Based on the above, we suggest the inclusion of the following activities:

- Work in groups of 15-20 participants
- Online scrapbooks, creating interactive online posters and wall charts that will allow our group to work together.
- Analysing artworks. Naming the differences between European and Asian art, learning about folk-art and folk tales
- Analysing media with asking questions.
- Digital storytelling. Finding similar folk tales in different cultures.
- Introducing other aspects of multinational and cross-cultural teamwork, stressing its advantages and disadvantages, backed with concrete examples and case studies.
- Sharing experiences with cultural miscues and language barriers for example acting out misunderstandings through role plays and express their views.
- Participants can be asked to identify the dimensions of culture provided by Hofsteede: "Individualism – Collectivism, Masculinity – Femininity, Power distance, Uncertainty avoidance, Long term – Short term orientation, Indulgence – Restraint."[3]

IV. RESEARCH FINDINGS

Guided by various instruments found in modern literature measuring (global) intercultural competency (for example Bennett's Intercultural Sensitivity Index (ISI) or Bhawuk's and Brislin's Intercultural Sensitivity Inventory (ICSI)) we developed our preliminary and simple questionnaire. The aim was to determine if our idea would be environmentally, technically, socially acceptable and sustainable and whether our participants would be interested in this kind of learning. Our sample size is 60 participants. Based on the fact that our region is cross-cultural we chose our participants randomly with equal probability of being included in the sample. We targeted members of higher education; therefore data for this study were collected primarily from teachers employed by universities (Vojvodina, Serbia) and also from undergraduate/ postgraduate students.

Besides gathering descriptive data on our participants (Questions 1 to 3) in the next section of the questionnaire the aim of the conducted study was to assess **1. numerical data** on: a) at what level was multimedia used in education (Questions 4 and 6), b) did they have positive experiences in multimedia aided learning (Question 5) and whether they ever used multimedia for learning a foreign language and **2. open-ended questionnaires** with questions such as: did they think it was useful (Question 7 and 9), c) what were their thoughts of using multimedia to teach cross cultural values (Question 13), d) whether they believed in cultural stereotypes (Question 11) and were asked to name the advantages of recognizing cross-cultural values (Question 10) as well as situations when knowing them would be advantageous *(*Question 14*),* also they were asked to identify how much knowing a foreign language could help them understanding different cultures (Question 8) which was measured using a 5-point Likert scale.

As a result of this study it was indicated that

- 80% of participants are females.
- 80% belong to the age group of 25-35
- 44 participants (73,33%) are employed as teachers. When asked whether they used multimedia in their class 90% of them responded affirmatively as showed in the following figure.

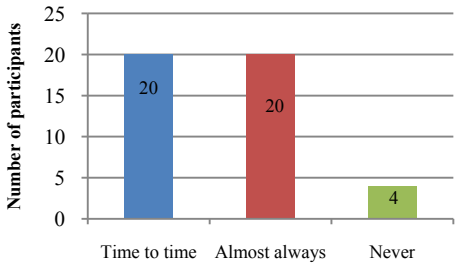

Figure 1. The use of multimedia in teaching.

- 100% of participants thought that multimedia can aid in learning a foreign language. 80% of participants had experiences in learning a language with multimedia. The remaining 20% despite stating that they had never used multimedia to learn a foreign language had thought that it could be useful;
- 100% of participants thought that learning a foreign language can help bridging differences with other cultures. This particular question indicates their attitude towards openness and that our participants recognized that learning a foreign language implies learning about that culture. Through the study of other languages individuals gain knowledge of the culture of that certain language, for example they learn ways of how to address people culturally appropriate. We believe that through foreign language learning in school, all our participants "met" with a different culture.
- 73% participants reported believing that multimedia can help promoting cross-cultural values.
- In general 73% of our participants didn't believe in cultural stereotypes.
- 67% thought it would be useful to implement cross-cultural training into education. As presented in Table 1, among the most common reasons are a) building tolerance, respect, b) living and working in multicultural environment, c) learning cultural values of other cultures.

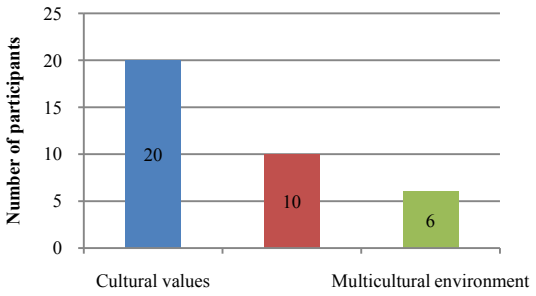

Figure 2. Benefits of implementing cross-cultural training into education

- In question 14 the participants were asked to put into words and describe in a few sentences their thoughts and name situations when cross-cultural values would be of service. With open-ended questions we wanted to give them the freedom to express themselves with their own words. We believe that our targets need to develop the ability to think and act outside of their particular cultural circumstance; hence we filtered out the most common recurring situations they identified (not limited to only one situation) and presented them in Figure 3.

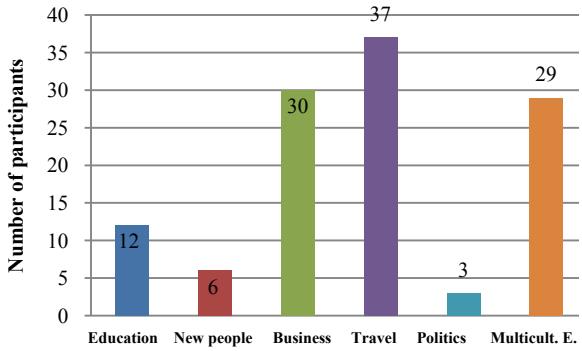

Figure 2. Situations of importance for assessing cross-cultural values

V. CONCLUSION

The purpose of this preliminary study was to assess the awareness of our citizens about cross-cultural values, stereotypes and their opinions and experiences about multimedia aided learning., our targets in higher education need to think

On the question whether multimedia aided learning of cross-cultural values have potentials we came to the following conclusion:

Based on the positive comments we received from our participants we consider that this research proves there is a legitimate need for involving multimedia in teaching cross-cultural values.

Their beliefs about cultural differences show us that they are open to other cultures and they identified that assessing cross-cultural values can help them in building tolerance and respect, deeper understanding of their multicultural environment. We appreciate their different views however we consider that the number of 16 participants who believe in cultural stereotypes is disturbingly high. We feel that considering 12 of them are teachers it should be lower.

We also concluded that the age of respondents had not influenced the responses.

Also, further understanding of how multimedia can support learning cross-cultural values is needed.

VI. POSSIBLE OUTCOME

The phase of realisation can be divided into three parts:

1. The first step is defining the indicative budget.
2. Finding partners. Considering that creating multimedia for learning cross-cultural values requires interdisciplinary skills, namely design skills, software development skills and detailed knowledge in culture, interdisciplinary teamwork is proposed.
3. Finding financial support for the realization of our idea.

Computer network applications, practical implementations and structural control system representations

Nderim Zeqiri*

* Faculty of Applied Sciences-Mechatronics – State University of Tetova, 1200 Tetovo, R. Macedonia, office, Mechatronics
nderimzeqiri@gmail.com

Abstract – The computer network play an important position for practical implementations of the differently system. To implement a system into network above all is needed to know all the configurations, which is responsible to be a part of the system, and to give adequate information and solution in real-time. So if want to implement this system for example in the school or relevant institutions, the first step is to analyze the types of model which is needed to be configured and another important step is to organize the works in the context of devices, as a part of the general system. Often before configuration, as important point is descriptions and documentations from all the works into the respective process, and then to organize in the aspect of problem-solving. The computer network as critic infrastructure is very specific so the paper present the effectiveness solutions in the structured aspect viewed from one side, and another side is, than the paper reflect the positive aspect in the context of modeling and block schema presentations as an better alternative to solve the specific problem because of continually distortions of the system from the line of devices, programs and signals or packed collisions, which are in movement from one computer node to another nodes.

Keywords: Computer network, implementations, modeling, structural representations.

I. INTRODUCTION

Often the first step in attempting to design a new part of software is needed to create firstly an algorithm which can be used to implement any practical solution. The main purpose of the paper is to bring information to the reader in general networks [5]. In this paper I have tried to restrain some formal rules and structural work in order to have a better content and be much more manageable and understandable to the reader. At the beginning of this paper, we present a brief introduction to some features of computer networks. The main part of the paper is to specifically include the purpose of the use and problems [2]. Also here is to clarify the reasons for the use of nets in relevant institutions, businesses (companies), while continuing to use them at home, then, we present the development and advancement of computer networks while being part of control systems [6]. A very special part is their use in social terms and their use by mobile users. Another objective of this work is to make the analyses and formulate mathematical model responsible and to develop algorithm for latter use or latter upgrade system [10]. So, this phase is an important step for extracting and gathering the requirements, such is, Figure.1 [12].

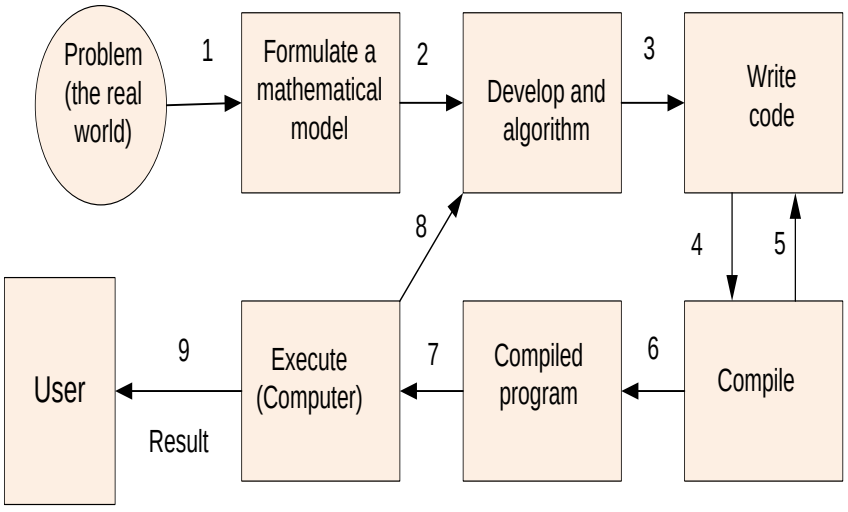

Figure 1. The process of problem-solving and respective elements

II. PROGRAM CODE AND COMPUTER PROBLEM-SOLVING THE CONTEXT OF TIMESET

In the next step is given program code in C#, to set up start time and end time for computer solving problem, and to return any value as true or false [10].

```
private bool TimesOverlap(System.DateTime dt1a,
System.DateTime dt2a,
 System.DateTime dt1b, System.DateTime dt2b)
{
   // technically the end time and start time of any back-
to-back
   // programs will fall within the same second
   dt2a = DateAndTime.DateAdd(DateInterval.Minute, -
1, dt2a);

dt2b = DateAndTime.DateAdd(DateInterval.Minute, -1,
dt2b);

   if ((dt1a <= dt1b && dt2a >= dt1b) || (dt1a >= dt1b
&& dt1a <= dt2b))
   {
      return true;
   }
   return false;
}
```

The method takes the input values of timeset1 start time, timeset1 end time, timeset2 start time, and timeset2 end time. It will return true if there is an overlap [12].

III. INTERNET ACCESS, AND THEIR INTERCONNECTIONS BASED ON RESPECTIVE ALGORITHM

In the next step is given general form, how to control any system, man-machine [8], LAN network, internet access, and all of them to be connected with Control system (to access an output object) such as robots in general context based on respective algorithm [13], Figure.2.

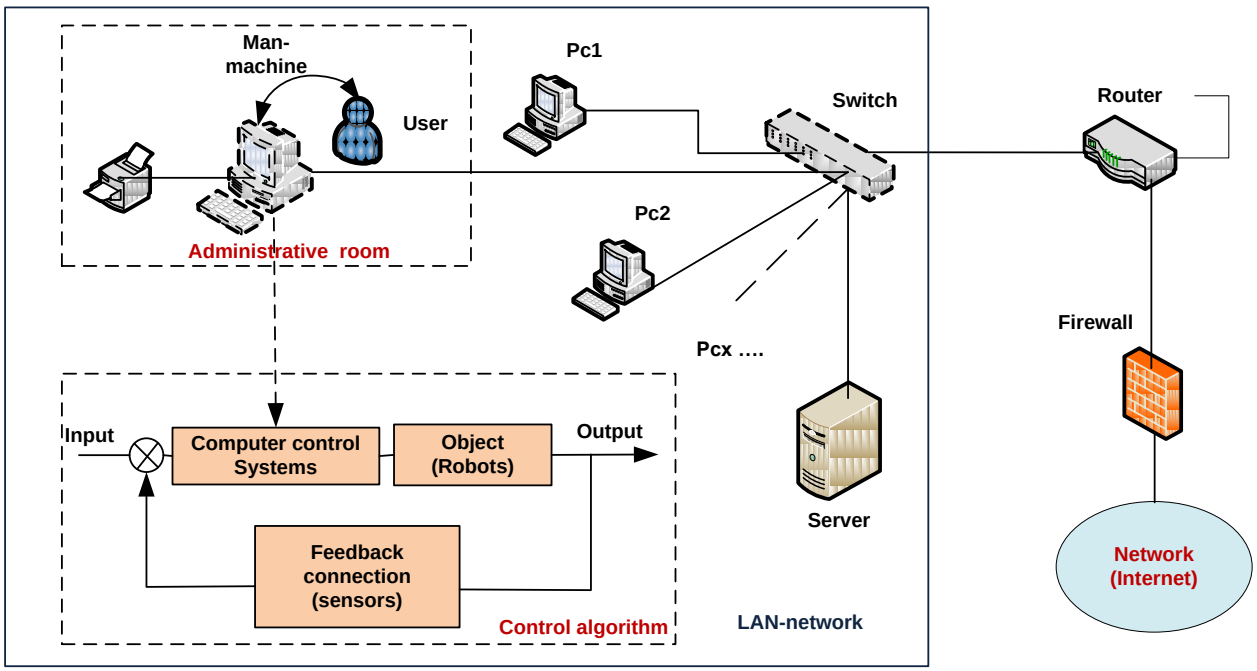

Figure.2.The control system (to access an output object) such as robots in general context, man-machine, LAN network, internet access, and their interconnections- based on respective algorithm

Very important part for above algorithm is the control algorithm, where can be installed in differently system, and also managed by human machine-interface [7], Figure 3.

In the next step, Figure 4, is given the part of the control system [2], where can be incorporated differently secured system, above all the system can be secured by smart card (with microcontroller) where can be stored the cryptographic algorithm to increase the security of the system [8].

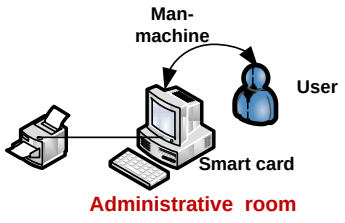

Figure 3. Man-machine, user, smard card as part of administrative room.

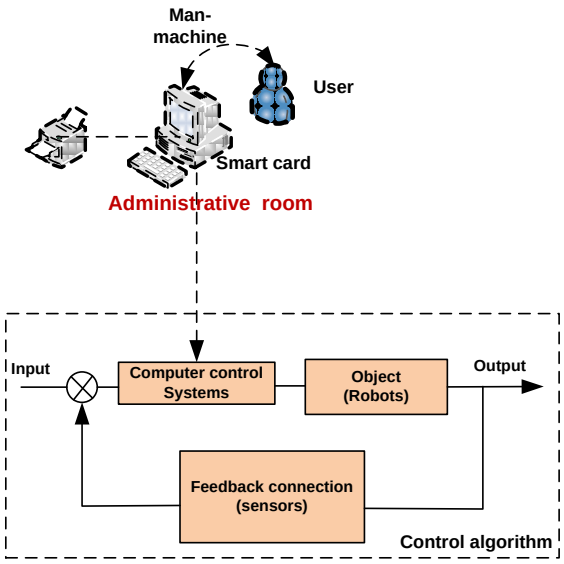

Figure 4.Control system as part of computer network, and administrative rooms, with smart card security.

IV. USING COMPUTER NETWORKS

Before we start to examine in detail the technical issues, it should be noted that although people are interested in computer networks and why use them. Ultimately, if no one were interested in using them, this means that fewer of them will be built. We will start with the company uses, and then we move to the use of home networks and develop capital last about mobile users and will conclude with social issues [4].

The basic elements of computer networks: for every computer network are required:

- At least two computers
- Every computer should have:
  - Network card
  - Cable, as intermediaries in communication
  - Passive and active device network
  - Operating Systems: Microsoft windows, Novell Netware etc.

Networks were developed as a result of business development. Business needed a solution on how to communicate effectively, how to avoid duplication of equipment and resources, and selection was carried out by networks of computers that increased productivity and saved money. Any manufacturing company creates hardware and software based on standards. As a result many companies were incompatible networks [4][5]. Network devices need to implement new technologies. One solution was the creation of standards for LANs, Figure 5. As a result compatible devices made by companies. New technologies definitely needed to distribute information between businesses, as far and as fast. Requirements of companies have a number of computers [4]. For example, a company might have a computer for every employee to view the products you design, to print brochures, and to do list for the payment of workers. The goal is to make all programs, equipment and especially data available to the entire network without having to connect the physical location, source or user. A clear example is the widespread and when some office workers share a common printer [1]. Small or large companies are vitally dependent on information. Most companies have customer data, product information, inventories, etc. financial statements [3] etc.

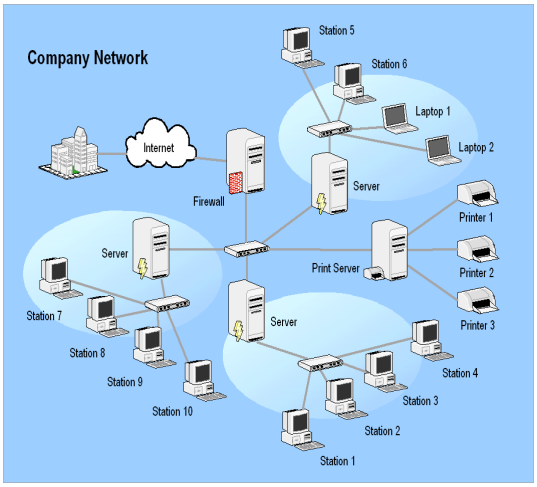

Figure 5.Company network (for example use a same printer-shared into the network)

Using nets and social issues: Social networks, message boards, information sharing sites allow people to share their views, beliefs, attitudes and above all their goals. Analytical-researchers of this practice argue that peer-to-peer networks and other content should be treated in the same way because they are all just "stream of bits" of network packets.

Foremost is the most used network is the Internet, which has enormous number up to the latest development of wireless networks. They use wherever you go people, resulting in a patchwork of coverage in cafes, in hotels airports, educational institutions, trains, planes. Anyone with a laptop and wireless modem can be connected to the Internet [7]. This approach increases the risk quickly to different situations created in the context of detection, the password and the performing harmful actions. Therefore, in Figure 2, is given the possibility of using the control system [8], where you can put a smart card for increased level of security through the use of different cryptographic algorithms [13]. However safety is always the threat from various factors, therefore the algorithm shown in Figure 2 enables flexibility to make updates, and generating respective insurance values.

V. THE PERFORMANCE OF THE COMPUTER NETWORK SYSTEM

For example, when is needed to compare the performance and to compare some characteristics of the computer Control system -to control robots movement and the role into the computer network system, firstly is needed to consider, which of the works are affirmative to be analyzed and to be in systematizations for dedicated procedures. If we suppose four tasks, so, if we have to

analyses the procedures of processing with differently structured systems, based in our (own) block structured system, here we may to give interesting results, with our (own) systems priority [11][12].

Computer Control System	Task1 (time-seconds)	Task2 (time-seconds)	Task3 (time-seconds)	Task4 (time-seconds)
Our (own) network -Tx	**3**	**3.5**	**2.5**	**3.5**
Network 2-Ty	**3**	**4**	**3**	**4.5**
Network 3-Tz	**4**	**4.3**	**3**	**4.8**
...	**...**	**...**	**...**	**...**

Table1. Performance verifications, for three differently system, and where is viewed the priority of own network control computer system

Tx-total time for (own) network Control system -to control robots),$T_{total\,x} = 12.5$; $T_{total\,y} = 14.5$; $T_{total\,z} = 16.1$.
So the better performance has our constructed system because, $T_{total\,x} < T_{total\,y} < T_{total\,z}$. So the better performance has the system that can be ready to solve any problem with short time of executions.

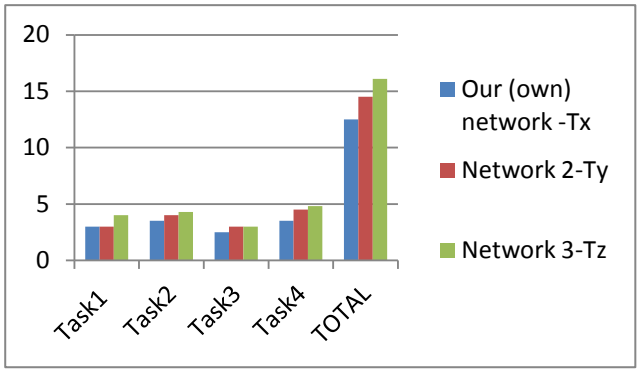

Figure.6. Graphical performance presentations, where can be seen, the own Control system -to control robots with duration time Tx-has a short time of executions, and so this system is with better performance.

VI. SOFTWARE ELEMENTS ANALYSIS

The most important task in creating a software product is extracting the requirements. Customers typically know what they want, but not what software should do, while incomplete, ambiguous or contradictory requirements are recognized by skilled and experienced software engineers [5]. Frequently demonstrating live code may help reduce the risk that the requirements are incorrect [7].
Specification: Specification is the task of precisely describing the software to be written, possibly in a rigorous way. In practice, most successful specifications are written to understand and fine-tune applications that were already well-developed.

Application Software:

- General business productivity applications: software program that perform a specific function directly for the end user, examples include: office applications.
- Cross-industry application software: software that is designed to perform and/or manage a specific business function or process that is not unique to a particular industry; examples include professional accounting software, human resources management [9].
- Utilities software: a small program that performs a very specific task. Examples include: compression programs, antivirus, search engines, font, file viewers, voice recognition software, etc [10].

VII. CONCLUSION

In this paper is presented computer network system and is given algorithm, to create a good space and meet the optimal requirements for the realization of the relevance of the use of computer systems. It is also made to find an adequate solution in the context of the domain, is simplified way of approaching the problem by improving access control and time, when using the respective operations. By determining the function of the carrier complex systems (systems with complex structure) used so far laid down rules which apply to the combination of dynamic elements. Also is given the Control system -to control robots, man-machine, LAN network, internet access, and their interconnections- based on respective algorithm [2]. Looking forward the rules are the basic rules of the control theory; also here can implement all the rules and methods of simplification, for dynamic systems and all complex structures can be transformed into basic and simple structure [13]. If our viewpoint is extended so we can create, a system, which can be interacted with others to increase the level of the observations. This level is very important to be stable system in the context of the practice because this may be a case to create the bridges for differently interfaces such as man-machine, field elements, remote control etc. Foremost is the most used network is the Internet, which has enormous number up to the latest development of wireless networks. They use wherever you go people, resulting in a patchwork of coverage in cafes, in hotels airports, educational institutions, trains, planes. Anyone with a laptop and wireless modem can be connected to the Internet. This approach increases the risk quickly to different situations created in the context of detection, the password and the performing harmful actions. Therefore, in Figure 2, is given the possibility of using the control system, where you can put a smart card for increased level of security through the use of different cryptographic algorithms. However safety is always the threat from various factors, therefore the algorithm shown in Figure 2 enables flexibility to make updates, and generating respective insurance values.

Email: {sashko.ristov, nevena.ackovska, Vesna.kirandziska}@finki.ukim.mk, darko.martinovikj@gmail.com

***Abstract*—The objective of the Microprocessors and Microcontrollers course is the students to meet the general idea and concepts of a low-level assembly language and controlling the hardware devices with embedded microcontrollers. Since this is the hardware based course, which requires a lot of efforts by both the teachers and students, the students avoid to learn its material for gaining knowledge, but just to pass the course and continue with their studies. Apart of the courses bad reputation, it is usually among the courses with the lowest throughput. Starting from 2010, the courses syllabus was changed each year towards making the course more practical exercises and exams where the students could use their software skills. In this paper we elaborate all changes that improved not only the course throughput, but also the courses reputation, average grade, curiosity to learn hardware, etc, which are presented through years.**

***Index Terms*—Education, Hardware, Teaching, Learning**

I. Introduction

A general impression for all undergraduate teachers is that hardware oriented courses are not the favored by the computer science students. Therefore, awaking the students interested in hardware courses is a great challenge. Teaching how hardware works requires interactive exercises where instructor's efforts are the most important part of the whole hardware teaching process. Starting from the Computer Architecture and Organization course, through the Microprocessors and Microcontrollers (MM), and finishing in Robotics and Modern Computer Architectures, the computer science students are usually stacked somewhere before graduation. Most of the students hate these courses and learn them only to pass, without keeping some knowledge after taking the exam.

This motivated us to make many radical changes of the curriculum and program during the several study years in order to improve the MM course. Our goal was to make this course more attractive to our students, to alleviate student learning process and increase student curiosity about hardware. This paper describes the progress the MM course through years and analyzes the main students parameters.

The rest of the paper is organized as follows. Section II presents the related work in the area of teaching the hardware based courses. Section III presents the MM course organization, while Section IV introduces the improvements made in the course through the years. The results from our experience are presented in Section V. The latest course's changes for further improvements are presented in Section VI. The final Section VII is devoted to conclusion and future work.

II. Related Work

Different methodologies exist for teaching the computer science students about hardware concepts. One teachers prefer teaching through working on real hardware equipment, others teachers propose the usage of modern visual simulators, while there are new proposal for distance learning and using the remote engineering in virtual laboratory.

The teachers must introduce the appropriate hands-on exercises, homework assignments and projects, apart from the lectures in order to make the course more interesting and to provoke the students to dive more deeply to learn how the microprocessors and microcontrollers works and can be programmed to control some task. Liang [1] performed a nice survey of hands-on assignments and projects.

A. Practical work on real hardware

The most important part of the teaching process is the practical work. It is preferable for students to actually have their hands on real hardware [2], [3], [4]. Working on real hardware in the laboratory is also very important [5], [6], [7], which requires a lot of effort by both the teachers and the students.

Wang [8] and Lee [9] proposed FPGA-based configurable processors to be used in laboratory exercises. In this case, the students can develop, implement and monitoring processor systems on real hardware.

B. Hands-on Exercises: Using Simulators

Introducing the appropriate visual simulators in the laboratory exercises lightens the teaching process and can significantly improve the students' interest in hardware generally [10], [11]. Due to lack of real hardware, appropriate simulators can be used for practical exercises [12], [13]. Ristov et al. [14] presented how their EDUCache visual simulator can be used in the computer architecture and organization course.

C. Virtual laboratories and distance learning tools

The simulators gathered with web online tools can share the laboratory equipment, thus removing the obstacles of cost,

time-inefficient use of facilities, inadequate technical support and limited access to design and laboratory resources [15]. Gusev et al. [16] presented the e-Learning and benchmarking platform for learning the Parallel and Distributed or other related courses.

D. Teaching Methodologies

Several authors presented methodologies to teach the hardware courses in general for computer science students. Reinbrecht et al. [17] present a methodology that integrates functionally verified ASIC (Application-Specific Integrated Circuit) soft cores into an FPGA in order to allow the students to learn the fundamentals of hardware and its designs challenges, not only development, but also verification and physical implications. Hatfield and Jin [18] designed and developed many laboratory exercises to design and implementation of an operating model of a pipelined processor.

Da [19] elaborated the common methods of classroom teaching and experimental teaching and some efficient methods for classroom and laboratory teaching. He [20] addressed five problems related to computer architecture education in multi-core era and suggested a possible solutions.

III. About the course

This section describes the courses material and organization.

A. The course material

The MM course is obligatory course for computer science students in their third year of studies. The course is lectured with 2 classes of theoretical lectures, 1 class of theoretical exercises and 2 classes of practical exercises per week. The practical classes are conducted in computer laboratories with a group of at most 20 students.

The teaching material is divided in two parts, by one for each midterm. The first midterm covers the x86 microprocessors internal architecture, its instruction set, the interrupt handling system, BIOS and system routines. The material for this part is based on [21] and various source code libraries.

The material for the second midterm is focused on analyzing the organization of several types of microcontrollers, their instruction set. Additionally, modern peripheral and embedded systems are also covered.

B. Grading scheme

Students are graded based on their activity on the practical exercises, their projects and the results from the midterms or final exams. Student's activity on the practical exercises includes solving some given problems, which should be solved during the laboratory classes.

Student projects are more complex programming assignments that students usually do at home. They require additional research in the areas not covered in the course classroom. There are two midterms during the semester and there are three more sessions for the final exam. The exams are divided in two parts theoretical and practical. They should properly test student knowledge, so they are based both on the theoretical part of the course and the more practical one.

C. The MM course objectives

In the previous curriculum for MM the programming assignments were done in an inappropriate programming and simulation environment. Microsoft Macro Assembler [22] along in the Programmers Work Bench (PWB) environment. Since many national contestants and good students had problems with the course, it was obvious that the environment did not give students the appropriate sense for programming in a low-level language.

Maybe one problem was that the students did not have the opportunity to make real world applications. Real application and working on real hardware should make the curse material less abstract and more practical which is one of the most valuable objectives of this course.

Another problem this course had was the disjointed material between lectures, theoretical and practical exercises. Following this methodology, students had much more material that had to be learned, but the differences made it impossible to grasp the most important parts of the lectures. This course need a more practical approach where the lectures and the theoretical exercises are both support for the most important practical exercises in this course.

Therefore, the courses organization and curriculum had to be changed. The decision was to migrate a hardware-based course such that it will become as close as the software-based one. That is, to create a course that will awake the computer science students curiosity about the hardware-based courses by challenging their software and high-level programming skills.

IV. Improvements through years

This section describes the changes made in the MM course each year, starting from 2010. These courses radically improved the course reputation, students grades, throughput, etc.

A. Awake the computer science students curiosity about the hardware - New course curriculum

The starting point for the changes was the year 2010, when the first task was to awake the students curiosity to learn the hardware, especially for the theoretical and practical exercises for both parts of the course.

The old DOS based Microsoft Macro Assembler (MASM) simulator was abandoned and replaced with a new modern visual simulator. This simulator enables students to watch registers, parameter values, memory locations, the program stack etc. Also it enables step-by-step program execution.

The other simulator for 8051 was also abandoned, since the students had a huge problem to learn similar, but not the same assembler. A totally new microcontroller PIC16F887 together with its development board was introduced. We decided to use Peripheral Interface Controller (PIC) platform mostly because of the large number of implementation and the availability of embedded software for a direct connection with PC and the availability of Flash memory [23].

B. Enforce the students to work on real hardware - New grading scheme

A new grading scheme was applied in order to properly reflect the changes in the curriculum previously explained [24]. The points for the practical part of the exam were increased from 50% to 80% (50% practical exam, 20% laboratory exercises and 10% for the mandatory project). Theoretical part was reduced from 50% to 20%. Additionally, a non obligatory project was introduced, which was mandatory a hardware project, i.e., working on real PIC. They can achieve maximum 20% for this project. Students that will decide to work on an additional project would have the opportunity to put their hands on PiC16F778. They faced an additional problem here, that is, lack of RAM or ROM memory, or both. Usually this is one interesting and a bigger student project. By doing this project students have a potential to achieve higher grades. Introducing the new grading scheme has also increased the students' curiosity about learning the hardware, as well as the desire to work on a real hardware and face with real problems.

C. Adaptive learning

Usually, the computer science students' structure is very discrepant, starting from the students that study computer science because they want to get a job easier to the students that are excellent in mathematics and computer science and are national or international contestants and even winners. This fact enforces us to introduce an adaptive learning, that is, to introduce the incrementally weighted exercises, as well as opportunities for bonus scores. It enables the students to group based on their gained knowledge and interest for a particular level of learning. Basic students need to work on the mandatory exercises that cover all learning objectives, while the advanced students are allowed and encouraged to work on harder tasks, since they had finished the mandatory exercise earlier. With this adaptive learning, the advanced students are more challenged and focused through the entire course.

D. Utilize the students' software skills - New hands on exercises

We introduced new practical assignments for the exercises that involve the visual simulators [25]. Doing this we abandoned the old hardware oriented practical exercises and introduced more software exercises. The new exercises include arrays and matrix, strings, procedures, macros etc., which are well known concepts of the programming courses.

The practical exercises for the material of the second midterm (microcontrollers) were also changed. They are based on mikroC programming language, the high-level language that the students are used to program in. They could use many additional hardware components with only a few lines of code. Components like alphanumeric LCD displays, ports for serial communication, EEPROM memory, Keypads and others were studied on the practical exercises. Using mikroC as a programming language was quite positively accepted with the students because of their previous experience in C.

E. Busy students - OER Approach

We introduced new practical assignments for the exercises that involve the visual simulators [EDUCON2013]. Doing this we abandoned the old hardware oriented practical exercises and introduced more software exercises. The new exercises include arrays and matrix, strings, procedures, macros etc., which are well known concepts of the programming courses.

The practical exercises for the material of the second midterm (microcontrollers) were also changed. They are based on mikroC programming language, the high-level language that the students are used to program in. They could use many additional hardware components with only a few lines of code. Components like alphanumeric LCD displays, ports for serial communication, EEPROM memory, Keypads and others were studied on the practical exercises. Using mikroC as a programming language was quite positively accepted with the students because of their previous experience in C.

F. Enforce the iterative learning Prepared students in the laboratory

As many education researchers reported, the laboratory still remains the place where the students can learn the hardware based courses and working on the visual simulators is not enough. Therefore, our new teaching methodology enforces the students to come prepared on the laboratory exercises. Tutorials with examples and solutions were announced a week before the corresponding laboratory exercise. The students then work on problems during the laboratory exercise and have to complete their activities during the laboratory classes. A minimum of 50% of all points must be achieved by a student in order to allow him / her to go on the final exam. Otherwise, he / she must reenroll the course in the next study year.

V. The results

This section presents the results of the students that were enrolled on the MM course through several years, starting from 2009 with the old course curriculum, and 2010 with the improved one.

A. The course's tasks completition

The percentage of completed students in each year has is depicted in Figure 1. This percentage has decreased for around 10% in 2011, and kept its value around 80%. This is the exact period of the iterative learning enforcement implementation, as described in Section III.F.

B. Improved the course's throughput

Figure 2 depicts the course throughput through years. It shows some paradox, that is, the percentage of the failed students increases starting from 2010, when the radical changes are implemented. Figure 3 depicts better the decreasing of the percentage of the passed students through years.

However, Figure 4 disproves this paradox, since it depicts that the percentage of the passed students that completed all tasks during the semester is increasing due to the implemented improvements. The 45% of the passed students in 2013 is

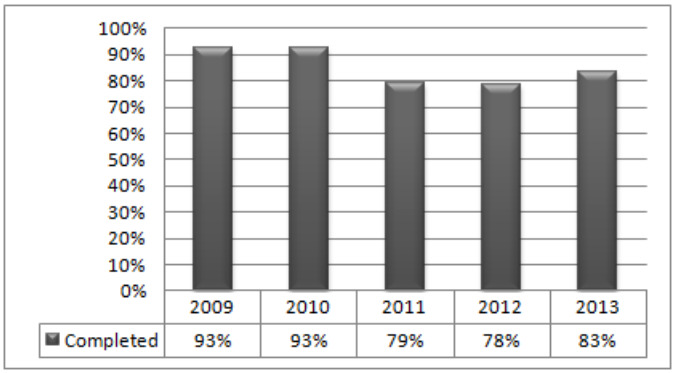

Fig. 1. Percentage of the students that had completed all tasks during the semester

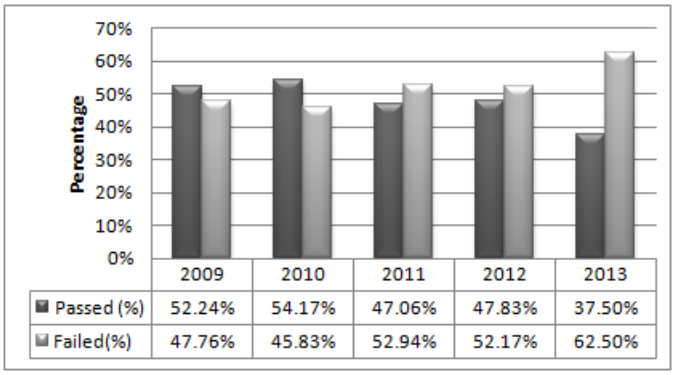

Fig. 2. Percentage of the passed students of all enrolled students

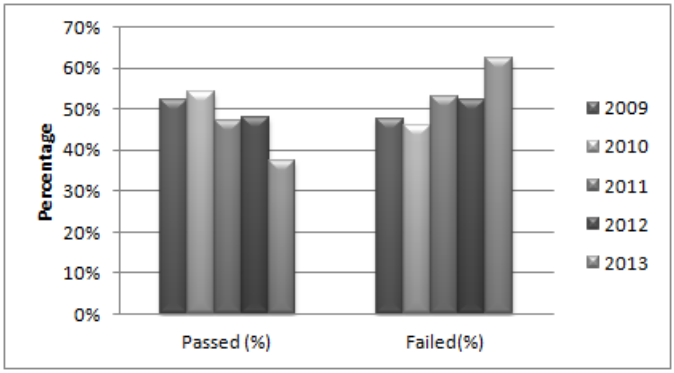

Fig. 3. Comparison of the percentage of the passed students of all enrolled students

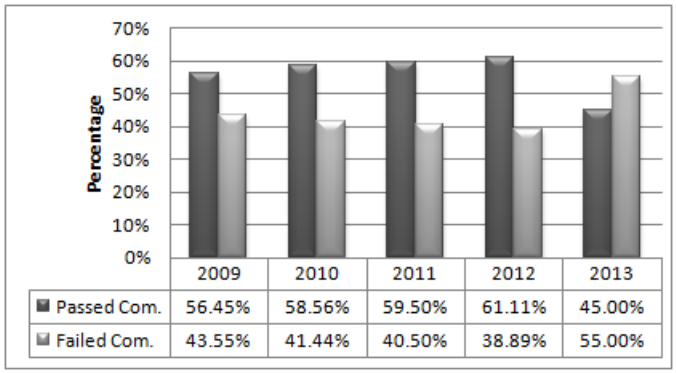

Fig. 4. Percentage of the passed students that had completed all tasks during the semester

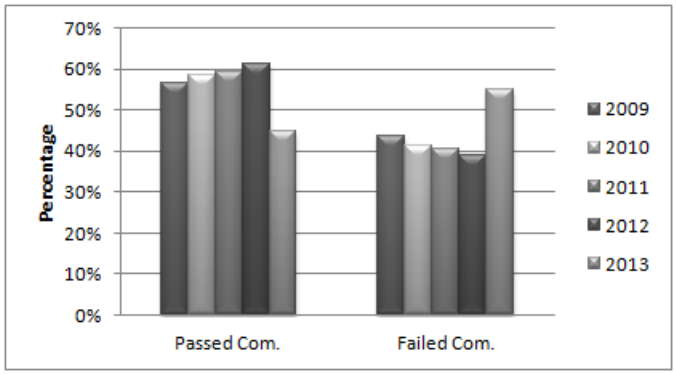

Fig. 5. Comparison of the percentage of the passed students that had completed all tasks during the semester

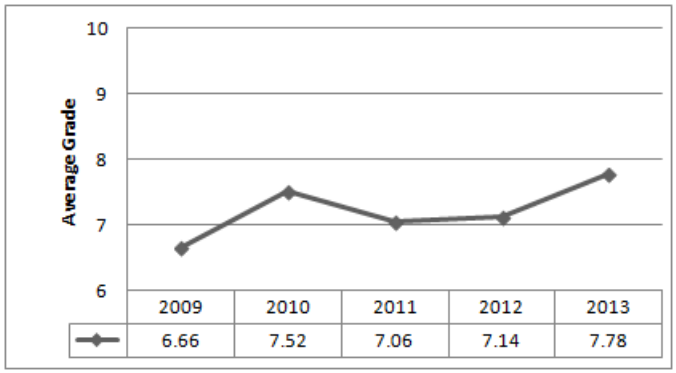

Fig. 6. The students average grades through years

low since only one session have passed and two additional session exist, where the authors believe that this percentage will be the greatest compared to prior years. Figure 5 depicts the improvement of the percentage of the passed students that completed the tasks through years even better.

C. Improved students' average grade

Another improvement is reported in the students average grade through the years after the implementations of the improvements, which is depicted in Figure 6. The average grade has increased for more than 1, that is, from 6.66 to 7.78 in 2013. This graph explains the student accomplishment through the years in general.

In 2010 a small jump in the average grade can be noticed. The average grade in 2010 is 7.52 which is higher than in 2009 and in 2011. The explanation is that the year 2010 was the first study year with the new revolutionary curriculum, and also 10 of 120 students that were enrolled in 2010 were honorable students, who later were chosen as demonstrators at our faculty.

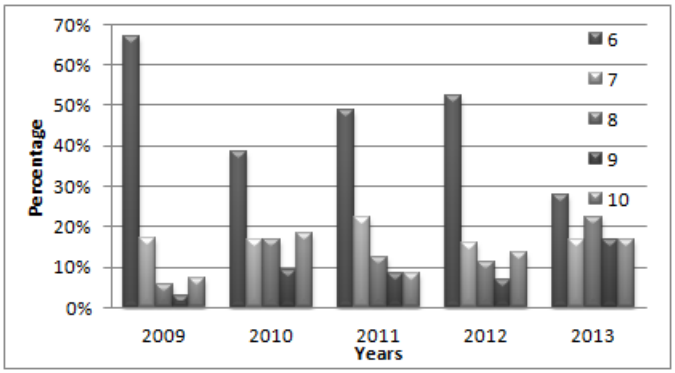

Fig. 7. The grade distribution per year

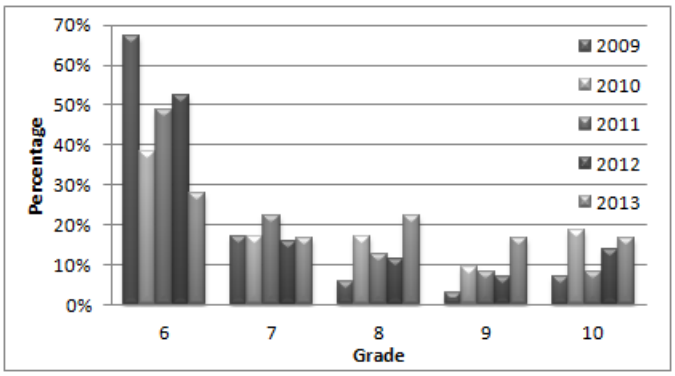

Fig. 8. The grade comparison through years

D. Improved grade distribution

The grade distribution through years is depicted in Figure 7. Let us examine firstly the year 2009, which is the year prior the improvements. More than 2/3 of the students achieved the minimum grade 6, or 84% of the passed students had the grade 6 or 7. The grade distribution is significantly improved starting from 2010, which is emphasized in 2013. However, probably similar grade distribution will be achieved after finishing this year course, since our analysis reports that the students achieve lower grades in the last two sessions.

E. Improved grades through years

Figure 8 compares the achieved grades through years. This figure shows that the grades 8, 9 and 10 are much greater after the implementation of the improvements, the percentage of the students that achieved grade 7 are constant, while the 6s are reduced significantly.

VI. Further course changes for additional improvements

Apart of the presented course changes and achieved improvements, there is still place for further changes. This section presents the changes of the course made this year.

A. Student Collaboration - Developing simple games

Starting from this year, collaboration is implemented in the nonobligatory projects. That is, the projects represent some interesting two-men game, such as battleship, X/0, checkers, memory etc., where the first student develop the game configuration and the artificial intelligence, while the other student develops the part for gaming. Programming games could be interesting and productive activity for students, where they can implement their knowledge gained in the previous artificial intelligence courses.

B. Separate the exam in two parts

Another change is the enforcement to have minimum 40% of the points for each part of the course, i.e., the microprocessors (assembly language) and microcontrollers (mikroC). Since this would made the course heavier, we allow the students to take the course parts separately.

The students can choose whether they can or like to take one or both parts of the exam in an exam session. This approach will enable the students to concentrate more on just one part of the exam in each session, thus enabling them to pass the exam with a higher grade.

VII. Conclusion and Future Work

This paper presents the changes that were made of the MM course several study years: the new curriculum, new grading scheme, adaptive learning, iterative hands-on, OER approach for busy students, and already prepared students for laboratory exercises. These changes had improved the course bad reputation, as well as the students' grades and throughput. But the most important thing is that the students finally started to love the course and to learn the hardware.

We believe that the last two curriculum changes, i.e., the student must passed each part of the course with more than 40% of the practical exam (the microprocessors and microcontroller) and the collaborative learning will improve even better both the students and the course. We will survey the students about the changes and continue to improve the course to improve the results od the students even more, without lowering the criteria for passing the course.

The other teachers could implement our proposed changes into their related based courses for computer science students in order to make the hardware based courses more software-based.

State of e-learning projects in Croatian companies

Tea Dragičević, Maja Ćukušić and Mario Jadrić
Faculty of Economics, University of Split, Split, Croatia
{tea.dragicevic, maja.cukusic, mario.jadric}@efst.hr

Abstract – The purpose of this research was to analyse the current state of e-learning projects in business settings in Croatia through the prism of organisations' technological and methodological approaches, which (along with the characteristics of the organisation) constitute the basic framework for the implementation of e-learning projects. The study was conducted in early 2013. The survey participants were employees of large Croatian companies with particular interests and working focus in e-learning area. The results indicate that Croatian organisations keep up with global trends, but there is certainly lot to improve. This kind of analysis has not been conducted so far. Other than bringing forth the analysis of the state of corporate e-learning projects in Croatia, the contribution of this pilot-study represents the basis for future research in the area of e-learning in business settings.

I. INTRODUCTION

The traditional concept of classroom training is gradually losing its dominant role in business settings, while e-learning is considered to be one of the newer and more and more implemented concepts that it is certainly breaking on the Croatian market. The propagation of e-learning use in business settings is based on a massive expansion and price drop of internet services, as well as the enormous time and cost savings and flexibility. All above mentioned variables encourage immediate knowledge sharing among all users, collaboration and computer-based assessments as some of the application areas within both SMEs and large organisations.

With regards to what e-learning in companies actually stands for providing the frame for the subsequent interpretations, we use the definition brought forth by HELIOS project [1]. Labelling different "territories of e-learning" e-learning in the workplace is defined as the use of ICT in the corporate (business) environment, public administration and agencies. The difference in the extent and approach to the implementation of e-learning between corporate and government environments largely depends on the organizational structure and practices and policies related to human resources management. Given the nature of the underlying systems for learning management and management of day-to-day activities related to human resources within business organisations the overarching e-learning programs are often implemented in smaller chunks as projects with definite scope, time frame and resources. Terms e-learning programs and e-learning projects are interchangeably used in the paper.

Today's workforce must process and master more and more information within limited time frame. This fact largely contributes to importance of e-learning area in business settings [2]. Technology is the mean that allows the management and efficient utilization of information and learning process [3], with its main purpose to ensure that the employees of whether small or large organisations can learn faster and "consume" new information more often [4] and at a convenient time. Ultimately, the main goal of e-learning in business settings is to serve corporate goals and needs in order to increase competitiveness, profit, efficiency and effectiveness [5].

In short, the mission of e-learning in business settings is to deliver up-to-date and cost-effective educational program to all employees [2]. One of the characteristics of future e-learning solutions in business settings is the sole focus on employees - in particular the spotlight will be set on a user-centric model implying that knowledge workers must be provided with all the appropriate services and techniques [6].

Although the technology enables and drives the implementation of e-learning in business settings, its use is largely shaped by social factors, including the objectives and priorities of those who specifically decide on the implementation of e-learning and manage the process [7]. It should be noted that cautious consideration of the methodological aspects, the way in which e-learning is organised, is one of the most important prerequisites for the successful implementation of e-learning [8]. Overlooking the methodological issues or the failure to meet the so-called "soft" requirements is the second most frequently listed reason for unsuccessful implementations of e-learning solutions in business settings; this is especially with regards to two causes [9]: the lack of focus on people and the inappropriate use of e-learning concepts and related tools.

Often, the main reasons for failure of e-learning projects are generally listed as [10]:

- problems with the technology,
- lack of management support,
- poorly designed courses and
- disregard for individual learning preferences.

It is clear that within the abovementioned causes, major problems are related to pedagogy/andragogy, i.e. poor design of learning courses and disregard for learning

preferences of learners. With regards to the lack of focus on people, one of the problems and reasons may be that businesses/corporations do not perceive their employees as learners [11].

This paper presents a short pilot-analysis of current scenario of use of e-learning concepts in business settings in Croatia. The results are presented through two different aspects – namely, the questions relate to both technological and methodological issues as well as to some organisational characteristics. The theoretical implications of e-learning implementations in business settings are presented in the second chapter. The third chapter brings forth results of the study and the fourth chapter concludes the paper.

II. E-LEARNING IN BUSINESS SETTINGS

A. *Different aspects of e-learning in business settings*

Generally, employees have a positive attitude towards workplace learning. According to a recently conducted study in the USA, 85% of employees prefer learning during working hours and 62% prefer learning in the office [12]. According to the same author, more than half (52%) of employees are advanced computer users and have a very positive attitude towards e-learning. The statistics show that 80% of learners (employees) can effectively "consume" learning in all forms and therefore the majority can safely, without any issues learn using the Internet.

Corporations have recognized this point of view as well as the positive perception towards e-learning by their employees, so it is no surprise that in the USA 95% of corporations use at least some kind of form of e-learning [13]. Therefor the majority does so in order to deliver a training or professional development courses to their employees [2]. The paradox today is that people need to learn a lot more but have less time for that purpose, so the question is: how do we know what we need to know it in the exact moment when we need it [14]?

One of the important motifs for use of e-learning in business settings is that all organisations do not have the capacity to organise face-to-face learning sessions [12]. Sometimes, face-to-face learning courses cannot be carried out because large organisations are dispersed in the form of multiple geographical locations and even multiple time zones while employing a large number of people with different levels of knowledge [2]. Evidently, there are major opportunities for learning during working hours, but the e-learning solution conveys even more convenience for the stay-at-home employees who live in remote areas or cities [12].

Learning in business settings is interdisciplinary and especially task-oriented [15]. What principally distinguishes majority of business organisations from learning organisations is that their primary goal is not learning itself [5]. Workplace learning comes down to use of e-learning applications and affects/results in changes to working practices [16]. One of the main characteristics of e-learning in business settings is cooperation, since knowledge sharing practices with working/learning peers is a very important part of the learning process itself (ibid).

Social networks are one of the new features and trends in organisational e-learning endeavours [17]. In fact, it was only a matter of time before social networking tools "migrate" to a professional environment with the purpose to increase the overall company knowledge-level [18]. Some predict that the development of e-learning tools and projects in business settings could progress straight to full integration with social networks [19]. The starting point for such predictions is the fact that people are progressively using more and more social networks and have gained confidence by sharing a variety of data, information and documentation over the Internet [18].

Most of the tools that should and could be used for e-learning in business settings already exist, but the only question is whether the companies are willing to use them [19]. Some of those tools which portray new forms of Learning Management Systems (LMSs) – the social LMS are (ibid): (1) calendar, (2) chat, (3) events, (4) articles, (5) survey, (6) blogs, (7) shoutbox, (8) pictures, (9) documents, (10) forums and etc.

Another trend in e-learning for businesses is the adoption of mobile learning technologies, or m-learning [17]. The increasing usage of mobile information exchange is a relevant signal for managers, to adapt and to develop an architecture for delivering learning material via smart phones and tablets [20] and more recently phablets.

Considering other technological trends in e-learning solutions, it is worth noting that LMSs should develop in the direction of becoming Personal Learning Environments (PLEs) [6]. To sum up, the approach to (workplace) learning should be socially-oriented, decentralized and above all individualised.

B. *The current state in Europe and Croatia*

After this brief literature overview, the question presents itself – what is the current situation in Croatia? Analytical insights of corporate e-learning in European enterprises, emphasizing Italian indicators, are presented in a recent study [21]. Based on the data, from Eurostat, an overview of development of e-learning in business settings for the period 2003 to 2009 is prepared and presented in Table 1.

According to the maximum percentage of e-learning use in business settings in 2009, Croatia takes the 19th place (31%) whilst the average of EU-27 takes the 26th place (24%). When the mean percentages of e-learning use in business settings through all seven years are observed, it can be stated that Croatia (23.86%) is keeping up well with the EU-27 countries (22.17%).

The data in the table is sorted by the progress (the delta) in the latest year (2009) from the start year (2003). For Croatia, the shift puts us in the 16th place overall with the increase of e-learning use in business settings of 12 percentage points. Therefore, a very high progress in comparison with the EU-27 average and other countries can be noted.

TABLE I. PERCENTAGE OF E-LEARNING USE IN BUSINESS SETTINGS 2003 - 2009 (ADAPTED FROM [21])

No	Country	Min	Max	Mean	Delta
1	Cyprus	25	59	46,14	34
2	Malta	22	51	29,86	29
3	Norway	14	43	29,14	29
4	Denmark	8	30	19,14	22
5	Bulgary	20	41	25,86	21

31	**UE 27**	**20**	**24**	**22,17**	**4**
32	Iceland	17	20	18,29	3

Since there is no detailed state analysis of e-learning in business settings in Croatia, an overview of pilot study is conducted and its results are presented in the following chapter. Such study was deemed important since there are no available studies examining the level of use of e-learning concepts in business settings in Croatia. In particular, it is interesting to inspect whether or not the corporate managers in Croatia recognised the importance and the potential of e-learning. Certainly, their level of recognition would manifest in terms of choosing the appropriate technologies, and in the number of methodological aspects taken in consideration when implementing the e-learning projects.

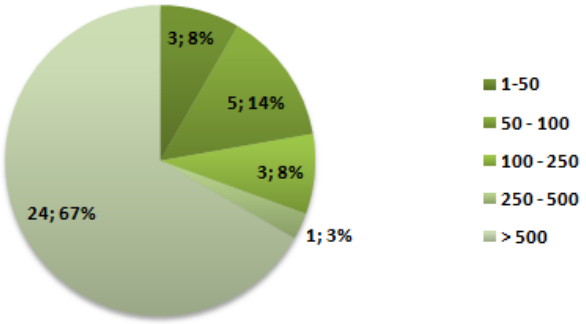

Figure 1. Number of employees in respondent's organisation (N=36)

III. STATE OF E-LEARNING IN BUSINESS SETTINGS IN CROATIA

A. *Research method and participants*

The study was conducted on a sample of business people in February and March 2013. The sample consisted of participants who are employed in large Croatian companies and have particular interests in the field of e-learning, i.e. they are working on or are planning to implement e-learning in their organisations. All the participants took part in the first conference related to e-learning in corporate settings titled "Knowledge in focus" which was held in company Podravka in September 2012.

A questionnaire was sent to 138 email addresses, and the total number of completed questionnaires was 36. It is a relatively small number mostly because activities related to e-learning are still in the early stages of development in Croatia (also illustrated by the fact that this was the first conference dedicated to this topic). A tool used for collecting data was Survey Gizmo. The questionnaire contained 15 questions of which 13 where questions with multiple choice answers and two open-ended questions. The complete questionnaire in Croatian is available at http://tinyurl.com/q7zoe5u. We chose to present the most interesting questions/replies. The questions are presented as the titles of the figures.

From 36 of respondents, 66.7% work in organisations with more than 500 employees (Figure 1). The results must therefore be considered and interpreted as an overview of e-learning state in large business organisations.

Figure 2 represents number of organisations with regards to a year in which they started with implementation of their e-learning projects. Most of the corporations started during the last 5 years (66%). The number of projects that have started in 2003 and earlier (17%) generally corresponds to the number from Bucciarelli's study [21]. The respondents had different roles (Figure 3) – those involved in creating courses (44%), execution of learning related processes (69%), technical support (25%) and process management (19%). Therefore their responses related to technological and methodological aspects of e-learning should be considered as relevant. But, considering the structure of the sample of respondents and the companies, it should be noted that it was not possible to collect data on the specific business requirements that should be aligned with e-learning

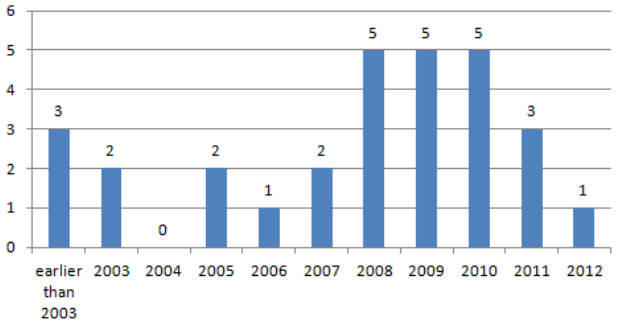

Figure 2. Number of organisations considering the year their e-learning projects started in

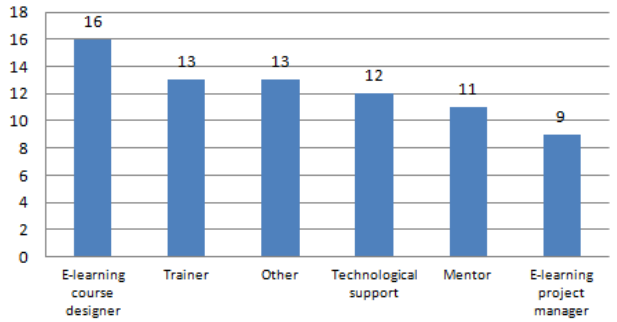

Figure 3. Respondent's role in e-learning processes in organisations

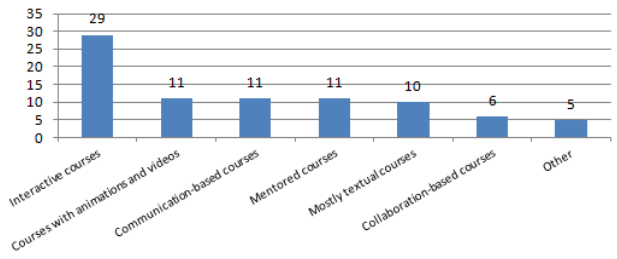

Figure 4. Types of e-learning courses in organisations

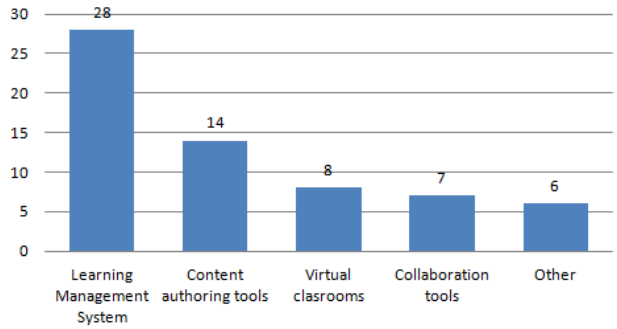

Figure 5. Types of technologies used for e-learning in oganisations

programmes. This is somewhat limiting the contribution of the research results.

Regarding the use of online courses, which organisations implement for various purposes, the most common usage is for improvement/advancement of professional knowledge and skills (72%) and for technical training (44%). Courses that provide training for the new products and services (39%) and jobs (14%) are also commonly implemented.

In terms of learning content (Figure 4), the most common response (81%) is that the courses are interactive, meaning that they contain both learning materials and assessment. In addition, 30% of the courses contain animations and videos while almost the same percent of courses (28%) contain only text. Also, over 30% of the courses are mentored. For over 30% of the courses, participants state that they support communication between the participants (e.g. forum, chat), while only 17% of courses support collaboration between participants (e.g. submission of joint work). The results confirm that the corporations have recognized the importance of methodological principles in structuring courses. Responses to questions such as: who are the participants of the courses, what is to be achieved by implementing the course, what are the organisational capabilities and etc., are all input for the first phase of designing an e-learning course. For example, if potential attendees/learners of an e-learning course are mainly dislocated, fully-online mentored e-learning course could be a better choice than a hybrid approach to e-learning (of course, this does not need to be set as a rule).

In terms of time a relatively small number of organisations provide learning during non-working hours (36%), i.e. employee cannot learn wherever and whenever he/she wants. This can and should be explained from the perspective of organisations, since 72% of the cases organisations enable e-learning activities to only take place during working hours. In some cases business processes, and consequently the learning material, can be considered as sensitive information and in some cases even a business secret. It is understandable that the access to such information may be restricted. In most cases courses are flexible regarding time, but 33% of organisations have scheduled and limited the time frame for e-learning related activities. Time management is considered to be one of the most important characteristics of successful learners whether they are participating in an online course or in traditional learning activities. The most successful learners engage at early stage, they participate frequently and make sure to have enough time in their schedule to ensure success in all aspects of online learning. However, in scenarios when employees have no limits regarding the time and place for accessing the e-learning content they are generally overwhelmed with other work-related obligations so they have to possess a very high level of self-discipline and motivation to conscientiously carry out the tasks in e-learning courses.

Motivation is being emphasized in both traditional and online education, since it is considered to have huge positive impact on learners/employees in e-learning settings. Intrinsic motivation is associated with the employees' desire to learn and acquire new knowledge, while extrinsic motivation is associated with the expectation and reaction to an award or a penalty such as the impact of assessment results, gaining certificates, etc. [22]. When planning and considering employees' motivation for accessing e-learning courses it is justified and recommended to cautiously combine extrinsic and intrinsic motivation mechanisms. However, the extrinsic

factors do predominate in the Croatian organisations, i.e. 42% issue certificates and in 31% of cases employees are required to gain a specific level of credits. But, the results have shown that employees are intrinsically motivated as well with visually attractive and interactive content (33%), by emphasizing the best participants (22%) and various awards (6%). The optimal combination for motivating participants contains moderate use of extrinsic and high intrinsic motivation [23].

The learning activities and e-learning courses are promoted more or less equally through direct communication (64%), intranet (61%) and e-mail communication (newsletters) (61%), while only 17% of organisations organise special events.

In terms of technology, it is important to differentiate between different e-learning technologies before presenting the results. Technological providers can be commercially differed as [24]:

- Technology providers, which are prerequisites to setting up solutions for e-learning in organisations (such as collaboration tools, content authoring tools, knowledge management systems, etc.),
- Service providers (providing service assessment and testing, system integrators, media hosts, etc.) and
- Content providers (offering soft-skill courses, IT courses, generic courses, simulation content, content aggregators, etc.).

The highest percentage of organisations (78%) from the sample use "classic" e-learning management system – LMS (Figure 5). This is followed by 39% of them which use tools for content authoring and 22% who use virtual classrooms. Less than 20% of corporations use collaboration tools, while only 17% do not use any of aforementioned tools.

Considering the implementation of e-learning content, results indicate that large number of organisations (81%) generate their own content while in addition 42% buy generic content (specifically IT and soft skills content). With regards to service providers, 31% of organisations use expert services for learning content creation, while 20% of them buy custom content. Only 3% of the organisations buy very specialized off-the-shelf simulation content. In short, organisations in Croatia use both off-the-shelf and custom solutions and services for e-learning project fulfilment.

Finally, it is important to emphasise the fact that more than half of the organisations (54%) have elaborated a strategy for e-learning. Unfortunately, only 23% of organisations enable mobile access to e-learning courses.

Considering that results have indicated that the majority of organisations initiated an e-learning project in the last five years, it is obvious that organisations are currently at different stages of e-learning implementation. Although there is some empirical evidence that number of organisations are in the higher stages of e-learning development cycle – they motivate employees, use custom content and strategically plan e-learning processes – most organisations are still somewhere in the middle of the development cycle, i.e. they recognize the advantages and best practices, but still have not fully established e-learning procedures.

IV. CONLUSION

Large organisations from all over the world, including the Croatian ones, became aware that by implementing e-learning solutions, they can reduce process costs and increase efficiency. Though both technological solutions and methodological mechanisms are widely available, they should be implemented optimally and in relation to specific business requirements of an organisation. Often, the problem arises when there is a need to integrate several solutions for organisation – organisational learning, knowledge management and business processes management solutions – with e-learning solutions, processes and projects. However, when the successful integration of the above mentioned areas is achieved the results are manifested as easier corporate development, as well as the encouragement of employees for learning and sharing knowledge, promoting innovation and as application of acquired knowledge in adequate way [25].

The paper illustrates that the larger Croatian organisations keep up to date with global trends, but there is certainly a lot of space for improvement. The contribution of this pilot study is primarily expressed in terms of analysis of the current state of corporate e-learning projects in Croatia. As already stated, considering the variations in the structure of the sample of respondents and the companies, the contribution of the research is somewhat limited on giving insight into the situation of a specific number of organisations. Nevertheless, considering this kind of analysis has not been conducted so far, this pilot study represents a good basis for future research in the field of e-learning in business settings. Apart from collecting data on the specific business requirements, that should be aligned with e-learning programmes, we plan to inspect which types of companies are more prone to in-house training, the correlations of e-learning projects' maturity with having research departments or higher percentages of highly skilled or better paid employees etc.

Even though some organisations are still not ready to implement a project of this type, we hope that the results of this study will motivate them to engage in e-learning projects. Starting with e-learning project in organisation is never easy, but it should definitely begin with good formed e-learning strategy. Strategy should be goal-driven, representing what the organisation wants to achieve. Three things should be kept in mind: technology, pedagogy and business priorities. Nowadays there are huge number of guidance and portals offering best solution for implementing e-learning (one of them being http://eucenje.efst.hr), but it should be clear that each project must be implement on individual basis, based on internal variables and limitations in the organization.

On the other hand, if organisations are already applying this concept, the results may encourage managers of human resources to try to form a better e-learning strategy having in mind some of the

recommendations we bring forth with regards to holistic approach, individualisation, motivation and other trends such as integration with social tools so that their needs and goals are fully supported by this concept and, therefore, achieve additional value.

Abstract - This article presents a computer program consisting of a paint program and a database of specially prepared forms in bitmap format for education of visual arts in secondary schools.

Since more theoretical issues are prevailing on the secondary school level this computer software, which is actually a paint program, is equipped with different forms in bitmap format, with yes/no questions, multiple choice questions, classic questions demanding full text answers and questions where school boys and girls have to apply the solutions of the questions on specific paintings presented in the questions.

By using this program, secondary school boys and girls can compare their own answers with the provided solutions in PaintArt 2.0 and enhance their knowledge of arts.

I. Introduction

Based on the main characteristics of their computer program PaintArt for primary schools presented at the last MIPRO Conference held in Opatija in 2013, the authors developed their program further to be suitable for teaching visual arts on the secondary school level, where more theoretical topics are usually elaborated. Enhancements are provided on two levels. On the first or technical level the program has now full freehand drawing possibilities, the delete function is enhanced and the windows can be resized not only to minimum and maximum size but also at every variable size desired. [7]

Secondly, this computer program now includes four different forms or screens in bitmap format, where it is possible to ask questions in the form yes/no, multiple choice, ordinary questions demanding answers in full-text or where real application and drawing of the solution is required.

So, if the lesson is about Baroque, the dominant artistic style during the 17th century which is characterized by intense emotion and a sense of movement, the teacher could show a painting of a well known artist and ask to which movement in painting it belongs in the form of yes/no, multiple choice or ordinary questions. It is also possible to present examples in sculpture, architecture etc.

Showing examples in architecture, i.e. a church in Baroque, it could be asked to draw a line in the painting of the church which is characteristic for Baroque. [1]

By presenting this software in the class and by sharing it, pupils can take it home and by comparing own answers with the provided solutions in the software they can verify their knowledge of the topics discussed at school.

II. The Structure of the Program

Before presenting the main menu of the program PaintArt 2.0 it has to be pointed out that in the System menu box it is possible now not only to close, minimize and maximize the size of the program window, but complete moving in all four directions and resizing of the window is also accomplished. [4] Fig. 1

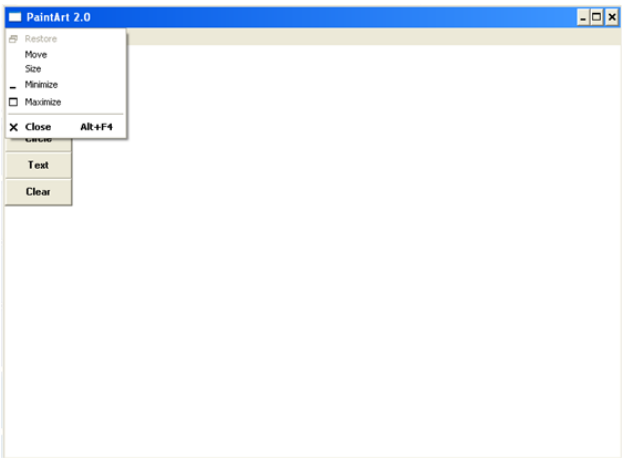

Figure 1. System menu box

As presented in the article of the last Conference the main menu of program PaintArt 2.0 is also divided in seven parts (submenus), i.e. the Load File submenu and the Save File, Drawing Color, Print, Paste from Clipboard, Paste to Clipboard and Exit submenus. Fig. 2 The Load File submenu enables the user to load or open a file in the current directory on the hard disk of the PC or even to change to different directories on the hard disk. To activate scroll bars it is only necessary to click and drag with the mouse. For that reason a complete support for a Microsoft compatible mouse is built in the program. [7]

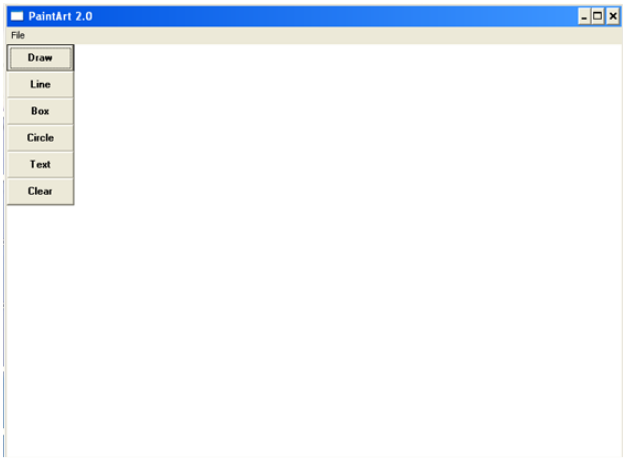

Figure 2. Main menu

The next submenus, as mentioned above, give the user the opportunity to save, print, change colors, paste to and from Clipboard and to exit the program. Fig. 2

The now enhanced graphics or painting capabilities of the computer program PaintArt 2.0 are part of the main window and enable the user to draw straight lines, boxes, circles, text, completely freehand and of course to clear or erase everything again. It is also possible to copy and paste the content or the bitmap image to the Clipboard or to a file. Fig. 3

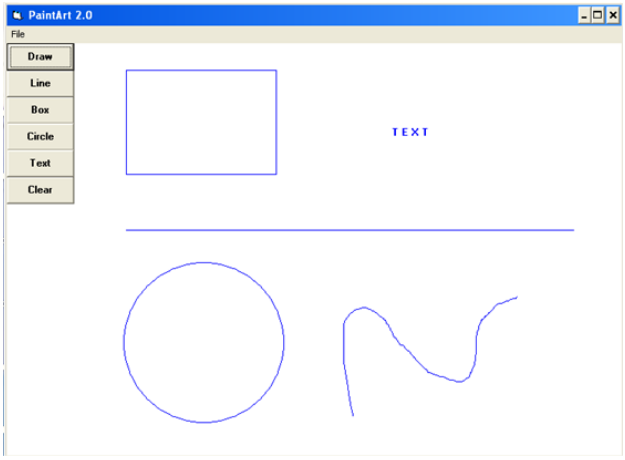

Figure 3. Painting capabilities

After the presentation of general characteristics of the computer program PaintArt 2.0 it is time to illustrate the built-in database of selected questions and answers which can be prepared in four ways or forms. [6] If the teacher of visual arts in secondary schools wants to teach about artistic styles, i.e. Baroque, the dominant artistic style during the 17th century which is characterized by intense emotion and a sense of movement, the teacher could show a painting of a well known artist (Caravaggio, Rembrandt, Velazquez etc.) and ask to which movement in painting it belongs in the form of yes/no, multiple choice or ordinary questions. It is also possible to present examples in sculpture, architecture etc. Showing examples in architecture, i.e. a church in Baroque, it could be asked to draw a line in the painting of the church which is characteristic for Baroque. It is recommended to choose paintings of well known artists, photos of famous buildings or sculptures which are a good example for the topic to be explored.

As part of the computer software, the art database - Baroque includes the following paintings of famous artists: Caravaggio – Taking of Christ, Rembrandt – Self Portrait, Velazquez – Las Meninas etc. Painting in Baroque was using a technique called "chiaroscuro" (light/dark), in which bright light forms a strong contrast with deep shadow, producing an effect like in theatres. [2] The paintings (photos) or bitmap files are numbered in consecutive order as a question (q01.bmp), answer of the pupil (q01a.bmp) and solution provided by the teacher (q01s.bmp). After the first painting or photo consisting of three files, the other paintings or photos follow as well in raising order, i.e. file number 2, 3 etc.

For illustration purposes we will present four forms of different questions all about Baroque. The first question is in yes/no form, i.e. is the statement correct or not. After having chosen the first question (q01.bmp) in the Baroque database the picture of the painting (Caravaggio) with the adequate question appears on the screen of the computer. Then the pupil imports its answer form, marks the right answer (yes/no) and saves it for later use (q01a.bmp). The solution together with the answer is provided in the solution form (q01s.bmp). Fig. 4

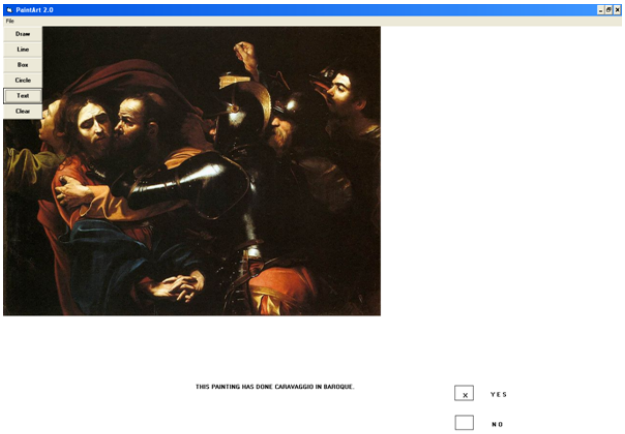

Figure 4. Yes/No form of questions

The second question is about another artist (Rembrandt) and his painting appears in the second file (q02.bmp). This time it is a multiple choice question and four answers about the author and the movement are presented, but only one is correct (a-d). After seeing the painting and having read the question the pupil should mark the appropriate answer in the answer file (q01a.bmp). Having done so the pupil can save that answer to the question in this or another file for later use and switch to the solution of the question the teacher has prepared and saved in another file. To do so, she or he has to open the third file connected to this question or the file containing the solution or the right answer (a, b, c or d) to the imposed question. In this case it is the file called (q02s.bmp). Fig. 5

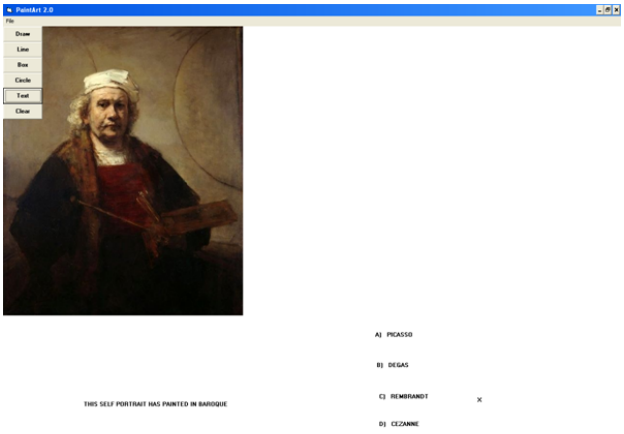

Figure 5. Multiple choice form of questions

The third sort of question (q03.bmp) is in the form of an ordinary question demanding answers in full-text mode about the artist (Velazquez) and the style (Baroque), i.e. the pupil should write down the answer and save it in a file as mentioned above (q03a.bmp). After that the solutions file (q03s.bmp) can be loaded and the answer and the right solution could be compared. Fig. 6

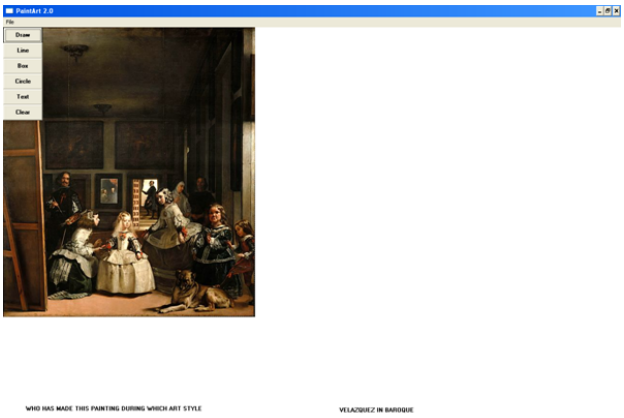

Figure 6. Demanding answers in full-text mode form of questions

The last sort of question could be one where a real application and drawing of the solution is required. A photo of the famous church Santa Maria della Salute in Venice will be displayed (q04.bmp) and the pupil should answer the name and the town of the church, to which art style it belongs and to draw a characteristic line in the photo itself by which this movement in architecture could be described. (A red line in the form of a wave or the letter «S») Then he or she can save the solution in a file (q04a.bmp) and compare it with the solution provided by the teacher (q04s.bmp). Fig. 7

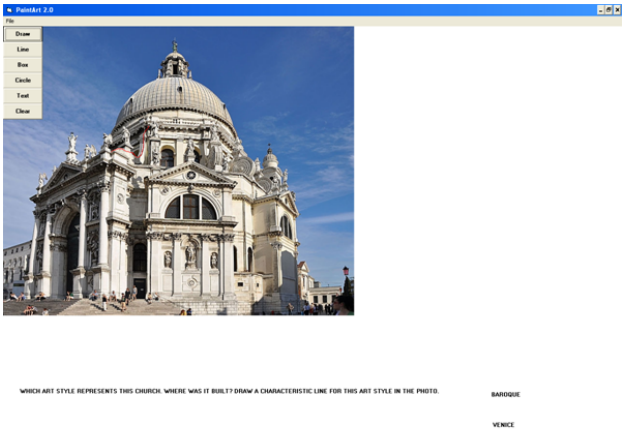

Figure 7. Real application & drawing of the solution form of questions

Additional questions and answers concerning other important artists being representative for this art movement, i.e. Baroque could be added, as well as other buildings, monuments or sculptures characteristic for this style. Having finished the database about Baroque, teachers could easily prepare lectures also for other movements like Gothic or Renaissance style for teaching visual arts in secondary schools. [2] [3]

III. Installation and Start of the Program

PaintArt 2.0 is an educational computer program for teaching visual arts in secondary schools where art database files in graphic format are included, so the installation and setup process is very simple. The program consists of only two application files, i.e. the PaintArt 2.0 program file (part2.exe) and the runtime module (vbrunxxx.dll). The Art database consists of at least 40 files in bitmap format (q01.bmp, q01a.bmp and q01s.bmp, etc.) for every single database (art style) called for example Baroque, Gothic, Renaissance etc.

To install the program PaintArt 2.0 it is necessary to copy all the files to a directory on the hard disk of a PC (for example c:\part2) and to start the program one should double-click the program file or icon (part2.exe) with a Microsoft compatible mouse.

IV. Conclusion

In this article a computer program consisting of a paint program called PaintArt 2.0 and a database of specially prepared forms in bitmap format for education of visual arts in secondary schools is presented.

The forms are containing questions in different forms (yes/no, multiple choice, ordinary questions etc.)

This program is designed and programmed in Microsoft Visual Basic for Windows, so it runs on PCs with Windows operating systems. For use with other operating systems like Linux adequate Windows program emulators could be used.

Abstract - This paper deals with information education in development of a knowledge-based society in Croatia. The basic objective of the paper is focused on systematic comprehension and analysis of the situation related to information education and its tendency. Hence, some concepts and models for IT education in Croatia were propounded. Accordingly, these tasks were fully accomplished. Application of ICT has contributed to education and introduced the possibility of distance education using the Internet and computers, without space and time limits. Nowadays referred to as electronic education, such an education is a trend in society. Acquiring electronic education, incorporated in different levels of educational systems - undergraduate, graduate post-graduate and especially lifelong education – is a demand of contemporary education and Bologna process requirement.

Key words: computer science, information society and knowledge-based society

I. INTRODUCTION

The contemporary world lives in information society in which more and more people work on data collection, transmission and processing of information. Thanks to information technology and global connections today, knowledge is created and shared faster than ever. Information science, as the skill of data management and collection, is still the kind of prevailing knowledge. It implies knowledge by which the small interest group gains dominance and advantage over the majority, becoming the most successful one. Information society, by its nature, has no boundaries. However, most of the world's population will not benefit unless they are not fully able to participate in expanding of information society based on knowledge.

Modern information and communication technologies, services and infrastructure, especially broadband Internet access, play the fundamental role in reaching economy and society of knowledge. These technologies ensure the use of knowledge in business. This opens the possibility of a number of new e-business opportunities, as well as so-called virtual markets - which means that Croatian companies can, without any difficulties, deliver their ideas, products and services anywhere in the world.

II. FACTORS OF KNOWLEDGE SOCIETY AND THE ROLE OF INFORMATICS IN IT

The term 'knowledge society' denotes and accepts the fact that defining characteristics of today's society are human knowledge, skills, science, and intellectual capital [1]. Today's society is often referred to as the "information society", in order to point out the growing impact of information and communication technologies. It is the society where low-cost information and ICT are widely used, thus forming the basis of "society of knowledge", and emphasizing the fact that the best profits comes from the investment in intangible, human and social capital and that the fundamentals of the social prosperity are knowledge and creativity. This new society offers great opportunities: new job opportunities, new tools for education and training, easier access to public services, better involvement of people with special needs and better connections between regions [2].

With the development of technology in the 1960s, many authors came up with scenarios about the future world. American writer and futurologist Alvin Toffler[1] published his theory of the three waves [3]. According to it, in the first wave people lived on the farms and were engaged in agriculture, in the second wave they moved to the cities and started the industrial society which, in the end, wiped out the information and knowledge in the third, information wave.

According to Toffler, we have just entered the fourth stage of the wave, when it is necessary to master new forms of communication and technology for survival. In previous technological waves, the source of survival and power was in assets, the ability of doing simple labour and mastering certain physical skills. In the new age, the ability of using the means of communication is essential, and IT knowledge has become the source of politics and economic power. Toffler's opinion is that individuals and groups, who do not adapt to new knowledge and technologies, are destined to fail [4]. Toffler insinuated the possible consequences of new technology and faster pace of life, and he named them 'change disease'. A disorder caused by the inability to cope and failure to adapt to the

[1] In his last book "Powershift", Alvin Toffler demonstrated that the only solution to all the future problems is - the knowledge society.

new changes are manifested in the information overload and the stress of decision-making [5].

Conceptual approaches, methodology and information technologies that are commonly used while studying this topic are identified by Web browsing, contacts with institutions or individuals, using the e-mail and, finally by detailed evaluation.

According to the World Bank, [2] knowledge-based society consists of four indicators:

- education and training (educated population is a prerequisite of creating, sharing and using of knowledge),
- information infrastructure (from radio to the Internet, in order to spread information),
- legal and economic framework (which will encourage the free flow of knowledge and investment in the economy, information and communication technology, as well as to encourage entrepreneurship),
- innovation system (a network of research centers, universities, private companies and community groups – in order to accept global knowledge and adapted to local needs, and to create new knowledge).

Of the four mentioned indicators, the last three apply knowledge, and first one works on its creation and dissemination. It illustrates the gap between what the knowledge society really is, and what is talked about it. On the other hand, the world experience indicates that for the better transfer of knowledge from science to the economy, one of the most important questions is whether the government policy provides adequate compensation for the work of universities and the public sector. Simply put, the knowledge-based society is a society where knowledge is the main creative force in the personal, economic, social, cultural and material progress. First of all, we advocate for the introduction of performance indicators for the information society, in accordance with the European and international standards and norms. In the knowledge society all individuals have an equal opportunity to gain and share knowledge, and to use it for personal development (applied knowledge). If we compare this definition with the perception of a knowledge – based society in Croatia, we notice the basic mistake: whenever we talk about knowledge society in Croatia, we talk only about the acquisition.

III. HOW TO GET TO THE KNOWLEDGE SOCIETY

Knowledge has become the primary source. It is valuable, but the comprehension of its value is valuable as well. The comprehension of the importance of the knowledge society is invaluable. Knowledge and information must be easily accessible to everyone. In contemporary society, based on e-business and the rules of the new economy, professional knowledge is a prerequisite of economic growth. Knowledge has become the basic economic resource and the main prerequisite for gaining competitive advantage. That is why the modern society is knowledge–based society [6]. Acquisition of knowledge is only one of the four indicators of a knowledge society. Croatia has set a strategic goal to reach the knowledge–based society, but its elaboration is more than annoying, because it is being handled without any order and schedule. The world's most accurate tool for placing countries on the list of the knowledge society is renewed every year, and the total index of the knowledge society is calculated by indexes of four indicators: education, innovation, legal and economic regulations and ICT structure. Besides, the World Bank generates the knowledge index which shows the impact of knowledge on the economic development of a country. Indexes are expressed in figures from 1to10[3].

On the scale of 140 countries, Croatia[4] ranks 38th, with an index of 7.05. If we look linearly, the result is not bad. However, if we perceive Croatia in the context of the EU 28 +2 (28 EU countries together with Norway and Switzerland, countries whose internal legislation and practice are in line with those in the EU), Croatia has only Bulgaria and Romania behind. Even these two countries are catching up, having advanced 10 to 12 places on this scale for the last ten years, while Croatia has regressed six places in the same period (being skipped by Latvia, Lithuania and Barbados).

If we look at the table of the knowledge society[5], Croatia has many reasons for dissatisfaction, being on the 38th place, but may find comfort in the fact that its knowledge index increased from 6.86 (2006) to 7.05.

IV. CONCLUSION

Informatics is very important for the future strategies of development; therefore investment in equipment, teacher training and other facilities for efficient realization of educational plan must take an important position in priorities of the education system.

Program contents in the field of information and communication technologies should provide:

- acquiring skills for using contemporary computers and application software;
- learning the basic principles and ideas that computers and ICT are based on;
- acquiring skills for applying information and communication technology to different areas.

We have also found that skills, basic knowledge and problem-solving are three components of the educational process which can be considered separately. However,

[2] The World Bank Institute has defined the pillars of the knowledge society (in the Knowledge for Development Program) in order to find easier way to the so-called knowledge-based economy for transition countries. (http://www.worldbank.org/kam).

[3] The placement of Croatia on the scale of the knowledge society is shown on the Knowledge Index (KI) of the World Bank. (www.worldbank.org).

[4] Ibid., op.cit..

[5] Ibid., op.cit.

only their interleaving can give participants a good foundation for future life-long learning.

Skills are closely related to the current situation of information and communication technology. With the change of technology, the necessary skills change as well. Managing of those skills is commonly called information literacy. Nowadays, those skills comprise:

- the procedure of turning on a personal computer (connecting hardware, the procedure of starting up)
- using the basic functions of the operating system (installing new applications, deleting unnecessary programs, launching applications, setting some parameters of the system);
- the use of word processing program and document formatting (fonts, layout, text positioning, editing and correcting);
- using of image processing software and drawing tools;
- connecting the computer to the network (connecting to a computer network physically, service provider login);
- using web design programs;
- the use of the Internet for finding information (using the browser);
- using computers to communicate with others (e-mail);
- the use of spreadsheet applications;
- the use of databases;
- the use of instructional materials for further exploring the possibilities of application programs, and mastering new programs (using of documentation, printed manuals and help-file).

Abstract - This paper discusses the place, role and importance of informatics education in contemporary society. The levels of computer science education are analyzed and explained, from elementary computer literacy, which is the basic requirement for the age of knowledge, to the education of professional IT experts. Implementation of computers in education, as a significant factor of educational development at all levels and areas of society was particularly emphasized. Some important clues for the future development and application of informatics are featured, together with its impact on the overall development of Croatian society.

Key words: informatics education, information technology, knowledge-based society

I. INTRODUCTION

The basic objective of this paper is to point out some relevant factors by which informatization contributes in joining the knowledge-based society.

In this sense, the paper is structured to point out important effects of development that are the basis for achieving the goal. Identifying developmental stages could raise the sensitivity of nation for Information Age as a prerequisite of the knowledge-based society.

Computer literacy should be implemented in widespread intervention through numerous models: through formal IT education (of children and adults), by enabling access to technology for all social groups, by development of online commercial markets and, what we do in Programme e-Croatia, creating conditions for business operations with the government via the Internet.

Basic knowledge is to some extent independent of the current state of technology and its concrete implementation. Being familiar with basic knowledge can facilitate lifelong mastering of new skills which are related to new forms of technology. Basic knowledge has more lasting value than skill does.

In education nowadays, information technology is not only a subject whose contents are studied by participants of educational process. It is the basis which primarily increases the efficiency of learning majority of subjects as well as effectiveness of educational process.

Lifelong education and training should be the focus of public policy and it should emphasize the significance of economic and social standards for the successful development of a knowledge-based society. The use of digital technology in society and a willingness of acquiring new skills that are necessary for the use of highly developed technology, as well as corporations based on knowledge - became the basic support of innovation and sustainable economic development. In return, the knowledge-based society can create new and better jobs and higher standards of living in order to achieve social prosperity. Therefore, the imperative is to reinforce the education that supports and accelerates the process of acquiring the current changes.

The knowledge-based society is built on the impact and development of contemporary information and communication technology and means a fundamental reshaping of the global economy from industrial to information society. [1] Its meaning goes beyond development of Internet companies and dot.com sector. The rapid ICT development has introduced profound changes in the way of work and life. ICT brings organizational, commercial, social and legal innovations.

II. IT EXPERT'S FUNCTION IN A KNOWLEDGE-BASED SOCIETY

The term IT expert implies knowledge and skills - usually a theoretical information systems and technologies, standards, languages and techniques an IT expert must have in order to perform tasks that particular systems require. Although the IT architecture is nowadays considered to be an integral part of web design, IT professionals involved in building and maintaining such complex business information systems value it as much as they value their job. Basic knowledge on web design,

[1] The term "Information Society" is commonly used for the new socio-economic paradigm which is the result of a constantly changing comprehensive process. The information society is not only a consequence of radical technological progress that is created due to "Research and Development (R & D)" or as a result of innovations in specific industrial sectors. It is the product of information technology and telecommunication technology integration that allows new, radical markets.

databases and programming languages, network systems and intelligent systems, therefore represent only necessary basis. On the other hand, the use of these systems (the most important of which is the search method) requires gaining of different skills and knowledge by IT experts, from search techniques, through understanding users' IT training and behaviour, to complete information systems.

The job of IT experts can be determined by the system they work on, or by the specifics of their employment, i.e. whether they are involved in the construction, maintenance or usage. Therefore, an IT architect participates (together with a graphic designer and a computer programmer) in building Web sites, Web portals, complex intranet systems and knowledge management systems. A digital librarian [2] forms digital collections using digital library software. IT specialist works on searching for information in the system, selection and evaluation of sources, and examining the usage of system in, for example, studies of users. Finally, in collaboration with experts of certain areas, a knowledge engineer [3] creates professional systems of these areas. Today it is common for IT expert to assume the role of a webmaster[4] or a web editor at a certain point, in order to perform maintenance and refreshing of the contents of the above systems.

III. ICT IN EDUCATION

Analyzing the influence of information technology on education, we have found that it works in three directions. The first is a growing supplement to classical education contents, its methods and forms of teaching with new information and communication technologies and other various innovations. The second is development of distance education, used at all levels of formal education, particularly at university. There are also different forms of informal education in virtual world, that meet individual needs of people (different courses, "university of the third age", etc.). The third is the extension of education, raising educational level of average people, democratization of education, vertical and horizontal linking of all levels and forms of education, increasing general and professional culture of the youth, and linking education and work.

The use of ICT in education, as well as e-learning technology, should be in every particular case effectively and directly linked to and aligned with the established educational (pedagogical) principles and objectives.

E-learning allows education "anytime, anywhere", which means that it is accessible during working hours and in free time, on work, at home or on a business trip.

The adoption of e-learning should be a strategic decision, and made by the administration of higher education institutions, in the context of a general strategy of actions and development of universities. Necessary resources should be provided to ensure applying of e-learning, and the process of introduction and application should be supported and constantly monitored by institutions and those in charge. The use of technology must be simple and adapted to the real needs of teachers and students. It has to be provided by high-quality, reliable, sustainable and efficient support system for e-learning.

Computer Science in education will aid teachers in acquiring a high level of professional and pedagogical knowledge for teaching in elementary and secondary schools - because that particular profession requires better knowledge of the fundamental areas of IT (operating systems, networks, programming).

The use of IT in education today is accessible even to those who are not computer experts. It takes only a basic ability to use a computer and the Internet for:

- available tools and software;
- making and implementation of education programs.

There are a large number of web pages designed specifically for lecturers, regardless of whether they are teachers in schools or professors at universities:

- tips on how to improve teaching with innovative approach;
- free print materials and their use in the classroom;
- a number of different tools for mastering certain parts of the teaching material.

Although distance learning is not a new phenomenon, with the Internet it gets a completely new meaning. The possibility of transmission and distribution of large amounts of information with the aid of new media turns over a new leaf in the concept of permanent education. The significance of this approach to education is recognized worldwide - especially in the EU countries and the U.S.A. Using their experiences and recognizing the value of distance learning, there is a big target group in Croatia that is interested in this kind of education.

Today's models of distance education almost entirely leave the classroom and move into virtual space. The Internet as a distributed network with millions of connected computers and computer networks is an ideal choice for its structure an content, because it assumes interaction and encourages collaboration. There are already thousands of quality and dynamic online projects in the field of e-Learning. Distance learning is no longer limited to one-way broadcast, but also includes a range of electronically transmitted educational materials and interactions within workgroups.

Lifelong education system is essential for growth and development of society and it is necessary in the era of rapid change of required skills and knowledge.

The educational system of lifelong education is more directed to users. Individuals become active participants in the educational process, which is greatly contributed by the use of information and communication technology. The use of ICT in education offers innovative methods of teaching and learning. Development of lifelong education[5]

[2] http://www. hidd.hr/virref/zanimanja_digitalni.htm
[3] http://www.hidd.hr/virref/zanimanja_inzenjer.htm
[4] http://www.hidd.hr/virref/zanimanja_master.htm

[5] The Cooperation Agreement on Promoting Lifelong Learning was signed on 2nd October 2007 by the Ministry of Education.

in Croatia is necessary because there is increasing number of seniors in total population. Sensibility and concern for this population should be developed by educational content and the media as well. Work, social and family relationships are changing with rapid development of new technologies, so people are expected to keep up with these changes and participate in society actively. One has to learn continuously in order to be able to keep pace with the changes.

The use of personal computer and the Internet, a global network which is an inexhaustible source of various information and knowledge, has enabled an outstanding change in the way of acquiring knowledge in educational process. Computer skills become one of the basic elements of literacy. The introduction of information technology in educational process has two aspects: knowledge about information technology, and ability to use it as a technological starting point in other subjects.

Computer Science should not be merely a content of a particular subject; it should rather be implemented in contents of other subjects and activities at school. There are a number of reasons for this. First of all there are global issues of organization and management processes in education.

New information technologies have become the backbone in application of multimedia in teaching. They provide great opportunities, but also require specific knowledge and skills together with appropriate implementation strategy. Using new technologies efficiently is a challenge for teachers who must acquire relevant knowledge and skills in order to respond to the increasing demands of educational process.

The introduction and application of information technology (IT) in primary and secondary schools have initiated new groups of tasks related to computer and communication infrastructure. Computer-communication infrastructure provides a wide range of applications in education, from finding information on the Internet, to virtual classrooms or schools. The introduction of IT in educational process should be encouraged and supported. It will be necessary to create digital textbooks, organize online courses, create programs for virtual classrooms, hold classes of other subjects in computer rooms, etc. At the same time, we should continue with education of teachers who will create more and more educational materials on the network and use them.

There is an increasing usage of information-communication technologies in the classroom [1]. Teachers often use presentations during classes. However, they should know certain rules for making a presentation in order to make it understandable and interesting for their audience.

The development and improvement of information and communication technologies play a crucial role in all aspects of human activity, as well as in education. Thus certain activities change their structure and functions of individual elements within it. In the teaching process we can observe the influence of technology from the perspective of every element of education: student, teacher, content / program or the context in which those elements are placed. Transformation of the teacher's role is particularly important in this process. With introduction of ICT, the teacher becomes a person who motivates and leads (more like a mentor or tutor) and thus helps a student transform the information into their own knowledge. In this process teachers are expected to find ways to transform their old traditional skills into new ones, to develop new paradigms of teaching, and to adopt new administrative and technical skills.

Bologna concept of studies implies adequate information support in the process of studying (Learning Resources Support). Therefore, it is necessary to install CourseWare applications as an aid in the process of teaching.

The new vision of higher education system[6], in which the student is at the center of the teaching process, opens possibilities of teaching and learning, which assume that teaching methods are tailored to student's needs. The methods of communication, assessment, feedback and overall 'teacher – student' and 'student – student' interaction, all of them are adjusted to individual student's needs.

Possibility of using IT in education nowadays is accessible even for those who are not computer experts. In creation and implementation of various educational programs over the Internet, there are so called CourseWare tools, available on the market.

Education and professional development of teachers are the main factors that affect the level of students' achievements. When talking about improving the quality of teacher education, we should keep in mind not only presumed higher education of teachers, but also their professional development from the perspective of lifelong learning. The aim of both forms of education is lifelong learning and renewal of knowledge and skills of teachers, but still in a function of lifelong learning of their students.

IV. INFORMATION EDUCATION IN CROATIA

The education system should adapt to society. Today's education is partially changed in the countries which had the need to change, whereas in many of them the system was not changed because the society did not change much.

Most of these changes were related to the organization of the system, e.g. education policy, but teaching itself has not experienced any necessary changes.

For present needs this approach to education is not efficient enough, and even the content is not often adequate. Despite new horizons are opened at all levels of education, the educational system is not able to provide what society needs.

All potentials provided by new insights on pedagogy and information technology are currently not used.

In the traditional way of teaching there is a discrepancy between the teaching material which is presented and knowledge or skills needed in the workplace.

[6] Source: http://hlede.net/portal/content/view/53/40/ (April 15, 2007)

In contrast to accomplishments of the second half of the last century, Croatian education system has lost qualities of an export product in demand, with few exceptions. At this point there are no indications of upcoming changes. Opening of private colleges at the level of professional studies has enabled competitiveness with foreign educational institutions. It is a risky venture because foreign educational products have already been used on the Croatian market, such as IBM and CISCO academies or e-learning courses.

It can be concluded that there are further necessary actions required for development of information society in the Republic of Croatia:

- creating appropriate economy initiative and institutional environment;
- creating a society of educated, flexible and creative people;
- making a dynamic information infrastructure;
- creating an efficient innovation system;
- adoption and adaptation of the legal infrastructure for the knowledge-based society;
- promoting the development of a knowledge-based society.

V. CONLUSION

It is well known that Croatia has a long tradition and significant results in primary, secondary and university education, which is a good presumption for development. However, it is necessary but not sufficient condition.The challenges of a global market of education impose imperative of changes on Croatia, changes which are rather radical and will enable global competitiveness of Croatian education, as it is indicated in this paper.

Highly educated and qualified professionals of Croatia, close cooperation of scientific and educational communities with the economy and society as a whole, based on high technologies, together with insistence on competitiveness of knowledge, they are the answers to the question of how to achieve a knowledge-based society in Croatia.

Visual Verification of the Properties of Pseudorandom Sequences

S. Predanić, G. Vujisić, T. Horvat
Polytechnic of Zagreb, Department of Electrical Engineering, Zagreb, Croatia
stipe.predanic@tvz.hr; goran.vujisic@tvz.hr; thorvat3@tvz.hr

Abstract - This paper describes properties of graphical presentation of pseudorandom number generator. Numerous more-or-less rigorous tests for randomness are available in the literature, and some of them are presented here. It is shown that both graphical and analytical tests give almost equal results, but graphical tests are simpler and closer to human perception. Because of that properties, visual tests combined with simple statistics are proposed as optimal for undergraduate higher education curricula. Mentioned methods are used on multiple courses at professional study of electrical engineering at the Polytechnic of Zagreb.

I. INTRODUCTION

Risen in everyday higher education environment and practice, initiated by students' problems, supported with Knuth [1] and motivated by Wolfram [2], multimedia modelling of telecommunication processes is illustrated with the case study of pseudorandom sequence (PRS) .

Born and grown in the ICT rich environment, students of the present expect multimedia lecturing as common educational standard. Short in time and with complex knowledge to be presented and adopted classic teaching methodology as mathematical formulas and graphs is to be augmented with audio and visual models. Visual randomness tests for the PRS are better because one can immediately conclude from the graph whether a PRS is random or not.

II. A PSEUDORANDOM SEQUENCE

Pseudorandom number generator is a deterministic algorithm that, given the truly random input binary sequence length k, outputs a binary string l>>k appears to be random. The input for the generator is called a seed, while the output is called a pseudorandom sequence (PRS).

One commonly used pseudorandom number generator is linear congruential generator (LCG), devised by D.H.Lehmer in 1948. It uses the following formula:

$$K_{i+1} = (a \bullet K_i + c) \mod m \quad (1)$$

The sequence is always repetitive, but one can get a random looking sequence when integer numbers a, c, m and first number K_0)(often called seed) are well chosen.

Example:

If there is a four-bit computer system that uses binary representation for integer numbers from 0 to 15, K_0 may be any number ("seed") between 0 and 15, in order to present the following formula:

$$K_{i+1} = (5 \bullet K_i + 3) \mod 16 \quad (2)$$

Given K_0 = 1, the PRS generated by (2) is: 8,11,10,5,12,15,14,9,0,3,2,13,4,7,6,1,8,11...

Another commonly used pseudorandom number generator is Lagged Fibonacci generator (LFG), which uses generalisation of Fibonacci sequence with formula:

$$Ki=(K_{i-1} \bigcirc K_{i-2} + c) \mod m \quad (3)$$

where $\bigcirc$ denotes any general binary operation (addition, subtraction, multiplication etc.)

Example:

If there is a four-bit computer system that uses binary representation for integer numbers from 0 to 15, K_0 and K_1 may be any number ("seed") between 0 and 15. If operation is addition, the following formula is used:

$$K_i=(K_{i-1}+K_{i-2}) \mod 16 \quad (4)$$

Given K_0=1 and K_1=4, the PRS generated by (4) is : 1,4,5,9,14,7,5,12,1,13,14,11,9,4,13,1...

III. RANDOMNESS TESTS

Verification is needed to determine whether the generated sequence seems to be random or not. Due to the question of useful randomness, some postulates and theories were devised and from there various tests for checking the randomness of a sequence. Standard tests are given in the Table 1. Their combination provides greater reliability for the randomness evaluation.

TABLE 1 RANDOMNESS TESTS [3]

Frequency (Monobits) Test
Test For Frequency Within A Block
Runs Test
Poker test
Random Binary Matrix Rank Test
Discrete Fourier Transform (Spectral) Test
Maurer's Universal Statistical Test
Lempel-Ziv Complexity Test
Linear Complexity Test
Serial Test
Approximate Entropy Test
Cumulative Sum (Cusum) Test

A. Golomb's randomness postulates

Golomb's randomness postulates were among the first attempts to establish some necessary conditions for periodic pseudorandom sequences that seem to look random, but these conditions are far from being sufficient for such sequences to be considered random.

If s is a periodic sequence of period N, and sequence is binary, Golumb's randomness postulates are as follows:

R1: In the cycle sN of s, the number of 0's and 1's is different by at most 1.

R2: In the cycle sN , at least half the runs have length 1, one-fourth have length 2, one-eight have length 3, and so on as long as the number of runs so indicated exceeds 1. For each of these lengths, there are almost equally many gaps and blocks.

R3: The autocorrelation function C (t) is two-valued. That is for some integer K.

$$N \cdot C(t) = \sum_{i=0}^{N-1} (2s_i - 1) \cdot (2s_{i+t} - 1) = \begin{cases} N, & \text{if } t = 0, \\ K, & \text{if } 1 \le t \le N-1. \end{cases} \quad (5)$$

B. Frequency (Monobits) Test

The purpose of the test is defining the proportion of 0's and 1's for the whole binary sequence. The test estimates the distribution of those close to ½. The number of 0's and 1's in the sequence should be about the same. All subsequent tests depend on passing this test.

C. Frequency Test within a Block

This test is focused on the proportion of 1's within the M-bit blocks. However, its purpose is to determine whether the frequency of the M-bit block is approximately M / 2, as expected under the assumption of randomness. If the block size in this test is M = 1, the test degenerates to Frequency (Monobit) test.

D. Runs Test

The basis of this test is the total number of runs in the sequence, where a run is a continuous sequence of identical bits. A run of length k consists of exactly k identical bits and with opposite values before and after the run. The purpose of the runs test is to estimate whether the number of runs of zeroes and ones of various lengths is as expected for a random sequence. This test determines whether such oscillations between zero and ones are too fast or too slow.

E. Maurer's universal statistical test

The basic idea of Maurer's universal statistical test is that it is not possible to compress significantly (without the loss of information) the output sequence of a random bit generator. So, if a sample is significantly compressed, the generator should be rejected as being invalid. Instead of actually compressing the sequence, the universal statistical test calculates the amount which relates to the length of the compressed sequence.

F. Approximate Entropy Test

The focus of this test is the frequency of overlapping m-bit patterns. The objective of the test is to compare the frequency of overlapping blocks in two consecutive / adjacent lengths (m and m +1) against the expected result for a random sequence.

G. Linear Complexity Test

The purpose of this test is to register the length of the generated feedback, and to determine whether or not a sequence is complex enough to be considered random. Random sequences are characterized by a longer feedback register. A short feedback register implies non-randomness.

H. Serial Test

This test is based on the frequency of overlapping in each m-bit pattern across the entire sequence. The purpose of this test is to determine whether the number of occurrence of 2m m-bit overlapping samples are approximately the same as it would be expected for a random sequence.

Some of these tests are suitable for teaching students in technical studies, because they do not require complex mathematical background. Graphical tests are even more suitable. They will be described in the next chapter.

IV. GRAPHIC / VISUAL REPRESENTATIONS OF RANDOMNESS TESTS

Scilab environment was used to get the graphical presentation of randomness tests. Why Scilab? Because it is free to download from the web and use without paying for it. So students can download it and use it at home to practice. They can develop their own random generators and the picture will tell them immediately whether the sequence is random enough or not.

For graphic analysis histograms and 2D plots of matrix are used. With these two tests it can be determined whether the sequence is acceptable. The following examples will show how to make a histogram and 2D plot of a matrix in Scilab.

A. Histogram

This test is an extension of the Frequency Test. Instead of their individual bits, bytes or their decimal equivalents their data are counted and resulting statistical frequencies are plotted at Figure 1 and Figure 2.

TABLE 2 LFG AND HISTOGRAM PLOTTING

```
h(1)=31;
h(2)=121;
for i = 3:n,
h(i)=modulo((h(i-1)+h(i-2)+13),255);,
end; //  To get LFG sequence
histplot(256,h,normalization=%f)
```

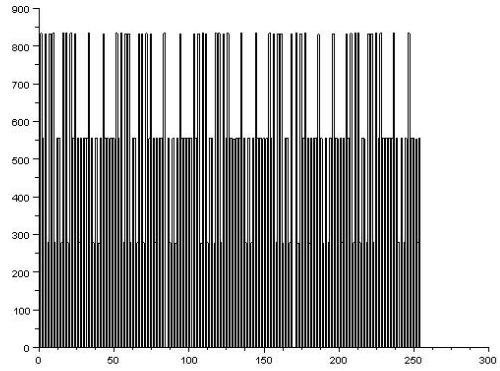

Figure 1 LFG Scilab Histogram

TABLE 3 . SCILAB RANDOM FUNCTION AND HISTOGRAM PLOTTING

```
r = pmodulo(round(10000*rand(N,1)),256);
// To get the random sequence
histplot(256,r,normalization=%f);
// To draw a histogram
```

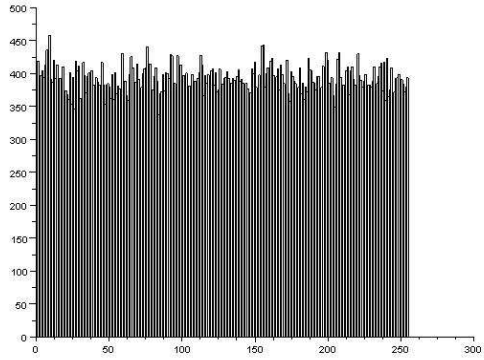

Figure 2 Random Scilab Histogram

In Figure 1 Histogram of Lagged Fibonacci generator (LFG) is shown. It is obvious that the distribution is not uniform. This means that a different random sequence generator should be used to get a better random sequence.

In Figure 2 another random sequence generator histogram is shown. From graph it is visible that the distribution of relative frequencies is close to uniform.

B. 2D Histogram

This test presents the frequency of ordered and overlapped bytes. It is expected that the distribution of pairs (2D) is uniform and that each byte relative to the previous one is of the uniform distribution as well. If not so, two conclusions are possible:

a. Pairs are not of equal probabilities

b. Transitions from one byte to another are not of equal probabilities.

In both cases algorithm is not to be accepted as good as RNG. 2D, 256x256 histogram matrix is plotted in Scilab environment for the LFG (Table 2) and the random function (Table 3).

Scarse point dispersion in Figure 3 indicates that transitions are not of equal frequencies.

In Figure 4., random function's 2D matrix plots is presented. Intensity of white is proportional to the correlation of each byte with the following one. If any pattern can be identified in the graph: circle, rectangle, line, triangle, etc..., that means the sequence is not random enough.

TABLE 4 2D MATRIX AND HISTOGRAM PLOTTING

```
for i=1:N-D,
z(1+r(i),1+r(i+D))=1+z(1+r(i),1+r(i+D));,
end; // Calculating the field
grayplot(1:256,1:256,z); //
To draw a 2D plot of matrix
```

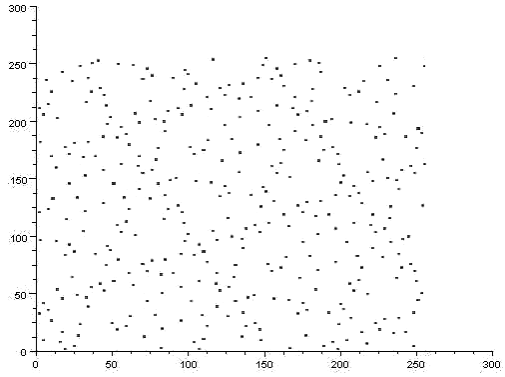

Figure 3 Scilab 2D matrix plot (LFG)

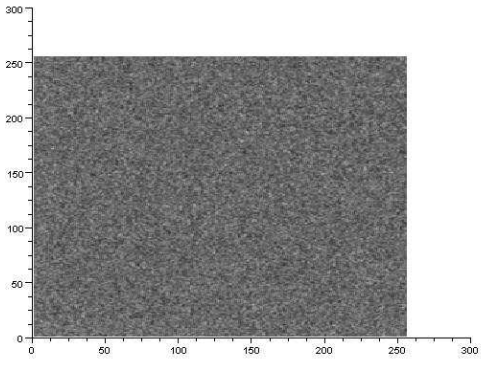

Figure 4 Scilab 2D matrix plot (random)

V. USE OF PSEUDORANDOM SEQUENCE

Pseudorandom sequences made and checked by described methods must be used in situations where true randomness is not necessary and described sequences could be called „random enough“. Simulations and models of communication channels can use pseudorandom sequences even if they don't pass all regular tests, while complex algorithms like those used in cryptography heavily depend on true randomness.

At the Polytechnic of Zagreb pseudorandom sequences are used in courses that have Matlab and Scilab based simulations and models of communication channels, protocols and encoding. For example this is used in laboratory exercises where all students get the same original message, and use a pseudorandom sequence with length of 32768 (15 bit) or 65536 (16 bit) numbers as a noise generator. Only Gaussian noise (white noise) is truly random, so even some repetition or unevenness in pseudorandom sequence can return real results. At the same time students can compare results and acknowledge difference in output depending on channel noise. Another use in modeling communication channel is for message itself when protocols are analyzed: by using a sequence length of 256(8 bit), a simulation of one byte (either binary or ASCII) can be made. Some repetition and unevenness is expected (and wanted) as most protocols use constant headers, and often some values of parameters are more used than others. Message can then be analyzed in comparison to constant noise in transmission channel, or it can be used to present coding and queueing theories.

VI. CONCLUSION

As described, it is easier for students when a large matrix of data is presented visually than numerically. Students can immediately recognize from the graph if the sequence generated is random or not. Basic statistical tests of randomness, combined with some visual tests should give a substantial reliability of the randomness. Both graphical and analytical tests give almost equal results, graphical tests are simpler and closer to human perception. Therefore, the graphic and visual mode is more suitable for the teaching purpose.

INTEGRATION OF CONCEPTUAL DATA MODELING METHODS: HIGHER EDUCATION EXPERIENCES

Lj. Kazi, B. Radulovic, I. Berkovic, Z. Kazi
University of Novi Sad, Technical faculty "Mihajlo Pupin" Zrenjanin, Serbia
leremic@tfzr.uns.ac.rs, biljana.radulovic66@gmail.com, berki@sbb.rs, zoltan.kazi@gmail.com

Abstract - One of the most important phases in information system development is data modeling. In higher education and in professional environment, the basic data models are ER model, relational model and object oriented model, i.e. class diagram. Since conceptual modeling is crucial data modeling activity, special concern on methods for conceptual modeling is given in this paper. Case study shows that application of separate conceptual data modeling methods produce different and incomplete models. This leads to the conclusion that it is important to use integration of these methods and apply them within the information system development process. Educational experiences of applying this approach at University of Novi Sad, Technical faculty "Mihajlo Pupin" in Zrenjanin are presented as description of class exercises and exams results.

I. INTRODUCTION

Information system development is based on the crucial phase related to business domain knowledge representation and client requirements specification [1]. Client requirements most often are presented in the form of textual description. Knowledge representation of business processes and data are commonly presented by business process models, data dictionary and data models [2], supported by CASE (Computer Aided Software Engineering) tools. The process of knowledge representation of a particular business domain starts with textual description of business process workflow and transformation to business process models such as data flow diagrams or business workflow diagrams. Within creating these diagrams, data dictionary is filled with data flows and data stores structure elements - data items. This way, business processes model presents a basis of functional aspect and data dictionary is basis for information aspect of an information system architecture [3], i.e. application architecture and information architecture within information system architecture [4]. Our approach for mapping of business process to use cases in application architecture is proposed in [5] and mapping of data dictionary elements to data models elements is proposed in [6].

Most commonly used data models within professional and educational working environments are ER model [7], relational model [8] and object-oriented model, i.e. class diagrams [9]. Scientific environments (as well as some advanced educational environments [10]) in recent years include domain ontologies creation as more complete method for business domain knowledge representation [11], with methods and tools for transformation of ontologies to conceptual data model [12] and relational data model [13].

Conceptual data models (CDM) are supported by CASE tools and widely used within higher educational environments. Automation of transformation of ER, relational and object-oriented models from one type to another is supported within CASE tools. Since ER model (often considered as conceptual data model) could automatically be transformed to relational and class diagram, the crucial activity in data modeling is conceptual modeling.

Our observations on data modeling teaching issues and initiative for improvements started at practical lectures and exams at University of Novi Sad, Technical faculty "Mihajlo Pupin" in Zrenjanin, Serbia (TFZR). These initiatives lead to research on students' data modeling errors and proposing teaching improvement implications [14], as well as development of software tools for automated evaluation of conceptual data models [15, 16]. The approach to the integration of conceptual modeling methods in conceptual modeling (including some new conceptual data models), as well as integration of application of these methods within an information system development were introduced in [6].

Integration of methods application within educational environment was formulated as a new methodology within this paper. This paper presents description of existing and new conceptual data modeling approaches and methods and the integration of these methods. A case study describes using separate methods and shows the necessity of their integration application. Experiences of the methodology application at practical exercises and exams is described with some conclusions. Further improvements suggestions are presented.

II. HIGHER EDUCATION IN CONCEPTUAL DATA MODELING

Conceptual data modeling at University of Novi Sad, Technical faculty "Mihajlo Pupin" in Zrenjanin, Serbia is included in subjects/courses of Databases (at 2nd year of study) and Information systems (4th year of study) at Bachelor study in IT. During Databases course, student

learn separate types of models (ER, relational) and their basic elements. They practice creating simple models by using very detailed (having all elements descriptions available), but simple examples of business domain descriptions. The context of creating a data model within an information system development is introduced at Information systems course.

Research on conceptual data modeling in higher education was conducted upon a small sample of higher educational institutions (Universities schools/faculties of electrical engineering from Zagreb (Croatia) [17], Sarajevo (Bosnia and Herzegovina) [18], Podgorica (Montenegro) [19], Skopje (FYR Macedonia) [20] and Belgrade (Serbia) [21]). At all these higher educational institutions, conceptual data modeling is taught within the Databases course at Bachelor study level, mostly at second year of study. In all these institutions, the topic of conceptual data modeling is tightly related with ER-diagrams. At almost all of these higher educational institutions, foreign literature on databases fundamentals is proposed as a main learning source and that literature do not include all conceptual data modeling methods, or even their integration and related issues. Educational contents of the examined database courses are mainly focused on different data models and technologies, rather than detailed approach to conceptual data modeling methods. Information systems courses (at the same sample schools/faculties) also do not cover all methods of conceptual data modeling.

III. CONCEPTUAL MODELING APPROACHES AND METHODS

In this section a short overview of approaches and methods for M is given as an introduction to the proposed integration approach.

Some *approaches* in conceptual data modeling that were described in related work are: (A) Direct (complete) modeling vs. Sequential (partial) modeling and integration [22, 23]; (B) New models creation vs. Using and modification of design patterns [23]; (C) Forward (direct) modeling vs. Reverse engineering [23]; (D) Data modeling as information system development phase vs. Data modeling within the whole information system development lifecycle [19] and (E) Iterative conceptual data model refinement [3].

Some *methods* that were described in related work are described in Table 1.

The new methods (from [6]) are presented in Table 2.

IV. THE METHODOLOGY FOR CONCEPTUAL MODELING METHODS INTEGRATION

The approach of integration of conceptual data modeling methods within an information system development is introduced in [6]. The proposed approach include two main aspects of integration:

1. Integration of conceptual data modeling methods - creation of models by application of different modeling methods and their integration to complete model;

TABLE 1. METHODS OF CONCEPTUAL MODELING IN RELATED WORK

Method	Method description
Grammar analysis of business domain textual description [23, 24]	Each noun is candidate for entity, gerund is candidate for entity, verb is candidate for relationship. Application of this method results in model with entities (from nouns) and relationships (from verbs).
Normalization of relations(tables) in relational model [3, 10, 23]	Each table in relational model should be in 1st, 2nd, 3rd normal form, or other normal forms.
Creating submodels based on: External schema [22], XML schema [23], Primitive process [23]	For each external schema, XML schema or primitive process, submodel is created and integrated to the whole system's conceptual model.

TABLE 2. NEW METHODS OF CONCEPTUAL MODELING [6]

Method	Short description
Assignment of entities to attributes from data dictionary	Data items from data dictionary from data flow diagrams are assigned to existing entities in model or new entities are created according to attribute name.
Data store decomposition by structure notation analysis	Decomposition of data stores by analyzing syntax anotation [25]) of their structure.
Data store normalization	Decomposition of data stores from data flow diagrams by application of 1st ,2nd , 3rd normal form.
UML use case models based partial modeling	Each use case is assigned to a conceptual data sub-model that presents data to be used by the specified use case.

2. Integration of the process of applying conceptual data modeling methods within information system development using artifacts from previous phases of information system development as an input to the process of conceptual data modeling.

In this paper we present the integration of approaches and methods as a new methodology that focuses on application of approaches: Direct (complete) modeling; New models creation; Forward (direct) modeling; Data modeling within the whole information system development lifecycle (by taking artifacts from previous information system development phases; artifacts are: a) business process model with data dictionary, b) use case diagram); Conceptual data model refinement (by using one conceptual modeling model after another, central model becomes more complete).

The proposed methodology integrates application of existing and new methods (described in the previous section) of conceptual data modeling within a particular sequential order. The order of methods application within the proposed methodology is presented in Table 3.

The methodology includes creating "integral model" by integration of results of conceptual data modeling methods application. There are two basic approaches to application of this methodology:

- Creating an „integrated“ model – application of each method separately and integration of all results from each method application;
- Creating a „central“ model – all methods are performed upon a central model, each enriching the central model with new elements and enhances quality of the final conceptual data model.

The methodology also includes methods for evaluation of created integral model by checking correctness and completeness of the created model.

Correctness of the model is evaluated from syntax and semantic aspect by using specific check list created according to Van Belle's framework for general model evaluation [26]. This check list (detailed description in [27]) is used within exercises (at TFZR) for evaluation of working models during classes, as self-checking tool for each student during practical exam and as a check list that is used by a teaching staff for assessment of each student's practical exam work. The proposed checklist includes characteristics in the scope of a whole model as well as each element category (entity, attribute and relationship) characteristics, quality features and metrics.

Completeness of the model is evaluated by checking completeness of entities, attributes and relationships of the central model. Completeness is checked regarding input material usage, i e. how much is the given input material «covered» by elements of conceptual diagram. Completeness is also evaluated by creating conceptual data sub-models for each use case. As an input material to conceptual data modeling process, a table of assignment of primitive processes to use cases, i.e. software functions (introduced in [5]) is also given and is consulted within the process of completeness evaluation of created conceptual data model.

TABLE 3. ORDER OF METHODS APPLICATION WITHIN THE PROPOSED METHODOLOGY

Order of methods application	INPUT - material	Method	OUTPUT – result
1	Textual description of business process	Grammar analysis of business domain textual description	1st draft model with: Entities, relationships
2	List of data dictionary data items	Assignment of entities to attributes from data dictionary	2nd draft model with : Entities with attributes assigned
3	Syntax structure of each data store from data flow diagram	Data store decomposition by structure notation analysis	3rd draft model with Entities, relationships,attributes,: cardinalities of relationships, IS-A hierarchy relationships
4	Data store structure, i.e. list of data items for each data store	Data store normalization	4th draft model with : Entities, relationships, attributes, identifiers, functional dependencies within entities, non-transitive functional dependencies within entities
Integrated/Central draft model			
5	Integrated draft model	Checking correctness and performing corrections	Correct model
6	Correct model, Table (created according to [5]) of primitive processes assignment to Use cases	Checking completeness and corrections	Correct and complete model
Correct and complete model			

V. CASE STUDY

A. Background

Within several recent years, all previously presented approaches and methods, as well as their parial integration were presented and applied within theoretical and practical lectures (exercises) and practical exams at TFZR within the Information systems course of Bachelor studies in IT at TFZR. Only method „Grammar analysis of business domain textual description“ is applied in a simplified form within *Databases* course of Bachelor studies in IT at TFZR.

B. Aim and Research Question

Aim of this case study is to prove the necessity of application of the methodology for integration of conceptual data modeling methods.

Research question: Does application of the methodology for integration of conceptual data modeling

methods give better results, than application of separate methods?

C. Research Method

Research is conducted by comparing results of application of separate methods to the result of integration of these methods application results. The research is performed as follows:

1. Each of the four methods for conceptual data modeling is applied upon material from the same business domain. Application of each method gives particular conceptual data model.
2. Integrated model is created as a result of integration of conceptual models that are results from application of particular methods.
3. Comparison is performed descriptively, based on number of entities, relationships and attributes.

D. Research material

The case study is applied in 2013/2014 school year during winter semester of practical classes in Information systems. The methods of conceptual data modeling are applied by using CASE tool Sybase Power Designer 10. The business domain of the case study is related to simple taxi organization, i.e. phone-service subdomain workflow. Material for conceptual modeling methods application in this CASE study consist of: textual description of business process, process tree, data flow diagrams, list of data items and data types/domains, table of mapping primitive processes from process tree to software functions, use case diagram with software functions.

E. Results

Results of separate application of methods are presented as separate conceptual data models. The first model (Figure 1) is created by application of method „Grammar analysis of textual description“. The second model (Figure 2) is created by application of method „Attribute assignment to entities“.

The third model (Figure 3)) is created by application of method „Syntax analysis of data store structure“. The fourth model (Figure 4) is created by application of method „Normalization of data stores“.

Final model presents integration of separate models (Figure 5).

F. Discussion and conclusion

Results of separate application of methods show that the resulting models are different and incomplete:

- Application of grammar analysis (first method) of textual description leads to incomplete conceptual data model, since it gives only entities and relationships, without attributes. *Incompleteness is in attributes.* It is important to mention that even textual descriptions could be given with more or less details and therefore are not a reliable source of knowledge.

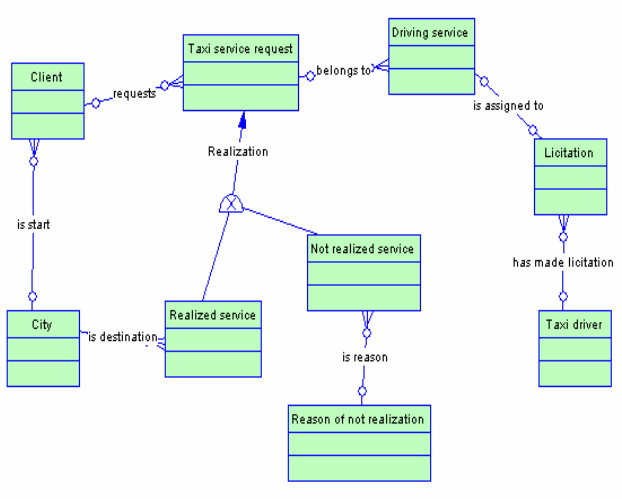

Figure 1. Conceptual data model as a result of the first method

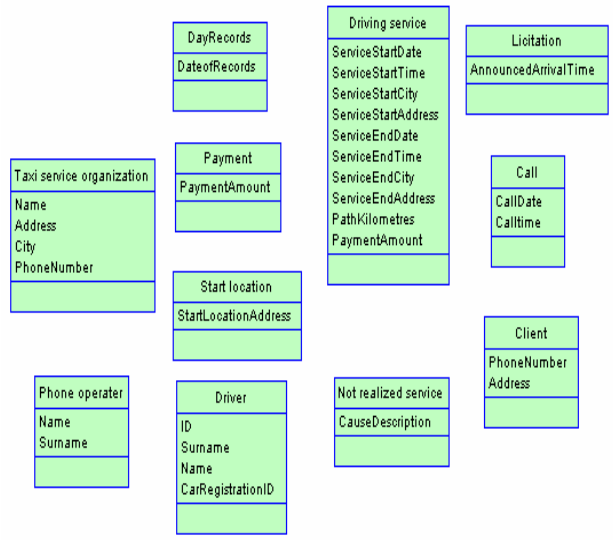

Figure 2. Conceptual data model as a result of the second method

- Application of attribute assignment to entities (second method) gives entities with attributes, with few (if any) relationships. *Incompleteness is in relationships;*
- Third method's *incompleteness is in lack of identifiers. Both methods (syntax decomposition and normalization) of data stores* could lead to non-connected conceptual data submodels (each submodel is related to one data store). *Incompleteness is in relationships among entities from different submodels.*

Conclusion: Comparation of previously presented diagrams shows that that only integrated model (i.e. model created by the proposed integration methodology) has all required CDM elements (entities, relationships and attributes) and could be considered a complete and correct model.

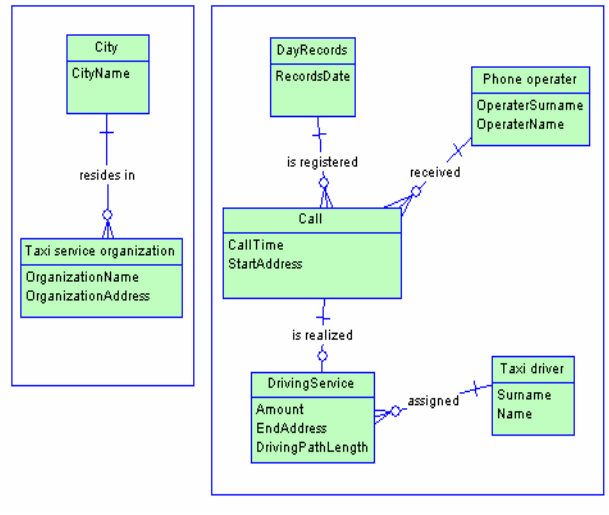

Figure 3. Conceptual data model as a result of the third method

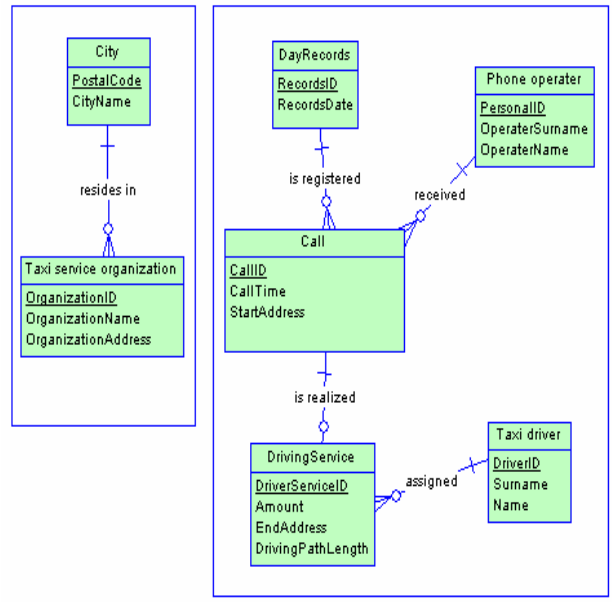

Figure 4. Conceptual data model as a result of the fourth method

VI. ISSUES IN EDUCATIONAL EXPERIENCES

Experiences of from practical classes and exams in conceptual data modeling at TFZR within Information systems course address some issues:

ISSUE 1: In the set of proposed methods, which order of their application to accept and which modality of integration to apply („central“ model or „integrated“ model approach). EMPIRICAL RESULTS (ISSUE 1): A questionaire was given to 56 students at TFZR in 2013/2014 school year regarding attitudes related to preferences on type of integration of methods.

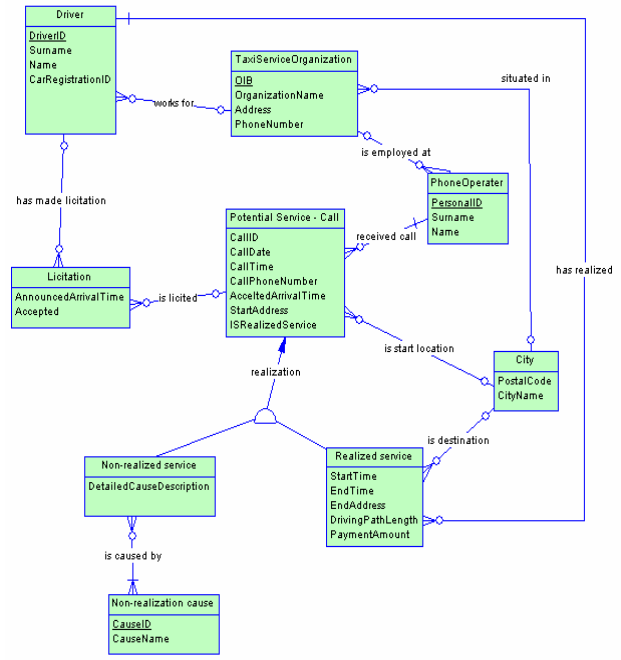

Figure 5. Integrated conceptual data model

In research population of 30 students, 92% of them choose „central“ model to be applied within practical exams, while „integrated“ approach they choose to be used within practical lessons, as a more appropriate approach.

ISSUE 2: Students are used to the “pattern thinking” from the Databases course and should adapt to the Information systems course requirements where more material and methods are given, the elements should be combined, and critical, analytical and synthetical skills should be performed. Students are faced to „similar-to-real-world“ situations in aim to be ready for professional environment. ISSUE 3: An issue for organizing practical exams arises from the problem of insufficient time for creating models of complex systems (real-world or similar to real – world examples) within limited time for practical laboratory exams (3-4 hours). PROPOSED SOLUTION: Students could choose practical exams (with simple examples) or projects (with more complex material).

EMPIRICAL RESULTS (ISSUE 2 and ISSUE 3): In 2013/2014 at TFZR, 20% of students at Information systems course chose to work on project assignments with real business problems. Other students chose to have practical exam with small examples. In past ten years, the trend at TFZR shows rise of students interest for projects [28].

ISSUE 4: Since the insufficient time for practical exams on conceptual modeling, for all methods to be applied, i.e. integrated methodology application, it is needed to focus on smaller set of methods to be used within practical laboratory exams. PROPOSED SOLUTION: Since data stores are concepts that represent data to be stored, the most appropriate method (if we have to choose among all methods) is data stores normalization or data stores decomposition according to the syntax

structure. EMPIRICAL RESULTS (Issue 4): During 2013/2014 school year, the application of the presented integrated methodology is introduced within practical exams at TFZR. There were two groups of students at examination. First group (15 students) applied integrated methodology, while second group of students (15 students) applied decomposition / normalization of datastores. Students from the first group had more complex models, but with more syntax errors. Students from second group created less complex models with less syntax errors.

VII. CONCLUSIONS AND FUTURE WORK

This paper presents new methodology of integration of conceptual data modeling approaches and methods within information system development. Educational experiences are presented within issues and empirical results from practical lessons and exams.

Future work will include further empirical research on applicability of the integrated methodology in higher education environment, research on new methods for conceptual data model quality assessment, pragmatics aspect and optimization, research on application of the proposed methodology within different educational environments, as well as possible using of the proposed methodology within professional environments.

ACKNOWLEDGEMENT

Paper presents results of project TR32044 – „The development of software tools for business process analysis and improvement“ financed by Ministry of science and technology development, Republic of Serbia.

Technology Use in EFL Learning

Darija Pešut,
Visoka škola za informacijske tehnologije, Zagreb, Croatia
dpesut@vsite.hr

Abstract - The connection between philology and technology is no longer considered unusual. The use of technology is being adopted in foreign language learning. In this context, the author wishes to present the good practice of using computers in teaching English as a foreign language. The article thus gives detailed examples of this use while teaching different language skills: reading, writing, speaking and listening. In order to reinforce the postulate of the benefits of using technology in foreign language learning, a survey has been conducted among EFL students at the College for Information Technologies, Zagreb. A comparison of survey results from 2010 will also be shown.

I. INTRODUCTION

Technology is being successfully integrated into the traditional foreign language curriculum. As the approaches to foreign language learning have changed significantly over time, today it is hard to define what a traditional approach actually is.

Lixian Jin and Martin Cortazzi define the traditional approach through five versions having five possible definitions shown in Table I [1].

The use of technology in the traditional approach to language learning was very limited. It usually involved the teacher playing cassettes / CDs on the player or using a graphoscope for showing pictures, while some of the teachers also used video / DVD players for showing movies and short films.

When learning any foreign language, it is of great importance to simulate an environment where learners are able to interact in the language of instruction. The language of IT is English, thus, using technology in EFL (English as a Foreign Language) learning is maybe most beneficial. This article presents ways of using technology in an EFL classroom at a higher education institution and also gives results of a new case study from 2013 in comparison to the one in 2010.

II. COMPUTER ASSISTED LANGUAGE LEARNING (CALL)

With the huge breakthroughs in the field of technology, computers are now a tool regularly used in language teaching and learning. Computer Assisted Language Learning (CALL) includes the use of Information and Communication Technology in foreign language teaching and learning [2]. Egbert defines CALL as "learners learning language in any context with, through, and around computer technologies" [3].

TABLE I. DEFINING 'TRADITIONAL' APPROACHES AS FIVE DIFFERENT VERSIONS

Conceptions of 'traditional'	Approximate timescale	Key features
Classical grammar-translation	up to 1900s	Uses of grammatical paradigms, explanations, bilingual vocabulary lists, translation exercises, use of L1 in classroom
Wider grammar-translation	1900s-2000s	Grammatical explanations, bilingual vocabulary lists, translation exercises, also oral elements and other practice exercises
Audiolingual	1940s-1960s	Emphasis on structures, oral skills, mimicry, memorization, substitution and pattern drills
Mainstream EFL	1930s-2000s	Mixed approach, includes presentation, practice, production, communicative activities
"Humanistic" or alternative	1970s-2000s	Total Physical Response, The Silent Way, Community Language Learning, Suggestopedia, and the Natural Approach

CALL began to develop in the 1960s with the first technology introduced into the classroom: the tape-recorder and film-strip projector [4]. The last 50 years of CALL can be divided into three stages: behaviourist CALL, communicative CALL and integrative CALL [5].

Stockwell [6] lists the various technologies that can be used in CALL as follows:

1. Interface design and authoring technologies.
2. Data management, access and portability.
3. Artificial intelligence and tutoring systems.
4. Automatic speech recognition technologies.
5. Natural language processing technologies.
6. Speech synthesis technologies.
7. Learner profiling systems.

8. Cognitive agent systems.
9. Mobile and communication technologies.

The listed technologies are explained in part V.

From the socio-behavioural aspect, Stroia [7] defines the advantages of using digital technology in the following respect:

1. Simultaneous addressing of several senses.

   Information can be perceived twice through two different channels (audio and visual).

2. Media offers a degree of variation and entertainment.

   This increases the motivation of the learner.

3. Virtual transposition to a natural environment.

   By using the new technology, the learner can virtually travel to the native environment of the foreign language, instead of physically travelling to a different country.

4. Communication with native speakers.

   Communication can be set up over the internet.

5. Manipulation of audio and video sequence.

   The audio and video recordings can be replayed and interrupted as many times as needed.

6. Updatability of digital materials.

   The ease of keeping materials up to date is especially notable for the online digital materials.

7. The authenticity of communication.

   The audio and video materials can have pieces of real communication.

8. Studying at learner's individual speed.

   The use of technology enables learners to study at their own pace, not having to follow the average speed of the whole group.

9. The availability of the means of learning.

   Learners can choose the time and place of study in case of a computer lesson.

10. Loss of insecurity.

    Learners do not feel shame in front of the computer when they make mistakes.

11. Interactive character of learning.

    Learners have to be fully active while doing their computer lesson and their minds cannot wander off.

12. Illustrating dynamic linguistic phenomena.

    Animations are used for the illustration of certain linguistic phenomena.

13. Immediate feedback.

    Computer provides immediate feedback for certain exercises, while for some there is still need for a human agent.

Using computers in language teaching and learning has prepared the basis for the development of new techniques and it has given teachers and learners a whole new perspective. The next part of the article gives real examples of using computers in an EFL classroom in the context of higher education and will support the advantages listed in this section.

III. GOOD PRACTICE IN EFL

The use of computers and technology in an EFL classroom at the College for Information Technologies in Zagreb will be explained in respect to four different language skills: reading, writing, listening and speaking. Different techniques are used in order to master these language skills, but in this article only the ones which use a certain technological aid will be explained. In this respect, different technologies (software and hardware) can be used. At this college, students use their own portable computers and have an uninterrupted access to the network.

A. Reading

The biggest breakthrough in mastering reading with respect to technology is definitely the invention of the internet. Updatability of information on the internet cannot even be compared to information in print. This is the reason why learners of language today can study and practice reading texts that deal with the most modern and up-to-date topics, as opposed to texts in coursebooks that were published a couple of months or years ago.

Using technology for mastering reading is used in two different ways according to the person who chooses the text. Online dictionaries are used in both of these situations.

The teacher chooses a text online, gives the URL address to the students and then they open it on their portable computers. The students are instructed to read the text and use an online dictionary in case of unfamiliar words. Discussion with the teacher, involving the whole class, follows after the reading. The teacher tries to elicit new words and writes them on the whiteboard. Comprehension questions are asked in the discussion.

In case of students being asked to choose a text online, they are assigned a certain subject area by the teacher. The students naturally choose different texts. The students are asked to read the most interesting paragraph to the class and to add a couple of sentences that best describe the topic of the article. Other students are incited to ask questions. In this discussion, which follows the reading, speaking skills are also mastered. One other example of combining language skills is when students are given a script to read before watching a video, when of course, reading and listening are combined.

The discussed techniques support the following advantages of Stroia [7], listed in part II of the article:

- Simultaneous addressing of several senses.

- A degree of variation and entertainment.
- Updatability of digital materials.
- Studying at individual speed.
- Availability of the means of learning.

B. Writing

Most of the writing is practiced by using the CD-ROM of the coursebook which offers interactive exercises. Students use the CD individually on their computers. The writing practice is divided into four areas: descriptions, academic, correspondence and articles. The exercises include cloze, matching and correct order. The CD offers the correction of answers.

Another way of practicing writing is after watching short videos, when the students are asked to summarize the main ideas of the video in a few sentences. The teacher checks the assignments after class.

In recent years, correspondence has mostly been carried out via e-mails. That is why practicing this kind of writing (formal or informal) is very important. Online exercises which provide practice in this area are used in the classroom.

The discussed techniques support the following advantages of Stroia [7], listed in the previous part of the article:

- Simultaneous addressing of several senses.
- Loss of insecurity.
- Interactive character of learning.
- Immediate feedback.

C. Listening

Listening to audioscripts from the coursebook was/is usually done by playing tapes/CDs on a portable player. The listening in this EFL classroom is done similarly, only the medium used is a portable or desktop computer. Playing audioscripts on computers enables better manipulation of the audio recording.

In addition, the internet offers a great selection of numerous audio clips, so the teacher can choose from presentations, videos, lectures, interviews, etc. which have not been artificially recorded as the ones on the course CD.

The mentioned techniques support the following advantages of Stroia [7], listed in the previous part of the article:

- Simultaneous addressing of several senses.
- A degree of variation and entertainment.
- Virtual transposition to a natural environment.
- Manipulation of audio and video sequence.
- Updatability of digital materials.
- Authenticity of communication.

D. Speaking

Within this language skill computers are used indirectly. The reason being that technologies like speech synthesis and artificial intelligence have not, yet, been used in this classroom. Students learn and practice their language skills using Microsoft Power Point software in order to prepare a presentation at home and then present it to the class.

During the lesson, students are asked to visit certain web pages and then report back to the class in smaller groups. This activity combines reading and speaking, while discussions after videos combine listening and speaking. Students are also encouraged to join webinars of their own interest, where they can practice listening and speaking in a native-speaker environment.

The mentioned techniques support the following advantages of Stroia [7], listed in the previous part of the article:

- Virtual transposition to a natural environment.
- Communication with native speakers.
- Authenticity of communication.
- Availability of the means of learning.

All the materials, URL addresses, etc. can be found on the official forum of the course, so that students can access them from home, especially in the case of being absent.

IV. SURVEY RESULTS

In order to reinforce the postulate of the benefits of using technology in an EFL classroom, a survey has been conducted among students of the College for Information Technologies in Zagreb. The survey conducted in 2010 at the same college showed that the students see considerable advantages in using technologically enhanced teaching and learning methods [8].

The same survey was given in 2013, where the number of valid respondents was 94, of which 8 were female. The questionnaire was composed of 10 statements. The respondents were asked to circle numbers from 1 to 5: 1 - I completely disagree, 2 - I mostly disagree, 3 - I cannot decide, 4 - I mostly agree, 5 - I completely agree, to show the degree of agreement with the following statements:

1. I am completely satisfied with my current English language textbook.
2. Extra materials are very important to me as an English learner.
3. Watching short movie clips in class helps me study the English language.
4. I sometimes need explanations when I am studying by myself.
5. I would like to have a book which would help me study by offering explanations even when I am not in class.
6. I miss having a dictionary as part of my English textbook.

7. I would like to have the possibility to make my own glossary and have it in a digital format.
8. Browsing the internet and using the online materials helps me in the study of the English language.
9. I enhance my knowledge of the English language by browsing through the web pages.
10. I am familiar with the term 'electronic book'.

Statement 2 was included in the questionnaire in order to show how students feel about using extra materials in general. 35.1 % of the students mostly agree and 30.9 % of the students completely agree with this statement, and only less than 10% students completely or mostly disagree (Fig.1).

Statement 3 shows the students' interest in audio-visual materials. 51.1 % of the students completely agree and 26.6% mostly agree that watching videos helps them in their study of the English language (Fig.2). The survey from 2010 gave similar results where 58% of the students completely agreed and 18 % of the students mostly agreed.

Statements 8 and 9 show the importance of the internet and various online materials in EFL teaching and learning. 57.4% and 61.7% of the students find the Web as a completely useful tool in English foreign language learning (Fig. 3 and 4). The percentages in the earlier study were quite similar, being respectively 53% and 68%.

The agreement of students to other statements in the questionnaire has not been individually analysed because of its lower significance to the reinforcement of the given postulate. The overall results are given in Figure 1.

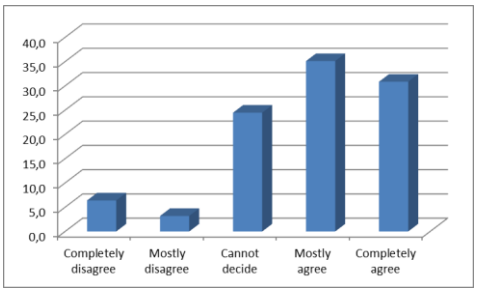

Figure 1. Statement 2

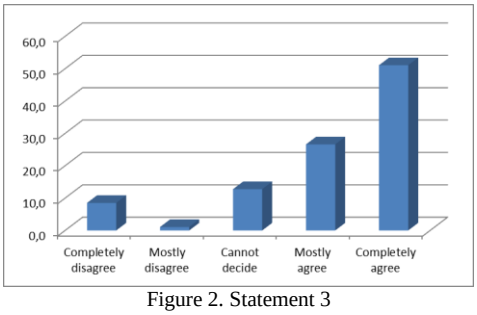

Figure 2. Statement 3

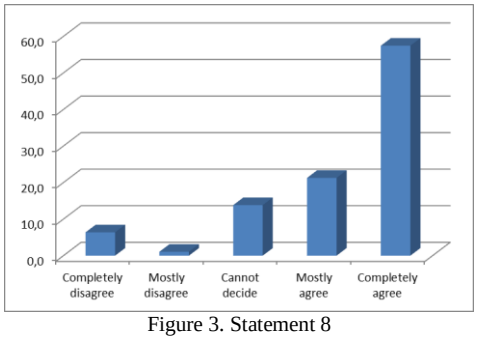

Figure 3. Statement 8

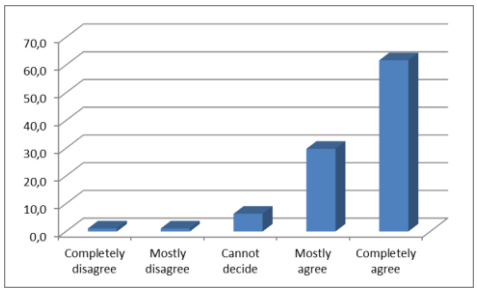

Figure 4. Statement 9

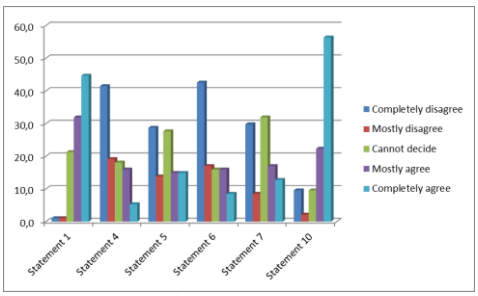

Figure 5. Results for Statements 1, 4, 5, 6, 7 and 10

V. TECHNOLOGY IN CALL

The explanation of the technology used in CALL which was listed in Part II is given in the following paragraphs.

1. Interface design and authoring technologies.

Authoring tools enable you to create multimedia software with less technical knowledge to master than with programming tools [9]. Teachers can thus use the right interface design and authoring software in computer assisted language learning.

2. Data management, access and portability.

The technologies used for data management refer to organizing, storing, securing and retrieving information. In language learning, this particularly refers to numerous online materials, the ease of access and the portability of information on different devices.

3. Artificial intelligence and tutoring systems.

The use of these technologies generates a new approach to language learning called the Intelligent Computer-Assisted Language Learning (ICALL). This

approach combines natural language processing and artificial intelligence in the form of intelligent tutoring systems [10].

4. Automatic speech recognition technologies.

These technologies involve recognizing speech and providing feedback. Special attention has to be paid to carefully designing learning activities so that the software would have a good recognition performance [11].

5. Natural language processing technologies.

NLP technologies are used in order to assess learner input and generate feedback according to grammatical and syntactical rules [12].

6. Speech synthesis technologies.

These technologies produce artificially synthetized human speech. They can be used in foreign language learning for transforming written text to speech. One example of speech synthesis can be found in online dictionaries where entries have an audio pronunciation.

7. Learner profiling systems.

There is a possibility of creating e-learning systems that are based on different learner profiles. With this approach, students are provided with learning materials which best suit their needs [13].

8. Cognitive agent systems.

An example of this technology is found in a study of a virtual agent used as a vocabulary trainer where via video stimuli learners engage in gesture-supported vocabulary training [14].

