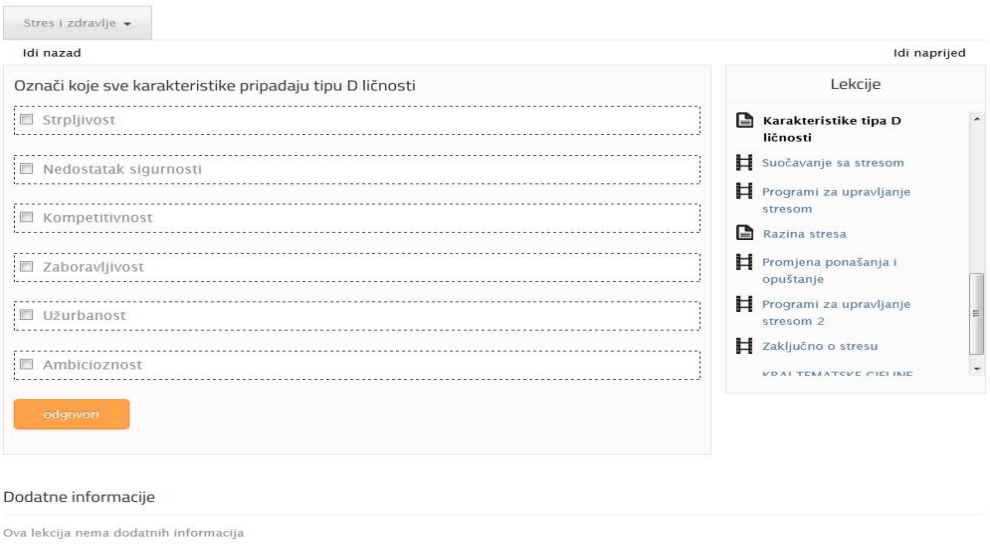

Figure 4. Answering questions inside virtual classroom

The course, which can be found on web address http://www.buraznanja.uniri.hr/courses/uvod-u-psihologiju, consists of a total of 12 thematic sections and 223 lessons, which makes 347 minutes of video material. By the 15th of January 2014, when the data were analyzed, the course was enrolled by 849 participants. Fig. 5 shows a huge drop in the number of video lessons watched after the first thematic section. The reason probably lies in the fact that a large number of people enrolled this course out of curiosity rather than interest in the material.

Fig. 6 shows times at which the participants were watching video lessons. This supports the idea that people need flexibility in organizing their learning, and if the flexibility is given, they use it.

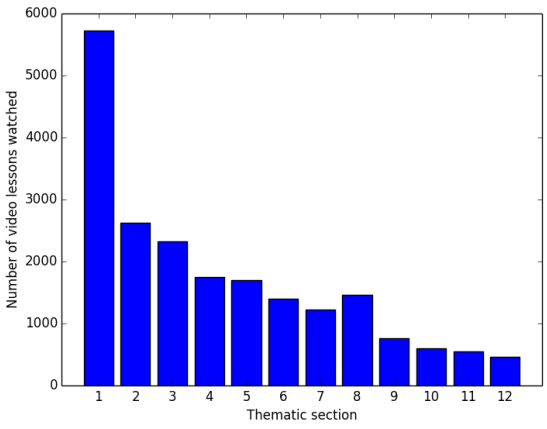

Figure 5. Video lectures watched inside each thematic section

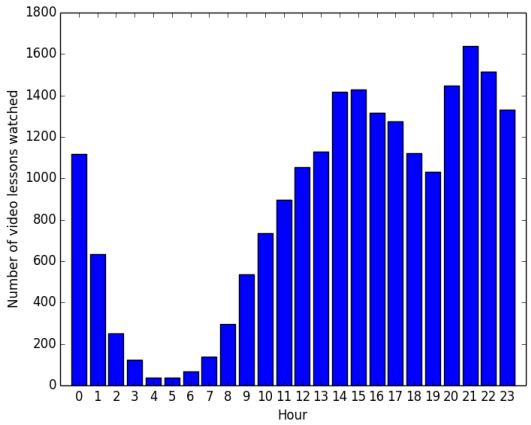

Figure 6. Video lectures watched in 24 hour day

V. CONCLUSION

The growth of popularity of MOOC courses in the world opens door to new research in various domains of science, from pedagogy and education to computer science, and based on the data created within a variety of learning systems. With new technologies evolving every day, teachers are faced with new challenges. For students, the biggest contribution of this type of courses is the possibility to watch lectures all over again whenever they want. The biggest benefit for teachers is that they can spend more time on practical work and research with their students. They can focus more on directing social communication, identifying students capable of mentoring, and identifying and selecting the most successful method of learning.

Using online multimedial learning and developing analytical tools, we are able to personalize and customize learning for each student individually. We can raise student motivation and student achievements by providing immediate feedback while learning (lecture questions) and by visualizing complex information. Our future work will focus on identifying the impact of combining multimedia courses with on campus teaching, and developing tools for estimating student motivation in an online environment.

ACKNOWLEDGMENT

We thank Marina Skocigoric for providing great illustrations for the course content.

Are they a perfect match?
Analysis of usage of author suggested keywords, IEEE terms and social tags

Dina Vrkić
University of Zagreb, Faculty of Electrical Engineering and Computing /
Central Library,
Unska 3, 10000 Zagreb, Croatia
dina.vrkic@gmail.com

Abstract - The majority of the scientific papers include keywords besides the obligatory title and abstract. The use of keywords is not just for the description of content, but it is a viral part of the scientific paper which is later used for information retrieval function. The aim of this paper is to present comparison of author suggested keywords in scientific papers of Faculty of Electrical Engineering and Computing (FER), IEEE terms and user tags in academic social network Mendeley.

This paper will examine the scientific papers represented in IEEE Journals and Magazines indexed in the IEEE/IET Electronic Library reviewing the overlap between author keywords and IEEE terms from a controlled vocabulary (IEEE thesaurus) and user tags in Mendeley. The results showed no significant use of controlled vocabulary and social tags, which leads to the conclusion that the authors are not aware of the importance of controlled keywords.

I. INTRODUCTION

The documentary (or indexing) language is the conventional language used by the information unit to describe the contents of documents with a view to the storage and retrieval of information [1].

Their function is shortening and simplifying natural language which controlled in this way enables a quick and successful search. This kind of example is provided by a thesaurus.

Thesaurus is a controlled and dynamic documentary language of semantically and generically connected terms which cover a particular field of knowledge. They usually consist of descriptors (standardized keywords) and non-descriptors (prohibited terms, for example, synonyms which usually stand with reference to the preferred term). Thesauruses are usually defined by the following relationships between terms: equivalence (synonymy), hierarchy (generic, partitive etc.) and associativity. According to the number of languages, there are monolingual and multilingual thesauruses; according to the level of analysis, thesauruses are divided into macro thesauruses and micro thesauruses. In its function, thesaurus is a tool for controlling the terminology which is used in the translation of natural language of a document, level of contents or user into a more limited "system language" (documentary language) [2].

The main users of a thesaurus are primarily professionals (indexers), and then users. Searching only by the title, author or keywords (freely formed) is not enough, but it is also necessary to connect the field of research to what is being searched in a certain way.

This paper will present comparison of author suggested keywords in scientific papers of Faculty of Electrical Engineering and Computing (FER), IEEE terms and user tags in academic social network Mendeley.

II. IEEE THESAURUS

IEEE thesaurus is a controlled vocabulary with more than 9600 descriptors for engineering and scientific terminology, as well as IEEE-specific society terms. The thesaurus represents a terminology and oral use of terms drawn from IEEE publications (transactions, journal articles, conference papers and standards). The basis of language was a natural language, English language from the speaking area of the USA with cross-references of the British spelling varieties. The scope and structure of the Thesaurus reflect the engineering, that is, technical and scientific discipline which are consisted of the societies, councils and communities of IEEE, together with the technologies which IEEE serves. Generally, the IEEE Thesaurus is a very simple controlled vocabulary consisted of descriptors for favorable terms and technical terms.

Descriptors are used for indexing within the IEEE/IET Electronic Library (IEL) (popularly IEEE Xplore Digital Library), subject analysis, search and inclusion in the publishing business through keywords which are considered preferred terms for forming keywords [3]. Since IEEE is also a publisher, journals and conferences which are under its jurisdiction are generally required to include the controlled vocabulary, and in this way include descriptors instead of freely formed keywords [4].

Thesaurus construction is based on the ANSI/NISO Z39.19-2005 standard, Guidelines for the Construction,

Format, and Management of Monolingual Controlled Vocabulary.. Each descriptor included in the thesaurus represents a single concept or unit of thought. The descriptors are considered the preferred terms for use in describing IEEE content. The scope of descriptors is based on the material presented in IEEE journals, conference papers, standards, and/or IEEE organizational material. A controlled vocabulary is a specific terminology used in a consistent and controlled fashion that results in better information searching and retrieval [3].

Each descriptor included in the thesaurus represents a single concept or unit of thought. The descriptors are considered the preferred terms for use in describing IEEE content. The scope of descriptors is based on the material presented in IEEE journals, conference papers, standards, and/or IEEE organizational material. A controlled vocabulary is a specific terminology used in a consistent and controlled fashion that results in better information searching and retrieval [3].

Taxonomy is a strictly hierarchically structured list of terms in which all the conditions are correlated and all the cross-references are excluded. Each term in taxonomy is in one or more parent-child relations to other concepts in the taxonomy.

IEEE taxonomy contains the first three hierarchical levels below any broader concept (branch). In this document, conceptual relations are presented in alphabetical order and highlighted in bold. Every parent term does not have more than tri sub terms with levels marked by dots (in groups of four dots) of previous conditions to the next level. Terms can appear in more than one hierarchical branch in a parent-child relation. IEEE taxonomy is defined in such a way that it is always a subset of the IEEE Thesaurus [5].

Taxonomy is used when it is necessary to review the list of acceptable terms, but a thesaurus is more convenient when it needs to be decided which term to use. Professionals will use a thesaurus because an alphabetical list of terms is enriched with descriptor relations which enhance the detection of terms (broader and narrower terms, related terms and references). Furthermore, taxonomy will be used as a reference document when the authors will ask for a list of keywords with which the authors describe their works or any situations when they will need an IEEE list of words.

IEEE Explore uses the IEEE Thesaurus for indexing articles, but not only those of IEEE publishers, but all the papers which become included in the database itself. Today IEEE publishes more than a quarter of all the publications related to electrical engineering and computer science. Through its scientific and technical publications, conferences and IEEE norms it publishes over 30 percent of the world's literature in electrical engineering and computer science and organizes over 300 major conferences annually and has more than 800 existing norms with another 700 in preparation.

The most famous of the IEEE guidelines for helping editors and authors in publishing papers is "IEEE Author Digital Toolbox" [6]. It contains valuable information, guidance and assistance in the preparation of an article and its submission to the editor, as well as in reviews and ordering reprints. It is enriched with frequently asked questions related to the topic of scientific communication. The part about keywords is particularly highlighted. Authors are encouraged to use Instructions for Authors with the use of keywords from the list of IEEE taxonomy, stressing that if the author does not find the appropriate term, he/she should add his/her own within the paper. This is ultimately another method to enter new words into controlled vocabulary. It has been noted: Authors are encouraged to select required keywords from the list of "recommended keywords for authors." They contain the first three hierarchical levels below which there are terms in parent-child relations of the most frequently used terms from the IEEE Thesaurus. If you cannot find the appropriate terms, you can always add your own [6].

The list of keywords (or thesaurus) is available as auto retrievable ASCII file which is sent to e-mail keywords@ieee.org. In a reply to e-mail an alphabetical list of approved IEEE index terms is sent. The latest version supersedes the previous one and in this way changes all the previous versions, which makes only the last one up-to-date and usable. If an outdated list is used, it will be harder to search the works [7].

III. BACKGROUND OF THESAURUS AND KEYWORDS

Keywords are listed after the abstract, but in the language of the summary [8]. They are of particular importance for detecting topic and focus of the paper. They reflect the content and the method described in the paper. The content is mainly described by nouns, and the method and procedure by nouns and verbs. Basic keywords represent important concepts and thus completely describe what the paper is about. In general, the author can choose keywords himself, but in some cases there are needs for choosing keywords with the use of a glossary or a particular thesaurus [8]. In order to successfully communicate with the information database, the user needs to formulate the aspect concepts using symbols – words, phrases and codes, as in communication with other people. If natural language is used as a language for finding information, the existence of homonyms and synonyms will increase problems in online search [8].

Therefore, keyword or term lists are essentially stripped-down versions of subject heading lists with little or no synonym control and often lacking cross-references; they generally do more harm than good for indexing purposes [9]. Subject heading is a word or phrase from a controlled vocabulary which is used to describe the subject of a document or a class of documents. Subject headings may be represented in individual bibliographical records [9].

Articles which include descriptors help to identify and summarize the importance of the work. Also IEEE stated that: Electronic searches for articles are often more productive when authors prove ide keywords (or "indexing terms") in addition to the abstract to locate articles.

- Concepts inherent (but unstated) in an article should normally be indexed unless they are so rudimentary as to be presumed by any novice looking for informal ton. An author should use judgment, but it is always better to err on the side of inclusion rather than exclusion.
- IEEE policy - and good indexing practice: assigns the most specific index in keywords available to describe the major points or topics covered in the art ice.
- Choosing keywords from the current IEEE Indexing list promotes standardized indexes [7].

A thesaurus provides access to words which are used in bibliographic records which have derived from a controlled vocabulary. However, there are also disadvantages. In this way they cannot compensate for the complexity of natural language and accordingly, expression, while the context cannot be recovered.

Uncontrolled languages give the user more possibilities with using them, and do not require precision for data input for the search, but have a higher probability of errors in the information output [7].

Indexing, or in this case, user labeling, is a popular method for users to allocate their own freely chosen words (tags) regardless of the fact whether or not they are in the controlled vocabulary [7]. That is why we speak about freely formed words. On the other hand, labeling has its advantage because it is free of charge and allows the user to connect the term with some terms which are no longer in controlled vocabularies (for example, the term *grid* as an old term and the term *cloud computing* as a contemporary one). IEEE Explore does not allow readers to tag articles. Therefore, we have introduced a new component into our research which allows such action – Mendeley, software for managing references.

Mendeley is a free reference manager and academic social network that can help scientists to organize your research, collaborate with others online, and discover the latest research [10]. Why Mendeley? Because altmetrics is popular today, which has dual function: scientific communication and a new approach to scientific measurability, associated for instance in Scopus, but mostly because of search in Mendeley which is indexed by Google as well.

Connecting author supplied keywords to the tags, Kipp mentioned [11], [12] adapted Voorbij's[13] thesaural analysis method to compare tags, author keywords and descriptors assigned to LIS articles tagged on CiteULike. Tags were more likely to match author keywords exactly (33%) than descriptors (16%), but author keywords were as likely to match exactly or be related terms of descriptors (19%) [12].

Thomas et al. [14] adapted identical thesaural comparison for books tagged in LibraryThing with associated Library of Congress Subject Headings finding that 6% of tags matched LCSH exactly while 31% matched thesaural categories and 35% were related to LCSH but not subject headings.

According to a notable number of recent studies carried out in the area of medicine, social and humanities sciences it is noticed a significant lack of literature and examples in area of technical sciences.

IV. RESEARCH METHODOLOGY

The research question is: do the users of the Faculty of Electrical Engineering and Computing use a recommended controlled vocabulary, prescribed by IEEE journals, while forming keywords in an article?

IEEE Xplore Digital Library is one of the most important databases of scientific and technical articles in the world, which covers a third of the world's literature in electrical engineering, computing, information and communication technologies, as well as many other interdisciplinary areas. By accessing the database you have the access to complete texts (PDF) for more than 3 million documents (2 million authors, 170 journals, 900 conferences, 2000 IEEE standards and 25000 new scientific articles per month).

After searching the database and extracting data, the collected results will be subjected to the method of comparing the keywords with IEEE controlled vocabulary and Mendeley (freely formed) tags.

On January 3, 2014 the data were collected from IEEE Xplore Digital Library with advanced search strategy in which only metadata elements were selected, Author Affiliation: Zagreb, Publisher: IEEE, Type of publications: Journals & Magazines, Publication year spam: from 1996 to 2014. Since the first year from the literature was 1995, in which for the first time instructions for authors and controlled vocabulary were mentioned, the year 1996 was taken as the first complete year which could go through implementation and indexing.

The results were later narrowed by Author Affiliation facet and forms of the name for the Faculty of Electrical Engineering and Computing of the University of Zagreb, which was represented less than 34 different terms. The forms which contained the term University of Zagreb in 4 versions were not taken into consideration.

The problem of diverse forms for a particular institution causes a difficult search of institutional production if the right manner of stating the name of an institution in which the scientist works is not properly regulated. In 2012 the Faculty of Electrical Engineering and Computing published an internal document "Specifying the name of the University and the Faculty within the papers of the FER employees" in Croatian and English. Since this provision was introduced in May 2012, we had to take into consideration the probability that a very small number of papers would be listed in the following order. Therefore, the decision was made that all forms of the name which were used by then would be extracted. All journal articles were coded for an easier tabular display.

V. RESULTS

The result of the search was 76 articles ranked according to the age from the oldest to the newest. Only the ones which fulfilled the conditions that articles contain keywords listed by the authors and IEEE index terms in the database IEEE Explore were taken into consideration. The final number of articles for comparison was two thirds of the total, that is, 53 articles.

A problem with reaching authors' keywords was perceived because they were not listed in the bibliographic record. Therefore, any paper which did not have the elements had to be opened and imported into the table. It was found that 9 articles did not have keywords and 14 articles did not have assigned IEEE terms in the database. In addition, the presence of social marks (tags) was verified on the network/software for managing Mendeley references.

The scientists predominantly focused on keywords taken from the titles of their papers. They used terms which were either too important or not important enough. A low number of keywords predominated. According to the instructions, a recommended number of keywords are up to 10 words, in an alphabetical order, separated by commas.

During the period between 1996 and 2009 IEEE Xplore listed 10 IEEE terms (in 31 papers), but from 2009 the number of terms has significantly varied: from 5 to 14 terms. The alphabetical order of keywords was noticed in 39 works, that is, three quarters. In the analysis only those terms which are almost identical were taken into consideration (except for tilde). The terms containing abbreviations with the full name were eliminated, as well as abbreviations as such, together with the relationship singular-plural in terms (for example authors' words) flexible manufacturing systems (FMSs) -> flexible manufacturing systems (IEEE terms); e-learning -> electronic learning (IEEE terms). It was noted that there were 25 papers with the terminology which in a small part coincides with the suggested IEEE keywords.

TABLE I. THE NUMBER OF KEYWORDS USED IN ARTICLES

Number of keywords in article	Number of articles with keywords
3	4
4	9
5	22
6	9
7	3
8	3
9	3

Thus we see how the authors predominantly decided for 5 keywords to describe the paper, 9 papers use 4 or 6 keywords, while a smaller number of papers contains 4 or more than 6 keywords.

TABLE II. COINCIDENCE OF THE NUMBER OF TERMS IN THE PAPERS WITH IEEE TERMS IN THE DATABASE

N of matching terms	N of articles with identical terms
1	17
2	6
3	2

By the number of terms that coincide with the authors' keywords and allocated IEEE index terms, we can conclude that the authors did not use *Authors instructions*, that is, IEEE taxonomy.

TABLE III. RELATED TAGS FROM MENDELEY AND IEEE TERMS

N terms	N articles with related M tags & I terms
1	3
2	1

Correlation of (freely formed) tags in Mendeley with IEEE terms does not show correlation to a greater number of terms, due to the fact that we can compare it only in two cases; with one or two terms.

TABLE IV. DISPLAY OF CORRELATION BETWEEN TAGS FROM MENDELEY AND IEEE TERMS (E.G. ARTICLE UNDER CODE N.11)

Author suggested keywords	IEEE terms	Mendeley Tags
losed-loop control hybrid stepper motor microcomputer implementation of optimal control algorithms optimal control algorithms	Acceleration Choppers Microcomputers Micromotors Motor drives Open loop systems Optimal control Permanent magnet motors Rotors Torque control	acceleration average torque bipolar supply chopper amplifier choppers (circuits) closed-loop control closed-loop optimal control algorithms closed loop systems control design control performance

The tag *choppers (circuits)* is already marked with the term from a higher hierarchical level in order to eliminate the possibility that these are, for example, choppers as engines. The tags that appeared in the research are mostly tags which mean something only to the authors who created them, while they are meaningless to a wider audience, for example: he, phaseread00, folder 5, hjacs, inscope, tech, etc. The presence of tags was unexpectedly below the expected number. A greater presence was expected due to the distribution of the net users, but also because of the concept of open access which enhances authors' visibility. Therefore, a well denoted document provides easy search ability which provides good visibility.

TABLE V. CORRELATION BETWEEN AUTHORS' KEYWORDS (AKW) WITH THE TAGS FROM MENDELEY

N terms	N articles with related AKW & M tags
1	2

The correlation of authors keywords with freely formed tags is special because it is the equal level of indexing, thus we speak about freely formed words. The result is realistic because we need to have in mind that the

user denotes the text according to the choice of the keywords which he or she knows the best.

TABLE VI. DISPLAY OF CORRELATION OF AUTHORS' KEYWORDS TO TAGS FROM MENDELEY (E.G. ARTICLE UNDER CODE N.32)

Author suggested keywords	IEEE terms	Mendeley Tags
Constrained systems constrained time-optimal control (CTOC) control invariant set discrete-time (DT) dynamic programming electronic throttle friction limp-home (LH) nonlinearity piecewise affine (PWA) systems	Combustion Computational modeling Control systems Electric variables control Engines Friction Optimal control Sampling methods Table lookup Valves	electronic throttle model predictive control

TABLE VII. AUTHORS' KEYWORDS CONNECTED WITH THE SAME IN MENDELEY (M-ASK) WITH IEEE TERMS

N terms	N articles with related AKW, IEEE terms & M-ask
1	2
2	1

The correlation of author suggested keywords to the ones from Mendeley (M-ASK) with the IEEE terms in the database IEEE Xplore show that a small number of authors have created words using a controlled vocabulary. This relation is an example of how you should, when creating a particular paper, already have in mind the use of a controlled vocabulary because process of taking a bibliographic record (either from the database or manual entry) requires keywords. If they have already been well formed, the possibility of better visibility is also improved in Mendeley. Although the term permanent-magnet motors was specified, it was decided to ignore the tilde between terms, in order to show better correlation between different terms.

TABLE VIII. DISPLAY OF CORRELATION OF KEYWORDS AND THOSE FROM MENDELEY WITH IEEE TERMS (E.G. ARTICLE UNDER CODE N.30)

Author suggested keywords	IEEE terms	Mendeley Tags	M-ASK
Air-gap permeance magnetic fields permanent-magnet motors	Air gaps Finite element methods Forging Geometry Magnetic analysis Magnetic fields Magnetization Permanent magnet motors Surface waves Torque	Air-gap permeance air gaps conformal transformation electromotive forcefinite element analysis finite-element simulations flux density Folder - zarko magnetic field distribution magnetic field modelling	Air-gap permeance magnetic fields permanent-magnet motors

TABLE IX. CORRELATED AUTHOR SUGGESTED KEYWORDS, TAGS AND AUTHOR SUGGESTED KEYWORDS IN MENDELEY WITH IEEE TERMS

N terms	N articles with related AKW, M tags, M-ASK & IEEE terms
1	2

The correlation of author suggested keywords, tags and author suggested keywords in Mendeley is an example of a well denoted article. If the users perceive in M-ASK how a controlled term is specified they can, what they most frequently do, rewrite it or enter the tags.

TABLE X. DISPLAY OF CORRELATION OF AUTHOR SUGGESTED KEYWORDS, TAGS AND AUTHOR KEYWORDS IN MENDELEY (E.G. ARTICLE UNDER CODE N.30)

Author suggested keywords	IEEE terms	Mendeley Tags	M-ASK
Air-gap permeance magnetic fields permanent-magnet motors	Air gaps Finite element methods Forging Geometry Magnetic analysis Magnetic fields Magnetization Permanent magnet motors Surface waves Torque	Air-gap permeance air gaps conformal transformation electromotive forcefinite element analysis finite-element simulations flux density Folder - zarko magnetic field distribution magnetic field modelling	Air-gap permeance magnetic fields permanent-magnet motors

TABLE XI. DISPLAY OF CORRELATION OF AUTHOR SUGGESTED KEYWORDS, IEEE TERMS, TAGS AND AUTHOR KEYWORDS IN MENDELEY (E.G. ARTICLE UNDER CODE N.30)

Author suggested keywords	IEEE terms	Mendeley Tags	M-ASK
Air-gap permeance magnetic fields permanent-magnet motors	Air gaps Finite element methods Forging Geometry Magnetic analysis Magnetic fields Magnetization Permanent magnet motors Surface waves Torque	Air-gap permeance air gaps conformal transformation electromotive forcefinite element analysis finite-element simulations flux density Folder - zarko magnetic field distribution magnetic field modelling	Air-gap permeance magnetic fields permanent-magnet motors

By the connectivity of author keywords, IEEE terms, tags and author keywords in Mendeley we can conclude that there is a circle between the way of connecting them, which shows that there is equal presence of freely formed terms – tags and M-ASK. User tagging, with its lower apparent cost of production, could provide additional access points to traditional controlled vocabularies and provide users with the associative classifications necessary to tie documents and articles to time and task relationships as well as other associations which are new and novel [11].

The correlation between author keywords, IEEE terms, tags and Mendeley author keywords (M-ASK) is not present because there is not a single example of such connection. Kipp examined author keywords in comparison to tags and subject headings using a modification of Voorbij's categories. She found that author keywords were more similar to tags in terms of term choice, but that there was still a high degree of overlap between tags, author keywords and subject headings when related term (RT) matches were taken into account [15].

As a reason for a small number of this we need to take into consideration that: some papers perhaps did not have author instructions in a form as they are now, editorships

(obviously) do not pay attention to forming keywords. But above all, the scientists themselves may not be aware of the advantage of using a thesaurus, by the Association and the library, natural language in technical sciences is suitable for abbreviations which scientists have relied on, but which do not match a controlled vocabulary – the terms are being resolved.

Regarding the possibility of outdated terminology, it can be clearly found in the IEEE Thesaurus, but the question is to which extent the authors will use it as it has already been noted in the paper that thesaurus is used by informational professionals, while the authors use taxonomy.

VI. CONCLUSION

Since IEEE continuously follows technological trends and in this way wants to maintain a quality organization, that is, engineering sciences and profession, it is recommended to use a controlled vocabulary. Since the results showed that the scientists do not use the proposed controlled vocabulary, it will be necessary to establish a connection between informational professionals, in this case a higher education library, which will raise awareness of the benefits of using the vocabulary and of the scientists themselves. Raising awareness of the use of a controlled vocabulary and better indexing for better searching, as shown in Mendeley, certainly has its benefits, especially when it comes to science where terminology is continuously changing.

We have shown how scientists adhere to the concept of forming keywords, but do not use the IEEE controlled vocabulary. Therefore, we can say that there is a problem of awareness about the importance of implementing a controlled vocabulary in writing papers. Some concepts are quite narrow, while others are quite broad. We have also managed to find a few errors in the IEEE indexing (symmetric terms, typos). Mendeley failed to give the results we were hoping for, that is, that a larger number of freely formed tags would be used. There is a large number of papers in which by the use of metadata a great number of metadata was extracted, so there is not a great number of social tagging.

Faculty of Computer Science and Engineering
Ss. "Cyril and Methodious University" in Skopje
{vesna.kirandziska, mile.jovanov, marija.mihova, marjan.gushev }@finki.ukim.mk

***Abstract*—Compilers is an important course in the curricula of Computer Science Faculties. A problem that we have faced while organizing the course at our institution was lack of prior knowledge of some students in the area of assembly programming and microprocessors. Due to the fact that the number of classes for the course was limited, we were not able to teach the necessary material on assembly programming. In this paper we present our idea for the lab project to be done by students through the course, that should enable them to grasp all necessary concepts in Compilers without a need of assembly programming. The idea was tested a few of years in a row, and most of the students managed to finish the project, and achieved better results in the final exams.**

***Index Terms*—compilers, learning**

I. Introduction and related approaches

By definition, a compiler is a computer program by which a high-level programming language is converted into low-level programming language that can be acted upon by a computer. Hence, for someone to be able to make a compiler, she needs to know the high-level programming language, and also to have a great understanding of the low-level language.

The course Compilers or similar courses named Compiler construction, Compiler and interpreter, Compiler Practicum, Programming languages and Translators are all in the computer science program at many Universities. At our Faculty of Computer Science and Engineering in Skopje this course is elective course in the sixth semester, by the proposed program. It is a compulsory course for students enrolled in some of the modules like 'Computer science' and 'Software engineering'. Each year we have around 40-70 students enrolled in this course. It is of a significant importance how this course is taught to the students and whether they can achieve the course goals.

There are different experiences worldwide. At the University of Virginia [1] a big accent in the curriculum is given to code generation. The course project consists of two programming assignment. The first is building a compiler for COOL (the classroom object-oriented language which is a high-level programming language) and the second is optimizing it. COOL has the essential features of a realistic programming language, but is small and simple enough so that its compiler can be implemented in a few thousand lines of code. The course Compilers [2] held at Stanford University also uses the COOL language as an example for building parts of a compiler through five different programming assignments. Even more, an optional course project is to write a complete compiler for COOL in C++ or Java.

Other universities use part of Java programming language as the high level-language that has to be translated. For example, at the University of Texas[3] as a student assignment, each student writes a compiler for Pascal and code is generated for a real processor and run on hardware. Beside heavy programming skills, hardware knowledge is crucial for creating a program written in a low-level language. One of the four distinct assignments in the project at this university involves code generation. A major part of the course held at the University of Waterloo [4] consists of an implementation of a compiler for a simplified Java-like language called Joos1W. The course project represents 75% of the student grade.

At all mentioned universities the project assignment represents the great deal of the student evaluation. Building their own compiler enables students to get more deeply involved in the crucial parts of a compiler and it enables understanding it better through all challenges that came up while working on their programming assignment.

Other thing in common for all Compiler courses lectured at different universities is that the compiler built usually translates in some version of an assembly programming language. At Stanford [2] the MIPS (Microprocessor without Interlocked Pipeline Stages) assembly is used, while at the University of Waterloo[4] use the Netwide Assembler dialect that runs on he Intel x86 architecture. So, for building a translator into low-level language the knowledge of assembly language is essential.

All programs for Compilers at other universities discussed above require knowledge form Data Structures, Algorithms, Programming, Microprocessors and Formal Languages.

At the Faculty of Computer Science and Engineering in Skopje Structural and Object Oriented Programming are courses taught in the first student year (by the proposed schedule), Data structures, Algorithms and Formal Languages are in the second student year, but the course Microprocessors is an elective course in the third or forth student year. The

curriculum of Microprocessors includes assembly language and programming 8086 microprocessor. As a result, usually students enrolled in the Compiler course, had not been enrolled on the course Microprocessors previously. This was a problem that had to be considered.

In this paper we are going to present our solution on how to teach students Compiler with no previous microprocessor and more precisely assembly knowledge.

In the next sections our idea for organizing the Compilers classes as well as the rules for student evaluation are presented. Afterward, our approach for presenting code generation to our students is explained in more details. Next, the results taken from our four year experience in teaching Compilers are presented. At the end a conclusion is given.

II. Course curriculum

The topics of this course follows the book "Compiler Construction: A Practical Approach" [5] and its main objectives are students to get familiar with a compiler and also to learn how a compiler is build. Here the Inger language is defined and used as an example language for which the compiler is built.

'Compilers' weights 6 ECTS credits and is organized with 5 classes a week: 2 classes for lectures, 1 for auditorium exercises and 2 for laboratory exercises. The lectures continuously cover each part of a compiler construction. In the curriculum of the Compiler course all parts of a compiler are considered in details.

The language for which a compiler is made can be represented through syntax diagrams, Backus-Naur Form or Extended Backus-Naur form. These approaches for language representation are contained in the first lectures.

Following these lectures lexical analysis is introduced to students. The part of the compiler which perform lexical analysis consists of a lexer implemented as a finite automaton and a parser implemented as a push-down automaton. Beside checking if one program is lexically correctly written, a compiler could detect and report the type of error that is found in a program and even where the error is found. This is also included in the curriculum.

Next, the part of the compiler concerned with checking the semantics of the programed code is presented. Between many different kinds of semantic errors that can be found, most of them involve variables or symbol names. A symbol table is usually used as a tool in semantic analysis and is included in the course.

The last part of the lectures is about the code generation module of a compiler. This is actually what we are concerned about in this paper. The classes dedicated to this part of the compiler are given in two lectures. The dedicated time does not allow the professor to teach about this part of a compiler, and additionally to show the basics of an assembly language since our students usually do not have any background knowledge in microprocessors. Consequently, we used our approach presented in this paper to teach students about this part of a compiler.

While during the lectures we cover the topics and we use auditorium exercises for more practical examples, at the laboratory exercises students work on the practical lab assignments given. In the next subsection the student evaluation for this course is presented.

A. Students' grading

Students are graded by the midterm exam(20%), final exam (25%), homework(15%) and by the grade for the final project assignment (40%). Exams cover the theoretical knowledge in the Compiler construction. Homework is different in different years, and for 2 years we have included an original on-line collaborative activity named "Ontology" also developed at our insitution [6].

Here we present the work on the project which was constructing a compiler. The whole project consists of several separated tasks:

- **Task 1:** Make a syntax diagram for the language A
- **Task 2:** Program a lexical analyzer (lexer) for the programming language A
- **Task 3:** Program a parser for the programming language A
- **Task 4:** Make a complete syntax analyzer with error detection
- **Task 5:** Make a complete semantics analyzer with error detection
- **Task 6:** Generate code in language B from the program in language A
- **Task 7:** Test the compiler

Divided in teams with 3-5 students in each group, students should do the assigned tasks needed to do the final project. Their involvement in the project should be on weekly basis, by upgrading the compiler with the newly learned module introduced on the lectures. The laboratory exercises are consultation exercises in which students ask question about their project and advance to its construction on regular bases.

Working in teams allows some students to work more then others and be more involved in the project, while others can be not involved at all. This arises the problem of how to grade students. One solution was giving the students a chance to grade by them selves their activity in the project. After grading the project itself, the students should all get the appropriate part of the points based on their involvement. Another approach is the teacher to grade each student in the group from an oral presentation about his/hers involvement in the project. Both approaches were used in the Compiler course in different years.

Because different students have different possibilities, background knowledge and ambitions, several variations of the final project were given. The hardest project scored 100 points, while the easiest one 65 points. In this way the projects ware leveled to the student knowledge. Students were given a possibility to choose the project level they think that suits them. Afterward, teams were formed out of the survey results.

In the next section the project assignment is defined in more details.