9. Mobile and communication technologies.

The rapidly changing world of ICT has introduced mobile and communication technologies which have brought about the world of social networking and microblogging. These kinds of technologies enable learners to stay in contact with the foreign language at all times, whether it is through receiving or producing information.

VI. CONCLUSION

It is unquestionable that technology enhancements bring about certain advantages. The same is true if you include technology in foreign language learning.

This article gives practical examples of using technology in an EFL classroom where numerous advantages of this kind of approach were listed. Using computers in the classroom adds a new dimension to the formerly used traditional approaches. Students are more exposed to the native language and use up-to-date materials which give them a feeling of actually being in the native environment of the foreign language.

The language of IT is English, which is why learning English as a foreign language in a computer-assisted environment has great benefits. At the College for Information Technologies students are aware of what technology has to offer in terms of foreign language learning. Other than help in the acquisition of language skills, technology can also enhance learner motivation.

In respect to the survey results and the methods described as good practice, FL teachers are encouraged to include computers in their everyday teaching methods, to blend the traditional and the electronic. However, teachers are not encouraged to use technology to make up for any lack of preparation, because they have to "put the same kind of thought into using technology in the service of the curriculum that they regularly do" [15].

Development of a computer system to support knowledge acquisition of basic logical forms using fairy tale "Alice in Wonderland"

Antonija Mihaljević Španjić*, Alen Jakupović*, Matea Tomić*
*Polytechnic of Rijeka, Business Department, Rijeka, Croatia
amspanjic@veleri.hr
alen.jakupovic@veleri.hr
mtomic@veleri.hr

Abstract - The knowledge acquisition of basic logical forms (term, statement, conclusion, and proof) is a prerequisite of the acquisition of any other knowledge and skills. Therefore, the knowledge acquisition of basic logical forms needs to be addressed in the earlier stages of education. In order to support the acquisition of knowledge and skills in the domain of logical forms, the authors of this paper propose the development of a computer based system for the presentation of thematic information, tasks and games based on the parts of "Alice in Wonderland" – fairy tale recognizable and popular due to Carroll's game with the basic forms of logical thoughts. The computer system would allow children and adults to gain the subject knowledge. A paper describes two initial phases of the aforementioned system - analysis and design. Analysis specifies in detail the basic system requirements, expressed in terms of learning outcomes. Design specifies in detail thematic information, tasks and games which will try to ensure achievement of learning outcomes specified in the analysis phase. The focus of design is in the use of a fairy tale Alice in Wonderland, and in the development of a computer based system.

I. INTRODUCTION

Logical forms indicate forms of human thought. The basic logical forms of thought are the term, statement, conclusion and proof. The term is encountered when there is a confrontation with an unknown object. In such a situation arises the need of understanding the meaning of that object and creating a clue about it. During a life and learning a person constantly acquires new concepts and expands his knowledge. In addition to directly perception of the object and acquisition of terms, it is possible to indirectly perform some conclusion on the basis of what is known about the object or event. When we want to confirm or refute a statement, this is made by use of proof, i.e. by application of rules of consistent logical reasoning. From the foregoing is evident that logical forms are in constant daily use and how much they are significant. Logical forms are subject to interest of logic as a scientific discipline that investigates shape or form and the ideal rules of thought. Logic and its subject logical forms are prerequisite for any human scientific or professional activity [6], [10], [11].

The intention of the author of this paper is to develop a computer system that would support the acquisition of knowledge and skills in the domain of logical forms. It would be available to a wide range of students, and would be tailored to the different age groups of students. The basic instructional method implemented in a computer system would be problem-based learning [1], [2], [5], [7]. The traditional method of teaching is subject-based learning. Figure 1 shows the basic difference between the two mentioned learning approaches [5].

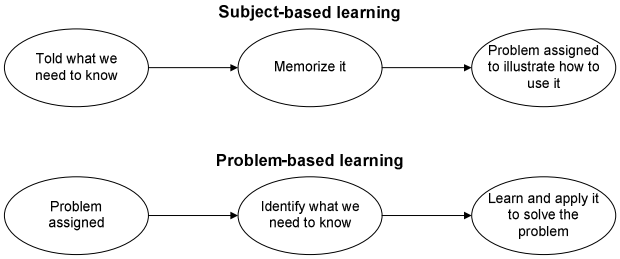

Figure 1. Difference between subject and problem based learning

In subject-based learning teacher provides content that is needed to learn. Students acquire the given content. Following the adoption, students are given problems to which they should apply the acquired knowledge.

In problem-based learning teacher first pose a problem to students. Guided by the problem, the students, together with a teacher, determine the content that is needed to resolve the problem. Then students adopt and apply identified content to a given problem. Problem-based learning is active, integrated, cumulative and connected [1].

Development of a computer system to support the acquisition of logical forms is based on the parts of "Alice in Wonderland" - fairy tale recognizable and popular due to Carroll's game with the basic forms of logical thoughts [4]. Also development of the system follows the ADDIE model, which consists of five phases: Analysis, Design, Development, Implementation and Evaluation [8], [9].

In addition to introduction, the paper consists of three chapters. In the second chapter - Analysis phase of system development to support the acquisition of logical forms - are shown the learning outcomes that students should

achieve, and for which the system will provide support. The third chapter - Design phase of system development to support the acquisition of logical forms – shows examples of the teaching content and the way they are presented to students by taking into account the problem-based learning method. The paper ends with a conclusion about the directions for further development of computer based system to support the acquisition of logical forms.

II. ANALYSIS PHASE OF SYSTEM DEVELOPMENT TO SUPPORT THE ACQUISITION OF LOGICAL FORMS

According to the ADDIE model of system development, analysis phase should determine the components that are needed in other phases of the system development. Basically we can say that the analysis should answer the question of what developed system must do, or which requirements should be satisfied by its work. Especially for the development of a system which should support the learning, analysis should provide answers to the following questions [8], [9]: Who is the learner? What is the instructional goal of the lesson? What are the delivery options? What instructional technology, if any, would enhance student learning? What will the students do to determine competency? What is the timeline? What are the online pedagogical considerations?

Computer based system to support the acquisition of logical forms should be used by learners of all ages, starting from elementary school age. In the first phase of system development focus will be on the students, because the authors of the paper participate in faculty teaching.

The learning outcomes whose achievement we want to be supported by the system are shown in Table 1. Stated are the learning outcomes for each logical form (term, statement, conclusion, and proof). In their definition has been applied Bloom's taxonomy of learning domains [3].

Computer based system to support the acquisition of logical forms should be available to the wide range of

TABLE I. THE LEARNING OUTCOMS FOR LOGICAL FORMS: TERM, STATEMENT, CONCLUSION AND PROOF

		LOGICAL FORMS			
		Term	Statement	Conclusion	Proof
BLOOM'S TAXONOMY OF LEARNING DOMAING	Knowledge	To recognize a word or sequence of words that signify the term in a given text or group of objects. To define the term.	To recognize simple statement and logical operators in a complex statement. Mark them by symbols (if they are written in some natural language).	To recognize simple logical elements in given logical form and classify them in the appropriate group – statement symbols and logical operators.	To recognize the logical forms of statements and conclusions in a given text and classify them in the appropriate group – the conclusion premises.
	Comprehension	To extract / identify higher and lower terms from the pair of terms or from a given text.	To appoint type of given statement and logical operators.	To identify the type of logical form - hypothetical syllogism, modus ponendo ponens, modus tolendo tollens, disjunctive syllogism, modus ponendo tollens, modus tolendo ponens.	To identify basic rules of conclusion in a given text using which one can prove a given statement starting from the premises.
	Application	To show given group of terms according to the range size.	To show simple statements and logical operators from which can be built complex logical statements.	To find logical statements and logical operators in a given text.	To mark by symbols all the logical forms – statements, conclusions and rules of conclusion by which it can be proved given statement starting from the premises.
	Analysis	To extract all terms from the given group of terms or text which are in certain logical relationship.	To extract all the simple logical statements and logical operators from the given set and by which one can build a certain type of complex statement. To extract all statements from the group of the statements or default text that are in some relation to logical square.	To extract all logical statements and logical operators from a set of logical statements, using which one can build a given form of conclusion.	To group logical forms of statements and conclusions, and the rules of equivalence that will be used in a proof.
	Synthesis	To find terms that are in corresponding relations with the given term and to build a table or devise a similar construction.	From the set of simple logical statements and logical operators to build a logical form of conclusion in a natural language. From the set of statements to select those statements that are in some relation to logical square.	To compile a logical form of conclusion by sequencing logical statements and link them by logical operators.	To build a proof using grouped logical forms, and basic rules for proving a given statement starting from premises.
	Evaluation	To reassess / show the relationship between given terms in Venn diagrams.	To check the validity of statement using a method of *reductio ad absurdum* and a boolean table.	To check the validity of conclusion using a method of *reductio ad absurdum* and a boolean table.	To build a new proof for the same statement based on the same premises, applying different rules and compare the existing proof with a newly built.

learners and that in the online and offline work mode. Availability should increase in the way that system can be used by desktop and laptop computers, but also by tablet computers and smart phones. It is assumed the minimum computer literacy of learners.

The system should support the learner-content interaction, i.e. without the instructor. This interaction will be supported with the instructional method of problem-based learning. To learners should be set a problem which they are trying to solve. In case they do not have enough knowledge for the solution of the problem, learners should be given the content that will allow them to adopt the necessary knowledge.

Through the established system learners should have the possibility to check the acquired knowledge. This should be realized in a way that they are given the problem which they are trying to solve – similar to the way in which the problem is set before acquiring knowledge. The difference is that now they do not have available content with the knowledge necessary to solve the problem.

The interaction of system and learners should be accomplished in several ways (for example by entering data, marking, positioning, choice, drag and drop, etc.).

III. DESIGN PHASE OF SYSTEM DEVELOPMENT TO SUPPORT THE ACQUISITION OF LOGICAL FORMS

Results of the analysis (the first phase of ADDIE model) enter the second phase of system development – the design phase. This phase needs to answer the question how the developed system would satisfy the requirements which are identified in the analysis phase. Especially for the learning supporting systems, design should provide answers to questions [8], [9]: which assignments student needs to perform in order to attain certain learning outcome specified in the analysis phase, which is targeted performance objectives of the student (what the student will do, under which conditions, and which the result is acceptable) and the manner in which will be tested the achievement of certain learning outcomes.

Not diminishing importance of responses to other questions, the authors of paper in this section provide an answer to the first question - description of the tasks that student needs to perform in order to reach the learning outcomes. This is to emphasize that system design wants to support problem-based learning. The logical form conclusion and its learning outcomes that fall in all learning domains (see Table 1) will be used as example (it includes all other logical forms). Descriptions have the following structure:

1. learning domain – learning outcome
2. description of the task which student needs to perform in order to achieve these learning outcome and its correct solution - the problem description
3. content that will be available to the student to solve the assigned task (problem) and reach a defined learning outcome.

In tasks for learning domain application, analysis, synthesis and evaluation, concrete examples of fairy tale "Alice in Wonderland" are used. In order to clearly present the learning outcomes, the corresponding description of the task, its solution and related content, the table view will be used. In analogy it can be created description also for other logical forms - term, statement and proof.

TABLE II. DESIGN FOR LOGICAL FORM "CONCLUSION" – LEARNING DOMAIN "KNOWLEDGE"

Learning domain: learning outcome
Knowledge: To recognize simple logical elements in given logical form and classify them in the appropriate group – statement symbols and logical operators.
Task – solution
From displayed logical form should be recognized logical elements and classify them in the appropriate group. (X ∧ Y) → ¬Z Statement symbols: ¬¬Z Logical operators: ¬(X ∧ Y) **Solution:** Statement symbols: X, Y, Z Logical operators: ∧, →, ¬
Content
Logical forms consist from statement symbols, and may contain logical operators. Statement symbols are used in the labelling of simple statements, and are used capital letters (e.g. A, B. .., X, Y, Z...). Logical operators are used for composing simple statements into more complex statements or for their negating. Logical operators are: conjunction ∧, disjunction ∨, implication →, equivalence ↔, and negation ¬.

TABLE III. DESIGN FOR LOGICAL FORM "CONCLUSION" – LEARNING DOMAIN "COMPREHENSION"

Learning domain: learning outcome
Comprehension: To identify the type of logical form - hypothetical syllogism, modus ponendo ponens, modus tolendo tollens, disjunctive syllogism, modus ponendo tollens, modus tolendo ponens.
Task – solution
Which type is the given logical form. (X ∧ Y) → ¬Z ¬¬Z ¬(X ∧ Y) **Solution:** Given logical form is type of modus tolendo tollens.
Content
There are six basic forms of conclusion that can be recognized according to the forms of premise and a conclusion.

Hypothetical syllogism	Modus ponendo ponens	Modus tolendo tollens
P → Q Q → R P → R	P → Q P Q	P → Q ¬Q ¬P
Disjunctive syllogism	**Modus ponendo tollens**	**Modus tolendo ponens**
P ∨ Q ili P ∨ Q ¬Q ¬P P Q	¬(P ∧ Q) P ¬Q	P ∨ Q ¬P Q

TABLE IV. DESIGN FOR LOGICAL FORM "CONCLUSION" – LEARNING DOMAIN "APPLICATION"

Learning domain: learning outcome
Application: To find logical statements and logical operators in a given text.
Task – solution
In displayed text it is necessary to find logical statements and logical operators. „Oh, you can't help that“, said Cat: „we're all mad here. I'm mad. You're mad.“ Alice didn't think that proved it at all; however, she went on: „And how do you know that you're mad?“ „To begin with “, said the Cat, „a dog's not mad. You grant that?“ „I suppose so “, said Alice. „Well, then“, the Cat went on, „You see a dog growls when it's angry, and wags its tail when it's pleased. Now I growl when I'm pleased, and wag my tail when I'm angry. Therefore I'm mad.“ „I call it purring, not growling“, said Alice. „Call it what you like“, said the Cat. **Solution:** Logical statements: A dog’s not mad.; A dog growls when it’s angry, and wags its tail when it’s pleased.; We're all mad here.; I'm mad.; You're mad.; I growl when I'm pleased, and wag my tail when I'm angry. Logical operators: therefore, then, and, not
Content
In logic the statement is a set of terms by which something is claimed or denied. Statement can be simple or composed. Statement „*A girl named Alice is the main character in a fairy tale written by Lewis Carroll - Alice in Wonderland. “* is an example of simple statement. Statement „ *A girl named Alice is the main character in a fairy tale written by Lewis Carroll - Alice in Wonderland,, and next to her in a fairy tale appear other interesting characters.“* is an example of composed statement. Composed statement consists of two simple statements related by some link that represents an appropriate logical operator. Displayed composed statement consist of two simple statements (*A girl named Alice is the main character in a fairy tale written by Lewis Carroll - Alice in Wonderland.* and *Next to Alice in a fairy tale appear other interesting characters.*) that are connected with „and“ which is a link for logical operator of conjunction. Linkers and appropriate logical operators are: 1. negation – linkers: no, nor... 2. conjunction. – linkers: and, but, than the, already, although, though, however... 3. disjunction – linkers: or, either... 4. implication – linkers: if … than, only if... 5. equivalence – linker: if and only if.

TABLE V. DESIGN FOR LOGICAL FORM "CONCLUSION" – LEARNING DOMAIN "ANALYSIS"

Learning domain: learning outcome
Analysis: To extract all logical statements and logical operators from a set of logical statements, using which one can build a given form of conclusion.
Task – solution
From displayed set of logical statements it is needed to extract those logical statements and logical operators by which one can build conclusion in form of modus tolendo tollens. A dog’s not mad. A dog growls when it’s angry, and wags its tail when it’s pleased. We're all mad here. I'm mad. You're mad. I growl when I'm pleased, and wag my tail when I'm angry. **Solution:** Logical statements: Dog's mad.; Dog growls when it's angry.; Wags its tail when it's pleased. Logical operators: Not = ¬; (Only if) Then = →; And = Λ
Content
It can be repeated content that is given in Tables 3 and 4.

TABLE VI. DESIGN FOR LOGICAL FORM "CONCLUSION" – LEARNING DOMAIN "SYNTHESIS"

Learning domain: learning outcome
Synthesis: To compile a logical form of conclusion by sequencing logical statements and link them by logical operators.
Task – solution
From given logical statements and logical operators should be compiled logical form of conclusion. Logical statements: Dog's mad.; Dog growls when it's angry.; Wags its tail when it's pleased. Logical operators: Not = ¬; (Only if) Then = →; And = Λ **Solution:** Dog’s not mad (only if) then (you see) a dog growls when it’s angry, and wags its tail when it’s pleased. (Is such that) a dog growls when it’s angry, and wags its tail when it’s pleased. Dog’s not mad.
Content
It can be repeated content that is given in Table 3.

TABLE VII. DESIGN FOR LOGICAL FORM "CONCLUSION" – LEARNING DOMAIN "EVALUATION"

Learning domain: learning outcome
Evaluation: To check the validity of conclusion using a method of *reductio ad absurdum* and a boolean table.
Task – solution
It is needed to check the validity of given conclusion using a method of *reductio ad absurdum* and a boolean table. (X Λ Y) → ¬Z ¬¬Z ¬(X Λ Y) **Solution:** Method of reductio ad absurdum (X Λ Y) → ¬Z ¬¬Z ¬(X Λ Y) ~~t t t t f t~~ t f t f t t t Conclusion is valid because the absurdity is in the first premise. Namely, implication is not true if the first element (implicator) is true, and the second is false. Method of boolean table X Y Z (X Λ Y) → ¬Z ¬¬Z ¬(X Λ Y) t t t t f f t f f t t t f t t t f t t t f t f t f t f f t f f f t t f t f f t t f t f t f f f t n f t t f t t f f t f t f t f f f f f f t t f t f Conclusion is valid, because there is no counterexample that would mean that from true premises follows the false conclusion.
Content
The validity of conclusion is one of the forms for preservation of truth. It can be checked by the method of *reductio ad absurdum* and by boolean tables. Both of these methods require translation of logical forms from natural language to the language of logic. Here we use a language of propositional logic. Language of logic has its own syntax and semantics. Syntax includes a list of symbols and formative rules, while semantics describes how formulas, occurred according to the rules of syntax, we can add the values. Building of boolean tables for composed logical forms starts with determining the values of simple statements. These values are recorded on the left side of table. Every statement has value of true or false. By increasing the number of simple statements increases the combination of values on the left side of table (for example, for two numbers the combination is 2 * 2 = 4, for three it is 2 * 2 * 2 = 8, or in general for n is 2^n). Values of composed logical form are set from simple elements to more complex. Method of reductio *ad absurdum* is a method in one line. Set of values go in reverse of set of values by boolean table – set of value takes place from values of main logical elements to those more simple. Both methods require knowledge of boolean tables of the main logical operations (negation, conjunction, disjunction, implication and equivalence).

IV. CONLUSION

This paper describes the first two phases (by ADDIE model) of the development of computer based system to support the acquisition of logical forms. The initial version of the analysis and part of the design is shown (for only one logical form of four of them). The system is based on problem-based learning and learner-content interaction.

The next phase in the development of the system is a further detailing of the design which should include the learning outcomes of all logical forms, definition of the ways of achieving verification of learning outcomes, and definition of levels of learning outcomes achievement which are considered acceptable.

Upon completion of the analysis and design phase follows the development phase. This phase should result in an initial version of the system with which learners will be able to be in online and offline interaction, and which will be widely available. For this purpose, the intention is to develop a system for the web environment (there is a possibility of interaction with other learners), but also as a standalone application for desktop, laptop and tablet computers, as well as smart phones.

In the implementation phase should be given an answer to the question of how the final version of the system will set up and how to make it available to learners. The intention is to set up a web version of the system on the server of the Polytechnic of Rijeka, which it already owns. On the same server will be set up a link through which the learner will be able to download the appropriate standalone application.

The evaluation phase should answer the question of how much the system successfully fulfils its purpose. To make this phase implemented, the intention is to put the system under evaluation of both, learners who have been interacted with the system, professors, as well as pedagogical experts.

Designing the Programming Assignment for a University Compiler Design Course

I. Budiselić*, D. Škvorc* and S. Srbljić*
* University of Zagreb, Faculty of Electrical Engineering and Computing, Zagreb, Croatia
{ivan.budiselic, dejan.skvorc, sinisa.srbljic}@fer.hr

Abstract - This paper analyzes the key properties of a programming assignment for a university compiler design course. After an overview of popular choices used at several universities in the world, we describe the assignment given to students of the *Programming Language Translation* undergraduate course at the University of Zagreb, Faculty of Electrical Engineering and Computing, and provide the rationale behind several design decisions through an analysis of its evolution in recent years. While most compiler programming assignments are based on tools like lexer and parser generators, our students actually build slightly simplified versions of these tools themselves. We discuss our experiences with this programming assignment over the last three years and qualitative differences in the results between this assignment and the tool based assignment we had been using before.

I. INTRODUCTION

Translation of programming languages and compiler technology is one of the topics that are ubiquitous in computer science undergraduate curricula. It is usually implemented as a single course in the curriculum that covers some portion of the *Programming Languages* knowledge area (KA) and a few topics from other KAs in the *Curriculum Guidelines for Undergraduate Degree Programs in Computer Science* published jointly by the ACM and IEEE [1].

However, while most of these courses cover a similar set of topics in lecture, there is no broad consensus on the design of the programming assignment that is an integral part of almost every compiler design course. In fact, this has been the case ever since this topic was included in the curriculum [2].

The common characteristics of programming assignments in most of the compiler design courses analyzed in [1] are that students build a complete compiler, and the success rate on the project significantly impacts the students' grades. Apart from this general commonality, the organization and scope of the compiler project diverge significantly.

Compiler courses are typically thought in the second half of the undergraduate program with prerequisites covering programming, basic algorithms and data structures, computer architecture and organization and sometimes introduction to the theory of computation. Since the compiler bridges the gap between the two abstractions of high-level programming languages and machine code, this order of courses in the curriculum ensures that students are familiarized with both of these abstractions prior to taking the compiler design course. Furthermore, a large part of a compiler is based on well understood and approachable formal models, and tools for building compilers are abundant. These factors put the compilers course in a somewhat unique position in the curriculum in that students can build a complete and complex system in their programming assignment. Consequently, the compiler project is frequently the largest and most challenging programming project students are involved in during their studies. A few papers mention that students talk about their compiler project experiences in job interviews [3,4], and in our own experience, we've found that a student's performance on this project provides valuable information for writing recommendation letters.

It is the scope of the project that allows the high level of diversity that is observed in practice. Specifically, the design of a compiler project is based on five somewhat competing goals, and different preference for these goals yield significantly different designs.

First, students should ideally get some insight into all stages of the compiler, and the project should reinforce the theoretical material presented in lecture [3,5,6,7]. Understanding the compiler is beneficial to students as it is one of the most frequently used tools in the software developer's toolbox.

Second, compiler technology has applications beyond translating higher-level programming languages into machine code, and students should ideally experience that in their project so that they can recognize opportunities for applying the technology in other domains of their professional work [6,7,8].

Third, the complexity of the project provides an opportunity or even the requirement to teach students software engineering best practices in software design, testing, the use of tools such as compilers and debuggers, scheduling work and other areas [3,4,6].

The fourth goal that is often encountered is teaching students teamwork and communication as the project is nearly universally done in groups [3,4,9]. This seems particularly important as industry feedback frequently suggests that students lack key teamwork skills [9].

Finally, the fifth goal that is often not explicitly mentioned is that creating a compiler can make students better programmers. Knowing how some language feature

is implemented in a compiler allows students to better understand the programming languages they actually use. For example, if the source language supports passing arguments by value and by reference, implementing this distinction in the compiler requires and reinforces complete understanding of the underlying concept.

In this paper, we discuss the challenge of balancing these goals through our experience with the compiler project in the *Programming Language Translation* (*PLT*) course at the University of Zagreb, Faculty of Electrical Engineering and Computing (UniZg FER).

The rest of the paper is organized in the following way. In Section II, we overview some related work on compiler design courses. In Section III, we overview the compiler project at seven leading computer science universities in the US and Europe. We describe the curriculum context of our *PLT* course in Section IV. In Section V, we discuss the organization of the *PLT* course and describe the evolution of the programming assignment from its initial to its current design. We conclude the paper in Section VI.

II. Related Work

Two useful classifications of compiler design courses and projects have been discussed in the literature. Schwartzbach [10] roughly divides compiler design courses into *front end heavy* and *back end heavy*. The former category focuses on formal languages and context free parsing, while the latter focuses on code generation, resource management and optimization for a realistic processor architecture. Semantic analysis and intermediate code generation, which are typically considered a part of the front end [11], are grouped into the *middle end* of the compiler, and both course categories cover these phases to some extent.

Under this categorization, a meaningful critique of both types of courses is that lexing and parsing are supported by easy-to-use tools, and that the compiler back end is typically reused as a component when building a compiler for a new language. Specifically, the bulk of the work in creating a new compiler is done in this middle end, i.e. in semantic analysis and intermediate code generation. Schwartzbach suggests that both front end heavy and back end heavy courses are somewhat constrained to using only simple languages in compiler projects. Instead, the paper presents a *middle end heavy* course and argues for projects that are based on large, feature-rich languages.

Waite [6] proposes three strategies for organizing the compiler design course and project that are mostly in line with the goals presented in the introduction. The *software project* strategy focuses on teaching software development techniques rather than compiler algorithms. To achieve this goal, compiler building tools are employed as much as possible. It is unclear which parts of the compiler should be thought in lecture and at what level of detail, but this strategy seems to stray away from a traditional compilers course in this sense.

Quite oppositely, the *application of theory* strategy focuses on theoretical models such as formal languages and attribute grammars. The goal of a course following this strategy is to teach students both the value and limitations of theory in computer science. The suggested programming assignments in this strategy are *tools based on theory*, which seems to imply that students should only build parts of a compiler.

Finally, the *support for communicating with a computer* strategy focuses on the applicability of compiler technology to many domains in software engineering. After completing such a course, students would be able to devise domain specific languages for various applications and use the compilers toolkit to implement these languages. Again, this strategy does not include a compiler project. Instead, students practice language design and use of tools.

III. Overview of the Compiler Project at Leading Computer Science Universities

In this section, we briefly overview the compiler design courses and accompanying programming assignments from some of the leading computer science universities in the US and Europe. The specifics of each course are shown in Table I.

We've estimated the percentage of lecture time devoted to lexical and syntax analysis (shown in the third column in Table I) from the courses' syllabuses available on their web sites. The three courses with no more than 15% of lecture devoted to these topics are either middle end or back end heavy by Schwartzbach's classification. They provide only a practical introduction to lexing and parsing with the goal of enabling students to either write or modify provided specifications for existing lexer and parser generators that are used mostly like black boxes. The remaining four courses with at least a quarter of lecture time devoted to the lexer and parser additionally cover the generator algorithms themselves at the expense of more advanced optimization approaches in the back end, but should not be classified as front end heavy.

All of the courses except the Columbia University course use fixed source and target languages in the compiler project. All of these source languages are object-oriented and typically syntactically and semantically resemble the language that is used in the introductory programming course in the curriculum. Similarly, the target architectures are typically those used in other parts of the curriculum as well.

Fixing the implementation language provides several potential benefits. First, it is easier to estimate the amount of code students will need to write to complete the assignment. Second, having a fixed implementation language makes it easier to provide starter code which can then be used to adjust the difficulty of the assignment without sacrificing the overall functionality of the compiler. Third, a specific lexer and parser generator can be used for that fixed implementation language and potentially covered in lecture or recitation. In fact, all seven courses use existing generators for these early phases of the compiler.

The project is usually done in small groups or even individually. Columbia uses the largest groups of five

TABLE I. KEY PROPERTIES OF COMPILER COURSES IN SOME OF THE WORLD'S LEADING COMPUTER SCIENCE UNIVERSITIES

University	***Course name***	***Lecture front end %****	***Source language(s)***	***Target language(s)/ architecture(s)***	***Implementation language(s)***	***Tools***	***Students per group***	***Project grade impact %***

* Approximate values

students with an emphasis on group organization [3]. On the other hand, groups of two students are most common, and students are often encouraged to solve the assignments with pair programming instead of splitting up the work.

Finally, the project accounts for between 40 and 70 percent of the students' grade in the class. To grade the project, most courses use a combination of objective testing where individual assignments are tested for correctness against a set of test inputs and either oral quizzes or extensive written documentation.

IV. THE CURRICULUM CONTEXT OF *PLT* AT UNIZG FER

Before discussing the design of the compiler project in our *PLT* course at UniZg FER, we will describe the position of the course in the computer science curriculum as it is an important factor in choosing the goals of the course and the design of the compiler project.

The *Programming Language Translation* course is taught in the fifth semester of the undergraduate curriculum. Students enrolled in the course previously complete an introductory programming course and a course on basic algorithms and data structures, a computer architecture course and a course covering the introduction to the theory of computation.

Both the introductory programming course and the algorithms and data structures course are taught using C and a small subset of C++ (basically C with classes). In the computer architecture course, students learn FRISC and are introduced to ARM. FRISC is a RISC processor architecture developed at Unizg FER specifically for teaching processor architecture. The *Introduction to Theoretical Computer Science* (*ITCS*) course extensively covers regular and context-free languages that are of particular interest for compiler construction.

Besides these enabling factors, there is one characteristic of the curriculum which makes the design of the compiler project more challenging. While students have an opportunity to learn several other programming languages through electives and skills, there is no single language that every *PLT* student is certainly familiar with except C. The costs and benefits of C make it a poor choice for the implementation language in a compiler course.

V. *PLT* COURSE ORGANIZATION AND GOALS

About a third of lecture time in *PLT* is devoted to lexical and syntax analysis. This provides students with an opportunity to apply what they've learned about automata theory in the previous *ITCS* course to two interesting problems which illustrates the general value of these models. Furthermore, understanding the algorithms behind lexer and parser generators makes it easier to avoid ambiguities when designing a language or to eliminate them if they arise.

The second third of the course covers semantic analysis and intermediate representations. Based on their programming experience, students generally have an intuitive understanding of the key topics in semantic analysis, such as declarations and type checking. By introducing attributes to the familiar model of a grammar, this intuitive understanding can be formalized in an approachable way. Similarly, attributed syntax trees can be easily understood through their relationship with parse trees that are also covered in *ITCS* and in the first part of *PLT*.

The final third of the course is dedicated to code generation and execution support, along with a limited introduction to both machine independent and machine dependent optimization. In this part, students draw from their experience writing FRISC and ARM programs.

The primary goal of the compiler project is to reinforce these concepts introduced in lecture with practical experience. In the remainder of this section, we describe the evolution of the compiler project in the last

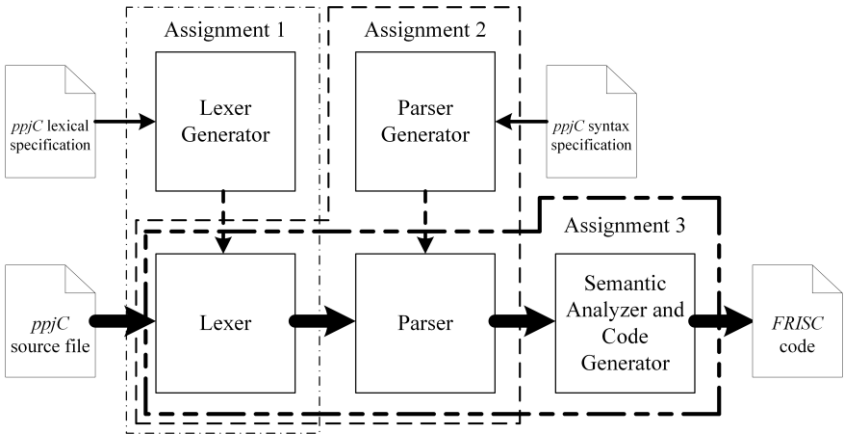

Figure 1. The design of the first iteration in the evolution of the compiler project in the *PLT* class at UniZg FER.

four years, from its initial organization to the one we are currently using.

A. Lessons Learned from an Ineffective Compiler Project Design

Up until 2010, the compiler project we used was fairly free-form, as students would design or choose their source, target, and implementation languages. This project design is intended to provide students with an opportunity for language design and familiarization with the compiler building tool chain, i.e. the second goal mentioned in the introduction is emphasized.

To prevent procrastination, we would set up two check points during the semester—one for lexical and syntax analysis and one for semantic analysis. At these check points student groups would demonstrate their current progress and group members would be quizzed on what they had done. At the end of the semester, groups would make their final code submission along with written documentation describing their source and target language, compiler architecture and key implementation ideas. Each group was also required to prepare a set of examples that showcase the capabilities of their compiler.

A teaching assistant would then read the documentation, run the provided examples, examine the compiler's source code, and come up with additional test cases. As a grading aid, we used an extensive list of possible language features, each of which was assigned some weighing factor corresponding to the difficulty of implementing it. This list included the most basic features like lexical analysis and support for variables and integral data to fairly advanced features like classes, inheritance and optimization.

After this preparation, the groups would come in for the final lab quiz focused on code generation, and the teaching assistant assigned to each group would go over the compiler's feature set with the group leader to make sure something wasn't overlooked.

The final scores were then scaled so that the most successful group would get 7.5% of the grade per member. The group leader was given the total group score and had to assign up to 7.5% to members, ideally depending only on their contribution to the project's success. The three lab quizzes contributed 2.5% of the grade each, so the project contributed a total of 15% to the grade.

While this project design allowed perhaps a few top students per generation to enjoy designing and implementing their own language, over several years of using it we noticed many significant problems.

The key problem was that at least half the groups didn't manage to finish the project. Difficulties usually arose during semantic analysis and code generation. This is understandable as lexical and syntax analysis were supported by *Lex* and *Yacc* equivalents, and appropriate definition files for many languages are available online. To get these stages working, students often simply modified existing generator input. This in turn made the start of the assignment very easy, giving students a false sense of the overall difficulty of the project and the time required to complete it.

Second, students were typically unsure about many design decisions in the early assignments as they didn't have a clear picture of what exactly they would be doing in later assignments. The most problematic point in this sense was the symbol table design which students often attempted to introduce in the lexer only to find later that their design was too limited.

Third, while students enjoyed the freedom to design their own source language, they often didn't choose an appropriate feature set. In particular, students often underestimated the complexity of some feature they wanted to include. Designing "the best" and most complex language became a goal for some groups, which often caused problems in completing the project.

Fourth, as the grading process was time consuming for teaching assistants and between 150 and 200 students take this class every year, we were forced to keep groups fairly large, usually between 10 and 12 students per group. Managing such a large group was understandably difficult for the group leaders, and this resulted in significantly different experiences for various members of the group. Usually, only the leader and a few other members would work on the compiler code, while others were assigned to creating test cases, writing the documentation or other supporting roles.

Finally, students often complained that the project is far too difficult for only 15% of the total grade. Furthermore, while we made every effort to keep project grading fair, this was a challenge as different teaching assistants graded different projects with different source

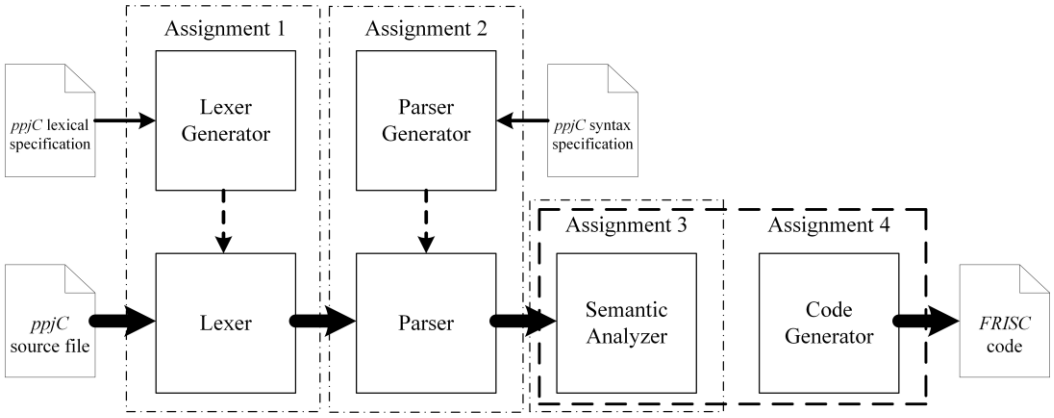

Figure 2. The design of the current compiler project in the *PLT* class at UniZg FER.

and target languages in an inherently subjective process. Specifically, it was difficult to correctly assign partial credit for features that weren't completely implemented, which was a common occurrence.

B. Evolution of the Compiler Project - the First Iteration

With the downsides of the old project in mind, in 2010 we set out to design a new project with the following ideas. First, we attributed most of the issues in the project to *underspecification*—students were given too many choices that they objectively weren't equipped to make. Most notably, we decided to specify both the source and the target language. We also included extensive advice on some key implementation details in the assignment document which was ultimately 60 pages long.

Second, we reduced the group size to nine students. While we were aware that the groups were still too large for effective organization, we had decided to make changes incrementally to avoid unexpected problems. For example, there was a concern that reducing the group size too much would result in some groups not having any strong programmers to lead the effort.

The design of this first iteration of the project is shown in Fig. 1. Unlike most other courses, we decided to have students implement their own lexer and parser generators instead of using existing ones. There are several motivating factors for this choice. First, all the algorithms required to write these generators are covered in lecture. Implementing these algorithms reinforces this knowledge. Second, the early assignments are made more challenging which is beneficial in that it doesn't portray a false picture of the complexity of the project as a whole, and students usually have more time to devote to projects early in the semester. Finally, building your own version of a tool forces you to understand it better, and hopefully teaches more than simply copying and editing existing lexical or syntax specifications.

With this in mind, the first assignment was to build a lexer generator that was a slightly simplified version of *Lex*. We provided students with lexical specifications for several example languages and for *ppjC* which was the source language we designed. We chose C as the basis for the language as that is the language that all of our students are exposed to early in the curriculum. The feature set of *ppjC* included a simplified integral and floating point type system, loops, branches, functions, single pointers, one dimensional arrays and structs. We intentionally kept the language fairly simple so that a majority of the groups would be able to complete the project.

The second assignment was to create a parser generator. We chose to use the *LR(1)*-parser as it allows the simplest and most intuitive grammars for specifying language syntax. Again, we simplified the syntax specification compared to a tool like *Yacc* so that the input is basically just the language grammar. As in the first assignment, we provided the syntax specification for several languages including *ppjC*. The students had to integrate the generated *ppjC* parser with the lexer they had generated in the first assignment.

Finally, the third assignment was to implement semantic analysis over the generated parse tree and generate *FRISC* code. We chose *FRISC* as the target processor as it is familiar to our students, which allows them to focus on the compiler itself. The semantics of *ppjC* were defined using natural language, mostly relying on the students' knowledge of C. Similar to the second assignment, students were again expected to integrate the new code with the results of the previous assignments.

As part of the third assignment instructions, we gave students a list of language features with weight factors, much like the one we had been using to grade the old project. The students were required to submit a similar list with the features they had implemented and test cases that exercise those features along with their documentation.

Overall, the changes we made felt like an improvement. While some students complained about the size of the assignment instruction text, nearly all groups managed to develop high quality solutions to the first two assignments. However, it was also clear that the third assignment needed significant additional improvement as many groups still stumbled in either semantic analysis or code generation. We identified two main reasons for this. First, compared to the first assignments, the third assignment was both underspecified and too big. Second, the fact that we required integration of all stages at every step made it difficult to recover from errors in earlier stages. For example, a small error in the parser generator made it nearly impossible to successfully finish the project.

C. The Current Design of the Compiler Project

In the next offering of the course, we made an effort to address these remaining problems. We split the third assignment into two separate assignments as shown in Fig. 2. Additionally, we completely removed the dependencies between all the assignments except the third and fourth. This means that the ability to complete an assignment is not negatively impacted by errors in earlier assignments. We achieved this by making the output of each assignment be the exact input for the next assignment. Specifically, the lexer outputs the token sequence of the input *ppjC* program which the parser transforms into a parse tree. The parse tree is then the input to both the semantic analyzer that outputs semantic errors and the code generator which is implemented as an extension to the semantic analyzer.

To further assist students in semantic analysis, we specified most of the semantics of *ppjC* in a formal way, using an attributed translation grammar, i.e. by adding attributes and computation rules to the *ppjC* grammar. The attribute values computation rules are designed for recursive descent on the parse tree, which is also covered in lecture. With this extension and additional implementation advice for the code generator, the assignment specification document grew to 80 pages, but we observed a significant improvement in the success rate of these later stages of the compiler which was our primary goal.

To address the grading problems, we introduced automatic evaluation of all assignments. Students submit their solutions to the web-based evaluator, which then runs several integration tests to check if the solution archive is properly formatted and correctly handles input and output. After the assignment deadline, all solutions are evaluated using 20-30 focused test cases that attempt to exercise various features of the particular stage of the compiler. The results of these tests contribute up to 15% of the student's grade. With the additional maximum 5% for each of the two assignment-oriented oral quizzes, we've increased the total grade impact of the project to 25%.

To reduce group management problems, we reduced the group size to six students. Additionally, to enable automatic evaluation, we constrained the implementation language choice to C, C++, C#, Python and Java. These are the languages the students are most likely to encounter in the curriculum depending on their course choices. Nearly all groups choose either Java or Python, with several groups choosing C# and C++ each year.

We also simplified *ppjC* by removing floating point numbers, pointers and structs. While this made the type system significantly simpler, it still offers a good insight into type checking and conversions.

With this design, we've achieved our primary goal of making sure most groups manage to implement at least some semantic analysis and code generation. In the last three years, the evaluation success rate was above 70% for the third assignment and above 50% for the fourth assignment, and only several groups fail to score any points on these assignments. The success rate for the first two assignments is consistently over 70%.

VI. Conlusion and Future Directions

In this paper, we've described the evolution and current design of the compiler project in our university compiler course. With a project with detailed specification of all the basic phases of the compiler, we've achieved significantly higher success rates in the later stages of the compiler than with the more free-form project we had been using in the past.

We've been getting positive feedback from students regularly, but many students still find the assignment too difficult. We are considering addressing this problem with designing two distinct assignment paths, where one would be a lower-credit version of the assignment focusing only on some parts of the compiler and language design. Additionally, we are also planning to further reduce group size which should minimize management problems, and more importantly, make the project experience similar for all students.

Acknowledgment

We would like to thank Ivan Žužak and Zvonimir Pavlić for their significant contribution to the improvement of the course and the compiler project in the last several years.

Abstract - In this paper we present the architecture of a new Micro Assessment (MA) system for "micro knowledge and skills control" that allows the manager to get information and status on knowledge gained on behalf of the employees, on very short status cuts during the working hours, rather than scheduling special meetings with them in order to assess their gained knowledge. This kind of micro testing saves a lot of time, does not cause stress among employees and allows more time to be dedicated for learning.

Two studies were undertaken as a part of this paper: study on the "knowledge platform" market and study on the "need for individual and professional upgrades". Based on the findings it appears that both challenges can be answered by initiating Software as a Service solution for small and medium enterprises built upon "lifelong learning" concept enabled on a Cloud computing architecture. Tools for "lifelong learning" not only enhance individual's involvement in social issues, but they are also enabling them with competitive skills required at their workplace.

I. INTRODUCTION

The constant development of the information society is surely automating and shortening each business process in one company. Due to the recent economic crisis, most of the managers and employers are trying to reduce the costs and become more efficient, thus investing in new software solutions, which will also cut the expenses on company's payroll. Moreover, the efforts to upgrade and strengthen the whole value and supply chain are highly appreciable. To be successful means to enable an environment where the workforce should constantly be exposed to acquiring new knowledge on solutions and services that could be easily adjusted and utilized for a specific field and business within which their company operates.

This paper presents the architecture of a new product, which is defined as a micro assessment system that should be implemented as a software service. It is intended for micro assessment of skills and knowledge of employees in order to increase and improve the productivity of the company, execution and knowledge of users, and adding additional value to their professional development.

The MA system for "micro knowledge and skills control" also allows the manager to get information and status on knowledge gained on behalf of the employees, on very short status cuts during the working hours, rather than scheduling special meetings with them in order to assess their gained knowledge. This kind of micro testing saves a lot of time, does not cause stress among employees and allows more time to be dedicated for learning.

The learning environment provided by this product helps individuals to use business intelligence to make faster decisions and improve response to critical business issues, ultimately contributing to the overall performance of their organization. One of the major benefits is that this solution is based on the world trends in teaching called "lifelong learning". Lifelong learning [1] refers to a society in which learning possibilities exist for those who want to learn [2]. Learning is not restricted to the classroom and to formal learning inside learning institutions; it is an activity, which happens throughout life, at work, play and home. In the modern knowledge-intensive era, lifelong competence development has become a major challenge to our educational systems that have not changed their educational policies and pedagogical models to support life-long learning. There is an increasing demand for new approaches towards fostering lifelong learning perspectives [3]. The MA solution is just one more answer to the increasing demand for new approaches.

Our solution for small or medium enterprises (SMEs) is built upon ideas of Cloud computing and Software as a Service, and relies on the cloud scalability to ensure enough resources and enables single instance of the software servicing multiple customers, or multi-tenancy (virtually partition customers data and configuration).

The rest of the paper is organized as follows. Background and essential definitions are given in Section II. Details of the software design and implementation are presented in Section III. Section IV presents related work about existing solutions and designs and Section V discusses about features of the new architecture and implementation. Section VI is devoted to conclusions and future work.

II. BACKGROUND

This section gives a brief description of Micro teaching, learning and assessment concepts.

A. *Micro teaching*

Micro teaching firstly appeared in the 60-ies at the Stanford University, based on critical views of traditional lecturing in teacher education [5]. This teacher training technique employs real teaching situations for developing skills and helps teachers get deeper knowledge regarding the art of teaching [4]. Methods of micro teaching, which have been developed and improved in many ways throughout the last decades, are the baseline for micro learning on the level of acquirement of skills and usage of

teaching methods and also on the level of reflecting on the learning processes [5].

B. Micro learning

The basic premise of the first international conference for "Microlearning" [6] is that people can learn better, easier, more effectively in a more enjoyable manner if information is broken down into smaller units and if learning takes the shape of small steps [6]. Bruck [6] presents three aspects that characterize this shift to micro learning:

- Reduce the overflow and complexity of information and structures it into small and well linked sequences;
- Undertake this reduction from the perspective of the person who needs to cope with big amounts of new information; and
- Allow individual learners to choose themselves time, place and pace of learning.

C. Micro assessment

The next step in the learning process is the assessment. Ristov et al. [7] present four generations of e-Assessment and e-Learning systems. These systems start with monolithic assessment applications (first generation) upgraded to modular architecture solutions (second generation) evolving to a system based on SOA architecture (third generation). Consequently, the fourth generation is represented by the eco-systems based on the cloud computing.

Micro teaching and learning impose an appropriate method of assessment, including micro assessment of skills, knowledge and abilities of individuals. Therefore, the micro assessment method is covered through assessing smaller units of gained knowledge.

III. Description of the SaaS solution

In this section we describe the software design and implementation details of the MA SaaS solution for micro assessment.

A. Functional description

The main functionality of the software product is to inform and assess the employees in the companies of innovations and services the same company offers, as well as to measure their activity. In the same time the solution is to be developed as a cloud solution applying multi-tenancy and scalability architecture. In order to install this solution, the company-user needs to register in a system and download the installation package. Package installation is activated on each computer separately in order to enable the service to start running in the background.

1) Primary features:

- Background activity - Activates user interface (UI) when the user is inactive (Measurement of user inactivity starts when all of the following criteria are in place, in preset time frames: keyboard, mouse and chosen process(s) or application(s) inactivity. UI can be displayed as Question UI, displaying question with several answers, and/or Information UI, displaying information for the company.),
- Testing and Survey - There is an option to do internal testing or surveys of the entire company or in groups (by department, by location, by work position etc., with same or different tests.),
- Reporting - Measuring the activity of the user (reports) and results of testing (This feature is very attractive for managers and/or superiors because it allows them to assess the performance of their employees and their workload. For example, managers can measure employees' activity in terms of working or taking tests and learning, or even determine whether the employees are performing better in the morning or in the afternoon. In addition, different departments' performance can be measured and compared with this tool. Finally, the system will allow to review and download reports for all activities of the user, including performance, efficiency, duration, etc.)

2) Secondary features:

- Access - to learning materials through a Web browser,
- Presentation - delivery of learning materials in a specific format,
- Announcing - system is automatically activated when the user is announced on the domain of the company,
- Customization - allows semantic solution - adapt the system to learn the current knowledge of the employee,
- Manipulating with materials - adding new teaching materials, areas for study and testing, system allows changing the curricula, tracking versions of the curriculum and changes,
- Delay, prolongation of the specified time - if a user does not want to answer the question at this moment, the question should be able to delay for a specified time - can be delayed for a period of time pre-entered by the user,
- Multi Language support,
- Automatic recognition of user – by logging on the company domain, each user is automatically detected. User recognition does not depend on the device but on the user's domain credentials,
- Tenant Customization – the ability to customize some parts of the application, such as color of the UI or business rules.

B. Architecture design

Two main components of this product are presented in Fig. 1 as server (cloud) side and client side components.

The cloud side components include:

- **Micro Assessment Service (MAS) –** This is the brain of the solution. The main goal of this service is to distribute data relevant to users and to process their response, and evaluate whether the answer is true or false. This service processes all the messages and communicates with the Client side;

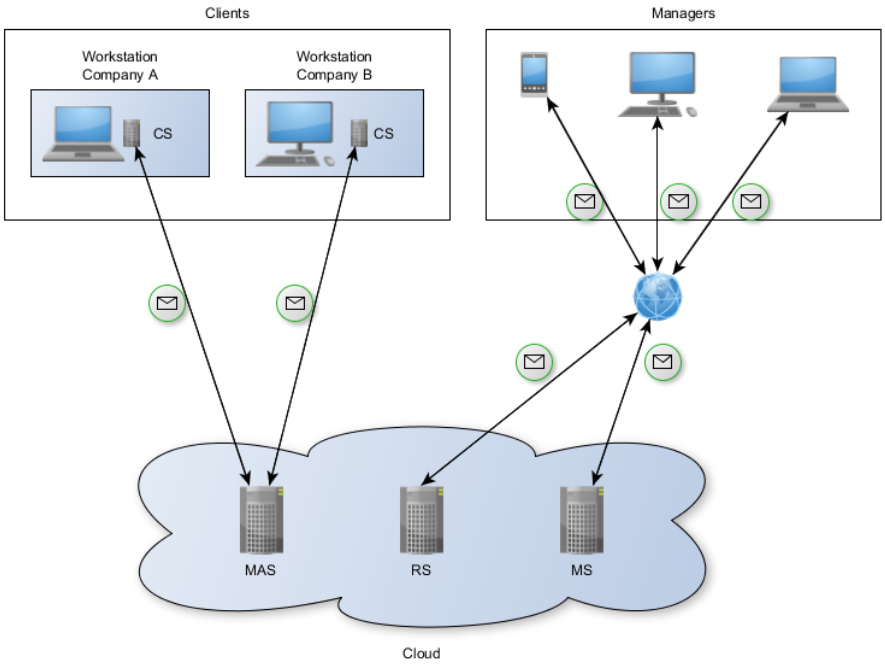

Figure 1. Architecture of the MA system realized as a cloud solution

- **Management Service (MS)** – A service used for users, courses, questions, exams and user authentication and authorization management. Most of the activities that are displayed on the clients display can be controlled by this service. The teaching material or the posted questions can be initiated and changed through this service,
- **Report Service (RS) –** The main function of this service is the preparation of reports from the answers and user activity. Access to these data is allowed only to authorized persons because of the sensitive data,
- **Database (DB) –** one database for all customers.

Client side component contains:

- **Client Service (CS)** – A service installed on every client computer, thin client installation. The main goal of this service is to monitor the activity of the user and display the data obtained from the MAS. When the user initiates transaction, this service sends a data request to MAS. After receiving the response from the MAS, data is displayed to the user. The answered question is sent back to the MAS.

There are two main user roles in MA system: managers and clients. The users in manager role manage the MA system functions: creation and administration of questions and answers in the system, testing, analysis of results, managing users and courses from his company, etc. The clients belong to a role that can take the exams and view their results.

C. Technical solution

There are several alternatives on how this technical solution can be developed to enable scalability and a multitenant pattern. The chosen technical solution is based on actions between the four major services mentioned above: CS, MAS, MS and RS.

The most utilized service of all will be the MAS service because it needs to be constantly active and available. This is due to the fact that all other client services are dependent on it, and the rest of the processes depend on the availability of this service. This service is actually the one that posts all the information and / or questions that are posted on behalf of the MS, and at the same time collects all the answers and reactions made on behalf of the client, that at a later stage are transferred to the MS and RS for further analysis, presented in Fig. 2.

On the other hand, MS and RS are secondary services that are needed periodically due to the fact that they only manage certain processes and activities. In addition, their actions are taken on request by the client (in this case management and HR team for example) and therefore the overload of these two services is not as big and as frequent as it is on the MAS service.

MS and RS are actually the enablers of the whole process to be started and finished, however the largest load of data absorption, distribution, display and collection is done by the MAS service. Consequently the MAS service will be the most overloaded and therefore needs to be scalable. In order to ensure this scalability of the system, we will install not one, but two (or more if needed) MAS services that will be enabled through the Network Load Balancing (NLB) technology. It is a clustering technology that is intended to provide high availability, reliability and scalability of mission-critical, TCP/IP-based services. These services would present a

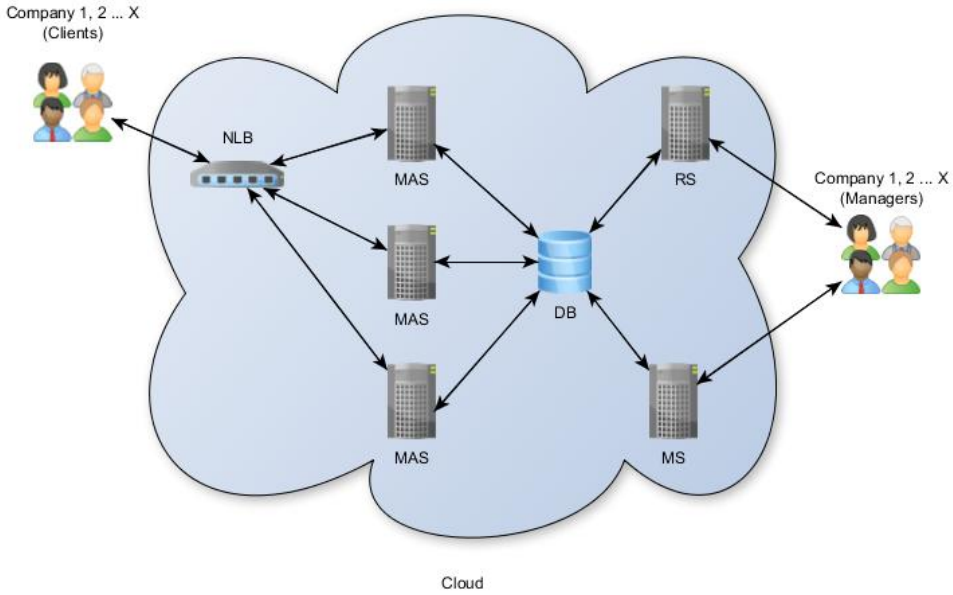

Figure 2. Micro Assessment system organization

"virtual service" address to the outside world, and when users attempt to connect, they would forward the connection to the most appropriate real service [13]. This assumes that the scalability will be guaranteed especially since the target clients of this Micro Assessment solution are SMEs, where the activity of all employees at given point of the day might be huge. As mentioned previously, our main goal is the MAS service to be always active and to be able to respond at any user inactivity.

In this paper we do not refer to security service and other related services. We concentrate on the definition of the core services required to realize the MA system.

Besides the scalability, our goal is to enable the MA solution on a multitenant architecture. In addition, given the fact that this is a cloud-based solution, we will have one joint database, one joint MS, RS and clustered MAS based on NLB technology. The proposed architecture setup will satisfy the multitenant pattern but will also cut on additional costs on different kinds of resources.

IV. Existing Systems

A. Analysis of existing solutions

According to our research of the "knowledge platform" market today, there are several systems for electronic learning, electronic testing and verification of knowledge; however those that meet the functionalities of Micro knowledge and skills assessment are SAP ® BusinessObjects ™ Knowledge Accelerator [9] and KnowledgePulse ® [11].

1) *SAP® BusinessObjects™ Knowledge Accelerator*

BusinessObjects Knowledge Accelerator is developed by SAP, a multinational consulting corporation. It is a strictly WEB-based learning, training and supporting tool, designed to help individuals' learn and apply business intelligence to their day-to-day activities [9], [10].

BusinessObjects Knowledge Accelerator provides end-users with relevant tutorials and reference materials to for self-service training and support of Business Objects products – when they want, at their desks, and at a pace that best suits them.

BusinessObjects Knowledge Accelerator helps individuals familiarize themselves with business intelligent processes, at their own pace and schedule, without having to leave the office. This helps organizations obtain maximum value from their Business Objects implementation as quickly and cost effectively as possible.

Drawbacks of the BusinessObjects solution are:

- Strictly WEB-based tool;
- Part of complex and expensive software;
- No interaction with the user after user inactivity; and
- No tests and survey.

2) *RSA KnowledgePulse®*

KnowledgePulse® is an advanced learning technology system developed by the Research Studios Austria. It consists of a client-server solution with a MicroStep Manager®, a content database, a user/course administration interface and a set of clients for PCs, notebook computers, handhelds and other devices [11], [12].

Knowledge Pulse as a software tool provides an opportunity to overcome a different material, such as foreign language, training for project management, training for product development or certificate required for promotion. The idea is that the absorption of knowledge to occur through small steps, which would avoid boring procedure of permanent and extensive learning, which is usually the result of eLearning systems.

For this solution one does not need a server infrastructure in their organization. KnowledgePulse® has a server infrastructure for an economical price. The server communicates with your PC or mobile phone via the

TABLE I. ANALYSIS OF MICRO ASSESSMENT SOLUTIONS.

Features	MA solution	Knowledge Accelerator	Knowledge Pulse®
tests and survey	✓	X	X
inexpensive	✓	X	X
no additional hardware expenses	✓	✓	X
interaction with the user after user inactivity	✓	X	✓
product of itself	✓	X	✓
displaying information	✓	X	X
displaying question	✓	X	✓
delay for the specified time	✓	X	X
measuring user activity	✓	X	X
measuring the results of testing	✓	✓	✓
access to materials via Internet	✓	✓	✓
easy to deploy	✓	✓	X
delivery of materials in a specific format	✓	✓	✓

Internet. When a computer or mobile phone is idle for a certain period, it sends small 'micro-lessons' in the form of flashcards with questions.

Drawbacks of the RSA KnowledgePulse solution are:

- No tests and survey;
- Expensive, server infrastructure need to buy from KnowledgePulse®;
- The server communicates with your PC or mobile phone via Internet;
- No delay after flashcards appear;
- On flashcards only displays questions, no displaying information for the company; and
- Algorithms and the method of calculating the data are performed on the client side. Thus, updates can be complicated, because it is necessary to deploy changes/updates to all client computers.

B. *Products comparison*

Table 1 presents the competitive features between proposed solution MA and the other two existing on the market, already analyzed and compared in [8]. MA solution satisfies all features, while the others not.

V. DISCUSSION

This section discusses advantages and benefits of the new MA solution and presents other solutions that have similar architecture as the new MA solution.

A. *Advantages of the new solution*

The implementation of a new Business Intelligence solution typically impacts a diverse range of user groups. This can make training and support overwhelming and costly. With this solution, one can affordably train and support a few hundred users at their own computers. In addition, it is extremely important provision of separate training available 24 hours a day. It is fully scalable and features extensive flexibility.

This solution speeds up user productivity, performance and knowledge, helping users add more value. This means faster decisions, better response to issues impacting critical business drivers and more consistent and accurate interpretation of data presented via reports and dashboards.

This solution will train users via job-specific skill development scenarios based on sample company data. In addition, it is customizable, hence it meets the requirements and relevancy of each user group, including varied training needs and tasks to be performed. Also it enables quick deployment of educational materials via the Internet. This means that training is delivered directly to the users' devices, giving them the flexibility they need to learn when and where it best suits them.

B. *Benefit*

There are three major benefits for the customers. This system allows measuring the activity and inactivity of employees and the managers can constantly have reports how active or inactive their employees are. Having a tool for educating your employees has never before been as practical, as this one. No more internal trainings will be needed, no more long staff meetings will be held, since all of the necessary information will be distributed by the tool. In addition to this, continuous education of employees will be enabled. Finally, testing the employees about the acquired knowledge will be on the tip of employers' fingers. Pop quizzes and ad hoc test can be introduced at any time. Also the users will be trained via job-specific skill development scenarios based on sample company data.

The companies and institutions that will have this solution in place will have state of the art mechanism, that none of their competitors have. They will be the new trend setters in measuring employees' performance. The value

added of this product is its multispectral purpose. It is not a necessary product, but it is a product that will give additional value and benefits both to the employer and the employee.

C. Solutions with similar funcionalities

Since e-Assessment cloud solution [7][7] has certain similar functionalities as the Micro Assessment solution, similar software architecture has been considered. In both cases major accent is put on the assessment activity and multi-client base that needs to follow the activities at same time. Therefore both scalability and a multi-tenant architecture are used in both solutions. Cloud is taken as a supporting platform since both solutions have a multi-client base.

VI. Conclusion and Future Work

Measuring employees' performance has always been one of the managers' biggest challenge. No more internal trainings will be needed, no more long staff meetings will be held. The new designed MA system is a product that can be beneficial from multispectral point of company's point of view. It educates employees, it measure performance and helps HR managers in their performance reviews and it tests employees how much they have learnt, i.e. how interested they are in company's prosperity, how motivated they are by their managers, how ambitious they are about getting promoted. Testing the employees about the acquired knowledge with pop-up quizzes and ad hoc test can be introduced at any time.

By enabling as many features as possible, one broadens the target groups in which the given solution might be applicable. Beneficiaries of this solution might be:

- SMEs (lawyer offices; bookkeeping offices; consultancy companies, i.e. computer based run businesses);
- Financial institutions (banks, insurance companies, pension funds); and
- Public administration (Government, Ministries, Governmental Institutions, Agencies of local self governance).

In this paper we presented a new model and architecture of a system for MA of skills and knowledge. The built MA system should be implemented as a software service that can run on cloud. The instructor can easily configure teaching materials and questions for knowledge assessment and skills to be able to join the existing systems for e-learning, etc.

The system is organized with two parts: the cloud side containing MAS, MS and RS services; and the client side with the CS service.

Finally, it is really a tool that might change the working and the educating culture and can bring a more realistic way of measuring employee performance.

In future we plan to design a pilot project to analyze scalability and multi-tenancy of the Micro Assessment cloud solution.

Summary - Information and communications (IC) technology influences all human activities but also plays an important role in development of various scientific disciplines and other types of technologies thus enabling their large scale implementation. This paper presents the relations among IC technology, experimental methods and multivariate analysis. As the development of experimental techniques and multivariate analysis paved way to revolutionary discoveries referring to IC technology, this, as a feed back, enabled further development and implementation of the mentioned methods in the most diversified fields of human activities. The necessity of the integral approach, based on implementation of multivariate analysis and adequate experimental methods and respective IC technologies is illustrated in the example of solving the problem of preservation, protection and evaluation of cultural heritage objects. In the process, various experimental analytic techniques based on principles of physics and/or chemistry are used along with IC technologies. In order to obtain the best possible analysis and interpretation of series consisting of enormous number of data, aiming to filter only the most important information relevant for particular object, statistical approach is necessary where a prominent position belongs to multivariate analysis - a task that can only be accomplished by using adequate statistics software.

I. INTRODUCTION

Aspiration for speeding up and facilitating the solving of problems experienced in using various experimental methods and analysis of obtained results, as well as in setting the theoretical model independent of measurements, resulted in creation of various devices, which are predecessors of modern computers.

During several past decades, development of IC technology influenced all aspects of everyday life. Networked computers, e-mail, databases, Internet, World Wide Web (www), on-line electronic conferences, on-line search engines, new media, social networks and similar have become integral parts of everyday life and entire society has been facing the accelerated development and implementation of such technologies in daily life activities. New IC technologies, particularly crucial IC services like Internet, have considerably influenced the change and development of society, known as the information society. As of beginning of the 21st century, the image of society has been rapidly changing so that impact of new technologies and media influences the remodeling of total social conscience, including views on economy, science, education and politics. Development in technical, social and art fields has been based on new forms of computers and IC technology.

The magnitude of using Internet is best illustrated by statistical data, shown in Figure 1 and the fact that 2.7 billion persons or 39% of world population uses it [1]. Respective graph shows that from 1996 onward, the number of users has been growing exponentially. Yet, the development of IC technology increased the existing gap between developed and developing countries. Considerable increase in using IC tools in Croatia was noted after year 2000. In 2011, 70% of population was using computers [2], so it is fair to assume that today the number equals to 80% (Figure 2).

The goal of this paper is to explore how scientific notions are connected to experimental techniques and how multivariate analysis influenced the development of the most important IC technology tools (computers, Internet, lasers ...) and how IC technologies irreversibly enabled further upgrade and implementation of these methods in various exploration fields. On the basis of the performed researches, the paper shows the importance and possibilities for implementation of these technologies and methods in solving various problems connected to

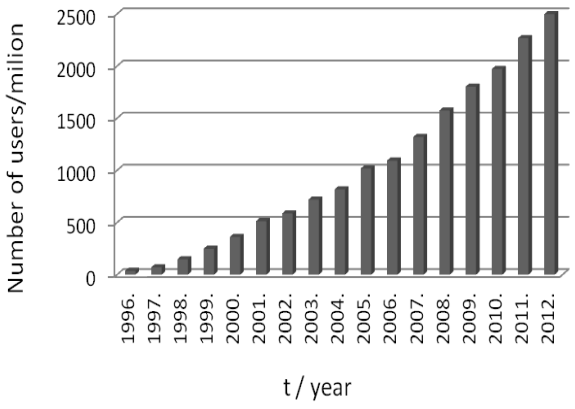

Figure 1. Increase of Internet users in the world from 1996 to 2012, according to World Stats.

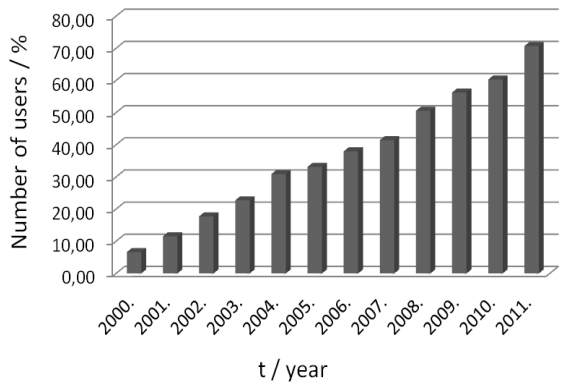

Figure 2. Presentation of increase in number of Internet users in Croatia from 2000 to 2011, according to Telecommunication Union

preservation and protection of cultural heritage objects.

After the introduction, interconnection of IC technology, experimental methods and multivariate analysis is presented as well as their role in cultural heritage. A separate chapter includes silver coin analysis, results of respective research and discussion of the results. This research aims to confirm the necessity of integral approach based on using multivariate analysis and adequate experimental methods and IC technology in acquiring relevant notions on cultural heritage object being explored.

II. CULTURAL HERITAGE AND TECHNOLOGY

Cultural heritage represents entire intellectual and material opus of individuals or groups in a given society. It is necessary to preserve the heritage, as it is of utmost importance for culture, history and identity of both individuals and entire people. Generally, cultural heritage includes material, movable and realty, and intangible heritage. Material heritage includes objects, while intangible heritage includes the totality of science, arts, philosophy, customs and similar.

Preservation and protection of cultural heritage, assumes identification, documentation, research, maintenance, protection, usage and promotion of its values and they play an important role in the process of knowing the cultural identity of given society and it is the proof of its existence and activity. In solving problems of preservation, protection and assessment of cultural heritage objects, it is necessary to emphasize the importance of interdisciplinary approach as, in the process, along with IC technologies, various experimental analytic techniques based on physical and/or chemical principles as used. In analyzing an enormous number of data obtained in experiments, of which some are to be eliminated while the others should be grouped and correlated, mathematical apparatus is indispensable, most often used in form of statistics and probability.

Implementation of digitalization techniques in the cultural heritage field enabled preservation and protection of original objects, which was done by making or printing publicly available protected 2D or 3D copies. Availability of digitalized materials through Internet infrastructure, i.e. through various network databases (virtual and digital libraries, archives and museums). Potential of 3D digitalization is used for a more authentic presentation of objects, for so called "virtual unification" (connection of various parts of an object located at distant locations), planning and carrying out restoration and conservation interventions by printing true replicas. 2D and 3D virtual reconstructions, made by means of IC technology, are most often used for popularization of cultural heritage, where digital reconstructions available on Internet and geolocation services enabled art and heritage to be even more available to users [3, 4].

The “experimental” method assumes process of observation of a phenomenon being examined under precisely defined conditions. These are most often laboratory conditions, enabling observation of phenomenon course and setting the very same conditions where, if necessary, the phenomenon may be reproduced [5]. Experimental methods, used for finding out quality and/or quantity element composition of material, belong to the group of spectroscopic methods. Application of such methods in exploring cultural objects enables to answer questions as to conditions of an object, degree of pollution, authenticity, chronology, origin or its material value. Before a cultural object becomes widely publicly available, it is necessary to analyze the object in detail in order to make decision on adequate preservation process. In exploring such objects, there are strict limitations in terms of selecting experimental methods adequate for implementation. Nondestructive, or minimally destructive, methods are selected. The reason is usually in object's value as it may be highly rare, has cultural and historical importance and variety of other circumstances, for example ownership or possession, which may require the nondestructive analysis. Besides, sampling and change of structural and aesthetic appearance of the object are to be avoided. If sampling is nevertheless necessary, a method requiring microscopic quantities of material required for analysis is selected. Complete information and answers in respect to some object are not possible to obtain using one single experimental method, rather, a combination of certain methods providing complementary results is necessary.

Non destructive or minimally destructive methods are particularly adequate for applying in cultural heritage field, for example X-ray fluorescence (XRF), Raman and micro-Raman spectroscopy, Laser-Induced Breakdown Spectroscopy (LIBS), thermography or multispectral imaging technology. Application of mentioned techniques produces emission spectra containing many complex data on the object. To obtain quality analysis and interpretation of strings containing large number of data and extract only the most important information relevant for given object, statistical approach is necessary, where multivariate analysis method holds a prominent positions. When analyzing such data types, most often used methods are principal component

analysis (PCA), cluster analysis and partial least squares (PLS) method. The main goal in implementing these methods is to reduce complexity of analyzed data set, particularly noted in high dimensionality and complexity of certain relations. These relations may be among some variables, but among measurements obtained for some samples and among some variables and some measurements. Therefore the PCA method or Cluster analysis is adequate for comparing several objects by some relationship, for example location where object was found and for obtaining information on their similarity or difference [6]. The partial least squares method is applied aiming to forecast some parameters on one or more analyzed objects. Most often, this refers to assessing quantitative element composition of sample on the basis of emission spectra obtained by adequate spectroscopic method.

Analysis of the ancient objects and identification of pigments in ancient fresco and modern paintings, as well as various stone and marble monuments, sculptures and ornaments and other glass or metal objects are good examples of applying nondestructive experimental methods in the world of tangible cultural heritage [7-12].

A. Experimental methods and IC technology

Set of experimental methods enabling to determine chemical composition and structure of a substance is called spectrometry. The beginnings of spectrometry are connected to scientific discoveries in early 17th century. The first scientific explanation of spectrum was the explanation of the rainbow by Marko Antonije de Dominis [13], the archbishop from Split. Complex nature of white light was discovered by Isaac Newton in 1666. Important discovery occurred in 1859, when Kirchhoff showed that all pure substances emit the unique spectrum [14, 15]. By the end of the 19th and in early 20th century various scientists were trying to explain the origin of spectrum phenomena. The problem of the universal explanation of spectrum for most elements was solved in 1925 by implementation of Heisenberg's uncertainty relation and Schröding wave equation [16, 17]. By the end of the 19th century, the existence of infrared, visible light and ultraviolet components of sunlight spectrum was known. Soon afterwards, radio waves, located far at the infrared side of electromagnetic spectrum, were discovered as well as X-rays and gamma rays, located far at the ultraviolet side of spectrum.

However, research of spectral phenomena of light, by the end of the 19th and in early 20th century, when optic spectrometry was at full blast, witnessed to the revolutionary invention of laser. This was preceded by series of researches in quantum mechanics, where most significant discoveries are connected to Max Planck and Albert Einstein.

Although as early as in 1870 Alexander Graham came to idea that visible light may be used as a communication medium, it was not possible to create a wave that would transport light from one point to another so his idea could not be realized until laser [1] was discovered in 1960. Multiple potentials of the laser were recognized so that production started in various laboratories all over the world.

In parallel with laser development, optic fibers were developed, featuring small losses and enabling light to be used as communication medium. Nowadays optic fibers build the backbone of modern telecommunication system. All forms of the modern communications, radio and TV signals, telephony, computer data and similar are based on signal carrier, i.e. wave with electromagnetic oscillation at certain frequency. Today, there is an enormous number of various lasers, which have been further developed, but new types have been discovered as well. Their implementation is enormous and they are applied, directly or indirectly, in almost all fields of human activity. Modern medicine could hardly function without using various types of lasers, particularly in surgery. In computer technology, lasers are used for storing and reading data on various media (CD, DVD), laser printers etc., while in military industry they are used for producing various weapons, although the original idea was to use lasers for development of spectroscopic methods. For past several years, implementation of lasers plays an important role in cultural heritage. Laser enable restoration and cleaning of various cultural (stone or metal) objects, including delicates works of art such as paintings or scripts [18].

Spectroscopy and its potentials of implementation have changed considerably, first by development of electronic computers that enabled complex calculations for large molecule spectra and offered increased precision for small molecules and then by using lasers.

Just like notions in physics led to the revolutionary discoveries in development of technology (lasers, computers, Internet,...), later they enabled further development of both theoretical and experimental notions. Over past several decades, spectroscopic methods have been applied in various fields of research, such as medicine, biology, ecology to researches in various cultural objects.

For quite a long time, computers are tools for acquiring new knowledges on nature and society. Notions on elementary processes and substance structure in the micro world are important for development of various science fields and therefore for development of new technologies in the macro world, so close to us all. Research in the micro world can happen in several ways. Experiment plays the important role there, where experiment generally consists of a device serving to make the microscopic particles suitable for research, then there is a device (most often laser) that shifts the particles to the selected energy conditions and finally, system that detects the particles or light photons. The function of computer is to control the experiment in terms of

[1] American scientist T.H. Maiman invented the first laser that emitted 694 nm wave length light; he induced laser emission by stimulated emission from ruby crystal excited by a flash lamp.

coordinating previously mentioned experimental entities. Data are collected, analyzed, saved and prepared for processing and presentation by means of computers. Yet, experiments are often too expensive as they may require high technology devices, so that there is a method of work where it is necessary to carefully design and precisely plan in advance. After that, basic processes should be recognized in the planned experiment, for which processes theoretical expressions in form of formulas mainly already exist and computer enables to create the computer simulated experiment, where basic measure values can be more easily changed as necessary than it could be possible in real experiment. Along with establishing relations between theoretical and experimental approach, IC plays an important role in data exchange process and possibilities for entire communication among scientists. Internet is used for basic communications, connecting and searching data bases, presentation and promotion of results in various science fields and similar. Web pages offer most diversified data, both old and the most recent scientific achievements, scientific magazines may be read, numerous books or instruments can be known or bought. The essence of Internet and web pages is in setting hyperlinks. Knowing a single one web address may provide the entrance and search of entire network.

B. Multivariate analysis and IC technology

Multivariate problems were addressed by numerous mathematicians such as Gauss, who, by the end of the 18th century set the basic methods of partial least squares or Galton, who, in the second half of 19th century, studied correlation matrix, defined correlation coefficient and linear regression [19]. His student, Karl Pearson, in 1901, trying to solve the data set dimensionality problem produced the interpretation of main components [20], while C. Spearman, explaining the human intelligence, formulated the basics of factorial analysis [21]. Till mid twentieth century, the largest part of the multivariate analysis was established.

The development of multivariate analysis was undoubtedly connected to the development of computer technologies and the first statistical programs. As early as in 1920', university and research laboratories in America used mechanically punched cards that served, among other things, to formulate complex statistical models such as variance analysis and linear regression [22, 23]. In mid 1960', the first statistical programs were developed, such as SAS (1966.), SPSS (1968.), Matlab (1970.), Minitab (1972.), etc. However, the revolution in implementation of the multivariate analysis started in 80' of the past century with development of personal computers, commercial multivariate program packages and particularly Internet that enabled availability of such programs to the "common" people. Till then, such programs, but computers as well due to their high prices, were used only in large scientific and research centers that could afford them. Today, it is rather difficult to count all programs used for various statistic processing, including the multivariate analysis. Prices for such programs are nowadays affordable to almost everybody. Many of these are offered at considerably lower prices for academic community and students. Great number of these is free, but such programs contain mainly only basic multivariate methods.

In order to understand completely the importance of Internet and IC technology in implementing multivariate methods for analysis the most different problems in various research fields, we analyzed scientific papers published on the Web of Science (WoS) database from 1955 to 2013. We searched the papers containing words *Multivariate Analysis*, *Principal Component Analysis* and/or *Partial Least Squares* in title, key word list or summary. Results are presented in Figure 3.

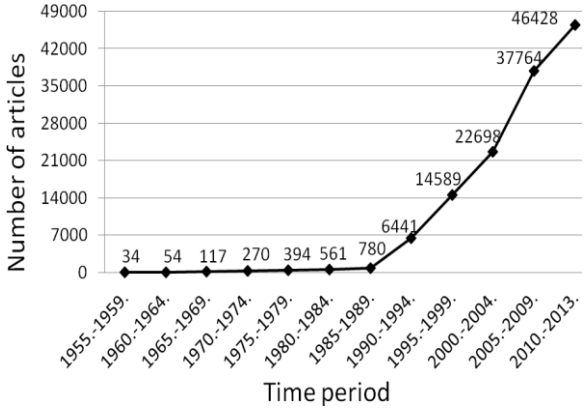

Figure 3. Number of works containing words *Multivariate Analysis*, *Principal Component Analysis* and/or *Partial Least Squares* in title, summary or key word list, published on the Web of Science (WoS) database from 1955 to 2013.

Based on these results, it can be seen that in early 1990' number of published papers grew considerably. The trend may be connected with the development of IC technology and particularly with availability of Internet. It can also be seen that multivariate analysis has been implemented on a large scale. In the same period, great number of papers were published in spectroscopy field as well, more precisely 2162 papers.

In order to comprehend as to how much multivariate analysis was used in combination with spectroscopic methods, we searched the database for papers containing words *Multivariate Analysis*, *Principal Component Analysis*, *Partial Least Squares* and/or *Spectroscopy* in title, summary of key words list. According to data shown in figure 4, a considerable increase in implementation of multivariate analysis in combination with spectroscopic methods started after year 2000, which matches the development of IC technologies.

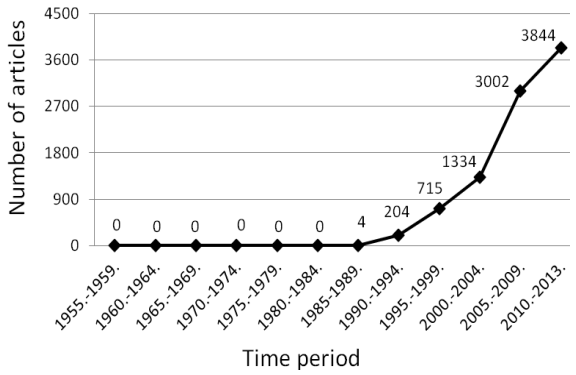

Figure 4. Number of works containing words *Multivariate Analysis, Principal Component Analysis, Partial Least Squares* and/or *Spectroscopy* in title, summary or key word list, published in the Web of Science (WoS) database from 1955 to 2013.

III. RESULTS OF THE SILVER COIN ANALYSIS

Nowadays, many nondestructive experimental techniques are used to determine the contents of elements in metal coins, but we used the Laser-Induced Breakdown Spectroscopy. The measurement was performed at *Laboratory for laser spectroscopy of cold plasma* at Institute for Physics in Zagreb. The goal of the experiment using the LIBS method was to make a shot of plasma spectrum generated by laser ablation of coin and determine chemical composition of the sample. Analyzed sample was a 10 crown coin, made in 1869 in Austro-Hungarian Empire. The silver concentration was 50%.

Used experimental setting consisted of Nd:YAG laser, optical system, sample (target), optic fiber, spectrometer system and computer. During measurement, gas argon was insufflated to target for spectral lines would be more emphasized and suitable for further analysis upon completion of laser ablation processing. When testing with laser ablation method, the sample is fixed on a stand, with it surface sloped at 45° to the laser beam direction. Measurement in one point lasted for 75 seconds, i.e. sample surface was shot by laser beams, each lasting one second, which resulted by 75 emission spectra. The first of them presents surface layer image, while the last one presents the bottom of the ablation made crater. The damage of sample resulting from ablation is micro sized and as such it is considered negligible.

Since the LIBS technique produces a large quantity of data, which are highly correlated, we used the principal component analysis technique for interpretation and reducing the dimensionality. The analysis was performed by means of the Unscrambler software exclusively intended for processing complex data sets by multivariate analysis.

Experiment data were processed using Principal Components Analysis (PCA) in order to select a few composition characteristic spectra out of 75 obtained by ablation at one point. Starting matrix **X**, of order 75 × 13508, of original data includes 75 rows, whose values represent spectra image after each consecutive second and 13508 columns with values that correspond to variables or wave lengths. After having run the PCA on the matrix, spectra were grouped in six groups. Objects (spectra) within one group are highly correlated in respect to observed variables (wave length). Therefore, it is sufficient to observe only one spectrum within each group for identifying elements. Figure 5 shows the results of the PCA, which explains 94% of variance with two main components. One spectrum was arbitrarily selected from each isolated group (16.3, 24.3, 33.3, 42.3, 66.3 and

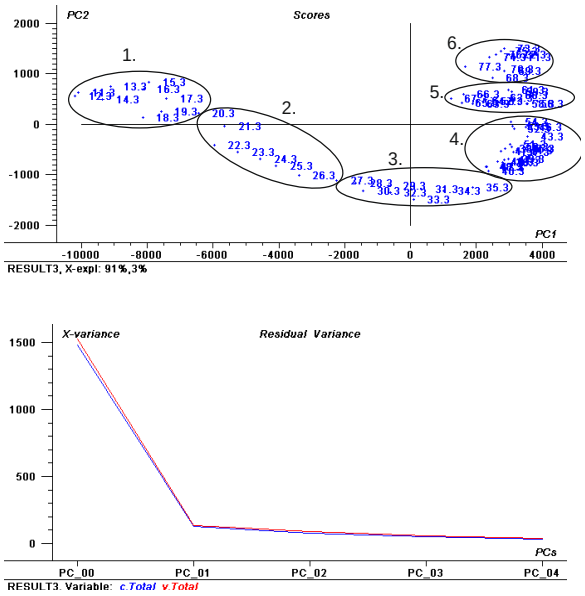

Figure 5. PCA of experiment data obtained by the LIBS method. The analysis was performed considering the first two main components, PC1 and PC2, where the first main component explains 91%, and the second 3% of variance in data.

73.3). Therefore, the element identification in sample was performed only from so selected emission spectra. Spectral lines read over entire range of wave lengths were compared to data in the NIST[2] database. Figure 6 shows the most intensive lines of identified elements from emission spectra, selected as described above, within wave length interval from 200 nm to 980 nm. Along with silver, in sample we identified presence of phosphorus, magnesium, copper, lead, calcium, sodium and chlorine from so selected emission spectra. Hydrogen and oxygen are from air since sample was not enclosed in vacuum chamber during measurement, while argon was purposefully insufflated to sample surface and therefore these three elements do not constitute its integral part.

We used the Origin software for processing the emission spectra and identification of spectral lines.

Since the LIBS method provides measurement by sample depth, we observed changes in intensity of detected lines. Namely, on the basis of changes in intensity of spectral lines of identified elements over time or by increase in depth from surface towards interior of sample, it is possible to make conclusion on presence of

[2] NIST = USA National Institute of Standards and Technology.

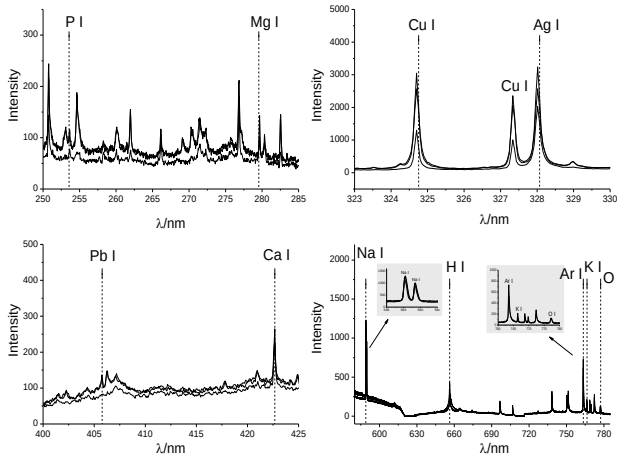

Figure 6. Identification of lines (elements) form LIBS spectrum of measured sample of wavelengths from 200 nm to 980 nm. Emitted radiation wave length is marked with λ, while Roman numerals following the elements represent their valency.

element in certain parts of the sample. Results of the observation are presented in figure 7.

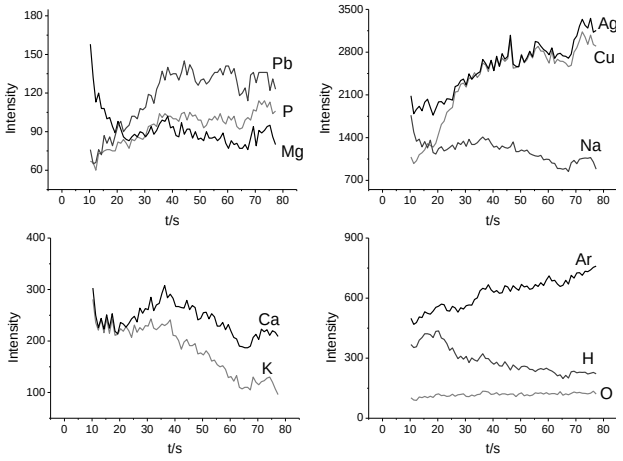

Figure 7. Intensity of most intensive lines for elements contained in sample as function of increase of depth, i.e., time. The Abscissa is time axis x, characterizing 75 different depths of craters generated by sample ablation at one spot. The ordinate represents change of line intensity from surface layers to the middle of sample.

IV. CONCLUSION

The researches performed point to the importance of the interdisciplinary scientific approach, based on the implementation of multivariate analysis and adequate experimental methods and respective IC technologies in solving problems in various activities. In this particular case, such an approach is indispensable for the process of preserving, estimate and protection of objects in the cultural heritage world. On the basis of the presented, we conclude that the development of experimental techniques and multivariate analysis resulted in important discoveries referring to IC technology, which in turn, irrevocably enabled further development and implementation of these methods. Accordingly, we expect that further development of IC technology will contribute to improvements of these methods, as well as to expand possibilities for their implementation in researching various problems in different research fields, including the cultural heritage.

The Views of Students and Teachers an Implementation af E-learning in Educational Process

Dragana Glušac*, Dragica Radosav*, Dijana Karuović*, Žolt Juhas*
* University of Novi Sad, Technical faculty "Mihajlo Pupin" Zrenjanin
glusacdragana.zr@gmail.com

Abstract –This paper presents a survey of students' opinions about the integration of e-learning in educational process. The results of how students are informed on distance learning and e-learning are presented. By analyzing the results, data can be obtained which clearly show what steps should be taken in order to implement a new methodology of education, e-learning methodology.

I. INTRODUCTION

E- learning is relatively a new product when we talk about new methods of learning. It represents a new type of education in our region which is not researched and implemented enough. Although there is a great number of people who want to improve their knowledge, this new type of education represents a potential risk of the unknown and therefore E- learning is being approached pretty carefully. This technology is now in developing phase and it will experience its maximum potential in the years to come. Nowadays, education in our country is performed in old, traditional way which is old fashioned and inappropriate for the 21st century and, as a result, Serbia is losing step with the world trends. The quality of education characteristic for our region in the past was recognized and respected but education should be developed and modernized today in accordance to the standards imposed by global trends.

Although there has been a lot of literature on e-learning so far they mostly include descriptions and technical information. We can rarely find empirical results given by pupils which explain effectiveness of this type of learning. It is interesting to obtain these data from primary school pupils because modernization of education has recently started in these regions and it is significant to pay atteention on pupils' informing from the beginning of their education. The facts about pupils' knowledge related to new technologies implemented in this type of education are of special significance, especially how much the pupils know about them and how helpful they are. It is important to emphasize that the very existence of new technologies in education is not sufficient but that the need for them exists. Only the symbiosis of these two factors can bring positive results in the long run. The survey of attitudes was carried out in Primary school "Jovan Mikić" in Subotica. Seven-form-pupils were interviewed by filling the questionnaire. By analysis of the results the assumptions are justified and these results will be presented in detail in this paper.

II. ACADEMIC FRAMEWORK OF E LEARNING

On-line education is a part of based on learning via Internet. It is wrong to understand E-learning only as digitalization of a classical text displayed on computer screen. Reading texts on the screen is not only bad for the eyes but it is monotonous too. Therefore, a crucial factor when creating on-line educational material is its extension and enrichment by multimedia content as well as implementation of tools for interaction enabled by Internet. For this reason it is necessary to adept the existing documents to cyber surroundings.

The first task within creation of such type of material for education is to identify the group which will use the material. This target group must be clear in relation to age, educational level, etc. Then, it is necessary to determine the aims of the survey. The next step is carrying out the survey which will conclude whether the aims correspond to those of the user's. In the case of e-learning there is an important rule that enables a user to identify him/herself with educational program. If it happens that a user is not interested in prepared material, he/she can leave the lecture by a simple click on the screen which cannot be done in classical education.

After realization of the first step it is possible to create educational material. Educational material should be divided into independent units – chapters according to the set aims. Within this task the application (ex. Trainersoft`s authoring tool) can help because it is easy to divide material in logical separate units by it. The more educational material is systematized the easier a user can use it. If it is possible, chapters should be limited in time not longer than 20 minutes. In E-learning this size of a chapter corresponds to one hour of classical lecture. Navigation within educational material is of high importance. Complicated educational material and lack of navigation possibilities result in frustration which leads to termination or withdrawal of users.

There are lots of new ideas which can be implemented or combined with those mentioned here within a creation phase. In the last ten years European Union has paid a lot attention to creation of digital society. Beside political and economic developing programs related to this issue, there has been a lot of researches in EU which resulted in the programs naturally related to researching this field. Nowadays, the effects of these programs and researches can be seen in the

society which is more digital than social. The result of this transiton is proved by the presence of digital education in institutions of higher education. Unfortunately, young experts are not given enough knowledge from this field and this unsatisfaction causes some changes at cultural, economic and political level. Because of challenges of digital society in various spheres of life in all political systems – for example, culture, education, health care, etc. – it is necessary to prepare and provide appropriate knowledge to students and experts in institutions of higher education therefore, if they have any dilemma or questions related to digital societies they will be able to recognize them and apply the achieved knowledge in solving them. It is recommended to apply 12 hints of Susan Moron-Garcie when educational material for E-learning is created:

1. Technology is used in education in order to make easier the access to quality educational surroundings.
2. In on-line education a user is in the centre and necessary activities are adjusted to aspects and opinions of users.
3. Let's try to create something new and not to copy what exists.
4. New technology brings new possibilities which should be implemented in education in order to increase interactivity and users' interest.
5. Positive, motivated and relaxed educational surroundings is essential in creation of educational material.
6. Slower tempo in getting used to new educational surroundings.
7. More frequent personal communication with users is necessary because of possible mistakes.
8. It is necessary to check knowledge and experience of users in the field of Information prior to group formation.
9. It is necessary to make time for testing and exercising in order to help users.
10. Personal ideas are not always the best solution. Users' ideas and suggestions are often good.
11. E-learning does not shorten the time. In the beginning more time is needed to prepare educational material but after that it is possible to save a lot of time.

Adaptation and improvement of existing methods for monitoring progress is good but it is necessary to monitor possibilities which new technology brings as well.

III RESEARCH METHODOLOGY

Based on these requirements - improvement of teaching methods, implementation of new technology, modernization of education – Primary school "Jovan Mikić" from Subotica was chosen. This school had shown interest for modernization and implementation of new technologies in order to achieve better success even before. School staff is consisted of a great number of young teachers who are not firmly linked to traditional way of education because they have experienced during their education modern methods. Pupils from the 7th form were chosen instead of eight-form-pupils because the latter had to prepare for secondary school preliminary exams.

For creating a questionnaire we needed a subject which most frequently deals with traditional way of education and is a result of modern technology as well. It can be concluded logically what subject belongs to the needed direction ; all this serves for comparing the research results which will be presented in detail. The results fulfill the expectation and for now it is enough to emphasize that implementation of new ideas in current school program is payable because in this way effectiveness of education can be improved.

The research results are based on two independent questionnaires presented in the Appendix. In order to increase pupils' attention it is necessary to limit the number of questions , minimum 10 and maximum 15. There are two kinds of questions in the questionnaire – classical questions which a pupil has to answer and questions in the form of a test where a pupil chooses one of the given answers. Questions in the form of a test can be categorized in two types. The first type has 2 offered answers (yes/no), and the second offers 5 answers. The second type was used in order to present results more precisely and differently. The majority of questions was expanded with one more possible answer (number 6), or the variation „Other" if neither of the offered answers expressed the attitude of the examinee. Both questionnaires contained identical questions adjusted to the subject.

The research results were analyzed by means of the program Stata 12. It is necessary to know certain notions for using this application.

Upon finishing the research the pupils were given CDs with video tutorial and installation of Adobe tools trial version for creation of a web page – Dreamweaver CS5. These tools were installed in IT study room in school. Video tutorial in which a creation of dynamic web page is presented was given as extra curriculum activity research. We waited for several days to give chance to greater number of pupils to watch video and then we visited the classes who took part in the research again.

The data obtained by this questionnaire are interesting especially those related to E-learning. The results were analyzed by means of the program Stata 12. The data were processed by „Fisher" and „Chi" trial. „Fisher" trial uses four cell (2x2) contingent tables for testing null hypothesis (independent elements). It is used for analysis of a small number of elements (according to the criterion for which the expected calculated limit value of any cell is smaller than 5). The trial does not use approximate value but it gives exact probability (p value) on the examined or even more extreme distribution beside the null hypothesis.

"Chi" trial is a type of analysis which serves for equation of expected and obtained results in which distribution of trial statistics in the case of null hypothesis

approximately describes „Chi“ square distribution. It is widely applied.

IV RESEARCH RESULTS AND DISSCUSION

During carrying out the survey all pupils were present. The questionnaire was filled in anonymously. The questionnaires were marked by coded signs in order to enable identification of pupils/respondents.

According to "Fisher type" the exact trial P value was higher than 0,005 (P<0,005) so the results obtained in this way were not valid. In other words, the research results are not representative and they serve only for presentation of opinions and attitudes of 7-form-pupils.

According to the survey, 54.06 % out of 76 pupils said that IT tools would help them in learning while 34 pupils thought contrary (*Table I*). Majority of pupils thought that the use of IT tools wasn't necessary but it can be useful. The Table presents precisely the number of pupils from two classes who like (17) and dislike Informatics (57).

The discussion was done for representative dimensions which can represent moderators.

		Would the use of IT tools help you to learn easier and better?		
		No	***Yes***	***Total***
Do you like Informatics classes?	***Yes***	32 56.14% 94.12%	25 43.86 62.50%	57 100% 77.02%
	No	2 11.76 5.88%	15 88.24 37.50%	17 100% 22.98%
	Total	34 45.94% 100%	40 54.06% 100%	74 100% 100%

Table I

Out of 76 pupils who participated in the research 30 of them would like a teacher to be present at classes physically (*Table 3*). From the Table can be seen in what extent the pupils need the presence of a teacher at classes.

		Do you think that a physical presence of a teacher at classes is necessary?		
		No	***Yes***	***Total***
	No	8 21.05% 50.00%	30 78.95% 50.00%	38 100% 50.00%
	Yes	8 21.05% 50.00%	30 78.95% 50.00%	38 100% 50.00%
	Total	16 21.05% 100%	60 78.95% 100%	76 100% 100%

Table 2

A half of the sample from the research thinks that a teacher's presence at classes is necessary (*Table 3*).

It was more difficult to obtain necessary data from teachers. Many of them didn't want to participate but still the idea was interesting to majority of them. Opinions of teachers didn't coincide with pupils' opinions which was expected.

More than a half of the pupils who participated in the research was not introduced to E-learning (*Table 7*). Only a few pupils would like to have this type of classes at this level of education. However, about 24% of pupils know or at least have an idea about e-learning.

Do yu know what is E-learning/distance learning?	***Answers***	***Answers in %***
No	45	59.21
I know what it is but I don't know what this type of class is like.	12	15.79
I know exactly what it means.	9	11.84
I know what it is and would like to attend such classes.	7	9.21
Other:	3	3.95

Table 3

V FURTHER DEVELOPING DIRECTIONS OF E-LEARNING

After the first part of the research both teachers and pupils who attended the lecture on possibilities of E-learning were interviewed. The students' results showed the following:

- ✓ 86% pupils think that video tutorial is useful and they would like to use it in the future.
- ✓ 36% of them would like to see a form of LMS within their education at Informatics classes.
- ✓ 100% pupils understand what E-learning is.
- ✓ 77% of them think that the use of E-learning would make their studying easier..

- ✓ 62% pupils think that there is no need for a teacher at Informatics classes if e-learning is used.

A high percentage of pupils was interested in further e-learning.

The teachers' results showed the following:

- ✓ 20% think that this method of learning is dangerous for pupils because they can find unreliable and unchecked subject matter as well as the people whose pedagogical background is problematical.
- ✓ 40% of them think that the implementation of this technology is more expensive than classical one so they don't want to use it.
- ✓ 30% teachers tried to use some of distance learning ways but they were not successful enough.
- ✓ 30% teachers think that the use of mobile phone in education can be appropriate but outside of school and definitely not at classes.
- ✓ all teachers share the same opinion according to which technical support for this type of education is not prepared yet.

VI CONCLUSION

In the last decade e-learning has experienced great expansion because of the progress at the field of ICT. Following the world trends and trying to improve quality of work in education a great number of educational institutions has included this method of learning in their regular programs. The results of this and similar researches show that there is a great interest and need for further expansion and improvement of these programs.

For their introduction it is necessary to have technical equipment and training as well as general education and knowledge of teachers because they are leaders of the whole process, therefore it is important to inform them about all advantages of new technologies and methods of learning.

The level of technical equipment was evaluated as satisfactory in the institution in which we carried out the research and there were also free solutions in the field of LMS which have been proved as successful in practice. We will emphasize two factors which, in great extent, contribute to recognition of e-learning as a crucial factor of developing strategy in this school :

- ✓ Education of a teacher because insufficient education and lack of knowledge related to implementation of new technologies can be a serious obstacle in relation to their introduction.,
- ✓ Appropriate motivation of teachers because resistance to changes is often a consequence of unreadiness for preparing a material for classes.

As for the sake of further researches and after this initial review of the state in this field, it is concluded that a detailed analysis of factors which influence implementation's success or failure of e-learning in this school should be the part of a plan. Afterwards, the model for implementation of e-learning will be developed on the basis of the obtained results.

Pupils' views about implementation of e-learning in educational process have confirmed our assumptions. The pupils would like to use any type of e-learning in their school but this aim can be fulfilled by appropriate informing on details of this type of learning. Teachers represent a key factor of success. Like we emphasized before, teachers should be motivated to make a step forward and accept new trends of learning and teaching in order to help their pupils enter the world of e-learning and make it the part of their education.

damir@ffri.hr
Eugen.Ban@azoo.hr

***Abstract* - The web-based system for online knowledge testing (*WbeTS*) is a hierarchical and modular autonomous system for remote knowledge assessment whose autonomy is based on remote video surveillance as one of the testing validation mechanisms. The main problem facing the system is the physical implementation of the video surveillance unit for remote monitoring of a student, as well as development of a decision making mechanism based on such monitoring. The monitoring would need to take place in conditions of widely available broadband Internet access and the use of a webcam. A possible solution is a model of the remote control described in this paper, which could solve this problem and make the system more reliable. The model is based on built-in elements and algorithms for visual recognition and motion tracking of the student, sound tracking, user (teacher) interface for assessing the validity of testing and of the system's kernel responsible for assessing the validity of the tests and reporting. The model is envisaged to be implemented accordingly to the wishes and needs of users, and can be integrated as a part of an integral e-learning environment. Although the model described is in principle technologically feasible, its practical realization requires professional refinement and experimental validation. Only by in-depth testing and experiences gained from the actual application of the system will be possible to identify all deficiencies and requirements that currently cannot be predicted.**

I. INTRODUCTION

Testing of the student knowledge is an integral part of every teaching and is as well of the e-learning environment. However, the implementation of such assessment of knowledge and the validity of the test results are often questionable. The reasons for this may vary: from the lack of skills and competencies of teachers to design and implement such tests, up to the so-called *methodological limitations* [1] of this kind of knowledge testing. Methodological limitations are evident in the inability to evaluate higher levels of achievement in the cognitive domain of achievements, according to the Bloom's taxonomy of educational objectives [2], [3]. The attempt to solve this limitation was to develop a concept of a hierarchical system for knowledge e-testing (*WbeTS*) [1], in which knowledge test should be implemented in stages, through established hierarchical blocks of various tasks, which difficulty corresponds to the level of achievement of these taxonomies. This hierarchical e-testing system is conceived as an autonomous system that enables less stressful and more casual and phased knowledge testing with a significantly higher level of validity in comparison to the results of the typical written or online tests. Phased accession enables the student to delay access to higher-level testing, having successfully solved the previous lower level, and the choice of final desired level of achievement. System at the same time, by using a subsystem for visual authentication and supervision of students, generally provides access to testing services from any location which greatly simplifies the technical preparation and organization of the testing performance. All this contributes to more casual and less stressful approach to knowledge e-testing, facilitating the organization and implementation of it, providing a more realistic insight into the actual level of achievement. However, the practical implementation of this system as a subsystem of an existing e-learning environment is facing a number of problems that can significantly impair quality and validity of the testing. One of the major problems needed to be successfully solved on the systemic level, on which the autonomy of the system is dependent, is the remote video surveillance of students.

II. PROBLEMS OF REMOTE SURVEILLANCE STUDENTS DURING E-TESTING

The validity of any knowledge testing system, including written and e-testing systems, is based amongst all on the content validity, i.e. on the choice of questions and tasks that measure what they are actually intended to. However, test results can vary depending on the subject's possibility to cheat. That is why it is necessary for any testing to be carried out for a limited time and in a controlled environment. This is validity that will further on be called *trivial validity*. Hierarchical autonomous knowledge e-testing system bases its autonomy on a remote student monitoring, which largely abolishes the possibility that the subject of testing cheats. Therefore, a remote surveillance system should provide an acceptable level of trivial validity with a minimum of necessary technical conditions. That minimum of technical requirements is relatively easy to determine and can be classified as a general requirement for the e-testing implementation, and the vast majority of students today can meet it. Such general requirements refer to the use of a standard personal computer (PC or laptop), or other categories of devices (notebooks or tablets) with the suitable Internet browser, a standard webcam with a microphone and

a broadband Internet connection. In order to avoid potential problems in video surveillance it is desirable to classify acceptable level of brightness and noise in the room. The monitoring subsystem should be carried out in terms of smooth network connection of the subject's PCs and the server. Therefore, server resources as well as the network throughput and resources of the client should comply with mentioned conditions, which is a standard practice today. However, the processing and transmission of video and image data can be a problem if one is working with high-resolution video signal or insufficiently optimized processing algorithms. Therefore, the overall video surveillance of the respondents should be based on a robust and well-optimized software motion and sound detection algorithms. Result will eventually be mathematically expressed as a numerical indicator of the trivial validation of the testing. The monitoring and detection process should be done in real time, while the filtering process and the data processing of the validity can take place with a delay.

III. MONITORING AND CLASSIFICATION OF MOVEMENT USING CAMERAS

In the contemporary visual surveillance systems different algorithms and techniques have been developed for the movement detection and classification. They are often tailored to specific applications in a particular area. Motion detection is one of the most active research topics in the field of computer vision [4] nowadays. Among traditional and widely known methods used to detect moving objects are: i) temporal differencing [5], [6], [7] ii) optical flow [8], and iii) background subtraction method [9], [10].

The temporal differencing method or the difference between correspondent pixels is, due to its relatively low level of programming complexity, not very demanding. This method comprises computer operations to determine the difference between two adjacent image frames in a sequence of a video clip images. The difference between extracted characteristic points of image frames is quantified by calculating Euclidean distance and variance. It was experimentally proved that the method of calculating the variance of the difference in picture frames is less sensitive to noise and can adapt to a variety of dynamic environments providing a good stability [4]. This method is not sensitive to luminance changes and can be adapted to different conditions of supervision and it is therefore suitable for the limited value detection and so-called harsh object movement.

The optical flow method is a key method for determining the speed and direction of a moving object. Optical flow represents an apparent speed distribution of light patterns [11] which may arise from the relative motion of objects and observers. The application of this method requires a short distance between two adjacent image frames, which makes multiple frame video more suitable for the application of this method, but at the same time it is much more complex to handle. This method uses the value of the points from the image, which results in moving field, and does not extracts characteristic image points as previous methods. Optical flow method does not require information about the previous scene, and can dynamically track the movements. Therefore, this method requires more computational resources due to long-time movement information processing and it can be greatly affected by even small changes in scene illumination. On the other hand, in the temporal differences method small variations in brightness can hardly affect the accuracy of detection, while the high brightness variations cause abrupt maximum value of the variance, which can usually be ignored [4]. In the practical application of this method for extraction of moving objects commonly is used Horn-Schunck algorithm [11] complemented with the modern techniques and algorithms to determine the contours of objects [8], [12].

Background subtraction method is, according to the manner in which it processes information about moving objects, similar to the functioning of the human eye [4] and it can be used to reduce the impact of changes in the moving scene by updating information about the background. HSV (*Hue, Saturation, Value*) space [13] is determined by three coordinates which define the tone (hue) of color, color saturation and brightness value to describe the color. In comparison to the RGB color space, HSV space is closer to the perception of the human eye and it is often used in image processing and in pattern recognition. Because of the frequent problem of reduced movement detection accuracy caused by variations in illumination, Stauffer and Grimson [14] proposed a process of updating the background by setting the background subtraction threshold. This procedure is based on the difference between the current frame and the one that represents the model of the background.

Background modeling is often performed with Kalman filtering approach [15] or by using statistical models [16]. In practical application, background updating process sets the subtraction threshold and then calculates the difference between the value of the key frame and background frame for each pixel. Pixels with a difference greater than the threshold value are considered to be a part of a moving object and their background value remains unchanged. Pixels with a difference of less than a threshold value are considered to be a consequence of changes in lighting and background frame pixels are replaced with the appropriate key frame pixels [4]. Since the object of observation is mobile, the background should be changed in real time – in practice this method is known as adaptive background subtraction technique [5]. It is difficult to adjust the background subtraction threshold using this method, which often leads to excessive operation upon pixel conversion from the RGB (Red, Green, Blue) to HSV space [13]. These operations can significantly slow down computation and implementation of monitoring in real time. Determination of the threshold for background subtraction, as a key part of this method, is often the subject of experimenting and empirical optimizing of the method.

In addition to these methods, which can be used individually, their particular advantages are more often combined and integrated recently in the different hybrid motion detection methods [4] , [17]. Hybrid method (Figure 1) can be designed in different ways and commonly uses a temporal differences method to extract the key frames for basic movement detection. After extraction of the key frame,

object in motion is being allocated using methods of optical flow and HSV background subtraction method. Video sequence will be processed with a most suitable method. Result of the processing is output data about moving objects, which can be additionally processed by a computer. Applying a hybrid method, here simplified, it is possible to accomplish optimum motion detection and characteristics of a moving object with minimal time and computational requirements needed to process video signals.

For the detection and classification of audio signals, in this case of speech, it is common to use VAD (*Voice Activity Detection*) techniques and algorithms [18], [19], [20], which are used for various applications, from audio conferencing and speech recognition, to speech and telephony coding [18]. Typical VAD algorithm consists of three stages: the first stage reduces the noise in the signal with certain methods, the second stage performs quantification of the input signal, and in the third stage the classification rule determines whether the signal is speech or not [18]. For the purposes of the subject, audio control of the minimum generic functionality of VAD algorithm is sufficient, based on which system is to extract speech from other sound signals.

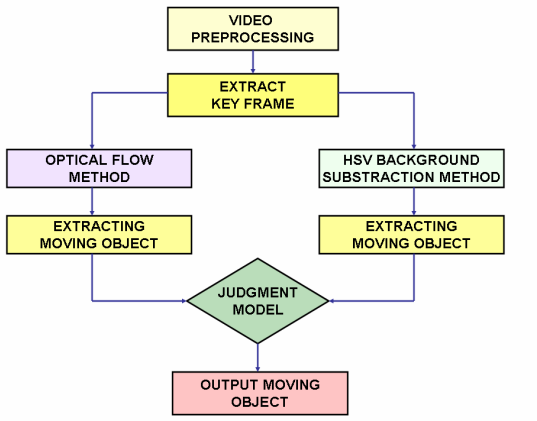

Figure 1. Flowchart of the hybrid method of visual tracking of a moving object [5]

IV. REMOTE RESPONDENTS SURVEILLANCE MODEL IN *WBETS* SYSTEM

Remote subject surveillance model (Figure 2) was developed by considering the requirements of it within a hierarchical e-testing system (*WbeTS*), current knowledge of the methods and algorithms for the detection and classification of movement and sound, as well as technical and technological limitations of hardware. The model is based on the use of a custom hybrid method of remote detection and basic movement characterization, and the use of a simple and robust VAD algorithm for sound detection. The model assumes that the trivial testing validity (V_T) can be described as a function of the so-called rough movement, or absence of subject from camera view (i), characteristic of fine head movements (g), lack of eye focus (o), and the detection of sound (speech control) (z). Given that the quantization of each controlled variable is more dependant of the duration than the number of detected phenomena, trivial validity can be described by a simple relation (1):

$$V_T = \sum_{1}^{Ni} t_i + \sum_{1}^{Ng} t_g + \sum_{1}^{No} t_o + \sum_{1}^{Nz} t_z \tag{1}$$

Where t is the duration of each occurrence that the system recognized as an anomaly and N is the number of occurrence of each anomaly. Accordingly, the trivial validity is actually an integer expression of the duration of all anomalies in seconds. This information has been proven to be the easiest to use in the analysis of video recordings of controlled online student knowledge testing.

Analysis of the video footage was conducted on a sample of 52 students of undergraduate and graduate studies at the Faculty of Humanities and Social Sciences in Rijeka, which were tested with 30-minute online tests prepared by the Department of Polytechnics. Testing and analysis were performed in order to classify movements of which trivial validity may depend, and the frequency of those movements in a completely valid test. Movements and anomalies which were entirely absent in a valid test were: rough movements, absence of subjects out of camera focus and sound anomalies related to the speech of subjects during the test. The position of the respondents head during the test has mainly been towards the video camera, with minor anomalies in all directions, which should be treated by the control algorithm as a tolerance orientation (an acceptable movement) of the head. During the valid test subjects blinked about 30 times a minute, each blink lasting less than a second, resulting in need for treating the blink as a movement and not detected as an anomaly by the tracking algorithm. According to this analysis, the valid test had an average of 23 movements of the head, which can be detected by the system as a change of the vector structure critical point set on the boundary lines of the head, which can be regarded as anomalies. These anomalies lasted between 0.7 and 3.4 s, which is an average of 177.45 seconds per test subject. These were anomalies that did not impair the validity of the tests, such as yawning, head scratching, stretching, etc. Therefore, duration of these movements could not cause copying or consultation amongst subjects, or similar activities that would disrupt trivial validity. When it comes to the eye focus, it is to be noted that the algorithm of the system, according to the analysis, should consider each eye position, where the lower third of the pupils are visible, valid eye focus. Thus, the analysis shows that the valid test has an average of only 3.7 absences of the eye focus per test, or altogether 15.2 seconds. From the analysis it can be concluded that the test, which is valid in terms of trivial validity, has up to 200 seconds of anomalies, or, $V_T \leq 200$ for a valid test.

Based on the analyzed movement which should be monitored by the system for compliance of trivial validation, above mentioned remote subject control model (Figure 2) has been designed and developed. The model, as an e-testing *WbeTS* subsystem, generally is consisted of user interface, which is an integral part of *WbeTS* system, and the

subsystem kernel, which performs video signal processing, video and audio signal filtering and validation. The user interface is designed for input of the desired parameters or requirements for monitoring facilities such as lighting, sound level, and the level of trivial validity. Projected video signal retrieved by the subsystem is, because of the computing resources optimization, limited to the usual webcam resolution of 320 x 240 pixels with 30 frames per second. Before retrieving the signal, the subsystem checks the desired conditions and, after they are met, retrieves the image that is "roughly" preprocessed, and converts it into a 2D binary image with the aim of reducing the computational complexity. At the beginning, the subject needs to choose the desired position, of which the system will warn him, in order to determine the reference relations between key points and the size of the observed scene (key frame). Rough processing includes identifying and monitoring key (characteristic) points, which represent the monitored virtual scene, on the subject's head. There is in total 9 boundary points of the subject's head and nose, and 8 points for the contour of each eye of the subject. After extraction of the key frame, system reduces a supervised background using the HSV background subtraction method, and tracks surfaces that bound the key points using optical flow method. Special attention is given to the monitoring of the respondent's eyes, or to be more exact, to the monitoring of the surface area of the eye and the pupil. For further algorithm elaboration it is important to emphasize that the monitoring of the points, which represent a key frame, should be performed with necessary movement tolerance for the entire area bounded by those points, and for the relation between these areas and the picture frame. Tolerance is necessary because the entire head of the respondent moves minimally during the test, while maintaining focus and mutual key point distances, which does not impair the validity of testing. Motion analysis found that overall differences in movement monitored area, and the points and their mutual ratio during a valid test do not exceed 12% of the initial reference value of those points. However, when making a practical implementation of the model, it is necessary to re-adjust and modify this value regarding experience. It should also be noted that the background subtraction algorithm should be performed under the condition that there is no other movements in the background of respondents, which means that the system may terminate testing if movement in the background appears, or treat the movement as a rough anomaly in testing, which may depend on specific implementation of the model. This isolated and reduced image with key points, areas that are monitored and seized background, is going through the proper filters in the further course of processing, which will then distinguish certain types of anomalies in accordance with their pre-defined characteristics. Therefore, the system detects every movement of the scene's key points, and determines whether the positions of the points, surfaces that they delimit, and their relations are within specified tolerance limits defined at the beginning of testing. Every absence of a key points, dodge and disproportion of mutual distances and/or surface areas which they delimit, are classified as anomalies and their duration is being determined. The lack of points is detected as an absence of the respondent or a rough movement, while is the disproportion of mutual distances and/or surfaces detected as an inappropriate movement of the head. At the same time surface areas of the eyes are being tracked as well, and each reductions below the predicted level is being detected and its duration is measured. If it lasts less than 1s, the movement is classified as a blink and the system does not record it, otherwise, the movement is classified as inappropriate eye focus and its duration time is marked of. The system also monitors and records sound environment during testing, which is classified as speech or other sounds based on the implemented VAD algorithm. When VAD algorithm classifies sound signal as speech, its duration is measured as sound anomaly in the testing. The duration of each of these anomalies is added to the previously recorded duration of equivalent anomalies, and their total time at the end adds up and turns into an integer amount of trivial validity V_T. Based on predefined trivial validity values, at the end of the testing the system decides whether the test is proper in terms of validity, and whether that information is entered into the corresponding field along with the test results of certain subject. Ultimately, this information is an integral part of the subject's test results and it is available via user interface that manages the e-testing system.

The described model is a generic algorithm structure for the remote surveillance implementation, which can be complemented by additional elements due to higher level of trivial validity. That said, the monitoring can begin with authentication of participants based on face recognition algorithm and the points taken as the parameters to be used during the surveillance. In addition, the system can, at the beginning of testing, or sequentially during the testing, retrieve images of the subject and store them in a database along with the test results. Stored images can be used when making an additional identity check, in the case of suspected subject swap during the test.

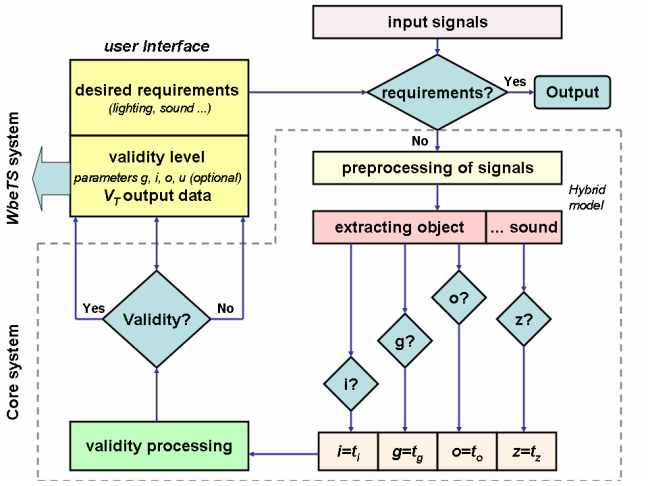

Figure 2. Simplified flowchart of the model of remote video surveillance in *WbeTS* system

V. POSSIBLE DIFFICULTIES IN THE IMPLEMENTATION OF THE MODEL

The model, here conceptually and partly technologically elaborated, needs to be developed and adjusted to the customer requirements in a specific e-learning environment, for experimental verification and improvement of the algorithm, the application, and of the model itself. There are possible problems in different tasks and levels of development and customization:

a) Problems in application development - the quality of the algorithms and procedures that will be developed to implement the model can greatly affect the applicability and relevance of application within which the model is implemented in the system. Video signals processing can use considerable computing resources, implying that the code should be well optimized and adapted to the standard computing resources used today, and the code should be tested in a real multitasking computing environment. During the application development a special attention should be paid to the eye focus monitoring algorithm, which is extremely important to ensure the quality of this kind of surveillance, but can be extremely challenging for software customization and optimization.

b) Problems of integration into the e-learning management system – as the model is a part of the WbeTS concept of e-testing system, and as such is designedto be integrated into any environment for e-learning, mostly into Moodle. The integration should follow developer's notes of the environment and its potential requirements and restrictions. Although it is not a limiting factor for the implementation, it is desirable that the model is developed in the form of a modular plug-in that can be easily integrated into the e-learning and e-testing system.

c) Problems in selecting the application's starting and executing method – as any network application is based on the communication between the client and the server, its performance depends on the quality and bandwidth of the interconnections. The application for remote control can be installed on the server, which means that the network signals travel to the server and are then processed there. Such a solution could, especially for a large number of simultaneous participants, quickly consume server resources and disable network communication. A much better solution is to run the application on the client side, which will at the end of the testing send the requested validity information and any additional information to the server.

d) Problems associated with the video surveillance requirements – as the subject of testing has the possibility to control the environment, there can be possible problems in meeting the testing requirements, which can be considered as a limitation from the subject's point of view. The environment in which the e-testing is conducted should be static and relatively quiet (home workspace, etc.), but can often be dynamic and noisy (public computer, waiting rooms, internet cafés, etc.). Furthermore, household lighting conditions can vary from poor home lighting to complete lack of it, or pretty dark environment, and so on. Because of these and similar problems, the implementation guidelines should clearly specify the required conditions regardless of the access location, and the application functioning requirements. Only in this way it will be possible to avoid many potential problems associated with the requirements for surveillance.

Although these groups of problems do not cover every possible situation, they are currently recognized and expected and they should be considered during the implementation. It is expected that future development and experimental verification of the remote control functioning in real life and/or in laboratory will discover additional problems and difficulties in the implementation of the model. Such development, soon to be realized, will also improve the model and the application, and will also discover new technological possibilities for realization of the desired goals.

VI. CONCLUSION

Modern knowledge e-testing systems, as a necessary and indispensable part of the e-learning system and environment, can greatly facilitate and accelerate the evaluation of the achievements of specific curriculum objectives. However, their trivial validity, because of which the teacher must supervise the process, often complicates the test implementation, especially when testing very large groups of students. Development of e-testing systems and concepts, and training of teachers on how to use them has largely counteracted all categories of validity. E-testing and online testing have become an integral part of contemporary mixed educational system. However, in order to satisfy trivial validity, it is still necessary to physically control the subjects. In this paper, a robust remote subject control model is presented, which is, on a theoretical level, trying to solve the problem of trivial validity. The model is based on the use of hybrid method for motion detection, VAD algorithm for sound classification, an algorithm for characterization and filtering of the detected movement, and the use of standard, affordable hardware and broadband internet. Although the model is designed to be a part of a hierarchical web-based system for knowledge e-testing (*WbeTS*), there are no obstacles for its implementation in other knowledge e-testing environments. For the model to become a part of the e-learning environment, it is necessary to develop a software module and integrate it in such environment, and distribute it to a wider audience. By implementation and testing in real conditions, it will be possible to further develop and improve the system and the model, and finally to gain users acceptance.

Web Application Development with Component Frameworks

V. Okanovic
Faculty of Electrical Engineering/Computer Science Department
Sarajevo, Bosnia and Herzegovina

Abstract – This paper describes development of dynamic web application using web frameworks based on web components. The paper considers several existing open source Java web component frameworks. Then, the paper provides basic features of the analyzed web frameworks and represents their main characteristics. To give an idea of which framework might use, the paper compares all analyzed web frameworks, and summarizes them and gives an overview of all their the most important characteristics.

I. INTRODUCTION

A web application framework is a software framework that is designed to support the development of dynamic web applications [1, 2, 3]. There are a lot of open source Java frameworks for web application development [4]. Depending on the type there are action based frameworks and component based frameworks.

To speed up web application development, action based frameworks mostly rely on external configuration files and less on Java code. Because of that they are not suitable for rapid development of web application.

The paradigm of component based frameworks is quite different. This type of frameworks creates a component abstraction in view tier. Thus, developer of web application defines a component in his application, and tells what the component does.

Regarding to numerous open source Java web frameworks, it becomes so difficult for developers to select a suitable framework for web applications development. Because of that, the purpose of this paper is to help web developers to easier choose the right framework for development of their web applications. The paper will analyze a few open source Java component based frameworks. Additionally, the paper will provide basic features of the analyzed frameworks as well as represent their most important characteristics. Also, in this paper the analyzed web frameworks will be compared and summarized.

II. OPEN SOURCE SOFTWARE

Open Source Software (OSS) is a software that can be freely used, changed and shared by anyone [5, 6]. OSS programming code is available on the Internet, so it can be used by people from all over the world. The software evolves when developers on the Internet can read and modify it freely. Many developers can work on open source software and they can modify and update it. The concept of open source software is good model for creating high quality software.

OSS is very important for student for several reasons. The programmers around the world are constantly developing many free tools and students can use them for their work. Students can learn from the best researchers and engineers in the world. They can open a software and see how programmers have organized it. By studying the source code written by the best developers, the students can learn to make better software. Thus open source software can help students to become better developers.

Also open source software is a good way for a young software developers to get an international recognition. Owners of existing open source projects are always looking for more collaborators. Developers can join to some open source project. By getting in the project, developers can create something useful as well as to develop their skills further.

For companies, organizations, governments and students in developing countries, OSS provides a way to prevent the widespread illegal copying of software, and an opportunity to raise the level of software development to international standards. The open source software has shifted proprietary software in many companies, governments and educational institutions. Besides being cheaper open source technology, executives in companies, governments and educational institutions have recognized that it offers better performance and reliability than proprietary solutions.

III. FRAMEWORK

In accordance with the free dictionary definition a framework is "a structure for supporting or enclosing something else, especially a skeletal support used as the basis for something being constructed" [7].

A framework can also be defined as a unitary entity formed of computer codes, scripts, classes, functions that offer a generic functionality and which is specialized or extended by a code generated by the user in order to obtain a specific functionality [8]. A framework provides architectural guidance by partitioning the design into abstract classes and defining their responsibilities and collaborations. A developer customizes the framework to a particular application by sub-classing and composing instances of framework classes.

Another defionition of a farmework is: a framework is typically an architectural pattern that provides an extensible template for applications within a domain [9]. By specifying a framework, developer specifes the skeleton of architecture, together with the slots, tabs, knobs, and dials that you expose to users who want to adapt that framework to their own context.

The most important benefits of frameworks are: modularity, reusability, extensibility and inversion of control. These major benefits provide what all developers want, and it is rapid application development, reuse of both code and design, reduced maintenance costs and ease of customization.

A. *Component based frameworks*

Unlike action based framework, philosophy of the component based frameworks is quite different. Component based frameworks create a component abstraction in the view tier. Event listeners capture user actions and map back to code in the controller tier. The major advantage of using components is modularity. Complex web pages can be composed easily using web components. Further, it is possible to reuse one or more web components on a few web pages of the same or another application. Moreover, component based frameworks make the collaboration between web designers and Java developers much easier.

A good framework can reduce the cost of developing an application. A Java component based frameworks are very popular type of framework. To give web developers an idea of which framework they might use, the following is analysis of basics features as well as representation of the most important characteristics of a few open source Java component based frameworks. For the sake of space, examples of web application development using these web frameworks will not be given or discussed in this paper. Also, specific examples and their detailed descriptions can be found in the cited references for these frameworks.

IV. TAPESTRY

Tapestry is open source component oriented web application framework written in Java [10, 11]. Using this framework developer can easily create robust and content rich web applications. An application developed with Tapestry is a collection of web pages. In Tapestry applications each web page is simple HTML page. The web pages are constructed using web components. That means each element of a web page is represented with some appropriate web component. Tapestry applications are built from HTML templates and specifications, and they can be run on any servlet container.

In web application development Tapestry implements Model View Controller (MVC) pattern [12, 13, 14]. In Tapestry applications developed using this design paradigm for separation, Model is consisted from domain object, View is represented with simple HTML files and Controller is implemented as XML page specification.

Tapestry framework is designed to support agile development of web application. In accordance with that, Tapestry takes care about many activities, such as dispatching user requests, monitoring the file system for changes of Java classes, managing server-side state, etc. In fact, Tapestry supports web developers to write less code. Thus web developers can use their time as much as possible for coding the application's functionality.

V. JAVASERVER FACES

JavaServer Faces (JSF) is Java web component application framework for creating user interfaces [15, 16, 17, 18]. JSF is part of the standard Java EE platform. Developed through the Java Community Process, JSF is a standardized display technology for building server-side user interfaces. JSF framework enables the reuse of web components. By using existing reusable web components JSF framework simplifies building of web pages and construction of user interfaces. There are many web components of JSF technology. Using them, this framework reduces the effort in building and maintaining web applications. Moreover, the framework provides processing component data and architecture for managing component state. In addition, JSF handles events and validates user input.

JSF application framework offers a clean separation between presentation logic and application logic. This framework implements Model View Controller pattern. JSF implementation of MVC design pattern makes applications much more manageable. Model manages data and logic of the application, View takes care about the user interface and Controller manipulates the user input. Regarding to team development, this approach of web application development allows that each member of the team can focus on individual part of work.

JSF framework uses JavaServer Pages for presentation logic and the standard tag libraries for representing the components of user interface. With JavaBeans components the framework defines functions of components on a web page. Beans configuration and page navigation rules are defined in configuration resource file of an application.

VI. WICKET

Wicket is a web component based framework [19, 20]. It is a web application framework for creating dynamic web pages by using web components. Wicket focuses on object-oriented design. By using this framework web pages can be built with reusable web components that can be extended by standard inheritance. A web component, such as a web page or a page section, is in the center of preoccupations in Wicket. This framework provides easy development of web applications. It uses only two technologies: Java and HTML. HTML pages are very cleanly separated from Java code. Thus, markup designer has complete freedom about how to design web pages. HTML designers can easely design and modify the pages by a visual HTML editor, like FrontPage, Dreamweaver, etc. Dynamic content processing and form handling is all handled in Java code. Each component in Wicket application is created in Java class and rendered in markup. The HTML file and Java class must have the same name. Also both of these files must exist in the same source structure.

Wicket provides a generic support for web applications. Web application concepts have corresponding classes in the Wicket framework and in the web application. For example, for the web application concept, Wicket has the *WebApplication* class. For a web page, Wicket has the *WebPage* class. Each web page in the web application has its own class that extends *WebPage*. Moreover, important feature of Wicket web applications is that they do not require XML configuration files. Instead XML configuration files Wicket uses a Java class for application settings.

VII. MODELIBRAWICKET

ModelibraWicket is open source Java component web framework and is part of Modelibra family [21, 22]. Besides ModelibraWicket, parts of Modelibra family are ModelibraModeler and Modelibra framework [21, 22].

ModelibraModeler is design and code generation tool. ModelibraModeler has been implemented to assist developers in domain model developing. The backbone of any software is a domain model. A domain model is a model of specific domain classes that describe the core data and their behavior.

Modelibra is a domain model framework [21, 22]. Its objective is to provide an easy to learn and easy to use framework. Its recommended use is in prototypes and small applications. It can be used in client and server applications. Modelibra has been designed to help developers of small applications in representing and using application domain models. Modelibra is useful for developing software around a domain model, for providing an easy installation for the users and for developing a web application to introduce software to the public audience. Modelibra uses XML files to save data of the current domain model. There is no need for any special software installation. However, Modelibra allows the use of both relational and object databases. The upgrade of an application from XML data files to a database does not require a single line of programming code to be changed. It is enough to change a domain configuration in XML and create a database and configure it to run the same application again.

ModelibraWicket makes a domain model alive as a web application, so that model data may be displayed as web pages and updated through forms. The model is metamorphosed into a web application with the help of its XML configuration. This web application can be considered as default application of the domain. It is important to realize that this web application is not a version that one would like to install as a web site. Its main purpose is to validate a domain model by designers and future users of the web application and consequently refine the domain model. In addition, ModelibraWicket has a collection of generic web components that may be easily reused in professional web applications to display or update entities. The generic web components may be easily reused in a specific web application. Their reuse consists of collecting data from a domain model by using Modelibra and by supplying the data as parameters to the web components. The generic web components from ModelibraWicket use Modelibra for a domain model and Wicket for application views.

VIII. COMPARISON OF WEB FRAMEWORKS

Today there are many open source Java web frameworks for development of web applications. Development of large number of web frameworks is caused by various reasons of web developers and user requests. Thus all web frameworks are very different and each of them has its benefits and limitations. Therefore, for web application developers it is very difficult to decide which framework to use for development of new project. To give web developers an idea of how a frameowork is suitable for their project, this section compares four above-described web frameworks and provides an overview of all their the most important characteristics.

The following are some factors that developers should consider when choosing a framework for creating a Java web application:

Maturity – determines how long the framework exists. Tapestry, JSF, Wicket and ModelibraWicket web frameworks exist for a number of years.

Community – refers to activity of community. Community of Tapestry, JSF and Wicket frameworks is active, but ModelibraWicket community is not active.

Documantation – determines the availability, quantity and quality of documentation. There are many books about Tapestry, JSF and Wicket frameworks. Also these three web frameworks offer good online documentation on their home pages. There are a few books and online manuals about ModelibraWicket framework, but this documentation is not large.

MVC structure – relates to how event calls are handled. All four frameworks (Tapestry, JSF, Wicket and ModelibraWicket) are component pull-based MVC frameworks.

Configuration – determines whether developer must create many XML, property or some other files to configure the framework. Only JSF is configuration framework, because in this framework there are several configuration files that must be configured.

Security – refers to implementation of security features for web application. Tapestry, JSF, Wicket and ModelibraWicket performs Java authentication and authorization security.

Localization – refers to internationalization, which means the ability to adapt web application to multiple languages. All four frameworks (Tapestry, JSF, Wicket and ModelibraWicket) support localization.

Ajax – relates to building of interactivity in web applications. Three of the four frameworks support automatic Ajax generation: Tapestry, Wicket and ModelibraWicket.

Page based – determines the ability of application development using web pages. All four frameworks (Tapestry, JSF, Wicket and ModelibraWicket) are a page based frameworks.

JSP based – relates to use of JSP pages to generate HTML. Only JSF is JPS based framework.

Template based – determines whether framework works with templates. Tapestry, JSF, Wicket and ModelibraWicket are a template based frameworks.

Inversion of Control (IoC) – refers to a mechanism used to look up internal or external services. Two of the four web frameworks directly support IoC: Tapestry and JSF.

Design and code generation – determines whether there is a possibility of design and code generation of web application. Only ModelibraWicket has this ability. For this purpose, ModelibraWicket uses ModelibraModeler, design and code generation tool.

An overview (of the existence or non-existence) of all these most important characteristics of the analyzed frameworks can be presented by a table (Table I).

TABLE I. OVERVIEW OF THE CHARACTERISTICS OF THE ANALYSED FRAMEWORKS

	Tapestry	**JSF**	**Wicket**	**Modelibra Wicket**
Maturity	+	+	+	+
Community	+	+	+	-
Documentation	+	+	+	-
MVC structure	+	+	+	+
Configuration	+	-	+	+
Security	+	+	+	+
Localization	+	+	+	+
Ajax	+	-	+	+
Page based	+	+	+	+
JSP based	-	+	+	+
Template based	+	+	+	+
IoC	+	+	-	-
Design and code generation	-	-	-	+

This table can be helpful for developers. Each developer can consider the table when selecting a component framework for creating a Java web application. Of course, many different criteria can be considered and developers can perform additional research if needed.

IX. CONLUSION

In this paper are discussed open source web component frameworks. The paper briefly describes four Java component frameworks: Tapestry, JavaServer Faces, Wicket and ModelibraWicket. These frameworks can be used for developing dynamic web application. Benefits and limitations of using these frameworks in development are indicated. The framework features are outlined, all four frameworks are compared and the overview of the most important characteristics of the analyzed frameworks is given.

Many people now wonder what to use for web application development. This paper can be used as a starting point for making a decision of selecting a framework for web application building. Thus, it can help web developers to increase their productivity. Also, this paper can be helpful for students. They can learn new concepts and simplifications, as well as advantages and limitations of all these four component frameworks. Thus, they can correctly apply their knowledge on real future projects as much as possible.

Agile Management: A Teaching Model Based on SCRUM

Ž. Požgaj*, N. Vlahović* & V. Bosilj-Vukšić*
* Ekonomski fakultet Zagreb, Trg. J. F. Kennedyja 6, Zagreb, Croatia
zpozgaj@efzg.hr; nvlahovic@efzg.hr; vbosilj@efzg.hr

Abstract – Work presented in this paper is based on the notion of creating a teaching model based on the principles of agile management. Developed and described model is based on Scrum, one of the most widespread agile methods. Since Scrum is primarily a framework for managing software projects and software applications development, during the development of the model it was crucial to negotiate the differences between Scrum and the teaching process itself. Teaching model in this paper covers the whole teaching process from first lessons to the final exam. Model consists of three separate units: (1) presentation of theoretical knowledge; (2) practical knowledge and student projects; (3) exams and admission of grades. Each of these units represents a Scrum that results with particular „products". Basic characteristics of Scrum like incremental development, iterations, roles and artefacts are implemented in the teaching model using the same principles as in the original Scrum even though their content is adjusted to the specifics of the teaching process. Model is implemented in the Managerial Informatics master study course "Business Application Development" at the Faculty of Economics and Business University of Zagreb.

I. INTRODUCTION

One of the topics within the curriculum of the course Business Application Development (cro. Razvoj Poslovnih Aplikacija) is "Agile software development methods". In order to familiarise students with knowledge and skills within this topic more closely, we intended to organise the teaching process according to principles of agile management. The selected method was Scrum. Scrum represents a framework for software product development. Final goal of Scrum project is to create a product that complies with intended requirements. Teaching process aspires to reach the same goal as a Scrum project. Project, in this case, pertains to the organisation and conduct of the teaching process in current academic year according to requirements defined in the curriculum of the course, with the final goal – successfully complete teaching year. Analysis of teaching process in described manner has shown that teaching process can be compared and affiliated with any other process, even with software development process. Scrum is a typical software product development method. Characteristics of the method are described in detail in this paper through the presentation of the proposed teaching model. Teaching model is achieved through three separate Scrums; each Scrum containing three phases. Teaching process is developed in the same way as software product using all the stages of the software process life-cycle, where different roles are assigned to different actors, specific artefacts are used, respective activities and iterations. From presenting theoretical knowledge in the first Scrum, through presentation of practical knowledge and skills during the development of student projects in the second Scrum, until the finalisation of the teaching process with the student exams in the third Scrum. Students work on their projects in accordance to agile work organisation (including teamwork, pair-programming, presenting features as stories, weekly meetings, etc.)

Review of current literature indicates several attempts of implementation of Scrum in the teaching process. In most of the available cases Scrum is implemented only in the segment of the teaching process concerned with the organisation of student projects. As expected, courses where Scrum is used in this way usually cover the topic of software engineering [10]; [5] even though there are a few examples of using Scrum in courses dealing with other topics [4]; [1]; [6].

The rest of the paper is organised in five separate chapters. After the introduction, in chapter 2, Scrum methodology is introduced with descriptions of its basic characteristics. Chapter 3 is the central part of the paper where developed teaching model based on Scrum is described in detail. Chapter 4 indicates possible improvements of the organisation of the teaching process. Finally, Chapter 5 summarizes the key points in the conclusions.

II. SCRUM METHODOLOGY

The emergence of novel, so-called lightweight agile software development methods, evolved in the mid-1990s. The main characteristics of agile software development methods are iterative and incremental development, agility, flexibility in requirement definition, collaboration, self-organizing teams etc. Creators of these methods join the Agile Movement that publishes Agile Manifesto in 2001. Agile Manifesto details the philosophy and principles behind agile methods [8]; [9].

In 1995 Ken Schwaber and Jeff Sutherland present a study where they describe a new software development method and call it Scrum. The term scrum is derived from rugby, where a scrum restarts the game after the ball has gone out of play. Applying the interpretation of the term scrum to software projects, a software scrum gets the team

back together and gets everyone moving in the appropriate direction [1].

For Schwaber and Sutherland [7] Scrum is a process framework that has been used to manage complex product development. It is not a process or technique for building products; rather, it is a framework within which one can employ various processes and techniques. Speaking in terms of agile management, Cervone describes Scrum as an agile, lightweight process for managing and controlling software and product development predicated on a team-based approach [2]. It consists of three groups of phases: Pregame, Game (or Development) and Postgame (Fig. 1.).

Detailed description of activities and artefacts in each phase of Scrum is given in the rest of the paper.

According to 7th Annual State of Agile Development Survey for 2011. 54% software developers use Scrum. Scrum together with Scrum variants methodologies is used by 72% of software developers which makes Scrum the most popular agile methodologies being used [12].

III. TEACHING MODEL

Teaching is a process, teaching process is a project. Every project, including teaching projects, has its own respective goal (for teaching projects, according to the curriculum, the goal is to provide students with particular knowledge and enable them to master particular skills), its starting point and its ending point (during the semester). Complex projects, such as teaching project, require teamwork, mutual collaboration and cooperation. This can be seen through the relationship of teachers and students.

Following the ideas of agile approach to project development, Scrum methodology was used for the creation of the teaching model for the Business Application Development course.

Due to undeniable differences between teaching process and software process Scrum methodology had to be adjusted accordingly. First of all, every Scrum represents a complete wholesome processing unit that results with a particular product. This methodology is to be used to cover the complete teaching process of the course, from the introductory lectures until the final exam and admission of the grades. Three separate integral units were detected: (1) presentation of theoretical knowledge; (2) mastering practical skills through student projects; (3) exam and admission of grades. Each of these units represents a separate Scrum process and each of these deliver a specific outcome - product or several products. Consequently, teaching model for the Business Application Development course consists of three Scrums, or three Scrum units.

A. *About the course*

Course Business application development is an elective course in Managerial Informatics master study at the Faculty of Economics and Business University of Zagreb. This elective course consists of 20 hours of teaching (10 hours of lectures and 10 hours of practical work in computer lab). During the course students use software tools for UML diagrams, eDraw UML Diagram, and programming language Visual Basic, Visual Basic 2010 Express Edition. Workload of the course is expressed using European Credit Transfer and Accumulation System (ECTS) and the course is worth 4 ECTS credits. As we can see the number of course hours is relatively small and the number of ECTS credits is quite substantial, students are expected to work in teams outside the supervised part of the teaching process. Therefore students have additional time reserved for their independent teamwork in the computer lab, and they can choose from three different two-hour periods during the week. Teaching is provided by two lecturers, one for the theoretical topics and the other one for the practical part of the course. In the academic year 2013/2014, 33 students chose this elective course. They were allowed to organise themselves into working teams and, as a team, negotiate and define their project assignment topics.

B. *Roles, sprints and artefacts in the model*

Basic roles in the teaching model are Scrum Master and Scrum Team [7]. Teacher takes on the role of the Scrum Master. Scrum Master is the person responsible for the entire Scrum process and in this case Scrum Master is responsible for the realisation of the complete teaching

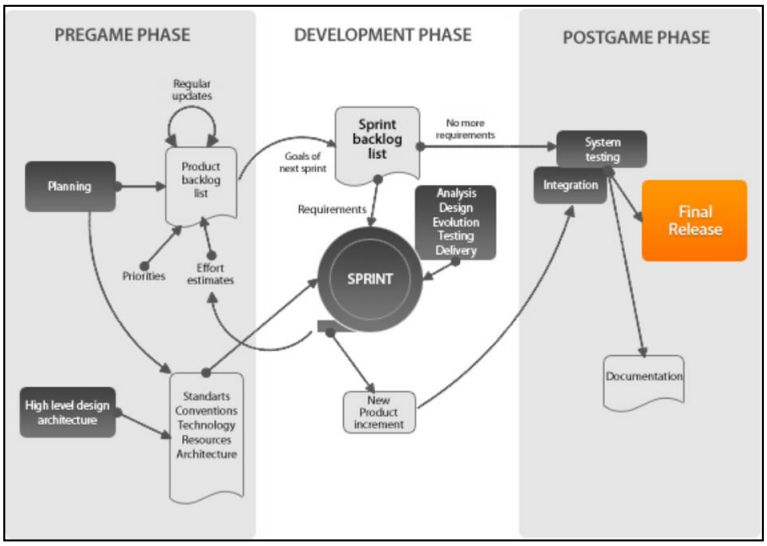

Figure 1. The Scrum phases [3]

process. This is why the role of Scrum Master includes the organisation of lectures and exercises, student consultations, advising students during project assignment topic selection, monitoring student progress and providing additional help during the development stages of student project assignments, grading of completed projects assignments, preparation and conduct of examinations, admission of grades, and so on. Role of Scrum Team is assigned to each student team. Students form teams by themselves and together as a team define project assignment topic. They delegate particular tasks among themselves during the development of the project, they communicate and consult with the Scrum Master, they observer the deadlines, write project documentation and present the project work when done. Role Product Owner is assigned to the team leader. Since student teams for the course Business Application Development consists of only two member, this role is not intended in this particular teaching model. In teaching processes where this role exists, Product Owner coordinates teamwork, takes care about the details pertaining to the project development progress and communicates with the Scrum Master. Product Owner represents the middleman between team members and Scrum Master. Soria et al. [10] recommend introduction of the additional role of Agile Coach in situations where students develop projects. According to [10] the Agile Coach encourages the teams throughout the Scrum process by cleaning the team's obstacles and emphasizing the use of tools. Designated Agile Coach represents the middleman between team members and Scrum Master and this role would be appointed to the lecturer that delivers the practical part of the course topics and exercises conducted in the computer.

Sprint represents a set of activities that are sequentially executed during each iteration of the development phase. In the teaching model, types of activities that will form each sprint are directly dependent on the Scrum unit the sprint cycle belongs to. For example, in the first Scrum unit activities within the sprints pertain to elaboration of theoretical knowledge about the topics of the course. In the second Scrum unit activities within the sprints follow the stages of the life cycle of the software product development.

Artefacts of the teaching model are specifically related by their content to the Scrum unit within which they are used. For example, in the first Scrum unit Product Backlog list, and later on Sprint Backlog list also, relate to requirements defined by the process of studying the theoretical knowledge about the topics of the course, while in the second Scrum unit both Product Backlog and Sprint Backlog lists relate to requirements defined by the project assignment topics i.e. particular software product being developed by the team. Project Topic Registration is also an artefact that is submitted by the student teams to the Scrum Master and it is only used in the Postgame phase of the first Scrum unit.

C. First Scrum – Theoretical introduction

Pregame phase contains activities that will enable students to participate in the upcoming Scrum units of the teaching model while successfully accomplishing and meeting the requirements that are continually requested from students during the teaching process. Activities defined for the first Scrum unit are providing students with the information about the course, presentation of theoretical knowledge about the topics of the course and preparation of students for the upcoming phases of the process. Key artefacts of this phase are Planning, Product Backlog list, Environment Architecture. Activities associated with the mentioned artefacts are performed by the Scrum Master. Artefact Planning involves creation of the teaching process agenda (possible innovations in the selection of the course topics in relation to the existing curriculum, determining scope of lectures for each topic by dates, planning the dates of midterm test and examination tests, defining methods of examination, determining primary and additional literature, determining dates for computer lab exercises, selection of software tools that will be used, and so on…) Product Backlog list contains features important for lecturer and students. So Product Backlog list contains each topic title, each weekly date for each lecture and corresponding topic that the lecturer will present, dates for the exam tests, instructions for the submission of student project assignment topics, deadlines for each activity, and similar information. Environment Architecture defines the required presentation equipment, lecture room features, computer equipment and corresponding software that is required during computer lab exercises and project development.

Game phase in the proposed teaching model spans over five weeks and in this period the teacher presents all of the theoretical knowledge topics as defined in the curriculum of the course. Product Backlog list is the basis for the creation of the Sprint Backlog list. Sprint Backlog contains a list of tasks to be completed during the Sprint. This is an ordered list of topics that the lecturer needs to present and they follow the stages of the software product life cycle. As topics are presented students gain required knowledge to be able to come up with project assignment topic for their own software product prototype during the second Scrum unit. List of basic and fundamental topics is enriched with topics such as software project management, software product quality metrics, and so on… List of tasks in Sprint Backlog that are to be completed by the students includes forming of project teams, completion of the Project Topic Submission forms, and similar activities.

Central part of this phase is dedicated to Sprints, i. e. incremental approach to completion of the tasks given in the Sprint Backlog list during separate iterations. Since the final number of hours of lectures for this course is ten, and there are two hours of lectures per week, model presumes five Sprints (5 x 2 hours). Each Sprint deals with one lecture. With the end of each Sprint, teaching process advances its progress in accomplishing the goals given in the Sprint Backlog list. Each lecture starts with the weekly „meeting“. The meeting agenda includes revision of topics presented on the previous weekly meeting, introducing students with the basic characteristics of the topic (or several topics) that will be presented during lectures and, finally, students get assignments for activities they should perform until the next weekly meeting (familiarise themselves with the content of a particular paper, retrieve particular information using Internet and similar…). Fifth

Sprint is different from the previous four since the location of the lecture is not in the lecture room but in the computer lab. Topic of this print is the modelling of business processes so the theoretical foundations are complemented with the drawing of particular UML diagrams using appropriate software tools.

After all of the items from the Sprint Backlog list are achieved, final phase of the Scrum unit begins – Postgame phase. For the lecturer this means that all of the required topics have been presented to the students. For the students that means that project teams are created, project topics determined and Project topic registration forms completed and submitted to the Scrum Master.

D. Second Scrum – Practical skills

Second Scrum unit of the teaching model is the most similar to typical Scrum that is originally defined as agile software development method. Since during second Scrum unit students develop their own software applications, Scrum is used as a framework for managing software applications development. Students develop their applications using Microsoft Visual Basic 2010 Express edition. Exercises are performed exclusively in the computer lab. Even though the primary part of this Scrum unit is dedicated to the development of software applications, basic information about programming in Visual Basic as well as the tutorial for the usage of the Integrated Development Environment is also covered. This is why in the Game phase during first three Sprints students are provided with necessary theoretical information after which exercises are performed using typical problem assignments that are similar to requirements in their project topics. Final two Sprints are dedicated to project work and the development of the software applications themselves.

In the beginning of the Pregame phase activity plan of the second Scrum unit is created. Product Backlog list is updated with the agenda of the practical part of the lectures. During planning Scrum Master is involved with defining the dynamics of presentation of programming basics by the topics and particular dates, defining practical examples of case studies related to specific lecture topics, defining required perquisite knowledge required for successful mastering of particular programing problems, defining deadlines for student projects and so on… Since in the previous Scrum unit 18 student teams submitted Project Topic Registrations, in the Product Backlog list only teams and their topics are entered in order to track basic features of student projects. This is why each Scrum Team compiles its own internal Product Backlog list. In these lists features of the software projects being developed are entered as well as corresponding requirements.

As mentioned earlier during the first Scrum unit, requirement for the particular software tools is defined as artefact in the Environment Architecture. Now, the testing of the installed computer resources is performed, and possible corrections are made if needed. When the final verification of the computer equipment is successful Game phase is ready to commence.