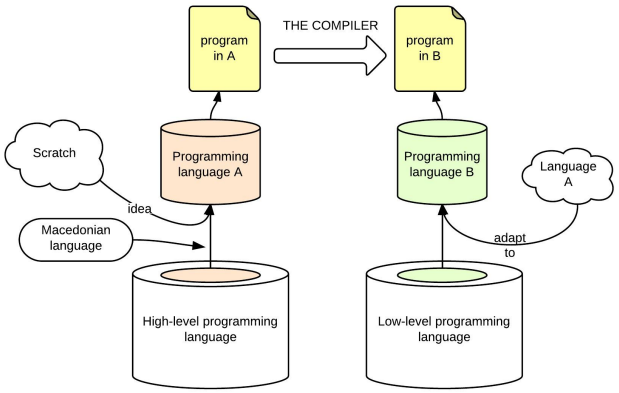

Fig. 1. A schematic view of languages A and B

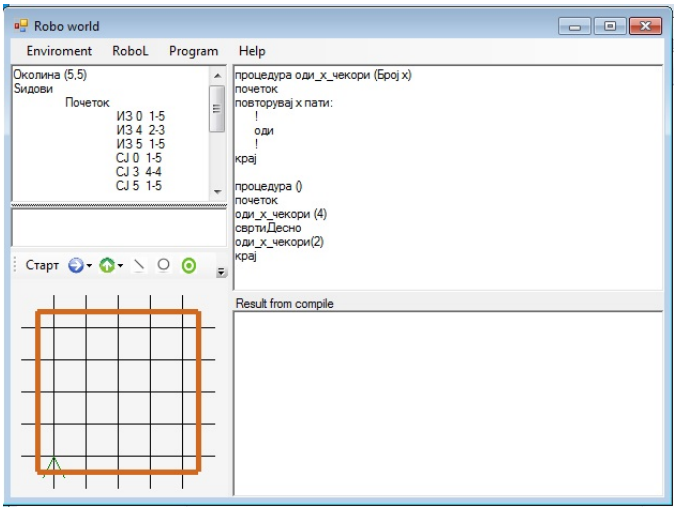

Fig. 2. A shell application for the compiler

B. Project Assignment

The project was stated as follows: Make a compiler for one given programming language A and translate it to another assembly-like programming language B.

The languages A an B are new languages that were introduced in our course. They are created just for this specific purpose. In all years the course was held, new (similar but different) languages A and B were introduced. On 1 a schematic view of these languages compared to existing programming languages is shown. As shown on the figure the programming language A is based on the procedural high-level programming languages like C, Basic or Pascal. A is not an object-oriented language. It includes the three most basic statements and other basic features. The key words in the language A are written in Macedonian language and so it differs form all other languages.

The inspiration for this language comes from turtle-based programming languages used for beginners in programming languages. Indeed, the elementary statements of the languages are actually commands for the movement of the specific turtle-object like a frog, robot, bird and so on. We have used all these objects in our course. The interesting content of the language and its statements made the project more interesting to students. As an example, a robot's program should move him in a specified environment and it must be careful not to hit the walls. Another example is a frog's program. This program should enable a frog to jump form one field to another considering water in the sense it should not step on it. Using these languages as introductory languages for young students that show interest in informatics, gives great results and we have included them in the strategy for education in informatics in our country [7].

As stated, these programs should be executed in a specific environment. A language for environment definition was used to define the environment. But, program execution is not in the scope of the course Compilers because here an interpreter of the language is needed.

The programming language B as explained on Fig. 1 is based on assembly, but has only the most basic statements needed for the translation to be possible. All hardware knowledge for the execution of a program written in this language is excluded.

In the rest of the paper we are going to explain in details only one of the project assignments (given in 2009). The language A defined was called RoboL (extension - rl) and was specialized for moving a robot in its environment. For the project assignment the students were given a shell application. It is shown on Fig. 2. This is just the interface of the compiler students should do. In this application a compiler for the language should be build in. The application is build in Microsoft Visual Studio. In the lower left corner a picture for the robot environment is given. Bold lines represent walls. On the right side a program written in RoboL is shown and on the left side a program for environment definition is given. The menu of this application should be implemented by students.

In the example project RoboL was translated into RIMAL (Robo Imaginary Meta Assembly Language). More about these languages will be explained in the next sections. The result from the compilation is the program translated in the RIMAL language (extension - rml) if the program is correct. But if the program is not correct, students should output messages for all errors found in the program code. These messages should be displayed in the lower right part of the application window.

III. The Languages for the Project

Next, the languages used for building a compiler are introduced.

A. The high-level language

RoboL poses the three simple, hierarchical program flow structures: sequence, selection, and repetition. There are 3 basic statements which are direct commands for the robot movement: go straight (one step), turn left or turn right.

```

```

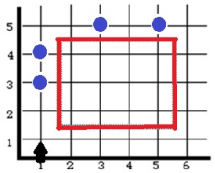

Fig. 3. An example program in RoboL and an environment in which it should be executed

Selection structure is realized trough the if-like statements. While-like repetition is not implemented, but a variant of do-while statements and for-statements is present in the language. There are five different variants of repetition (loop) statements.

In the language only integer and a kind of character types can be declared. The character variables are specific variables that can be considered as an enumeration. Indeed, these variables contain information about the direction of the robot position that can be South-S, North-N, West-W and East-E. As a result, arithmetic operators have no meaning with these character variables. Integer variables can be only positive. Arithmetic operators for addition, subtraction and multiplication can be used with integer variables and constant values. For logical expressions relational operators for comparison are used. These can be used as conditions in selection and repetition statements.

Other conditions used in these statements address the environment in which the robot is. The robot environment has walls (red lines) and marks (blue lines). In each moment a robot is in one point that is an intersection of one vertical and one horizontal line. Also the robot heads in one of the four directions (S,N,W,E). Considering this, other conditions implemented in the language are based on:

- **Wall**: If the robot is exactly in front of a wall the expression will be true
- **Mark**: If the robot is on a mark the expression will be true.
- **Some direction (S,N,W or E)**: If the robot is pointed in the stated direction the expression will be true

RoboL supports the concept for procedures. Functions and return statements are not supported.

The definition of the language was given to the students with a written tutorial. Example programs in this language were also available.

B. The low-level language

As stated in the Introduction, because our students in general have no knowledge in assembly as low-level language we made an artificial language RIMAL simulating a real assembly.

Robo Imaginary Meta Assembly Language (RIMAL) is a simulation of a simple assembly. The idea of this language is not to be used for program execution but to be used for educating students. The code written in this assembly-like language can not be executed by some hardware. This language has the most basic features of an assembly. Indeed, the language has similar instructions as the assembly language. But, some of the instructions are omitted from this language and some are added to it. The final product of student project beside giving error messages for the syntax and semantic errors, is the code generated in RIMAL. By making this code students learn and practice how code generation is implemented in a compiler.

As in assembly 8086, in RIMAL registers, variables and stack can be used for storing data. Because in the high-level language RoboL arrays are not implemented other memory are not used in RIMAL. 3 registers can be used:

- regN - for storing integer data
- regD - for storing character data
- regC - for constant values

As shown, all registers have a specific usage and should be used for the appropriate data. Note, that although logically there are registers in the language, there are no actual registers. Other important similarity to assembly language is the usage of labels to label code lines. In RIMAL also, any string different then the key words can be labels. After the label : (colon) should be written.

Instruction type	Instructions	Assembly
Move instructions	move	modified
Arithmetic instructions	inc add sub mul	✓
Function instructions	call, ret	✗
Comparator instructions	cmp	✓
Robot movement instructions	rl (go left) rr (go right) go (go)	✗
Jump instructions	je, jne jl, jle jm, jme	✓
Stack instructions	push, pop	modified

TABLE I
RIMAL INSTRUCTION SET

In Table I the instruction set of the newly defined language is represented. For each instruction type the instructions are given. Also, a comparison with the assembly language is roughly given. For example, move instructions which are used for coping data from one location to another is modified with respect to the mov instruction in assembly. Beside the instruction name, the operands can only be: variables and registers. Similarly, the stack instructions are modified so that the instruction 'push' pushes the value in the register regN on the stack.

Arithmetic, comparison and jump instructions are similar with the instructions in assembly language. There is a difference only in the operand values in these instructions.

```
odi_do_x_oznaki:
data x
mov regN,x
start:
go
cmp reC,$M
jne next
sub regN, 1
next:
cmp regN,0
jne
ret
main:
data k
data br
move k, 4
move br, 0
cmp reC,$M
jne next
move br, 1
next:
```

```
move regN,0
start:
go
cmp reC,$M
jne next
push
move regN, br
add regN, 1
move br, regN
pop
next:
cmp regN,k
jne
rr
call
odi_do_x_oznaki(br)
ret
```

Fig. 4. An example program translated in RIMAL

Call instructions are different then in assembly language. The call instruction has one operand which is the label where the function is written in the code. But in assembly the operand is the address where the first instruction in the function is written. When calling a function in assembly the IP (Instruction pointer) register is pushed on the stack and the address of the new instruction is put in the IP. But, here the knowledge for the instruction pointer and also the instruction stack is omitted. In in RIMAL the function definition ends with the key word ret. After the code in the function is executed the program continues after the function call. This approach allows does not allow recursion functions.

The RIMAL language is enriched with three robot movement instructions. Because in the RoboL language there are instructions for moving the robot straight ahead, left or right by one step, RIMAL also has some version of these instructions. These are the instructions go, left and right, accordingly.

As a conclusion RIMAL has a very similar syntax with assembly. The valuable feature of RIMAL is that students are not concerned with the semantic of its instructions and their execution. This help students to see this language just like another (non high-level) programming language. Computer hardware on which the low-level language should be executed is not known. This makes the problem of understanding the language easier, but also gives students a little sense of what an assembly language looks like.

In Fig. 4 an example code translated in RIMAL is given.

IV. Results from the lab project assignment in the Compiler course

With the laboratory project given, successful student project included more then 5000 lines of programming code for building a compiler. By doing the project students went through the whole process of making a compiler by which they practically learned what a compiler is and how does it work.

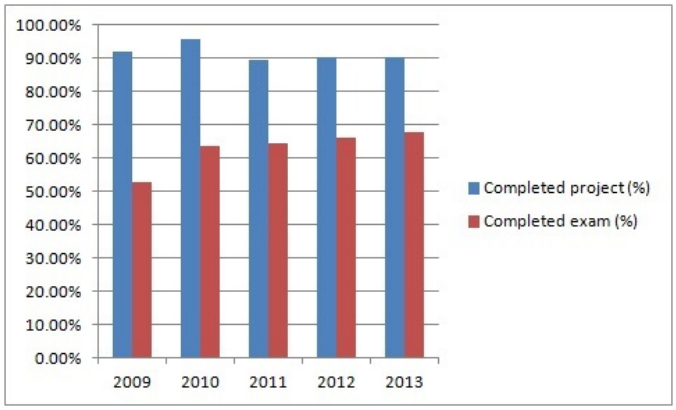

Fig. 5. The percentage of students with completed projects compared to the percentage of students with completed exam

Students worked in groups with 2-5 students in each group. In the laboratory exercises all team members could consult with their lab demonstrator or teacher about the project. In each exercise students were given a specific task towards creating the compiler which was the end objective in their project. As a result the compiler was built step-by-step on weekly bases. Each class students were given a chance to ask some questions about the task from the previous week. This approach gave students many opportunities to learn more about their project and to improve on their teamwork skills.

Also this approach yield great results in completion of the student projects. On Fig. 5 a graph for the percentage of students that completed the project is given. The results presented are since 2009 until today. Only around 10% of the students do not complete the project at the end every year. In 2010 only 4% of the students did not make a compiler enough for passing the exam. Even more in 2012 15 out of 17 given projects, which is more then 88%, were completed.

The percentage of completed projects is a promising result. There may be several reasons and some of them are given here.

First, working in groups is a challenging, but motivating task in which students make a great effort to do the assignments given. Groups may have different profiles of students and due to their difference they could not only get better results, but also learn from their teammates.

Another explanation is that students choose their project from more project variants with different difficulty levels. Because students are usually aware of their skills, knowledge and ambitions they choose a project with appropriate difficulty and in most cases manage to complete the project. As a result, suitable projects are available for each student. The most difficult project that can be chosen includes visualization module with which a program in RoboL is interpreted. This is the most interesting project for students, and each year more and more students are interested in taking the most difficult,

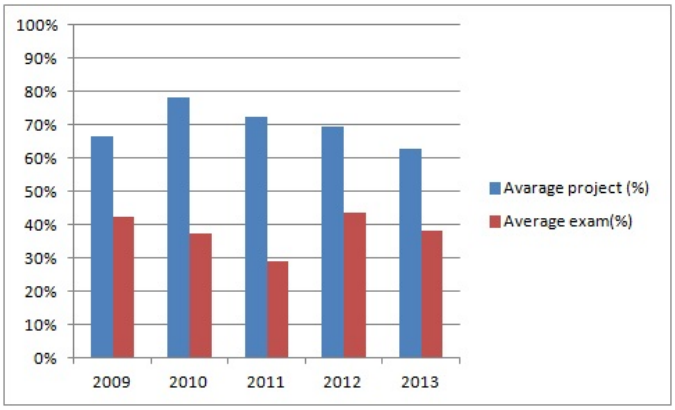

Fig. 6. Comparison of student project assignment and student exam percentage in 2009-2013

but most interesting project.

The last explanation for the high percentage of project completion is due to the organization of the laboratory exercise. Step-by-step tasks given to students enable students to complete most part of the projects during the classes. The help from demonstrators on the laboratory exercises also improves the project accomplishment result.

In Fig. 5 the percentage of students that completed their project is compared to the percentage of students that have completed or passed the exam. Because the project covers all the material from the lectures it is expected that the project would improve the percentage of students who completed the exam. Every year, more than 50%, and up to 70% of the students were able to pass the exam.

In all years from 2009 to 2013 the percentage of students that completed the project is higher then those who completed the exam. This is expected because the project assignment is much more attractive and interesting because of, among other previously stated features of the project, teamwork included.

The project in general helps students learn the course material and pass the exam. Indeed, through students activity in the project, students are stimulated to learn the theoretical part of the exam, even though it is hard and rather ”boring” for most students.

The final course grade depends on the project assignment grade as well as from the final exam. Fig. 6 shows that students got higher results on the project then on the exam. The exam validates student's theoretical knowledge for compilers, while the project checks the practical understandings of compilers and its implementation in some programming language. Students could choose from Java and C++ as programming languages for implementation.

The average project grade given in percentage in the last 2013 was something above 60%. Best results are noticed in 2010 where the average student score was around 80%. The average exam grade in 2010 was little below 40%.

The difference between the the project and exam grade (%) is notable decreasing from 2011 until today. In the future more close average grades for the project and exam are expected. Students should be motivated to work more on the project. One possibility is to assign roles for each student. Also, a group manager could be assigned. The manager should give an evaluation for the effort and activities of each student in his/hers group. The fact stated that working on the project helps students learn the theoretical material is our assurance for future improvement.

The last accomplishment of our approach presented here is that most part of the students managed to learn the RIMAL language without previous knowledge of microprocessors. Truly, completing a project means that students also did the code generator part of the compiler where RIMAL language was used for translation. Even though they did not have any knowledge in assembly, they could understand this language and use it in the project.

V. Conclusion

In this paper we discussed the organization of the course Compilers at our Faculty of Computer Science and Engineering. We presented our original method of teaching compiler production trough a practical project in the conditions where students does not necessary have prior knowledge of an assembly language and in the field of microprocessors.

The presented results from 5 years teaching the course confirm that this approach is efficient, and it can be used by others when similar conditions occur. This was the main intention of the authors when writing the paper. We plan to continue our work in the following years, making adjustments with every following generation of students.

Analysis of elective courses selection in post-Bologna programmes

I. Rožanc and B. Slivnik
Faculty of Computer and Information Science, University of Ljubljana, Tržaška 25, SI-1000 Ljubljana, Slovenia
{igor.rozanc, bostjan.slivnik}@fri.uni-lj.si

Abstract - One of the most important results of the Bologna reform at the Faculty of Computer and Information Science at the University of Ljubljana is a much larger number of elective courses. The elective courses of the academic study programme were grouped into modules while the professional study programme permits selection of individual elective courses under minor restrictions. Both approaches fulfilled the reform requirements. However, the academic study programme is more rigid and thus easier to carry out than the professional one but students prefer the flexibility of the latter. In this paper we analyze the actual data of elective course selection by students of both programs. First, we examine the link between different module selections to optimize the distribution of elective courses into modules. This examination is possible as a number of students, i.e., the most successful ones, were allowed to select courses regardless of modules. Second, we investigate whether some commonly selected groups of elective courses of the professional study programme could be identified in order to simplify the programme and its implementation. The results show some important improvements could be introduced.

I. INTRODUCTION

In recent years the Slovenian higher education adopted the principles of the Bologna declaration [1]. The main goal of this reform is to define clear requirements for specific academic study levels. These requirements specify a standard three level classification of the study programmes. With implementation of the Bologna principles, the comparison between the programs is clearer, and the recognition of the academic degrees between the European states became much simpler [2, 3, 4, 5]. The reform is aimed to enhance migration of educated young people providing better communication and the basis for better economic outcome in EU [6].

The declaration is specified as a compromise using the "least common divisor" logic, thus uniting sometimes quite diverse solutions that are currently implemented in higher education of different European countries. Consequently, implementation of the declaration was not equally difficult to implement everywhere. In some states the reform implementation caused radical changes of the framework and the length of study, or introduction of previously not implemented principles (i.e., elective courses). This caused diverse reactions ranging from approval in states where similar principles were already in power to substantial opposition in other states.

As the Bologna declaration was a solution of an important issue, most European countries accepted it with the idea that "any solution is better than no solution". Our country was among them as the Slovenian Ministry of Higher Education decided all undergraduate and graduate educational programs to meet Bologna criteria by 2010 and to gradually implement them afterwards.

Faculty of Computer and Information Science at University of Ljubljana started to offer Bologna programs in the academic year 2009/10. The adaptation of undergraduate programs was gradual. In 2009/10 only the first year of those programs was taught in the new way, and in 2010/11 the second year students experienced the changes. In 2011/12 all three 1st level Bologna programs were defined, and by 2013/14 the second level study programmes were introduced as well.

The required level of changes was substantial as our previous academic study followed somehow different (German) study model, while the Bologna declaration enforces more English-like study model. Practically, the Bologna reform influences teaching in two ways. The first part of Bologna changes is about the program structure: the length of study programmes, a program framework consisting of the obligatory and elective (free choice) courses, the uniform course definition, and the conditions for promotion based on course credits (ECTS), etc. The second part advises different teaching style. The main goal of this part is enhanced efficiency of practical work with students i.e., by using new tools [7] or motivating approaches emerged from practice [8, 9, 10]. Those should be evaluated during the course and not only at the end of it.

After the Bologna reform implementation several interesting issues emerge [6]. Several papers address this experience in different European countries and institutions [2, 3, 4, 5, 11], some pointing out specific evaluation methods for the Bologna process [12, 13]. In 2011 we conducted a research on the effect of the Bologna reform on specific programming course at our faculty as well [14]. With more experience (and more data) a more general question of optimal introduction of elective courses is addressed in this paper. Before the Bologna the electiveness of courses was limited and consequently the pre-Bologna study programmes were without elective courses. Still, two study programmes had three variations of curriculum students could choose between. The new programmes introduce electiveness in two ways: moderately through definition of modules, and freely by enabling large number of individual course selection. The advantages and problems of both approaches are pointed out, and some interesting propositions resented.

The issue was studied on three the 1st level study programmes: the academic program of Computer Science and Informatics (CSI), the academic program Computer Science and Mathematics (CSM), and professional programme Computer Science and Informatics (CSI). Their direct pre-Bologna predecessors were the academic undergraduate program of Computer Science and Informatics, the academic undergraduate program Computer Science and Mathematics, and professional undergraduate programme Computer Science and Informatics. All programmes follow the IEEE Curriculum [15] which defines a series of courses that Computer Science students should attend during their studies.

In the second section all 1st level study programmes taught at our faculty are presented, pointing out the electiveness issues. The third section introduces the analysis background, namely the data and methodology used to study the issues. The fourth section presents the four analysis, and discuss the results obtained. Finally, the last section concludes the paper.

II. THE STUDY PROGRAMMES DESCRIPTION

As mentioned above, the three 1st level study programmes offered by the Faculty of Computer and Information Science were taken into consideration; the rest were left aside. There are three main reasons for this. First, the vast majority of all students are enrolled in one of these three programmes. Second, sufficient amount of data to make analysis viable is available for these three programmes only. Third, these are the three study programmes that the students enrolled in the second level study programmes are recruited from.

A. The two academic study programmes

Prior to the Bologna reform, the principal 4-year academic study programme of Computer and Information Science was more or less rigid. After completed the second year of the programme, students were required to choose one of the three subjects (hardware, software, or informatics). Each subject defined a set of courses the student enrolled in, but the rules of the study programme didn't permit choosing courses of two different subject. Although a student could apply for a special permission to do so, such cases were extremely rare since the student had to pass all curses of the chosen subject regardless of an extra course that he applied for.

The structure of the new 3-year academic study program of Computer and Information Science [16] is more flexible. As it is shown in Fig. 1, a student must pass 20 obligatory courses, 9 elective courses and prepare the undergraduate thesis (considered as another course).

However, out of 9 elective courses, a student can select 1 professional and 2 general courses freely; the remaining 6 elective courses are determined by choosing 2 out of 8 modules each consisting of 3 courses. To further enhance the programme's flexibility, students with average grade higher that 8 out of 10 (5 is negative) need not choose two modules but are permitted to freely choose the remaining 6 elective courses from the pool of courses modules are made of.

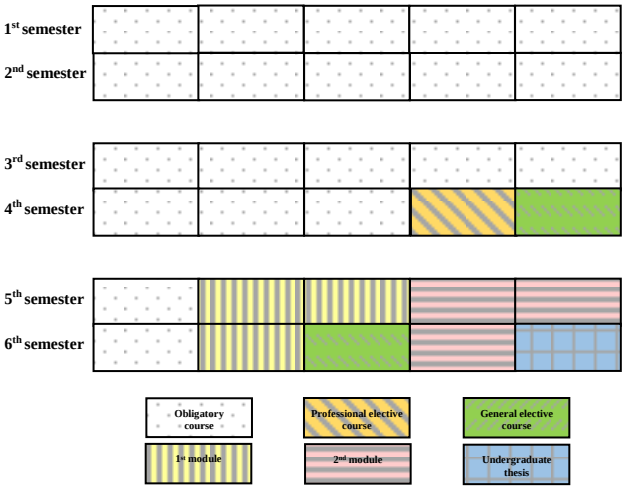

Figure 1. The structure of the 1st level academic study program of Computer and Information Science.

More than two thirds, i.e., 20 out 29 courses, of this study programme are still made of obligatory courses. There are restrictions regarding the selection of elective courses, more of them for average and less for better students. Based on the pool of general and professional elective courses offered in the academic year 2013/14, there are 2604 different alternatives available to average students and more than 12.5 million different alternatives available to their more successful colleagues.

The 3-year academic study programme Computer Science and Mathematics is less flexible. There are no elective courses in the first two years. In the third year, one module of the Computer and Information Science programme must be chosen and 1 professional elective course out of 9 mathematical courses. Additionally, a student must gain further 10 ECTS by enrolling in courses of any academic study offered by the University of Ljubljana. Because of the latter, the total number of reasonable alternatives is hard to estimate since, for instance, taking a course Obstetrics and gynecology might seem attractive to (male) students but can hardly be permitted in practice.

B. The professional study programme

Prior to the Bologna reform, the 3-year professional study programme of Computer and Information Science was more or less similar to and thus as rigid as its academic counterpart except that it was one year shorter. However, the remodeling of this programme was more radical - far more flexible system with more elective courses were introduced.

The structure of the new 3-year professional study programme [17] is shown in Fig. 2. Each of the six concentric rings in Fig. 2 represents one semester where the innermost ring (actually a circle) represents the first semester and the outermost one represents the last semester. The white circles represent 13 obligatory curses, mostly in the first two semesters but including industrial practice and undergraduate thesis in the sixth semester as well. All other circles represent 34 elective

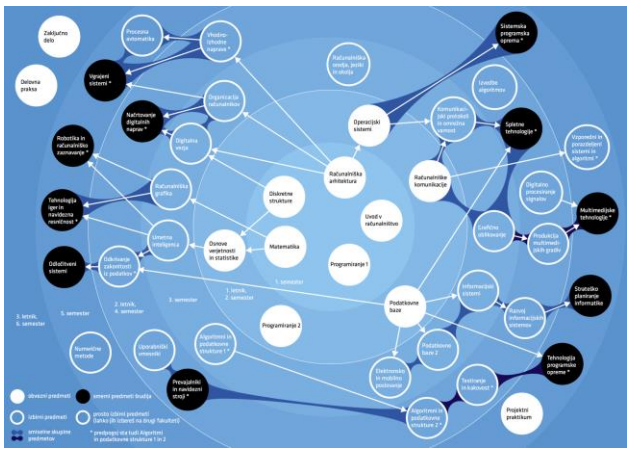

Figure 2. The structure of the 3-year professional study programme of Computer and Information Science [courtesy of the Faculty of Computer and Information Science, University of Ljubljana]

courses. 11 elective courses represented by black circles are target courses - each student must select at least two target courses. Arrows in the Fig. 2 indicates preconditions: an arrow leading from one course to another implies that the course the arrow starts at must be selected in order to select the course the arrow points to.

If the list of courses picked up by an individual student of the academic study programme includes more than two thirds of obligatory courses, almost two thirds of all courses, i.e., 17 out of 27, taken by a student of the professional study programme are elective courses. Taking preconditions into account, there are more than 43 million alternatives for every student.

The dark glue between certain courses in Fig. 2 indicates recommended groups of courses a student may select together. Note, however, that these groups are recommended but in no way enforced - together with preconditions and target courses (both specified by the study programme) groups are provided merely to help students find out reasonable assortments of courses.

III. ANALYSIS BACKGROUND

Five years after the implementation of the Bologna reform compliant study programmes it is appropriate time to check the suitability and quality of both solutions. The complete analysis is definitely complex as several perspectives should be taken into consideration. Most importantly, the level of student knowledge at the end of the study should be objectively assessed as well as the overall cost of such study programme performing, the invested staff effort and the satisfaction of students and teachers to name just a few ones. Thus several diverse metrics involving a large quantity of data should be taken in to consideration [18, 19].

In real world it is impossible to get a complete set of diverse data to conduct such comprehensive analysis, and the usual approach is to use what you've got. In other words, the analysis is driven by the information available to the researchers. In our case adequate information on actual student knowledge after the graduation is not available. Similarly, the objective measurement of the invested staff effort or student satisfaction is not obtainable. But we are lucky enough to have the access to the data of the old web student information system e-Študent.

The web student information system e-Študent provided electronic support for student selection and enrolment, the student course selection management, detailed management of examination records and grades, the alumni records management, and several student data analysis executions [20, 21]. For more than a decade it was used at several faculties (including the Faculty of Computer and Information Science) of the University of Ljubljana. In 2008 the University of Ljubljana decided to replace e-Študent due to the introduction of the Bologna reform. Unfortunately, the first solution did not meet the expectations, and a considerable effort was invested to adequately upgrade and maintain the old system in last few years. Finally the valuable domain knowledge was extracted from it and implemented into to his successor [22, 23]. Finally, in academic year 2013/14 the new information system was deemed adequate and thus replaced old e-Študent.

After the implementation all data were copied from the old system to the new system, but they were not removed from it. The old system still contains the original of all data for the era before academic year 2013/14 and those were used to perform the analysis. The quality of this data could be a problem as the upgrades implemented in the last stage (to meet the new Bologna requirements) changed the structure of recorded data as well. Nevertheless, due to careful maintenance the system preserved the consistent data structure and contents.

Three interrelated groups of data from the old e-Študent system were used for the analysis:

- **the enrolment data** describing the student enrollment into the specific year of the study programme in selected academic year,
- **the curriculum data** defining all (obligatory and elective) courses comprising the year of certain study programme, which is performed in selected academic year, and
- **the elective courses data** specifying the elective course and students, who selected them from the curriculum of the study programme a student is enrolled into.

The Bologna programmes were first introduced in 2009. In this year the 1st year of both academic studies was introduced, but no data were suitable for analysis as all courses were obligatory. On the other hand all three years of professional study were introduced at once and last two years had a lot of elective courses in curriculum. Still, only the elective courses for the 2nd year enrollment were taken in consideration, because for the 3rd year special rules were applied. In the following academic years enrollments with selection of elective courses became frequent. Till academic year 2013/14 586 such enrollments in both academic study programmes were recorded, and 611 enrollments in the professional programme, respectively.

To prepare a consistent base for further research, the data had to be cleansed. The majority of possible elective

courses in the curriculum are defined in the same study programme, but the student is allowed to select a few elective courses from a different programme or even from a different faculty. Those selections are recorded in the data as well, but they can be considered obsolete and thus removed. In practice the data related to a predefined set of courses, i.e., 27 courses in case of academic study programmes, and 37 courses in case of the professional programme, were retrieved only.

Most of the elective courses data should be consistent with the curriculum rules, like the summa of ECTS points of selected elective courses (per enrollment in a certain year and study programme) should be approximately the same. Due to the introduction of the new study, a number of students were considered special cases and the rules were not strictly enforced. Additionally, in some cases diverse rules were applied to diverse groups of students, i.e., in case of enrollment in academic study programmes students with average mark above 8.0 were allowed to individually select courses, while the others had to select entire modules. The data in such cases may seem strange, but it was still taken into consideration if it was related with the predefined set of courses.

IV. ANALYSIS AND DISCUSSION

We would like to determine the hidden rules that can be resolved by the analysis of preferences in selection of the elective courses by students. More precisely, three different curriculum models, i.e., the rigid model without elective courses as in the pre-Bologna programmes, a moderate model with modules as in the Bologna academic course, and the free model with a large number of elective courses like in the professional programme, could be compared by different aspects: the ease of implementation and student satisfaction.

Even without objective analysis we might guess the rigid model is simpler and its performance demands less organizational effort than the model with a large number of individual elective courses. On the other hand the last model is more adaptive and thus it better suits the student's needs. But is it really so? Do the students really select so many different combinations of elective courses, or could the study implementation become simpler and thus perhaps even cheaper?

The characteristics of data obtained allow some analyses in this direction. In the following subsections we present the results of several analyses we performed. Additionally, a short discussion is provided to point out the important conclusions.

A. The number of elective courses

The analysis was performed to determine the typical number of elective courses per student's enrollment. The results for academic (AP) and professional (PP) study programmes are presented in Table I.

The analysis shows that the usual number of elective course at academic programmes is 1 or 2 (in case of enrollment in the 2nd year), 3 or 4 (in case of enrollment in the 3rd year CSM) or 6 or 7 (in case of enrollment in the 3rd year CSI). For professional programme, the students enrolled in the 2nd year select 4 or 5 elective courses, while the students enrolled in the 3rd year select 9 or 10 elective courses. The summa of numbers in each row equals the total number of enrolled student (586 in case of academic and 611 in case of professional programme).

TABLE I. THE NUMBER OF STUDENT ENROLLMENTS WITH SPECIFIC NUMBER OF ELECTIVE COURSES

	1	**2**	**3**	**4**	**5**	**6**	**7**	**8**	**9**	**10**	**11**	**12**	**13**	**14**	**15**
A	344	72	12	16	9	31	101	1							
P			1	33	159	7		8	101	280	14		5	1	2

B. The favorite courses

This analysis reveals most frequently selected courses. Additionally, a rule for finding out courses popular enough is formulated. The number of courses selected in at least 50%, 30% and 10% as many times as the course selected most frequently, i.e., the one with the maximum number of selections, is shown in Table II.

TABLE II. THE COURSES WITH HIGHEST NUMBER OF SELECTIONS

	Max. number enrollments per course	**%**	**Number of courses with more than 50% max**	**Number of courses with more than 30% max**	**Number of courses with more than 10% max**
AP	198	33.8	6 out of 27	10 out of 27	18 out of 27
PP	410	67.1	11 out of 37	18 out of 37	28 out of 37

The analysis shows the student's favorite courses and the number of courses of reasonable popularity using diverse assessments. In the optimal situation, all courses would be approximately equally popular, thus they would be between the courses with more than 50% (or at least 30%) of the maximal number. This is not the case and the number of popular courses is in the best case a half of all courses offered (in case of the professional programme) or a third (in case of the academic programme).

Quite large (between a quarter and a third) is the number of courses with less than 10% of selections in comparision with the maximal number. These courses might be considered considered obsolete. The number of such courses is quite large (between a quarter and a third). Surprisingly, a larger number of obsolete courses was found at academic programmes, even though the requested limit, i.e., the number of enrollments, was lower than in case of the professional programme.

C. The favorite sequences of selected courses

The previous analysis was upgraded to study the sequences of selected courses. First, the courses in each selection were ordered by the course ID to avoid repetition of results. Next, we analyzed the data to find out all different sequences of certain length. Finally, the sequences were checked to determine the most popular ones. The results in Table III were measured for the length of sequences up to the largest number of selected courses per enrollment.

TABLE III. THE SEQUENCES OF COURSES WITH HIGHEST NUMBER OF SELECTIONS

Number of courses in sequence	Max. number of one such sequence (academic prog.)	%	Max. number of one such sequence (professional prog.)	%
2	110	18.8	332	54.3
3	106	18.1	275	45
4	58	9.9	158	25.9
5	31	5.3	105	17.2
6	29	4.9	69	11.3
7	16	2.7	39	6.4
8	1	0.2	27	4.4
9			12	2
10			4	0.6
11			2	0.3
12			2	0.3
13			2	0.3
14			1	0.2
15			1	0.2

In the academic programmes there are many sequences of three courses with similar frequency as those which constitute the module. Still, none of such sequences is too popular. On the other hand the professional programme preserves some popular sequences up to the six courses without modules. Thus, some popular combinations could be easily determined.

D. The number of different sequences

In the next analysis we checked the number of different ordered selected course sequences of certain length and compared that number with the theoretically maximal number of sequences of the same length (calculated as a simple number of combinations disregarding the preconditions). Additionally, the number of important sequences (with the number of enrollments higher than 10% of maximum number) were counted as well. The results are presented in Tables IVa and IVb.

The results per both types of study programmes prove the number of actual different course sequences to be radically lower than it could be. There are obvious reasons for that: the academic programmes have modules, and some other limitations, i.e., professional elective course, while in the professional program these are preconditions in case of some courses. Additionally, the number of enrollments is too low to yield so many sequences.