Game phase consists of five Sprints. After first three Sprints students were able to master the basics of programming and acquired required skills they are ready to start with the development of their projects. Final two weeks of the semester are allocated for the development of the projects, which corresponds to the last two Sprints of the teaching model. Scrum Teams have absolute autonomy over the organisation of their work on the projects, but within the limitations set by the rules of Scrum. This means that Scrum Teams compile their Sprint Backlog lists, define activities for each Sprint, define goals of each Sprint, delegate work tasks among team members, estimate timing and deadlines for particular Sprint activities, and so on… Since the amount of lecture hours in this period is reasonably small, Scrum Teams spend additional time and effort doing teamwork outside Sprint teaching model. This is why weekly meeting have pronounced importance during these two Sprints, since Scrum Teams report their progress from the previous week to Scrum Master. They report of what has been achieved in the previous period but also activities that they have planned for the next Sprint. This allows Scrum Master to follow the dynamics of the project development for each Scrum Team, giving them appropriate advice for the next Sprint, and so on… Each Scrum Team develops their project according to requirements given in the Sprint Backlog list, consequentially through the activities of each Sprint (Analysis, Design, Evolution, Testing, Delivery), iteratively using adequate number of Sprints and incrementally until all of the requirements are reached and the final version of the software product is developed.

Organisation of the work done during student projects is aligned with the recommendations of agile development of software products [9] and Extreme Programming (XP) [8]. Some of these recommendations include pair-programming and pair- process modelling using driver-navigator approach [11], writing stories (describing features and requirements) within the Product Backlog list and weekly meetings.

In the Postgame phase Scrum Teams continue their work by creating and compiling project documentation. Project documentation contains detailed description and disposition of the project assignment topic, UML diagrams (namely, decomposition diagram, use-case diagram at the system level, activity diagram and sequence diagram for a particular segment of the software product that was developed as a prototype), description of basic functionalities and characteristics of the software application, description of user interface, source code, course of testing activities, and final conclusions. Integral part of the project documentation that Scrum Teams attach to the documentation itself is the software product in both source code and executable form. All of these are submitted to the Scrum Master.

E. Third Scrum – Examination

Third Scrum represents the finale of the complete teaching process. By this Scrum everything that was set out by the curriculum of the Business Application Development course is completed. All of the topics given in the curriculum are presented, practical part of the course in the computer lab has been completed as well,

Scrum Teams have developed their software applications along with the appropriate project documentation and they have submitted the resulting work (project documentation and software applications) to Scrum Master. The last thing that remains in the teaching process to complete the course is the organisation and realisation of the examination. Third Scrum is concerned with examination on a particular date that is carried out as one complete unit. Final product of this Scrum for the Scrum Master is the conclusion of the exam date (project assignments are graded, exam is conducted, grades are registered) and for the students, grades are admitted in their indexes while the course Business Application Development has been successfully passed.

Pregame phase

In the Product Backlog list main properties for the examinations are registered: planned date of the examination, requirement that students that want to take the exam need to register for it, requirement that students need to have their index with valid entry noting that they have applied for the course in the beginning of the academic year. One of the most important artefacts that is entered in the Environment Architecture is the list of rooms that are reserved in the appropriate time when the examination is planned to take place. The method of publishing examination details is organized at the level of the Faculty and thus is not a part of the model.

Game phase

Sprint Backlog list contains the information about the exam date, including precise time and place where the exam will take place, as well as the list of students that have applied for the examination. Duties of the Scrum Master at this point are to compile exam questions and exam tests and prepare adequate number of test. Students are expected to take the test at the published date, time and place of the exam, while providing their indexes for inspection.

Since the model covers only one exam date, Game phase consists of only one Sprint cycle. Sprint lasts for a predetermined time period after which students submit the completed tests and after Scrum Master grades the written exams, students that have achieved minimum requirements and passed the test continue with the Postgame phase of the Scrum unit. Rest of the students are returned to the Pregame phase of this Scrum unit and are referred to the next exam date as it becomes available.

Postgame phase

In this phase for the students that have successfully passed the written exam Scrum Master calculates the final grade for the course where the final grade is structured as follows: 50% of the final grade is made from the grade of the written exam, 40% is contributed by the project assignment grade and the final 10% is contributed by the student activity during the course. The final grade is admitted in student index and registered in the exam list of the Faculty Information System.

IV. FURTHER IMPROVEMENTS IN COURSE ORGANISATION

The presented teaching model introduces a number of advantages and benefits for the students but it also faces a few challenges that need to be overcome and allow for improvements. Limitations of the model do not influence the structure of the teaching model but influence the suboptimal improvement of the teaching process quality. Some of the most prominent limitations are:

- Restrictive number of hours of lecture and exercises for the rich content of the course topics defined by the curriculum
- Limited background knowledge of the students that take this course that may require additional effort from the students to successfully finish their project assignments
- Relatively small number of students that creates challenges while forming student teams.

In order to improve the quality of the teaching process and resolve at least some of the limitations for the Business Application Development course an increase of the number of hours was proposed. From the current 20 hours additional 10 hours were suggested. This proposal was accepted by the Faculty bodies, so the next academic year there will be 10 hours of lectures reserved for the theoretical introduction to the course topics and 20 hours allocated for the practical part of the course that covers the development of student projects as well.

Next possible improvement pertains to the organisation of student project topics. The key idea here is that entire generation of students would develop the same complex software application and all of the Scrum Teams would make their contributions. They would still be independent self-organising and self-managing, but each Scrum Team would have 3 to 5 members. The project assignments would be given by the Scrum Master to the Scrum Team leaders. Scrum Team leaders would be assigned with the role of Product Owner according to the model described earlier in this paper, and each Product Owner would be assigned one segment of the software application that would be developed my their respective Scrum Team. The only restricting factor in this case would be the complexity of the student projects since there is limited background and prior knowledge of the students about course topics and programming. This limitation can be somewhat alleviated by the increased number of hours of practical work in the computer lab and Visual Basic.

V. CONCLUSION

Paper clearly shows how teaching process can be customised according to methodology initially planned for realization of completely different kind of processes. Scrum is chosen due to its specific advantages in comparison to other agile methodologies: (1) Scrum is presented as an integral part of the course in the topic „Agile software development methods“; (2) teaching process, as well as Scrum, is achieved through the incremental development: through presentation of theoretical knowledge, practical work and student project

as well as examination; (3) theoretical knowledge and practical skills are presented and thought iteratively: topic by topic; (4) student projects are organised and developed according to Scrum methodology: roles are assigned; required computer equipment is defined as a part of Environment Architecture; features of software products being developed are entered on the Product Backlog list; software requirements are defined according to Product Backlog list and the team member responsibilities are delegated through the Sprint Backlog list; software product is developed incrementally and iteratively through a number of Sprint cycles until final version is developed; (5) project documentation is created and compiled.

In this paper some of the limitations and possible improvements of the teaching model are given that could further raise the quality of the current teaching process.

Abstract - While social network friendships between teachers and students are forbidden in Great Britain, they are allowed in Croatia. However, there are no recommendations on the student/teacher communication by any of the relevant institutions. A study conducted in the Ante Kovačić Elementary school in Zlatar, Croatia in June 2013 shows that more than two thirds of students have at least one teacher as a Facebook friend. Even though this social network is a convenient medium for teachers to make the learning faster and more interesting to students, this potential is seldom utilized. The study shows that both teachers and students think that their friendship and communication on Facebook cannot get them into trouble with the school board or the parents and that this does not undermine the teacher's authority. Until there is no regulation on student/teacher relations on Facebook in Croatia, every school can solve this through creation of its own Social Media Policy. In the absence of Media Education, the IT teachers and the school librarians are those who should inform the students about the critical use of Facebook and the media by teaching Information literacy.

I. INTRODUCTION

Mark Zuckerberg, a psychology student, who was also a very crafty programmer, started several services for online networking for his university friends at a very early age. These networking websites connected the students that took the same university courses (Coursematch), or were used to grade the physical attraction of the students from the university (Facemash). At the beginning of 2004, or to be more precise, on February 4th 2004, he started Thefacebook (at thefacebook.com), the social network for Harvard university students. By March, this social network had spread to Stanford, Columbia, and Yale and later to other universities across the USA and Canada but it was initially intended for university students only.

Mark Zuckerberg was soon joined by two of his university colleagues, Dustin Moskovitz and Chris Hughes. The network became profitable and Mark and Dustin left school to completely dedicate themselves to developing this social network that was named Facebook in the summer of 2005, buying the *facebook.com* for 200,000 dollars. But more money was needed to develop it and soon several million-dollar investments came, including the one from Microsoft [1].

At the time, Facebook was still a social network open exclusively to students. In order to catch up with and surpass MySpace, Friendster, Bebo and other social networks, Zuckerberg abandoned the idea of Facebook being exclusively for university students and on September 26th 2006, he opened the door to anyone older than 13 with an e-mail address who wanted to register [2].

The term friend very quickly got a completely new meaning and today Facebook has over 1.15 billion users [3] and there are over 1.6 million of Croatian citizens registered on this social network [4].

Communicating through social networks such as Facebook opens up a wide array of possibilities. If we examine Howard Rheingold [5] who claims that the power of virtual society and computer networks stems from four unique features of computer communication (it is a medium that a number of people can use to communicate; it allows people to connect in new ways; the power of technology will increase through the focus on digital forms of the media; cyberspace, the overall connection between people through computer and telecommunications has solid foundations to become the basic platform, the starting point for innovations that will enable the entrepreneurs to find new use for the new media), we can deduce that the power of Facebook is enormous as this network can be used for communication between more than one billion people connecting in new ways – communicating through notifications (messages, photographs, video and audio clips…), comments and likes.

However, one should also bear in mind that each form of communication mentioned can be visible to the entire community and this means a large number of people. When dealing with communication between teachers and other individuals, between students and other individuals, between two teachers, between two students, or a student and a teacher, it can quickly become available to all other members of the community, such as other students, teachers, homeroom teachers, school principals,

parents… Not only is this communication instantly visible, but is available for a longer period of time, perhaps even forever or until one of the participants deletes it.

This work will show the situation among the seventh and eighth grade students (since younger students are not allowed to have a Facebook account) and their elementary school teachers with regard to their level of knowledge of Facebook, and answer whether the students are Facebook friends with their teachers, how they established that friendship, what is the nature of their communication and whether it can cause problems in school or life in general. In addition, we shall see whether and how Facebook can be used for educational processes. This paper will also show an example of a country in which the communication between students and teachers through social networks is forbidden and explain what mechanisms are used to regulate that.

This paper aims to confirm or disprove the following hypotheses:

1. Some of the elementary school students and their teachers in Croatia are friends on Facebook.
2. Facebook is underutilized in the teacher/student(s) communication in class.
3. Both the teachers and the students do not think that Facebook communication could cause problems for them with the school board or parents.
4. Both the teachers and the students think that these friendships and Facebook communication help improve the teacher's authority.

II. GREAT BRITAN, AN EXAMPLE OF A COUNTRY IN WHICH THE TEACHER/STUDENT COMMUNICATION ON SOCIAL NETWORKS IS NOT ALLOWED

In Great Britain, schools have regulations policies that forbid communication between teachers and students on social networks. Not only that, these regulations often stipulate that Facebook, MySpace, Bebo, Twitter, Youtube, Internet forums [6] … must not be used during class and even the school employees are unable to access them through computers as the school's access to these websites is often blocked through filters.

Some of these regulations on using social networks are brief and concise and contain only three pages [6], while others contain up to 12 pages [7] with a detailed description for each potential situation.

Granby Primary School has the Personal Use of Social Media Sites Policy [7] that states that the employees are held responsible for the content published on their social networks and that they have to be aware that everything that they post is publicly available. This Personal Use of Social Media Sites Policy explicitly states that in order to prevent any form of conflict of interests, the employees are not allowed to send the friendship requests to students or to accept their requests. There are some exceptional circumstances when the student in question is the teacher's son or daughter, but not even then can the friendship be accepted immediately as the school principals have to be consulted on this matter.

The teachers may not post any kind of information on social networks that would reveal the identity of students, students must not be mentioned in the discussions, nor should the photos or video clips posted include students or their homes. The teachers are forbidden to post any kind of information that could cause the school to get a bad reputation. The Granby Primary School's Personal Use of Social Media Sites Policy forbids its employees to express their views or opinions on social networks as the stance or attitude of the school and the local authorities. Usage of any kind of offensive, discriminating, or in any way inappropriate language is forbidden as is disclosing any kind of confidential information.

The teachers should be aware that posting the photos on social networks that are visible to a large number of people can be used to establish where and with whom they work, and this could increase the risk of false accusations and threats. In addition, the social network sites may enable the identification of children or vulnerable adults which could even put the safety of the students at risk.

The policy regulations state that the teachers should be aware that students finding inappropriate photographs of their teachers posted on social networks could cause an embarrassing situation for the teacher and harm not only their professional reputation but the reputation of the entire school as well. This could also reveal the place of residence of the employees and this could have further implications on their individual safety. Because of this, the first and the basic guideline for the employees is to evaluate every information before publishing them on social networks and to set their privacy settings.

The Granby Primary employee groups, e.g. Facebook groups, are allowed, but the founders of the group are held responsible for all published content. Breaching any part of the guidelines results in disciplinary measures.

When it comes to any form of use of social networks in class, Social Media Policy and Use of Mobile Phones and Digital Photography Policy, enforced by the Worfield Endowed CE Primary School [6] states that the school principal has to be asked for permission before any kind of use.

Ambleside Primary School's Social Media Policy [8] is rigorous even when it comes to former students and states that the school employees are not only forbidden to be friends with the current students but with all former students as well until they turn 18.

III. CROATIA, AN EXAMPLE OF A COUNTRY IN WHICH THE TEACHER/STUDENT COMMUNICATION ON SOCIAL NETWORKS IS ALLOWED

CARNet has created a proposal for school safety policy named "Acceptable use of computers in school" [9], but in terms of using Facebook and other social networks with regard to student/teacher or teacher/teacher communication, there is no formal or informal

recommendation from the relevant institutions. Thus, everything is left at the liberty of schools, principals, or to be more precise, the teachers themselves (the only teacher that has dealt with this issue in more detail so far is Miljenko Hajdarović [10]), as one of the crucial factors in class. In other words, everything that is not forbidden is allowed. However, one should bear two things in mind regarding this communication.

A. *The students and the teachers are always a part of the didactic triangle "teacher – content – students"*

First of all, the teachers must never forget their role (in class). They are one of the three factors that make up the so-called didactic triangle [11]. The teacher is an expert that organizes an efficient educational process and the class itself by teaching the students. The teachers should always (indirectly) let the students know that they, like the second factor of the class, are acquiring education through systematic teaching and individual learning. The third factor of the didactic triangle is the teaching or educational content, and this is what might connect the teachers and the students in communication through social networks. This exact type of communication as the special factor of education that is vital for participating in social networks emphasizes the need for information technology which turns the didactic triangle into a didactic quadrangle

B. *Many-to-many and the rules of conduct on Facebook*

Secondly, unlike the old, classic media with expensive technology that included the so-called "one-to-many" communication, Facebook allows you to have a meaningful "many-to-many" communication [5]. This is possible as you do not need expensive technology to become a user of this social network. This fact implies two things.

Facebook is easily available to all users, even primary school students. Most students have personal computers or laptops that have fast Internet connections (ADSL) with flat rate access. A lot of them have an ADSL device that enables them to have wireless Internet connection with a satisfactory signal throughout their entire home and this allows them to be constantly connected to Facebook using either laptops or smart phones that can be purchased at very reasonable prices.

The following aspect is even more important. The classic media, e.g. the newspapers, radio, and television, are centralized. The new media, including Facebook as a social network, generally do not have their own journalists, producers, directors, or editors, that is, persons that would control which notification is appropriate, polite etc. And it is among children that this could cause a problem as they are at an age at which they could, intentionally or unintentionally, cross the line either as a creator or as a receiver of inappropriate messages.

Therefore, it would be good to adhere to general rules of behaviour while online, that is, to behave according to the code of desirable conduct on the Internet, the so-called netiquette [12] that originally stems from Usenet and has now spread onto the entire electronic communication [13] as is the case with Facebook. This social network has whole array of statements, standards, and rules [14] that one should read before creating a personal profile and that one is supposed to adhere to, and particular attention should be paid to setting the level of protection in privacy settings.

Despite of everything, one must always bear in mind that Facebook (much like the rest of the Internet) contains content not appropriate for children (impolite or offensive). The USA tried to solve this problem in 1996 through legal means as a part of the telecommunications reform when the American Congress passed the Communications Decency Act [5], but the Supreme Court overruled this act as unconstitutional, claiming that Internet communication cannot be limited to children only.

IV. METHODOLOGY

The method for collecting data chosen for this study was the survey method since it is the most convenient method for descriptive and causal studies and also because the costs are minimal. The "distribute and collect" survey had 12 questions mostly closed-type questions that were formulated relatively simple and created so as to raise interest of the surveyed students as one should bear in mind that the participants in hand were children. The surveys were filled out in June 2013 by the students from seventh and eighth grades and Ante Kovačić Elementary School in Zlatar was chosen as a sample for the study.

A total of 44 out of 47 seventh-grade students (94 %) filled out the questionnaire as did 64 out of 65 eighth-grade students (98 %). This means that the data regarding the use and familiarity with this social network was collected from 108 out of 112 students (96 %) older than 13 that can be legally registered on Facebook.

The survey questionnaire that the teachers and school associates (school counsellor, school psychologist, librarian) filled out contained 14 questions and was structured similarly to the one given to the students and 31 out of 35 school employees filled it out (89 %).

V. RESULTS AND DISCUSSION

A. *Students and Facebook*

Out of 108 students that took part in the survey, 102 of them have an active Facebook account. As much as 98 per cent (43) of seventh-grade students and 92 per cent (59) of eighth-grade students are Facebook users.

The question "How would you rate your knowledge and usage of Facebook?" had four possible answers and no students chose the answer "none at all". While the eighth-grade students rated their knowledge of Facebook with high marks (36 students chose "excellent", 23 students chose "good"), four seventh-graders said that their knowledge of Facebook is "poor" while a similar portion of students chose "excellent" (19) and "good" (20).

The question "Do you know how to set the privacy settings?" yielded similar answers. All eighth-graders

chose "YES" while only two seventh-graders answered "NO".

The explanation for better familiarity and skills of eighth-grade students lies in the fact that their age allows them to have more experience with social networks as does the fact that the students cover the topic of privacy settings in school library and homeroom classes that deal with information literacy.

As much as 70 per cent (30) of seventh-grade students and 71 per cent (42) of eighth-graders have at least one teacher or other school employees (counsellor, psychologist, librarian) as a Facebook friend. Of those students, 70 per cent of them communicate with their teachers through Facebook (likes, comments, notifications).

The survey showed that students are not afraid that their communication with their teachers could cause any problems with the school board or parents. Some 77 per cent of seventh-grade and 76 per cent of eighth-grade students are not afraid of that scenario (Figure 1).

All friendships between the students covered by this survey and their respective teachers were established solely on the request of students.

When asked "Do teachers lose some of their authority with virtual friendships with students?", 69 students (67,6 %) answered "NO", 17 students (16,7 %) claimed "YES", while 16 students (15,7 %) think that teachers actually gain authority through this (Figure 2). The percentages are similar for students from both grades, and for students who are friends and who are not friends with their teachers. The only exception is that one portion of eight-graders that are friends with their teachers (29 %) believe that the friendship increases the authority of the teacher.

This is a very important piece of information as we carry our teachers in our memory as the living reminder of the time when we were formed as persons. The authority is the first trait that makes good teachers as it gives them credibility and sets them as the firm anchorage for the students [15]. The eighth-graders see this as a sign of maturity from their teachers.

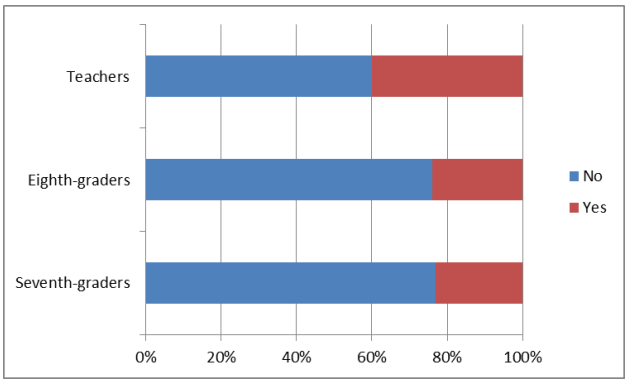

Figure 1. Do you think teacher/student relations could cause problems for teachers/students with the school board or the parents?

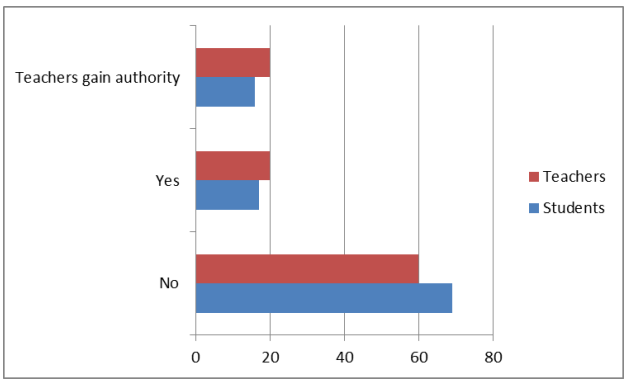

Figure 2. Do teachers lose some of their authority with virtual friendships with students?

When it comes to using Facebook for school needs, the survey included the question "Have you ever used Facebook for education?" The percentage of students who have used it is 65 per cent for seventh-graders and 81 per cent for eighth-graders.

When asked about their school use for Facebook, the students provided the following answers: "I ask my colleagues about my homework, I ask for help regarding homework, I check if I did my homework right, I practice for my tests, I ask other students what I should focus on when studying, we have a class group and we are talking about which high school to choose, Facebook can only be good, I broaden my horizons, we talk about creating posters and preparing presentations, we discuss on how to improve the relations in class, I ask about the things I don't understand, we talk about the way the school is organized when the school has a project day the day after, I ask about what we've covered in school if I was sick, I ask my teachers to explain what I don't understand, I practice my foreign language by talking to my friends from other countries."

B. Teachers and Facebook

The survey was filled out by 31 out of 35 teachers and school associates (school counsellor, psychologist, and librarian) in Ante Kovačić Elementary School, that is, 89 per cent of employees. Only 12 of them have an active Facebook account which means that only 39 % of them are users of this social network. When looking at their age, we may see that 67 per cent of school employees younger than 40 have a Facebook account, while only 21 per cent of employees older than 40 have a Facebook account.

They also had to rate their level of familiarity with Facebook. Half of them rated it as "excellent", 42 per cent as "good" and only one of them rated it as "poor". The teachers younger than 40 rated their skills with Facebook higher than their older colleagues. All school employees said that they know how to set the privacy settings.

Only 42 per cent of school employees that have their profiles on Facebook are Facebook friends with their students regardless of their own age. They established their friendship exclusively when requested by their students and all teachers that are Facebook friends with

their students use it to communicate with them (likes, notifications, and comments).

The question "Do you think communication with your students could cause problems for you with the school board or the parents?" yielded conflicting answers from the teachers. As much as 40 per cent believe there is such a risk (Figure 1). However, 60 per cent of school employees think that they do not lose any authority through this communication, 20 per cent state that they gain some authority and the remaining 20 per cent said that they lose some of their authority (Figure 2). The answers to this question are encouraging if we consider role the teachers have in terms of accepting desirable modes of conduct by their students.

The teachers stated that they use Facebook in communication with their students to answer to their questions regarding school content, homework, tests (only when students are not sure about something) or to answer any questions students may have regarding school-related activities and the organization of classes.

However, no answers were given regarding the teacher/parent(s) or teacher/teacher(s) communication in this survey. Facebook could be in such a way that the teachers send the parents various notifications regarding school activities, organization of classes due when special events are planned in school, the students' obligations, field trips and related issues. Facebook could also be used to connect all teachers within a school, teachers for certain groups of classes or teachers of same classes from neighbouring schools to exchange the preparations for class, discussing classes, and sharing publications or Internet content used, forwarding information regarding professional seminars and exchanging ideas, experiences, advice and suggesting solutions to various problems. All three types of communication (teacher/student(s), teacher/parent(s), teacher(s)/teacher(s)) is best done within closed groups.

When asked "How would you react if you see inappropriate content on your student's profile", the teachers said they would: "talk with the student, warn the student about the inappropriate behaviour, notify the school associates (school counsellor, school psychologist, or school librarian), notify the parents if I were his/her homeroom teacher, indirectly warn the student – so that everyone in class can hear".

VI. CONCLUSION

The chalk and blackboard are slowly becoming a thing of the past, overhead projectors are also not seen in classes very often and mass media are not bad at all if the teachers know how to use them properly.

The study shows that more than two thirds of elementary school students have at least one of their teachers as a Facebook friend. Considering the fact that almost all students have Facebook accounts, this social network represents a convenient medium through which the teachers could make learning fun but also make the process of understanding the teaching content faster and easier: from posting useful and additional materials regarding the lesson covered in class, reminding the students about their homework and other school obligations, discussing the topics from homeroom classes to working on class, school, or even inter-school/international projects or notifying the students about the results of their exams – of course, all through closed groups or class pages. However, the teachers very seldom utilize the potential of this social network, although with some rare exceptions [16, 17]. This is also reflected in the fact that less than one half of teachers that have Facebook accounts have students as their Facebook friends even though there is no obstacle against that in Croatia.

After all, the study shows that both the teachers and the students do not think that their mutual communication through Facebook could get them into trouble with the school board or the parents. The percentage of students who think this way is 77 %, while 60 % teachers feel the same way, and it would be good for some rules of conduct in teacher/student relationship to be established. Adults are accustomed to act according to certain predetermined patterns, and written recommendations or rules would create the space for the teachers to feel safer in their communication with students on Facebook and/or would increase the number of teachers that have their students as Facebook friends. More teachers in this communication would pave the way towards new ideas for using Facebook in class. Creativity can only happen where there is enough freedom within certain boundaries.

When it comes to authority, the study shows that Facebook friendship and communication between teachers and their students does not diminish the authority of the teacher. This is particularly important as the job of a teacher is public and they have to pay attention to their general and professional competence and their authority and general personal profile at all times. The authority is based on reciprocity and mutual respect and love and this is the crucial aspect of every humane [18] relationship, especially in education. In this respect, the teachers have to be careful to avoid any superficial, confusing, and especially inappropriate communication. The teachers have to be aware that their every post (texts, photos, video clips) can instantly become visible to their students. However, one could set the "custom" privacy settings so that the students cannot see any of the posts made by the teacher in question. The alternative is to create two profiles: the official one (through which the teachers communicate with their students) and the private one. However, this is not in accordance with the Statement of Rights and Responsibilities [19] that stipulates that you must not create more than one personal account. When it comes to communication through private messages, the teachers should be as formal as possible and not erase the messages or conversation from their Inbox.

There is no doubt that social networks represent an important means of communication, but the fact remains that the legislature is not keeping up with this, or to put things mildly, it has not done enough. It is hard to believe that we might get any kind of regulations or recommendations for teacher/students Facebook interaction in near future here in Croatia, considering that the media were mentioned only six times in the National

Youth Action Program from 2002, and only three times in the National Youth Action Program from 2009 to 2013, while the draft of the Strategy for Education, Science and Technology from 2013 does not even mention the media, media literacy, or the media culture [20] even though the media will be the school of the future [21] and even though the 2007/65/EC and 2010/13/EU directives require that EU member countries include media literacy and Media Education into their systems of education [22]. As long the situation is like this, it is up teachers to choose whether or not to befriend their students on Facebook.

Until the relevant institutions create regulations or recommendations for teacher/students Facebook relations, a possible solution for each school is to bring their own social media policy which would clarify that friendships between teachers and students are allowed and that it is up to the teachers to choose whether or not to befriend their students on Facebook, which means the teachers are those who accept and not those who send friend requests. The teachers can show their proactivity through closed groups or class pages in which friendship with students is not a condition for communication.

Since the teachers know almost all the students in their schools and know which class they attend (if they are uncertain, they can use the E-Matrix to check [23]), the social media policy should also contain a statement which clearly indicates that the teachers are not allowed to accept friend requests from the students under the age of 13, accept such students into groups or create class pages for students under the stated age.

The policy should also regulate the procedure in case of inappropriate behaviour from one of the students, which can be a warning, either public or via private Inbox message, with the request that the student in question immediately deletes the inappropriate content, or the notification for the homeroom teacher, school counsellor or school psychologist. Inappropriate communication can stem from the fact that the students of today are media literate, but only in the technological sense and not in the critical sense [20].

In the absence of Media Education, the teachers without adequate training are forced to teach children about the media. This void could be filled by IT teachers or the school librarians who could talk about the critical use of Facebook as a part of their Information literacy programme.

The school social media policies should open up the possibility of using social networks in classes through class pages or closed groups.

In addition, the social media policy should be used to emphasize that the teachers, due to their role in the intellectual, moral, and social development of the children, are held responsible for the content published on their social networks and should conduct themselves on Facebook the way they behave in class with students, or in their life outside of school, which primarily means avoiding discussing school and work and mentioning the students in their posts on Facebook.

Abstract - Computer security, school security policy and school computers usability should be important for all school computers and network resources users. But instead of implementing security policy, users often unintentionally compromise computer functionality and security out of ignorance or negligence. Since Windows is the default operating system in the majority of Croatian schools, students often have to use computers in the role of administrator. Bearing in mind the multitude of new technological solutions and continual changes which happen in this industry, this paper tries to provide an overview of software solutions for IT administrators of school computers, which are also applicable in libraries, colleges, universities and other public places which use computers with Windows OS.

Keywords: Classroom, Security, Windows, Policy.

I. INTRODUCTION

Windows is the *de facto* standard operating system for desktop computers in Croatian schools. It is in IT teacher's best interest to keep the maintainance of computers as simple as possible and to require as little interventions as necesarry during classes. Because of that, and due to ignorance or negligence, the configurations in computer classrooms are mostly intended for the users in the administrator role, regardless of who is logged in: a teacher or a student. When students are logged in as administrators, they have the freedom to do whatever they want. As they are curious by nature, they like to explore on their own to see what they can change on the computer or what they can access and make all sorts of mischief: change the desktop backgrounds and screen savers, delete files from the computer, install programs and games and use the installations to add different toolbars in the web browser. For children who have an advanced knowledge of computers, possible limitations and restrictions represent a kind of challenge. In this context, we will show some guidelines for increasing the operational security in computer classrooms where Windows OS is installed, but these guidelines are partially applicable to other operating systems as well.

II. OPERATIONAL AND PROGRAM SECURITY

"Operational security includes two aspects of computer security; the first represents the ways of increasing the awareness of possible actions among the potential victims, while the second represents the ways in which computer criminals can be prevented from committing these acts". [1] It should be made clear to the employees that security is threatened and that everyone shares the risk and the responsibility. "The only way in which operational security can function completely is by implementing operational security in the programs of physical insurance as well as the personnel security and communications within an organization. In fact, the operational security is primarily used as an aid in making those security programs as productive as possible." [1]. This could be argued. Namely, the authors of this paper believes that operational security, apart from the education of users, is the most important element of the security system of an organization, as well as of a person as an individual or as a part of an organizational structure. However, it is perfectly obvious that an organization can never stop searching for vulnerable spots, breaches of security and methods of prevention, and can never stop discovering successful breach attempts, all this along with continual training of employees and users. [1]

"There are two types of systems: open and closed ones. If you use open source software you can analyze and inspect the code of security mechanisms and practically be sure that it will do what it is designed to do and nothing more. That means that you can check it for existence of trapdoors and backdoors, and in the end be sure that it will not send any data to manufacturer's servers (it is really not important what it sends, it is important whether it sends the data without your permission – this is how your privacy gets violated). If you use closed source software, the only thing that can help are patches and service packs, but you will not have a guarantee of the data leek (except for the manufacturer's promise)."[2] A recent discovery in the computer industry is the "cloud computing", which is [3] "a technology that keeps up data and its application by using the internet and central remote servers". According to Harauz and Kaufman [4] "we have the ability to utilize scalable, distributed computing environments within the confines of the Internet." Regarding data, i.e. data security, the safety of these systems is questionable: "So let's pause to consider the alter ego of the cloud as panacea: the cloud as a platform for malice. How bad could it get? [5]" If we look at the system administrator's side, it is an excellent solution, because the other side takes care of the security, integrity and maintenance of the computer. There are global players, and in Croatia a local ISP, "Croatian Telecom", started offering their Cloud computing service at the end of May 2013, where the user is given the right to use their computer. The user is shown a desktop with the applications that the ISP offers and the user immediately has a functional computer without the necessity to maintain it or worry about its security. [6]

One of the fundamental postulates of operational security is to create a user account that doesn't have administrative authorities (limited user). In Unix-like operating systems that is the only possibility, and completely normal, but in Windows OS it is an option that makes the daily use very complicated. Very often, the users change the settings of the operating system without even being aware of it. Any need for intervention or

repairing from the administrator, usually an IT teacher, is a waste of valuable time during classes or leads to unpaid working hours of the IT teacher in the role of system administrator. Considering the installed OS – Windows, the computers in Croatian schools often have inadequate hardware capacity. Apart from that, it is a fact that Windows OS works more and more slowly as more time passes from the day of the installation (problem with Windows Registry). Altogether, computers are slow, and become slower with time, which increases the amount of time that needs to be spent on them. In the modern world, which is turbulent and accelerated, it is important to minimize the amount of time necessary for computer maintenance, i.e. to strive towards minimizing that time by automatization. There are on average 19 computers in Croatian computer classrooms [7]. Based on that, we can approximately calculate the necessary time for their minimal maintenance, providing that there are no unforeseen situations. It is necessary to update the OS monthly, which takes at least ten minutes, depending on the speed of the computer, speed of the administrator and the internet connection. It equals a total of four classes a month, if we don't count the updating of user programs, control programs and additional programs; such as Java, Flash, Shockwave, programs for pdf files, video and audio files, etc., and sometimes the updating of the latest versions of antivirus programs. Web browsers are the favorite targets of attack on computers. Therefore it is important that they, as well as their add-ons and plugins, are independently updated. Web browsers such as Firefox, Google Chrome and Opera can be independently updated, but they require administrative authorities. Internet Explorer usually requires an intervention from the administrator during the installation of a newer version.

Servers should be equipped with smart UPS in case of an unexpected electricity loss and voltage stabilization, in order to keep the public services alive, and in order to protect the hardware from damage with controlled shutdown, in case the power supply loss lasts longer. It is desirable to protect the BIOS of personal computers with a password, because although the password is easy to cancel, it is necessary to open the PC case, which slows down and discourages the potential attacker. Safety copies of the data which is important for the school should be kept on a dislocated medium. The likelihood of a flood in schools is minimal, but the likelihood of a fire is greater. Permanent copies should be made at least once a year at the end of every school year. Safety copies of the data should be made depending on the importance and the amount of the generated information, and for critical data, safety copies should be made automatically, in real time.

III. Access to Operational Security

There are two basic types of computer classrooms in Croatian schools: thin client with or without multiseat technology and PC/laptop based classrooms. In a thin client approach, one or more powerful servers provide the central intelligence and control center for the security system. The end-user terminals display the graphical interface and process input from the mouse and keyboard. Most of the intensive processing happens on the server(s). It is also possible to start up the OS of the computer through the network using the Open Thin Client OS (http://openthinclient.org/).

Multiseat systems resemble thin-client systems with client interfaces (mouse, keyboard and monitor) attached directly to the computer that does the processing. That computer runs a program or operating system capable of managing multiple user sessions at the same time. Userful Multiplier and Windows Multipoint Server 2012 are two programs that fall into this category. PCs are computers that only one user can work on at a certain point – the one that is logged in to the operating system at that point. Locking the computers (which we will explain below) has its advantages:

a) there is less likelihood that a computer will pick up a virus or some other malware,
b) the administration of the computers is easier, (which leaves more time for other things),
c) there is less disk fragmentation due to constant installation/uninstallation of applications,
d) there are fewer (non-standard) applications which represent a safety hazard.

We will suggest several ways in which a satisfactory level of OS computer security can be achieved.

A. Group Policies for Various User Groups

These group policies reinforced with passwords make a good start. For example, administrators have all the rights (installation/uninstallation of programs; adjusting, adding and removing hardware), while regular users have the right to start an internet browser, office applications, etc. This approach has its limitations, because it is necessary to create several user groups and more access levels (for example, student, teacher, administrator), and these groups need to be administrated. Nevertheless, using group policies is much more efficient if the computers are cloned, or even better, if a domain group policy is used so it can be easily controlled by the domain controller.

B. Lockdown Software

This type of program enables the administrator to determine which devices users can access, which programs they can start, which folders they can see and access (for example, hiding the control panel and certain programs). These programs are not demanding, i.e., they don't require a large amount of knowledge or a centralized server. Depending on the computer classroom configuration and the program options, the administrator can control all these setting from one central computer. Disk protection programs that automatically delete all changes on the disk upon the next computer start up, user log out, or some other setting of the program, also fall into this group. Using this approach, a lot of people will think, "Why bother using antivirus protection?" But bearing in mind the increasing ingenuity of malware programmers and the fact that viruses keep getting more and more complicated and hard to discover, installing an AV solution for a greater computer safety is still recommended. Also, by updating, you don't only install patches, but also newer versions of programs (for example, Internet Explorer), as well as various improvements. Although the installation of an antivirus solution decreases the total available performance of the computer (which is sometimes extremely important), it is recommended to have an active and updated antivirus software. Each computer should be adjusted so that it

automatically downloads virus definitions. These are some software solutions for locking the settings: Fortres Grand Fortres 101, Deepfreze, Faraonics WINselect, KioWare, Rollback RX, Faraonics DeepFreeze and Centaurion Technologies DriveShield.

Deskman program [8] has one button to lock down workstations. It has the kiosk mode which tightly secures desktops and locks computers and it also has the ability to set up custom restrictions. It can freeze an application to create a safe environment and stop unwanted applications.

Deep Freeze [9] allows you to restore a PC on every restart. It has a virtual drive, an on/off protection switch so if administrators need to make any updates on a deepfreeze workstation, they have to turn off the deep freeze protection which requires a system restart.

When compared to above programs, Drive Vaccine [10] does not need to be turned off in order for any updates or software installations to be made, and protects the Master Boot record. Below we present a table with an overview of possibilities of particular programs:

TABLE 1. COMPARISON OF COMPUTER LOCK DOWN AND SYSTEM RESTORE PROGRAMS

Type of program	Name	License	Limitations / requirements	Publisher(URL)
System restore or disk protection	Deep Freeze	Commercial	Linux version only supports the SuSE Linux Enterprise Desktop, 10% free hard drive space	Faronics(1)
	Fortres Grand Clean Slate	Commercial	There is no version for Windows 8 and Linux	Fortres Grand(2)
	RollBack Rx	Commercial	There is no Linux version	Horizon DataSys(3)
	Drive Vaccine	Commercial	There is no Linux version	Horizon DataSys(4)
	Returnil System Safe 2011	Free for non-commercial, personal home use	Does not work on Windows 8, does not have Linux version	Returnil Virtual System(5)
Lockdown PC	Toolwiz Time Freeze	Freeware	Does not support Linux	Toolwiz(6)
	HDGuard	Commercial	Does not support Linux	RDT – Global(7)
	Faraonics WINselect	Commercial	Does not support Linux	Faraonics(8)
	SiteKiosk 8	Commercial	Does not support Linux	Provisio(9)
Application Launch Restriction	Windows 7 UAC	Commercial	Requires Windows 7	Microsoft

If a school has a "server-client" logical network configuration, the administrators can control permissions from one computer. In case of a peer-to-peer network, the best solution is to clone the adjusted computer. When you clone the Windows OS (with the exception of the sysprep option for Windows 7), it is almost always necessary to have the same or quite similar (chipset) configurations of the cloned computers because of HAL, which is considered to be the driver for the motherboard and allows instructions from higher level computer languages to communicate with lower level components, but prevents direct access to the hardware. [11]

C. VHD (Virtual Hard Disk)

A virtual hard disk is a file that encapsulates a hard disk image. [12] It may contain what is found on a physical HDD, such as disk partitions and a file system, which in turn can contain files and folders. It is typically used as the hard disk of a virtual machine (VMware, Oracle VM VirtualBox, Windows Virtual PC, Microsoft Hyper-V Server). VHD contains the disk image which is loaded into the memory of the computer and all changes can later reflect on the OS itself (or not, depending on the options), so a layer is created between the computer resources and the program itself and there is no danger of compromising the security and integrity of the OS which is installed on the physical disk. It is recommended to use the native Windows 7 boot because the virtualization program still puts a burden on the computer.

D. Live CD/DVD

A live CD or a live DVD is a completely bootable computer operating system which boots from a CD, DVD or a USB and runs in the computer's memory. Live USB flash drives have the ability to write changes back to their bootable medium.

IV. WINDOWS SPECIFIC ISSUES

Windows XP is an incredibly resilient OS and is used by the majority of teachers in schools, but for which the support expired on April 8, 2014. Usually, the computers have a version of Windows already pre-installed on them, so the installation of a newer version would either be a license violation, or the right to an OS upgrade would need to be bought. **This is where the responsible government department comes in and mostly makes (pays for) an agreement with Microsoft that allows "a free" OS upgrade for the computers that already have a license, which is renewed every 3 years.** However, the Windows OS upgrade often does not end adequately, and it is necessary to reinstall the entire OS and all the required program support. But using outdated computers [7] that aren't capable of **running** newer OS versions eliminates any possibility for change within the Windows domain, which is notoriously demanding regarding hardware. Also, OS upgrade is a rather time-consuming job for an IT teacher, even if it is just for one computer, so it's normal that they are usually not thrilled about doing it. Alternatively, a version of Linux OS could be installed, but that brings many other problems (mostly subjective, due to user habits, and to a smaller extent objective), that could all be summed up as lack of time and/or desire to change.

As a result of the agreement that was signed between the Department of Science, Education and Sports and the Microsoft Company in June 2011, about licensing Microsoft software for primary and secondary schools, as well as for higher education institutions and public science institutes - „Microsoft Campus and School/Academic Agreement", all primary and secondary schools encompassed by the agreement have acquired the right to use licensed Microsoft software that can be downloaded from the web page: https://msdc.skole.hr/. Also, in November 2013, the Minister of Science, Education and Sports Željko Jovanović, Ph.D. and the Chief Executive

Officer of Microsoft, Steve Ballmer, signed the "Education Transformation Agreement" (ETA) with the aim to improve the Croatian education system [13] which, among other things, includes free use of Office 365 system for about 550 thousand students, college students, teachers and professors. There is also an interesting possibility for the IT teachers who have started using Windows 7 (but available and limited only for the Enterprise and Ultimate versions [14]): creating VHD disks and starting the computers from those disks. VHD is a format in which the disk is virtual. It contains everything that is on the hard disk of the computer (partitions and files) and it is used as the physical disk of a virtual computer. It enables the computer to set it up and to boot from the OS that is stored on it. This technically demanding principle is made simpler for teachers by selfless enthusiasts: Mark Minasi and his "Steadier State" [15], and the Finnish programmer Sami Laiho and his tool "Wioski" [16]. Wioski is a "self-healing kiosk-computer running Windows 7/8". It is a "wrapper that surrounds your own WIM-file of Windows 7/8 OS installing it on a VHD-file and using a differencing disk for writing incremental data." [16] Steadier State "freezes the computer as an image and creates a snapshot of the current activity as a virtual C:\. Restarting gives the option to roll back or keep the new snapshot." [15]

Windows 8 shows great functionality in the form of "refresh" and "reset" functions. [17] "Refresh" preserves user settings, user data, and applications bought through the Windows store. Everything else is removed and restored to defaults. Reset purges all applications and data, and reinstalls the operating system reverting it to a brand new fresh installation which requires reentering a license key and performing initial setup when completed. Programs that check whether a particular program has a newer version (such as Secunia PSI) can be helpful with computer maintenance. Another interesting possibility is using one program to start the installation of many others, such as InstallPad (http://installpad.philisoft.com/), where we first need to enter the URL addresses from which the instalation will be downloaded, and then the program downloads and installs them on the computer on its own. It is even better to visit Ninite.com (http://ninite.com/) and choose all the programs that need to be installed from the web page, and then they are downloaded and installed through one installer on their own.

Legal aspect of Windows licenses

When it comes to creating images, bear in mind that Microsoft Volume Licensing programs are not a source of full license for the Windows operating system. These programs offer only upgrade licenses for the Windows desktop PC. [18] Volume License media can be used to deploy software only to licensed desktop PCs. A customer cannot acquire an initial or “full” Windows desktop PC license through any Microsoft Volume Licensing program. The Windows desktop PC operating system upgrade license is for upgrades only. [18]

Reimaging is permitted if the copies made from the Volume Licensing media are identical to the originally licensed product. Windows Enterprise is not available outside the Volume Licensing programs and, therefore, is not eligible for reimaging. [19] Customers can use these copies from Microsoft media only if they are the same product and version, contain the same components, and are in the same language. [19] Reimaging using Volume Licensing full version media requires that customers have licensed the Windows desktop operating system either preinstalled through the OEM or as an FPP retail product. [19] A licensed version of Windows 7 OS is also required for the Windows upgrade license through Volume Licensing, where "customers must first acquire a full license for a qualifying operating system preinstalled by an OEM". [18] Bear in mind that one cannot actually upgrade from Windows XP to Windows 7. [20]

Windows Deployment

The most popular open source deployment solutions nowadays are Clonezilla and FOG. Clonezillla has an archaic text-based interface and it is not recommended for novice users while FOG provides a web-based interface accessible from any computer on the network. It also has the ability to deploy images from mobile devices. [21] If an administrator has to deploy images across the network, setting up a dedicated cloning server is required. "For Clonezilla SE, this means setting up a Diskless Remote Boot in Linux (DRBL) server by installing it on top of a Debian or CentOS server." [21] Another option (for small networks) is to use the DRBL live CD to convert the machine into a temporary server. If all of the machines for imaging are not on the network, Clonezilla is a must, because FOG can clone only from an imaging server. FOG, by default, requires hosts to be registered (recording a unique MAC address) before imaging and before deployment (it can be overridden with an enabled Capone plug-in [22]). Clonezilla doesn’t require registering a host.

When it comes to installation, FOG "installation script creates the components required for an imaging server on top of a standard LAMP server." [21] The "FOG server is designed to integrate with existing network infrastructure such as DHCP and DNS servers, although it can also set these up on its own." [21] If an existing DHCP server is used, PXE traffic must be forwarded to the FOG server and the firewall must be configured to pass traffic to the server. The FOG service has additional features and can "schedule tasks, such as deploying images, installing and managing printers, tracking access to cloned machines, powering up a computer remotely using Wake-On-LAN, and installing applications remotely via a feature called snap-ins." [21] "With snap-ins you can directly push the executable installer for a simple application to a Windows computer." [21] Snap-ins can also be used for pushing software updates to client computers. FOG's menu has additional features and "offers options to wipe a disk, restore deleted files, scan a disk for bad blocks, and run a virus scan using ClamAV." [21]

If the person in charge of computer maintenance decides to use the Windows server, they have the technology called WDS (Windows Deployment Service) at their disposal. WDS is included as a Server Role in all 32-bit and 64-bit versions of Windows Server 2008. Deployment must be performed with the "sysprep tool" which is included in every instance of Windows 7 and Windows 8. The machine must be sysprepped (all system-specific information from an installed Windows image is removed; including the computer security identifier (SID)) and then the image can be deployed using WDS. There is no limit to the number of times that the Sysprep command can run on a computer, but the clock for Windows Product Activation begins its countdown the first time Windows starts. Sysprep/generalize command can be used to reset the Windows Product Activation a maximum of three

times. If the Sysprep command needs to be run multiple times on a single computer you have to use the SkipRearm setting in the Microsoft-Windows-Security-Licensing-SPP component to postpone resetting the activation clock. [23] There is probably no need to have outside experts perform the deployment in schools (as far as students are concerned), because according to article 12, paragraph 11 [24], students' documents are only kept until the end of each school year. Below we present a table with some solutions for Windows deployment.

TABLE 2. POSSIBLE SOLUTIONS FOR WINDOWS DEPLOYMENT

Name[URL]	License	Specific requirements
Smart Deploy[1]	Commercial	It has a platform pack (PC drivers for different vendors)
Fog project[2]	Free	**A**pache, **M**ySQL, **P**HP but they are automatically downloaded by the software
Clonezilla[3]	Free	-
System Center 2012 R2 Configuration Manager[4]	Commercial	Active Directory schema must be extended, SQL Server is required, and multiple site server roles have to be configured.
Symantec Altiris Deployment Solution[5]	Commercial	-

V. RECOMMENDATIONS FOR THE IMPROVEMENT OF SCHOOL COMPUTERS SECURITY

Administrators should lock the rooms where computers are stored, and also set up authorized video surveillance. If, despite the fact that all deadlines have expired, security policy still doesn't exist, it should be imposed on schools by the responsible government department. It must be introduced to all school employees who should be given a test to make sure they are familiarized with the security policy, under the threat of having their salary reduced until they have successfully passed it. After that, all other users such as outside collaborators and students should be familiarized with the policy. Users of public computers should sign an agreement stating they will use the computers in conformity with the security policy. This could be achieved by having a simple application appear when the computer starts, with the following message: "By using this computer you accept the terms of use that are in accordance with the institution's regulations and the ISP." The application could be more complex so that before using the computer, the user must answer correctly three randomly picked questions about the security policy of the institution and the ISP. Apart from the digital message on the computers, detailed regulations should be displayed in the classroom so that everyone could read them. Regulations should include the ways the equipment and resources can be used, as well as the proper behavior. A few guidelines that should be listed:

1) Who has the right to use the computers? (for example, the age limit for using the computers, chat rooms and social networks as well as a list of web pages allowed for persons under 18)
2) Strictly forbidden actions, i.e., a ban against disrupting the physical integrity (against slamming, hitting and breaking the computers, equipment and the cables), as well as a ban against moving the equipment (mouse, keyboard, printer…)
3) For what purposes the computers can be used and a ban against sharing files and illegal distribution of copyright protected material.
4) A ban against changing the settings of the computer's OS (downloading illegal programs and malware, using BitTorrents, visiting and downloading pedophile and porn material), the possibility or impossibility to print, save files to various media, run external programs or download programs.
5) Disciplinary actions for those who don't abide by the previously stated rules (the possibility of charging for damage, reporting to authorities, banning against further access and use of the computers and equipment). Public computer labs should "protect themselves from possible lawsuits by educating their staff, clients, and students about copyright law." "Users need to be educated that installing unlicensed software is a prohibited activity." [25]

As more and more devices (PDAs, mobile phones, tablets) are connected to the internet, communication security becomes more important. It is necessary to design and configure a network according to the rules of the trade – it is not a layman's job and it should be given over to an outside company or CARNet, in case the IT teacher is not competent enough. Within the domain of operational security, if Windows are used, then XP should be abandoned and upgraded at least to Windows 7 and also a functional solution should be implemented for locking the settings and/or restoring the computer to a desired state. We recommend the VHD technology and its possibilities, since it is available within Windows, but a live CD/USB of a Linux version is not a restrictive solution since the school curriculum doesn't mandate the platform/software, but only the topics that have to be covered. If it is financially possible, the cloud, i.e. a virtual desktop is an even simpler solution. If the computers are too weak/old and the Windows 7 or newer versions cannot be installed on them, then the options of replacing the computers with newer ones or installing a newer version of Linux distribution should be considered, or the PC computers should be converted into clients with the acquisition of a strong Windows server. Concerning the Windows deployment, it is necessary to keep in mind the Windows licenses, and in practice we recommend a version of Windows server and Windows deployment service, considering that their use in schools is free of charge, or perhaps open source programs such as FOG and/or Clonezilla. "Clonezilla SE makes the most sense for networks with clients that don't require much administration after being imaged, such as those in Internet cafes, libraries, and school labs." [21] If the machines aren't connected to a network, Clonezilla must be used. Taking care of computer security also means creating a set of rules for using the computer equipment, and taking care of all aspects of security must never stop.

VI. CONCLUSION

Nowadays, the concern for security on the internet, on the computer, on social networks and in everyday life is

becoming more and more important. Since more and more devices are being connected to networks, and technology and mobile devices are becoming more available and have become a constituent part of everyday life, we should think hard about introducing the topic of IT security and computer security into our curriculums. In the primary school practices, there is very little regard for computer security. In the authors' opinion, this will not change until a very serious incident occurs in an institution; until then, very little attention and time will be spent on it. It appears that it all comes down to the IT teacher, i.e., to how much will and knowledge he/she can invest in the students' education and the computer classroom. Investing time in some solutions for locking the settings, deleting the changes made on the computer, live distribution, or a cloud solution are some viable options for every person, but it all greatly depends on financial capacity, responsibility and concern for the confidentiality of information, and on personal attitude, knowledge and skills. Regardless of the path, there are two crucial choices: a) whether to use Windows or not and b) whether to lock the settings or give complete freedom (all users as administrators)? Things are well as long as the responsible government department is making agreements with Microsoft and gives Windows products for teachers to use "free of charge", but what can be done once there is no more money or once the politics instruct all state institutions to switch to open code for some reason? In that case, the only legal and correct solution is to switch to an "alternative", free of charge and much safer OS (for example Linux). This way every line of the code would be under control and we would be sure that a certain part of the code is working the way it was meant to. Concerning the question of whether or not to lock the settings or give complete freedom to users, the authors believe that it is more productive to give almost complete freedom to users, i.e., to use some sort of technology for deleting the changes, i.e., for restoring all the settings, even if that means that computers should often be cloned. Further research is necessary in the field of computer security, such as: what is the level of computer security in Croatian institutions, and how much do the IT teachers in schools (especially the ones who play the role of system administrators) know about computer security and maintenance which include broad topics such as security, hardware, software, networks and application of IT technology in class, HCI and creating digital educational material. Finally, how much do the students, whom the schools and teachers are here for, know about IT and computer security and do the perceived shortcomings in the system significantly influence the knowledge they acquire through informal channels?

Elementary school students using Facebook: A case study of Croatian elementary school ban Josip Jelačić

Martina Draženović
Ban Josip Jelačić elementary school, Zagreb, Croatia
martina.drazenovic@gmail.com

Abstract - After the survey was conducted two years ago in this particular school, I determined certain difficulties regarding usage of Facebook among our students. During the last two years I addressed the problem and begun giving social networking lectures to students, their parents and teachers, later I have incorporated social network workshops in curriculum and especially emphasized the importance of Netiquette. This paper will deal with the status of Facebook in Croatian elementary school ban Josip Jelačić, it will point out the problems that students had and still have, and it will show what has changed during this short period of time.

I. INTRODUCTION

The usage of Facebook can start from thirteen years of age, but it has made clear by the students themselves that it can start earlier than that. During my time in this school, many students younger than thirteen approached me with some kind of problem which happened to them while they were using Facebook. Since they do not fulfill required age limit, I instructed them to tell their parents and, if required, to inform the police. I held presentations and conducted workshops with students, their parents and colleagues from my school. It is very important to emphasize that during these workshops we never logged in Facebook nor visited the Facebook page. Although challenged with this situation, we managed to execute these workshops successfully.

A. Facebook in school

According to "Ordinance on the treatment of teaching staff in schools in undertaking measures of preserving student rights and report each of these rights violation to authorities" [1] the school is required:

a) To inform students and parents about the rules of safe use of modern technologies, particularly mobile phones and the Internet,

b) To inform students and parents about the consequences of inappropriate communication on social networks (insulting, embarrassing, public lynching, photos, videos, etc.) and on the conduct of school facilities concerning information about violence in the electronic media in accordance with the Protocol of procedure in cases of violence among children and youth. [2]

This means that even though Facebook cannot be used until thirteen years of age, the school is required to introduce students and their parents to social networking.

B. Present needs

The students need to be prepared to use social networks before they turn thirteen. Numerous cases of abusing via Facebook prove this thesis. Teachers should be able to help their students (delete student's Facebook profile or to help them secure it better). For the present time, this is impossible because Facebook states that no person younger than the age of thirteen can create an account (and it is considered that no one under this age has Facebook account). There aren't any laws in Croatia which would help teachers bypass this situation if in deed their students were younger than thirteen and would want to erase their account or secure it better. The only thing the teachers can do (if the student is below 13 years of age) is to teach about Facebook via presentation or conversation.

II. THE RESEARCH

A. Past research

During 2012, we had an outbreak of Facebook incidents in our school. We weren't familiar with the law regarding using Internet in school (later we found out that there is no such law which would apply to school) and since we haven't had any incidents before, we had to learn how to deal with this situation. This situation led us to reexamine our school policies and act accordingly. As an informatics teacher, I felt obligated to react and try to lower the risks. Therefore, I researched the problem and provided guidelines in a manner of lectures and workshops to students, their parent and fellow colleagues. From these guidelines, my school modified its policy introducing restrictions concerning virtual behavior and cellphone usage on school territory. The research has been conducted in 2012 amongst students who take informatics classes and are older than 13 years of age. Total of 97 students participated in the research. According to the research, 73% of surveyed students were using Facebook which indicates the popularity of Facebook in our school as well as that all 100% of the students were familiar with Facebook. 69% stated that they use Facebook more than an hour a day which also indicates the importance of Facebook in their lives. 39% of surveyed students stated that they had received threatening messages via Facebook and 12% stated that they do not know every person they added as a friend on Facebook. 21% of them stated that they didn't share their account information with their

parents and 77% have computer in their own room which indicates the lack of adult supervision while online. [3]

B. Specific problems

Since 2012 we had encountered some specific problems which concerned our students. Students experienced hacked Facebook accounts and cyber-bulling (insults, threats, groups and pages created strictly to offend and mock them). Later, they realized that some of their behavior while online can endanger them; leaving an open profile, sharing their detailed personal information, taking photos of themselves and their family, liking various groups and pages which promote violence and sharing their critical thoughts about the community they live in. Also, I discovered frustration with collecting "likes" on Facebook. Many of my students said that it is very important to them to collect as many "likes" as possible which would indicate the popularity of the individual in school. Some of them admitted that they added strangers as their friends on Facebook because the more friends they had on Facebook the more they feel popular in "real life".

C. Workshops

Since our informatics textbooks don't cover social networking [5], I was forced to improvise in a way that I incorporated social network workshops in curriculum. I divided workshops into 5 parts:

1. "Introduction to social networking" – here we covered general information about social networking (variety of social networks, their popularity in the world and user agreements).
2. "Benefits of social networking" – here we covered positive sides of social networking, how to use social networks to help their community, reach to other people and how to use them for future business possibilities.
3. "Dangers of using social networks" – we discussed various hurtful situations which might happen as a direct result of incautious behavior while online. This is the part where we spent most of our time discovering and identifying various risks and how to avoid them. Students gave their personal input on the negative experiences they had while using Facebook and how they dealt with it.
4. "Laws" – we discussed laws which would apply while an individual incautiously uses Internet. Laws are divided into two groups, criminal [9] and misdemeanor [10]. We identified the connection between certain behavior and the gravity of penalty. This part also included student's understanding of law threw their parent's eyes since their parents are held accountable for their child's behavior until they turn 14 years of age.
5. "Netiquette" – we discussed Netiquette and practiced proper virtual communication. [11]

After finishing these 5 parts we decided to raise awareness towards using social networks and distribute this information to our community. The students built web-page about dangers of Facebook, they made posters and presentations. We published the link to their web-page and presentations on school's official website and displayed posters around school property. Parents also had a role in raising awareness. After initial parent-teacher conference, during which they were introduced to social networking and potential dangers of using them, they demanded to stay updated, they organized themselves (if something happens they would all know about it and try to reduce the damage) and they moved computers from their children's rooms where they would be able to supervise their child while online. Parents commended the initiative and admitted that they had poor knowledge of social networking as well as what might happen to their children and to them. I introduced my colleagues into social networking and while some of them had already been using Facebook to distribute school assignments and news updates to students, the others had poor knowledge about social networks. My colleagues welcomed the initiative and collaboration amongst students, their parents and themselves. [4]

D. The students

Total of 120 students voluntarily completed anonymous survey. They had been given 26 questions regarding Facebook. The goal of this research is to see how the students are contemplating Facebook now in comparison from two years ago. Some of the students are the same, but most of them left the school since 2012. I have highlighted some of the questions which are the same in both researches:

1. Are you a Facebook user?

2. Are you familiar with Facebook?

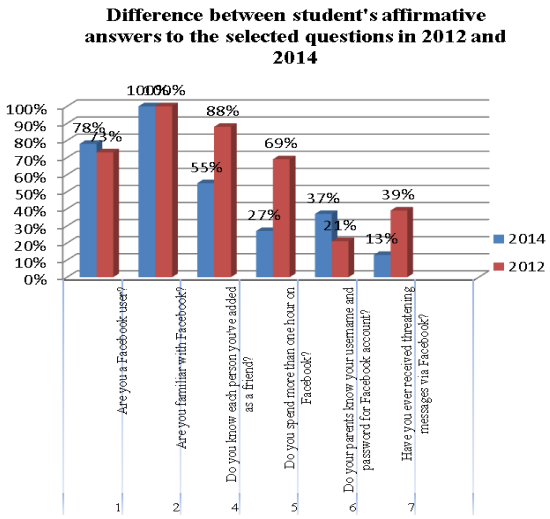
3. Where is your computer located in the house?

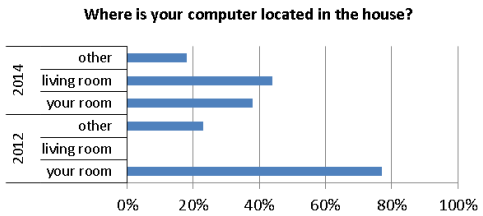
4. Do you know each person you've added as a friend?

5. Do you spend more than one hour on Facebook?

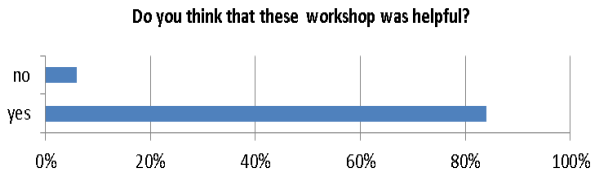
6. Do your parents know your username and password for Facebook account?

7. Have you ever received threatening messages via Facebook?





Students who were surveyed in 2014 were asked additional questions regarding workshops. The question „Do you think that the workshops were helpful?“ was crucial for the workshops because it tells me whether I should reexamine these workshops, change them or simply cancel them.



E. The parents

The parents were given surveys to voluntary fill out after parent – teacher conferences. They were asked to anonymously answer several questions regarding dangers of using social networking and workshops. Total of 33 parents were surveyed. 32 out of 33 parents think that workshops were very useful and that I should continue conducting them. 13 out of 33 parents are using Facebook.

F. The results

The results regarding student's surveys:

1. 5% more students are Facebook users.

2. All of the students are familiar with Facebook.

3. In 2012, 69% of students spent more than an hour on Facebook while in 2014 that number decreased to 27% which indicates the fall of Facebook popularity in our school.

4. In 2014, 16% more students shared their account information with their parents.

5. In 2012, 39% students received threatening messages whilst now that number is 13%.

In just two years a serious differences can be seen with students using Facebook. According to this research, popularity of Facebook is starting to decline, students spend less time on Facebook and receiving threatening messages had also declined. In 2012 almost 80% of students had computer in their room, whilst now that number is below 40%. 84% of the students think that social network workshops I conducted helped them. Parents asked me to give presentations more often to them and to their children, to keep emphasizing the dangers of using social networking and to keep updating them.

III. CONLUSION

This research indicates that Facebook isn't as popular among students as it was two years ago, it indicates that students now have more supervision at home while online and it shows decrement in negligence while using Facebook.

Evaluation Study and Results of Intelligent Pedagogical Agent-led Learning Scenarios in a Virtual World

M. Soliman*, and C. Guetl*,**
* Graz University of Technology/IICM, Graz, Austria
** Curtin University/School of Information Systems, Perth, Australia
muhamed.soliman@gmail.com, christian.guetl@iicm.tugraz.at

Abstract - The use of intelligent pedagogical agents (IPAs) has shown to provide positive learning results and new learning possibilities. The IPA has specific importance in immersive learning environments to enable 24/7 availability, offer a learning companion opportunity, and increase learner engagement. In that regard, a proof of concept prototype implementation of an intelligent pedagogical agent (IPA) in the Open Wonderland virtual world environment was created. This paper reports a qualitative evaluation study and experiment performed by a team of six experts in relevant areas of expertise. Those areas include cognitive science, computer science, e-education, and virtual worlds. The experiment studied key prototype components in relation to four learning scenarios with distributed control between the learner avatar and the pedagogical agent to answer questions relevant to their effect on learning attributes such as motivation, engagement, and the learning experience. Given the qualitative nature of the experiment, the paper also analyzes and reports results relevant to expert input of how the prototype can better contribute to future pedagogical agent realizations and the impact on learning enhancement.

I. Introduction and Background

In attempts to discover various methods for new technology enhanced learning, immersive environments provide interesting properties for learning support. Those properties include 3D visualization, collaborative learning, and more to add to convenience, remote access, and cost effectiveness, [1]. A particular implementation of immersive environments is virtual worlds which has Open Wonderland [2][3] as an example. Virtual world environments are accessible through Internet browsers while representing each user as an avatar. The user avatar can thus roam into the 3D space and perform available learning activities alone or in collaboration with others who are online.

An important challenge in virtual worlds is learning support. Given the convenience of the time and location, the immersive environment can be occupied with many users. It can be infeasible to achieve 24/7 human learning support through avatars. Furthermore, a learner who cannot find peers to collaborate with or be in an inhabited world can find it uninteresting to proceed.

The use of intelligent pedagogical agents (IPAs) has shown to provide positive learning results and new learning possibilities. [4] shows increase in learner perception and performance through the motivational role of the *persona* effect of animated pedagogical agents. IPAs are life-like characters that can be thought of as points of interaction between the learner and the immersive environment to provide learning support, [5]. There has been research in the area of pedagogical agents from different dimensions, [6][7]. The motivation for incorporating IPAs in an immersive environment target interesting properties of 24/7 learning support, enable learning peers, and offer intelligent learning support.

The goals of the IPA are pedagogical oriented to increase learner engagement and interactivity in the virtual world and to provide effective learning services while monitoring learner progress. To discover feasible interaction possibilities between the learner and the IPA in learning scenarios, in the learning context, a simulation was achieved to show interaction patterns [8]. Furthermore, adding intelligence abilities to the IPA was also studied in [9].

Realizing the IPA has been reported in [10] providing a prototype of an IPA in the Open Wonderland virtual world to offer different types of services. In order to achieve it, a Non-Player Character (NPC), a multi-modal communication module, and supporting elements were developed and amended with Bot Chat module. The purpose of the multi-modal communication module is to enable interaction with the IPA. Furthermore, a voice chat was added through voice synthesis tool, [11]. The developed prototype in reference to the performed simulation provided further details of interaction in the implementation of Open Wonderland virtual world. This formed different learning scenarios, in each of which the pedagogical agent provides specific learning services with objectives. Fig. 1 shows a visual 3D scene for a pedagogical agent and a learner avatar in corresponding interaction in relation to an experiment object in the Open Wonderland virtual world, [2].

In order to assess the prototype and evaluate its impact on the learning experience in the virtual world, an evaluation experiment is required. There were two approaches to obtain the evaluation: through user evaluation or through expert evaluation. The second approach, which is selected, is in relation to the method of performing a qualitative experiment to obtain experts opinion on various aspects.

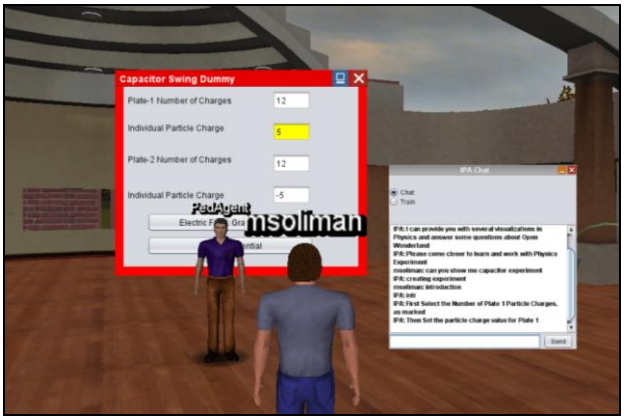

Figure 1. IPA interacts with a learner avatar on an experiment object in Open Wonderland. A text chat tool is used for communication.

II. EXPERIMENT SETUP

A. Research Questions and Design

The following hypotheses are formed to be checked in the experiment:

H1: The IPA, in the provided setting, provides appropriate mechanisms for increasing learner engagement in the virtual world.

H2: The IPA, in the provided setting and through awareness of the learning object, furnishes important guided instruction as an approach for enhancing the learning experience.

H3: The IPA contributes positively to learner motivation through guidance and task-completion support.

H4: The IPA provides the learner with an appropriate feedback mechanism that is positive to the learning experience.

H5: The pedagogical agent positively contributes to the learning experience in the virtual world setting.

In addition, the study has the following objectives:

O1: Evaluating and testing hypotheses H1:H5.

O2: Evaluating appropriateness and alternatives of the design elements such the text chat tool.

O3: Evaluating how can the prototype implementation potentially support the IPA concept.

B. Apparatus

To test hypotheses and objectives, the prototype setting is used through four learning scenarios in Open Wonderland. Participants refer to experiencing the following scenarios before filling a questionnaire.

- **IPA Proximity:** Captures learner intention to start learning activity as well as IPA's attempt to engage the learner through two proximity zones.
- **Using Multi-modal communication:** Refers to Learner to IPA interaction in either text or voice. Answers to questions are given through an AIML module, [10][12].
- **Tutoring:** The IPA tutors a sample simulation experiment.
- **Activity Feedback:** The IPA observes and provides feedback to the learner in relation to the learning object visual module.

C. Participants

Given the qualitative nature of the experiment, the study incorporated six experts in relevant fields. All of the participants are working at least one year in research on related topics having experiences in the following: computer science, cognitive science, e-education, and virtual worlds. Table I shows their areas of specialties and their distribution. Some of the experts are in research of more than one field. The age of the participants are in the range of 24-44 with (Mean = 30.3 & SD = 7.2). Three (50%) of the participants are females and three (50%) are males.

TABLE I. EXPERTS AREAS OF SPECIALTY AND RELEVANCE TO THE STUDY.

Area, relevance, and number of participants (%) in each area.		
Area	***Relevance***	***Number (%)***
Cognitive Science	Thought processes of the learner, exposure to artificial methods for e-education.	3 (50%)
E-education	Experience with tools and methods for electronic instruction.	4 (67%)
Computer Science	Facilitating methods of IPA foundations.	5 (83%)
Virtual Worlds	Main immersive environment the pedagogical agent operates in.	5 (83%)

D. Procedure

The procedure of the study includes four main steps for each participant, as follows:

1. Filling pre-questionnaire by the participant
2. Introduction to the system
3. Participant performs four IPA supported scenarios
4. Filling post-questionnaire

E. Pre and Post Questionnaires

The purpose of the pre-questionnaire is to obtain demographic data and prior expert knowledge in the relevant areas as discussed in Section C. The contents of the post-questionnaire are for the hypotheses and objectives testing. The majority of the questionnaire questions are Likert based, except questions 2, 3, and 21. The post-questionnaire also obtains qualitative opinions through open questions. Table II shows Likert and multiple choice questions of the post-questionnaire.

TABLE II. POST-QUESTIONNAIRE QUESTIONS.

Q	***Likert Question*** *(1-Strongly agree, 2-Agree, 3-Neutral, 4-Disagree, 5-Disagree)*
1	**I think using the question answering tool supports the learning activity.**
4	**I felt that IPA gestures are helpful to the learning experience.**
5	**I thought that the voice capability of the pedagogical agent is important.**
6	**I felt that the pedagogical agent has some sort of intelligence.**
7	**I find the method of detecting avatar proximity is good to determine learner intention to run the activity.**
8	**The proximity scenario helps to increase learner attention to the learning activity in the virtual world.**
9	**In tutoring and activity feedback scenarios, the pedagogical agent increases learner attention to the learning task.**
10	**I felt that the IPA encourages me to interact more with it.**
11	**I felt the IPA encourages the learner user to interact more with the environment (learning object).**
12	**I think the tutoring scenario by the IPA contributes positively to the learning experience.**
13	**I think the observing and providing activity feedback scenario is important to the learning experience.**
14	**I think that the IPA support to learning by doing improves the learning experience in this virtual world setting.**
15	**Overall, the IPA contributes tactics that positively support the learning activity in a virtual world**
16	**I felt that the IPA furnished guided instruction with the learning task, as an approach for enhancing the experience.**
17	**Through the task-completion support, the IPA helps improve learner motivation.**
18	**I learned something new about pedagogical agents.**
19	**I think the IPA is an essential learning component to an immersive learning environment.**
20	**The virtual world can become more interesting to the learner being more inhabited with pedagogical agents.**
	Multiple Choice Questions
2	**Which tool is preferable for activating pedagogical agent functions and obtaining its responses?** *(Choices: Text Chat tool, Traditional 2D menu, Other)*
3	**Having both the text and voice chat options are important to the user.** *(Choices: Yes, No)*
21	**I view that the virtual world learner user will prefer to learn with a similar pedagogical agent***….(Choices: None of the time, Some of the time, Most of the time, All of the time)*

III. RESULTS

A. Pre-Questionnaire Results

Participants answered the open question "*Which application types you find a virtual world useful for*" with different application types of *collaboration, simulation and visualization, language learning, scientific research,* and *games*. Their views on the advantages of virtual worlds for e-education included: *flexible location, visualization in 3D, spatial information, immersion, freedom, collaboration, simulation of history, physics, learning together for physically apart students, and meeting native speakers for language learners*. In response to stating disadvantages of using a virtual world for e-education, the following are included: *The demanding requirements of good Internet connection and graphics, usability issues, being hard for new users, user interface challenges, not always up to date, can seem to be complicated for users with low IT skills.*

Only two (33%) participants indicated prior knowledge about pedagogical agents with "Agree" response, three (50%) are neutral, and one participant (16.7%) doesn't have pedagogical agent knowledge (disagree). One participant (16.7%) agrees to have prior experience with pedagogical agents in virtual worlds, one is neutral (16.7%), three (50%) disagree, and one (16.7%) strongly disagrees. Participants indicated expectations on the IPA as: *to provide guidance and hints, explanations and repetitions, being intuitive, easy to use, and flexible.* They see advantages of IPA in the virtual world to: *help in the learning efforts, help to perform a task, having more knowledge, provide easy instructions, support learning at any place and any time.* Their indicated views on disadvantages included: *distraction of the task, and of possessing less in personality.*

B. Post-Questionnaire Results

The purpose of the post-questionnaire is to test for hypotheses and objectives. The majority of choice questions are in Likert scale [11][13] (1-Strongly agree, 2-Agree, 3-Neutral, 4-Disagree, 5-Strongly disagree), except for three questions. The post-questionnaire also includes open questions to obtain qualitative opinions relevant to hypotheses and prototype design elements and how to improve them. Table II shows choice questions in the post-questionnaire. While there is a disagreement, in specific areas of research, for calculating the mean of Likert items, the reason is due to assumptions on equal distances among the items. Thus, further measures are added including the Standard Deviation (SD), the Mode (most repeating response), and the frequency for each response, [14]. Table III summarizes the responses to each Likert question giving the various measures used.

IV. ANALYSIS OF RESULTS AND HYPOTHESES EVALUATION

Each hypothesis is tested based on different related questions from the questionnaire. While Table II shows the questions, Table III shows the results and calculations for individual questions. In addition, open questions provide qualitative input and discussed below.

A. ***H1:*** *The IPA, in the provided setting, provides appropriate mechanisms for increasing learner engagement in the virtual world.*

This hypothesis is tested through questions 8-11. On the overall, participants agree on questions relevant to this hypothesis. A combined score of (M = 1.95, SD = 0.75, Mode = 2) is obtained assuming equal weights. On the overall, 83.5% of the participants agree, 4% disagree, and 12.5% are neutral.

Open question responses such as "*You feel personally involved when a chat starts", "Very nice approach to make learners curious", and "You feel personally involved when a chat starts"* indicate support to the hypothesis in relation to specific elements of the prototype.

TABLE III. LIKERT QUESTIONS: RESPONSES AND BASIC CALCULATIONS

Q	*Mean*	*SD*	*Mode*	*No. of Participants for each Response (1-Strongly agree, 2-Agree, 3-Neutral, 4-Disagree, 5-Disagree)*				
				(1)	(2)	(3)	(4)	(5)
1	2.17	1.17	1	2	2	1	1	0
4	3.00	1.10	3	0	2	3	0	1
5	2.33	1.21	1	2	1	2	1	0
6	3.33	1.21	2	0	2	1	2	1
7	1.33	0.52	1	4	2	0	0	0
8	1.50	0.55	2	3	3	0	0	0
9	2.00	0.63	2	1	4	1	0	0
10	2.33	1.03	2	1	3	1	1	0
11	2.00	0.63	2	1	4	1	0	0
12	1.83	1.17	1	3	2	0	1	0
13	1.50	0.84	1	4	1	1	0	0
14	1.67	1.21	1	4	1	0	1	0
15	2.17	0.98	3	2	1	3	0	0
16	2.33	1.03	2	1	3	1	1	0
17	2.00	0.63	2	1	4	1	0	0
18	1.67	0.52	2	2	4	0	0	0
19	2.33	0.82	3	1	2	3	0	0
20	1.50	0.55	2	3	3	0	0	0

B. ***H2:*** *The IPA, in the provided setting and through awareness of the learning object, furnishes important guided instruction as an approach for enhancing the learning experience.*

This hypothesis is tested through questions 12, 13, 14, and 16. On the overall, participants agree on questions relevant to this hypothesis. A combined score of (M = 1.83, SD = 1.05, Mode = 1) is obtained assuming equal weights. On the overall, 50% strongly agree, 29% agree, 8.3% are neutral, and 12.5% disagree in combining with equal weights. In Agree/Disagree calculation, 79% agree on the overall. Accordingly, it is approximated to support this hypothesis with *Agree*.

Participants indicated support to this hypothesis with *responses "Hints/Visual Hints (yellow marks) where was the focus"* are liked*, "The IPA telling me about right and wrong inputs."* Participants stressed the importance of providing more detailed and specific feedback by the IPA as an improvement suggestion.

C. ***H3:*** *The IPA contributes positively to learner motivation through guidance and task-completion support.*

This hypothesis is checked through questions 8, 17, and 20. On the overall, participants agree on questions of this hypothesis with combined score of (M = 1.67, SD = 0.59, Mode = 2). On the overall, 100% of the participants agree, if excluding one neutral opinion. Accordingly, this hypothesis is supported with *Agree*.

Participants indicated strong support to this hypothesis with several responses as a good approach such as *"Fits very well", providing guidance, It is not forcing the learner", "By motivating and by giving hints & how to solve the simulation",* and more.

D. ***H4:*** *The IPA provides the learner with an appropriate feedback mechanism that is positive to the learning experience.*

This hypothesis is checked through questions 9, 13, and 16. On the overall participants agree on questions relevant to this hypothesis. A combined score of (M = 1.9, SD = 0.87, Mode = 2). On the overall 77.78% of the participants agree, 5.56% disagree, and 16.67% are neutral. Accordingly, it is approximated to support this hypothesis with *Agree*.

Participants indicated support to the hypothesis through open questions such as "*Feedback helps during experiments", "Wrong answers (actions) gets corrected immediately".* They also provided area of improvement in this aspect which is to "*provide more specific feedback of what went wrong, and how to perform it correctly".*

E. ***H5:*** *The pedagogical agent positively contributes to the learning experience in the virtual world setting.*

This hypothesis is checked through questions 12-17 to give an overall result of (M = 1.91, SD = 0.97, Mode = 1) with equal weights. On the overall 41.67% of the participants strongly agree, 33.33% agree, 8.33% disagree, and 16.67% are neutral. Accordingly, it is approximated to support this hypothesis with *Agree*.

Responses to open questions in relation to particular elements also support this general hypothesis. The hypothesis is also related to Q21, in which 5 participants (83%) chose some of the time while one participant (17%) indicated most of the time choice to conclude its positive contribution to learning experiences in the virtual world, but not in all cases.

F. *Measuring Prototype Tools Appropriateness to the Learning Activity*

Questions 1-5 are relevant to tools appropriateness to the learning activity; see Table II for questions and Table III for results. Experts in general agreed to the importance of the text chat tool and preference over a traditional 2D menu to interact with the pedagogical agent, and activate its functions. Less importance is then given to the IPA gestures. Furthermore, suggestions are provided to enhance the text chat tool through auto-completion features and action recommendation.

G. *How the Prototype Supports the IPA Concept*

Questions 18-21 are relevant to generic statements about the prototype in relation to the IPA concept in general; please see Table III for calculations for each question. In general, the prototype has provided input to have something new about pedagogical agents with agree (M = 1.67, SD = 0.52, Mode = 2), see Fig. 2. Participants either

agree or strongly agree to support IPA influence on giving users the feel of the virtual world being more inhabited (M = 1.5, SD = .55, Mode = 2). Fig. 3 shows the resulting calculation of this question of 3 (50%) participants strongly agree and 3 (50%) agree.

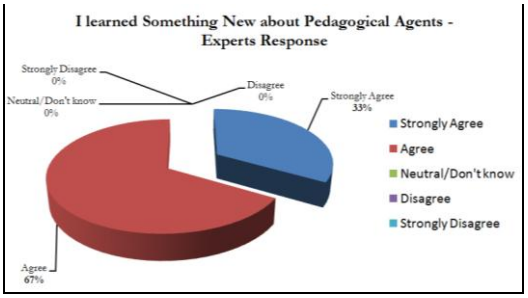

Figure 2. Results of questions Q18 which is related to the IPA concept.

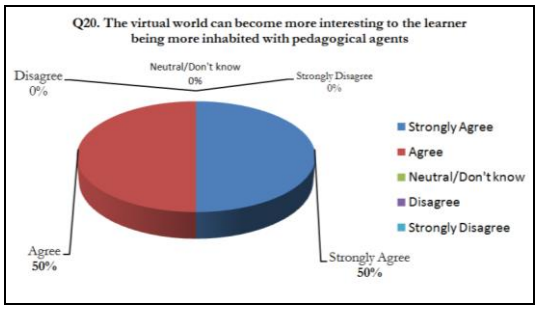

Figure 3. Results of questions Q18 which is related to the IPA concept.

H. Further Study Conclusions and Outlook

The study can thus shed light into most important aspects of the learning scenarios and design elements of the prototype. One of the key scenarios is the proximity scenario, as the IPA attempts to reason about learner intentions for performing learning activity and hence motivates to get engaged accordingly. The relevant questions (Q7, Q8) had results of (M = 1.33, SD = 0.52, Mode = 1) and (M = 1.5, SD = 0.55, Mode = 2) and with 100% agreement, see Tables II, III.

Regarding prototype elements importance, experts indicated the importance of the text chat module as a key component for communication with the IPA and triggering actions. They also suggested elements of enhancement with adding auto-complete feature and action recommendations by the pedagogical agent.

V. CONLUSION

The paper described an experiment setup and results to evaluate intelligent pedagogical agent learning scenarios in a virtual world. The purpose is to evaluate relevant hypotheses to pedagogical agent influence on the learning experience in a virtual world. The study had a qualitative nature, and was conducted by six expert participations from cognitive science, computer science, e-education, and virtual worlds. A pre-questionnaire and post-questionnaire are filled by each participant. The questions were in relation to four learning scenarios by the pedagogical agent in the Open Wonderland virtual world environment. Most questions are Likert questions and open ended questions to capture general opinions. On the overall, support was obtained on the relevant hypotheses (H1-H5), as discussed.

On the overall, **t**he pedagogical agent positively contributed to the learning experience in the virtual world setting. The results showed particular support to learner engagement addition by the pedagogical agent and the importance of the proximity learning scenario. Through the open questions, the study suggested key prototype elements including a text chat module and suggested further improvements to the learning scenarios.

ACKNOWLEDGMENT

Appreciation goes to anonymous expert participants from TU-Graz for contributing their time and effort to provide valuable contribution to this study.

LeCTo: a rich lecture capture solution

P. Pale, J. Petrović and B. Jeren
University of Zagreb, Faculty of Electrical Engineering and Computing
Department of Electronic Systems and Information Processing, Zagreb, Croatia
juraj.petrovic@fer.hr

Abstract - Lecture capture is a term referring both to learning materials based on recordings of live lectures as well as software and hardware support systems enabling lecture recording and reproduction. As lecture captures are today becoming more and more valued learning materials, there is a strong need for quality yet simple to use lecture capture systems supporting their creation. In this paper we describe a software solution for rich lecture capture recording and reproduction. LeCTo, an application developed to maximize lecture capture learning potentials and simplify lecture capturing process is presented through its functionality as well as problems and solutions encountered during its implementation.

I. INTRODUCTION

Lecture capture learning materials are today used not only in distant learning [1], but also as live lecture supplements [2]–[4]. Like most digital learning materials, lecture captures offer learning advantages like scalability and self-pacing, they can include multimedia rich materials to account for the recommendations of today dominant learning theories [5], [6], and finally they can provide the learner with the freedom to choose when and for how long will he learn.

Today there are various commercial and free lecture capture systems available focusing on different aspects of lecture capturing process: some focus on simplifying the recording process [7], [8], or automatizing camera control during recording [9], [10], some attempt to improve lecture reproduction properties by allowing the consumer to focus and manage only target region of interest in the lecture video [11] or by improving synchronization mechanisms [12], while some systems focus on hosting and indexing of lecture capture materials [13].

In this paper, we describe LeCTo (Lecture Capture Tool) focusing on several identified aspects of lecture capture systems. In particular, LeCTo is designed to:

- simplify lecture capturing process,
- enable creation of multimedia rich lecture capture materials, so called rich lecture captures, and
- offer a simple solution to their online management and reproduction.

II. A RICH LECTURE CAPTURE

The idea preceding the implementation of LeCTo was that lecture captures are not necessarily just recordings of events and learning materials from a live lecture, but rather they could be digital learning materials based on the lecture recording and enriched using additional materials to fully utilize the potential of digital learning environments. A rich lecture capture can contain the following types of contents:

- One or more video files that may be recordings of the lecturer, the desktop of his computer, his smartboard writings, a live experiment or demonstration or any other video material. A rich lecture capture can contain any number of videos, although it is usually two: the lecturer and his desktop.
- Additional lecture contents, in particular: links to additional online learning materials, online learning material that will be presented not as a link, but as the very content it refers to, typically graphical material or online applications, a quiz, speaker notes, lecture transcript or related textual materials and frequently asked questions or FAQ that students pose during the lecture.

Starting from the definition of a rich lecture capture, LeCTo was designed and implemented to support recording and reproduction of such multimedia learning materials. LeCTo has two components: LeCTo Recorder, a desktop application for recording lecture video materials, LeCTo Player, an online application for reproduction of rich lecture captures, and finally LeCTo PowerPoint plug-in, to help creating additional lecture contents.

III. LECTO RECORDER

LeCTo Recorder is an application enabling recording of one or several videos related to the lecture using any video camera device attached to the computer. Recording parameters that can be set include recorded file location, source camera for each video stream, video parameters (bitrate, framerate, and video scaling factor for each video stream), and audio parameters (source microphone and audio bitrate). Configuration settings can be saved, exported or imported, and several presets are also available.

Once the recording configuration has been defined, the lecture can be recorded using *record* and *stop* buttons of the application interface. Recordings are stored as separate files. Flash video (*.flv*) file format was chosen as supported video format since it is one of the most common file formats for delivering online videos today.

IV. LECTO POWERPOINT PLUG-IN

LeCTo PowerPoint plug-in was designed and implemented to provide support for creating the additional content to the lecture (Additional Lecture Content, ALC). It was designed as a Microsoft PowerPoint plug-in, as it is one of the most commonly used programs for creating lecture slideshows. Plug-in and contains of six buttons offered in the add-ins tab on the PowerPoint ribbon.

Four of those six buttons correspond to additional lecture content types: links, web contents, quizzes, and FAQ, while the fifth button allows the user to add textual indices or slide tags, enabling a more efficient navigation over the lecture. Each of those materials is edited in a small pop-up window which appears upon clicking the corresponding button. The fifth type of additional lecture content is speaker notes, can be edited directly in the space provided for them originally in PowerPoint. Every presentation slide can have all five types of ALC associated to it, meaning that every slide can have its own links, tags, online content, quiz, FAQ and speaker notes.

The sixth LeCTo button in the add-ins tab has a function of exporting all of the edited additional lecture contents into textual XML files with *.alc* extension which can later be used in LeCTo Player. Each content type is stored as a separate file.

Another important function of LeCTo PowerPoint plug-in is recording of slide transition times. Once installed, this add-in will track slide change times for every PowerPoint presentation performed in the full-screen mode. When the presentation is finished, a dialog box is opened asking for the user to choose whether the performed presentation was part of a lecture recorded by LeCTo Recorder. If so, a XML file containing all slide transition timestamps with *.cce* (context change event) extension is created. Otherwise, the transition timestamps will not be saved. Transition timestamps are accompanied with slide titles and slide ID's generated by PowerPoint.

V. PLAYER SETUP FILE

Once all lecture materials have been created (*.flv* video files, *.alc* files and *.cce* file), they need to be uploaded to the web to enable their online reproduction. LeCTo is designed so that lecture materials can be stored at virtually any online location, or even at several different locations. This means that institutions with available web space can utilize their own storage locations, while private users can store their files using any of the numerous free online file storing services.

The exact URL location of every lecture file can be specified to the player one by one. More convenient way is to define them in the player setup file, an XML file with *.psu* extension, which can be generated using LeCTo Recorder. The user only needs to define URL's for every file he wants to include in the lecture in a simple input form. The *.psu* file is generated automatically upon filling in the corresponding form in LeCTo Recorder.

VI. LECTO PLAYER

LeCTo Player is a browser-based application designed to enable reproduction of rich lecture captures. In order to reproduce a rich lecture capture, the user should upload the corresponding *.psu* file defining locations of online lecture materials to the LeCTo application, but he can also manually add URL's of all additional lecture *.alc* resources he wants to use. Alternatively, a LeCTo lecture can also be started directly if the link to the *.psu* file is added to LeCTo Player's URL. There is no limit on number of files included in the lecture: any number of video files as well as any number of *.alc* files can be included in the lecture, although providing the learner with too many learning materials will probably result in cognitive overload [14]. A practical limitation is also space available on the screen.

In the LeCTo Player's main interface each of the lecture materials, represented by a corresponding file, is displayed in a separate window so it can be easily manipulated. All LeCTo windows are opened within one, same web browser window. All *.alc* files, i.e. additional lecture contents, are synchronized with the video files and display only the contents associated to the current context being defined either by time or by presentation slide ID of the lecture.

Lecture navigation in LeCTo is supported in three ways: through chapter or slide index, video slider as well as through permuted index. Permuted index is an index of all words appearing in any additional lecture contents presented with two words appearing before and two after the target word to help to determine the context of its appearance in the text. Each word in the index is a link to the target chapter or presentation slide.

VII. IMPLEMENTATION

A. LeCTo Recorder

LeCTo Recorder was implemented in Java in order to make it a platform-independent application. Surprisingly, Java has a relatively weak multimedia support, so several multimedia support libraries were taken into consideration before exact implementation.

- Xuggler is a library enabling efficient manipulation with media streams directly from Java, effectively hiding the unneeded low-level manipulation aspects, yet it had to be rejected since it did not provide camera support.
- JavaCV is a Java interface to OpenCV, a library of programming functions for real time computer vision. Although it could have technically been utilized, it had been rejected since it provides a large variety of functions not needed and not originally intended for the purposes LeCTo Recorder would be used for.
- JMF or Java Media Framework was perceived as a potentially useful Java multimedia support for LeCTo Recorder, yet it turned out its last stable release was released in 2003 and will probably soon become deprecated. Two similar libraries with the same potentials and problems including lack of updates during the last few years are LTI-CIVIL and FMJ (Freedom for Media in Java).

- Libvlc is a C++ library for supporting HTTP streaming, video, desktop and audio recording, and was chosen for LeCTo Recorder implementation since it provided necessary support for desired LeCTo functionalities. Libvlc is included in the installation of VLC Player, a popular free and open source cross-platform media player that is regularly improved through new releases.

1) Vlcj library

Since Libvlc is written in C++ programming language, it cannot be utilized directly from Java code. This problem of accessing and using Libvlc library from Java was solved by utilizing vlcj, a library enabling Java interface to Libvlc and its methods. vlcj is an open source library using Java Native Access library to access native code (in this case C++) directly from Java. To achieve this, Java Native Access library *jna.jar* and *platform.jar*, enabling easier native code access depending on the operating system, and the location of the Libvlc need to be added to the project execution path. Libvlc is located in the VLC Player installation folder and has a different extension depending on the operating system*: .dll* on Microsoft Windows, *.so* on Linux, and *.dylib* on Mac OS X.

2) Camera detection

One of the necessary parameters to utilize vlcj for camera stream recording is the camera name or ID. The detection and recognition of cameras connected to a computer has turned out to be a platform-specific problem. On Windows platform, Direct Show Java library (DSJ) can be used to identify cameras currently connected to the computer. On Linux platform, camera device detection is based on reading the device names set as video0, video1 and so on from the /dev/ directory. A more elegant solution left for the future improvements includes support camera detection using Video For Linux For Java library shortly called v4l4j. Both DSJ and v4l4j libraries include many other functions which were not needed in this implementation of LeCTo Recorder. In Mac OS X, only the predefined system camera is offered to be used, since an older version of VLC Player not including all required functions was still recommended in the time of implementing LeCTo Recorder. Future improvements for Mac OS X include utilizing VLC Player 2.x Libvlc libraries which enable camera detection support. Libraries currently utilized for LeCTo Recorder are schematically represented in the Figure 4.

3) LeCTo PowerPoint plug-in

LeCTo PowerPoint plug-in was adapted from Pyramidia plug-in application, a part of one of LeCTo's predecessors [15], [16]. LeCTo PowerPoint plug-in was designed as a Microsoft Office extension written in C# using .NET framework. All the additional lecture content edited in the presentation is stored directly in the PowerPoint presentation making its storing and transporting as simple as possible. In the very presentation, all types of additional lecture contents are stored as invisible textboxes on the corresponding presentation slide.

Once they are created, the additional lecture contents can be exported from PowerPoint presentation to *.alc* files. Each *.alc* file uses the following XML scheme:

- type attribute, appearing at the beginning of the file defines to which of the five ALC types the file corresponds;
- <window> element including child elements with metadata on size and location of the corresponding ALC window in LeCTo Player, the name of its author and a list of its contributors;
- <frame> element including child elements describing ALC content (exact child elements depend on the type attribute defined at the beginning of the file) and display time information (either as exact time interval during which the defined content should be displayed or presentation slide ID to which it should be associated to).

The *.cce* file, automatically generated after a presentation in PowerPoint, also uses an XML scheme with <frame> elements, usually each referring to a presentation slide or chapter. Each <frame> elements contains the following child elements:

- <contextID>, referring to the unique integer number automatically assigned by PowerPoint to each presentation slide,
- <title>, defining the title of the slide or presentation chapter, and
- <occurrence>, defining the start and end time or just duration of the slide or chapter.

Since *.alc* and *.cce* files are stored as text, they can be edited or even created even outside PowerPoint in any textual editor.

B. Player setup file

The player setup file defines all that is needed to watch a LeCTo lecture: it defines lecture materials and their URL-s (*.flv* video files, *.cce* time events file, and *.alc* supplemental files). Since it is also a textual file, the *.psu* file defining lecture resources and their locations can easily later be re-edited. The *.psu* file uses the following XML scheme:

- <video> elements including child elements describing display properties and URL of each lecture video material,
- <cce> element defining the .cce file URL, and
- <alc> elements including child elements describing window size, position, and URL of each lecture ALC material.

Just like *.alc* and *.cce* files, *.psu* file is also stored as text, so it can be edited late if any of the contents changes its location.

1) LeCTo Player

LeCTo Player was implemented in javascript and PHP programing languages. The basic idea behind the

implemented structure is that as much processing and implementation logic should be performed on a viewer's computer rather than on the server. From the implementation perspective, LeCTo Player can be described in two segments: manipulating input files and lecture reproduction.

7.4.1. Manipulating input files

To start a lecture, one must first define LeCTo input files comprising a lecture capture on the LeCTo Player initial page, which should include at least one *.psu* file defining online locations of lecture video and optionally additional *.alc* files. The *.psu* file, as well as optional *.alc* files, can be uploaded through viewer's computer or can be defined by typing in their URL's. The file upload form has been supported through uploadify, a jQuery plugin enabling multiple file upload functionality.

Once they are defined, the input files should be transferred to a viewer's computer where they will be parsed to extract required information, minimizing server's processing load. However, due to the javascript's same origin policy those input files cannot be transferred directly. Same origin policy means that, due to possible safety issues, an application running in a web browser cannot access files at a different domain then the one it belongs to. This rule does apply to web browsers, but not to web servers enabling a simple solution of first using the server to download all the defined input files to a predefined temporary server location, and finally transferring files from the server to the viewer's computer stored as XML DOM objects. XML DOM defines a standard for accessing and manipulating XML documents, in this case *.psu*, *.cce* and *.alc* files.

When all input files have been transferred to a viewer's computer, it is time to initialize the lecture. The LeCTo user interface has been designed using jQuery user interface library enabling support for elements like buttons, menus and dialogues, and their manipulation. Lecture initialization is performed through opening of video dialogues (windows), one navigational dialogue and dynamically generated dialogues for all defined .alc files.

7.4.2. Lecture reproduction

To reproduce lecture video file, LeCTo Player utilizes jwplayer, an embedded platform independent video player. It was chosen since it enables easy web page integration, is HTML 5 compatible and has a javascript API. It is also free for usage on non-commercial sites. jwplayer supports two types of video transport: using HTTP protocol and using RTMP (Real Time Messaging Protocol). If the remote server where video files are stored supports RTMP protocol, videos can be streamed so the user can access even the parts of the lecture that have not been downloaded yet, which is not the case for regular HTTP transfer. Alternatively, video streaming can also be supported through HTTP pseudostreaming protocol. During the lecture reproduction, the video files are synchronized so that if any of the play, pause or slider controls is used, a method performing the same action on all other video streams is performed.

Synchronization of additional lecture contents with lecture videos is performed using a simple javascript mechanism which checks lecture time every 1.5 seconds during the lecture replay. After the lecture time has been checked, the same mechanism checks weather any of the ALC dialogues should be synchronized and performs the synchronization if necessary.

VIII. CONCLUSION

The applications described in this article, LeCTo Player, Recorder and PowerPoint plug-in, present a full solution to lecture capturing, enrichment, and reproduction. Each of those components is designed to be as simple as possible, yet offers authors of digital learning materials based on lecture captures a wide range of possibilities and platform independence. LeCTo Player, Recorder and PowerPoint plug-in can be accessed and used under the Creative Commons license at www.lecto.org.

ACKNOWLEDGMENT

The work described in this paper was conducted under the research project "Complex System Modeling" (036-0362214-1987), supported by the Ministry of Science, Education and Sports of the Republic of Croatia.

Using Data Mining for Learning Path Recommendation and Visualization in an Intelligent Tutoring System

I. Jugo, B. Kovačić and V. Slavuj
University of Rijeka, Department of Informatics, Rijeka, Croatia
{ijugo; bkovacic; vslavuj} @ inf.uniri.hr

Abstract – Since the creation of Web-based learning systems researchers have tried to make them adaptive to various characteristics of learners in order to increase the quality of learning. The application of data mining (DM) methods on learning system logs is often used as a basis of intelligent tutoring systems (ITS) that have the ability for automatic adaptation of some aspect of the learning process. Such a system was developed at our institution in the previous years and has been used in a number of courses. To improve our system we added an integration application to create a continuous feedback loop with a DM tool. Our goals, from the student's perspective, are to improve the quality of knowledge acquired by students as well as shorten the learning time by offering recommendations based on mined patterns of learning paths through the knowledge domain. From the perspective of teachers, our goal is to create a rich data visualization system (in the form of a Web application using standard Web technologies to create visualizations) to give them new insight into students' behaviours. In this paper we present the structure of our system and the research design that will be used to verify its results.

I. INTRODUCTION

The main problem with e-learning is lack of feedback concerning students' work. The two most commonly used e-learning systems in the EU are Moodle and Blackboard, which, however, in their basic installation version do not offer any tools that could be used for tracking the work and behaviour of each student. Such information would be of great help to teachers and would enable the adaptivity of learning dynamics, make communication easier, etc. In addition, it would help teachers in identifying patterns in student's learning paths through the learning domain as well as in identifying possible problematic learning units.

Adaptive e-learning systems aim to improve student's results by taking a particular aspect of the system and adapting it to the identified characteristics of the student [1]. Certain systems adapt the way they present the learning content based on the learning style of the student, others adapt content adaptivity based on the assessed level of knowledge, yet others adapt the difficulty of test questions, etc.

An intelligent tutoring system for e-learning based on dialogue was developed at our institution [2]. The system guides the learner through the learning domain by alternating between sequences of learning about particular concepts from the domain and sequences of knowledge testing, in order to offer support and skip the concepts that have been learned previously. The system was further enriched by adding the module for statistical analysis of student activity [3], which aims at providing feedback to both the student and the teacher. Feedback to the student includes an overview of his/her progress, more specifically, the number of visits for each knowledge unit (concept), the number of questions answered and tests taken, and the success rate of her answers. Conversely, the teacher receives detailed information on each student's progress and knowledge, but also an overview of the entire domain, which allows her to take appropriate action concerning any problematic concepts in the domain. In order to assess the impact of the implemented changes on system users and their attitudes towards using the system, we have undertaken an evaluation which revealed the possibilities for further development of the system [4].

Educational Data Mining is an emerging discipline, concerned with developing methods for exploring the unique types of data that come from educational settings, and using those methods to better understand students, and the settings in which they learn [5]. In the last overview paper of the state-of-the-art in EDM [6] a new set of important research objectives was set and among them were: a) EDM tools have to be designed to be easy to use for educators or non-expert users in DM, b) the DM tool has to be integrated into the e-learning environment as one more traditional authoring tool.

In this paper we put forth our model of an adaptive ITS paired with an integrated EDM tool designed for educators and non-experts in DM. Our research aims to develop a system that offers students a better learning environment, teachers a better supervision over the teaching process, and DM experts the possibility to continue their work in a specialized tool and easily add new analyses into the system.

The paper is organized into five sections. Section 2 describes the theoretical foundations of this research and situates this work in the area. Section 3 presents the architecture of our system and points out its most important contributions. In Section 4, we describe our research plan that will be used to verify the expected results of the application of the system at our Department. Finally, we conclude the paper with an emphasis on future work.

II. RELATED WORK

Educational data mining (EDM) is a relatively new appellation for an area of research in which classic DM methods (originating from the areas of machine learning and artificial intelligence), along with some new ones, are used on data collected from e-learning systems in order to clarify the problems related to e-learning. The results of these methods are often used as a basis for automatic adaptation of e-learning systems to the needs, expectations and habits of their users. Although the term EDM appeared around 2005, some authors started using DM methods to analyse or predict the behaviour of ITS users much earlier [7].

Today, EDM is a fast growing area of research with the number of papers published per year rising exponentially. Authors applied existing DM methods and developed new ones specifically for EDM to research a very wide number of topics regarding e-learning, user success prediction, user clustering, user modelling, intelligent recommendation systems, intelligent examination systems, etc. There are a small number of overview papers of the field, e.g., [8] (published in 2007), [9] (published in 2009), while the last one was published in 2010 and cited over 300 references [6].

Our research deals with and connects two main areas: a) learning path pattern analysis as a basis of creating an intelligent recommendation system, and b) visualization of those patterns, particularly data visualisation in the Web browser using standard Web technologies (to avoid the need of using plugins such as Java or Flash).

Many authors have developed applications for DM-based data visualizations, but rarely using standard Web technologies. In [10] authors developed a Flex/Flash based application in the field of Bioinformatics, while in [11] authors developed a Java/Matlab based application that accepts data file uploads and returns results from a small set of DM algorithms. In [12] authors developed a student forum activity visualization tool using the Scalable Vector Graphics (SVG) web standard. A very recent paper [13] describes a rich data visualization system for visualizing student activities in a ITS that was developed as a standalone Java application that will be used as a reference point for our visualization that will differ in that it will be developed as part of our Web-based Integrator application using standard Web technologies (SVG, Canvas) and emphasize on real-time updates that will allow the teacher to watch users navigating through the knowledge domain and indicate their successfulness on related exams. In [14] authors created a Java application that used DM algorithms (namely, Hypertext Probabilistic Grammar – HPG) to discover patterns in navigation trails (paths) through the ITS content and create static visualizations using directed graphs and text labels to point out the direction and frequency of mined paths. A similar visualization approach was used in [15] where interactions with a motivationally aware tutoring system called M-Ecolab and its previous version without that capability (Ecolab 2) where mined to discover patterns in behaviour in connection with motivational feedback. In [16] authors used DM algorithms (namely, association rules and classification trees) to find rules in students usage of the ITS and visualize those rules to teachers in a tool called Author Assistant.

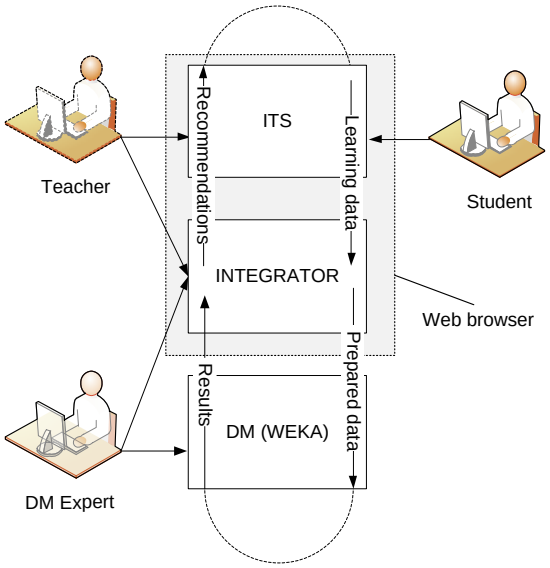

Figure 1. Learning system integrated with a DM tool [17]

Our research aims to combine these two areas of research by creating an intelligent tutoring system that will offer recommendations to students to both strengthen their knowledge acquisition process and shorten learning time. It also aims to offer relevant insight to teachers by providing real-time visualizations of learning activity patterns with additional information about students' results in testing their knowledge. All this information will be based on an integration module that will collect data from the ITS, send it to a DM tool, retrieve results and feed it into modules for offering suggestions and data visualization. To the best of our knowledge this type of system was not developed previously.

III. SYSTEM ARCHITECTURE

The main idea behind this integrated system is to allow non-experts to best use the potential of DM in e-learning, as well as to improve the existing e-learning systems by introducing adaptivity through recommendations.

The utilization of DM in e-learning systems or everyday classrooms is far from widespread use. We presume that by integrating DM tools with e-learning systems (and the educational process in general) we can help broaden the application of DM in education significantly. This integration should be seamless to the end user. In this way the teachers could stay in the familiar environment of the Web browser and the e-learning system they regularly use, and start using new DM powered features that will bring novel, helpful insights to their work.

The overall process of DM defines a set of steps that have to be followed to apply it to the target system and gain useful insight. Although some steps of this process are very technical, we feel that it can be implemented in such a way that (once connected to the ITS) it is mostly invisible to the teacher, and that it can be done in a familiar environment of a Web browser. In the case of

EDM being applied to an ITS, the result of this system would be a continuous feedback loop from the ITS (providing usage/learning data) to the Web interface (providing various prepared EDM procedures), to a DM tool (performing DM algorithms on prepared set of features). The feedback then goes back to the Web interface (providing insight via rich data visualizations) and finally, the user implements the suggested changes into the ITS. This process is depicted in Figure 1 [17].

We propose a system consisting of four basic modules. Block diagram of the system can be seen in Figure 2. First, the Learning Data module is used to make the connection to the ITS and define data sources needed for various EDM actions. The sources consist of attributes from multiple tables. This module monitors data sources and periodically pulls new data from the ITS. This module is used by the DM expert. For our system, the primary interest lays in knowledge domain structure analysis, so data about paths through the knowledge structure created by the students is needed. We also analyse data concerning access times, learning session duration and frequency, learning materials usage, quiz and test results, etc. Once data sources are defined, this module does not need further attention from the DM expert.

The central part of the Integrator Web application is the Actions Repository module. It is envisioned as an extensible set of DM-based operations of interest to the teachers (analysis toolbox). Every action offers a different analysis concerning the learning process, for example, prediction of student success in a course. Actions define the necessary data preparation routines, feature extraction, discretization, etc., needed for the DM algorithm to be used. Actions are run in predefined data intervals (week, month, and semester) or in an interval defined by the teacher. This part of the system is primarily used by teachers. Concerning our system, one of the first Actions we will develop will be pattern discovery in student's paths through the knowledge structure.

The DM expert is able to connect to the system, analyse the ways teachers use the actions, and modify or create new Actions. As the system will be open source, other developers will be able to develop and install new actions. Each Action employs the DM tool in the background, concealed from the end-user. The DM tool is contacted via API calls, by the Input/Output module that receives data from the Action selected by the user, and creates a set of arguments to make a correctly formatted call to the Weka API. It also handles the output file of the DM tool by preparing it to be used by the Data Visualization module, which also has the role of the user interface of the application. So, this module consists of a data visualization area, the Actions toolbar and a data manipulation (intervals, filter) area. The key contribution is that the user interface is not DM-oriented, i.e. it does not mimic user interfaces of common DM tools like Weka, but is instead user-oriented and optimized to bring real value in the form of insight into the learning progress of the students. Consequently, it optimizes the overall efficacy of the educational process.

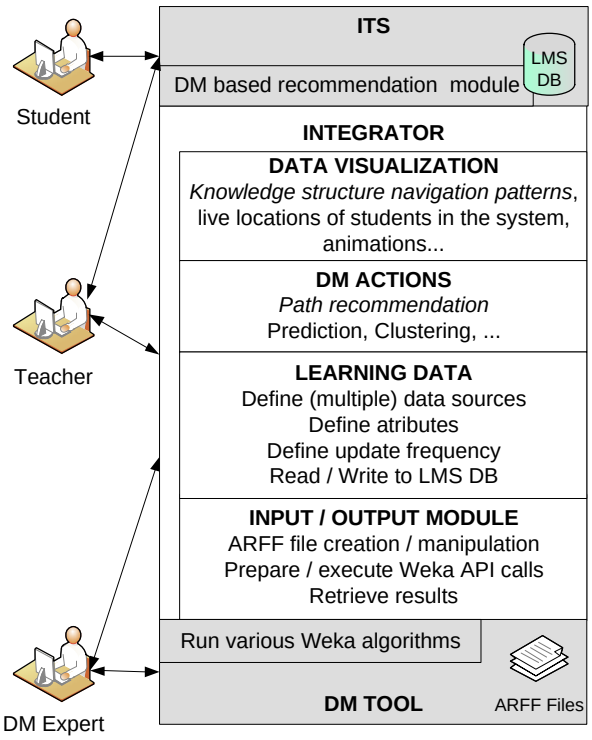

Figure 2. Block diagram of the system

Teachers can use the Data Visualization module, run various Actions and use the provided insight to modify the ITS in two Web browser tabs, without the need to learn about or even see DM tools, algorithms, database queries or any other technical details. The role of a DM expert is minimized after the initial connections with the ITS are defined in the Learning Data module. Although the system could be fully integrated into our ITS, we believe that creating a separate system with powerful connection abilities will enable other LMSs and educational data providers to use our system for their analysis and new applications.

The conceptual design of our visualization system is presented in Figure 3. Because the knowledge structure (domain) can contain hundreds of units (concepts) the objects representing them need to be kept small in order to display the whole structure on one screen. Concept names and student names will be revealed by tooltips when the teacher positions the mouse pointer over the objects. As the visualisation will be refreshed every few seconds teacher will be able to see students moving from concept to concept.

The number of students at each concept is displayed in a circle. The thickness of the lines and the arrow orientations display the common paths though the knowledge domain. Red lines depict returns indicating a possible problem with teaching materials or the structure of the domain. Dashed lines represent the original structure of the domain as created by the teacher. The

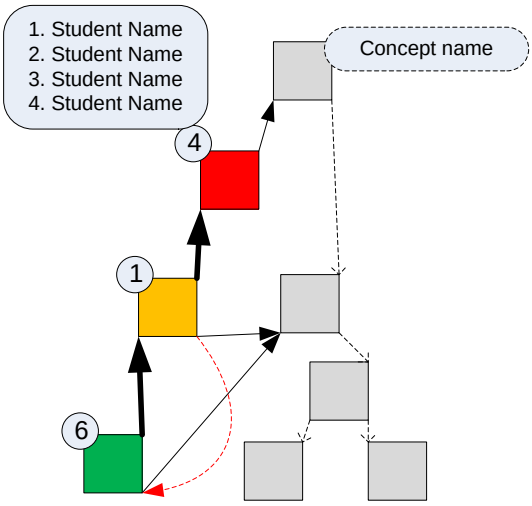

Figure 3. Visualization concept design

colour of the concept depicts the average student success on exams about that particular concept. Grey objects represent "no-data". This part of the system is currently under development.

IV. RESEARCH DESIGN

The development of this system is a part of an extensive research into the ways of improving the quality of acquired knowledge of students and shortening learning time. In addition, it will enable teachers to easily use DM on learning data and to get a visual insight into student activities. The research phases are described below.

A. *System development and implementation*

Basic functionalities for students are: learning (through lessons or individual knowledge units), examination (can be used for pre-testing, practice and grading) and collaboration (each lesson and knowledge unit have forums where students can post/read questions for the teacher or other students).

From a technical perspective this is a MVC Web application based on the Phalcon PHP and JQuery frameworks with a responsive user interface that can be used on smartphone, tablet and PC monitor screens without any loss of functionality.

New versions will be available at http://ditus.uniri.hr as the development progresses.

B. *Acquiring and transforming data*

To perform any kind of data analysis, we need to capture raw data from the application. There are two main approaches to this: using Web server log data or creating a custom data format and a logging service. Both approaches have their pros and cons: Web logs are "free", i.e., they are gathered without our intervention, but contain a very large amount of unwanted/unusable entries that need to be removed before data is pre-processed. Using a custom log format and a logging service requires development time, but grants a clean set of entries that can already be prepared for DM, which saves the time needed for data preparation/cleaning and, partly, pre-processing. We plan to choose the latter approach: adapt the well-known and widely used PSLC DataShop Tutoring Message Format [18] to our needs and develop a logging service as an integral part of the ITS and DM integrator application. Once the integrator application is connected to the ITS database, it can transform the relational data to our log format which can then be used for DM.

C. *Data mining for learning path pattern discovery and recommendation generation*

There is a large number of well-known pattern discovery algorithms used today. To discover patterns in learning paths of ITS users, some authors employed the already existing algorithms, while others developed new ones. Algorithm selection depends on the overall goal of the DM process. When trying to discover daily learning patterns, Hung and Zhang in [19] used sequential association rules. In [20], the author developed an algorithm for detecting "to-be-enhanced" learning paths and used fuzzy sets to make learning recommendations more understandable to end-users. Before using mined learning path patterns for making recommendations, we need to connect them to final student results in the course or some other source of data that will help in identifying which patterns to use. In [21], authors used sequential pattern mining to extract most frequent learning patterns and then applied distance-based clustering to group students according to their learning performance. In [22], authors proposed a cross-level learning suggestion process using FP-tree and FP-growth algorithms.

In order to identify the patterns that will be the base of our path recommendation process, we will grade mined patterns according to the following two criteria: the student's overall course success and the total time they needed to cover the course material (number of patterns, number of items in a pattern, total duration of a pattern). After this, we will have a set of preferred patterns to be used in the recommendation module of the ITS.

All the DM procedures in our system will be performed according to the CRISP-DM model [23].

D. *System evaluation*

Before we begin the final experimental phase, both the visualizations (for the teacher part of the system) and the overall user satisfaction with the system (relatively small sample of student population – testers) will be measured using the approach described in [4].

Evaluating data visualizations is a complex problem due to the fact that it cannot be measured objectively. We will implement the three step data visualization evaluation approach used in [13] which was based on [24]

E. *Final experiment and results verification*

The final stage of the research will consist of an experiment that will verify whether the initial goals of

the research, from the standpoints of both students and teachers, have been met. For the previous version of the system, two knowledge domains (Operating Systems 1 and 2, consisting of approximately 80 knowledge units per domain, and approximately 200 questions per domain) have already been developed and used over 2 semesters with groups of up to 100 students. Two more domains will be developed (Web development 1 and 2) for the purposes of the experiment. Students will be divided into three groups: a control group (will not use the system), the first test group (will use the ITS without recommendations) and the second test group (will use the ITS with DM-based recommendations). The final results will be statistically analysed and used to either confirm or reject our hypothesis that this system will both improve the results of the learning process and shorten learning time required to cover the course materials.

Even though it is still being developed, at the time of writing of this paper, the system had a responsive user interface, basic learning functionalities and communication with the DM tool. We are still developing "live" data visualizations in the browser using standard Web technologies without the need for any additional plug-ins.

V. CONCLUSION

Educational data mining has developed to a point where its findings can and should be made easily available to those that can benefit from it the most, namely teachers at various levels of the educational system. As e-learning, e-classrooms, computers and tablets are becoming more common, so should the widespread application of EDM. One of the main obstacles preventing the widespread use of DM in learning is the need for expert knowledge. We aim to overcome the obstacle by creating an easy-to-use Web-based system, integrated with an ITS used on a daily basis, which offers an extendable set of Actions providing useful information. Teachers do not have to know that these Actions run DM algorithms on ITS data in the background; they just receive useful information at the click of a button. This system, paired with rich data visualization, can bring a new dimension to the e-learning experience. Students will benefit from the suggestions given by the ITS, which aims at time saving and learning "the right way" also powered by DM algorithms. The main contribution of the system will be the continuous integration of the two systems, which will enable the overall system and its algorithms to be employed on daily updated data, and provide the teachers and students with better results as well as useful trend analysis.

Abstract: Security of wireless networks is lower than the security of wired networks and it remains he greatest security risk of a local network . This is primarily due to the communication medium (air), which is accessible in a specific radius of action as well as the inadequate use wireless network protective mechanisms. Besides, administrators of wireless networks usually respond to damage caused by a system security breach only after it had already happened. The aim of this research is an evaluation of the safety parameters that affect the security of wireless networks. For this purpose a questionnaire was designed to test the expertise in educational institutions in the Republic of Croatia: CARNet system engineers will evaluate the parameters that affect the security of local WLAN. The collected data show individual evaluation of wireless network security parameters that affect the WIFI security. The results will be used for recommended safety guidelines.

Keywords: *wifi, security policy, educational institutuions, CARNet*

I. INTRODUCTION

The development of information-communication technology greatly contributes to the quality improvement in teaching at secondary school and university levels. The rise of computer networks and internet has created new opportunities for communication between teachers and students. Global developments and empirical reseearch indicate increased use of wireless access to local networks at the primary school levels too. Croatia is lagging behind global trends on primary and secondary school level, while the introduction of wireless access at university education level keeps up with the European average. The reasons for this, has been stated, are financial problems, lacking interest in the leading bodies of educational institutions and problems of network infrastructure maintenance. In order to find good a solution for the use of wireless networks including adequate security level, a sound development strategy is needed, departing from the analysis of actual possiblities and needs.This shoud be the basis of their impelementation. Accordingly it is necessary to offer pupils and students supported acess of wireless network from their personal computers.

II. WIRELESS NETWORK STANDARD IEEE 802.11

The emergence of wireless network standard IEEE 802.111 has expanded the possibilities of local networks based on IEEE 802.3 ethernet standard. The possiblity of wireless connectivity to local networks (LAN) was added. Bearing in mind the use of radio waves in the context of medium carriers of widely spread signal, this signal is used to connect clients and make their communication possible from access points (AP). Standard IEEE 802.11 (11 meaning work group that developed it) was published in 1997, and prescribed the following specifications as shown in table 1 [11].

TABLE 1. SOME SPECIFICATIONS OF IEEE 802.11 ETHERNET STANDARD

Reach within buildings	depending on the number and type of obstacles
Work frequency	from 2.4 to 5 GHz
Bandwith	0.7 Mbit/s and up
Data transfer	2 Mbit/s and up[2]
Reach	Up to 75 meters (in open air) depends on the standard (a,b,n,g,..)

III. SECURITY BREACH OF WIRELESS NETWORKS

Network security can be endangered by events which compromise availability, credibility, integrity and confidentiality of saved or transferred information and/or service provided by such networks or systems.

[1] International non-profit organisation IEEE (*Institute of Electrical and Electronics Engineers*).

[2] Standard IEEE 802.11 ac has transfer of 7 Gbit/s.

Vulnerability of wireless networks is due either to security weakness or to system shortcomings. The attacker can take advantage of system vulnerability in order to compromise its security with the aim of unauthorized access. Regular control of system vulnerability can eliminate threats to a system's security.

The principal security problems are:

- Program vulnerabilities,
- Malicious code,
- Social engineering.

Potencial sources of attack on wireless networks can be classified as follows:

- Internal attacks,
- External attacks.

Internal attacks may come from the network system itself. Users of a network system (operators, operatives authorized to access the system) fall under direct jurisdiction of system's administrator. Valid users can harm the network system and wireless network itself by accidental errors.

External attacks come from without the system and such threats are beyond the system administrator's control. There are many possible external threats, ranging from criminal organizations, commercial companies bent on collection of confidential data, investigative agencies in search of information, to simple enthousiasts trying to prove their ability to interfere with wirelesss network security. It is important to point out that wireless networks are often potential attackers' targets due to their characteristic capacity of receiveing radio waves.

Security policy defines planning and describes goals or security procedures. Security policy can be defined as the declaration of aims reached by particular procedures. Conditions under which security policy can have an effect are general – they are not specific. The implementation of security policy is a draft of security within a specific system [1].

Peltier [1] argues that an information security program should be a part of a security protection program of an organization's entire property. A security program is not made to satisfy the need for security or revision requirements, but as a process providing the management instruments necessary for management of responsibility. An organization's management is responsible for securing necessary protection control of an organizations/ínstitution's property where the security policy is implemented.

- In order to make use of optimal methods of risk management by means of security policy, it is necessary to:
- Know the number of users of a wireless network and their identification,
- Define network servers and the services that they provide,
- Define authorized persons who may introduce wireless network equipment ,
- Have a clear definition of the user rights level and procedures of gaining and losing user rights,
- Determine and secure physical access to wireless access points,
- Define security properties of wireless access points,
- Define wireless network type and program support (type and model),
- Define the procedure in case of loss of a network device,
- Define the procedure in case of a security incident,
- Define the procedure for use of encryption and management of keys,
- Define the frequency and range of the estimated security risks.

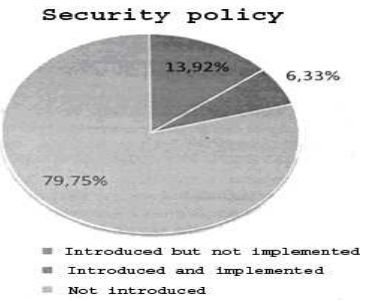
IV. SECURITY POLICY IN EDUCATIONAL INSTITUTIONS OF THE REPUBLIC OF CROATIA

Security policy in educational institutions as well as in other business organizations involves every single computer user. Final users are responsible for administering their own passwords in computer systems. On the other hand system administrators are in charge of supervision, interventions and recovery of security lapses. Crucial responsiblity in carrying out security policy lies with every individual (employee of the institution). Security policy cannot predict every possible breach of security integrity, but it can secure a solution to every problem. Bearing in mind levels of responsibility, a user on the lowest level imperils the security of the entire network if he/she permits compromise of his/her own computer. Employees of educational institutions (both teaching and other personnel) often do not take care of data privacy and the manner of use of network resources. Quite often, due to negligence, computer systems are in jeopardy. Research results show that employees themselves are a high security risk in most instutions.

Institutions in Croatia react to damage done to the security system only after it had already happened. Radojević [3] draws attention to the fact that security in educational institutions is subject to gross deviations: on the one hand he sees it as a major problem when it is discovered, to oblivion when the problem is solved – till the next such incident.

The CARNet survey from 2009 showed that only 45% of the surveyed institutions declare to have proscribed security protection. The survey forms were filled out by CARNet coordinators, i. e. persons who represent the insitution's interests in the CARNet community. The results show that the CARNet coordinators are not experts of computers or of informatic profile, rather they are professionals in the field that is of primary importance for the institution in which they work.

The following graph shows the results from the survey held in November 2010 among system engineers. 20% of the institutions have a defined security policy and only 6% of them do indeed carry it out.



Graph 1. The results of CARNet questionnaire about using security policies in the educational institutions [3].

V. A PROPOSAL OF A GENERAL WIRELESS NETWORK PROTECTION CONCEPT AND RESEARCH METODOLOGY

In the construction of a security system it is necessary to follow certain steps that can also be validated in practice. The funcionality of a security system must be periodically checked or (incidentally) due to the awareness of increased risk of attack on wireless network.

The definition of security level entails a creation of a security system based on optimal choice of parameters that affect it. Efficient functionality of a system requires determining acts that internally connect all elements of the security system. These acts steered as well.

It is also necessary to define security policy and security strategy. Determining security strategy includes the defnition of the security concept that is being constructed. Depending on the security concept of educational institutions, the introduction of the chosen system will be entrusted to system engineers within the institution, or to an external company. While defining the security system, internal resources for construction and execution of necessary protection measures will be considered, as well as the cost of the utilization of external services. According to the graph 2. 100% percent of security level is not possible.

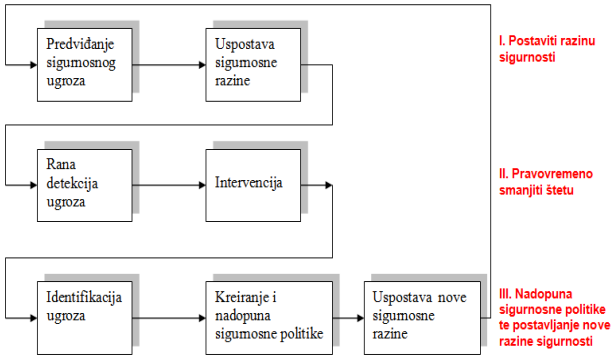


Figure 1. A proposal of a general wireless network protection concept and additional measures of security policy . Author's own source.

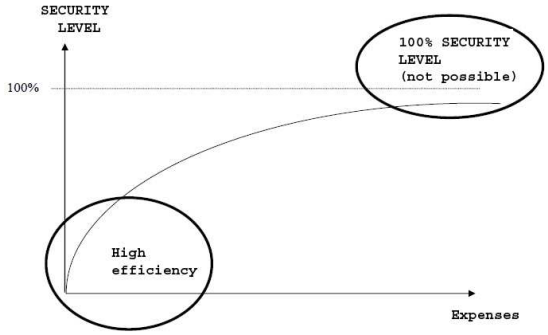

Graph 2. Graphic presentation of possible security levels [10].

In order to investigate and evaluate security parameters that influence wireless network security, a questionaire was composed to test the evaluation of exprets in educational institutions of parameters affecting local wireless network security. A random sample of respondents (**N=59**), system engineers employed in the educational institutions – CARNet members (35 faculties and 24 high schools). Questionnaire was distributed online over the CARNet mailing list *sistemci.hr* at September 2013. Total number CARNet member institutions is 1651 and due to technical constraints[3] and the unavailability was not possible to contact all member institutions. One of the reasons is that the member institutions (primary and secondary schools) have no system engineers (like college) than resource administrators who do not necessarily know the professional field of network security. For the evaluation was the scale of 5 levels of intensity: 1 = not at all important parameter in safety , 2 = partly important , 3 = parameter is important for safety , 4 = parameter very affects the safety , 5 = parameter completely affects the security . The study analyzed the level of security of wireless local area networks, which are based on the calculated average score of selected parameters: the use of encryption , type (model) of wireless network equipment , network coverage , the use of firewall , the

[3] Respondents are those members whose system engineers are subscribed to the mailing list *sistemci.hr*

number wifi users , the existence of security policies at the institution , used network services and the use of a VPN .

The questionnaire consisted of ten questions:

1. Does a local wireless network exist in the institution?
2. Does a security policy exist in the institution?
3. Evaluation of the wireles network in the institution.
4. Evaluation of importance of wireles security parameters, such as :

   a)Encryption algoritms/certification,
   b)Type (model) of network equipment,
   c)Spatial wi-fi network coverage,
   d)Use of *firewal*l,
   e)Number of wireles network users,
   f)Stricly defined security policy,
   g)Simplicity of authenication and authorization,
   h) Types of network serves/services,
   i) Use of VPN;

5. Existence and use of encryption algoritms/certificates in the existig local network;
6. Existence and use of RADIUS protocol and LDAP;
7. Evaluation of efficiency of RADIUS protocol in the sercurity user authenitcation;
8. and 9. Occurence and number og security incidents in the local wireles network;
10. Time needed for detection of security incidents in the local wireless network.

Here are the following answers of the questions from questionnaire.

A. Question nr. 1. Does your institution have a wireless network?

88% of the respondents answered positively to the question on implemented local wireless network in the institution where they are employed, and 12% responded negatively. One could expect that the majority of institutions do have a wireless network due to broad avalilability of wireless technology, acceptable price of equipment and rather simple implementation of computer network in the institutions. The institutions have also recognized economic acceptability of wireless network implementation of the 802.11 standard in comparison to the more expensive cabeling by means of the ethernet 802.3 standard. Wireless connenction possiblities have also increased mobility of users in the institution. This is of great importance when it concerns the use of new teaching and learning systems and of new applicable technologies like e-diary or Tablet that can be used in the education process.

B. Question nr. 2. Does your institution have a defined security policy?

To the question concerning the existence of security policy in the institution 53% of the respondents answered negatively and 47% answered postively. One of possible reasons for omitting security policy as an important factor of security of information systems in educational institutions is the estimate of the importance of information in need of protection. There is a widespread belief that in such institutions information is not essential and thus needs no protection. That is the the main reason for the lacking security policy in educational institutions. The Law on information security suggested the need for security policy under which the security of wireless network access also definitely falls [4]. At primary school level security policy practically does not exist, while academic subjects have differing records when it concerns defining and implementing security measures. The main reason for lacking security policy in institutions of higher learning is the same as in primary schools. An example to the contrary are the systems existing primarily in academic institutions like ISVU, Prehrana, IFIS, NISpVU and SmartX. These systems are applied only in academic institutions, thus not on primary and secondary school levels. In order to implement efficient security policy, system enigineers in academic institutions should have the support from the governing bodies since the adequate protection system requires financial resurces. Besides, investment in security policy is justfied by the very nature of information they are supposed to protect. In conclusion: the existence of security policy in educational institutions is of paramount importance for the security of their information system and thus of wireless network access.

C. Question nr. 3. How do you judge the security level in your institution?

The estimated wireless network security level shows that 47% of the respondents finds the security level satisfactory. Institutions do care about the wilreless network security level, but there is still room enough for raising its quality. System engineers in academic institutions again need the support of governing bodies to finance the expense of more efficient protection, even more so since the resources must come from each institution individually. 5% of the respondents claim not to use any security mechanism for wireless network access protection. It is possible that the institutions possess network equipment with wireless network access, but they do not use it (for example ADSL routers). It is not very probable that the possiblity of wireless access exists, though unprotected by certain protection mechanisms. Additional 5% of the respondents claim to use exceptionally high level of security, which implies that thay have a more substantial backing from the institutiom's governing bodies/management. 22% of the respondents declare that their institution maintains a satisfactory security level and 20% of them report a high level of securty.

D. Question nr. 4a. Evaluate the importance of cited parameters in planning wireless network security.

Encryption algoritms and certification have emerged in answer to question 4 as one of the most important factors in wireless network security. 54% of the respondents consider encryption and certification to be the most important local wireless network security mechanisms and only 2% believe that these are not important for seccurity access to wireless network. On the other hand the respondents gave highest marks to encryption and certification as the most important security mechanisms. Three types of algoritm for secure communication were represented acccording to the following standards: a) Wired Equivalent Privacy - WEP, b) Wi-Fi Protected Access - WPA, c) Wi-Fi Protected Access II – WPA2 [11]. One can guess that the most frequent encryption algoritm in use is WPA2, bearing in mind that this one meets the highest security standards in comparison to both WPA and WEP (see chapter II). Encryption algoritms are the most frequently used security mechanisms in wireless network access protection and as such are implemented in program support of wireless networks devices (routers, access points, wireless clients). Due to the problem of compatibility of wireless network equipment it is necessary to gain additional information on applicability of encryption algoritm to every single network communication device.

E. Question nr. 4b. Do you use of firewall?

Answering the question on the use of firewall 61% of the respondents consider firewall to be of paramount importance for the wireless network security. Firewall got the highest mark. Firewall has the role of filtering the wireless network traffic. In the context of wireless network according to the IEEE 802.11 standard, firewall can be used as an additional security mechanism. It is placed between the local wired network and network devices that make possible wireless connection to a local network (in most cases access points or routers). Protective walls are fitted in such a manner that they require a rigorous authenication and authorization of network access and as such are a very efficient mechanism in the network protection. The respondents have apparently recognized the importance of firewall for the secure access to wireless networks. It is also important to stress that the use of firewall is only one additional mechanism in the security of both wired and wireless networks, although it only provides protection on the network borders, having no influence on the internal security.

F. Question nr. 4c. What is the number of network users?

41% of the respondents find that the number of network users is extremely important for the security planning. The number of wireless network users is proportionate to the security level. If the number of users is high, the number of possible security dangers grows too. A small number of users does not require a more complex approach to the wireless network security. The reason for this is the possibility of detailed monitoring of every single user at the moment when he/she uses the wireless network. 27% and 20% of the respondents consider the number of wireless network users as important and very important in planning the network security and only 5% of the do not consider it important.

G. Question nr. 4d. The type (model) of network equipment.

32% of the respondents think that the type (model) of network equipment is important in the optimal planning of wireless network security. Considering that the market offers a variety of active wireless network equipment, one can expect variety in their technical characteristics and possiblities of use of recommended security mechanisms. One can find in the market equipment marked „WIFI certified“, issued by the non-profit manufacturers' organization Wi-Fi Alliance, whose goal is stimulation of mutual compatibility and promotion of their products. Wi-Fi Alliance, with a network of independent test laboratories carries out tests in order to safeguard mutual compatibility of active wireless equipment and to render support to secure communication. The cited certificate [5] guarantees interoperability, security, simple installation and reliability in operation. 29% of the respondents evaluated the type (model) of wireless equipment as exceptionally important in the planning of security, and only 2% find the type and model of wireless equipment not important in the planning of wireless network security.

H. Question nr. 4e. Spatial coverage by wi-fi network.

Spatial coverage was considered as exceptionally important in the planning of network security by 57% of the respondents. 0% of them consider the spatial coverage as not important. 17% and 19% of the respondents consider it as being important and very important respectively. Bearing in mind the covered space and the limited range of the wireless network signals emitted by the active wireless equipment (access point, wireless routers) and the phenomenon of “secondary petal?” effect the higher degree of spatial coverage by the wireless network represents also a higher security risk. Therefore it is extremely important to know, at the installation of active wireless equipment, what will be the spatial coverage and thus spatial accessibility of the wireless network.

I. Question nr. 4f. Strictly defined security policy.

The existence of security policy in the institution (organization) was recognized by 42% of the respondents as exceptionally important for the security of the information system in the institution as well as in the case of of local wireless network security. 24% and 27% of the respondents consider the security policy as important and very important respectively, and 0% of them think that a strictly defined security policy is not an important security factor in the planning of the wireless network

security. As has been mentioned in Chapter IV of this thesis, CARNet has elaborated a proposal of security policy for schools titled Acceptable use of computers in schools and another document titled Security policy of information systems for the CARNet members. These documents treat the security policy in general terms, and focus on the user rights and responsibilites. These documents carry also instructions realting to the use and wireless network security (elaboration of the documentation of the computer network in the institution, record of the assigned IP addresses range to specific parts of the computer system, fine tuning of the wireless network before operation, the importance of encryption of the network traffic, implementation of the encryption and authenitaction method, etc. The task of the security policy inculdes also monitoring changes in properties of the newtwork equipment in order to respond swiftly and efficiently to security incidents. Bearing in mind the presented research findings one can conclude that the respondents are well informed with respect to the importance of the security policy in the institution and on the influence of security policy in the planning od security of the local wireless network. In conclusion one can say that security policy should be planned often, should be implemented and supplemented by new rules and guidelines (recommendations) in order to make it as efficient as possible in preventing security risks and damage to confidetial information in the system.

J. *Question nr. 4g. Simplicity of authentication and authorization.*

53 % of the respondents consider the simplicity of the user authentication and authorization to be of the paramount importance for the wireless network security, 27% of them find it very important and 12% important. Seen from the user side it is necessary to make simple authorization possible. Complex systems where the authentication and connection to wireless network is complicated for the user (like hand written SSID and IP address and network domains) should be avoided, except in cases when security standards are set very high. Educational institutions should choose a wireless security model that provides high security level, but should also simplify the user authenication and access of wireless services. It is interesting to note that 0% of the respondents consider simplicity of authentication/authorization process unimportant for a certain security level. User authentication should as a rule take place in such a way that the user can find the corresponding wireless network SSID and authorize himself by introducing access data (e. g. from AAI@edu.hr system). System EDUROAM also provides a simple access provided the user makes use of the client application on the client computer. podešene na klijentskom računalu (eng. Supplicant).

K. *Question nr. 5. Do you use RADIUS protocol and LDAP in the local (wireless) network?*

The presence of the RADIUS protocol together with LDAP service has been reported in 39% of the institutions and 61% of them do not use RADIUS+LDAP service. It is important to stress that academic institutions (polytechnics, universities and scientific institutes) do use RADIUS protocol te LDAP imenik. The reason for this is that they possess their own infrastructure with CARNet backing, as the key institution supporting member institutions. Elementary and secondary education does not use ADIUS+LDAP in theiw own systems. Electronic user identities in the AAI@edu.hr system are based on the existence of the RADIUS+LDAP systems. From there the users access other systems like ISVU or specific network services (FTP). Security level is reached by the use of the network protocol itself, LDAP service and firewall with the aim of limiting network traffic svrhu ograničenja u mrežnom prometu and permitting the use of specific network services. This system is used in the access of wireless network whereby the security is not based on the use of encryption algoritms, but on the certificates (WPA+TKIP)and client applications on the users' computers korisničkim računalima (e.g. secureW2 client application with in advance defined profile "Eduroam" [6]). The stress lies on the user authenitication process which is carried out by EAP[4]-TTLS protocol. According to the CARNet CERT document CCERT–PUBDOC–2008–01–216 [7], EAP protocol is used on the data network layer OSI (eng. Open System Interconnection) of the referring model. Implementations of the protocol meant for networks with routers and for switched networks are available. In case of wireless networks the impelementation takes place at access points and switches. The advantage of this authentication protocol is the possibility of expanding it ? by selection of the authentication method and simple addition of new methods without having to change the entire implementation of the protocol.

L. *Question nr.6. Which encryption /certification algoritm do you use in the wireless network protection?*

39% of the respondents declared that they use WPA2+PSK certification in order to protect the network from unauthorized access. 12% of them use WPA encryption algoritm, 8% WEP, 15% do not use any encryption algoritm/certification, 7% use WPA and the rest is used by 5%. Although the majority of the respondents recognized the WPA2 certification more efficient in preventng security breaches than WPA/WEP

[4] Extensible Authentication Protocol EAP (Extensible Authentication Protocol Eng.) enables authentication using a supported method of forty, and is commonly used in wireless computer networks.

algoritms, the vulnerability of WPA2 certification is reflected in the use of WPA2+PSK[5] [9].

M. Question nr.7. Evaluate the effciency of the RADIUS protocol and LDAP in the security user authentication.

The efficiency of the RADIUS protocol and LDAP imeničkog service in the security of user authentication according to IEEE 802.3 and IEEE 802.11 standard got from 39 % of the respondents the highest mark. 30% and 27% of them value it as good and very good.5% of the respondents gave it a negative mark. RADIUS protocol and LDAP imenički service are among the main components in the AAI@edu.hr. System. LDAP imenik contains data on electronic identities, RADIUS server is primarily meant for authentication aimed at security in network access (wired and wireless access as well as AOSI web service for data access and maintanence of the LDAP imenika. It is important to stress that the wireless network access due to the need for a higher security level necessarily requires the use of encryption algoritm that protects it.

N. Question nr.8. Have you recorded a security incident in your institution that happened by way of wireless network?

19% of the repondents report at least one security incident and 81% of them claim that no such incidents have happened. Recording security incidents can be related to the question number 3., where 47% of the respondents declared that their institution has a satisfactory level of access protection to wireless network system. That brings us to the conclusion that the institutions take care about the security of wireless network and that they are not exposed to simple security perils that can damage the system (e.g. unprotected wifi network signal, the use of WEP encryption, etc.).

O. Question nr.9. how long did it take you to discover the incident?

The answers to the last question can draw attention to the current state of affairs in the educational institutions. 42% (5) of the respondents report that they needed several days to discover the incident that had occurred. 33% (4) of them discoered the incident after several hours . It is important to note that question number 10. Is consequentially connected to the question that preceeds it on the record of security incidents. 19% (11) of the repsondents have recorded security incidents. Bearing in mind the survey results on can conclude that the security perils are noticed mainly on time. If the institutions could employ more qualified system engineers and/or make a better division in the IT department of the institution, the result would be even better. It is a fact that the system engineers in the educational institutions often deal with a wide scale of IT tasks and thee remains less time to cope with monitoring the system security. Reaction to a signalled problem ususally occurs when one of the services stops functionioning, or does not function any more while possible „interception“ of security perils requires constant monitoring of the system and more work from the system engineers. Anyway, system engineers in the educational institutions do take care of the security system and they also repair the damage to it on a short notice. 0% of the respondents declared that they needed longer than a month's time to discover a security incident.

[5] Pre Shared Key – shared secret key with one of the modes WPA2 certification in the security of wireless networks. The same is not proved reliable because it is possible to bypass through the available software tools such as Aircrack.

VII. CONCLUSION

The research results presented in this paper refer to the field of security of wireless networks with the emphasis on the educational institution in the Republic of Croatia. The reasons for choosing the relation of wireless network security and the educational institutions are the security lapses and perils that occur in practical use of the network and in the analysis of security parameters. A very important role of network administrators, that are not present in all educational institutions, is also stressed in the present paper. Besides, the knowledge of the network security is not equally spread in all educational institutions. And since security levels range from complete absence of security to protected networks, the present paper aims at presenting the current state of affairs in the matters of local wireless network security in educational institutions in order to sketch possible future guidelines for the optimal security model. Some average quantitative values of security parameters and assigned weighting factors in the research are shown in table 2 and table 3.

TABLE 2. AVERAGE QUANTITATIVE VALUES OF SECURITY PARAMETERS (RESEARCH)

Security parameter	Average score (research)
1. Encription	**4,03**
2. Type of network hardware (equipment)	**3,74**
3. Wifi coverage	**4,15**
4. Using of firewall	**4,24**
5. Number of wlan users	**3,77**
6. Defined security policy	**3,93**
7. Network services	**3,81**
8. Using of VPN	**3,41**
9. Using RADIUS + LDAP	**3,66**
Average score (total)	**3,86**

TABLE 3. ASSIGNED WEIGHTING FACTORS (WEIGHTS) SECURITY PARAMETERS ACCORDING TO THE RESULTS OF RESEARCH

Security parameter	Ponders (value)	Ponders %
1. Encription	0,15	15,00%
2. Type of network hardware (equipment)	0,08	8,00%
3. Wifi coverage	0,18	18,00%
4. Using of firewall	0,21	21,00%
5. Number of wlan users	0,09	9,00%
6. Defined security policy	0,13	13,00%
7. Network services	0,1	10,00%
8. Using of VPN	0,02	2,00%
9. Using RADIUS + LDAP	0,04	4,00%
Total	**1,00**	**100 %**

According to research presented weights show a high correlation (strong relationship defined within ± 0.70 to ± 0.90) with the results of the study (r = 0.78). Two parameters (VPNs, RADIUS + LDAP) have low weights (2% and 4%) and are almost negligible in the final evaluation, because their ratings are almost no influence on the final result. Table 4 shows the values of the security parameter in the overall security that can display numerical values of 1 - Insufficient security level to 5 - very high level of security.

TABLE 4. SECURITY LEVELS (VALUES) OF RESEARCH

Security level	Value (MIN)	Average (AVG)	Value (MAX)	
1	0	20	29	
2	20	40	49	
3	50	60	69	
4	70	80	89	(r)
5	90	100	99	0,779604014

The present paper researched and analysed the theoretical properties of wireless network security, the existing pieces of legislation relating to security policy in the educational institutions, the well-known types of security perils, the survey of possible security parameters, the specific cases of security lapses and the statistical review, based on a sample, of the current wireless network security status in the educational institutions. The presentations of the theoretical wireless network security properties includes also the study and analysis of the literature dealing with the subject matter and general properties of secuity as well.

Use of iPads in foreign language classes

K. Starkl Crnković
OŠ Vežica, Rijeka, Croatia
klarastnkv@gmail.com

Summary

The implementation of iPads in the process of teaching and learning brings new opportunities for teachers and learners in and beyond the classroom. This work deals with the experience of the very first five months of the 1:1 model of implementation of iPads in foreign language classes with 11 and 12-year-olds in a primary school in Rijeka, Croatia.

I. INTRODUCTION

By implementing iPads in the teaching process of a group of eight graders, Primary School Vežica started last year a unique project in Croatia. Being the results highly encouraging, the 1:1 implementation model was extended to fifth and sixth graders at the beginning of this school year. Teachers of all subjects have adopted iPads to support their teaching and have been training students to use their own iPads to personalise their learning.

The way iPads are used in and beyond the classroom depends, to some extent, on the subject taught. This work will deal with the way iPads have been integrated in foreign language classes with 11 and 12-year-olds throughout the period of the very first five months of their implementation.

II. GETTING USED TO iPads

Adaptation to the use of the device ran smoothly because most of the students had been using smart phones for a few years and was already well-acquainted with touch screen technology. Furthermore, navigating the touch-based software is a very intuitive process, so none of the students encountered major problems.

During the first three-week-period of familiarisation with the device's main options, such as installing and using an app, an e-book or dictionaries, using writing tools like *Pages* and using the school's virtual learning environment (*Edmodo*), teachers discussed with the students how to do with their iPad what they used to do before with pens and paper, desktop PCs and books as well as how they can learn in ways that were never possible before.

III. iPads AT WORK

Being English he first foreign language for all students in the above mentioned school, teachers of English can easily take advantage of the enormous number of apps available in English. But teachers of other languages such as German, Italian and French (taught to smaller groups of students as second foreign languages in the same school) have successfully implemented the use of iPads in their classrooms being the number of educational apps available for the study of these languages substantial (although somewhere lacking for that particular age group). Besides the greater amount of existing apps for the study of English (as a first language or foreign language), teachers of English can choose from a wider range of educational apps in their target language designed for other subjects in order to integrate topics and material from other subjects into English in a cross curricular learning vision.

With more than 500,000 apps available for use the question of how you find those that best suit your students' educational needs and programme sometimes arises. Collaboration among teachers is in this case essential. In the case described the use of iPads has encouraged greater sharing of resources and ideas among teachers. Teachers can also refer to web sites which provide lists of apps for particular subjects and needs, categorise most used apps according to Bloom's taxonomy and

give useful advice on how to use some apps effectively.[1]

However, we have been able to try out the use of iPad in every phase of the learning process from motivation to revision and assessment for all of the four skills: listening, reading, speaking and writing without completely replacing traditional methods of teaching or becoming a paperless classroom.

Being the iPads fully compatible with online teaching and learning platforms such as *Quizlet*, we made a great use of them in the foreign language classroom, instructing at the same time our students to make the best use of them outside the classroom.

Tools such as audio and video recorders are highly useful in foreign language classes. It is easy to imagine how the iPad with an incorporated camera and microphone makes the difference. Not only the way learning takes place, but also the way homework is completed changes. Students can be encouraged to take part to a live debate for their evening homework and marked on their level of engagement and responses or can be given the task to use the language in a particular exercise, record their voice and send it to the teacher. The latter activity can be a great opportunity for the less self-confident students, who usually do not do much talking in class, to build their confidence gradually.

IV. COMMUNICATION, COLLABORATION AND SHARING

A major effort was put into getting students used to new ways of communication, collaboration and sharing.

The regular, ongoing contact between teacher and student made possible by the device, gives each student individually feedback and information as to which skills or knowledge they should approach at each stage and allows discovery of student's interests, strengths and areas for improvement.

Teachers can in that way help their students learn how to personalise and channel their learning. They can become facilitators for personal learning rather than instructors of facts. The device enables students to approach and process new language content by themselves, in pairs or small groups extremely well. For instance, while reading a new text in the target language, students have at hand a number of options by which they can look up the meaning of a new word or expression, hear it pronounced (and replay it as many times it is necessary), find the translation in their mother tongue, see the word used in different contexts, find images, videos, links and so one. The result is a more integrated learning experience which makes students used to problem solving and handling complex tasks and which is more engaging and because of that, more memorable for students.

In such a learning environment students are expected to put much more effort into the learning process than they used to do before. They are also expected to take responsibility for their learning. Our fifth-grade-students have been instructed to create, use and reuse their material in different ways in order to study, reinforce or revise lexical units or grammar points. They decide for which words or expressions they need to practise spelling or pronunciation and they insert them in apps such as *Dragon Dictation* or *Spelling Notebook* which they can easily access as many times they feel they need to. Most importantly, each time they access and practise the material, they get immediate feedback about their progress. They are able to check and keep track of their progress and became aware of their own learning. They are in that way taught to plan their learning and become more organized.