TABLE IVA. THE NUMBER OF DIFFERENT SEQUENCES OF SELECTED COURSES FOR ACADEMIC PROGRAMME

Number of courses in sequence	Max. possible number of different sequences	Actual number of different sequences	Number of different sequences with number of courses more than 10% max
1	27	27	18
2	702	238	72
3	17550	758	103
4	421200	1176	162
5	9687600	951	137
6	213127200	389	67
7	4475671200	66	21
8	89513424000	1	1

TABLE IVB. THE NUMBER OF DIFFERENT SEQUENCES OF SELECTED COURSES FOR PROFESSIONAL PROGRAMME

Number of courses in sequence	Max. possible number of different sequences	Actual number of different sequences	Number of different sequences with number of courses more than 10% max
1	37	37	28
2	1332	623	174
3	46620	4100	546
4	1585080	13655	1495
5	52307640	30415	2175
6	1673844480	44660	2470
7	$5.18 * 10^{10}$	44030	2552
8	$1.56 * 10^{12}$	31314	1213
9	$4.51 * 10^{13}$	17712	1251
10	$1.26 * 10^{15}$	8525	8525
11	$3.41 * 10^{16}$	3419	3419
12	$8.87 * 10^{17}$	1053	1053
13	$2.22 * 10^{19}$	228	228
14	$5.32 * 10^{20}$	31	31
15	$1.22 * 10^{22}$	2	2

Still, these are the complete data and if carefully used these data point out important rules. By using information of the first analysis (A) only certain lengths of sequences are relevant as we have enough enrollments with that number of selected courses. If we consider the important sequences only (the 10% rule), the number of different sequences becomes very small in cases of all programmes. It is smaller in case of academic programme, but the numbers for professional programme are close to that value. Thus, we can conclude so much electiveness in latter case does not yield results, and a more rigid system could do the job too.

V. CONCLUSION

The study presented in this paper provides some empirical results indicating the popularity of courses within the context of Bologna study programmes with different degrees of flexibility regarding the elective courses. Furthermore, it includes some preliminary analysis and opinions.

The results of the analyses confirmed the expected differences between the academic and professional programmes. The rigidness of the first is shown in smaller number of different sequences experienced and more uniformly distributed selections between them. The professional programme yields a larger number of different sequences and larger discrepancy between popular and non-popular courses. Still, data proves only a small part of the flexibility provided by the professional programme is used, and a more rigid solution could work as well.

In both cases the results reveal unpopular courses. Using a careful analysis of past elective courses selections different modules could be proposed in case of the modified academic programmes, and some coursees could perhaps be removed from the professional programme.

However, one must not confuse the popularity of a course with its significance within the syllabus. The core courses are quite often less popular but should not be removed from the study programme at any cost, and this study should not be used as a justification for that. Even though it has not been explicitly mentioned so far, the authors are aware that the popularity of a course might be significantly influenced by the lecturer's popularity. At present, unfortunately, the lecturer's popularity cannot be taken into consideration due to the Law on Protection of Personal Data.

Abstract - One of the major challenges in the implementation of e-learning systems is motivating students to use it. E-learning systems are mostly unadapted to mobile platforms because they do not use responsive web design and progressive enhancement based on browser, device or feature detection. This paper presents the evolutionary cycle, current status and potential development of new platforms for e/m-learning in higher education. Educational computer games that serve as a motivational element in e/m-learning are presented, as well as the data structures that can complement the existing models of e/m-learning. The University of Rijeka uses MudRi e-learning system, which is based on Moodle open source software. This system collects data on the activity of participants in the educational process, which is suitable for data mining. A preliminary research on the correlation between the activity in forum discussions and the course pass or fail grade is carried out. The possibility of using data mining based on the data structure of the Moodle system and the models of e/m-learning and learning through play is described, aiming at finding optimal ways of learning and optimal learning results. Finally, a model of integrated system user interaction on which our future research will be based is presented.

I. INTRODUCTION

Technologies available through new generation mobile devices, such as smartphones and tablets, are increasingly used as a primary platform for Internet access. These devices are suitable for learning on the go, and their capabilities often surpass desktops and laptops, primarily because of the sensors such as accelerometers, gyroscopes, magnetometers, and GPS which desktops and laptops lack. Using them for learning can be fun and available wherever there is mobile signal.

Unfortunately, to the best of our knowledge, no statistics exists on the number of students in Croatia who use these devices. Therefore, in our future work we plan to investigate this issue thoroughly.

Mobile learning (m-learning) systems can directly and indirectly generate and store large amounts of data. Direct data refer to the learning materials such as video lectures, presentations, forum posts, etc. Indirect data are user activity logs, as well as user locations when mobile phones are used for accessing the system.

Motivational element is an important part present in all forms of the educational process. The main motivation of students in the educational process of higher education is based on collecting the required number of points with regard to the course requirements, regardless of the content and the form. Since learning with reduced motivation results in lower exam achievements, reaching the highest level of creative knowledge in students is not possible without high motivation.

The use of serious and educational computer games can increase the level of interactivity in e/m-learning systems. When students master educational content via computer game elements, the level of their motivation is raised because learning becomes fun. Learning through computer games is an upgrade of e-learning. Therefore, the same advantages and disadvantages presented in the subsequent section relate to them, but with the positive effect on motivation, and negative effect on the time needed to create the system.

Data mining techniques are used to analyse data obtained through these systems. By performing data mining in e-learning systems, new methods for specific types of information related to education are developed [1]. In addition to the data contained in the user profile and system check-in, actions taken by the student based on the available content can also be monitored.

II. E-LEARNING SYSTEMS

There is a number of e-learning definitions. E-learning is often seen as an upgrade of distance learning [2] and computer-assisted learning. All of these categories are characterized by the lack of face to face interaction between the student and the teacher and by some kind of technology (usually a computer) that is used for communication as well as for accessing educational content [3]. Advantages and disadvantages of e-learning are described in Table I [4]. From our point of view, e-learning systems can be described as:

- *classic* – fixed (desktops) or portable (laptops, which are portable, but not mobile in the sense that in general they cannot be used while walking or standing)
- *mobile* – can be used while moving.

We strongly believe that e/m-learning on mobile devices can provide equivalent or even better content experience compared to conventional devices, i.e. desktops and laptops, ever since 2008 onwards, or more precisely, since the advent of smartphones and tablets.

TABLE I. ADVANTAGES AND DISADVANTAGES OF E-LEARNING SYSTEMS

Student		**Teacher**		**Educational institution**	
Advantages	***Disadvantages***	***Advantages***	***Disadvantages***	***Advantages***	***Disadvantages***
Interactivity	Alienation	Automatic system adjustment to the student on the basis of prior knowledge	Less personality and possibilities for intervention	Unlimited number of students	Not all students and teachers have IT skills
Availability	Need for self-organization	Availability	Less activities involving education and more involving moderation	Availability	Dependence on IT
Independence from group	Poor motivation	Besides IT resources, other material resources are less necessary	Communication with the student is primarily written	Lower cost in the long run	Poor influence on usage and motivation
Self-assessment and progress tracking	Rare physical contact with teacher	Students' feedback	Rare physical contact with teacher	Quick course adjustment	Long-term development

A. Classic systems for e-learning

Classic systems are adapted for use on devices with large screens and high resolution. They are most commonly supported in web environments (an Internet browser is sufficient for use) of the following operating systems: Windows, Linux and Mac OS. The keyboard and the mouse, and lately the touchscreen, are used as primary input units for interaction with these systems.

B. Systems for mobile learning

With the invention of PDAs (personal computer assistants) and mobile phones with small screen resolution, m-learning comes into existence and makes it possible to use the e-learning system anytime and anywhere.

In the past six years m-learning has become linked to smartphones. A smartphone is a mobile phone with a mobile operating system that provides standardized interface and platform for application development. It has a built-in camera, a web browser, location services support, and the ability to play multimedia. The most common mobile operating systems are Android and iOS, followed by Windows Phone, Symbian, BlackBerry OS, Bada and others. The touchscreen is used as a primary input unit for interaction with the smartphone system. A tablet uses a mobile operating system and is basically a smartphone with a giant screen; the possibility of making telephone calls is set aside in favour of the facilitated interaction with the device.

With regard to the education system, m-learning is more represented in higher education because most of the students have their own mobile devices. Up to this point of time, courses have not yet been developed in accordance with the capabilities of technology. Most of the applications of m-learning available at universities include news, and calendars with lecture schedules, instead of the content to be learned [5].

Although using m-learning on devices that support new technologies is conducive to students in comparison to the conventional e-learning, exam results might be weaker [6]. The reason for this is usage on the move or in situations where the environment can adversely affect concentration. Therefore, it is necessary to consider additional elements, such as learning through computer games, in order to gain more attention and put more focus on the content. Furthermore, the fact that all new mobile operating systems support multi-touch (up to 10 fingers simultaneously) and identifying the orientation of the screen needs to be taken into account. Hence, it is necessary to use new methods and technologies in developing systems for mobile e-learning.

To achieve greater unification in developing e-learning systems, the technology such as HTML5 ecosystem can be used, which tends to reduce the problem of fragmentation among and within mobile and classic devices.

III. COMPUTER GAME-BASED LEARNING

Computer games are interactive software applications that have fun as the basic objective while users engage in them. By using multimedia, networking and other technologies, they lead users to solve problems and achieve goals in a virtual environment [7]. Unlike computer games, whose primary purpose is fun, learning through computer games should include the following:

- motivational elements but not necessarily fun,
- active participation in problem solving,
- providing feedback,
- adjustment of the level of knowledge,
- clarity in the presentation of the objectives and learning content,
- presentation of content that can be replicated in the virtual world, while drawing parallels with the real world,
- scalability to a large number of simultaneous users.

Computer games with the above listed elements are called educational games. In addition to educational, there are also serious computer games with fun as a motivational element. These are primarily regular games with educational elements, e.g. simulations. The two areas are often intertwined in order to achieve good balance of educational content load and fun.

According to Prensky [8], the new generation of students born in the last quarter of the 20th century is developing different cognitive styles in comparison to the previous generation (Table II).

TABLE II. NEW PREVAILING COGNITIVE STYLES IN STUDENT LEARNING: GENERATIONS WHICH GREW UP WITH COMPUTER GAMES

New cognitive styles	Old cognitive styles
Twitch speed	Conventional speed
Parallel processing	Linear processing
Graphics first	Text first
Random access	Step-by-step access
Connected	Standalone
Active	Passive
Play situations	Work situations
Payoff	Patience
Fantasy	Reality
Technology-as-friend	Technology-as-foe

Related studies point to the benefits of designing educational content through computer games, because students have shown several times higher interest, i.e. the time spent using the content has been recorded as follows: 7-8 times higher compared to the textual content, and 3-4 times higher compared to the audio/visual content [9]. The disadvantage is reflected in the demanding and time-consuming preparation.

According to students, motivational elements to use computer games in higher education sorted by relevance are the following [10]:

- challenge – appropriate level of difficulty, achievement of multiple objectives for the coming victory, constant feedback, unpredictability,
- curiosity – optimal information dosing,
- cooperation – helping each other to achieve common goals,
- competition – comparison of results with other users,
- control – ability of choice and perception of consequences,
- recognition – sense of satisfaction with the achievements,
- imagination – identification with the role.

Learning based on computer games can have a positive impact on learning [11]. The content is interesting not only because students have grown up with computer games [12], but also because it is an alternative way of learning which can be more efficient than the classical one [13, 14].

Educational computer games have an action-based scenario. The most common question is how to adjust the game 'plot' when the virtual world needs to suit the real one.

In certain scenarios students can work together to solve problems, while in others they can play against the computer or compete with each other through competitive games in order to achieve better results [15].

Computer games can teach computer science students to develop and apply algorithms for solving problems, and to simulate, evaluate and detect logical errors [16].

Previously mentioned studies on using computer games for learning, although of a newer date, do not take into account the variety of mobile platforms, and are therefore restricted to a specific range of compatible devices. This means that the problem presented at the end of the previous chapter manifests itself here as well, and it can be largely solved in a similar manner, i.e. by the development of HTML5 compatible games run in an Internet browser.

IV. SYSTEMS FOR COMPUTER GAME E/M-LEARNING AND DATA MINING

Data mining forms the main component and an integral part of the process of knowledge discovery in large amounts of data [17]. Knowledge discovery in data comprises the following tasks: data cleansing (deviation and inconsistency detection), integration (in cases where data from multiple sources can be combined), data selection (only data relevant for the analysis), data transformation (consolidation in the appropriate form, and related operations), data mining (detection of patterns in the data), pattern evaluation (determination of patterns that represent the desired result, i.e. the knowledge that wants to be revealed), and knowledge presentation (using visualization and representation techniques).

E/m-learning and computer game learning are based on the interaction between the student and the application, and thus generate a variety of data suitable for data mining. Although e-learning systems hold large amounts of data, they are primarily designed to support learning rather than the analysis of the stored data [18]. Moodle System (Modular Object Oriented Development Learning Environment), on which MudRi system of the University of Rijeka is based, is one of the most used open source systems for e-learning. Moodle version 2.5 includes over 200 tables in its database structure [19]. These tables store configuration settings, user profiles, courses, access and activity data, etc. Forums rely on eight tables. In Moodle, user authentication is performed by password. The problem with the data from e-learning systems is their interdependence which violates the assumption that majority of machine learning algorithms are based on. For example, forum answers can build on previous ones. Previous studies on data mining in e-learning systems [20] include the following techniques:

- regression – predicting the time students will spend logged onto the system, or predicting to what extent students will be satisfied with the educational institution,
- grouping – establishing models of students who work in similar conditions and recommending activities the student has not yet used which would help him or her in the acquisition of knowledge depending on the predisposition,

- classification – predicting students' final grades, according to their activity in the system,
- association rules – recommending elective courses.

By taking into account the data produced by modern m-learning systems, the database can also record geolocation to find out how often the system is used with regard to the location. Furthermore, if geolocation is recorded periodically, at short intervals, it can be verified whether the system is actually used on the go. Such systems may include all of the data structures from e-learning systems. By using the available APIs, social networks such as Facebook and Twitter can be integrated into the system. Therefore, current conventional communication through forum discussions can be partially or completely replaced. Data mining of texts can be used for analysing student activity on social networks and its effect on the results. Interaction model of the system for computer game e/m-learning and data mining is presented in Fig. 1.

It is evident that the new m-learning systems tailored for smartphones and tablets are related to the classical e-learning systems in a way that e-learning has become a subset of m-learning, while with the old mobile devices and associated systems this relation is reversed (Fig. 2). Accessing e-learning systems via mobile devices makes it possible to identify and track how users access content through certain platforms, and therefore makes it possible to offer appropriate design (a single column or two columns instead of multiple columns, etc.) or adapt to the screen resolution.

In educational computer games places where most mistakes are made can be annotated by following the paths of information and interaction with the interface [21]. The start time, exit time before the end of the game (the student has not passed the whole content) and end time (the student has passed the whole content) can be recorded. Various data can be studied: how many times has the game been played, has the student who passed the whole game come back to it again, etc.

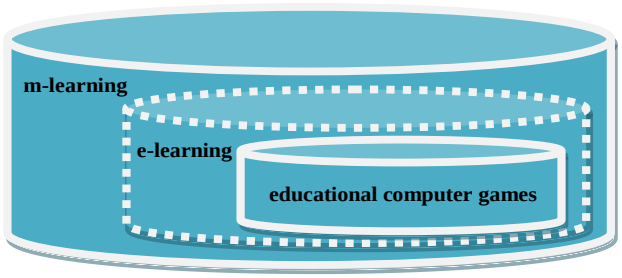

Figure 2. Display of data systems for learning with computer games compared to systems for e/m-learning

Students can be distracted in using the system when accessing it with mobile devices which have the incoming call feature (tablets do not usually fall into this category), SMS, MMS, e-mail, and other messages.

Due to its complexity, data mining may be performed by system administrators or by teachers who create e-courses [22]. The results may help teachers (to find ways to improve the level of acquired knowledge of their students, and to improve the development of e-courses), students (if the system recognizes their level of knowledge and their behaviour, more time-efficient learning can be offered or learning can be supplemented with additional content sources and activities), and administrators (to achieve optimal server load and network resources parameters).

Knowledge discovery in different data systems that form the basis of m-learning can be particularly challenging and complex in initial preparatory activities. The reason for this is the diversity of data which is mostly unstructured (they require special processing methods and techniques, including natural language processing which can be particularly challenging in cases of microblogging service where the number of characters is limited and messages frequently use combinations of abbreviations and sign language).

A further problem lies in various purpose services (e.g. SMS, MMS, geolocation) which are adapted to aggregate data and integrate it into a single unit.

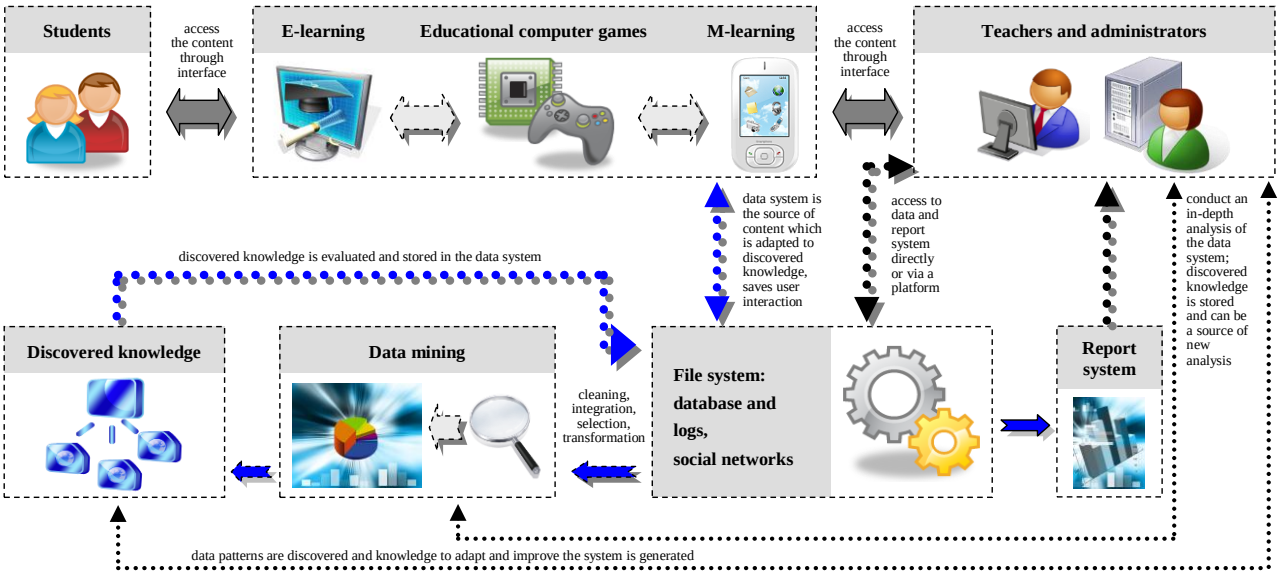

Figure 1. Representation of the user interaction model with data mining of computer game assisted e/m-learning in higher education

V. PRELIMINARY RESEARCH

The analysis presented in this paper includes student activity in forum discussions of the MudRi system and their final pass or fail grade. The simplest way to measure user activity relates to the measurement of the number of posts of a particular user. Mostly users write a post, which is mainly a query, and others give answers to the query. The number of posts can often lead to false conclusions. For example, a user can write only two posts, one may be a detailed answer to a complex problem, and the other only a thank-you note. Using the previously mentioned method, these posts would be rated equal, so a correction is applied which takes into account the average size of posts and the total number of characters in the post. This in turn can again lead to false conclusions because one may copy and quote the entire post as an additional source of information, while someone else may only add a link. Users who give answers to the questions are considered experts in a particular area, and those who ask questions are considered seekers of knowledge. The user type can be observed through the time of posting, so forums can be classified according to their prevailing activity time: morning, weekend, night, etc. This approach can be combined with the aforementioned post counts.

This study analyses the data from two generations of students enrolled in the course Programming 1 at the undergraduate study of Informatics at the University of Rijeka. The research related to the generation 2010/11 includes 72 students, and the one related to the generation 2011/12 includes 76 students. Students who have posted at least once to a forum, i.e. who have been actively engaged in the discussion are further on referred as Forum members. The number of posts is 145 in 2010/11, and 86 in 2011/12. Forum members are those students who have written at least one post in one or both of the discussion forum categories. Namely, the observed forum discussions can be grouped by content, and described as follows:

- Forums with lectures and exercises handle notifications of problems and seeking help to solve problems, and issues related to the content of the script, homework and exams. Generation 2010/11 includes 79 posts, i.e. 54 % of the total, and generation 2011/12 includes 21 post, i.e. 24%.
- Forums with student tutorship mainly relate to the confirmation of arrival to the tutorship. They include 66 posts in 2010/11, i.e. 46% of the total, and 65 posts in 2011/12, i.e. 76%.

To calculate the correlation between students who actively post on forums and those who do not in regard to whether they pass the course, a statistical Chi-square test with one degree of freedom is employed (1) using the data from Table III.

$$\chi^2 = \sum \frac{(f_0 - f_t)^2}{f_t} \tag{1}$$

TABLE III. COURSE PASS/FAIL GRADE COUNTS OF FORUM MEMBERS AND NON-MEMBERS

Passed course	**YES**		**NO**	
	2010/11	***2011/12***	***2010/11***	***2011/12***
Forum members with lectures and exercise	18 $a_{1\text{-}2010/11}$	8 $a_{1\text{-}2011/12}$	6 $b_{1\text{-}2010/11}$	1 $b_{1\text{-}2011/12}$
Forum members with student tutorship	22 $a_{2\text{-}2010/11}$	24 $a_{2\text{-}2011/12}$	10 $b_{2\text{-}2010/11}$	6 $b_{2\text{-}2011/12}$
All Forum members	28 $a_{3\text{-}2010/11}$	26 $a_{3\text{-}2011/12}$	13 $b_{3\text{-}2010/11}$	6 $b_{3\text{-}2011/12}$
Non-members	13 $c_{2010/11}$	20 $c_{2011/12}$	18 $d_{2010/11}$	24 $d_{2011/12}$

By replacing the cell values in Table III with letters a, b, c and d, we obtain:

$$\chi^2 = \frac{N \cdot \left(|ad - bc| - \frac{N}{2} \right)^2}{(a+c)\cdot(b+d)\cdot(c+d)\cdot(a+b)}. \tag{2}$$

The null hypothesis H_0 set in the Chi-square test assumes that there are no differences in passing the course between different categories of Forum members and non-members. The working hypothesis H_1 assumes the dependence between these values and categories.

The level of significance is set to P=0.05 with Yates's correction, due to the small number of posts in some categories, i.e. less than 10.

According to the results shown in Table IV, the null hypothesis is not validated in five out of six monitored cases. To sum up, there is a statistically significant correlation between the course pass or fail grade and the activity in forum discussions.

The working hypothesis is not validated only in the case of Forum members with student tutorship in generation 2010/11. The reason for this may lie in the purpose of the forum for student tutorship; it is not clear whether the students attend tutoring because they need supplemental tuition or advanced tuition.

Generation 2010/11 has an additional motivating factor: they are invited to post the errors identified in the script, and to propose corrections. Thereby, the number of students actively participating in forum discussions is higher in that generation. Text mining in that group might identify and differentiate students who provide assistance and solutions from those who seek help.

TABLE IV. CHI-SQUARE TEST RESULTS OF FORUM MEMBERS AND NON-MEMBERS

Forum members' categories	χ^2		**P**	
	2010/11	***2011/12***	***2010/11***	***2011/12***
Forum members with lectures and exercise	4.744	4.048	0.0294	0.0442
Forum members with student tutorship	3.564	7.456	0.0591	0.0063
All Forum members	3.985	8.494	0.0459	0.0036

VI. CONCLUSION AND FUTURE WORK

The evolution of e-learning and m-learning systems is in progress since the Internet is increasingly accessed via smart mobile devices (phones and tablets). Simultaneously with the development of e/m-learning systems, various studies are conducted regarding how to increase the use of these systems, since distance learning reduces direct communication among participants in the educational cycle. Consequently, this situation is demotivating in most cases. Different methods are used to increase the motivation; one of the most present in today's field of research is the application of educational and serious computer games.

With data mining in e/m-learning a personalized approach to each student can be achieved in a way that it can optimally adapt to both, students who possess sufficient knowledge as well as students who have difficulty in acquiring new material. This is done either by accelerating the path of learning or by offering additional learning sources. In addition to the impact on the quantity and quality of content, this enables new experience in the acquisition of knowledge, which is particularly interesting to new generations of students.

Further research in this area might involve the following stages of development: creating the application and the associated data system in HTML5 ecosystem for easier use on smart mobile devices, processing certain topics (e.g. programming) through computer games and knowledge acquisition through levels, and integration with the existing data from the MudRi system.

Data mining can provide us with a range of answers on the relation between students' activity in the system and their final grade. The efficiency of the optimized learning model can be verified by using the model for processing different generations of students, as well as different courses. Previous studies on data mining in e/m-learning systems mainly relate to a particular educational institution or a course. This raises the question of generalization. Hence, it would be interesting to conduct a study that would synergistically involve both, similar and different universities in Europe and worldwide.

ACKNOWLEDGMENT

This research has been supported under the Grant No. 13.13.1.3.03 of the University of Rijeka.

E-education 2.0: students' digital identity and online learning activities

Snježana Babić, Mario Krešić and Karla Kućel
Polytechnic of Rijeka/Business Department, Rijeka, Croatia
{sbabic, mkresic1, kkucel}@veleri.hr

Abstract - In general, the implementation of second generation web technologies enabled the user to have an active role in creating and sharing online resources on global scale with the ability to self-manage the personal online reputation and create different digital identity in the virtual world. Privacy, responsibility, trust and security are just some of the problems of the new technology. Unlike the implementation of e-learning 1.0 in higher education - which enables students to manage their online identities within the virtual learning environments created at one of the traditional platforms (e.g. learning management system Moodle) - in e-learning 2.0 there is a need for directing the students in the process of online identity self-management. Even though certain technical solutions can be found on the market (e.g. new generation e-learning systems which offer access to numerous Web 2.0 tools), it is considered that the digital identity is the important component of e-learning 2.0 in organizational, pedagogical and social sense. This paper describes an example where online service Google Drive has been used for executing online learning activities, and which preceded the study of student general opinion about digital identity and online reputation in e-learning 2.0.

I. INTRODUCTION

The term "*e-education 2.0*" stands for the area of e-education in which the second generation of web technology is used.

In numerous works, Bubaš et al. [1] confirm many advantages of introducing Web 2.0 tools to online learning activities (e-tivities): "*fostering collaborative and peer-to-peer learning, enrichment of learning experiences and the development of ICT related competencies"*. Furthermore, Zanamwe et al. [2] assert that social network technologies help students in developing social skills in different forms of online communication.

Along with the positive effects in e-education, Bubaš et al. [3] list potential disadvantages of using Web 2.0 technology: *students' concern about privacy, security and misuse of their personal information*.

On the other hand, Dalsgaard i Paulsen [4] claim that the possibility of higher transparency of collaborators' personal data has a positive effect on the quality of educational work. Therefore, the authors [4] point out the importance of the possibility of choosing the *transparency levels* with regard to privacy of personal information and participants' contribution and the problem of finding the optimum level of transparency.

Higher education teacher perceives the usability of Web 2.0 technology in the learning process through its educational usability, however, seen from the organizational aspect of higher education institution there is a problem of controlling the access to new technologies [5].

In the first generation of e-education there was a significant developmental improvement in e-learning systems (e.g. Moodle, Blackboard and others) which enabled the controlling of the educational process and users by the higher education institutions. In the closed learning communities the possibility to manage and control the user access is enabled. Although in traditional e-learning systems there is a possibility of using the Web 2.0 tools (e.g. wiki), the new generations of e-learning systems have been created which offer better choice of Web 2.0 tools (e.g. *Elgg*; see Orehovački et al. [6]).

Even though Web 2.0 technology enabled a more open and flexible approach to e-education, Strawbridge [5] states that many higher education institutions restrict the use of Web 2.0 technologies or limit their original purpose by user access control.

In general, Web 2.0 tools with educational potential are innovation in higher education practice and its implementation makes the higher education teacher one of the most important figures in the educational process with certain level of responsibility in organizational, pedagogical and technical sense.

Based on the above mentioned, this paper poses the following question: *to which extent is the teacher responsible for the way the Web 2.0 tools are implemented in the educational process and what is the responsibility of students while creating their online identities and using them in online learning activities?*

The paper continues with the overview of the researched literature, followed by the description of online learning activity using the Web 2.0 technology which preceded the research. Subsequently, the paper describes methodology and results of the research conducted on the full-time first-year students from different departments of the Polytechnic of Rijeka.

II. LITERATURE REVIEW

A. Digital identity and online reputation

Oztok et al. [7] state that „*identity is simultaneously an individual, social, and cultural phenomenon and that identity is constructed at the intersection of these locations*“. Costa and Torres [8] inspect digital identity, as the new phenomenon, through 2 macro areas:

- *presentation*: the way in which an individual publishes personal information, interacts and communicates in the virtual communities;
- *reputation*: other participants' perception of the individual's online behavior.

Mansouri and Mrabet [9] single out the possibility of monitoring digital identity as the mixture of the following "digital footprints":

- *passive "digital footprints"*: databases containing personal information (such as name, phone number, address, interests, profession, political affiliations, etc.) without any intentional intervention from the user;
- *active "digital footprints"*: voluntary and intentional posting and sharing of the content (articles, reviews, videos, photos, opinions, tweets, "the likes", comments and all the sharing on private and professional social networks).

Furthermore, it is important to point out that the possibility of posting "*positive and negative*" content by other people in virtual environment may influence the development of individual's digital identity [9].

As an example, viewed from the security aspect of social networks, De Paula [10] determines the key characteristic of social identities as "*the ability of the individual to share different social information with different groups*". Online reputation management and tagging technologies can help the users in estimating the trustworthiness of online information about other users (according to [10]).

B. E-education 2.0 and the problem of digital identity

The implementation of Web 2.0 technology in educational practice generates the possibility of creating multiple digital identities of all its participants.

De Paula [10] emphasizes that Web 2.0 applications (e.g. blogs, wiki, forums, social networks) enable each user to publish a great number of information simultaneously in different online locations. Therefore, the new technology leaves the users to choose the behavior and the manner in which they will „*build online trust and facilitate the identification of resources within a trusted social network*“ [10].

In her work, Costa and Torres [8] points out that even though creating the digital identity is not a direct goal of Web 2.0-based educational activities, they do represent the ways of creating digital identities in the very beginning of their use.

Students in different forms of educational practice in e-education 2.0 have the ability to create new identities presenting incorrect personal information in various virtual environments, which indicates the possibility of greater diversity of digital identities [11]. For that reason, Bati and Atici [11] introduce the term "*Identity 2.0*" which they consider to be crucial for the new type of socialization process.

Oztok et al. [7] confirmed there is a significant influence of individuals' different identities on their online learning practices, i.e. the influence of self-representation on individuals' identities creation.

It is important to point out that Microsoft in conjunction with *Data Privacy Day 2011* conducted a research in 5 countries (United States, Canada, Germany, Ireland and Spain) whose results confirm that only 44% of adults „*actively contemplate the consequences of their online activities on how other people see them*“, and mere 38% of interviewees „*think about the effect their online activities may have on the reputations of others*“ [12].

On the sample of 414 students, Bati and Atici [11] examined the effect of the Web 2.0 technologies on their identity constructions and found that 82.4% „*use at least one of the Web 2.0 tools*“; 67.1% of students „*do not distinguish between online and offline and do not have another personality online*“; and 71.7% „*think that others can find their personality totally in Web 2.0 environments*“.

Mansouri and Mrabet [9] conducted a research on the sample of 500 students and found that „*83.8% of the respondents use Facebook to share information, 54.4% use it to share videos, and 45.2% use it to share pictures*“ with the limited access to the content (only 26.4% of them), 42% of the students interviewed state that they never show their true identity, 50.8% of the students assert that they know about the "*online reputation*" concept. In this research the authors concluded that the national strategy influences the student perception of the importance of online reputation management.

Unlike the physical traditional classroom, digital identity management is particularly prominent in virtual learning environment 2.0, according to [8]. Therefore the authors stress that the participants of educational process have the task of finding the optimum "*model behavior*" while the teacher plays the key role.

C. The example of online learning activity: creating the project task using Web 2.0 tool – Google Document

During the academic year 2013/2014, the full-time students enrolled in different departments (Information science, Transport, Entrepreneurship) were using a free *Google Docs* office suite within *Google Drive* service for creating, sharing and posting educational content as a part of the course "*Basics of computer science*".

Students were supposed to create educational content based on a certain IT topic through a collaborative work. The online activity was assessed as a part of the educational element "*in-class activity*". Each student had the ability to independently choose an educational topic previously posted in the online course "*Basics of computer science*" which was created in the University's LMS Moodle. The students could not see the list of other student applicants while choosing the members of their group. There was a possibility of student collaboration in physical or other virtual environments outside the educational process.

After selecting the topic, the students were shown the online list of their group members and had to choose the group leader. The group leader needed to determine the method of collaboration for creating the new document which involved creating the online document within Google Drive and sharing the document with team members, including the teacher (shown in Fig. 1).

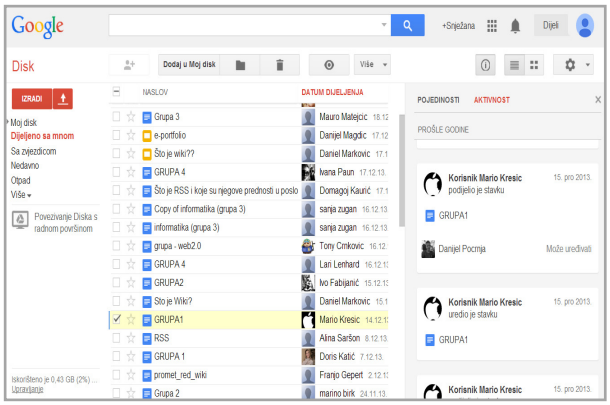

Figure 1. Application of Google Drive (Google Docs) while working on project tasks as part of the educational element "in-class activity" of the "Basics of computer science" course

The teacher had access to the collaborative teamwork using the features of Google Drive service itself. Additional internal communication among students took place on Facebook where teacher had no access. In the traditional classroom all group leaders presented their collaborative work.

The instructions about work methods were given to students in traditional classroom, as well as in online course created in LMS Moodle e-learning system. However, students were not given directions on the choice of user account they will use in an online educational activity using the Google Drive tools, which is closely related to their digital identities.

The practice has shown that students used the existent user accounts which they use privately. Also, it is important to mention that most of the students did not have experience with collaborative work method while creating the document using Google Docs, and that they did not fully understand the way teacher will supervise their work. This can indicate different levels of students' computer literacy, but it can also demonstrate a degree of awareness regarding monitoring their online activities by other people in virtual environment, which is related to personal management of online reputation.

In this case, the practice illustrates the diversity in creating digital identities by students, both in the sense of posting personal information as well as leaving „*active digital footprints*" [9] which is in accordance with the findings of the previously researched relevant literature.

III. RESEARCH METHOD

The basic problem of this research is to examine to which extent are the students familiarized with the online reputation management and their awareness of the importance of digital identity and online reputation in e-education 2.0. The research was conducted on the Polytechnic of Rijeka, after some time has passed since their involvement in online learning activity described in the previous chapter. It is important to emphasize that the students had already been assessed for their effort in the project.