Not only communication between teachers and students has been enhanced, peer communication has also improved. The fact that students can easily share materials of any kind (texts, audio, photos, videos, links) gives great opportunity for collaboration to take place. After certain content has been learnt, it can be put in a similar or different context with the employment of students' creativity. *Puppet Pals* is an app which has proved to be very effective in the language learning process because it allows students to create an animated story and make the characters talk by recording their voices. In fact it makes

[1] See for example
iPads for Learning

Bloomin' Apps, http://www.schrockguide.net/bloomin-apps.html
103 Interesting Ways to use an iPad in the Classroom,
https://docs.google.com/presentation/d/1UJnqyK52X26az5zN5kr1ISTNPwbdUbxfG6M-9WMW4Do/present?slide=id.i21

them practice the target language in a fun and relaxed context. If the aim is practising writing, than a suitable app could be *Strip Designer*, an app for creating comics.

The last two apps mentioned are the ones that seem to be the most appealing to our foreign language students and that have been rated as very effective by our teachers. However they are, like the other apps mentioned in this work, just a few drops in the ocean of learning possibilities offered by the use of iPads in and beyond the classroom.

V. CONCLUSION

In the described case of implementation of iPads in the teaching and learning process both teachers and students have experienced positive results such as continuous access to engaging educational materials; different ways to help students learn new concepts, express their creativity and personalize their learning; easy ways for learners to connect, collaborate and share and, in more general terms, education moving from a content to a problem solving paradigm.

Both teachers and students have become aware of the enormous potential of the use of iPads, a potential that still has to be explored and put into practice firstly by those who have in mind the pedagogies the device supports: teachers and educators.

Tablet PC & smartphone uses in education (TabletTours)

Krunoslav Bedi
School of Civil Engineering, Art and Craft Čakovec
Športska 1, HR-40000 Čakovec, Croatia
krunoslav.bedi@ck.t-com.hr

Abstract - This paper presents the development and design of TabletTours application, high-school students' extracurricular project activity. TabletTours application is designed and implemented as a virtual tablet-based travel guide.

The additional purposes of this paper are to examine the manner in which students use new technologies (tablet PC, smartphone) and to showcase an example of a successful implementation of acquired ICT knowledge and skills in a project-oriented classroom.

Keywords: tablet PC, smartphone, multimedia computer interaction

* In 2013, the application "TabletTours" was presented and won the 3rd Prize at Info kup – Primošten 2013. The trailer of the game can be accessed via – http://www.youtube.com/watch?v=NGKlsL30wlM.

I. INTRODUCTION

In this day and age children are immersed into the digital world. To overlook and / or ignore this fact would be a fatal mistake. The teaching staff have to be given a fair chance to effectively capacitate the children for the world in which they live and will continue to live in. A change in the teaching process itself is necessary. Two approaches to enable a wider population to benefit from ICT revolutions are: to enhance level of ICT literacy (including basic, functional technology and computer education), and to design appropriate IT tools around the capabilities of users [1].

Digital technologies, primarily tablet PCs, smartphones or laptop computers, are currently imposing a need for a new pedagogical paradigm. The new learning environment calls for educational and technological innovations. The involvement of educational experts, professors and teachers is crucial to ensure that new multimedia technology serves the educational process benevolently. There is a need for further investigation of student attitudes and teachers views about the use of tablet PCs [2].

Tablet PC is the most popular computer of our time which is a portable personal computer typically smaller than a notebook computer but larger than a smart phone, and it is easy to transfer the data by means of its internet and memory device [3].

Smart Phone: It is a kind of communication device that has been designed by adding the features of PDA. Due to the fact that smart phones have mobile operating system and many applications, they are very common devices used actively in all areas for different purposes [3].

The need for information and the increasing degree of educational autonomy require a proactive approach hence curiosity and exploration in the digital world, which are the natural drivers of learning, enable an even faster retrieval of desired information. The integration of mobile technologies into the educational system goes beyond its sole availability [4].

Social networks are not only a new, increasingly important social dimension but also a gateway to improving speaking and writing skills.

In a traditional educational environment only the teachers, possibly parents, could have read student assignments. However, it is now necessary to take into account that these assignments will be available and visible to a wider audience. New technologies are also suitable for students with learning disabilities. The use of tablet PCs becomes a tool to give greater attention to this type of student with school difficulties [5].

Characteristics and personality traits of each child are improved and made flexible by digital technologies. A growing number of scientific disciplines indicate the importance of interactive learning approaches which are made available through digital contents and applications. In simple terms, multimedia-digital contents become a relevant source of information displayed in an attractive way with the possibility of direct communication and student interaction. Such digital contents open many audio and visual channels for students to choose from according to their respective personal preferences. This situation motivates exploring the potential of education-aimed netbooks and tablet PCs with a view to determining which of these devices would be the most appropriate for the classroom [6].

For example, a cleverly designed digital textbook becomes an important source of the latest information presented in a visually appealing way with the possibility of direct communication and interaction between the student and the "environment". Namely, the digital textbook allows simultaneous audio and visual stimuli. If a child-student shows more interest, available links and websites provide the possibility for further knowledge deepening in any area of interest. Smartphones are no longer cutting-edge communication gadgets, but are now necessities in peoples' lives. For smartphone users, their phone is the first thing they look at in the morning, and the last thing they look at before going to sleep [7].

The concept of a new upcoming school system changes the role of the teacher / educator significantly. It is obvious that the teacher is no longer the primary source of information. The focus shifts towards giving meaning and sense to new information in a wider context which would allow the children to understand these complex processes better. The teacher would also have a significant role in helping students engaging in the process of abstracting and differentiating important and reliable information from the less important one. Due to the fact that unlimited access to large databases imposes an entirely new task for the children, the professional help of teachers is extremely important in this crucial cognitive process. This reality has prompted considerable interest in finding fruitful ways of integrating mobile technologies, such as wireless laptops and tablet computers, into educational settings [6].

II. THE APPLICATION OF DIGITAL TEACHING IN THE SCHOOL SYSTEM

To educate and optimally prepare the children for the digital world is not only one of the fundamental tasks of the contemporary school system but a responsibility of the society as a whole. The quick and recent upsurge of mobile IT devices is a relevant development for education [8].

Is it really so or is it yet another craving for profit? Large firms always have strong marketing strategies and their expensive computers offer a number of features regardless of the fact that many of these software packages and options are rarely, if ever, used. We have failed to develop a proper system of setting professional educational criteria and assessing the quality of the offered equipment and educational materials. It is therefore not difficult to assume that the educational website "market" could become a commercial jungle very soon if an effective way of establishing order and adherence to generally accepted criteria is not introduced.

The slow and complex process of preparing textbooks for print contributes to delays in the teaching material modernization. A tablet PC, which every schoolchild could have eventually, would provide a systematical syllabus update offering children the latest knowledge and scientific discoveries tailored to fit their age. Should we compare the prices of a lower price range laptop/tablet to a set of class textbooks, workbooks and school paraphernalia, the investment would certainly pay itself off within a period of two or three school years. We all agree that children are a country's greatest wealth and therefore the quality of their education determines the overall development of a society. With the growth and convergence of mobile and social computing technology, mobile media are accorded new social meaning manifested in different aspects of our everyday life [9].

III. DIGITAL TEACHING EXPERIENCES

Many countries are turning to digital textbooks with the ambitious goal of fully digitalizing textbooks for primary, secondary and tertiary educational institutions by the year 2015. However, there are initiatives which include combining digital with paperback textbooks. Mobile devices such as personal digital assistant (PDA), mobile phone, and Tablet PC are nowadays more user friendly and user convenient than before. They are coming with major improvement in memory storage, interactivity features and high data transfer speed. Mobile devices are neutral to teaching and learning theories; they can be used with traditional learning theories such as behaviorism and new learning theories such as constructivism [10].

The development of new communication technologies, especially collecting and processing of required or new information, is likely to change the curricular context in the near future, emphasizing the individual approach and the technical knowledge necessary for using all available sources of information and knowledge. The proliferation of mobile technology provides a myriad of opportunities to support learning and performance both inside and outside the classroom. With mobile technology, the learning environment can go with the student to the field site, to the laboratory and beyond. There is an opportunity to leverage mobile technology to better support students not only in the classroom, but also as students navigate to the context of their learning. Mobile technology opens the door for a new kind of learning and performance support in the field, providing anytime and anywhere access to information, processes, and communication [11].

Today's digital communication technology, if used wisely, could most certainly serve as a useful eduactional platform for developing quality school programmes and curricula. Mobile media devices (MMDs), consisting of smartphones and tablet computer s (e.g., iPad, Surface RT), not only strengthen our social bonds but also provide us a

completely new way to interact with information [12].

A very interesting developmental project "One Laptop per Child (OLPC)" was launched in the year 2002. Its aim was to open new doors for children in developing countries and give them a chance to learn and access information easily. If we consider the fact that in today's world there are still almost two billion children without adequate access to education, which is readily available to their peers in developed countries, each step taken in this direction is not solely a humanitarian gesture. It is a firm foundation for strong and long-term development and offers assistance to developing countries. The project of a technical device which would enable easier learning thus modernizing the educational process certainly transcends the Internet Age.

The schools are to use the iPads for replacing physical book and submitting coursework, while there will be no longer be a place for the more traditional pens, pencils, blackboards or even classrooms, which are replaced by 'subject rooms' [13]. The BYOD (Bring Your Own Device) model is becoming an increasingly attractive and inexpensive option. That is, students bring their own devices. The cost of the devices, their maintenance and connectivity plans are usually shouldered by the students. In a world increasingly dominated by mobile devices BYOD projects can be implemented quickly and cheaply in areas where most students have such devices. However, BYOD has serious limitations if it fails to accommodate students who do not have mobile hardware or creates situations where some students have more sophisticated devices than others [14].

IV. „TABLETTOURS" APPLICATION PROJECT

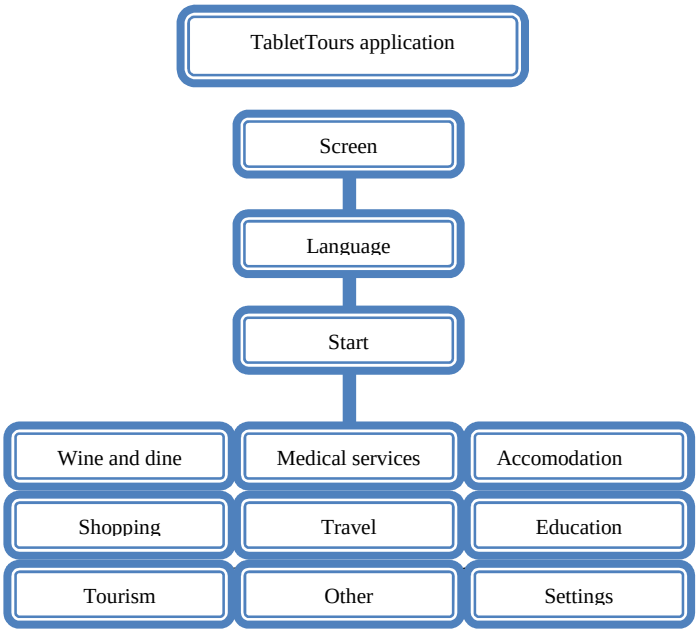
Two fourth-grade students started creating the entitled „Tablet Tours" application under the mentorship of the author of this paper. A wide range of software normally used in the four-year course was utilized. In a four-year web-designer/media technician course the entire necessary software infrastructure has been provided by the Ministry of Education and Sports of the Republic of Croatia. The work itself was team-organized since teamwork had proven to be far more efficient than individual work, more precisely, one of the students doing the programming and the other one the visual designing. The students worked on the application during their optional subject/activity time with the key role of the coordinator assigned to the mentor, i.e. the optional subject teacher, who is also the author of this paper. In their teamwork, the students chose a specific name, "DreamLand"", which can be seen from the Youtube attached trailer. The assigned name has given the teamwork a whole new dimension and a touch of "professionalism" as well as additional motivation for the students. A Facebook profile (a group) promoting the application was created for the purpose of the State IT Competition – Infokup 2013. Primošten.

TabletTours project, derived from project-based learning, was developed in co-operation with the local Tourist Board. Prior to the development of the application itself usability and marketing-driven approaches had been contemplated on so that the application could be launched in practice.

The application is designed not only as a virtual guide but as a specific guide for tourists as well. In fact, travel guides offered by TabletTours application can be used as a helpful tool in a particular field of work or sightseeing. Tourists / customers can use the application in accordance with their particular interests.

The application idea comes from the observations and experiences of students during school or travel (for example, a school trip).

Application scheme:



Processor	1GHZ+
Memory	256MB
Resolution	Automatic
Operating systems	Android v2+, iOS, Windows 7, 8

Teamwork

Developmental background

Software used in the making of „Tablet Tours“ and assigned documentation: Adobe Flash CS5.5 Professional, Adobe Premiere Pro CS5.5, Adobe Photoshop CS5.5, Adobe After Effects CS5.5, Microsoft Word 2010, te Camtasia Studio 8.

Graphic design

The graphic designer had to develop a functional, dynamic, understandable and interactive user interface. His additional jobs were designing a promotional leaflet as well as the project's website. The graphic designer used the following software: Adobe Photoshop CS5.5 i Adobe Flash CS5.5 Professional.

Programming

The task of the programmer was coordinating all the graphic design concepts with the software solutions. In the making of „TabletTours“ application the programmer used ActionScript as the basic software system which ensured the application would work properly. The programmer showed the respective skills in the use of Adobe Flash CS5.5 Professional with AdobeAir technology (for Android, for iOS, Windows).

Video design

The task of the video designer was coordinating the multimedia and content requests with functionality and the educative quality. He made this possible by using the following software: Adobe After Effects CS5, Adobe Photoshop CS5.5, Adobe Premiere CS5.5.

Audio design

The application's audio design consisted of producing trailer music and adjusting sound to „listening“ option.

Application control

The tablet has a touchscreen enabling touch control of the appplication. However, if the tablet supports a dock keyboard, a mouse/keyboard can be used. The application is adjusted for Android, iOS and Windows 8 operating systems.

Application screenshots

TABLE 1. PANELS/BACKGROUNDS FROM TABLETTOURS APPLICATION

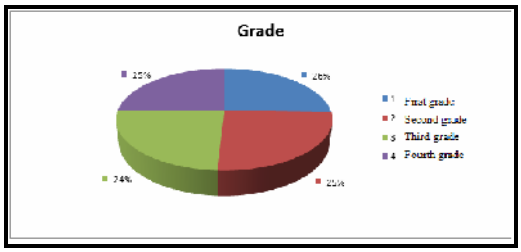
V. RESEARCH METHODS

In order to obtain relevant data, a research involving a sample of 311 students (first, second, third and fourth grade respectively) was conducted. All of the students involved attend the following vocational programmes in School of Civil Engineering, Art and Craft Čakovec: media technician, web-designer, interior architecture designer and ceramics designer. The research was conducted by survey. The survey sample included both sexes, 140 male and 171 female students. The students were given the possibility to withdraw at all times, to participate or decline participation, therefore one can assume that the obtained data is relevant.

The aim of the survey was to get feedback on:

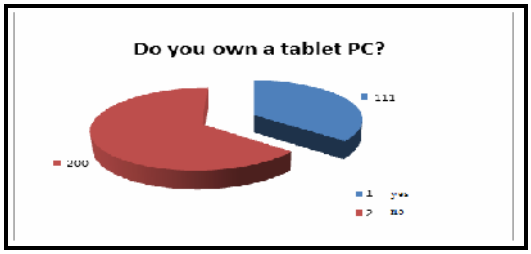
- whether today's students have a tablet PC or a smartphone
- whether today's students use or will use a tablet PC or a smartphone
- whether students use a tablet PC or a smartphone to follow lectures
- the extent in which they justify the use of a tablet PC or a smartphone
- the reasons for using new technologies instead of "paper" handouts
- any indication of future use
- whether the results indicate a change in digital content acceptance

VI. RESEARCH RESULTS



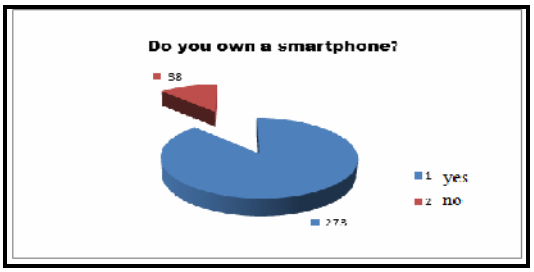
Graph 1. The percentage of students participating in the survey

An equal number of first-, second-, third- and fourth-grade students participated in the survey, as follows; 26 percent of first-grade students, 25 percent of second graders, 24 percent of third graders and 25 percent of fourth-grade students.



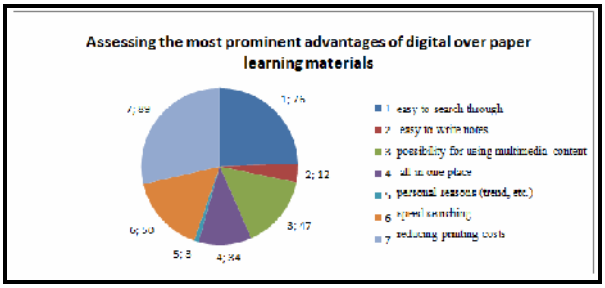
Graph 2. Owning a tablet PC

The majority of the students included in the survey do not own a tablet PC.



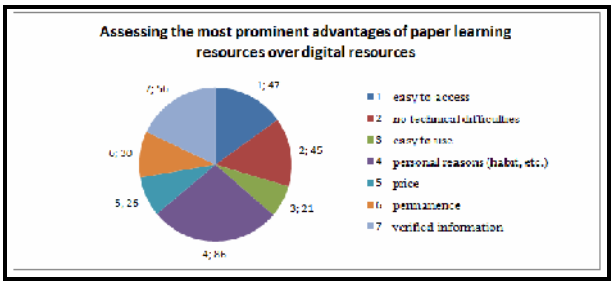
Graph 3. Do you own a smartphone?

The given chart illustrates the fact that the majority of the participants own a smartphone, which could be explained in the context of popularity of smartphones among younger population.



Graph 4. Assessing the most prominent advantages of digital resources over paper learning resources

The students consider speed searching to be the most prominent advantage of digital over paper learning resources (89 out of 311 students). The students have also sincerely admitted the importance of personal reasons (50 out of 311).



Graph 5.Assessing the most prominent advantages of paper learning resources over digital resources

When assessing the advantages of paper learning resources over digital ones, the largest number of responses falls in the "personal reasons" category, i.e., habit. It is obvious that the students still consider paper-based learning material to be indispensable. The evident uniformity of the remaining answers indicates that there is no undue preference.

VII. CONCLUSION

Tablet PCs offer a new perspective to the children by enabling a simpler and friendlier way of learning, gathering new information, switching to interactive and / or multimedia world. Here and now learning has the ability to engage learners because of its authentic learning and context based applications [11].

We all agree that an abrupt change is not good for the educational system. New technologies, in spite of their many advantages, should not replace paper textbooks completely.

Therefore, the common conclusion is that a combination of digital and paper textbooks is the most acceptable one, that is, tablet PCs should be made available as classroom tools. It is not possible to replace all paper materials with digital ones without affecting learning efficiency. We should keep in mind that there are advantages and limitations in the use of new technologies in lesson planning. Although tablets are increasingly popular in education, there are still obstacles and barriers that may limit the use of them in the educational landscape and more specifically in teaching [15]. However, there is only one possible answer to the question „will new technologies change the teaching process“ – a resounding yes.

Informatika kao izborni predmet ili izvannastavna aktivnost u razrednoj nastavi

Jelena Šurić, mag. prim. educ.*, Tea Pavičić, mag. prim. educ.**, dr. sc. Mario Dumančić, doc.***

* Osnovna škola „Braća Radić“, Koprivnica, Croatia, suric.jelena@gmail.com
** Prva osnovna škola, Varaždin, Croatia, tea232pavi@hotmail.com
*** Učiteljski fakultet, Sveučilište u Zagrebu, Croatia, mario.dumancic@ufzg.hr

Sažetak - **Glavni cilj ovog rada i istraživanja bio je sistematizirati i prikazati važnost uvođenja informatike kao izbornog predmeta ili izvannastavne aktivnosti u područje razredne nastave. Provjeren je i odnos djece u dobi od 7 do 10 godine prema digitalnoj tehnologiji, njihova empatija i znanje. Istraživanje je provedeno na prigodnom uzorku od 400 učenika razredne nastave u pet osnovnih škola u Varaždinu i Koprivnici. Svaki je učenik ispunio anketni upitnik Računalo i ja. Rezultati su pokazali da gotovo svi učenici posjeduju i koriste računalo i Internet. Većina ispitanika dio svog slobodnog vremena provodi koristeći digitalnu tehnologiju isključivo za zabavu i suzbijanje dosade. Rezultati konkretnih informatičkih pitanja pokazuju nezavidno znanje učenika o osnovama digitalne tehnologije, no njihova zainteresiranost za stjecanjem novih, informatičkih znanja stvara temelje za stručnim uvođenjem učenika razredne nastave u svijet informatike.**

I. UVOD

Glavni cilj nastave informatike podrazumijeva osposobljavanje učenika za korištenje osobnog računala. To korištenje osobnog računala obuhvaća znanja o dijelovima računala i njihovim ulogama te o programima za upravljanje i sigurnom radu na računalu. Zašto bismo ova znanja i sposobnosti ograničili samo na učenike viših razreda osnovne škole? Zašto učenicima nižih razreda osnovne škole, koji također žele, znaju, mogu i uče vrlo brzo, uskraćujemo tu priliku?

U Nastavnom planu i programu Republike Hrvatske ne postoji dio koji bi obuhvatio informatiku od 1. do 4. razreda osnovne škole. Ovaj složeni zadatak izrade nastavnog plana i programa još uvijek nije napravljen. Izrada programa informatike mora obuhvatiti niz specifičnosti poput starosne dobi učenika, njihov psiho-fizički razvoj, mogućnosti ICT tehnologije, specifičnosti metodičkog i didaktičkog pristupa itd. Na primjer, uzimajući u obzir dob, znamo da se sposobnosti rješavanja problema kod djece razlikuju ovisno o dobnim skupinama, kao i ono što su oni u stanju razumjeti. Osim toga, ne smijemo uzeti u obzir samo globalni koncept (Nastavni plan i program, udžbenike za različite razrede, scenarije predavanja i terminologiju koja se koristi u zadatcima za učenike), nego i pedagoški materijal i odgovarajući obrazovni softver.

Bischof i Sabitzer u svome članku *Computer Science in Primary Schools – Not Possible, But Necessary?!* neostvarivost naslovom postavljene teze vide u problematici planiranja i programiranja nastave informatike i određivanja njezinog glavnog cilja [3]. Prema njima, najvažniji didaktički principi, iza samog sadržaja, koji nužno mora biti prilagođen spoznajnim i razvojnim psihosocijalnim karakteristikama djeteta, moraju podrazumijevati istraživačko učenje i timski rad. Autori smatraju da bi glavni cilj provođenja nastave informatike u razrednoj nastavi između ostaloga trebao biti: povećanje, odnosno stvaranje interesa za korištenje ICT, motiviranje djevojčica u korištenju tehnologije, proširivanje stava prema ICT, usmjeravanje prema pravilnom načinu korištenja računala i pokazati učiteljima da podučavanje područja ICT nije toliko teško kao što mnogi od njih pretpostavljaju [3].

U članku Laurie Patsalides, *Why and How to Use Computers in Classrom,* pronalazimo neke prednosti pravilne integracije računala u nastavni proces gdje bi učenici stjecali vještine obrade teksta radeći zajedno na projektima i razvijali međusobnu suradnju između učenika te između učenika i učitelja. Rad na računalu zahtjeva više razine razmišljanja, potiče učenje putem pokušaja i pogrešaka te razvija odgovornost, samostalnost i osjećaj postignuća [11]. U Velikoj Britaniji istraživanja su pokazala izrazito poboljšanje obrazovnog učinka nakon ulaganja u ICT u osnovnim britanskim školama [13]. Učinak ICT-a promatran je u trima područjima: engleskom jeziku, matematici i znanosti na kraju osnovnog obrazovanja. Utvrđena je pozitivna korelacija između financiranja u ICT po učeniku i postignućima u engleskom jeziku.

Ron Canuel i Thierry Karsenti 2009. godine pokreću istraživanje u jednoj kanadskoj osnovnoj školi. Istraživanje je pokrenuto s ciljem stjecanja što boljeg razumijevanja prednosti i izazova u korištenju prijenosnih računala u osnovnim i srednjim školama. U svrhu istraživanja podijeljeno je oko 5 600 prijenosnih računala učenicima od 3. do 11. razreda. Rezultati istraživanja prikazuju mnoštvo prednosti korištenja prijenosnih računala u nastavi grupiranih u četiri glavne kategorije: olakšavanje i unaprjeđenje školskih zadataka,

unaprijeđeni psihosocijalni faktori – motivacija, autonomija, interakcija (između učenika, učitelja i roditelja) i pažnja, olakšan pristup informacijama, učenje je prilagođeno pojedincu, stjecanje i razvoj vještina i otvorenost prema svijetu i prilika za budućnost. Spomenute prednosti jasno pokazuju da korištenje prijenosnog računala ili intenzivno korištenje informacijsko komunikacijske tehnologije ima veliki utjecaj na učenički uspjeh te potencijalno i na njihov budući akademski uspjeh, društveni i poslovni život [7].

Proučavajući neke europske obrazovne kurikulume i razine školovanja uočeno je da se vrijeme uvođenja informatike u školovanje djeteta značajno razlikuje. Njemački, Švicarski i Austrijski obrazovni kurikulumi informatičko obrazovanje najčešće započinju oko 13.-14. godine života. Francuski obrazovni sustav visoko je centraliziran i podijeljen u tri faze: primarno obrazovanje (od 6. do 11. godine), sekundarno obrazovanje te više obrazovanje (diplomski studij, magisterij i doktorat). Primarno obrazovanje traje 5 godina i podijeljeno je u dvije glavne razine učenja. Informatika (Technology) kao predmet javlja se u drugoj razini primarnog obrazovanja koju pohađaju djeca od 8. do 11. godine života i zauzima prosječno 2,30 sati tjedno. S nastavom informatike nastavlja se i na sljedećoj obrazovnoj razini (prva razina sekundarnog obrazovanja) samo s povećanim brojem tjednih sati.

Ne želimo reći da korištenje računala u nastavi i učenju ima samo pozitivne utjecaje, ima i negativnih, no njih ne smatramo prijetećima ukoliko naglasak u cjelokupnom radu stavimo na pozitivnu stranu, a ono negativno osvijestimo i pokušamo korigirati. Uzmemo li u obzir nužnost i neophodnost primjene informatike u radu i životu djeteta ne preostaje nam drugo nego fokusirati se na osmišljavanje načina, metoda i programa rada u nižim razredima osnovne škole.

„(...) spomenuli smo da je pred vratima učionice uvijek gužva, ali još su nezaboravniji komentari učenika koje čujemo kad idu kući: Bilo je super! Baš je super na infici! Šteta da je već gotovo! Najčešće rad ne prekida školsko zvono, kao što je uobičajeno, već gašenje računala od učitelja – inače neki ne bi još dugo poslije zvona napustili učionicu! Nije li to najbolji dokaz da većina učenika računalo shvaća igračkom, a da njegove velike odgojno – izobrazbene uloge nisu niti svjesni.“ [8]

II. ISKUSTVA UČITELJA INFORMATIKE NIŽIH RAZREDA

Uvođenje informatičke kulture kao i samog predmeta informatike u škole odvijao se vrlo sporo. Nakon niza pokušaja i pokusa, 1985. godine informatika prodire u cjelokupan odgojno-obrazovni sustav, uključujući i vrtiće. Taj je način uvođenja informatike bio vrlo kritiziran i slabo prihvaćen od strane društva i samih djelatnika odgojno-obrazovnih ustanova. Radni materijal bio je neprilagođen i neprimjeren za pedagošku uporabu te nerijetko nepotpun, a izobrazba učitelja bila je nedovoljna i najčešće se temeljila na kratkim tečajevima koji su bili organizirani od strane škole. Kao glavni uvjet da bi informatika prodrla u škole, navodi se postojanje nastavničke ekipe koja bi bila informatički obrazovana i dovoljno motivirana za rad [9].

Tko danas može opisati mjesto koje će informatika zauzimati u obrazovanju 2060. godine, kada u mirovinu odu nastavnici koji su počeli raditi 2010. godine? No, Lesourne ističe činjenicu da prelazimo iz društva materije i energije u društvo znakova. Živimo u svijetu gdje će svaki pojedinac morati znati mnoštvo jezika te gdje će njegova uspješnost i njegovo snalaženje u društvu ovisiti velikim djelom o sposobnostima da dekodira još prije nekoliko godina nepoznate znakove. Sudeći prema navedenim činjenicama, informacijska će tehnologija morati imati svoje mjesto i u početnom obrazovanju osnovnoškolaca [9].

U Republici Hrvatskoj, informatika kao predmet u razrednoj nastavi, provodi se danas samo u nekim školama. Kako bismo saznali nešto više o samoj realizaciji i učinkovitosti predmeta informatike, ispitali smo nekoliko učitelja koji predaju informatiku u nižim razredima na području Republike Hrvatske.

Zanimalo nas je tko provodi nastavu informatike, kolika je zainteresiranost učenika za spomenuti predmet te koje su, po njima, prednosti ili eventualni nedostaci nastave informatike u nižim razredima.

Saznali smo da se informatika kao predmet u nižim razredima provodi isključivo kao izborni za koji učenici ne dobivaju opisne ni brojčane ocjene. Nastavni kadar koji provodi nastavu informatike vrlo je raznolik. Većinom su to učitelji razredne nastave koji imaju završenu informatiku kao pojačani predmet ili učitelji razredne nastave s položenim informatičkim tečajem, dok su rijetko na tim mjestima zaposleni diplomirani učitelji informatike. Posebna edukacija za provođenje ovog predmeta uglavnom nije potrebna. Učitelji obrađuju teme po HNOSU i uglavnom nisu zadovoljni planom i programom koji je tamo ponuđen. Smatraju da je programiranje u nižim razredima suvišno i da je to bespotrebno opterećenje učenika u toj dobi. Neki su pak nezadovoljni i kažu da su prepušteni sami sebi, što se tiče plana i programa. Ne rade po udžbenicima jer je to izborni predmet i kao takav ne smije zahtijevati od roditelja dodatno financijsko opterećenje, što bi kupovanje istih podrazumijevalo.

Zainteresiranost učenika za spomenuti nastavni predmet već od prvog razreda je maksimalna. Gotovo 100% učenika pohađa informatiku kao izborni predmet u školama koje to omogućuju. Učenici dolaze s bogatim predznanjem. Gotovo svi učenici znaju upaliti i ugasiti računalo te pokrenuti neku igru. Malo je onih kojima je to prvi susret s računalom, no prema učiteljima, to je najbolji način da učenici pravilno nauče koristiti računalo.

Poučeni svojim osobnim iskustvom i radom, učitelji informatike smatraju da uvođenje informatike kao predmeta u niže razrede ima znatne prednosti i da je više nego potrebno. Kao glavne prednosti navode da ranije učenje informatike sprječava usvajanje pogrešnih navika vezanih uz korištenje i rad za računalom koje je kasnije jako teško, gotovo nemoguće, ukloniti. Umjesto besmislenog surfanja i igranja igrica, učenici kvalitetno primjenjuju i nadograđuju svoje znanje. Samostalno i kontrolirano istražuju i služe se Internetom, prezentiraju svoje uratke te svakim novim otkrićem stječu dodatnu motivaciju pokazujući veliki interes za daljnji rad. Također, razvijaju logičko mišljenje i prihvaćaju računalo kao jedan od „alata“ koji im može pomoći kod rješavanja svakodnevnih zadataka. Naposljetku, predznanje spomenutih učenika daleko je veće u višim razredima od učenika koji se tek tada upoznaju s informatikom kao predmetom.

Osim spomenutih prednosti, dobili smo uvid i u neke od nedostataka koje za sobom nosi uvođenje informatike kao predmeta u niže razrede osnovne škole. Većina učitelja kao glavni razlog navodi neadekvatnu stručnu spremu učitelja koji provode informatiku te smatra da bi bilo potrebno organizirati više informatičkih tečajeva. Veliki problem predstavlja i slaba opremljenost škola informatičkom opremom, što onemogućuje provođenje nastave. Kod učenika pak postoji opasnost od razvijanja ovisnosti o računalima, ona im postaju jedina zabava i preokupacija u slobodno vrijeme zbog čega može doći do raznih senzornih oštećenja i zdravstvenih problema (pretilost, tromost, umor).

III. METODOLOGIJA ISTRAŽIVANJA

Budući da je cilj našeg istraživanja bio ispitati, sistematizirati i prikazati važnost uvođenja informatike kao izvannastavne aktivnosti ili izbornog predmeta u razrednu nastavu provjerili smo kakav je odnos učenika razredne nastave prema informatici, računalu i internetu. Na osnovu toga, postavili smo cilj istraživanja: Prikupiti informacije o korištenju i poznavanju računala i interneta učenika razredne nastave, saznati njihovo mišljenje o nastavi informatike, provjeriti na koje se sve načine učenici služe računalom te kako se pritom osjećaju.

Istraživanjem smo željeli provjeriti odnos učenika razredne nastave prema informatici i digitalnoj tehnologiji stoga polazimo od sljedećih hipoteza: Većina učenika posjeduje računalo i koristi ga više od 1 sata dnevno. Učenici većinu svog slobodnog vremena provode koristeći računalo no to ne podrazumijeva visoku razinu njihova informatičkog znanja. Učenici već u samim početcima korištenja računala uviđaju važnost informacijske pismenosti.

IV. UZORAK

Istraživanje je provedeno školske godine 2012./2013. na uzorku od 400 učenika razredne nastave, od toga 190 djevojčica i 210 dječaka. Istraživanje je provedeno u pet osnovnih škola: u Varaždinu (207 učenika – 51,75% ispitanika) i u jednoj koprivničkoj osnovnoj školi (193 učenika – 48,25% ispitanika). Uzorak je prigodan.

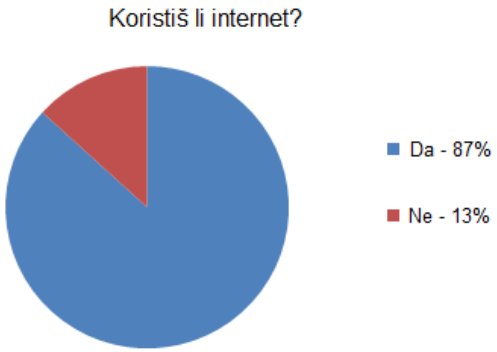
TABLICA I. PRIKAZ UZORKA - BROJ UČENIKA PREMA SPOLU (M – MUŠKO, Ž - ŽENSKO) I RAZREDU (R)

	1.r.	**2.r.**	**3.r.**	**4.r.**	**UZORAK**
m	58	34	59	59	210
ž	56	46	43	45	190
Ukupno	114	80	102	104	400
%	28,5	20	25,5	26	100

Odnos učenika prema računalu i internetu te njihov stav prema nastavi informatike ispitan je anketnim upitnikom *Računalo i ja.* Upitnik se sastoji od 16 pitanja. Pitanja su većinom zatvorenog tipa, od kojih neka pitanja nude mogućnost samostalnog davanja odgovora. Zadatak učenika bio je odabrati i zaokružiti jedan od ponuđenih odgovora ili dopisati svoj odgovor. Ispitivanje su proveli autori ovoga rada u dostupnim osnovnim školama. Nakon što su učenicima objašnjeni svrha i cilj ovog anonimnog istraživanja i način njihove provedbe pročitana je uputa o načinu ispunjavanja anketnog upitnika i krenulo se u samu provedbu koja je trajala 15ak minuta.

V. PRIKAZ REZULTATA

Sukladno našim očekivanjima, prije provedenog istraživanja, analizom anketnih upitnika utvrđeno je da 98% učenika posjeduje i koristi računalo, a čak 87% njih služi se internetom.

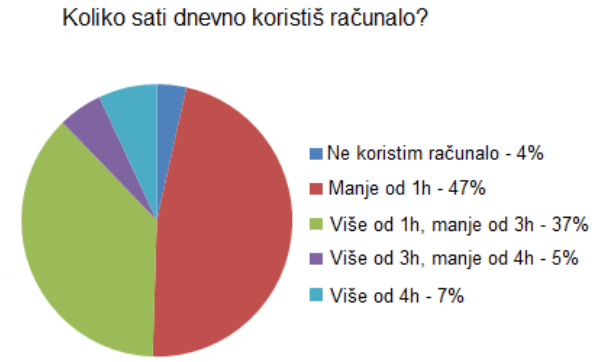


Graf 1. Prikaz učenikovih odgovora na pitanje o posjedovanja računala (N=400)

Dublja analiza odgovora na pitanje o zadovoljstvu učenika prilikom korištenja računala pokazala je da se većina učenika (62,5%) osjeća sretno, kod 37% njih korištenje računala ne izaziva nikakve posebne emocije (osjećaju se isto kao i kad rade nešto

drugo), dok se samo dvoje učenika (0,5%) prilikom korištenja računala osjeća tužno. Učenici su upitani znaju li njihovi roditelji uvijek što oni rade na računalu. 87,8% ispitanika odgovorilo je da su njihovi roditelji upućeni u njihove aktivnosti na računalu dok navodno manji broj roditelja (10%) ne zna čime se njihova djeca bave kad koriste računalo.

Pri analiziranju odgovora na pitanje koliko sati dnevno koriste računalo dobili smo s jedne strane zabrinjavajući, ali također i poticajni podatak. Smatramo da je dobiveni postotak zabrinjavajući obzirom na dob ispitanika, njihove razloge i informiranost o tehnologiji koju koriste, što ćemo detaljnije i prikazati daljnjom analizom našeg istraživanja. Međutim, ovaj visoki postotak prikazuje njihovu visoku motiviranost i interes za korištenje računala, što bi se svakako trebalo nadopuniti, iskoristiti i usmjeriti k ostvarenju zajedničkog društvenog i osobnog cilja, a to je vođenje mlađih naraštaja k informatičkom društvu znanja.



Graf 2. Prikaz učeničkih odgovora na pitanje o vremenu koje provode za računalom (N = 400)

Analiza odgovora na tvrdnjama *Kada najčešće koristiš računalo* (Tablica II.) pokazala je da najviše učenika (63,3%) računalo koristi tek kad izvrši sve svoje školske obveze. Veliki broj učenika (17,5%) naveo je da računalo koristi kad im roditelji dopuste ili kad imaju slobodnog vremena. Važno je istaknuti kako 11,7% učenika navodi da računalo koristi kad god želi.

TABLICA II. DESKRIPTIVNA STATISTIKA POJEDINIH TVRDNJI O VREMENU KORIŠTENJA RAČUNALA

Tvrdnja	Dječaci		Djevojčice		Ukupno	
	N	%	N	%	N	%
Uopće ne koristim računalo	4	1,9	6	3,2	10	2,5
Kad napišem svu zadaću	137	65,2	116	61,1	253	63,3
Kad sam sam/a kod kuće	12	5,7	8	4,2	20	5
Kad god hoću	23	11	24	12,6	47	11,7
Neki drugi odgovor	34	16,2	36	18,9	70	17,5

Učenici su također ispitani o razlozima zbog kojih najčešće koriste računalo (Tablica III). Uspoređujući odgovore djevojčica i dječaka možemo zaključiti da većina djevojčica (45,3%) koristi računalo samo kad im je dosadno, dok najveći broj dječaka (39%) koristi računalo zato što to voli. Zanimljiv je podatak da veći broj djevojčica (14,2%) koristi računalo za izvršenje nekih zadataka, nego dječaci (9%). Iako manje vole računala od dječaka, djevojčice u većoj mjeri uviđaju prednosti i mogućnosti računala.

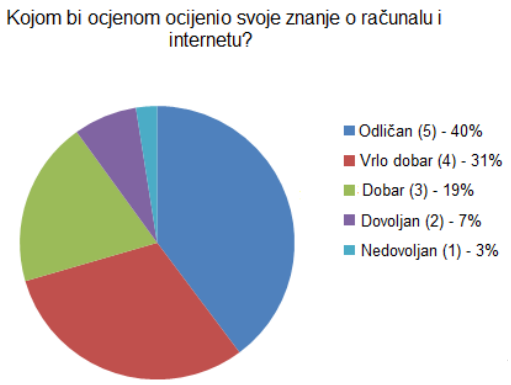
TABLICA III. DESKRIPTIVNA STATISTIKA POJEDINIH TVRDNJI O RAZLOZIMA KORIŠTENJA RAČUNALA

Tvrdnja	Dječaci		Djevojčice		Ukupno	
	N	%	N	%	N	%
Samo kad mi je dosadno	76	36,2	86	45,3	162	40,5
Zato jer to volim	82	39	61	32,1	143	35,8
Zato jer svi moji prijatelji koriste računalo	10	4,8	4	2,1	14	3,5
Kad imam neki zadatak	19	9	27	14,2	46	11,5
Nešto drugo	23	11	12	6,3	35	8,8

Većina učenika, njih 83%, kaže kako su čuli da na Internetu postoji mnoštvo opasnosti koje vrebaju na njih, dok preostalih 17% nije upoznato s tom činjenicom. Činjenicu o postojanju ružnih i/ili neugodnih stvari koje se događaju na Internetu, potvrdilo je 16,7% učenika, dok na naše zadovoljstvo, ostali učenici koji koriste Internet (75,8%) nisu imali neugodnih i/ili ružnih iskustava.

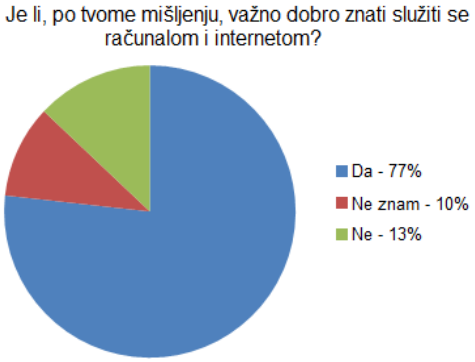
Vođeni pretpostavkom da učenici nižih razreda osnovne škole provode veliki dio svog slobodnog vremena koristeći računalo, kratkim pitanjima željeli smo provjeriti njihova znanja o osnovnim dijelovima računala i računalnim programima. Rezultati su pokazali da 87,25% učenika zna da je monitor dio računala na kojem vidimo sve što radimo, dok njih 12,5% to ne zna. Pitanje *Za što nam služi program Word* donijelo nam je sljedeće rezultate: 50,7% učenika točno je odgovorilo na postavljeno pitanje, njih 9% misli da Word služi za gledanje filmova, 7,1% učenika misli da se Wordom pretražuje Internet, dok 33,2% odabire odgovor *Ne znam* na postavljeno pitanje. Nešto bolji rezultati dobiveni su teorijskom pitanju o programu Bojanje. Gotovo svi učenici (93,5%) znaju da je Bojanje program koji služi za crtanje. Teško je sa sigurnošću reći, je li tako visoki postotak pokazatelj njihova znanja ili rezultat sugestije samog naslova programa.

Veliki broj učenika ne zna što je monitor, Word i Bojanje, a ipak je većina njih je pokazala nekritičan stav prema svome znanju.

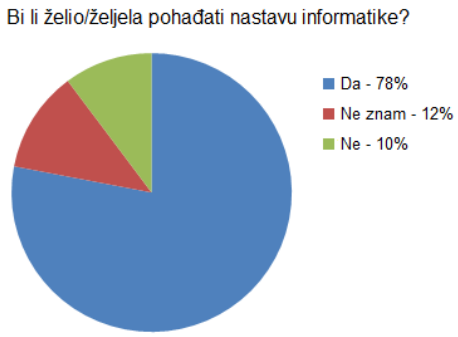


Graf 3. Prikaz samovrednovanja učenika (N = 400)

Na kraju našeg istraživanja zanimalo nas je jesu li najmlađi naraštaji svjesni činjenice da je računalna tehnologija neizostavni aspekt razvoja današnjeg društva i temelj budućeg razvoja. Graf 4. pokazuje da učenici uviđaju važnost tehnologije, a iz Grafa 5. vidljiv je njihov izrazito visok interes za digitalnom tehnologijom.



Graf 4. Prikaz odgovora o važnosti korištenja računala i Interneta te učenikovih preferencije prema informatici kao nastavnom predmetu (N = 400)



Graf 5. Prikaz odgovora učeničkih preferencije prema informatici kao nastavnom predmetu (N = 400)

VI. ZAKLJUČAK

Dvije neosporive činjenice su da živimo u društvu koje nužno treba informatički sposobne i pismene pojedince te da su djeca od svoje najranije životne dobi u dotaciju s digitalnom tehnologijom. Ovim radom željeli smo prikazati važnost, ali i mogućnost vođenja djece niže životne dobi do informatički sposobnih i pismenih pojedinaca koji su potrebni našem društvu.

Cilja našeg istraživanja bio je prikupiti informacije o korištenju i poznavanju računala i Interneta učenika razredne nastave te saznati njihovo mišljenje o nastavi informatike. Zanimalo nas je i na koje se sve načine učenici služe računalom i kako se pritom osjećaju.

Rezultati istraživanja sugeriraju zaključak da gotovo svi ispitanici koriste računala što ih ispunjava i čini sretnima (62,5%). Računala najčešće koriste u svrhu zabave dok je edukativna uloga računala slabije zastupljena. Iako su pokazali nezavidno znanje o osnovama računala, ipak smatraju da je ono izrazito visoko, samim time što provode veliki dio svog slobodnog vremena koristeći računalo.

Iz cjelokupnog rada vidljivo je da našu poruku i ideju o važnosti uvođenja informatike kao izbornog predmeta ili izvannastavne aktivnosti u razrednu nastavu podupiru, ne samo anketirani učitelji, već gotovo i 80% naših ispitanika. Spoznaja da mlađi članovi naše društvene zajednice uviđaju važnost i potrebu informacijske pismenosti, ali da ujedno imaju i visoku razinu motiviranosti za istu, trebala bi biti veliki poticaj vođama našeg odgojno – obrazovnog sustava, ali i društvu u cjelini, da ih krenemo voditi od najranije dobi prema željenom cilju.

Primjer projekta u nastavi informatike – što je lijepo ljudskom oku

Vesna Skočir
X.gimnazija "Ivan Supek", Zagreb, Republika Hrvatska
vesna.skocir@skole.hr

Sažetak - Projektna nastava ima velike potencijalne mogućnosti. Jedna, osobito važna, je da se kroz takav oblik nastave učenici mogu upoznati s istraživačkim elementima. U radu je predstavljen projekt grupe učenika trećega razreda prirodoslovno - matematičke gimnazije koji su ponovili eksperiment Gustava Theodora Fechnera, prvog eksperimentalnog psihologa iz 19. stoljeća. Cilj je bio ustvrditi hoće li ljudsko oko među sličnim likovima kao najljepši izdvojiti onaj u kojemu je implementiran omjer zlatnog reza. Iako je u ponovljenom eksperimentu bilo nekih nedostataka, rezultati su istovjetni Fechnerovim: najveći broj ispitanika "prepoznao" je ljepotu zlatnog reza. Pored opisa i rezultata eksperimenta u radu se diskutira kako učinkovito koristiti računalo kod pripreme ovakve vrste projekta, rada na projektu te predstavljanju rezultata.

I. UVOD

Istraživanje u središte stavlja problem kojega želimo riješiti ili naprosto bolje upoznati. Prirodna radoznalost učenika (djeteta) snažan je motivacijski faktor pa je različite oblike istraživanja dobro poticati već u najranijoj dobi. Koristi su neizmjerne, iako uobičajenim testovima nemjerljive; razvija se kreativnost, vještina komunikacije, odgovornost, kritičnost prema svom i tuđem radu, samosvijest. Učenici se s istraživačkim elementima mogu upoznati u okviru projektne nastave.

Projektna nastava takav je oblik nastave u kojem su učenici u grupama ili samostalno usmjereni na rješavanje odabrane problemske situacije ili obradu neke otvorene teme pri čemu put do cilja nije odmah dokučiv[1]. Zbog nedostatka vremena u tradicionalnom sustavu obrazovanja kakav je naš, ovakav oblik nastave u svoj svojoj punini teško je provediv. Budući da je tema otvorena, uloga nastavnika i učenika različita od one na koju su navikli, trajanje projekta teško je predvidjeti. Tijekom istraživanja može se pojaviti potreba za (čak i znatnijom) korekcijom plana izvedbe, pa i prekidom projekta ukoliko se pokaže da tema (ipak) nije u domeni iskustva učenika, da ne vladaju strategijama koje dovode do rješenja ili da naprosto nema dovoljno interesa za obradu teme. Stoga je osobito važan odabir teme koja će učenicima, a i nastavniku, biti dovoljno intrigantna da ustraju u istraživanju.

[1] Idealno bi bilo da to vrijedi za sve sudionike projekta, dakle i za nastavnika. Nastavnik koji "sve zna" nije autentični sudionik istraživanja. Rezultat do kojeg dođe, učenik neće dalje propitivati u sebi; zadovoljit će ga pozitivan odgovor nastavnika. U najboljem slučaju takav učenik može osjetiti zadovoljstvo dobro obavljenog posla, ali pravo zadovoljstvo pronalazača bit će mu uskraćeno.

Stara dilema o kojoj su rasprave vodili filozofi i matematičari, *je li matematika nešto stvarno ili nešto otkriveno*, odnosno *jesu li istine već tu samo ih još ne znamo*, može se uvijek nanovo aktualizirati kroz pojam zlatnog reza. Savršenu proporciju koju matematički opisuje broj Φ, nalazimo u ravnoteži, harmoniji i simetriji prirode. U toj se, kako je još nazivaju, božanskoj proporciji, dijelovi cjeline jedan prema drugom odnose isto onako kako se cjelina odnosi prema većem dijelu. Manifestacije zlatnoga reza vežu se i uz pojam *ljepote*. Ljepota nije nešto apsolutno i nepromjenjivo; različiti koncepti ljepote sukobljavali su se u različitim razdobljima, a ponekad i unutar iste kulture [1]. Zlatni rez i pojam lijepog teme su osobito prikladne za istraživanje u srednjoj školi. Razloga ima više: tom su uzrastu ovakve teme privlačne, većina je spremna i sposobna njima se intelektualno i emotivno posvetiti, a budući da je riječ o širokoj temi mogućnosti istraživanja su velike.

Polazište za naše istraživanje bio je rad Gustava Theodora Fechnera (1801.-1887.), kojega smatraju prvim eksperimentalnim psihologom [2]. On je mjerenjem ustanovio da brojni pravokutni predmeti koji ga okružuju (knjige, kutije, zgrade…) imaju omjer duljina stranica blizak broju Φ. Pretpostavio je da je to stoga što se većini ljudi taj omjer sviđa. Poslije je to dokazao eksperimentom: ispitanicima je pokazao niz pravokutnika različitih omjera, a oni su kao najljepši prepoznali baš taj omjer.

U načelu istim eksperimentom ispitali smo 79 ispitanika i potvrdili Fechnerove rezultate. Pored testa s pravokutnicima, istim ispitanicima pokazani su crteži ljudskih lica, tri ženska i tri muška lica. Par detalja na jednom ženskom i jednom muškom licu bilo je nacrtano u omjeru bliskom broju Φ. Rezultat je bio istovjetan prvom – lica s "ugrađenim" zlatnim rezom prepoznata su kao najljepša.

Projektna nastava je u načelu interdisciplinarna. Tako se i ovaj projekt mogao ostvariti u okviru matematike, likovne umjetnosti ili psihologije. No njemu je zasigurno mjesto i na satovima informatike budući da se ovakvim projektima učenici usavršavaju u korištenju informacijske tehnologije te uče kako tu tehnologiju upotrijebiti da bi priredili i prezentirali stručni rad. Ovim radom namjera je pokazati da i teme koje nisu vezane za područje informatike, ali su dovoljno interesantne, mogu biti korisne za razvijanje informatičke pismenosti učenika. Pogotovo je to slučaj s onom dubljom razinom pismenosti kod koje učenik ne samo da zna kako nešto u danoj aplikaciji napraviti, već i koju od mogućih opcija za određenu situaciju upotrijebiti. Naposljetku, tu je i

prikupljanje informacija preko Interneta. I mada se čini da je to područje kojim učenici jako dobro vladaju, praksa pokazuje da kod prikupljanja informacija za izradu stručnoga rada postoje problemi. Međutim, dobro definiranim zadacima nastavnik može pomoći učeniku da proradi informacije i s razumijevanjem ih prilagodi jer kao što upozorava K. P. Liessmann [4], u protivnom "većina informacija naprosto ostaje izvanjska". On pretpostavlja da je to stoga što lakoća pristupa (informacijama) sabotira tvorbu znanja. Tako dolazi do toga da studenti, a i drugi "sve više brkaju mehaničko kopiranje seminarske radnje s interneta sa samostalnim pisanjem takve radnje " [4].

II. OPĆI PRIKAZ TEME

A. Eksperiment Gustava Fechnera

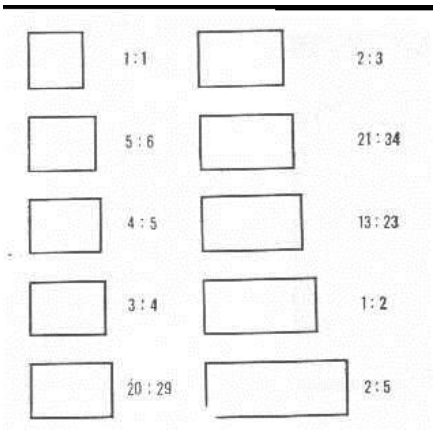
Uobičajena je sljedeća definicija zlatnog reza[10]: Točka Z dijeli dužinu $\overline{AB}$ u omjeru zlatnog reza ukoliko je omjer duljina cijele dužine $\overline{AB}$ i njezina većeg dijela $\overline{AZ}$ jednak omjeru duljina većeg dijela $\overline{AZ}$ i manjeg dijela $\overline{ZB}$ (Sl.1). Označimo li sa *a* duljinu dužine $\overline{AB}$, a sa *x* duljinu njezina većeg dijela $\overline{AZ}$, treba biti $a : x = x : (a-x)$. Kad ovo matematički izračunamo, dobijemo:

$$x = \frac{\sqrt{5}-1}{2}\, a \approx 0.6183a$$

Broj $\frac{\sqrt{5}-1}{2}$ označava se s Φ i zove se zlatni omjer.

1860. godine Gustav Theodor Fechner istražuje osjećaj ljepote i harmonije kod odraslih ljudi. Pripremio je niz od deset bijelih pravokutnika, među kojima je jedan imao omjer duljina stranica blizak omjeru zlatnog reza, 5:8, odnosno 0.625. Omjeri duljina stranica ostalih pravokutnika varirali su između 1:1 i 2:5. Sudionici eksperimenta (228 muškaraca i 119 žena) bili su zamoljeni da pogledaju pravokutnike i odaberu onaj koji im se najviše sviđa. Prema grafičkim rezultatima preuzetim iz [2] vidimo da se većini ispitanika (35%) "zlatni" pravokutnik najviše sviđa. Visok postotak ispitanika (blizu 40%) odabrao je pravokutnike omjera stranica bliskih "zlatnom" (2:3 i 13:23), dok se za svaki od preostalih pravokutnika odlučilo manje od 10% isitanika. Približno iste rezultate u ponovljenom su pokusu dobili i engleski znanstvenici 1958. god. [8]. Iako se jednostavno može konstruirati pravokutnik kojemu su stranice u omjeru broja Φ, u praksi se, pa tako i u Fechnerovom eksperimentu, pribjegava aproksimaciji (Sl.2.). Tako je primjerice "zlatni" pravokutnik negdje predstavljen omjerom 5:8, a negdje omjerom 21:34 (usp. [2], [6] i [8]). Iako se prema [2] i [8] dade naslutiti da su u Fechnerovom eksperimentu pravokutnici bili različitih površina, čini se da nije bilo tako. Prema [10] svi su pravokutnici imali

Slika 1. Zlatni rez dužine



Slika 2. Fechnerovi pravokutnici, omjer duljina stranica "zlatnog" pravokutnika je 21:34 (preuzeto iz [8])

jednake površine. Prema istom je izvoru nepoznato u kojem su položaju pravokutnici predočeni ispitanicima; koja je od stranica (veća ili manja) bila smještena vodoravno. Prema svim navedenim izvorima pravokutnici su bili "poslagani u red" u kojem se "zlatni" pravokutnik nalazio na sedmom mjestu.

Slične su eksperimente ponavljali i drugi psiholozi te dobivali katkad proturječne rezultate [7]. Michael Godkewitsch sa Sveučilišta u Torontu to objašnjava činjenicom da u zapadnom svijetu nije moguće verbalno iskazati što znači estetska sklonost prema određenom omjeru stranica pravokutnika, a da taj iskaz bude pouzdan [7]. Pitanje je prema kojem će kriteriju jedan omjer biti ljepši, privlačniji od drugoga? Kroz povijest estetika proporcije poprimala je različite i sve složenije oblike. Stari su Grci uz pojam lijepog vezali osobine prikladnosti i mjere, dok primjerice mediji potrošačkog društva 20. i 21. stoljeća kao uzor ljepote nude šminku i potpisanu odjeću. Stoga, premda dopušta da "onkraj različitih poimanja Ljepote postoje jedinstvena pravila za sve narode i stoljeća", Umberto Eco u knjizi Povijest ljepote [1] ne trudi se tražiti ih, već upravo suprotno, ističe razliku.

Pojam lijepog bila je i ostala velika i otvorena tema. I mada ne možemo točno odrediti što ljepota jest, istraživanja doživljaja lijepog, kao što je primjerice Fechnerov eksperiment, zasigurno imaju smisla.

B. Priprema projekta

Upoznavanje s temom dobro je početi popisom literature koju bi trebalo proučiti prije početka istraživanja. Budući da je riječ o srednjoj školi to mogu biti svega jedno ili dva djela (članak, odlomak neke knjige). Poželjno je da to bude neko zaista vrijedno djelo kao što su primjerice *Tajni kod* P.Hemenwaya [2] ili *Povijest ljepote*, knjiga koju je priredio Umberto Eco [1]. Iako je riječ o satovima informatike, ne bismo se smjeli ograničiti samo na multimedijalno čitanje; kvaliteta djela trebala bi biti jedini kriterij izbora.

Kad je na ovaj način dobio osnovne spoznaje o temi koja se obrađuje, učenika treba uputiti da prema ključnim

riječima istražuje Internet i pokuša doći do novih informacija i tako još više približiti danu temu.[2]

Za čitanje treba predvidjeti dovoljno vremena budući da se na taj način osim informacija prikupljaju ideje i zapažanja. Kad se dobije širi uvid, rasplet više nije predvidiv - i sam cilj istraživanja može se izmijeniti.

Neophodno je da učenici osnovni tekst shvate u cjelini i pojedinostima. Ukoliko ima problema dobro je pribjeći zajedničkom čitanju. Čitati treba polagano, pažljivo, strpljivo, pogotovo ako je riječ o težim dijelovima. Na trenutke treba prekidati čitanje kako bi se ono što se čita dovelo u vezu s iskustvom i ranije stečenim znanjem. Prema tekstu treba imati kritički odnos; treba vidjeti je li neka činjenica/ideja vezana za temu koja se obrađuje te je li neka ideja prihvatljiva ili nije. Dobar je trenutak da se učeniku objasni razlika između činjenice i ideje.[3]

Usporedo s čitanjem teksta treba pisati zabilješke. Prikladna je forma natuknica, a kako bi se izbjegao "copy-paste" efekt, poželjno je izabrati klasični medij – olovku i papir. Naposljetku se dobivene informacije zajednički diskutiraju. Treba biti siguran da se razumije njihovo značenje, a potom ih smisleno povezati i staviti u suodnose.

III. OPIS EKSPERIMENTA

A. Ponovljeni eksperiment Gustava Fechnera

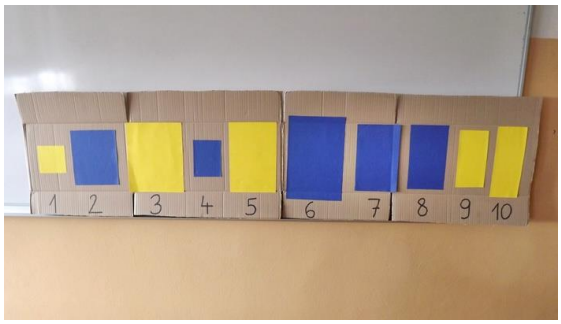
Pravokutnici zadanih omjera prikažu se na nekom mediju i predoče ispitanicima. Omjeri duljina stranica i redoslijed pravokutnika treba biti isti kao u Fechnerovom eksperimentu (prema [2]). Ispitanici će biti zamoljeni da bez razmišljanja odgovore koji im se pravokutnik najviše sviđa. Predviđeno je i dodatno pitanje – izdvojiti najružniji pravokutnik, dakle onaj koji bi prema estetskim kriterijima smjestili na dno ljestvice.

Hipoteza je da će se ispitanicima više sviđati pravokutnik koji ima odnos stranica blizak broju Φ. Hipotezu ćemo smatrati potvrđenom ukoliko većina ispitanika "zlatni" pravokutnik izabere kao najljepši. Očekuje se da će najmanji broj ispitanika ovaj pravokutnik prema estetskim kriterijima staviti na dno ljestvice.

B. Provedba i rezultati eksperimenta

Sugestija je bila da se pravokutnici prikažu na klasičnom mediju.[4] Učenici su ih nacrtali na debljim papirima u boji (plava i žuta boja), izrezali i zalijepili na veći karton (Sl.3).

Sudionicima eksperimenta rečeno je da se ispituju karakteristike broja Φ. Budući da su, s izuzetkom jedne starije osobe, sudionici bili učenici prvog razreda



Slika 3. Ponovljeni Fechnerov eksperiment; sedmi po redu je "zlatni" pravokutnik

TABLICA I. REZULTATI PONOVLJENOG FECHNEROVOG EKSPERIMENTA

Broj pravokutnika	Omjer stranica	Odabir najljepšeg u postocima
1	1:1	11.84
2	5:6	10.53
3	4:5	7.89
4	3:4	9.21
5	20:29	11.84
6	2:3	5.26
7	**5:8**	**14.47**
8	13:23	10.53
9	1:2	9.21
10	2:5	9.28

gimnazije te djeca starije vrtićke dobi [5] možemo pretpostaviti da gledajući pravokutnike nisu procjenjivali duljine stranica i njihove omjere. Zamoljeni su da bez puno razmišljanja izdvoje pravokutnik koji im se najviše sviđa. Poslije su na isti način odredili pravokutnik koji im se najmanje sviđa.

Budući da je većina ispitanika (Tab.1) kao najljepši izabrala pravokutnik kojemu su duljine stranica u omjeru zlatnog reza, hipotezu smatramo potvrđenom.

Usporedba s rezultatima Fechnerova pokusa prikazana je grafički na Sl. 4. Pravokutnik kojemu je omjer duljina stranica najbliži broju Φ, a to je pravokutnik na sedmom mjestu, u oba se eksperimenta najviše svidio ispitanicima. Međutim u našem se eksperimentu daleko manji broj opredijelio za taj pravokutnik; svega 14.47% ispitanika za razliku od 35% ispitanika koji su u Fechnerovom eksperimentu taj pravokutnik doživjeli kao najljepši.

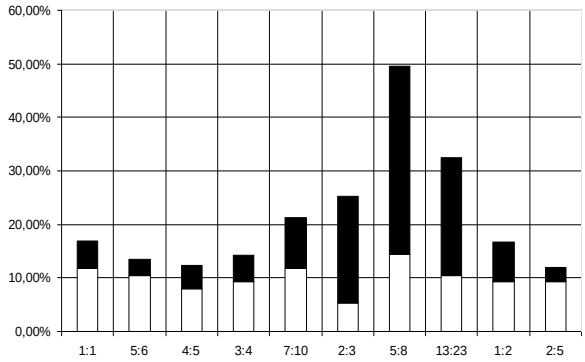
Za šesti i osmi pravokutnik koji su omjera bliskih "zlatnom" sedmom po redu pravokutniku, u našem se eksperimentu, u usporedbi s Fechnerovim, odlučio relativno mali broj ispitanika. Disproporciju nalazimo u

[2] Svakako treba izbjeći da učenik osnovne informacije o temi pokuša saznati samostalno preko Interneta. Praksa pokazuje da učenik posao obično odradi formalno, a nerijetko se "zabavi" i drugim sadržajima.

[3] Ideja je činjenica koja je na neki način interpretirana. Stoga je i njena istinitost upitna. Uočavanje ovih razlika na konkretnim primjerima usmjerava učenika na kritičko čitanje teksta.

[4] Učenici bi se trebali "igrati" različitim medijima, kritički odmjeravati i argumentirati prednosti i mane pojedinog medija.

[5] U istraživanju je sudjelovalo 11 osoba 1995. godište, 33 osobe 1997. godište, 1 osoba 1998. godište, 17 osoba 2006. godište, 13 osoba 2007. godište i jedna starija osoba čije godište nije poznato.



Slika 4. Usporedba rezultata našeg (svijetli dio) i Fechnerovog eksperimenta (tamni dio); sedmi po redu je "zlatni" pravokutnik

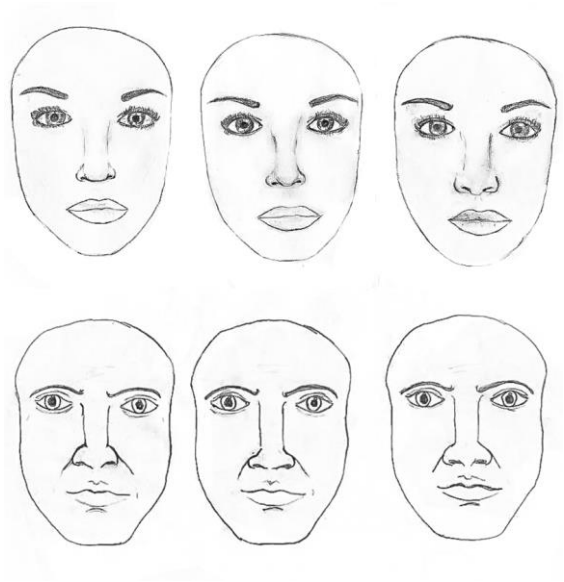
još nekim slučajevima. Primjerice kod pravokutnika koji su prvi i deseti po redu (omjeri 1:1 i 2:5), situacija je obrnuta; za njih se u našem eksperimentu odlučilo osjetno manje ispitanika nego u Fechnerovom.

Ovi rezultati ne začuđuju ukoliko uočimo boje pravokutnika: šesti, sedmi i osmi pravokutnik su plave boje, a prvi i deseti žute. Ispitanici su očito dali prednost žutoj (toploj) boji u odnosu na plavu (hladnu) boju. Isto se dogodilo i s ostalim pravokutnicima u nizu s izuzetkom drugog i četvrtog.

Osim plave boje "zlatni" je pravokutnik površinom bio među manjima i malo "savijen" jer se nalazio na pregibu kartonske podloge. Za pretpostaviti je da bi rezultat bio još uvjerljiviji da je eksperiment bio bolje pripremljen: da su pravokutnici bili iste boje (najbolje bijele – neutralne) te da se njihove površine nisu previše razlikovale.

C. Proširenje Fechnerova eksperimenta

Pored testa s pravokutnicima, istim ispitanicima pokazani su crteži ljudskih lica, tri ženska i tri muška lica. Lica su nacrtali učenici trudeći se da u jedno žensko i jedno muško lice "ugrade" omjer zlatnog reza. Riječ je o par detalja koji se nalaze na sredini lica. Žensko lice s elementima zlatne proporcije je drugo po redu, a muško treće. (Sl.5). Rezultat je bio istovjetan prvom – lica s "ugrađenim" zlatnim rezom prepoznata su kao najljepša. Žensko lice s takvim detaljima kao najljepše je doživjelo 57.89% ispitanika, a muško s istim karakteristikama 44.74% ispitanika.



Slika 5. Drugo po redu žensko lice i treće po redu muško lice ima par detalja u omjeru bliskom omjeru zlatnog reza

Rezultati su zanimljivi, ali da bi bili ozbiljno razmatrani, crteže je trebalo bolje pripremiti. Svakako bi dalja istraživanja valjalo nastaviti u tom pravcu.

D. Kako smo koristili računalo?

Računalo je univerzalno pomagalo koje koristimo u svakodnevnom životu nerijetko takvim automatizmom da to ni ne zamjećujemo. Na taj smo način i mi koristili računalo, primjerice za dobivanje informacija pretraživanjem web stranica, komunikaciju elektroničkom poštom ili onda kad smo programom za obradu teksta (MS Word) zapisivali planirane aktivnosti, pripremali anketna pitanja i slično. Dijelom smo na isti način koristili i program za rad s proračunskim tablicama (MS Excel) te program za izradu prezentacija (MS PowerPoint) budući da su korisnička sučelja osnovnih programa MS Office, učenici upoznali tijekom ranijeg školovanja. No u srednjoj nas školi ne bi trebala zadovoljiti činjenica da učenik zna tablično u Excelu prikazati podatke, obraditi ih i predočiti grafom ili kreirati slajdove PowerPoint prezentacije, već i da taj rad bude u skladu sa zahtjevima koje bi stručni rad trebao zadovoljiti. To je razlog da je dio rada na projektu ostvaren kao radionica u kojoj smo između ostaloga pokazali i diskutirali:

- koja je vrsta grafa prikladna za ilustraciju dobivenih rezultata;
- zašto je potrebno dokumentirati rad te kako to učiniti;
- kako činjenice i ideje predstaviti tako da oni kojima se prezentira razumiju što im se želi reći, da ih zainteresiramo za ono što govorimo i da sve to od njih ne iziskuje posebni napor;
- kako tehnički osmisliti prezentaciju, koji su fontovi/boje dobri, a koji nisu, koji podaci trebaju pisati na početnom slajdu…
- kako se pripremiti za predstavljanje rada, kako suzbiti tremu i slično.

U praksi često, u okviru različitih predmeta, učenici dio gradiva obrade sami, a potom izrade odgovarajuću prezentaciju. Dobar dio nastavnika smatra da je na taj način nastavu učinio modernijom, a argumenti su i da se učenici s kompjuterima dobro snalaze i da to vole raditi. Praksa pokazuje da učenici vole takve zadatke jer su s njima obično brzo gotovi, a zahvaljujući Internetu radovi se mogu obogatiti efektnim ilustracijama. Opasnost je da se bez dodatnog znanja, promišljanja i iskustva pri izradi takvih radova, dobivaju uradci upitne kvalitete koji su često ocijenjeni visokom ocjenom. Na taj se način njeguju loše navike korištenja računala.

Ljudi čitaju mnogo više nego što pišu. Brojne studije pokazuju ako se poveća kvantiteta pisanja to ne znači da će se nužno popraviti kvaliteta pisanja. Hipoteza da stil pisanja proizlazi iz čitanja, ne iz pisanja je u skladu s onim što je poznato kao jezična akvizicija: Bogatstvo jezika dolazi iz ulaza, ne izlaza, iz razumijevanja, a ne produkcije [3]. Slično, kvaliteta prezentacije neće se popraviti izradom većeg broja prezentacija, ukoliko izostane dubinsko razumijevanje onoga što se predočuje, promišljanje o svakom elementu koji će popratiti prezentaciju, bilo da će se naći na slajdu ili će biti izgovoren. Pretpostavka su i osnovna znanja o tome što stručni rad jest i kako bi trebala izgledati njegova prezentacija. Supervizija, kritički osvrt je neophodan.

Istraživački su projekti, poput projekta opisanoga u radu, motivirajući za učenike, stoga su dobra prilika da se učenike poduči što je stručni rad, kako bi ga trebalo napisati[6], a kako prezentirati.

IV. ZAKLJUČAK

U radu je predstavljen projekt ostvaren na satovima izborne nastave u trećem razredu prirodoslovno - matematičke gimnazije u kojem su učenici ponovili eksperiment psihologa Gustava Theodora Fechnera, a taj je ustanoviti hoće li ispitanici među pravokutnicima čije stranice imaju duljine različitih omjera, kao najljepši izdvojiti onaj kojemu su duljine stranica u omjeru zlatnog reza. Unatoč nedostacima koji su u ponovljenom eksperimentu bili na štetu "zlatnog" pravokutnika, upravo je taj pravokutnik, kao i u Fechnerovom eksperimentu, prepoznat kao najljepši.

Daljim istraživanjima valjalo bi ustanoviti da li, i u kojoj mjeri, dob i spol ispitanika utječu na rezultate eksperimenta. Na sličan bi način valjalo istražiti u kojoj se mjeri lijepima doživljavaju elementi zlatnog reza na složenijim objektima, primjerice građevinama, biljkama, ljudskom licu i slično.

Paralelno s prikazom eksperimenta u radu se diskutira na koji način voditi učenike kroz ovakav oblik istraživanja, posebno na koji način učinkovito koristiti računalo u fazi prikupljanja informacija, obrade podataka i predstavljanja rezultata.

Pomoću novih tehnologija možemo brzo doći do rezultata. I tu leži opasnost. U brzini mnoge stvari promaknu, pa se ponekad zadovoljimo izvanjskim, površnim znanjem koje se uglavnom temelji na činjenicama. A to je ono što svakako treba izbjeći. Želimo da učenik razumije činjenice te da iz tih činjenica dobije ideje. Svijet računala, poglavito Internet, globalna je i sveprisutna pojava, pa je tako i prisutnost novih tehnologija u obrazovanju neupitna. Zato je pogotovo važan način kako ćemo ovu snažnu tehnologiju koristiti da se učenik kao osoba razvije na najbolji mogući način.

[6] Učenike bi trebalo upoznati sa strukturom pisanog stručnoga rada, uputiti ih na razlike pisanog i govornog jezika, ukazati na važnost pravopisne i gramatičke korektnosti i slično.

Primjena interaktivnog videa u obrazovnim nastavnim sredstvima

Danijel Vrbanc, dipl. ing.
Željeznička tehnička škola – Moravice, Vrbovsko, Hrvatska
danijel.vrbanc@skole.hr

Sažetak - U radu je prikazan način interpretacije električnih shema iz dvaju predmeta: Elektronički sklopovi i Učinska (energetska) elektronika. Prikaz je namijenjen učenicima i studentima koji su na nastavi, tj. predavanjima bili upoznati s radom određenih elektroničkih sklopova, a za bolje razumijevanje i zornost rada istih - trebao bi im poslužiti interaktivni video. Dok se pisani i slikovni sadržaj u udžbenicima ili prezentacijama uglavnom koristi na uobičajen način, interaktivni video u danim primjerima ne rabi pisanu riječ već samo slike i pokretne slike tijeka struje i iscrtavanje valnih oblika (uglavnom napona i struja). Time se paralelnim i slijednim promatranjem objašnjava princip rada određenog sklopa, a izostanak pisane riječi omogućuje jednostavnu internacionalizaciju. Princip rada ovog prikaza prikazan je na dva primjera. Za prvi primjer je odabran rad mosnog punovalnog ispravljača (Graetzov spoj), na kojem su pokazani mehanizmi rada videa. Drugi primjer je iz učinske elektronike, (opis rada ciklopretvarača), kojim se jedan složeniji elektronički sklop interpretira na način kojim ga je jednostavnije pojmiti. Dakle, naglasak rada je stavljen na pokazivanju nevidljivog vidljivim. Zna se da je električna struja usmjereno gibanje nosioca naboja, pa se ta definicija, zajedno s valnim oblicima, koristi u prikazivanju električne struje u danim primjerima.

I. UVOD

U današnje vrijeme se mogućnost ostvarivanja učenja na daljinu već praktički udomaćila. Način dislociranog učenja u svrhu usvajanja novih sadržaja ili utvrđivanja gradiva postaje sve više jedan od modela obrazovanja. Učenje na daljinu nije vezano samo uz pojavu računala. Već se nekoliko desetljeća koristi sustav učenja putem radija i televizije kroz obrazovne programe. Oni su se redovito svaki dan emitirali a i danas se emitiraju ali u smanjenom obimu. Pojavom i širenjem računalne tehnike te izgradnjom širokopojasnog interneta, informacija je postala dostupnija pa se tako i ta mogućnost iskoristila za proces obrazovanja.

Sadržaji koji su se emitirali ili se emitiraju putem radija i televizije su uglavnom slijedni i vezani uz jedan određeni termin emitiranja. Postoji mogućnost snimanja programa putem video snimača i naknadnog prikazivanja, ali takvi sadržaji opet imaju mogućnost samo slijednog (sekvencijalnog) gledanja. Danas su također medijski obrazovni sadržaji locirani na računalu ili mreži te se mogu koristiti na isti način. No računala imaju i drugu mogućnost koja se prije nije mogla ostvariti, a to je sustav usvajanja znanja na računalu kroz programske pakete koji služe za razne proračune, simulaciju laboratorijskih vježbi i slično. Međutim uporaba takvih računalnih paketa ima svoje nedostatke. Uglavnom njihova uporaba je vezana uz potrebu licenciranja, a osim toga potrebna je određena vještina kako bi se mogli koristiti u pravom obimu za koje su namijenjeni. Dakle to iziskuje znatna financijska sredstva kao i vještine za njihovu uporabu. U elektrotehnici je primjer takvih programa „Elektronic Workbench“, „SIMPLORER“ i slično.

II. MULTIMEDIJA U NASTAVI ELEKTROTEHNIKE

Dakle, za usvajanje osnova iz određenog predmeta potrebno je na početnoj razini objasniti suštinu. Da bismo u elektrotehnici i posebno elektronici, matematički gledano, podskupu elektrotehnike, mogli lakše proučiti pojave koje se događaju, postavljaju se razni modeli prikaza određenih fizičkih veličina poput struje, napona magnetskih i električnih polja (silnica). Predočavanjem kroz različite simbole i matematičkim prikazom valnih oblika, pojednostavnjuje se prikaz prirode raznih pojava u poluvodičima i strujnim krugovima, tj. povećava se zornost električkih pojava.

U elektronici postoji čitav niz aktivnih elemenata različitih osobina čije djelovanje u strujnim krugovima nije jednostavno objasniti, a time nije niti jednostavno usvojiti kod slušatelja. Ako pri tome uzmemo da postoje predavači koji nemaju podjednake kvalitete predavanja, kao i to da uvijek postoji mogućnost izostanka učenika i studenata sa predavanja, tada još više dolazi do izražaja problematika vezana uz prijenos i utvrđivanje znanja.

Udžbenici su, pored predavanja, glavna poluga u usvajanju znanja, ali je njihova nedostatnost (naročito zadnjih godina pa i desetljeća u Hrvatskoj), jedan od glavnih nedostataka. U doba kada nije postojala računalna i mrežna infrastruktura postojalo je kontinuirano obrazovno nakladništvo. Nažalost u ovo računalno „moderno“ doba, broj naslova koji se pojavljuje na hrvatskom obrazovnom području se smanjio.

Na sveprisutnom internetu se može pronaći niz obrazovnih sadržaja. Nažalost, pregledavajući razne postavljene datoteke na mreži (PowerPoint, PDF...), često se nailazi na radove koji sadrže tzv. „copy-paste“ električnih shema, valnih oblika kao i teksta iz knjiga koje su objavljene kao udžbenici, te koji su nerijetko, kršeći autorska prava, završili u raznim seminarskim radovima ili predavanjima objavljenih na internetu. Uporaba Web 2.0 alata je prisutna, ali u jednoj mjeri koju bi trebalo povećati. U nastavi se najviše koristi PowerPoint prezentacijski alat, dok se ostali alati koriste jedanput do dva puta tjedno i to najviše u svrhu razmjene audio ili video materijala [2]. Dakle razvoj računalne

tehnike i infrastrukture ne prati i kvalitetan obrazovni sadržaj koji je vrlo često kompilacija prethodno objavljenih, a često i kopiranih dijelova već objavljenih radova.

U ovom radu će se pokazati pristup kojim se želi napraviti jedan iskorak u procesu poučavanja a koristi danas sveprisutne računalne i mrežne mogućnosti. Na dva primjera, jedan iz elektroničkih sklopova a drugi iz učinske (energetske) elektronike pokazat će se primjena interaktivnog videa.

Pretpostavimo u obzir čimbenike u poučavanju i to redoslijedom kako je napisano:

- predavanje,
- udžbenik,
- rješavanje zadataka,
- računalni simulacijski program.

Predavanje kao takvo je vezano uz određeni prostor (ako nije predavanje na daljinu) i točno određeno vrijeme, dok se udžbenik, zadaci i simulacijski programi uglavnom mogu rabiti kao takvi u bilo koje vrijeme i uglavnom na bilo kojem mjestu.

U tom slijedu interaktivni video spada u nastavno sredstvo koje se može koristiti u predavanju ali i kao samostalni medijski sadržaj koji u dobroj mjeri može nadomjestiti predavanje. To je u biti osnova, polazište, kojim se objašnjava princip rada pojedinog elektroničkog sklopa. On nije računalni program s mogućnostima koje takav program daje, već daje osnovnu predodžbu funkcionalnosti određenog sklopa i sadrži početne uvjete spoznaje koji su uobičajeni u radu toga sklopa kako bi se što jednostavnije predočila njegova funkcionalnost.

Cilj obrazovanja u elektrotehnici je poimanje interakcije među fizikalnim veličinama i tvarima koji su golim okom nevidljivi. Te pojave ne možemo direktno promatrati jer nemamo receptore za takve pojave, ali možemo promatrati ili mjeriti učinke koji su iz toga proizašli. Zato se ukazuje potreba za predočivanjem električnih veličina (napon, struja, silnice magnetskog ili električnog polja i sl.) tj. da se te električne pojave - ljudskom oku prikažu prihvatljivim nadomjesnim simbolima. To se već usvojilo na razne više manje unificirane načine pri pisanju udžbenika i objavi električnih shema.

Za razliku od klasičnog udžbenika (koji može biti u elektronskom ili materijalnom obliku) interaktivni video koristi pokretnu sliku za objašnjenje funkcionalnosti određenog elektroničkog sklopa. U tu svrhu koriste se slijedeći elementi prikaza:

- Tijek struje
- Valni oblici strujnog kruga (većinom napona i struja)
- PiP (picture in picture) – slika u slici, tj. video u videu
- Prikaz pojedinih ili svih prikaza na određenoj električnoj shemi
    - supstitucija postojeće sheme sa nadomjesnom shemom
    - uključivanje samo nekih ili određenih prikaza valnih oblika
- Klasične funkcije kod prikaza videa (kreni, stani, skok na određenu poziciju, postavi video na početak, postavi video na kraj zapisa)

A. Tijek struje

Kao što je poznato električna struja je usmjereno gibanje nosioca naboja kroz medij. U ovom interaktivnom videu električna struja je prikazana kroz elementarnu česticu naboja u obliku stošca (slika 1).

Gledajući taj element s njegovog vrha, vidi ga se kao kružnica s točkom u sredini – dakle naboj se kreće prema promatraču. U suprotnom pogledu, vidi se baza stošca, koja na sebi ima križić pa je i u tom slučaju postignut sklad s definicijama smjera struje u vodičima.

Struja se sastoji od niza usmjerenih elementarnih naboja koji prolaze kroz medij. Prema tome se struja unutar vodiča u shemama elektroničkih sklopova prikazuje kao neprekidni niz elementarnih stožaca koji idu jedan iza drugog u određenom smjeru (slika 2).

Orijentacija stošca i njegovo kretanje određuju smjer struje.

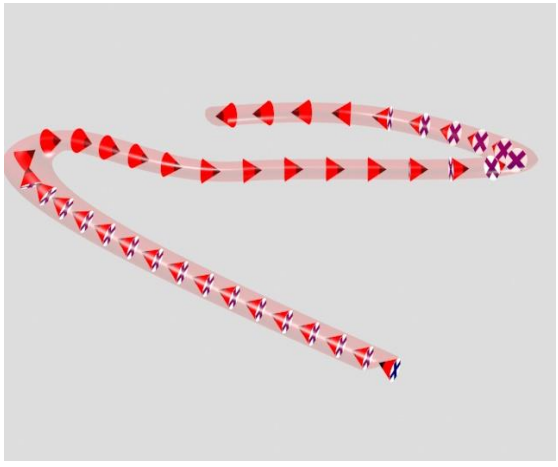
Brzina kretanja struje u vodičima je veličina koja se može podudarati sa brzinom kretanja u interaktivnom videu pa je tim jednostavnije pojmiti kretanje struje kroz vodiče.

Struja u vodičima može imati različiti karakter. Može biti stalnog iznosa, pa kažemo da je istosmjerna, a može biti i promjenjivog karaktera. Najpoznatija struja promjenjive veličine je izmjenična struja sinusnog valnog oblika. Bilo da se radi o istosmjernoj struji stalnog iznosa ili izmjeničnoj struji promjenjivog iznosa, element struje će biti prikazan kroz njegovu veličinu. Dakle veća struja - veći elementarni naboj tj. veći stožac, manja struja manji simbol elementarnog naboja tj. stošca.

B. Valni oblici strujnog kruga

Prikaz tijeka električne struje kroz vodiče i elemente

Slika 1: Stožac kao prikaz elementarnog naboja u prostoru



Slika 2: Struja električnih naboja kroz vodič (primjer protjecanja struje)

elektroničkih sklopova je najvažniji i najbitniji element za razumijevanje rada sklopa. Napon kao razliku potencijala je na sličan način teže prikazati pa se za njegovo prikazivanje koriste simboli i valni oblici pridruženi tim simbolima.

Valni oblici, većinom napona i struja, prikazani su kroz grafičke prikaze funkcija koji su već prema željenom odabiru vidljivi ili sakriveni na videu.

C. *Slika u slici (PiP –Picture in picture)*

Kako bi interaktivni video bio to u svom punom značenju, koristi se prikaz slike u slici kako bi se što jednostavnije objasnila funkcionalnost pojedinog sklopa. U početku pregledavanja videa koristi se osnovna shema na kojoj se promatra način rada, a onda se dodaju dodatni sadržaji kao što su na primjer, nadomjesna shema, ili ostali video sadržaji koji pojašnjavaju rad sklopa.

D. *Prikaz pojedinih ili svih prikaza na određenoj električnoj shemi*

Pored glavne sheme spoja postoji slobodan prostor koji se rabi za prikaz valnih oblika. Zbog toga je važno da se koristi format videa 16:9 kako bi se što efikasnije i svrsishodnije iskoristila zadana površina. Pojedini prikazi tijekom prikazivanja videa mogu se po želji uključivati i isključivati kako bi gledaocu shema bila što prihvatljivija s njegovog osobnog stanovišta ili faze usvajanja principa djelovanja.

E. *Klasične funkcije kod prikaza videa*

Pri uporabi interaktivnog videa koriste se klasične funkcijske tipke i klizač („slider“) za navigaciju kroz video: kreni, stani, skoči na poziciju, skoči na početak, skoči na kraj. Svi video zapisi koji se nalaze unutar interaktivnog videa sinkronizirani su sa tim tipkama za navigaciju (slika 3).

III. PRIMJERI INTERAKTIVNOG VIDEA

U ovom radu obrađena su dva primjera interaktivnog videa. Prvi primjer je izvedba mosnog ispravljača (Graetzov spoj) koji je dobro poznat svim elektrotehničarima i kojim se pokazuju principi rada interaktivnog videa. Drugi primjer je iz učinske (energetske) elektronike gdje se objašnjava princip rada ciklopretvarača.

A. *Mosni punovalni ispravljač (Graetzov spoj)*

Kao prvi primjer na kojem je najjednostavnije pokazati funkcionalnost interaktivnog videa je jednostavan sklop za ispravljanje izmjenične struje u istosmjernu. (slika 4).

Na videu se zamjećuju putujući elementi koji predstavljaju električnu struju. Ovisno o amplitudi, elementi struje su veći ili manji. Također je definiran i smjer struje koji se za izmjeničnu struju također mijenja.

Prva pojava koja se zamjećuje je ta, što struja mijenjajući orijentaciju kretanja, odabire i druge vodove za svoj prolazak.

Slika 3: Navigacijske tipke u interaktivnom videu (skroz nazad, stani, reprodukcija, skroz naprijed – ispod tipki je navigacijski klizač

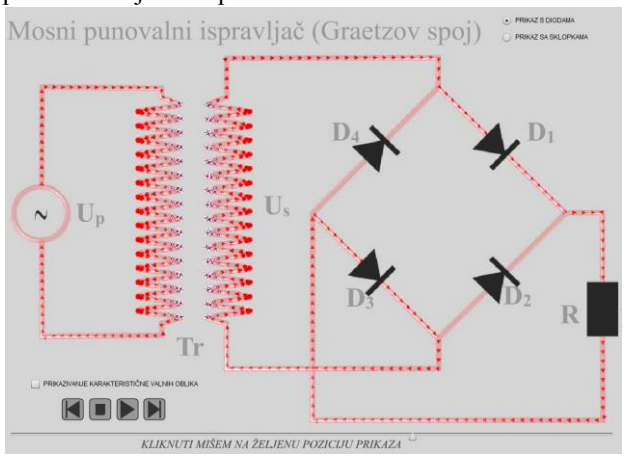
Zbog toga video ima opciju promjene aktivne elektroničke komponente. Može se pokazati nadomjesna shema gdje su diode zamijenjene s neupravljivim sklopkama (slika 5). Sklopke se otvaraju i zatvaraju ovisno o polaritetu napona koji se nalazi na njima.

Dakle, na nadomjesnoj shemi je prikazana sklopka umjesto diode i u ovom slučaju se jasno vidi da prolaskom jedne cijele periode električne struje iz transformatora (pozitivne i negativne poluperiode) – kroz otpor, prolaze samo pozitivne poluperiode. Ovime je postignut efekt punovalnog ispravljanja.

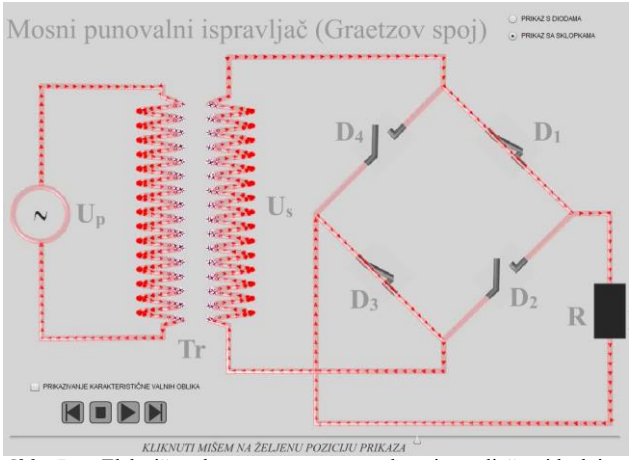
Kako plastična slika same sheme i tijeka elektrona kroz vodiče, pasivne i aktivne elemente nije dovoljna, potreban je grafički prikaz pojedinih električnih veličina. Interaktivni video omogućava prikaz pojedinih karakterističnih veličina struja i napona. To se radi postavljanjem kvačice u kvadratić „PRIKAZIVANJE KARAKTERISTIČNIH VALNIH OBLIKA“. (slika 5)

Odabirom na shemi može se sada kombinirati prikaz valnih oblika po vlastitom nahođenju. Grafički prikazi funkcija nisu stacionarni već su sinkronizirani s događanjima u električnoj shemi (slika 6).

Svaki od pojedinih valnih oblika se može isključiti i ponovno uključiti u prikazu.



Slika 4: Električna shema mosnog punovalnog ispravljača s poluvodičkim diodama (Graetzov spoj)



Slika 5: Električna shema mosnog punovalnog ispravljača s idealnim sklopkama koje zamjenjuju diode

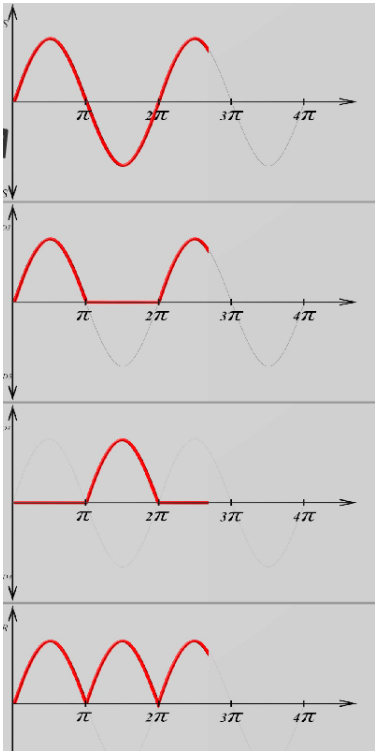
Kompletna slika rada punovalnog ispravljača je pokazana na potpuno popunjenom prikazu interaktivnog videa za taj sklop (slika 7).

Iz samog prikaza je vidljiva popunjenost zaslona sa mnogo podataka. Zbog toga je važno imati opciju za uključivanjem pojedinih prikaza po vlastitom nahođenju kako bi slika rada sklopa bila što razumljivija.

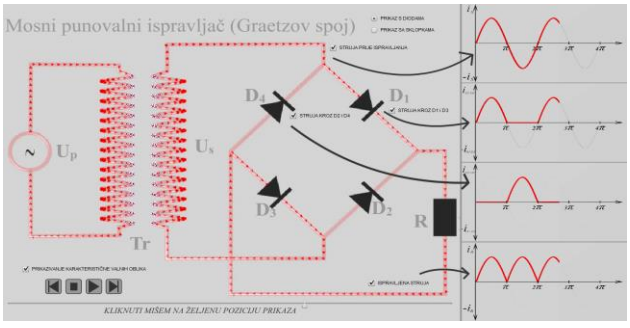
B. *Ciklopretvarač*

Mnogo kompliciraniji za objašnjenje principa rada je pretvornik frekvencije pod nazivom ciklopretvarač. U biti to je sklop učinske elektronike koji se koristi za transformaciju karaktera električne mreže na velikim snagama. U ovom primjeru se mijenja frekvencija.

Princip rada mu je na prvi pogled isti kao i kod Graetzovog spoja. Međutim ovdje se umjesto dioda u mostu uporabljuju upravljive sklopke (tiristori, GTO-i, IGBT). Obzirom da je potrebno objasniti princip rada ciklopretvarača, aktivni element učinske elektronike će se zamijeniti upravljivom sklopkom. Mehanizam upravljanja sklopkom nije predmet ovog razmatranja pa se neće niti spominjati.



Slika 6: Detalj prikaza valnih oblka na karakterističnim točkama Graetzovog spoja (odozgo prema dolje: izmjenična struja, poluvalno ispravljanje jedne grane, poluvalno ispravljanje druge grane, punovalni iznos struje na otporu R)



Slika 7: Kompletan izgled zaslona interaktivnog videa s primjerom punovalnog ispravljača (Graetzov spoj)

Shema spoja prema [1] je prikazana na slici 8.

Osnovno pitanje koje se postavlja je: kako od ulazne frekvencije ω_1 dobiti izlaznu frekvenciju ω_2? Za odgovor na ovo pitanje nam je potreban prikaz ulaznog napona i napona koji prolazi kroz otpor R.

Ciklopretvarači mogu konvertirati frekvenciju samo na niže ($\omega_2 < \omega_1$). Odgovarajućim uklapanjem i isklapanjem sklopki dobit će se jedan interesantan valni oblik (slika 9).

Na slici je vidljivo da se idući po osnovnoj sinusoidi ulazne frekvencije, izmjeničnim uklapanjem i isklapanjem sklopki dobiju dijelovi sinusoide koji na odsječku od 0-10π imaju uglavnom pozitivan predznak, a na odsječku od 10π-20π uglavnom negativan predznak.

Ako se hoće vidjeti srednja vrijednost napona za te odsječke onda treba u strujni krug staviti induktivitet koji zajedno sa otporom čini vremensku konstantu koja utječe na faktor glađenja („peglanja“) krivulje tj. smanjenje amplituda viših harmonika koji se ovakvim načinom pretvorbe frekvencije javljaju u izlaznom signalu.

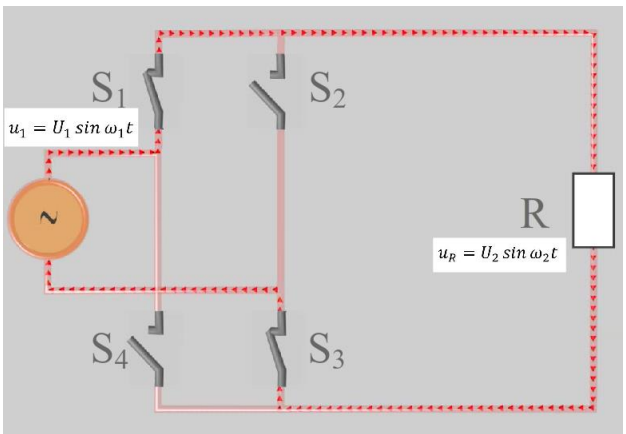
U tu svrhu se s radio gumbom promijeni shema prikaza (slika 10).

Isto tako se i upotpuni valni oblik s izravnatom („ispeglanom“) krivuljom (slika 11). Iz slike na interaktivnom videu je vidljivo da je ovime dobivena promjena frekvencije koja je na izlazu 10 puta manja.

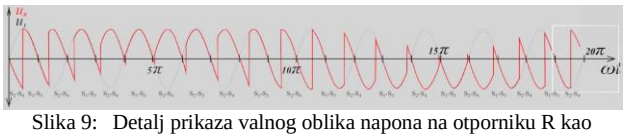
Naravno da je to idealizirana slika, te da prava slika rada ciklopretvarača treba biti verificirana kroz simulacijski program ili mjerenjem.

Kako je na zaslonu slika stvaranja valnog oblika relativno mala i nepregledna, to je kreiran jedan detalj slike koji se prati tijekom projiciranja videa. Dio sadržaja koji se posebno može pratiti je na slici 11 označen s bijelim kvadratom, a sam izgled dodatnog prozora je prikazan na slici 12.

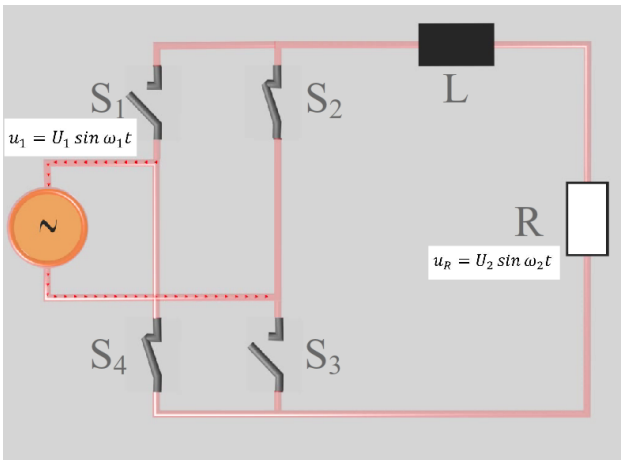
Kompletan prikaz interaktivnog videa s ciklopretvaračem i svim otvorenim prozorima te mogućnostima, prikazan je na slici 13.



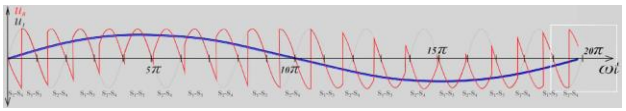
Slika 8: Osnovni prikaz sheme spoja ciklopretvarača uključujući idealne sklopke (S_1-S_3 i S_2-S_4 koje ukapčaju i iskapčaju u parovima) [1]



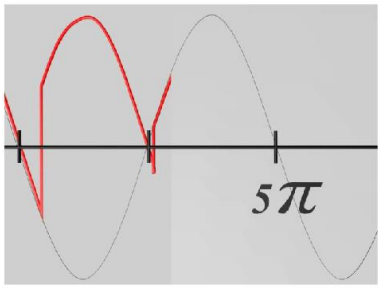
Slika 9: Detalj prikaza valnog oblika napona na otporniku R kao posljedica određenog ritma ukapčanja i iskapčanja parova sklopki S_1-S_3 i S_2-S_4



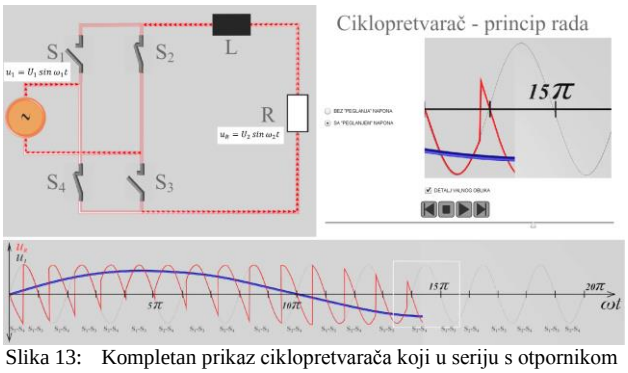
Slika 10: Detalj prikaza ciklopretvarača koji u seriju s otpornikom ima induktivitet L koji služi za izravnavanje krivulje



Slika 11: Detalj prikaza valnog oblika napona na otporu R (plava krivulja) kao posljedica „izravnavanja“ krivulje induktivitetom L



Slika 12: Detalj prikaza krivulje koja se iscrtava tijekom rada



Slika 13: Kompletan prikaz ciklopretvarača koji u seriju s otpornikom ima induktivitet L koji služi za izravnavanje krivulje

Na primjeru ciklopretvarača se ne spominju kvantitativni podaci o veličinama koje se koriste u prikazu. U ovom slučaju je npr. bitna vremenska konstanta L/R sklopa, koja mora biti u određenom odnosu s vremenom trajanja periode ulaznog i izlaznog signala, kako bi mogla efikasno (do određene mjere) izgladiti napon niže frekvencije u svrhu dobivanja izlaznog signala što sličnijeg sinusnom obliku.

Tako je predviđeno i u ostalim primjerima interaktivnog videa, čime se ispunjava osnovna zadaća ovog nastavnog sredstva koji je upućen na objašnjenje rada sklopa. Za egzaktne odnose fizikalnih veličina se mogu koristiti simulacijski računalni programi.

ZAKLJUČAK

U dosta primjera uporabe moderne računalne i mrežne tehnologije, ne vidi se toliki napredak iste za obrazovne svrhe [2]. Još uvijek se računalo koristi za pregledavanje i razmjenu medijskih sadržaja koji se koriste na sličan način kao da čitamo udžbenik ili gledamo televiziju. Dakle sadržaj je isti, način prezentiranja sadržaja isti, a jedina je razlika u pomagalu koji koristimo. Dok je to prije bila isključivo knjiga kao fizička jedinica – danas je to pored knjige: računalo, tablet, čitač knjiga, mobitel. Ili rečeno nastavnim rječnikom – nastavno sredstvo je ostalo isto, samo se promijenilo nastavno pomagalo (tu se izuzima uporaba simulacijskih programskih paketa koji imaju nemjerljivu ulogu danas u odnosu na nekada – ali imaju nedostatak, kao što je važno ponoviti iz uvoda, što su većinom vezani uz licencu, a trebaju i ne malu vještinu za njihovu uporabu).

U tu svrhu uporaba interaktivnog videa ima svoju opravdanost. Snaga računala koja se danas rabe, premašuju potrebe ove vrste prikaza, te njihovo uvođenje u nastavni proces ima smisla. Nameće se potreba za eventualna poboljšanja, nadogradnje i ostale izmjene kojima bi se zornost takvog načina prikaza poboljšala. Potrebu za unificiranjem tj. nekom vrstom standardizacije ovakvog načina prikaza, trebalo bi isto tako razmotriti, te time napraviti iskorak u smislu poučavanja.

I na kraju ostaje pitanje: kako kvalitetno opisati interaktivni video u pisanom obliku? Ovaj rad je samo pokušaj dočaravanja njegovih odlika koje treba doživjeti i ocijeniti na zaslonu prezentacijskog uređaja.

Sažetak – U radu je opisana primjena e-portfolija u nastavi računalstva učenika strukovnih usmjerenja. Realizacija je temeljena na sustavu otvorenog koda Mahara. Aktivnost je bila usmjerena na domaće zadaće i seminare, no može imati puno širu primjenu. Pokazalo se da je motivacija za rješavanje problema bila veća na ovaj način, nego na klasične načine koji su dosad korišteni. Učenici su pozvani da portfolio razvijaju kroz cjelokupno školovanje, te da ga popunjavaju kako bi sačuvali svoje uratke. Završetkom školovanja, uz pretpostavku čuvanja radova iz svih predmeta struke, mapa struke može biti vidljiva budućim poslodavcima ili u daljem školovanju. Na kraju prve faze provedena je anketa, kako bi se uočile prednosti i nedostaci. Temeljem rezultata ubuduće će biti uvedene određene promjene.

I. UVOD

Ishodi učenja i kompetencijski sustav postavljeni su u prvi plan u Nacionalnom okvirnom kurikulumu, kao temeljnom dokumentu koji određuje bitne sastavnice odgojno-obrazovnog sustava. U suvremenom društvu nove kompetencije pojedinca usmjerene su na razvoj inovativnosti, stvaralaštva, rješavanja problema, razvoj kritičkog mišljenja, poduzetnosti, informatičke pismenosti, socijalnih i drugih kompetencija. To je potrebno realizirati kroz strukovne, predmetne ili školske kurikulume.

Neki od pokazatelja razine usvojenosti znanja i vještina su ocjene, rezultati državne mature, rezultati natjecanja, završni radovi i sl. No, konkretni uradci koji su nastajali kroz nastavne aktivnosti uglavnom ne ostaju sačuvani. Učenik koji će tražiti posao ili ići na fakultet na kraju školovanja tako ne može prikazati svoj cjelokupni slijed napredovanja u struci.

Uporaba sustava za udaljeno učenje donekle rješava taj problem. Uradci ostaju sačuvani, te je napredak učenika jasnije vidljiv. Ipak, korak dalje je sustav koji može omogućiti izradu elektroničkog portfolija, životopisa, te određeno druženje i funkcionalnost društvene mreže.

S ciljem unapređenja nastavnih aktivnosti, poboljšanja motivacije, te organizacije spremišta uradaka proveo sam aktivnosti rješavanja programskih zadataka, te njihovo spremanje u e-portfolio. Učenici tijekom ili nakon odrađene cjeline mogu pokazati koje su praktične vještine usvojili. Kako se ne bi previše opteretili, zadatak koji su imali bio je podijeliti dnevnik i dodati datoteke kao zapis u dnevnik.

Provedena je anketa kojom se nastojalo sagledati stavove učenika u vezi s elektroničkim portfoliom i domaćim zadaćama. Kroz anketu je ispitano što je učenicima predstavljalo najviše problema, čime su zadovoljni, a što bi trebalo poboljšati.

II. DOMAĆE ZADAĆE I PROJEKTI

Internet je ušao u sve pore današnjeg društva. Djeca ga koriste već od malih nogu. Nakon toga vezan je uz nastavni proces kroz osnovnu i srednju školu. Već u srednjoj školi, a pogotovo na fakultetu upotrebljava se i u struci. Neke su struke direktno, a većina indirektno vezane uz njegovu uporabu. Može se doći do zaključka da je uz današnje generacije Internet neraskidivo vezan.

Elektronička komunikacija koja kao medij koristi Internet ubrzava i olakšava komunikaciju, ali joj daje i nove dimenzije. Materijali za učenje uobičajeno su na web stranicama, a nastaju i e-udžbenici. Elektronička pošta se u nastavnom procesu sve više predmeta podrazumijeva kao uobičajeni medij komunikacije. Istovremeno se dio ili cijela nastava određenih predmeta provodi online uporabom sustava za udaljeno učenje.

Kroz svoje školovanje učenici rješavaju domaće zadaće ili rade na školskim projektima čiji rezultat je digitalni dokument, ili ostaje neki drugi digitalni trag. Radovi se šalju elektroničkom poštom, ostavljaju unutar određenog CMS-a ili dostavljaju nastavniku na mediju i preko mreže. Nažalost, kroz određeno vrijeme ti radovi se izgube, izbrišu ili pak ostaju arhivirani.

Učenici strukovnih usmjerenja kojima je temelj struke tehnika u više predmeta koriste računalo kao osnovni alat u nastavi. U računalstvu izrađuju dokumente u uredskim aplikacijama, programiraju u raznim programskim jezicima, izrađuju web stranice i multimediju. Unutar struke izrađuju sheme, predloške, crteže, simulacije, programiraju i dokumentiraju određene radove. Dio učenika u izvannastavnim i izvanškolskim aktivnostima, te samostalno usvaja dodatna znanja i stječe vještine.

Poželjno bi bilo na određeni način sačuvati uratke tijekom cjelokupnog školovanja, kako bi prilikom zapošljavanja poslodavac mogao sagledati kojim kompetencijama vlada njegov budući djelatnik. Ujedno bi visokoškolska ustanova na kojoj učenik nastavlja školovanje mogla procijeniti početno stanje kompetencija, te kurikulum i grupe urediti tako da je napredak studenta optimalan. Kako bih započeo aktivnosti sa navedenim ciljevima, odlučio sam uputiti učenike u rad s elektroničkim portfoliom.

III. ELEKTRONIČKI PORTFOLIO

Portfolio se u poučavanju i bilježenju učeničkih postignuća koristi već niz godina u više područja. Vizualni i literarni uradci ili pak primjena u arhitekturi tradicionalni su načini uporabe. Radovi su se spremali u mape i čuvali, no ograničenje im stvara prostorna udaljenost, a teško ih je i prilagoditi za određenu uporabu.

Digitalno doba donijelo je medije za pohranu i prijenos slika, zvuka, videa i dokumenata raznih vrsta. Razvojem

sustava za upravljanje sadržajima (eng. Content management system - CMS) poučavanje je dobilo nove mogućnosti. Materijali za učenje, zadaci i rješenja, te sama komunikacija izašli su iz tradicionalnih učionica.

U novom tisućljeću počeo je i veći zamah elektroničkih portfolija. Počele su se razvijati tehnologije, funkcionalnosti i osobine. Danas se e-portfolio smatra jednim od načina sakupljanja dokaza učeničkog napretka i razvoja obrazovnih postignuća unutar određenog predmeta, struke ili institucije[I].

Kako bi e-portfolio polučio uspjeh nužno je obratiti pažnju na određivanje ishoda učenja, razumijevanje učenikovih potreba, identificiranje dionika, određivanje aktivnosti u poučavanju, evaluaciju portfolija, uključivanje više oblika uradaka, te vrednovanje učinka e-portfolija[II].

Elektronički portfolio je vrijedan alat za proces poučavanja, ali i vrednovanja i ocjenjivanja. Može poslužiti kao administrativni alat za pomoć u vođenju procesa učenja, za prezentaciju riješenih zadataka, te bilježenje ciljeva, rada i postignuća. Uporaba tehnologije omogućuje uporabu bilo kad, bilo gdje, pojedinačno ili u grupi i sa povratnom informacijom.

Učenički portfolio kao skup radova moguće je upotrijebiti kao jedan od načina vrednovanja i ocjenjivanja postignuća u nastavnim aktivnostima. Moguće je pratiti napredak kroz školsku godinu tako da se određena aktivnost odradi na početku, sredinom i na kraju razdoblja. Na taj način nastavnici, roditelji i učenici dobivaju pokazatelj razvoja učenika.

Ukoliko pak učenik tijekom nastavnog procesa odabere svoje najbolje uratke, može ih također uključiti u e-portfolio. Takav skup radova može se ocijeniti, ali i sačuvati kao dokaz stečenih kompetencija u školovanju.

Različita iskustva uporabe e-portfolija u Republici Hrvatskoj, nastavne aktivnosti i pedagoške osnove uporabe prikazane su u priručniku nastalom iz projekta „Uporaba sustava e-portfolija u sveučilišnoj nastavi“[III].

IV. Uporaba Mahare za izradu učeničkog portfolija

Mahara je e-portfolio sustav temeljen na sustavu otvorenog koda. Omogućuje izradu plana učenja, obaveza i ciljeva, izradu i nadopunjavanje životopisa, izradu stranica, komunikaciju i prikupljanje postignuća. Omogućuje i pisanje blogova, te razvoj komunikacije kroz određenu vrstu društvene mreže.

Korisnik Mahare može urediti svoje osobno okruženje za učenje, te za praćenje vlastitog razvoja. Dijelove sustava koje želi može podijeliti s drugim korisnicima, nastavnicima ili poslodavcima.

Mahara počiva na tri stupa. Sakupljanjem i sastavljanjem izrađuje se osobni profil, dodaju se datoteke, piše životopis ili blog. Drugi stup podrazumijeva organizaciju i prezentaciju portfolija kroz oblikovanje stranica različitim elementima i medijima. Treći stup je komunikacija, dijeljenje, prezentiranje, komunikacija i diskusije.

V. Praktični zadatak

Učenici strukovnih usmjerenja završetkom školovanja stječu kvalifikaciju određene razine, obujma, profila i kvalitete. Ona se dokazuje javnom ispravom, no poželjno je da učenik ima i materijalne dokaze kompetencija. Oni nastaju u nastavnom procesu, no nakon ocjenjivanja, njihova važnost kao da se zaboravlja. Upravo time sam pokušao učenicima pokazati da im porfolio nije nametnut, nego da će od njega imati koristi.

Zadatak učenika je bio izraditi program u jeziku C na određenu temu. Teme uglavnom pokrivaju primjenu u struci, a učenici ih mogu birati sami. Ovisno o kompleksnosti algoritama, uloženom trudu i pokazanom napretku vrednuje se i rad.

Kako bi portfolio započet u srednjoj školi učenici mogli koristiti i u visokoškolskom obrazovanju, upotrijebljena je instalacija Mahare Centra za učenje na adresi https://moodle.srce.hr/eportfolio/. Jedna od prednosti ove instalacije je uporaba AAI@EduHr autentikacijske i autorizacijske infrastrukture. Time je administrativni dio za mene kao nastavnika bio sveden na minimum. Prvotna ideja bila je instalacija i podešavanje Mahare za potrebe škole, no takvo rješenje imalo bi više nedostataka nego prednosti.

Za potrebe komunikacije i dijeljenja sadržaja izrađene su grupe za Srednju školu Krapina i za pojedine razrede prema godini upisa. Nakon prijave učenici su se samostalno prijavljivali u navedene grupe. Mogli su popuniti stranicu „O meni“, no to im nije nametnuto kao obveza. Životopis je također dio portfolia za koji nije traženo da se popuni.

U anketi je uočeno da shvaćaju važnost životopisa, no kako trenutno nisu očekivali da će biti pregledavan, uglavnom nije bio ni popunjen.

Učenici su sadržaj dijelili pomoću stranice. Na linku „Moj portfolio“, unutar područja „Stranice“ izradili su novu stranicu. Ovisno o željama mogli su urediti izgled. Važno za dijeljenje je bilo povlačenje bloka za prikaz cijelog dnevnika, te njegovo dijeljenje na linku „Podijeli stranicu“. Ovlasti su mogli dodijeliti samo profesoru, razredu ili školi.

Uratke su učenici dodavali kao zapise u dnevnik. Zapisu su prilagali datoteke. Trenutni prostor kojim raspolažu je 20 MB. Savjetovano im je da prema potrebi koriste poveznice na svoj prostor u određenom oblaku (Google Drive, SkyDrive, Dropbox i sl.). Svaki novi uradak bit će novi zapis u dnevniku, za čije dodavanje učenik treba vrlo malo vremena.

Slika 1: dijeljenje sadržaja

Slika 2: povratna informacija

Iako su svi učenici dobili jasne upute, korak po korak, bilo je problema s postavljanjem i dijeljenjem sadržaja. Dosadašnje uratke uglavnom su ostavljali na mrežnom disku, za što je trebao minimum uloženog truda, pa je dio učenika pružao otpor početnim podešavanjima e-portfolia.

Nakon nekog vremena, tek nekoliko učenika svoje uratke nije postavilo na e-portfolio. Sukladno dogovoru, upisane su povratne informacije koje su uz obrazloženje ocjene saopćene i na nastavnom satu.

VI. REZULTATI ANKETE

Za istraživanje je korištena anketa provedena u Srednjoj školi Krapina. Anketirano je 77 učenika i učenica drugog i trećeg razreda strukovnih usmjerenja. Određena pitanja postavljena su tako da je korišteno obrnuto bodovanje kako bi ispitanici razmislili o svakom odgovoru.

Prva skupina pitanje odnosila se je na ocjenu vlastitog iskustva s e-portfoliom. Učenici su se uglavnom složili da e-portfoliom mogu pokazati usvojenost znanja, vještina i kompetencija, da omogućuje vidljivost uradaka nastavniku, te čuvanje uradaka za duže razdoblje na jednom mjestu. Navedeno mišljenje prevladalo je kod 70 do 80 % učenika. Kompleksnost početnih podešavanja nešto je veća u postotku od kompleksnosti uporabe. Navedeno je smatralo čak do 50% učenika. Povratnu vezu i mogućnost komunikacije neki nisu ni uočili, iako upotrebljavaju društvene mreže svakodnevno.

Prikupljanje radova velika većina (76%) je smatrala kao najvažniju mogućnost u e-portfoliju. Slijedi plan rada, obveza i ciljeva, izrada životopisa, dijeljenje iskustva, razmišljanja i informacija, te osobne stranice sa oko 50%. Najmanje smatraju da je važno pisanje dnevnika, odnosno bloga. Kako većina ovih aktivnosti nije ni tražena, teško je bilo bez vlastitog iskustva očekivati da će se moći procijeniti važnost aktivnosti.

Treća skupina pitanja odnosila se je na domaću zadaću. Uratke koji su postavljeni na Maharu, učenici su u određenom vremenskom razdoblju radili kod kuće. Osim tih uradaka, ranije su dobivali i druge domaće zadaće. Većini učenika (60 do 70%) zadaća pomaže u učenju, a istovremeno je zadaća primjerena sposobnosti, pomaže u razumijevanju gradiva obrađenog na satu i pomaže u stjecanju radnih navika. Nažalost, tek 16% učenika uživa raditi domaću zadaću. Oko 60% učenika je previše opterećeno domaćim zadaćama i piše ih zato da ne bi dobili kaznu ukoliko ih ne izrade. Nešto više od pola učenika misli da domaće zadaće ne treba zadavati. Ovime se vidi da su učenici svjesni važnosti domaćih zadaća, ali nedostaje motivacija. Na tome treba svakako poraditi u budućnosti.

Testiranjem razlika s obzirom na usmjerenje utvrđeno je da su tehničari za mehatroniku pokazivali veće slaganje s tvrdnjama, odnosno da su pozitivnije procjenjivali navedene aspekte.

Testiranjem razlika s obzirom na razred utvrđeno je da učenici trećih razreda vide kao veću prednost mogućnost dokazivanja usvojenosti svojih znanja i vještina (M=2,94, sd=0,74) od učenika drugih razreda (M=2,51, sd=1,06). Prikupljanju radova, projekata i sličnih dokumenata također daju učenici trećih razreda veću važnost (M=3,06, sd=0,78) od učenika drugih razreda (M=2,60, sd=0,98). Slična je još situacija s pisanjem dnevnika-bloga gdje treći razredi daju važnost (M=2,44, sd=0,86), a drugi razredi (M=1,93, sd=1,01). Može se doći do zaključka kako su stariji učenici već sakupili određenu količinu radova kojom bi se mogli pohvaliti, ali i da su sve svjesniji slijedeće stepenice u svojem životu u kojoj im mogu zatrebati određeni dokazi o kompetencijama.

U dijelu u kojem su učenici mogli samostalno dodavati komentare i prijedloge uočeno je nesnalaženje unutar sučelja i konstatacije o kompleksnosti upotrebe Mahare.

Nakon nekoliko godina korištenja vrijedilo bi postaviti pitanje "planirate li nastaviti koristiti e-portofolio", kako bi se mogla raditi regresijska analiza - da li se na osnovi tvrdnji može predvidjeti buduće korištenje e-portofolia

VII. ZAKLJUČAK

Elektronički portfolio može postati dio procesa cjeloživotnog učenja, svatko ga može prilagoditi svojim potrebama, učenik mu je u središtu, a web tehnologija omogućuje dostupnost bilo gdje i bilo kad.

Nove tehnologije sve se više ugrađuju u nastavni proces. Ponekad ih uključujemo možda i više iz razloga popularnosti kod mladih, nego prepoznatljive edukativne vrijednosti. Jedan od faktora koji je bitan kod planiranja e-porfolija su dosadašnje navike, odnosno kultura. Uvijek postoje otpori uvođenju novih tehnologija, čak i ako je vidljivo da donose mnogostruko više koristi od uloženog truda.

Generalni zaključak ankete može se svesti na činjenice da učenici prihvaćaju e-portfolio za čuvanje svojih uradaka, no na žalost ne uživaju raditi domaću zadaću. Moguće je ipak da će vrijeme pokazati da e-portfolio postaje nezaobilazan pratitelj učenika, studenta i njihovih edukatora.

Bonton digitalnog doba

Marina Mirković, dipl. inženjer elektrotehnike
Tehnička škola, Požega, Republika Hrvatska
marina.mirkovic@po.t-com.hr

Sažetak

Informatičko/informacijska pismenost je nužnost današnjeg digitalnog doba. Ponašanje na internetu, u virtualnoj zajednici mora biti u skladu s kulturno-civilizacijskim i poslovnim normama. Usvajanje pravila bontona u raznim situacijama u kojima koristimo moderne tehnologije pomoći će nam da steknemo dobre manire.

Važno je definirati skup pravila poželjnog ponašanja u internet zajednici. Pridržavanje pravila u slanju i primanju elektroničke pošte nije samo stvar bontona već je neophodno i zbog očuvanja sigurnosti, stvaranja ugleda i održanja produktivnosti poslovanja.

Brojna su pravila kojih se moramo pridržavati pri primjeni mobilnih telefona, elektroničkoj komunikaciji putem elektroničke pošte, u virtualnim zajednicama kao što su News grupe i forumi, kao i društvenim mrežama.

U Tehničkoj školi Požega nizom godina učenici sudjeluju u projektu «Sigurnost djece na internetu» te su provedena istraživanja i prikupljanje podataka o iskustvima učenika prilikom korištenja interneta, kao i primjene pravila e-bontona. Analiza rezultata ankete pokazuje da u školama učenici moraju upoznati e-bonton i primjenjivati ga u svojoj digitalnoj komunikaciji. Pravila lijepog ponašanja u virtualnom svijetu objavio je Hrvatski Telekom izdavanjem e-bontona koji je podjednako obuhvatio mišljenje sudionika komunikacije na društvenim mrežama i mišljenje eksperata s iskustvom promatranja najraznovrsnijih oblika komunikacije kao međuljudske interakcije.

Osim djece i mladih, poslovni ljudi, zaposlenici u tvrtkama također moraju posebnu pažnju posvetiti digitalnom bontonu. Edukacijom zaposlenika u tvrtkama moguće je zaštititi sebe i tvrtku od nezgodnih pitanja odgovornosti. Važno je osigurati e-bonton politiku koja se odnosi na sve zaposlenike.

I. UVOD

Moderno doba i nove tehnologije donijele su nove izazove a time i promjene normi lijepog ponašanja. Osnovne karakteristike i dalje su: ljubaznost, poštovanje, obzirnost i tolerancija. Svojim ponašanjem utječemo na okolinu. Usvajanje pravila bontona u raznim situacijama u kojima koristimo moderne tehnologije pomoći će nam da steknemo dobre manire a ujedno učiniti naš privatni i poslovni život ugodnijim i uspješnijim. Lijepim ponašanjem naša zajednica postaje bolje mjesto življenja. Koliko se pridržavamo pravila bontona i shvaćamo li njegovu važnost kao i praktične koristi koje nam pruža? Kako se mladi, djeca, naši učenici odnose prema njemu, poznaju li i pridržavaju se pravila?

Ulaskom u Europsku unija, Hrvatska mora poraditi i na školskom sustavu. Prema anketi portala EduCentar, u kojoj je sudjelovalo 400 ispitanika, hrvatski građani bi među novim nastavnim predmetima u školski program najprije uveli bonton. Najviše ispitanika (39%) podržava uvođenje bontona u školstvo, jer problem s bontonom imaju odrasli, a time, nažalost i njihova djeca [1].

II. PONAŠANJE KOD PRIMJENE DIGITALNE TEHNOLOGIJE

Mnogi, a posebno mladi ljudi su postali sve ovisniji o mobitelima, neprestano su uz njih. Mobilni telefoni služe za kratku razmjenu informacija ili hitne pozive. Dugi i glasni razgovori uslijed dosade, uz prisutnost drugih osoba, posebno na javnim mjestima, nisu primjereni. Nepristojno je u prisutnosti drugih osoba neprestano provjeravati pozive, poruke ili surfati po internetu. Mnogi su u društvu, na zabavi ili jednostavnom druženju opsjednuti mobitelom. Nepristojno je dugotrajno pisanje poruka, na što mladi ne obraćaju pažnju. Ponekad ne isključuju mobitele tamo gdje su oni nepoželjni (predavanja, u kinu, kazalištu, crkvi, muzeju ili knjižnici). Mobitele često koriste za fotografiranje pri čemu je važno voditi računa o tome koga su slučajno «uhvatili» na fotografiji i u kojoj situaciji. Ne smijemo narušavati tuđu privatnost, posebno ako namjeravamo fotografije objaviti na društvenim mrežama [2].

Elektronička pošta putem interneta nije sasvim sigurna. Nužno je pažljivo postupati sa slanjem svojih privatnih informacija i voditi brigu o zaštiti sadržaja. Nikako nije poželjno prosljeđivati ili započinjati «lance sreće» jer oni nisu dopušteni na internetu. Zbog toga pristup mreži, forumu ili servisu može biti uskraćen [3].

Ukoliko šaljete velike količine podataka, moguće je «zakrčiti» elektronički poštanski sandučić ili povećati troškove korisnicima koji e-poštu otvaraju na privatnom pametnom telefonu. Iz istog razloga nepoželjno je odnosno zabranjeno nezatraženo e-mail oglašavanje (spam).

Pismenost je važan dio pristojnosti pri slanju elektroničkih poruka. Treba izbjegavati pisanje svih riječi velikim slovima. Korištenje slova u raznim bojama otežava čitanje i djeluje neozbiljno. Ne smijemo pretjerivati s emotikonima u porukama [4].

Forum je virtualna zajednica korisnika sa sličnim interesima. Pri tome se korisnici moraju pridržavati pravila online bontona. Poruka koju pišete mora biti jasna i jednoznačna. Poštujte temu o kojoj se raspravlja i ne pokušavajte ju mijenjati. Za privatne razgovore koristite privatne poruke ili elektroničku poštu. Važno je nastojati ne stvarati nesporazume u kojima se može uočiti arogancija ali i agresivnost.

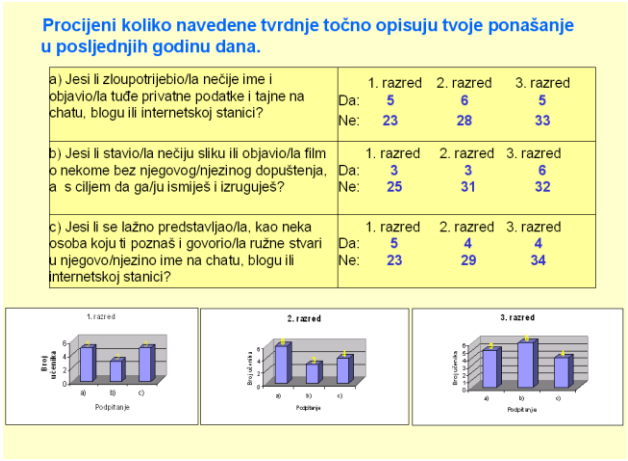
Putem društvenih mreža dijelimo iskustva i mudrosti na koje smo naišli ili naučili. Otkrivamo što se ljudima sviđa, kako se ponašaju, što dijele i komentiraju. Treba nastupiti prijateljski, oprezno prema osobama iz neke druge kulture. Ne treba otkrivati previše osobnih detalja. To nije mjesto gdje ćete iskazati svoje frustracije i bijes, javno se osvećivati ili rugati. Pazite što stavljate na društvene mreže. Sve ostaje zapisano, a netko to može iskoristiti protiv vas.

Facebook je nažalost postao rasadnik nekulturne mase koja na ovoj društvenoj mreži čini stvari koje se u stvarnom životu mogu usporediti sa psovanjem, vikom, tučnjavom i sličnim. Mnoštvo aplikacija korisnicima pomaže da budu što dosadniji i naporniji. Blokiranjem aplikacija riješiti ćete problem. Pretjerivanje u psovanju i vrijeđanju najodbojnija je stvar na društvenim mrežama. Česti su dosadni statusi, pojavljuju se najnaporniji i najneugodniji korisnici koji vas neprestano pozivaju na različite događaje i aktivnosti. Uz njih su naporni i hvalisavci.

Privatno i poslovno na društvenim mrežama mora biti odvojeno. Mnogi ne znaju ili se ne pridržavaju bontona na društvenim mrežama. Ne shvaćaju važnost primjene pravila uz više od milijun korisnika društvenih mreža u Hrvatskoj. Ponašanje u digitalnom svijetu odraz je i našeg ponašanja u pravom životu. Pokažimo da se znamo ponašati. Nepristojne korisnike na vašim društvenim mrežama bez ustručavanja obrišite s popisa prijatelja.

III. ANALIZA UČENIČKOG PONAŠANJA U DIGITALNOM SVIJETU

Učenici moraju uočiti povezanost između primjene pravila bontona u digitalnom svijetu i sprječavanja mogućnosti nasilja i doživljavanja neugodnih situacija u radu na internetu. U Tehničkoj školi Požega nizom godina učenici sudjeluju u projektu «Sigurnost djece na internetu» te je provedeno istraživanje i prikupljanje podataka o iskustvima učenika prilikom korištenja interneta. U anonimnom anketiranju o sigurnosti i zaštiti djece na internetu u veljači 2010. godine, putem upitnika na nastavi računalstva sudjelovali su učenici razrednih odjela: 1.f, 1.h, 2.a, 2.b, 2.e, 2.f, 2.h, 3.f, 3.h - sveukupno 100 učenika. U analizi odgovora, među ostalim, otkriveno je da dio učenika (13%) pokazuje znakove "internet nasilnika" (slika 1). Djeca i mladi moraju postati svjesni kakve posljedice može imati njihovo ponašanje na internetu. Potrebno je istaknuti kako su distribucija i prosljeđivanje nasilne, uvredljive, ponižavajuće poruke jednako loši i mogu imati jednako teške posljedice kao i ponašanje osobe koja je začetnik poruke.



Slika 1. Analiza odgovora jednog pitanja ankete učenika o sigurnosti i zaštiti djece na internetu

U svibnju 2013. godine 109 učenika Tehničke škole u Požegi (iz razrednih odjela: 1.h, 1.f, 2.a, 2.b, 2.f, 2.h. 3.b. 3.f. 3.h) sudjelovalo je u anonimnoj anketi o pisanju SMS i poruka elektroničke pošte [5]. Analiza njihovih odgovora, prema pitanjima u anketi prikazana je u tablici 1.

Analizirajući rezultate anketiranja, iznenađuje broj učenika koji šalju poruke s uvredljivim sadržajem, kao i uporaba elektroničke pošte za raspravu o povjerljivim informacijama. Dio učenika prosljeđuje lančana pisma i odgovara na spam. Velika brzina pri pisanju/tipkanju navodi ih da pišu dugačke rečenice u porukama, a neprestana prisutnost i povezanost s digitalnom tehnikom omogućuje odgovaranje po primitku poruke. Mnogi učenici ne razmišljaju o smislenom naslovu poruke elektroničke pošte.

Većina učenika pročita poruku prije nego ju pošalje, dok se dio učenika ne pridržava tog pravila. Pri tome šalju poruke s pravopisnim, gramatičkim i interpunkcijskim pogreškama. Ne smijemo biti brzopleti, važno je provjeriti tekst poruke jer ćemo tada poslati učinkovitiju poruku i izbjeći nesporazume i neprikladne komentare. Budući da je čitanje s ekrana teže nego čitanje s papira, struktura i raspored vrlo su važni za e-mail poruke. Kod uporabe oblikovanja u porukama, pošiljatelj ga možda neće vidjeti ili će vidjeti drugačije fontove od željenih.

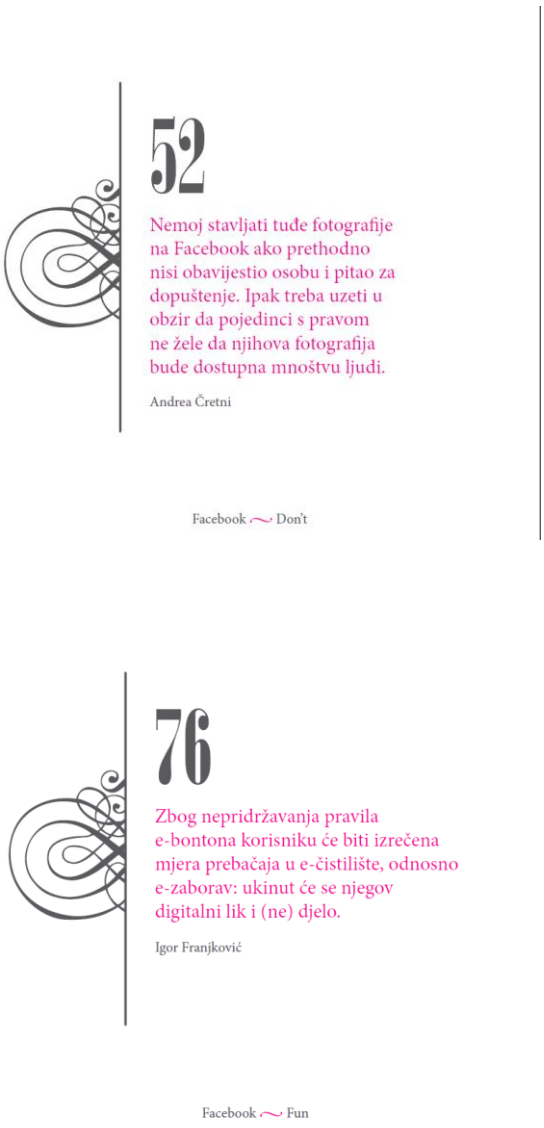
Rezultati istraživanja ukazuju na činjenicu da je potrebna daljnja edukacija učenika o važnosti primjene e-bontona, kao i opasnostima i načinima samozaštite djece prilikom korištenja računala i interneta.

Tablica 1. Rezultati ankete učenika Tehničke škole u Požegi o pisanju SMS i e-mail poruka

Anketno pitanje	Odgovor DA Broj učenika	DA postotak	Odgovor NE Broj učenika	NE postotak
Pišeš kratko i jasno	91	83 %	18	17 %
Paziš na gramatiku	47	43 %	62	57 %
Odmah odgovaraš na poruke	72	66 %	37	34 %
Koristiš nepotrebne privitke	21	19 %	88	81 %
Pišeš velikim slovima	17	16 %	92	84 %
Kod odgovora, uvijek uključiš prethodne poruke	56	51 %	53	49 %
Pročitaš poruku prije nego je pošalješ	91	83 %	18	17 %
Pažljivo koristiš kratice i emocionalne ikone	64	59 %	45	41 %
Pažljivo formatiraš poruke	47	43 %	62	57 %
Prosljeđuješ lančana pisma	14	13 %	95	87 %
Uključuješ tuđu poruku ili privitak bez dozvole	16	15 %	93	85 %
Koristiš e-poštu za raspravu o povjerljivim informacijama	26	24 %	83	76 %
Koristiš suvisli predmet – naslov (Subject)	29	27 %	80	73 %
Koristiš riječi HITNO i VAŽNO	40	37 %	69	63 %
Pišeš dugačke rečenice	57	52 %	52	48 %
Šalješ poruke s uvredljivim sadržajem	31	28 %	78	72 %
Prosljeđuješ hoax (lažna upozorenja)	11	10 %	98	90 %
Odgovaraš na spam	19	17 %	90	83 %

IV. POUČAVANJE O E BONTONU

Pravila lijepog ponašanja u virtualnom svijetu objavio je Hrvatski Telekom izdavanjem e-bontona koji je podjednako obuhvatio mišljenje sudionika komunikacije na društvenim mrežama i mišljenje eksperata s iskustvom promatranja najraznovrsnijih oblika komunikacije kao međuljudske interakcije [6]. Autori ovog priručnika su tako fejsbukovci, tviteraši, blogeri i forumaši, svakodnevni korisnici društvenih mreža koji su svojim prilozima pomogli osmisliti prvi hrvatski priručnik za lijepo ponašanje na društvenim mrežama kao što su Facebook i Twitter. Priručnik sadrži 130 odabranih pravila a dostupan je u digitalnom i tiskanom izdanju (slika 2).

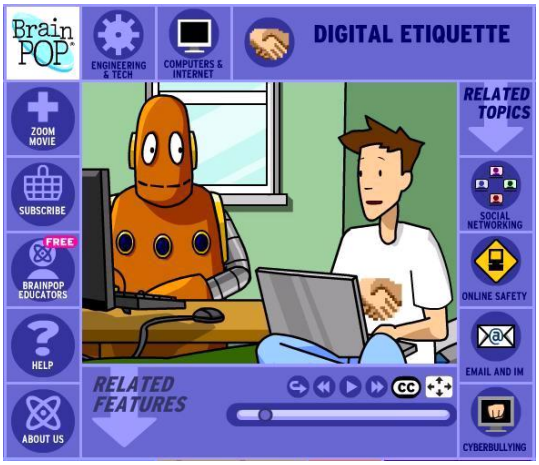


Slika 2. Pravila iz Prvog hrvatskog e-bontona čiji je izdavač Hrvatski Telekom

U primjeni pravila bontona kod učenika, pored nastavnika veliku ulogu imaju i roditelji. Premda se osjećaju zbunjeni kad je riječ o novim tehnologijama jer smatraju da djeca o tome znaju više nego oni, roditelji moraju biti svjesni da o životu znaju više od svoje djece i da moraju imati nadzor nad njihovim ponašanjem na internetu. Djetetovo pravo na privatnost ne smije spriječiti roditelje pri postavljanju granica, kao i naglašavanju primjene pravila online bontona.

Internet bonton učenici mogu proučiti i na CARNet-ovom portalu kroz pravila komunikacije pojedinaca i komunikacije u grupi [7].

Na portalu BrainPOP (obrazovne web stranice) učenici mogu na zanimljiv način, multimedijskim prikazom upoznati online pravila (slika 3), kao i online komunikaciju i zaštitu na internetu [8].



Slika 3. Edukativni sadržaji o digitalnom bontonu na portalu BrainPOP

Učenicima osnovne škole zanimljiv će biti alat Digitalna putovnica kojeg je pokrenuo Common Sense Media. To je interaktivna mrežna platforma za učenje, na engleskom jeziku, koja pomaže učiteljima u poučavanju i pripremi njihovih učenika kako bi postali dobri digitalni građani koji će se spremno uključiti u korištenje online i mobilnih tehnologija. Kroz pet interaktivnih modula učenici se upoznaju s osnovama sigurnosti i zaštite, osnovama lijepog ponašanja u digitalnom svijetu i razvijaju istraživačke vještine [9].

Dan sigurnijeg interneta, koji se obilježava svake godine u veljači, pruža mogućnost da se u školama pažnja posveti bontonu primjene digitalne tehnologije (slika 4). Kroz razne teme o sigurnosti i zaštiti djece na internetu, učenici upoznaju i kritički razmišljaju o svojim online pravima i odgovornostima. Analiziraju utjecaj novih medija na pojedinca i društvo, raspravljaju o prednostima i manama široke uporabe medija novih tehnologija u svakodnevnom životu. Pri tome upoznavaju računalnu etiku, dogovaraju pravila ponašanja na internetu te definiraju posljedice kršenja tih pravila.

Slika 4. Aktivnosti povodom obilježavanja Dana sigurnijeg interneta u Tehničkoj školi, Požega

V. ZAKLJUČAK

Novi komunikacijski kanali, moderne tehnologije, nedostatak vremena i težnja ka pojednostavljivanju i ubrzavanju protoka sve većeg broja informacija nužno utječu na prirodu komunikacije i pravila lijepog ponašanja. Svatko od nas ima pravo odabrati kako će se postaviti u primjeni digitalne tehnologije, ali okvir pravilnog online ponašanja ipak mora postojati. Proučavanjem e-bontona mnogi korisnici će možda napokon shvatiti svoje pogreške te ih uspješno početi ispravljati. Važno je ispoštovati e-bonton i unaprijediti online zajednicu, počevši od sitnih, ali bitnih pravila komuniciranja.

Osim djece i mladih, poslovni ljudi, zaposlenici u tvrtkama također moraju posebnu pažnju posvetiti digitalnom bontonu. Tri najvažnija razloga zbog kojih je važno paziti na e-poštu i digitalnu komunikaciju su profesionalizam (korištenje odgovarajućeg jezika utječe na sliku tvrtke), učinkovitost (jasno napisane poruke ubrzavaju poslovanje) i pravna zaštita (osviještenost o opasnostima e-pošte zaštitit će tvrtku od skupih sudskih parnica). Osobnom edukacijom i educiranjem zaposlenika možemo zaštititi sebe i svoju tvrtku od nezgodnih pitanja odgovornosti. Važno je osigurati e-bonton politiku koja se odnosi na sve zaposlenike. Sastavni dio etičkog kodeksa škole i tvrtki mora biti i provedba pravila online bontona. On se može definirati i u okviru školske Politike prihvatljivog korištenja interneta i računala u školi radi sigurnosti školskih računala, opreme i korisnika koji se moraju ponašati odgovorno i u skladu s etičkim načelima i u stvarnom i u virtualnom svijetu.

IKT, ljudski resursi te informacijska i računalna sigurnost u hrvatskom osnovnom školstvu

Mario Zovkić*, Tedo Vrbanec**
*Osnovna škola Barilović, Barilović & Osnovna škola "Katarine Zrinski" Krnjak, Krnjak, Hrvatska
**Učiteljski fakultet, Sveučilište u Zagrebu, Zagreb, Hrvatska
*mario.zovkic1@skole.hr, **tedo.vrbanec@gmail.com

Abstract - Nastavnici informatike u hrvatskim osnovnim školama često su "volonteri" u ulozi sistemskih administratora. Ta je uloga tehnički i tehnološki zahtjevna, a vremenski izuzetno zahtjevna. U školama se takav angažman uglavnom ne primjećuje. Sistemsku administraciju dodatno otežavaju sljedeće činjenice: (a) računala su često različitih hardverskih konfiguracija što onemogućava neke metode održavanja, (b) računala su u prosjeku stara osam godina pa imaju slabije hardverske mogućnosti (slabiji procesor te nedovoljna/minimalna količina radne memorije), zbog čega su spora. Računalne učionice u prosjeku sadrže 19 računala, što predstavlja problem ako su razredna odjeljenja većeg broja učenika, a razredna odjeljenja nije moguće dijeliti na manje grupe. U manjim školama nastavnici informatike često su pored računalne učionice zaduženi za održavanje i svih drugih računala u školi. Učenici se uobičajeno prijavljuju na računala u svojstvu administratora, sve se više raznih uređaja poput pametnih telefona, tableta i fableta spaja na školsku mrežu, a informatičari i ostali nastavnici zbog kroničnog nedostatka novaca za stručno usavršavanje nisu dovoljno educirani s novim prijetnjama i metodama zaštite u pogledu računalne i informacijske sigurnosti. Stoga edukacija o IKT sigurnosti ovisi o dobroj volji, slobodnom vremenu i entuzijazmu pojedinog nastavnika (informatike). Rad predstavlja pregled sigurnosti internet komunikacija te fizičke sigurnosti IKT u školskim računalnim učionicama.

Ključne riječi: e-sigurnost, IKT, računalna učionica.

I. UVOD

Računala u hrvatskim osnovnim školama krajem svake školske godine najčešće su puna virusa, pomiješanih/izbrisanih prečaca, promijenjenih ikona, izbrisanih programa ili programa koji javljaju čudne greške i/ili se jako dugo pokreću, nakrcana su raznim nepotrebnim programima (engl. bloatware), zbog svega toga su usporena i općenito se nalaze u jednom konfuznom stanju – reklo bi se da su "zrela za reinstalaciju" OS-a i svih potrebnih programa. Ukoliko se o sigurnosti ne vodi računa te ukoliko se u nj ne uloži potrebno vrijeme i trud, za godinu dana simptomi su isti.

Nastavnici informatike u hrvatskim osnovnim školama najčešće su i administratori školskih IT resursa. Prema CARNetu, [1] administrator je "u ime članice odgovoran za ispravnost i stabilnost funkcioniranja resursa koje je CARNet stavio na raspolaganje članici, kao i za opće tehničko i sigurnosno stanje računalno-komunikacijskog sustava članice spojene u CARNet mrežu." Realnost je da se s vremena na vrijeme, unatoč svim poduzetim mjerama zaštite, poneka računala zaraze malicioznim kodom koji se potom počne širiti - lokalnom mrežom, prijenosnim medijima (tipično USB memorijama) ili elektroničkom poštom. Bez obzira no to ima li škola pristup Internetu putem CARNeta ili putem nekog drugog ISP-a, isti može zbog pritužbi Abuse službi, biti prisiljen ukinuti pristup Internetu cijeloj ustanovi dok se problem ne riješi. Tko za taj propust i kome odgovara? Trenutno odgovara nastavnik informatike i to najprije ravnatelju, a onda potencijalno i CARNetu[1] koji može [2] "privremeno ili trajno uskratiti pravo korištenja mreže i njezinih servisa", odnosno "u slučaju težih prekršaja, povrede zakona, CARNet će prekršitelja prijaviti nadležnim organima".

U svakodnevnom radu, nastavnicima informatike se (prirodno) nameće zahtjev da njihova sredstva rada pomoću kojih održavaju nastavu i ona kojima se učenici služe tijekom nastave, budu upotrebljiva, funkcionalna, bez malicioznog koda i grešaka u radu. Kad god postoji problem s računalima u informatičkoj učionici, nepisano je pravilo da ga nastavnik informatike sam riješi. U protivnom je ostao bez dijela sredstava za rad (računala) zbog čega trpi nastava. To je to više izraženo što je veća disproporcija broja učenika i računala. Ne riješi li nastavnik informatike problem, (zbog nedostatka vremena, neznanja, dobre volje ili jednostavno zato jer to nije ni dužan raditi), mora čekati dozvolu ravnatelja odnosno raspoloživost financijskih sredstava škole kako bi se računalo poslalo u servis, te čekati na (uvijek skuplji negoli je potrebno) popravak. Što je škola po broju učenika manja, to je problem veći, jer u Republici Hrvatskoj škole primaju financijska sredstva za materijalne troškove prema broju učenika [3]. Nadalje, kolektiv očekuje, a ponekad čak i zahtijeva od nastavnika informatike, da rješava računalne probleme cijele ustanove. Ponekad ravnatelj takvo zaduženje i formalno dodijeli nastavniku informatike. Naizgled je logično da nastavnik informatike održava računala u školi, ali u suštini je nepravedno ukoliko ga se proporcionalno ne rastereti nastave. Ilustrirajmo to primjerom: želi li nastavnik informatike naučiti ili usavršiti strani jezik, po istoj bi ga logici tome trebao besplatno naučiti nastavnik stranog jezika; a za usavršavanje matematike, besplatno bi ga trebao podučiti nastavnik matematike, itd. Dakle, da li bi računalo drugih nastavnika trebao besplatno servisirati nastavnik informatike? Svi ti popravci i održavanje računala (uključujući i instalaciju sigurnosnih zakrpi, ažuriranja programa i slično), rade se izvan nastave, a svi ostali poslovi koje nastavnik ima u zaduženju odgađaju se za kasnije. Ipak, u praksi nastavnici informatike obično

[1] Gotovo sve škole u Hrvatskoj imaju besplatan pristup internetu preko CARNeta, a troškove pokriva MZOŠ.

rado educiraju svoje kolege, pomažu im savjetima i rješavaju njihove IT probleme, ali to je stvar prijateljstva ili kolegijalnosti te bi trebalo biti dobrovoljno.

U sklopu obrazovnog sustava, malo se toga može postići. Nastavnik informatike je u prošlosti dobivao uz satnicu i funkciju "voditelj informatičke učionice", pod uvjetom da je ravnatelj osnovne škole to zatražio od MZOS-a te dobio dozvolu. Time mu se oslobodilo dva do četiri sata nastave na ime održavanja računala. Posljednjim važećim kolektivnim ugovorom za zaposlenike u osnovnoškolskim ustanovama (koji je 27. prosinca 2013. odlukom Vlade Republike Hrvatske otkazan, a trenutno teče otkazni rok od tri mjeseca [4]) naziv "voditelj informatičke učionice" je izbačen. Škola koja do sada nije imala voditelja informatičke učionice teško da će je dobiti jer je funkcija vezana za određenu školu koja je tu dozvolu po starom kolektivnom ugovoru ishodila. Male škole (prema osobnom iskustvu autora) u pravilu ne dobiju odobrenje da se nastavniku informatike do popunjenja satnice odobri nekoliko sati tjedno za održavanje računala. U srednjim školama RH zakonski je uređeno zapošljavanje osoba kojima je jedini zadatak brinuti o ispravnosti, ažurnosti i sigurnosti računala i računalnih mreža [5]. U susjednoj Sloveniji "Pravilnikom o normativih in standardih za izvajanje programa osnovne šole" uvedeno je 2007. godine radno mjesto [6] "računalnikar - organizator informacijskih dejavnosti" kojem se priznaje određen dio sati u redovnu satnicu s obzirom na broj odjeljenja u školi, pa ako primjerice škola ima do 8 razrednih odjeljenja onda računalnikar dobije 0,20 udjela radnog mjesta, a ako škola ima 46 odjeljenja onda je udio radnog mjesta 1, odnosno puno radno vrijeme prema članku 11 [6].

U Njemačkoj se u srednjim gimnazijskim školama (5-9 razred) predaje informatika, a za održavanje se zapošljava druga osoba ili se informatičaru to ubraja u satnicu. U SAD-u, obrazovne institucije u cijeloj obrazovnoj vertikali (osnovne škole, srednje, fakulteti) zapošljavaju tzv. "Computer Technician" koji su zapravo dio radnog mjesta pod imenom "Chief Operating Officer"[2]. Svaki okrug (district) samostalno plaća osobu, a institucija samostalno određuje da li je ta pozicija striktno vezana za IT ili npr. mrežu koja ne uključuje posao poučavanja. "Building technicians" kako ih zovu u SAD-u prosječno provedu oko 1.5 dana svaki tjedan u manjim školama, dok u većim školama svaki tjedan provedu oko 4-5 dana. [7]

Primjeri na koje bi se u Hrvatskoj mogli ugledati jesu Makedonija i Indonezija (Sumatra) gdje postoje tzv. "Student Support Technician Clubs" (SSTCs) u kojima se učenici/studenti organiziraju u grupu/sekciju koja je zadužena za održavanje računala. [8] Skupine se sastoje od najuspješnijih učenika/studenata koji i poučavaju mlađe generacije o brizi za računalima.

U nastavku donosimo pregled osnovnih tema računalne sigurnosti u informatičkoj učionici: fizičke sigurnosti i sigurnosti komunikacije uz koje ćemo predložiti neka poželjna pravila korištenja računala.

[2] Drugi nazivi koji se još susreću su: School Technology Integration Coordinator, Technology Coordinator, Director of Educational Technology.

II. INSTITUCINALNI OKVIR ZA JAČANJE E-SIGURNOSTI U RH

U Hrvatskoj se pitanjima informacijske, komunikacijske, računalne, podatkovne i ostalih oblika sigurnosti te privatnošću i povjerljivošću uvelike bavi CARNet, posebno sa svojim projektom "Informacijsko-komunikacijska tehnologija u obrazovanju – ICT Edu" koji se provodi kroz 3 modula, po jedan za svaku školsku godinu. On ima za cilj [9] "upoznati sve učitelje, nastavnike, stručne suradnike i ravnatelje osnovnih i srednjih škola u Republici Hrvatskoj s brojnim sadržajima i uslugama koje im pruža MZOS i CARNet, te ih o nekim sadržajima detaljnije educirati". Sa stajališta ICT sigurnosti, projekt sadrži teme iz "Sigurnosti na internetu" gdje su dani savjeti za roditelje i učenike o štetnim programima te problemima komunikacije na Internetu.

MUP, Ministarstvo uprave, Hrvatska akademska i istraživačka mreža - CARNet, Tehničko veleučilište u Zagrebu, Udruga „Suradnici u učenju“, Poliklinika za zaštitu djece Grada Zagreba, Agencija za zaštitu osobnih podataka i drugi pridružujući partneri Ministarstva znanosti, obrazovanja i športa, Ministarstvo socijalne politike i mladih, Agencija za odgoj i obrazovanje, Učenički dom Hrvatskoga Radiše i Hrvatska agencija za poštu i elektroničke komunikacije su 05. lipnja 2012. godine potpisali Sporazum o strateškom partnerstvu na uspostavi Centra za sigurniji Internet [10] kojem je cilj zajedničko promicanje računalne i informacijske sigurnosti u RH, te se "zalagati za institucionalizirano uvođenje računalne i informacijske sigurnosti u obrazovni sustav, npr. kao dio nastavnog programa informatike za osnovne i srednje škole." Taj centar omogućava prijave eventualnih povreda on-line sigurnosti djece (svih nezakonitih, štetnih i opasnih sadržaja počinjenih na štetu djece i mladih) te je predstavljen 28.rujna 2013. u Zagrebu. Nastao je kao dio IPA twinning projekta pod punim nazivom „Jačanje kapaciteta u području suzbijanja seksualnog iskorištavanja i seksualnog zlostavljanja djece te pružanje pomoći policije ranjivim žrtvama kriminaliteta.“ Takvi centri za sigurniji Internet (engl. Safer Internet Center) su trenutno smješteni u svih 28 zemalja EU te u Islandu, Norveškoj i Rusiji [11] te su dio Insafe-INHOPE joint mreže.

U RH je CARNet 19. srpnja 1996. osnovao CCERT (CARNet Computer Emergency Response Team) - nacionalno središte za sigurnost računalnih mreža. Dobivanjem suglasnosti Ureda vijeća za nacionalnu sigurnost, u CARNetu je 13. svibnja 2009. počeo s radom Odjel za Nacionalni CERT osnovan u skladu sa Zakonom o informacijskoj sigurnosti RH i prema tom zakonu jedna od njegovih zadaća je [12] "obrada incidenata na Internetu, tj. očuvanje informacijske sigurnosti u RH", a misija "prevencija i zaštita od računalnih ugroza sigurnosti javnih informacijskih sustava u Republici Hrvatskoj." Nacionalni CERT preuzeo je ulogu i nasljednik je CARNet CERT-a.

Europska mreža centara za sigurniji Internet - Insafe i Međunarodna zajednica online linija za pomoć – INHOPE, obilježavaju Safer Internet Day - SID. SID [11]

organizira "Insafe" u veljači svake godine s ciljem promicanja sigurnije i odgovornije uporabe online tehnologije i mobilnih telefona, posebice među djecom i mladima diljem svijeta. Inicijativa je pokrenuta u okviru Programa za sigurniji Internet Europske komisije, a jednom godišnje poziva na uključivanje u aktivnosti za stvaranje sigurnijeg i boljeg Interneta za djecu i mlade. SID je prvi puta u svijetu obilježen 2004. g., u RH 2009-te, a svake godine se provode razne akivnosti na određenu temu.

Najnoviji projekt pod nazivom "Sigurnost djece na Internetu" ima za cilj ući u Hrvatski kvalifikacijski okvir, tj. pokušaj je da se MZOS-u dokaže da teme e-sigurnosti uđu u kurikulum predmeta (koje će ministarstvo tek izraditi za svaki pojedini predmet). Nositelj gore navedenog projekta je OŠ Veliki Bukovec, a partneri osnovne škole: OŠ Popovača, OŠ Mato Lovrak iz Nove Gradiške, OŠ Gripe iz Splita i OŠ Mladost iz Osijeka. Projekt će trajati od 19. kolovoza 2013. do 19. prosinca 2014. uz sudjelovanje učenika, učitelja, roditelja te lokalne i šire zajednice. [13]. U sklopu tog projekta učitelji iz nabrojanih pet osnovnih škola iz Hrvatske izradit će i zatim primijeniti školski kurikulum o sigurnosti djece na internetu u sklopu Hrvatskog kvalifikacijskog okvira kojim će direktno biti uključeno 200 učitelja, 220 učenika te 220 roditelja. Bit će izrađeni i priručnici, radni materijali, multimedijalni sadržaji i interaktivne igre za pomoć u edukaciji djece, roditelja i učitelja te prevenciji elektroničkog nasilja. Školski kurikulum bit će pripremljen za sve razrede osnovne škole, odnosno organiziran u četiri grupe prema uzrastu učenika. Svi pripremljeni sadržaji bit će besplatni i dostupni za korištenje svim školama u Hrvatskoj. Projekt financira IPA program Europske unije s 2,5 milijuna kuna. [13]

III. FIZIČKA SIGURNOST ICT-A U ŠKOLI

"Osnova fizičke sigurnosti je zaštita fizičkog dijela informatičke infrastrukture, zgrade u kojoj je ona smještena, kao i medija za pohranu podataka te komunikacijske opreme. Mjere fizičke sigurnosti obuhvaćaju sve obrambene mjere poduzete u svrhu zaštite računalne infrastrukture od prirodnih nepogoda, problema u okolini, nezgoda i namjernih oštećenja". [14] "Značaj fizičke zaštite sustava je distribucijom opreme i podataka te uključivanjem u Internet postao još važnijom, ali i znatno složenijom." [15]

Nastavnik informatike mora utvrditi tko ima izravan fizički pristup računalima, da li je to neophodno te kako zaštititi računala od oštećenja ili krađe. Oprema poput monitora ili kućišta može se pričvrstiti na radni stol s raznim kablovima ukoliko postoje utori na samom sklopovlju, običnim i jeftinim jednokratnim plastičnim vezicama (engl. "tie straps") ili se pričvršćuju vijcima za radni stol (LCD i LED monitori). Manje je predmete, poput miša i tipkovnice, teže osigurati od krađe, no u tom slučaju poželjno je na takve stvari staviti inventarni broj ili neko drugo obilježje (npr. logo/natpis ustanove). Na taj se način obeshrabruju lopovi, a ujedno je situacija uvijek spremna za popis inventure.

Za neophodnu razinu fizičke sigurnosti, preporučljivo je zaključati komunikacijske ormariće i prostorije u kojima se nalazi mrežna oprema i poslužitelji. Ukoliko u informatičkoj učionici nema video nadzora, kada se ona koristi uvijek bi trebao biti nazočan netko od zaposlenika škole, a kada se računala ne koriste prostoriju bi trebalo zaključavati.

A. Videonadzor

Video nadzor učionice, uz jasne obavijesti o njegovu postojanju, vrlo je poželjna zaštitna mjera koja obeshrabruje potencijalne lopove i vandale. Računalo skromnih performansi i web kamera [16] dovoljni su za izradu jednostavnog video nadzora "iako je uporaba video-nadzora u Republici Hrvatskoj u samom začetku i nedovoljno normativno uređena" obzirom [17] "na ograničenu uporabu tehničkih snimki kao dokaza u postupcima (kazneni i prekršajni)". Zakonom o kaznenom postupku [18] donesenim 2008. godine započela je primjena načela pretežitog interesa kod kojeg postoji mogućnost korištenja tehničkih snimki te drugih dokaza pribavljenih na nezakoniti način ako interes pravde i pravičnosti preteže nad interesom zaštite dobara. "Što se tiče valjanosti tehničkih snimki u prekršajnom postupku, Prekršajni zakon propisuje da su bilješke i tehničke snimke i formalno dokazi u prekršajnom postupku ukoliko ih je ovlaštena službena osoba tijela državne uprave sačinila u okvirima svojih nadležnosti za provođenje nadzora provedenog neposrednim opažanjem. U tim situacijama takve snimke mogu poslužiti kao dokaz u prekršajnom postupku, ali i tada sud može provjeravati njihovu vjerodostojnost te slobodno ocjenjivati njihovu dokaznu vrijednost." [19]

Što se tiče videonadzora u školama, postavljanje videokamera predstavlja važnu odluku za položaj radnika, jer se radi o mjeri u svezi sa sigurnošću na radu, o kojoj se poslodavac mora savjetovati s radničkim vijećem što je propisano [20] u odredbi čl. 149. st. 1. Zakona o radu. Prema Agenciji za zaštitu osobnih podataka, po pitanju videonazdora u školama [21], a na temelju odredbi Zakona o zaštiti osobnih podataka [22] članaka 2. stavak 1. točka 1. razvidno je da video snimka dobivena video nadzornom kamerom predstavlja osobni podatak fizičke osobe – ispitanika. Člankom 9. [22] propisana je obveza informiranja ispitanika prije prikupljanja bilo kojih osobnih podataka. Dakle škole bi trebale "adekvatnim internim aktom regulirati uporabu istog (svrha, opseg tj. zahvat podataka koji se prikupljaju, način i vrijeme čuvanja te uporaba snimljenih podataka kao i zaštita prava ispitanika) a s činjenicom kojeg postavljanja bi na odgovarajući način pravovremeno trebalo upoznati učenike (roditelje) i zaposlenike." [21] Nadalje, "potrebno je ukazati da predmetni video nadzor (postavljen u svrhu sigurnosti) treba pokrivati samo zajedničke prostore škole (hodnike, ulazni prostor i sl.) kao i moguće dvorište škole (bez zahvaćanja u okolni javni prostor), dok nije prihvatljivo da video nadzorom budu pokrivene učionice, svlačionice i toaletni prostori. Također, kod uvođenja (postavljanja) video nadzora potrebno je uočljivo i nedvosmisleno označiti (slikom i tekstom) da je odnosni prostor pod video nadzorom, koja informacija mora biti pružena svim trećim osobama koje dolaze u školu, za

ostvarivanje spoznaje da ih se snima i na taj način prikupljaju njihovi osobni podaci." [22]

Škola može angažirati pravnu i fizičku osobu registriranu za obavljanje poslova tehničke zaštite, na način i pod uvjetima utvrđenim [23] Zakonom o privatnoj zaštiti koja će izraditi projektnu dokumentaciju prema Pravilniku o uvjetima i načinu provedbe tehničke zaštite [24] koji određuje tko ga smije postaviti i određuje uvjete, poput elaborata, održavanja. Na ovaj zadnji način je snimanje legalno.

B. Sigurnosne mjere za korisnike

Prema M. Bači [14] "najveća ranjivost svakog računalnog sustava i najveća prijetnja računalnom sustavu su ljudi koji s njim imaju vezu, kroz svakodnevni rad i kroz povremeno održavanje." Prema K. Rhodesu [25] zaposlenici u organizaciji imaju ključnu ulogu u prevenciji i detektiranju sigurnosnih incidenta. Dok su sistem administratori odgovorni za sigurnu konfiguraciju vatrozida i poslužitlja, korisnici su odgovorni za vježbanje sigurnosnih protumjera poput odabira i zaštite odgovarajućih lozinki. Stoga, za efektivnu sigurnost, korisnici moraju napraviti svjesne odluke da bi se pridržavali organizacijske sigurnosne politike i da bi prihvatili računalno sigurnosno ponašanje.

Nastavnik informatike često puta je jedina osoba koja u školi ima (dostatno?) znanje o računalima i računalnoj sigurnosti. Učitelji uglavnom koriste USB memorijske štapiće često zaražene virusima koji se šire na računalo u zbornici ili preko mreže, često jedni drugima "posuđuju" osobna korisnička imena i lozinke za prijavu na službene servise (npr. E-matica, CMS školskog web sjedišta), koje koriste na javnom računalu za koje se ne može uvijek pretpostaviti da je čisto od virusa i drugih malicioznih programa.

U novije vrijeme su učestali slučajevi da neki učenici pomoću aplikacije za udaljeni pristup računalu (npr. TeamViewer), u odsutnosti učitelja instaliraju aplikaciju, a kasnije se pomoću pametnog telefona spajaju na računalo te ga kontroliraju. Takva je nepodopština kažnjiva prema člancima 226. i 227. Kaznenog zakona [26] na što je 4.10.2013. reagiralo i ravnateljstvo policije RH poslavši dopis MZOS-u, a potonji proslijedio dopis svim osnovnim i srednjim školama te učeničkim domovima [27].

CARNet je temeljem dokumenta CDA0035 [2] točke 1. stavka 1. propisao: "Obveza je svake ustanove članice propisati sigurnosnu politiku na svojoj ustanovi...". Ustanova članica CARNeta ima obavezu izraditi sigurnosnu politiku te s njome upoznati svoje djelatnike i korisnike o dužnosti poznavanja i primjenjivanja iste. Do danas tek je nekolicina osnovnih škola izradila sigurnosnu politiku iako je trebala biti donesena još u rujnu 2006-te, odnosno šest mjeseci od dana spajanja u CARNet mrežu [2]. Provedba sigurnosnih mjera među korisnicima koji teško prihvaćaju promjene i ne shvaćaju opasnosti korištenja ICT-a teško je izvediva, no ovdje je riječ o visoko obrazovanim korisnicima i možemo reći da je žalosno što je tako.

IV. SIGURNOST INTERNET KOMUNIKACIJA U ŠKOLI

Internet je medij putem kojega korisnici žele komunicirati s osobama kojima vjeruju kao i onima kojima ne vjeruju, a isto vrijedi i za uređaje posredstvom kojih bi se ta komunikacija trebala odvijati. Na žalost ne postoji pouzdani način razlučivanja jednih od drugih. Kriptografija u koju se polagalo puno nade, nije uspjela iznaći pouzdane metode zaštite računala i korisnika od mreže u kojoj je četvrtina računala pod utjecajem bot mreža, a polovina e-maila neželjena pošta [28].

U školama uobičajen problem predstavlja nedozvoljeno posjećivanje društvenih mreža, stranica sumnjivog (ilegalnog) sadržaja, pa čak i stranica za odrasle. Doduše ako su računala spojena na Internet putem CARNetove mreže, ona imaju djelomičnu "zaštitu" od neželjenih i neprimjerenih sadržaja - "content filtering" baziran na CA eTrust Secure Content Manager content filter sustavu. O učinkovitosti ovog filtera bi se dalo raspravljati, jer ponekad blokira i sasvim legalne stranice i poveznice za preuzimanje legalnih programa, no zaštita se neprestano razvija i poboljšava. Još jedno rješenje za osnovno filtriranje sadržaja na internetu je projekt OpenDNS koji blokira sadržaje na DNS razini, a po potrebi se razina filtriranja može detaljnije konfigurirati. Konfiguriranje se vrši unutar postavki korisničkog računa, a osim već unaprijed definiranih kategorija po kojima se vrši filtriranje, moguće je dodavati svoje unose u listu dozvoljenih i zabranjenih domena.

Unutar škole bi bilo poželjno imati dvije (pod)mreže: jednu za učenike, a drugu za djelatnike. Na taj način rasterećujemo mrežni promet, a ako dođe do nekog sigurnosnog incidenta ili malicioznog programa koji se počne širiti jednom mrežom, druga će podmreža ostati netaknuta ukoliko mreže međusobno štitimo i filtriramo promet između njih. S 2011/2012. nastavnom godinom CARNet je krenuo u praktičnu realizaciju projekta e-dnevnik te preporuča prilikom planiranja bežičnih mreža dati učenicima mogućnost spajanja na nju. Projekt e-dnevnik je web aplikacija za vođenje razredne knjige u elektroničkom obliku, koji je iste godine uveden kao pilot projekt u tri srednje škole: XV. Gimnaziji u Zagrebu, Gimnaziji Požega i u Medicinskoj školi Ante Kuzmanića u Zadru. Dakle službena evidencija se vodi u aplikaciji, a nastavnici u razrede ulaze s tablet računalima putem kojih pristupaju aplikaciji. "E-dnevnik je izradio CARNet te ona ima sve funkcionalnosti postojeće razredne knjige, uz dodatne funkcionalnosti koje omogućava uporaba informacijsko-komunikacijskih tehnologija (ICT)." [29] Od školske godine 2013./2014. se za njegovo korištenje prijavilo preko 250 škola uključujući područne škole.

U Europskoj uniji se nastoji izglasati novi zakon pod imenom "Pravo na zaborav informacija". [30] Ukoliko to osoba zatraži, neugodni, netočni ili jednostavno osobni podaci morati će biti izbrisani s Interneta ili bilo kakvih baza podataka kompanija. Europska Komisija smatra da se pojedincu mora omogućiti da zatraži brisanje podataka o njoj/njemu, ukoliko ne postoje pravne prepreke za to. Također, pojedinac ima pravo da se njegovi podaci ne skladište u podatkovnim centrima te ne koriste za obradu, ukoliko to ne želi [30]. Nedavno je i bivši izvršni direktor Googlea Eric Schmidt izjavio: "Ovaj manjak gumba za brisanje na Internetu je u biti važno pitanje." [31] "Pravo

na zaborav" još nije doneseno kao dio EU prava niti je prošlo ili stavljeno u praksu. Ovaj zakon (ako bude donesen) će u praksi biti teško provesti. "Jednom kad se osobna informacija objavi, nemoguće ju je tehničkim mjerama spriječiti, ili čak promatrati/slijediti, stvaranje neautoriziranih kopija te informacije. U otvorenom sistemu kao što je Internet, pravo na zaborav se ne može ojačati samo tehničkim mjerama. Ojačanje mora polaziti na kombinaciji tehničkim i međunarodnih pravnih osiguranja." [32]

V. ZAKLJUČAK

Nastavnici informatike u RH su de facto "sistem administratori u malom" koji svoj posao rade uglavnom volonterski, ali ponegdje/ponekad i prisilno (poštivanjem odluka ravnatelja), snose pravnu i moralnu odgovornost kako za ispravnost mreže tako i za računala. Njihova motivacija je u njihovom pozivu i osobnoj satisfakciji u onome što rade. Gotovo uvijek sami rješavaju različite probleme vezane za informatiku iz učionice ili zbornice. Educiraju svoje učenike i kolege i ukupno gledajući su u neravnopravnom položaju u odnosu na svoje kolege iz drugih predmeta. Na žalost tako će i ostati neko vrijeme u RH barem što se tiče situacije u osnovnoj školi. Jedan od mogućih smjerova u budućnosti (pod pretpostavkom još većih problema s financiranjem škola/opreme) jest da se problem održavanja prebaci na učenike, tako da učenici donose sami svoja prijenosna računala, tablete, fablete i pametne telefone pa ih i održavaju. (U Americi škole su već počele primjenjivati takav način rada poznat pod skraćenicom (BYOD - bring your own device) gdje učenici donose sami svoje uređaje no kako ne bi bilo još više problema (npr. zaražena računala) trebalo bi prije toga svakako educirati i učenike o sigurnosti računala. Jedan od preduvjeta takvom načinu rada jest pokrivenost Internetom u cijeloj školi, pa posebnu pažnju treba posvetiti konfiguraciji mreže. Slijedeće riješenje koje autori predlažu jest da se na razini općina ili županija odaberu (kvalifikacijskim ispitom ili formalnom potvrdom kvalificiranosti) osobe koje bi bile svojevrsni helpdesk za računala u školama. Nastavnici bi mogli preko on line obrazaca ispuniti kratki opis problema, a hepldesk bi uz pomoć telefona i/ili videokonferencije i spajanja na nastavnikovo računalo rješavao problem (ako kvar nije fizičke prirode ili ne zahtijeva intervenciju "in vivo"). Takvih osoba vjerojatno ne bi ni trebalo biti puno. U budućnosti bi se mogla provesti reorganizacija posla da osobama kojima nedostaju nastavni sati u školama dobiju dopunu do pune satnice na način da satnicu dopune radom u helpdesku. Moguća druga rješenja su zaključavanje postavki računala, virtualizacija ili brisanje promjena na računalu (npr. VHD ili sandbox tehnologijom).

Učinkovitost elektroničkog učenja u nastavi

Martina Sertić
Industrijsko-obrtnička škola Slavonski Brod, Republika Hrvatska
Studentica PDS Informacijskih i komunikacijskih znanosti Filozofskog fakulteta u Zagrebu, Republika Hrvatska
sertic_79@yahoo.com

Sažetak - Učinkovitost elektroničkog učenja u obrazovanju možemo prikazati korištenjem modernih tehnologija današnjice. Upotreba ovih modernih sredstava u nastavi vodi nas do nekoliko pitanja na koja trebamo odgovoriti. Neka od pitanja su: povećava li upotreba moderne tehnologije učenikovo znanje i vještine, i ako da, na kojoj razini i koliko? Može se pretpostaviti da će u budućnosti razne računalne aplikacije i računalni sadržaji stvoriti novu generaciju učenika. Za te nove generacije tehnologija će postati neophodan sadržaj i sredstvo za učenje, zabavu i komunikaciju.

I. UVOD

Ovim radom pokušat ću prikazati i predstaviti primjenu Bloomove taksonomije u nastavi. Bloom je podijelio odgojno-obrazovne aktivnosti na tri područja: kognitivno (znanje), psihomotorno (vještine) i afektivno (stavovi). U radu ću se ponajviše orijentirati na kognitivno područje i primjenom manjeg istraživanja korištenjem eksperimenata pokušati dokazati kako korištenje digitalnih nastavnih sredstava (računala, projektora, interneta) povećava razinu znanja kod učenika. Eksperiment ću provesti pod nastavom filozofije kroz kontrolnu i eksperimentalnu skupinu. Uzorak će biti učenici dva četvrta razreda, oba spola. Navest ću i ljestvice mjerenja znanja, standardiziranu prema hrvatskom sustavu ocjenjivanja na pet ocjena.

II. PROCJENA ZNANJA

Procjena znanja zapravo je sustavan proces u kojem nastavnik prikuplja podatke, analizira ih i tumači kako bi odredio u kojoj su mjeri učenici savladali obrazovne ciljeve.

Procjenjivanje znanja uključuje nekoliko postupaka:

- opažanje i s njim povezane tehnike (npr. usmeno ispitivanje) ,
- mjerenje, odnosi se na proces određivanja brojčane mjere nečijeg postignuća ili osobine. (Marina je riješila 15 od 20 zadataka),
- vrednovanje – davanje vrijednosti procijenjenom znanju, tj.ocjenjivanje.

Izmjereno se znanje izražava ocjenom koja ima određenu poruku. [6]

U našem sustavu to su ocjene:

- 1 (nedovoljan),
- 2 (dovoljan),
- 3 (dobar),
- 4 (vrlo dobar),
- 5 (odličan).

U dolje prikazanim tablicama može se vidjeti grafički prikaz odnosa znanja i ocjena kod nastavnika. Tablica I. prikazuje realnu ljestvicu znanja kod sustava ocjenjivanja od jedan do pet. Tablica II. prikazuje ljestvicu znanja, tj. ocjenjivanje po tom istom sustavu kod strožeg nastavnika, dok tablica III. prikazuje ljestvicu znanja, tj. ocjenjivanje kod nastavnika blažih kriterija. [6]

Tablica I. Prikaz realne ljestvice znanja

ZNANJE				
1	2	3	4	5

Tablica II. Prikaz ljestvice znanja kod strožeg nastavnika

ZNANJE				
1	2	3	4	5

Tablica III. Prikaz ljestvice znanja kod blažeg nastavnika

ZNANJE				
1	2	3	4	5

Svako ocjenjivanje, svaki ispit, test ili usmena provjera zapravo spadaju u mjerenje znanja. Tim postupcima nastavnik pokušava izmjeriti znanje učenika.

Svako mjerenje ima tri uvjeta:

- predmet mjerenja (olina, veličina, objekt),
- instrument mjerenja,
- tehnika mjerenja.

A. *Tehnike ispitivanja znanja*

Dvije su glavne tehnike ispitivanja znanja:

- usmeno ispitivanje znanja,
- pismeno ispitivanje znanja.

U daljnjem tekstu navedene su prednosti i nedostatci ovih tehnika ispitivanja znanja:

Usmeno ispitivanje znanja:

Prednosti usmenog ispitivanja znanja su:

- nastavnik može reagirati na odgovore učenika i tako primjerenije ispitati stvarno znanje učenika,
- nastavnik može bolje ispitati razumijevanje učenika,
- tijekom ispitivanja znanja učitelj može uočiti i reagirati na odgovore koji su približno točni ili one koji su potpuno apsurdni,
- učenici češće uče s razumijevanjem ukoliko očekuju usmeno ispitivanje. [6]

Nedostatci usmenog ispitivanja znanja su:

- vremenski je neekonomično,
- subjektivno, nastavnik je mjerni instrument različito reagira na različite učenike,
- učenici dobivaju i različita pitanja pa je teško usporediti znanje te ovise o sreći hoće li dobiti pitanje na koje znaju odgovor,
- obuhvaća manje gradiva. [6]

Pismeno ispitivanje znanja:

Prednosti pismenog ispitivanja znanja su:

- manji utjecaj subjektivnosti,
- svim učenicima su postavljena ista pitanja,
- isti je režim rada isti uvjeti za sve,
- ocjenjivanje je objektivnije jer je moguće lako izračunati postotak riješenih zadataka,
- može obuhvatiti više gradiva,
- vremenski je ekonomično jer se mogu u jednom satu ispitati svi učenici. [6]

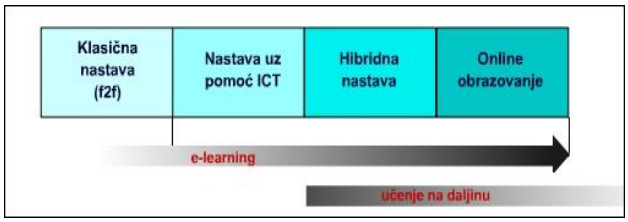
Nedostatci pismenog ispitivanja znanja su:

- često se traži samo reprodukcija materijala, proces pamćenja i sjećanje činjenica,
- ne uspijeva zahvatiti razumijevanje ili primjenu znanja,
- najčešći oblik jest pismeno postavljanje pitanja i ispravljanje zadaća,
- međutim, taj način da se redom pregledaju, procjene i zatim ocjene zadaće najmanje je valjan.
- ako je pak očekivao manje nego što je dobio u prvim zadaćama, nastavnik će dići kriterij pa će prve zadaće biti u boljem položaju,
- bilo bi dobro malo pregledati zadaće prije ocjenjivanja da se dobije raspon i da se odredi zajednički kriterij. [6]

III. VRSTE UČENJE

Osnovna klasifikacija učenja, tj. nastave, može se podijeliti na:

- klasično učenje (*f2f* ili *face-to-face*),
- učenje uz pomoć ICT-a (*ICT supported teaching and learning*) tj. elektroničko učenje,
- hibridnu ili mješovitu nastavu (*hybrid/blended learning*),
- online nastavu (*fully online*) . [1]



Slika 1. Prikaz vrsta učenja tj. nastave

A. *Klasično učenje*

Klasično učenje predstavlja model učenja u kojem nastavnik predaje, a učenik sluša i zapisuje predavanje nastavnika. To je takozvano klasično učenje licem u lice tj. *f2f* ili *face-to-face.*

B. *Elektroničko učenje*

Elektroničko je učenje interaktivan ili dvosmjeran proces između nastavnika i učenika uz pomoć elektroničkih medija pri čemu je naglasak na procesu učenja dok su mediji samo pomoćno sredstvo koje upotpunjuje taj proces.

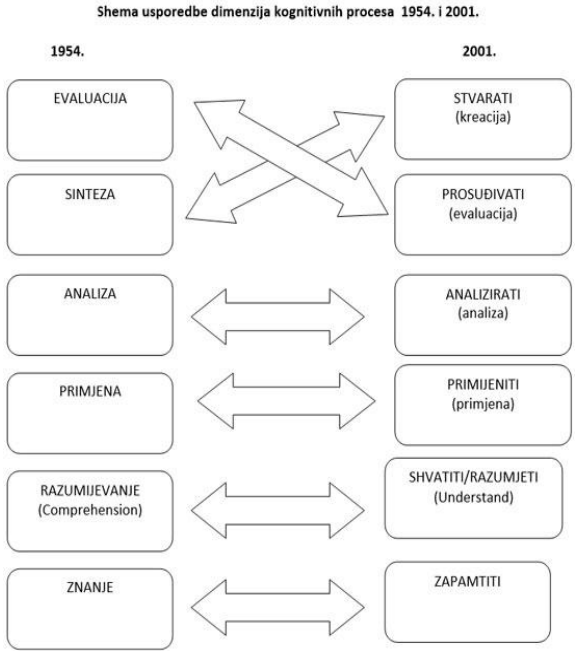
Elektroničko učenje je bilo koji oblik učenja, poučavanja ili obrazovanja koji je potpomognut uporabom računalnih tehnologija, a posebno računalnih mreža temeljenih na internet tehnologijama. [2]

IV. MJERENJE ZNANJA PREMA BLOOMOVOJ TAKSONOMIJI

Jedan od najkorištenijih teorijskih okvira za planiranje, pripremu i vrednovanje osnovnoškolskog, srednjoškolskog i visokoškolskog obrazovanja te tečajeva za odrasle na području obrazovanja i industrije Bloomova je taksonomija znanja (Kirkpatrikov model vrednovanja učenja (*Kirkpatrick learning evauation model*), 1959. podjednako je raširen). Nastala je tijekom 50. tih godina 20. stoljeća na temelju analiza intelektualnih ponašanja uz pomoć kojih učenici stječu akademska znanja. [5]

A. *Bloomova taksonomija*

Krajnji je cilj školskog učenja stjecanje trajnih i upotrebljivih znanja i umijeća. Znanje i umijeće su produkt mišljenja. Mišljenje se odvija u mozgu osobe, a u njemu su pohranjeni i znanje i umijeće, te nisu direktno opažljivi i mjerljivi. O njima zaključujemo na temelju onoga što učenik pokaže prema van: na temelju opažljivog ponašanja (Slika 2). [5]



Slika 2. Shema usporedbe dimenzija kognitivnih procesa prema Bloomu 1954. i 2001. [3]

Bloom i suradnici na učenje gledaju kao na umijeće ponašanja. Cilj njihovog rada bilo je sistematiziranje kategorija ponašanja koja se koriste tijekom učenja kako bi učiteljima pomogli pri planiranju i procjeni školskog učenja. Ciljevi učenja i ponašanja koja učenik koristi tijekom učenja podijeljeni su u tri kategorije koje su međusobno povezane i preklapaju se. [5]

Kategorije su područja učenja:

1. kognitivno (intelektualna sposobnost, tj. znanje ili mišljenje).
2. afektivno (osjećaji, tj. odnos ili stav),
3. psihomotorno (fizičke vještine, tj. ono što osoba može činiti) (Grafikon I.).

Bloomova taksonomija godinama je znanstveno provjeravana, korištena i dorađivana. 1990. godine revidirali su je Anderson i Krathwohl. U početku je bila orijentirana samo na kognitivno područje. Kasnije je definirano i afektivno i psihomotorno područje. Sva tri područja znanja jednako su vrijedna. Unutar svakog područja obrazovni su ciljevi razvrstani u kategorije koje predstavljaju razine znanja i hijerarhijski su poredane na temelju težine ili složenosti, od najjednostavnijih do najsloženijih. [5]

Grafikon I. Tri osnovna područja ili domene odgojno-obrazovnih aktivnosti prema Bloomu

B. *Razine znanja i ciljevi učenja prema Bloomovoj taksonomiji*

Bloomova taksonomija ciljeva u afektivnom (stavovi) odgojnom-obrazovnom području.

Podijeljena je na 5 kategorija:

1) percepcija,
2) reagiranje,
3) usvajanje vrijednosnih stavova,
4) organiziranje vrijednosnih stavova,
5) primjena vrijednosnih stavova na praktičnoj razini. [3]

Bloomova taksonomija ciljeva u psihomotornom (vještine) odgojno-obrazovnom području.

Ciljevi su razvrstani u 4 kategorije :

1) gruba koordinacija,
2) fina koordinacija,
3) neverbalne komunikacije,
4) govorno ponašanje. [3]

Razine znanja i ciljevi učenja na kognitivnom području su:

Tablica IV. Ciljevi učenja prema Bloomu [5]

Razine	CILJEVI (ISHODI) UČENJA Značenje razine
I.	**DOSJETITI SE (Znanje)** Dosjetiti se, prepoznati ili reproducirati informaciju, ideju i princip u približno onakvom obliku u kojem su naučeni.
II.	**SHVATITI (Razumijevanje)** Uočiti i povezati glavne ideje. Prevesti, razumjeti, objasniti ili interpretirati naučeni sadržaj. Izvesti logičan zaključak iz dostupnih informacija. Zaključiti o uzroku i predvidjeti posljedice.
III.	**PRIMIJENITI (Primjena)** Rješavati probleme primjenom naučenog u kontekstu učenja ili u novoj situaciji na nov način. Odabrati i primijeniti podatke i principe za rješavanje problema ili zadatka u drugom području.
IV.	**ANALIZIRATI (Analiza)** Raščlanjivati informacije kako bi se utvrdili dijelovi cjeline, njihovi međusobni odnosi, organizacijski principi, uzroci i posljedice, izveli dokazi i zaključci i podržale generalizacije. Prepoznati skriveno značenje. Razlikovati činjenice i zaključke.
V.	**PROSUĐIVATI (Evaluacija)** Usporediti i pronaći sličnosti i razlike među idejama. Procijeniti valjanost ideja i/ili kvalitete uratka na temelju poznatih kriterija. Dokazati vrijednost. Izabrati mogućnost i argumentirano obrazložiti.
VI.	**STVARATI (Sinteza)** Kreativno koristiti postojeće znanje za stvaranje nove cjeline. Stvarati nove ideje i rješenja. Izvoditi generalizacije na temelju dobivenih podataka. Povezati znanje iz različitih područja.

V. PRIMJENA ELEKTRONIČKOG UČENJA U NASTAVI

Znanje mjerimo kada je maksimalno smanjen utjecaj subjektivnih čimbenika o kojima smo govorili pri procjeni znanja. Objektivno ispitivanje znanja provodi se pomoću nizova zadataka objektivnog tipa (ZOT) i pomoću testova znanja. Zadaci objektivnog ispitivanja znanja primarno služe za praćenje napredovanja učenika, a testovi znanja na formalnim ispitima nakon određenog obrazovnog perioda (npr. na kraju školske godine). Po svojoj se formi ZOT i testovi znanja ne razlikuju jer sadrže iste vrste zadataka objektivnog tipa. [7]

Za ispitivanje znanja u ZOT i testovima znanja koriste se različiti zadaci objektivnog tipa. Za sve je karakteristično da odgovori mogu biti jednoznačno interpretirani i objektivno vrednovani kao točni ili netočni.

Vrste zadatka objektivnog tipa:

a) zadaci dosjećanja i dopunjavanja,
b) alternativni zadaci, tj. alternativne tvrdnje,
c) zadaci višestrukog izbora,
d) zadaci s dva tipa kriterija izbora,
e) zadaci ispravljanja,
f) zadaci sređivanja,
g) zadaci povezivanja,
h) esejski zadaci,
i) zadaci rješavanja problema. [7]

A. *Provjera znanja iz novovjekovne filozofije (Gordano Bruno, Rene Descartes i Gottfried Leibnitz)*

ZADACI OBJEKTIVNOG TIPA

Škola:_____
Razred:_____
Spol: _____ M/Ž

1. Giordano Bruno vjeruje da je planet Zemlja?

a) u središtu sunčevog sustava
b) zvijezda
c) planet koji se kreće po kružnoj stazi oko Sunca
d) planet koji se kreće po eliptičnoj stazi oko Sunca

2. Rene Descartes poznat je po svojoj rečenici:

a) mislim dakle postojim
b) mislim dakle jesam
c) homo homini lupus
d) _____

3. Giordano Bruno poznat je po svojem izrazu za čovjeka:

a) mislim dakle postojim
b) zoon politikon
c) homo homini lupus
d) _____

4. Gottfried Leibnitz napisao je:

a) Monadologiju
b) Mondologiju

5. Navedi dva filozofa predstavnika racionalističke filozofije 17. stoljeća:

_____
_____

6. Zaokruži djela koja je napisao Descartes, a podvuci djela koja je napisao Leibnitz:

Rasprava o metodi

Rasprava o metafizici

O principu pojedinačnog

Načela filozofije

O meteorima

7. Gottfried Leibnitz osmislio je modernu formu:

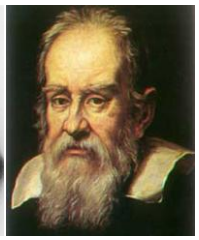
a) heksadekadskog računa
b) binarnog računa
c) dekadskog računa
d) oktalnog računa

8. Po kojem filozofu je kartezijev sustav dobio ime

a) Galileu
b) Descartesu
c) Leibnizu
d) Kepleru
e) _____

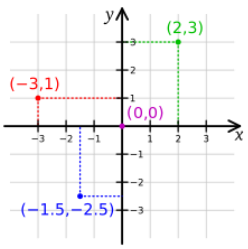
9. Kako još nazivamo kartezijev sustav _____ _____ i gdje ga koristimo.

10. Ispod slika napiši imena filozofa, znanstvenika.



_____ _____ _____

11. Ispod slike napiši što slika predstavlja.



_____ _____

12. Pitanje za eksperimentalnu skupinu: Skiciraj Brunov planetarni sustav i Keplerov planetarni sustav korištenjem računala.

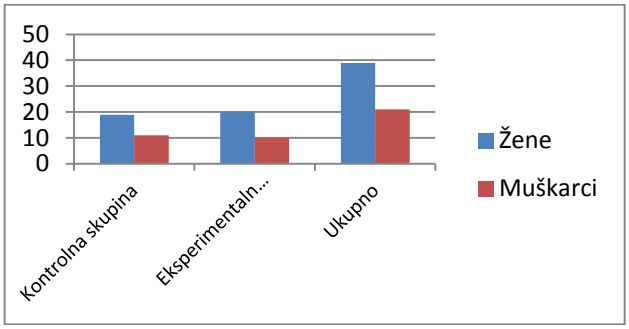
Pitanje za kontrolnu skupinu: Skiciraj Brunov planetarni sustav i Keplerov planetarni sustav.

B. Rezultati istraživanja

Istraživanje je provedeno na uzorku od 60 učenika, od toga je bilo 39 učenica ženskog spola i 21 učenik muškog spola. Učenici su pohađali nastavu filozofije u četvrtom razredu po nastavnom programu za gimnazije. Učenici su u prosjeku imali 18 godina (Tablica V.).

Istraživanje je provedeno kroz dvije skupine – kontrolnu i eksperimentalnu skupinu. U kontrolnoj skupini sudjelovalo je 30 učenika jednog razreda, a u eksperimentalnoj skupini sudjelovalo je 30 učenika drugog razreda. Kontrolna skupina slušala je predavanja od tri nastavna sata iz novovjekovne filozofije korištenjem klasičnog tipa predavanja. Eksperimentalna skupina slušala je ista ta predavanja iz novovjekovne filozofije korištenjem informatičke opreme (računala, projektora, interneta, digitalnih sadržaja, multimedijalnih prezentacija, animacija i video isječaka (Grafikon II.).

Grafikon II. Prikaz broja ispitanika po skupinama i spolu



Svaka od skupina (kontrolna i eksperimentalna) rješavala je po dva testa (zadaci objektivnog tipa) na početku predavanja i na kraju predavanja (nakon odrađene tri nastavne jedinice). Na ovaj sam način pokušala izmjeriti znanje učenika prije i poslije održanih predavanja kod obje skupine.

Rezultati istraživanja su očekivani i zadovoljili su obje hipoteze.
Prva hipoteza je glasila: elektronička nastava povećat će razinu znanja kod učenika.
Druga hipoteza je glasila: postignuta razina znanja u eksperimentalnoj skupini bit će veća nego u kontrolnoj skupini.

Tablica V. Prikaz broja ispitanika po skupinama i spolu

	Žene	**Muškarci**	**Ukupno**
Kontrolna skupina	**19**	**11**	**30**
Eksperimentalna skupina	**20**	**10**	**30**
Ukupno	**39**	**21**	**60**

Iz prikazanoga je vidljivo da su učenici četvrtih razreda, u skladu s očekivanjima, bili puno više zainteresirani za sadržaje u elektroničkom tj. digitalnom obliku, nego za sadržaje vezane uz klasičnu nastavu (udžbenik, bilježnica).

VI. ZAKLJUČAK

Današnje mlade generacije sve su sklonije korištenju interneta i računala. Cijeli njihov svijet svodi se na ta dva medija. Zato je postalo sve očitije da nove mlade generacije učenika koriste i žele koristiti računalo i njegove mogućnosti ne samo za zabavu i druženje, već i za učenje.

Elektroničko učenje potiče nove generacije na kreativnost i radoznalost koja često sa sobom nosi i neke opasnosti novog globalnog svijeta. Elektroničko je učenje postalo sastavni dio današnjih škola, fakulteta i ostalih institucija za obrazovanje ljudi.

Digitalne nastavne jedinice mnogo su razvijenije te se sastoje od individualnih lekcija, nastavnih cjelina ili tečajeva u interaktivnom obliku. Korištenjem digitalnih nastavnih jedinica jednostavnije je i lakše kreirati mnoge različite digitalne obrazovne sadržaje; primjerice, lekcije iz fizike, filozofije, geografije, matematike te mnogih drugih predmeta u nastavi.

Sve više se čini da je pokrenuta informacijsko-komunikacijska revolucija nezaustavljiva i da će uskoro većina našeg obrazovanja i razmijene znanja postati dio virtualnog svijeta, a to je ono što nove generacije učenika pokreće ka kreativnom stvaranju i pamćenju potrebnih sadržaja te kreiranju novih ideja.

Analiza uspješnosti u usvajanju algoritamskog načina razmišljanja kod učenika u prvom razredu novog strukovnog kurikuluma za zanimanje Tehničar za računalstvo

K. Blažeka, Tehnička škola Čakovec, Čakovec, Hrvatska
kristinka.blazeka@ck.t-com.hr

Sažetak: U školskoj godini 2013./2014. u dijelu srednjih škola krenula je eksperimentalna provedba nekoliko novih strukovnih kurikuluma. Učenici upisani u prvi razred za zanimanje Tehničar za računalstvo također su krenuli po novom bitno osuvremenjenom programu. Već u prvoj godini školovanja uveden je novi nastavni predmet Algoritmi i programiranje sa naglaskom na usvajanje znanja i razvoj vještina u području analize problema i dizajna njegovog rješenja prilikom izrade računalnih programa. Predmet se osim u prvom razredu treba realizirati i u drugom. Prema ishodima učenja u početnim je mjesecima stavljen naglasak na usvajanje važnosti algoritama u procesu rješavanja problema i razvoj algoritamskog razmišljanja s ciljem odabira i osmišljavanja odgovarajućeg algoritma na što se nastavlja učenje i savladavanje sintakse odabranog programskog jezika. Kako već površne analize pokazuju da su logičko zaključivanje, kreativno stvaralaštvo i algoritamsko razmišljanje, iako nužne općenito za rješavanje problema, na žalost vještine prečesto zanemarene u osnovnoškolskoj nastavi, potrebno je uložiti prilično napora kako bi učenici dobili upotrebljive temelje za uspješnije stvaranje računalnih programa. S ciljem preispitivanja postignuća učenika prije učenja sintakse programskog jezika istraženo je koliko su učenici bili uspješni u usvajanju osnova algoritamskog razmišljanja. Dobiveni rezultati trebali bi pomoći u uočavanju aspekata u kojima učenici trebaju dodatnu pomoć, za eventualne modifikacije kurikuluma, a mogu poslužiti i kao inspiracija nastavnicima koji obavljaju složen zadatak razvoja vještina algoritamskog razmišljanja i programiranja kod učenika.

I. UVOD

Unatoč dobronamjernim pokušajima integriranja u nastavni kurikulum, učenici nakon završene osnovne škole većinom pokazuju nedovoljnu razvijenost algoritamskog načina razmišljanja i strategija rješavanja problema, neophodnih vještina potrebnih kod učenja programiranja računala. Prečesto i sami nastavnici izborne nastave informatike zaključuju (bez opravdanih razloga što pokazuju brojna istraživanja) kako je učenje algoritamskog razmišljanja radi konstruiranja algoritama i razvoja vještina programiranja nešto nepristupačno i neshvatljivo gotovo svim mlađim učenicima.

Primjenom danas dostupnih, vrlo primjenjivih alata, olakšano je razvijanje i usavršavanje logičkog i matematičkog razmišljanja kod učenika koji, upotrebljavajući ove često vrlo izazovne alate, pokazuju ne samo da mogu usvajati algoritamsko razmišljanje i učiti programiranje već da u tome uživaju. Pri tom nije zanemariva ni činjenica potpore roditelja koji i sami potiču interes učenike svjesni svrhovitosti i značajne upotrebljivosti razvoja ovih vještina.

U mnogim je državama tako trend da se moguća zabavna i zanimljiva narav programiranja mlađim učenicima približava kroz vizualne okoline kao što su Scratch i Kodu (npr. kurikulum u Engleskoj i Njemačkoj)[1]. Na žalost, još uvijek nije rijetkost nedostatak kvalitetno pripremljenih nastavnika koji mogu uspješno poučavati osnove računalnih znanosti, s obzirom da često nemaju nužno dovoljno poznavanje programskih koncepata koji počivaju u pozadini ovih okolina. Tek na takav način oni mogu olakšati razvoj i usvajanje osnovnih principa programiranja umjesto da upotrebu ovih moćnih i izazovnih alata svode na puku upotrebu aplikacije.

Osim toga, nisu rijetki ni slučajevi da se nastava početnog učenja programiranja (obično u smanjenom opsegu) koncentrira na sintaksu programskog jezika stavljajući u drugi plan aktivnosti usmjerene stjecanju iskustva u analizi rješavanja problema i razvoju algoritamskog razmišljanja. Poželjan način učenja dizajniranja i pisanja programa trebao bi u dovoljnoj mjeri naglašavati veliku važnost učenja sustavnog načina pristupa traženju rješenja i prevođenja tog rješenja u funkcionalni program. Ta sustavnost podrazumijeva rigorozno slijediti korake koji uključuju analizu problema, kreiranje plana rješavanja, konstruiranje algoritma (npr. dijagramom tijeka), implementacija algoritma (u izabranom programskom jeziku) te konačno provjeravanje i ispravljanje algoritma. Kao raširena metoda, dijagrami tijeka pomažu početnicima vizualizirati i razumjeti proces, od njegove formulacije preko traženja do oblikovanja rješenja, te olakšavaju uvježbavanje logike osnovnih upravljačkih struktura kao i uočavanje mogućih problematičnih točaka u razvoju programa.

Bez obzira na pristup i izabranu metodu, preporučljivo je u početku davati odgovarajuće, lakše primjere. Tako se, primjerice, za početni, uvodni, jednostavan proces ili slijed koraka može tražiti uočavanje osnovih koraka kod čestih životnih situacija kao što su pripremanje čaja ili sendviča, odlazak u školu, zbrajanje brojeva kalkulatorom i slično. Za učenje uvjetnih struktura koje uključuju potrebu donošenja odluka ovi se problemi dodatno mogu zakomplicirati određenim (realnim) situacijama (npr.

zaslađivanje čaja šećerom ili medom, odabir prijevoznog sredstva kod odlaska u školu ili potreba da se svrati po pecivo i dr.). Petlje, odnosno ponavljajuće strukture također se bez problema mogu uvoditi uspoređivanjem sa nekim svakodnevnim situacijama (npr. izračunavanje prosječne ocjene svih predmeta jednog, odnosno više učenika) [2].

Nastavak teksta podijeljen je na cjelinu u kojoj se govori o pristupu novog strukovnog kurikuluma za stjecanje kvalifikacije Tehničar za računalstvo koji u prvoj godini učenja (a nastavlja se u drugoj) uvodi predmet naziva Algoritmi i programiranje. Slijedi analiza predznanja učenika i usvojenosti predviđenih ishoda nakon završetka prvog polugodišta za prvu generaciju upisanih učenika u promatranoj školi. U zaključku su dana završna razmatranja, komentari i prijedlozi mogućih praćenja, odnosno mjera za poboljšanje stanja, kao i moguća buduća istraživanja.

II. NOVI STRUKOVNI KURIKULUMI I NASTAVNI PREDMET: ALGORITMI I PROGRAMIRANJE

Vezano uz predmet razmatranja ovog rada, izvođenje predmeta Algoritmi i programiranje, u uvodnom standarda kvalifikacije Tehničar za računalstvo navodi se kako će učenici planirano usvojiti slijedeće kompetencije i ishode učenja: upotrijebiti i primjenjivati temeljene programske i podatkovne strukture i algoritme (nizove, polja, petlje, grananja) u izradbi programskih rješenja manjeg stupnja složenosti korištenjem metoda i alata sekvencijalnog programiranja, što treba biti nužan i dovoljan temelj kako bi mogli i projektirati i izraditi složenije računalne programe sa grafičkim sučeljem za prezentaciju rezultata i stanja, uz korištenje algoritama pretraživanja te komunikaciju s bazom podataka, korištenjem objektno orijentiranih razvojnih alata i programa što bi trebali usvajati kroz nastavu drugih stručnih predmeta odgovarajućeg izabranog modula. Cilj i svrha nastave predmeta Algoritmi i programiranje je razvoj algoritamskog načina razmišljanja u rješavanju problema i ovladavanje osnovama korištenja programskog jezika kao alata za rješavanje problema. Sukladno tome definirani su slijedeći ishodi učenja [6]:

1. objasniti važnost algoritama u procesu rješavanja problema
2. razmotriti tipične strukture podataka i pripadnih algoritama te prepoznati važna svojstva algoritama
3. odabrati i osmisliti algoritme za rješavanje jednostavnijih problema
4. koristiti naredbe za upis i ispis podataka
5. koristiti naredbe za grananje i ponavljanje dijelova programa
6. koristiti algoritme za pretraživanje i sortiranje
7. kreirati i koristiti funkcije u programu
8. koristiti pokazivače u radu s poljima i funkcijama
9. kreirati i koristiti strukture podataka
10. kreirati i koristiti datoteke

III. RAZVOJ ALGORITAMSKOG RAZMIŠLJANJA

Algoritam možemo pojednostavljeno definirati kao postupak za rješavanje problema koji se sastoji od točno određenih uputa. Uspješno nalaženje odgovarajućeg algoritma usko je povezano sa razvijenim algoritamskim razmišljanjem koje predstavlja jednu od najvažnijih kompetencija u području računarstva. Na nju se izravno nadovezuje pisanje računalnih programa kao vježba logičkog razmišljanja u samom temelju računarstva s obzirom da su računala neupotrebljiva bez skupa naredbi koji im objašnjava što trebaju raditi, bez obzira na vrstu aplikacije koja se na računalu izvodi.

Zbog znatne složenosti poučavanja vještina algoritamskog razmišljanja koje inkorporira kritičko razmišljanje, a u konačnici i razvoj programske logike, tehnologije i sintakse, nastavnici ove discipline moraju biti izvrsni u vještinama koje poučavaju i pri tom uzimati u obzir specifične karakteristike i potrebe mladih i početnika. Njihov interes može se pojačavati naglašavanjem činjenica kako su algoritmi snažan alat primjenjiv u nizu zanimljivih aktivnosti prema postizanju značajnog napretka kroz nove ideje i to ne samo u području računarstva i programiranja računala.

Algoritamsko razmišljanje objedinjava niz sposobnosti vezanih uz stvaranje i razumijevanje algoritama. Tu je neizostavno potrebno uključiti sposobnost preciznog definiranja i analiziranja danog problema, sposobnost uočavanja i nalaženja osnovnih problemu odgovarajućih postupaka, sposobnost stvaranja korektnog algoritma za dani problem upotrebom osnovnih postupaka, sposobnost razmišljanja o svim mogućim posebnim i uobičajenim slučajevima problema, sposobnost evaluacije i poboljšavanja korektnosti i učinkovitosti algoritma.[3] Mnogi humani kognitivni čimbenici utječu na sposobnost algoritamskog razmišljanja i tu se prije svega može istaknuti apstraktno i logičko razmišljanje, disciplinirano sustavno i formalno razmišljanje, razmišljanje u strukturama, kreativnost i kompetencija rješavanja problema.

Uz to, algoritamsko razmišljanje u određenoj je mjeri neprirodno. Dok u svakodnevnom životu probleme rješavaju ljudi, algoritamsko razmišljanje učenik ipak mora posebno uvježbati jer je povezano s nalaženjem rješenja koje će biti ukodirano u računalo, koje mora biti „razumljivo“, izvedivo na stroju kodirano njegovim nizom instrukcija iz skupa naredbi koje može izvoditi.

Očito je da takva složenost nužno čini algoritamsko razmišljanje teškim za usvajanje i objašnjava potrebu za izbjegavanjem neuspjeha primjenom dobrih didaktičkih pristupa posebno kod početnika. Razloga za neuspjeh kod usvajanja vještina programiranja može biti više, a uključuju: nedostatak zrelosti kod učenika, nedostatak vještina kritičkog razmišljanja, nedostatak praktičnog rada u laboratoriju, nedostatna matematička predznanja ili sposobnost logičkog razmišljanja,neodgovarajući zadaci za uvježbavanje potrebnih vještina, prebrzo napredovanje kroz gradivo, a javlja se i strah od programiranja kao slijed straha od matematike.

IV. KAKO POUČAVATI ALGORITME I ALGORITAMSKO RAZMIŠLJANJE?

Više je načina na koje se može stimulirati razmišljanja o algoritmima. Odgovarajući pristup može biti razvijanje neformalnih (ali učinkovitih i korektnih) algoritama za rješavanje bliskih i razumljivih problema i zagonetki, nealgoritamske zagonetke koje potiču rigorozno logičko zaključivanje i analize slučajeva, jednostavni zadaci u kojima učenici prate i slijede dobro definirani niz uputa, zadaci u kojima učenici ispituju i istražuju snagu i slabosti danog algoritma kroz proučavanje njegovog ponašanja (traženjem približnog broja koraka ili scenarija najlošijeg slučaja) potičući kod učenika tako razmišljanja o računalnoj složenosti. Također, učenicima se mogu zadavati zadaci u kojima trebaju naći grešku u nizu naredbi ili moraju upotpuniti iscrpan skup ulaznih scenarija kako bi ispitali korektnost danog algoritma, čime se uvježbavaju u usvajanju važnih karakteristika algoritma prezentiranog vlastitim programskim kodom: ispravnosti, učinkovitosti i robustnosti. Zadaci koji se zadaju učenicima mogu podržavati jedan, ali i kombinaciju spomenutih pristupa pazeći da rješavajući ih učenici razvijaju nužan sustavan pristup razvoju algoritma, prateće tehnike manipulacije podacima, brzinu i djelotvornost.

Kako bismo svu složenost učenja algoritamskog razmišljanja približili učenicima njihovi zadaci i akcije koje uključuju trebaju učenicima biti bliski iz svakodnevnog života, a algoritmi opisani prirodnim opisnim jezikom i izvedeni na sustavu koji će izvoditi algoritam, a na kojem učenici istovremeno mogu i eksperimentirati kako bi preko kvalitetne povratne veze ostvarili neposredna iskustva učenja. U usvajanju algoritamskog razmišljanja pomaže i rješavanje što većeg broja problema, no posebno je za početnike važno da su ti problemi izabrani vrlo pažljivo i da ih je moguće opisati prihvatljivim načinom, npr. pseudo kodom ili vizualizacijskim alatom (npr. dijagramom tijeka). Problemi ne bi smjeli biti prejednostavni, no formulacija problema treba biti lako razumljiva. Upotreba složenih problema također je smislena jer što su problemi složeniji, više je prostora za razvijanje kreativnosti i neuobičajenih rješenja. No bez obzira na složenost, nastavnici ne bi trebali prezentirati gotova rješenja već poticati učenike u njihovom procesu učenja motivirajući ih u napretku prema nalaženju rješenja.

Pri razumijevanju principa algoritama korisne su animacije koje izvode računalni programi, no isto tako poželjni su pristupi sa zadacima i scenarijima koji isključuju upotrebu računala [4] ili [5].

V. ANALIZA REZULTATA ISPITIVANJA UČENIKA

Uzimajući u obzir konstruktivističku teoriju učenja koja učenje objašnjava kao proces u kojem se smisao novih informacija stvara kroz spektar postojećih znanja, najbolje je kad su tvorci i izvoditelji kurikuluma svjesni prethodnih znanja i iskustva učenika pa im kroz nadogradnju izazivaju postojeće ideje. Poželjno je da se nastavnik u tom procesu postavlja u ulogu vođe i dizajnera obrazovnih iskustava, a ne tek pukog predavača. [7]. Dodatno, kurikulum bi trebalo sagledavati i kroz konstrukcionističku teoriju učenja i poučavanja građenu na konstruktivističkim idejama pri čemu se postavlja kako ljudi najbolje uče razvojem ideja i stvaranjem [11].

Konstruktivistička perspektiva učenja traži od nastavnika da prije nego pristupi nastavnom procesu poučavanja jasno identificira ideje koje učenici razvijaju o algoritamskom razmišljanju, s posebnim naglaskom na dva aspekta: algoritme i programiranje. Te ideje nastavniku omogućavaju da nastavu razvija u vidu nadogradnje pri čemu učenici napredovanjem u učenju usvajaju određen skup ideja i vještina omeđeno donjom točkom sidrenja (koja opisuje ideje koje učenici imaju prije pohađanja nastave) i gornjom točku sidrenja (koja opisuje očekivane ciljeve ili ishode koje bi učenici trebali ostvariti završetkom nastave). Između tih točaka obično se nalazi više međurazina.

S ciljem dobivanja uvida u prethodno znanje i izloženost osnovnim idejama i konceptima algoritamskog načina razmišljanja, odnosno postavljanja donje točke sidrenja, provedeno je ispitivanje na uzorku od 25 učenika prvog razreda u zanimanju Tehničar za računalstvo.

Anketa je pokazala kako su svi upisani učenici učili programski jezik Basic u osnovnoj školi, dakle trebali su biti formalno izloženi usvajanju algoritamskog načina razmišljanja što je izrijekom napisano u opisu ciljeva izbornog predmeta Informatike: „... učenici moraju naučiti djelotvorno upotrebljavati računala i biti sposobni ugraditi osnovne zamisli algoritamskog načina razmišljanja u rješavanje svakodnevnih problema.“[8].

Programski jezik Basic bio je gotovo jedini odabir nastavnika, a učenici su ga učili najviše u izbornoj nastavi Informatike koju je pohađalo 88% upisanih učenika. U nastavi Tehničke kulture učilo ga je 20% učenika. S obzirom na trajanje učenja, u izbornoj nastavi učenje se svelo na manje od jednog polugodišta kod 45% učenika, dok ih je 31% taj programski jezik učilo više od jedne godine .

Iako su učili programiranje tek je 7 odnosno 28% učenika odgovorilo da su prije srednje škole čuli za algoritam kao pojam, no nitko od učenika nije znao imenovati, niti navesti neki algoritam za koji su čuli ili ga koristili.

Nadalje, učenicima je na početku nastavne godine dan zadatak prepoznavanja problema i oblikovanja uputa za njegovo rješavanje. Svi su učenici pronašli neki svoj problem iz svakodnevnog života, no 4 učenika (16%) nisu postupak njegovog rješavanja uspjeli opisati ni na najjednostavniji način. 8 (32%) učenika je u svom problemu posredno postavilo strukturu grananja, a tek 2 učenika (8%) u opis rješavanja unijelo je i ponavljajuću programsku strukturu.

Oblikovanje i izvođenje naredbi korak po korak jedna je od temeljnih vještina u području algoritamskog razmišljanja. Ova se aktivnost može kod početnika uvježbati tako da jedan učenik prema zadanoj slici daje upute drugom kako nešto nacrtati [5]. Svrha te aktivnosti je pokazati učenicima i značaj osiguravanja preciznih uputa drugima i ne malu izazovnu prirodu takvog zadatka kad se to svede isključivo na pisane instrukcije (upućene stroju).

Krajem prvog polugodišta učenici su najviše kroz vizualizaciju algoritama dijagramima tijeka ili kroz pseudokod već trebali bolje usvojiti osnovne pojmove vezano uz algoritamsko razmišljanje i predstavljanje rješenja za bilo koju instancu zadanog problema. Oblikovanje postupka za rješavanje jednostavnog problema izrazito su dobro riješila tek 2 učenika (8%), 24% učenika pri tom je pokazalo manje nepreciznosti, dok ih je najveći broj , njih 15 ili 60% prilično površno i neprecizno. 2 učenika taj su zadatak nisu na zadovoljavajući način riješila.

Kod ispitivanja poznavanja pseudokoda, svi su ispitani učenici riješili zadatak slijednog pridruživanja vrijednosti varijablama, dok ih je 68-88% uspjevalo riješiti zadatak sa strukturom grananja. Najmanji postotak riješenosti imao je zadatak sa ponavljajućom strukturom. Taj je zadatak točno riješilo tek 40% učenika.

Pokazuje se kako je dobar pristup razvoju ideja o algoritamskom načinu razmišljanja kroz aktivnosti bez računala i one na računalu. Naime, kad ne koriste računala učenici razvijaju koncepte u kontekstu svakodnevnih životnih situacija. I kurikulum ovog predmeta aktivnosti sa računalom predviđa tek naknadno, u drugom polugodištu. U radovima se može naći niz različitih vrlo uspješnih pristupa poučavanju programiranja [npr. 9].

Kako bi se kurikulum potpunije evaluirao ove rezultate bilo bi korisno usporediti sa rezultatima koje će učenici ostvariti na kraju nastavne godine.

VI. ZAKLJUČAK

Skup vještina i kompetencija poželjan za zapošljavanja konstantno evoluira. Poslodavci danas uz vještine komuniciranja, etičke, interpersonalne i personalne navode i znanja programiranja [Aasheim, 2012, Gruba 2004] relevantna prilikom rješavanja suvremenih problema. No, iako bi učenici, bar oni uključeni u izbornu nastavu Informatike, trebali već tijekom osnovnog školovanja (kad im se može pokazati kako je računalo razmišljanje moguće integrirati i u druge predmete) usvojiti osnovne zamisli algoritamskog načina razmišljanja pokazuje se kako taj cilj uglavnom nije ostvaren.

Analizom dobivenih podataka uočava se kako je izvođenjem nastave predmeta Algoritmi i programiranje ostvaren napredak u usvajanju algoritamskog načina razmišljanja kod učenika. Ovim istraživanjem dobivene informacije mogu se iskoristiti kako bi se usmjerilo ili korigiralo izvođenje inicijalnog eksperimentalnog kurikuluma. Bilo bi dobro istraživanjem prikupiti podatke i iz drugih sredina i usporediti ih međusobno.

"Programming is exciting, stimulating, fun and develops new ways of thinking". [10]

iPad u nastavi matematike i fizike

Mirela Babić*
* OŠ Vežica, Rijeka, Hrvatska
mirelababic@me.com

Sažetak - U suvremenom svijetu informacijsko-komunikacijske tehnologije imaju velik utjecaj na svakodnevni život , pa ti alati poprimaju sve veću i važniju ulogu i u obrazovanju. Otvaraju se brojne mogućnosti i perspektive unutar obrazovnog procesa kao što su vizualizacija, simulacija, čitanje digitalnih knjiga, slušanje zvuka, provjera vlastitog izgovora na stranom jeziku. Za razliku od tradicionalne nastave u kojoj je učitelj sveznajući prenositelj informacija, on se pretvara u vodiča i trenera u svijetu informacija. Učenici pak postaju aktivni učesnici obrazovnog procesa, sve je veća interakcija u odnosu učitelj-učenik i učenik- učenik. Iskorak prema "školi budućnosti" učinjen je u OŠ Vežica u kojoj se već drugu godinu provodi nastava pomoću tableta 1:1. Početna istraživanja pokazuju da smo na dobrom putu.

I. UVOD

Prije nekoliko godina nove tehnologije ušle su kroz vrata naših učionica u vidu prezentacijskih slajdova i pretraživanja interneta. U našoj smo školi otišli korak dalje kada su prije dvije godine za učenike jednog odjeljenja 8. razreda pribavljeni iPad uređaji. Započelo se s edukacijom učitelja koja se kontinuirano i dalje provodi, oformljen je tim za tehničku podršku , škola je tehnički opremljena i bili smo spremni za nove izazove.

II. NASTAVA FIZIKE

Osobno sam učiteljica matematike i fizike, a rad u „iPad“ odjeljenju započela sam predavajući fiziku. U mojoj nastavi iPad nije isključivo nastavno sredstvo, već dodatna vrijednost i dobrodošla pomoć u nastavi. Pronalazila sam alate, odgojne-obrazovne aplikacije za koje sam smatrala da će mojim učenicima i meni olakšati rad i učiniti nastavu zanimljivijom i dinamičnijom. Neke od tih aplikacija su: Xperica, SerialBulbs, ParallelBulbs, RayOptics, PhysicalSci. Web stranice fizika-os.webs.com, stevespanglerscience.com omogućile su uvid u simulacije i demonstracije eksperimenata uvijek i ovdje (u školi ili kod kuće) . Dakle, potraga za informacijama odvija se u realnom vremenu.

Prilog1.

Priprema za izvođenje nastave

Nastavna cjelina: Valovi
Nastavna jedinica: Zvuk. Ton i šum.
Tip sata: obrada
Cilj nastavne jedinice: upoznati svojstva zvuka

Ishodi učenja:

- Objašnjavati nastajanje i rasprostiranje zvuka
- Nabrajati izvore zvuka
- Definirati područje čujnosti
- Razvijati sposobnost promatranja i zaključivanja
- Stjecati naviku istraživanja promatranjem

Oblici rada: frontalni, individualni

Nastavne metode: rasprava, demonstracija, praktični rad, rad na ipad uređaju

Nastavna sredstva i pomagala: ploča, kreda, ipad, aplikacije PhysicalSci Science By CPO

Ključni pojmovi: zvuk, ton, šum

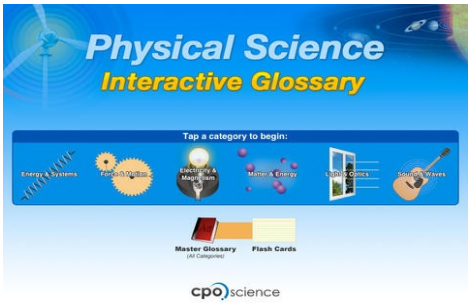
Tijek nastavnog sata

Uvodni dio sata:

- na početku sata učiteljica reproducira zvuk klavira koristeći aplikaciju PhysicalSci By CPO Science

https://itunes.apple.com/hr/app/physicalsci/

Koristi se dio:Sound and Waves



Središnji dio sata:

Učiteljica otvara problem pitanjima: Kako čujemo zvuk? Što je uzrok zvuka na klaviru? Kako ljudi proizvode zvuk dok pričaju?

Kroz raspravu dolazi se do zaključka da zvuk nastaje titranjem tijela u elastičnom sredstvu, a tijela koja proizvode zvuk su izvori zvuka. Zvuk je longitudinalni val frekvencije od 20-20000 Hz. Učenici zapisuju bilješke.

Učiteljica daje upute za otvaranje aplikacije PhysicalSci By CPO Science, uz pomoć koje učenici slušaju zvukove iz različitih izvora(padanje pera, ljudski šapat, razgovor dvoje ljudi, bušilica, rock koncert). Zvukove koje su učenici čuli ,pokušaju razvrstati na tonove i šumove. Definirati ton kao pravilno titranje , a šum kao nepravilno titranje tijela u zraku, te buku kao skup tonova i šumova.

Učenici se podijele u dvije skupine , jedna na mrežnim stranicama http://m.youtube.com/home pronalazi tonove, a druga šumove. Nakon 2 minute nekoliko učenika sa svog uređaja reproducira pred cijelim razredom pronađeni zvuk.

III. NASTAVA MATEMATIKE

Ove školske godine u našoj školi nastava s tabletima 1:1 odvija se u 5 odjeljenja, tri 5. razreda i dva 6. razreda. Predajem matematiku u dva 5.razreda. Okosnicu nastave čini društvena mreža za obrazovanje Edmodo. Pokazalo se da je Edmodo omogućio povezivanje s učenicima na njima vrlo prihvatljiv način. Društvena mreža je zatvorena jer se učenici priključuju preko koda koji im dodjeljuje učitelj. Kreirala sam grupe i podgrupe pojedinih odjeljenja, kako za redovnu tako i za dodatnu nastavu. Nastava putem Edmoda ubrzo je pokazala mnoge vrijednosti i prednosti: direktna razmjena informacija, materijala i obavijesti, kreiranje kvizova, praćenje rada pojedinog učenika, ažuriranje biblioteke, trenutna povratna informacija učenicima o njihovoj uspješnosti, povezivanje s drugim učiteljima diljem svijeta. Osim Edmoda u nastavi koristimo brojne matematičke aplikacije poput: Math Zombies, Geometry, Math Drill, Dragon Box, BasicFraction, SketchExplorer. Kroz neke od njih učenici kroz igru mogu usavršavati vještinu računanja, vizualno doživljavati razlomke, uvježbavati tehniku rješavanja jednadžbi i sl. Najveći dio aplikacija dozvoljava rad na više nivoa težine čime se proces učenja prilagođava individualnim potrebama učenika.

Prilog2.

Priprema za izvođenje nastave

Nastavna cjelina: razlomci

Nastavna jedinica: osnovno o razlomcima

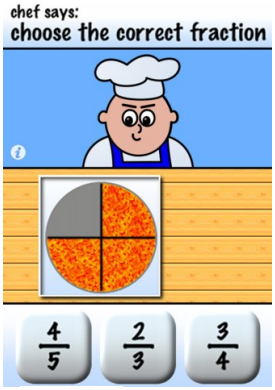
Tip sata: uvježbavanje

Cilj nastavne jedinice: usvojiti pojam razlomka

Ishodi učenja:

- Definirati pojam razlomka, brojnika , nazivnika i razlomačke crte
- Povezivati razlomak s računskom operacijom dijeljenja
- Prepoznati razlomak na konkretnom primjeru
- Prepoznati uporabu razlomaka u svakodnevici
- Razvijati pozitivan odnos prema matematici, odgovornost za svoj uspjeh i napredak te vijest o svojim matematičkim postignućima

Nastavna sredstva i pomagala: ploča, kreda, ipad, aplikacije Pizza Fractions 1By Brian West,Fraction lite by rana nir, zMath fraction by Zenitech, društvena mreža Edmodo. Tijek nastavnog sata



Uvodni dio sata:

Na početku sata ponove se osnovni pojmovi vezane uz pojam razlomka i povezuju se s uporabom u svakodnevici (npr. kruh, čokolada, pizza)

Učiteljica daje upute za otvaranje aplikacije Pizza Fractions 1By Brian West

(https://itunes.apple.com/hr/app/pizza-fractions)

Učenici dijelove pizze povezuju s odgovarajućim razlomkom i na zanimljiv način uvježbavaju pojam razlomka.

Središnji dio sata:

Za uvježbavanje u središnjem dijelu sata učenici prema

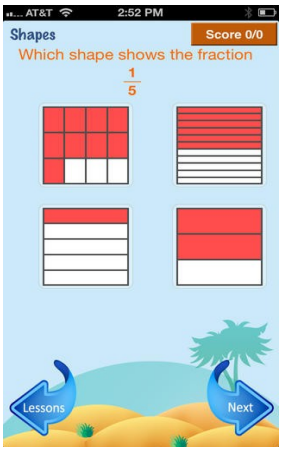
uputama učiteljice koriste aplikacije: Fraction lite by rana nir

(https://itunes.apple.com/hr/app/fraction-lite/

IzMath fraction by Zenitech)

(https://itunes.apple.com/hr/app/zmath-grade-3-fractions-lite/)

U ovim aplikacijama učenici kroz različite oblike (krug, kvadrat, mnogokut…) uvježbavaju pojam razlomka na više razina složenosti. Svaki učenik samostalno bira razinu na kojoj će započeti rad. Ukoliko se neka razina pokaže preteškom za učenika, vraća se na nižu.



Završni dio sata:

Razina usvojenosti sadržaja provjerava se kroz petminutnu pismenu vježbu koju učenici rješavaju preko aplikacije Edmodo: https://itunes.apple.com/hr/app/edmodo/id

Aplikacija pruža mogućnost brze povratne informacije koju učenici dobivaju u roku od nekoliko sekunda.

IV. ZAKLJUČAK

Suvremeno obrazovanje postalo je nezamislivo bez primjene informacijsko-komunikacijske tehnologije. Generacije naših današnjih učenika postavljaju pred nas učitelje izazove s kojima se moramo i želimo uspješno nositi na zadovoljstvo svih sudionika odgojno obrazovnog procesa. Pred nama učiteljima je ogromna odgovornost, ali i osjećaj da nismo bespomoćni , da postoje načini i mogućnosti za promjene koje od nas iziskuje galopirajući razvoj tehnologije. Lao Ce, kineski filozof iz 6.st.pr.Kr. rekao je:"Učenje je kao veslanje uzvodno, čim prestane, odmah se kreće unatrag." Budućnost će od naših učenika tražiti da ubrzano "veslaju uzvodno", a mi ih za to moramo pripremiti.

#codeEU

Ivana Ružić
I. osnovna škola Čakovec,
Ulica kralja Tomislava 43, Čakovec, Hrvatska
ivana.ruzic@skole.hr

#codeEU je inicijativa pokrenuta od Europske komisije sa ciljem da se što više ljudi diljem Europe potakne da uče programirati. Programiranje je kreativno područje koje svima nama nudi mnogobrojne mogućnosti da ostvarimo svoje ideje i zamisli. Inicijativa je usmjerena na djecu i mlade, nezaposlene osobe ali i na sve nas nudeći svima nama mogućnost da postanemo aktivni sudionici u kreiranju budućnosti čovječanstva ili osiguramo vlastitu egzistenciju. Ovaj rad opisuje inicijativu koja ruši državne granice, jezične barijere ili bilo koji oblik diskrimacije, ukazujući svima na potrebe zajednice u bližoj budućnosti, nudeći mogućnost izbora, priliku za usvajanje novih znanja i vještina iz područja ICT te ukazuje na važnost cjeloživotnog učenja.

I. UVOD

#codeEU je inicijativa koju je pokrenula Neeile Kroes uz podršku DG Connect u Europskoj komisiji sa ciljem da se ljude potakne da uče programirati, da se svima nama pruži prilika da ostvarimo vlastite ideje i promijenimo svijet. Tehnologija oblikuje naše živote ali manjima odlučuje što ćemo i kako koristiti. Mi možemo učiniti puno više od korištenja, dijeljenja i „lajkanja“. Mi možemo ostvariti naše „lude“ ideje i izgraditi usluge i stvari koje će donijeti radost drugima. Nikada nije bilo lakše napraviti vlastitu aplikaciju, izgraditi vlastitog robota ili izmisliti leteće automobile, zašto ne pokušati? To nije lagan put ali to je putovanje puno kreativnih izazova, zajednica koja pruža podršku i mnogo zabave. Jeste li spremni prihvatiti izazov i postati stvaratelj?

Slika 1. Logo inicijative #codeEU

II. ZAŠTO PROGRAMIRANJE?

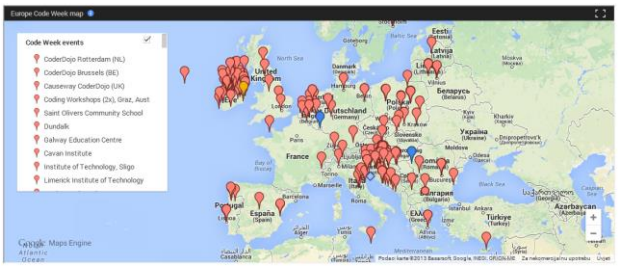
Programiranje je svuda oko nas. Svaka interakcija između čovjeka i računala je podržana programskim kodom. Programiranje je puno više od mnoštva različitih alata, to je način gledanja na svijet: razdijeliti zadatke u sve manje podskupine. To je zabavno i kreativno područje ispunjeno velikim ljudima i strastvenom zajednicom. Treba li spomenuti da će 2015. u EU nedostajati 900.000 ICT stručnjaka?

Programiranje zaslužuje veću pažnju javnosti i stoga je organiziran prvi Europski tjedan programiranja od 25. do 30. studenoga 2013. sa željom da se organizira niz prigodnih događaja diljem Europe - sve sa ciljem upoznavanja građana s programiranjem kao i učeći ih ovu vještinu.

Cilj inicijative je poboljšati programiranje na europskoj razini, motivirati ljude da počnu učiti programirati te povezati pojedince, skupine, ustanove, organizacije i tvrtke koje su spremni pomoći ljudima doživjeti radost i relevantnost programiranja. Između ostalog cilj inicijative je i pokretanje velike lavine koja će se vidjeti izvan naših uobičajenih krugova, lavine toliko velike i snažne da ne može biti ignorirana od strane medija, bez obzira na najnovije celebrity tračeve. Znamo koliko je zabavno graditi stvari, a mi smo spremni dijeliti našu strast. Programiranje je zabavno. Kreativno. Njime se bavi mnogo poznatih ljudi i odlikuje se snažnom zajednicom. Jeste li se već okušali u usvajanju znanja i vještina programiranja, jeste li pomogli ljudima oko sebe da upoznaju ljepotu programskog koda? Uvijek je zabavno graditi, stvarati.

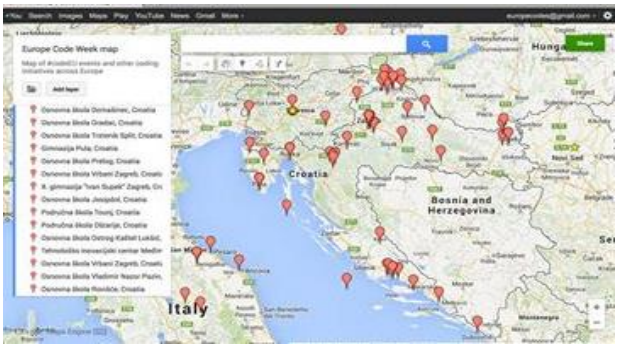
III. AKTIVNOSTI U EUROPSKOM TJEDNU PROGRAMIRANJA

Između 25. i 30. studenog 2013. godine diljem Europe organizirano je preko 300 različitih prigodnih događanja u kojima se okupilo nekoliko desetaka tisuća sudionika. Time je dokazano da je Europski tjedan programiranja i službeno postigao veliki uspjeh, a programiranje je na svojevrstan način ujedinilo Europu. Najveći interes zabilježen je u Irskoj, a Hrvatska kao najmlađa članica Europske unije po brojnosti događanja i sudionika zauzela je drugo mjesto. Karta svih prijavljenih prigodnih događanja dostupna je na: http://codeweek.eu/map/



Slika 2. Karta inicijative #codeEU

U Hrvatskoj su se u ovoj inicijativi okupile ukupno 64 osnovne i srednje škole, fakulteti i udruge sa gotovo 4000 sudionika.



Slika 3. Karta inicijative #codeEU u Hrvatskoj

Održane su različite radionice programiranja za djecu i mlade svih uzrasta od osnovnoškolskog do akademskog obrazovanja. Sudionici su imali prilike upoznati programske jezike C++, Phyton, Logo, Small Basic, HTML, CSS, JavaScript, Game Maker, Kodu, Scratch,… ispisane su tisuće linija koda, radošću stvaranja ozarila su se mnoga lica, ostvarene su mnoge suradnje i vjerujemo da se zakotrljao veliki kotač koji će mnogim sudionicima inicijative ili onima koji će te to postati do slijedeće godine i novog Europskog tjedna programiranja donijeti mnogo novih znanja i vještina.

Slika 4. Radionica programiranje Lego robota u I. OŠ Čakovec

Sadržaji radionica i aktivnosti bili su zaista raznoliki i prilagođeni uzrastu i predznanju polaznika radionica, osmišljeni na način da se polaznike dodatno motivira i potakne na kontinuirano učenje i usvajanje novih vještina, samostalno istraživanje, uključivanje u obrazovnu online zajednice istih i/ili sličnih interesa.

Poseban interes pokazan je za programiranje robota što uključuje sastavljanje robota od kockica, motora i senzora, na računalu izradu programa za upravljanje robotom, prijenos programa usb sučeljem s računala na robot te pokretanje robota tj. gledanje njegovog izvršavanja postavljenih naredbi.

S posebnom pažnjom pripremale su se aktivnosti radionica programiranja za najmlađe polaznike, učenike prvih i drugih razreda osnovnih škola. Tynker je nova računalna platforma dizajnirana u Silicijskoj dolini namijenjena poučavanju djece vještinama programiranja na zabavan i maštovit način. To je jednostavna platforma smještena u oblaku koja ne traži nikakve posebne zahtjeve, a temelji se na otvorenim web standardima poput JavaScripta, HTML5 i CSS3. Tynker omogućuje djeci da uče koncept računalne znanosti kroz otkrića, kreativne aktivnosti i eksperimentiranja. Najmlađi sudionici Europskog tjedna programiranja usvojili su logički slijed događaja i modeliranje stvarne situacije, razvili su svoje algoritamsko razmišljanje i sposobnosti dizajna.

Slika 5. Radionica programiranja u Gospodarskoj školi Buje

Vjerujemo da računalno razmišljanje i računalno programiranje treba biti dio jezgre nastavnog plana i programa u obrazovanju sa ciljem da svako dijete izgradi čvrste temelje STEM-a (znanosti, tehnologije, inženjerstva i matematike) kako bi ih pripremili za karijere 21. stoljeća .

Interes za uključivanje u ovu inicijativu iskazale su mnoge fizičke i pravne osobe, stručnjaci iz područja ICT koji su volonterski održali niz radionica, predavanja i sličnih aktivnosti ili su donacijama potpomogli održavanje aktivnosti. Uključivanjem stručnjaka iz privrede u inicijativu pridonijelo je većem interesu i motiviranosti učenika za sudjelovanje u aktivnostima, a jasno je pokazan interes i potreba privrede za ICT stručnjacima.

Inicijativa je u Hrvatskoj pridobila veliki interes javnosti, regionalnih i državnih medija, šire obrazovne zajednice i lokalnih čelnika što je doprinjelo još većem značaju i popularizaciji inicijative i samog programiranja. Aktivnosti vezane uz #codeEU inicijalizirale su osnivanje prvog Coderdojo kluba u Hrvatskoj sa sjedištem u I. OŠ Čakovec, organiziranje ljetnih radionica programiranja za osnovnoškolce u odmaralištu grada Čakovca u Dramlju. Razvoj svijesti o važnosti programiranja te poticanje na kontinuirano usvajanje novih znanja i vještina iz područja

programiranja na europskoj razini nastavlja se pripremama i organiziranjem drugog Europskog tjedna programiranja koji će se obilježiti od 11. do 17. listopada 2014.

IV. ZAKLJUČAK

Međunarodne inicijative i projekti mogu obogatiti cjelokupan nastavni proces, povećati motiviranost učenika za usvajanje novih znanja i vještina. Ukoliko se inicijativa predstavi i prepozna kao korisna i u svakodnevnom životu primijenjiva, interes i motiviranost za sudjelovanje u projektnim aktivnostima je veći. ICT je nezaobilazna u svakoj sferi života, a upoznavanje i savladavanje novih programskih alata ovisno o interesima sudionika osigurava zadovoljstvo učenika i veću angažiranost.

Sažetak - Republika Hrvatska je jedna od 146 država u svijetu koje su u nekoj od faza uvođenja nacionalnog kvalifikacijskog okvira. S tim ciljem je u 2013 donesen Zakon o Hrvatskom kvalifikacijskom okviru, te su u izradi dva pravilnika koji će regulirati područja priznavanja informalno i neformalno stečenih znanja i vještina te ustroj registara Hrvatskog kvalifikacijskog okvira (HKO). Ovim člankom se sukladno Zakonu o HKO i objavljenom prijedlogu pravilnika o registrima HKO nastoji predložiti logički entitetsko-relacijski model podataka registara HKO koji će uključiti opis atributa koji opisuju skupine ishoda učenja, standarde zanimanja, standarde kvalifikacija te obrazovne programe kao i programe za vrednovanje neformalnog i informalnog učenja. Predloženi logički relacijski model podataka uzet će u obzir odnose između pojedinih entiteta, ali isto tako i predviđene procedure izmjena i dopuna podataka te praćenje verzija, kako ih predlažu zakonska i podzakonska rješenja. Članak stoga daje moguću podlogu za razvoj budućeg informacijskog sustav koji će predstavljati potporu punoj implementaciji Hrvatskog kvalifikacijskog okvira, sukladno aktualnom Zakonskom rješenju.

I. UVOD

Poticaj razvoju nacionalnih kvalifikacijskih okvira u tranzicijskim državama i državama u razvoju često je uvjetovan potrebom povećanja kvalitete ljudskog kapitala i željom za povećanjem konkurentnosti. S druge strane, potaknuto aktualnom gospodarskom krizom i recesijom koja je pogodila brojna svjetska gospodarstva, uvođenje nacionalnih kvalifikacijskih okvira je postalo jedan od važnih alata koji doprinose političkom cilju povećanja zaposlenosti i zapošljivosti. Kao rezultat navedenih tendencija nacionalni kvalifikacijski okvir je do sada uvelo ili uvodi 146 država [1], među kojima je i Republika Hrvatska. Iako je ideja o uvođenju Hrvatskog kvalifikacijskog okvira (HKO) bila prisutna i ranije, službeno je proces u Hrvatskoj započeo u ožujku 2006 osnivanjem Povjerenstva za uvođenje HKO od strane Ministarstva znanosti, obrazovanja i sporta. U srpnju 2007 Vlada Republike Hrvatske prihvatila je polazne osnove HKO [2] da bi iste godine bilo osnovano i povjerenstvo Vlade RH za razvoj HKO. Konačno je u svibnju 2010 imenovano i novo povjerenstvo Vlade RH za uvođenje HKO koje je dovršilo rad na Zakonu o HKO [3] koji je Hrvatski Sabor donio u veljači 2013. Predmetnim Zakonom i pripadajućim Pravilnikom o registru HKO [4], koji je u trenutku pripreme ovog članka dostupan u javnoj raspravi, definirani su osnovni elementi HKO i njihovi međusobni odnosi. Dodatno, člankom 11 Zakona [3] je propisana izgradnja informacijskog sustava za vođenje registara HKO, dok Pravilnik [4] propisuje elemente temeljnih dokumenata koji će biti pohranjivani u registre i time definira svojstva budućeg modela podataka. Pored navedenog pravilnika, Zakon [3] predviđa i donošenje pravilnika o priznavanju i vrednovanju neformalnog i informalnog učenja koji će postaviti dodatne zahtjeve na model podataka i na pripadajući informacijski sustav.

Imajući u vidu navedenu zakonsku regulativu te podzakonske akte koji su još u nastajanju, kao i europsku ESCO taksonomiju [5] i pripadajući informacijski sustav koji je za nju razvijen, u nastavku će biti predložen mogući logički podatkovni model registara HKO koji bi omogućio buduću integraciju informacijskog sustava HKO sa ESCO i EURES [6] platformama.

II. ELEMENTI SUSTAVA KVALIFIKACIJA

Sukladno članku 2 Zakona [3], HKO se uspostavlja kao instrument uređenja sustava kvalifikacija u Republici Hrvatskoj koji osigurava jasnoću, pristupanje stjecanju, utemeljeno stjecanje, prohodnost i kvalitetu kvalifikacija kao i povezivanje razina kvalifikacija u Republici Hrvatskoj s razinama kvalifikacija u Europskom kvalifikacijskom okviru (EQF) [7] te posredno s razinama kvalifikacija kvalifikacijskih okvira u drugim zemljama. Kako bi ostvario navedenu funkciju uređenja sustava kvalifikacija, HKO definira osnovne elemente sustava, pri čemu se koriste i kratice kako slijedi:

- **Standard zanimanja** (SZ): popis svih poslova koje pojedinac obavlja u određenom zanimanju i popis kompetencija potrebnih za njihovo uspješno obavljanje.
- Metodološka podloga za izradu standarda zanimanja: predstavlja skup dokumenata i postupaka njihove izrade koji osiguravaju dokaze strateške, sektorske i analitičke utemeljenosti za izradu standarda zanimanja. Dio metodologije predstavlja i upitnik za istraživanje potrebnih kompetencija po zanimanjima i radnim mjestima [8].

- Kompetencije: znanja i vještine te pripadajuća samostalnost i odgovornost. Grupirane su u skupove.
- **Standard kvalifikacije** (SK): sadržaj i struktura određene kvalifikacije koja uključuje sve podatke koji su potrebni za određivanje razine, obujma i profila kvalifikacije te podatke koji su potrebni za osiguravanje i unapređenje kvalitete standarda kvalifikacije. Sastoji se od skupova ishoda učenja.
- **Skup ishoda učenja** (SIU): najmanji cjelovit skup povezanih ishoda učenja iste razine, obujma i profila.
- Ishodi učenja : kompetencije koje je osoba stekla učenjem i dokazala nakon postupka učenja.
- Sektor: skupina kvalifikacija jednog obrazovnog područja i zanimanja koja koriste ishode učenja tih kvalifikacija na radnim mjestima.
- Program za stjecanje kvalifikacija: postupci provedbe obrazovanja (kurikulum, studijski program) koji dovode do stjecanja ishoda učenja koji su navedeni u standardu predmetne kvalifikacije.
- Program za stjecanje i vrednovanje skupova ishoda učenja: postupci provedbe obrazovanja (kurikulum, studijski program) i postupci provedbe provjere znanja koji dovode do dodjele potvrde o posjedovanju skupa ishoda učenja.
- Program za vrednovanje skupova ishoda učenja: postupci provedbe provjere znanja koji dovode do dodjele potvrde o posjedovanju skupa ishoda učenja.

Navedeni elementi sustava kvalifikacija definirani su sa svojim svojstvima (atributima) i predstavljaju osnovu za izradu logičkog podatkovnog modela HKO. U naravi se radi o dokumentima ili skupinama dokumenata koje osiguravaju jasnoću, pristupanje stjecanju, utemeljeno stjecanje, prohodnost i kvalitetu kvalifikacija. Pored navedenih dokumenata, HKO uvodi i upravljačku strukturu koja se sastoji od niza organizacijskih jedinica i pravnih osoba sa propisanim odgovornostima i ovlastima. Upravljačka struktura HKO se realizira kroz:

- Ministarstvo znanosti, obrazovanja i sporta te Ministarstvo rada i mirovinskog sustava i Ministarstvo nadležno za regionalni razvoj. Navedena ministarstva obavljaju poslove koordinacije primjene i razvoja HKO-a.
- Nacionalno vijeće za razvoj ljudskih potencijala koje je središnje strateško tijelo Republike Hrvatske za razvoj HKO-a.
- Sektorska vijeća koja su dionički sastavljena savjetodavna i stručna tijela koja skrbe o razvoju ljudskih potencijala u skladu s potrebama tržišta rada unutar pojedinih sektora. Ustrojiti će se ukupno 13 sektorskih vijeća zaduženih za strukovna i 12 vijeća zaduženih za opća područja te jedno interdisciplinarno vijeće, ukupno 26.
- Stručne agencije koje djeluju u području obrazovanja bit će zadužene za provođenje vanjskog osiguravanja kvalitete HKO-a, uz nadležnost koja ovisi o obrazovnoj razini. Stručne agencije zadržavaju i dosadašnje zakonske ovlasti vezane uz inicijalnu akreditaciju programa.

Pored navedenih institucija i organizacija koje su dio organizacijsko – upravljačke strukture, u kvalifikacijskom sustavu će djelovati i druge pravne osobe koje omogućuju primjenu HKO. Važnije su:

- Akreditirane obrazovne ustanove koje svoj program za stjecanje kvalifikacije žele kroz inicijalnu akreditaciju i kasniji trajni nadzor kvalitete (npr. kroz reakreditaciju) uvrstiti u HKO.
- Akreditirane pravne osobe koje svoj program za stjecanje ili vrednovanje skupa ishoda učenja žele kroz inicijalnu akreditaciju i kasniji trajni nadzor kvalitete (npr. kroz reakreditaciju) uvrstiti u HKO.
- Pravne osobe koje će sukladno akreditiranim programima provoditi vrednovanje neformalno i informalno stečenih ishoda učenja, a koje će također zadovoljiti uvjete inicijalne akreditacije i trajnog nadzora kvalitete i time biti uvrštene u sustav HKO.

Kvalifikacijski okvir se izgrađuje kao instrument koji će građanima omogućiti jasnoću i kvalitetu stjecanja kvalifikacija, što će posredno doprinijeti između ostalog i poslodavcima te društvu u cjelini. U tom smislu ključni dionici i korisnici kvalifikacijskog okvira, koji nisu do sada navedeni i nisu formalno pozicionirani kroz zakonsku regulativu su i građani zainteresirani za stjecanje kvalifikacija ili certifikata o posjedovanju skupova ishoda učenja, ali isto tako i poslodavci, karijerni savjetnici, agencije za zapošljavanje, roditelji i društvo u cjelini.

Hrvatski kvalifikacijski okvir nije obvezni instrument uređenja sustava kvalifikacija što znači da će uz programe koji su uneseni u kvalifikacijski okvir i koji odgovaraju SK moći postojati i drugi programi koji ne zadovoljavaju te uvjete. Tu se ne radi samo o neformalnim programima nego i o dijelu formalnih koje danas postoje temeljem aktualnih propisa.

III. LOGIČKA STRUKTURA HKO

HKO svoju opisanu funkciju ostvaruje kroz uvođenje razmjerno složenog mehanizma odobravanja i osiguravanja kvalitete standarda zanimanja, skupova ishoda učenja i standarda kvalifikacije, što predstavlja podlogu za inicijalnu akreditaciju programa (nekog od tri navedene vrste). Ključna promjena paradigme koju kvalifikacijski sustav uvodi jest javno vođenje registara standarda zanimanja i kvalifikacija koji predstavljaju jasne i nedvosmislene opise ishoda učenja odnosno kompetencija koje su nužne za rad u određenom zanimanju ili su uključene u pojedinu kvalifikaciju, te inzistiranje na potpunoj implementaciji tih ishoda učenja u programe. Analizirajući postojeći način izrade i inicijalne akreditacije programa na nekoj razini obrazovanja, obično nalazimo nekoliko faza koje uglavnom nisu regulirane, iako često koriste propisane obrasce s jasno navedenim atributima:

- Istraživanje potreba društva kao podloga za definiranje sadržaja programa izvodi se obično kroz ankete poslodavaca, fokus grupe, praćenje razvoja područja i tehnološkog napretka, smjernice za sastavljanje obrazovnih programa koje mogu davati strukovna udruženja i drugo.

- Potrebe identificirane u prethodnoj fazi obično služe kao podloga za definiranje obrazovnih ciljeva, ishoda učenja i sadržaja obrazovnog programa (obično na razini nastavnog plana).
- Konačno se u fazi izvedbe programa u nekoj konkretnoj ustanovi i od strane konkretnog nastavnika planira se izvedbeni plan koji u sebi obično ima i raspored odvijanja nastave, potrebnu literaturu, materijalno - tehničke uvjete, popis tema koje su uključene u svaku nastavnu cjelinu itd.

Model inicijalne akreditacije programa unutar HKO značajno je složeniji jer osim propisanih formi pojedinih dokumenata uvodi i osiguravanje kvalitete u svim ključnim točkama provedbe postupka te u velikoj mjeri uključuje neovisna vanjska tijela (ponekad dionički sastavljena) ovlaštena procjenjivati kvalitetu predložene dokumentacije.

U logičkom smislu postupak započinje u trenutku kada zainteresirana pravna ili fizička osoba odnosno tijelo državne uprave koji za to imaju opravdani interes žele izvršiti upis standarda zanimanja, standarda kvalifikacije ili skupa ishoda učenja u registar. Ukoliko radi usporedbe sa već opisanim mehanizmom akreditacije programa pretpostavimo da se radi o zahtjevu obrazovne ustanove koja ima krajnji cilj akreditirati program za stjecanje kvalifikacije (obrazovni ili studijski program) postupak bi bio slijedeći:

A. Podloge za izradu standarda zanimanja

Budući da sukladno članku 12 Pravilnika [4] predlagatelj mora dokazati utemeljenost novog standarda zanimanja odnosno skupova kompetencija obrazloženjem strateške, sektorske i analitičke utemeljenosti zahtjeva, on ima mogućnost koristiti već postojeće stručne podloge za izradu standarda zanimanja u skladu s metodologijom koju je razvilo Ministarstvo nadležno za rad ili te podloge može samostalno razvijati. Stručne podloge obuhvaćaju Profile sektora i analizu potrebe i regulacije tržišta rada za ona zanimanja za koja se predlaže standard, a ako ih predlagatelj samostalno razvija one se baziraju na upotrebi već postojećeg on-line upitnika za poslodavce o potrebnim kompetencijama po zanimanjima te analizom i grupiranjem njihovih rezultata u formi tablice kompetencija. U dijelu formalne provjere predanog zahtjeva standarda zanimanja, Ministarstvo nadležno za rad provodi i vrednovanje kvalitete stručnih podloga.

B. Izrada standarda zanimanja

Standard zanimanja je nužni dio dokumentacije u postupku inicijalne akreditacije programa isključivo ukoliko se program, i prije njega standard kvalifikacije, akreditira za potrebe tržišta rada. Standard zanimanja, između ostalog, sadrži i skupove kompetencija potrebnih za rad na odgovarajućim radnim mjestima a koje su razvijene temeljem stručnih podloga. Provjera predloženog SZ izvodi se u dva stupnja. Prvi stupanj čini formalna provjera predane dokumentacije koju provodi Ministarstvo nadležno za rad. Temeljem odabira odgovarajućeg sektora, zahtjev se upućuje sektorskom vijeću/vijećima koje u području svoje nadležnosti provodi stručno vrednovanje uključujući i ocjenu opravdanosti pokretanja postupka za upis u Registar. Sektorsko vijeće je neovisni element osiguravanja kvalitete koji strukturom svojih članova osigurava dionički utjecaj ali i stručni razvoj sektora [9]. Pozitivno mišljenje sektorskog vijeća uvjet je upisa SZ u podregistar SZ, koji se u formalnom smislu provodi odlukom Ministra. Republika Hrvatska do uvođenja HKO nije koristila SZ, osim dokumenta sličnog sadržaja koji su od 2009 prisutni u srednjoškolskom strukovnom obrazovanju.

C. Izrada standarda kvalifikacije i skupova ishoda učenja

Standard kvalifikacije izrađuje se i predlaže sa tri moguće svrhe: za tržište rada, za nastavak obrazovanja i za ostale potreba pojedinaca i društva. Samo je u prvom slučaju SZ obvezni element za razvoj SK, dok u druga dva slučaja opravdanost predloženog SK treba dokazati na drugi način. SK se u osnovi sastoji od popisa SIU koji se u slučaju kvalifikacije za tržište rada izrađuju temeljem postojećeg SZ i tamo navedenih skupova kompetencija. Kako bi osigurao jasnoću, transparentnost i upravljivost u sustavu kvalifikacija HKO propisuje obvezu korištenja već postojećih SIU za izgradnju novih kvalifikacija kada je to moguće. Konkretno, ukoliko se izrađuje SK temeljem SZ koji sadrži više skupova kompetencija, kod izrade SK je prvo nužno za svaki od skupova kompetencija provjeriti postoji li odgovarajući SIU u javnom registru SIU. Ukoliko postoji nužno je koristiti taj postojeći kako bi se nove kvalifikacije izgrađivale od jednakih gravidnih elemenata kao i one već postojeće, osiguravajući na taj način modularnost i prenosivost ishoda učenja za građane. Za one skupove kompetencija za koje ne postoji odgovarajući SIU predlaže se dodavanje novog SIU u podregistar SIU. Svaki SIU raspoređuje se u odgovarajući od 26 sektora i u odgovarajuću od 8 razina i 4 podrazine HKO-a [3], a njegov upis u podregistar SIU izvodi se bilo pojedinačnim zahtjevom ili skupno u trenutku unosa novog SK u podregistar SK. Kao i kod SZ, pozitivno stručno vrednovanje sektorskog vijeća podloga je Ministru za upis SIU ili SK u odgovarajuće podregistre HKO.

Pojedini SIU u sebi sadrži, između ostalog, zapise 5-10 ishoda učenja te primjere njihovog vrednovanja (provjere znanja) i on može imati najmanje jedan kreditni bod (npr. ECTS). Cilj uvođenja kvalifikacijskog okvira je između ostalog svaki SIU koji izgrađuje bilo koji SK koristiti i za druge SK ako je primjenjiv. Dodatno, ako se neki SIU radi za kvalifikaciju koja je vezana za neki SZ, nužno je postojanje logičke poveznice između SIU i odgovarajućeg skupa kompetencija u SZ članak 29 Pravilnika [4]. Treba naglasiti da ne postoji obveza da svi ishodi učenja u pojedinom SIU odgovaraju u potpunosti kompetencijama u povezanom skupu kompetencija, nego SIU može biti i širi od skupa kompetencija. Usklađenost SIU i skupa kompetencija određuje sektorsko vijeće u postupku stručnog vrednovanja SK ili SIU.

D. Inicijalna akreditacija programa sukladno metodologiji HKO

Inicijalna akreditacija programa se do uvođenja HKO izvodila temeljem odgovarajućih normativnih akata specifičnih prije svega za razinu obrazovanja i vrstu programa koji se akreditira. U tom postupku su uglavnom

korišteni ulazni (engl. Input) parametri odnosno izvodila se provjera zadovoljenja formalnih uvjeta u smislu potrebnog prostora, opreme, nastavnog kadra i slično. Kod pojedinih programa postojalo je i stručno vrednovanje sadržaja programa, ali ono nije bilo vezano uz konkretan i javno objavljen standard koji odgovara točno tom programu i koji program mora zadovoljiti u smislu usklađenosti ishoda učenja. Kako bi osigurao kvalitetu, transparentnost i jasnoću kvalifikacija, HKO proširuje postupak inicijalne akreditacije programa uvođenjem dodatnih elemenata koji se odnose prije svega na usklađenost predloženog programa odnosno ishoda učenja koje izgrađuje sa izabranim SK ili SIU. Konkretno, sukladno članku 34 Pravilnika [4] propisuje se da je preduvjet za upis programa u Registar postojanje odgovarajućeg SK, odnosno odgovarajućih SIU upisanih u Registar i pozitivno mišljenje nadležne agencije o provedenom vrednovanju usklađenosti prijedloga programa s odgovarajućim SK, odnosno s odgovarajućim SIU. Programi za stjecanje kvalifikacija se upisuju temeljem odluke Ministra u podregistar SK, dok se programi za stjecanje i vrednovanje skupova ishoda učenja i programi za vrednovanje skupova ishoda učenja upisuju u podregistar SIU. U postupku vrednovanja nadležna stručna agencija u području obrazovanja više nema obvezu samo skrbiti o generalnim „input“ parametrima propisanim postojećom regulativom, nego joj je dana dodatna obveza provjeriti usklađenost ishoda učenja ugrađenih u program sa pripadnim SK te provjeriti zadovoljenje specifičnih zahtjeva za stjecanje i vrednovanje navedenih u SK i SIU. Predlagač koji program želi akreditirati prema HKO slobodan je, kao i prije HKO, samostalno oblikovati program u smislu njegovog izvedbenog plana, rasporeda izvođenja, literature i slično, ali je dužan u njega ugraditi i sve ishode učenja uključene u pripadni SK, te dodatno zadovoljiti uvjete za stjecanje i vrednovanje propisane unutar SK i svakog njegovog SIU. Postupak inicijalne akreditacije programa koji se predlažu radi nastavka obrazovanja ili ostalih potreba pojedinaca i društva biti će nešto kraći i jednostavniji jer on za zahtjeva izradu stručnih podloga niti standarda zanimanja. Ipak, kod primjerice kvalifikacija koje se predlažu za nastavak obrazovanja bit će nužno identificirati odgovarajuće takve kvalifikacije u HKO.

Logička organizacija HKO i veze pojedinih elemenata opisane su unutar ovog poglavlja, dok je fizička implementacija registra HKO predviđena kroz izgradnju ukupno tri podregistra kako slijedi:

- Podregistar SIU koji sadrži: SIU, programe za stjecanje i vrednovanje SIU, programe za vrednovanje SIU, popis ovlaštenih pravnih i fizičkih osoba za dodjelu potvrde o stečenim SIU i drugo;
- Podregistar SZ koji sadrži: SZ, skupove potrebnih kompetencija za odgovarajuća zanimanja i drugo;
- Podregistar SK koji sadrži: SK, programe za stjecanje kvalifikacija, popis ovlaštenih pravnih osoba za dodjelu isprave o stečenoj kvalifikaciji i drugo.

IV. ER MODEL PODATAKA HKO

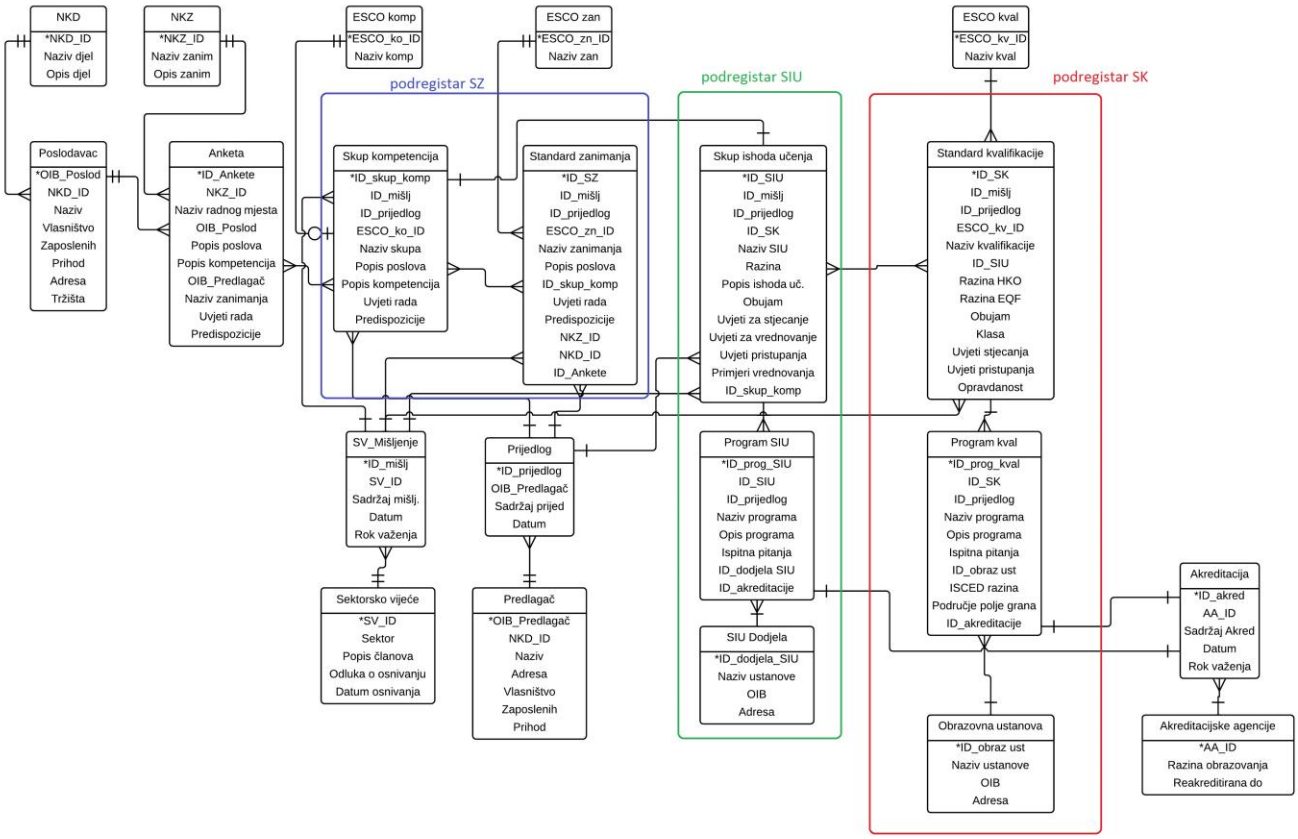
A. *Metodologija izrade*

Za prikaz podatkovnog modela biti će korišten entitetsko – relacijski dijagram (ERD) temeljen na Crow's Foot notaciji [10] koji počiva na analizi potreba definiranoj zakonskim rješenjima i u osnovi opisanoj u prethodnim poglavljima. Potporu procesu modeliranja entiteta i njihovih veza dali su propisani obrasci za predlaganje SZ, SIU i SK jer vrlo jasno navode set svojstava odnosno atributa koji će biti ugrađeni u dijagram. Budući da je dio zakonske regulative još uvijek u nastajanju, razvoj će biti ograničen samo na logički model podataka dok bi se implementacija fizičkog modela trebala realizirati u trenutku izrade specifikacije informacijskog sustava HKO. Također, iako su Zakonom [3] definirana tri podregistra unutar Registra HKO, predloženi model podataka biti će izgrađen na temelju šireg shvaćanja HKO koji u sebi uključuje i moguće buduće vanjske reference sustava (npr. ESCO ili registar ljudskih potencijala), te vodeći računa o osiguravanju kvalitete i institucijama koje su za njega zadužene. To konkretno znači da on neće biti ograničen samo na tri navedena podregistra nego da će nastojati prepoznati i povezati sve entitete ključne za uspostavu HKO.

B. *Popis entiteta*

Entiteti prikazani ER modelom dani su tablicom 1.

Oznaka	***Opis***
Standard zanimanja	Standard zanimanja
Skup kompetencija	Skup kompetencija
SIU	Skup ishoda učenja
Standard kvalifikac	Standard kvalifikacija
NKZ	Nacionalna klasifikacija zanimanja
Program za kval	Program za stjecanje kvalifikacije
Program za SIU	Program za vrednovanje ili stjecanje i vred. SIU
Prijedlog	Prijedlog za odobrenje Skup ko, SIU, SK ili SZ
SIU dodjela	Akreditirana osoba za dodjelu potvrde o SIU
Obrazovna ust.	Akreditirana osoba za stjecanje i dodjelu SK
ESCO	ESCO komp i ESCO kval taksonomija naziva
Sektorsko vijeće	Sektorsko vijeće
AA	Akreditacijska agencija
Akreditacija	Odluka o akreditaciji
Poslodavac	Poslodavac
Anketa	Podloga za izradu SZ (anketni rezultati)
NKD	Nacionala klasifikacija djelatnosti
SV Mišljenje	Odluka o vrednovanju skup komp. SZ, SK, SIU
Predlagač	Predlagač novog skup komp., SZ, SK ili SIU



Slika 1. Prijedlog logičkog ER modela podataka HKO

C. *Opis predloženog ER logičkog modela*

Sukladno slici 1, predlaže se logički model podataka koji osim zakonom propisanih podregisara koristi i brojne vanjske referentne izvore podataka i javne registre na razini Republike Hrvatske i EU. Prikaz modela je radi ograničenosti dostupnog prostora i preglednosti donekle apstrahiran, tako da nisu prikazane pojedine relacije kojima se uključuju atributi iz javnih registara, ali je njihova poveznica jasno prepoznatljiva kroz navođenje identičnih i intuitivnih naziva atributa. Osnovni domaći vanjski registri koji se koriste su Nacionalna klasifikacija djelatnosti (NKD) i Nacionalna klasifikacija zanimanja (NKZ). Predviđeno je korištenje NKD i NKZ šifre sa punim dostupnim brojem znamenki. Nadalje, predviđeno je i korištenje sva tri ključna elementa ESCO taksonomije radi koherentnosti naziva skupina kompetencija, zanimanja i kvalifikacija sa EU taksonomijom koja omogućuje i lakše buduće povezivanje na EURES portal tržišta rada. Ova poveznica prema EURES portalu nije predložena unutar modela sa Slike 1 budući da ona predstavlja definiranje dodatnog registra ljudskih potencijala čije uvođenje jest predviđeno strateškim dokumentima, ali ne postoji za sada provedbena regulativa niti su poznati temeljni atributi.

Izrada novog prijedloga moguća je od strane predlagača koji sukladno Zakonu [3] može biti pravna ili fizička osoba. Ukoliko se radi o prijedlogu skupa kompetencija ili SZ, predlagač je obvezan pripremiti odgovarajuće metodološke podloge koje su opisane u modelu podataka i prikazane unutar entiteta Anketa. Ove podloge predlagač će obraditi koristeći primjerice pristup tablice kompetencija [8] i na temelju njih predložiti skupove kompetencija ili standard zanimanja. Nakon provođenja osnovne formalne provjere koja nije prikazana modelom podataka, prijedlog predlagača u obliku neodobrenog skupa kompetencija, SZ, SIU ili SK upućuje se na odgovarajuće sektorsko vijeće koje daje svoje mišljenje. Sukladno prikazanom modelu podataka, poveznicom mišljenja i sektorskog vijeća osiguran je dostup ostalim podacima koji su nužni dio SIU, SZ i SK a koja opisuju sektorsko vijeće kroz dokument o njegovom osnivanju, mandat i članove. Skupovi kompetencija su gradivni elementi SZ, dok su s druge strane oni i direktno povezani sa odgovarajućim SIU vezom 1:1. Naime, kvalifikacijski okvir i njegov informacijski sustav mora dati jasnu informaciju o tome koji su sve skupovi kompetencija koji se primjerice traže na tržištu rada pokriveni sa SIU, što znači da su pokriveni nekim vidom stjecanja i/ili vrednovanja, a koje obrazovni sustav trenutno ne pokriva. Objekti unutar entiteta SIU predstavljaju također i temeljne gradivne elemente SK i to poveznicom više na više budući da svaki SIU može sudjelovati u više SK i da svaki SK može imati više SIU.

Končano, pojedini SK i pojedini SIU mogu imati više odgovarajućih programa za stjecanje i/ili vrednovanje što je prikazano vezom jedan na više. Ovi programi provode se od strane akreditiranih ponuđača, što je evidentirano kroz zapis o adekvatnoj akreditaciji i njenom roku važenja. Budući da je predviđen parametar vremena trajanja pojedinog objekta kao što su SK, SZ, SIU, Program i slično, očekuje se od informacijskog sustava trajno pohranjivanje svih objekata uz postojanje informacije o njihovoj aktivnosti. Tako je moguće da će SIU istog naziva koji se koristi u više SK u nekom trenutku biti promijenjen. Zapis starog objekta ostati će trajno pohranjen u bazi podataka kako bi se u bilo kojem trenutku mogao rekonstruirati sadržaj bilo kojeg SK, ali će biti označen kao neaktivan uz oznaku perioda njegove aktivnosti.

Povezanost pojedinih entiteta trebala bi u konačnici omogućiti primjerice dobivanje brzog i automatskog odgovora na pitanje usklađenosti pojedine kvalifikacije koju ima pojedinac sa zahtjevima nekog radnog mjesta. Kako bi sustav moga dati odgovor na takvo pitanje krenuo bi od usporedbe skupova kompetencija koje se nalaze u SZ koji je vezan uz pojedino radno mjesto, te bi preko njih došao do popisa SIU koji su sa njima jednoznačno povezani. Poznavanjem šifri svih SIU koji odgovaraju skupinama kompetencija, razmjerno je lako pronaći SK koji u sebi sadrži njihov najveći broj i pripadajuće programe za stjecanje SK. Odgovor koji bi zainteresirani građanin mogao dobiti na tako postavljeni upit bio bi popis skupova kompetencija za koje ne postoje povezani SIU (dakle kompetencija koje nije moguće trenutno akreditirati jer ne postoje za njih programi), te popis SIU koji nedostaju osobi koja ima određenu kvalifikaciju kao i popis programa i ponuditelja kod kojih je takve SIU moguće steći ili certificirati.

V. ZAKLJUČAK

Zakonom o HKO [3] te pravilnikom o registru HKO [4] Republika Hrvatska je napravila značajan iskorak u implementaciji nacionalnog kvalifikacijskog okvira te si je postavila zadatak ne samo izgraditi zakonsku regulativu HKO nego i prateći informacijski sustav. Budući da se radi o složenom i sveobuhvatnom instrumentu koji objedinjuje ne samo sustav obrazovanja nego i tržište rada i zapošljavanje, predmetni informacijski sustav planira se razvijati u suradnji Ministarstva nadležnog za obrazovanje i Ministarstva nadležnog za rad, koristeći pri tome postojeće javne registre poput NKZ i NKD te imajući u vidu obvezu budućeg povezivanja HKO sa Europskim kvalifikacijskim okvirom ali i ESCO inicijativom i EURES portalom. Već samo navođenje pojedinih atributa unutar podzakonskih akata, koji predstavljaju vanjske reference unutar nekih entiteta dalo je jasan poticaj da se preloženi ER logički model podataka ne veže samo uz tri propisana podregistra, nego da se obuhvati nešto širi kontekst. Na ovaj način cilj je izbjeći izgradnju novog informacijskog sustava bez njegovog povezivanja na postojeću infrastrukturu, budući da je i HKO zamišljen kao neobvezujući evolutivni razvojni instrument koji ne narušava postojeće stanje nego ga nastoji dodatno unaprijediti. Ovakav pristup razvoju HKO, pa time i njegovog informacijskog sustava, nastao je na temelju dioničkog rada na razvoju sustava ali i niza stranih negativnih iskustava koja su pratila nagle i nepripremljene reforme ili kopiranje tuđih rješenja koja nisu uklopiva u pojedini nacionalni kontekst [11].

Tako su definirani i entiteti poput sektorskih vijeća ili akreditacijskih agencija koje predstavljaju upravljačke elemente sustava kvalifikacija, dok su svoje mjesto pronašli i nužni dokumenti poput akreditacijskih preporuka ili mišljenja sektorskih vijeća ili obveznih metodoloških podloga.

Predloženo rješenje nastalo je na temelju promišljanja trenutno postojećih zakonskih rješenja, uzimajući u obzir kroz njih propisane entitete i atribute te njihove relacije, ali bez implementacije rješenja u stvarno okruženje. Zbog toga očekujemo da model predložen ovim člankom može biti korisna vodilja kod pripreme fizičkog modela podataka, ali je vrlo izvjesno da će u implementaciji stvarnog rješenja biti potrebno uvesti dodatne entitete i niz internih atributa koji će osigurati potpuno uklapanje svih nužnih internih i eksternih elemenata. Konačno, imajući u vidu kako se radi o nacionalnoj podatkovnoj infrastrukturi koju će koristiti brojni građani i institucije i koja će osigurati jasnoću i prepoznavanje naših kvalifikacija i u inozemstvu, kod dizajniranja baze podataka biti će potrebno posebni naglasak staviti na nužnu buduću interoperabilnost, racionalizaciju i optimizaciju upita i strukture baze podataka.

Autori ovog rada proveli su istraživanje na populaciji maturanata i brucoša u Hrvatskoj na temu odabira obrazovnog puta i karijere. Istraživanje je obuhvatilo 4968 anketiranih koji su se izjašnjavali o odabiru svoje karijere, željama u daljnjem obrazovanju i planovima za budućnost. Autori istraživanja poslužili su se raspoloživim (besplatnim) informacijskim tehnologijama: Facebook i *open source* platformama – PHP i MySQL. Kombinacijom tri navedena alata napravili su aplikaciju za istraživanje te na efikasan i efektivan način dosegli ciljanu publiku.

Istraživanje je bilo segmentirano u dvije skupine: Maturanti i brucoši 2013., a sastojalo se od 25 pitanja po skupini. Kako ispitanici pripadaju generacijski sukcesivnim i analognim populacijama, pored statičkih podataka, voditelji projekta stekli su uvid i u dinamiku istih varijabli sličnih populacija.

Cilj istraživanja bio je dobiti uvid u motivaciju za odabir studija i proces donošenja odluke o odabiru studija kod maturanata te zadovoljstvo upisanim studijem kod brucoša. Rezultati istraživanja namijenjeni su tome da povećaju efikasnost komunikacije između fakulteta i maturanata zainteresiranih za upis studija.

I. UVOD

Polazeći od ciljeva istraživanja – uvid u motivaciju za odabir studija i proces donošenja odluke o odabiru studija kod maturanata te uvid u zadovoljstvo upisanim studijem kod brucoša – organizatori su se našli pred nekoliko ključnih izazova od kojih su neki u proturječju, kao primjerice doseg što većeg broja ispitanika i ograničen budžet za provedbu istraživanja.

Izazovi su kako slijedi:

1. Definiranje segmenata ispitanika
2. Na temelju definiranih segmenata odabir medijskih kanala za dosezanje tih segmenata.
3. Definiranje parametara ankete i definiranje pitanja na temelju tih parametara
4. Motiviranje ispitanika da popune anketu iskreno i u potpunosti.
5. Pronaći tehnologijsko rješenje (platforma, programski kod, baza podataka, korisničko sučelje)
6. Pronaći mehanizam provjere valjanosti ispunjene pojedinačne ankete
7. Projekt razviti u što kraćem roku i uz minimalni raspoloživi budžet
8. Podatke dobivene kao rezultat istraživanja organizirati u korisne informacije te iste prezentirati javnosti na efikasan način

Kako bi riješili prikazane izazove organizatori istraživanja podijelili su ih na organizacijske, marketinške i tehnologijske te definirali poslove prema toj podjeli. Na taj način su mogli pokrenuti paralelne procese kako bi se skratilo vrijeme izvedbe projekta. Najveći segment prikazanih izazova potpali su pod marketinški segment koji je uključivao dva odvojena aspekta. Prvi; dizajn i arhitektura cijelog istraživanja i drugi; odabir medija i partnera u projektu te odnosi s javnošću. Sljedeći ne manje važan segment izazova obuhvaćen je tehnologijskim procesima koji su uključivali razvoj programskog koda, baze podataka te povezivanje navedenog sa sustavom Facebook aplikacije, kako će kasnije u tekstu biti preciznije razjašnjeno. Posljednji proces, ali ne manje važan, odnosi se na organizaciju i povezivanje različitih tipova izvođača u projektu

(marketing, mediji, programiranje, dizajn) te brigu oko budžetiranja i same efikasnosti projekta.

I. ISTRAŽIVAČKI PROCESI U PROJEKTU

Iz definiranih izazova u uvodu proizlazi da su poznavanje marketinga i stručna primjena marketinških znanja i vještina ključni za ovaj projekt. Dva su bitna aspekta:

1. Poznavanje procesa segmentacije i istraživanja tržišta kao jednog od osnovnih funkcija marketinga[1].
2. Poznavanje medijske komunikacije i poglavito poznavanje digitalnog marketinga kao interdisciplinarnog područja koje obuhvaća i tehnologijske aspekte projekta.

A. Proces segmentacije i arhitektura istraživanja

Prema definiciji istraživanja, metodologiji i tehnikama ovo istraživanje je deskriptivno s ciljem opisivanja osobina određene populacije (maturanti i brucoši), njihovih stavova, uvjerenje i ponašanja. Instrument istraživanja je bila anketa. Istraživanje također nosi i kauzalne elemente jer dovodi u vezu odabir studija, poziciju odabira i zadovoljstvo odabranim. Tehnike korištene u anketi su bile zaokruživanje i nadopunjavanje.

Polazeći od ciljeva istraživanja prvi korak je bio precizno odrediti segment ispitanika u populaciji. Kako se radi o tematici odlučivanja o upisu studija te zadovoljstvu upisanim studijem, samo definiranje segmenata nije predstavljao problem. U vrijeme provođenja istraživanja (lipanj, 2013.) segmenti su definirani po demografskom principu: maturanti i brucoši za školsku i akademsku godinu 2012./2013., odnosno preciznije za maturante svi koji su namjeravali upisati studij akademske godine 2013./2014., dakle i osobe koji su maturirali i ranijih godina.

Od demografskih varijabli prikupljene su sljedeće: godina rođenja, spol, završena srednja škola, uz obavezno navođenje prvih pet odabranih fakulteta. Tražena je i jedna geografska varijabla a to je grad završene srednje škole.

Složeniji proces koji je uslijedio bilo je precizno definiranje pitanja ključnih za ispunjenje osnovnog cilja istraživanja. Kako se ovdje radi o psihografskim varijablama (motivi, namjere i odluke) te o bihevioralnim varijablama (upis) potrebno je bilo napraviti kratko pred-istraživanje na malom uzorku studenata u vidu intervjua. To pred-istraživanje poslužilo je kao orijentacijski okvir za definiranje pitanja. Kao uzorak „poslužili“ su studenti 1. godine studija primijenjenog računarstva na Visokom učilištu Algebra – Visokoj školi za primijenjeno računarstvo.

Nadalje, kako je administracijski proces kvalifikacije i upisa na studij strogo definiran, ta je činjenica poslužila kao baza za ona pitanja koja se odnose na administrativne aspekte upisa poput segmentacije izbora studija i sustava bodovanja[2].

Dio ovog procesa koji je zahtijevao složeniji pristup bio je aspekt procesa odlučivanja i definiranje parametara koji utječu na odluku. Pored intervjua u pred-istraživanju organizatori su uzeli u obzir i mnoga istraživanja koja su rađena na adolescentima, a tematika im je bila upravo donošenje odluka[3].

U spomenutim istraživanjima ustanovljene su karakteristike adolescenata (društvene, kognitivne, emotivne, bihevioralne) koje određuju načine na koje adolescenti donose odluke, a razlikuju se, u manjem ili većem iznosu u odnosu na donošenje odluka kod „odraslih“ ljudi.

Adolescencija je razdoblje psihološkog, kognitivnog, društvenog i emotivnog rasta i promjena. Zbog intenzivnijih mijena adolescenti će biti skloniji rezoniranju koje je u suprotnosti sa činjenicama, skloniji rezoniranju temeljenom na lažnim premisama, više će se oslanjati na procjenu nego na pronalaženje i analiziranje podataka iz okoline.

Kako adolescenti u prosjeku provode podjednako vremena sa svojim vršnjacima kao i sa svojim roditeljima za pretpostaviti je da će utjecaji jednih i drugih na odluke pojedinca biti podjednako jak, a ti utjecaji mogu međusobno biti i proturječni. Jači utjecaj vršnjaka primijećen je kod mlađih adolescenata dok se kod starijih adolescenata umanjuje. Pokazalo se također da je kod društvenih utjecaja na odluku važnije koga adolescent identificira i odabire kao „utjecatelja“ (eng. *influencer*), tek onda taj određeni „utjecatelj“ ima više upliva na odluku pojedinca. S emotivnog aspekta prepoznato je da se tijekom samog procesa odluke važno emotivno stanje. Ako je ono pozitivno adolescent je manje sklon da sagleda negativne posljedice loše odluke. Utjecaj vršnjaka je i ovdje prisutan jer se u doba adolescencije ispitanici izjavljuju da je najbolje osjećaju kad su s vršnjacima – o odnosu na vrijeme kad su sami – tada se osjećaju dosadno.

Adolescenti su populacija koja dosta konzumira medije, prema istraživanjima[4], provode 4.5 sati gledajući televiziju, 1.5 sati na računalu, a 7.5 sati konzumiraju medije za zabavu. Posljedica toga je da se ne može zanemariti utjecaj medija na donošenje odluke.

Imajući sve navedeno u vidu organizatori su sastavili anketu kako bi dobili što bolji uvid tko i što utječe na odluke o upisu studija, u stvari na odabir karijere.

S obzirom da se radi istraživanje na dvije različite populacije – maturanti i brucoši, oformljene su dvije slične, ali ne i iste ankete. Cilj ovakvog načina istraživanja je da se pokuša prepoznati odnos između procesa odluke i zadovoljstva istom te da se prepoznaju trendovi na analognim populacijama.

Poseban naglasak anketnih pitanja stavljen je na već spomenute psihografske čimbenike koji se tiču stava o određenim mogućnostima studiranja (privatne naspram državnim studijima), motivima upisa i vanjskim utjecajima na odluku.

B. *Odabir medija i partnera*

Prilikom odlučivanja o načinu provođenja ankete organizatori su si postavili dva općenita, ali važna cilja – efikasnost i efektivnost. Efikasnost se trebala manifestirati kroz maksimalni doseg ankete (po broju ispitanika i kvalitetnoj segmentaciji). Efektivnost se trebala manifestirati kroz maksimalni broj kvalitetno ispunjenih anketa. Kako samo Visoko učilište Algebra nema adekvatne medijske alate, za pronalaženje načina postizanja željenog dosega organiziran je *brainstorming* s postavljenim zahtjevima efikasnosti i efektivnosti.

Već u ovoj fazi donesena je odluka da će platforma za provođenje ankete biti Facebook, temeljila se na javno dostupnim istraživanjima[5] i spomenutom pred-istraživanju koje je u vidu intervjua provedeno prije. Ona se temeljila na sljedećim prednostima:

1. Facebook koristi iznimno velik postotak adolescenata.
2. Adolescenti su dobro „umreženi“ i u prosjeku imaju 300 prijatelja na Facebooku.
3. Facebook nudi vrlo fleksibilne mehanizme za povezivanje prilagođenih aplikacija sa svojom bazom.
4. Facebook nudi mogućnost preuzimanja podataka od korisnika (uz njihovu dozvolu) koji također pomažu u stvaranju psihografske slike populacije nad kojom se istraživanje vrši.
5. Medijska moć Facebooka leži i u činjenici da se akcije njegovih korisnika dijele i mogu ih pratiti ostali umreženi članovi – prijatelji.

Nadalje, organizatori su se u ovoj fazi suočili s izazovom – kako dosegnuti ciljanu populaciju, kako bi ih uopće usmjerili na anketu smještenu na Facebooku. Odabrana je strategija da se pronađe odgovarajući medij koji bi za ovu svrhu imao najpreciznije ciljanje. Dodatni zahtjev je bio da s obzirom na vrlo ograničen budžet taj medij ne bude preskup i u obzir su zbog svoje interaktivnosti i povoljne cijene dolazili samo *online* mediji.

Analizom različitih medija, od vodećih hrvatskih portala do specijaliziranih blogova odabran je jedan portal čija je tematika vrlo bliska problematici projekta – srednja.hr. Prednosti ovog portala su visoka posjećenost srednjoškolaca motiviranih za upis studija kao i vezana Facebook stranica idealna za inicijalni medijski doseg. U vrijeme provođenja istraživanja gotovo 20000 *fanova*. Dogovorom između Visokog učilišta Algebra i portala srednja.hr definiran je partnerski odnos u projektu i osiguran je aspekt efikasnosti provođenja istraživanja.

Sljedeći korak bio je osigurati što veću efektivnost, tj. motivirati ispitanike da u što većem broju ispune anketu savjesno i do kraja. Dio ovog zahtjeva zadovoljile su sljedeće karakteristike projekata: Kako adolescenti prema istraživanju[6] koriste društvene mreže na dnevnoj bazi, njih 3/4, velika je vjerojatnost da će zamijetiti ponuđenu anketu odnosno preciznije percipirat će njeno početno otvaranje kao minimalan napor. Anketa je vizualno „ugrađena“ u samu Facebook stanicu stoga im i okruženje anketiranja neće biti strano. Dodatna karakteristika projekta koja je povećavala vjerojatnost da će anketa biti efektno ispunjena se skrivala u tome da je tema ispitanicima bila bliska (maturant i brucoši), i da su bili motivirani sudjelovati u tematici upisa na studij.

Ipak sama familijarnost sa korisničkim sučeljem te bliskost s tematikom ne bi bili dovoljni. Organizatori su procijenili da je bila potrebna dodatna motivacija kako bi ispitanici ispunili anketu do kraja. S odabranim partnerima i sponzorima dogovorena je suradnja na način da su svim ispitanicima nudili mogućnost da osvoje nagrade. Partneri su za uzvrat dobili medijsku prisutnost u projektu.

Zadatak medijskog partnera, srednja.hr bio je da u relativno kratkom roku (14 dana) mobilizira što veći broj ispitanika. Glavni kanali promoviranja ankete bili su sami portal te pripadajuća Facebook stranica.

II. TEHNOLOGIJSKI PROCESI U PROJEKTU

Nakon postavljanja zahtjeva, ciljeva i strategija projekta te nakon izrade arhitekture istraživanja pristupilo se odabiru tehnologija na kojima će se istraživanje vršiti. Zahtjevi koje su trebala zadovoljiti tehnologijska rješenja kretali su primarno od korisnika, a onda se razmišljalo o resursima potrebnim za izradu:

1. Kvalitetno korisničko sučelje, minimalan napor za ispitanika i jednostavnost korištenja.
2. Kvalitetno programsko rješenje, baza podataka i server.
3. Jednostavnost povezivanja s platformom Facebooka i Graph APIjem.

Kod izrade korisničkog sučelja dizajner se vodio smjernicama dobrog UXa (*User eXperience*) i odlučio se na minimalistički pristup kako bi jasno istaknuo pitanja, polja za upis i ostala polja obrasca. Kako je anketa opširna bilo je potrebno veliki obrazac za unos i odabir odgovora podijeliti na više manjih dijelova, njih pet. Na taj način se smanjila vjerojatnost da će korisnik odmah odustati od ispunjavanja. Dodatno, u svakom koraku naznačeno je točno koliko je koraka odrađeno i koliko je još do kraja kako bi korisnik u svakom trenutku znao gdje se nalazi.

Nadalje, specifičnost obrasca je bila njegova kauzalna izmjenjivost upisnog polja. Primjerice, ispitanik je odabirom grada završene srednje škole pokrenuo pozadinski proces koji je iz baze podataka ispitaniku ponudio srednje škole koje se nalaze samo u tom gradu. Također isti princip je primijenjen kod odabira fakulteta, jer se za svaki odabrani fakultet kauzalno nudio studij na

tom fakultetu. Ovaj pristup je zakomplicirao izvedbu programskog koda, ali je za rezultat imao smanjenje napora za ispitanika što je navedeno kao primaran cilj korisničkog sučelja. Ovo je tipični primjer prioriteta u procesu donošenja odluka o dizajnu korisničkog sučelja. Oko odabira programske platforme nije bilo dileme, jer je zbog raspoloživih resursa odabrana kombinacija PHP programskog jezika i MySQL baze podataka. I jedno i drugo rješenje razvijeno je na *open source* tehnologiji.

Kako je PHP popularan jezik, SDK (*software development kit*) elementi postoji i za Facebook[7] tako da nije bilo dodatnih zahtjeva za programiranjem procesa komunikacije između programskog koda istraživanja i samog Facebooka. Korišteni Facebook SDK obuhvaća gotove unaprijed pripremljene funkcije koje služe za spajanje na Facebook Graph API[8]. Ovim rješenjima programer koristi gotove Facebook funkcije ugrađene u vlastiti kod kako bi slao parametre s ciljem dodavanja, izmjene, brisanja i čitanja podataka iz Facebook baze podataka.

Čitanje i općenito pristup podacima iz Facebook baze je strogo kontroliran proces i Facebook „pazi“ da se ti podaci ne mogu čitati bez odobrenja vlasnika pojedinog profila. Iz tog razloga nezaobilazan korak u pristupanju anketi je bilo odobrenje korisnika(ispitanika) kako bi organizator ankete mogao raspolagati podacima unesenim u Facebook profil. Facebook često mijenja ili bolje rečeno dodaje nove značajke svojoj Graph aplikaciji stoga je preporučljivo pratiti novosti na Facebook službenim stranicama za *developere*[9].

Podaci koji se ovim putem automatizmom preuzimaju od korisnika su sljedeći: ime, prezime, spol, e-mail adresa, datum rođenja, završena srednja škola, stranice koje je kontaktirani korisnik *lajkao*. Prednosti ovog rješenja su velike. Za samog ispitanika to znači da nema potrebe za ispunjavanjem navedenih polja, a za organizatora ankete uvid u profil korisnika koji nadilazi klasične demografske karakteristike. Prvenstveno se mogu analizirati afiniteti i društvene karakteristike vlasnika profila.

III. ORGANIZACIJSKI PROCESI U PROJEKTU I BUDŽETIRANJE

Produkcija i organizacija samog projekta navedeni su kao poseban proces jer obuhvaćaju angažiranje vanjskih suradnika (mediji, partneri, dobavljači tehnologija) kroz prizmu ograničenih resursa (budžet, vrijeme). Mediji i partneri mogli su biti kontaktirani tek u fazi projekta kad su bili detaljno razrađeni plan nastupa (komunikacija prema ciljnoj skupini), arhitektura, metodologija i tehnike istraživanja. U ovom procesu dakle, pored stručnih znanja i organizacijskih sposobnosti bile su potrebne i persuazivne pregovaračke vještine za pridobivanje medija i partnera u projekt u uvjetima niskog raspoloživog budžeta. U konačnici je zahvaljujući partnerskom odnosu i ravnopravnom investiranju vremena i resursa svih uključenih strana dogovoren kompenzacijski model gdje se moneta razmjene manifestirala kroz uložene radne sate, medijsku vrijednost *brandova* (srednja.hr, sponzori) i stručnost u provedbi i organizaciji projekta (Visoko učilište Algebra – Visoka škola za primijenjeno računarstvo).

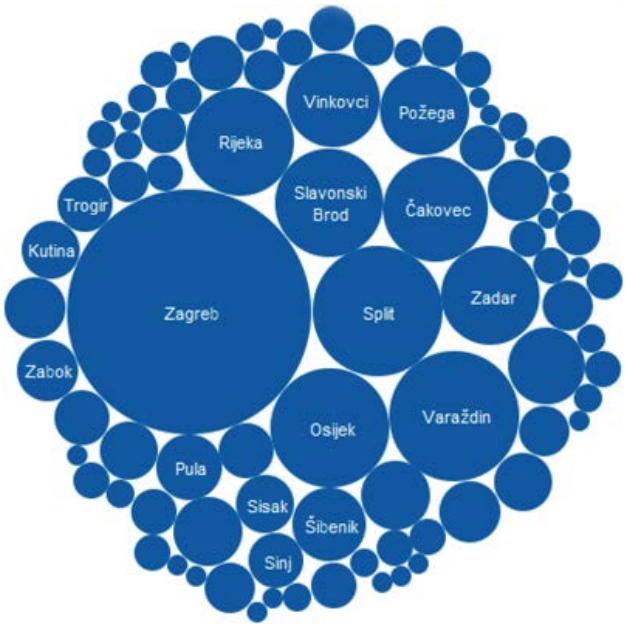
IV. REZULTATI ISTRAŽIVANJA

Po završetku anketiranja nastupio je proces obrade podataka i pronalaženje vrijednih informacija iz baze. Prije sistematičnog pristupa podacima baza se morala iščistiti od neispravno unesenih podataka, dvostrukih ili višestrukih unosa, do lažnih unosa podataka. Kao posebni parametar za provjeru valjanosti ankete uzet je *timer* postavljen s ciljem da se izmjeri vrijeme provedeno uz anketu. Odabirom svih ispitanika po parametru provedenog vremena izbačeni su svi koji su anketu ispunili za manje od 3 minute, koliko je bilo otprilike potrebno da se najbržim klikanjem bez čitanja pitanja završi anketa.

A. *Demografski i geografski podaci*

Starost ispitanika određena je godinama rođenja prema distribuciji: 63% rođenih 1994., 19% rođenih 1993., 18% rođenih 1995. godine. 58% ispitanika bilo je ženskog, a 42% ispitanika muškog spola. Distribucija ispitanika po gradovima prikazana je grafikonom proporcija na slici 1.

Ispitanici su u prve izbore odabirali studije u Zagrebu, a tek je jedan osječki fakultet (filozofski) dospio u prvih deset najpoželjnijih (TABLICA I.).



Slika 1. Prikaz proporcija frekvencije gradova u kojima su sudionici pohađali srednju školi

B. Psihografski i biheviоralni podaci

Prvo važno pitanje koje se tiče procesa odlučivanja bilo je pitanje motiva upisa odabranog studija. Od više ponuđenih odgovora izdvojit će se koncentracije iz kojih se mogu izvući zaključci.

1. Kao najvažniji parametar odluke iskristalizirao se osobni afinitet prema tematici studija – 81% maturanata 2013. godine izjavilo kako je to svakako važan motiv
2. Društveni aspekt pokazao se utjecajan kod važnosti upoznavanja novih kolega sa sličnim pogledima na svijet i profesionalnu karijeru – 89,85% izjavilo je da im je to važno ili relativno važno
3. Upitani pak za motiv u vidu poznanika ili prijatelja koji već studiraju na odabranom fakultetu, tek je 10,66% izjavilo da im je to svakako važno, a čak 56,78% da im nije uopće važno
4. Racionalni aspekti motivacije poput visine plaće i perspektive zapošljavanja u struci navedeni su većinom kao relativno važni – u rasponu od 40%-50% za afirmativne odgovore.
5. Situacijski parametar motivacije u smislu ne postojanja prilike za zapošljavanje u trenutku polaganja mature ili odabira studija većinom je odbačen kao važan – 82,06% nije se složilo s ovakvom motivacijom

Pored motivacije organizatori istraživanja željeli su ustanoviti tko i koliko može utjecati na odluku o odabiru studija – karijere (društveni utjecaj). Na pitanje tko je utjecao na njihov odabir studija odgovori su otkrivali sljedeće:

1. Na odluku o upisu najviše su utjecali roditelji i prijatelji/poznanici koji rade u struci odabranog studija, a ponajmanje vršnjaci (poznanici 52%, roditelji 58%)
2. Kod analize odgovora na ovo pitanje ustanovljeno je da je kod onih studenata koji su nezadovoljni odabranim studijem veći utjecaj imali su roditelji nego kod onih studenata koji su zadovoljni odabirom.

Kod pitanja što je utjecalo na odabir studija, gdje su ponuđeni razni parametri od troškova studiranja, preko blizine stanovanja do certifikacijskih pogodnosti tijekom studija i utjecaja medija, odgovori su pokazali sljedeće:

1. Očekivano su najveći utjecaj imali troškovi studiranja, ali i blizina stanovanja (oko 2/3 ispitanika)
2. Posjedovanje diplome priznate i u inozemstvu, te međunarodni certifikati imali relativno manji utjecaj na odluku (gotovo 50% ispitanika izjavilo je da ova stavka nema utjecaj na odluku)

TABLICA I. NAJPOŽELJNIJI FAKULTETI 2013. GODINE

Redni broj	Fakultet	1. odabir
1	Filozofski fakultet (Zagreb)	6,16%
2	Ekonomski fakultet (Zagreb)	4,68%
3	Fakultet elektrotehnike i računarstva (Zagreb)	4,05%
4	Tehničko veleučilište u Zagreb	3,46%
5	Pravni fakultet (Zagreb)	3,33%
6	Učiteljski fakultet u Zagrebu	3,04%
7	PMF (Zagreb)	3,00%
8	Medicinski fakultet (Zagreb)	2,78%
9	Zdravstveno veleučilište u Zagrebu	2,57%
10	Filozofski fakultet (Osijek)	2,53%

3. Utjecaj medija naveden je samo kao djelomičan, više od 50% ispitanika navelo je da utjecaja medija nema, a tek oko 10% ispitanika je navelo da svakako utječe.

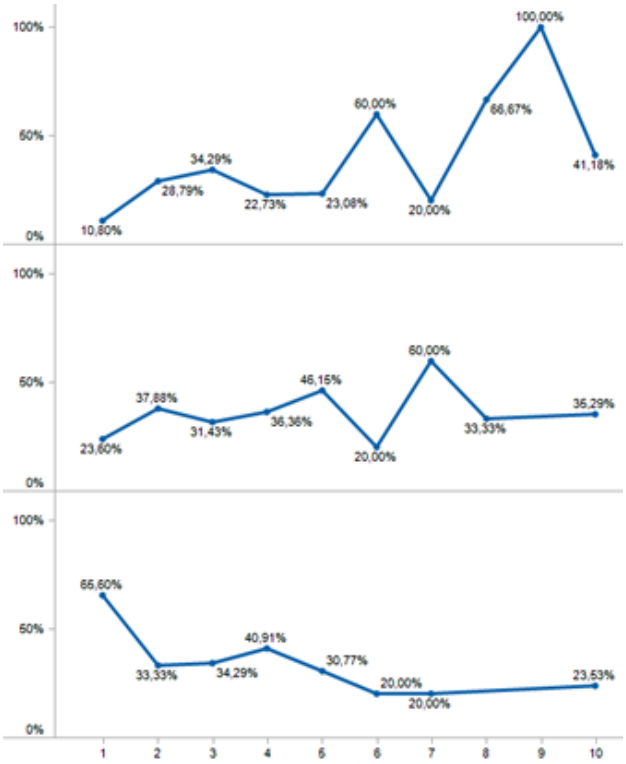
Na pitanje vezano na pripreme za maturu 52% ispitanika pohađalo je neku vrstu priprema, bilo da su pripreme bile organizirane u školi ili su na njih išli u specijalizirane institucije, 10% ispitanika pohađali su individualne instrukcije.

U istraživanju jedno je pitanje bilo naglašeno vezano uz STEM područje (studiranje prirodnih i tehničkih znanosti), direktno je bilo usmjereno na činjenicu da se relativno mali broj maturanata odlučuje na upis studija iz STEM područja. Dominantan odgovor je bio da su takvi studiji teški, a većina želi diplomu bez previše truda (50% ispitanika).

Kako je već ranije navedeno, istraživanje je obuhvatilo i populaciju brucoša, a ta populacija bila je pitana i koliko je zadovoljna odabirom studija, odnosno bi li ispitanici iz te populacije mijenjali svoj odabir. U korelaciju organizatori su stavili varijable ranga odabira studija (1-10) i sklonost promjeni (da, možda, ne) te su dobili očekivani rezultat – studenti koji su upisali studij prvih izbora bili su više zadovoljni svojom odlukom, odnosno bili su manje skloni promjeni odabira. (Slika 2.)

Kako su se organizatori u istraživanju koristili i podacima iz Facebookove Graph aplikacije, pored osnovnih podataka dobili su i dopuštenje samih korisnika da zavire u njihove profile i time steknu uvid u kulturne aspekte života starijih adolescenta u Hrvatskoj, stoga su ovdje navedeni trivijalni podaci kao demonstracija snažnog društvenog aspekta jedne internetske aplikacije – Facebooka.

U obrađenom uzorku prosječan broj *lajkanih* stranica je 553, a najmotiviraniji *lajker* imao ih je 4724. U lipnju 2013. promatrana populacija najviše je lajkala Hrvatsku .



Slika 2. Odnos ranga odabira studij i sklonosti promjeni studija

rukometnu reprezentaciju (12.46%), Slavena Bilića (12.34%) i nogometni klub Barcelonu (11.65%), za ilustraciju dakle, ovdje je odabrano područje sporta.