For this research the method of opinion poll was used. It was prepared as the paper form. The data selection was carried out in student groups, according to their departments, and took place in a traditional classroom. After initial instructions were given, the surveying was performed by the examiner (addressed to the student). A new opinion poll form was created with 19 questions, and in its creation results from previously researched relevant literature described in this paper ([2], [3], [7], [8], [9], [10], [11], [12]) were used. In the first part of the questionnaire, besides basic demographical information (age, gender, status, department), there were a more closed-type questions related to the use of social networks and creation of user accounts, as well as self-evaluation about the knowledge of online reputation management which is closely connected to digital identity (according to [2], [9], [10], [11], [12]). Furthermore, the second part of the questionnaire included 10 questions concerning student evaluation of the importance of digital identity and online reputation in e-education 2.0 which was measured using Likert scale (1=strongly disagree to 5=strongly agree).

The data was collected from 194 students at the *Polytechnic of Rijeka*, among whom 19 did not complete the question form correctly. The final number of interviewees in this research was 175 students whose age was between 18 and 23, among them 74 women and 101 men. All examinees were full-time first-year students of *Information science* (31%), *Entrepreneurship* (22%) and *Transport* (47%).

IV. PRESENTATION OF RESULTS

As shown in Fig. 2, the interviewed students have evaluated their knowledge of online reputation management in e-education 2.0 as good (57%) with the average grade of 3.2 (SD=0.67). This may indicate that the majority of students is not familiarized enough with the general concept of online reputation management.

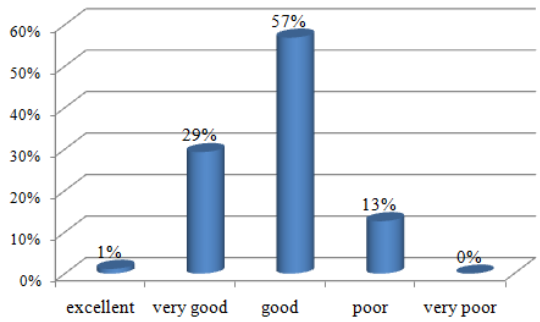

Figure 2. Percentage of responses regarding students' self-evaluation about the knowledge of online reputation management in e-education (N=175)

The research results show that 99% of students have Facebook accounts while other social networks are used considerably less: Google Plus (54%), Twitter (15%), Myspace (5%), LinkedIn (1%), others (19%). It can be concluded from the practice that the number of created user accounts on Google Plus social network has significantly risen because of the need of having that account for the previously described online learning activity. However, the results show that 46% of the students still do not have Google Plus user account which indicates that the students shared the document created using Google Drive via other user accounts.

Regarding the question about the number of user accounts on Facebook, 87% of students answered that they have only one user account which confirms previous findings by other authors indicating that students do not separate work life and private life in virtual environment (see [11]).

It is evident from the Fig. 3 that students use social networks mostly for online communication with other students at faculty (33%), followed by social activities (27%) and education (18%). We can conclude that social networks are used for education (51%), the conclusion also reached by Zanamwe et al. [2] in their study which was used in creating that particular survey question.

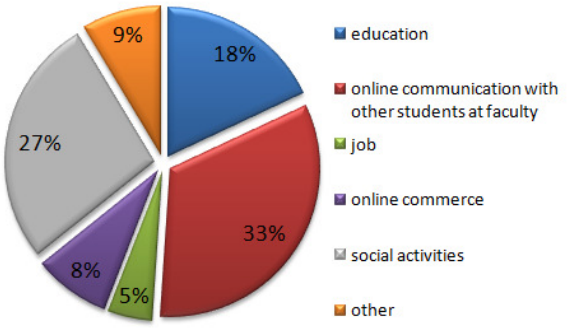

Figure 3. Percentage of student responses regarding the reason for using social networks (N=175)

Student opinion about the importance of digital identity and online reputation in education 2.0 has been examined by their level of agreeing with certain statements which they had to express using the Likert scale from 1 to 5.

Therefore, 68% of students „strongly agree“ and „agree“ with the statement that “*a student's digital identity influences the other people's perception of that student's personality*”, however, 25% have answered that they are “neither agree nor disagree” (see Fig. 4) which may indicate an insufficient awareness about the subject.

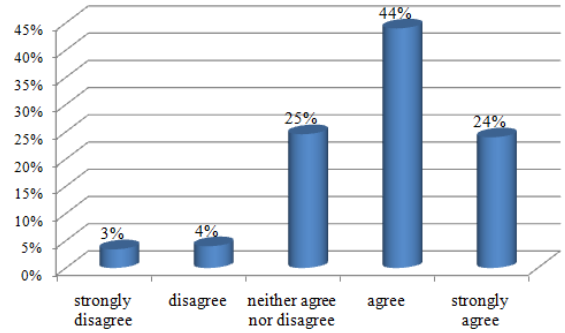

Figure 4. Percentage of student responses regarding the statement about digital identity influencing the individuals from the environment (N=175)

The student opinion about “*...the influence of online reputation on their long-term goals (e.g. during the employment process or after graduation, etc.)*” is very positive (79%). However, 13% of students are unsure regarding the statement, and 8% of students have negative opinion which is considered a significant percentage because they are the ones who can cause negative online reputation of others, which is in accordance with the results from the previously reviewed relevant literature (see [12]).

In this research the students have shown their highly developed awareness of the need to protect personal information in the field of e-education 2.0. This is confirmed by 88% of students who feel it is necessary to take into consideration personal data protection. However, to the statement regarding “*...creating new user account for the educational purposes to protect student privacy*” 28,6% of students are “neither agree nor disagree” and 16% disagree with the statement (see Fig. 5). Such result may indicate the fact that students trust Web 2.0 technology regarding the protection of their personal data.

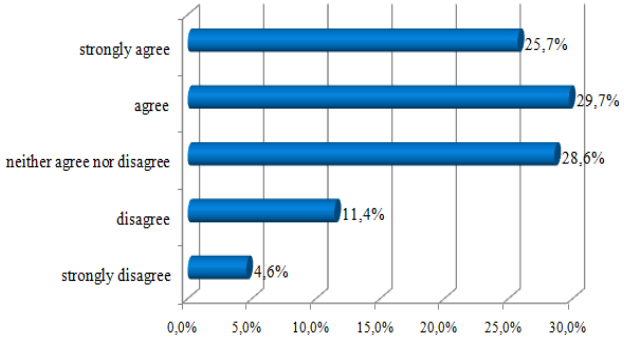

Figure 5. Percentage of student responses regarding the importance of creating new user account for the educational purposes to protect their personal data (N=175)

Furthermore, 46% of students have the negative opinion about the colleagues who post inappropriate data and information about themselves and others (text, images, video, audio, etc.) on social networks (e.g. Facebook), while 31% opted for the response "neither agree nor disagree". The gathered results could be connected to the fact that Facebook is the most commonly used network and there is a thin line between physical and virtual environment where individuals act in different ways, which is in accordance with the researched relevant literature in the paper (see [11]). At the same time, 50% of the students "strongly agree" and 27 % "agree" with the statement that "*…while publicly posting personal data it is necessary to consider appropriate names*" which can also be related to the results of the previous statement and highly developed awareness of the importance to protect personal data.

Since the students took part in the online learning activity which preceded this research, they could use that collaborative experience as basis for their evaluation of how "*…individual responsibility while posting personal data and creating mutual trust during working in online social communities influences the quality of collaborative work*". The results show that 61% of students agree with the mentioned statement. It is interesting that only 22% of students "strongly agree" with the claim which can indicate that the students perceive their colleagues on the friendly basis as well, while tolerating their behavior in the virtual environment (see Fig. 6).

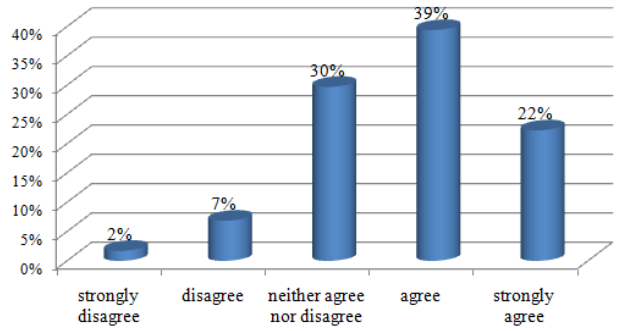

Figure 6. Percentage of student responses regarding the statement about the influence of digital identity on the quality of collaborative work in an online environment (N=175)

To the statement about "*...guidelines in the process of managing online reputation while using social software in educational process*" 68% of students expressed positive opinion (see Fig. 7), which indicates the high level of awareness of potential problems regarding the integration of the second generation web technology in the educational practice. It can also be concluded that in e-education 2.0 students have certain expectations from the teachers in terms of managing online reputation, which is in accordance with the researched relevant literature in this paper (see [9], [12]).

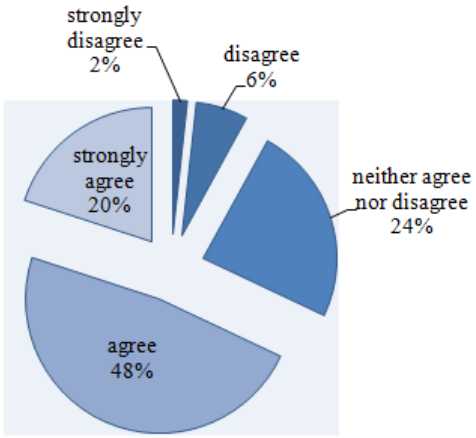

Figure 7. Percentage of student responses regarding the statement about the need for guidelines on how to manage personal online reputation in the educational process (N=175)

V. CONLUSION

Based on the reviewed relevant literature it can be concluded that the *digital identity* and *online reputation management* are important components of *e-education 2.0*, whose influence can be monitored on the level of a certain participant in the educational process, institutional, national and global level. Also, it is important to emphasize that in the past few years the effort has been made to develop individual awareness of protecting the online privacy and online responsibility on national and global level which is confirmed by the research results in this paper. Second generation web technology enables students to be highly creative in constructing their digital identities, but at the same time to create a number of different identities as well.

However, unlike the physical world, in the virtual environment individuals – with their online activities – can take part in creating other people's digital identities (see [2], [11], [12]). The research results in this paper confirmed that students use social networks mostly for educational purposes and that majority have only one user profile. Also, they take into consideration the amount of personal data they post thus protecting their privacy. It is a valid conclusion that students believe it is sufficient to protect their personal information within the service being used. On the other hand, it can be asserted that students do not actively think about the possible influence of others on the creation of their online image, and vice versa, which is in accordance with the existent results in the reviewed relevant literature.

While introducing new web technology into the educational practice, the higher education teacher takes a part of the responsibility in guiding the students towards reaching the learning goals which include the expected "*behavior model*" (see [8]). This can be affirmed viewed from the aspect of teacher experience in educational practice while using Google Document online tool, which is described in this paper. On the other hand, viewed from the student aspect, the same is confirmed by research results – 68% of students want to be guided in the process of managing their online reputation for the educational

purposes. Most of the gathered results are in accordance with the findings of the existent studies. The future studies should encompass broader range of questions.

Usefulness of Prezi and PowerPoint presentation

A. Špernjak
Faculty of Natural Sciences and Mathematics, University of Maribor, Maribor, Slovenia
E-mail: andreja.spernjak@uni-mb.si

Abstract - In everyday teaching practice great helping to the clearness and visualization of the content are presentations. Two decades ago, the blackboard notes were replaced with traditional slides and overhead projector. With the availability of computer hardware and software are traditional slides converted to electronic slides. In our area the most frequently are used PowerPoint slides, but the problem is payable package of the ´Microsoft Office´. Users looking for free of charge and useful presentation programs. For teachers and students is Prezi a free online presentation service provider, where the applicability in four years grow up to more than 500 million users. The article presents the results of the usefulness of PowerPoint and Prezi presentations among university biology students. They mostly use the PowerPoint presentations because generally they do not know Prezi presentations. Students also expressed the advantages and disadvantages of one and the other presentation program.

I. INTRODUCTION

Computer is an indispensable element of everyday life. It became a must in terms of the education and instruction system. In courses it helps teachers to be more efficient in auditory. For more visual senses and in order to achieve permanent, effective and fluent teaching most teachers use the PowerPoint, which, included in the ´Microsoft Office´ package is a powerful presentations tool. Originally PowerPoint was developed for commercial and business purposes, but it has quickly penetrated the scientific and educational circle as well.

Why teachers use the instructional presentations, for entertaining or education?

Science employs an iconic sign system [1] and have visualisations [2] and argumentation deeply rooted into the study material. In science classes, these visual representation enable scientific meaning to be constructed and make meanings that no teacher or student can readily convey in a different mode of communication or in one mode alone. These visualizations would affect the shaping of knowledge in a positive way [3]. Especially science teachers should therefore use graphic organizers in presentation during which they display the explicit structure of the information covered by previous classes [4]. Some students and many teachers reported that presentations might prove to be more diversion than useful tool, because the slideshows presentations capture students' interest – pay attention or helps them ″stay awake″ in class [5].

Many studies have examined the effect of PowerPoint presentations on motivation, self-efficacy and the academic successes of students, and many studies have compared PowerPoint with traditional classes. Different results have been reported. Reference [6] argued that the self-efficacy of students is high and their attitudes are positive in classes taught with PowerPoint presentations. Reference [7] found that the attitudes of students towards PowerPoint presentations were positive, and that PowerPoint presentations have an impact on short-term memory when designed appropriately. In contrast, reference [8] compared classes using PowerPoint presentations with teacher cantered classes, and found no statistically significant difference between the two methods according to students' academic success. PowerPoint has a negative effect on students' exam performances, although students state that they learn more in the courses taught with PowerPoint [9]. The results [10] of study show that most of the students become more successful when they are taught with traditional method. However, PowerPoint has neither a positive nor a negative effect on students' academic success.

Many studies have compared effect of PowerPoint presentation with traditional classes. PowerPoint presentation has already received much criticism from researchers, but just a few researchers examined effects between PowerPoint and some other presentation like Xerte, Keynote, VoiceThread or Prezi. Reference [4] compered effect of PowerPoint slides with Prezi presentation. They found out there is no significant differences in learning outcomes, self-efficacy, cognitive load and two motivational variables (attitude toward behaviour, intrinsic motivation) between PowerPoint and Prezi presentation. Prezi is relatively new, so the technology is still unfamiliar to researchers and educators, especially in the field of social work. Table I represents general software options of PowerPoint and Prezi presentations.

TABLE I: Comparison of general software options of PowerPoint and Prezi presentation.

General options of	PowerPoint	Prezi
linear sequence	✓	✓
a free-flowing presentation – effect of zooming	×	✓
animations between slides	✓	✓
creating own templates	✓	✓
capability of integrating text	✓	✓
capability of integrating images	✓	✓
capability of integrating animation	✓	✓
capability of integrating audio	✓	✓
capability of integrating video seamlessly into a single presentation	✓	✓
autoplay a single animation or slide	✓	✓*
printing slides	✓	×
free of charge	×	✓
need of high-speed Internet connection	×	✓
publishing presentations online	×	✓
shared, allowing multiple people to	×	✓

collaborate on a single presentation		
support for different plug-in (mathematic, chemistry, physic, …)	×	✓

*possibility just three different times of autoplay (4, 10 or 20 sec)

The question is why use the Prezi if with studies found out no differences between presentations? Traditional presentation software like PowerPoint is requires preparing a linear story line using a storyboard approach (Figure 1).

Figure 1: Linear sequence of PowerPoint presentation.

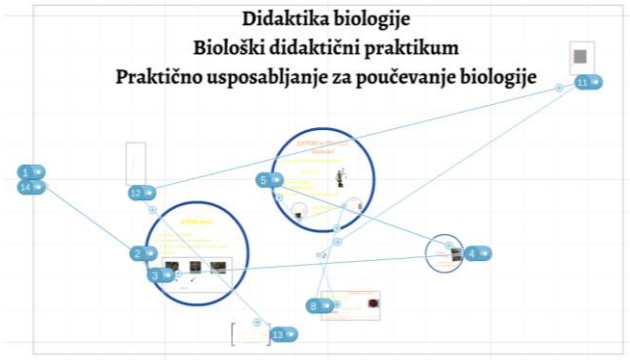

Figure 2: Free-flowing Prezi presentation.

Prezi, on the other hand, allows for both a linear and a free-flowing presentation of a story line (Figure 2). The user creates a presentation on a large blank workspace called the canvas, where all the elements of a presentation are visible. A story line is then created by arranging the elements on the canvas [11]. With Prezi user can group the visual elements info frame and zoom in and out on different objects. It allows making multi-dimensional presentation. The creation of a Prezi presentation does not require the user to have advanced in information communication technology skills, so they can interact on-line for creating highly impactful virtual portfolios [4] Moreover, Prezi encourages using graphic organizers (concept maps, mind mapping, non-linguistic representation) and these could be an alternative to the linear sequencing in PowerPoint presentation [4]. This is also an opportunity to revitalize the interest in graphic organizers, which are not frequently implemented in classrooms [13].

The aim of the current study was to survey biology students´ opinions on and attitudes to PowerPoint and Prezi presentation usage. We wanted to find out which one they use more frequently in reasons why.

II. METHODS

The participants for this study were student biology who volunteered for this study. They were from the 3th and 4th university years at the Faculty of Natural Sciences, University of Maribor in Slovenia. They completed a questionnaire prepared for the purpose of the study. They completed it in electronic form. The quastionare was prepared with Google Drive. We collected 63 questionnaires from 47 women (74.6 %) and 16 (25.4 %) men.

The questionnaire contained three parts. The first part of the questionnaire solicited demographic data such as gender. The second part concerned students' attitudes about usefulness of different presentations (Prezi and PowerPoint). The answers were measured by a 5-point Likert scale. The scale questionnaire was as follows: 0 = I have no base for answer; 1 = definitely disagree; 2 = disagree; 3 = agree; 4 = definitely agree. Students were to value percent's of their university professors' usage of presentations during lectures. The scale questionnaire was as follows: 1 = 0 – 24 %; 2 = 25 – 54 %; 3 = 55 – 74 %; 4 = more than 75%; 5 = all professors. The third part was an open question about advantages and disadvantages of Prezi and PowerPoint presentation. Similar answers were grouped in to four complexes which describe the same answers.

The reliability of the questionnaire about usefulness of different presentations (Prezi and PowerPoint) was measured by the Cronbach coefficient. The Cronbach reliability coefficient was 0.94 for the 7-item scale, which can be considered satisfactory. Microsoft® Excel 2010 was used for data input. The analyses were performed with the statistical package SPSS 21.0, where we used descriptive statistics; One-way ANOVA was used to examine differences in opinions by student gender why they use presentations. The Chi-Square test (χ^2) was not used for comparison of differences between results from the student opinions about the advantages and disadvantages of PowerPoint and Prezi presentation because we have no results of Prezi usage.

III. RESULTS AND DISCUSSION

In a primary or secondary school 36 students (57.1 %) learned about presentation, 20 students (31.7 %) learned about presentation at university classes and just 6 students (9.5 %) claimed that they learned about presentation by them own across investigation. No one took the special lessons or training to learn about e-presentation. PowerPoint presentation use 57 students (90.5 %) and just 6 students (9.5 %) use PowerPoint and Prezi presentations. We have no students to use just Prezi. Students mostly do not use the Prezi because they do not know it and almost the same results are at professors' usage of Prezi presentation. We asked students who many professors at lectures use presentations and 53 (84.1 %) students claimed that more than 75 % of professors during lectures use the presentations but less than 10 % of them use Prezi presentation. Across my researching I found at that Prezi use just one professor and his field is computer science.

With questioner we asked students about advantages and disadvantages of Prezi and PowerPoint presentations but we could not made s comparison of differences between results because just 6 students know the Prezi presentation and these results cannot be relevant. Students who use Prezi claimed that it is good because it is free of charge and because of zooming in and out it is more interesting than PowerPoint. Why students do not use other presentation than PowerPoint is clear out of those statements:

- ″I saw Prezi presentation. It is very interesting but I do not use it because I do not know how″.
- ″I do not use the Prezi because all lecture room has no Internet connection″.
- ″I use PowerPoint presentation because I am familiar with it, it is accessible and mostly use it″.
- ″I will not use Prezi because it is too trumpery″.
- ″Prezi has no support for different plugins for Chemistry, Physic, Mathematic … but PowerPoint has″.
- "I use PowerPoint because I do not know the other presentation programs.″
- ″PowerPoint meets my all presentations needs and therefore I do not use other applications″.

PowerPoint is a user-friendly package [14] and our study also confirms it. 54 (85.7 %) our students said that it is easy to use PowerPoint presentation. There are no significant differences at statement of using PowerPoint presentations by gender. Students mostly use it for the creation of visually clear. Three students (4.8 %) use it because the professors request. Even 6 (9.5. %) students thing just of herself; they use PowerPoint to make their oral presentation easier. These students are not interest in audience and how to effective to represent the contents but just to do it and by easier way. Out of this item these students while preparing PowerPoint presentations do not follow the principles that need to be followed. Hence, presentations which are prepared without following the appropriate principles have a negative effect on learning [14]. According to our study students missing the lectures about appropriate presentation principles and they are not sure how to make a good and effective presentation.

Students need more instructions how effective make presentations. At the lectures they see finished presentations but they can to make it effective if they do not kwon how or if they do not follow the principles that need to be followed to make effective presentation.

IV. CONLUSION

Out of our study we can conclude that our students are no familiar with Prezi presentations although it is free of charge. They mostly use a powerful presentation tool, the PowerPoint software as like as those university professors. They use it first of all for better visualization of contents and self-efficacy. Out of the early findings is for motivation, self-efficacy or the academic successes not important which software for presentation is used; PowerPoint, Prezi or which other else. Most important factor for effective presentation is ″preparing the presentation with an appropriate design″ [15]. For development of effective presentation slide as multimedia instructional materials, teachers should conceptually understand design principles regarding what makes high- or low-quality presentation slides [16].

In further research we would like to represent Prezi presentation to our students and make them to use it. After while we would like to find out which one of software presentation; Prezi or PowerPoint; they would like to prefer.

An On-line Solution Verification System for Programming Competitions

A.S. Dorofeev*
* National Research Irkutsk State Technical University, Irkutsk,
Institute of Cybernetics, Department of Computer Engineering, Russian Federation
Dorbaik2007@mail.ru

Abstract – An application of an on-line solution verification system for programming competitions is considered in the paper. The system has been developed at in National Research Irkutsk State Technical University and used within the competition events. It has client-server architecture and has been implemented on the base of a cluster using parallel schemes of verification algorithms. The system supports several programming languages, such as C++, Pascal, Java. The verification algorithm can also be used to check the results of laboratory works of "Programming" disciplines. The system allows teacher to automate routine activities of students' algorithms correctness verification.

I. INTRODUCTION

Today the student competitions on different disciplines are an integral part of the educational process. The competitions are becoming more and more popular. They let the faculty stuff check the acquired competencies, allow finding talented young people, develop creative abilities, increase an interest in the research work, *etc.* [1]. In addition, for the competition winners, wide career opportunities are opened. Often, the outstanding students become senior developers and even technical directors of software development firms just after only two or three years after the graduation [2].

Every year, a number of programming competitions are held in Department of Computer Engineering of the National Research Irkutsk State Technical University [3]. The winners of regional and All-Russian competitions participate the quarterfinal and semifinal competitions of the world team championship on programming under the auspices of ACM.

To involve more students to the competitions the faculty stuff improves the quality of the competition organization, in particular, minimizing the time period of the task solution verification and expert assessment. Earlier, the process was organized as follows: department staff prepared the terms of the problems to be solved, their correct solutions and test cases before the competition. The competitors solved the problem using personal workstations, and placed their solutions in a specific directory on the local disk of the workstations. At the appointed time, the organizers collected participants' solutions (programs) and distributed them among inspectors. Each inspector executed a program in an environment prescribed the by the programming language, verified its operability and executed the prearranged test case. The test case usually consisted of 10-15 tests, and covered boundary value checks, the productivity of the proposed solution, and other aspects of the solution quality. The verification of the solutions took from about 3 to 5 hours for a large number of the participants.

The results of the test cases execution were recorded in a protocol. The protocol data included the number of tests passed. The results were aggregated by the participants and by the problems, and the winner and two medalists in the individual competition have been determined. If a competition was of an intercollegiate or All-Russian character, the winning team is determined by three best participants of a university paying no attention to their original team memberships.

The next day was dedicated to work of appellate commission; the participants could file requests for reconsideration of their solutions. Then, the final results of the competition are determined after possible appeals.

Naturally, this approach did not exclude the human factor. Mistakes made during the verification and in the final standings could appear. In addition, it was difficult to estimate the productivity of a solution, the number of the program versions passing the test cases. As a result, the probability of the fact that some participants of the competition will occupy the same place is increased. In this case one must pay more attention to the assessment of the quality and the productivity of the program code, *i.e.*, the results became depended upon the expert's intuitive activity.

In order to rise the organization quality of the competitions we needed to solve the following problems: construct a storage, protocols and programming interfaces for automatic solutions accumulation; create an on-line verification engine of the solution variants of a competition participant (an participant can suggest several variants of the solution, and all of them must be checked); develop a time tracking and penalty time accounting subsystem. So, we decided to develop a programming system for the routine activities automation, which is also aimed at exclusion of the human factor in the distributions of the places in the final standing.

II. A PROGRAMMATIC SOLUTION

The first step towards the problem solution was to write auxiliary programs as batch scripts, which allow

verifying the solution on a set of predesigned test cases. These scripts conserved greatly the time taken to check the solutions. The next step was to create a system of automatic solution verification of the competition problems. The system has been developed by collective of the department of Computer Engineering. The system has a client-server architecture and is written in Java.

To get acquainted with the procedure of solution submission before the main round of the competition, a trial round is being conducted with one simple problem, *e.g.*, addition of two numbers. After the familiarization with the system of on-line solution verification, the main round is started, and all the participants receive the problems at the same time. Average number of problems varies from 6 to 8. The complexity level also varies: there are always one simple encouraging problem and at least one complex. The variety of the complexity levels develops tactical skills of the participants. Many solutions at the competition are based on the knowledge of algorithms of discrete and other branches of mathematics. The time of the main tour is usually from 4 to 6 hours depending on the level of the competition.

The solution is accepted if it is solved completely. The completeness of the solution is determined by the number of the test cases passes. The solution to be verified must be represented in one of the following programming languages: Java, C, C++ and Pascal; The following IDEs also supported: Eclipse, Code::Blocks, Free Pascal IDE and Delphi.

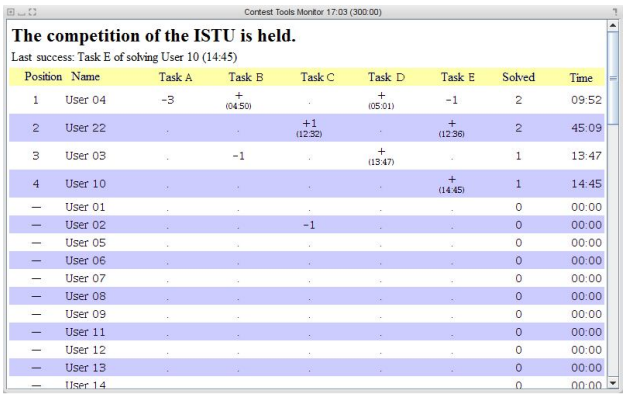
A competition participant submits the solution by means of opening the corresponding file or copying its text from the clipboard. The solution is accompanied with the language name; it is selected by the participant before submitting the solution. All submitted programs are queued on the server side. The verification results are displayed to each participant with a message and to all participants with a standings positions in an application.

Possible responds of the verification system are as follows:

- The solution is accepted.
- Wrong output: the algorithm is probably wrong.
- Data representation error: the program produced malformed output due to, *e.g.*, the incorrectness of the solution, or the task is incorrectly specified.
- Time is out. Possible causes of the respond could be low performance of the submitted algorithm; an error that led to a program hang; the program waits user input after producing output.
- Exceeded the process memory limits. The possible cause is that the program allocates memory, but does not free it.
- Runtime error. This can be produced due to an error in the program, the absence of `return 0` statement in C/C++ programs; the solution could be incorrectly specified; the program consumes too much memory; Java class contains mo method `main()`, *etc*.
- Compile error. Probable causes are as follows: a syntax error in the program; incorrectly specified the implementation programming language, a class having `public static void main (String [])` method not found in a Java program.
- Access violation. The program attempted to execute an action prohibited by the rules of the competition. In this case, a disqualification of the participant could be initiated by jury.

As mentioned above, the solutions of each problem are verified on predefined test cases. The tests are executed in a random order. The test cases are executed by programming system "Checker" that had been developed by competition organizers. Solution of the problem is accepted if it passes all tests. If a test case failed the system returns the number of the test case to the author of the solution. The results of some test cases are presented with the problem statement as examples of input and output of the program to be written. The verified solution is accepted with the time spent by the author to develop the solution: it is assumed that the solution has being developed since the very start of the main round. A so-called penalty time is calculated as a sum of the elapsed times for all accepted problem solutions for each of the competitors. Unsuccessful attempts of a solution submission results in penalty time increase by 20 minutes for each unsuccessful attempt if the solution is finally accepted. If a solution is not accepted, its penalty time is not accounted. So, the penalty time consists of the time spent to produce a solution for each accepted problem and a penalty time for each failed attempt of a solution submission if it is finally accepted.

An hour before the end of the main round, monitoring the place of a participant in the standings is stopped. However, the team leaders and jury can watch the results and the places of the participants during the full time of the round on a special workstation. The final standings positions are distributed according to a number of solved problems, and the penalty time if the number of tasks solved is the same. At the team competitions the places are distributed similarly by taking into account the total number of problems solved by top three members of a command and their total penalty times (Fig. 1).



Contest Tools Monitor 17:03 (300:00)

The competition of the ISTU is held.

Last success: Task E of solving User 10 (14:45)

Position	Name	Task A	Task B	Task C	Task D	Task E	Solved	Time
1	User 04	-3	+ (04:50)	.	+ (05:01)	-1	2	09:52
2	User 22	.	.	+1 (12:32)	.	+ (12:36)	2	45:09
3	User 03	.	-1	.	+ (13:47)	.	1	13:47
4	User 10	.	.	.	.	+ (14:45)	1	14:45
—	User 01	.	.	.	.	.	0	00:00
—	User 02	.	.	-1	.	.	0	00:00
—	User 05	.	.	.	.	.	0	00:00
—	User 06	.	.	.	.	.	0	00:00
—	User 07	.	.	.	.	.	0	00:00
—	User 08	.	.	.	.	.	0	00:00
—	User 09	.	.	.	.	.	0	00:00
—	User 11	.	.	.	.	.	0	00:00
—	User 12	.	.	.	.	.	0	00:00
—	User 13	.	.	.	.	.	0	00:00
—	User 14						0	00:00

Figure 1. Interface of the stangings monitor application

At the end of the competition a rating is figured out, the monitor restarts showing the places of the participants in the final standings, but at this time it shows the real names and universities of their origin instead of the encoded name. After that the prizes are distributed.

The next step was implementing the system according to a parallel scheme (Fig. 2) to verify the solutions on multiple workstations [4] simultaneously; the workstation form a horizontal cluster of undedicated nodes. The usage of the cluster significantly reduced the response time with respect to verification of the queued solutions on one server workstation. The participant might wait for a response about 3-5 minutes. The cluster reduced the time to less than one minute that is very important at the very end of the competitions.

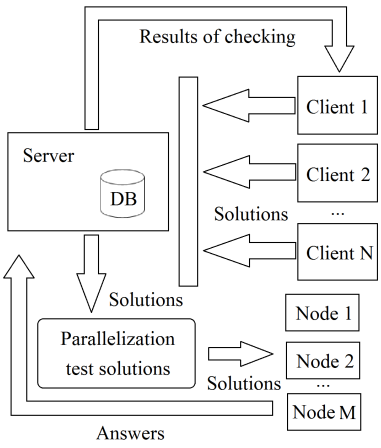


Figure 2. Distribution of the verification tasks between cluster nodes

Now an idea of the system utilization in the class of programming appeared. Viewing the source codes of solutions of student's laboratory work is a rather time-consuming procedure, and it is not always possible to find logical errors in the program. Also it does not always provide an objective monitoring and assessment of the learning outcomes.

In the laboratory works, the programming tasks is often required to be written as a program in one of the programming languages that reads input data in a specific format, processes the data in accordance to the task formulation; the result must be displayed in a particular format as output. This form of user interaction of the laboratory program is typical for the programming competitions. So the developed system is suitable for automatic inspection of the solutions obtained in laboratory works. The test cases and an obviously correct solution are prepared preliminarily.

III. CONLUSION

The benefits of the presented automated approach to the organization of the competition events are obvious: there are less number of routine activities; effectiveness of the final standings results formation; impartiality of the verification; the rating is calculated with formal rules; more detailed registration of the results of the competitions, in particular, all submitted solutions are stored in the database in the sequence of their submission, fixing the submission time within one second; the probability that some participants will take the same place is decreased; to announce the results of verification and the final standings monitor device is used, forming and issuing rankings more efficiently.

Thus, the paper presents the experience of an application of an automatic verification of solutions of problems stated at student programming competitions. The automation reduces the routine activity of the competition organizers on viewing and verification of the problem solution represented as program source code. The system provides an independent and objective verification. It provides teachers and students a convenient means of viewing quality statistics of the submitted solutions. In addition, the system can be used to demonstrate the testing techniques for the students studying the information technologies.

Implementation of information competencies as key employment skills at the Faculty of Humanities and Social Sciences

Špiranec, Sonja*, Ivanjko, Tomislav * and Pečarić, Đilda *·
* University of Zagreb, Faculty of Humanities and Social Sciences,
Department of Information and Communication Sciences
sspiran@ffzg.hr, tivanjko@ffzg.hr, dpecaric@ffzg.hr

Abstract - In order to improve the quality of their study programs, universities/faculties today are facing increasing demands to include employment skills into their curricula in order to maximize the potential of their students for a successful career. One of the key aspects in developing such skills is increasing students' employability - a set of skills, understandings and personal attributes that make graduates more likely to gain employment and be successful in their chosen occupations, which benefits themselves, the workforce, the community and the economy. While there is a broad consensus amongst key stakeholders in the process (HEI, employers, students) on the importance of addressing employment skills within higher education, there are still open questions on how this can be achieved. While universities/faculties tend to put more emphasis on developing specific knowledge and skills within their field of education, a number of reports issued by employers urged them to make more explicit efforts to develop the "transferable" or "generic" skills needed in many types of high-level employment. In an ever increasing world of information, as one of the core components of these generic skills is developing information competencies – skill set needed for effective gathering, evaluating and communicating information in all its forms and contexts. This paper aims to explore how these information competencies are implemented at the Faculty of Humanities and Social Sciences, University of Zagreb by conducting research across its study programs on the masters' level. Following that approach, this research will provide a snapshot of current situation and give recommendations on possible optimizations in including information competences into the curricula at the faculty level.