V. ZAKLJUČAK

Pregledom informacija dobivenih iz ovog istraživanja doneseni su sljedeći opći zaključci:

1. Gotovo polovica ispitanih studenata koji su prošle godine upisali fakultet, razmišlja o promjeni studija, dok bi svaki peti sigurno odabrao nešto drugo da može ponovno birati.
2. Maturanti prilikom odabira studija najviše cijene mišljenje poznanika koji rade u struci, a oni koji se vode savjetima roditelja u velikom broju budu nezadovoljni upisanim studijem.
3. Unatoč činjenici da su maturanti prilično samosvjesni prilikom odabira fakultete, ipak značajno raste utjecaj poznanika, obitelji, prijatelja i profesora – analiza pokazuje da je najkorisnije slijediti savjete pojedinaca koji već rade u struci kojom se želite baviti, a da savjeti roditelja mogu biti i prilično neobjektivni.
4. Tri najpoželjnija fakulteta u državi su zagrebački Filozofski fakultet, Ekonomski fakultet i Fakultet elektrotehnike i računarstva.

S obzirom na velik broj dosegnutih ispitanika, gotovo 5000, a uz investirana minimalna financijska sredstva organizatori zaključuju da su postignuti opći ciljevi efikasnosti i efektivnosti. Facebook kao platforma, te *open source* tehnologije PHP/MySQL pokazali su se kao snažan alat za dobivanje relevantnih informacija koje su stavljene na raspolaganje prvenstveno organizatoru, ali i zainteresiranim javnostima za donošenje odluka.

Nastavni plan i program za predmet programiranje u prirodoslovno -matematičkim gimnazijama

Julijana Novaković
III.gimnazija, Matice hrvatske 11, Split, Republika Hrvatska
Telefon: 021-384 933 Fax: 021-322 754 E-mail: julijana.novakovic@skole.hr

Sažetak - Usprkos sve raširenijoj primjeni e-učenja u obrazovanju programera, postoje brojne barijere koje udaljavaju učenike od pravilnog pristupa programiranju. Problemi koji se pojavljuju pri podučavanju programiranja su ili fokusirani na razvojnu okolinu ili na sintaksu više programskih jezika kojih tijekom obrazovanja učenici usvajaju te se tako u potpunosti gubi osnovni smisao programiranja, a to je usvajanje osnovnih koncepata algoritamskog načina rješavanja problema. Iako je u nizu programskih jezika danas zaista teško izabrati pogodan za učenje programiranja smatram da treba napraviti redizaj postojećih nastavnih sadržaja. U ovom radu ću ponuditi prijedlog nastavnih sadržaja koji potiču razvijanje apstraktnog i algoritamskog načina razmišljanja.

Redizaj nastavnih sadržaja potaknut je, između ostaloga, željom da se unaprijedi kvaliteta učenja programiranja te time odgovori na zahtjeve natjecanja u kategoriji algoritmi. Članak donosi praktična iskustva autora, aktivnosti i rezultate implementacije u dodatnoj nastavi informatike. Rezultati su vidljivi u motivaciji učenika i povećanoj aktivnosti te potrebi da se na nivou škole sistematizirano i metodički oblikovano vodi dodatna nastava informatike. U tijeku je izrada pilot-projekta „Teorija grafova u natjecateljskim zadatcima" namijenjen učenicima kao dodatni sadržaj, a realizirat će se u suradnji s Prirodoslovno-matematičkim fakultetom Split. Na temelju tih iskustva planira se izrada nastavnog programa dodatne nastave programiranja za školsku godinu 2014./15.

I. UVOD

Nastava u III.gimnaziji obiluje brojnim i raznolikim inovacijama u procesu učenja i poučavanja, a posebno se ističe inovativnim primjenama uporabe informacijsko komunikacijskih tehnologija u odgojno-obrazovnom procesu. Izradi nastavnih sadržaja kojima se bavi ovaj rad predhodila je SWOT analiza (Sl. 1).

Izradi novih nastavnih sadržaja za drugi, treći i četvrti razred prethodio je projekt izveden tijekom školske godine 20012./13. u dodatnoj nastavi informatike koja se bavi pripremom učenika za natjecanje u kategoriji algoritmi. Trenutno je izrada idejnog rješenja nastavnih sadžaja koje ima za cilj planiranje, izvođenje te postavljanje novih i redizajniranje postojećih nastavnih programa.

Osnovni cilj je stvaranje poticajnog okruženja za razvoj i sistematičnu poduku programiranja kako bi se uspješno kod učenika razvijao algoritamski pristup rješavanja problema koji je do sada uvelike zapostavljen. Programiranje se nerijetko svodi na učenje sintakse određenog programskog jezika.

Projekt se također bavi uvođenjem u nastavni proces eučenja koje bitno doprinosi unapređenju kvalitete toga procesa i kvalitete ishoda obrazovanja. Analizom tehničkih i pedagoških aspekata e-okoline LMS Moodle sustava za administraciju nastave (engl. *Learning Management System*, LMS) utvrđeno je da sustav Moodle podržava jezgru nastavnih aktivnosti i omogućuje olakšano komuniciranje i intenzivniju suradnju između učenika i nastavnika te između učenike i učenika. Učenici stječu nove vještine kao što su timski rad, komunikacijske vještine, istraživački pristup rješavanju problema i sl., a važne za njihovo kasnije obrazovanje i rad.

Sl.1 SWOT analiza

II. E-OKOLINA–TEHNIČKI OKVIR IMPLEMENTACIJE PROJEKTA

Moodle platforma je izabrana kao tehničko rješenje. Na školskom serveru je instaliran sustava Moodle. Popularno nazvan eTrema (Sl. 2).

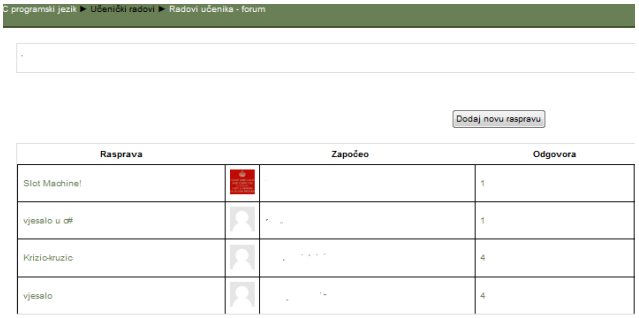
Sl.2 eTrema-portal za eučenje III.gimnazije Split

Moodle je programska aplikacija za izradu i održavanje *online* kolegija putem Interneta i može služiti za samostalno učenje ili kao nadopuna klasičnoj nastavi. Riječ Moodle je akronim od *Modular Object-Oriented Dynamic Learning Environment* što u prijevodu znači modularna objektivno-orijentirana dinamična okolina za učenje. To je projekt otvorenog koda (*open source*) što znači da je korisnicima omogućen uvid u izvorni kôd, uz mogućnost promjene aplikacije i prilagodbe vlastitim potrebama. Softver je besplatan i može se preuzeti sa http://www.moodle.org.

Moodle je web aplikacija, te je kao takva dostupna iz nekog od standardnih preglednika weba, poput Internet Explorera. U okvirima aplikacije integrirane su alati za kreiranje web stranice premeta i alati za kontrolu pristupa, koji omogućavaju jednostavan način postavljanja nastavne građe, vođenje online rasprava i razgovora, izradu kvizova i anketa, te prikupljanje i predaju zadataka.

Moodle platforma se koristi za :

- distribuciju materija za vježbu
- „spremanje“ vježbi kako bi učenici mogli vrijeme učenja jednim dijelom prilagoditi svom tempu
- timski rad koji je potaknuo natjecateljski duh i samostalno učenje (Sl. 3 Radovi učenika postavljeni na forum)



Sl. 3 Radovi učenika postavljeni na forum

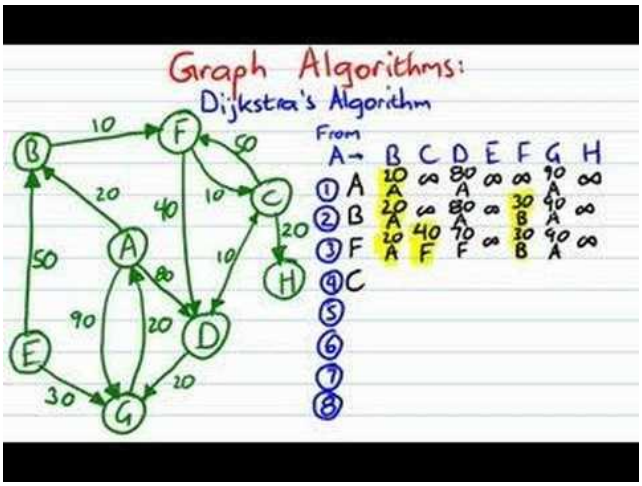
III. TEORIJSKI OKVIR

U procesu pripremanja zadataka s natjecanja počevši od školske razine zaključeno je da nastavno gradivo ne prati nastavne sadržaje redovite nastave programiranja. Tom zaključku je uslijedila detaljna analiza izvedbenog nastavnog programa. Naime, programiranje u prirodoslovno-matematičkim gimnazijama se uči od drugog razreda. U prvom razredu unutar nastavne cjeline osnove programiranja učenici se upoznaju s algoritamskim pristupom rješavanju problema potpuno neopterećeni učenjem sintakse programskog jezika.

Učenici su bili uključeni u veći dio aktivnosti. Te aktivnosti otvorile su čitav niz informacija koje su bitno doprinijele implementaciji i vođenju projekta. Unutar njih iščitavani su interesi učenika, njihove želje ne samo za nastavnim sadržajima koji prate gradivo na natjecanjima nego i novim načinima poučavanja i učenja.

Aktivnosti koje su provedene u okvirima teorijske implementacije projekta:

- Upoznavanje učenika sa novim tehnologijama e-učenja, konkretno upoznavanje s Moodle platformom
- Testiranje redovitog nastavnog programa. Tad je došlo do bitnih informacija, a to je da učenici oko 70% nastavih sadržaja ne poznaju i ne koriste redovitoj nastavi. Primjerice, strukture podataka kao što su liste, stabla, algoritme sortiranja.
- Skupljanje informacija o interesima učenika za učenje naprednog programiranja koje je u korelaciji s matematikom, kombinatorikom i teorijom grafova (Sl.4 Dijkstrin algoritam).



Sl.4 Dijkstrin algoritam

IV. PRIJEDLOG IZVEDBENOG PLANA I PROGRAMA NASTAVE INFORMATIKE (PROGRAMIRANJE)

Danas je u nizu programskih jezika teško odabrati onaj koji je pogodan za učenje programiranja. Takav bi jezik s jedne strane morao biti fleksibilan i jednostavan, kako bi prve programerske korake učinio što bezbolnijim. S druge strane on bi trebao biti dobra podloga za nastavak programiranja u bilo kojem drugom programskom jeziku. Naše je iskustvo da većina učenika ima poteškoća u usvajanju osnovnih koncepata algoritamskog načina rješavanja problema zbog savladavanja detalja pojedinih progra mskih jezika te posebice zbog uporabe različitih programskih jezika tijekom obrazovanja. Uobičajeno se na početku koriste jezici (LOGO, BASIC,Pascal, C), a kasnije kod podučavanja naprednijih koncepcija programiranja koriste se jezici za izradu velikih programskih projekata (C++, C#, Java). Navedeni jaz između „jednostavnih“ i „moćnih“ jezika zasigurno je smanjen pojavom Pythona. Radi se o jeziku koji s jedne strane može biti vrlo jednostavan i kao takav može poslužiti početnicima,a istovremeno je Python i moćan jezik koji podržava objektno-orijentirani princip programiranja [1].

Na prijedlog da se u III.gimnaziju Split uvede programiranje u Phytonu većina kolega aktiva informatike se nije pozitivno izjasnila. Još jedna od od prednosti koju

ima učenje Phytona je postojanje udžbenika koji na sistematičan i metodički oblikovan način vodi nastavnike kroz gradivo.

Ovaj rad se neće baviti prednostima programskih jezika tako da se izvedbeni plan može primijeniti na bilo koji objektno-orijetirani programski jezik.

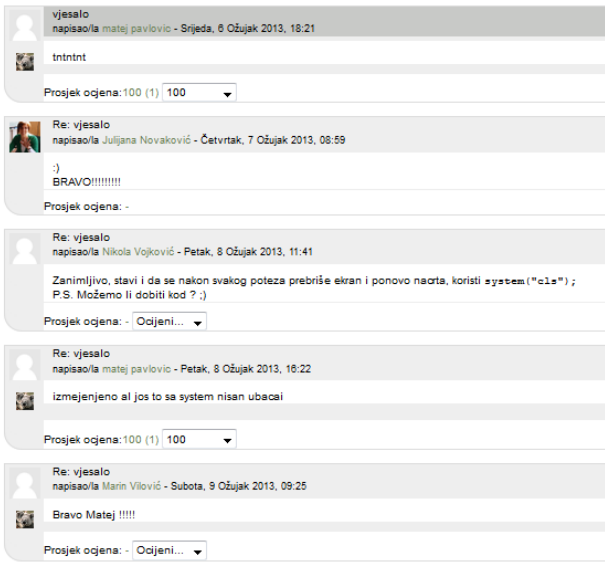
A. Programiranje pseudo jezik – algoritamski pristup

Pseudo jezik se sastoji od kratkih izraza na govornom jeziku koji opisuju i ukratko objašnjavaju pojedine radnje algoritma.
Pri zapisivanju algoritma pseudo jezikom treba nastojati zadatak razložiti na što manje radnje. Te bi radnje trebale biti tako male da se za svaku od njih može naći odgovarajuća naredba pseudo jezika. Kako u pseudo jeziku ne postoje ograničenja koja svaki programski jezik ima, pseudo jezik omogućuje mnogo pregledniji i jednostavniji prikaz načina na koji se zadatak može riješiti.

B. Nastavne metode i oblici rada

Nastava se odvija u informatičkoj učionici, dva puta tjedno i svaki od učenika radi sam. Računala imaju pristupi internetu.

Od verbalnih nastavnih metode koriste se sve metode počevši od objašnjavanja, razgovora i pripovijedanja, jer se novi pojmovi i nastavna građa na upoznaju i uvježbavaju na nastavi. Moodle platforma ne koristi se za samostalno učenje. Preko nje učenici ostvaruju komunikaciju koja nije vođenja od strane nastavnika (Sl.5 primjer komunikacije).



Sl.5 primjer komunikacije

Od neverbalnih nastavnih metoda koristi se metoda demonstracije.

C. Nastavni sadržaji

Dodatna nastava programiranje kao dodatni nastavni sadržaj podučava učenike:

- rješavanje problema
- pisanje algoritama
- razumijevanju i kritičkoj ocjeni prikupljenih informacija
- donošenju zaključaka na temelju prikupljenih informacija.

Zadaće ove nastave su upoznavanje s:

- standardnim numeričkim algoritmima (djeljivost, prosti brojeve, savršeni brojevi,...)
- s poljima (pretraživanje, sortiranje,...)
- s rekurzivnim potprogrami
- sa stringovima (palindromi, parsiranje,...)
- sa složene strukture podataka (vezana lista, red, stog,stablo,...)

U tablici (Tablica 1) je prikazan izvedbeni paln i program dodatne nastave naprednog programiranja za školsku godinu 2012./13. i 2013./14.

Naziv nastavne cjeline (kompleksa)	Sadržaji
1. STRUKTURE PODATAKA I ALGORITMI	Uvodni sat 1.1. Pojam algoritma i način zapisivanja 1.2. Pseudojezik i dijagram toka 1.3. Neki algoritmi za prirodne brojeve 1.4. Nizovi i sortiranje 1.5. Još neki matematički algoritmi
2. NAPREDNIJI C++-u	2.1. Pokazivači 2.2. Strukture 2.3. Elementarni algoritmi 2.4. Biblioteke 2.5. Funkcije 2.6. Klase i objekti 2.7. Standard Template Library
3. LISTE	3.1. Općenita lista 3.2. Stog 3.3. Red
4. STABLA	4.1. Uređeno stablo 4.2. Binarno stablo
5. GRAFOVI	5.1. Modeliranje pomoću grafova 5.2. Zapis grafa 5.3. Flood fill algoritam 5.4. Dijkstrin algoritam 5.5. BFS 5.6. Eulerovska staza
6. OBLIKOVANJE ALGORITAMA	6.1. Metode izbrajanja 6.2. Modeliranje rekurzivnim relacijama 6.3. Metoda „podijeli pa vladaj 6.2. Dinamičko programiranje 6.3. „Pohlepni“ pristup 6.4. Backtraking

Tablica 1.

D. Okvir prijedloga novih nastavnih sadržaja redovite nastave

U tablici 2 je izvedbeni plan i program za 2. i 3. razred prirodoslovno-matematičke ginazije

Tablica 2

Naziv nastavne cjeline (kompleksa)	Sadržaji
1. OSNOVE PROGRAMSKOG JEZIKA C++	1.1. Osnovna struktura programa 1.2. Komentari 1.3. Ključne riječi 1.4. Kompajliranje i pokretanje programa
2. KONSTANTE I VARIJABLE – OPERATORI I IZRAZI	2.1. Konstante i varijable 2.1.1. Imena varijabli 2.1.2. Tipovi podataka 2.1.3. Tip void 2.1.4. Veličine podataka 2.1.5. Konstante 2.1.6. Deklaracije 2.2. Operatori i izrazi 2.2.1. Aritmetički operatori 2.2.2. Unarni operatori 2.2.3. Relacijski i logički operatori 2.2.4. Operatori pridruživanja 2.2.5. Uvjetni operator: ? 2.2.6. Prioriteti i redoslijed operatora
3. ULAZ I IZLAZ PODATAKA	3.1. Funkcije getchar i putchar 3.2. Funkcije iz datoteke <iostrem> 3.3. Funkcije gets i puts 3.4. Funkcija cin 3.4.1. Učitavanje cijelih brojeva 3.4.2. Učitavanje realnih brojeva 3.5. Funkcija cout 3.5.1. Ispis cijelih brojeva 3.5.2. Ispis realnih brojeva 3.5.3. Ispis znakovnih nizova
4. KONTROLA TOKA PROGRAMA	4.1. Izrazi i naredbe 4.2. Naredbe uvjetnog grananja 4.2.1. If naredba 4.2.2. if-else naredba 4.2.3. Višestruka if-else naredba 4.3. switch naredba 4.4. while petlja 4.5. for petlja 4.6. do-while petlja 4.7. Naredbe break i continue
5.POLJA	5.1. Definicija i inicijalizacija polja 5.2. Polja znakova 5.3. Biblioteka string 5.3. Funkcije za rad sa stringovima 5.5. Sortiranje
6. FUNKCIJE	5.1. Definicija funkcije 5.2. Deklaracija funkcije 5.3. Prijenos argumenta 5.4. Inline funkcije 5.5. Rekurzivne funkcije 5.6. Funkcije s varijabilnim brojem argumenata 5.7. Polje kao argument funkcije (prenos po adresi)
7. BIBLIOTEKE	7.1. Naredba include 7.2. Naredba #define 7.3. Uvjetno uključivanje 7.4. Predefinirani makroi.
8. Standard TemplateLibrary	8.1. Vector 8.2. List 8.3. Map
9. OSNOVE OBJEKTNO USMJERENOG PROGRAMIRANJA	9.1. Klase i objekti
10. SLOŽENI ALGORITMI I TRAJANJE NJIHOVA IZVOĐENJA	
10. ALGORITMI SORTIRANJA	10.1. Buble sort 10.2. Mergesort 10.3. Quicksort

E. Vrednovanje

Kako je dodatna nastva napredovala, sadržaji i aktivnosti su se obogaćivale tako su učenici pokazivali sve više interesa za timskim radom koji bi se izvodio online.

Učenici su bili zadovoljni jer se na nastavi nastojalo rješiti što više natjecateljskih zadatka.

Pripreme za nastavu su bile opsežne i kompleksne. Trebalo je obuhvatiti gradivo od struktura podataka do teorije grafova. Nije uvijek sve išlo dobro. Najveći problem je nedostata sistematičnih i metodičko-oblikovanih nastavnih sadržaja.

Koliko programiranja i kada nam treba u kurikulu za osnovne i srednje škole?

Marina Čičin-Šain*, Snježana Babić**
* Ekonomski fakultet Rijeka/Rijeka, Hrvatska
** Veleučilište u Rijeci, Rijeka, Hrvatska
*marinacs@efri.hr
** sbabic@veleri.hr

Sažetakt – Danas je učenicima razvoj znanja, vještina i sposobnosti iz područja programiranja omogućen na različim obrazovnim razinama u različitom obimu kroz formalni, neformalni i informalni oblik obrazovanja. Međutim obrazovna praksa pokazuje da je programiranje za većinu učenika poput matematike, uglavnom slabo prihvaćeno i nepopularno. Stoga je važno pronaći načine koji će olakšati process učenja i poučavanja programiranja, te potaknuti kod učenika želju za razvojem u području programiranja. S druge strane, važno je pronaći odgovarajuću razinu zastupljenosti programiranja u kurikulu za osnovne i srednje škole. (A moglo bi biti lakše.). Ovaj rad opisuje jednu mogućnost kako se to može postići.

I. UVOD

Činjenica je da današnji učenici koriste računala, da provode svakodnevno često i više sati za računalom, tabletom, pametnim telefonom i drugim uređajima uz pomoć kojih vrše različite aktivnosti, od privatnih, poslovnih do obrazovnih.

Tako danas kao jednu od glavnih komponenata obrazovnog sustava imamo generaciju koju je Prensky [1] još 2001. godine nazvao "*digitalni urođenici*". Autor navodi, da nova generacija učenika "… *ubrzano prima informacije, voli paraleno obrađivati i raditi nekoliko poslova istovremeno, da najbolje rade u interentskom okruženju, da su više skloniji igrama nego ozbiljnom radu, ...*". Današnja praksa, nažalost, potvrđuje u velikom broju slučajeva da su upravo njihove online aktivnosti češće gubitak vremena nego aktivnosti koje doprinose njihovom razvoju, edukaciji i napretku.

S druge strane, u okviru formalnog osnovnoškolskog i srednješkolskog obrazovanja učenicima je omogućeno stjecanje znanja, vještina i sposobnosti iz područja informatike/računalstva kroz informatičke predmete ili pak kroz primjenu računala u drugim nastavnim predmetima. Pod utjecajem različitih trendova, sadržaji kurikula za osnove i srednje škole iz područja informatike se kontinuirano mijenjaju.

Tako se danas javlja potreba za razvojem pismenosti više razine u području informatike vezane uz programiranje. Premda je programiranje u svijetu informatike vezano uz početak samog razvoja znanstvenog područja informatike, danas upravo postoji potreba za razvojem kompetencija učenika u tom smjeru.

Stoga se u nastavku ovoga rada upravo vraćamo djelomično u prošlost koja u današnjim okvirima ima ponovno veliki potencijal u procesu učenja i poučavanja mladih ljudi u području programiranja.

II. ZAŠTO PROGRAMIRATI?

Studija na razini europske zajednice [2] upozorava da možemo biti zadovoljni digitalnom pismenosti naših učenika, ali da u većini zemalja uopće ne može biti govora o zadovoljstvu što se tiče informatičke edukacije, pod kojom se podrazumijeva ozbiljnije poznavanje rada računala (algoritmi, programiranje, paralelizam i sl.) U istoj studiji naglašava se da se stanje u tom području značajno pogoršava nakon pionirskih pokušaja iz 1970. i 1980. godine. Oni koji su stariji sjetit će se da je zaista kod početka uvođenja računala u škole programiranje bilo znatno više zastupljeno nego danas!

I konačno, ista studija upozorava europljane, da je digitalna pismenost nedovoljna, ako ne želimo biti svedeni na čiste potrošače novih tehnologija, a ne njihove kreatore i autore, za što je naravno potrebno znanje na višoj razini.

Navedeni zaključci koji vrijede na razini Europe za Hrvatsku vrijede još i više. U našoj zemlji glavni su problemi nezaposlenost i odljev mozgova. Zanimanja koja su u bogatijim zemljama deficitarna su upravo zanimanja za koje je potrebna informatička edukacija. No dok za druga zanimanja "rad za druge zemlje" znači i selidbu u te zemlje, za informatička zanimanja to uopće ne mora biti tako. Informatičari mogu fizički ostati u Hrvatskoj, a raditi za naručitelja iz bilo kojeg dijela svijeta.

III. KADA ZAPOČETI?

Da bi se postigla dovoljna razina znanja ne može se sa ozbiljnijim temama započeti tek na fakultetu, nego je potrebno započeti ranije, dakle u osnovnoj i srednjoj školi.

Prva je autorica ovog teksta počela programirati nakon studija teoretske matematike na PMF-u kao programer pripravnik u Ini prije 45 godina. U ono vrijeme bila je rijetkost da netko uopće uči programirati ili koristiti računalo na bilo koji način, a učenje o računalima nije uopće bilo uključeno u nastavu u školama. Dakle, ako se nešto o računalima i učilo, to je bilo nakon formalnog školovana. To sigurno nije bilo dobro i već onda se znalo da je bolje početi ranije.

Pitanje je koliko ranije? Odgovor je čim ranije, onda kada se i druge stvari uče, primjerice računati, čitati, raspoznavati boje, pisati, strani jezici i slično. Djeca koja su kao malena naučila strani jezik, igrati tenis ili skijati bolje to rade od svojih vršnjaka koji su počeli tek kada narastu. Sa programiranjem je ista stvar, samo način na koji djeca uče mora biti prilagođen uzrastu djece. Zato za sasvim malu djecu ni jedan postojeći programski jezik nije dosta dobar. Za sasvim malu djecu oni su svi preteški. Djeca mogu učiti koristiti kompjutor, ali ne i programirati na nekom od postojećih jezika, čak ni ako se radi o Logu ili Basicu.

Pa ipak, učiti programirati može se učiti tako prirodno i lako, kako se pomoću slikovnica može učiti čitati, pomoću igre Čovječe ne ljuti se brojati ili pomoću crtanih filmova i dječjih stihova engleski jezik. Prva autorica ovih redaka je prije više od trideset godina razvila metodu pomoću koje su djeca mogla napisati program, provjeriti kako program radi, naučiti koliko je važan redoslijed naredbi, kako se ponašaju varijable u memoriji računala, a sve su to radila pomoću igre i igračke koju su sami izrađivali. Igračku smo nazvale "Mema".

IV. TKO TREBA PODUČAVATI I NA KOJOJ OPREMI?

Ako se radi o osnovnoj školi programiranje po metodi koja se predlaže može predavati učitelj ili učiteljica bez nekog posebnog znanja iz područja programiranja.

Možda je to i glavna prednost ove metode, da zapravo ne zahtjeva nikakvu dodatnu edukaciju učitelja ili učiteljica!

Druga prednost je da za ovu metodu nije potrebna nikakva dodatna oprema, osim za učitelja ili učiteljicu računala s mogućnosti spajanja na Internet kako bi mogli pristupiti nastavnim materijalima tijekom pripreme za nastavni sat.

V. POČETNICA PROGRAMIRANJA

Metoda koju preporučujemo opisana je još 1990. u knjizi "Kompjutersta početnica", koju je izdala Školska knjiga [3]. Knjiga se sastojala iz dva dijela: prvog, koji je bio namijenjen radu sa djecom u prvom ili drugom razredu osnovne škole i nije zahtijevao računalo, te drugog dijela koji se nadovezivao na prvi u kojem su bile opisane osnove u radu na programskom jeziku Basic.

Upravo prvi dio knjige je ono na što želimo upozoriti, jer je on danas aktualan isto kao i daleke 1990. Za razliku od drugog dijela koji se može smatrati zastarjelim.

Novost je da je koautorica ovog rada, ove godine taj prvi dio priredila za korištenje na računalu i da je dostupan na adresi:

www.magistra-nova.hr/dokuwiki_pocetnica/doku.php

Važno je naglasiti sljedeće:

- Metoda je namijenjena učitelju ili učiteljici, koji su voljni učenike osnovne škole pripremiti za programiranje.
- Učitelj ili učiteljica pri tom ne moraju znati mnogo o računalima, zapravo nije potrebno nikakvo predznanje.
- Zamišljeno je da učitelji zajedno sa svojim učenicima uče, korak po korak.

Na online stranicama [4] učitelji mogu pronaći nastavno gradivo kao i upute za svaki nastavni sat.

U okviru nastavne metode u prvoj fazi "*učenja programiranja bez računala*" koristi se igračka nazvana "Mema" koju djeca sama na nastavnom satu izrađuju od uobičajenih stvari, kao što su: bojice, ljepilo, papir i slično (vidjeti: sliku 1).

Slika 1. Igračka Mema koju djeca sama izrađuju

Početnica programiranja se sastoji iz sljedećih dijelova:

- Kada početi programirati?
- Opis metode
- Kako početi?
- Izrada "Meme"
- Ulaz
- Izlaz
- Obrada
- Igrokaz "Moj kompjutor"
- Napredniji rad s "Memom"
- Sljedbenik i prethodnik
- Ponavljanje gradiva
- Slikovnica "ANDOR"
- Priprema za LOGO
- Igre na dvorištu
- Umjesto zaključka: što smo sve naučili?
- Zadaci: 1, 2, 3, 4, 5,6, 7
- Pitanja za grupu B
- Pitanja za grupu C.

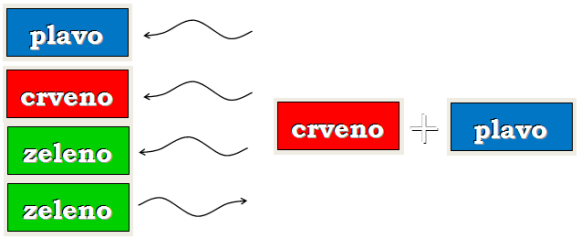
Tijekom primjene metode učenici neće biti dodatno opterećeni, učit će ono što ionako uče u prvom razredu: zbrajati i oduzimati do dvadeset, raspoznavati boje, crtati, razvijati motoriku.

Pri tome će sasvim usput učenici čuti za neke pojmove iz informatike, ne na razini definicija, nego upravo čemu te stvari služe. Kao primjer neki od pojmova su:

- korisnik

- program
- naredba
- varijabla
- redoslijed naredbi
- ulaz
- obrada
- izlaz
- podaci
- konstante
- kompatibilnost
- kapacitet polja
- adresa i još mnogi drugi

Način na koji će se usvajati navedeni pojmovi iz područja informatike, učitelj ili učiteljica doznaje radom iz nastavnog sata u sat. Tako na primjer, u nekom trenutku učenik ili učenica upoznaju program za zbrajanje kao što je prikazano na slici 2.



Slika 2. Program za zbrajanje

Nove tehnologije omogućuju komunikaciju postavljanjem pitanja kad nešto nije jasno ili upozorenjem ako smo u nečemu pogriješile. Učitelji i učiteljice pozivaju se da nas obavijestite kako napreduju u svom radu, da nam pošalju koju fotografiju svojih učenika i učenica dok rade, koji crtež koji su izradili, neku njihovu primjedbu koju smatraju zanimljivom i sl. Već sama činjenica da netko razmišlja o tome da radi po ovoj metodi dovoljna je da nam se javi s eventualnim primjedbama.

O korisnicima metode će ovisiti koliko će metoda ponovni uspjeh.

Pri radu sa učiteljima ili učiteljicama često se nailazi na pitanje: "*A što ako mi učenik ili učenica postave pitanje na koje ne znam odgovoriti*?"

Ne treba strahovati od takvih pitanja, ona su sasvim prirodna. Djeca puno puta postavljaju pitanja na koja odrasli nemaju odgovor. Po našem mišljenju takva pitanja i takvi učenici ili učenice su prava blagodat; zahvaljujući njima i sami ćemo uvijek biti prisiljeni učiti. Nastavnik se ne treba pretvarati da zna odgovor, ako ga slučajno ne zna. Bolje je pohvaliti pitanje i pokušati naći odgovor na njega do slijedećeg sata. Možda i u tome možemo pomoći.

VI. Što dalje

Nakon prvih koraka treba nastaviti. Paralelno sa nastavom matematike, može se u nižim razredima osnovne škole i za programiranje još neko vrijeme koristiti Mema. Sadržaji koje bi tu trebalo uvesti svakako su grananje i petlje, što u Početnici nije obuhvaćeno.

Naravno da u višim razredima treba početi programirati i na računalu. Kada su učenici u osnovnoj školi usvojili osnovna znanja, njima je znatno lakše koristiti neki pravi programski jezik [5].

Svjedoci smo da studenti primjerice na fakultetu, koji nikad ranije nisu programirali vrlo teško usvajaju ta znanja, odnosno usvajaju ih samo oni koji su za to talentirani. Tvrdimo je da i prosječan učenik može naučiti programirati, samo ako počne dosta rano s edukacijom.

VII. Zaključak

Korištenje računala na tipično korisnički način je lakši, ali i lošiji način. Odustajanje od programiranja pokazalo se kao loša praksa.

Pa ako je učenje programiranja važno, čak jako važno za jednu zemlju poput Hrvatske, onda je važno i kako ta znanja učiniti dostupna našim učenicima.

Učenicima će biti lakše ako uče postepeno i počnu čim ranije. Metoda i Internet stranica iz ovoga rada mogu pomoći učiteljima i učiteljicama da osnovna znanja prenesu svojim malim učenicima.

Webinar u funkciji promicanja prava na pristup informacijama

Tamara Horvat i Renata Pekorari
Digitalni informacijsko-dokumentacijski ured Vlade Republike Hrvatske
Zagreb, Hrvatska
thorvat@hidra.hr, pekorari@hidra.hr

Sažetak - Pravo na pristup (službenim) informacijama, jedno od osnovnih ljudskih prava, u Republici Hrvatskoj je Ustavno i zakonsko pravo. Rad će se baviti jednim od mogućih načina promoviranja tog prava. Digitalni informacijsko-dokumentacijski ured proaktivnom objavom službenih dokumenata tijela javne vlasti na svojim mrežnim stranicama direktno osigurava pravo na pristup informacijama svima zainteresiranima. Promicanju prava na pristup informacijama daje svoj doprinos i putem edukacijskih programa namijenjenih državnim i javnim službenicima i zainteresiranoj javnosti. Kako je nemoguće doći „uživo" do svakog potencijalno zainteresiranog službenika ili građanina, Ured razvija i izvodi i *online* edukacijske programe. Nakon prvog asinkronog *online* programa *Naučite kako, brzo i lako, do pravnih propisa!* ponuđenog svima u slobodnom pristupu na mrežnim stranicama, Ured se usredotočio na razvoj i izvedbu *webinara* koji su se u zadnjih nekoliko godina razvili u vrlo popularan edukacijski alat. U radu će se opisati projektni plan jednog od prvih *webinara* izrađenih u sklopu državne uprave kao i prvi pokazatelji njegova uspjeha. Također, rad će predstaviti i daljnje planove za korištenje *webinara* u svrhu razvijanja svijesti o pravu na pristup informacijama.

I. UVOD

A. Pravo na pristup informacijama

Pravo na pristup (službenim) informacijama, jedno od osnovnih ljudskih prava, u Republici Hrvatskoj je Ustavno i zakonsko pravo. U ožujku 2013. godine stupio je na snagu novi Zakon o pravu na pristup informacijama [1] (u daljnjem tekstu Zakon) koji, za razliku od prethodnog iz 2003. godine [2], snažno naglašava važnost proaktivne objave informacija u ostvarivanju prava na pristup. Smisao je informaciju, koja može biti zanimljiva i većem broju zainteresiranih, čim prije objaviti na mrežnim stranicama i tako je učiniti dostupnom. Zainteresirani korisnik moći će je pronaći i koristiti i bez postavljanja pojedinačnog zahtjeva za istom informacijom tijelu javne vlasti. Digitalni informacijsko-dokumentacijski ured Vlade Republike Hrvatske [3] (u daljnjem tekstu Ured) proaktivnom objavom službenih dokumenata tijela javne vlasti na svojim mrežnim stranicama direktno osigurava pravo na pristup informacijama svima zainteresiranima.

Promicanju prava na pristup informacijama Ured doprinosi i edukacijskim programima namijenjenima tijelima javne vlasti, dakle državnim i javnim službenicima koji trebaju provoditi Zakon, ali i zainteresiranoj javnosti u svrhu upoznavanja sa zakonskim pravima. Kako je nemoguće doći „uživo" do svakog potencijalno zainteresiranog službenika ili građanina, Ured u zadnje dvije godine, uz klasične, razvija i izvodi i *online* edukacijske programe. Nakon prvog asinkronog *online* programa *Naučite kako, brzo i lako, do pravnih propisa!* [4] ponuđenog svima u slobodnom pristupu na mrežnim stranicama, Ured se usredotočio na razvoj i izvedbu *webinara* koji su se u zadnjih nekoliko godina razvili u vrlo popularan edukacijski alat.

B. Webinar kao edukacijski alat

Webinar je izraz koji je preuzet iz engleskog jezika i skraćenica je od sintagme *web based seminar*. U hrvatskom jeziku ne postoji prijevod ovog izraza. Predstavlja alat kojim se seminari prenose putem mreže. Osim seminara to mogu biti razne duže ili kraće prezentacije, predavanja, radionice, konferencije i ostali događaji koji se prenose u realnom vremenu putem interneta.

Njihova osnovna prednost je jednostavnost korištenja, nema troškova i velikih zahtjeva za korisnike. Sustav za *webinare* uključuje video, audio i tekstnu komunikaciju između korisnika, razmjenu i zajednički rad s datotekama, anketiranje sudionika, preuzimanje nadzora nad udaljenim računalima i drugo. *Webinari* omogućuju davanje, primanje i komentiranje informacija, što omogućava interakciju između predavača i sudionika koji se nalaze na više različitih fizičkih lokacija [5].

Za potrebe prvog *webinara* Ureda korištena je usluga koju je uspostavio Centar za e-učenje pri Srcu [6]. Usluga korisniku omogućava otvaranje virtualne sobe u kojoj priprema i održava *webinar* te definira način pristupa, radnu površinu, sudionike i njihove uloge. U svakoj sobi standardno su unaprijed definirane tri radne površine: za razmjenu, za suradnju i za diskusiju, a korisnik usluge može otvoriti i izraditi nove radne površine i kombinirati dostupne alate u sustavu.

U sustavu postoji više uloga, a osoba kojoj se odobri otvaranje sobe za *webinar* ima ulogu domaćina. Sudionike *webinara* domaćin poziva u sobu pozivnicom preko e-pošte koja sadrži dan i sat/vrijeme održavanja te URL-adresu sobe, a sudionike se može i unaprijed upisati ili im odobriti ulazak prije samoga početka. Sustav također omogućava snimanje *webinara* radi njegova eventualnoga kasnijeg prikazivanja. Ovaj alat za e-učenje sigurno će biti zanimljiv svima koji drže nastavu na raznim lokacijama ili žele održati seminare ili

konzultacije s osobama koje se nalaze bilo gdje u svijetu. Osim što omogućavaju prisutnost i slikom i glasom, *webinari* ujedno štede vrijeme i visoke troškove putovanja

II. PRVI *WEBINAR* U DIGITALNOM INFORMACIJSKO-DOKUMENTACIJSKOM UREDU

A. Koraci u izradi webinara Predstavljanje tražilice pravnih propisa Republike Hrvatske - CADIAL

Ured već nekoliko godina provodi prezentacije uživo na kojima predstavlja tražilicu pravnih propisa Republike Hrvatske CADIAL. Sadržaj prezentacija uživo pretočen je i u prvi *webinar* Ureda, ali i jedan od prvih i na razini cijele državne uprave, pod nazivom *Predstavljanje tražilice pravnih propisa Republike Hrvatske – CADIAL.*

S obzirom na sve veće zahtjeve korisnika za održavanjem prezentacija izvan Zagreba, odnosno izvan mjesta sjedišta Ureda, kao i limitirana sredstva za službena putovanja, krenulo se u premošćivanje takve situacije. Osim korisnika koji su dislocirani, povećao se broj zainteresiranih za edukaciju onih kojima radne obveze ne omogućuju duže izbivanje s radnog mjesta. Sve to vodilo je prema osmišljavanju novih načina da Ured što kvalitetnije i što sveobuhvatnije nastavi promovirati svoje informacijske resurse i informacijske usluge i tako ispunjavati svoju misiju, odnosno ostvarivanje prava na pristup informacijama za sve zainteresirane.

Kada je donesena odluka da se osmisle i počnu izvoditi *online* programi, pristupilo se odabiru prikladnih alata imajući u vidu profil korisnika i željeni ishod učenja koji će omogućiti da zainteresirani korisnici, nakon što prođu edukaciju, mogu suvereno koristiti tražilicu i vrlo lako pronalaziti pravne propise koji im trebaju [7].

Odabran je *webinar* kao najprikladniji alat s obzirom da je profil potencijalnih korisnika informacijskih usluga Ureda raznovrstan, a fizički su dislocirani. Također, *webinar* kao alat nije tehnički zahtjevan, a brz je i jednostavan za instalaciju i početak korištenja. Sudionik *webinara* mora na svom računalu napraviti vođenu provjeru kojom će utvrditi jesu li mu računalo i pretraživač propisno spojeni s programom *Adobe Connect*. Nema ostalih posebnih tehničkih zahtjeva, sudioniku su od dodatne opreme potrebni samo zvučnici, a predavaču zvučnici i mikrofon, te po želji web kamera. Sve to upućuje da alat nije skup niti za sudionika niti za predavača. Osim toga, alat je intuitivan i jednostavan za korištenje te se svatko s malo iskustva u komunikaciji putem interneta može lako snaći. Jedna od velikih prednosti *webinara,* kao što je već naglašeno, jest i njegova interaktivnost. Naime, predavača može biti više te također ne moraju biti na jednome mjestu, a mogu međusobno i sa sudionicima komunicirati u realnom vremenu. Sudionici su također prisutni uživo i ponuđena im je mogućnost da se, osim što slušaju predavanje, mogu u bilo kojem trenutku uključiti u razgovor putem *chata* ili pak dati signal predavaču da uspori, ubrza predavanje, ohrabriti ga virtualnim pljeskom ili podizanjem ruku te postavljanjem pitanja.

Webinar pruža i opciju kojom se sudionicima omogućuje javljanje glasom i slikom, međutim, zbog vjerojatne inkompatibilnosti opreme i predvidivih smetnji, uobičajeno je da im se omogući javljanje samo *chatom*.

Ovaj alat se sve više koristi unazad nekoliko godina, pogotovo u znanstvenoj zajednici i u svim skupinama koje teško mogu pronaći adekvatno fizičko mjesto i vrijeme za razmjenu mišljenja i ideja.

Ideja o korištenju *webinara* kao edukacijskog alata u Uredu je potvrđena i pohađanjem nekoliko *webinara* koje je organizirala Inicijativa Partnerstvo za otvorenu vlast [8]. Naime, razne radne grupe ove Inicijative [9], koriste već nekoliko godina *webinare* za širenje informacija o svom radu, različitih analiza i rezultata istraživanja, preporuka te za komunikaciju sa sudionicima iz zemalja članica Inicijative diljem svijeta. Koriste isti *Adobe Connect* program s tim da redovito *webinare* snimaju kako bi ih svi zainteresirani koji nisu mogli sudjelovati uživo mogli pregledavati i preslušavati u vrijeme kada njima odgovara [10]. Njihovi su *webinari* poslužili kao dobar primjer i ukazali na sve prednosti jednog takvog *online* programa.

Nakon odabira alata stupilo se u kontakt s Centrom za e-učenje pri Srcu koji je na zahtjev, besplatno, otvorio virtualnu sobu namijenjenu *webinaru Predstavljanje tražilice pravnih propisa Republike Hrvatske - CADIAL*. Na predavačima je bilo osmisliti sadržaj odnosno prilagoditi već postojeći koji se provodi uživo te testirati sustav.

U rujnu 2013. godine održan je pilot *webinar* na koji su pozvani eksperti iz područja e-učenja, odnosno stručnjaci koji se bave sličnim sadržajima. Zamoljeni su da daju svoje mišljenje i o sadržaju i o kvaliteti tehničke izvedbe. Povratne su informacije bile odlične te se krenulo u redovite mjesečne izvedbe prvog *webinara* Ureda.

B. Realizacija webinara

Planom edukacijskih programa Ureda, predviđeno je održavanje *webinara* jednom mjesečno. Nekoliko dana prije zadanog termina održavanja *webinara*, na izabrane ciljane adrese šalju se obavijesti o održavanju, datumu i vremenu u kojem se održava te načinima prijave sudionika. Nakon što se sudionik prijavi, šalju mu se upute koje sadržavaju adresu *webinara*, način prijave u virtualnu sobu (sudionici se prijavljuju kao gosti, a lozinka nije potrebna), poveznicu za testiranje veze, napomenu da su od dodatne opreme potrebni samo zvučnici te naputak što učiniti u slučaju problema s priključivanjem. Naime, najčešći su problem sigurnosne postavke na serverima sudionika na kojima njihovi informatičari trebaju omogućiti izlazak na standardne portove Srca. Također, na mrežnim stranicama Ureda objavljene su stalno informacije o *webinaru* te *online* prijavni obrazac s naznačenim datumima održavanja *webinara* putem kojega se

mogu prijaviti i svi ostali zainteresirani. Po prijavi dobivaju istovjetne upute kao i oni prethodni. Na sam dan *webinara*, svim prijavljenim sudionicima šalje se kratki podsjetnik da *webinar* na koji su se prijavili uskoro počinje i ponovo se šalje adresa *webinara* kako ne bi morali pretraživati „stare" mailove.

Predviđeno trajanje *webinara* je 60 minuta, a pri otvaranju virtualne sobe postavljen je od strane Srca limit od 100 sudionika po jednoj izvedbi *webinara*. Predavači se prijavljuju u sustav pola sata prije zakazanog početka, te do početka programa komuniciraju sa sudionicima putem *chata*. Kada u zakazano vrijeme započne *Predstavljanje*, predavači se uključuju zvukom i objašnjavaju sudionicima pravila rada te započinju s edukacijskim programom. Edukacijski program se sastoji od *PowerPoint* prezentacije i sadržaja koji se pokazuju direktno na mrežnim stranicama Ureda. Sudionicima je ostavljena mogućnost da se cijelo vrijeme uključuju pitanjima i komentarima putem *chata.* S obzirom da su predviđena dva predavača za ovaj sadržaj, koji rade na odvojenim računalima, vrlo je lako posvetiti se predavanju sadržaja i komunikaciji sa sudionicima u isto vrijeme. Dok jedan predavač govori i može se u potpunosti koncentrirati samo na taj dio posla, drugi odgovara na pitanja i komentare sudionika. Prema potrebi, može se i drugi predavač glasovno uključiti kako bi potaknuo prvoga da na traženje sudionika nešto još bolje pojasni ili ponovi, a može i sam, kad je potrebno, nadopuniti izlaganje prvoga.

Pilot izvedba *webinara* održana je početkom rujna 2013. godine. Nakon dobivenih odličnih povratnih informacija, održano je do kraja siječnja 2014. godine još pet *webinara*. U Tablici I. prikazan je broj prijavljenih polaznika ukupno te broj prijavljenih polaznika izvan Zagreba. Veliki skok u broju prijavljenih u siječnju zasigurno ohrabruje. U prosincu je prvi put poslan poziv na prijavu na *webinar* i svim jedinicama lokalne i područne samouprave što je rezultiralo velikim povećanjem broja prijavljenih izvan Zagreba u siječnju.

Tablica I.

datum webinara	*broj prijavljenih*	*broj prijavljenih izvan Zagreba*
11.09. (pilot)	17	
20.09.	27	3
25.10.	29	8
29.11.	9	2
20.12.	10	5
28.01.	41	18

Broj prijava za *webinar* u veljači 2014. godine, iako još nije poslan službeni poziv za taj termin, ukazuje na trend povećanja broja sudionika u narednom periodu.

Pitanja i komentari postavljeni putem *chata* predstavljaju vrlo vrijedne povratne informacije. Ukazuju jasno što je potrebno od sadržaja obuhvatiti opsežnije, a što temeljitije izložiti.

III. PLANOVI ZA IZRADU NOVIH *WEBINARA*

S obzirom da Ured prema Zakonu direktno osigurava proaktivnu objavu službenih dokumenata kroz uspostavu i vođenje Središnjeg kataloga službenih dokumenata (u daljnjem tekstu Središnji katalog), postoje dodatni zahtjevi za edukacijskim programima, mimo onih koje Ured već provodi.

Naime, kako je Zakon relativno novijeg datuma, te obvezuje tijela javne vlasti dostavljati službene dokumente u Središnji katalog radi njihove formalne i sadržajne obrade te trajne pohrane i dostupnosti (čl. 10. stavak 2.), nameće se potreba za naputcima tijelima kako i što dostavljati u Središnji katalog. Kako bi Ured osigurao da Središnji katalog, kao središnje mjesto pristupa službenim dokumentima, bude učinkovit, potrebno je uspostaviti dobru komunikaciju s tijelima kako bi ona pravodobno dostavljala sve propisane dokumente.

Sva se tijela, obveznici dostave dokumenata u Središnji katalog, susreću s obvezom koja u Zakonu nije precizno razrađena, pa postavljaju pitanja Uredu o tome što i kako dostavljati. Kao pomoć pri odgovaranju na ta pitanja Ured je izradio dokumente u kojima se preciznije objašnjavaju obveze tijela. Ipak, s obzirom na različit profil tijela i osoba zaduženih za kontakt s Uredom i Središnjim katalogom, praksa je pokazala potrebu za dodatnim edukacijama koje će pomoći u osiguranju provedbe Zakona i time ostvarivanju prava na pristup informacijama. Problem predstavlja brojka obveznika dostave u Središnji katalog. Radi se o preko 5.000 tijela javne vlasti koja su dislocirana.

Kako Ured nije u mogućnosti u razumnom roku osigurati kvalitetnu edukaciju za sva tijela uživo, a što bi znatno utjecalo na dostavu dokumenata u Središnji katalog i na osiguranje kvalitetnog pristupa informacijama, odlučilo se za daljini razvoj *online* edukacije. Ponovno je, zahvaljujući svim prednostima i iskustvu dobre prakse, kao alat izabran *webinar*.

Planira se tijekom 2014. godine osmisliti *webinar* o načinu i sadržaju dostave službenih dokumenata u Središnji katalog, koji će biti namijenjen tijelima javne vlasti. Isti tim koji je izradio već predstavljeni *webinar* odredit će trajanje i sadržaj novog edukacijskog programa te se opredijeliti za platformu na kojoj će se uspostaviti virtualna soba.

IV. ZAKLJUČAK

Ured ima vrlo značajno mjesto u ostvarivanju prava na pristup informacijama. Poželjno je stoga pronalaziti neprestano nove načine kako bi se to pravo osvješćivalo i time se u sve većoj mjeri ostvarivala provedba Zakona. Kako je spektar usluga koje Ured nudi vrlo širok, treba koristiti što više kanala koji na bilo koji način mogu pomoći ostvarivanju postavljenih ciljeva Ureda.

Svaku ponuđenu uslugu potrebno je promovirati. Ukoliko se to ne učini, često će izostati željeni rezultat. S obzirom na doba u kojem računala kontinuirano povezuju

zainteresirane neovisno o mjestu na kojem se njihovi korisnici nalaze, puno je lakše pronaći prave kanale. Edukacijski alati koji se nude uvelike mogu olakšati način rada odnosno poslovanja.

Webinar se kao alat pokazao više nego primjerenim za trenutne potrebe rada Ureda, kao što je i asinkroni *online* program 2012. godine ispunio svoju svrhu. Iako korisnici kojima su edukacije namijenjene teže prihvaćaju nove načine usvajanja znanja i vještina, ipak se vide pomaci, koji su najviše vidljivi po sve većem interesu za izrađeni *webinar*, kao i odobravanju koje stiže nakon najava o održavanju *webinara* i o drugim srodnim sadržajima.

Webinar Predstavljanje tražilice pravnih propisa Republike Hrvatske – CADIAL jedan je od prvih webinara u okviru državne uprave. Trebao bi poslužiti kao primjer dobre prakse. *Webinar* kao alat jednostavan je za korištenje, tehnički i financijski nezahtjevan, omogućuje prijenos seminara, prezentacija, predavanja, radionica, konferencija i ostalih događaja koji se prenose u realnom vremenu putem interneta. Omogućuje davanje, primanje i komentiranje informacija, što omogućava interakciju između predavača i sudionika koji se mogu nalaziti na više različitih lokacija. Sve su navedene prednosti izuzetno značajne, posebice u današnje vrijeme nedostatnih financijskih sredstava i kroničnog nedostatka vremena.

Za prvi *webinar* Ureda postojao je predložak u vidu prezentacije uživo, dok će *webinar* o dostavi dokumenata u Središnji katalog zahtijevati više napora u osmišljavanju sadržaja. Ipak, upravo se njime planira doprijeti do svih onih koji na dnevnoj bazi moraju surađivati s Uredom kako bi svi zajedno, kreirajući Središnji katalog, radili na ostvarivanju prava na pristup informacijama.

Izračun viših momenata distribucija pomoću VBA programskog jezika u Excelu

M. Gardijan*, B. Šego* i T. Škrinjarić*

* Ekonomski fakultet Sveučilišta u Zagrebu, Katedra za matematiku, Zagreb, Hrvatska
mail: mgardijan@efzg.hr, bsego@efzg.hr, tskrinjaric@efzg.hr

Sažetak - Standardni Markowitzev model optimizacije portfelja temelji se na dva parametra pojedinačnih dionica i samog portfelja – na očekivanoj vrijednosti te varijanci i kovarijanci kao mješovitom momentu. Izračun u Microsoft Excelu sastoji se od nekoliko koraka, pri čemu se koristi alat Rješavatelj. Međutim, ekonomska teorija i empirijska istraživanja pokazali su kako je u analizu potrebno uključiti i više momente: treći moment – koeficijent asimetrije, te četvrti moment – koeficijent zaobljenosti. Uvođenje viših momenata znatno otežava optimizaciju samog portfelja jer je potrebno računati sve mješovite momente trećeg i četvrtog reda. Ovaj rad nastoji, prvi puta u svijetu, prikazati kako se izračun samih momenata može znatno olakšati programiranjem u *Visual Basic for Application* (VBA) za Excel. Korištenjem VBA, dizajnirana je radna knjiga u kojoj se pokreću makronaredbe s funkcijama koje na temelju unesenih podataka o cijenama računaju prva četiri momenta distribucije prinosa te dobivene podatke prikazuju u radnim listovima na pregledan način. Funkcije zahtijevaju interakciju s korisnikom za što su implementirane korisničke forme i dijaloški prozori. Korišteni kod je jednostavan i koristi logičke petlje koje se lako mogu prilagoditi i za izračun viših momenata uvođenjem dodatnih varijabli.

I. UVOD

Tržišta kapitala, kao i druga financijska tržišta, dugi su niz desetljeća od velikog interesa investitorskoj i akademskoj zajednici. Upravljanje rizicima i optimalno upravljanje portfeljem jedna su o ključnih pitanja ekonomskih istraživanja, posebice u doba različitih turbulencija na financijskim tržištima, kao i u doba krize čije se posljedice još uvijek osjećaju. Markowitzev model (Markowitz 1952) kao temeljni model moderne teorije portfelja danas je dobro poznat u području financijskog investiranja. Temelji se na dva parametra distribucija prinosa dionica: prvi moment (očekivana vrijednost) te drugi moment (varijanca, te kovarijanca kao mješoviti drugi moment). Markowitz je, dakle, pretpostavljao da su jedino prva dva momenta distribucija prinosa važna za donošenje odluka o formiranju portfelja. Međutim, od samog nastanka ovog modela javljaju se kritike na račun istog. Pokazano je na teorijskoj razini, ali i u empiriji kako investitori uzimaju u obzir i treći te četvrti moment prinosa portfelja. Uvođenjem viših momenata u analizu, znatno se otežava sama optimizacija. Empirijski radovi koji se bave ovakvim modelima pojavljuju se tek 1991. godine (Lai 1991), pri čemu je u analizu najprije uključen treći moment, a četvrti je tek prije nekoliko godina uveden. Analiza inicijalnog Markowitzevog modela u Microsoft Excelu već je dobro poznata (pogledati, primjerice, Aljinović, Marasović i Šego 2008, 2011), dok s druge strane, izračun viših momenata distribucija prinosa, kao i sama optimizacija portfelja koji ih koriste nije. Ne postoji komercijalni *software* koji bi temeljem unesenih podataka o kretanju prinosa računao sve potrebne momente i mješovite momente te ih koristio dalje u optimizaciji. Ono što se smatra kompliciranim za izračun u pravilu predstavlja limitirajući faktor za daljnja istraživanja, što uzrokuje da su i pogledi na određena područja limitirani. Stoga je cilj ovoga rada prikazati kako pomoću Excela i programskog jezika VBA modelirati izračun viših momenata kao prvi korak u analizi optimizacije portfelja koji uzimaju u obzir spomenute momente, i proširiti mogućnosti za istraživanje na području optimizacije portfelja

II. MARKOWITZEV MODEL I KRITIKE

Markowitzev model u okvir ekonomike izbora smješta izbor portfelja temeljem očekivanog prinosa portfelja s jedne, i varijance koja mjeri rizik s druge strane. Pretpostavlja se da investitor raspolaže s podacima o cijenama za $i \in \{1,2,...,I\}$ dionica u posljednjih $t \in \{1,2,...,T\}$ razdoblja. Prinosi na dionicu i u vremenskom razdoblju t računaju se kao kontinuirani prinosi formulom

$$R_i(t) = \ln\left(\frac{P_i(t)}{P_i(t-1)}\right), \tag{1}$$

pri čemu $R_i(t)$ predstavlja prinos na dionicu i za razdoblje t, a ln prirodni logaritam. Očekivani prinos $E(R_i)$ dionice i, $i \in \{1,2,...,I\}$, računa se kao aritmetička sredina prinosa na tu dionicu $R_i(t)$, $t \in \{1,2,...,T\}$:

$$E(R_i) = \frac{1}{T}\sum_{t=1}^{T} R_i(t), \tag{2}$$

dok je varijanca prinosa σ_i^2 dionice i dana formulom

$$\sigma_i^2 = E\left[R_i(t) - E(R_i)\right]^2 = \frac{1}{T}\sum_{t=1}^{T}\left[R_i(t) - E(R_i)\right]^2. \tag{3}$$

Očekivana vrijednost prinosa pojedinačne dionice predstavlja nagradu koju investitori očekuju ulaganjem u dionicu. S druge strane, varijanca prinosa predstavlja rizik koji je pritom potrebno preuzeti. Kovarijanca kao mješoviti moment mjeri povezanost kretanja prinosa jedne dionice s kretanjima prinosa druge. Kovarijanca prinosa između dviju dionica i i j dana je izrazom

$$cov(R_i, R_j) = E\left[\left(R_i(t) - E(R_i)\right)\left(R_j(t) - E(R_j)\right)\right] =$$
$$= \frac{1}{T}\sum_{t=1}^{T}\left(R_i(t) - E(R_i)\right)\left(R_j(t) - E(R_j)\right). \tag{4}$$

Označimo li s w_i relativni udio dionice i u portfelju P, očekivani prinos portfelja $E(R_P)$ računa se kao ponderirana aritmetička sredina prinosa na pojedinačne dionice koje ga sačinjavaju, pri čemu su ponderi udjeli w_i:

$$E(R_P) = \sum_{i=1}^{I} w_i E(R_i). \tag{5}$$

Očekivani prinos portfelja konstruira se kao vagana aritmetička sredina pojedinačnih očekivanih prinosa dionica, dok se varijanca portfelja konstruira temeljem pojedinačnih varijanci prinosa dionica,

te kovarijanci kako bi se konstruirao portfelj kojeg će karakterizirati struktura koja će ostvarivati maksimalni mogući prinos za danu razinu rizika, odnosno minimalnu varijancu (rizik) za danu razinu prinosa.

Varijanca portfelja dana je izrazom

$$\sigma_P^2 = \sum_{i=1}^{I} w_i^2 \sigma_i^2 + 2 \sum_{\substack{i,j=1 \\ i \neq j}}^{I} w_i w_j cov\left(R_i, R_j\right) = \sum_{i=1}^{I} \sum_{j=1}^{I} w_i w_j \sigma_{ij}. \quad (6)$$

S obzirom da je w_i relativni udio dionice u promatranom portfelju, mora vrijediti

$$\sum_{i=1}^{I} w_i = 1, \quad (7)$$

što znači da zbroj relativnih udjela svih dionica koje sačinjavaju portfelj mora biti jednak jedinici (samo te dionice čine portfelj i niti jedne druge). Ako se pretpostavi da postoji mogućnost kratke prodaje, ne nameću se nikakve restrikcije na predznak udjela w_i. U suprotnom, isključi li se kratka prodaja, uvode se ograničenja:

$$w_i \geq 0, \forall i. \quad (8)$$

Temeljem uvedenih oznaka za očekivani prinos pojedine dionice, varijancu te same udjele dionica u portfelju, model pronalaska efikasne granice uz isključenje mogućnosti kratke prodaje simbolički pišemo ovako:

$$\max_{w_i} \quad E\left(R_P\right) = \sum_{i=1}^{I} w_i E\left(R_i\right)$$

uz ograničenja

$$\sigma_P^2 = \sum_{i=1}^{I} \sum_{j=1}^{I} w_i w_j \sigma_{ij} \leq c \quad \text{(I)}$$

$$\sum_{i=1}^{I} w_i = 1$$

$$w_i \geq 0, \quad i \in \{1,\ 2,\ ..,\ I\}.$$

Varijable odlučivanja su udjeli dionica w_i, dok je c proizvoljno zadana razina rizika. Uz pretpostavku postojanja mogućnosti kratke prodaje, posljednjih I ograničenja o nenegativnosti udjela svih dionica u portfelju nestaju. Izračun svih potrebnih elemenata te sama optimizacija ovog modela u Excelu prikazana je u Aljinović, Marasović i Šego (2011).

Iako su Markowitzevi doprinosi omogućili znatan napredak u području investiranja, od samog nastanka modela javljaju se kritike na pretpostavke na kojima se temelji. Jedna od najviše kritiziranih pretpostavki modela jest ona o normalnoj distribuciji prinosa dionica. Ako je zadovoljena pretpostavka o normalnoj distribuciji prinosa dionica u portfelju, dovoljno je samo prva dva momenta koristiti u optimizaciji. Međutim, financijske serije karakteriziraju nesimetrične leptokurtične distribucije. Negativna ili pozitivna asimetrija odnose se na broj nastupa ekstremnih prinosa, s jedne strane ispodprosječnih, a s druge nadprosječnih. Ako je prisutna pozitivna asimetrija distribucije prinosa, nadprosječne prinose karakterizira veći broj nastupa u odnosu na ispodprosječne. S druge strane, negativno asimetrična distribucija ukazuje kako postoji veći broj nastupa ispodprosječnih ekstremnih prinosa (gubitaka). Uvođenjem trećeg momenta u analizu, koeficijenta asimetrije i koasimetrije, uzimaju se u obzir takvi ekstremni događaji, pri čemu se nastoji maksimizirati pozitivna asimetrija portfelja. Leptokurtične distribucije karakteriziraju šiljatiji vrhovi u odnosu na normalnu distribuciju, stoga su repovi tih distribucija deblji, dok platikurtične distribucije karakteriziraju plosnatiji vrhovi i tanji repovi u odnosu na normalnu distribuciju. Kako se debljina repova distribucije veže uz vjerojatnosti nastupa ekstremnih događaja, važno je uključiti u analizu i četvrti moment distribucija – koeficijent zaobljenosti i kozaobljenosti. Pri tom se teži minimizaciji zaobljenosti portfelja, kako bi se smanjila vjerojatnost nastupa ekstremih događaja jer su, po pretpostavci, investitori neskloni riziku (Markowitz 1991, Fabozzi i Markowitz 2002).

Prikažimo izračun viših momenata samih prinosa dionica te portfelja. Raspolaže li investitor s prinosima i očekivanim prinosima pojedine dionice, koeficijent asimetrije jednak je[1]:

$$s_{iii} = E\left[\left(R_i - E\left(R_i\right)\right)^3\right]. \quad (9)$$

Promatranjem zajedničke distribucije prinosa R_i i R_j, koasimetričnost s_{iij} se definira kao[2]

$$s_{iij} = E\left[\left(R_i - E\left(R_i\right)\right)\left(R_i - E\left(R_i\right)\right)\left(R_j - E\left(R_j\right)\right)\right]. \quad (10)$$

Analogno izračunu koasimetričnosti s_{iij}, definira se i koasimetričnost s_{ijj}:

$$s_{ijj} = E\left[\left(R_i - E\left(R_i\right)\right)\left(R_j - E\left(R_j\right)\right)\left(R_j - E\left(R_j\right)\right)\right]. \quad (11)$$

Važno je uočiti simetričnost u izračunu koasimetričnosti. Naime, vrijedi $s_{iij}=s_{iji}=s_{jii}$, kao i što u slučaju za više od dvije dionice vrijedi:

$$s_{ijk} = E\left[\left(R_i - E\left(R_i\right)\right)\left(R_j - E\left(R_j\right)\right)\left(R_k - E\left(R_k\right)\right)\right], \quad (12)$$

pri čemu je $s_{ijk}=s_{ikj}=s_{jik}=s_{jki}=s_{kij}=s_{kji}$, što je posljedica zakona komutacije za množenje realnih brojeva. Na taj način, zbog simetričnosti je u slučaju I dionica potrebno izračunati $\binom{I+2}{3}$ različitih koeficijenata asimetrije i koasimetrije, koristeći formulu:

$$s_{ijk} = \frac{1}{T}\sum_{t=1}^{T}\left(R_i(t) - \bar{R}_i\right)\left(R_j(t) - \bar{R}_j\right)\left(R_k(t) - \bar{R}_k\right),$$
$$i \in \{1,2,...,I\},\ j \in \{1,2,...,I\},\ k \in \{1,2,...,I\}. \quad (13)$$

Koeficijent zaobljenosti za pojedinačnu dionicu se može definirati formulom

$$k_{iiii} = E\left[\left(R_i - E\left(R_i\right)\right)^4\right]. \quad (14)$$

Općeniti zapis kozaobljenosti svodi se na:

$$k_{ijkl} = E\left[\left(R_i - E\left(R_i\right)\right)\left(R_j - E\left(R_j\right)\right)\left(R_k - E\left(R_k\right)\right)\left(R_l - E\left(R_l\right)\right)\right]. \quad (15)$$

Kao i u slučaju izračuna koasimetrije, i prilikom izračuna kozaobljenosti prisutna je određena simetrija. U slučaju I dionica potrebno je izračunati $\binom{I+3}{4}$ različita koeficijenata zaobljenosti i kozaobljenosti, koristeći formulu:

[1] Sve formule i rezultati u ovome dijelu rada izvode se i detaljno objašnjavaju u Škrinjarić (2013b).
[2] R_i i R_j su zapravo $R_i(t)$ i $R_j(t)$.

$$k_{ijkl} = \frac{1}{T}\sum_{t=1}^{T}\left(R_i(t)-\bar{R}_i\right)\left(R_j(t)-\bar{R}_j\right)\left(R_k(t)-\bar{R}_k\right)\left(R_l(t)-\bar{R}_l\right),$$

$$i \in \{1, 2, ..., I\}, j \in \{1, 2, ..., I\}, k \in \{1, 2, ..., I\}, l \in \{1, 2, ..., I\}. \quad (16)$$

Uvedeni pojmovi sintetiziraju se u model optimizacije portfelja uzimajući u obzir više momente[3]:

$$\max_{w_i}\left[E(R_P) = \sum_{i=1}^{I} w_i E(R_i)\right]$$

$$\min_{w_i}\left[\sigma_P^2 = \sum_{i=1}^{I}\sum_{j=1}^{I} w_i w_j \sigma_{ij}\right]$$

$$\max_{w_i}\left[S_{Pr} = \frac{\sum_{i=1}^{I}\sum_{j=1}^{I}\sum_{k=1}^{I} w_i w_j w_k s_{ijk}}{\sigma_P^3}\right]$$

$$\min_{w_i}\left[K_{Pr} = \frac{\sum_{i=1}^{I}\sum_{j=1}^{I}\sum_{k=1}^{I}\sum_{l=1}^{I} w_i w_j w_k w_k k_{ijkl}}{\sigma_P^4}\right] \quad \text{(II)}$$

uz ograničenja

$$\sum_{i=1}^{I} w_i = 1$$

$$w_i \geq 0, \quad i \in \{1, 2, ..., I\}.$$

Dakle, radi se o pristupu optimizacije četiri funkcije cilja, pri čemu se maksimizira očekivan prinos portfelja te koeficijent asimetrije portfelja, dok se minimiziraju rizik (varijanca) te koeficijent zaobljenosti portfelja. Navedeni pristup sastoji se od višekriterijske optimizacije četiri funkcije cilja na skupu mogućih rješenja.

III. TEORIJSKA I EMPIRIJSKA OPRAVDANJA KORIŠTENJA VIŠIH MOMENATA

Athayde i Flores (2004) obrazlažu da investitori preferiraju veće vrijednosti neparnih momenata portfelja (tu ubrajamo očekivani prinos i asimetričnost), dok teže manjim vrijednostima parnih momenata portfelja (rizik te zaobljenost) kako bi na taj način smanjili gubitke i povećali vjerojatnosti ostvarivanja dobitaka. U posljednjih nekoliko godina interes za proučavanjem viših momenata u okviru optimizacije portfelja i vrednovanja imovine sve je veći, i to iz razloga koje spominju Jurzcenko i Mallet (2006): rastući interes i briga investitora za ekstremne rizike, uspjesi koje su ostvarivali investicijski fondovi čija distribucija imovine nije bila normalna, ali i teorijski, ekonometrijski i statistički napredak u izgradnji modela koji uzimaju u obzir više momente. Sam Markowitz (Fabozzi i Markowitz 2002) priznaje da promatranjem empirijskih distribucija prinosa dionica možemo uvidjeti je li opravdano ili ne koristiti samo prva dva momenta, ili pak i više ako distribucije prinosa nisu normalne.

Već se 1953. godine javlja interes za višim momentima vrijednosnica u radu Kendalla i Hilla (1953), koji su utvrdili prisutnost asimetrije kao i zaobljenosti u empirijskim distribucijama prinosa dionica. Uslijedili su i radovi Mandelbrota (1963a, 1963b) koji je zaključio kako su vremenske serije promjena cijena šiljatijih vrhova i debljih repova u odnosu na normalnu distribuciju. Cootner (1964) i Fama (1965) donose slične zaključke za distribucije vrijednosnica. 1967. godine Arditti (1967) je pokazao kako je pojedini investitor skloniji većoj asimetriji portfelja, što je u skladu s pojmom smanjujuće apsolutne averzije rizika. Alderfer i Bierman (1970) proveli su istraživanje u kojemu su ispitanicima nudili nekoliko investicijskih alternativa koje su bile slične što se tiče rizika i prinosa, ali su bile veoma različite što se tiče asimetrije distribucije prinosa. Željeli su potvrditi istraživačku hipotezu kako viši prinosi distribucija prinosa, s naglaskom na asimetriju, imaju značajan učinak na odabir vrijednosnica u portfelj. Rezultati istraživanja su potvrdili njihovu hipotezu, to jest investitori su preferirali pozitivnu asimetriju prinosa, čak i uz manji očekivani prinos!

U sedamdesetim godinama prošlog stoljeća dolazi do jačanja interesa za proučavanjem viših momenata u teoriji portfelja. Samuelson (1970) je prvi razmatrao očekivanu korisnost investitora temeljem tri momenta portfelja, a uskoro je uslijedio i doprinos Rubinsteina (1973) koji je proširio model procjenjivanja kapitalne imovine uzimanjem u obzir trećeg momenta distribucija[4]. U teorijskoj analizi se, dakle, najprije uvodi treći moment portfelja u analizu, zbog relativno jednostavnijeg izračuna u odnosu na četvrti moment. Tek 1988. godine Graddy i Homaifar (1988) proširuju analizu portfelja na četvrti moment. Zaobljenost je dugo zanemarivana u analizi, jer je s porastom dimenzije momenata portfelja koji se analiziraju teže dati njihovu interpretaciju (Jurczenko i dr. 2006). Uvođenje viših momenata u analizu znači kako funkcije korisnosti investitora neće više biti kvadratne (ne ovise samo o prva dva momenta), već u njih je potrebno inkorporirati preferencije prema asimetričnosti i zaobljenosti. Müller i Machina (1987) dokazali su teorem o funkciji korisnosti koja to uzima u obzir: „maksimizator korisnosti kojeg karakterizira neprekidna von Neumann-Morgensternova funkcija korisnosti $U(\cdot)$ rangirat će distribucije vjerojatnosti temeljem njihovih prvih m apsolutnih momenata ako i samo ako je $U(\cdot)$ polinom stupnja manjeg ili jednakog m."

Empirijski radovi koji rješavanju problem optimizacije portfelja uz više momente javljaju se od 90-ih godina prošloga stoljeća. Najčešći pristup jest provođenje kompromisnog programiranja, i tu ubrajamo radove Lai (1991), Chunhachinda i ostalih (1997), Prakasha i ostalih (2003), Sun i Yan (2003), Yang i Hung (2010) te od domaćih radova Škrinjarić (2013a). Svi navedeni autori, osim posljednje navedene, optimiziraju akademske primjere, dakle, koriste veoma mali broj dionica u analizi, što iziskuje relativno malo posla u Excelu. Međutim, povećavanjem opsega problema, kao što je to učinjeno u Škrinjarić (2013a), sam izračun se znatno otežava, s obzirom da ne postoji ustaljena procedura koja bi omogućila elegantno dobivanje rješenja. Stoga se iduće poglavlje bavi rješavanjem ovakvoga problema s kojim bi se investitori mogli suočiti u budućnosti.

IV. IZRAČUN MOMENATA U EXCELU

Računala omogućuju implementaciju i testiranje mnogih matematičkih modela u ekonomiji koji su desetljećima bili osuđeni na čekanje trenutka kada će primjena moćnijih računala omogućiti testiranje njihove valjanosti. No, većina korisnika računala oslanja se na korištenje već gotovih računalnih programa, što uzrokuje problem kada za istraživanje nekog problema nije dostupan već razvijeni softver. To je bio slučaj i u ovom problemu kod koje je dobra ideja trebala biti ostvarena korištenjem značajnog broja izračuna.

Prva četiri momenta za pojedinu dionicu nije problem računati, ali izračun komomenata zahtijeva repetitivan posao koji se značajno komplicira s višim momentima, što je vidljivo iz (13) i (15). Ako je I broj dionica, T broj mjeseci, a r red komometa kojeg treba izračunati, za svaki r-ti komoment prvo treba izračunati očekivani prinos za I dionica (izraz (2)), odstupanja ostvarenih od očekivanog prinosa $\left(R_i - E(R_i)\right), \forall i \in \{1,..,I\}$, umnoške svih mogućih kombinacija

[3] Izvod svih formula i objašnjenja u modelu dan je u Škrinjarić, T. (2013b).

[4] Uvođenje bezrizične imovine u portfelj analizirali su Jean (1971, 1972, 1973)[4] i Ingersoll (1975), dok su Arditti i Levy (1975) proširili analizu portfelja s tri momenta na višeperiodnu analizu. Kraus i Litzenberger (1976) nastavili su svoj rad na ideje Rubinsteina iz 1973. godine, pri čemu je njihovo istraživanje prvo empirijsko testiranje troparametarskog CAPM modela.

izračunatih *I* odstupanja od *r* elemenata (bez ponavaljanja) (12), te konačno prosjek izračunatih vrijednosti po mjesecima (13). Ako bi se takav posao radio ručno, izvršitelj mora razviti određeni sustav praćenja i evidentiranja kombinacija koje treba izračunati, za što je osim vremena potrebna i jako dobra koncetracija. Primjenjivost svakog modela za optimizaciju portfelja značajno ovisi brzini rješavanja problema. Zbog toga je bilo nužno napraviti program koji će u kratkom roku izračunati podatke koji su potrebni za rješavanje problema. Microsoft Excel je alat koji se često koristi za obradu i analizu financijskih podataka, pa se programiranje makronaredbi u Visual Basic for Application (VBA) za Excel nametnuo kao praktičan izbor.

Istraživanje je bilo usmjereno za traženje načina za brži izračun trećih i četvrtih komomenata distribucije potrebnih za rješavanje problema optimizacije modela (II), ali radna knjiga Excela, koja je dizajnirana za potrebe istraživanja ovog problema, sadržava i markonaredbe koje omogućavaju izračun svih momenata potrebnih za optimizaciju kako bi korisnik najjednostavnije došao do svih potrebnih podataka. Radni list je oblikovan tako da usmjerava korisnika na pravilno unošenje podataka o cijenama dionica kako bi ih funkcije mogle koristiti. Korisnik unosi ulazne podatke o izabranim dionicama u radni list „*cijene*“ počevši od ćelije B2. Svaka je dionica tako određena rednim brojem stupca u kojoj su njeni podaci uneseni. Na dnu radnog lista „*cijene*“ postavljeno je više *ActiveX* kontrola (slika 1) koje aktiviraju makronaredbe za izračun prinosa, matrice kovarijanci te viših momenata. Korisnik može birati za koliki broj svih dionica odnosno razdoblja, počevši od prve dionice i prvog razdoblja, želi izvršavati makronaredbe unoseći te podatke u dijaloški okvir. Na listu su postavljene i kontrole koje pokreću kopiranje izračunatih momenata u jedan radni list, kako bi se ti podaci lakše koristili u daljnoj optimizaciji.

Klikom miša na kontrolu s naslovom „*Izračunaj prinose*“ izvršava se makronaredba *lnReturn* koja računa prinos. Nakon što korisnik unese podatke o broju dionica (*nbSt*) i broju mjeseci (*nbMo*), procedura briše listove koji imaju naslov *lnPrinosi#* te stvara novi radni list *lnPrinosi#*:

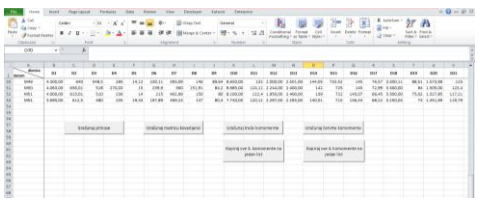
```
For Each ws In ActiveWorkbook.Sheets
   If Left(ws.Name, 10) = "LnPrinosi#" Then ' brisi postojece listove
      Application.DisplayAlerts = False
      ws.Delete
      Application.DisplayAlerts = False
   End If
Next

Set ws = Sheets.Add(After:=Sheets(Worksheets.Count)) 'stvori novi
list
ws.Name = "LnPrinosi#"
Worksheets("LnPrinosi#").Activate.
```

U određenom rasponu aktivnih listova (definiranom prema vrijednostima *finishRow=nbMo* i *lnfinishCol=nbSt*+1) svakoj se ćeliji (*I, J*) dodjeljuje svojstvo, tj. vrijednost formule za izračun prinosa (1) koja vuče vrijednosti s relativnih pozicija iz radnog lista „*cijene*“ koristeći dvije petlje FOR…NEXT :

```
   With Selection
      For J = 2 To lnfinishCol
         For I = 2 To finishRow
            Cells(I, J).Value = "=+LN(cijene!R[1]C/cijene!RC)"
         Next I
      Next J
   End With.
```

Nakon što se petlje FOR…NEXT izvrše, funkcija u zadnjem retku



Slika 1 – Prvi list radne knjige u Excelu

(*averRow*) radnog lista računa prosjek vrijednosti izračunatih u svakom stupcu, a koji se odnose na mjesečne prinose za svaku dionicu:

```
averRow = nbMo + 1
For J = 2 To lnfinishCol 'izracun prosjeka
   Cells(averRow, J).Select
   ActiveCell.FormulaR1C1 = "=+AVERAGE(R2C:R[-1]C)"
Next J.
```

Funkcije za brisanje i stvaranja novih radnih listova, te za računanje prosjeka su uz prilagodbu korištene i u ostalim makronaredbama. Za izračun matrice kovarijanci preuzeta je funkcija koja je prilagođena ovom radnom listu [4]. Funkcija se aktivira kao dio makronaredbe preko kontrole „*Izračunaj matricu kovarijanci*“ te stvara novi radni list u kojem se ispisuje matrica kovarijanci za željeni broj dionica i broj razdoblja.

Za izračun trećih komomenata napisana je makronaredba *momenti3* koja se aktivira klikom miša na kontrolu „*Izračunaj treće komomente*“. Makronaredba poziva nekoliko podprocedura i funkcija, između ostalog računa prinose za zadani broj dionica i razdoblja, te za svaku od *I* dionica kreira novi radni list u kojem se računaju koasimetričnosti. U svakom *i*-tom radnom listu s 3. komomentima, $i \in \{1,..,I\}$, računaju se koasimetričnosti s_{ijk} (12) za *i*-tu dionicu po mjesecima. U ovoj fazi se definiraju 3 varijable koje kontroliraju izmjenu članova umnoška iz formule (12): varijabla *I* koja poprima vrijednosti od 1 do *nbSt* te kontrolira redni broj dionice, odnosno prvi član umnoška od tri člana kao i otvaranje novog radnog lista, varijabla *J* koja poprima vrijednosti od *I* do *nbSt* te kontrolira izmjenu drugog člana umnoška i, konačno, varijabla *K* koja poprima vrijednosti od *L* do *nbSt* te kontrolira izmjenu zadnjeg člana umnoška. Svakoj aktivnoj ćeliji u prvom retku raspona (*nbSt*, *nbMo*) u aktivnom radnom listu se dodijeljuje formula s različitim vrijednostima varijabli *I, J* i *K* pomoću petlji FOR…NEXT te svojstva *formulaR1.C1* koje vuče vrijednosti s relativnih pozicija radnog lista *lnPrinosi3*. Tako se kontrolira da se u svakoj ćeliji računa različita koasimetričnost s obzirom na različite kombinacije između dionica *J, K, L*. Svaka sljedeća definirana varijabla (dakle, *J* i *K*) poprima najmanju vrijednost jednaku vrijednosti prethodne varijable što onemogućava neželjeno ponavljanje izračuna kombinacija, pa je broj izračuna u svakoj *i*+1 iteraciji manji nego u prethodnoj *i*-toj iteraciji. Kod je sljedeći:

```
For I = 1 To nbSt
  Range(Cells(2, 2), Cells(finishRow, finishCol)).Select
    With Selection ' racunaj momente
        For J = I + 1 To nbSt + 1
        If J > (nbSt + 1) Then
            J = 2
          Else: J = J
        End If
         For K = J To (nbSt + 1)
          ActiveCell.FormulaR1C1 = "=(LnPrinosi3!RC" & I + 1 &
"-LnPrinosi3!R" & averRow & "C" & I + 1 & ")*(LnPrinosi3!RC" &
J & "-LnPrinosi3!R" & averRow & "C" & J & ")*(LnPrinosi3!RC"
& K & "-LnPrinosi3!R" & averRow & "C" & K & ")"
           ActiveCell.Offset(0, 1).Range("A1").Select
            Next K
        Next J
If I = nbSt Then 'pozicija zadnjeg stupca
      lastCol = 2
    Else
      lastCol = Cells(2, 2).End(xlToRight).Column
 End If
      Range(Cells(2,2),Cells(2,lastCol)).AutoFill
Destination:=Range(Cells(2, 2), Cells(finishRow, lastCol)),
Type:=xlFillDefault.
```

U zadnjem retku radnog lista funkcija računa prosjek izračunat u svim razdobljima promatranja:

```
Range(Cells(averRow, 2), Cells(averRow, lastCol)).Value =
"=+AVERAGE(R2C:R[-1]C)".
```

Procedura se zatim obavlja za sljedeću vrijednost varijable *I*. Nakon što se prodecura izvrši za svih *I* dionica, u radnoj knjizi je stvoreno upravo *I* novih radnih listova u kojima su u zadnjem retku izračunate koasimetričnosti. Izračun koasimetričnosti pomoću svojstva *ActiveCell.FormulaR1C1* je slijedio iz dva razloga: prvo, korisnik u svakom trenutku može vidjeti na koji način i za koje dionice je izračunata koasimetričnost u određenoj ćeliji, a drugo, mogućnost korištenja funkcije *AutoFill* koja kopira formulu za izračun u svim preostalim recima odnosno stupcima, što je doprinijelo brzini izračunavanja potrebnih vrijednosti.

Prosjeci, koji su izračunati u zadnjem korištenom retku u svakom kreiranom radnom listu s 3. komomentima su zapravo jedini inputi koji su potrebni za daljnju analizu modela (II), pa je u radnom listu „*cijene*“ postavljena *ActiveX* kontrola s oznakom „*Kopiraj sve 3. komomente na jedan list*“ kojom se stvara novi radni list s ispisanim svim očekivanim komomentima (prosječne vrijednosti) na jedan list („*3komomenti-prosjek*“).
Za izračun četvrtih momenata se obavlja slična prodecura, samo što je u kodu dodana još jednu varijabla-brojač koja kontrolira izmjenu četvrtog člana umnoška iz (15) od četiri člana, odnosno dodatne petlje u kodu.

ZAKLJUČAK

Na opisani način konstruirana je radna knjiga s makronaredbama koje su pristupačne korisniku i na prosječnom osobnom računalu u relativno kratkom vremenu (u usporedbi s vremenom potrebnim za ručni izračun u Excelu) računaju potrebne ulazne podatke za rješavanje problema optimizacije portfelja dionica uzimajući u obzir i treće i četvrte komomente distribucije. Ilustracije radi, za manualni izračun trećih i četvrtih momenata na uzorku od 24 dionice kroz 52 mjeseca koristeći Excel i „razvlačenje formula“ potrebno je izgubiti značajan broj sati rada, odnosno dana rada (prema našem iskustvu 3 tjedna), a u tom periodu su korišteni podaci već zastarjeli i nove dionice postaju kandidati za ulazak u portfelj. Na prosječnom računalu s 64-bitnim operativnim sustavom, *i*3 procesorom s 2,13GHz i 3Gb RAM-a, makronaredba za izračun 3. momenata se izvršava za približno 33 sekunde, a makronaredba za izračun 4. momenata u prosjeku za nešto više od minutu po dionici. Također, funkcija koja kopira sve vrijednosti na jedan list izvršava se jako brzo, a kod kopiranja 4. momenata je ipak potrebno nešto manje od minute. Smatra se da će takva radna knjiga u budućim istraživanjima olakšati analizu financijskih podataka i drugim potencijalnim korisnicima, te da će druge korisnike potaknuti i uputiti na dizajniranje programa prema vlastitim potrebama. Kako i optimizacija s dobivenim podacima zahtijeva značajne napore u izračunu, sljedeći korak je dizajniranje makronaredbe u Excelu koja korištenjem ovih podataka uz pomoć Rješavača rješava problem optimizacije portfelja.

VAŽNOST UVOĐENJA NOVIH TEHNOLOGIJA U OBRAZOVNE INSTITUCIJE ZA RAZVOJ LOKALNOG GOSPODARSTVA

Mr.sc.Anica Vukašinović*
*Brodsko-posavska županija/Upravni odjel za obrazovanje šport i kulturu, 35 000 Slavonski Brod, Hrvatska
e-mail:anica.vukasinovic@gmail.com

Sažetak - U kontekstu velikih globalizacijskih izazova poput znanstvenog i tehnološkog napretka,demografskih promjena,transformacije nacionalnih gospodarstava, zahtjeva za brzim stjecanjem znanja i vještina potrebnih sve zahtjevnijem tržištu rada te potrebi za cjeloživotnim učenjem, sustav odgoja i obrazovanja u Hrvatskoj potrebno je mijenjati i usklađivati s gospodarstvima razvijenih zemalja utemeljenim na znanju. Na taj način moguće je pokrenuti kotač gospodarske aktivnosti u Republici Hrvatskoj prema naprijed s ciljem osiguranja zapošljivosti radno aktivnog stanovništva, osiguranju kvalitete života i kulture življenja njenih stanovnika. Trend pada BDP-a u 2013.godine ogleda se u daljnjem smanjenju vrijednosti proizvedenih roba i usluga te zaposlenosti. Uloga obrazovnog sustava tu je ključna, posebice u dijelu strukovnog obrazovanja koje u razvijenim europskim zemljama vrlo uspješno odgovara na izazove današnjice uvođenjem novih tehnologija, stvaranju novih kompetencija, razvoju ljudskih potencijala s ciljem gospodarskog rasta i razvoja a time i održive zapošljivosti. Obzirom na višegodišnja relativno mala izdvajanja iz državnog proračuna za obrazovanje u Hrvatskoj u odnosu na druge razvijene zemlje i tendenciji daljnjeg smanjenja izdvajanja, teško možemo govoriti o kvalitetnim i brzim promjenama u obrazovnom sustavu. Fiskalni kapaciteti jedinica lokalne uprave i samouprave nisu ujednačeni i u pravilu rijetko osiguravaju viši standard obrazovnim institucijama na svom području. Korištenjem sredstva fondova EU obrazovne institucije u Hrvatskoj otvaraju vrata izazovima razvijenog društva, koristeći nove tehnologije, unapređujući odgojno obrazovni rad, provodeći brojne aktivnosti kojima se proširuju kompetencije nastavnika strukovnih škola i stvaraju materijalni preduvjeti za najsuvremeniju strukovnu nastavu, a u skladu s aktualnim potrebama gospodarstva. Strukovne obrazovne ustanove imaju mogućnost obrazovati učenike koji će biti konkurentni na tržištu rada, koji će svojim znanjima i vještinama biti pokretači gospodarskih aktivnosti na lokalnoj razini.
Na primjeru ulaganja u strukovne škole na području Brodsko-posavske županije pokazati ćemo važnost razvoja novih tehnologija u obrazovnim institucijama i njihov utjecaj na razvoj gospodarstva Brodsko-posavske županije.

Ključne riječi: nove tehnologije, obrazovne institucije, razvoj ljudskih resursa, tržište rada, kompetencije nastavnika

I. UVOD

U uvjetima globalne gospodarske krize, povećanja nezaposlenosti posebice mladih ljudi posjedovanje znanja, vještina i inovativnosti presudni su za razvoj pojedinca i sredine u kojoj djeluje. Razina stečenih znanja i vještina u formalnom obrazovanju u mnogim razvijenim zemljama, pa tako u Hrvatskoj pokazala se nedovoljnom za uključivanje mladih ljudi u svijet rada. Planiranje i razvoj kvalifikacija potrebnih tržištu rada već dulje vrijeme nije primarna aktivnost obrazovne politike u Republici Hrvatskoj, što je rezultiralo velikim brojem mladih nezaposlenih osoba. Gospodarski rast i razvoj kako lokalne tako i nacionalne razine odraz je neusklađenosti obrazovnog sustava i potreba gospodarstva.

Područje strukovnog obrazovanja najizravnije i najuže je povezano sa tržištem rada. U njegovoj je prirodi omogućiti stjecanje stručnih kompetencija koje su relevantne, suvremene i što je najbitnije, koje podupiru gospodarstvo i razvijaju ga na suvremen i konkurentan način.

I. OBRAZOVANJE I GOSPODARSKI RAST

Planiranje razvoja kvalifikacija ključno je pitanje svakog obrazovnog sustava u Europi i svijetu.
Istraživanja tržišta rada širom svijeta ukazuju na ključnu ulogu strukovnog obrazovanja u društvenom i gospodarskom razvoju. Preduvjet tomu je osmišljavanje relevantnih nastavnih planova i programa koji se temelje na identifikaciji i analiziranju potreba na tržištu rada. U prvoj fazi prema [1] identifikacija potreba na tržištu trebala bi se promatrati sa tri aspekta:

1. Poslovnih odnosa uključujući ciljeve, resurse i međunarodnu orijentaciju,
2. Izbor ljudskih resursa, tehnološke i menadžerske čimbenike
3. Trendove na tržištu rada, ponude i potražnje, buduće potrebe i ekonomske politike.

U drugoj fazi prilikom izrade kurikuluma treba uzeti u obzir:

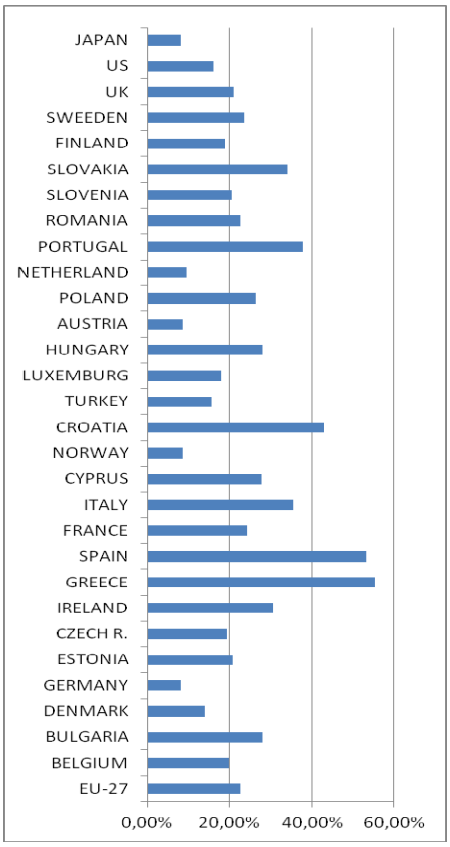
1. Učenike i njihove potrebe, posebno njihovo prethodno obrazovanje, sposobnosti i mogućnosti zapošljavanja
2. Stav učenika prema obrazovanju općenito,
3. Utvrđivanje svrhe škole

Utvrđivanje stvarne svrhe svake strukovne škole jedan je od važnih zadataka u budućem planiranju unapređenja strukovnog obrazovanja, koliko one zadovoljavaju sadašnje i buduće potrebe tržišta rada i s njima povezuju razvoj vještina i kompetencija kroz nastavni plan i program. Obrazovanje, povećanjem produktivnosti rada također doprinosi gospodarskom rastu. Produktivnost se prema [4] povećava s rezultatima obrazovanja i povećanjem zarada radne snage sa višom razinom obrazovanja. Relevantna literatura na temu pokazuje da se gospodarski rast ubrzao u zemljama gdje je razina obrazovanja viša. Doprinos obrazovanja gospodarskom rastu u nekim je slučajevima više od fizičkog kapitala kada se uzme u obzir stručnost radne snage i potrebe gospodarstva. U zemljama gdje je stupanj obrazovanja i gospodarski rast viši stopa izdvajanja iz nacionalnog dohotka za obrazovanje je viša, veća je kvaliteta rada, kao i mogućnosti dugoročnog zapošljavanja.

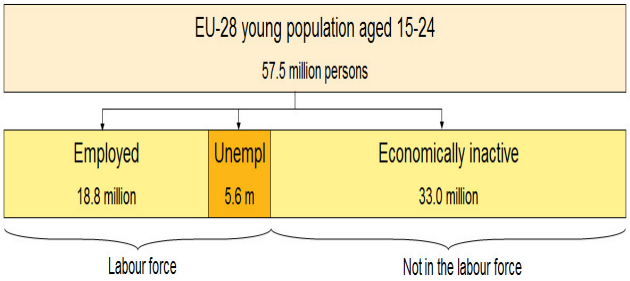
II. UČINCI EKONOMSKE KRIZE NA TRŽIŠTE RADA

Ekonomska kriza na tržištu rada EU odražava se kroz stopu nezaposlenosti. U prosincu 2013.godine 5.544.000 mladih osoba (do 25 godina) u EU-28 bilo je nezaposleno, od čega 3.500.000 u eurozoni (Slika 2). U odnosu na prosinac 2012.godine (Slika 1) nezaposlenost mladih smanjila se za 184 000 u EU-28, a za 77 000 u eurozoni. U prosincu 2013, stopa nezaposlenosti mladih iznosila je 23,2% u EU-28 i 23,8% u eurozoni, u usporedbi s 23,6% i 23,9%, koja je zabilježena u prosincu 2012. U prosincu 2013 najniže stope zabilježene su u Njemačkoj (7,4%) i Austriji (8,9%), a najviše u Grčkoj (59,2% u listopadu 2013), Španjolskoj (54,3%), i Hrvatskoj (49,2% u četvrtom kvartalu 2013 godine). Ukoliko promatramo tržište rada u SAD-u u prosincu 2013, stopa nezaposlenosti bila je 6,7 %, što je pad od 7,0% u odnosu na prethodni mjesec. U prosincu 2012. godine stopa nezaposlenosti u SAD-u iznosila je 7,9%.

Analize tržišta rada eurozone ukazuju na važnost posjedovanja potrebnih obrazovnih kvalifikacija radi lakšeg pronalaska zaposlenja. Ta karakteristika zabilježena je u svim zemljama članicama EU u 2012. godini. Stopa nezaposlenosti osoba sa nižim srednjim obrazovnim kvalifikacijama u 2012.godini kod osoba između 25 i 64 godine života, iznosila je 16,8% dok je kod onih koji su završili tercijalno obrazovanje niža i iznosila je 5,5%. Globalizacija i tehnološki napredak imaju sve veći utjecaj na svakodnevni život, a potražnja za različitim poslovima i radnim vještinama razvija se brzim tempom. Poduzeća u nastojanju da poboljšaju

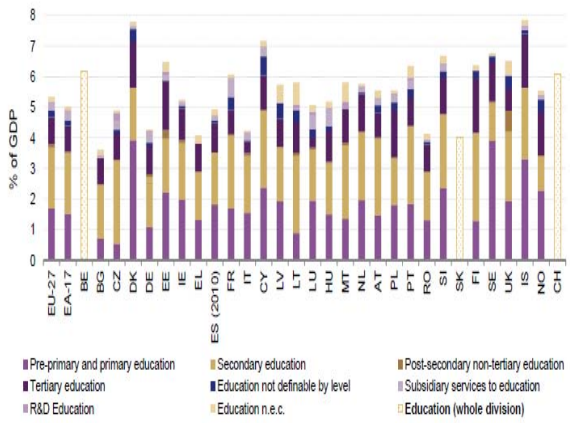


Slika 1. Stopa nezaposlenosti mladih do 25 godina u 2012godini. Izvor: Eurostat

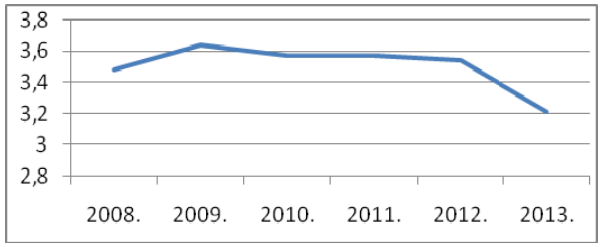


Slika 2.Mladi od 15-24 godine, EU-28, 2013. Izvor: Eurostat

svoju produktivnost, konkurentnost i inovativnost, trebaju sve fleksibilniju radnu snagu. Strategija Europa 2020 koju je donijela Europska komisija navodi viziju europske socijalne tržišne ekonomije za 21. stoljeće. U njoj su sadržane aktivnosti koje idu ka rješavanju uzroka globalne ekonomske krize, velike stope nezaposlenosti mladih ljudi, stvaranju potrebnih znanja i vještina, socijalnim politikama, uključujući i prijedloge usmjerene na institucije za obrazovanje i osposobljavanje, odnosno mjere za stvaranje (radnog) okruženja pogodnog za više stope aktivnosti i veću produktivnost rada. Tu su i inicijative usmjerene na povećanje stope mladih na tržištu rada.



Slika 3. Izdaci opće države za obrazovanje,% od BDP-a,2011
Izvor: Eurostat



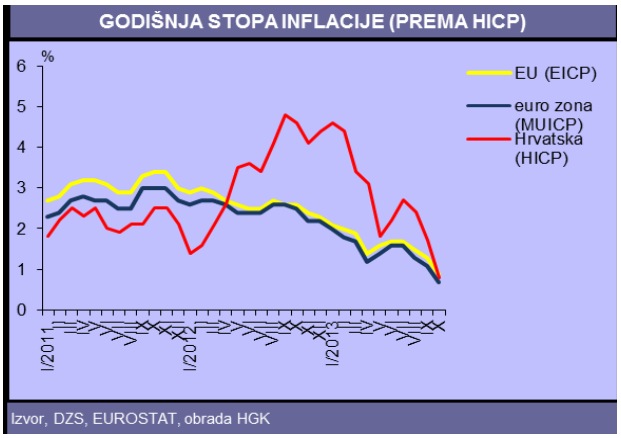
Graph 1. Izdvajanja iz proračuna RH za obrazovanje
Izvor: Ministarstvo financija, 2013

A. Neujednačenost proračunskih izdvajanja za obrazovanje

Iznos proračunskih izdvajanja za obrazovanje utječe na kvalitetu i učinkovitost obrazovnog sustava. Proračunski udio u BDP-u za obrazovanje EU-27 u 2011.godini iznosio je oko 347 milijardi eura (Slika 3). Značajnija izdvajanja za obrazovanje zabilježena su na Islandu (7,9 % BDP-a), Danskoj (7,8 % BDP-a) i Ciparu (7,2 % BDP-a), dok se najviše izdvajalo u u Estoniji (16,9 % ukupnih rashoda države), i Islandu (16,7 % ukupnih rashoda). Najniži omjer državnih rashoda za obrazovanje u BDP-u zabilježen je u Bugarskoj (3,6 % BDP-a), Slovačkoj (4,0 % BDP-a), Grčkoj i Rumunjskoj (obje na 4,1% BDP-a). U 2013. godini u Hrvatskoj su izdvajanja za obrazovanje iznosila 3,2% BDP-a s tendencijom daljnjeg smanjena (Graph 1).

B. Hrvatsko gospodarstvo u uvjetima globalne ekonomske krize

Prema [7] u 2013.godini u Hrvatskoj se nastavlja pad gospodarske aktivnosti koji se ogleda u smanjenju vrijednosti proizvedenih roba i usluga te zaposlenosti. Prema podacima Državnog zavoda za statistiku, u prva tri kvartala 2013. godine realni BDP je smanjen za 0,9%, pri čemu je najmanji pad (-0,6%), pod utjecajem dobre turističke sezone, zabilježen u trećem kvartalu. Struktura BDP-a za prvih devet mjeseci 2013.godine pokazuje da je i u Hrvatskoj najveći problem daljnji nastavak pada domaće potražnje, realno smanjena ukupna vrijednost



Slika 4. Godišnja stopa inflacije u periodu od 2011.-2013.godine
(premaHICP)

izvoza roba i usluga. U usporedbi s drugim članicama EU takvo kretanje BDP-a stavlja Hrvatsku među najneuspješnije članice, odnosno samo je Grčka (-4,3%) u razdoblju od 2008. do 2013. godine imala veću prosječnu stopu pada BDP-a od Hrvatske (-1,7%). Hrvatska i Grčka su ujedno jedine dvije zemlje kod kojih se u razdoblju od 2009. do 2013.godine konstantno bilježio pad BDP-a. Prema [7] sam oporavak od krize u 2013.godini u Hrvatskoj je među najsporijima, pa je svrstana među deset članica EU čiji je BDP realno manji nego u prethodnoj godini. U kontekstu rekordne nezaposlenosti i jakog eura, inflacija je slabila u 2013.godini na području cijele skupine zemalja EU-28 (Slika 4). Pritom je primjetno rastao broj zemalja koje su bilježile deflaciju (Grčka, Bugarska, Cipar, Irska) ili su na njenom samom rubu s razinom inflacije od 0,0% (Španjolska, Latvija, Portugal).

C. Tržište rada u Hrvatskoj

Evidencija Hrvatskog zavoda za zapošljavanje, u prvih deset mjeseci 2013. godine bilježi prosječno 342.107 nezaposlene osobe. Toliki broj nezaposlenih zabilježen je jedino 2002. godine, kad je evidentirano preko 389 tisuća nezaposlenih. Tada već, s podacima za nepunu 2013. godinu, nezaposlenih je osoba bilo otprilike 17% više nego prethodnih kriznih godina (računavši prosjek od 2008. do 2012.), sa očekivanjem daljnjeg rasta. Od ukupno 344.444 nezaposlene osobe registrirane na Zavodu krajem listopada 2013.godine, najviše njih (63%) imalo je završenu trogodišnju ili četverogodišnju srednju školu. Najmanja razina nezaposlenosti evidentirana je među onima s najvišim stupnjem obrazovanja (4,5%), dok je nešto više od četvrtine ukupno nezaposlenih osoba bez škole ili imaju završenu samo osnovnu školu. Podaci ukazuju na gotovo 30% nezaposlenih osoba između 20 i 29 godina dok je najmanje onih između 15 i 19 godina (školovanje), kao i osoba koje imaju 60 godina i više.

II. GOSPODARSTVO NA LOKALNOJ RAZINI:BRODSKO-POSAVSKA ŽUPANIJA

Želeći dati svoj doprinos u ublažavanju posljedica gospodarske krize odnosno poticanju gospodarskog

razvoja na svom području, bez pretenzija i velikih očekivanja obzirom na vrlo ograničena sredstva i utjecaj regionalne i lokalne samouprave na makroekonomska kretanja, Brodsko-posavska županija samostalno i u suradnji s drugim institucijama provodi niz aktivnosti i projekata u cilju poticanja gospodarstva odnosno poduzetništva te stvaranja preduvjeta za povećanje konkurentnosti županije kao regije (poticanje konkurentnosti poduzetnika i županije kao regije, kreditiranje poduzetnika uz subvenciju kamata, efikasno korištenje državnih potpora, poticanje obrtništva, županijska razvojna agencija, informiranje i edukacija poduzetnika, korištenje EU fondova, te poduzetničke zone u Brodsko-posavskoj županiji). Krajem prosinca 2012.godine u Brodsko-posavskoj županiji stopa aktivnosti (omjer aktivnog stanovništva-zbroj zaposlenih i nezaposlenih i radno sposobnog stanovništva) iznosila je 51,4%. U isto vrijeme stopa aktivnosti u Republici Hrvatskoj iznosila je 62,1%. U istom razdoblju stopa zaposlenosti (omjer zaposlenog stanovništva i radno sposobnog stanovništva) iznosila je 33,5% u Brodsko-posavskoj županiji, a evidentirana stopa zaposlenosti u Republici Hrvatskoj 49,6%. Broj zaposlenih izračunat je na temelju podataka o broju aktivnih osiguranika obveznog mirovinskog osiguranja pri Hrvatskom zavodu za mirovinsko osiguranje. Niske stope aktivnosti i zaposlenosti čine veći problem od visoke stope nezaposlenosti na području Brodsko-posavske županije.

A. Tržište rada na području Brodsko-posavske županije

Krajem prosinca 2013. u Hrvatskom zavodu za zapošljavanje, Područnom uredu Slavonski Brod registrirano je 18619 nezaposlenih osoba, što je za 560 osoba više nego u prethodnom mjesecu i za 71 osobu više nego u prosincu 2012. godine. Dakle, u prosincu 2013. godine nezaposlenost je povećana u usporedbi s prethodnim mjesecom za 3,1%, dok je u usporedbi s istim mjesecom 2012. godine povećana za 0,4%. U obrazovnoj strukturi nezaposlenih osoba najbrojnije su osobe sa završenom srednjom školom za zanimanja u trajanju do 3 godine i školom za KV i VKV radnike (7184 ili 38,6%), osobe sa završenom srednjom školom za zanimanja u trajanju od 4 i više godina (4258 ili 22,9%), slijede osobe sa završenom osnovnom školom (3835 ili 20,6%), osobe bez škole i s nezavršenom osnovnom školom (1699 ili 9,1%), osobe s višom školom (659 ili 3,5%), osobe fakultetskog obrazovanja (532 ili 2,9%), te osobe sa završenom gimnazijom (452 ili 2,4%). stopa nezaposlenosti u Brodsko-posavskoj županiji u 2013.godini iznosila je 32,1%.

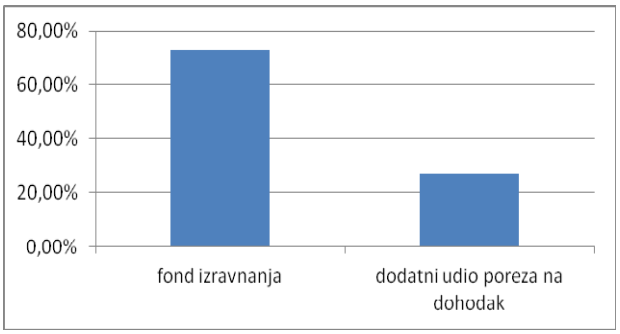
B. Važnost ulaganja u ljudske potencijale,reforma strukovnog obrazovanja

U razvijenim zemljama temelj gospodarskog i društvenog napretka čine ljudski potencijali. Ulaganje u ljudske potencijale nužno je u Hrvatskoj posebno kroz obrazovni sustav u kojem će se smišljeno otkrivati, njegovati, usmjeravati te poticati individualni potencijali i sposobnosti. Jedan od načina je cjeloživotno učenje i obrazovanje kroz koji je moguće učinkovito i pravovremeno, a nadasve smišljeno pomagati pojedincima u razvijanju njihovih talenata, vještina i znanja, bez obzira na dob. U sustave cjeloživotnog učenja u Hrvatskoj uključen je mali broj građana, iako je velik broj nezaposlenih i obrazovanih s nedovoljnim osnovnim kompetencijama za opstanak na tržištu rada ili za stalno prilagođavanje društvenim i gospodarskim promjenama i izazovima. Uvođenje učinkovitog sustava strukovnog obrazovanja važno je za transformaciju postojećeg gospodarstva u gospodarstvo temeljeno na znanju. Učinkovitost podrazumijeva reformu strukovnog obrazovanja koja treba ići u pravcu modernizacije strukovnog obrazovanja, prohodnosti, partnerstva s gospodarstvom, usklađenosti s potrebama tržišta rada i potrebama i sposobnostima pojedinca. Resorno ministarstvo donijelo je Strategiju razvoja strukovnog obrazovanja i Zakon o strukovnom obrazovanju s ciljem prilagodljivosti strukovnog obrazovanja potrebama polaznika i tržišta rada kroz modernizaciju sadržaja, metoda strukovnog obrazovanja i osiguranja mogućnosti nastavka obrazovanja. Agencija za strukovno obrazovanje i obrazovanje odraslih je od svoga osnutka aktivno uključena u provedbu brojnih međunarodnih i bilateralnih projekata u području strukovnog obrazovanja i osposobljavanja kako bi dodatnim izvorima financiranja unaprijedila kvalitetu strukovnog obrazovanja u Republici Hrvatskoj.Projekcija daljnjih proračunskih smanjenja izdvajanja za obrazovanje nameće nužnost traženja drugih izvora financiranja. Obzirom na mala proračunska izdvajanja za obrazovanje u Hrvatskoj obrazovne ustanove koriste mogućnosti koje im pružaju sredstva EU fondova.

C. Sredstva fondova EU – dodatno ulaganje u unapređenje obrazovnog sustava

Dobivena sredstva iz EU fondova srednjoškolskim obrazovnim institucijama osiguravaju uvođenje suvremenih i inovativnih sadržaja u nastavu, prijeko potrebnih strukovnim školama, unutar postojećeg sustava strukovnog obrazovanja i osposobljavanja, a u skladu sa Zakonom o strukovnom obrazovanju i Zakonom o odgoju i obrazovanju u osnovnoj i srednjoj školi. Istraživanje tržišta rada i potreba poslodavaca ukazuje na problem pronalaženja mladih ljudi s potrebnim tehničkim znanjima i vještinama koje gospodarstvo u određenom trenutku treba. Najizraženije su potrebe za mladim ljudima koji su završili srednje strukovno obrazovanje. Njihova postojeća znanja i vještine potrebno je dodatno unaprijediti kako bi mogli odgovoriti zahtjevima tržišta rada. Usklađivanje postojećeg sustava odgoja i obrazovanja sa potrebama gospodarstva treba biti prvi korak ka reformi obrazovnog sustava. Važnost strukovnog obrazovanja značajno varira od zemlje do zemlje, kao i sama organizacija, financijska izdvajanja za obrazovanje koja su uglavnom proračunska i o kojima

ovisi kvaliteta obrazovnog sustava, a time i strukovnog obrazovanja.

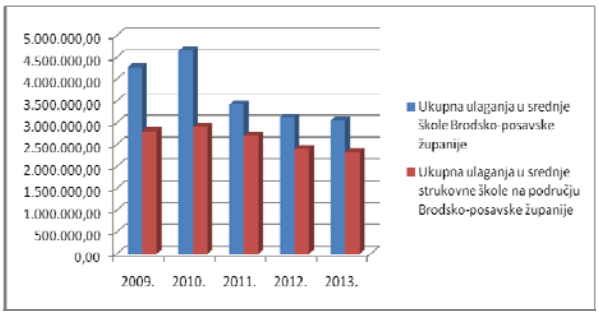


Graph 2.Decentralizirane funkcije srednjeg školstva Brodsko-posavske županije u 2013.godini-struktura prihoda
Izvor: Ministarstvo znanosti, obrazovanja i športa, 2013

D. Ulaganja u strukovne škole na području Brodsko-posavske županije

Brodsko-posavska županija uložila je značajne napore u izgradnju institucionalnih kapaciteta neophodnih za učinkovitu apsorpciju EU sredstava, a osobitu pozornost posvetila je upravo podizanju razine kvalitete strukovnog obrazovanja. Tako su u razdoblju od 2007. do 2013. kroz programe CARDS i IPA, srednje strukovne škole na području Brodsko-posavske županije realizirale EU projekte ukupne vrijednosti 28.883.000,00 kn, što je izuzetno značajan iznos, osobito ako ga usporedimo s ukupnim ulaganjem iz proračuna same županije.
Najznačajniji rezultati tih projekata su izgrađena infrastruktura, opremljeni praktikumi i laboratoriji, podignuta razina znanja strukovnih i drugih profesora, kao i razina znanja učenika, a sve s ciljem povećanja konkurentnosti učenika strukovnih škola i usklađivanja strukovnog obrazovanja s potrebama tržišta rada.
Kvaliteta strukovnog obrazovanja na području Brodsko-posavske županije određena je prvenstveno proporcionalnim izdvajanjima za srednje obrazovanja u Proračunu Republike Hrvatske, koja se potom raspoređuju jedinicama lokalne i područne (regionalne) samouprave (Brodsko-posavska županija)koje su osnivači srednjih škola na svom području. Osnivači srednjih škola utvrđuju prioritete ulaganja koji su u pravilu primarni.

U 2013.godini Brodsko-posavska županija zbog vrlo niskog BDP po stanovniku i fiskalnog kapaciteta, 72,9% prihoda za osiguranje minimalnog financijskog standarda srednjih škola ostvarila je prihodima iz sredstava poravnanja (9.075.637,00 kn), a tek 27,1% od prihoda od dodatnog udjela poreza na dohodak (3.373.027,52 kn)(Graph 2). Dakle izvorni prihodi Proračuna Brodsko-posavske županije ne doprinose unapređenju obrazovnog sustava na svom području niti u jednom segmentu, nego jedino održavanju minimalnog standarda.



Graph 3.Ulaganja u srednje obrazovanje na području Brodsko-posavske županije u periodu od 2009.-2013.godine
Izvor:Izračun autora,Proračun Brodsko-posavske županije

Iako realno Brodsko-posavska županija iz izvornog Proračuna nema sredstava kojim bi unaprijedila rad srednjih škola na svom području, gotovo 50% ukupnih sredstava koje dobiva iz Fonda poravnanja (Državni proračun) ulaže u srednje strukovne škole na svom području (Graph 3). Međutim sva ta sredstva nisu dovoljna za učinkovitije strukovno obrazovanje na području Brodsko-posavske županije i sve zahtjevnije potrebe tržišta rada. Mogućnosti za unapređenje strukovnog obrazovanja obrazovne institucije nalaze u korištenju sredstva EU.

E. Primjeri dobre prakse

- *Srednja škola „M.A.Reljković" Slavonski Brod*

Kako je riječ o županiji u kojoj je glavna gospodarska grana poljoprivreda, projekt IPA IIIc koji je provela srednja škola „M.A.Reljković" Slavonski Brod uz stručnu pomoć Brodsko-posavske županije i županijske razvojne agencije imao je dodatnu težinu. Radi se o izgradnji regionalnog centra za biotehnološka istraživanja i razvoj Brodsko-posavske županije kako bi se potaknuo gospodarski rast u županiji, temeljen na istraživačkim i razvojnim aktivnostima i transferu novih tehnologija u poljoprivredi. Regionalni centar čini jezgru inovativnog načina proizvodnje bezvirusnih sadnica (u Županiji i potencijalno u široj regiji) i pokretač je partnerskih aktivnosti vezanih uz istraživanje, edukaciju i razvoj u poljoprivredi. Na taj način se poljoprivrednim proizvođačima omogućava besplatna edukacija i savjetovanje u području agrotehnologije i razvoja poduzetničkih znanja i vještina kako bi uspješno proizvodili visoko profitabilne kulture, uveli bezvirusni materijal u proizvodnju te primjenjivali principe inovativne dinamičke proizvodnje. Ujedno projekt snažno podupire umrežavanje istraživačkih institucija i institucija koje pružaju potporu poslovanju poduzetnika s privatnim sektorom.

- *Industrijsko- obrtnička škola, Nova Gradiška*

U okviru programa IPA IV komponenta (razvoj ljudskih resursa) škola je provela projekt pod nazivom „Nova metodologija poučavanja i komunikacije u izvođenju praktične nastave u području CNC tehnologije". Navedenim projektom pojačalo se uvođenje suvremenih i inovativnih sadržaja u nastavu u strukovnim školama unutar postojećeg sustava strukovnog obrazovanja i osposobljavanja, s ciljem osiguranja

njihove prilagodljivosti na tržištu rada, povećanja kapaciteta za pružanje suvremene školske praktične nastave te ispunjavanja potreba gospodarstva utemeljenog na znanju. Realizacijom projekta dana je potpora strukovnim školama u razvoju pristupa „bottom –up“ (odozdo prema gore) kako bi svojim učenicima mogle osigurati kompetencije i pristup najnovijim tehnologijama podižući tako njihovu relevantnost na tržištu rada, a istovremeno pridonijeti razvoju obrazovnog sustava u Brodsko-posavskoj županiji u skladu s potrebama gospodarstva.

- *Tehnička škola, Slavonski Brod*

Opći cilj projekta ove škole temeljio se na razvoju i modernizaciji strukovnih obrazovnih sustava u Republici Hrvatskoj. Osim razvoja i modernizacije, specifični cilj projekta bio je unaprijediti profesionalne, materijalne i tehničke uvjete u strukovnoj školi, kao i provedbu novog kurikuluma (tehničar solarnih sustava) kroz razvoj demonstracijskog centra za solarne sustave. Naznačeni projekt osigurao je dva aspekta modernizacije obrazovnog sustava unutar Tehničke škole Slavonski Brod:

1. Razvoj kurikuluma koji prati gospodarske trendove (razvoj i primjenu solarne energije kao alternativni izvor)
2. Najefikasnije metode i tehnike prijenosa znanja unutar struke.

Tehnička škola u solarnom demonstracijskom centaru danas ima:

1. Proizvodnju električne energije - solarna centrala od 10kW (jedinstvena kao takva na području regije)
2. Praktikum za učenike s 15 radnih mjesta
3. Videokonferencijsku salu (udaljeno učenje).

IV. ZAKLJUČAK

Obrazovne institucije prepoznale su potrebu reforme obrazovnog sustava u Hrvatskoj, posebno strukovnog obrazovanja i svojim uključenjem u provedbu projekata EU na lokalnoj razini doprinijele su provedbi reforme na nacionalnoj razini. Dodatna razvojna sredstva s EU razine predstavljaju način kojim se područja i stanovništvo žele osnažiti kako bi što uspješnije koristili sve prednosti jedinstvenog tržišta roba, kapitala, radne snage i usluga. To uključuje veće tržište, veću mobilnost u radu i obrazovanju, veći izbor usluga i mnoge druge prednosti.

U pretpristupnom razdoblju Hrvatska je na raspolaganju imala oko 150 milijuna eura godišnje. Od 1.srpnja 2013.godine taj se iznos povećao na 450 milijuna, a u 2014. godini na 1,08 milijardi eura. To su doista značajna sredstva. Stoga treba pozdraviti sve aktivnosti obrazovnih institucija u provedbi natječaja za dodjelu sredstava iz EU fondova kako bi se reforma obrazovnog sustava što prije provela i unatoč skromnim izdvajanjima iz državnog proračuna Republike Hrvatske. Reformom strukovnog obrazovanja postepeno bi se smanjila stopa nezaposlenosti posebice mladih ljudi, te pokrenule gospodarske aktivnosti u zemlji. Primjeri dobre prakse strukovnih škola na području Brodsko-posavske županije omogućiti će mladim ljudima lakše i brže uključivanje u svijet rada jer će posjedovati potrebna znanja, vještine i kompetencije koje lokalno tržište rada traži i koje su važne za razvoj gospodarstva na tom području.

Izrada programskih komponenti u TIA Portal programskom okruženju

Danijel Maršić, Goran Malčić i Ivica Vlašić
Tehničko veleučilište u Zagrebu/Elektrotehnički odjel, Zagreb, Hrvatska
danijel.marsic@tvz.hr

Sažetak - Kod izrade programske podrške u sustavima upravljanja koji su realizirani uporabom PLC uređaja kao upravljačkog dijela i SCADA računala, odnosno HMI panela kao nadzornog dijela, uobičajena je praksa kreiranje gotovih programskih modula koji odgovaraju određenoj vrsti procesne opreme kako nalaže S88 norma. Izrada programske podrške upravljačkog i nadzornog dijela za PLC uređaje tvrtke Siemens unutar programskog paketa TIA Portal V12 dio je obavezne nastave na specijalističkom studiju elektrotehnike Tehničkog veleučilišta u Zagrebu. U okviru laboratorijskih vježbi studenti izrađuju programske dijelove upravljačkih komponenti i povezuju ih sa nadzornom HMI aplikacijom za koju također izrađuju vizualno sučelje. Ovakav pristup izvođenju laboratorijskih vježbi rezultira ishodima učenja koji su direktno primjenjivi u praksi.

I. UVOD

Sustavi automatizacije u proizvodnim procesima mogu biti jednostavni (mogu upravljati samo jednim strojem u proizvodnoj liniji) do vrlo složenih (koji upravljaju procesom proizvodnje u cijeloj tvornici). U tu svrhu razvijaju se univerzalna i specijalistička rješenja sustava automatizacije proizvodnih procesa. Cijena univerzalnih rješenja velikih tvrtki u području automatizacije često je prevelika za investitora jer specijalistička rješenja mogu koristiti samo za određeni proizvodni proces. Zbog toga se javlja potreba za razvojem vlastitog univerzalnog sustava automatizacije koji je moguće koristiti u jako širokom spektru proizvodnih procesa. Tvrtke koje izrađuju programsku podršku za sustave automatizacije, ukoliko žele biti prisutne na svjetskom tržištu, moraju to raditi prema naputcima koji su navedeni u S88 norme za šaržne procese. U šaržnim procesima izlazni učinak procesa se javlja u količinama materijala. Šaržni proces ima početak i kraj te se obično neprestano ponavlja. Šaržni procesi posjeduju neke karakteristike diskretnih i kontinuiranih procesa no zasebna su vrsta industrijskih procesa. Primjere šaržnih procesa najčešće nalazimo u industrijama pića, prehrambenoj, cementnoj, farmaceutskoj industriji i slično.

Kontrolni modul (CM) je najmanji dio sustava upravljanja koji izvršava neku osnovnu funkciju koji se prema primijenjenom S88 standardu naziva komponenta. Kontrolni modul (eng. *Control Module, CM*) je najosnovniji element fizičkog modela kojeg S88 standard ga definira kao: "*Kontrolni modul je u pravilu jedan ili grupa senzora, aktuatora, ostalih kontrolnih modula, i povezane procesne opreme, koji sa stajališta upravljanja djeluje kao zaseban uređaj*". [1] Dakle, svaki kontrolni modul osigurava izravnu "poveznicu" sa procesom preko aktuatora i senzora te tako izvršava neke osnovne upravljačke funkcije. Komponente programske podrške standardizirane su prema najčešćim tipovima uređaja korištenih u industrijskim postrojenjima. Komponente mogu biti mjerni uređaji, osjetnici, aktuatori, ali i programske komponente kao što je PID regulator koji se izvodi u programirljivom logičkom kontroleru (PLC). Koristeći ove standardne komponente moguće je lako sve kontrolne module upravljačkog sustava uklopiti u upravljački program PLC uređaja koji je povezan sa SCADA sustavom.

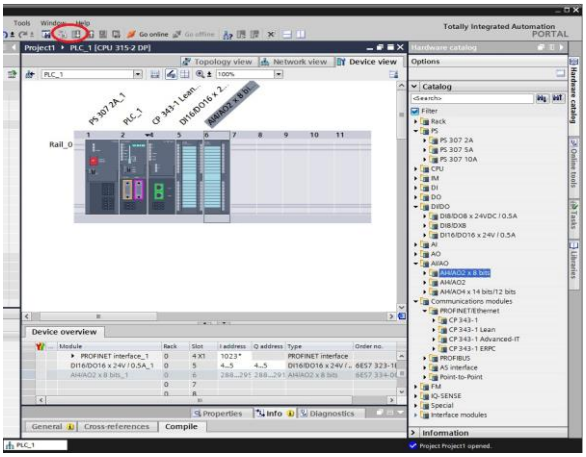
U sklopu laboratorijskih vježbi na kolegiju Sustavi upravljanja i nadzora postrojenja obrađuju se tematike vezane za izradu kontrolnih modula kroz više vježbi.

II. ALAT TIA PORTAL

Prvi dio kroz koji studenti svakako moraju proći je upoznavanje i rad sa razvojnom okolinom odnosno programskim editorom. *Totally Integrated Automation Portal* (*TIA Portal*) objedinjuje *SIMATIC Totally Integrated Automation* (*TIA*) proizvode u jedinstvenu programsku aplikaciju. Svi *TIA* proizvodi rade zajedno unutar istog programskog okruženja i pružaju podršku korisniku u svim segmentima potrebnim za stvaranje rješenja automatizacije. *TIA Portal* se koristi za konfiguraciju i programiranje PLC uređaja, ali i za vizualizaciju procesa u jedinstvenoj razvojnoj okolini. Svi podaci se spremaju u zajedničku projektnu datoteku, koristi se zajedničko korisničko sučelje za sve zadaće preko kojeg je moguće pristupiti svim programskim i vizualizacijskim funkcijama u svakom trenutku.

Prvi korak na vježbama je postupak sklopovske konfiguracije jer bez poznavanja tipa procesora nije moguće pisati programski kod. Ovim postupkom potrebno je unutar programske podrške definirati raspored i vrstu modula PLC uređaja koji odgovaraju konfiguraciji stvarnog uređaja. Kod dodavanja sklopovlja, odnosno modula treba biti obraćena pažnja da se odabere ispravan modul i njegova verzija. Zato je potrebno obavezno pročitati kataloški broj modula na njegovoj prednjoj strani i na temelju toga odabrati taj modul iz kataloga opreme u programskoj podršci. U protivnom će PLC nakon učitavanja hardverske konfiguracije javljati grešku.

[1] ISA Philadelphia Section: *ANSI/ISA S88 Batch standard – A General Overview*, 2002., www.isa.org



Slika 1. Prozor za izradu sklopovske konfiguracije

U TIA portalu spomenuti kontrolni moduli mogu biti izvedeni kao funkcije ili funkcijski blokovi koji se programiraju i pozivaju u glavnom programu OB1. Nedostatak korištenja funkcijskih blokova u odnosu na funkcije je to što se za svaki poziv funkcijskog bloka treba kreirati i pripadajući podatkovni blok, čak i ako se više puta poziva jedan te isti blok. Kod korištenja funkcija dovoljno je kreirati jedan globalni podatkovni blok u koji se spremaju podaci svih funkcija. Budući da funkcija sama po sebi ne može imati pridruženi vlastiti podatkovni blok, unutar nje se treba nalaziti neki podatkovni tip koji sadrži sve varijable koje se koriste u procesu. Pomoću tog podatkovnog tipa sve te varijable u globalnom podatkovnom bloku mogu dobiti svoju adresu u memoriji. Na taj način omogućeno je da se funkcija koristi za više istovrsnih procesa, jer će za svaki proces varijable biti na drugoj adresi.

U vježbama je dano i opisano kreiranje funkcija, njihovo programiranje, pozivanje u glavni program te rad s podacima. Radi lakšeg razumijevanja osim općenitih opisa koristi se nekoliko tipičnih primjera iz industrije.

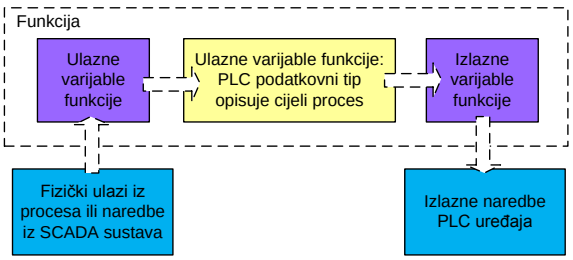
III. IZRADA UPRAVLJAČKE LOGIKE

Funkcije omogućuju izradu univerzalnih blokova koji se pozivaju u OB1 i tamo im se pridjeljuju fizičke adrese. Sva logika je sadržana u bloku koji kada pozovemo u glavnom programu ima vidljive izvode za fizičke ulaze i izlaze. Kao što je već spomenuto, nemaju vlastitu memoriju, nego se podaci spremaju preko PLC podatkovnog tipa koji sadrži varijable cijelog procesa. Ulazne varijable se upisuju pod *Input*, izlazne pod *Output*, ulazno - izlazne pod *InOut*, dok se privremene upisuju pod *Temporary* (Slika 2.). U donjem dijelu programa piše se program u jeziku ljestvičasti dijagram.

	Name	Data type	Offset	Comment
1	Input			
2	Ulaz	Bool		Ulaz
3	Output			
4	Izlaz	Bool		Izlaz
5	InOut			
6	Proces	"Proces_1"		
7	Ulaz	Bool		Ulazni uvjet
8	Izlaz	Bool		Izlaz
9	Alarm	"ALARM"		Alarm
10	Temp			
11	<Add new>			
12	Return			
13	Block_1	Void		

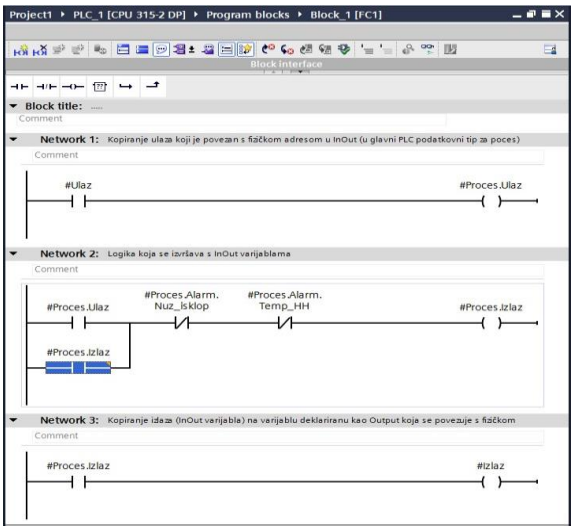
Slika 2. Primjer procesnih varijabli

Odnose između tipova varijabli deklariranih u zaglavlju najbolje prikazuje Slika 3. Sadržaj varijabli deklariranih kao *Input* treba se kopirati u odgovarajuće varijable u *InOut*. Isto tako sadržaj odgovarajućih varijabli iz *InOut* treba se kopirati u varijable u *Output* funkcije.



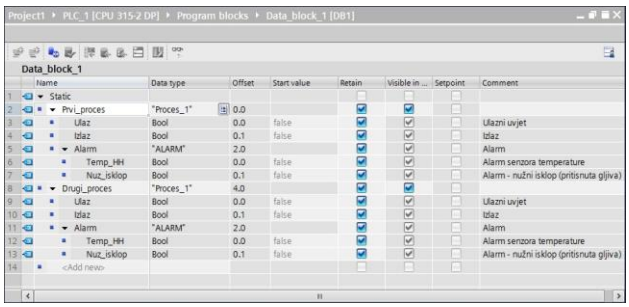
Slika 3. Blokovska shema toka podataka u funkciji

Slika 4. prikazuje logiku rada funkcije "Block_1" koja je isprogramirana u ljestvičastom dijagramu. Kod pisanja programskog koda u funkcijama ne koriste se fizičke adrese nego adrese u memoriji. Fizičke adrese dodjeljuju se bloku nakon poziva u OB1. U prikazanom primjeru bloku će se moći dodijeliti dvije fizičke adrese, na "Ulaz" i "Izlaz" te jedna adresa iz podatkovnog bloka na "Proces" koja će biti adresa varijable čiji će tip biti "Proces_1". Može se reći da se obrada podataka u bloku (funkciji) vrši pomoću varijabli deklariranih kao *InOut*. Varijable koje su deklarirane kao *Input* i *Output* služe za ulaz podataka u blok, odnosno za izlaz iz bloka i nemaju definiranu adresu u memoriji.



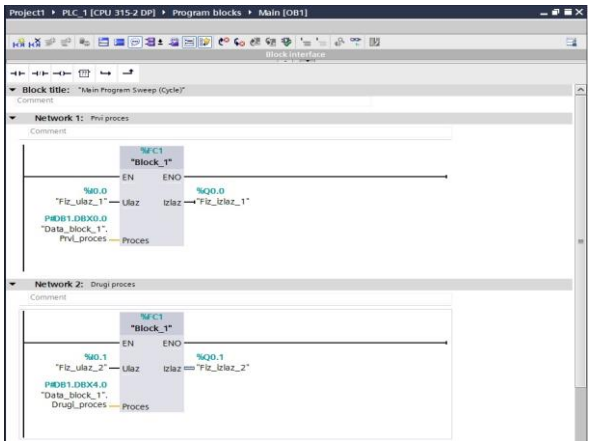
Slika 4. Logika rada funkcije "Block_1"

Varijable koje se nalaze u funkciji moraju imate definirane adrese u memoriji kako bi se podaci imali gdje spremati. To omogućuju globalni podatkovni blokovi. Slika 5. prikazuje izgled globalnog podatkovnog bloka gdje je vidljivo da su adresirane memorijske lokacije za dva procesa. Adresiranje se vrši tako da svaka varijabla koja je tipa "Proces_1", dobije početnu (referentnu) adresu, a varijable koje pripadaju toj varijabli dobiju neku vrijednost za koju su udaljene od referentne adrese. Procesi iz primjera međusobno su jednaki ali se mogu odvijati neovisno jedan o drugome. To znači da se blok sa logikom procesa mora pozvati u OB1 dva puta, za svaki proces posebno.



Slika 5. Globalni podatkovni blok

Slika 6. prikazuje izgled blokova kad se pozovu u OB1. U ovom slučaju pozvana je funkcija "Block_1" (otprije kreirana). Varijablama "Ulaz" i "Izlaz" pridružene su fizičke adrese, a pošto te varijable same po sebi nemaju definiranu adresu u memoriji, neće moći spremati podatke. No, kao što je vidljivo sa slike 4. to nije ni potrebno zbog toga jer je u logici bloka određeno da se ulazni i izlazni podaci pridružuju odgovarajućim varijablama koje su iz podatkovnog tipa "Proces_1", a te varijable imaju definiranu adresu u memoriji (Slika 5.)



Slika 6. Poziv funkcije Block_1 i pridruživanje adresa

Kako bi se funkcija izvršila mora biti pozvana iz OB1, u protivnome se ona neće nikad izvršiti. Nakon što je funkcija pozvana njenim ulazima su pridružene fizičke adrese iz procesa ili SCADA aplikacije. Podaci se sa ulaza šalju u odgovarajuće ulazno - izlazne varijable čije memorijske adrese su definirane u globalnom podatkovnom bloku. Unutar funkcije se tada odrađuje programirana logika (sve sa varijablama čije su memorijske adrese definirane u globalnom podatkovnom bloku) i rezultati (izlazni podaci) se šalju na izlaze funkcije kojima su pridružene fizičke adrese.

Na ovakav način se izvode tri vježbe za zasebne kontrolne module:

- direktno pokretanje motora,
- digitalni ulaz za diskretne senzore,
- analogni ulaz za analogne senzore.

Prolazeći kroz ove tri vježbe studenti nauče osnove rada u programskom okruženju TIA Portal V12. Najdetaljnije je objašnjena uporaba PLC podatkovnih tipova, funkcija i podatkovnih blokova. Vježbe se temelje na izradi modula koji su univerzalni za određeni tip procesa. Takvi moduli mogu se koristiti za programiranje bilo kakvog sustava ako on sadrži takve procese. To je dobra stvar za programere jer mogu puno brže napraviti programsko rješenje za zadani sustav, a izrađeni su moduli su izravno primjenjivi u praksi. Modul za direktno pokretanje i nadzor motora može se koristiti za upravljanje nekim vratima ili u nekom sličnom procesu gdje ne treba regulirati brzinu vrtnje. Modul za digitalni ulaz može se koristiti za provjeravanje stanja neke sklopke. Modul za analogni izlaz može se upotrijebiti za čitanje naponskog signala pretvarača neke fizikalne veličine i pretvaranje tog signala u stvarnu vrijednost mjerene veličine (npr. mjerenje temperature). S obzirom da je logika rada detaljno objašnjena u pisanim materijalima koji se dobiju na vježbama, student je može jednostavno razumjeti.

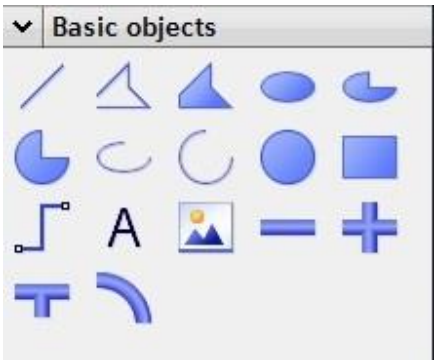
IV. IZRADA NADZORNE APLIKACIJE

SCADA (eng. ***S**upervisory **C**ontrol **A**nd **D**ata **A**cquisition*) je tehnologija koja omogućuje prikupljanje odnosno praćenje svih signala i veličina iz jednog ili više udaljenih postrojenja u kojemu se odvijaju neki procesi, te omogućuje slanje upravljačkih signala u postrojenja čime se dobiva stalni nadzor i upravljanje nad procesom.

Programska podrška *TIA Portal* koristi za kreiranje slika vizualizacije procesa na ekranu HMI (eng. *Human Machine Interface*) uređaja koji služi za upravljanje i nadgledanje strojeva i postrojenja. Prethodno definirani objekti i elementi dostupni unutar programa olakšavaju stvaranje tih ekrana. Grafički objekti i elementi su svi oni elementi koji mogu biti korišteni za vizualizaciju projekta u HMI sustavu. To uključuje tekst, tipke, dijagrame ili grafike za vizualizaciju dijelova procesa (senzori, aktuatori, uređaji). Grafički objekti mogu biti statično vizualizirani ili korišteni kao dinamički objekti uz pomoć oznaka.

U vježbama je objašnjeno uređivanje svojstava grafičkih objekata i elemenata korištenih prilikom vizualizacije procesa. Prvi korak vježbi je umetanje HMI uređaja i otvaranje njegove konfiguracije. Unutar projektnog stabla potrebno je odabrati naredbu *'Add new device'* i odrediti za koji tip odnosno veličinu ekrana će se raditi nadzorna aplikacija.

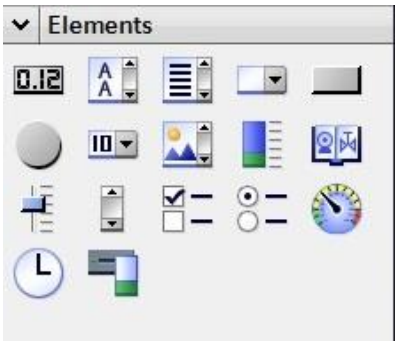
Osnovni grafički objekti nalaze se u kartici '*Toolbox*' pod nazivom 'Basic objects'. Pod osnovne objekte spadaju prethodno definirani objekti prikazani na slici 7.



Slika 7. Osnovni grafički objekti

Osnovni grafički objekti su jednostavni objekti koji mogu poslužiti za izradu odnosno dizajniranje jednostavnih rješenja vizualizacije procesa, ali se od njih također mogu stvoriti kompleksni objekti potrebni za vizualizaciju složenih procesa. Svojstva osnovnih objekata su prikazana po kategorijama i mogu se pronaći u prozoru namijenjenom za prikaz dodatnih informacija o odabranom objektu. Osim uređivanja svojstava osnovnih objekata moguće im je postaviti animacije što isto vrijedi i za naprednije grafičke objekte elemente.

Također se može raditi i sa predefiniranim elementima koji se nalaze se u kartici *'Toolbox'* pod nazivom *'Elements'*. Pod osnovne objekte spadaju prethodno definirani objekti prikazani na Slici 8. Svojstva elemenata prikazana su po kategorijama i mogu se pronaći u prozoru namijenjenom za prikaz dodatnih informacija o odabranom objektu.



Slika 8. Predefinirani elementi

U prvoj vježbi je prikazan postupak izrade jednostavne aplikacije za upravljanje motorom sa svim elementima koji se koriste prilikom vizualizacije procesa. U projektnom stablu, unutar mape *'Screens'* potrebno je odabrati opciju *'Screen'* kako bi se prikazao ekran na kojem će se dizajnirati SCADA aplikacija. Nakon što je kreiran prozor aplikacije, unutar njega se razmještaju ostali objekti i elementi koji su potrebni za funkcionalnost aplikacije.

Sljedeći korak, nakon dizajna aplikacije, je kreiranje tablice oznaka HMI uređaja (eng. *HMI Tag Table*). Tablica oznaka kreira se kako bi varijable definirane unutar tablice povezali sa objektima i elementima unutar SCADA aplikacije kako bi oni dobili funkcionalnost. Svaku od oznaka HMI uređaja potrebno je povezati sa stvarnim oznakama PLC uređaja kako bi mogli upravljati procesom putem SCADA aplikacije na HMI uređaju. Tablica oznaka kreira se unutar mape 'HMI tags' u projektnom stablu.

Objekte i elemente unutar SCADA aplikacije potrebno je povezati sa HMI oznakama kako bi aplikacija bila funkcionalna. Ukoliko bilo koji od objekata nema pridjeljenu pripadajuću HMI oznaku, objekt neće imati nikakvu funkciju animacije unutar aplikacije osim dekorativne.

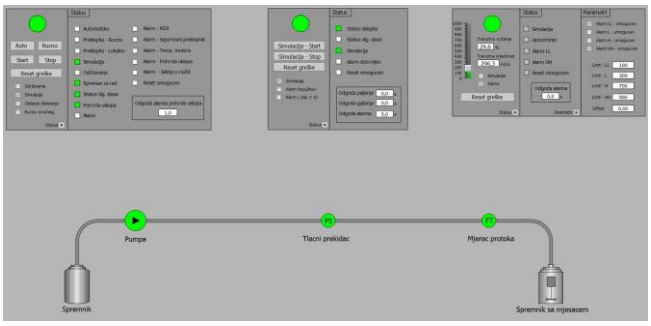
Radi lakšeg snalaženja prilikom uređivanja aplikacije objektima i elementima je potrebno dodati naziv. Svi korišteni elementi će se kasnije grupirati unutar jedne skupine i ukoliko im nisu promijenjeni nazivi vrlo je teško raspoznati koji element čemu služi (npr. korištene su dvije tipke čiji su nazivi *'Button_1'* i *'Button_2'*). Kada na ekranu postoji više aplikacija potrebno je korištene objekte i elemente unutar svake aplikacije grupirati u skupine. To se radi prvenstveno iz razloga lakšeg razmještanja prozora aplikacija, ali i radi dodavanja efekata pojedinim prozorima.

Završna faza prve vježbe je simulacija SCADA aplikacije na osobnom računalu koju studenti pokreću pomoću tipke *'Start simulation'* na alatnoj traci programske podrške *TIA Portal*. Na slici 9. prikazan je primjer izrađene aplikacije koja sadrži dva pravokutnika, dvije tipke, krug, potvrdni okvir, tekstualno polje i U/I polje upravljanju radom direktno pokretanog elektromotora. Moguće je pokrenuti i zaustaviti motor, zadati vremensku odgodu uključenja alarma nakon pojave greške te pratiti stanje rada motora.

Slika 9. Primjer aplikacije za upravljanje motorom

Druga i treća vježba su temeljene na istom pristupu izrade jednostavne nadzorne aplikacije za komponente digitalnog ulaza i analognog ulaza za koje su studenti prethodno izradili upravljački program na PLC uređaju. Nakon izrade svih komponenti pristupa se zadnjoj vježbi koja integrira sva prethodno stečena znanja na vježbama.

Vježba integracije svih komponenti je izrada sustava koji se sastoji od pumpe, tlačnog prekidača (eng. *Pressure switch*), mjerača protoka (eng. *Flow transmitter*) i dva spremnika. Spremnici su grafički objekti koji nemaju funkciju. Slika 10. prikazuje takav sustav u radu. Zelena boja indicira da sve komponente sustava rade ispravno. Pritiskom lijeve tipke miša na bilo koju od komponenata sustava (osim spremnika) otvara se dodatni prozor sa osnovnim dijelom aplikacije. Ponovnim pritiskom lijeve tipke miša na bilo koju od komponenata sustava zatvara se dodatni prozor komponente. Kako bi prikazali kartice 'Status' pojedinih komponenata potrebno je lijevom tipkom miša pritisnuti na tipku 'Status' koja se nalazi u donjem desnom uglu osnovnog dijela aplikacije.

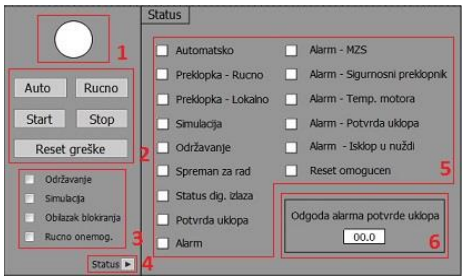


Slika 10. Zaslon vizualiziranog procesa

Studenti u završnom dijelu vježbe testiraju rad kako kompletne SCADA aplikacije tako i zasebnih prozora aplikacije. Zbog toga su na sljedećim slikama su prikazani i ukratko objašnjeni prozori aplikacije za svaku pojedinu komponentu sustava.

Slika 11. prikazuje prozor aplikacije za nadzor i upravljanje radom motora pumpe koji je sastavljen od sljedećih osnovnih dijelova sa pripadajućim funkcijama:

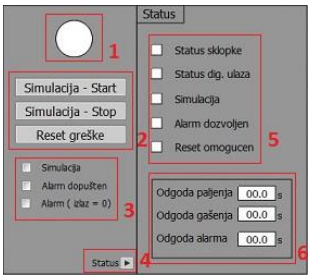
1) Indikator stanja pumpe.
2) Prostor sa tipkama za automatsko pokretanje motora, ručno pokretanje motora, simulaciju pokretanja motora i reset greške odnosno alarma.
3) Prostor unutar kojeg se aktivira način rada 'Simulacija' ili 'Održavanje'.
4) Tipka 'Status' kojom se prikazuje kartica 'Status'.
5) Prostor sa indikatorima stanja.
6) Prostor sa U/I poljem za zadavanje odgode alarma potvrde uklopa sklopnika.



Slika 11. Prozor aplikacije za nadzor i upravljanje motorom pumpe

Slika 12. prikazuje prozor aplikacije za upravljanje tlačnim prekidačem koji je sastavljen sljedećih funkcija koje su na raspolaganju operateru sustava:

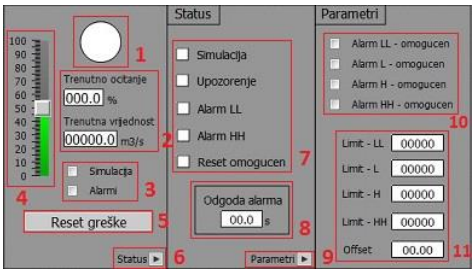
1) Indikator stanja tlačnog prekidača
2) Prostor sa tipkama za simuliranje aktivacije i deaktivacije tlačnog prekidača i reset alarma.
3) Prostor unutar kojeg se aktivira režim rada 'Simulacija' i dopuštaju alarmi.
4) Tipka 'Status' kojom se prikazuje kartica 'Status'.
5) Prostor sa indikatorima stanja (bijela boja – stanje nije aktivno, zelena boja – stanje aktivno).
6) Prostor za zadavanje odgode



Slika 12. Prozor aplikacije za upravljanje tlačnim prekidačem

Slika 13. prikazuje prozor aplikacije za upravljanje mjeračem protoka sastavljen od sljedećih funkcija:

1) Indikator stanja mjerača protoka.
2) Prostor za prikaz mjerene veličine.
3) Prostor unutar kojeg se aktivira režim rada 'Simulacija' i omogućavaju alarmi.
4) Klizač za ručno zadavanje vrijednosti mjerene veličine u režimu rada 'Simulacija'.
5) Tipka za reset greške odnosno alarma.
6) Tipka 'Status' kojom se prikazuje kartica 'Status'.
7) Prostor sa indikatorima stanja
8) Prostor za zadavanje odgode uključenja alarma.
9) Odabir se prikaza kartice 'Parametri'.
10) Prostor unutar kojeg se dopuštaju željeni alarmi.
11) Prostor za zadavanje granica uključuja alarma.



Slika 13. Prozor aplikacije za upravljanje mjeračem protoka

V. ZAKLJUČAK

Izrada upravljačke logike pojedinih komponenti procesa, vizualizacija procesa te mogućnost reakcije na proces u stvarnom vremenu postala je nezaobilazna potreba u industriji od početaka pa sve do danas. U tu svrhu najčešće se koristi PLC računalo i HMI sustav preko kojega čovjek nadzire i upravlja strojem. Radi boljeg razumijevanja procesa te lakšeg nadziranja i upravljanja procesom, izrada vizualizacije na HMI uređajima od velike je važnosti.

U ovom radu je prikazano kako studenti savladavaju problematiku izrade upravljačkog programa izradom pojedinih programskih komponenti te za iste njihovo vizualno sučelje. Korištene komponente su neizbježne u samoj praksi te znanja stečena na vježbama su sigurno primjenjiva u budućem radu. Završni dio svega je vježba koja integrira i upravljački i nadzorni dio u jednu cjelinu.