I. THEORETICAL BACKGROUND

In the wake of rapid growth in higher education and the increase in global market competition experienced by many employers, universities came under intense pressure to equip graduates with more than just the academic skills traditionally represented by a subject discipline and a class of degree. A number of reports issued by employers' associations and HEI organizations urged universities to make more explicit efforts to develop the 'key', 'core', 'transferable' and/or 'generic' skills needed in many types of high-level employment [1].

Head et al., [2] list studies have been published about employers' perceptions of information literacy needs throughout the workplace [3] [4]. In these studies, most employers were unfamiliar with the phrase "information literacy", yet they agreed it was important for employees to be able to find, evaluate, and use information. Employers frequently had a difficult time distinguishing information literacy and research skills from other skills such as presentation, writing, and technology competency. Authors conclude that these studies show that employers place a higher premium on graduates' information competencies, but the results do not say which information competencies are important in the workplace and why [2].

In defining what those skills should be some authors are using the term "core" for discipline-specific skills, and "generic" to represent "the so-called transferable skills that can support study in any discipline" [5]. Developing those generic skills is increasing students' employability - a set of skills, understandings and personal attributes that make graduates more likely to gain employment and be successful in their chosen occupations, which benefits themselves, the workforce, the community and the economy [6]. For some employers, even the degree subject studied is not as important as the graduates' ability to handle complex information and communicate it effectively and that graduate recruiters want a variety of other skills, personal and intellectual attributes, rather than specialist subject knowledge [7].

In an ever increasing world of information, as one of the core components of these generic/transferrable skills for graduate students is developing information competencies – skill set needed for effective gathering, evaluating and communicating information in all its forms and contexts [8]. In this context, becoming information literate is considered a product that can be measured against a set of educational standards. Claims emanate from the library and education sectors about the generic and transferable nature of skills gathered under the term "information literacy". The concept of information literacy as a skills-based process is increasingly being adopted by training colleges and universities as a "graduate outcome" [9]. *Information literacy competency standards for higher education* [8] provide a framework for identifying what an information competent/literate individual is able to do:

- Determine the extent of information needed
- Access the needed information effectively and efficiently
- Evaluate information and its sources critically
- Incorporate selected information into one's knowledge base
- Use information effectively to accomplish a specific purpose
- Understand the economic, legal, and social issues surrounding the use of information, and access and use information ethically and legally

Although these competencies are related to information technology skills, they have broader implications for the individual, the educational system, and for society, because "the information literacy of young people has not improved with the widening access to technology: in fact their apparent facility with computers disguises some worrying problems" [10].

In the tertiary education landscape the generic qualities of information literacy are emphasized. Information literacy is viewed as a suite of skills which constitute a competency, developing student information skills which can be applied across a range of academic disciplines and which prepare students for continued formal learning throughout life [11].

To provide an overview how these information competencies are implemented at the Faculty of Humanities and Social Sciences at the University of Zagreb, a research across its study programs on the masters' level is conducted. Following that approach, this research will provide a snapshot of current situation and give recommendations on possible optimizations in including information competences into the curricula at the faculty level.

II. METHODOLOGY AND SAMPLE

After consulting key documents on the topic, the *Information Literacy Competency Standards for Higher Education* (ALA, 2000) was selected as a joint framework for research on which the terminology and the definition of key components of information competencies were based. Following the information competencies present in the Standards, research across study programs [1] at the masters' level of the Faculty of Humanities and Social Sciences, University of Zagreb was conducted in order to explore how these information competencies are implemented in the projected course outcomes.

At the faculty students can study 4 master studies from the area of Social Sciences (Information and Communication Sciences, Pedagogy, Psychology, Sociology) and 30 master studies from the area of Humanities[2].

A total of 34 master study programs were analyzed with a total of 1752 courses. Each course description and outcomes were analyzed and investigated for potential inclusion of generic information competencies in its curricula.

III. RESULTS

From 34 master programs analyzed, in 9 of them no generic information competencies were found. All of 9 studies belong in area of Humanities. Since these studies, all except one can be studied only as double major we assume that students other major could provide courses with generic information competencies.

Out of 1752 courses in 128 (7.3%) courses in 25 study programs generic competencies were identified which makes an average of 3.8 courses per study.

Further analysis of generic information competences was based on those 128 courses in which they were found.

A. *Social science vs. Humanities*

When comparing the presence of courses with generic information competence in Social Sciences and in Humanities, we found that all 4 studies (100%) in Social Sciences have generic information competencies, and 21 (70%) out 30 studies in Humanities have courses that include generic information competencies.

Number of courses with generic information competencies in Social science was 31 (13%) out of a total of 236. Since one of studies in Social Science is Information and Communication Sciences we assumed that it will have more courses with generic information competences than other studies. Analysis confirmed that assumption showing that generic competencies were found in 16 (52%) courses in Information and Communication Sciences, which is more than all other 3 Social Sciences studies combined (pedagogy, psychology, sociology) where they were found in 15 (48%) courses.

Number of subjects with generic information competences in Humanities was 97 (6.4%) out of total number of 1506.

Distribution of total number of courses per study, number of course with generic information competences (GIC) and percentage of courses with generic information competences (GIC) of total number of courses in study is shown in Fig. 1.

[1] Graduate programs at Faculty of Humanities and Social Sciences, University of Zagreb. URL: http://www.ffzg.unizg.hr/programi/diplomski.html (20.12.2013)

[2] Anthropology, Archaeology, Art history, Comparative literature, Croatian studies, Czech language and literature, Dutch studies, English studies, Ethnology and cultural anthropology, French language and literature, German studies, Greek language and literature, History, Hungarian studies, Italian language and literature, studies of India-based languages, Latin language and literature, Linguistics, Philosophy, Phonetics, Polish language and literature, Portugal language and literature, Romanian language and literature, Russian language and literature, Slovak language and literature, South Slavic languages and literature, Spanish language and literature, Swedish language and culture, Ukrainian language and literature, Turkish studies.

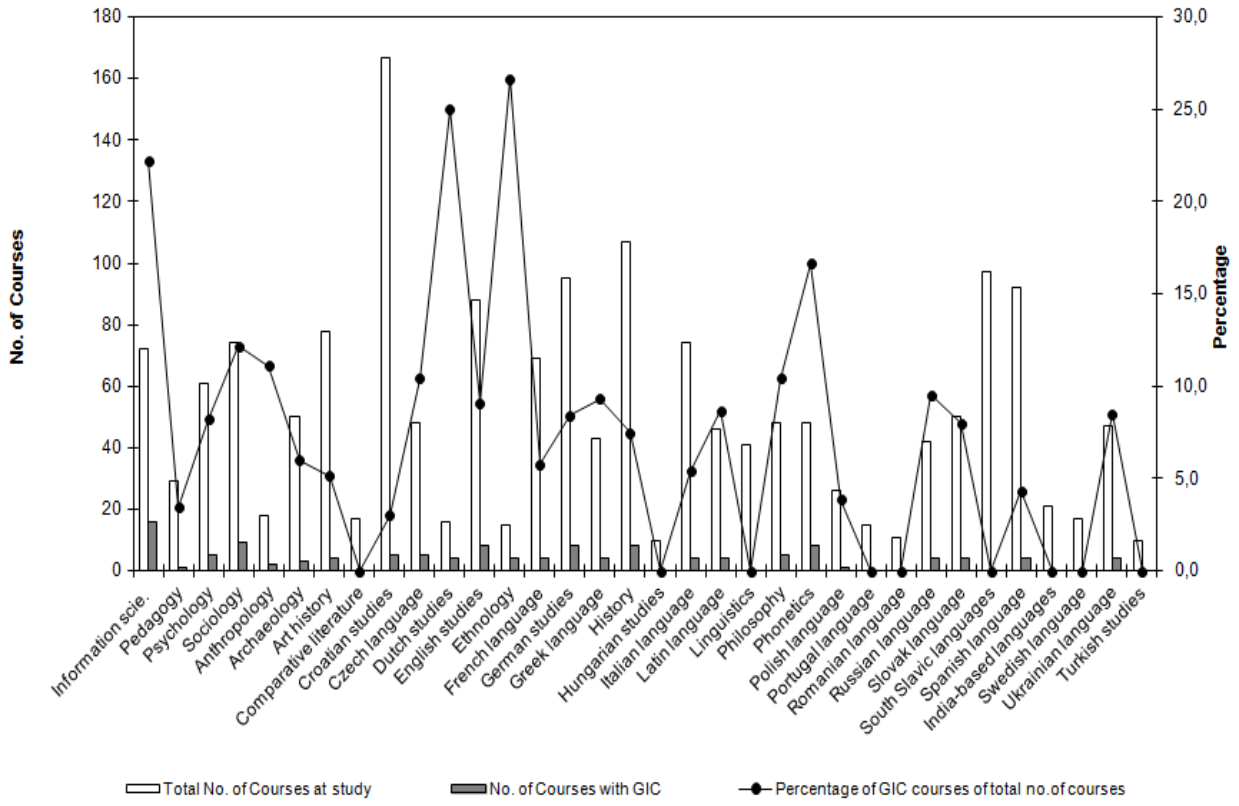

Figure 1. Distribution of courses with generic information compentences by studies

B. Mandatory vs. Elective Courses

Since all of the studies analyzed have mandatory and elective courses, it was important to further analyze the presence of generic competencies based on those criteria. If competencies are present in any of the mandatory courses we can say that all students from that study will be obliged to acquire them. Elective courses, however students can pick and chose, which means that students will adopt those competencies only if they chose to enroll in that course.

It was shown that only 9 studies have courses with generic information competencies in its mandatory curricula. Out of 9 studies 2 of them are Social science studies and 7 are Humanities studies.

TABLE I. DISTRIBUTION OF COURSES WITH GENERIC INFORMATION COMPENTENCES BY TYPE OF COURSE

Area	**Number of courses**				
	Mandatory courses		*Elective courses*		**Total**
		Teaching module		Teaching module	
Social sciences	14	2	11	4	**31**
Humanities	11	17	17	52	**97**
Total	**25**	**19**	**28**	**56**	**128**

Out of 128 courses with generic information competencies 44 (34.4%) courses are mandatory and 84 (65.6%) courses are elective courses (table 1).

Social sciences have 16 (52%) mandatory courses out of 31 courses with generic information competencies, and 15 (48%) elective courses. On average social sciences have 4 mandatory courses per study and 3.8 elective courses per study in which generic competencies were found. Most of the mandatory courses 11 (69%) are courses from Information and communication Sciences, while other 5 are all from Sociology.

Humanities have 11 (29%) mandatory courses out of 97 courses with generic information competencies, and 69 (71%) elective courses. On average Humanities have 0.9 mandatory courses per study and 2.3 elective courses per study in which generic competencies were found.

C. Teaching module

Each of 34 master studies can have they own specialization. For example English study has 4 specializations in graduate program: Literature and Culture, Linguistics, Translation and Teaching. Each student chooses only one specialization in order to achieve graduate degree. In all 34 master studies we found 80 different specializations across studies.

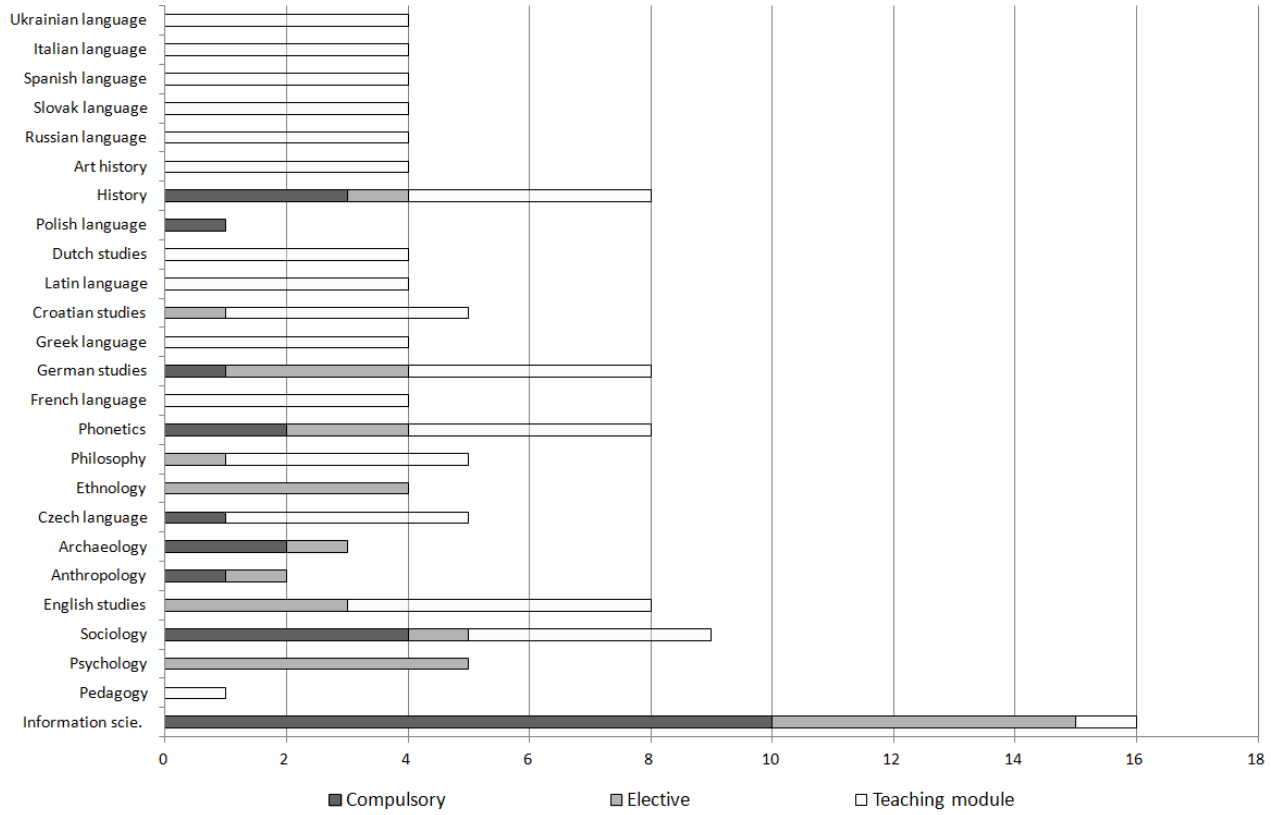

Figure 2. Distribution of courses with generic information compentences by type of course

Analyzing 128 courses with generic information competencies, we found that a big part of those courses (75 courses or 58.6%) belong to the teaching module. Only students interested in obtaining a teaching degree have to enroll in that module.

From 75 courses in teaching module only 19 (25.3%) are mandatory courses and 56 (74.7%) are elective courses. In social science 50% of courses in teaching module are mandatory courses. While in Humanities 25% of courses in teaching module are mandatory courses (Fig. 2).

Also, 11 studies offered courses with generic information competencies that are included only in teaching module: 1 (25%) in social science and 10 (33.3%) studies in humanities.

In we reexamine data from mandatory and elective courses by including courses from teaching module also into electives we can see that most of the courses with generic information competencies will be elective courses (Fig. 2). Out 128 courses with generic information competencies 25 (20%) courses are mandatory and 103 (80%) courses are elective courses i.e. elective courses and courses from teaching module. Social sciences have 14 (45%) mandatory courses out of 31 courses with generic information competencies, and 17 (55%) elective courses. Humanities have 11 (11%) mandatory courses out of 97 courses with generic information competencies, and 86 (89%) elective courses (Fig. 2).

IV. CONCLUSION

This paper provided an overview how information competencies are implemented across study programs on the masters' level at the Faculty of Humanities and Social Sciences at the University of Zagreb.

A total of 34 master study programs were analyzed with a total of 1752 courses. The results have shown that 9 study programs from the area of Humanities do not teach their students generic information competence, and only in 128 (7.3%) courses in total generic competencies were identified.

Analyzing 128 courses with generic information competencies, we found that a big part of those courses (75 courses or 58.6%) belong to the teaching module which only students interested in obtaining a teaching degree have to enroll in, an in addition only 19 (25.3%) of them are mandatory courses.

Lowden, et al. [12] argue that developing graduate employability skills and attributes should be included in HEIs' strategic and faculty/departmental level planning. Universities need to promote employability skills and attributes in their mission statements, learning and teaching strategies, course framework, strategic documents and practical guidance. The analysis has shown that most of the study programs rely on either elective courses or teaching module to teach information competencies to students, with the logical exception of Information and Communication Sciences study program. Being as it is means that a large majority of students will adopt those competencies only if they chose to enroll in

some of the elective courses offered at the faculty, but their study program mostly offers only "core", discipline related skills.

We can conclude that information competencies as a vital part of the employability skills aren't strategically incorporated at the Faculty level and that the implementation of information competencies is still not recognized as a vital part of the curricula being only sporadically present across different study programs.

Abstract - One of the main difficulties in Learning Management Systems (LMS) is how to maintain the balance between learning and management. The primary aim of LMSs was to assist educators to manage learning. As a result of this way of thinking, features such as managing content, roster students, and similar, mostly were promoted. As time goes by, the accent of research is more in student experiences and efficacy of the tools. On the other hand some educators argue that as a result of evolving Web 2.0 applications, students can be better served by an LMS alternative, a toolbox of web resources that could contain social bookmarking tools, document sharing applications, social networking applications, timeline tools, and media options offered in the cloud. Primary to this approach is the idea that students should become more experienced with today's technology tools since these skills will be practical in the workplace. As a result, some institutions have begun to offer LMS alternatives, and some teachers are using these options to support their students' learning.

The paper analyses both sides of the latest approach toward LMSs and presents their implications for teaching and learning.

I. INTRODUCTION

The use of computer technologies in teaching and learning started several decades ago at the dawn of the information revolution. Though in the beginning the role of computers for education was an object of discussion, in the 90's the explosive use of personal computers, and the World Wide Web placed computer-assisted teaching and learning at the center of the educational process.

This trend has initiated a rapid development of Learning Management Systems (LMS) – learning platforms with a set of teaching and learning tools designed to improve student's learning by including computers and Internet in the learning process. An LMS covers almost all aspects of managing a course, from administrative functions to course content delivery and assessment. Actually an LMS makes it possible to the teachers to develop and deliver course resources and activities in an online learning environment and in the meantime students can access course content and participate in online learning activities.

From the perspective of LMS deployment in Higher Education institutions, the following three approaches are identified: commercial, open source and in-house development. While a few commercial vendors have attained considerable market share, development of in-house software and open source software are significant trends in higher education. The trend of in-house and open source often lies in apparent inadequate functionality or pedagogic limitations of commercial offerings, despite platform functionality becoming increasingly customizable. At the same time many higher education institutions show interest to maintain institutional autonomy over the development of systems that are key tool in teaching and learning, especially as they can represent valuable intellectual property [8], [10], [12].

Presently multiple LMS solutions for higher education can be purchased from the commercial sources such as the Blackboard Corporation, the leading provider in the United States with more than 50 percent of the educational marketplace, or obtained from the open-source community without any licensing cost. At the same time, European countries rely more and more on free open-source learning management systems based on their commitment to knowledge as a community advantage which should be available to all regardless their economic status.

II. CURRENT TRENDS AND NEEDS

Currently, many higher education institutions have deployed some form of Learning Management System. But the problem is that LMSs usually have been acquired without a comprehensible plan for what they are aimed or how they would impact the learning experience. The initial wave of LMS implementation to a large extent was done locally, with many faculties and other entities within the higher education institution deploying different systems [1], [2], [15].

As e-Learning becomes a mainstream activity for most institutions and for some fundamental to their strategy, the importance and profile of the LMS has increased. However, the existing LMS practices present a significant experience in both technological and teaching aspects [3], [13]. These practices, among other things, show that it is the LMS experience itself that enables many of the users to distinguish the possibilities in the technology and to ask

more of an LMS, by what they become the key drivers towards the LMS change and enhancement. Hence one of the main concerns in the LMS deployment in an institution is to identify user requirements [14]. Based on these requirements, many evaluation and assessment criteria for such systems can be developed.

It is remarkable that with a relative maturity of the LMSs, as the latest report on LMS trends from Brandon Hall Group[1] suggests, almost half of the institutions that have some LMS deployment are trying to improve their LMS or to move from their previously acquired LMS to a new product (Fig.1).

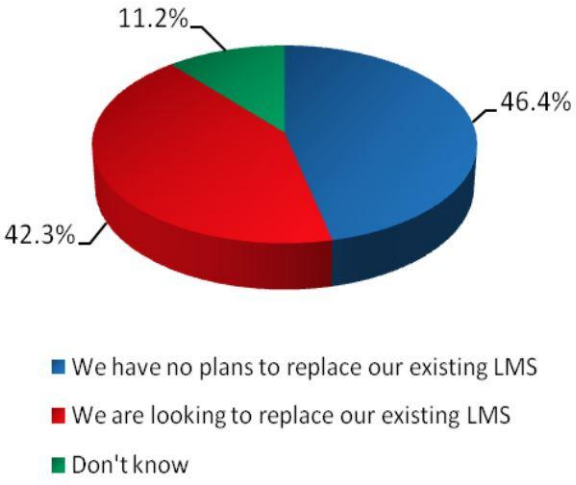

Figure 1. The percentage of institutions looking for a new LMS [7]

This approach is generally motivated either by an attempt to reduce the cost of licensing and maintaining the system or by dissatisfaction with the existing LMS. The dissatisfaction from the existing LMSs is mainly due to the lack of reporting features, difficultness of the system to use and poor support from the vendor. As shown in Fig.2 the requirements from the new LMS mainly include ease of use the system, robust reporting features and ability to integrate with other university software [7].

A recent trend in the LMS market is the rise of cloud-based LMS solutions that offer eLearning services in a distributed computing environment on the Web. There is one noteworthy case among them OpenClass, a cloud-based learning management system that educational publisher Pearson has offered for free as a joint venture with Google. An additional trendy cloud-based tendency in eLearning is the use of massive open online course (MOOC) offerings by either individual higher education institutions or 'consortium' platforms like Coursera [11]. The MOOC phenomenon could be placed within the framework of open educational resources movement focused on creation and distribution of free and open-source educational materials and supporting software [10].

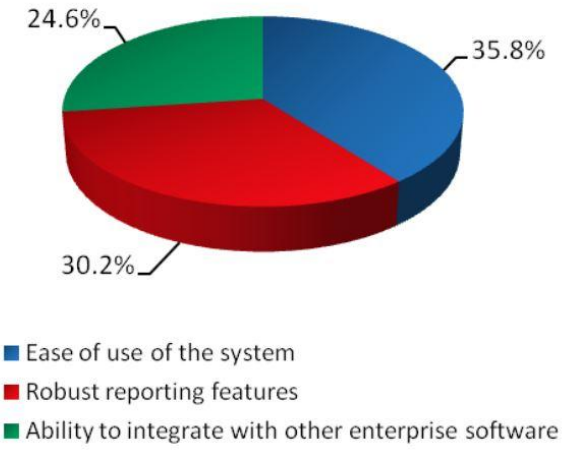

Figure 2. Top features for the new LMS [7]

With the advance of Web 2.0, contemporary LMSs moved towards integration with multiple Web 2.0 enhanced technologies such as Facebook, Twitter, visual and audio tools, and ePortfolio supporting software. Learning management systems also increasingly support mobile devices such as smart phones and iPad-like tablet devices.

III. WEB 2.0 IMPLICATIONS ON LMSS

Web 2.0 is principally accepted as a trend in the use of World Wide Web technology that aspires to increase creativity, information sharing, and particularly, collaboration among users. These concepts have led to the development and evolution of Web-based communities, such as social-networking sites, wikis, and blogs. One of the key principles here is the fact that users have the opportunity to add value and further harness collective knowledge. Consequently, the technology should be set in a manner so that it encourages this participation [6]. As far as the development of Web 2.0 applications is concerned, the following strategies are suggested [17]:

- Release early and release often. This statement of the open source development model is now a critical success factor for Internet-based software. It promotes the use iterative development methodologies to wrap up bug fixes and enhancements into incremental releases that respond to user feedback.
- Engage users as co-developers and real-time testers. The best way for assessing new product is through real-world user behavior. The nature of Web-based applications and the developers' possibility for active monitoring the software usage is a dramatic shift which gives the opportunity for more statistics and controlled experimentation used for informed product decisions.

[1] Brandon Hall Group is a preeminent research and analyst firm that provides world-class research, data and expertise in Learning & Development, Talent Management, Leadership Development, Talent Acquisition, and Human Resources.

- Instrument the product. In the development process, is important to plan and implement not only the customer-facing application but also a framework for capturing how the product is used. Usually, what users do inform more than what they say.
- Incrementally create new products. The product should change and evolve through frequent releases, user feedback and instrumentation.
- Use dynamic tools and languages. The development model would meet best the above mentioned strategies if the appropriately flexible development tools and languages are used. The use of platform-independent, dynamic languages will enable better adaptability to change, speed, and productivity.

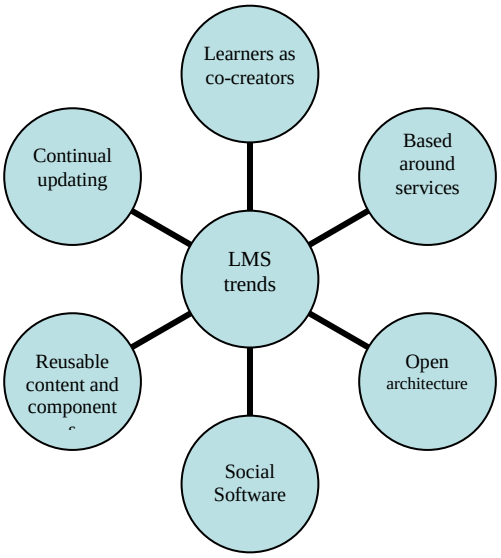

Figure 3. LMS trends

Based on the above mentioned Web 2.0 tendency, one could consider what the implications for e-Learning are and try to foresee the challenges for the future LMSs (Fig.3).

The primary challenge is how a LMS should be constructed and what are the technology aspects of LMS. Accordingly, there are two perspectives for the future LMS issue. On one side it is about the technological adjustments, and on the other side about the educational issues and how we approach and develop the modules for student use. So far the trend was on developing modules that meet the particular needs of a course or group of students. The accent nowadays is on developing modules that can be reused or joined in various ways. In order to achieve this, based on the above mentioned Web 2.0 strategies, new LMS modules initially should be available to certain group of users. And further on, based on its evaluation, the module is released for broader usage among all students [15]. In this manner the LMS develops into a medium for new technologies and good experience that can be dispersed across higher education institutions.

Although many of the Web 2.0 principles are in-line with open source approach towards LMSs, yet a future LMS can be a combination of open source with other existing in house systems in the institution [2],[19]. The key issue is that it is an open architecture, based on standards, and designed in a manner that can support the easy combination of modules mentioned above. Some of these modules may be open source and others in – house solutions. From their content point of view, many of these modules would be from the educational sector, but it is very possible that the future LMSs will incorporate other modules outside the educational sector such as Flickr or Google tools [18].

In context of Web 2.0's impact on educational experiences, the most important principle is that of the collective intelligence. It could be accomplished in many ways, but its main aim is to engage students as co-developers. An example of achieving this is by posting a certain course content on a blog or a wiki and giving the students the opportunity to comment, modify the course content, create shared bookmarks, etc.

Another issue, which is natural in the Web 2.0 mode of functioning, is reuse. It can be approached from two points of view regarding LMSs. On one hand reuse is important in terms of application with meaning reuse of tools and various components. On the other hand reuse can be applied to content as well. For instance, there are many learning object repositories and open content initiatives which aim to promote reuse.

IV. LMS ALTERNATIVES (ADVANTAGES AND WEAKNESSES)

Another interesting impact of the web 2.0 is in finding alternative applications for the traditional LMSs. Actually, some teachers argue that because of evolving Web 2.0 applications, students can be better served by an LMS alternative, a toolbox of web resources that might include social bookmarking tools, document sharing applications, social networking sites, timeline tools, and media options available in the cloud [4],[9].

Fundamental to this approach is the idea that students should become more familiar with contemporary technology tools because these skills will be crucial for them in the workplace. As a result, some higher education institutions have begun to offer LMS alternatives, and some teachers are using this choice to support their students' learning. The framework of an LMS alternative may offer the user a coordinating center with a dashboard or other interface that gives easy access to selected web-based tools according to course and project requirements.

LMS alternatives cover a wide range of tools and functions. One option might be a complex system built in-house at a higher education institution, designed to perform many of the functions of a traditional LMS while giving access to outside applications. Another one might be a mash up of web applications collected by an individual teacher and hosted from a blog platform or a social networking site.

The tools that faculty members select as LMS alternatives usually are free, easy to learn and use, and robust enough to support students learning without any difficulties. Ideally, the LMS alternative might integrate with applications already in use in the institution. In such a design, students could select from among the offered applications to complete their assignments.

The reason for seeking LMS alternatives is also the lack of the services from the traditional LMSs. In this sense, any faculty or higher education institution that supports blogging or uses a collaboration tool like Google Drive in a way is employing an LMS alternative.

The tools obtainable in the cloud offer students various advantages over those in the traditional LMS since web tools are designed to be used easily. The students can learn them rapidly, use them for multiple projects, and share them among their peers. Furthermore, the variety of the tools available makes it possible for teachers and students to choose the tool that best fits a learning exercise.

The weakness of the LMS alternative is that it is a time consuming process for the teachers and the students to evaluate new tools and match them with appropriate assignments or projects. The LMS control is not in the institution and this fact raises concerns about interruptions of service, the security of data and personal information, and the effect on an institution's reputation that could result from a security break.

From another point of view, the LMS is also a tool that makes it possible to monitor the course delivery and to generate various reports on the course content and teachers/student performance [20]. With LMS alternatives the institutions are limited and out of the course schema of a certain course. Also, institutions have little or no option if the alternatives are poorly maintained, shut down for repairs, or ceases to exist. In addition, any alternative LMS could raise issues about a lack of technical support, a lack of faculty support, an increasingly fragmented student learning environment.

However, regardless the drawbacks of the LMS alternatives, they have a positive impact on the teaching and learning process [6]. Actually the use of LMS alternatives encourages teachers and students to perceive learning as an evolutionary process where effective tools are emerging constantly. Such an environment prompts learners to become familiar with a variety of tools rather than any specific one [19]. At the same time, if teachers start adopting tools outside the LMS it may induce institutions to take a new better look to the LMS service they offer. In this manner, the institution may discover the advantages in providing access to a wide variety of tools that enable strong support for teaching and learning.

The use of LMS alternatives may hold the promise of a more student-centric approach, one that encourages students to reach across the limitations of academic terms and learning disciplines and to see their education as a coherent process that they can maintain using a range of applications. By going outside the LMS to use tools that provide more space for student engagement, more effective collaboration, and more active learning in general, teachers could establish new expectations for the LMS. While some of the features they seek from the Web 2.0 world might never make it into the teaching tool's collection of most of the teachers, they may still help push the LMS to its next iteration.

V. CONLUSION

The great interest for original pedagogical-educational practices is a reaction to the community needs for educational change. Such needs come out as a result of the huge request and massification in to higher education, the need to raise competitiveness, mainly through the raise of the human potential and the necessity to take into account new approaches to learning.

These original innovative practices in education presently are mainly available through e-Learning and the most pervasive e-Leaning tools in higher education currently are the Learning Management Systems. LMS have been present for about two decades in higher education. In spite of this they are still changing and evolving due to the technological advancements as well as the change in approaches towards teaching and learning in higher education institutions.

The latest reports show that LMSs have their common role, where a few standard features for supporting teaching and learning are still the most used features [5]. In parallel with their common usage there is a line of new trendy features present in current LMSs. These trendy features are usually blogs, wikis, and similar social and connective Websites that facilitate elements to uncover and share new information.

Among the important challenges to LMSs mentioned by researchers, is a necessity to include constructivist instructional design methods and pedagogy, particularly emphasizing active and shared learning and personalized attention to all students.

The ability of modern LMSs to integrate multimedia and Web 2.0 tools made a significant impact on instructional design and teaching practice. In particular, Web 2.0 applications may be used to enhance student interaction and collaboration. Simulations and serious games are also finding their way into eLearning environment. Finally, a LMS must be adapted by using technologies in order to merge teaching, research, IT, the changing environment, as well the financial accountability and managerial models.

Faculty of Humanities and Social Sciences
University of Zagreb
kpavlina@ffzg.hr

Abstract - Modern society is characterized by an increasing complexity of tasks which require broad general knowledge and on the other hand a narrow specialization. Because of these conflicting principles modern education recognized the need for development of generic competences on the one hand, and information competences that match the modern information society on the other. In addition to education, which has recognized the need to develop generic and information competences, employers also pay great attention to these competences while hiring. In modern information society information competences become one of the fundamental basis for the development of other generic competences. Information and generic competences are directly linked because information is a fundamental element of learning which is based on the collection, organization, search and interpretation of acquired information. Development of modern information environment is characterized by growing complexity in quantitative and qualitative terms that require additional research of information competences required for the transition from the tertiary education sector to the labour market. This paper presents a survey of students' attitudes about the development of information competences during the study and their opinions about necessary information competences for their future professional careers.

I. INTRODUCTION

Contemporary understanding of information literacy is observed within two complementary directions; a list of competencies and a sociotechnological phenomenon [1]. Information literate people are those who possesses competences to effectively find and use the necessary information [2] and these competencies should be developed in spite of the development of technology [3]. Information literate people are "... those who have learned how to learn. They know how to learn because they know how knowledge is organized, how to find information, and how to use information in such a way that others can learn from them. They are people prepared for lifelong learning, because they can always find the information needed for any task or decision at hand. To be information literate, a person must be able to recognize when information is needed and have the ability to locate, evaluate, and use effectively the needed information" [4]. Doyle [5] complements this definition by integrating new found information into an existing corpus of human knowledge in order to create critical thinking.

Sociotechnological phenomenon rests on the impact of social and technical development. The information literate person adapts to social change by aligning personal goals with economic, social and technological changes [6], [7]. Technical innovations brought by development of information and communication technology greatly improved information searching for appropriate information [8]. Shapiro and Hughes [9] describe information literacy as the new liberal art because of the synergy of using a computer for the purpose of finding the appropriate information that is then critically evaluated from the perspective of their own cultural, philosophical, social and technical context .

Information literacy follows sociotechnological development of society and is seen as a foundation that brings together other kinds of literacy; basic literacy, library literacy, technological literacy, media literacy and visual literacy [10]. The increasing influence of technology leads to strengthening links between information literacy and other digital literacies. Mishra and Mishra [11] argue that information literacy unites seven different types of literacy characteristic for 21st century; media, computing, networking, digital, science, visual and critical literacy. Media literacy is the kind of literacy which aims to communicate messages structured into appropriate format (audio, visual, textual) [12]. Computer literacy refers to the knowledge of IT infrastructure visible in the proper use of hardware and software, while network literacy enables use of World Wide Web [11]. Bawden [13] observes digital literacy in terms of understanding of hypertext, which includes understanding of the text, images and sounds in online environment or in digital format. He gives great importance to critical thinking and forming informed attitude towards found information. Showalter (paraphrased in [14]) thinks that scientifically literate individual possesses the scientific knowledge which is evident in knowledge and application of scientific theories, laws and principles in solving problems which is aided by the use of technology. On that basis scientifically literate individual is able to create a general knowledge that characterize scientific experts [15]. Visual literacy is a kind of literacy which refers to the use of images and visual objects with the intention of conveying information to others, but also receiving and interpreting visual information transmitted by other people [16]. Critical literacy involves deeper reflection based on the analytical skills of writing, reading and speaking on the basis of which it develops critical thinking [17].

SCONUL 's model of information literacy in higher education [18], [19] is intended for students from undergraduate to postgraduate research level. This model covers three academic levels of study (undergraduate, graduate and postgraduate), starting from the lowest levels of the undergraduate program where students are taught fundamental library skills. The foundation is identifying information need and knowledge of the different types of printed and digital resources to be able to choose the resource that best suits requested information query. ICT skills in this model are required to be able to find information, compare information from different sources, organize and synthesize information with intention of creating new knowledge. At the level postgraduate study, students should possess skills in all seven pillars of information literacy.

Because of such understanding information literacy has become basic literacy for 21st century that unites the seven different types of literacy. Modern educational process in higher education should harmoniously complement these types of literacy for contemporary flows of information and communication age. Higher education should develop all these types of literacy because they are fundamental competences expected for professional work in contemporary world.

II. METHODOLOGY

The research was conducted by survey on students of Faculty of Humanities and Social Sciences at University of Zagreb. Respondents were asked to rate the level to which certain information competences are developed during their studies at university and how important are certain information competencies for future work in their profession. The development of information competence is measured on a scale from 1 (not developed) to 5 (maximum development) and the importance for future work in their field was rated on a scale from 1 (not important) to 5 (most important). This research used a list of information competences defined by Australian and New Zealand Information Literacy Framework [20]. A questionnaire was filled out by 128 respondents using Google Forms service. The sample by gender comprised of 96 females (75%) and 32 males (25%). One of the goals of this research was to investigate the attitudes of more experienced students about the importance of certain information competences. So 20 students were on 3rd year of undergraduate study (16%), 40 students were 1st year of graduate study (31%) and 68 students 2nd year of graduate study (53%). Research also aimed to investigate possible differences in the attitudes of information professionals and general population, so sample included 54 students in information science and 74 students of other studies on Faculty of Humanities and Social Sciences.

III. RESULTS

The results in Table I. show that students highly valued importance of information competencies for their future professional work (4.11). It is interesting to note that at the same time they hold that during their study their information competencies were moderately developed (3.33).

TABLE I. SOURCES OF INITIAL INTRODUCTION TO OPEN SOURCE SOFTWARE

Source	Developed	Importance
1.1. Define and articulate the information need	3.33	4.14
1.2. Understands the purpose, scope and appropriateness of a variety of information sources	3.45	4.17
1.3. Re-evaluate the nature and extent of the information need	3.36	4.06
1.4. Use diverse sources of information to inform decisions	3.41	4.25
2.1. Select the most appropriate methods or tools for finding information	3.25	4.19
2.2. Construct and implement effective search strategies	3.16	4.19
2.3. Obtain information using appropriate methods	3.39	4.14
2.4. Keep up to date with information sources, information technologies, information access tools and investigative methods	2.73	4.17
3.1. Assess the usefulness and relevance of the information obtained	3.63	4.47
3.2. Define and apply criteria for evaluating information	3.33	4.11
3.3. reflects on the information seeking process and revises search strategies as necessary	3.13	3.86
4.1. records information and its sources	3.56	3.86
4.2. organises (orders/classifies/stores) information	3.36	4.14
5.1. compares and integrates new understandings with prior knowledge to determine the value added, contradictions, or other unique characteristics of the information	3.38	4.06
5.2. communicate knowledge and new understandings effectively	3.52	4.42
6.1. acknowledge cultural, ethical, and socioeconomic issues related to access to, and use of, information	3.20	3.94
6.2. recognises that information is underpinned by values and beliefs	3.30	3.88
6.3. conforms with conventions and etiquette related to access to, and use of, information	3.67	4.13
6.4. legally obtains, stores, and disseminates text, data, images, or sounds	3.08	3.91
AVERAGE	3.33	4.11

Students of information science evaluated the importance of information competencies almost the same (average grade 4.11) as other students (4.12) . Larger difference is visible at a level of development of information competence at university, where students of information science, as expected, assess the development with higher average grade of 3.47, while other students assess the development with an average score of 3.22. It is interesting to notice the difference in the assessment of the most important information competencies for future work. Students of information science as the most important

competency evaluated *3.1. Assess the usefulness and relevance of the information obtained* (4.44), the other students also highly valued this competence (4.49), and they rank it second. Second most important competence by information science students is *4.2. Organises (orders/classifies/stores) information* (4.41). Unlike information science students, other students evaluated this competence with average importance of 3.95, so it ended up ranked in 17th place. The third most important competence by students of information science was *1.4. Use diverse sources of information to inform decisions* (4.37), other students ranked importance of this competence for future work on 9th place with average grade 4.16.

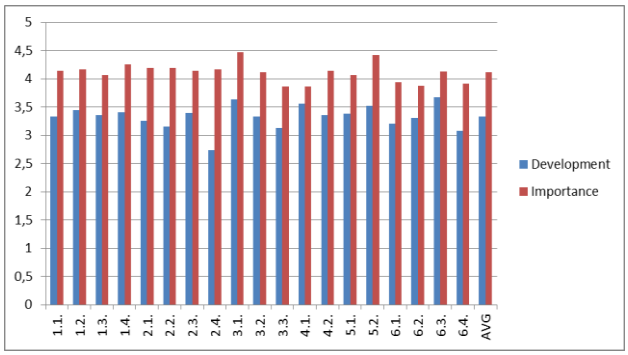

Figure 1. Development and importance of information competences

The results in Figure 1. show that as best information competency developed during the study, students assessed *6.3. Conforms with conventions and etiquette related to access to, and use of, information* (3.67). It is followed by competence *3.1. Assess the usefulness and relevance of the information obtained* (3.63) which is interesting to point out that students perceived it as the most important competency for future work. Although it is one of the most developed competence it can be noted that there is a big difference in the level of development of competence during the study and expressed importance of future work in the profession (0.84). Third best developed competence is *4.1. Records information and its sources* (3.56) in which students also expressed the slightest difference in importance for future work and development during the study (0.30).

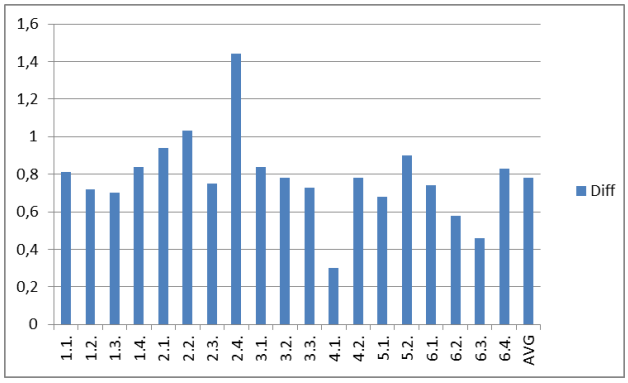

Figure 2. Difference between develoment and importance of information competences

The biggest difference between the importance for future work and development during study was detected at competence *2.4. Keep up to date with information sources, information technologies, information access tools and investigative methods* (1.44), where it can be concluded that teachers should take a greater effort to track with the development of information resources, technologies, tools and methods (see Figure 2.).

IV. CONCLUSION

The results of this research show that students attribute high importance to information competencies for their future professional work. It is necessary to improve the curricula contents that develop information competences, because there is a significant difference between the perceived level of importance of information competencies for future professional work (4.11) and the extent to which they are developed during the study (3.33). Curricula should regularly be updated in order to track the development of information technology, resources and search method, and thus enable quality education for future professional work.

Abstract - The research study investigates the development approach and analyses of m-learning course management system developed as case study. The contribution of the research study is the analyses of the task based instructional strategy and conceptual definition of the assessment methods regarding the level of mobile learning outcomes while assessing different software engineering aspects of development mobile application for Windows phone 8. The analysis also covers the development with primary focus on mobile learning using ASP.NET MVC 5 technology, and design issues for responsive techniques. Finally insights are stated, results of the analyses are provided and recommendations and discussions of the approach are described.

I. INTRODUCTION

Because the constant changing of the technologies, how the learners learn and interact, their demands are constantly growing for different types of learning materials [2], [3]. For example we might say that a professor has shared youtube.com video URL and the professor demands of the student to know the context of the particular video. The older management system did not allow the users to share easily video URL's [9]. Then the students had to copy the link and transfer it to a web browser, and the content can be easily accessed by a single click, and be opened by a mobile browser quickly and from anywhere at any time.

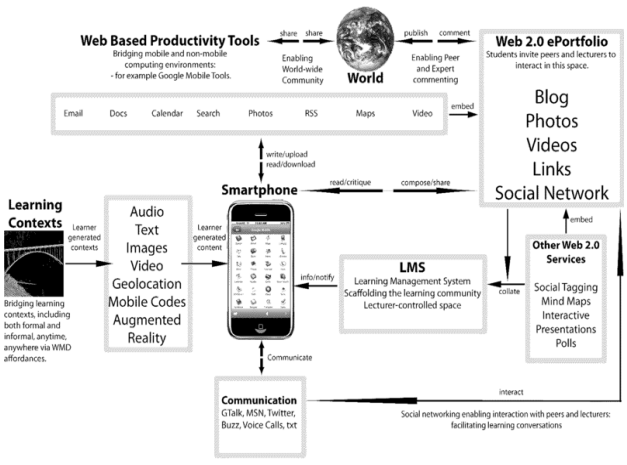

Figure 1. Mobile Web 2.0 Concept Map[2]

This interoperability has inflicted the need to create new and improved learning systems, that not only could assist the learning of contents but also speed up the process of interaction, allow different ways of conducting it, and allow for it to be accessed literally from any device or any place.

II. ANALYSES OF M-LEARNING PROJECTS AND TRENDS

An example of mobile learning system called GoLearn from the initial Merrill Lynch pilot is given by ADL Mobile Learning Team [9]. Standards for delivery on the BlackBerry were established in design, technology, security and privacy. The goals of the pilot included proving the access, usage and the effectiveness of learning delivered via the BlackBerry to the global population. Additionally they sought to:

- Deliver training with no degradation to learning effectiveness
- Achieve 25% of eligible participation
- Achieve a comparable average score to the control groups, and
- Obtain a 10% higher completion rate in 10% less time

Over a seven-week period, the learning materials were wirelessly pushed to over 2,100 investment bankers and select support staff.

The outcomes exceeded the goals. Higher scores were obtained in half the time. Bankers who completed the training did so in 54 less minutes and tested higher on the final assessment tests than the remainder of the firm. Mobile users also completed their training twenty days earlier than those who trained via MLU.

According to [8] VPs and higher leveraged the mobile materials the most. Of the 2100 eligible employees, 61% launched the content at least once. 317 people completed 704 courses. Overall the mobile learners obtained a 12% higher completion rate in 30% less time than the control group.

170 employees responded to a survey indicating:

- 99% felt the format and presentation supported the learning
- 100% would complete more training in this format

• More than 75% praised the benefits of convenience, time management and training with no distractions

With this successful pilot, Merrill Lynch moved into the next phase with additional training topics such as onboarding for new hires, ethical decisionmaking, performance management, market abuse, and sexual harassment.

According to [4] there is an increasing number of colleges and universities who are adopting mobile wireless technologies as teaching and learning tools. More than 90% of public universities and 80% of private universities in the US have some level of mobile wireless technologies, such as mobile wireless devices and networks.

According to [4] Task based learning as instructional strategy has been shown as the most appropriate for mobile learning compared with inquiry, project and problem based learning. The user filling the 4 task defined each semester week out of 15 weeks is guided and not left alone but instructed and forced to work regularly and in exact time periods.

An important advantage of the handheld computer and mobile devices in general is that can be accessed from anywhere at any certain time, providing learning resources to be articulated in the learning and other actions [4]. There are advantages in using a mobile device offering individual, private and learning at own pace and learning within specific contexts which can provide 'reliable cultural and environmental indications for understanding the uses of information which may enhance encoding and recall and enable learners to access relevant information when and where it is needed'. The learners and institutions that consume m-learning systems because of the changing dynamics and can benefit from it.

III. RESEARCH METHODOLOGY

The study focused on fundamental research on m-learning, curent projects and trends, exploratory research regarding the conceptual design and afterwards action research to buidl a software solution to test the insights gained from previous phase. In order to evaluate the results the solution was evaluated from different participants. Participants were students, teaching and administrative staff of the Contemporary Sciences and Technolgies Faculty of the South East European University.

IV. CONCEPTUAL DESIGN

The main purpose of the web application is to provide learning system to students, professors and educational institutions with option to be accessed fryom anywhere at any time. In this regards the web application is available for any internet capable device such as mobile phone devices, mobile touch devices (tablets and slates) and television sets with internet connection through a browser. This application at this first version primarily focuses on knowledge assessment for students with given administration rights to the professors folowing the guidelines from [11].

The M- Learning aspect of this application gives it a huge importance in today's dynamic world where distance learning and constant connectivity to internet are a regular state. On the other side the usa ge of the ASP.NET MVC 5 framework gives it a huge advantage because it is the latest technology and the easiest framework available to maintain in regards of updating the business logic or the design.

Primarily the idea was to make just a quiz generating application, but during the research study process we realized that what this world lacks of is more learning assessment systems based on mobile learning and using latest and best technologies. Learning assessment systems now are hugely needed not only to evaluate the knowledge of the final user, but also to specify the direction in which the learning process should go and declare where the final user did not pay attention.

This application also has a big advantage in the aspect of scalability, and for development, testing and presentational purposes, will be hosted on the Cloud, a cloud hosted by Microsoft called Windows Azure [13].

In essence the main research questions is: "how to develop a good and easily changeable and maintainable m-learning web application accessible from any device?"

Below is given the Activity diagram in which are represented the activities in a general form for the web application. Represented is the flow of the application. At first the client needs to access the website where he has only access to data that is available to all users. If he wishes to interact with the web application he needs to verify his credentials. He sends his credentials information's to the ASP.NET identity membership provider [10]. He is then verified by the application using the Azure MS SQL Server.

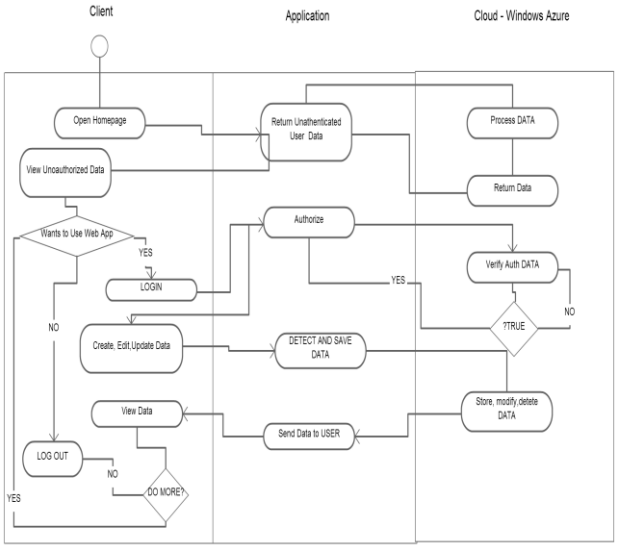

Figure 2. Activity diagram of the developed solution

If the user gets verified correctly he has access to the web application. If the user wishes to interact with the application, according to his role in the system the user gets different options. In general the user can create, edit and update data on the web application. For example, if the user has a role of administrator he has access to every

functionality of the web application except for solving quizzes which is a functionality of the web application only accessible to users with the role student [1].

The data is stored on Microsoft SQL Server on Windows Azure Cloud [5], [6], [7], [10], [12]. When the user is finished, if he wants to delete his session, cookies and exit the application he can easily log out.

On figure below is shown the sequence diagram for an example scenario when an administrator is creating a course. Here we have four objects which literally present the Model View Controller software architecture [13]. When the user first demands a website resource he is firstly encountered in the background of http process with the routing rules of the application. In MVC the paths, URL's or routes are defined in the routing module [12]. The application decides where it will send the request to, to which controller it will be directing the user. The controller gets the data from the model which takes the data from within itself connecting to the database and applies its methods and presents the data to the end user using the view [5].

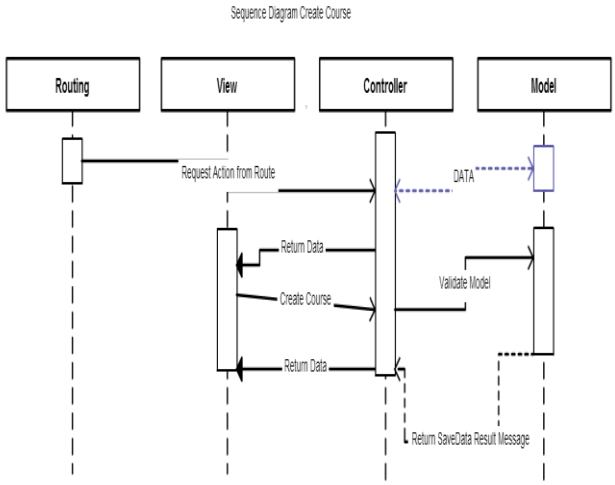

Figure 3. Sequence diagram of the developed solution

Created the following classes: Course, Enroll, Quiz, Question, Answer, StudentQuizTake and studentAnswers. We are using these classes in order to organize my web application in a way that the system has courses which have students enrolled.

In each course created quizzes with questions and answers. Afterwards when the student goes's to solve a quiz he creates a new instance of the StudentQuizTake class as an object.

The user fills the StudentAnswers class with his answers to the appropriate questions in the quiz. In order to differentiate users from one another will be using the new ASP.NET identity membership provider.

The ASP.NET identity uses the following classes: UserRole class, ExternalLogin class, LoginViewModel class, User class, UserSecret class, RegisterViewModel class, Role class, UserLogin class and ManageUserViewModel class.

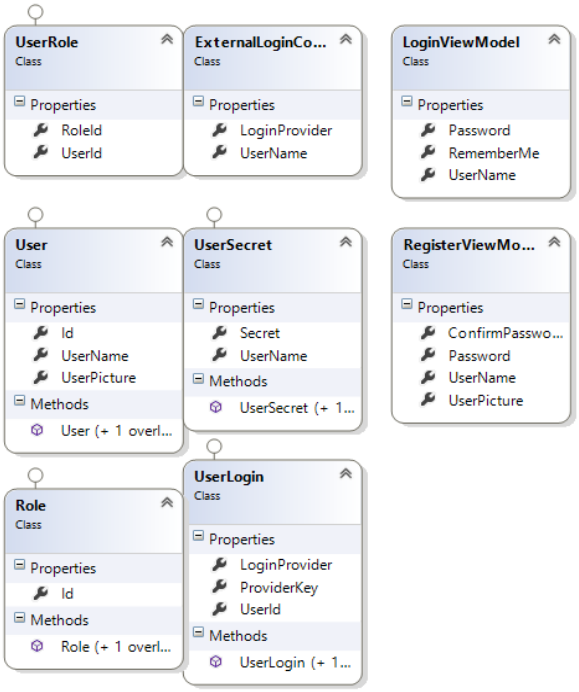

Figure 4. Class diagram identity

V. Development Aspects and Approach

The name of the developed solution is Prof Sys Engine, and it is developed in ASP.NET MVC 5.

We have used Microsoft Visual Studio Ultimate 2013 Preview, .NET Framework 4.5 folowing the guideliness from [11] and [13] .

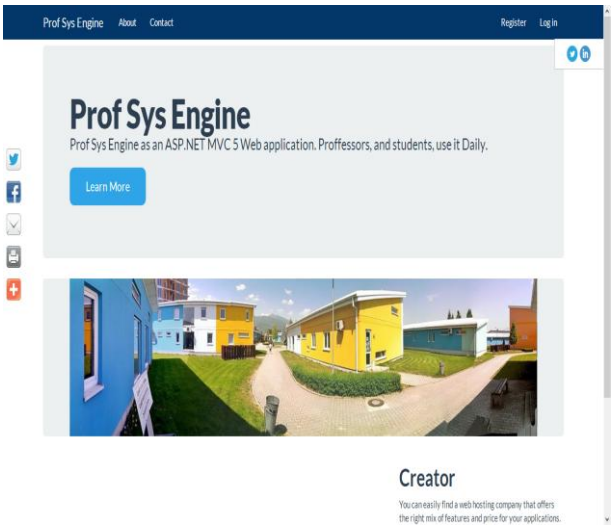

Figure 5. The screenshot of the developed solution

According to [13] Microsoft defines the ASP.NET MVC framework as follows: The Model-View-Controller (MVC) architectural pattern separates an application into three main components: the model, the view, and the controller. The ASP.NET MVC framework provides an alternative to the ASP.NET Web Forms pattern for creating Web applications. The ASP.NET MVC

framework is a lightweight, highly testable presentation framework that (as with Web Forms-based applications) is integrated with existing ASP.NET features, such as master pages and membership-based authentication. The MVC framework is defined in the System.Web.Mvc assembly.

The developed solution is a cloud application; it is being hosted on Windows Azure Cloud platform by Microsoft. It is using a SQL Server on the cloud. This feature of the web application gives it enormous advantage because it is scalable, flexible and cost friendly. In one in a million case it could happen that the page in its first month of being published online to get thousands of users. Having the web application on the cloud allows me to scale the servers up and get new processors for serving the website, expand database space or the other way around.

Another of its best features is that the security of the application is being provided by a cloud service. Also if the server fails the cloud system transfers the applications to another server and in seconds time it is up.

In order to differentiate the web application users we have created a filter that is used just as an attribute in a declaration of controller classes. The code for the authorization filter follows:

```
namespace Mvc5website1.Filters
{
   [AttributeUsage(AttributeTargets.Class |
AttributeTargets.Method)]
   public class AuthorizeRedirection : AuthorizeAttribute
   {
      private const string IS_AUTHORIZED =
"isAuthorized";
      public string RedirectUrl =
"~/Error/UnauthorizedUser";
      protected override bool
AuthorizeCore(System.Web.HttpContextBase
httpContext)
```

This filter allows us to easily restrict access or allow access to a particular role in the controllers. So just by using "[AuthorizeRedirection(Roles = "student")]" The code communicates with the ASP.NET MVC Framework that will only allow access to the particular action or controller to the users which have a role of "student".

Also listed all of these classes in the DbContext class called MyDbContext. The DbContext class is used by Entity Framework to reference the already declared classes in the project, in order to allow Entity Framework to understand what the developer wants its business logic/ model work like. Upon starting the application, if the DbContext classes in instantiated the referenced classes or DbSet's in DbContext are created as entities in a database which connection string have declared in Web.config.

Entity Framework analyses the defined classes and looks at the data types, the relationships declared between the class properties of different classes. If the class contains Data Annotations, Entity Framework uses them to constraint the values, define foreign keys or just change the display name [12].

We have enabled Entity Framework Migrations in the web application project. With the enabling of Entity Framework Migrations allowed automatic migrations, and allowed Entity Framework to update the database model automatically based on the changes made in the classes declared as DbSet's in my DbContext class. So in the case when wanted to add user pictures to the user class and save that information to the database Entity Framework upon calling detects the changes in the model and applies the changes to the database.

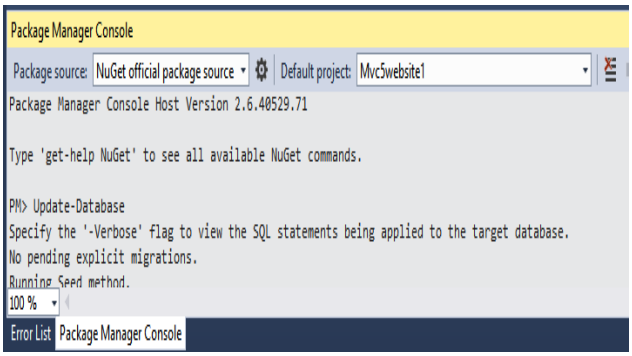

Figure 6. Database migration

The "Update-Database" shown in figure above tries to detect the changes in the model and finds out there is no pending explicit migrations, and finally executes the Seed method. Created a Seed method that populates the database with startup users end roles as seen in the use case diagram there are three user roles and those are administrator, professor and student. For each role assigned one startup user.

On the screenshot below is shown the management panel where the administrator of the web application can change the roles of the users registered to the web application.

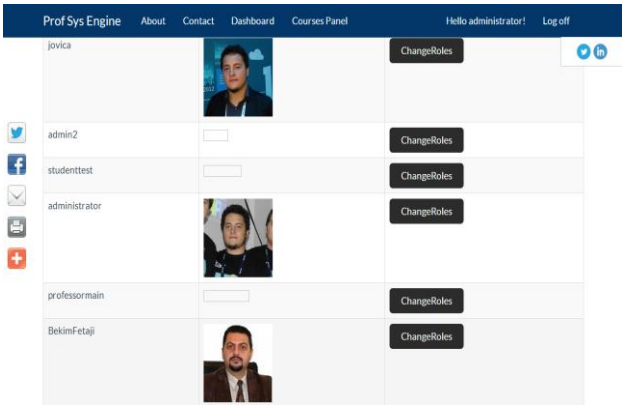

Figure 7. Administrator options available

The following screenshot displays the view for creation of a course. Only the administrator has the right to create courses. Also only he has the privilege to edit or delete them. Professors who are owners of a course, can only edit the information about the course they own, and if they try to change a course that they do not own, the

Course Controller in the web application will redirect them to an error “Unauthorized”.

Only the administrator has the right to delete a Course from the web application.

Upon Creating a Quiz, the Professor or Administrator will declare the duration of the Quiz. So if a Quiz is declared by the professor with 20 minute mark, the student will only get results for the answers he gave in that period.

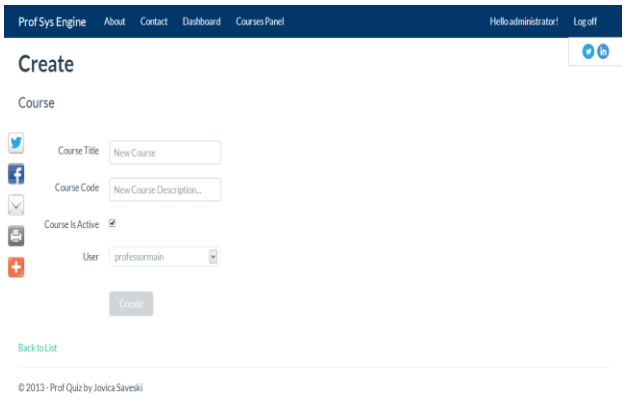

Figure 8. Course creation functionality

The only place, that only a student has access to, it is the student controller which is used to display his quiz data and direct the user to solve the quiz. When a student starts to solve a quiz this system notes the time when the user has started solving the quiz. In the meantime for each answers submissions the application stores the student’s answers. After the student finishes the quiz, the result is given to him.

VI. NATIVE MOBILE CLIENT ON WINDOWS PHONE 8

The project also includes a native mobile client on Windows Phone 8. This native mobile application gives the user who in this case is the student the options to check in the system in which courses he is currently enrolled in, the option to view the quizzes that he needs to solve (he has not solved them yet) and view the names of the quizzes he has already solved. In the case if the user decides to solve another quiz or just visit the web application he can use the button to go to the web application, in which case he is transferred to default browser.

Used a Microsoft HTTP client libraries in order to bring the common functionality of the HttpClient class.

```
c1 = new HttpClient();
c1.BaseAddress = new Uri("{URL}/api1/");
```

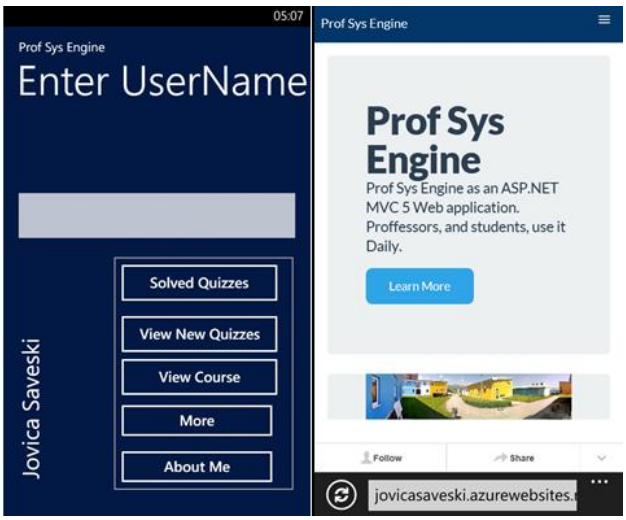

Figure 9. Native mobile aplication for Windows Phone 8

VII. TESTING

In order to check if the existing and planned functionality of the application is all right, conducted tests on four kinds of display.

First and foremost tested the functionality, usability and design on a Windows 8 (15” display monitor). Afterwards tested it on a 10” android tablet. After summarizing the results of the previous two devices conducted another two tests. One on a 4” Windows phone HTC 8s and finally tested the application on a 42 display using a television set.

The results were satisfying in the means of that in every device the user could access the needed data, functionality and resources. The front end of the web application was equally responsive to the display size and type on every devise.

Engaged and had the help of 10 collaborating testers, who tested the web application and gave me feedback. All of the feedback that was received was positive, and helpful. The beta testers during the time of testing and feedback giving gave advice on some other features that might be implemented in the future.

They successfully managed to access to web application, also it was easy for them to create courses and manage them. They used the panels to create quizzes, and even made a small competition among them taking the quiz.

Five advanced users were among the beta testers which had some kind of knowledge of the process of creating applications. And five of them were regular users which interests were not developing applications, but using it for their own needs and for sharing an expanding the knowledge among people.

Different beta testers got different users roles, some of them were students, some of them were professors and some were administrators.

VIII. CONLUSION

For the research study and project used ASP.NET MVC 5 and although at the time it is a very new framework it has flawlessly worked during the creation, testing debugging and publishing the project. The web application works in the defined parameters and specs and is equally functional and tested its responsive on a Windows 8 laptop (Asus k52jt), on Android Tablet (10" Quart QP1070), and on HTC 8s Windows Phone (4" mobile phone).

The web application after the testing is evaluated a useful to the students as it is for the professors; it allows interaction between the standing parties. The best feature of the web application is that it is available equally among all capable devices. It saves the precious time of the professors, giving immediate results to the student, without the need for the professor to check each and every one of the quiz takes, if the professor needed to check all of the quiz results by hand. That is another advantage, if the student base expands, the professors cannot manually manage the learning assessment in the same time as they did before.

A great feature is that it can be easily changed, in a way that the market demands. The web application can easily be upgraded to become a big learning management system, with features like no other. Feedback from users can quickly be heard and implemented, thanks to the MVC software architecture pattern.

In the future we can implement a fully grown API, for all kinds of developers, and make it more available to even more devices, such as Raspberry PI, Windows Kinect, and even an electronic news feeder tool.

If this web application is implemented in another institution, it can quickly adapt it to its needs. For example if this web application is implemented as an assistance tool for conferences guests' lottery, we can add this functionality fast using Entity Framework Migrations.

For the future work intended is to add more common functionality, such as course based real time chat, messaging, file sharing, library and wiki panel.

Abstract - As contribution the research study as outcome developed a software application and programmed several new recognition gestures and presented a set of tools supporting the spectrum of software engineering natural user interfaces to be used in University promotion and marketing. This research study tries to foster several contributions. Firstly, this system is built on basis of separate library used for the gesture recognition part of the application, which can also work separately from the system and can be used in different contexts. It is very extendable and allows the users to implement new gestures on top of the library, thus enriching its context and provides easy start for the user allowing him to concentrate to the business logic instead of the low level programming of the gesture recognition algorithms. Secondly, in addition to the basic gestures, created are several other gestures that add additional value to the library itself. New gestures that are added to the library are DownSwipe, UpSwipe, ClockwiseCircle, CounterClockwiseCircle, Push gestures, ManualDoorOpen gesture, AutomaticDoorOpen gesture and WalkingGesture. Thirdly, this research also contributes to researchers and professionals who are dedicated to a research in the area of natural user interfaces and their efforts in finding an effective algorithm for human gesture recognition. This research investigates different approached to gesture recognition, such as Record and recognize approach, Neural Networks approach and Gesture composition approach, presented which are their advantages and weaknesses and presented why chosen is the Gesture Composition approach.

I. INTRODUCTION

The research study investigates the effectiveness and efficiency of the several gesture recognition approaches.

Natural user interfaces as discussed in [5] are continually becoming important part of the contemporary human-computer interaction. They are introduced in almost every new device [2] easing the interaction between the user and the device itself. According to [6] from touch-sensitive displays to 3D cameras and infrared sensors, natural user interfaces make the electronic devices usage much easier, faster and more intuitive. Some of the natural user interfaces require minimal contact between the human and the device [2].

The most advanced interfaces don't require any contact and they combine different kinds of cameras and sensors to use the human body as an input source [1].

II. BACKGROUND RESEARCH

Since the beginning of the computer era, many computer engineers were searching for a solution to improve and ease the way people interact with the computer systems [1]. Good user interface will improve user experience with the computer and other mobile devices [3] and will make the interaction as discussed in [12] easier, accessible and more optimal.

One of the most important devices [5] that take the NUI usage on the next level is the appearance of the Microsoft Kinect for Xbox and Microsoft Kinect for Windows [8]. This device allows the player to control the system using his/her body movements. The user doesn't have any direct interaction with the system, but his body is captured and gestures are recognized using one RGB and one Infrared camera. Kinect quickly became interesting device for the programmers worldwide. Many people have found a lot of interesting applications of Kinect in the real world environments.

The concept of Natural User Interface (or NUI) is firstly introduced by Steve Mann [8]. Steven Mann is a researcher and inventor best known for his work on computational photography, particularly wearable computing and high dynamic range imaging. According to [10] Mann holds degrees from the Massachusetts Institute of Technology (PhD in Media Arts and Sciences '97) and McMaster University, where he was also inducted into the McMaster University Alumni Hall of Fame, Alumni Gallery, 2004, in recognition of his career as an inventor and teacher. In the period of 1970s – 1990s he developed many different devices which were meant to replace the standard command line interface and graphical user interface. For his projects he had used several terms, including 'Natural User Interfaces', 'Direct User Interfaces' and 'Metaphor-Free Computing' [7].

According to [8] August de los Reyes, Director for Surface Computing in Microsoft firstly mentioned the Natural User Interface as the next phase in the user interface evolution. Although natural user interfaces can't replace graphical user interfaces, since most of the NUIs

use graphical user interface to show the result, natural user interface tries to replace the WIMP (window, icon, menu and pointing device) principal. Later, on several conferences, representatives from Microsoft talked about the importance of the natural user interfaces and their efforts in providing best experience to the users using NUI features. According to [6] gesture recognition system is natural user interface which tries to follow the body movement and produce input out of this information. According to [11] there are two kinds of gesture recognitions systems: systems which require physical contact with the body and systems which can follow the body without physical contact.