Student kroz ove vježbe lagano i postepeno gradi svoj prvi sustav automatizacije procesa, kroz čiju izgradnju dobije uvid u svu problematiku i rad sa sustavom. Vježbe traju pola semestra, no zadovoljstvo studenata se očituje kroz provedene ankete koje su više nego pozitivne. Naravo, dio njih smatra da je tematika preteška za studij, ali naše je nastojanje da budemo u korak sa potrebama tržišta rada.

Primjena industrijskih računalnih mreža u nastavi sa energetskim pretvaračima

Danijel Maršić, Goran Malčić i Veselko Tomljenović
Tehničko veleučilište u Zagrebu/Elektrotehnički odjel, Zagreb, Hrvatska
danijel.marsic@tvz.hr

Sažetak - Energetski pretvarači napona i frekvencije za upravljanje elektromotornim pogonima temeljenim na asinkronim motorima dio su obavezne nastave na stručnim studijima elektrotehnike. Njihovo povezivanje na više tipova industrijskih računalnih mreža je nadogradnja koja je nužna za primjenu u industriji. U radu je prikazana konfiguracija i primjena takvih sklopova koja se koristi na laboratorijskim vježbama iz područja industrijskih računalnih mreža. Prikazan je energetski pretvarač tvrtke ABB u pogonu s mrežama Profibus, EtherNet/IP i PROFINET I/O kako bi se studentima pokazale mogućnosti konfiguracije uređaja različitih proizvođača na različitim tipovima mreže s različitom programskom podrškom.

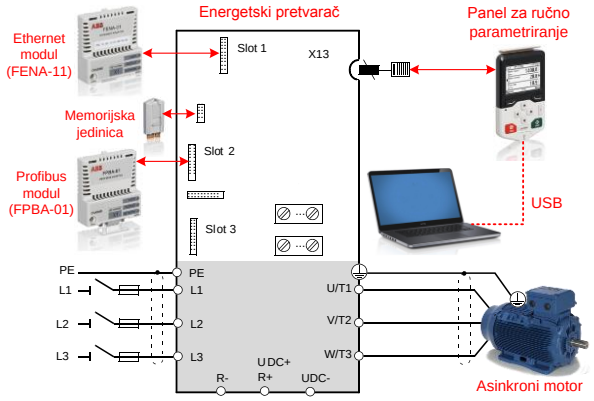
I. UVOD

U okviru kolegija Industrijske računalne mreže koji se predaje na Tehničkom veleučilištu u Zagrebu izvode se laboratorijske vježbe na kojima se pokazuje konfiguracija i rad sa više tipova mreža koje su najčešće u upotrebi. Kao krajnji objekt upravljanja na mreži koristi se energetski pretvarač napona i frekvencije koji je spojen na trofazni asinkroni motor čijim radom upravljamo. Prilikom svake vježbe, krajnji je cilj, naučiti studenta konfigurirati energetski pretvarač za rad na mreži, konfigurirati upravljačku mrežu preko osobnog računala te isprogramirati PLC računalo kao glavni upravljački element. Student se kroz ove vježbe susreće s više programskh i konfiguracijskih editora, kao i s problemom njihovog međusobnog povezivanja.

Na početku svake vježbe konfigurira se pretvarač napona i frekvencije i to ili preko ručnih komandi na samom pretvaraču ili preko programske podrške tvrtke ABB. Nakon konfiguracije uređaja, podešava se rad odabrane mreže i testira komunikacija između pretvarača i PLC uređaja. Kao zadnja stavka ostaje izrada upravljačkog programa za PLC računalo gdje se i testira rad sustava. Ovim vježbama se pokazuje koliko široko stručno znanje treba imati inženjer koji se bavi industrijskom automatizacijom, kao i koji mogući problemi mogu nastupiti kod upotrebe raznih tehnologija. Cilj vježbi je osim samoga rada na mrežama i njihovom sklopovskom opremom i programskom podrškom, pokazati i kako je poštivanjem mrežnih specifikacija moguće upogoniti opremu raznih proizvođača na istoj mreži što je ovdje slučaj. Za izvođenje vježbi su pripremljeni pisani materijali i izrađeni posebni laboratorijski modeli na kojima moraju zajedno raditi dvojica studenata da bi vježba bila uspješno izvedena.

II. KONFIGURACIJA ENERGETSKOG PRETVARAČA

Početni korak koji treba napraviti na vježbi je konfiguracija objekta upravljanja. Na ovim vježbama to je energetski pretvarač napona i frekvencije tvrtke ABB tip ACS880 za asinhrone motore snage do 2,5 kW na 400 VAC. Pretvarači su opremljeni ručnim upravljačkim komandama preko jednostavnog panela s tipkama i zaslonom na kojemu se vide parametri pretvarača u radu. Pregled energetskih i upravljačkih priključaka energetskog pretvarača prikazan je na sljedećoj slici.



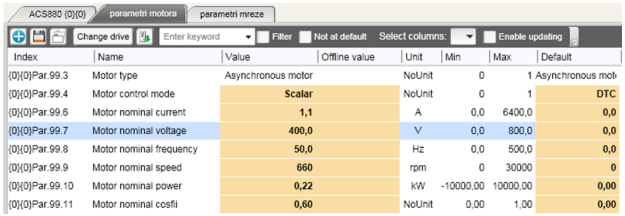
Slika 1. Osnovni dijelovi energetskog pretvarača ACS880 (ABB)

Studentima se na vježbama tumači kako se pretvarač može konfigurirati ručno, ali se konfiguracija ipak pokazuje preko namjenske programske podrške *Drive Composer Entry* tvrtke ABB koja se izvršava na osobnom računalu spojenom na pretvarač preko USB sučelja. Preko istoga student mora:

- upravljati pogonom: start, stop, smjer, referentna brzina / moment / frekvencija referenca,
- pratiti rad i stanja pogona,
- pregledati i podešavati pogonske parametre,
- pratiti signale u numeričkom i grafičkom obliku,
- stvoriti korisnički specifične radne prostore za prilagodbu parametara,
- rukovati radnim prostorom.

Na početku je potrebno u pretvarač unijeti parametre motora kako bi uređaj znao koje su njegove nazivne vrijednosti te s kojim modom upravljati njime, kako ne bi došlo do nedozvoljenih prekoračenja nazivnih vrijednosti.

Sve vrijednosti koje su potrebne za podešenje pretvarača nalaze se na natpisnoj pločici elektromotora i opisu tehnološkog procesa gdje se ugrađuje kao pogonski stroj.



Slika 2. Izgled programske podrške za podešavanje parametara

Drugi dio koji se mora podesiti na energetskom pretvaraču je mrežna komunikacija. Kako bi se spojio pretvarač na mrežu potreban je odgovarajući mrežni adapter. Svaki pretvarač opremljen je s dva mrežna adaptera i to Profibus adapter te ethernet adapter koji se upotrebljava za EtherNet/IP i PROFINET protokole. Njih je potrebno konfigurirati preko programske podrške Drive Composer Entry ili ručno preko panela da bi energetski pretvarač bio vidljiv i upravljiv preko mreže.

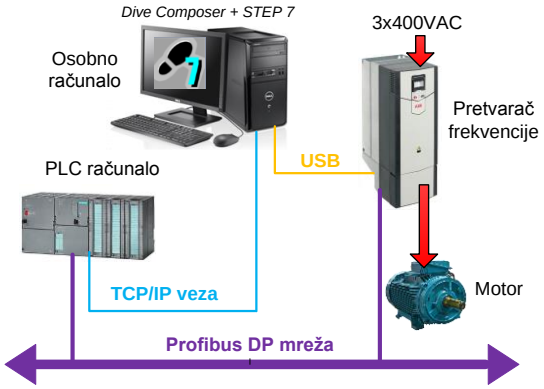
FPBA-01 Profibus DP adapterski modul je opcijski uređaj za ABB-ove pretvarače koji omogućuje spajanje pretvarača na Profibus DP mrežu. Pretvarač se u tom slučaju na Profibus mreži ponaša kao *slave* tj. kao podređeni uređaj. FENA-11 modul je kompatibilan sa svim trenutno važećim ethernet mrežnim standardima i podržava tri komunikacijska protokola: Modbus/TCP, EtherNet/IP i PROFINET IO. FENA-11 modul podržava 10 Mb/s i 100 Mb/s brzine prijenosa podataka te automatski detektira korištenu brzinu u mreži.

Preko adaptera tj. mrežnog modula moguće je upravljati pretvaračem dajući mu naredbe za npr. start, stop. Preko modula je moguće uspostaviti referencu za brzinu i moment elektromotora, te način zaustavljanja. Adapter također šalje stvarne vrijednosti stanja energetskog pretvarača, tako da se može upravljati povratnom vezom, mijenjati vrijednosti parametara pretvarača te prema potrebi resetirati grešku.

III. KONFIGURACIJA PREKO PROFIBUS MREŽE

Profibus je serijski komunikacijski standard koji omogućuje razmjenu podataka između komponenti na mrežnoj sabirnici. Profibus komunikacija se ostvaruje na razini polja gdje distribuirane jedinice kao što su ulazno/izlazni moduli, pretvarači napona i frekvencije, uređaji za analizu, mjerni sustavi, nadzorni terminali mogu komunicirati sa sustavom automatizacije u realnom vremenu [1]. Pogramirljivi logički kontroler (eng. Programmable Logic Controller, skraćeno PLC), koji radi kao nadređeni uređaj, čita ulazne podatke s podređenog uređaja te natrag šalje izlazne upravljačke veličine [5]. Vrijeme ciklusa Profibus sabirnice ovisi o broju čvorova na mreži i to vrijeme mora biti barem dva puta kraće od vremena ciklusa programa PLC računala što je važno i neophodno za vremenski kritičan prijenos podataka.

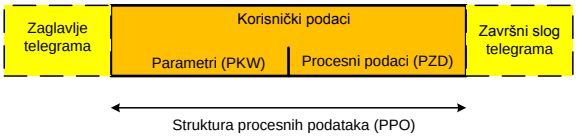
U okviru praktičnog dijela laboratorijskih vježbi uspostavlja se komunikacija između PLC uređaja serije S7-300 (Siemens) i pretvarača frekvencije serije ACS880 (ABB) spojenog preko FPBA-01 adapterskog modula na Profibus DP mrežu. Osobno računalo je spojeno preko ethernet mreže na komunikacijsku procesorsku jedinicu PLC računala i preko njega se konfigurira Profibus mreža i programira PLC računalo. Također, preko osobnog računala se konfiguriraju postavke mreže na energetskom pretvaraču tako da ga se spoji preko USB kabela (Slika 3.)



Slika 3. Principijelna blok shema sustava – Profibus DP

Preko programske podrške Drive Composer Entry potrebno je podestiti tzv. komunikacijske profile i adresu pretvarača na Profibus mreži. Komunikacijski profili su načini prenošenja upravljačkih naredbi tj. upravljačke riječi, statusne riječi, reference i stvarne vrijednosti između nadređenog uređaja i pretvarača. Za ove vježbe koristi se PROFIdrive profil koji se odnosi na strukturu procesnih podataka tj. PPO (eng. *Parameter Process data Object*). On definira strukturu podataka kojom *master* (hrv. nadređena stanica) može pristupiti *slave* (hrv. podređenoj stanici) uređaju, tj. pretvaraču koristeći metodu cikličkog prijenosa podataka. Podatkova struktura PPO za ciklički prijenos podataka podijeljena je na dva dijela:

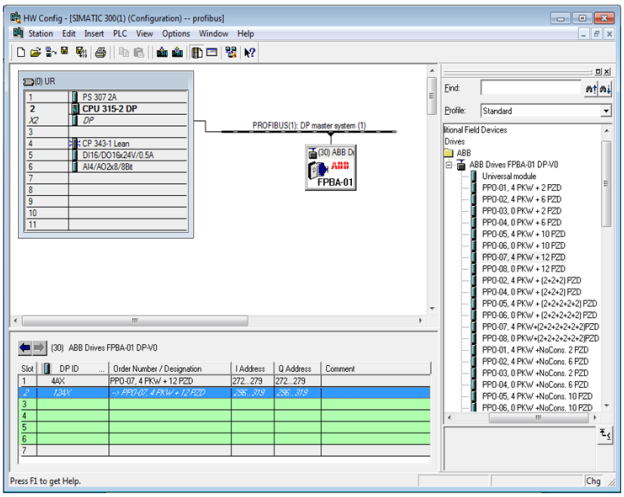
- PKW = Parametarsko područje za čitanje i mijenjanje parametara u pretvaraču. Parametarsko područje osigurava korisniku pristup i mijenjanje svih parametara pretvarača frekvencije. Može se koristiti i za čitanje dijagnostičkih poruka te poruka o greškama.
- PZD = Prikazuje procesne podake, upravljačke riječi, informacije o statusu pretvarača i aktualne vrijednosti. Procesni podaci se stalno prenose i to najvišim prioritetom prijenosa. Koriste se za upravljanje pretvaračem frekvencije na DP mreži, njegovo pokretanje i zaustavljanje, postavljanje referentnih vrijednosti i slično.



Slika 4. Podatkovna struktura PPO za ciklički prijenos podataka

U nastavku vježbi studenti u programskom paketu SIMATIC Manger konfiguriraju i programiraju i PLC uređaj, kako bi omogućili komunikaciju s energetskim pretvaračem. Prvo je potrebno u alatu za izradu sklopovske konfiguracije definirati virtualnu Profibus DP mrežu koja je u stvarnosti jednim krajem spojena na DP

sučelje procesorske jedinice PLC uređaja, a s druge strane na adapterski modul za komunikaciju pretvarača frekvencije. Isto tako, u sklopovsku konfiguraciju je potrebno upisati adresu prevarača na mreži koja je već prethodno odabrana u parametrima pretvarača. Profibus DP mreža se definira unutar sklopovske konfiguracije dvostrukim klikom na X2 koji predstavlja DP sučelje. Nakon uspješnog definiranja Profibus DP mreže i odabira adrese, na radnoj površini student vidi konfiguraciju PLC računala s pripadujućom DP mrežom koje je prethodno kreirana (Slika 5.). Za konfiguraciju nadređene stanice potrebna je GSD vrsta datoteka. Za komunikaciju sa DP-V0 Profibus protokolom postoji GSD datoteka imena proizvođača ABB. Kada je PPO struktura procesnih podataka jednom ubačena u komunikacijski modul tada je u konfiguracijskoj tablici moguće uočiti i zapamtiti adrese procesnih podataka (PZD) koje je potrebno znati prilikom izrade ljestvičastog dijagrama za nadzor i upravljanje pretvaračem frekvencije.



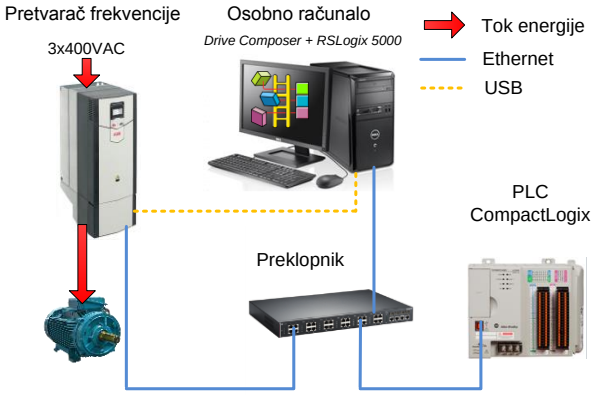
Slika 5. Podešena sklopovska konfiguracija u programu STEP 7

Zadnji dio vježbe je izrada upravljačkog programa upotrebom pripadajućih adresa procesnih riječi. Tek nakon što je konfiguracija, kako energetskog prevarača tako i PLC uređaja, provjerena od strane voditelja vježbi studenti mogu energetski pretvarač pustiti u pogon. Studenti koji prije predviđenog vremena prođu kroz obavezni dio vježbi, u okviru dodatnog zadatka provjere i Profibus komunikaciju upotrebom naprednijih struktura procesnih podataka (PPO).

IV. KONFIGURACIJA PREKO ETHERNET/IP MREŽE

EtherNet/IP (eng. IP – Industrial Protocol) je jedna od tehnologija ethernet mrežnih rješenja u industriji bazirana na otvorenoj tehnologiji, koristeći aplikacijski nivo – Common Industrial Protocol (CIP). EtherNet/IP se koristi s TCP/IP za slanje eksplicitnih poruka te se u svakom tom paketu osim aplikacijskog podatka nalazi i značenje podatka i servis odnosno zadatak koji se treba obaviti nad njime [4]. EtherNet/IP također zadovoljava i standard UDP/IP (User DatagramProtocol/Internet Protocol) koji je zbog svojih performansi i višekorisničke funkcionalnosti pogodan za potrebe rada s podacima u realnom vremenu – još poznato kao slanje implicitnih poruka (slanje poruka od jednog uređaja na mreži prema jednom ili više korisnika). Zbog toga što zadovoljava TCP/IP i UDP/IP protokole, EtherNet/IP proširuje mogućnosti rada na mreži i korisnici ga mogu upotrebljavati kako za prijenos podataka tako i za nadzor sustava (SCADA).

Laboratorijske vježbe se temelje na uspostavi komunikacije između PLC uređaja serije CompactLogix (Allen Bradley) i pretvarača frekvencije serije ACS880 (ABB) opremljenog FENA-11 adapterskim modulom. Na taj način su osobno računalo (ethernet kartica), PLC uređaj (integrirani ethernet priključak) i energetski pretvarač (FENA -11 adapter) međusobno povezani preko ethernet mrežnog preklopnika (Slika 6.).



Slika 6. Principijelna blok shema sustava – EtherNet/IP

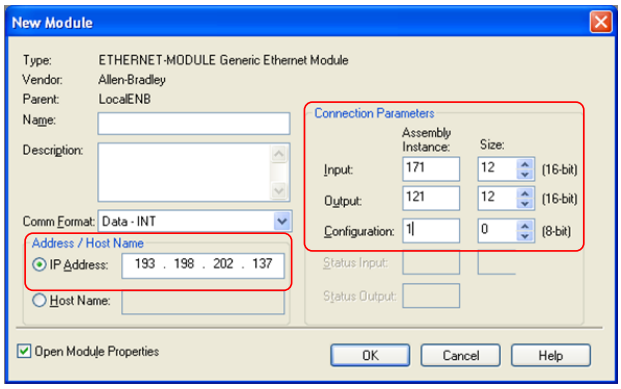
U prvom dijelu vježbi se preko USB kabela podešavaju postavke pretvarača za komunikaciju preko EtherNet/IP komunikacijskog protokola. Potrebno je unijeti IP adresu pretvarača na ethernet mreži i podesiti jedan od više različitih načina komunikacije koje podržava EtherNet/IP protokol. U ovom slučaju se koriste eksplicitne poruke kojima se zapisuju podaci na pretvarač i čitaju informacije s pretvarača. PLC uređaj obavlja ovu funkciju samostalno i direktno upisuje podatke i naredbe u parametre pretvarača i čita povratne informacije s pretvarača. Za upravljanje pretvaračem putem EtherNet/IP pretvarač mora zaprimiti upravljačku riječ koja određuje status pretvarača i reference kojima se pojedini parametri pretvarača mijenjaju. Povratne informacije koje se čitaju s pretvarača su trenutna vrijednost upravljačke riječi koja se naziva statusna riječ i trenutne vrijednosti pojedinih referenci. Za bolje i lakše upravljanje pretvaračem koriste se različite vrste poruka, tzv. Instance od kojih je svaka namijenjena za određeni tip upravljanja [2].

U ovoj vježbi studenti odabiru izlaznu instancu 121 koja omogućuje poboljšane mogućnosti upravljanja pretvaračem i podešavanje parametara pretvarača posredstvom programa iz PLC računala. Isto tako, koristi se ulazna instanca 171 u kojoj PLC računalo prima statusne informacije o smjeru vrtnje, greške i upozorenje, radna stanja, trenutnu brzinu pretvarača i sl. (Slika 7.).

Bajt	Bit 7	Bit 6	Bit 5		Bit 3	Bit 2	Bit 1	Bit 0
0	Dostignuta referenca			Pogon spreman	Vrtnja unazad	Vrtnja unaprijed	Upozorenje	Greška
1								
2	Trenutna brzina (niži bajt)							
3	Trenutna brzina (viši bajt)							
4...24	Ulazni podaci 1...10							

Slika 7. Struktura ulazne komunikacijske instance 171

U drugom dijelu vježbe studenti koriste programsku podršku RSLogix 5000 namijenjenu konfiguriranju, programiranju i praćenju rada PLC računala tvrtke Allen Bradley. Prvo je potrebno u postavkama ethernet sučelja PLC uređaja unijeti IP adresu pretvarača i ulaznu (171) odnosno izlaznu (121) instancu komunikacijskih poruka (Slika 8.).



Slika 8. Konfiguracija ethernet modula u RSLogix 5000

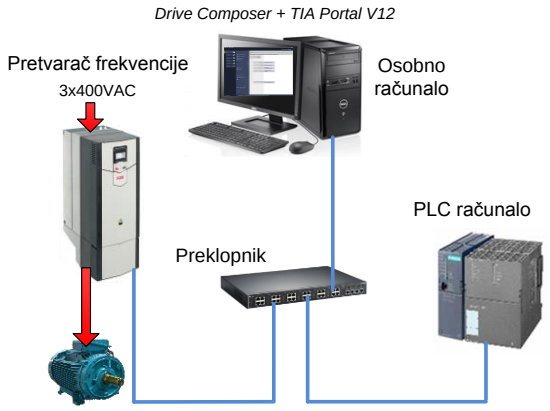
Nakon toga studenti upotrebom pojedinih adresa navedenih instanci izrađuju ljestvičastu logiku (eng. Ladder logic) za nadzor i upravljanje radom pretvarača frekvencije preko Ethernet/IP mreže. Zadnji dio vježbe je puštanje energetskog pretvarača u pogon i provjera ostalih komunikacijskih instanci za naprednije studente.

V. KONFIGURACIJA PREKO PROFINET IO MREŽE

PROFINET (*Process Field NETwork*) je otvoreni standard tvrtke Siemens za industrijsku komunikaciju temeljenu na Ethernet tehnologiji. PROFINET pruža dva različita komunikacijska protokola: PROFINET CBA i PROFINET IO. Za komunikaciju PLC računala s energetskim pretvaračem uređaja na laboratorijskim vježbama, koristimo PROFINET IO protokol koji općenito omogućava komunikaciju u realnom vremenu između distribuiranih jedinica na industrijskoj ethernet mreži. Uz standardne mrežne topologije (zvijezda, stablo, prsten). Profinet I/O podržava linijsku topologiju karakterističnu za sabirničke industrijske mreže, a to je ostvareno preko preklopnika integriranog u UI uređaj [3].

U ovoj laboratorijskoj vježbi koristi se nadređeno PLC računalo serije S7-300 (Siemens) sa zasebnim komunikacijskim modulom (CP 343-1 Advanced) koji upravlja radom pretvarača napona i frekvencije ACS880 (ABB) preko industrijske računalne mreže PROFINET I/O. Slika 9. prikazuje idejno rješenje konfiguracije sustava.

Kako bi PLC uređaj mogao komunicirati preko zasebnog komunikacijskog ethernet modula s pretvaračem frekvencije u upravljačkom programu potrebno je koristiti komunikacijske blokove FC11 „PNIO_SEND“ (za slanje podataka) i FC12 „PNIO_RECV“ (za primanje podataka). Zadaća komunikacijskoga bloka FC11 je prenositi podatke iz korisničkog programa odnosno centralne procesorske jedinice u ethernet modul CP343-1 Advanced. Funkcijski blok FC12 prima podatke iz modula CP343-1 Advanced i upisuje ih u korisnički program.

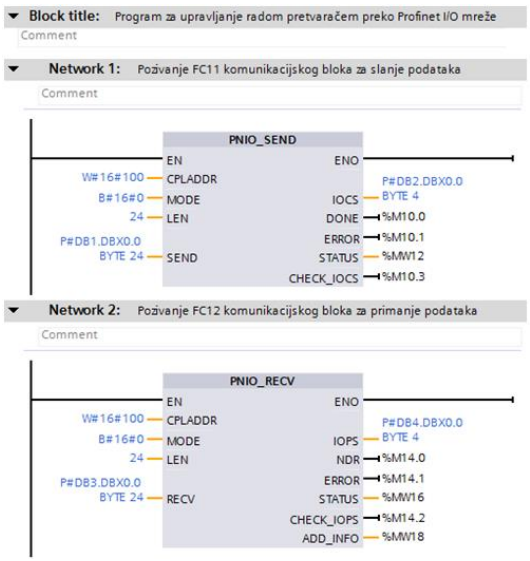


Slika 9. Principijelna blok shema sustava – PROFINET IO

Nastava se provodi korištenjem programskog paketa TIA Portal V12, tvrtke Siemens, pa su u sklopu vježbi objašnjene i osnove rada u tom paketu. TIA Portal V12 je novija generacija programske podrške za rad s PLC računalima tvrtke Siemens, koja je uvedena s namjerom da u potpunosti zamjeni programsku podršku STEP 7, koja se koristi već dugi niz godina.

U prvom dijelu vježbi se preko USB kabela podešavaju postavke pretvarača za komunikaciju preko PROFINET IO komunikacijskog protokola. Odabire se IP adresa pretvarača na mreži i strukturu procesnih podataka (u ovom slučaju PPO 7), s obzirom da PROFINET IO tehnologija koristi jednake komunikacijske profile kao i Profibus DP. U drugom dijelu vježbe studenti unutar programskog okruženja TIA Portal V12 definiraju virtualnu PROFINET IO mrežu te unose IP adresu i komunikacijske profile koji su već prethodno podešeni u parametrima pretvarača.

U zadnjem dijelu vježbe studenti izrađuju upravljački program upotrebnom komunikacijskih blokova FC 11 i FC12, te puštaju energetski pretvarač u pogon nakon provjere ispravnosti sustava od strane voditelja vježbi.



Slika 10. Prikaz primjene FC11 i FC12 komunikacijskih blokova

VI. ZAKLJUČAK

Razlog za uvođenje upravljanja energetskim pretvaračima unutar kolegija Industrijske računalne mreže je potreba za ovakvim specifičnim stručnim znanjima ne samo studenata, već i zaposlenih ljudi u industriji. Procesna industrija ne može opstati na tržištu bez kontinuiranog uvođenja novih tehnologija, a kako je razvoj računalnih mreža u industriji jedno od područja koje stalno napreduje, potreba za ovom nastavom se nametnula sama po sebi.

Kako bi se nastava izvodila što kvalitetnije, zbog obima i kompleksnosti vježbi, studenti rade u paru na jednom laboratorijskom modelu. Konstruktivistički pristup učenju, gdje studenti zajedničkim radom izrađuje mrežnu strukturu uređaja, podešavaju i programiraju uređaje na njoj, pokazao se kao najbolji za proučavanje takve tematike.

Kod ove vrste laboratorijskih vježbi, nastavnik je samo voditelj, a nikako predavač. Naime student mora naučiti da će se u svom budućem poslu na ovakvim sustavima svakodnevno susretati s potrebom čitanja tehničkih priručnika za rad s određenom opremom te uputstva za njihovo programiranje i konfiguraciju. Tako i u ovim vježbama studenti sami moraju pročitati detaljne upute i rukovoditi se njima da bi uspješno završili vježbu te ujedno se naučili koristiti tehnologijom. U radu nije navedeno da uz nastavne materijale, studenti na stolu i u računalu imaju originalne priručnike opreme na kojoj rade. Ispitivanje naučenog gradiva ne postoji, već samo to da su nakon vježbi koje traju tri školska sata uspjeli podesiti i isprogramirati uređaje smatra se prolaznom ocjenom.

Nastavni materijali su radi jednostavnijeg praćenja prepuni slika, ali uz ograničenu količinu teksta tako da studenti sami moraju shvatiti i povezati kako vježbu izvesti uspješno. Kako bi se na slikama mogli raspoznati detalji, potrebno je nastavne materijale tiskati u boji.

Problem na koji ćemo sigurno naići je činjenica da je zbog brzog razvoja tehnologije potrebno stalno nadopunjavati i osuvremenjivati nastavne materijale. Drugi problem je taj što su tehničke inovacije često popraćene novim stranim riječima koje je teško točno prevesti pa se je lakše služiti originalnom riječi.

U ovom radu, koji obiluje tehničkim detaljima, a koji su samo dio problema koje student mora riješiti na ovim vježbama željelo se pokazati koliko je ovo kompleksna tematika i zašto se takve vrste vježbi rijetko izvode na visokoškolskim institucijama. Naime često se potcjenjuje rad na laboratorijskim vježbama u odnosu na predavanja, no ovim se pokazuje da to često neopravdano.

E-učenje: koncept i primjene u europskom vojnom školstvu

Vlasta Zekulić i Darko Možnik
Ministarstvo obrane Republike Hrvatske
Hrvatsko vojno učilište „Petar Zrinski“
Ilica 256B, Zagreb, Republika Hrvatska
Telefon: 01-3786 840 Fax: 01-3786 466 E-mail: vzekulic@morh.hr
Telefon: 01-3784 613 Fax: 01-3784 747 E-mail: dmoznik@morh.hr

Sažetak - Rad opisuje i objašnjava teorijski koncept i praktične primjene odnosno primjere e-učenja u europskom vojnom školstvu. Navode se motivi, prednosti i nedostaci, razlozi i mogućnosti od teorijskog koncepta do smjernica i konkretnih primjera primjene uspješnih procesa e-učenja u vojnom školstvu u nekim zemljama članicama EU.

Opisani su elementi e-učenja, vrste tehnologija e-učenja (združeno napredno distribuirano učenje /engl. JADL/ i napredno distribuirano učenje /engl. ADL/, CBT - Computer Based Training, immersive learning tj. virtualno učenje, m-learning tj. mobilno učenje, blending learning tj. hibridno učenje i kolaborativno učenje i alati /chat soba, forumi, wiki, webinar - web based seminar i webcast/).

Prikazani su razvoj i primjeri tečajeva e-učenja u europskom vojnom školstvu, kao i u primjeri primjene e-učenja u vojnom školstvu u MORH-u i OS RH na Hrvatskom vojnom učilištu (HVU) „Petar Zrinski“.

Kroz pogled u budućnost prikazuje se mjesto, uloga i značenje e-učenja u transformaciji HVU-a u visoko obrazovnu i znanstveno-istraživačku vojnu ustanovu u OS RH i MORH-u i sastavnicu sveučilišne zajednice u RH.

Sadašnje i buduće sposobnosti e-učenja u europskom vojnom školstvu. Zaključna razmatranja.

I. UVOD

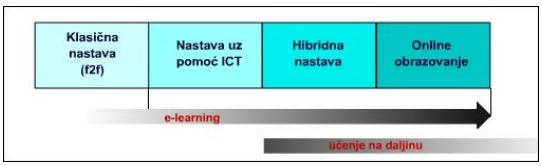
E-učenje i *učenje na daljinu* primjenjuju se u obrambenim i vojnim sustavima zemalja članica NATO saveza i EU. U obrambenim i vojnim sustavima zemalja članica NATO saveza *e-učenje* se koristi i primjenjuje pod nazivima: JADL (engl. *Joint Advanced Distributed Learning*) i ADL (engl. *Advanced Distributed Learning*).

O*pen source* sustavi za upravljanje učenjem tj. LMS-ovi (engl. *Learning Management Systems*) **MOODLE** (engl. *Modular Object-Oriented Dynamic Learning Environment*) najviše koriste akademske zajednice, dok se **ILIAS** (njem. *Integriertes Lern Informations und Arbeitsko-operations System*) koristi u obrambenim i vojnim sustavima zemalja članica NATO saveza i EU.

U MORH-u i OS RH u sustavu vojnog obrazovanja za *e-učenje* se koriste LMS sustavi MOODLE i ILIAS kao platforme i skupovi alata. Također, provodi se projekt "*Uvođenje novih načina usvajanja i održavanja znanja*" odnosno *e-obrazovanje u OS RH i MORH-u.* Određeni pripadnici OS RH i djelatnici MORH-a, a poglavito nastavnici Hrvatskog vojnog učilišta "Petar Zrinski" osposobljeni su vlastitim resursima, učinkovitim korištenjem ILIAS-a, razvijati i primjenjivati *online* ADL tečajeve i module za obrambene i vojne potrebe.

II. E-UČENJE I UČENJE NA DALJINU

E-učenje kao oblik obrazovanja postoji na više razina: kao potpuno samostalan oblik, ali i kao sastavni dio ili nadopuna klasičnog obrazovanja. Proširena klasifikacija ili "vremenska crta" *e-obrazovanja* prikazuje obrazovanje kao kontinuum e-učenja.



Slika 1. Prikaz "kontinuum"a *e-učenja*

Na slici 2. prikazan je odnos *e-učenja, učenja na daljinu i online obrazovanja*. Iako se *e-learning* i *učenje na daljinu* često izjednačuju, nije riječ o istim oblicima obrazovanja: postoje vrste *e-obrazovanja* koje se ne odvijaju online, a isto tako postoje i oblici *učenja na daljinu* koji ne koriste ICT.

A. E-učenje

E-učenje je vrsta komunikacijskog kanala kroz koji se odvija učenje. Postoje dvije skupine definicija *e-učenja* i to: 1. skupina "tehničkih" definicija stavlja naglasak na tehnologiju (na "*e*" dio u imenu). Primjer jedne od "tehničkih" definicija glasi: *"E-obrazovanje* je bilo koji oblik učenja, poučavanja ili obrazovanja koji je potpomognut uporabom računalnih tehnologija, a posebno računalnih mreža temeljenih na Internet tehnologijama.*"* i 2. skupina "pedagoških" definicija ima naglasak na obrazovanju, tj. na učenju i poučavanju ("*learning*" dio u imenu). Jedna od takvih definicija je: *"E-learning* je interaktivan ili dvosmjeran proces između nastavnika i učenika uz pomoć elektroničkih medija, pri čemu je naglasak na procesu učenja, dok su mediji samo pomoćno sredstvo koje upotpunjuje taj proces [1].*"*

Među glavnim prednostima *e-učenja* su: a) vremenska i prostorna fleksibilnost; b) interakcija (komunikacija) između polaznika i nastavnika, koja se odvija putem računala (na primjer: e-mail, forumi) te je često neposrednija i intenzivnija nego komunikacija u razredu; c) komunikacija i grupni rad na zajedničkim projektima između polaznika međusobno; d) programi *e-obrazovanja* su dostupni putem Interneta nevezano za fizičku lokaciju na kojoj se polaznici nalaze; e) programe *e-obrazovanja* mogu putem Interneta pohađati polaznici koji zbog svog posla ili drugih obveza ne mogu nazočiti tradicionalnoj nastavi u vrijeme u koje se ona odvija; f) materijali pripremljeni za *e-obrazovanje* relativno se lako obnavljaju, prilagođavaju i ponovo koriste za različite grupe polaznika; g) korištenje *interaktivnih sadržaja za učenje* i različitih *medija* za prezentiranje sadržaja te *dostupnost* sadržaja 24 sata *online*.

B. Učenje na daljinu

Učenje na daljinu (engl. distance learning, distance education) je obrazovanje ili obuka koja se nudi učenicima na različitim mjestima odnosno fizički udaljenima od učitelja ili izvora informacija. U praksi je učenje na daljinu puno složenije od ove definicije jer uključuje korištenje novih tehnologija i novih interaktivnih nastavnih metoda. Termin učenje na daljinu u novije vrijeme se zamjenjuje terminom online učenje, čime se naglašava da je riječ o posebnom obliku e-learninga ili e-obrazovanja.

Tipičan sustav za e-učenje u osnovi je web aplikacija kojoj korisnici pristupaju putem web preglednika na svojim računalima. Neke od najbitnijih prednosti e-učenja su uklanjanje prostornih i vremenskih ograničenja, olakšan pristup sadržajima za učenje te neposredno povezivanje polaznika za e-učenje. Sustavi za e-učenje omogućavaju samostalno učenje, ali i komunikaciju i suradnju, pri čemu omogućavaju i veću kreativnost nastavnika, mobilnost i fleksibilnost nastavnika i polaznika (u smislu vremena i prostora), personalizaciju, veću dostupnost materijala za učenje, nove komunikacijske kanale za suradnju nastavnika i polaznika, nove metode procjene znanja, potporu promjenama, partnerstvima i transformaciji procesa učenja i uštedu vremena, jednostavnu evaluaciju, trenutne povratne informacije i neposredno praćenje napretka pri *online* procjeni znanja.

III. KONCEPT E-UČENJA

Danas je sveprisutna potreba, ali i želja da se unaprijedi kvaliteta i dostupnost različitih obrazovnih programa. Pri tome je obrazovanje postalo *cjeloživotnim procesom* i potrebom, pa se briga o dostupnosti i kvaliteti odnosi na sveukupni ciklus *cjeloživotnog obrazovanja*. Postalo je jasno da se navedeno ne može ostvariti bez odgovarajuće i učinkovite uporabe informacijskih i komunikacijskih tehnologija u obrazovnom procesu. Upravo kvalitetna implementacija tehnologija e-učenja donosi niz prednosti u obrazovni proces i omogućava željeno novo, moderno i kvalitetno obrazovanje.

E-učenje omogućava: učenje prilagođeno individualnim potrebama studenta (bilo kada, bilo gdje), aktivno sudjelovanje i aktivnu ulogu studenata, aktualnije i ažurnije obra-zovne materijale, globalni pristup različitim obrazovnim sadržajima, smanjenje „pritiska“ na fizičke resurse (omo-gućavajući virtualne učionice, virtualne laboratorije), više komunikacije nastavnik-student i student-student, timski rad, projektni rad nastavnika i studenta, bolju iskorištenost vremena (za kvalitetnije sadržaje) pri kontaktima nastav-nik-student, samostalnu provjeru znanja i kontinuirano mjerenje i praćenje napretka studenta [5].

To je učenje i poučavanje koje je usmjereno na studente.

IV. UPRAVLJANJE PROCESOM E-UČENJA

Model upravljanja procesom e-učenja se sastoji od 3 faze: *planiranje, organiziranje i kontroliranje* procesa e-učenja. Proces upravljanja e-učenjem napreduje kroz slijedeće faze: *planiranje* procesa e-učenja (izrada operativnog plana odnosno scenarija e-učenja), *organiziranje* odnosno implementacija procesa e-učenja (uz provedbu scenarija e-učenja u praksi), *kontroliranje* procesa e-uče-nja (tj. vrednovanje različitih aspekata procesa) i *pobolj-šanje procesa i platforme*. Osnovni princip ovog procesa je *ponavljanje* - jednom kada se potvrde ili odbace početne pretpostavke kroz fazu vrednovanja, ciklus se ponavlja uz primjenu poboljšanja [6].

PLANIRANJE je iznimno bitan za cjelokupni uspjeh e-učenja, a najčešće obuhvaća aktivnosti od analize suvremenih trendova u obrazovanju i identificiranje karakteristika polaznika tečajeva za e-učenje; zatim osmišljavanje okoline za učenje koja odgovara sadržaju, ciljanoj publici i tehničkoj platformi te odabira odgovarajuće platforme; pa sve do formuliranja očekivanih ishoda i izrade operativnog plana odnosno scenarija e-učenja. Cilj faze planiranja procesa je osmišljavanje ishoda i scenarija prema određenom kontekstu. Ishodi učenja predstavljaju instrument razvoja plana i programa, te provjere njegove konzistentnosti. Na razini programa preporučeno je definirati 15 do 30 ishoda učenja, na razini predmeta 5 do 10, a na razini nastavne cjeline 5 do 15 ishoda učenja [12].

ORGANIZIRANJE osnovnog sadržaja e-učenja najčešće se radi pomoću LMS sustava koji omogućuju polaznicima da kolegije istražuju nelinearno, a isto tako i nastavnicima omogućuju izradu tečajeva na fleksibilan način, nelinearno. Redoslijed dodavanja materijala i funkcionalnosti u sam kolegij ovisi isključivo o nastavniku. Ako nastavnik i ne zna gdje započeti, npr. nije siguran treba li organizirati kolegij oko tjednog ili tematskog oblika, treba ipak odabrati jedan oblik i početi s dodavanjem materijala. U slučaju da primijeti kako je ipak drugačiji oblik prikladan za danu situaciju, nastavnik, jednostavno može promijeniti format i rasporediti sadržaj drugačije. U tradicionalnom okružju za učenje, polaznici i nastavnici koriste zajedničke prostore poput učionica, hodnika i dvorišta koja potiču društvene veze i neformalnu komunikaciju koje pojačavaju ostvareno pedagoško iskustvo. U obrazovnom okruženju gdje se koriste LMS-ovi nastav se može odvijati i u potpunosti *online*. Može se organizirati procjena i samoprocjena znanja kroz: zadaće, kvizove, lekcije i radionice.

KONTROLIRANJE napretka i ponašanja polaznika, polazi od postavljanja standarda mjerenja, mjerenja performanse, njene usporedbe sa standardima te poduzimanja potrebne korektivne akcije u svrhu poboljšanja cjelokupnog procesa e-učenja. Svrha faze kontroliranja može se najbolje izraziti kao promatranje i procjena cjelokupnog procesa e-učenja i očekivanih rezultata u odnosu na postavljene ciljeve. Aktivnosti kontroliranja napretka i ponašanja polaznika su: korištenje numeričkih skala procjene napretka polaznika, bilježenje te uvoz/izvoz ocjena na kolegiju, prikupljanje statistika o aktivnostima polaznika, otkrivanje plagijarizma u predanim radovima, prikupljanje log datoteka, prikupljanje povratnih informacija od polaznika raznim upitnicima itd.

V. TEHNOLOGIJE E-UČENJA

Postoji više tehnologija obrazovanja i obuke primjenom e-učenja, a prema NATO-voj podjeli, to su:

1. združeno napredno distribuirano učenje - JADL (engl. *Joint Advanced Distributed Learning*) i

napredno distribuirano učenje - ADL (engl. *Advanced Distributed Learning*),
2. učenje pomoću ICT-a odnosno CBT (engl. *Computer-Based Training*),
3. „uronjeno“ učenje (engl. *Immersive learning*),
4. mobilno učenje (engl. *M-learning*),
5. suradničko ili kolaborativno učenje (engl. *Collaborative learning*) i
6. kombinirano ili hibridno učenje (engl. *Blended learning*) [5].

5.1. JADL i ADL

ADL (engl. *Advanced Distributed Learning*) proizvod je *ADL inicijative* uspostavljene 1997. godine u Ministarstvu obrane SAD-a za standardizaciju i modernizaciju upravljanja „obukama“ i „edukacijama“ te načinima poučavanja. Vizija navedene inicijative je osigurati pristup učenju najviše kvalitete koja može biti „skrojena“ tj. prilagođena pojedinačnim potrebama i isplativa u pravo vrijeme i na pravom mjestu. ADL koristi strukturne i suradničke (engl. *collaboration*) metode iz industrije, akademskih zajednica i vlada koji razvijaju standarde, alate i sadržaje učenja.

Zemlje članice NATO saveza i EU mogu koristiti izrađene obrazovne on-line tečajeve za različita područja u obrambenim i vojnim sustavima.

5.2. CBT (engl. *Computer Based Training*)

CBT je obrazovni ili obučni tečaj dostavljen direktno na studentsko računalo putem CD-ROM-a ili nekog drugog uređaja za pohranu. On se razlikuje od ADL-a po tome što se ne isporučuje preko weba ili putem sustava za upravljanje učenjem i ne zahtijeva usklađenost sa SCORM (engl. *Sharable Content Object Reference Model*) standardom. Studenti se ne prijavljuju na sustav (engl. *login*) CBT, a praćenje napretka polaznika može biti praćeno lo-kalno ili po završetku tečaja.

5.3. „URONJENO“ UČENJE (engl. *Immersive learning*)

„Uronjeno“ (engl. *Immersive*) učenje koristi računalno simulirano okruženje koje se događa u stvarnom životu ili hipotetsku situaciju u grafički bogatom i dinamičnom okruženju. Studenti su stavljeni u situaciju i uključeni su u proces učenja kroz interaktivne simulacije i igre temeljene na *game-based* aplikacijama. *Immersive* učenje podupire jednog učenika ili više malih timova da rade zajedno kako bi riješili problem, uvježbali tehnike ili poboljšali svoje vještine. Ova vrsta učenja može biti web orijentirana, preuzeta na samostalna računala ili mobilne uređaje.

5.4. MOBILNO UČENJE (engl. *m-learning*)

Mobilno učenje (engl. *m-learning*) je uporaba prijenosnih računalnih uređaja, kao što su različiti iPad-i i drugi tableti, prijenosna računala, osobni digitalni pomoćnici (PDA) i pametni telefoni povezani s bežičnim mrežama. To omogućuje da se podučavanje i učenje proširi i na prostore izvan tradicionalne učionice te daje nastavnicima i polaznicima povećanu fleksibilnost i nove mogućnosti za interakcije koje su prikladne i dostupne virtualno s bilo kojeg mjesta.

5.5. SURADNIČKO ILI KOLABORATIVNO UČENJE

Suradničko ili kolaborativno učenje (engl. *Collaborative learning*) podupire nastavu kroz interaktivne metode ili online komunikacije koristeći društvene medijske alate kao što su chat sobe, tribine i video alate kao što su webi-nari i web-emitiranja. Ovi alati se mogu implementirani u učionici i online okruženju kako bi podržali tijek nastave. Oni daju mogućnost velikom broju polaznika da rade zaje-dno s nastavnikom-instruktorom. Kolaborativno učenje može biti sinkrono, kada se učenje događa u stvarnom vremenu ili asinkrono učenje, kada se ne odvija u stvarnom vremenu. Kolaborativni alati za učenje uključuju: chat sobu, forume, wiki, webinar-e/webcast-ove.

Slika 2. Suradničko ili kolaborativno učenje

5.6. KOMBINIRANO ILI HIBRIDNO UČENJE (engl. *blended learning*)

Ponekad je e-learning prisutan u klasičnom obrazovanju u školama i na fakultetima, tako da se računalo i Internet koriste za vrijeme nastave ili u izradi domaćih zadaća. U drugim sluča-jevima se obrazovni programi djelomično izvode online, tj. uz pomoć Interneta ili uz pomoć materijala distribuiranih na CD ROM-u, a djelomično na tradicionalan način. Taj se oblik zove «blended learning», «hybrid» ili «mixed mode». U zemljama članicama NATO saveza i EU koriste se LMS-ovi MOODLE i ILIAS.

VI. PRIMJENA I KONCEPTI E-UČENJA U EUROPSKOM VOJNOM ŠKOLSTVU

Vojni se sustavi oslanjaju na *obuku* i *izobrazbu* pojedinaca i postrojbi kako bi izveli iznimno teške zadaće na visokoj razini, u visoko stresnim uvjetima. I obuka i izobrazba su jednako potrebne: *obuka* jer se njom podiže razina znanja i vještina nužna za izvođenje vojnih zadaća, a *izobrazba* jer omogućava vojnom osoblju na svim razinama donošenje odluka kako, kada i gdje uporabiti vještine usvojene obukom. Dodatno, vojskama su jednako važni i učinkovitost programa (količina usvojenog znanja), kao i isplativost (potrebno vrijeme i uloženi resursi) [9].

Vojne organizacije diljem Europe imaju gotovo apsolutnu kontrolu nad obrazovanjem svojih pripadnika od dana kada pristupe u vojsku do umirovljenja. Međutim zbog suvremenih sigurnosnih trendova te raspršenosti pripadnika oružanih snaga diljem svijeta, takav centralizirani sustav izobrazbe postao im je i značajan teret. Naime, vojnici moraju kontinuirano učiti, simulirati,

uvježbavati bilo da su u matičnoj bazi, u tranzitnim zonama ili u području operacije. Mogućnost obučavanja **bilo kada** i **bilo gdje**, postao je ključni preduvjet održavanja vojne spremnosti i učinkovitosti. Stoga su oružane snage uložile u istraživanje, razvoj i implementaciju tehnologija, načela i programa kojima mogu dio odgovornosti za vojno obrazovanje prenijeti na same pripadnike oružanih snaga. Okretanjem tehnologiji, povećana je dostupnost, učinkovitost, ali i isplativost vojne izobrazbe i obuke.

Dva ključna modela koju većina vojnih organizacija primjenjuje danas su učenje na daljinu i simulatori. Danas je najveći dio nastavnih materijala za vojne potrebe mobilan i značajno smanjuje troškove jer se svi nastavni i obučni materijali pohranjuju na webu i postaju dostupni kroz računalne sustave. To omogućava kontinuirano dorađivanje nastavnih materijala, njihovu relativno laku distribuciju preko raznih računalnih platformi pa i preko „pametnih telefona“ (engl. *Smart phones*) do krajnjih korisnika. Ipak ono što je najvažnije je mogućnost prilagodbe sadržaja svakom vojniku - on sam određuje tempo, mjesto i vrijeme učenja, što je iznimno važno u području mirovnih misija i operacija, čime samostalno održava kontinuitet rasta znanja, a bez pritiska skupine ili potrebe da se prati njezin tempo. Vojnici se dodatno usmjeravaju na nove sadržaje koje trebaju usvojiti, a ne na ono što već znaju.

Uvođenjem e-učenja s jedne strane smanjuje se trošak i vrijeme potrebno za uvježbavanje, a s druge povećava spremnost, učinkovitost i sposobnost vojnika da odgovore na suvremene prijetnje. Dodatno, ADL sustavi i strategija njegove uporabe prikladna je i za distribuciju naučenih lekcija s jednog dijela područja operacija u drugo, što zahtijeva stalnu suradnju softverskih programera sa obučavateljima i instruktorima, te usklađivanje funkcionalnih i tehničkih mogućnosti vojnog sustava.

VII. UPORABA E-UČENJA U VOJNOM ŠKOLSTVU EUROPSKE UNIJE

Iako individualne zemlje članice, ranije navedene procese tehnološkog unaprjeđivanja vojne izobrazbe, provode samostalno, Europska unija je kao zajednica otišla i korak dalje. Naime, sustav europskog vojnog obrazovanja prepoznao je 2008. godine potrebu da se europsko vojno školstvo na poseban način sinkronizira, uskladi i usmjeri prema ispunjavanju europske zajedničke sigurnosne politike (engl. *Common Security and Defense Policy - CSDP*). Razlog tome su tri ključna elementa:

1. Promjene u suvremenom sigurnosnom okruženju su iznimno brze, nepredvidive i njima se teško upravlja. Pojava pojedinačnih ili usložnjenih hibridnih prijetnji u jednom kriznom području, gotovo će se sigurno pojaviti i u drugima, te vojno obrazovanje mora imati sposobnost kontinuiranog informiranja postrojbi na terenu kako bi se naučene lekcije i razvijene taktike što prije dostavile na „prvu crtu“;
2. Suvremene, međunarodne operacije prije svega provode male taktičke postrojbe kojima su zapovjednici niži, mlađi časnici čina poručnik do satnik. Sve češće se događa da taktičke postrojbe ostvaruju strateške rezultate. Ovaj element implicira da je potrebno što je moguće ranije započeti s interdisciplinarnim, međunarodnim obučavanjem kadeta i mladih časnika, kako bi već po stupanju na prvu časničku dužnost mogli odgovoriti suvremenim sigurnosnim zahtjevima zapovijedanja na terenu i
3. Sigurnosne politike Europske unije inzistiraju na rješavanju svjetskih kriza na europski način (nasuprot NATO politikama kojima upravljaju sigurnosni i politički interesi SAD-a). Krizno promišljanje u skladu s načelima i principima europske kulture i sigurnosne politike zahtijeva posebnu obojanost i usredotočenost obuke u EU vojnim akademijama.

Oblikovanje vojne izobrazbe s ovim ključnim smjernicama, dovelo je do osnivanja Fakulteta za europsku sigurnost i obranu (engl. *European Security and Defense College – ESDC*) u Brusselesu (osnovano je aktom Vijeća Europe broj 2008/550/CFSO 23.06.2008.), razvoja programa *ERASMUS militaire*, ili EMILYO (engl. *Exchange of Military Young Officers*) i mnogih drugih. Tu je posebna važnost ESDC jer on sa svojom specifičnom strukturom predstavlja „čvornu mrežu“ (engl. *hub network*) svih vojnih akademija u EU, te je kao takav ključna polaznica za distribuciju informacija, diskusija, analiza i iskustava.

U listopadu 2008. godine Instutut za strateške studije EU (engl. *EU Institute for Startegic Studies*) objavio je izvješće u kojem elaborira sve manjkavosti postojećeg neujednačenog europskog vojnog školstva te navodi nužne korake za poboljšanje. Svi uključuju web aplikacije i tehnološki pristup, a među tri najvažnija su:

- Europska obrambena agencija (engl. *European Defense Agency*) mora „razviti virtualni obučni centar koristeći svoje postojeće i buduće studije kao i druge ključne tekstove o europskoj kooperaciji. Ta web stranica se također mora koristiti kao sredstvo dizajniranja tečajeva za obuku nacionalnih voditelja programa (engl. *Progra-mme Managers*);
- Mora se stvoriti baza podataka nacionalnih obučavatelja i tečajeva dostupna svima u EU vojnom školskom sustavu;
- ESDC mora razviti klasičnu ili tradicionalnu nastavu (engl. f2f – *face-to-face*) i online tečajeve o CSDP-u, kooperaciji i kooperativnim programima koji će se provoditi kod njih, ali i u svim drugim nacionalnim vojnim akademijama [10].

Slika 3. Hijerarhija polaznika i aktivnosti u ESDC-u

Iako su diljem Europe postojali razni virtualni obučni centri poput *S-cube, Elia, European patent office* i drugih, u skladu s ovim preporukama, razvijeni su i oni specijalizirani za vojne i sigurnosne teme i trendove i to

pod okriljem ESDC-a. Nastavni materijali, knjige, izvješća, ali i čitavi ADL tečajevi dostupni su kroz sustav LMS-a pod nazivom ILIAS koji za ESDC administrira rumunjsko ministarstvo obrane.

Iz slike 1. vidljivo je kako je cijeli sustav ESDC obuke, od temeljne do najviše razine polaznika i zahtjevnosti materijala, praćen IDL (engl. *Internet based Distance Learning*) sadržajima, tečajevima i programima [11]. Uz to, razvijeno je nekoliko zajedničkih, akreditiranih i verificiranih tečajeva iz raznih područja CSDP-a koji se provode za potrebe svih zemalja članica EU-a, a jasno su i u cijelosti usredotočeni na poboljšavanje prepoznatih kritičkih vrijednosti EU-a. Ti, takozvani „zajednički moduli" (engl. *Common Modules),* su: (1) *Common module on CSDP* (sadržaj obuhvaća sve teme nužne za upoznavanje europske sigurnosne politike)*;* (2) *Common module on media training* (razvijen zbog važnosti poznavanja načina rada s medijima u području operacija); (3) *Common module on Crisis Management and Peace Support Operations* (provodi se u četiri pod-modula s ciljem obučavanja kadeta i mladih časnika svim fazama stožernog i terenskog rada u mirovnim misijama); (4) *Common module on Law of Armed Conflict* (poznava-nje ratnog prava krucijalni je preduvjet legitimnosti rada u mirovnim misijama i operacijama); (5) *Common module on Maritime Leadership* i *Common module on Maritime Navigation* (tečajevi za kadete i mlade časnike pomorske struke kako bi mogli učinkovito djelovati u multinacionalnim pomorskim operacijama poput anti-terorističke operacije *Active Endeavour* na Mediteranu ili protu-piratske operacije *Atalanta* u Somaliji) i (6) *Common module on Basic Military English* razvijen je s ciljem savladavanja i uvježbavanje engleske vojne termi-nologije.

Svaki od njih obuhvaća dva krucijalna dijela: IDL fazu i f2f fazu. U skladu sa smjernicama o potrebi lake dostupnosti informacija s jedne strane, te ograničenja troškova i vremena provedbe obuke s druge, svaki tečaj se prvo mora završiti on-line preko IDL sustava, a tek nakon toga se kadeti i mladi časnici mogu uputiti na ciljane akademije u trajanju do tjedan dana. Ova kombinacija završenih složenijeg dijela tečaja on-line (otvara se u pravilu tri mjeseca prije planiranog početka obuke) uz finalizaciju i uvezivanje svih naučenih sadržaja kroz jednotjednu f2f fazu, dovodi do mogućnosti vrednovanja ovih programa kroz ECTS sustav s 3-5 bodova.

Kroz IDL platformu ESDC-a moguće je pristupiti i drugim relevantnim vojnim institucijama i znanstvenim skupina-ma, pregledati postojeće priručnike, izvješća, pronaći postojeće pravilnike i standarde usvojene na vojnom odboru EU i sl. [15]. Također je dostupan i forum na kojem polaznici mogu razmjenjivati informacije i komentare o tehničkim ili sadržajnim aspektima platforme.

Upravo iz tih komentara i interakcije s korisnicima, uvedene su promijene 2012. godine jer je prijašnji software omogućavao ostanak na mreži samo do završetka upisanog obučnog modula. Međutim nakon prigovora polaznika da su im informacije dostupne na mreži potrebne i korisne i u kasnijem radu, a ne samo tijekom on-line tečaja, sustav je prilagođen te danas omogućava pristup svim zainteresiranim, registriranim korisnicima u matičnim akademijama, ali i u području operacija.

Danas gotovo sve vojne akademije u EU, uključujući i Hrvatsko vojno učilište „Petar Zrinski" imaju svoje IDL platforme na kojima pohranjuju i distribuiraju obučne materijale. Većina ih inzistira na završavaju određenog broja ADL tečajeva prije dolaska na neku od njihovih obuka ili seminara. Također, vojna obučna središta poput Obučnog središta za međunarodne vojne operacije i mirovne misije OS RH, koji imaju veliki broj stranih polaznika i instruktora na svojim obukama, imaju preko svojih web stranica pristup ILIAS-u te je obveza svih polaznika prije dolaska završiti određeni broj ADL programa kako bi se ujednačila inicijalna znanja većine polaznika i omogućio maksimalni učinak f2f faze obuke.

7.1. PRIMJER PRIMJENE E-UČENJA U VOJNOM OBRAZOVANJU NORDIJSKIH ZEMALJA

Nordijske zemlje Europe (Finska, Švedska, Norveška i Danska) otišle su najdalje u uporabi IT tehnologija u vojnom školstvu. Razvijenost, dostupnost i iskoristivost interneta dosegla je vrhunac 2010. godine kada je u Finskoj pravo na pristup internetu uvršteno u popis ljudskih prava [14].

2009. godine nordijske su zemlje razvile projekt „*Learning online – LONAF*" utemeljen na prepoznatim, zajedničkim izazovima u implementaciji *on-line* učenja u vojnim organizacijama. Iako *on-line* učenje i društveni mediji privlače značajnu pažnju, iznimno se slabo izučila mogućnost uporabe ovih sustava za potrebe vojne obuke i izobrazbe. Stoga su stručnjaci iz svih vojnih akademija NORDCAP-sa zajedno razvili program „*Learning space on Facebook*" na kojem su postavljeni edukacijski tekstualni i video materijali koji objašnjavaju kako učinkovito koristiti mehanizme e-učenja, s ciljem pružanja dobrih primjera praktične uporabe *on-line* alata za učenje kako bi dodatno ohrabrili daljnju uporabu ovih sredstva u vojnoj obuci.

Kako bi osigurali kontinuirani razvoj tehnologija i za e-učenje, Norveška posljednjih 8 godina, za potrebe NORDCAP-sa organizira ADL konferenciju s temom *„Kako ADL i nove tehnologije podržavaju vojno obrazovanje i obuku?"* [13] Raspon tema na ovim konferencijama ide od tehničkih postavki i načina razvoja ADL tečajeva primjerice uporabom interaktivnih PDF aplikacija (*Adobe Captivate and Adobe Connect)*, ili načina izrade modula e-učenja za iPAD i Android aplikacije, pa do predstavljanja civilne organizacija i kompanija koje vojnom obrazovanju mogu ponuditi neka od već razvijenih rješenja ili otvoriti prostor za zajednički rad iz područja ADL tehnologija poput: kognitivnog izučavanja sustava za učenje s ciljem povećavanja učinka učenja, utjecaja nastavnih tehnologija u specifičnim okruženjima kako bi se odredile specifičnosti e-učenja u raznim okruženjima (od učionice do terena u Afganistanu), razvoja elektronskog sustava mentorstva utemeljen na prirodnim jezičnim načelima gdje sustav koristi pitanja, napomene i sažetke kako bi „vodio" polaznika do konačnog zaključka kao što bi to radio i pravi nastavnik, razvoja i izrade video materijala za potrebe obuke i sl.

Također se na konferencijama prezentiraju uspješni primjeri primjene ADL-a poput onih na *Nordic Defense College* gdje se prvi modul Zapovjedno-stožerne škole u cijelosti završava kroz ADL ili ADL rješenja u vojnim školama diljem Europe poput Njemačke (sustav *SuTBw*), Belgije, Srbije i dr. Dodatni primjer je bio rješavanje problema obuke pilota na najsuvremenijim nadzvučnim

zrakoplovima (poput F-35, Grippena, Eurofightera i sl.), s obzirom da je ta obuka dugotrajna, skupa i sigurnosno klasificirana kao tajna, te se ne mogu koristiti vanjski suradnici i stručnjaci za izradu simulatora već je bilo nužno razviti vlastite IT sustave, nastavne module i simulatore.

Na njima se mogu prezentirati i uspješni vojni projekti. 2012. godine je tako predstavljen *MoLE (*engl. *The Mobile Learning Environment)* kojeg su razvili *Coalition Warfare Program NATO-a* usmjeren na rješavanje problema ograničenja koje donosi mala propusnost, ograničen pristup internetu i ograničena infrastruktura, pružajući rješenja kroz globalnu mobilnu umreženost, mobilne, satelitske tehnologije i sl. U projektu MoLE sudjeluju 24 države, od kojih je 13 iz EU. 2013. godine je predstavljen NORDCAP-sov projekt CAMO *(Cultural Awareness in Military Operations)* koji je odgovor na EU smjernicu u potrebi kulturološke senzibilizacije i obuke mladih časnika za rad u međunarodnom okruženju. Projektom je izrađen *game-based simulation*, 3D virtualni svijet u kojem se provode međunarodne operacije, a koji omogućava stavljanje mladog časnika u razne situacije i testiranje njegovih reakcija u njemu.

VIII. POGLED U BUDUĆNOST

HVU je u procesu transformacije u visoko obrazovnu i znanstveno-istraživačku vojnu ustanovu odnosno instituciju tj. sastavnicu sveučilišne zajednicekoji od ove jeseni provodi dva nova preddiplomska sveučilišna studijska programa za potrebe OS RH. Vizija je da se uvođenjem e-učenja želi u procesu obrazovanja ostvariti aktivan partnerski odnos nastavnika i polaznika, prilagođen osobinama i potrebama svakog polaznika, s jasno postavljenim obrazovnim ciljevima i jasno dodijeljenim odgovornostima za postizanje tih ciljeva. Misija je sustavnim uvođenjem e-učenja doprinositi kvaliteti sadašnjeg i budućeg sveučilišnog obrazovanja kroz stvaranje okruženja u kojem se potiče i omogućava aktivna suradnja nastavnika i polaznika. Uvođenjem i aktivnom primjenom e-učenja HVU namje-rava ostvariti četiri strateška cilja:

- unaprijediti kvalitetu obrazovanja,
- omogućiti nastavnicima i studentima ostvarivanje novih uloga u obrazovnom procesu,
- povećati konkurentnost i dostupnost učilišta i učilišnih programa i
- osposobiti studente za uporabu tehnologija cjeloživotnog učenja.

I u europskom vojnom školstvu ponuđen je određeni broj tečajeva i zajedničkih modula u području e-učenja. Svaki od njih obuhvaća IDL i f2f fazu. Sadašnje sposobnosti su na zavidnoj razini, a njihovim daljnjim razvojem, koje su precizirane Smjernicama za daljnje unapređenje sustava e-učenja osnažit će se novim sposobnostima, a polaznici će sistematizirati postojeća i usvojiti nova znanja, vještine i sposobnosti kojima će biti osposobljeni za još učinkovitiju njihovu primjenu u svakodnevnim zadaćama.

X. ZAKLJUČAK

U informacijskom društvu i vremenu *e-učenje* kao i *distribuirano* odnosno *učenje na daljinu* dobivaju sve više na značenju poglavito u europskom vojnom školstvu. Može se zaključiti kako je i u europskom vojnom školstvu napravljen značajan pomak u razvoju i uporabi sustava e-učenja, ali zbog važnosti stalnog izlaganja međunarodnom okruženju tijekom obuke i izobrazbe, većina ih ipak uvezuje ADL i f2f module u vojnom školovanju svojih pripadnika. Razvijen je i ponuđen veliki broj „gotovih" *online* tečajeva za potrebe obrambenog i vojnog sustava. Stvoreni su potrebni preduvjeti za implementaciju *e-učenja* i u obrambenom i vojnom sustavu RH.

„Znanjem u budućnost" moto je sadašnjih naraštaja i ostat će moto i naraštajima koji će doći na vojno obrazovanje u škole Hrvatskog vojnog učilišta „Petar Zrinski" u Zagrebu.

Sažetak - Pojava Interneta i e- učenja promijenila je zahtjeve i pristupe edukaciji unutar samih tvrtki i edukaciji korisnika, te tako značajno utjecala na razvijanje novih pristupa, alata, modela i metoda učenja. Ciljevi ovog članka su opisati edukaciju unutar privatne tvrtke Carpio d.o.o koja se bavi prodajom ERP vlastitog softvera.

Ovim člankom će se opisati potrebe privatne tvrtke Carpio koji su doveli do uvođenja e- učenja. Zatim će se opisati Carpio Web Akademiju kao jedinstveno i višedimenzionalno internet mjesto edukacije u kojoj je tvrtka objedinila sve materijale potrebne za edukaciju svojih klijenata. Također, opisati će se model ubrzanog usvajanja znanja kao način na koji se provodi edukacija na Carpio web Akademiji te načini na koji tvrtka koristi e-učenje u svom poslovanju.

Time se želi dati uvid u jedan novi način primjene e-učenja u poslovnom svijetu koji ne zahtijeva izradu novih alata nego uspješnu primjenu postojećih na nov i inovativan način.

I. UVOD

Nagli razvoj Interneta i ekonomskog tržišta ostavilo je trag na brojne tvrtke i njihovo poslovanje jer su uvidjele da samo stalnom edukacijom i školovanjem zaposlenika mogu konkurirati na globalnom tržištu.

Čovjek koji je sposoban samostalno obavljati svoj posao u što kraćem roku cilj je svake tvrtke. Velika količina dostupnih informacija i brzina njihove razmjene dovela je do problema kako najjednostavnije i najbrže educirati korisnika. Potreba da sve informacije koje mogu biti korisne uvijek budu dostupne na jednom mjestu utjecale su na tvrtke koje educiraju da ih postave u edukacije.

Tvrtka Carpio je prepoznala da klasični načini educiranja u smislu seminarskih predavanja koje je provodila do tada, teško mogu zadovoljiti sve ove potrebe. Okrenuvši se novim tehnologijama i okruženjima kao što je Internet i mogućnostima koje on pruža osmislila je nov pristup tehnologijama e – učenja, Carpio Web Akademiju na kojoj je provodila edukaciju svojih korisnika.

Tvrtka Carpio se bavila prodajem vlastitog ERP[1] softvera posebno prilagođenom za praćenje poslovanja građevinskih tvrtki. Glavni autor članka aktivno je sudjelovao u razvoju projekta Carpio Web Akademije još 2007.g. Projekt je započeo dopunom edukacijske dokumentacije novim oblicima resursa. Standardni priručnici prevedeni su na oblik prihvatljiv za e – učenje, a video animacije i animacije rađene sa Camtasia Studiom[2] pratile su proizvode tvrtke zaokružile su ponudu resursa. Tvrtka je prešla na edukaciju putem Internet Akademije 2010.g i koristila ju je za za educiranje i certifikaciju svojih klijenata, partnera i vlastitih zaposlenika sve do 2014.g..

II. CARPIO WEB AKADEMIJA

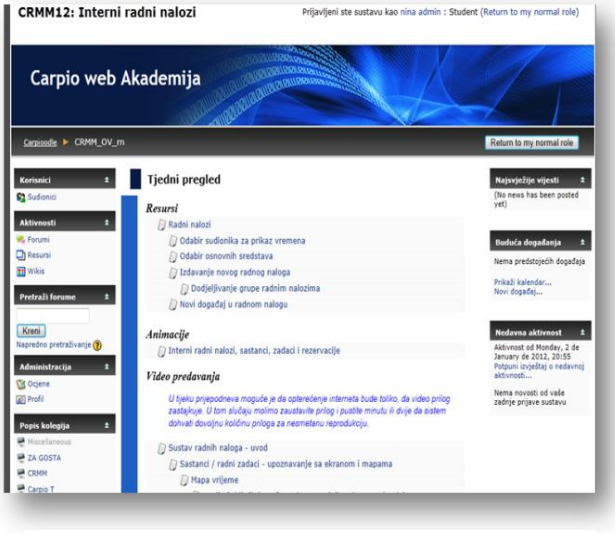
Carpio web Akademija je internet mjesto napravljenom sa Moodle 1.9x[3] alatom za učenje te ima sve karakteristike Moodle internet stranice. Akademiju ćemo opisati na dvije razine.

Prvo ćemo opisati njezino sučelje, odnosno vanjski izgled onakav kakav je vidljiv polaznicima gdje ćemo

[1] skraćeno od Enterprise Resource Planning

[2] Camtasia Studio – alat za snimanje aktivnosti na ekranu, dostupno na http://www.techsmith.com/

[3] Moodle (skraćenica za Modular Object-Oriented Dynamic Learning Environment) je besplatan softver za e-učenje u obliku platforme, također poznat kao sustav za upravljanje učenjem, ili Virtual Learning Environment (VLE), dostupan na https://moodle.org/ .



Slika 1. Izgled kolegija Carpio web Akademije

opisati izgled početne stranice te kolegija. Nakon toga ćemo opisati unutrašnju strukturu Akademije koja nije dostupna polaznicima a u kojem ćemo obuhvatiti pitanja, resurse i administriranje. korisnika.

A. *Izgled sučelja Carpio web Akademije*

Početna stranica Akademije organizirana četiri grupe kolegija. Jedna od njih je otvorena za pregled neregistriranim korisnicima, a ostale tri prate module softvera tvrtke. Na početnoj stranici je vidljivi su kolegiji koji vide neregistrirani korisnici te nazivi kolegij čiji je pregled omogućen samo registriranim korisnicima.

Izgled kolegija registriranih korisnika Akademije prikazan je na Slici 1. Kolegij je vizualno podijeljen u tri stupca. Kolegiji u centralnom dijelu se sastoje blokova resursa, animacija, video animacija, aktivnosti te drugih blokova kojima se nećemo baviti u ovom članku.

Resursi su uglavnom dijelovi priručnika vezani za temu kolegija objavljeni u htm[4] formatu, animacije su animirano objašnjenje određenih postupaka ili problema vezanih za temu kolegija.

Video animacije su, za razliku od animacija, dijelovi seminarskih predavanja koje je tvrtka snimila te prilagodila potrebu e – učenja. Video animacije su različite dužine trajanja ovisno o temi koju obuhvaćaju i sadrže strukturu koja pomaže korisniku lakše snalaženje.

Aktivnosti su kolaboracijski dio kolegija koji se sastoji od dva foruma i wiki[5] kolegija. Dio Certifikacija je vezan za certificiranje korisnika, a za određeni kolegij certifikacija se provodi putem testova koji su dostupni u određeno vrijeme i zaštićeni lozinkom pristupa.

Na Slici 1. također je vidljivo da se u lijevom gornjem uglu nalazi ime kolegija. Sa lijeve strane nalaze blokovi vezani za korisnike, aktivnosti, ocjene te kolegiji na koje je korisnik upisan pod nazivom „Popis kolegija. U desnom gornjem uglu vidljivo je ime polaznika koji se nalazi na akademiji. Blokovi vijesti, budućih događanja i nedavnih aktivnosti nalaze se sa desne strane.

B. *Unutrašnja struktura Carpio web Akademije*

Kao pravi Moodle sustav i Akademija ima određenu unutrašnju građu koja omogućuje administratorima da upravljaju s njom i njenim kolegijima. Akademija se također sastoji od:

- Banke pitanja (na različitim nivoima)
- Baze resursa
- Korisnika
- Ostale administracije vezane za pravilan rad Akademije (administracija web servera i PHPa te same baze podataka)

Pri kreiranju baze pitanja tvrtka je koristila samo tri tipa pitanja (Točno / Netočno (eng. False /True), Višestruki odabir (eng. Multiple choice), Spajanje parova (eng. Matching)). Banka pitanja svakog od kolegija Akademije je organizirana tako da je svakom pitanju određena njegova težina neovisno o tipu pitanja, nego ovisno njegovom sadržaju i zahtijevanom odgovoru.

Testovi na Akademiji sadrže slučajno odabrana pitanja iz banke pitanja odabranog kolegija. Test sadrži 20 pitanja, a njegova težina je regulirana omjerom količine jednostavnih pitanja u odnosu na one složene. Testovi na Carpio web Akademiji imaju sva pitanja na istoj stranici, te su zaštićeni pristupnim lozinkama tako da određenom testu može pristupiti samo onaj polaznik koji ima pristupnu lozinku testa. Kriterije ocjenjivanja testa određuje voditelj edukacije.

Sadržajno na Carpio web Akademiji su korištena tri tipa resursa. To su:

- Priručnici u htm formatu (standardni priručnici tvrtke koji su prilagođeni sadržaju svakog od kolegija).
- Animacije (animirani postupci različitih redoslijeda upisa podataka u sustav ili naglasci rješenja na različite sadržaje ili problem.).
- Video predavanja (snimljeni seminari koje je tvrtka održala. Sadržajno i strukturno su prilagođeni sadržaju svakog kolegija).

Akademija ima definirano ukupno15 uloga od kojih su glavne: administrator (ima prava nad kompletnim sustavom), nastavnik (ima pravo upravljati kolegijem ocjenjivati polaznike i mijenjati aktivnosti), nastavnik mentor (ima pravo dodavati ili mijenjati predavanja i ocjenjivati polaznike kolegija), kreator kolegija (ima pravo kreiranja kolegija, ali ne i interakcije sa polaznicima), student (ima prava pregledavanja i sudjelovanja u kolegiju u koji je upisan), uloge sa pravima studenta (uloge koje su dodijeljene tvrtkama korisnicima edukacije na Akademiji, a koje nećemo navesti radi zaštite njihove privatnosti), gost (imaju prava pregledavati samo

[4]Datoteka Htm formata je Hypertext Markup Language (html) datoteka.

[5]Wiki je kolekcija više Internet dokumenata nastalih suradnjom različitih autora.

Slika 3. Struktura carpio web Akademije

one javne dokumente i sadržaja) i posjetitelj (prava gosta sa dozvolom pristupa na forume, testove na onim kolegijima koji su javni).

C. Struktura Carpio web Akademije

Struktura Akademije prikazana je na Slici 3. Vidljivo je da svi korisnici, koji to imaju pravo, pristupaju cijelom sustavu preko jedinstvenog sučelja, Carpio Web Akademije i na taj način koriste akademiju. Pristup sustav upravljanja bazom podataka i upravljanju modelima omogućen preko bloka Administracija na sučelju Akademije, koji je vidljiv samo administratorima. Pristup ustavu upravljanja dokumentima je kroz kolegije i glavnu stranicu Akademije ovisno o tome gdje se dokument želi koristiti.

Blok sustav upravljanja dokumentima sadrži različite vrste objave testova. Testovi mogu biti dostupni svima, grupi vezanoj za kategoriju, potkategoriju, kolegij ili posebno namijenjenoj grupi ovisno o svrsi testa. Određeni test objavljen je na 24 sata te je na taj način dostupan korisnicima u različitim vremenskim zonama. Moguće je otvaranje foruma raznih namjena, ćaskanje (eng. chat) te zadavanje raznih zadaća i sličnih zadataka.

Sustav upravljanja bazom modela se svodi na administriranje kolegija, potkategorija odnosno samih kategorija brisanje ili dodavanjem novih kolegija, potkategorija ili samih kategorija, sigurnosnih kopija (eng. backup) svih podataka, dodjeljivanje raznih prava korisnicima, njihovo organiziranje u grupe raznih svrha, kreiranje profila i drugo.

Sustav upravljanja bazom podataka sadrži mehanizme za upravljanje i kreiranje same baze pitanja. Obuhvaća kreiranje tri različite vrste pitanja, administraciju dokumenata, slika, izvještaja, pisanih dokumenata te mogućnost kreiranja analiza testova te samu fizičku sigurnosnu kopiju baze pitanja i resursa.

Ovaj blok još sadrži i mehanizme za dodavanje ili brisanje novih korisnika, njihovih podataka, te administraciju grupa, same MySQL baze[6] i HTTP poslužitelja[7].

Moduli softvera organizirani su u kategorije sa potkategorijama unutar kojih se nalaze kolegiji. Unutar svakog od kolegija nalaze se testovi, resursi (materijali), forumi i ostali elementi baze dokumenata. S druge strane baza pitanja, statistike i rezultati testova i zadaća te razne analize kao elementi baze podataka zaokružuju svaku od potkategorija.

Tijekom rada sustava modeli mogu sami dohvatiti potrebne podatke iz baza podataka ili baze dokumenata, a nakon izvođenja rezultati pohranjuju u bazu podataka ili dokumenata.

Bazu podataka čine baza korisnika sa svim njihovim upisanim podacima i uloge koje su im dodijeljene, baza uloga sa definiranim pravima pristupa za svaku od uloga, baza pitanja, web stranice, htm dokumenti, animacije i sl. Baza dokumenata su priručnici, forumi, testovi na svim nivoima Akademije, mail korespondencija, ćaskanje, između svih korisnika, zadaće i wiki za sve kolegije kao novi oblik dokumenata koje korisnik sam može dopunjavati.

Kategorije se sastoje od nekoliko potkategorija. Potkategorije se sastoje od nekoliko kolegija, a svaki kolegij se sastoji od svoje baze podataka, baze pitanja, baze resursa i baze osobnih statistika s jedne strane.

S druge strane, postoji mogućnost administriranja aktivnosti, resursa te osobnih podataka ,uloga i grupa te izrade raznih statistika za svaku aktivnost, resurs te za samog korisnika.

Kolegij se sastoji od korisnika koji mogu imati razne uloge od učitelja raznih nivoa, administratora do studenata, gosta ili nekih korisnički definiranih uloga. Mogu imati pristup raznim resursima, wikijima,

[6]MySQL je besplatan, open source sustav za upravljanje bazom podataka.

[7]HTTP poslužitelj je web poslužitelj za različite platforme.

forumima, ispitima, zadacima, svojim osobnim podacima, statistikama ili podacima drugih korisnika, raznim statistikama ispita, pitanja, resursa ili zadaća ovisno o dodijeljenoj ulozi.

III. MODEL UBRZANOG USVAJANJA ZNANJA

Model ubrzanog usvajanja znanja sastoji se od dvije razine koje su međusobno isprepletene:

- *Metode ubrzanog usvajanja znanja* (metode pomoću koje se svakom polazniku edukacije dodjeljuje uloga edukacije na Carpio web Akademiji).
- *Trokuta komunikacije* (trokut odnosa glavnih elemenata nekog procesa i komunikacije između tih elemenata).

A. *Metoda ubrzanog usvajanja znanja*

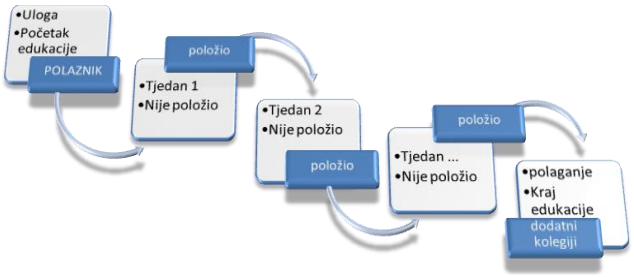
Metoda ubrzanog usvajanja znanja sastoji se u tome da se svakom polazniku Carpio web Akademije prije početka edukacije dodijeli uloga po kojoj će se ta edukacija odvijati.

Dodjeljivanje uloge edukacije ovisi o zadacima polaznika, obujmu njegovog posla te odgovornosti koju ima unutar organizacije u kojoj radi. Sastoji se određenom redoslijedu kolegija kroz koje polaznik edukacije prolazi.

Nakon što mu je dodijeljena uloga polaznik počinje sa edukacijom. Napredovanje sa kolegija na kolegij unutar uloge uvjetovan je prolaskom na testovima i aktivnosti kolegiju.

Jedan kolegij traje 7 dana. Polaznik nakon što položi kolegij na kojem se trenutno nalazi odmah kreće na sljedeći kolegij koji mu je dodijeljen ulogom. Nakon što završi sve kolegije predviđene ulogom polaznik ima mogućnost polaganja dodatnih specifičnih kolegija za posao koji obavlja ili mjesto u tvrtki.

U slučaju da polaznik ne zadovolji uvjete i ne položi kolegij on ostaje na kolegiju kojeg nije položio sve dok ne zadovolji uvjete za prolazak na sljedeći kolegij.



Slika 4. Diagram metode ubrzanog usvajanja znanja

Polaganje testa

Prvi od uvjeta za prolazak kolegija. Prolaz na testovima obuhvaća izlazak i zadovoljavanje minimalnih uvjeta za prolazak testa. Po kolegiju se polažu 2 testa jednake dubine zahtijevanog znanja i opsega znanja. Testovi se rade slučajnim odabirom pitanja iz banke pitanja kolegija, pa edukator nema utjecaja na to koje će se pitanje pojavit na kojem testu, osim u slučaju da tvrtka koja se educira ne traži suprotno.

Postoji nekoliko težina testova ovisno o dubini znanja koje je tražena. Jednom izabrana težina testa uloge ona se ne mijenja do završetka edukacije.

Pregledavanje ponuđenih materijala na Akademiji

Drugi uvjet za prolazak kolegija, Pregledavanje ponuđenih materijala na Akademiji pretpostavlja da polaznik provede neko vrijeme na kolegiju pregledavajući ponuđene materijale. To vrijeme se mjeri i automatski zbraja pregledom logova svakog polaznika kolegija posebno.

Poslovne funkcije kao uloge

Poslovna funkcija je skup povezanih poslova kojima se najsvrsihodnije obavlja određeni zadatak tvrtke sa ciljem stvaranja proizvoda odnosno pružanja usluge. Funkcijski dio organizacijskih struktura u svojoj osnovici ima grupiranje istorodnih, sličnih, neposredno zavisnih ili međusobno uvjetovanih poslova u tvrtki. Poslovne funkcije su predstavljene ulogama i grupirane po logici koja prati potrebna znanja za obavljanje poslova u tvrtki.

Imamo tri skupine uloga:

- RAC (računovodstvo)
- CT (građevinski dio)
- CRM

Duljina edukacijske uloge ovisi o njenoj složenosti i traje od 4 do 10 tjedana. Početni kolegiji su općeniti i kreću se prema sve složenijima i sve više specijaliziranima za određenu poslovnu funkciju. Neki kolegiji su zajednički svim ulogama, a neki su vrlo usko specijalizirani i jedinstveni za određenu ulogu.

B. *Funkcija trokuta komunikacije modela ubrzanog usvajanja znanja*

Trokut odnosa je trokut glavnih elemenata nekog procesa. Kako je komunikacija proces razmjene informacija na različite načine zaključujemo da je trokut komunikacije tada trokut u kojem je moguće na jednostavan način opisati odnose glavnih elemenata komunikacije nekog procesa.

U ovom članku govorimo o procesu razmjene znanja unutar modela ubrzanog usvajanja znanja. Razmjena znanja je složen proces čiji je važan dio komunikacija, no ima glavne elemente koji se tradicionalno mogu

predstaviti trokutom odnosa. Mjesto odvijanja razmjene znanja je Internet Akademija.

Model ubrzanog usvajanja znanja imati će dva glavna trokuta ili razine na kojoj će se odvijati. Prvi je vezan za komunikaciju a drugi za razmjenu znanja ili informacija između glavnih sudionika procesa.

1) Razina komunikacije

Razina komunikacije može se predstaviti trokutom komunikacije koji pokazuje ključne elemente tog procesa, znanje, izvještaje i unutrašnju komunikaciju.

Trokut komunikacije je u slučaju metode ubrzanog usvajanja znanja pomaknut. Temeljni dio je znanje, literaturu u klasičnom trokutu komunikacije predstavljaju izvješća, a unutarnja komunikacija predstavlja jezik kao treći kut tog trokuta.

Polaznik na Akademiji stječe znanje na osnovu kojeg rade se izvještaji. Izvještaji dovode do unutrašnje komunikacije u tvrtki čiji se zaposlenici educiraju. Iz trokuta razmjene prikazanog na slici 5. vidljivo je da unutrašnja komunikacija utječe na stjecanje i vrstu znanja. Svi elementi ovog trokuta utječu jedan na drugoga te na taj način poboljšavaju komunikaciju tijekom edukacije.

2) Razina razmjene znanja

Razmjena znanja kod metode ubrzanog usvajanja znanja je složeni proces čiji se glavni elementi mogu predstaviti trokutom.

U centru trokuta je Akademija kao mjesto na kojem se odvija razmjena znanja. Edukator odnosno tvrtka koja educira predstavlja izvor znanja, na odredištu su polaznici Akademije odnosno zaposlenici tvrtke koje se educira. Na vrhu trokuta je uprava odnosno rukovodstvo tvrtke koja se educira.

Akademija je mjesto na kojem se nalaze resursi koji predstavljaju znanje kako koristiti softver. Njih je tamo postavio edukator. Polaznici Akademije se koriste tim resursima i na taj način predstavljaju jednu stranicu trokuta Akademije.

Slika 5. Trokut komunikacije Modela ubrzanog usvajanja znanja

Razmjena znanja se događa u momentu kada se polaznici uče pomoću resursa kolegija Akademije. Dubina i količina znanja potrebna za neku poslovnu funkciju određuje uprava odnosno rukovodstvo. Povratnu informaciju predstavljaju uspjeh na testovima i vrijeme provedeno na kolegiju.

3) Trokut komunikacije

Trokut komunikacije kod modela ubrzanog usvajanja znanja ima elemente trokuta razmjene znanja te ih spaja sa procesom komunikacije kao što se i vidi na Slici 5. Vrhovi trokuta su:

- Edukator,
- Polaznik odnosno zaposlenik,
- Uprava odnosno rukovodstvo.

U centru modela je Akademija pa se ona nalazi i u centru trokuta modela ubrzanog usvajanja znanja. Jednu stranicu tog trokuta čine edukator i polaznik. Edukator putem resursa Akademije polaznicima predaje znanje, dok polaznici edukatoru daju povratnu informaciju o usvojenom znanju putem aktivnosti. Također polaznici mogu edukatoru ukazati na probleme u edukaciji i na taj način mu omogućiti da ju poboljša.

Druga stranica trokuta opisuje odnos edukatora i uprave odnosno rukovodstva tvrtke. Taj odnos se zasniva na raznim izvješćima koje edukator daje upravi o usvojenom znanju i raznim aktivnostima zaposlenika na Akademiji i o tijeku edukacije. Na osnovi tih izvješća uprava edukatoru daje povratnu informaciju o slijedećim koracima i načinu nastavka edukacije.

Treća stranica trokuta je ona između zaposlenika i uprave tvrtke koja se educira. Taj odnos odlikuje unutrašnja komunikacija tvrtke koja se odnosi na Akademiju i e – učenje.

4) Praćenje napretka edukacije

Način praćenja napretka je vrlo važan faktor u edukaciji te određuje njene daljnje korake i tok ovisno o željama tvrtke čiji se zaposlenici educiraju. Njen napredak prati se na dva nivoa:

- *Praćenje edukacije i ponašanja polaznika*
- *Izvještavanje o napretku i tijeku edukacije*

Ponašanje korisnika na Akademiji se analizira prateći količinu vremena i mjesto na kojem je polaznik bio na kolegiju. To se radi pomoću korisničkih logova, dok se tijek edukacije prati uspjehom na ispitima kolegija te na osnovi komunikacije koju je ostvario sa edukatorom.

Izvještavanje o napretku edukacije polaznika daje se pomoću pisanih izvješća koja se šalju svakom polazniku i upravi odnosno rukovodstvu putem e – poruka ili na neki drugi način specificiran od tvrtke čiji se zaposlenici nalaze na Akademiji.

Izvješća upravi odnosno rukovodstvu su grupna izvješća koja sadrže vrijeme svih polaznika edukacije te

tvrtke povedeno na Akademiji pojedinačno i ukupno po grupi korisnika ili na neki drugi način specificiran od strane tvrtke koja se educira. Također, ona sadrže i prolaznost na kolegijima, uspjehe svih sudionika edukacije koji su zaposlenici te tvrtke ili specificirani kao njeni članovi i plan edukacije za sljedeći period. Izvješća mogu sadržavati i dodatne informacije koje tvrtka koja se educira smatra važnima.

IV. ZAKLJUČAK

Pojava Interneta značajno je utjecala na nove pristupe poslovanju a samim time i na nove načine odnosno procese usvajanja znanja. Danas je e – učenje sastavni dio svakodnevnog života ljudi i tvrtki.

Mogućnosti učenja putem kolaboracije i razmjene informacija u što kraćem vremenskom roku velikom broju ljudi postavila je nove potrebe i trendove e – učenja.

Potrebe tvrtki koje žele educirati svoje zaposlenike su da sve informacije koje mogu biti korisne uvijek budu dostupne na jednom mjestu. Te potrebe utjecale su na tvrtke koje educiraju da ih postave i u zahtjeve svojih edukacija.

Carpio web Akademija tvrtke Carpio napravljena Moodle alatom. Predstavlja jedinstveno višedimenzionalno mjesto na kojem se nalaze svi edukacijski materijali vezani uz ERP softver tvrtke i odgovori na većinu pitanja korisnika koji rade ili počinju raditi softverom tvrtke. Sadrži dodatne informacije i iskustva vezana uz određene funkcije proizvoda tvrtke u obliku wikija i foruma. Akademija je dostupna klijentima od 0 do 24 sata na dan bez obzira na gdje se on nalazi u svijetu.

Unutar nje se svakom od polaznika kroz metodu ubrzanog usvajanja znanja dodjeljuje grupa (ovisno o kojem se korisniku (tvrtki) radi) ali i uloga (ovisno o poslovnoj funkciji koju polaznik obavlja unutar tvrtke). Uloga određuje kroz koje kolegije će se edukacija odvijati i traje od 4 do 10 tjedana.

Neki kolegiji su zajednički za više uloga, pa će se na njima nalaziti polaznici sa različitim ulogama a neki su vrlo usko specijalizirani i namijenjeni su polaznicima koji su prošli dio zajedničkih kolegija. Kolegiji unutar uloge su vezani a kroz njih polaznik prolazi individualno ovisno o tome da li je zadovoljio uvijete za prolaz kolegija ili nije. Uvjeti za prelazak na novi kolegij su prolazak na testovima i zadovoljavanje minimum aktivnosti na kolegiju. Oni su unaprijed određeni i jednaki za sve kolegije, grupe i uloge. Na takav način se korisnik 'vodi' kroz edukaciju sve do onog trenutka kada je sposoban obavljati svoj posao sa novim softverom.

Kako uloge ne ovise o korisniku nego o poslovnoj funkciji koju polaznici imaju unutar tvrtke moguće je dodjeljivanje uloga i grupa za više korisnika istodobno, neovisno o njihovoj veličini ili broju polaznika koje žele educirati. Završavanje edukacije nastaje u onom trenutku kada polaznik zadovolji sve uvjete iz svih kolegija, dakle unutar 4 do 10 tjedana.

S druge strane se polaznik, preko trokuta komunikacije, prati kroz edukaciju. Testovi koje rješava i aktivnost na kolegiju kojeg pohađa daju uvid u njegovo znanje, zalaganje ali i u onaj dio znanja u kojem bi mu trebala pomoć pri savladavanju sadržaja. Na taj način polaznik može proći kroz kolegije brže i upotpuniti svoje znanje.

Iako nam se ovaj pristup edukaciji čini prirodan i logičan, moramo uzeti u obzir da se radi o edukaciji u poslovnom okruženju gdje još uvijek vrijedi pravilo e-seminara. Vođena edukacija ovakve vrste vrlo se rijetko susreće jer je još uvijek 'primjerena školskom pristupu'.

Ipak tvrtka Carpio je uspjela primijeniti ovakav model edukacije. Kroz njega je pratila implementaciju svog softvera kod klijenata raznih veličina i profila. Kratko vrijeme edukacije ovom metodom od samo 4 do 10 tjedana znači i kratko vrijeme implementacije koja inače traje godinama a katkada nikada ne uspije.

Vidljivo je da je model ubrzanog usvajanja znanja primjenjiv, brz i efikasan. On zahvaća sve nivoe i elemente tvrtke koje se educira i stvara nove kanale komunikacije sa edukatorom ali i unutar same tvrtke.

Ovakav nov pristup postojećim tehnologijama e – učenja omogućio je inovativan način edukacije i dao tvrtki Carpio i njenim klijentima prednost na tržištu koji su tražile.

Masovnost, uspješnost i prolaznost u masovnim otvorenim *online* kolegijima

M. Melinščak
Veleučilište u Karlovcu, Trg J. J. Strossmayera 9, 47000 Karlovac
e-mail adresa: martina.melinscak@gmail.com

Sažetak – Masovni otvoreni online kolegiji (engl. *massive open online course* – MOOC) relativno su nov fenomen otvorenog učenja. Mogu se promatrati kao proširenje otvorenog učenja, odnosno kao nadogradnja klasičnog učenja na daljinu. Ključna je razlika u tome što su takvi kolegiji dizajnirani za neodređen broj polaznika. S obzirom na njihovo brzo širenje vode se mnoge diskusije i postavljaju pitanja o daljnjim trendovima njihova razvoja. Obilježava ih masovnost, ali je zabilježen i malen postotak polaznika koji završavaju upisane kolegije. Svrha je ovog rada u stjecanju uvida u razloge i značenje fenomena niskog postotka prolaznosti. Analizirane su ankete, dostupni izvještaji i znanstveni radovi te se daje prikaz rezultata takve analize. Izvedeni su zaključci o uzrocima značajnoga pada broja polaznika tijekom kolegija i obrazlaže se eventualni doprinos porastu postotka polaznika koji bi uspješno završavali kolegije.

I. UVOD

Masovni otvoreni *online* kolegiji (engl. *massive open online course* – MOOC) su besplatni kolegiji otvoreno dostupni neograničenom broju polaznika. I ranije su postojali otvoreni *online* kolegiji i razne varijante učenja na daljinu. Ono što MOOC-ove bitno određuje je masovnost [1-3].

Takvi kolegiji su objavljeni na Internetu, besplatni, dostupni svugdje na svijetu svakome tko posjeduje računalo i internetsku vezu, a omogućuju ih platforme kao što su *Coursera*, *edX*, *Khan Academy*, *Udacity* i druge. Pružatelji *online* kolegija su uglavnom sveučilišni konzorciji ili su blisko povezani sa sveučilištima. Štoviše, povezani su s elitnim sveučilištima poput Stanforda, Berkeleya, Harvarda, i Columbije [4].

Neki ih smatraju revolucionarnim preokretom koji nagovještava novu eru u visokom obrazovanju. U ovom ranom stadiju teško je predvidjeti daljnji tijek razvoja. *Online* obrazovanje zasigurno nije novi pristup učenju i podučavanju. To je pristup koji se razvijao godinama. MOOC-ovi su logična posljedica te evolucije. *Online* kolegiji su među najučinkovitijim i najefikasnijim metodama dijeljenja sadržaja i vještina na globalnoj razini. Mnoge uobičajeno navođene prednosti *online* kolegija su raznolikost studijskih programa i nastave koje se nude, mogućnost fleksibilnog raspolaganja vremenom, i mogućnost da polaznici balansiraju između zaposlenja i obrazovanja. Uočljivo je da *online* pokret dramatično raste i to je dovelo do kreativnijih modela poput MOOC-ova. Njihova pojava promiče razmjenu informacija širom svijeta i stvara mnogo prilika za učenje i podučavanje u različitim disciplinama [5-7].

Svaka rasprava o MOOC-ovima vodi do mnogih izazovnih i značajnih pitanja kao što je primjerice utjecaj na tradicionalno obrazovanje. Važno je pitanje ekonomske održivosti. Vrlo je upitno mogu li takvi masovni otvoreni *online* kolegiji s nekoliko stotina tisuća upisanih polaznika osigurati dovoljno kvalitetno znanje i kvalifikacije potrebne za osobni ili profesionalni razvoj i usavršavanje. Nezanemarivo je pitanje mogu li takvi kolegiji davati certifikate koji poslodavcima jamče savladano znanje i vještine. Pitanje koje je od velikog značaja za sadašnji oblik visokog obrazovanja jest tko će plaćati tradicionalno obrazovanje i koji će se zahtjevi nametnuti ako postoji mogućnost besplatnog slušanja kolegija s prestižnih sveučilišta.

Jedan od velikih izazova MOOC-ova je visoka stopa odustajanja. Kolegiji uglavnom imaju stopu završavanja od 10 % do 20 %, nekoliko kolegija bilježi čak i postotak od 2 % [7]. Glavni cilj rada je istražiti fenomen niske stope prolaznosti i kao rezultat analize dati uvid u bolje i dublje razumijevanje MOOC-ova te naći alternativne pristupe koji bi MOOC-ove činili efikasnijim. Dodatni razlog je što nam analiza *online* učenja daje dublje uvide o samom učenju i podučavanju. Prikupljanjem i razumijevanjem razloga odustajanja polaznika možemo poboljšati i *online* kolegije i tradicionalne kolegije. I konačno, analiza visokog postotka odustajanja važna je zbog ulaganja sredstava u organiziranje MOOC-ova, potrošenog vremena profesora i ostalog osoblja u organiziranju kolegija.

U radu su analizirane dostupne ankete, izvještaji, znanstveni radovi koji daju uvid u statistički relevantne značajke masovnih otvorenih *online* kolegija, njihovih polaznika i prolaznosti. Za takvu analizu su relevantni pokazatelji koji prikazuju širok raspon polaznika, ne samo studente pojedinačnog sveučilišta, nego je važna informacija struktura polaznika (studenti, studenti na doktorskom studiju, profesori, zaposleni kojima treba dodatno usavršavanje, umirovljenici…), kolika je zastupljenost u pojedinim zemljama, koji su motivi za upisivanje kolegija, koja su očekivanja, kolegiji iz kojih područja znanosti su zastupljeniji itd.

II. ANALIZA NISKE STOPE PROLAZNOSTI MASOVNIH OTVORENIH *ONLINE* KOLEGIJA

A. Opis masovnih otvorenih kolegija

MOOC-ovi su relativno nov fenomen *online* učenja. Razvili su se od ranih primjera prije pet godina a danas izazivaju značajnu medijsku pažnju i značajan interes visokoškolskih ustanova i tvrtki koje u njima vide poslovnu priliku. Mogu se smatrati proširenjem postojećeg *online* učenja, u smislu otvorenosti pristupa i neograničenosti broja polaznika [8].

Kolegiji su uglavnom organizirani kao zasebne cjeline i polaznici mogu dobiti potvrdu o završavanju (engl. c*ertification of completion*). Iako su u nekoj mjeri slični konvencionalnim predavanjima, ono što je bitno različito je što su MOOC-ovi besplatni, traže jedino pristup Internetu te interes i volju. Tipičan kolegij sastoji se od tjednih lekcija, nekoliko tema razbijeno je u kraće cjeline. Većina videa sadrži nekoliko ugrađenih kvizova (ili odabir jednog ili nekoliko od ponuđenih odgovora ili odgovaranjem u samostalnoj formi). Zatim postoje tjedni problemski zadaci koji se ovisno o vrsti kolegija sastoje također ili od pitanja ili problemskih zadataka (programiranje) ili pisanja eseja (uglavnom kolegiji iz humanističkih znanosti). Često postoji ispit na sredini kolegija i na kraju, ili samo na kraju kolegija (završni ispit). Tjedne zadaće, kvizovi i završni ispiti imaju rok nakon kojeg predaja više nije moguća (engl. *hard deadline*).

Treba napomenuti da postoje i MOOC-ovi koji se ne održavaju u određenim terminima, već je njihov materijal konstantno dostupan – tzv. *self-paced* MOOC-ovi. U radu je analiza ograničena na MOOC-ove u ograničenim terminima jer kod njih je prolaznost bolje definirana.

Moderna sveučilišta su daleko više nego samo sakupljeni kolegiji. Između ostaloga, velika vrijednost za studente je što su u bliskom kontaktu s kolegama, što sudjeluju u raznim aktivnostima unutar kampusa i u radu istraživačkih laboratorija. Možda je ova nova vrsta kolegija i načina obrazovanja dobra zamjena za prosječan kolegij s velikim brojem polaznika, no to je još uvijek na vrlo niskoj razini [5].

Jedna od ključnih značajki koja razlikuje MOOC-ove od ranijih oblika *online* učenja je što su besplatni. Polaznici ne plaćaju nikakvu naknadu. Posljedica toga je masovnost.

Pedagogija na kojoj se baziraju MOOC-ovi je također različita od tradicionalnog *online* učenja. Lekcije su drukčije strukturirane. Umjesto 45 do 60 minutnih lekcija u tradicionalnom obrazovanju i dosadašnjem stavljanju sadržaja *online*, za MOOC-ove je specifično da su predavanja uglavnom razlomljena na module čvrsto usmjerene na pojedine teme u prosječnom trajanju od 12 do 15 minuta. Glavni cilj ovakvih razlomljenih video lekcija u kraćem trajanju je omogućiti polaznicima da ih što lakše uklope u svakodnevne obveze, čime se prilagođava polaznicima raznih profila.

MOOC-ovi su inicijalno bili orijentirani na tzv. STEM discipline (engl. *Science, Technology, Engineering and Mathematics* – prirodne znanosti, tehnologija, inženjerstvo i matematika) koje dopuštaju kvantitativne procjene. Međutim MOOC-ovi se šire i na ostala područja znanosti (primjerice humanističke znanosti) time što platforme omogućuju ocjenjivanje putem istorazinske prosudbe (engl. *peer review*).

Kod klasične nastave studenti imaju redovito priliku izravno komunicirati s nastavnikom. Također imaju korist od podrške kolega koji slušaju isti kolegij. No kod MOOC-ova, unatoč nekoj vrsti podrške putem foruma i osoblja koje se povremeno uključuje u rasprave i daje odgovore i pojašnjenja, od studenta se ipak očekuje velika razina samostalnosti. MOOC-ovi daju mogućnost kvalitetnog i interaktivnog učenja, no organizirani su tako da je interakcija u virtualnom obliku, koji možda još nije dovoljno zaživio (putem blic pitanja tijekom lekcija, kvizova, zadaća), unatoč popularnosti društvenih mreža. Iskustvo je dosad pokazalo da je stvaranje snažne *online* zajednice ključna komponenta za dobro organiziran MOOC. Za učenje je nužna ljudska interakcija, makar ona bila i u virtualnom obliku. Današnja tehnologija je dovoljno razvijena da pruži medij za takvu interakciju. Unatoč važnosti tehnologije često se naglašava da se ne radi o IT revoluciji, već o revoluciji u načinu obrazovanja.

Iskustva nastavnika koji su organizirali MOOC svjedoče da treba uložiti više vremena u pripremu, bez obzira koliko dugo je nastavnik već predavao taj kolegij na sveučilišnoj razini. Činjenica da nećete biti u istoj prostoriji s polaznicima gdje je u tijeku stalna interakcija i gdje se istovremeno dobivaju povratne informacije, znači da cijeli tijek mora biti planiran do najsitnijih detalja i to prije početka kolegija. Osim samog planiranja kolegija, lekcije moraju biti snimljene, zabilježene u pisanom obliku, interaktivni kvizovi i zadaće moraju biti unaprijed pripremljeni [9].

B. Struktura polaznika i motivacija za upis

Što motivira polaznika MOOC-a? Motivacija za sudjelovanje u MOOC-ovima je značajno područje interesa za mnoge visokoškolske institucije. Mnogi su čimbenici koji utječu na motivaciju polaznika, primjerice buduća ekonomska korist, razvoj osobnih i profesionalnih vještina i znanja, izazov i postignuće, uživanje i zabava.

Prema anketi provedenoj na Sveučilištu Duke [8] polaznike svrstavaju u četiri kategorije kada je u pitanju motivacija. To su:

- Pomoć u cjeloživotnom učenju ili stjecanju i razumijevanju gradiva, bez posebnih očekivanja i potrebe za potvrdom o završavanju
- Zabava, razonoda, socijalno iskustvo i intelektualna stimulacija
- Praktičnost, često u kombinaciji s preprekama za tradicionalne mogućnosti obrazovanja
- Želja za doživljajem i istraživanjem *online* obrazovanja

Na anketi koja je prethodila kolegiju, zabava i užitak su odabrani kao važni razlozi za upis većine studenata (95 %), dok je na anketi nakon završenog kolegija većina odabrala opći interes za temu (87 %). Neki studenti upisuju *online* kolegij kako bi im to iskustvo pomoglo u odluci koji fakultet ili koje kolegije žele upisati (15 %). Značajna

manjina je tvrdila da si nije mogla priuštiti formalno obrazovanje (10 %).

Daljnja istraživanja su potrebna kako bi se razumjela motivacija polaznika na početku, ali i ono što održava motivaciju polaznika tijekom trajanja kolegija.

Uočeno je da su većina polaznika MOOC-ova ljudi koji već imaju diplomu. U tom slučaju je pitanje valjane potvrde o završetku kolegija manje važno, pošto im nije potrebno kao dokaz da su prisustvovali programu učenja i time usvojili određena znanja i vještine.

Trenutno, većina polaznika koja upisuje MOOC-ove su internacionalnog podrijetla i češće profesionalci nego studenti koji pohađaju neko sveučilište.

Paradigma MOOC-ova vjerojatno najbolje odgovara polaznicima koji su vješti u samoorganizaciji i koji su samodisciplinirani.

Prema rezultatima na *Courseri* [10] većina polaznika nisu učitelji ili profesori, samo 9 % radi na sveučilištima, 4 % u srednjim školama i 2 % u vrtićima. Velika većina polaznika bi bila jako ili u nekoj mjeri zainteresirana da uvodni materijal bude dostupan prije početka kolegija. Studenti čine 27 % polaznika, 28 % su stručnjaci i 43 % „cjeloživotni učenici“. Na pitanje o mogućnosti direktne komunikacije s instruktorom 42 % polaznika odgovara da je jako zainteresirano, 29 % odgovara da je zainteresirano, 23 % da je donekle zainteresirano i samo 5 % da nije zainteresirano. Velika većina polaznika (86 %) prati MOOC-ove od kuće, samo 8 % njih na radnom mjestu. U interakciji s ostalim polaznicima uživa 34 %, 60 % uglavnom ne komunicira s ostalim polaznicima i 6 % ne uživa u komunikaciji s ostalim polaznicima. Broj polaznika koji odgovara da im je vrlo važno dobiti certifikat o završavanju je 32 %, 25 % da im je važno, 25 % da im je donekle važno i 18 % da im uopće nije važno.

Rezultati koji se mogu istaknuti kao važni i uočljivi su vrlo visok postotak polaznika koji je zainteresiran za komunikaciju s nastavnikom. No s druge strane većina ne komunicira s ostalim polaznicima što bi bila alternativa komunikaciji s nastavnikom.

Preko 80 % polaznika na *Courseri* [9] su barem prvostupnici, a više od 40 % su magistri ili doktori znanosti, uz značajan broj upisanih koji su studenti na visokoškolskim institucijama. Mnogi polaznici upisuju kolegije iz profesionalnih ciljeva i interesa, no oni kojima takvo učenje predstavlja „hobi“ su ipak značajna većina. Na kolegijima s nižom razinom potrebnog predznanja zabilježeni su polaznici ispod 18 godina koji vjerojatno upisuju kolegije kako bi lakše odredili što ih zanima i koje sveučilište i kolegije će odabrati.

Analizom ankete na *Courseri* [9] slijedi da je najveći broj polaznika iz Sjeverne Amerike (35,2 %), zatim slijede Europa (28,2 %), Azija (21,4 %), Južna Amerika (8,8 %), Afrika (3,6 %) i Oceanija (2,8 %).

C. Postotak prolaznosti

Masovni otvoreni *online* kolegiji imaju potencijal omogućiti besplatno sveučilišno obrazovanje neodređenom broju polaznika. Zabrinutost se obično javlja zbog toga što od tisuća koje upišu kolegije samo mali dio ih uistinu završava. Broj polaznika koji odustanu od upisanih MOOC-ova je ogroman. Taj je fenomen prema nekima zanemariv jer i ako 5 % od 100000 upisanih završi kolegij to je još uvijek 5000 polaznika, odnosno daleko više nego što pohađaju studenti fizičkom prisutnošću neki kolegij u sklopu tradicionalne nastave. No ipak, ta činjenica dovodi u pitanje uspješnost MOOC-ova. Niska stopa prolaznosti i dalje se smatra jednom od većih prepreka za njihovo širenje. Godine 2007. 56,1 % akademskog osoblja je to smatralo važnom ili vrlo važnom preprekom, već sljedeće godine postotak je narastao do 61,9 %, a 2012. godine se čak 73,5 %, odnosno gotovo tri četvrtine slagalo s time [1].

O razlozima odustajanja u tradicionalnom učenju na daljinu postoji dovoljan broj studija, samo je nekoliko istraživanja provedeno za *online* obrazovanje, a za MOOC-ove koji su inačica *online* obrazovanja gotovo da i ne postoje. Vode se mnoge debate, ali nije sasvim jasno koji su to razlozi koji utječu na tako veliku stopu odustajanja, a pogotovo koji su razlozi zastupljeni u kojoj mjeri i na koje se može utjecati i kako.

Postotak prolaznosti je jedna od mjera efikasnosti *online* programa. Uz to, gubitak polaznika je trošak u smislu vremena, znanja i novca (pitanje financijske održivosti MOOC-ova je zasebno pitanje koje neće biti razmatrano u radu). Kvaliteta programa se dijelom može odrediti računanjem postotka završavanja [11] i ona je značajno niža kod *online* kolegija. Prema tomu bi se moglo zaključiti da su *online* programi manje kvalitetni i popularni no treba ipak analizom niske stope prolaznosti uvidjeti je li zaista tako. Vjerojatno prvi razlog veće stope odustajanja u slučaju *online* kolegija koji se nameće jest što su oni besplatni, neobvezni i takvo odustajanje ne snosi nikakve posljedice, što nije slučaj u tradicionalnom obrazovanju. No to zasigurno nije jedini razlog i treba sagledati koja je struktura polaznika, koji su njihovi motivi i očekivanja, uslijed čega dolazi do nezadovoljstva da bi se dobio cjelovit pogled i mogla provesti detaljnija analiza i dobiti točniji uvid u nizak postotak prolaznosti.

Trenutno ne postoje službene statistike koje obuhvaćaju sve kolegije, odnosno informacije su uvelike nepotpune. Analiza istraživačice Katy Jordan [7] pokazuje kako je najveći broj upisanih polaznika zabilježen za pojedini MOOC 180000. Još uvijek malen broj kolegija prelazi 100000 upisanih polaznika, a najčešće se kreće između 20000 i 70000. Ukupan broj polaznika koji završavaju kolegij zasad doseže najviše 20 %, no to je rijetkost i većina kolegija ima stopu završavanja ispod 10 %. Prema [8] stope odustajanja polaznika MOOC-ova koje nudi Standford, MIT i UC Berkley su od 80 do 95 %.

Treba istaknuti da se MOOC-ovi razlikuju od tradicionalnih *online* načina davanja pristupa *online* sadržaju. Mnogi stručnjaci i istraživači koji se bave analizom ovog modela učenja su naglasili velike izazove koji predstoje MOOC-ovima koje moraju savladati kako bi postali konkurentni klasičnom modelu *online* obrazovanja [6].

Problem je u tomu što kad polaznici odustanu od *online* kolegija, svaka veza s njima je izgubljena i teško je dobiti bilo kakvu povratnu informaciju. Platforme koje pružaju MOOC-ove redovito daju polaznicima ankete koje prethode početku kolegija i ankete nakon završetka, no polaznici koji su odustali od programa najvjerojatnije

ne ispunjavaju te ankete i time je nemoguće dobiti direktan odgovor o razlogu odustajanja.

Ono što također još nije jasno jest mogu li MOOC-ovi utjecati na povećanje broja diplomiranih studenata, pošto su studentima ista predavanja koja su im obvezna u sklopu programa tradicionalnog obrazovanja dostupna i kao MOOC. Zabilježeni su slučajevi u kojima, nakon što profesori organiziraju MOOC iz kolegija kojeg predaju na sveučilištu, velik dio studenata prestane pohađati nastavu i upiše MOOC. Upravitelji akademskih ustanova su i dalje sumnjičavi predstavljaju li MOOC-ovi održivu metodu nuđenja *online* kolegija, ali vjeruju da pružaju značajne spoznaje o pedagogiji *online* učenja. Manjina (23 %) upravitelja akademskih ustanova smatra da su rezultati *online* učenja inferiorni u odnosu na klasično obrazovanje [1]. Značajno je da upravitelji s institucija koje i same nude MOOC-ove imaju bolje mišljenje o rezultatima *online* obrazovanja.

Prema izvještajima posljednjih nekoliko godina pada postotak godišnjeg porasta ukupnih upisa studenata u SAD-u (primjerice sa 6.9 % 2009. godine na -0.1 % 2011. godine), no udio *online* upisa u ukupnom broju upisa raste i to kontinuirano kroz sve godine (primjerice s 9,6 % 2002. godine na 32,0 % 2011. godine). Nedavni rezultati pokazuju da 44,6 % akademskog osoblja smatra da treba više vremena i vještina za organizaciju online kolegija nego tradicionalnog, dok se samo 9,7 % ne slaže s time [1].

Zanimljivo je da veći postotak smatra *online* kolegije većim izazovom u institucijama koje nude takvu vrstu obrazovanja. Mišljenje osoblja s institucija koje ne nude niti jednu vrstu takvog obrazovanja mogu se u nekoj mjeri smatrati nerealnom prosudbom koja nije temeljena na iskustvu. U statistikama je ponekad teško razlučiti stvarne pokazatelje jer one nisu dostupne zasebno za institucije koje nude MOOC-ove i one koje ih ne nude, a izgleda da to značajno određuje njihovo stajalište.

Ono oko čega se vode rasprave jest je li *online* obrazovanje prikladno za sve studente. Godine 2007. preko 80 % akademskog osoblja je izrazilo da „studenti trebaju imati više discipline kako bi bili uspješni u *online* kolegijima“ i disciplina se smatra jednom od većih prepreka za široku primjenu *online* obrazovanja. Iskustvo s *online* obrazovanjem je samo učvrstilo taj stav i 2012. godine se 88,8 % akademskog osoblja izjasnilo o potrebi veće discipline studenata za uspješnost u *online* kolegijima [1].

III. RASPRAVA

Prema nekim autorima [8] jednaki su razlozi odustajanja i u tradicionalnom obrazovanju i u *online* obrazovanju. Iako neki razlozi mogu biti identični, sigurno se fenomen odustajanja od *online* kolegija ne može u potpunosti poistovjetiti s razlozima odustajanja u klasičnom obrazovanju. Svakako je korisno sagledati poznate uzroke odustajanja u klasičnom obrazovanju i razmotriti koji od njih su valjani i za *online* obrazovanje.

Razlozi odustajanja u klasičnom obrazovanju se dijele na akademske, osobne i financijske [8]. S obzirom da su MOOC-ovi besplatni teško da financijski razlozi imaju znatniji utjecaj. Mogu biti razlog kod *online* obrazovanja koje se plaća i koje nude neke tvrtke.

Slično kao i u pohađanju klasičnih kolegija do odustajanja najviše dolazi tijekom prva dva tjedna. Neki od razloga odustajanja su primjerice nezadovoljstvo *online* okruženjem, razlike između profesionalnih i osobnih interesa, struktura tečaja, niska razina povjerenja u učenje na daljinu, dvojbe oko uspješne *online* komunikacije, nesposobnost efikasne uporabe softvera potrebnog za učenje na daljinu, nedovoljno predznanje i preopterećenje informacijama te konačno depresonalizirano okruženje [8]. Poglavito treba razmotriti manjak centralne uloge koju ima nastavnik u klasičnom obrazovanju i koje su posljedice izostanka njegove uloge.

Gotovo svaki instruktor učenja na daljinu kao i svaki student imaju različita objašnjenja zašto studenti odustaju od pohađanja kolegija. Ipak, sva se objašnjenja mogu svrstati u dvije kategorije [12]:

1. studenti odustaju od učenja na daljinu iz istih razloga kao i kod klasičnih kolegija
2. razlozi za odustajanje su povezani s fundamentalnim razlikama između dva modusa učenja

Razlozi zbog kojih polaznici upisuju *online* programe su uglavnom: fleksibilnost rasporeda (polaznik sam određuje vrijeme kad će ispunjavati obveze predviđene programom kolegija), udobnost i učinkovitost koje pruža rad od kuće ili s bilo kojeg mjesta (gdje postoji veza s Internetom i računalo), vjerovanje da će se program kolegija dobro uklopiti u njihove profesionalne ciljeve, profesionalno usavršavanje, postizanja višeg stupnja znanja iz pojedinog područja i povjerenje u uglavnom prestižna sveučilišta koja pružaju usluge masovnih otvorenih *online* kolegija.

Razlozi odustajanja mogu biti uvelike raznoliki. Nije zabilježen razlog koji bi se pokazao dominantnim. Razloge se može podijeliti u osobne, razloge povezane sa zaposlenjem ili razloge povezane sa samim programom i organizacijom kolegija [8]. Osobni razlozi mogu biti primjerice pomanjkanje vremena za završavanje zadataka (iako je za svaki MOOC navedeno prosječno i očekivano tjedno opterećenje u satima), teško usklađivanje s rasporedom kolegija, obiteljski problemi i drugo. S obzirom na visok postotak polaznika koji su zaposleni razlozi odustajanja mogu biti poslovne obveze koje se mijenjaju tijekom trajanja kolegija i nisu predvidljive pri samom upisu, manjak podrške od strane poslodavca, preveliko opterećenje kod punog radnog vremena i istovremenog pohađanja *online* kolegija itd. Kada su u pitanju razlozi vezani za sam program kolegija, oni mogu biti: preteško ili prelagano gradivo, zadaci, kvizovi; preveliko ili premalo predznanje (kod svakog MOOC-a je navedeno potrebno predznanje, no nekad polaznici možda ne procjenjuju realno svoje znanje); problem može nastati kod istorazinske prosudbe kojom polaznici mogu biti nezadovoljni (pogotovo kada se radi o humanističkim znanostima jezik može biti problem – s jedne strane manjak znanja jezika polaznika kojima engleski nije materinji otežava pisanje i istovremeno nezadovoljstvo polaznika engleskog materinjeg jezika koji dobivaju procjene svojih radova od polaznika s nedovoljnim znanjem jezika); manjak komunikacije jedan na jedan koja je svojstvena klasičnom obrazovanju bilo da

su konzultacije studenta i nastavnika ili studenata-kolega međusobno (postoje forumi, ali veći dio polaznika ne sudjeluje na njima, barem ne aktivno, unatoč popularnosti društvenih mreža i takve vrste komunikacije); manjak interesa za program kolegija i neispunjena očekivanja. Ponekad razlozi mogu biti i tehničke prirode, primjerice manjak podrške od strane instruktora, težak pristup Internetu u nekim zemljama, hotelima itd.

Treba li se zabrinuti zbog stope polaznika koji odustaju, ili ne, jest stalni predmet rasprava. To uvelike ovisi o pretpostavljenoj namjeni MOOC-ova. Ako je cilj dati priliku otvorenim i besplatnim visoko kvalitetnim kolegijima s elitnih sveučilišta tada nas visoka stopa odustajanja ne treba brinuti. Međutim, većina se slaže da bi bilo korisno povećati stopu prolaznosti i uvidjeti razloge zašto i u kojim fazama polaznici odustaju od pohađanja kolegija. Pitanje je žele li sveučilišta pridobiti najbolje studente ili doprinijeti društvenom dobru ili pojačati i povećati vlastitu važnost. Želimo li razviti dublje razumijevanje ljudskog kognitivnog rasta ili usavršiti metode podučavanja za specifičan sadržaj [13].

Proslavljeni fizičar, nobelovac, poznat po svojim predavanjima, Richard Feynman, u predgovoru svojoj knjizi *Six Easy Pieces* [14] napisao je da je dobro podučavanje moguće jedino ako postoji izravni individualni odnos između studenata i dobrog nastavnika – situacija u kojoj student raspravlja o idejama, misli o stvarima, govori o stvarima. Nemoguće je naučiti mnogo samo sjedeći na predavanjima, pa čak ni rješavanjem zadataka koji su dodijeljeni. Nažalost njegova vizija podučavanja često nije prisutna ni u tradicionalnoj nastavi. No kada profesor organizira kolegij u obliku MOOC-a, mora biti svjestan da ta vrsta osobne interakcije zasigurno nestaje. Kod MOOC-ova koje obilježava prvenstveno ono „M“, to jest masovnost mogućnost da se razgovara sa svakim pojedinim studentom nestaje, nestaje prave interakcije, tijek je asinkron i uglavnom u jednom smjeru – od profesora prema svim studentima odjednom. To znači da polaznik postaje potpuno odgovoran za svoje svladavanje gradiva, ne postoji jedan na jedan interakcija, no može biti student na student, organiziranim u male studijske grupe. Zadaća organizatora MOOC-a je omogućiti tu interakciju.

IV. ZAKLJUČAK

MOOC-ovi se uglavnom razlikuju od konvencionalnog *online* učenja na daljinu nedostatkom ili vrlo limitiranom akademskom podrškom.

Zaključno, istraživanja pokazuju da su razlozi za odustajanje kod MOOC-ova kompleksni, višestruki i međusobno povezani. Stjecanjem uvida u razloge odustajanja polaznika institucije koje pružaju takve programe mogu profitirati razvijanjem strategije za smanjivanjem odljeva polaznika i održavanja što više stope upisa u svojim programima. Na neke razloge se može utjecati, na neke ne jer su posljedica same prirode MOOC-ova.

Mnogo je različitih čimbenika koji mogu uzrokovati da polaznici odustanu od upisanih kolegija. Zasigurno je manjak osobne podrške nastavnika i način na koje MOOC-ovi daju povratne informacije jedan od važnijih razloga. Slijede loša organizacija kolegija, nedostatak vremena ili motivacije da se završi kolegij. Zasad ne postoji zabilježena korelacija između trajanja kolegija i stope završavanja kolegija. Jedan od uzroka su teškoće uslijed pohađanja kolegija na nematerinjem jeziku. Postoje neki dokazi da istorazinska prosudba može utjecati na veću stopu odustajanja, vjerojatno vezano uz višu razinu potrebnog angažiranja koje se traži od polaznika, kao i problemi koji nastaju uslijed nedovoljnog poznavanja jezika. Ostali faktori mogu uključivati razinu i kompleksnost gradiva koje se izlaže u kolegiju.

Neki organizatori MOOC-ova počinju istraživati nove načine pružanja više razine osobne podrške. No, pružanja osobne podrške kod tako velikog broja polaznika, u kolegijima čije je glavno obilježje masovnost, ostaje velik izazov. Organizatori kolegija i nastavnici zasad pružaju podršku u vidu foruma. Pružanje osobne podrške jedan na jedan, odnosno nastavnik-polaznik bi značajno povećalo troškove i oni bi rasli s brojem polaznika. Neki profesori pokušavaju prebroditi taj problem potičući studente koji su diplomirali ili završili kolegij da učestvuju u izvođenju MOOC-ova i pomognu u pružanju dodatne podrške i usmjeravanju polaznika.

INVITED PAPERS

Learning From Success Cases in Steel Industry Electrical and Automation Applications

Paolo Paganini
* A.I.S. – Automation Integrated Solutions S.p.A., Sovizzo (Vicenza), Italy
p.paganini@ais-automazione.it

Abstract - This paper presents an overview on the evolution of the application of electrical and automation technologies in the industrial processes, with more details in the hot rolling mills for metals.

Different aspects are taken into consideration, like electrical motors, power electronics, process control and information management.

Finally, a proposal of a target framework for the future possible applications matching the present needs of industries, like improvement of production procedures and energy saving.

Rather than going into deep details, the aim is to bring to the surface a certain amount of topics in order to support future actions requested by industries managers as well by electrical and automation companies.

I. INTRODUCTION

The overview begins with an analysis of the features of some typical industrial processes. Although the results can be applied to quite a wide range of industries, we focus on some specific applications, which can be considered as good example and, at the same time, are well present in the geographical area of South-Eastern Europe and Mediterran.

It is useful to first define the industrial processes considered in this paper in order to set the limits of this analysis.

The focus is on those processes where production is powered by medium to big electrical motors, each rated hundreds of kW, where production flow must be coordinated by a centralised control and where processes are repetitive.

According to this definition it comes that the the focus is mostly on metals production and processing, cement, material handling, oil & gas, mining.

It is worth to highlight that, even though with some difference among countries, all these kinds of processes are well established in Europe.

However, most of those industries are now facing well known problems of energy tariffs and availability, environmental issues and, last but not least, cost and quality of finished products.

All such matters must necessarily play a major role in the design of modern applications.

II. THE TECHNOLOGY BEHIND THE PROCESSES

Fig.1: Old Style “Cross Country” rolling mill

When considering the “heavy”industrial processes, it comes logical to consider only the evolution of the process design and layout. In other words, the focus is on the process technology itself, a glimpse of whose is easily achievable when viewing the process.

Just as an example, if we consider old style hot rolling mills we would come across the so called “cross country” design like the one shown in Fig.1:

Here only one electrical motor, usually operating at fixed speed, was powering several machines (stands). In most cases, such motors was a slip ring motor (or wounded rotor type), whose power and speed and consequently torque could not be controlled. (Fig.2)

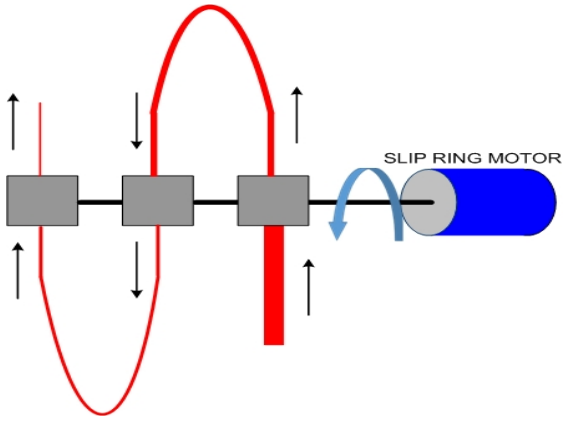

Fig.2: Schematic of “Cross Country” layout

Fig.3: Modern “In Line” rolling mill

The major step forward in this process evolution was the upgrading to continuous in line rolling mills, like in the next picture, where each machine (stand) is powered by an independent electrical motor. (Fig.3)

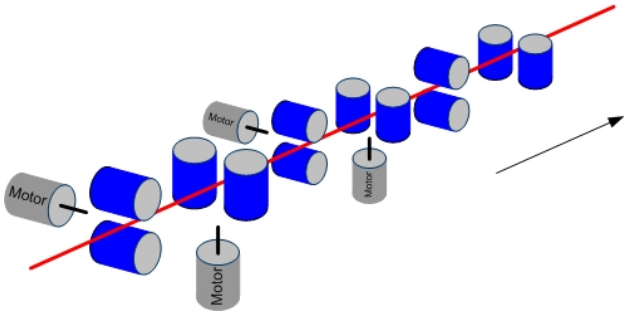

Fig.4: Schematic of “In Line” rolling mill

This layout was an outstanding breakthrough in the rolling mills technology, thanks to innovative and future oriented approach of many companies and workshops supplying mechanical equipment for rolling mills, several of those were located in Italy.

III. The Role of Electricals and Automation

The previous examples is interesting because its shows a well known technology, but what it has been the role of electrical equipment and automation?

It may not be immediately noticed that the evolution of rolling mill design has been possible because there was the availability of electrical motors, whose power, speed and torque could be controlled with accuracy.

The slip ring motors of obsolete “cross country” mills were replaced by DC (direct current) motor; the control of the voltage and current of a DC motor allows the regulation of the delivered speed and power by means of DC power converters.

DC motors have been on the market since almost 150 years but only after semiconductors technology has been broadly available, it has been possible to have accurate and not expensive DC power converters built with semiconductor thyristors.

IV. Unexpensive High Technology

This is an intersting pattern: we have old and well established technology (rolling of steel bars), we have DC motors (150 years old technology) and both of them have been brought to a new life by an innovative and unexpensive technology.

The semiconductor technology was developed by engineers and researchers in the Universities in cooperation with big Companies, but after only a few years the application market was almost completely ruled by small and medium companies.

In Italy, the country I know better, between late ’60 and ’90 there has been a period were a significative portion of the production of the DC power converters, one of the pillar of the modern industrial processes, was located in only one industrial district around the city of Vicenza, that someone called the “Italian Silicon Valley” (by the way, it is not by chance that Mr.Federico Faggin [1], one of the inventors of the one of the very first industrial microprocessor in California (the Zilog Z80) was born and received first years of education in Vicenza)

Only a few years before the availability of semiconductors, none of these small and medium companies could have had access to the supply of electricals and automation for the steel plants.

The new technology and an excellent background of education provided by technical high schools and nearby Universities boosted an economical “miracle”, whose effects are still there today, even though the peak period has been reached 15 years ago.[2], [3]

The example of rolling mill is interesting not only for the intrinsic technological properties but also because it helps to highlight a common condition that should never be neglected: the electrical and automation suppliers are not generally the owners of the process technology, which is in the hands of the process and mechanical suppliers. It means that the success of a new electrical and automation technology is based either on the cooperation with a design supplier or, on the opposite, on a solution that is not relying on the process.

It is a matter of fact that several big design companies have acquired in house capacity in electricals and automation or some big electrical decided to move toward the process design.

V. Looking at the Future

So the question today is: how can we adopt the same “DC motors and DC converters approach” approach using state of art technology and apply it to industrial processes, without being a big Corporation?

To get a good answer it is first necessary, however, to finish this quick survey of the effects of electrical and electronic equipment on the industrial processes.

(By the way, just as a mention, today DC motors technology is being replaced by AC motors with inverters, allowing higher efficiency and accuracy)

A. *The Control Systems*

The next step upwards is toward the control systems: the availability of big electrical motors controlled by semiconductor power electronics was not fully effective without an automatic control system, delivering set points and operating control loops. The computer technology was requested and MIPRO audience is the most appropriate to appreciate this technology.

B. *The Returning Pattern*

The technical evolution of power electronics and industrial control systems has been quite similar and moving along parallel paths: after a first research and development stage, a period has followed where many companies proposed their own products with proprietary technology. They have been quite successful because they fulfilled the industrial companies demand, no matter how they were designing their products.

C. *The lesson to be learned*

Of course, there were (and there are) also some dangerous situations to be avoided in order to keep a company safe.

The model of the successful small/medium company, selling its high tech and unexpensive products all over the world collapsed when the products became naturally aged after some years of operation, but the original supplier was not existing anymore or located too far away from the plant or the documentation lost.

So only those companies featuring good products, a solid structure, a distributed geographical presence and compliance with standards have been able to survive.

In addition to this, the market is now dominated by electrical and automation products manufactured with excellent quality and low prices by companies much bigger than the average european typical size.

So now it is not requested to know how to manufacture most of the electrical and automation equipment, but rather how to use it at best and the lowest cost.

VI. THE CONCLUSIONS

Going back to the previous question, where do we have to look for interesting opportunities in the application electrical and automation technology in the heavy industry processes, without being a big Corporation and without being a process design company?

If we look at the conditions fostering the success of the electrical suppliers back in the age of “DC motors and first computers”, we can see which were the common grounds:

- there was availability of a basic technology
- the technology was well tested
- the technology was not expensive
- there were the request of the heavy industry to improve production.

So, today, which electrical and automation technology is well tested, technologically stable, not expensive and easily available?

Here we propose an answer: information management and processing has never been so powerful as today, thanks to the merging of low cost and really portable devices with distributed data transmission and processing.

Moreover, data processing capacity can be installed anywhere, not only in the “traditional” computers. It means that we can have huge processing power also inside a power converter controlling a motor but also thousands kilometers far away from the industrial process.

Moreover, which are the needs of the industry today, with emphasis on Europe? Some are here proposed:

- Energy savings
- Structured maintenance scheduling
- Detailed collection of data on production
- Improve production procedures: merging the analysis of process parameters with production data can improve the fine tuning of production procedure, resulting in cost reduction.
- Support to technical staff: easier training, troubleshooting and access to documentation

These technologies can be developed also by small/medium sized companies, this is the good new.

Anyway, the good old workhorse of the heavy industries, the DC motor, will not disappear. The upgrading of power converters towards full integration with distributed data processing is still at the first step.

Abstract - Rapid development of new technologies adds to an architectural complexity of multimedia devices. The last generations of multimedia devices combine features of multiple devices into a single device. Complex devices require more testing and verification methods, and more time to find a fault. Very often inoperative device has to be transported to operator's facilities for complete diagnostics. Transportation of inoperative devices to repair/service centers prolongs time from a problem reporting to problem correction, increases costs, and adds to the customer's discontent. Field test system comprises various input interfaces which cover multimedia device's audio/video output, and allows functional verification, wide A/V analysis and picture quality measurement. Field test system is ideal for verification of STB/DVD/Blu-ray player's devices at customer's homes or retailers offices and also for monitoring of head-end signal quality in broadcast systems.

I. INTRODUCTION

Rapid development of new technologies combined with higher demands for user interaction contributes to architectural complexities of multimedia devices. Latest developmental trends merge features of different devices into a single multipurpose multimedia device. The integrated device requires additional tests and verification methods, which increases time needed to find a fault. Often an inoperative device is transported to operator's facilities for comprehensive diagnostic. Transportation of inoperative devices to either repair or service centers prolongs time from a problem reporting to the problem correction, and thus increases repair costs and user's discontent.

It does not surprise that a prompt problem solution is highly evaluated in customers' satisfaction surveys [1]. A need exists to relocate the device comprehensive health diagnostics to customers' homes. In many cases, a device that the customer reports as inoperative is fully functional and the 'fault' is incorrect use of the device. Such cases can be easily eliminated and solved with troubleshooting steps that can be navigated with the help of remote customer support. However, if the device is inoperative, many faults can be easily solved at the customer's home with a portable test system that can detect nature of the fault at the location. Some benefits of such diagnostic system are: fast and reliable device health diagnostics, no transportation, supplement unit rental or storage costs, saved personal data, and increased user's satisfaction. Although the system would decrease service costs significantly – the estimated annual saving is over $35,000 [2], envisioned system is not commercially available. Current state-of the-art is in the phase of research and prototypes, reported by S3Group [3] and Regenersis [4] who are still facing problems with power and connector blocks. In this paper we describe successfully deployed field test system prototype, which has powerful features and compact size.

II. THE FIELD TEST SYSTEM

Field Test system (Fig. 1) is a portable, stand alone, automated multimedia device test system intended to be used in customers' homes for verification of unit's functionality. Typical deployments are in a field service vehicle. The system equips field technicians with a powerful tool which performs fundamental functional tests in order to diagnose possible malfunctions of customer's device. The system enables greater flexibility of test environment, wide range of tested devices, rapid adaption and easier applicability to new device releases. Carefully designed with optimized parts guarantees good overall retail system cost. The system adds to greater reliability of testing during the test and verification process, and facilitates and speeds up the field work of a technician.

Figure 1. Prototype of the Field Test System

This work was partially supported by Ministry of Education, Science and Technological Development of the Republic of Serbia, under grant No. TR32034, year 2011-2015.

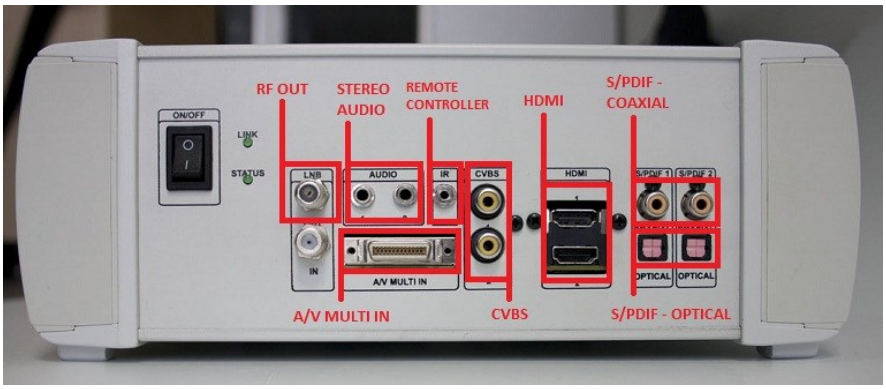

Figure 2. Front-view of the Field Test System prototype

Integrated software modules enable testing of devices that allows black box testing approach. The black box testing approach [5]-[6] is a testing in which system can influence only input and output signals of a device under test (DUT), while internal structure of the DUT remains hidden and unknown to the testing system.

The system prototype comprises various input interfaces which cover any DUT's audio/video output and enables wide audio-video analysis and picture quality measurement. The prototype is particularly good for verification of set top boxes (STB), DVD and Blu-ray players. Complete infrastructure for field diagnostics allows technician to reliably decide whether to replace inoperative device or to correct minor defect. Field test system includes protocols for transfer of collected test execution information to central service center database and generates reports necessary for repair process.

Field test system device supports real time capture and streaming of SD, ED and HD video content up to 1080i60 from wide variety of digital or analog A/V sources, captures digital or analog audio up to 192 kHz with 24-bit resolution. The prototype has built-in VHF/UHF Modulator, grabber device, internal power supply, and control unit. It has a 10-inch touch screen display and Windows 8 Pro Operating System, and can be used with specially developed Executor Home Screen application.

Available connectors for the prototype are shown on Fig. 2 and summarized in Table 1.

TABLE I. FIELD TEST SYSTEM CONNECTORS

Connectors	
2x Analog audio input	Stereo audio on 3.5 mm TRS jack connector
2x HDMI	Type A receptacle HDMI
1x Multi A/V input	26 pin Mini Delta Ribbon (MDR) connector - Component, S-Video, SCART
2x Composite NTSC/PAL input	RCA connector
2x LNB in/out	F type connector
2x S/PDIF coaxial	Coaxial RCA connector
2x S/PDIF optical	TOSLINK
Power supply	Integrated in platform cover with passive cooling, 20-240V 10W
IR	Remote control emulator output

Interface specification for the Field Test System prototype is listed in Table 2.

TABLE II. FIELD TEST SYSTEM INTERFACES

Interfaces	
VHF/UHF Modulator output	RF, support for most QAM-, OFDM- and VSB-based modulation standard
Supported Modulator Output	Support for most QAM-, OFDM- and VSB-based modulation standard Direct digital conversion to 47..1000MHz Play out of I/Q sample files up to 9.14Msamp/s Programmable attenuator
Digital Video Input	HDMI, SDI
Analog Video Input	Composite, Component, S-Video, SCART
Supported HD Format	720p50, 720p59.94, 720p60, 1080PsF23.98, 1080p23.98, 1080PsF24, 1080p24, 1080PsF25, 1080p25, 1080PsF29.97, 1080p29.97, 1080PsF30, 1080p30, 1080i50, 1080i59.94 and 1080i60
Supported SDI formats	HD and SD SDI Receiver, with complete SMPTE Video and Audio Processing, as per SMPTE 425M, 292M and SMPTE 259M-C
Supported SD formats	625/25 PAL, 525/29.97 NTSC and 525/23.98 NTSC
HDMI Compliance	HDMI 1.3
Multiple Rate Support	SDI, HDMI and component analog video connections are switchable between SD and HD. SDI switches between 270 Mb/s standard definition SDI and 1.5 Gb/s HD-SDI

Rear view of the prototype is shown on Fig. 3, on the next page. Rear interfaces include:

- USB – connector used for barcode scanner,
- Serial port – used for barcode printer,
- Power supply – for the device.

Field test system has live preview through LAN interface. This feature enables extra help from external source center, such as remote service operator. Field test system has included automatic video signal and standard detection.

Figure 3. Rear-view of the Field Test System prototype

The prototype system captures and stores images or video sequences to internal memory for on device image processing, transfers grabbed images/video to host device (Tablet) for future analyzes, allows easy image capture or video streaming of multiple A/V signals into single computing server which can be spatially dislocated from video source, sampling of analog video, audio and control signals up to 32MBPS for measurement of amplitude and temporal characteristics of the signals, DSP based platform which is capable to execute desired processing or analysis algorithm on captured audio and video content, voltage and frequency measurement on A/V inputs (CVBS, RGB, Line In, LNB etc.), embedded remote control emulator, support and compliance with consumer and professional A/V standards.

Test environment has to be configured before the Executor Home Screen application first run. The list of configuration files which need to be set is shown on Fig. 4, on the next page.

TestEnvironmentConfiguration.ini file saves a list of all devices used in testing process and files with macros related to specific devices.

TestDeviceConfiguration.ini saves relations between DUT and created test plans. These relations are based on barcodes of DUTs and IDs of the test plans.

During initialization the user chooses server and database to connect. This will be saved for next log in (Fig. 5).

The cursor of the application's main page is positioned on the Barcode field, as shown on Fig. 6.

The barcode can be scanned or entered manually. Next, the test plan is selected and during execution the test cases are displayed with test case results (fail/pass), as shown on Fig. 7.

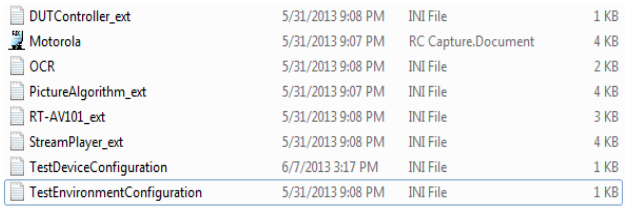

Figure 4. Configuration files for Executor Home Screen application

Single test steps can be checked during the execution at the bottom of the page. System Check displays the list of devices used for testing.

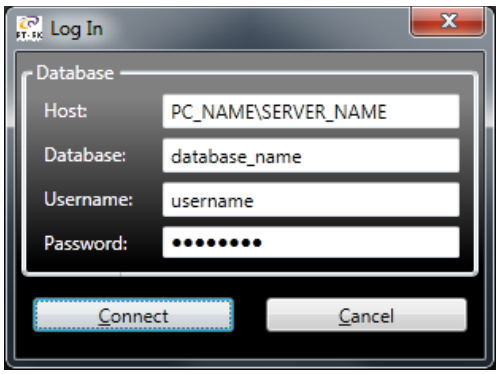

Figure 5. Login screen for Executor Home Screen application

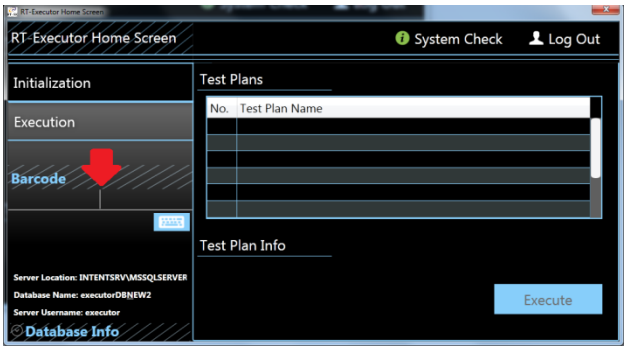

Figure 6. Main page of the Executor Home Screen application

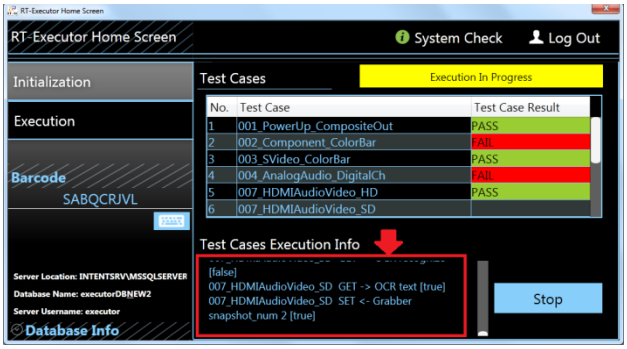

Figure 7. Test execution

III. CONCLUSION

Technology development has changed roles of multimedia devices from relatively simple tasks and limited interactions with users to multifunctional devices that cut across various dimensions. The role changes have brought different user habits and added to complexity of devices. Customers demand high quality of service and rapid problem solving response time. This leads to demands to automate the test process to cut the test time and to reduce costs. The core issue is to develop reliable tests and test hardware. Mobility of such test stations is an issue due to device's size and robustness. Current trend is to take reported device to the service facility. This adds additional costs and does not address "no fault found" issue. However, what has been missing is a powerful portable tool that would enable to move the test from repair facilities to home. We described a test field system, compact in size, loaded with testing features that will enable field technician to conduct tests previously reserved for testing locations, at user's home. Although the system is intended for use at customer's home, it can be deployed at retailers' offices or used by service providers to monitor head-end signal quality in broadcast systems.

PAPERS

Static characteristic and describing function of polynomial compensated nonlinearities

O. Kuljača, K. Horvat and Z. Eškinja
Brodarski Institute, Zagreb, Croatia
ognjen.kuljaca@hrbi.hr, krunoslav.horvat@hrbi.hr, zdravko.eskinja@hrbi.hr

Abstract - Paper deals with polynomial compensation nonlinearities. Most actuators are nonlinear sporting nonlinearities such as deadzone, saturation and others. One way of dealing with such actuators is to try to compensate nonlinearities by polynomial representation of inverse nonlinearity. Compensated actuators can improve behavior of the system, but then we have a new nonlinearity in the system, polynomial compensated nonlinearity. Paper will show how to obtain static characteristic and describing function of such nonlinearities.

I. INTRODUCTION

Every control system contains at least one actuator. Virtually all actuators have nonlinearities. Depending on the control system these nonlinearities can be neglected or one has to deal with them in some way. Nonlinear control theory is rich with different methods of compensation or stability analysis of systems with nonlinear actuators ([9],[11],[12],[13],[14]).

Many actuators have odd nonlinearity followed by linear filter type element. Examples are some electrical motors, hydraulic cylinders and solenoid actuators. There are different methods for dealing with such systems (introduction of ditter signal, different anti wind-up schemes etc,). This paper deals with static characteristic and describing function of such nonlinearities compensated by polynomial representation of inverse actuator nonlinearity. Examples are given for compensated nonlinearities of type dead zone, saturation, deadzone with saturation and friction.

II. DESCRIBING FUNCTION

Many actuators with odd nonlinearity can be represented by structure shown in Figure 1.

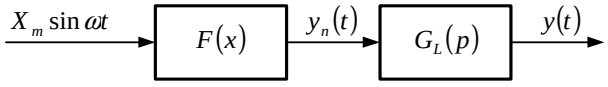

Figure 1. Actuator represented with decoupled nonlinear F(x) and linear parts $G_L(p)$, p=d/dt

Describing function is an equivalent gain of nonlinear element, defined by the harmonic linearization method of nonlinear static characteristic ([2], [9], [10], [11], [12] and many others). It is a known method of analysis and synthesis when nonlinear system can be decoupled into linear and nonlinear parts. If the linear part of the system has the characteristics of low-pass filter and if we apply periodical signal to the system, output signal will have the same base frequency as input signal with damped higher frequencies.

If the amplitudes of higher harmonics are relatively small when compared to the amplitude of the first harmonic, i.e. if filter hypothesis holds, output signal can be approximated by it's first harmonic. Mathematically, first harmonic of the output signal, for the sinusoidal input signal $X_m \sin \omega t$, can be expressed by Fourier expressions:

$$y_N(t) \approx Y_{P1} \sin \omega t + Y_{Q1} \cos \omega t \tag{1}$$

$$Y_{P1} = \frac{1}{\pi} \int_0^{2\pi} F(X_m \sin \omega t) \sin \omega t \, d(\omega t) \tag{2}$$

$$Y_{Q1} = \frac{1}{\pi} \int_0^{2\pi} F(X_m \sin \omega t) \cos \omega t \, d(\omega t) \tag{3}$$

where Y_{P1} and Y_{Q1} are first Fourier coefficients. Describing function is the ratio between first harmonic of the output signal and input signal in complex form:

$$G_N(X_m) = P(X_m) + jQ(X_m) = \frac{Y_{P1}}{X_m} + j\frac{Y_{Q1}}{X_m} \tag{4}$$

where $P(X_m)$ and $Q(X_m)$ are coefficients of the harmonic linearization ([2], [9], [10], [11], [12] and many others).

Determination of describing function boils down to the determination of integral expressions for the known static characteristic of the nonlinear part of the system.

There are many conventional nonlinearities for which static characteristics and describing functions are theoretically derived and given in analytical form.

The problem arises when the static characteristic of nonlinear system cannot be analytically expressed or integral expressions cannot be solved. In that case describing function can be determined by experiment or simulation ([3], [4], [5], [6], [7], [8]) or some method of numerical integration [10].

In this work we will use numerical integration in Simulink as given in [10]. The approach is very simple, yet effective. In essence, equations (2) and (3) are directly

Research was partially supported by HZZZ grant 09/193 Fuzzy Logic Adaptive Elastic Controller.

applied in Simulink on nonlinear element outputs. More details on this approach to obtaining describing function are also given in [13] and [14].