In 2012 Microsoft released a new Kinect device meant to work only with personal computers. Unlike the older version which was originally published for Xbox 360, the new version had better resolution of the RGB camera and the depth infrared sensor.

Together with the new Kinect for Windows device, Microsoft released a new version of the software development kit. The new version of the SDK included improved skeleton recognition in different positions, better stabilization algorithm and additional tools for easier development of Kinect enabled applications.

According to [7] Kinect device is composed of several parts. Main parts of the device are the RGB camera and the infrared sensor.

The RGB camera is retrieving RGB video of the objects in front of the device. It supports resolution up to 1280x960 at 30 FPS. The resolution that will be used is programmable using the software development kit.

Next to the RGB camera is located the infrared sensor [7]. The infrared sensor is consisted of infrared transmitter and infrared receiver. When the infrared wave is transmitted, it is reflected from the objects in the front, and it is returned to the receiver. The time that the wave needed to return to the sensor can determine the distance between the object and the Kinect device [7].

Each Kinect device also has 4 microphones located on different places on the device, 3 in the front and 1 in the back of the device.

Using the 4 microphones, Kinect supports advanced audio features, such as beam formation to detect the audio source, noise suppression and echo cancelation and easy integration with Microsoft's speech recognition platform.

Kinect also has a motorized tilt, which together with the gyroscope is responsible for vertical angle position of the Kinect sensor.

III. RESEARCH METHODOLOGY

The research study is fundamental research focusing on exploratory research and then action research developing a software solution to implement the insights gained from the fundamental research. The research investigation is focused on the Kinect sensor, programming new gesture recongnitions and their features. The Kinect sensor allows users to interact with the system without any physical contact with it. The user stays in front of the sensor (2-4 meters away). The Kinect uses its RGB and Infrared cameras to capture the user position in the space. This information can be retrieved easily from the sensor, but what is missing in the Kinect software is the gesture recognition part.

The research study ivestigates the effectiveness and efficiency of the several gesture recognition approaches. The primary focus of research is the test for accuracy, speed and correctness of the different algorithms. The final system is implemented in Microsoft .NET technologies. Researched is how the gesture recognition system can be implemented in the .NET framework and be reused in many different projects. Participants were students, teaching and administrative staff of the Contemporary Sciences and Technolgies Faculty of the South East European University.

IV. GESTURE RECOGNITION APPROACHES

Gestures and gesture recognition systems are main power driver for the Kinect device and Kinect enabled applications. Kinect for Windows SDK provides full skeleton information about the people in front of the device including location information about each joint on the skeleton, but the real power and value of the Kinect is fulfilled using the gestures and gesture recognition systems.

Since its beginning and first appearance on the market, Kinect became main topic of research of many computer professionals and enthusiasts all around the world [7]. Many of them researched how it can recognize a gesture and do specific action for each gesture. Few different approaches were discovered, each of them with several advantages and disadvantages.

A. Record and Recognize Aproach

According to [6] one of the very first approaches to gesture recognition systems was the 'record and recognize' approach. With this approach each gesture is recorded once and is memorized by the underlying application. After the gesture is memorized as a valid gesture, then it can be used to recognize other movements and perform an action if the specified gesture is recognized.

The advantage of this algorithm is that it can be easily implemented [4]. The complete procedure consists of two phases. One phase is to follow the gesture, convert it to computer-understandable information and save the gesture in the memory or the database. The second phase is to record the algorithm, convert it to computer-understandable information using the same algorithm as in the first phase and search for that information in the data store. If the algorithm is recognized, perform the desired action.

This approach has several disadvantages when applied to a real application. First, this approach has no fault tolerance. Even very small distortions will prevent the algorithm from recognizing the gesture. Several error and distortion correction algorithms can be applied to this approach to minimize or reduce the error, but since the

data is very sensitive and not deterministic, it will still contain different data and the algorithm will fail.

Second problem with the approach is that when one gesture is recorded and saved in the data store, it would hardly be possible to use the same gesture model for different person. People have different body structure, size and natural movements and the gestures that are naturally performed by one person, are not same for another person.

B. Neural Networks Approach

According to [9] Neural networks approach was also used as one of the first algorithms for gesture recognition. Neural networks are used for different pattern recognition algorithms, including optical character recognition and are proven to be reliable and intelligent approaches to different real world problems.

Neural networks approach for gesture recognition is reliable and proven mechanism. Its advantage is that after sufficient training with different data sets it can recognize simple gestures. However, although this approach is good for academic and research environments, it's not very useful in a production, application environments, when the training time should be avoided.

Main disadvantage of the neural networks approach is that they require big input, training dataset [4]. The dataset should contain different gestures from big number of people, with different body structure, different size and different cultures because they have different natural movements. This is hardly achievable, and besides research environments it is hardly usable and effective in application environments.

Another disadvantage is the initial effort time for creating the neural network. The developer will need a lot of time to research and conclude which type of network and network structure is more suitable for the gestures that are needed to be recognized by the system.

C. Gesture Composition Approach

According to [6] gesture composition approach was introduced in its initial version by a group of employees at Microsoft Corporation in United Kingdom. Right after the appearance of the Kinect for Windows Software Development Kit, they had made internal research about what is missing as part of the development kit. They found out that in order to make a Kinect enabled application, one of the main parts of the system should be gesture recognition system. They provided a simple gesture recognition approach which was based on creating a composition or a model of the gesture upon which the application is able to recognize the gesture.

Gesture Composition Approach is a complete and reliable approach that is proven to work with different people in the same way. We tested this approach on 50 different employees in our company. We found out that each of them would require 5-10 minutes in order to learn and practice the gestures that we have made in our system. After the learning time, each user was able to efficiently use our application and play our games.

During our analysis we found out that the gesture is made of parts. Each gesture could be effectively divided in different parts. Each part presents a position in which specific body parts or joints are located in the space and relative to the other body parts which are relevant for the gesture. When these parts of the gesture are executed in a specific order in a specific time frame, we can say that the gesture is performed.

V. DEVELOPMENT OF NEW GESTURE RECOGNITIONS

Gesture Recognition Library is developed in .NET Framework, which is the framework on which Kinect for Windows SDK works and on which most Kinect enabled applications are developed. In its base it uses the libraries and APIs from the Kinect for Windows SDK in order to communicate with the Kinect, send commands to the device and get the input streams for the RGB and depth sensing cameras [9].

Skeletal recognition function enables the Kinect to recognize the human body (skeleton) in front of the device and track its movements. Kinect recognizes the skeleton and provides the position of the skeleton together with the body joints to the programmer. There are several body joints provided by default: AnkleLeft, AnkleRight, ElbowLeft, ElboxRight, FootLeft, FootRight, HandLeft, HandRight, Head, HipCenter, HipLeft, HipRight, KneeLeft, KneeRight, ShoulderLeft, ShoulderCenter, ShoulderRight, Spine, WristLeft, WristRight [10]. For each joint its position in meaning of x, y and z coordinates in the space is provided [12].

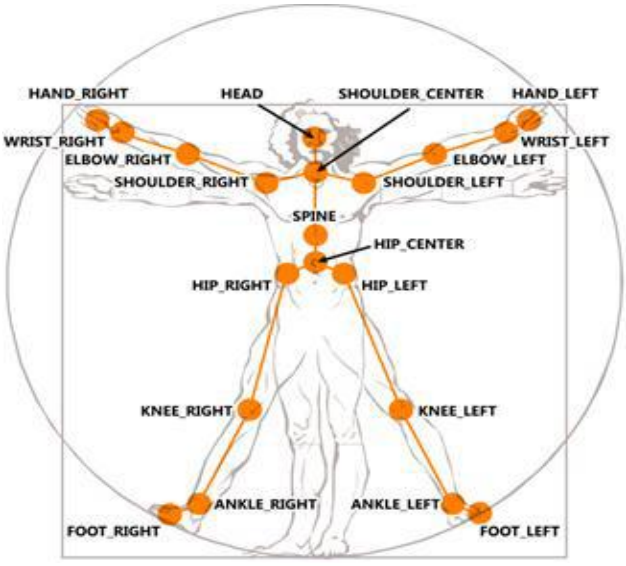

Figure 1. Body Joints that are recognized by the Kinect SDK Framework

Within the research study developed are several gestures that were needed for experimenting and for the development of the University Exploration System.

All these gestures are included in the library and are presented in the following parts. However, its design is very extensible and anyone with no huge effort can develop additional gestures that can be added to the library and very easily integrated.

The library is consisted of several main classes, such as KinectManager and GestureManager which are the main components of the library. Apart from that, there is class for each part of a gesture that is defined in the library.

The current implementation within the research study of the GestureType contains 13 gestures which are already implemented in the library: WaveRight, WaveLeft, DownSwipe, UpSwipe, ClockwiseCircle, CounterClockwiseCircle, PushLeft, PushRight, ShortLeftSwipe, ShortRightSwipe, ManualDoorOpen, AutomaticDoorOpen and Walking.

VI. CONCEPTUAL DESIGN OF THE UNIVERSITY EXPLORATION SYSTEM

One of the applications developed on top of the gesture recognition library is the university exploration system. This application is targeted to the new students and all the people who are interested in the university structure, study programs on different faculties and all additional information about the university itself. Using natural user interfaces as primary input source, this application provides extraordinary user experience, especially for the future students. Providing natural user interface as a first contact between the student and the university, it's promoting the university in the best way to the future students and introduce them to the advanced topics of the information technology.

Figure 2. GUI of the University Expolaration system

The University Exploration and Presentation System is implemented in .NET framework version 4.5 and works in the same runtime environment together with the gesture recognition system. It utilizes all the features that the gesture recognition library provides and is complete example of the usage of the library.

Figure 3. Facylty Exploration System

The application is implemented as a Windows Presentation Foundation (WPF) application. The main application object is the MainWindow which implements the IPageSwitcher interface. There is one Switcher static class which is responsible for switching the content of the main application window. The idea behind this approach is to have one MainWindow which can display any WPF user control in its content. In this way there will be single window application which can just switch between different components and only show the currently active component. Every component, such as menu component, panorama component and HTML view component is implemented as separate WPF user control.

Complete configurability of the application allows extensibility and easy maintenance of the application during its lifecycle. The backend user is allowed to change the structure, content, texts and image resources at any time, and with one quick restart of the application complete new system state could be achieved.

Modularity and configurability of the application allow the application to be distributed to different locations and configured remotely form centralized system. The university is able to set different points on different locations that will perform individually and at the same time the administrator is able to control and configure the content and the behavior of the application.

A. Implementation of Menu Component

Menu component is one of the main components and the entry point of the application. Upon starting with the usage of the application, the user is able to select from one of the three official languages of the university as a main language and to continue to use the application with the selected language.

This component provides easy and intuitive navigation through the menu using swiping gestures with the hands and selection of the menu items with performing push gesture with the right hand or performing a walking gesture. Every menu item is configurable and different image can be assigned per item. The action is also configurable and based on the configuration it can open another menu, open a HTML view component or can start different component, such as panorama view component.

The configuration of the component is done using XML files stored in the same directory with the application executable. This allows the application to be easily configurable and extendable with new content and resources. The XML file contains configuration for the current menu and can also contain link to different XML file which defines another menu which is specified using the action attribute of the item configuration.

Location of the main menu or entry menu configuration for the application is specified in the applications app.config file, which is XML configuration file intended for a .NET application. When the application is started, it looks for the location of the entry point configuration, loads the configuration and renders the menu (shown in figure 6.1). One simple menu configuration is shown below.

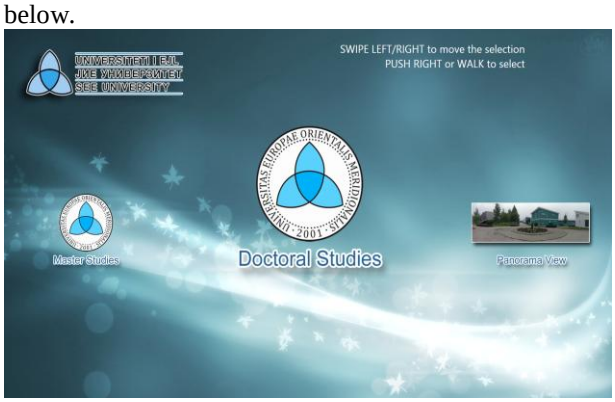

Figure 4. Menu component

B. *Implementation of the Web View*

Web View component presents any HTML content to the user, which is able to navigate in the content using hand swipe gestures. This component is very useful for presenting rich content to the user, including text resources, images, animations and any other objects which can be displayed using Hypertext Markup Language.

The user is able to navigate or scroll through the content of the HTML view using the hand swipe gestures. The advantage of this component is that the content is configurable and it can be stored locally or if the client has internet access it can be stored on any place on the web. This allows real time content update and centralized content location for all distributed clients. In the background, this application uses Internet Explorer engine for rendering the HTML content, so it is able to show any content that is compatible with Microsoft Internet Explorer web browser.

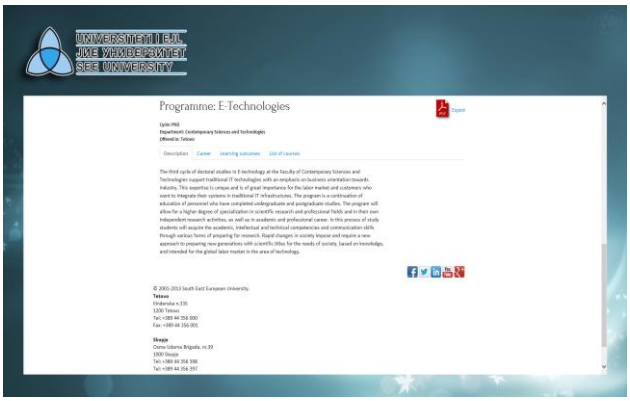

Figure 5. Web View Component Implementation

HTML view component is widely used in the University Exploration and Presentation application for showing different type of content. Study programs, text resources and additional information for different topics are all shown using the HTML view component. It allows easy and consistent rendering of the information equally to all the clients. Additionally, the feature for showing HTML content from a web page allows some part of the information to be directly get from the university website (www.seeu.edu.mk), in that way providing easy update of the application and keeping the content consistent between the website presentation and application presentation of the university.

C. *Panorama View Component*

The third component of the base application components is the panorama view component, which shows panoramic images to the user in interactive way.
The user is able to move the image to the left or right using hand gestures and move the panoramic view to the left or right, thus allowing the user to explore the space in 360 degrees view.

Figure 6. Panorama View Component Implementation

This component allows the user to see the objects nearby his current location and get more information about each object in the current view. Easier navigation is achieved using the hand gestures which allow moving from one object to another one.

VII. RESULTS

After the completion of the system, different kinds of tests were performed in order to ensure the system performance, functionality and stability.

Usability testing that was performed on the system ensured that the system is usable and responds to the user behavior as expected during the design phase. Testing of the system was performed by people from different age ranges with different habits in order to test the system for its stability and acceptability.

The results from the testing show that the users learn the gestures very fast and they start to effectively use the system in a very short amount of time.

TABLE I. Time needed for people from different age to start to effectively use the system

Age Range	Up to 2 minutes	2-7 minutes	7+ minutes
< 15	40%	52%	8%
15-20	77%	19%	4%
20-25	68%	23%	9%
25-30	63%	24%	13%
30-35	45%	39%	16%
35-40	22%	40%	38%
> 40	14%	34%	52%

From the table above we can see that 78% of the people from before-university grade will start to effectively use the application features in less than 2 minutes. Also, most of the people in the age range of 15-30 years will master the system in less than 2 minutes.

From all the people younger than 30 years which tested the system, more than 90% of them learnt how to use it in less than 7 minutes, while more than 50% of all the tested people achieve the same goal in less than 7 minutes.

WaveLeft and WaveRight gestures also have high percentage of recognition, about 90%. They are natural to the user but are composed of more gestures and are more complex for the system. At the bottom of the list are ClockwiseCircle and CounterClockwiseCircle which are the most complex gestures. They are consisted of 4 different positions which should be performed in a specific order. These movements are not so natural to the user, they are not present in the everyday movements and they are not so easily performed by the person.

This concludes that the gestures which are composed of smaller number of states are much easier for performing. The gestures should also be natural to the user and intuitive enough so the person doesn't need much time for learning the gesture. Before composing a new gesture, user behavior should be monitored and taken in mind, the gesture should be designed with as little states as possible and it should be natural to the performer.

VIII. CONLUSION

This research tries to make several contributions in the development and application of Natural User Interfaces and university promotion and presentation providing a new approach.

First, it presents different approach for presenting the university and any of its internal institutions to the outside people and future students. Besides the traditional brochure and TV/radio marketing campaigns, with this system the university is able to present itself to the public in different, remarkable and distributed way throughout the whole university year, with little or no costs at all. The highly interactive way of communication between the user and the system will leave high impression and great mark at the user experience.

Second, this system is built on basis of separate library used for the gesture recognition part of the application, which can also work separately from the system and can be used in different contexts. Since this application thesis will remain in the university library, it can be basis for any other future research papers and systems that utilize the Kinect device for gesture recognition systems. It is very extendable and allows the users to implement new gestures on top of the library, thus enriching its context and provides easy start for the user allowing him to concentrate to the business logic instead of the low level programming of the gesture recognition algorithms.

In addition to the basic gestures provided by the employees at Microsoft department in United Kingdom, created several other gestures that add additional value to the library itself. New gestures that were added to the library are DownSwipe, UpSwipe, ClockwiseCircle, CounterClockwiseCircle, Push gestures, ManualDoorOpen gesture, AutomaticDoorOpen gesture and WalkingGesture. After additional testing and small code improvements, the new gesture library is planned to be sent to Microsoft team working on the Kinect SDK and also to publish it online as an open source contribution to the community of programmers who are working on natural user interfaces improvements..

For the future work intended is to add more common functionality, such as course based real time chat, messaging, file sharing, library and wiki panel. Also will try to introduce new gestures and implement new components.

The future research will focus on head-driven gestures, i.e. gestures which are performed only with movements of the head. One of the main challenges is also configuration of the gestures using XML files instead of the programmatic approach which will also improve the extensibility of the application and new gestures could be added without modifying the application code.

davor.gadze@tvz.hr, milivoj.puzak@tvz.hr, dragutin.haldek@tvz.hr

ABSTRACT - Circuit breakers are one of the most common safety devices in electrical circuits. Presentation of their characteristics to the students will be shown in this article. Characteristics could be shown in three different ways. First way as convenient experiment with standard instruments and mutual presentation of achieved results. Second, as building model in mathematical modeling software and critical review of corresponding results. And third as fully automated experiment with programmable logic controller for control and data acquisition and visualization software for automated results presentation. All three ways of presentation of these characteristics to the students will be critically reviewed.

I. INTRODUCTION

Circuit breakers must simultaneously satisfy several conditions: as shown in Fig 1, continuously leads full load current - area [1], occasionally leads short overcurrents - area [2], delayed disconnects long overcurrents - area – [3], immediately disconnects short circuit currents – area [4]. All of these characteristics have also fuses, as shown in Fig 2, but not so fine tuned. Similarities are in areas [1], [2] and [3]. As shown in Fig 3, this first part of characteristic is called thermal, and both circuit breaker and fuse have it incorporated.

Thermal part depends on heat dissipation, I^2t, and disconnects supply in case of circuit cabling temperature rises to limit, during hours. Maximum admissible temperature at the conductor is 70°C for PVC type of insulation, and 90°C for XLPE and EPR types of insulation (table 52-4 of IEC 60364-5-52), [4].

Second part of circuit breaker characteristics is called magnetic, instantaneous or slightly time delayed. Magnetic part depends mostly on current, I. This magnetic part enables faster break in case of short circuit. It also disconnects supply in case of circuit cabling temperature limit rises to 125%, during short circuit. It is assumed that during this time, typically fraction of a second, generated heat inside conductor remain in conductor, causing its temperature to rise.

Magnetic part of characteristics also disconnects supply in case of particular fault. During this fault, exposed conductive parts which are not normally alive, has become alive. Protection from such fault is in IEC 61140 called "Fault protection", former "protection against indirect contact". Maximum safe duration of the assumed values of AC touch voltages from 230V to 400V is 0,2 seconds.

Current IM, on Fig 1, for B or Z characteristics of circuit breaker (so called *fast*) is typically 3-5xIn, for C characteristics (*slow*) is typically 5-10In, and for D or K (*extra slow*) characteristics is typically 10-20xIn. Letters B, C and D describes circuit breaker characteristics for domestic use (IEC 60898, 0 level maintenance) and letters B, C, D, Z, K are for industrial use (IEC 60947-2).

These two different characteristics, thermal and magnetic, have different time domains. Thermal is shown in hours, and magnetic is shown in milliseconds. Except different time domains, characteristics also have different current domains. Thermal one covers current ranges from 1xIn, to 1,5xIn, and magnetic one covers current ranges from 3xIn to 50xIn. Due to these reasons, characteristics could be better presented if both axes have logarithmic scales, instead of linear ones.

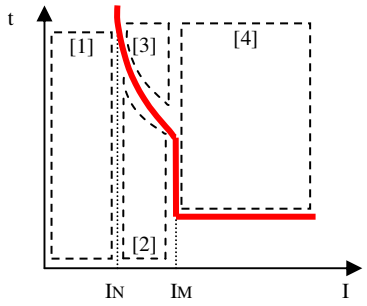

FIGURE 1: CIRCUIT BREAKER CHARACTERISTICS

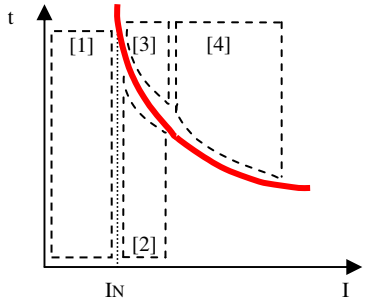

FIGURE 2: FUSE CHARACTERISTICS

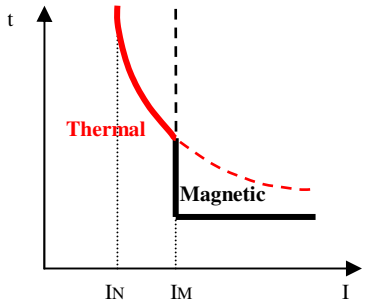

FIGURE 3: CIRCUIT BREAKER TWO PART CHARACTERISTICS

This introduction is held at lectures, before exercises, and gave students knowledge of basic principles in domain of circuit breakers.

II. CONVENINENT EXPERIMENT

As first exercise, students should connect circuit breaker to high short current supply. Circuit breaker is standard miniature circuit breaker, B or C characteristics, nominal current from 6 to 16 Amps. Nominal current is limited through supply capacity. Trip of circuit breaker should be measured at least for two different currents, whose ratio is at least 2 for magnetic part. For C characteristics it means 20xIn (320Amps), and 40xIn (640Amps).

So big ratio is pointless on thermal part, since time limitation in laboratory testing are 20 minutes for each current. This leads to minimum current of about 1,8xIn. A bit smaller currents, causes timeless experiments, e.g. 1,45xIn is 1 hour, causing impossible to carry experiment out on 1 hour lectures.

Experimental results of 3 pole short circuit on 3x400V 50Hz network with circuit breaker C63A are shown on Fig 4 and Fig 5. During short circuit voltage remarkably drops (Fig 4), and currents are remarkably high (Fig 5). Shown experiment lasts for 5,5ms, which could be better read from currents durations.

There is no doubts that, so short tripping time is caused because of magnetic part of circuit breaker characteristics. During first stage of short circuit, during current is rising, voltages drops to value defined only by current and impedance of short circuit. On second stage, during current is falling, voltage is defined by network impedance.

In laboratory experiment such oscillograms wouldn't be measured, due complexity of acquiring instruments. Only effective values of current and voltage will be measured.

Due short trip time, it is impossible to read off the current and voltage values during experiment, so some type of storage on instrument should be applied.

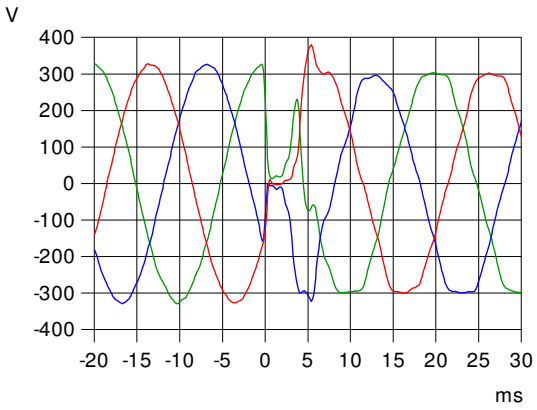

FIGURE 4: SHORT CIRCUIT, PHASE VOLTAGES, U1, U2, U3, [2]

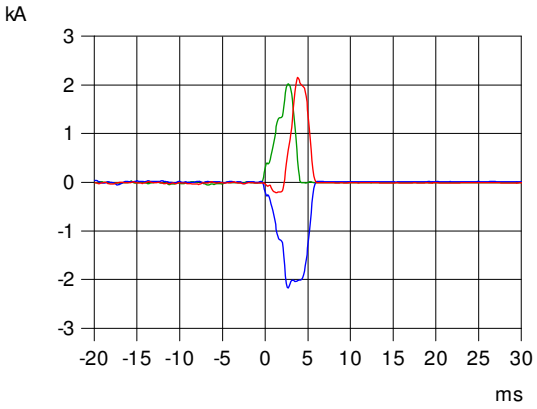

FIGURE 5: SHORT CIRCUIT, PHASE CURRENTS, I1, I2, I3, [2]

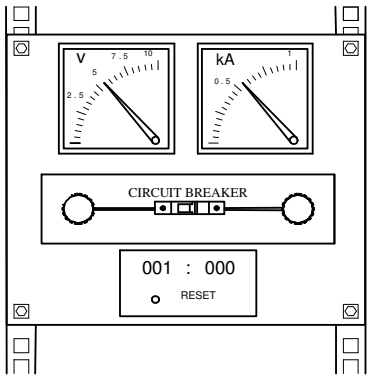

FIGURE 6: 19 INCH MODEL FOR CONVENIENT EXPERIMENT

Thermal part of characteristics lasts remarkably longer, for thousands of periods. With current "I" and breaker voltage "Ub", on thermal part, could be calculated internal resistance and power loss of circuit breaker. They are typically 10mΩ, for both impedance and resistance. Power loss are typically 2-3 Watt per pole, [5].

Students needs to adjust current supply for few current values, each causing breaker trip. When current start to flow, stopwatch is automatically started. This should be done with current sensing relay. When breaker opens

contacts, stopwatch is automatically stopped, with SD auxiliary breaker contact. Circuit breaker warms up during experiment, so current values should be adjusted in descending order, starting with highest value. Stopwatch should measure milliseconds for magnetic part, but also minutes for thermal part of characteristics. For 6 digit stopwatch maximum time limit is 16 minutes.

Advantages of this method to students are simplicity of the experiment, and good perception of physical conditions, leading to breaker trip, especially for thermal part of characteristics. Magnetic part, due its short reaction time, is a bit more difficult to recognize.

This convenient method doesn't have real disadvantages. Only one, according to students, is that experiment isn't modern one.

III. MATHEMATICAL MODEL

As second exercise students should build a mathematical model in Matlab software, Fig 7. They are modeling separately magnetic and thermal part of characteristics. And also, separately test these both parts of characteristics. Finally they incorporated these two parts into one model, and generate experiment report.

Modeling software offers complete test to be carried out, for whole range of currents, or even for whole range of circuit breaker, without limitation of experiment duration. These are obvious advantages of this method.

Disadvantage of this method, in the first row, is neglecting of circuit breaker complexity, [1] and [3], and too simple circuit breaker model. But, more complex model will result that students won't understood matter at all.

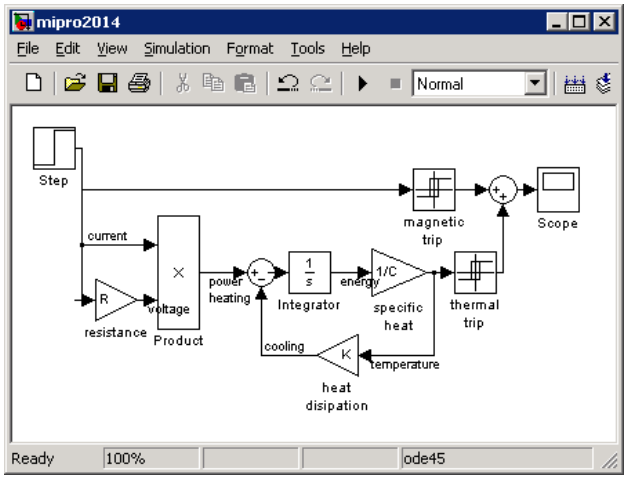

FIGURE 7: CIRCUIT BREAKER MATHEMATICAL MODEL

Second disadvantage is that students haven't good perception of circuit breaker propose. Currents in model are understood as numbers, not real Amps, through conductors become warm. Conductors' temperatures students could feel in other two ways of experiment.

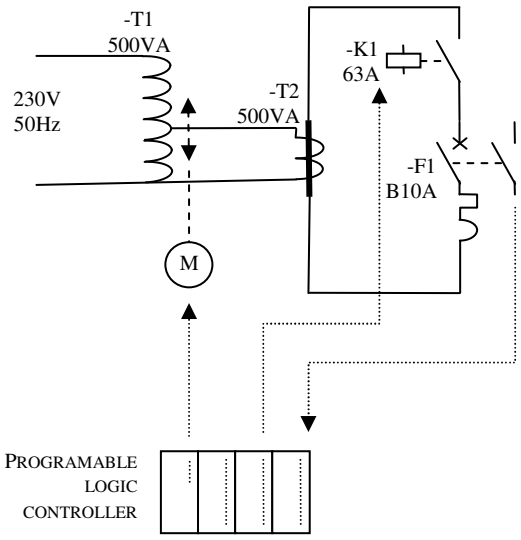

FIGURE 8: AUTOMATED EXPERIMENT SCHEME

IV. AUTOMATED EXPERIMENT

In third exercise students needs to select current range according to circuit breaker nominal current. Experiment is held as traditional one, with automated current set point adjustment, and automated acquiring and visualization of achieved results.

Programmable logic controller automatically defines current set point, according to programmed descending order, and forwards it through two digital outputs (Step up/step down) to high short circuit supply. This supply are two transformers connected in serial, -T1 and –T2, on Fig. 8. Transformer –T2 is oppositely connected current transformer, for this experiment apparent power of current transformer is 500VA, despite that current transformers usually have apparent power to 60VA. In laboratory experiments short circuits are carried out at significantly decreased voltage (few volts). With higher voltages, transformer with higher apparent power must be used, with nominal current at least 10 times then nominal current of tested circuit breaker.

PLC also automatically measures time from closing contactor –K1 till breaker –F1 trips. Contactor closing and breaker trip are recognized through digital 24V input wired on auxiliary contacts. PLC cycle could be as short as 1ms. For described "protection against indirect contact" in first subtitle maximum safe duration is 200ms, so resolution of 1ms is small enough.

Visualization of achieved results is shown on screen, Fig 9. Both results are shown, temporary one, with voltage, current, and time, from present current set point. Shown are also final results, with time vs. current curve.

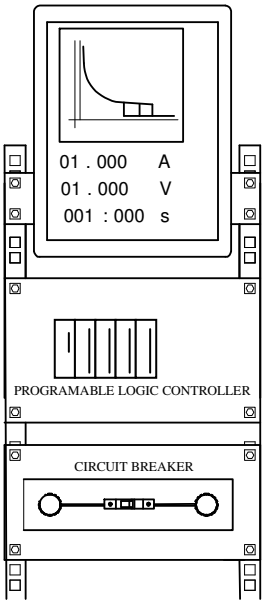

FIGURE 9: 19 INCH MODEL FOR AUTOMATED EXPERIMENT

All time limitations as in convenient experiment are present. This model could be also described as automated traditional experiment, because despite automation of adjusting set point and acquiring and visualization of achieved results, there is no other difference to convenient experiment.

V. CONCLUSION

It is impossible to say that one way is better than the other one. Each approach to the problem has its own advantages, so after introductory lecture, all three ways of experiment should be held to the students. In first one, they are forced to be active on exercise. They have a lot of manipulation, connecting circuit breaker, adjusting current set point, write down archived times. In second one, they have a lot of work on a PC, to build a mathematical model, and to handle all the result data. Finally at third one, after connecting circuit breaker, and choosing right testing procedure, they sit in front of model, and look at experiment as some multimedia presentation, but with real feel about conductors' temperatures, and feel of smell of burned dust on these conductors.

Web-based control of programmable logic controllers in process control computers education

R. Buinac, D. Maršić and G. Malčić
Department of Electrical Engineering, Polytechnic of Zagreb, Zagreb, Croatia
rade.buinac@tvz.hr

Abstract - Industrial control computers can be connected to the Internet, and equipped with a Web interface. This enables access to process data from any computer with a set of common web-related software applications. This paper deals with laboratory exercises performed as a part of courses regarding process control computers, which include tasks dealing with this topic. Integration of Java and HTML technologies is described, and an example of a simple process and its Web interface is given. PLC computers equipped with an advanced communication modules are connected to a personal computer (PC) via Ethernet. Alongside implementation of Java applets in Web environment, human machine interface design is regarded.

I. INTRODUCTION

Programmable logic controllers (PLCs) are the most popular type of process control computers, used in a variety of industrial automation systems, controlling plants producing almost everything, from food and beverages to steel and cement. PLCs are controlled by programmed code created on a PC and downloaded to memory of the controller. Depending on the state of the inputs and results of programmed functions, the controller will activate proper outputs. Even though a PLC can control a part of a process, or an entire process automatically, it is desirable to have complete diagnostics of the process available for supervision and intervention by the human operator.

A system for operator control and surveillance enables management of an industrial process. Such a system is called SCADA, abbreviated from Supervisory Control And Data Acquisition. Main characteristics of a SCADA system are visualization of the process and control from a central location, intended to simplify surveillance and control of the process. SCADA system installed on a server computer can be controlled by any PC-type computer connected to the server via Ethernet, and a commercial SCADA system can be replaced by a Web-application control system for some types of processes, as described in [1].

PLCs are modular devices and this modularity is often used to provide additional functions, e.g. modules increase the number of available inputs and outputs for the PLC CPU or provide inputs with greater sampling frequency for fast paced processes. A composition of PLC CPU, power supply unit and modules is called a station. Some modules allow connectivity to certain types of networks, and sometimes provide additional, advanced computer networking functions and services.

The modules used in the exercises described in this paper have *Profinet* and gigabit Ethernet connections. Some industrial network specific services are supported, but its' IT functions are of interest in creating a Web-based system for process control [2].

II. WEB AND PLC INTEGRATION

The most demanding part of work in integrating the Web and PLC was done by module manufacturer. IT functions of the module include HTML process control, FTP functions and E-mail sending. Ability to monitor devices and process data using HTML is the fundament of the integration. In order to achieve it File Transfer Protocol functions for file management are required.

In fact, the module can be looked at as a web-server with pre-installed JavaBeans library, connected to the controller and able perform surveillance and control tasks over the process assigned to the PLC, as represented on Figure 1.

Java is a class based object-oriented programming language designed to be platform independent, meaning it can be compiled on one software or hardware platform, and run on another without the need to be recompiled. The JavaBeans concept allows Java programming language objects, most often classes, to be created and linked

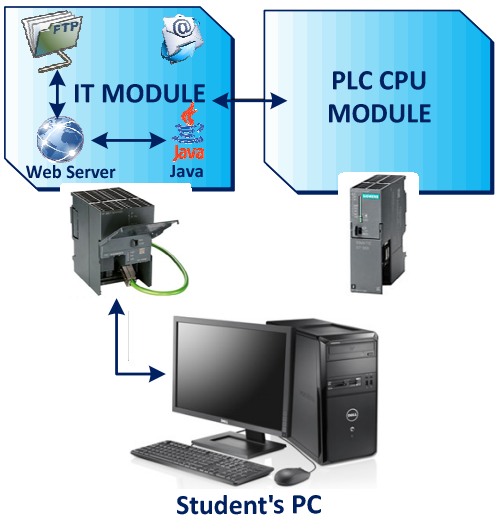

Figure 1. Information movement in the system configuration

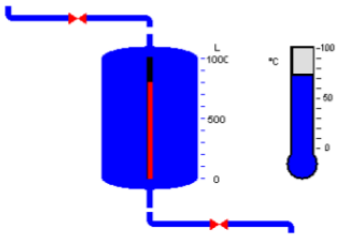

Figure 2. Graphic applets for display of memory variables

simply to executable objects [3].

In HTML process control JavaBeans are used as applets in HTML pages used for web diagnostics and control of the PLC. An applet in general is a small application performing a pointed task as a part of another programming interface, usually much more complex. Java applets are used in Web pages of general use as auxiliary applications, but here they are intended to be used to read and write data to the CPU module of the PLC.

JavaBeans Library pre-installed on the module contains applets specially designed for this type of usage called *S7 Beans Class Library*. The object classes contained in this library can be used for object-oriented access to a variety of information on the PLC CPU and for graphic display of process variables on the web page. Applets are inserted into HTML pages by their names when an applet call is embedded in an HTML page. Besides the name, certain attributes and parameters should be specified when calling the applets. This increases the amount of HTML code required to insert into the web page, but allows easier setup of the applets. These parameters define the usage of an applet, graphic display function, or its' type, etc. For example, some of the most useful applets are:

- *S7IdentApplet* is used to identify a module in a station
- *S7StatusApplet* queries the status information of a specified module
- *S7GetApplet* cyclically reads data or data areas
- *S7PutApplet* receives values entered by the user and transfers them to the PLC CPU [3].

These applets, integrated with additional *S7 beans* are used to create graphical interfaces on the Web pages. Beans used for graphical display vary from simple input fields and buttons, to more complex graphical solutions, such as the ones on Figure 2. Utility Beans performing simple functions such as reading date and time can also be used.

Advanced applications of Java beans could create the need for modification of existing beans or even creation of new ones, which requires builder tools and a Java programming environment. The builder tools are a part of the Java Development Kit, and a development environment can be chosen from one of the most popular integrated development environment (IDE) solutions. An IDE is a software application consisting of comprehensive set of tools whose purpose is facilitation of software development. New beans can be used for Web control after being imported into the library.

The S7 Beans class library provides an open interface allowing extended process data evaluation. This data can be transferred or used in table calculation, or in management information systems [3].

SCADA system is usually installed on a server computer, and any computer connected to the server via Ethernet can be used to control it. If a commercial SCADA system is replaced by a web application, there is still the need to have a central application and/or web application server in order to control the process from a visually acceptable interface [1]. However, HTML process control function and JavaBeans class library remove the need for the controller to be connected to a server computer – they are connected to the module, and the module is connected to an industrial computer network.

In order to use the module, and its' advanced functions and services, one needs to configure the hardware. During the hardware configuration process user accounts for control of the PLC station need to be created. Users can be granted rights to:

- Use the symbol table
- Read variables with absolute addresses from PLCs' memory
- Write variables with absolute addresses in PLCs' memory
- Access the files on the station with FTP
- Send an email
- Query the status of modules on the station
- Query the order number of modules.

Regarding user access level, there are three types of user accounts: accounts with no permissions, restricted permissions accounts, and administrator accounts. For instance, the automation engineer will have administrative account in order to get the system up and running, but the operator will have restricted access. Security is an important issue in all computer networks, but especially on the Internet, and it should be regarded as high priority if industrial processes are managed and controlled over the web. A tool for maintaining a decent security level in this system is definition of user accounts. Regarding security, the module has IP access protection providing security functions, e.g. restriction of communication with the station via the module for specified IP addresses.

III. LABORATORY EXERCISES

The goal of the exercises for the students is to explore remote surveillance and control possibilities given by Advanced IT modules for PLC automation. Additional goal is to give the students insight to Web control of PLCs basics, including introduction to HTML code and simple web pages design, FTP server manipulation and usage of Java applets for PLC control.

At the beginning of the exercise students are given a short introduction to basics of technologies used in the exercise, including Java, FTP, HTML and Web from the server point of view. PLC station configuration and PLC programming are familiar from exercises performed

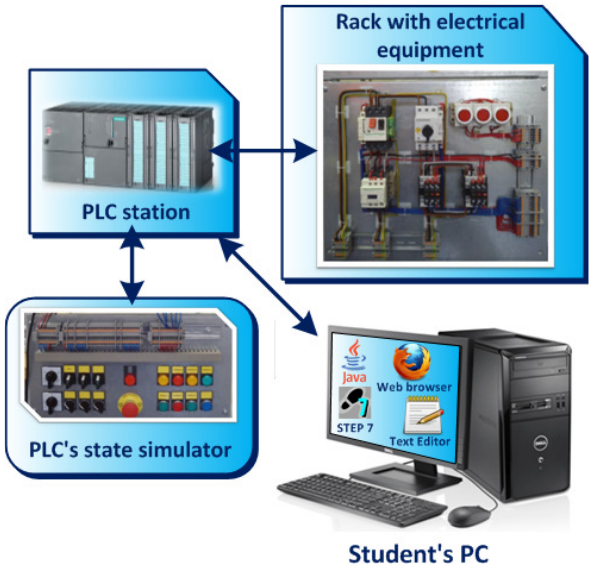

Figure 3. Workplace in the laboratory

earlier in the course. In case the short introduction is not enough, students can look up for more information in the teaching materials written for the exercise they are equipped with at the beginning of the class.

In the exercise manual students can find information needed to complete each step of the exercise. After an introduction to goals of the exercise and technology used to accomplish them there is a short review of the knowledge and skills gained so far. Detailed information and simple instructions can be found in the remaining chapters, following the tasks performed in order to complete the exercise. Educational goals of the exercise are accomplished by fulfilling the technical goal which is setting up a PLC station, programming it to control a simple process and deploying the Web control of the process. Students' workplaces are equipped with PCs connected to Ethernet and the Internet, a PLC state simulator module and racks with PLC stations and electrical equipment often used in automation industry, e.g. switches, buttons, relays, etc. Software installed on the PC is manufacturer's software for PLC configuration and programming, a Java runtime environment, a Web browser, and an advanced text editor for HTML code editing. Although HTML pages can be edited in a basic text-editing program it is much easier to work in an editor that has syntax highlighting capabilities, and it is important in the exercise because it helps students recognize parts of the code. Block diagram of the student's workplace can be seen on figure 3.

First step of the exercise is hardware configuration of the PLC station, performed always at the beginning of a new task for the station. During the configuration, the students should define IP address and the user accounts and passwords. If they are looking to know more, they can explore possibilities given by the software, under guidance of the teaching assistant, in order to modify settings related to Addresses, Diagnostics, IP access protection, etc. Second task is the design of the program for process control. This is done using ladder diagram logic.

Third task is symbols configuration – symbols simplify Web pages design by enabling Java applets to read or write data from a location called by a symbol, not an absolute address. Symbols configuration is basically adding text to a certain memory address of the PLC.

Fourth task is web page design and FTP server upload. During this task students are guided from making a simple web page with text only, to creating a web page including Java applets controlling the PLC. First version of a web page contains only title and a short text, in order to familiarize the students with writing HTML pages. After saving the page, it is uploaded to the module using a FTP client, and then opened by connecting to the module using a web browser. Second version of a web page has different background color and an image inserted, and the third version contains a simple applet. Applets code is copied from HTML files available at the students' computers' desktops. The code is copied in order to spare time, but also to avoid mistyping errors.

As a result of the exercises, student create a web page containing a text, an image and several applets. First applet shows catalog numbers of modules, second one shows status of the CPU module. Third and fourth applet allow modification of memory locations and the last one shows thermometer displaying the state of a certain memory address. The page is shown in Figure 4. After creating a page, students upload the final version to the module, and control the virtual process from the web browser on their PC.

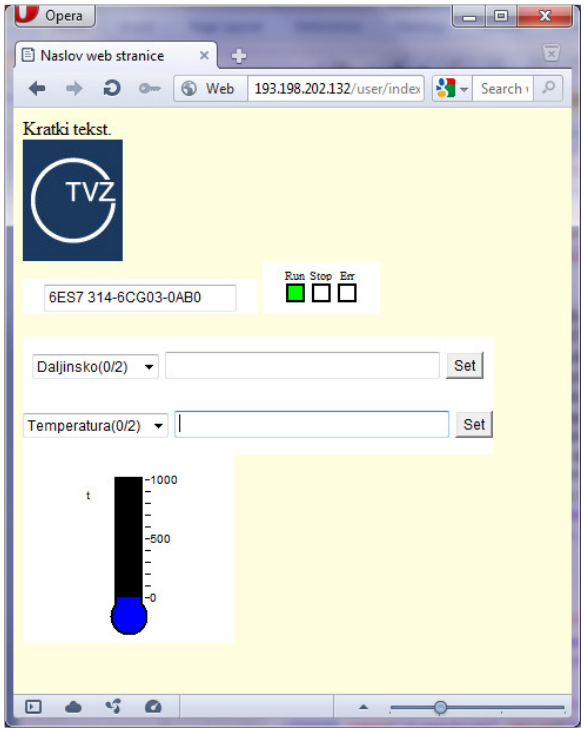

Figure 4. Web page created at the end of the exercise

IV. CONLUSIONS

Students' responses vary depending of their knowledge, IT skills and interests. While few of them find the exercise interesting, most of them find it too difficult. Lack of computer related skills is the greatest difficulty for most of the students. However, an electrical engineer should have the knowledge and skills to implement computer software components, especially if one is to work in the field of industrial automation, which has the need for versatile experts.

An advantage of this exercise is the ability to perform it from a remote location, for example at home. Student only needs appropriate software installed on the PC, and the IP address of the module to connect to in order to complete the exercise.

Towards more efficient teaching

Janko Žufić, Tomislava Žajgar
Juraj Dobrila University of Pula / Department of Educational Sciences, Pula, Croatia
jzufic@unipu.hr, tzajgar@gmail.com

Summary: The enclosed study provides analysis and describes experiences from teaching the subject "Audio and video processing" conducted at the Teachers' Academy at the Juraj Dobrila University of Pula. During the first year of the collegium, audio processing was performed using the application "Audacity", and video by Adobe Premier CS4. Processing of the materials was done using examples assigned by a teacher. Some changes were introduced in the following two years of the collegium. Besides the work described above, students were tasked with a creation and development of an idea for a short movie, recording and editing of the material. The final product was a film 3-10 minutes in length. This approach led to a better success rate among the students: from GPA 3.52 (at the scale 1-5; σ = 0.83, N=29; 2 students did not pass; average number of exam attempts per student was 1.79, σ = 1.05) to 4.33 (σ =0.80, N=21; 2 students did not pass; average number of exam attempts per student was 1). Evaluation of teachers by students performed as a part of the official institutional evaluation also changed: "*Classes encourage interaction and team work among students*" went from 3.63 (σ = 1.11) to 4.0 (σ = 0.89); "*My work during the semester was regularly evaluated and graded*" went from 4.07 (σ =0.94) to 4.83 (σ =0.47); "*Tasks corresponded with the contents of the collegium*" went from 3.89 (σ = 1.15) to 4.33 (σ =0.82); "*Grades received during the semester have impact on the final grade at the exam*" improved from 4.25 (0.80) to 5.00.

Key words: Audio processing, video processing, more efficient teaching

I. INTRODUCTION

Students of the primary class teaching program at the Department of Educational Sciences at the University of "Juraj Dobrila" in Pula, after the first year of study opt to select one of the two offered modules: "Informatics" or "English Language". In addition to the basic competencies of the teaching profession, they also achieve additional competencies in one of the two modules. Each of the offered modules represents up to 25% of the total hours.

The module „Informatics" comprises, among the other subjects, of the collegium „Audio and video editing", with 60 hours of teaching. The general idea behind the introduction of this module in the curriculum of the Teaching studies was to enable future teachers for the individual camera recording and audio-visual material editing utilizing computer application and its application in the primary teaching. The intention was to enable future teachers to use information technology as much as possible, as it becomes more accessible and easier to use and obtain.

Similar Teacher Education faculties in the Republic of Croatia (at the University centers in Rijeka, Zagreb, Split and Zadar) do not offer such courses, while the Teacher Education Faculty in Osijek has one elective course („*Graphics, animation and films*" represented with a total of 30 hours), and the program is partially similar to the course „*Audio and video editing*". Similar courses, but with substantially more hours (and even a separate study program), exist at the Academy of Dramatic Art in Zagreb.

During the first two years (2009/2010 and 2010/2011) of the course, students practiced camera recording, editing of the audio and video material and were given home works, but the teacher's impression was that students made minimal efforts and was of the opinion that their acquired knowledge and skills would not be long-termed. In the following two years (2011/2012 and 2012/2013), teacher changed the teaching method.

A. *Project teaching*

Thinking how to change the teaching discourse, the teacher did not want to use traditional forms of teaching, as the outcome of teaching was not entirely accomplished. In the end, he opted for the method of demonstration and a segment from the Theory of Constructivism that focuses on students that are actively involved in the teaching process and come to the personal cognition through the individual experience. Path to learning is unique for each student as they through individual activity, „construct" their own knowledge with an individual effort based on their personal experience. Constructively efficient teaching is founded on the relevancy of the existing knowledge, immediate experience in reality, integral experience, reflectivity of learning and teaching, effective creativity of the inner motivation, role of the teacher and the method of integrity of teaching [1]. Furthermore, some of the characteristics of the contemporary teaching are achieved through learning by discovery, self-initiative of students, individual problem solving, divergent, creative thinking [2]. De Zan emphasizes teaching models such as problem-oriented teaching, learning based on problem solving, creative teaching, research-oriented teaching, project teaching etc. The common thread to all these models is the existence of the problem that needs to be resolved.

The Project Method applied by the teacher is the specific type of learning by discovery [3], and it is considered the most complex method of learning by experience as it implies work of several groups of students on a complex problem set in a real life environment [4]. Teacher needs to put an extra effort due to possible difficulties and uncertain outcome of the project, in spite of that, the method itself is very interesting and motivating for the students. Teacher plays the role of a project manager that supervises students during the entire process, while it is important for students to be able to work in a team environment, as they need to take up parts of the

assignment and complete their part of the tasks in order to successfully complete the project [5]. Project teaching requires more time, but achieved results are better and long-lasting [6].

Using the project method in teaching involves a student-centered partnership between a student and a teacher, an openness to the problem' situations and tasks from the real life, correlation with other areas of science and human activities, methods of cooperation and team-work, development of organizational and communication abilities of students, application of new teaching methods.

A1. Role of a student in the project tutoring

Project tutoring teaches students to learn individually and to be individually responsible. Students in most parts organize their learning processes. The problem is that schools in general do not provide these competencies to students and existing conditions in schools, such as large study groups, defined time frames, limited financial abilities and teachers that obstruct development of individual responsibility in students. These factors make the process of qualifying students for learning via project teaching that much harder [7]. Learning process in project teaching includes: definition of distinct goals, formation of working groups, decision on time frames and adhering to them, work assignment and its coordination, team-work, constructive conflict management, implementation of all activities to the end, presentation of individual results to other coworkers in the team control and evaluation of one's own work and other team-mates work.

A2. Role of the teacher in the project teaching

Teachers are assuming roles that outgrow the traditional roles. Depending on the project phases, roles will be changed in alternation. Teachers need to become familiar with the roles and help students understand what roles they assumed [7]. Roles of the teachers are: A) *Coordinators:* depending on the age group and project experience of students, teachers will at the beginning observe passively development of the project and only if necessary, coordinate the project. In this role, teachers are establishing external contacts thus simplifying the path to these contacts for the students. B) *Moderators:* Teachers observe the course of learning and make sure that all participants in the projects have appropriate conditions for the participation in the learning process. Teachers as moderators will not have any impact on the formulation of the process, but they can open the free space and give wider prospective. C) *Coaches, advisors, assistances:* Teachers are always ready to provide directions and offer a helping hand in case those activities come to the dead-end or if problems arise. D) *Conflict managers:* Teachers need to mediate in situations when conflicts within the working groups arise, but also in the situations that involve external groups and persons that are not part of the school environment. It is necessary to develop several scenarios and methods to bring parties to the conflict to a favorable solution. To prepare for this role, teachers might need to have additional qualifications. E) *Professionals:* In each project and in individual situations, teachers need to present their professional knowledge. F) *Teachers are learning too:* Project themes, in their complexities, sometimes outgrow the teacher's spectra of knowledge. Therefore, teachers on the project often acquire important learning experiences. Presentation of the role of a person who permanently learns is something that needs to be mentioned to the students in order to help them experience learning as a continual process.

A3. Phases in the project teaching

Phases in the project teaching are: preliminary phase, planning, implementation, project presentation and valorization. Each of the phases has several steps [8].

Preliminary phase: a) selection of the project theme – it needs to be interesting, under researched, within the area of the student's affinities; b) Selection of the task, or the project goal, while keeping them feasible.

Planning: a) familiarization of students with the selected theme – directing students to the literature or showing the initial steps that would help them with the project implementation and b) writing a project implementation plan that would incorporate the following: definition of place and time for the work on the project, duration of the project, definition of length of each phase of the project; selection of material and work methods; formation of teams and work division within teams; anticipation of problems and possible resolutions.

Implementation: Following the project plan with a permanent teacher's supervision.

Presentation of the project results: Upon the finalization of the project, results of all teams need to be merged and the implementation documented via recording, posters, web sites, lectures.

Valorization consists of: a) evaluation of the accomplishment of the project outcomes and b) critical analysis of the work on the entire project – difficulties, successes etc.

B. Realization of the project teaching

B1. Preliminary phase

Preliminary phase consisted of selecting goals and sub goals. The main goal was to independently (or in teams in certain elements), on a general level and by the principals of profession, participate in making, recording and editing of multimedia materials. Sub goals were: to get familiar with the functions of a video camera, to set and work with a camera, to work with a tripod and lighting, to master basic framing, interior and exterior lighting, separate audio recording on a video camera, transfer of recorded material to a computer and post-production of recorded material. Additionally, to edit and ad visual effects and prepare and convert material for posting on a web site or store it on a DVD media. Students formed groups for the additional tasks that included finding ideas for a film (documentary, feature or experimental films), writing of a screen-play, treatment and shooting script for the feature and experimental films, i.e. drawing a sketch for the screen-play and select locations, camera positioning, background text and questions, in case of a documentary film. They also had to find actors for the feature and experimental films and obtain all necessary authorizations for the filming locations.

B2. Planning

Planning consisted of: a) preparation of students for the selected theme – each student, or group of students, was introduced to the basic functions of the equipment and students decided how they would use it. For example, students independently chose the positioning of camera, camera angle, exposition, frames for shooting etc for each individual scene; b) writing a project implementation plan that would include (for each phase) selection of place and time for the work start, and also duration of the activities.

Forming groups of students was made in the preliminary phase and division of tasks within the groups was reduced to the decision who and when would use the camera (apart from the personal cameras, there was just one more camera available to all groups as per schedules). This phase involved also anticipation of problems that might occur and ways for their resolutions (obtaining authorizations for filming on certain locations, permission to work with children, transportation to the place of filming etc).

B3. Implementation

Implementation phase consisted of following the plan. After all the work tasks were assigned and students given basic instructions how to approach them, realization started with an active involvement of the teacher and his time equally divided to all groups.

B4. Presentation of the project results

Once a week, each group (or an individual in cases of writers of screen-plays or shooting scripts) had to present what was done during the previous week. Students from other groups and the teacher commented on what was well done and what needed to be redone. It went on every week for three months. In the end of that period, students completed their tasks. A total of 16 films (during the last two years) were made. Films were shown in a review of films that was organized for that occasion in a public cinema in Pula. Screening was organized before an audience of approximately 100 viewers (mostly students, their friends and families) and it was also mentioned in the biggest daily news magazine „The Voice of Istria“ („Glas Istre“).

B5. Valorization

Valorization consisted of a) evaluation of the percentage of the assigned project goals and b) critical analysis of the work on the entire project – difficulties, successes etc. An important fact needs to be mentioned and that is that none of the students had any pre-existing knowledge in any element used in their tasks, and the accomplishment is so much greater when compared to their starting level. Teacher was also very satisfied with the achieved results and convinced that knowledge and skills acquired through laborious work would be long-lasting. Feedback from the students was also more than encouraging, and it might be illustrated by the experience of a student.

A learning experience of filmmaking at the Teacher Education faculty – a student's point of view

> *We all know how to comment that a film is poorly made, or that story is bad, but do we know how the films are made? Experience of learning how to make a film at the Teacher Education program is something that changes your approach to the film art and it convinces you that filmmaking is art. None of the students had previous knowledge of camera, but we all recorded something with our cell phones. When we received our tasks, the problems arose, such as how to position the camera – color, contrast, camera angle and what that means. We had theoretical knowledge and knew the terminology from the module „Culture of media“. To apply it in practice was by far more challenging. We learned that filmmaking is a creative process and not only telling a story. This type of art demanded complete dedication and we traveled a long way from the idea to the realization. At the beginning we had many ideas that were, through mutual pondering, slowly building in one that made us say „Yes, this is going to be my film“.*
>
> *We had to gather ample documentation and it was time consuming. Each of us wrote at least 20 pages of text for a 3-minute video film and it took us three months to complete it. Each frame, scene, every movement, sound, facial expression and gesticulation needed to be put on paper prior to filming. Many students found writing shooting scripts problematic, as they were mostly visual types. What each frame means, how it would express tension or relief, which one made sense and which one did not – we all mastered that through the script writing and the film recording itself. Why is the shooting script important? It is one of the most important document in the filmmakinging project. It is based on the screen-play and it visually and technically presents the film prior to its filming. The most important task in the shooting script is the whole film, each scene written (and sometimes even drawn) by frames…*

II. RESEARCH METHODOLOGY

The goal of the research was to determine the presence of statistical deviation in the quality of teaching with the traditional approach and the project teaching in the module „Audio and Video editing“. The tools utilized for this research were: a) records of the exam's marks and number of attempts retrieved from the ISVU system (Information Service of the Institution of the Higher Education) and b) results of the institutional evaluation of all teachers and courses performed annually by the University. The tool utilized for the evaluation was in the form of a questionnaire and it was used by students who anonymously evaluated elements of the course and the teacher in the range between 1 (*Extremely bad*) to 5 (*Excellent*). Questions presented to the students were: *1. I received clear and detailed information on the goals and*

content of the course and what are the expectations; 2. Assignments were presented clearly and comprehensibly; 3. Themes were reasonably selected and in accordance with the assignment; 4. Teacher is drawing parallels between the assignment and other courses and the profession in whole; 5. Teacher promotes analytical, critical and argumented thinking; 6. I was encouraged to actively participate in lectures (participation in debates/ posing questions/answering questions..); 7. Course requirements are in line with the ECTS; 8. Teacher is accessible and open for communication; 9. Overall I am satisfied with the course.

III. RESULTS

Results (marks) of the students are presented in the Table I., and results of the institutional evaluation of teachers are presented in the Table II.

TABLE 1. ACHIEVED RESULTS OF THE STUDENTS

	2009-11	2011-13
Number of students N	29	21
Average mark by students	3,52	4,33
Standard deviation of the received marks	0,83	0,80
Wilcox test with correction z=3,245		
Average number of attempts at passing exams	1,79	1,00
Standard deviation of the number of attempts at passing exams	1,05	0,00
Wilcox test with correction z=3,459		
Did not qualify for the exam	2	2

TABLE II. RESULTS OF THE INSTITUTIONAL EVALUATION OF TEACHERS

No.	**Statement**	***N***		**Arithmetic mean[1]** $\overline{X}$		**Standard deviation σ**	
		2009-11	***2011-13***	***2009-11***	***2011-13***	***2009-11***	***2011-13***
1	I received clear and detailed information on the goals and content of the course and what are the expectations	28	21	4,32	4,50	0,67	0,55
2	Assignments were presented clearly and comprehensibly	28	21	**3,57**	**4,50**	0,96	0,55
3	Themes were reasonably selected and in accordance with the assignment	27	21	3,89	4,17	0,75	0,41
4	Teacher is drawing parallels between the assignment and other courses and the profession in whole	28	20	**3,71**	**4,00**	1,01	0,00
5	Teacher promotes analytical, critical and argumented thinking	27	21	**3,89**	**4,50**	0,89	0,55
6	I was encouraged to actively participate in lectures (participation in debates/posing questions/answering questions..);	27	21	4,04	4,33	1,06	0,52
7	Course requirements are in line with the ECTS	27	21	**4,00**	**4,60**	0,96	0,55
8	Teacher is accessible and open for communication	29	21	**4,38**	**4,83**	1,01	0,41
9	Overall I am satisfied with the course	29	21	**3,55**	**4,50**	1,06	0,55

In addition to the results obtained via marks and institutional research, students also provided verbal feedback that could be abridged in the following:

> *Watch the video films made by previous generations of students and learn from their mistakes.*
>
> *In addition to the program package for video editing Adobe Premiere CSx, learn also Adobe After Efects that is of great help during the post-production of the video material and for addition of special effects in order to make better final product.*
>
> *In addition to the public screening in the end of the school year, organize internal competitions of student's video works.*

IV. ANALYSES OF RESULTS

Analysis of the student's accomplishments reflect significantly higher score (from 3,52 to 4,33 – statistically significant difference - Wilcox test with correction z=3,245 that is much higher than the required 1,96 with p<0,05), and lower number of attempts at passing the exam (from 1,72 to 1 – statistically significant difference - Wilcox test with correction z=3,459 that is much higher than the required 1,96 with p<0,05). In both cases, two students failed the exam (they didn't qualify for entering the exams – they abandoned the program).

Analysis of the institutional evaluation of teachers indicate that students in all nine questions gave higher marks to the teacher (statistical difference was present in 6 of the 9 questions). Wilcox test was utilized in all researches and correction was introduced due to the equality of levels. For all cases, the border was set at z=1,96 i.e. p<0,05.

In total, student's accomplishments are better, students expressed more satisfaction, the teacher was more satisfied, results are long-lasting and the course incorporated elements from other courses (Culture of Media, Literature, Dramaturgy etc) although the effort of students and teachers was increased and more time was consumed.

V. CONCLUSION

The article presents experience gained during the course of „Audio and Video editing“ at the Teacher Education program in Pula, with the application of the project teaching method. Project teaching approach requires more time for preparation of teachers and substantial commitment of students, but the accomplishment is better and long-lasting.

Abstract - This paper presents a research study that was conducted in the aim to investigate the perception of students and teachers about the potential of multimedia in teaching cross-cultural values. Our aim was to provide a helpful insight into the challenges of cross-cultural collaboration and the benefits of multimedia aided teaching. Critical thinking as a process that allows the average citizen to not absorb all the information as a sponge but learn how to filter all the information critically.

Key words: Multimedia, Cross-Cultural, Education, Critical thinking.

I. INTRODUCTION

The overall purpose of this research is to determine whether multimedia can contribute to promoting and acquiring cross-cultural values. The questions we hope to address can be formulated as follows:

Does multimedia aided learning of cross-cultural values have potentials?

What are their believes of cultural diversity?

We hope that our findings will help us assess their relationship and define activities strategies.

II. INTRODUCTION TO CROSS-CULTURALISM

Awareness of cultural diversity is present since the time of ancient Greece, moreover, with the word barbaros (βάρβαρος) greeks identified anyone who was *not Greek or was a stranger*. Acquiring cross-cultural skills is of increasing importance. Hofsteede defines culture as "*the collective programming of the mind that distinguishes the members of one group or category of people from others*". [1] Beside the term Cross-Cultural in contemporary literature we find confusing terms like transculturalism, interculturalism, multiculturalism and seemingly they all have a similar meaning. However, each has its own meaning that differs. In multicultural environments cultures are living side by side, in cross-cultural environments certain cultures are related to others, while in intercultural environments there are exchanges between different cultures.

Hammer et al. use the term ‘‘intercultural sensitivity’ to refer to the ability to discriminate and experience relevant cultural differences, and (...) intercultural competence to mean the ability to think and act in interculturally appropriate ways.” [2] Hofsteede for instance implied that “*culture is more often a source of conflict than of synergy. Cultural differences are a nuisance at best and often a disaster”* [3] Hammer et al. suggested in their work that “cross-cultural research has posited the importance of intercultural competence in both global and domestic contexts” and Bennets earlier work “has additionally suggested an underlying theoretical framework, which he calls the Developmental Model of Intercultural Sensitivity (DMIS), for conceptualizing intercultural sensitivity and competence.” [2]

For understanding the complexity of culture is often used Hall's "iceberg" analogy of culture, according to which only 1/10th of the iceberg is visible, while the larger part is hidden under the water. Visible, like art, literature and folklore are easier to recognise to the outsider, but underlying beliefs, values, thought patterns, tastes... are recognisable only with time. [4] Situations and occupations that require certain cross-cultural skills are more common nowadays than a century ago.

Welsch also states that “Modern societies are multicultural in themselves, encompassing a multitude of varying ways of life and lifestyles.” [5] In the EU for instance the fundamental principle of free movement of workers entitles EU citizens among others to look for a job in another EU country and work there without needing a work permit. [6] It has simplified the migration within the EU, insomuch that “*at the end of 2012, 14.1 million EU citizens were residing in another Member State*”. [7] Other situations that require cross-cultural skills are for instance working in a multinational company, where the individual is in a situation where he/she often works daily with other employees from other cultures. Sometimes he/she is being transferred to other countries or even continents and being the only member of a culture can trigger cultural shock. Oberg Calervo in the 1960s introduced first the concept of Cultural Shock (Kulturschock) which implied “an occupational disease of people who have been suddenly transplanted abroad. (...)

Cultural shock is precipitated by the anxiety that results from losing all our familiar signs and symbols of social intercourse (...) when to shake hands, what to say when we meet people, when and how to give tips, (...) when to take statements seriously and when not." [8]

In 1992 Bhawuk and Brislin developed for example The Intercultural Sensitivity Inventory (ICSI) which was used to measure an individual's ability to modify behaviour in culturally appropriate ways when moving between different cultures. The results of their research was that that participants with three or more years of cross-cultural experience showed a greater degree of intercultural sensitivity .[9]

Bennet observed that as people became more interculturally competent they moved from ethnocentrism to ethnorelativism. With the term "ethnocentrism" he refered to the experience of one's own culture as "central to reality." He suggested that the beliefs and behaviours that people receive in their primary socialization were unquestioned.The term "ethnorelativism" is the opposite of ethnocentrism. (...) The more ethnorelative worldviews are ways of seeking cultural difference, either by accepting its importance, by adapting perspective to take it into account, or by integrating the whole concept into a definition of identity. [10]

A typical situation when cross-cultural values are essential is for example working in a multinational corporation or team. One can experience the benefits of multinational team work in the form of different approaches, working styles or working relationships. These teams are nowadays often virtual teams with co-workers who rarely if ever meet in person. Godar and Pixy Ferris states that "virtual teams may be especially vulnerable to communication miscues because of their reliance on electronic rather than F2F communication and because team members may speak different languages or come from different cultural backgrounds, where communication styles vary." [11] Managers who are aware of cultural diversities (for example how different cultures react in the same business settings) can avoid subtle miscommunication and cultural miscues.

III. MULTIMEDIA

In this paper we will examine the potentials of using ICTs, namely multimedia in teaching cross-cultural values. Considering that multimedia applications enable the synergy of media and simultaneous effects on multiple sensors (speech, sight, and sound), their use in education has many advantages:

- Engaging students in the teaching process,
- Eliminating the barriers between different objects,
- Supporting individual learning
- Enhancing creativity, moreover convergent and divergent thinking is evolving.

The results are reflected in increasing cognitive abilities of students, as well as reducing the time required to master the same material.

With interaction the students actively participate and receive feedback on the quality of their work; they have an interactive experience. Considering multimedia can contribute to successful training only if it is didactic and pedagogically optimised we emphasize the importance of **multimedia didactics**. The approaches of teaching with integrated information and communication technologies represent a relatively new way of teaching that pedagogically differs from classical teaching methods.

Some authors like Johnson believe that the key to successful diversity education is integrating visual arts into the curriculum. She believes in the "capacity of visual arts to inform and reveal the history, the political and social ideals, the literature, the folklore, and the underlying psychosocial dynamics of a culture" also states that "art not only provides genuine insight into particular cultural experience, but also expresses the universal truths of our shared collective genealogy. [12]

Gonzalez identified that students need to "develop critical thinking skills" accordingly she recognized the importance of following skills:" [13]

- Analytical Thinking & Critical Analysis
- Associative Thinking
- Creative Thinking
- Critical Thinking
- Evaluative Thinking
- Hypothesis Problem Solving
- Perceptual thinking – Interpretation & Summarizing
- Questioning
- Synthesizing"

The author also agrees with Gonzales' idea, that exercising all nine of the above skills (implemented in multimedia) can contribute to learning cross-cultural values.

The aim is to develop user friendly interface design and collaborative multimedia application. Considering, web-based software and applications provide superior accessibility and collaboration our multimedia should also be in the cloud. The advantages of **web based multimedia** are communication and interaction in wider circle, access from any web-enabled computer, interactivity-active participation and also cost efficiency.

A. Overcoming cultural stereotypes

As introduced above, our main aim is overcoming cultural stereotypes that are unfortunately often too reduced to its essentials and consequently easily

recognizable, but on the other hand often are hidden in everyday life for example in media (newspaper, TV, internet...). Therefore it is important to have the ability to question the sources of information. In connection to this Hobbs defines 5 questions for teaching media analysis that enables students to "*merge their understanding of construction and intention together to consider their own personal response to media or a media message"* [14]*:*

- Who is sending the message and what is the author's purpose?
- What techniques are used to attract and hold attention?
- What lifestyles, values and points of view are represented in this message?
- How might different people interpret this message differently?
- What is omitted from this message?

These "literacy" skills/abilities will help to encode and decode symbols and to synthesize and analyse messages. Anaïs Nin notes that "We don't see things as they are, we see them as we are."

B. Possible activities