III. Polynomial Compensation of Odd Symmetric Nonlinearity

Ideally, if one could completely compensate a nonlinearity, a compensated nonlinearity would become a linear gain. This, in general, is not possible for many reasons. However, some level of compensation could be achieved. In this paper we deal with polynomial compensation of odd symmetric nonlinearities. Two main characteristics of such nonlinearities is that they are odd symmetric and time invariant.

A static neural network compensation scheme that yields polynomial compensation is described in more details in [13] and [14].

We deal with actuator with architecture shown in Figure 1. It is important that in practice $y_n(t)$ is measurable. This is often the case because many motor drives and hydraulic drives have nonlinearity in part of their electronic driver and this value can be measured. We then connect an input with changeable amplitude and measure and save inputs and outputs. Once this is done we will use recorded data to train simple neural network in such way that we try to achieve neural network that will have opposite, i.e. inverse action to nonlinearity. Of course, it is impossible to achieve exact opposite action, but in many cases it is possible to achieve good enough representation to improve nonlinear characteristic. Schematic of data generation and recording is shown in Figure 2.

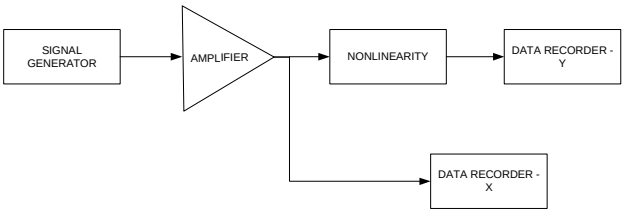

Figure 2. Data generation and recording

Then, we can use neural network to compensate for nonlinearity as shown in Figure 3 ([13], [14]).

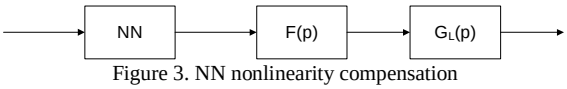

Figure 3. NN nonlinearity compensation

where NN stands for neural network, F(p) is nonlinearity and $G_L(p)$ is linear part of the system.

The idea is that neural network compensates for some effects of nonlinearity since neural network is trained to act as inversion of nonlinear function.

However, realizing neural network sometimes can be complicated. One possibility is to replace the neural network with its describing function. Describing function can be graphically obtained by using procedure given in [10] and described in more details in [13] and [14].

Realization of neural network or graphical representation of describing function can be complicated, with number of calculations included in the process or with need to realize detailed look-up tables for describing function. So, the next step is to obtain polynomial form describing function that could be used in final compensation of given nonlinearity.

So, we represent graphic describing function of compensating neural network by polynomial $G_{NN}(x)$:

$$G_{NN}(x) = a_n x^n + a_{n-1} x^{n-1} + \ldots + a_1 x + a_0 \qquad (5)$$

Polynomial approximation is easier to realize than neural network, i.e. we can use simpler hardware to do so.

The procedure is experimental and it works as follows. First, we decide on domain of input signal (X, Figure 2). Then, we generate and record the signal to use in training neural network.

In our case datasets X and Y were generated using chirp signal generator with starting frequency 0.1 Hz, final frequency 20 Hz and simulation end time 1000s with fixed step size 0.001. Odd symmetric nonlinearities are static nonlinearities so frequency really does not have an effect on them but we used chirp signal in order to generate a number of different data points.

After data was recorded, one can use dataset Y as network input and dataset X as network output for training. There are many tools available for neural network training. Here, Matlab neural networks toolbox was used. Feed forward network had two layers, first layer with seven nodes and sigmoid tangent activation function and one node in output layer with linear gain activation. Network was trained for seven hundred epochs with gradient descent with adaptive learning rule backpropagation. The same network architecture was used for all nonlinearities described in this paper. Choice of number of nodes and activation functions is heuristic and depends on required precision.

IV. Static Characteristic And Describing Function Of Polynomial Compensated Nonlinearities

As explained before, polynomial is obtained from describing function of obtained neural network. The degree of polynomial is determined heuristically. Then, one should inspect static characteristic of compensated nonlinearity to obtain the picture of behavior of polynomial compensated nonlinearity. In this Section we will deal with examples for deadzone, saturation, deadzone with saturation and friction.

Compensation with polynomial is shown in Figure 4.

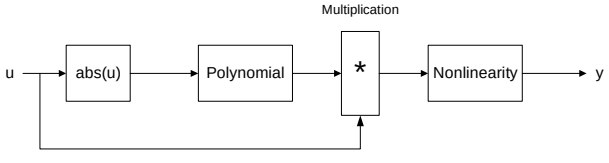

Figure 4. Compensation with polynomial

NN training data for deadzone with upper and lower limits equal to 1 was obtained using scheme from Figure 2 with amplification of 5. For describing function we used amplitudes from 0 to 3.53. Frequency is of no importance since we deal odd symmetrical nonlinearity so imaginary part odd describing function is 0.

Static characteristic of deadzone with upper and lower limits equal to 1 is shown in Figure 5.

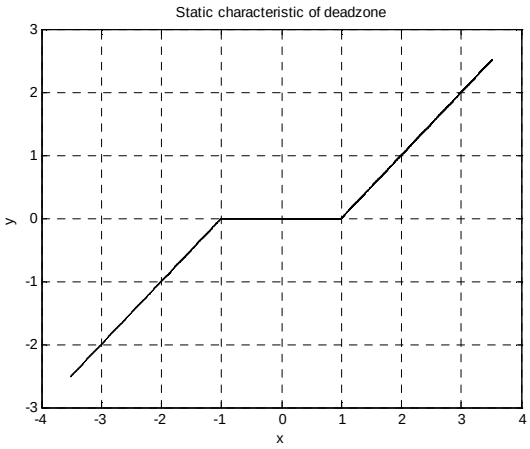

Figure 5. Static characteristic of deadzone with upper and lower limits equal to 1

With given data and described procedure deadzone shown in Figure 5 was compensated with third order polynomial function:

$y=-0.3024x^3+2.2337x^2-5.4734x+5.9814$

Static characteristic of compensated deadzone is shown in Figure 6.

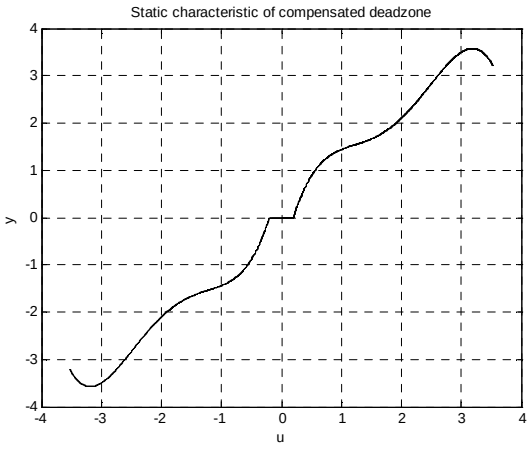

Figure 6. Static characteristic of compensated deadzone

NN training data for saturation with upper and lower limits equal to 0.5 was obtained using scheme from Figure 2 with amplification of 3.53. For describing function we used amplitudes from 0 to 3.53. Frequency is of no importance since we deal odd symmetrical nonlinearity so imaginary part odd describing function is 0.

Static characteristic of saturation with upper and lower limits equal to 0.5 is shown in Figure 7.

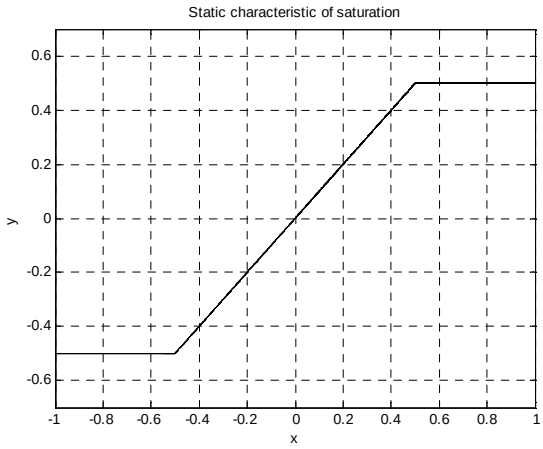

Figure 7. Static characteristic of saturation with upper and lower limits equal to 0.5

With given data and described procedure saturation shown in Figure 7 was compensated with third order polynomial function:

$Y=0.1929\ \ x^3-1.0843x^2+1.2508\ x+1.4042$

Static characteristic of compensated saturation is shown in Figure 8.

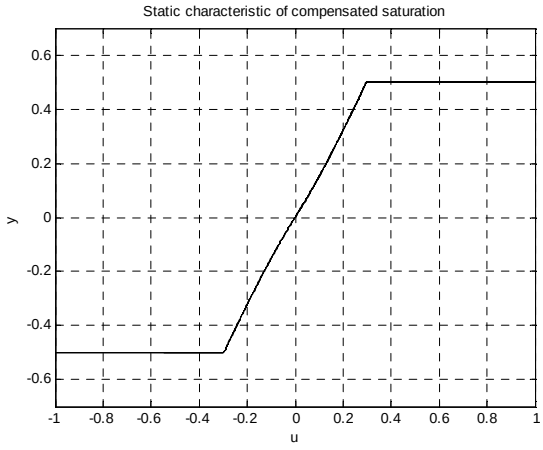

Figure 8. Static characteristic of compensated saturation

Static characteristic of dead zone with saturation with upper and lower limit equal 1 with start and end of dead zone equal to 0.3 is shown in Figure 9.

NN training data for saturation with upper and lower limits equal to 0.5 was obtained using scheme from Figure 2 with amplification of 1.5. For describing function we used amplitudes from 0 to 1.5. Frequency is of no importance since we deal odd symmetrical nonlinearity so imaginary part odd describing function is 0.

With given data and described procedure deadzone with saturation shown in Figure 9 was compensated with fifth order polynomial function:

$y=-4.4035x^5+20.8821x^4-39.8614x^3+38.8677x^2-19.7612x+5.7324$

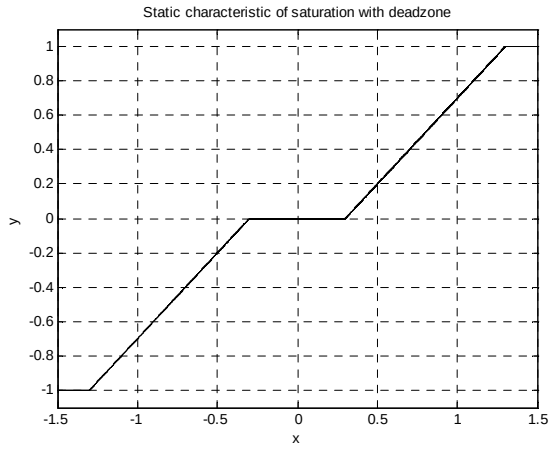

Figure 9. Static characteristic dead zone with saturation with upper and lower limit equal 1 with start and end of dead zone equal to 0.3

Static characteristic of compensated dead zone with saturation is shown in Figure 10.

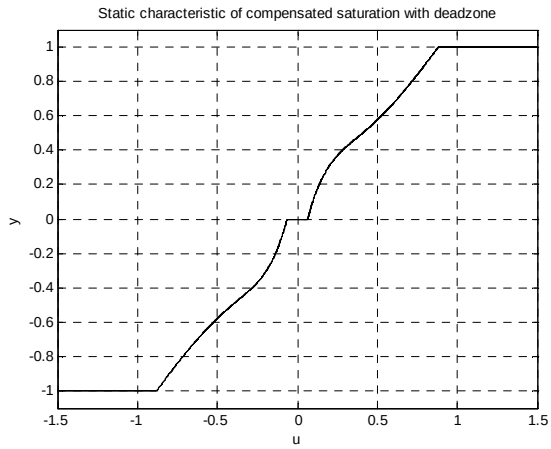

Figure 10. Static characteristic of compensated dead zone with saturation

Static characteristic of friction function y=sign(x)[abs(x)+0.5] is shown in Figure 11.

With given data and described procedure friction shown in Figure 11 was compensated with fourth order polynomial function:

$y= 0.0461x^4-0.3810x^3+1.0264x^2-0.8100x+0.5233$

Static characteristic of compensated friction is shown in Figure 12.

It can be seen that for case of friction, as with the case of saturation effects of compensation are not so clearly seen. This is due to hard limits nonlienarities which are very hard to approximate in general. Thus, it is hard to compensate them as well.

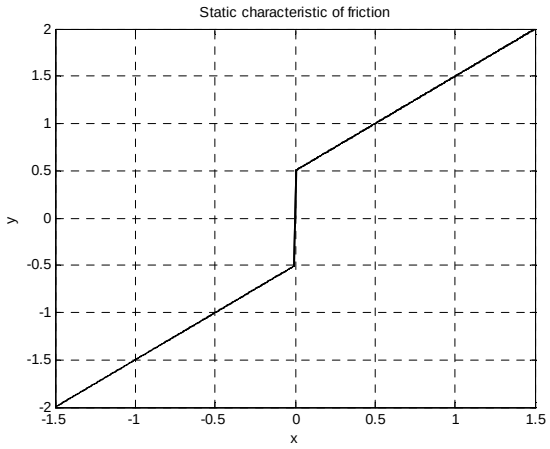

Figure 11. Static characteristic of friction

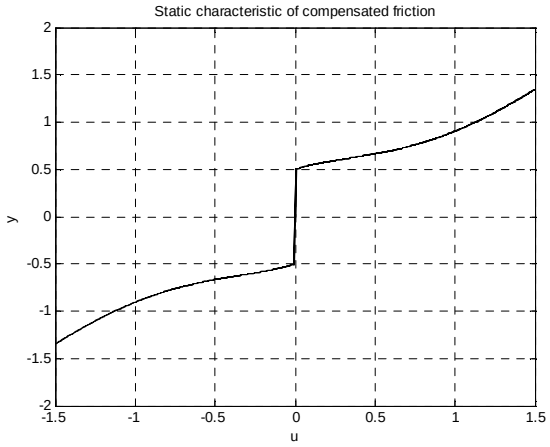

Figure 12. Static characteristic of compensated friction

The case involving the deadzone show much better compensation results. This is due to fact that deadzone can be actually inverted.

Since neural networks are universal approximators with respect to smooth functions it is expected that in case of smooth functions compensation would show better results than for hard limit nonlinearities. This is the goal of future research.

It can be seen that all static characteristics of compensated nonlinearities are still odd symmetric. Thus, their describing function will depend only on gain. Describing functions of polynomial compensated nonlinearities are obtained using method described in [10], [13] and [14] are shown in Figure 13-Figure 16.

All describing functions are, as expected, positive and not dependent on frequency. Thus, a stability analysis of a system with compensated nonlinearity can be performed using linear stability analysis methods ([9], [12]).

V. CONLUSION

The paper dealt with static characteristics and describing functions of polynomial compensated odd symmetric nonlinearities. It was shown that polynomial compensated nonlinearity will be odd symmetric if the original nonlinearity is odd symmetric. That fact results in positive frequency invariant describing functions of compensated nonlinearities that allow for use of linear stability analysis methods.

Abstract – A solution to the steel slab design problem provides huge savings in the steel industry. Generally, this is a combinatorial optimization problem and it is NP-complete. In this paper a dynamic programming model is presented in order to provide an elegant optimal solution for one variation of the problem. The heuristic used in the model is presented as well. The computational results obtained on real-life instances of the problem are reported and compared with the results obtained on the same instances with the legacy optimization model, and they show a considerable improvement.

I. INTRODUCTION

There are many types of metal products produced in the steel industry. One of the produced types is rectangular steel plates. The process of production planning usually begins with the Book of Orders, i.e. list of orders that need to be met with the appropriate priority. The orders specify the dimensions and desired steel (quality) grade of the steel plates. On the other side, objects with cuboid shape and different dimensions called slabs are used as raw material in the process of production. The slabs are obtained by casting the molten steel and have their own chemical and mechanical structure. The slabs are processed further and subsequently rolled into large steel plates (mother-plates) with the same volume and steel grade as the slabs. Mother-plates are finally cut across their length into plates with dimensions and steel grade as required in the corresponding orders.

A major problem in the steel industry is combining of ordered steel pieces for maximum utilization of the material from the mother-plate, and maximum utilization of required resources. Resolving this issue is important because minimal improvements in the manufacturing process can result in huge savings. The combination of the assortment problem and the trim loss problem is known as the cutting stock problem (CSP).

The general problems associated with the standard one-dimensional cutting are known as NP-complete problems. In many cases this kind of problems can be modeled using mathematical programming and solution can be found using approximate methods or some heuristics. The goal is to design a plan for one-dimensional cutting of necessary pieces of material into many pieces of ordered products in such manner that the overall loss will be minimized while various requirements that may occur in practice will be satisfied.

There are several known attempts to resolve the problem of cutting pattern generation in the literature. The beginnings and the first definitions are set by Kantorovich since 1960. Scientific research has led to several formulations and solutions. The most famous formulation has been composed by Dyckhoff [4] in 1990. According to his theory, the problem can be classified based on four characteristics: size, type of task, the semi-product assortment (raw material) and product range. There is a strong connection between the cutting and packaging, so the same classification scheme applies to both categories of problems.

Many of the models and solution techniques for CSP have been used as useful starting points for this research. This paper continues with a literature study covering few different formulations and solution methods of the CSP in the steel industries, in section II and III. In section IV we present a formulation for the specific CSP and the legacy implemented solution of the problem in Section V. Section VI presents the new implemented algorithm for the problem. In section VII, the performances of the proposed algorithm are compared to the performances of the initially implemented one by analyzing the results obtained on real-life instances of a local large scale steel production company. Finally, the conclusions are presented in section VIII.

II. BASIC CONCEPTS OF CSP

The CSP is a type of matching problem on a sparse graph, allocating set of materials to a given set of orders. Each order contains information on the required quality,

the dimensions of the plates and the required number of pieces (these are the most important parameters for simpler modeling of our problem). Through the quality and some of its other attributes, each order limits its conceivable material i.e. slabs. Several orders can be produced from the same slab and there are no limitations on the number of slabs that can be requested. There are many other constraints that make the problem hard to solve, and the solution to such a problem depends on the size and diversity of the products and the technology applied in the production process.

The optimal grouping of orders as well as defining the optimal production should give answers to the following questions:

1. Which orders will be produced?
2. Which slabs should be rolled into necessary mother-plates to be further cut into ordered plates?

It is necessary to meet all the production constraints to answer the above questions and to address the following issues:

1. reducing the waste material i.e. achieving a minimal rest;
2. reducing the number of created "free" slabs (slabs that have no defined order);
3. increasing the capacity utilization (slabs strive to be as many as possible within the limits);
4. producing all the ordered products as scheduled;
5. increasing the number of emergency orders produced.

III. REVIEW OF THE RELATED WORK

Basically, three different classes of solution methods for solving CSP exist. Algorithmic methods guarantee to find the optimal solution for the problem. The drawback of the algorithmic methods is the computational complexity which often results into high running times, especially on larger instances. For this reason, purely algorithmic approaches for solving CSP have been rare until the past few years. On the other hand, heuristic methods hardly ever find the optimal solution, but usually generate an acceptable solution faster. A heuristic is considered acceptable if the found solutions are close enough to the known or believed optimal solution. Heuristic methods are also highly domain-dependent, in sense that they use information about the particular problems for which they are developed. Therefore, these methods usually cannot be used in solving even similar problems. Meta-heuristic methods are solution methods that orchestrate an interaction between local improvement procedures and higher level strategies to create a process capable of escaping from local optima and performing a robust search through the solution space (Hiller, 2010). These methods include procedures that employ strategies for overcoming the trap of local optimality in complex solution space and efficiently explore the search space to find optimal solution.

A. Linear programming

A solution of the problem can be obtained by use of Linear Programming (LP), and there are several such methods for finding solutions of CSP already. For example, Gilmore and Gomory [2] have suggested a "column generation" method which shows excellent results over a small number of subjects. However, since the problem relies on combinatorics, this method cannot be effectively applied to the steel plate production process where there exist wide range of products and many limiting factors. This model has to generate all possible solutions to ultimately choose the best solution, but it prolongs execution time significantly. Heinz et al. [5] have introduced an integer program solver to solve the problem by removing the naturally arising symmetries. Further, Gargani and Refalo [3] have stated that the models used for constraint programming approaches to this problem are basically linear models over binary variables and these models are not well suited to a constraint programming approach because of the limited domain reduction they produce. Integer programming solvers can tighten the formulation by adding cutting planes and they use the relaxed optimal solution to guide the search. Therefore, the authors, based on the structure of the problem, have introduced logical global constraints. Additionally, with their particular strategy for variables and their values, they have defined a particular heuristic for searching the results around specific combination i.e. Large Neighborhood Search (LNS). Moreover, by using certain static constraints in their model, they try to avoid creation of symmetrical solutions. Finally, they have got pretty fast solution, but a solution that is suitable for smaller instances. The solution that uses their model and limitations, leads to poor performance when searching for results in case of larger instances.

B. Delayed Column Generation

The problem can be solved more efficiently with certain modifications, i.e. the desired result can be achieved without having to create every possible combination. The idea is to use the Simplex method and the process of determining the next cutting pattern to be based on a basic pattern obtained by LP solution complemented with global and logical constraints. This is achieved exactly with the delayed column generation (DCG) technique which provides greater and more efficient propagation in the search for solutions. Before using DCG methods, it is necessary to drop the limitation on variables to be integers only. When the non-integer solution is found, the approximation (rounding) to integer can be achieved in few ways. For example, the proposed solution can be rounded down to the nearest integer. But if the solution is rounded to the lower integer, then a residual material will be created and that material must be filled with appropriate orders separately by some ad-hoc methods, otherwise the combination would not be acceptable and would not be an allowed solution.

According to Belov et al. [7], two points are important for the practical solvability of the column generation subproblem: the quality of cutting planes and a robust rounding heuristic. The heuristic helps to find an optimal solution long before cutting planes have forced integrality.

In 2006, Bettinelli et al. [6] have introduced linear relaxation of their model and have created an effective solution which is optimized with column generation and the lower bound found in this way is used in a branch-and-price algorithm.

C. *Sequential heuristic procedures*

The basics of heuristic approach are laid by Haessler in 1971, who is particularly concerned with problems arising in the paper industry. In his papers he has proposed that sequences of setting the product should be produced and generated using heuristics, and this would give fast but not exactly the most optimal solution. Therefore the speed is achieved but the proposal is not an effective one. With the aim to improve the solution, Haessler and Sweeney [10] have proposed a hybrid solution that basically is a delayed column generation method complemented with heuristics.

The prominent example of the "local heuristic search" class of procedures, we have analyzed the Sequential Heuristic Procedures (SHP) method. The SHP procedures outperform the capabilities of linear programming and can be used for solving more complex problems. These procedures create the decisions sequentially (one by one) by defining templates until all the necessary requirements are met and thus the smallest material waste is achieved. The SHP procedures not only allow control of the waste, but also control of other factors for which the standard LP procedure does not provide it.

Eshghi [8] has designed an Ant Colony Optimization (ACO) algorithm for solving the one-dimensional cutting problem. This algorithm is based on designed probabilistic laws and it is inspired from the ants' social behavior when they are looking for the shortest way. Eshghi stated that "meta-heuristics for solving the one-dimensional cutting problem will result in much desired answers with small solving time that could be a good basis for researchers' future research".

IV. MATHEMATICAL MODEL OF CSP

The definition of CSP represents correlation between orders, mother-plate and the corresponding slab. The width of the mother-plate is determined by the widest order, and before you allocate all orders in a mother-plate it is impossible to calculate its width and weight. On the other hand, there are many eligible slabs with different geometries for each order. So, for a given weight of a

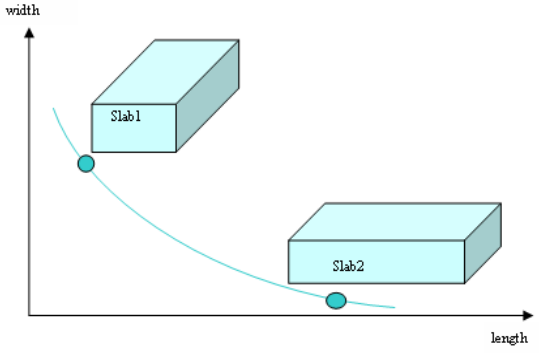

Figure 1. Eligible slabs with different geometries for each proposal

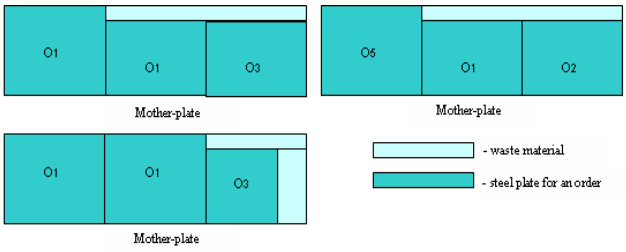

Figure 2. Correlation between mother-plate and orders

mother-plate, the length of the slab is strongly dependent on the width of the slab, as shown in Fig.1.

The trim loss strongly depends on the cutting plan of the mother-plate and the mother-plate can be cut into plates for suitable orders with or without trim loss. Examples of cutting plans with trim loss are shown in Fig.2.

The specific CSP that is being solved in this paper can be described in terms of inputs, outputs, and constraints for production design. The inputs to the problem are the following:

- List of orders with information about size of the rectangle, number of commissioned plates, quality grade, and constraints defined with specific chemical and mechanical properties;
- List of slabs with size of the rectangle, quality grade, and chemical and mechanical structure;
- Table of quality grades and their interdependence;
- Table of coefficients for material transformation from slabs to steel plates;
- List of values of approved dimension ranges for steel plates, values of several different ratios between dimensions of slabs and steel plates.

The output is a list of slabs and corresponding mother-plates along with the locations of the orders on each mother-plate.

There are few constraints in the real production process and they are described as follows:

- The weight of the mother-plate is equal to the weight of the used slab transformed by appropriate coefficient depending on the size of the mother-plate;
- The quality grade of the mother-plate is equal to the quality grade of the used slab;
- An order can be produced from slab with higher quality than the order's quality;
- The dimension of the mother-plate must be in the defined dimension range;
- Mother-plate length-to-width ratio must be in a predefined range.

We define the model as follows. Assume that there are n orders to be produced by a certain set of slabs. Orders o_1, o_2... o_n (*further referred directly with 1, 2 ..., n*) have a measured weight w_o. For a simpler presentation of

our model and in order to show the use of constraints, we will make the assumption that all constraints are replaced with just one "color constraint", and the new rule that should be satisfied is that one slab can be used for production of orders with up to two different colors. This modification can be perceived as a slight generalization of CSP and it is known as the knapsack problem with color constraint in the integer programming community [11]. Therefore, for each order o we define color c_o, where $o \in \{1, 2 \ldots, n\}$, and let's suppose that there are d different colors i.e. $c \in \{1, 2 \ldots, d\}$.

Let's suppose that we have m slabs $s_1, s_2 \ldots, s_m$ with u_s, $s \in \{1, 2 \ldots, m\}$, where u_s represents the measured weight (capacity) of slabs.

In a solution of CSP:

1. The total weight of the orders allocated in a slab must not exceed the weight of the slab.
2. The orders allocated in a slab can be of two different colors only.

Let the matrix X_{nm} represent the affiliation of orders to a slab, where each element $x_{os} \in \{0, 1\}$ and $x_{os} = 1$ iff the order o can be produced by the slab s.

The second matrix Y_{nm} with elements $y_{cs} \in \{0, 1\}$ represents the color of the orders, where $y_{cs} = 1$ iff the slab s contains at least one order with color c. According to the restrictions we can define that an order may be produced only by one slab. Therefore we define the matrix X'_{nm} which represents the final affiliation of orders to a slab, where each element $x'_{os} \in \{0, 1\}$ and $x'_{os} = 1$ iff the order o is proposed to be produced by the slab s. Finally, we have:

$$\sum_{s=1}^{m} x'_{os} = 1, \forall o \in \{1,2,..n\} \quad (1)$$

The weight of the orders must not exceed the weight of the slab (the coefficient for material transformation from slabs to steel plates is presumed to be one):

$$\sum_{o=1}^{n} w_o x'_{os} \le u_s, \forall s \in \{1,2,..m\} \quad (2)$$

If an order is proposed to be produced by a slab then it is obvious that the slab contains that order's color, and $x_{os} \le y_{cs}$, for every $o \in \{1, 2 \ldots, n\}$. The color constraint could be expressed by $\sum y_{cs} \le 2$, where $c \in \{1, 2 \ldots, d\}$, $s \in \{1, 2 \ldots, m\}$. The goal is to achieve the required production orders using less slab weight or in other words to produce orders from slabs while waste material is minimal:

$$\min(u_s - \sum_{o \in \{1,2,..n\}} w_o x'_{os}), \quad s \in \{1,2,..m\} \quad (3)$$

The solution we defined above is quite different from the basic model of CSP. For a clearer picture of the goal we seek, we have defined the rest of the slab and we are trying to minimize that unused weight of slabs. It is obvious that the lower limit of this minimization is 0 (zero) which means that we have achieved proposal for production of orders with the same weight as the weight of the allocated slab.

V. INITIALLY IMPLEMENTED SOLUTION

The current system in the company that we have initially implemented uses algorithm implemented in the Oracle PLSQL programming language and it is integrated in an ERP environment.

The implemented algorithm is based on LP procedures complemented with branch and bound and constraint satisfaction algorithms of constraint programming [9]. It starts by defining the relation between slabs and orders in such manner that provides information about which slab can be used for production of each order according to the rules. This selection prevents the algorithm from irregular combinations because in the next step the algorithm creates possible combinations of previously selected orders for each slab. Employed symmetry breaking constraints and some heuristics exclude undesirable combinations. The process of combining the orders uses the weight of orders to fill the slab until the full capacity of slab is reached or exceeded. Additionally, orders are combined starting with the biggest order – a heuristic that provides us with better propagation in searching. The algorithm uses greedy approach [12] and tries to fill the slab with one order first. In the next step, results are sorted and the best combination is selected for each slab. This approach finds the patterns and possible solutions in a sequential and iterative way.

The implemented algorithm generates solutions with high quality and provides large savings in the company [13]. But, it is a time-consuming process and the execution time is significantly prolonged when it is used on large instances. Therefore, we implemented additional heuristics that provide acceptable solution without the need for creating all possible combinations. In that way, we obtained the optimal solution to our CSP.

Our further research was aimed at improving the execution time and brought us to a better algorithm developed by using dynamic programming paradigm [14], as presented in the next section.

VI. THE PROPOSED ALGORITHM

The analyzed problem is a problem in combinatorial optimization. It can be decomposed into overlapping subproblems and it has an optimal substructure i.e. optimal solution to the given problem can be obtained by using optimal solutions to its subproblems. Therefore we can use methods of dynamic programming paradigm to find an optimal solution to the problem. At first, we simplify the problem by breaking it down into simpler subproblems and we try to find solutions to the subproblems. We use bottom-up fashion to search the possible combinations of orders [15]. Equation (3) makes us sure that the combination with minimal trim loss will be selected. In the next step, we construct the solution to the main problem using the solutions to all the smaller subproblems. The algorithm is implemented in an integrated information system using the Oracle PLSQL programming language.

We classify orders into groups of orders $g \in \{1, 2..., i\}$, and each group consists of orders which may be combined together to be produced from one slab. This means that each group consists of orders with the same quality, thickness and width. Let's define the array C_g of possible combinations of orders for each group of orders $g \in \{1, 2 ..., i\}$, and $C_g(l) \in \{0, 1\}$, where $l \in \{1, 2 ..., k\}$. Each element l of the array represents the total length of orders i.e. the length of the constructed mother-plate, and the capacity or weight of the mother-plate can be calculated easily because the other dimensions are already defined by the group where the orders belong to. Further, $C_g(l) = 1$ iff there is a possible combination of orders with total length equal to l. Initially, each array will have the value 1 for the zero element: $C_g(0) = 1$. This default value will be used later in the algorithm to create a combination for the order being considered. Next, each order from the appropriate group will search the array in reverse order from the highest element with value 1 in the array to the first element. For each element l that has value 1 in the array, we define a new element l' in the array and the value of l' will be set to one, i.e. $C_g(l') = 1$. The newest element in the array represents the total length of orders i.e. $l' = l + l_o$, where l_o is the length of the current order. We have at least one new element which is the length of the current order according to the predefined value $C_g(0) = 1$. As previously mentioned, each element in the array can be easily converted into the weight of combined orders i.e. the minimal weight of the slab required for production of the combined orders.

According to the production constraints it is not necessary to expand the arrays with all possible combinations of orders, but it is sufficient to perform combining the orders until the maximum allowable length of mother-plate is reached. Analogous to the above, some calculated values in the array can be excluded if the corresponding slab (a theoretical slab with weight equal to the weight of combined orders) has dimensions smaller than the minimum allowed. These restrictions are similar to the color constraint in the entry model of CSP, and the basic algorithm does not create irregular combinations of orders using matrix Y.

The next step is to find appropriate slabs. For that purpose, we calculate the weight of the orders in any proposed combination of orders (where the element has value 1 in array C_g). Further, for each match of suitable slab and element of the array that satisfy the rule defined in (2), the unused material of slab is calculated.

It is worth to mention here that in our extended model we use a cube structure (3D array) instead of one-dimensional arrays. The first dimension of the cube is the length of the constructed mother-plate i.e. the element l of the array C_g. The second dimension represents the various groups of orders, and the third dimension of the cube is used for storing values of C_g as well as values of other attributes of orders which are used for checking whether the real-life production constraints are met.

At the end, the best results are selected starting from the slab with the smallest waste and the appropriate combination of orders, as it is defined in (3). Additional procedure ensures the validity of the final affiliation of orders to a slab, as presented in (1).

The steps of the algorithm are summarized as follows:

```
S1: create group of orders (GO) and initialize array Cg
S2: create possible combinations of orders:
    for each GO loop
      for each order O in GO take length lo and loop
        get last element l of Cg with value 1
        loop (start searching Cg from the end)
          if lo + l < max_len_mother_plate then Cg(lo+l)=1
          get element prior to l
        end loop for Cg
        take next order
      end loop for orders
      next GO
    end GO loop
S3: find appropriate candidate slab
    for each slab S loop
      for each Cg with the same grade as the slab loop
        find the last element l of Cg
        loop
          if weight_of_orders <= weight_slab and
             constraints_are_satisfied
          then Xos=1, where o represents all orders from Cg(l)
          get element prior to l
        end loop
        get next Cg
      end loop for Cg
      get next slab
    end loop for slabs
S4: select the best results – define X'
```

VII. EXPERIMENTS AND RESULTS

In this section the computational performances of the initially implemented algorithm and the proposed algorithm are presented and analyzed. We have created an environment on PC Intel Pentium 3,4GHz, 2GB of RAM, Windows XP operating system and Oracle Database 10g, for the testing purposes. Both the initially implemented algorithm and the proposed one were implemented and compared in this environment.

The test data sets were obtained from the existing ERP system and they are real-life production data. To monitor the performances of the proposed algorithm under various conditions, the test instances were grouped together into three different-sized data sets (groups): a small data set, a medium and a large data set. The small data sets used for testing consisted of 300 slabs and 500 orders, the medium sets 1000 slabs and 1500 orders, and the large data sets 2000 slabs and 3000 orders.

The main purpose of the computational tests was to validate the newly proposed algorithm with actual data given by the company, to compare the two models specified above and to find the impact of the new approach on everyday production. Table 1 summarizes the characteristics of the real cutting stock data sets and presents adequate numerical results for these examples. The data set specifications (number and weight of slabs and orders) are rounded and the results are averaged within each group of data sets. The first column gives the identification of data set groups and the second column identifies the algorithm we have used. The next columns

TABLE I. PERFORMANCE OF CURRENT AND PROPOSED ALGORITHM FOR CSP

		Slabs		Orders		Used Slabs		Satisfied orders		Performance	
Data set group	**Algo rithm**	**Pcs**	**Weight (t)**	**Pcs**	**Weight (t)**	**Pcs**	**Weight (t)**	**Pcs**	**Weight (t)**	**Execution Time (s)**	**Trim loss (%)**
Small	Init.	300	1490	500	1600	220	1150	360	1130	25	1,74
	Prop.	300	1490	500	1600	260	1250	400	1230	22	1,6

	Prop.	2000	9650	3000	9500	1690	8070	2560	7900	250	2,11

refer to quantity information about slabs and orders that have been used for testing purposes. Further, we show the number and total weight of used slabs, the number and total weight of satisfied orders as well as the total loss produced by the algorithm. The last two columns provide us with information about the quality of the obtained solutions in terms of algorithm execution time and produced waste material. It is noticeable that the proposed algorithm ***creates solutions with better utilization of available orders*** (weight of satisfied orders over weight of orders), the proposed design of mother-plates ensures ***better usage of slabs*** i.e. less trim loss, and the proposed algorithm ***takes less time*** than the initially implemented one. The results vary in different circumstances and there are bigger improvements in propagation and quality of solutions when larger data sets are used.

Table 2 provides information about the achieved improvements on satisfied orders and execution time with the proposed algorithm over the initially implemented algorithm. If we compare the obtained results, we can see that we have achieved improvement from 10% on execution time on small data sets, up to almost 30% better execution time on large data sets. Also, there is over 17% improvement in satisfied orders when the algorithm is used on large data sets.

VIII. CONCLUSION

In this paper we presented a new approach for maximum utilization of the mother steel plates for rectangular steel plates' orders. The model we have presented is based on dynamic programming paradigm and is more effective than the linear programming model complemented with global constraints. The results show the fact that a portion of production trim loss can be reduced by better planning and those results can be obtained faster with the proposed algorithm. The use of optimization techniques reduces waste materials which results in huge savings in steel industry. Furthermore, the better production planning provides better utilization of stock material, and improves the financial performance of the company by improving the investment level of the stock material.

TABLE II. NEW ALGORITHM RESULT IMPROVEMENTS

	% of improvements	
Group of data sets	**Satisfied Orders**	**Execution Time**
Small	8	10
Intermediate	11	16
Large	17	29

ACKNOWLEDGMENT

The research presented in this paper is partly supported by the Faculty of Computer Science and Engineering, at Ss. Cyril and Methodius University in Skopje.

The authors wish to express their gratitude to paper reviewers for the valuable suggestions for the improvement of the paper.

Abstract: This paper proposes a simulation environment for creating simulated ranging data of high resolution sonar systems. It enables the assessment of underwater object reconstruction techniques and the verification of various methods for automated target detection. As an input, the proposed environment uses the AUV's trajectory, a model of the sonar system attached to the AUV and 3D CAD models of underwater objects. As an output one can get a point cloud of the whole underwater object or 2D images, i.e. range data, which are smaller parts of a large object's 3D model. Noise is modeled and used as additional input in order to generate outputs that are closer to the real-world. The simulated data is processed and evaluated, where well known sonar signal processing methods are used to process the simulated acoustic signals. Automated target detection is achieved by processing the simulated 2D range data with advanced image processing techniques.

Keywords: Simulation Environment, 3D Models, Object Reconstruction, Automated Target Detection, Sonar.

I. INTRODUCTION

Underwater Inspection Mission (UIM) is usually carried out by a human divers and remotely operated vehicles (ROV). In order to automate UIM, Automated Unmanned Vehicles are used recently. Usually, AUV is moving underwater in a 3D space by following a predefined 6D trajectory of AUV configurations, i.e. 3D positions and 3D orientations, c.f. Fig. 1. Generally, a trajectory is planned in a manner that the surface under inspection is in the sonar scanning range. Sonar system is attached on an AUV and it enables range data calculation. As a scanning result, a large set of 3D points is obtained, a.k.a. point cloud. Point cloud enables surface inspection on a dry end of the system, i.e. on a computer's screen.

II. SIMULATION ENVIRONMENT

Signal processing in sonar systems is computationally intensive task. Computational complexity grows with increasing the number of time samples, the number of transducer elements and the number of antenna beams [1]. Various methods for sonar signal processing and their different implementations are compared in [1]. Proposed methods are implemented in MATLAB and C++ programming languages. In order to implement mentioned signal processing methods in C++, a special programming environment is used [2]. It reduces the implementation and verification time by combining MATLAB and C++ programming languages.

When using methods with large execution time values, simulation lasts long too. In order to speed up a range finding method, a straight forward approach is used in [3]. Instead of calculating range data with time consuming signal processing methods, a range finding is simulated by 3D model-based geometry approach. Range data is calculated as an intersection point between each 3D model's triangle and each antenna's beam, and it is done for each AUV's configuration, i.e. position and orientation. Intersection points are calculated in the antenna coordinate system and are transformed to the environment coordinate system. AUV trajectory planning is done in [3] by placing convex polygons around ship hull models and by placing straight lines beside harbor wall models. With known AUV's trajectory it is possible to transform calculated intersection points from the antenna c.s. to the referent c.s. Finally, a set of intersection points between antenna beams and model's triangles forms a point cloud.

Intersection point calculation is implemented in a GPU in order to speed up the reconstruction mission simulation [4]. Total speedup is between 100 and 200. GPU-based solution is involved in order to accelerate the execution time. Measured average speed-ups were ranging from 100 to 200.

Automated target detection is done in [5]. Firstly, a 20 cm edge length cubes are placed on the model's surface as anomalies. They are representing the so called Mine Like Objects (MLO). Automated MLO detection is done in [5] by projecting 3D range data to a 2D range image. Subsequently, image processing techniques are applied. Each 2D image correspond to a 10 m long scanned model part. Images are made with orthographic projection of a point cloud on a 2D trajectory-relative backplane.

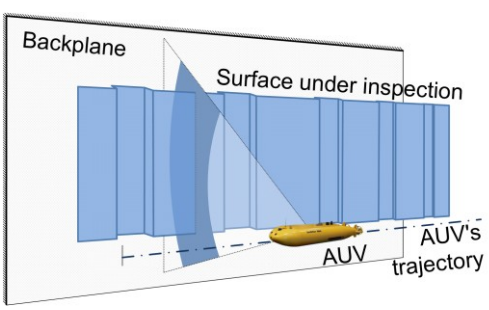

Figure 1. Underwater Inspection Mission (UIM) carried out by an Autonomous Underwater Vehicle (AUV) which is following predefined AUV's trajectory.

A. Point Cloud Reconstruction

Simulation model proposed in this paper can provide a user with a 4D point cloud, where each point consists of a 3D point $\mathbf{p}_W$ and 1D color. For the point cloud reconstruction, input parameters are: 3D environment model, 6D AUV trajectory and antenna parameters.

In this paper 3D models are made of N triangles, where each triangle has three 3D vertices. Therefore, the environment is described with the matrix of size $N \times 9$. As an example, the pyramid model is illustrated in Fig. 2.

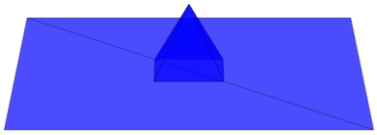

Figure 2. Environment model of a pyramid made of triangles.

Antenna parameters define the number of time samples $n = 1,\ldots,N$, the number of transducer elements $m = 1,\ldots,M$ and the number of beams $k = 1,\ldots,K$. In each of k beams, range finding method provides a time sample n_k from which the range r_k is calculated for corresponding k-th azimuth φ_k and elevation θ_k angle. From r_k, φ_k and θ_k a point cloud point is defined in polar coordinates. Transformation to Cartesian coordinates is done with eq. (1).

$$\mathrm{p_w} = \mathrm{r_k}[\cos(\theta_\mathrm{k})\sin(\varphi_\mathrm{k}) \;\; \cos(\theta_\mathrm{k})\cos(\varphi_\mathrm{k}) \;\; \sin(\theta_\mathrm{k})]^\mathrm{T} \qquad (1)$$

Parameter $\mathrm{w} = 1,\ldots,\mathrm{W}$ defines an index of a point in the point cloud ${}^2\mathbf{p}_W = [\mathrm{x_w} \;\; \mathrm{y_w} \;\; \mathrm{z_w}]^\mathrm{T}$ in the antenna's c.s.

AUV trajectory consists of AUV 3D position $\mathbf{p} = [x\ y\ z]^T$ and 3D orientation $\mathbf{a} = [\alpha\ \beta\ \gamma]^T$. Antenna c.s. can be relatively transformed concerning the AUV's c.s. It can be translated by the position $\mathbf{p}_A$ and rotated by the orientation $\mathbf{a}_A$. Let $\mathbf{R}(\mathbf{a})$ be the rotation matrix by orientation vector $\mathbf{a}$, and let ${}^2_0\mathbf{H}$ be the transformation matrix that transforms point cloud points ${}^2\mathrm{p_w}$ from the antenna c.s. S_2 to the points ${}^0\mathrm{p_w}$ in the referent c.s. S_0, c.f. eq. (2) and Fig. 3.

$$\begin{gathered} {}^0\mathrm{p_w} = {}^2_0\mathbf{H} \cdot [\,\mathrm{p_w^T} \;\; 1\,]^T \\ {}^2_0\mathbf{H} = {}^1_0\mathbf{H}\,{}^2_1\mathbf{H} = \begin{bmatrix} \mathbf{R}(\mathbf{a})\mathbf{R}(\mathbf{a}_\mathrm{A}) & \mathbf{R}(\mathbf{a})\,\mathbf{p}_A + \bar{\mathbf{p}} \\ [0\ 0\ 0] & 1 \end{bmatrix} \\ {}^1_0\mathbf{H} = \begin{bmatrix} \mathbf{R}(\mathbf{a}) & \bar{\mathbf{p}} \\ [0\ 0\ 0] & 1 \end{bmatrix}, \quad {}^2_1\mathbf{H} = \begin{bmatrix} \mathbf{R}(\mathbf{a}_\mathrm{A}) & \mathbf{p}_A \\ [0\ 0\ 0] & 1 \end{bmatrix} \end{gathered} \qquad (2)$$

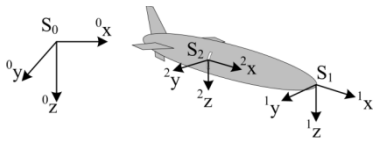

Figure 3. Referent coordinate system (c.s.) S_0, AUV's c.s. S_1 and antenna's c.s. S_2.

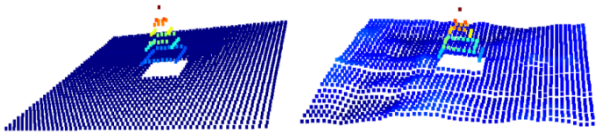
In this work, a noise is added to the simulation in two ways. Range noise is added to the calculated range $r_k' = \mathrm{r_k} + \xi_\mathrm{k}$. Reconstructed point cloud is illustrated in Fig. 4, in cases with/without the range noise.



(a) (b)

Figure 4. Reconstructed point cloud: without noise (a); with the range noise (b).

In order to correlate noise in neighbor points, a 2D low pass filtering operation is incorporated.

Orientation noise is added to the AUV orientation with two components: measureable and non-measureable noise. Measureable noise Ω_i is caused by the underwater environmental forces that are moving an AUV off the referent trajectory. Non-measureable noise Ω_i' is caused by the angular sensor measurement error. Finally, orientation $\mathbf{a}_i' = \mathbf{a}_i + \Omega_\mathrm{i} + \Omega_\mathrm{i}'$ is filtered and unwrapped to the interval $\pm\pi/2$. One can observe that the orientation noise cause changes in point cloud density, c.f. Fig. 5.

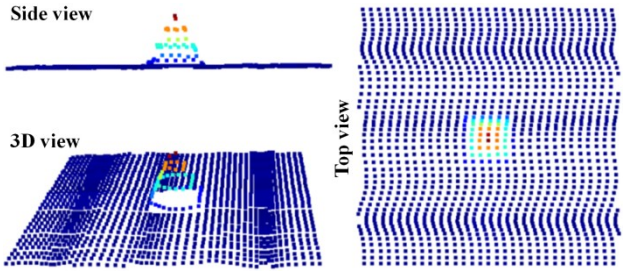


Figure 5. Reconstructed point cloud with added angular noise.

B. Range Image Reconstruction

Range image reconstruction is an orthographic projection of a 3D point cloud on a 2D image plane. It is done for a certain part of AUV's trajectory. In this work, a 10 m long trajectory is used for simulated imaging of one part of the underwater object. Main goal is to calculate a distance along a normal vector of a 2D image plane. Distance is calculated from a certain pixel position in 2D image to an intersection point with a 3D model, c.f. Fig 6.

Proposed projection is done in a trajectory-relative manner. Firstly, the centroid $\bar{\mathbf{p}}$ and mean orientation $\bar{\mathbf{a}}$ is calculated from one part of AUV's trajectory. If sonar imaging is placed in z,y-plane, with zero beam in y-direction, normalized vector $\mathbf{v}_1$ represents scanning direction and is defined with eq. (3), c.f. Fig. 7.

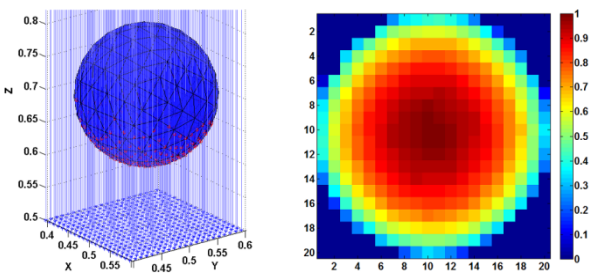

Figure 6. Orthographic projection of a 3D sphere model (a) on a 2D image (b) by calculating distance along perpendicular line between a certain pixel in 2D image and the intersection point with 3D model.

$$\mathbf{v}_1 = [\mathbf{R}(\bar{\mathrm{a}}) \cdot [0\ \ 1\ \ 0]^{\mathrm{T}}]^{\mathrm{T}} \tag{3}$$

Distance values $d_w^{'} = \mathbf{v}_1^{\mathrm{T}}({}^0\mathbf{p}_w - \bar{\mathbf{p}})$ is calculated between a point $\mathbf{p}_w$ and a plane placed in the centroid $\bar{\mathbf{p}}$ and the normal vector $\bar{\mathbf{v}}_1$. With distances $d_w^{'}$, mirrored image is represented since it is calculated from the antenna origin. In order to get the real image, distance values must be inverted $d_w = \max(d_w^{'}) - d_w^{'}$.

In order to get 2.5D height map, i.e. a range image, a point cloud rotation is required. Normal vector of a back-plane is set along the z-axis, i.e. in the $\mathbf{z} = [0\ \ 0\ \ 1]^T$ direction. Rotation is done by angle $a = \angle(\mathbf{v}_1, \mathbf{z})$, c.f. eq. (4), about the new axis $\mathbf{v}_2 = (\mathbf{v}_1 \times \mathbf{z})$, c.f. eq. (5) and Fig. 7.

$$a_{\mathbf{v},\mathbf{z}} = \angle(\mathbf{v}_1, \mathbf{z}) = \tfrac{\pi}{2} - \mathrm{atan2}(v_z, \sqrt{v_x^2 + v_y^2}) \tag{4}$$

$$\mathbf{v}_2 = (\mathbf{v}_1 \times \mathbf{z}) = \begin{bmatrix} \mathbf{x} & \mathbf{y} & \mathbf{z} \\ v_x & v_y & v_z \\ 0 & 0 & 1 \end{bmatrix} = [v_y,\ -v_x,\ 0]^T \tag{5}$$

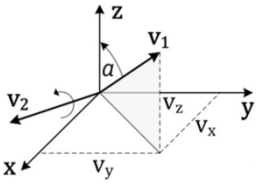

Figure 7. Rotation about vector $\mathbf{v}_2 = (\mathbf{v}_1 \times \mathbf{z})$ by angle $a = \angle(\mathbf{v}_1, \mathbf{z})$.

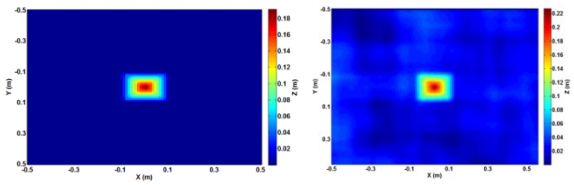
Proposed rotation is done with the axis-angle rotation matrix $\mathbf{R}(\mathbf{v}, a)$. In order to get the image borders in alignment with x, y-coordinates, additional rotation is required about the z-axis by the angle $\psi_b = \mathrm{atan2}(v_{1,y}, v_{1,x})$. Finally, rotated point cloud points $\mathbf{p}_{w,R}$ are defined with eq. (7).

$$\begin{aligned} \mathrm{p}^{'} &= \left(\mathrm{R_z}(\psi_\mathrm{b}) \cdot \mathrm{R}(\mathrm{v}, \mathrm{a})\right) \cdot {}^0\mathrm{p_w} \\ \mathrm{p_{w,R}} &= [\mathrm{p}^{'}(1)\ \ \mathrm{p}^{'}(2)\ \ \mathrm{d_w}]^{\mathrm{T}} \end{aligned} \tag{6}$$

Proposed techniques are used to reconstruct the 2D range image, c.f. Fig. 8, of the 3D point cloud which is illustrated in Fig. 4.



(a) (b)

Figure 8. Reconstructed range image from the point cloud illustrated in Fig 4.: without noise (a); with range noise (b).

C. Sonar Signal Simulation

Continuous wave pulse echoes are simulated using proposed 3D model-based simulation environment. In this work, carrier signal is defined with 8 periods of sinus function, carrier frequency $f_c = 1$ MHz, pulse duration $t_{pulse} = 8/f_c$ and the sampling frequency $f_s = 5$ MHz. Let $\mathbf{t}$ be time sample vector with time samples. Points ${}^0\mathbf{p}_w$ are intersection points between sonar's beams and model's triangles, while points $\mathbf{p}_m = [x_m\ \ y_m\ \ z_m]^T$ are centers of transducer elements in the antenna c.s., c.f. Fig. 9.

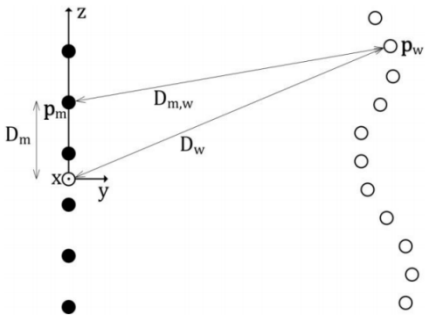


Figure 9. Transducer elements array (left) and the calculated point cloud points (right). Distances define time delays for CWP superposition.

Distance $D_w = |\mathbf{p}_w|$ is a distance between the antenna origin and an echoing point, while $D_{m,w} = |\mathbf{p}_w - \mathbf{p}_m|$ is a distance between an echoing point and a certain transducer element.

Echoes from a point cloud points are superimposed, as it is proposed in Alg. 1. Time delays $\tau_{m,w}$ and phase shifts $\varphi_{m,w}$ are calculated for M transducer elements and W echoing points (Alg. 1, Lines 1-2). If w-th echoing point is in the antenna range (Alg. 1, Line 3) and the CWP's time samples are inside the interval $[1, N]$ (Alg. 1, Lines 6-9), w-th echoing point amplitudes are superimposed to m-th channel signal (Alg. 1, Line 11). Amplitude A can be a constant value or a distance dependent function [6].

Algorithm 1. Superimposing sonar signal echoes from a point cloud.

Inputs: $f_c, f_s, \mathbf{t}, D_w, D_{m,w}, t_{pulse}, M, N, W, \vartheta_{max}, \vartheta_{min}, A, c$
Output: $\dot{x}$

1: $\tau_{m,w} = (D_{m,w} + D_w)/c$
2: $\varphi_{m,w} = \tau_{m,w} \cdot 2\pi f_c$
3: **For each** w
4: **If** $\mathrm{atan2}(z_w, y_w) \le \vartheta_{max} \ \wedge\ \mathrm{atan2}(z_w, y_w) \ge \vartheta_{min}$
5: **For each** m
6: $i_0 = [\mathbf{t}(1) \cdot f_s]$
7: $i_1 = \lfloor \tau_{m,w} \cdot f_s \rfloor - i_0$
8: $i_2 = \lfloor t_{pulse} \cdot f_s \rfloor + i_1 - i_0$
9: **If** $i_1 < 1 \ \vee\ i_2 > N$
10: **Go to** line 4
11: $\dot{x}(m, i_1{:}i_2) = \dot{x}(m, i_1{:}i_2) + A \sin\left(2\pi f_c \cdot \mathbf{t}(i_1{:}i_2) - \varphi_{m,w}\right)$

Sonar system with $N = 3378$ time samples, $M = 128$ channels, $K = 91$ beams, distance ranging from 5.5 m to 6.0 m, artificial for the 64th channel is shown in Fig. 10.

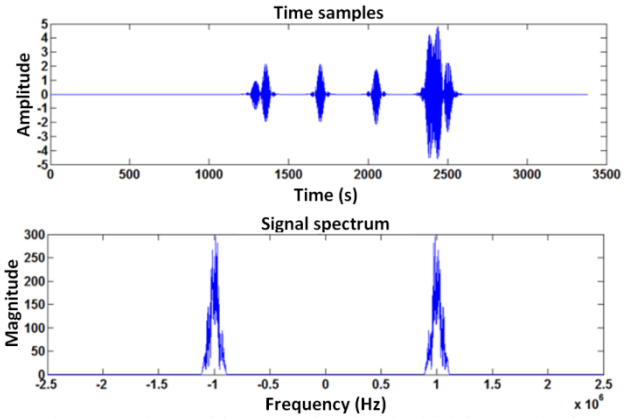

Figure 10. Time and frequency domain of artificial sonar signal.

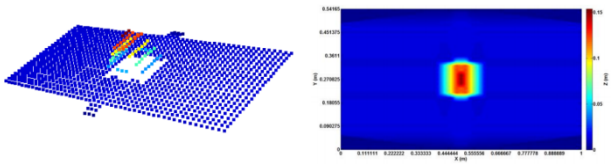

(a) (b)

Figure 11. Reconstructed pyramid: point cloud (a); range image (b).

Simulated point cloud reconstruction of a pyramid model and the use of artificial signals is shown in Fig. 11. One can observe a different noise when compared with the ones described in Subsections II. A and II. B. Noise presented in Fig. 11 is caused by digitization errors and algorithmic imperfections.

D. Parallel GPU Implementation

CPU-based (central processing unit) simulation is time consuming and it sometimes last a few hours. Therefore, a GPU-based (graphic processing unit) simulation is used to accelerate the computationally intensive task of underwater reconstruction simulation [4]. Generally, speed-up is 50-100x without any optimization involved [7]. Proposed simulation environment has a speed-up of 150-250x. GPU implementation reduces the execution time of a simulation from 4 hours to a few minutes. Basic idea is to accelerate the intersection points calculation in parallel on a GPU, c.f. Fig. 12.

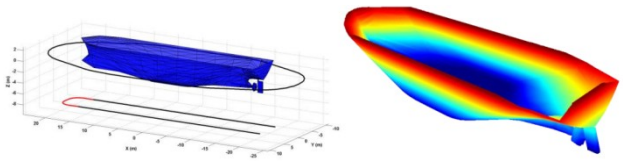

Figure 12. Ship hull model and AUV's trajectory (a); Reconstructed point cloud of the ship hull (b).

E. Automated Target detection

Main goal of an automated target detection is to detect anomalies on a ship hull during the underwater inspection mission [5]. Usually, a human technician analyses recorded images after the underwater scanning procedure ends. With the use of computers and acoustic vision it is possible to replace human vision. Automated target detection used in proposed simulation environment uses orthographic projection of a point cloud in order to create 2D images. Subsequently, 2D image processing algorithms are used to detect anomalies, e.g. MLOs (Mine Like Object). Top hat filter is used to detect MLO-like cubes with 20cm edge length. Thresholding technique is applied to segment detected MLOs from its surrounding background. For example, a harbor wall-like model with three MLOs is illustrated in Fig. 12 a, while detected MLOs are illustrated in Fig. 12 b.

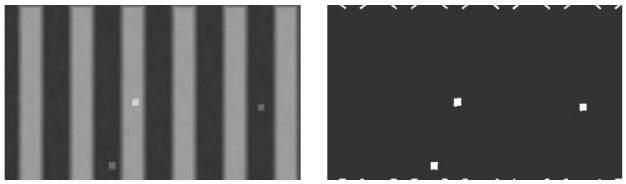

Figure 12. Ship hull model and AUV's trajectory (a); Reconstructed point cloud of the ship hull (b).

III. Conclusion and Discussion

In this work a simulation model is presented for creating artificial sonar data, 3D point clouds and 2D range images. Main goal of proposed simulation is to create the environment for automated target detection. Noise is modeled as a range noise and AUV's orientation noise, measureable and non-measurable. Range noise is simulating signal processing errors of a target range detection, while the orientation noise simulates AUV trajectory following. GPU accelerated parallel intersection point calculation is involved in order to reduce the simulation duration. With achieved speed up of 200x, a few hours long simulation of complete ship hull reconstruction is reduced to only a few minutes long simulation. Proposed simulation model is applicable for simulating other range data-based systems.

Abstract - The increase of vehicle numbers in recent decades resulted in road traffic congestion problems. Such congestions are a characteristic of densely populated urban areas and occur daily during morning and afternoon rush hours. Urban areas have been suffering from the lack of space needed to build new road infrastructure. The traffic congestion problem can be solved by applying new traffic control approaches from the domain of intelligent transportation systems (ITS). One of the applied methods from ITS is known as ramp metering and is used to increase the throughput of urban highways with many on- and off-ramps. Nowadays ramp metering is used in cooperation with additional control approaches like variable speed limit control (VSLC). Prior to implementation, such cooperative traffic control systems have to be tested in simulations using real world traffic data. One of the used simulators is CTMSIM which enables macroscopic simulation of highway traffic and local ramp metering approaches. In this paper the CTMSIM simulator is augmented to enable simulation of cooperative ramp metering algorithms, stand-alone VSLC, and cooperation between ramp metering and VSLC. Augmented simulator is tested using some limited available traffic data with the Zagreb bypass urban highway as a case study.

I. INTRODUCTION

Urban highways cannot fulfil originally projected high level of service (LoS) today anymore. LoS is defined as a group of qualitative measures which characterize operational conditions within traffic flow and their perception by motorists and drivers [1]. Main reason for low values of LoS on today's urban highways is high amount of traffic during increased daily (also known as rush hour) or seasonal traffic demand. In the same time urban highways are in most cases integrated into the urban road network and environment so there is no more space for infrastructural build-up.

On- and off-ramps on urban highways are common places for bottlenecks since they are the merging points of mainstream and on-ramp flow. Congestions at on-ramps become problematic if mainstream and/or on-ramps are overburdened with heavy transit traffic or/and a large number of local drivers. Local drivers prefer to use the urban highway instead of the local urban road network in time of daily migration [2]. Such a traffic scenario is common at most urban highways.

Regarding mentioned problems, new traffic control concepts are being applied to ensure desired LoS. On-ramp merging control method known as ramp metering and mainstream variable speed limit control (VSLC) are the most used control methods on urban highways [3]. Ramp metering and VSLC are important services used in intelligent transportation system (ITS) based traffic control architectures.

Ramp metering implementations are generally simulated by using various traffic simulation programs with the ability to simulate interaction of all existing traffic flows in a highway system. Traffic simulators are divided into two major categories: macroscopic and microscopic. Macroscopic simulators compute cumulative traffic flow parameters (e.g. speed, flow, and density) and their relationships to each other according to traffic flow equations. Individual vehicles are not considered. Most used macroscopic simulators are: CTMSIM, FREFLO, AUTOS, METANET and VISUM. Microscopic simulators continuously or discretely compute parameters (e.g. position, speed, maximum acceleration rate, etc.) of every individual vehicle during simulation. Most used microscopic simulators are: PARAMICS, MITSIM, CORSIM, VISSIM, AIMSUN, and TRANSIM.

This paper tackles the problem of cooperative highway traffic control systems simulation using a macro-simulation environment. CTMSIM is selected as a suitable macroscopic-highway simulator because of its open architecture based on Matlab. New functionalities and control approaches can be easily added and verified. In order to perform analysis and to validate the impact of cooperative control systems on highway traffic flows, it is necessary to adequately extend CTMSIM. In its original version it only supports local ramp metering algorithms without the possibility to simulate cooperative control approaches between several on-ramps or speed limit control (SLC) systems.

CTMSIM simulator is augmented to support SLC using a modified graphical user interface (GUI) to set a fixed speed limit value for every segment (cell) of the highway model. This value is used as the default speed limit value. Additionally, it is possible to change the speed limit value during simulation, which transforms SLC into variable SLC (VSLC). In order to enable cooperative ramp metering simulation, a hierarchical control simulation framework is developed and added to

CTMSIM. Using mentioned augmentation cooperative ramp metering algorithm, HELPER is implemented to verify the new framework. Augmented CTMSIM also enables simulation of cooperation between the implemented ramp metering algorithm HELPER and VSLC. Zagreb bypass highway is used as test case for evaluation of the developed hierarchical control framework and VSLC.

This paper is organized as follows. Second section briefly describes concept and problems which can be mitigated by application of ramp metering. Concept of cooperation between on-ramps and other highway control systems in order to achieve better results in ramp metering is presented in third section. Fourth and fifth sections describe basic features of the CTMSIM simulation environment and implemented augmentations. Sixth section contains simulation results of the comparative analysis of implemented ramp metering algorithms, VSLC and cooperative approaches. Paper ends with conclusion and future work description.

II. RAMP METERING

Common source of congestions on urban highways is merging of mainstream and on-ramp traffic flows as presented in Fig. 1. Area where these two types of traffic flows are actually interacting is known as downstream bottleneck. Consequences of highway congestions manifest through the following indicators: traffic demand exceeding road capacity, increased number of accidents and incidents, on-ramps queues that spill over into the urban arterial roads and peaks in traffic demand resulting from platooned vehicle entries from on-ramps [4]. Location of the downstream bottleneck close to the on-ramp and the spillback effect on the adjacent local urban road network is denoted in Fig. 1.

The main objective of ramp metering is to control queues at on-ramps in order to maintain maximal capacity flow on a highway. This is achieved by restricting access of on-ramp traffic to mainstream traffic with special traffic lights and appropriate signalization [5]. Visualization of complete installation of a local ramp metering system on a highway is shown in Fig. 2. Most important part of the ramp metering system is the algorithm which determines the "access rate reduction" for every on-ramp flow.

Generally it is possible to divide ramp metering algorithms in two major categories: local (or isolated) and coordinated. Local strategies take into account only traffic conditions on particular on-ramp and nearby segment of

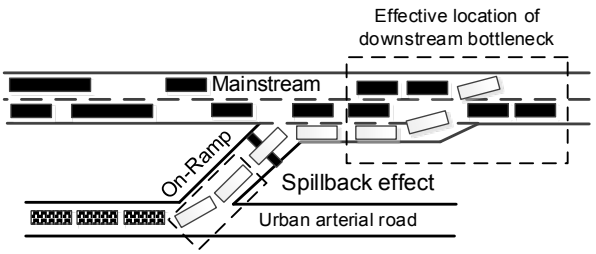

Figure 1. Graphical illustration of downstream bottleneck and spillback effect

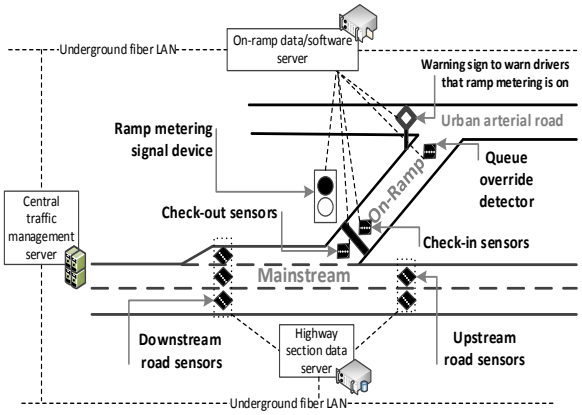

Figure 2. Basic ramp metering installation on a highway section

highway where they are applied. Most representative member of this algorithm category is ALINEA. Main working principle of ALINEA is to keep the downstream occupancy of the on-ramp at a predefined value using a closed loop control structure [6].

Coordinated algorithms consider traffic situation on the overall highway system. According to overall highway traffic state, metering rate for every on-ramp is adjusted. These coordinated ramp metering algorithms are further divided into cooperative, competitive and integrated algorithms. Simulation of cooperative algorithms is addressed in this paper and therefore they will be explained in the next section with more details. Competitive algorithms first compute two or more sets of metering rates using different algorithms types. The more restrictive one will be selected as the actually implemented rate. Typical representative of competitive ramp metering algorithms is SWARM. The SWARM algorithm has two major modules. First module performs local, while second module conducts global predictive ramp metering based on the same traffic control scenario. Metering rates for every on-ramp obtained by local and global algorithm are compared and smaller value is selected as final ramp metering rate [7]. Integrated algorithms are based on optimization of a specific LoS value while considering constraints such as maximum allowable on-ramp queue, bottleneck capacity, etc.

Some authors also make an alternative classification of real-time (traffic-responsive) and fixed-time ramp metering strategies [6]. Real-time ramp metering strategies are based on real-time traffic data obtained from highway sensors while fixed-time strategies use historical data without insight into the current traffic situation.

III. COOPERATIVE RAMP METERING

A cooperative control system is defined as a set of control entities that share information and/or tasks to accomplish a common, though perhaps not singular, objective. Cooperation in ramp metering was originally achieved by exploiting adjacent on-ramps queue capacity in order to perform effective mitigation of congestion related to a particular area with several close on-ramps. In such a highway network configuration, there exists the risk that mainstream congestion originating from an on-ramp can cause severe congestion that includes one or

more upstream on-ramps. Such congestion spread closes the access of mainstream vehicles to upstream off-ramps enlarging the congestion problem.

Latest work in cooperative ramp metering includes cooperation between classic cooperative ramp metering framework and other highway management services, driver information systems and vehicle itself [7]. In such a way, cooperation with additional highway traffic control systems can be established.

A. Cooperation between on-ramps

As mentioned, main problem with local or isolated ramp metering is a risk of fast upstream congestion propagation known as a "shock wave". This traffic scenario is common at a highway section with an on-ramp when local ramp metering cannot efficiently control the merging process between high traffic demands at on-ramp or/and in mainstream. This situation creates a mainstream "shock wave" which in relation to the motion of the vehicles travels backward or upstream. Upstream on-ramps with local ramp metering applied are not aware of downstream traffic conditions and therefore cannot provide an adequate solution to prevent the congestion spread.

Cooperative ramp metering algorithms work in two phases. In the first phase metering rate for each on-ramp is computed by its local algorithm. The second phase involves further adjustment of each local metering rate according to overall highway system information. Overall information involves traffic data from every on-ramp and its associated mainstream section traffic data. This phase is done in a cooperative unit. Main goal of mentioned cooperation is to achieve higher highway throughput by adjusting on-ramp metering rates upstream of the on-ramp affected by congestion.

HELPER was the first algorithm which used the mentioned cooperative ramp metering principle. It contains local traffic responsive metering algorithm and a cooperative unit. The cooperative unit uses data obtained from local ramp metering units to monitor the whole controlled highway section. If congestion or a long on-ramp queue is detected, it declares the belonging highway section with its on-ramp as master. Furthermore, several upstream on-ramps are declared as slave on-ramps. Slave on-ramps have the role to create virtual queues in order to reduce queue length on the congested on-ramp.

B. Cooperation with additional traffic control systems

Except cooperation between several on-ramps, additional cooperation can be established within the form of a superstructure containing several traffic control sub-systems. Such sub-systems are: VSLC, line prohibiting changes and various driver information services. In cooperation with the core ramp metering system they can provide better control over involved traffic flows. In this paper, emphasis is on cooperation between VSLC and ramp metering. VSLC is applied shortly before HELPER creates virtual on-ramp queues and ends when the congestion is reduced.

IV. SIMULATOR CTMSIM

CTMSIM is an interactive simulator based on macroscopic traffic models specifically designed for highway traffic flows simulations. Its original version supports several local and competitive ramp metering algorithms including on-ramp queue control. Highway model is based on the Asymmetric Cell Transmission Model (ACTM) and allows implementation and development of user-pluggable on-ramp flow and queue controllers [8]. In order to apply ACTM, the highway is divided into I cells. Basic ACTM architecture with marked variables is shown in Fig. 3.

Detailed ACTM used in CTMSIM is explained in [8] and in continuation basic equations are given. Simulation time is divided into K intervals with length Δt. Number of vehicles moving from cell i to cell $i+1$ (or mainstream flow) during interval k can be obtained according to (1):

$$f_{i[k]} = \min\{v_i(1-\beta_{i[k]})\left(n_{i[k]} + \gamma r_{i[k]}\right), w_{i+1}\left(\bar{n}_{i+1} - n_{i+1} - \gamma r_{i+1[k]}\right), F_{i[k]}\}, \quad (1)$$

$$F_{i[k]} \triangleq \min\{\overline{f_i}, \frac{1-\beta_{i[k]}}{\beta_{i[k]}}\bar{s}_i\}, \quad (2)$$

where $\beta_{i[k]}$ denotes split ratio for off-ramp flow, and γ represents on-ramp flow blending coefficient, both from interval [0, 1]. The blending coefficients define amount of traffic flow added or separated from mainstream traffic flow before its value is computed [9]. Furthermore, v_i denotes normalized free flow speed and $n_{i[k]}$ represents number of vehicles (or mainstream density) in cell i at time step $k\Delta t$. The parameter $r_{i[k]}$ denotes number of vehicle entering cell i, from its associated on-ramp at time step $k\Delta t$, while w_{i+1} represents normalized congestion speed in cell $i+1$. $F_{i[k]}$ denotes congested flow which leaves cell i, and $\overline{f_i}$ represents mainline capacity of cell i while $\bar{s}_i$ denotes off-ramp capacity in cell i. On-ramp flow values are now determined with constraints given by:

$$r_{i[k]} \leq l_{i[k]} + d_{i[k]}, \quad (3)$$

$$r_{i[k]} \leq \vartheta_i(\bar{n}_i - n_{i[k]}), \quad (4)$$

$$r_{i[k]} \leq c_{i[k]}, \quad (5)$$

where $l_{i[k]}$, denotes number of vehicles queuing in the on-ramp in cell i at time $k\Delta t$, and $d_{i[k]}$ represents demand for on-ramp in cell i. The parameter $c_{i[k]}$ denotes value of metering rate computed by the chosen ramp metering algorithm, while ϑ_i denotes on-ramp allocator parameter. On-ramp flow (metering rate) that can be merged with mainstream is obtained by:

$$r_{i[k]} = \min\{l_{i[k]} + d_{i[k]}, \vartheta_i\left(\bar{n}_i - n_{i[k]}\right), c_{i[k]}\}. \quad (6)$$

Equation (7) describes computation of off-ramp flow in cell i during time interval k:

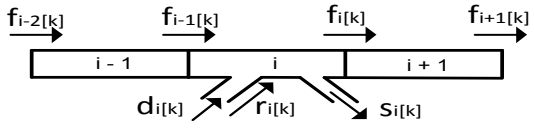

Figure 3. Basic ACTM architecture [9]

$$s_{i[k]} = \frac{\beta_{i[k]}}{1-\beta_{i[k]}} f_{i[k]}. \quad (7)$$

Mainstream density in the cell *i* during interval *k+1* can be computed from mainstream conservation equation:

$$n_{i[k+1]} = n_{i[k]} + f_{i-1[k]} + r_{i[k]} - f_{i[k]} + s_{i[k]}. \quad (8)$$

Mainstream speed in the cell *i* is obtained according to the following equation:

$$v_i^c = \min\left(\frac{f_{i[k]}/(1-\beta_{i[k]})}{n_{i[k]}+\gamma r_{i[k]}}\left(\frac{L_i}{\Delta t}\right), v_i^{ff}\right), \quad (9)$$

where v_i^{ff} represents free flow speed value for cell *i,* and L_i denotes length of cell *i*.

V. AUGMENTATION OF CTMSIM

In order to simulate cooperative ramp metering control, additional high level traffic control framework was developed as augmentation of the original CTMSIM simulator as presented in Fig. 4. The ACTM equations are modified to enable definition of a speed limit value for each cell separately.

A. Cooperative ramp metering module

In order to simulate cooperative highway control systems first step in CTMSIM augmentation was to enable cooperation in ramp metering. This is enabled through the cooperative ramp metering module. As it can be seen in the bottom part of Fig. 4 the original CTMSIM simulation sequence goes only through defined cells in a particular time step. In the proposed augmentation, additional simulation step is added at end of each time step. It is computed after all cells have been simulated. This additional simulation step is related to the cooperative ramp metering module and it has access to data from all cells so it can compute optimal local ramp metering rates and VSLC values used in the next time interval *k*.

First task of this cooperative ramp metering module is to monitor traffic conditions at every on-ramp during simulation. If critical density is exceeded in a current simulation time step, the central monitor module marks this cell's on-ramp as the "master" on-ramp. Metering rate at the "master" on-ramp is then decreased by 10 % of current traffic demand. Three upstream cells with on-ramps of the "master" on-ramp are declared as "slave" on-ramps. Metering rate at the "slave" on-ramps are decreased by 40 % of current traffic demand what creates virtual queues on them.

Second task of cooperative module is to enable override possibility for every metering rate, previously

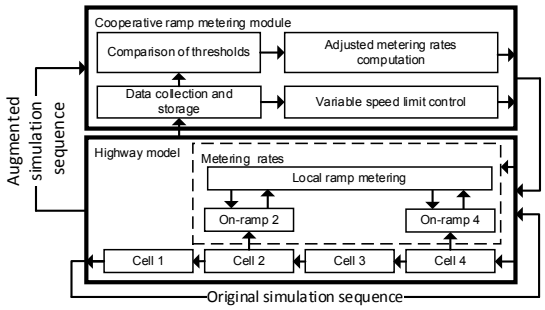

Figure 4. Augmented CTMSIM simulation structure

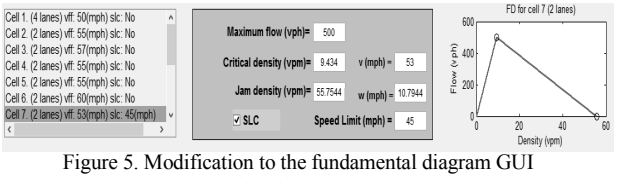

Figure 5. Modification to the fundamental diagram GUI to include the SLC option

computed by a local ramp metering algorithm. This feature is important for the HELPER algorithm which firstly computes metering rates for each on-ramp based on a local algorithm and then uses the cooperative module to obtain the final ramp metering value for each on-ramp.

B. Speed limit module

Second modification of CTMSIM involves implementation of SLC for every cell in the simulation model. SLC is implemented through modification of the cell mean speed equation given with (9) into:

$$v_i^c = \min\left(v_i^{SLC}, \frac{f_{i[k]}/(1-\beta_{i[k]})}{n_{i[k]}+\gamma r_{i[k]}}\left(\frac{L_i}{\Delta t}\right), v_i^{ff}\right), \quad (10)$$

where v_i^{SLC} denotes the current SLC value for *i*-th cell. SLC value must be lower than free flow speed value of the current cell. Original CTMSIM traffic fundamental diagram GUI is modified for definition of SLC parameters as presented in Fig. 5.

VI. SIMULATION RESULTS

To test the CTMSIM augmentations, different simulation scenarios were defined. Each traffic scenario includes increased traffic demand at the on-ramp in cell 6. Such scenario enables a simulation environment to test cooperative highway control strategies when congestion starts to build up. Obtained simulation results are divided into three groups. First group of simulation results contains comparative analysis of local ramp metering algorithms. Analysis is conducted using the following ramp metering algorithms: local (ALINEA), competitive (SWARM) and cooperative (HELPER). For comparison, simulation scenario without ramp metering control is also added to the analysis. Second group of simulation results are addressed to VSLC validation. Third simulation group presents cooperation of VSLC with the HELPER ramp metering algorithm.

A. Zagreb bypass and traffic flow data

Urban highway section between the nodes Jankomir and Lučko on the Zagreb bypass is selected to be the simulation use case model. Mentioned section contains 70 % traffic generated by the nearby town Zagreb [10]. Additionally, this section has increased traffic load during the whole day and also experiences a significant effect from daily migrations. Traffic demand for every on-ramp on this section is reconstructed according to Ljubljana bypass traffic flow data, since accurate hourly traffic flow data for the Zagreb bypass are not available. For this reconstruction Zagreb bypass average daily traffic flow from [10] and Ljubljana daily flow change characteristic were used. Graphical presentation of the ACTM model of highway section between nodes Jankomir and Lučko is presented in Fig. 6. Green colour represents on-ramps and blue colour off-ramps. First cell is denoted yellow.

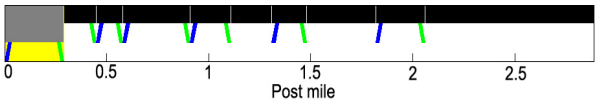

Figure 6. ACTM model of section between nodes Jankomir and Lučko

B. *Cooperation between on-ramps*

In order to compare obtained simulation results appropriate LoS measures have to be used. LoS measures used in this analysis are: travel time (TT) and delay. TT is a simple LoS measure which gives information how much time one vehicle needs to travel through observed highway segment. This measure is used to observe throughput of mainstream in the same time ignoring queues at on-ramps. TT is measured in minutes. Delay is defined as the difference between the actual time spent by all vehicles on a congested highway and the time spent in case they have travelled at free flow speed. Delay also considers vehicles which are waiting in on-ramp queues or in mainstream queues caused by the bottlenecks. It is measured in vehicle-hours.

Results of LoS analysis are shown in Tab. I. According to Tab. I. among the stand-alone ramp metering algorithms, cooperative algorithm HELPER has achieved best TT due to its restrictive nature. Lowest delay was achieved in the simulation scenario without ramp metering. In this basic scenario the blending coefficient γ was set to 1. This means that all vehicles from the on-ramps are immediately merged with mainstream under the condition that in a current cell maximal mainstream capacity is not exceeded. Such behaviour induces smaller on-ramps queues but significantly increases traffic density of mainstream which also increases average TT. These specific behaviours can be seen in Figs. 7 and 8.

HELPER maintains increased mainstream throughput by distributing vehicles and consequently the waiting time to the "slave" on-ramps queues. This behaviour causes longer queues at particular "slave" on-ramps increasing the delay, respectively. Additionally, "slave" on-ramps decrease the number of incoming vehicles from the upstream on-ramps regarding the current bottleneck location. This reduces impact of congestion back-propagation on the mainstream throughput which consequently decreases TT.

C. *Variable speed limit control*

Firstly, VSLC is analysed as a standalone highway traffic control strategy. Analysis includes comparison of simulation results obtained without and with applied VSLC at the same highway simulation model. VSLC is applied in the cells 2, 5 and 6. Main goal of VSLC is to

TABLE I. Results of cooperative analysis between different traffic control algorithms

Traffic control algorithm	TT (min)	Delay (vehicle-hour)
None	7.06	15.87
ALINEA	3.90	36.88
SWARM	3.71	41.49
HELPER	3.40	22.63
VSLC	5.59	12.24
HELPER + VSLC	3.30	21.50

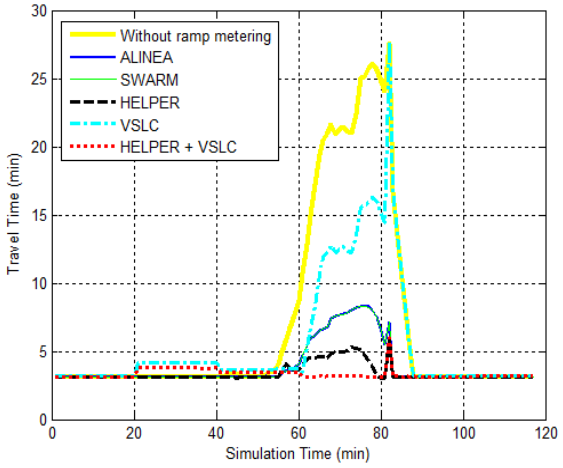

Figure 7. Results of comparative analysis according to travel time

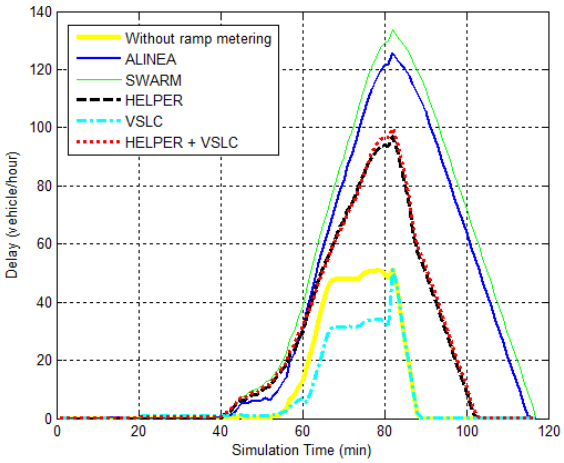

Figure 8. Results of comparative analysis according to delay

gradually decrease speed of the upstream flow before congestion starts. Such approach firstly gradually decreases mainstream speed, but enables higher mainstream speed during the congestion period unlike the scenario without VSLC.

Analysis of mainstream speeds can be seen in Fig. 9. VSLC prevented traffic standstill during most of the congested period. VSLC produces vehicle platoons which are traveling at lower speeds in comparison to the free flow speed by decreasing mainstream speed. This impacts the process of mainstream congestion back-propagation. From Fig. 10 it is possible to notice that mainstream density is lower at upstream cells of the congested cell 6

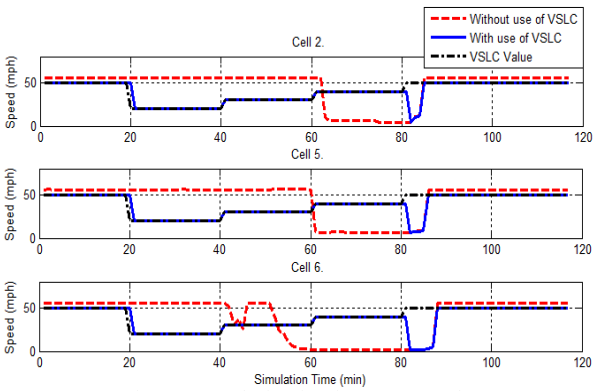

Figure 9. Analysis of mainstream speed with and without VSLC

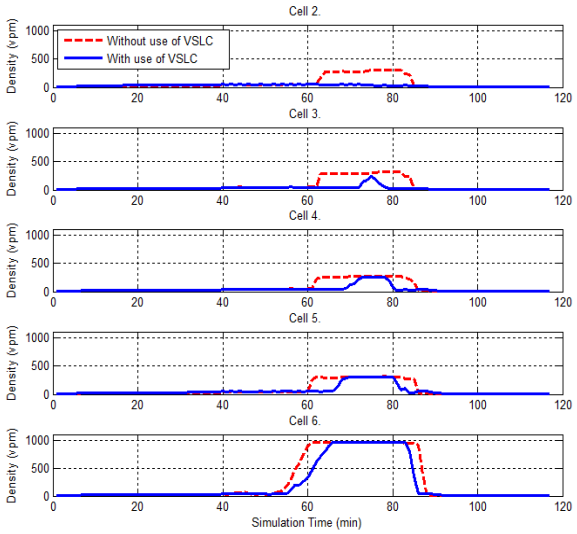

Figure 10. Analysis of mainstream density with and without the use of VSLC

with VSLC in contrast to the situation without VSLC.

D. Cooperation between on-ramps and VSLC

In this scenario cooperation between HELPER ramp metering algorithm and VSLC is simulated. Results of comparative analysis presented in Figs. 7 and 8 show that cooperation between HELPER ramp metering algorithm and VSLC produces smallest TT. VSLC decreases mainstream speed starting in the cell before the last "slave" on-ramp cell and ending in the congested cell. This decreases speed of the incoming vehicles to the area between last "slave" on-ramp and congested cell. Decreased speed of mainstream vehicles contributes to the lower values of density in the area between congested and last "slave" on-ramp. It can be concluded that virtual queues provided by cooperation between HELPER and VSLC significantly reduce traffic density upstream of the congested on-ramp. Lower upstream density of the congested on-ramp leaves additional mainstream capacity to accept vehicles which have origin from congestion back-propagation.

HELPER, as the standalone ramp metering algorithm and cooperation between HELPER and VSLC produce similar values of delay. The reason for such results is HELPER's reduction of metering rate on the "slave" on-ramps in order to reduce mainstream density upstream of the congested on-ramp. VSLC as the part of HELPER and VSLC cooperation does not have a strong influence on the delay as in the case of TT due to lower mainstream density. It can be concluded that VSLC has lower influence on delay if the mainstream density is decreased by HELPER exploitation of on-ramp queues. Standalone VSLC produces better delay results because of higher value of mainstream density. Other ramp metering algorithms produce higher values of delay due to higher number of vehicles in the congested on-ramp queue.

VII. Conclusion And Future Work

In this paper cooperative systems simulation in traffic control is tackled. Possibilities of cooperative control application in urban highway management are described. Cooperation between on-ramps in ramp metering, and between ramp metering and VSLC are chosen as most common systems. Simulation requirements are explained and framework for macroscopic highway traffic simulator CTMSIM augmentation is proposed. Proposed framework includes additional simulation step for cooperative control computations (between on-ramps and between ramp metering and VSLC) and augmentation of the ACTM highway model to include SLC. Both traffic control systems can be used as standalone or in cooperation.

To test implemented CTMSIM augmentations the ramp metering algorithm HELPER and VLSC are used. Simulations verify operational work of the proposed cooperative framework. All simulations are made using part of Zagreb bypass, the segment between nodes Lučko and Jankomir. Simulation results show that cooperation between VSLC and cooperative ramp metering provides best TT and delay values in comparison with other ramp metering algorithms involved into analysis.

Future work will include implementation of additional cooperative ramp metering algorithms and an optimization algorithm for cooperation between ramp metering and VSLC.

Acknowledgment

The research reported in this paper is partially funded by the FP7 - Collaborative Project: Intelligent Cooperative Sensing for Improved traffic efficiency - ICSI (FP7-317671) and by the EU COST action TU1102. Authors wish to thank Nikola Bakarić for his valuable comments.

Abstract - This paper reports the results of a system based on hidden Markov models (HMM) that is used to interpret both static and dynamic divers' hand signals using real time video feed. Two methods of collecting features that describe diver gestures are described and two types of HMMs are investigated: one based on discrete outputs variable distribution and the other based on mixture of Gaussians outputs variable distribution. For 8 basic diver gestures, 800 data samples were collected and the results were analyzed for the purpose of determining the most appropriate *i)* feature vector describing diver gestures, *ii)* HMM parameters (number of states and mixture components), and *iii)* type of the hidden Markov model. Finally, the quality of performance for recognition of each gesture is evaluated and analyzed, and necessary steps for improving the overall system are reported.

I. INTRODUCTION

Divers operate in a very challenging environment where even the slightest unexpected situation can have catastrophic results. Professional divers are usually involved in risky underwater operations some of which include surveying a part of a seabed (search and recovery missions), collecting samples (marine biology missions), documenting a site (marine archaeology missions) or performing inspections of underwater facilities (underwater inspection and maintenance missions). Having in mind the dangers that divers are exposed to during their activities, in the last couple of decades, underwater robots are being put to use more frequently. However, application of autonomous underwater vehicles or remotely operated vehicles still cannot completely replace a human diver, especially during highly sophisticated operations such as intervention, repair, etc.

The FP7 CADDY project (Cognitive Autonomous Diving Buddy) recognizes the necessity for a human diver and has a goal to develop a multicomponent robotic system, consisting of a surface autonomous marine platform and an autonomous underwater vehicle that will help divers during their underwater activities by performing a role of a diver "guide" (leading the diver through the underwater), diver "observer" (monitoring diver behaviour), and diver "slave" (helping the diver perform different set of tasks). In order to achieve these roles, establishing a communication channel between the diver and the buddy robot is of high importance. Since divers usually communicate using a predefined set of hand gestures, it is natural to use the same symbolic language as means of communication between divers and robots underwater.

Gesture recognition is an intriguing research area and different methods such as hidden Markov models (HMM), conditional random fields, particle filtering and condensation, finite-state machine as statistical modeling, optical flow, skin colour, connectionist model, etc. are being investigated, [5]. Among these methods, HMM has proved to be the most frequent tool, [2-7]. It has been successfully applied for spatial-temporal processes such as speech recognition [2], protein modeling [6] and gesture recognition [4].

This paper focuses on the application of the HMMs for interpretation of divers' hand signals using real time video feed. In this paper, we use the output mixed Gaussian distribution in HMM to improve the recognition rate.

The paper is organized as follows. The continuing part of Section II briefly describes the image processing system used to obtain gesture features. Section III focuses on the HMM theoretical background directly related to the applied approach. Section IV gives details on the specific problem of interpreting diver gestures and Section V describes experiments and provides analysis of the results. The paper is concluded with Section VI.

II. IMAGE PROCESSING SYSTEM

The image processing system has been mostly adopted from the publicly free-to-use system described in [1]. The software locates important hand features accurately and increases recognition tolerance to different hand rotations and tilt. A feature vector provided by the software as output includes three components: x and y coordinates of the palm center in the video frame, and the number of fingers that are stretched out and currently visible. All three of the mentioned features are of high importance for gesture recognition.

The research leading to these results has received funding from the European Union Seventh Framework Programme under FP7-ICT project "CADDY - Cognitive Autonomous Diving Buddy" Grant Agreement Number: 611373.

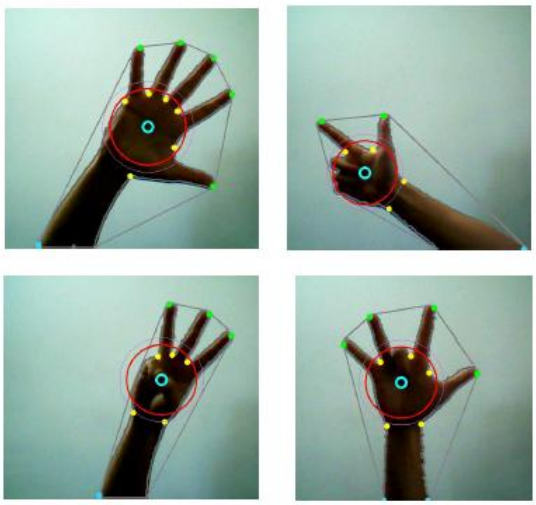

Figure 1. Snapshots from [1] showing hand images as recognized by the image processing system.

The software takes an RGB image captured by a web camera as an input and processes it to generate a binary image which provides enough information of hand contour. The binary image is used to calculate the contour and the convex hull of the contour. The palm position can be initially estimated by the information extracted from convex hull, and the fingertips' position can be detected from the hand contour. Examples of the results obtained from the image processing software are shown in Fig. 1.

III. HIDDEN MARKOV MODELS

Here we briefly review the theory of hidden Markov models (HMM) and some problems related to HMM training and human gesture recognition. Detailed description of the conventional HMM can be found in [2].

HMM is a statistical Markov model in which the system being modelled is assumed to be a Markov process with unobserved (hidden) states. HMM is characterized with *N* (number of states in the model, where individual states are denoted as *S*), *M* (the number of distinct observation symbols by state, where individual symbols are denoted as *V*) and $\lambda = (A, B, \pi)$ where,

$A = \{a_{ij}\}$ is the state transition matrix with

$$a_{ij} = P\left[q_{t+1} = S_j | q_t = S_i \right], \quad 1 \le i, j \le N , \quad (1)$$

$B = b_j(k)$ is the observation symbol probability distribution

$$b_j(k) = P\left[v_{k,t} | q_t = S_j \right], \quad 1 \le j \le N ; 1 \le k \le M , \quad (2)$$

and $\pi = \{\pi_i\}$ is the initial state distribution

$$\pi_i = P\left[q_1 = S_i \right], \quad 1 \le i \le N \quad (3)$$

where $S = \{S_1, S_2, \ldots, S_N\}$ is a set of states, q_t is a state at time *t*, and $V = \{v_1, v_2, \ldots, v_M\}$ is a set of symbols.

Given the observation sequence $\boldsymbol{O} = O_1 O_2 \ldots O_T$ and a model $\lambda = (A, B, \pi)$, the task is to efficiently compute the probability of the observation sequence $P(O | \lambda)$ with the given model (Problem 1), and to adjust the model parameters $\lambda = (A, B, \pi)$ to maximize $P(O | \lambda)$ (Problem 2).

The observation symbol probability distribution $P\left[v_{k,t} | q_t = S_j \right]$ can consist of discrete symbols or continuous variables. If the observations are discrete symbols, the observation model can be represented as a matrix in the form

$$B(i,k) = P\left[v_{k,t} | q_t = S_i \right]. \quad (4)$$

If the observations are vectors, it is common to represent $P(O_t | q_t)$ with a Gaussian:

$$P\left[v_{x,t} | q_t = S_i \right] = N\left(\boldsymbol{x} | \boldsymbol{\mu}, \boldsymbol{\Sigma} \right) \quad (5)$$

$$N\left(\boldsymbol{x} | \boldsymbol{\mu}, \boldsymbol{\Sigma} \right) = \frac{1}{\sqrt{(2\pi)^d}\sqrt{|\boldsymbol{\Sigma}|}} e^{-\frac{1}{2}(\boldsymbol{x}-\boldsymbol{\mu})^T \boldsymbol{\Sigma}^{-1}(\boldsymbol{x}-\boldsymbol{\mu})} . \quad (6)$$

A more flexible representation is a mixture of M Gaussians

$$P\left[v_{x,t} | q_t = S_i \right] = \sum_{m=1}^{M} P\left[M_t = m | q_t = S_i \right] \times N\left(x_{m,i} | \mu_{m,i}, \Sigma_{m,i} \right) \quad (7)$$

where M_t is a hidden variable that specifies which mixture component to use and $P\left[M_t = m | q_t = S_i \right] = C(i,m)$ is conditional prior weight of each mixture component. In our approach, we implement both discrete and mixture of Gaussians outputs variable distribution.

A. Solution to Problem 1

In order to calculate the probability of the observation sequence $\boldsymbol{O} = O_1 O_2 \ldots O_T$ with the given model $\lambda = (A, B, \pi)$ the most straightforward way of doing this is through enumerating every possible state sequence of length *T* (the number of observations), but fortunately there is more efficient procedure called *forward-backward* procedure. Solving this problem will provide us with the answer how to successfully recognize which trained HMM model (trained gesture) is the closest match to our observation sequence (gesture).

The general approach will be to iteratively update the weights. We do this by defining

$$\alpha_t(i) \triangleq P(\boldsymbol{o}_1 \boldsymbol{o}_2 \ldots \boldsymbol{o}_t, \; q_t = S_i) \text{ and} \quad (8)$$

$$\beta_t(i) \triangleq P(\boldsymbol{o}_{t+1} \boldsymbol{o}_{t+2} \ldots \boldsymbol{o}_T | q_t = S_i) \quad (9)$$

where $\alpha_t(i)$ is the probability that model is in state q_i at step *t* having generated the first *t* elements of sequence $\boldsymbol{O}$, and $\beta_t(i)$ is the probability that the model is in state $q_i(t)$ and will generate the remainder of the given target sequence, i.e., from $t+1 \to T$.

We can solve both for $\alpha_t(i)$ and $\beta_t(i)$ inductively (initialization – (10) and (12), induction – (11) and (13), and termination – (14)) :

$$\alpha_1(i) = \pi_i \cdot b_i(\boldsymbol{o}_1), \quad 1 \le i \le N \tag{10}$$

$$\alpha_{t+1}(j) = \left[\sum_{i=1}^{N} \alpha_t(i)\, a_{ij}\right] b_j(\boldsymbol{o}_{t+1}), 1 \le t \le T-1, 1 \le j \le N \tag{11}$$

$$\beta_t(i) = 1, \quad 1 \le i \le N \tag{12}$$

$$\beta_t(i) = \sum_{j=1}^{N} a_{ij} b_j(\boldsymbol{o}_{t+1})\, \beta_t(j), \; 1 \le t \le T-1, 1 \le j \le N \; . \tag{13}$$

We can also derive

$$P(O|\lambda) = \sum_{i=1}^{N} \alpha_T(i) = \sum_{i=1}^{N} \beta_1(i) = \sum_{i=1}^{N} \beta_t(i)\, \alpha_t(i) \; . \tag{14}$$

B. Solution to Problem 2

The most difficult task is to adjust the model parameters $\lambda = (A, B, \pi)$ to maximize $P(O \mid \lambda)$ because given any finite observation sequence as training data there is no optimal way of estimating the model parameters. This is the main issue when training specific HMM models for a specific gesture. But we can choose the model parameters so that $P(O \mid \lambda)$ is locally maximized using the *Baum-Welch* procedure (part of the expectation-maximization method).

First we define the probability of being in state S_i at time *t*, and state S_i at time *t+1* , given the model and observation sequence, i.e.,

$$\xi_t(i, j) = P(q_t = i, q_{t+1} = j | \boldsymbol{O}, \lambda) \; . \tag{15}$$

From definition of the forward-backward algorithm, we can rewrite $\xi_t(i, j)$ in the form:

$$\begin{aligned} \xi_t(i, j) &= \frac{P(q_t = i, q_{t+1} = j | \boldsymbol{O}, \lambda)}{P(\boldsymbol{O}|\lambda)} = \\ &= \frac{\alpha_t(i)\, a_{ij} b_j(\boldsymbol{o}_{t+1})\, \beta_{t+1}(j)}{P(\boldsymbol{O}|\lambda)} = \\ &= \frac{\alpha_t(i)\, a_{ij} b_j(\boldsymbol{o}_{t+1})\, \beta_{t+1}(j)}{\sum_{i=1}^{N}\sum_{j=1}^{N} \alpha_t(i)\, a_{ij} b_j(\boldsymbol{o}_{t+1})\, \beta_{t+1}(j)} \end{aligned} \tag{16}$$

and the probability of being in state S_i at time *t* :

$$\gamma_t(i) = \sum_{j=1}^{N} \xi_t(i, j) \tag{17}$$

It has been proven by Baum et al. in [11] that maximization of $Q(\lambda, \bar{\lambda})$ over $\bar{\lambda}$ leads to increased likelihood (19) what leads to the estimation of an HMM.

$$Q(\lambda, \bar{\lambda}) = \sum_{Q} P(Q|O, \lambda) \log\left[P(Q, O|\bar{\lambda})\right] \tag{18}$$

$$\max_{\bar{\lambda}}[Q(\lambda, \bar{\lambda})] \Rightarrow P(O|\bar{\lambda}) \ge P(O|\lambda) \tag{19}$$

A set of reasonable re-estimation formulas for A, B and π are:

$$\bar{a}_{ij} = \frac{\text{no. of transitions from state } S_i \text{ to } S_j}{\text{no. of transitions from state } S_i} = \frac{\sum_{t=1}^{T-1} \xi_t(i, j)}{\sum_{t=1}^{T-1} \gamma_t(i)} \tag{20}$$

$$\bar{b}_j = \frac{\text{no. of times in state } j \text{ and symbol } \boldsymbol{v}_k}{\text{no. of times in state } j} \tag{21}$$

where $\bar{\pi}(i) = \gamma_1(i)$ is expected frequency in state S_i at time $t = 1$.

In other words if we define the reestimated model $\bar{\lambda} = (\bar{A}, \bar{B}, \bar{\pi})$, computed using (20) and (21), we have found a new model from which the observation sequence is more likely to have been produced. If we iteratively use $\bar{\lambda}$ instead of λ and repeat the estimation calculation, we can then improve the probability of the observation sequence from the model until some limiting point is reached.

IV. SYSTEM IMPLEMENTATION

In this section, we present details of our proposed model, applied to recognize 8 prime diver hand signals, as shown in Fig. 2.:

"Look at me" – static gesture with two fingers straight up pointing to eyes,

"I have a cramp" – dynamic gesture with the fingers bending to and from the palm,

"Going up" – static gesture with a thumb pointing up,

"Running out of air" – dynamic gesture with an open palm facing down and moving left and right,

"Turn around" – dynamic gesture with one finger pointing up and making a circle in the horizontal plane

"Danger" – extended arm with open palm moving left and right,

"Slow down" – dynamic gesture with an open palm facing down and moving up and down

"Stop" – static gesture with an open palm and fingers together pointing up.

A simplified scheme of the envisioned approach is given in Fig. 3. The first step is to detect the hand from the sequence of image frames. Using the image processing system the hand is recognized and the hand feature vector is obtained for the training and recognition process. The image processing system only extracts hand features when the hand is detected, therefore reduces the computation load when the hand is not detectable.

In this paper we observed HMM models that use two different feature vectors. In the first case, the feature vector, an observation in HMM, includes 3 components:

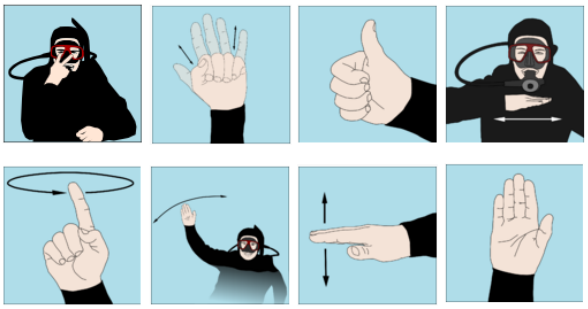

Figure 2. Diver hand signals used in the paper: "Look at me", "I have a cramp", "Going up", "Running out of air", "Turn around", "Danger", "Slow down" and "Stop" (source: Wikipedia)

$$O = (x, y, \text{number of fingers})$$

where x and y are coordinates of the palm centre in the video frame and the third component is the number of fingers stretched out and currently visible. This feature vector is given directly from the image processing system. In the second case, the feature vector includes two components:

$$O = (\text{orientation, number of fingers})$$

where the second component is the same as the third component in the first feature vector and the first component is orientation feature. The orientation is determined between two consecutive points from hand gesture path, using

$$\theta_t = \arctan\left(\frac{y_{t+1} - y_t}{x_{t+1} - x_t}\right) \quad t = 1, 2, \ldots T-1 \qquad (22)$$

where T represents the length of gesture path. The orientation θ_t is quantized in segments of 20° in order to generate codewords from 1 to 18.

As a part of research presented in this paper, we implemented three different training models, to test their efficiency and, based on the experimental results, choose the best among them. The models are chosen based on the form of the feature vector (three or two component feature vectors) and also on the type of output (and input) for the HMM (discrete or mixture of Gaussians outputs variable distribution). The models that have been taken into account are listed in Table I.

V. EXPERIMENTAL RESULTS

The experiments were conducted in such a way that for each of the 8 diver gestures reported in the previous section, 100 video samples were taken and used for the training dataset. For each sample, a total of 36 images were taken with the camera during a period of around four seconds (camera has a rate of 8.6 fps), meaning that every gesture is described using 36 feature vectors extracted from the images. All the experiments were implemented in Visual C++ (using OpenCV library) and Matlab R2009a. The used camera was a Truevision webcam (640x480 pixel image resolution).

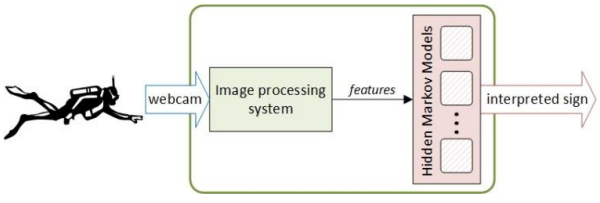

Figure 3. System scheme

TABLE I. HMM TYPES USED IN ANALYSIS

MODEL SHORT NAME	NO. OF COMPONENTS IN FEATURE VECTOR	OUTPUT TYPE
MG-2	2	mixture of Gaussians outputs variable distribution
D-3	3	discrete outputs variable distribution
D-2	2	discrete outputs variable distribution

The HMM parameters are derived through the training process. The training loop was programmed to end either when the maximum number of iterations has been achieved (5 in this particular case) or when the logarithm of likelihood does not increase.

This extensive set of collected data was used to determine the most reliable HMM model that can be used to determine diver gestures. To evaluate our approach overall, we carried out the following analysis from the obtained data:

- The first analysis aims to determine whether the recognition rate is higher using a model based on 3 or 2 component feature vector.
- The second analysis is to determine the best number of states and/or mixed Gaussians and to compare the recognition rate of the models in regards of their outputs variable distribution, whether it is mixture of Gaussians or discrete.

A. *First analysis – choosing the feature vector*

In order to determine whether the proposed feature vector containing two (orientation of motion and number of fingers) or three (hand position and number of fingers) components gives better performance, models D-2 and D-3 with discrete outputs variable distribution were observed. For the sake of generalization, multiple experiments were analyzed for the cases with different number of states Q. The results are shown in Fig. 4.

As the experiment shows, regardless of the number of states, better recognition is achieved using the D-2 model. The recognition rate using the D-2 model is around 50%,

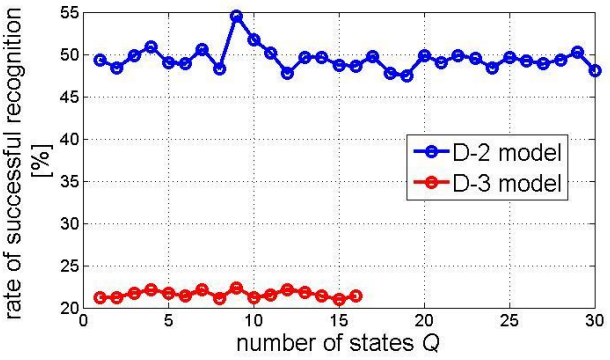

Figure 2. Rate of successful recognition for D-2 and D-3 models.

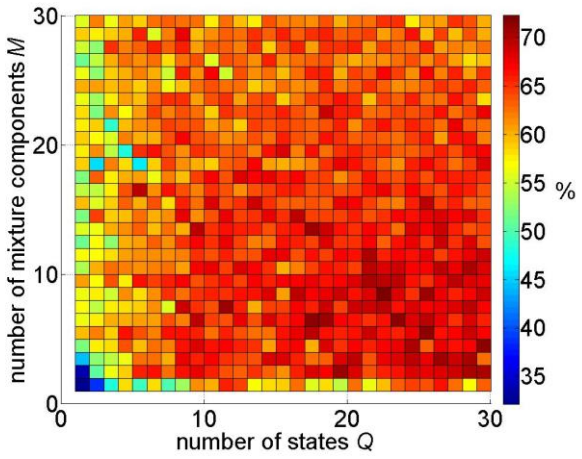

Figure 3. Rate of successful recognition for the MG-2 model.

peaking at 54% with a HMM with 9 states, where for the same number of states the recognition rate for the D-3 model is barely above 22%, with an average 21.5%.

The conclusion raised from this experiment is that models using two-component feature vector give significantly better results.

B. *Second analysis – choosing the number of states and/or number of mixture components, and outputs variable distribution*

This experiment was performed in order to determine which model has better performance relative to the output variable distribution, the one that uses discrete or mixture of Gaussians. Models D-2 and MG-2 were tested. These two models significantly depend on the model parameters.

The D-2 model depends on the number of states Q. As it was shown in the previous experiment (see Fig. 4), the best recognition rate of 54% was obtained with Q=9.

The MG-2 model, on the other hand, depends on two parameters: M – the number of mixture components and Q – the number of states. Both parameters were varied in the region from 1 to 30. The results of recognition rate are shown in Fig. 5. The MG-2 model has produced a recognition rate of 72%, improving the recognition rate of the D-2 model by almost 20%. It is clear from Fig. 5 that better results are acquired for a higher number of states and the number of mixtures being around 10.

C. *Full diver symbol verification*

The previous analysis has shown that the best results are obtained using a mixed Gaussian HMM model with M=8 and Q=22. For the sake of full verification of the system, we performed verification of the model for all 8 gestures. The comparison between the D-2 and MG-2 model is summarized in Table II and Table III where rows represent the commanded gesture, and the columns are the interpreted gesture. For the sake of clarity, we entered only the values for the dominant interpretation.

In the case of D-2 model, the gesture "Slow down" appears most often as an interpretation of the commanded gesture. The reason for this is that during this gesture the whole palm is not visible, therefore the image processing system cannot accurately calculate the position of the hand nor the number of fingers. Gestures "Cramp" and "Stop" are very similar when observing the component orientation. Their main distinguisher should be the component number of fingers, which is, as explained in the image processing system, a component that is not

TABLE III. RATE OF SUCCESSFUL RECOGNITION PER GESTURE FOR THE D-2 MODEL.

		INTERPRETED GESTURE							
		"Look"	**"Cramp"**	**"Going up"**	**"Out of air"**	**"Turn around"**	**"Danger"**	**"Slow down"**	**"Stop"**
COMMANDED GESTURE	**"Look"**							95%	
	"Cramp"		67%						
	"Going up"			33%				40%	
	"Out of air"				50%		37%		
	"Turn around"					70%	28%		
	"Danger"						90%		
	"Slow down"							80%	
	"Stop"		28%					28%	40%

TABLE II. RATE OF SUCCESSFUL RECOGNITION PER GESTURE FOR THE MG-2 MODEL.

		INTERPRETED GESTURE							
		"Look"	**"Cramp"**	**"Going up"**	**"Out of air"**	**"Turn around"**	**"Danger"**	**"Slow down"**	**"Stop"**
COMMANDED GESTURE	**"Look"**	~ 45%							
	"Cramp"		>95%						
	"Going up"			~ 60%					
	"Out of air"				>95%				
	"Turn around"					>95%			
	"Danger"						>95%		
	"Slow down"							~ 70%	
	"Stop"		~ 70%						13%

being accurately calculated and therefore in need of improvement. The gesture “Out of Air”, like the gesture “Danger”, are the only two gestures with left-right movement, and so the model has trouble distinguishing between them. The similar scenario appears for the gesture "Turn Around", since the movement of the hand in a circle trajectory is transferred to a left-right movement on the 2D camera frame. Again, the main distinguisher should be the component number of fingers.

In the case of the MG-2 model, the situation has significantly improved for all gestures except for the "Stop" gesture where the accuracy of interpretation decreased to 13% with the most cases of interpretation as the "Cramp" gesture.

To sum up, while the DP-2 gives somewhat reliable interpretation of only 4 out of 8 trained gestures, the MG-2 model gives high chances of correct recognition for 6 gestures and misinterprets only one gesture.

D. Comments on the experiments

From the presented results, it is clear that the MG-2 model gives the best results, compared to other tested models. However, a few comments should be stated.

During our research, we also covered the ergodic and LR (left-right) HMM. For the ergodic model, a connection can be made between any two different states, while in the LR model only a forward connection can be made, i.e. once a state has been passed it could not be achieved again. Our experiments showed no significant difference between these two models so all above mentioned experiment results are ones achieved using the ergodic model.

Another important parameter in the training of the HMM is initial value of the parameter matrices that have been set to random values in the experiments presented here.

It should also be mentioned that in some cases (e.g. when training the D-3 model with 17 or more states) matrices describing the HMM would become singular and model parameters could not be calculated.

The covariance matrix is another parameter that should be taken into consideration when analyzing the quality of the HMM. There are three different type of covariance matrix: diagonal, spherical and full. Experiments have shown that using the diagonal covariance matrix with more mixture components produced better results in comparison to the full covariance matrix with fewer mixture components. As a result, the diagonal covariance matrix was used and its value was kept constant during the experiments.

VI. CONCLUSIONS

This paper describes a HMM based system for recognizes diver signals from colour video image sequences. Our database contains 100 video sequences for each isolated gesture, as well as 100 test video sequences for each of the 8 prime diver signals.

We have shown that the HMM with the mixture of Gaussians outputs variable distribution and a two component feature vector gives the best performance among the tested models. The results show an average of 72% accuracy.

Although the system showed some good features there is room for improvement. The system is suitable for real-time application, however some modifications and additional research effort has to be invested in order to apply it to the underwater.

In the conducted experiments, the camera was fixed in from of the test subject. Since this methodology has to be applied on a diver, by observing her/him from a moving underwater vehicle, the approach to recognizing gestures had to be changed. Some research on compensation of the observing vehicle movements has been reported in [12]. Our future research will focus on measuring hand motion relative to the divers head, i.e. in the divers coordinate system. It is expected that this would solve the problem of a moving observation underwater vehicle.

Further on, the presented approach will be extended to the detection of dynamic gestures that are performed using both hands, thus extending the interpretation of the diver vocabulary.

In addition to that, we will investigate the possibility of using stereo-cameras and high resolution sonars to obtain the highest possible hand reconstruction quality, thus improving the image processing algorithms.

Abstract – Establishing a cooperative heterogeneous robotic system comprising autonomous vehicles operating in air, on ground and on/under water is a challenging task that can significantly contribute solving complex problems related to environmental monitoring (e.g. prediction, prevention and recovery from natural disasters) and security (e.g. border control, fight against terrorism). This paper presents a short overview of a project that involves cooperative control of heterogeneous robotic systems at the University of Zagreb Faculty of Electrical Engineering and Computing. An overview of the vehicles to be used in the heterogeneous systems is given and the envisioned scenario of neutralization of suspicious underwater objects is presented. Tasks of each vehicle are described and emphasis is placed on the actions and communication routes that are required to ensure cooperative behavior.

I. INTRODUCTION

Heterogeneous robotic systems are systems that comprise mobile robotic units operating on land, in air and on/under water. While individual robotic systems today successfully perform complex tasks in their medium, activities through all three media are imposed by industrial needs as well as in seven societal challenges defined by the European Commission within the Horizon 2020 programme, specifically in the areas of:

1. environment: prediction, prevention and recovery from natural disasters; development of systems for global surveillance and informing about the state of the environment, and

2. security and protection: fight against crime and terrorism; strengthening security through border control; increasing resilience in cases of crisis and disasters.

The primary motivation for research in the areay of cooperative control of heterogeneous robotic systems is to enable sinergy between autonomous unmanned land, air and marine robots for the purpose of accomplishing a joint mission (e.g. surveillance of sea and land borders). The idea of the research is to unite existing robotic systems acting in different media into a unique cooperative heterogeneous system shown in Fig. 1.

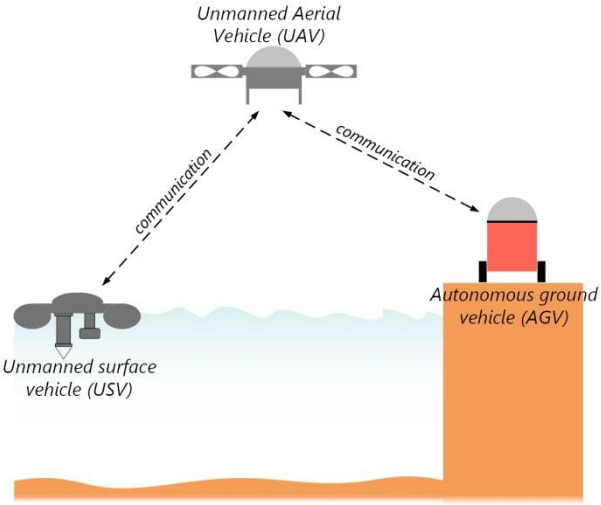

Figure 1. Concept of a cooperative heterogeneous robotic system.

The aim of the proposed research is to develop and experimentally validate cooperative control algorithms that maintain formation comprising three autonomous mobile robots (land vehicle, surface marine vessel and an autonomous aerial craft) and thus ensure their coordination. In order to accomplish this research goal, the following activities have to be performed:

1. Development and implementation of robotic cooperative control algorithms with kinematic and dynamic constraints as well as constraints in the communication channel.

2. Field trials using real robotic systems for the purpose of experimental validation of the developed algorithms and identification of necessary modifications and improvements. The developed algorithms will be tested in a scenario where autonomous robots are moving in a formation in which the aerial craft has a function of ensuring communication channel between the land vehicle and the surface marine platform.

The work described in this paper has been supported by the University of Zagreb as a short term financial support under the contract number 2013-ZUID-19.

Figure 2. Photos of the vehicles comprising the heterogeneous robotic system: a) autonomous surface marine platform (*PlaDyPos* made at UNIZG-FER), b) autonomous aerial vehicle (*ArduCopter Quad* by jDrones) and c) autonomous ground vehicle (*Guardian* by Robotnik) with a manipulator.

II. AUTONOMOUS MOBILE ROBOTS

Mobile robots that will be used are available from three research laboratories from the Faculty of Electrical Engineering and Computing at the University of Zagreb: Laboratory for robotics and intelligent control systems – LARICS (unmanned aerial vehicles), Laboratory for Underwater Systems and Technologies - LABUST (unmanned underwater and surface marine vehicles) and Autonomous Mobile Robotics Group (autonomous land vehicles)

The **unmanned surface vehicle (USV)** is an overactuated platform with 4 thrusters forming the "X" configuration. This thruster configuration enables motion in the horizontal plane under any orientation. The platform has been developed at LABUST and the current version is 0.35m high, 0.707m wide and long, as it is shown in Fig. 2a), and it weighs approximately 25kg. The control computer (isolated from environmental disturbances inside the platform hull) is in charge of performing control and guidance tasks (dynamic positioning, path following, diver following) and all the data processing. Apart from the compass, batteries and CPUs, the platform is equipped with a GPS for determining the platform position, Ultra-Short Baseline (USBL) used to determine the position of the diver relative to the platform, a wireless modem used to transmit data from the platform to the surface station. The platform has been primarily developed for the purpose of diver tracking, [1]. More information on the characteristics of the platform can be found in [2].

Due to its simple mechanical design and open-source software, **unmanned aerial vehicle (UAV)** *ArduCopter Quad*, from jDrones company, shown in Fig. 2b) is one of the most popular aerial platforms with 4 propellers. Electronics, designed around Arduino processor, comprise complete set of sensors and features – 6 Degree of Freedom IMU stabilized control, gyro stabilized flight mode enabling acrobatics (loops and barrel rolls), magnetometer for heading determination, barometer for altitude hold, IR sensor integration for obstacle avoidance, and sonar sensor for automated takeoff and landing capability. Sophisticated control algorithms allow mounted camera stabilization. Ground station software modules provide automated waypoint navigation and wireless command & telemetry for long distance communication with real-time graphs of flight data. On board flight telemetry data storage can be used as well. This vehicle has recently been used to test hybrid adaptive control for aerial manipulation, [3].

The **autonomous ground vehicle (AGV)** is a *Guardian* produced by Robotnik from Spain, specially designed for applications in the domains of safety, inspection, research, and the high level of mobility allows it to move in rough and inaccessible terrain (stairs, slopes, etc.). The vehicle has an embedded computer with Linux OS that can be connected to either wirelessly or via etherner. The complete programming platform is based on ROS (Robot Operating System) that allows easy extension if the vehicles capabilities. Fig. 2c) shows the Guardian vehicle with a Powerball manipulator and a tool, both produced by a German company Schunk.

III. SCENARIO DESCRIPTION

The scenario that has been chosen for the demonstration of the cooperative heterogeneous robotic system is neutralization of unexploded underwater ordnance (UxO) which is an extremely dangerous and destructive activity since an underwater explosion has a destruction radius much higher relative to the one on land. The scenario does not deal with the neutralization process itself (defusing the UxO) but rather with handling the UxO and transporting it to a safe location. The proposed scenario can significantly contribute to expelling UxOs to the surface and taking them to a safe place on land autonomously, without human intervention or with limited intervention from a safe distance.

The proposed procedure is described in the following steps:

- Step 1: Attaching and activation of the self-inflatable balloon to the underwater object

A diver or a remotely operated underwater vehicle (ROV) attaches a balloon that can be inflated either by using acoustic activating signal from a safe distance, or by using a timer. Once the diver or ROV are at a safe distance, the balloon is inflated and the unknown dangerous object emerges to the surface. The balloon can optionally emit GPS coordinates so the location of the

UxO is known with a precision of a couple of meters radius.

- Step 2: Positioning the heterogeneous cooperative robotic system

The unmanned surface vessel (USV) and the unmanned aerial vehicle (UAV) that hovers above the USV, go to the location where the UxO is positioned.

- Step 3: Tugging the UxO to land

The USV followed by the UAV tugs the UxO to the location on land, next to the sea line, where the autonomous ground vehicle (AGV) with a robotic manipulator is located.

- Step 4: Autonomous ground vehicle takes the UxO

The AGV, equipped with a manipulator, takes the object out of the sea and carries it to a safe location where neutralization can be performed.

As a part of the proposed experiment, the following simplified mission will be executed. The mission is explained from the perspective of each individual vehicle.

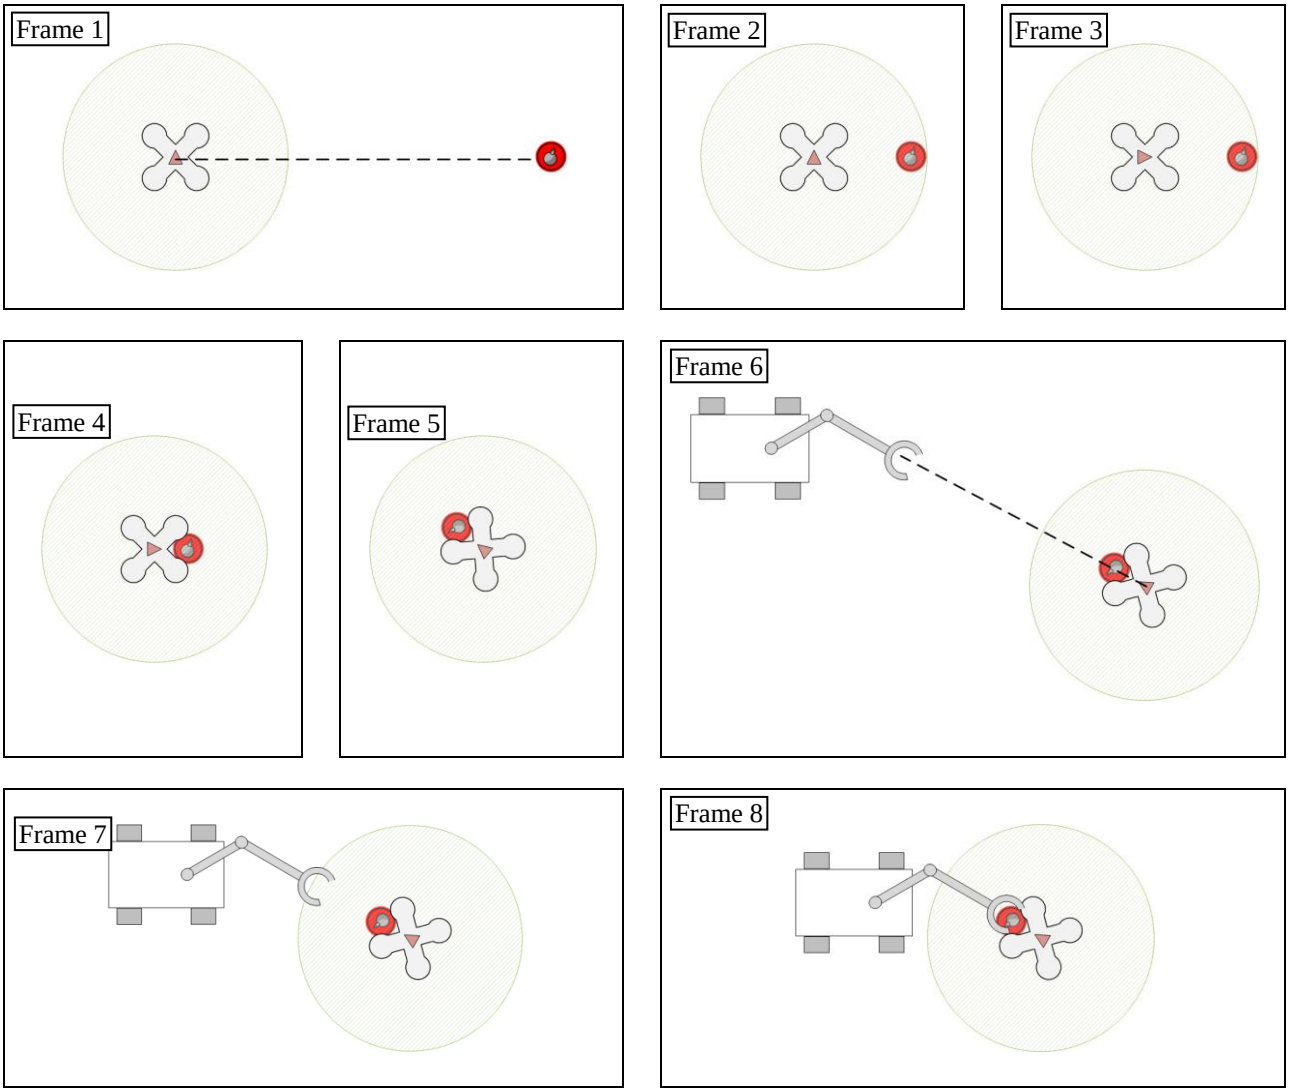

Figure 3. The scanario execution shown in time frames. The gren circle around the USV shows the dowwards field of view of the UAV hovering above the USV. Red circle represents the UxO.

A. The USV mission states

The USV mission states are comprised of the following elementary maneouvres: dynamic positioning (DP), heading control, and line following. Detailed description of the implemented algorithms used to execute these maneouvres can be found in [4], [5].

The following five states are executed sequentially.

1. Initial dynamic positioning (DP)

The USV dynamically positions around a predefined point A until the UAV receives the information about point B where the object (UxO) is located. The transition to the following mission state is executed when the USV receives position B.

2. Line following towards the object

Once the point B is known, the USV begins the line following maneuver from its initial point to point B where the UxO is located, as it is shown in Frame 1 of

Fig. 3. For this maneuver, only sensors onboard the platform are used (compass and GPS). At the moment when the UAV detects the UxO in the field of view (as shown in Frame 2 of Fig. 3), i.e. when relative distance between the platform and the object can be determined, the transition to the following state is executed.

3. "Grasping" the UxO

In this state, fine positioning of the platform relative to the UxO is possible since precise data on relative distance between the Uxo and the USV in the USV's coordinate system are available. The USV rotates towards the UxO so that it can "grasp" it between the two legs as it is shown in Frame 3 of Fig. 3. Once the desired orientation is achieved, the DP algorithm that minimizes the distance between the platform and the object is initiated, as shown in Frame 4 of Fig. 3. The mission transitions to the following state once the contact between the platform and the object is detected from the UAV field of view, and when the position of the autonomous ground vehicle (AGV) C sent by the UAV is available.

4. Line following towards the AGV

Once the contact between the USV and the UxO is achieved, and when position C is available, the USV rotates towards the ground vehicle while holding the object between the two legs as it is shown in Frame 5 of Fig 3. Once the desired orientation is achieved, line following from the current position to position C is initiated as shown in Frame 6 of Fig. 3. Only sensors onboard the USV are used (compass and GPS) for this maneuver. When the UAV detects the AGV in the field of view as shown in Frame 7 of Fig. 3, i.e. when relative distance between the USV and the AGV can be determined, the transition to the following state is executed.

5. Approaching the AGV

In this state, fine positioning between the USV and the AGV is possible since precise data on relative distance between the USV and the AGV is available. The USV dynamically positions itself to a point in front of the AGV, determined by the UAV, as shown in Frame 8 of Fig. 3. Once the desired position is obtained, the USV rotates with the UxO towards the AGV so that simple object grasping by the AGV is enabled.

B. The UAV mission states

The UAV mission states are based around hovering above the USV extending the field of view from above. The field of view of the UAV is represented as a green circle in Fig. 3.

The following five states are executed simultaneously during the whole mission.

1. Visual DP above the USV

The UAV detects the USV position within the video frame at all times and positions itself above the USV using DP algorithms based on position obtained from the video image. The UAV keeps constant altitude at all times while the orientation is arbitrary.

2. Transmitting UxO coordinates

If the UAV has information about the UxO coordinates (these coordinates will be transmitted to the UAV by an operator through the wireless link), they are transmitted via WiFi to the USV below. In this state, the UAV serves as an extended antenna for the USV.

3. UxO detection

The UAV searches for the UxO (a predefined marker on the object) within the video image all the time. If the object is found, the UAV sends the relative distance between the detected object and the USV to the USV.

4. AGV detection

The UAV searches for the AGV (a predefined marker on the AGV) within the video image all the time. If the AGV is found, the UAV sends the relative distance between the detected AGV and the USV to the USV.

5. Transmitting AGV coordinates

The UAV sends the AGV coordinates via WiFi to the USV all the time. These coordinates are received from the AGV itself.

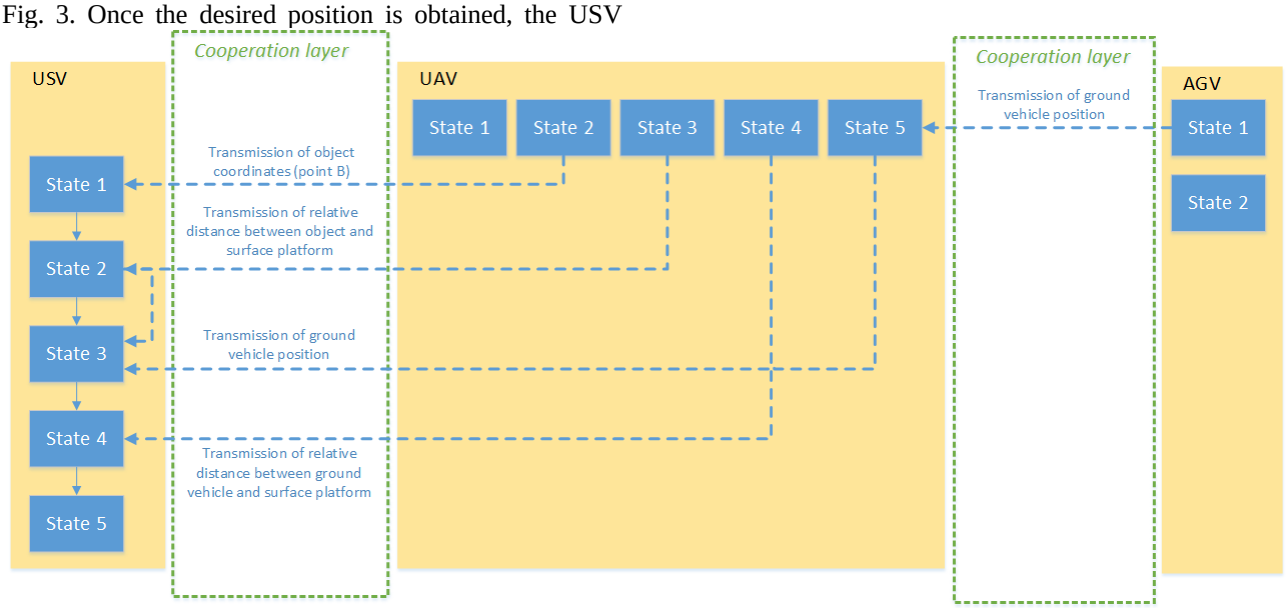

Figure 4. The conceptual representation of the mission flow from the perspective of the each unmanned vehicle.

C. The AGV mission states

1. Transmitting position coordinates

The AGV is at a location on ground next to the sea line and transmits its own GPS coordinates to the UAV through the wireless link all the time.

2. Remotely operated object grasping

Once the UxO is close enough to the AGV, the remote operator can use the manipulator onboard the AGV to grasp the UxO and carry it to a safe location for neutralization.

Fig. 4 graphically shows the mission states from the perspective of the individual unmanned vehicles. In the same figure, the cooperation layers are shown. These layers in fact represent the communication that occurs between the vehicles. The data that is being communicated is the baseline of the cooperation of the heterogeneous robotic system.

IV. CONLUSION

This paper presents an overview of the project with the task to establish a cooperative heterogeneous robotic system. The systems that will be used for experiments are described and the scenario of neutralization of the unexploded ordnance is given.

The next step is to combine already existing vehicle behaviors to support the cooperative system. The cooperation will be established by maintaining the formation between the unmanned surface vehicle and an unmanned aerial vehicle that serves as an extended antenna and a communication router. Once the algorithms are verified in a simulation, real life experiments will be conducted.

ABSTRACT - This paper describes designing complex process control in a cooling system. Control solutions specifically designed for simple cooling system are already available and these simple control designs include temperature control limited to one cycle of operation. For more complex cooling processes with variable operation cycles it is necessary to introduce a superior process control design, which coordinates the operations of simple processes. Within each cycle temperature is controlled by temperature regulator, while cycle operation exchange of individual processes is managed by microprocessor device whose program was written in LADDER logic in this study.

I. INTRODUCTION

Today majority of small modern cooling systems used for food storage demand simple temperature control. Cold room temperature is monitored by room probe and evaporator temperature is monitored by defrost probe. Automatic temperature control is maintained in one cycle with two different periods. In first period refrigerating process is done, with compressor, condenser and expansion valve controlled by room temperature probe and pressure probes used to monitor refrigerant pressure in suction and discharge lines. Second period is used for defrosting process, meaning that the ice that was accumulated on evaporator section during refrigeration period needs to be melted. Second period is only needed in storage rooms with temperature below and around 0°C, with first period being significantly longer than the second. After one cycle, overall process repeats.

Most electronic temperature regulators used for simple cooling process control can be used for one cycle regulation with refrigeration/defrost period. More complex electronic regulators can control two different time cycles of operation.

Storage and freezing of various types of food and goods demand different levels of cooling process complexity. While with most goods simple one cycle processes are satisfying, there are situations when more complex control must be designed. This type of cooling process control can easily be designed by incorporating two devices: electronic temperature regulator for temperature control which is subjected to electronic device operated by LADDER logic and used for time cycle control.

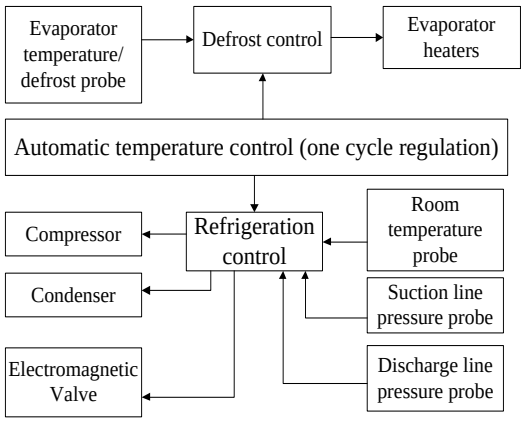

Fig. 1 Block diagram of simple cooling process

II. TIME FLOW DIAGRAM IN COMPLEX COOLING SYSTEMS

Basically, previously described simple cooling process is now expanded into complex by having variable instead of fixed refrigerating and defrosting periods and by taking into account the number of cycles. This process is being designed with consideration to nature of goods that need to be stored or frozen. In some cases individual quick freezing processes in freezing tunnels demand various time cycles of operation because the type of food or goods that is processed on that occasion exhibits different levels of humidity into local atmosphere during overall process, thereby creating additional ice in the evaporator section. This results in earlier defrost demand and shortened refrigeration period when process is in the earlier stage of operation.

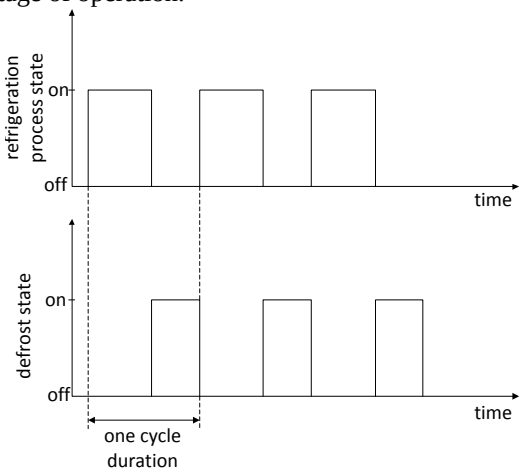

Fig. 2 Time flow diagram of simple cooling process

Refrigeration control is done by switching compressors, condenser fans and electromagnetic valves according to room temperature and lines pressure. When defrost control is in charge evaporator heaters are switched according to evaporator temperature probe, commonly known as defrost probe. Time flow diagram of described simple cooling process is shown in fig. 2.

In complex cooling process variable cycles are introduced, meaning that refrigeration and defrost periods are also variable. While electronic temperature regulators allow only one cycle of operation, time cycle control can be done by microcontroller device. Electronic temperature regulators have several digital inputs with various functions, and one of them is a defrost start signal. This type of signal can be used for signalling end of refrigeration period and start of defrosting period. Small period called pause period has to be incorporated in LADDER program to ensure that switching of refrigeration components is blocked while defrost components are still in operation and vice versa. This period also ensures that electric power supply of cooling system isn't overloaded with unnecessary load, because defrost heaters operation is not needed, even for a few seconds, while refrigeration period is in charge and may cause inappropriate tripping of electric protection devices. In pause period all system components are switched off.

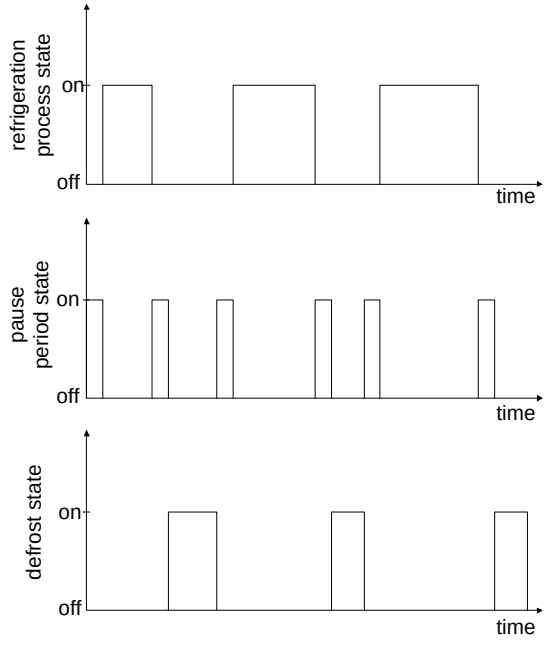

Fig. 3 Time flow diagram of complex cooling process with three cycles of operation

First step in designing complex cooling process control is time flow diagram design. One has to take into account overall time needed for goods to be frozen, number of cycles of operation and different operation period times. As mentioned before, earlier periods of cooling or freezing process demand shorter periods of refrigeration and longer defrosting periods. The freshness of goods and humidity that is transferred from goods to local atmosphere results in creating additional ice on the evaporator section. Later periods of refrigeration process can be longer with shorter defrosting periods, as goods are now drier and humidity is lower. Time flow diagram example of such a process is shown in fig. 3.

III. TEMPERATURE CONTROL IN COMPLEX COOLING SYSTEMS

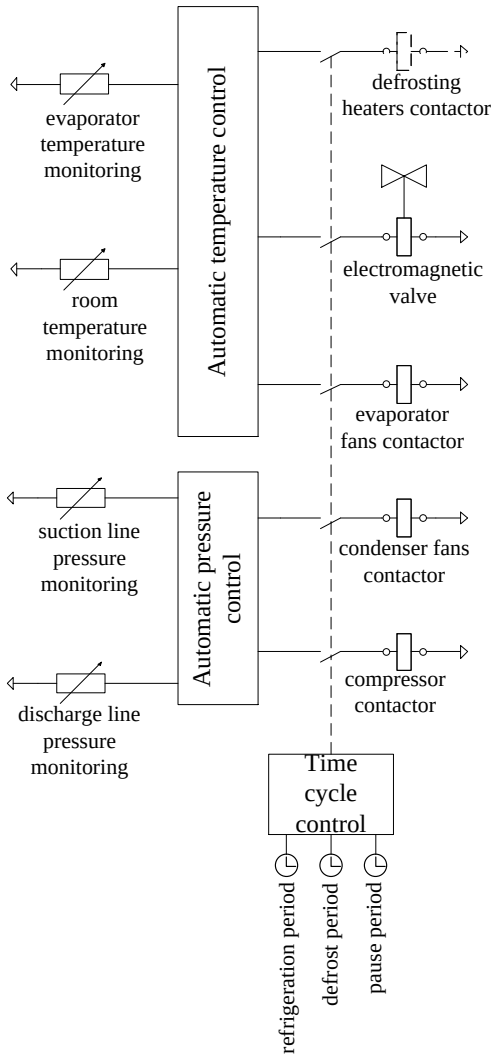

Fig. 4 Block diagram of complex cooling process control

Temperature control in complex cooling system is subjected to time cycle control. Electronic temperature regulators give signals to contactors with respect to measured temperature and pressure signals. Contactors are being switched in two stages with relay contacts. First stage operates according to the period of operation cycle in time cycle control, and the second stage operates according to measured temperature and pressure in temperature control.

Due to independent regulations of pressure and temperature in temperature control, pause

period has to be implemented. This way, safe switching of various components is ensured as mentioned before. In simple cooling process temperature regulator is working in one cycle and ensures safe switching of various elements. In complex systems operations of defrosting heaters (controlled by evaporator temperature), compressor, condenser fans (controlled by lines pressure), evaporator fans and electromagnetic valve (controlled by room temperature) are all independent operations and have to be treated in such manners, when creating a process design.

Block diagram of complex cooling process is shown in fig. 4.

There are more simple systems operated in complex manners, such as cooling systems of minor electric powers. Pressure control in these systems works only as a protection with electromechanical pressure control devices, while room temperature is main element in providing satisfying cooling in cold rooms of such systems. Regulation of these simple systems consists only of superior time monitoring device and temperature regulator, without pressure probes as monitoring elements. In this paper, a more complex approach has been selected. Temperature and pressure regulations with four independent probes are more common in cooling systems that demand complex cooling process design.

IV. TIME CYCLE CONTROL IN COMPLEX COOLING SYSTEMS

Time cycle control in complex cooling system is superior to temperature control mentioned before. In this stage of control microcontroller operated by LADDER logic program gives orders to electronic temperature regulator as a signal for defrost start/stop and gives signals to contactors according to current period of operation. All LADDER diagrams shown in this paper are based on actual diagrams written and simulated in easySoft® pro 6 software package, and are meant to be used with Eaton's EASY® relay devices.

First period of each cycle is pause period, after which refrigeration period takes control. In refrigeration period compressor contactor and condenser fans contactors are controlled by pressure regulator. Evaporator fans and electromagnetic valve are operated by electronic temperature regulator.

First pause period in each cycle starts with M01 signal and its contact set to ON stage, which sets timer T01 and begins counting time scheduled for pause period. After T01 counts up its contact closes which ensures resetting of defrost period timer and markers while setting refrigeration period marker. This is also a starting period in overall process. When refrigeration period timer T02 counts up, its contact ensures resetting first pause marker M01 and timer T01 and setting second pause period marker M03 and timer T03.

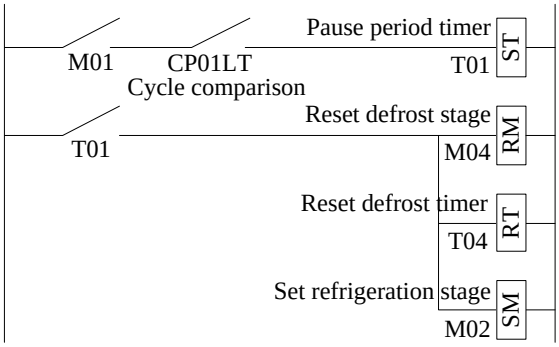

Fig. 5 LADDER diagram for pause period control, after defrost and before refrigeration period

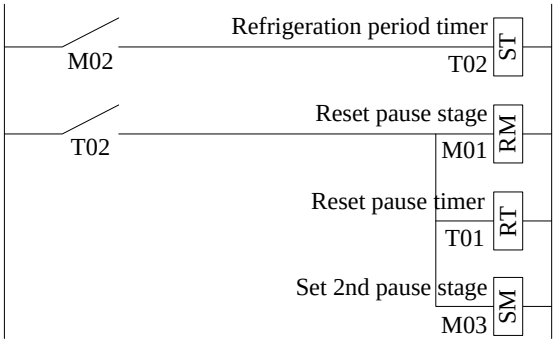

Fig. 6 LADDER diagram for control of refrigeration period

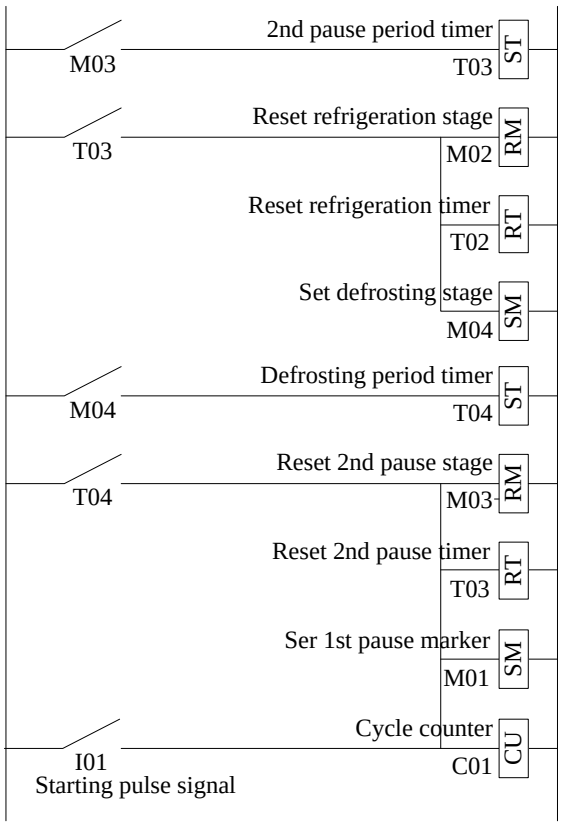

Fig. 7 LADDER diagram for pause period control before defrost and defrosting period

In defrost state pressure control works independently but contactors of condenser fans and compressor remain switched off, since time cycle control does not allow them to be switched on. Also, pressure probes in both lines do not allow compressor and condenser fans to operate, since electromagnetic valve is turned off and there is no refrigerant flow through lines.

After 2nd pause period timer T03 counts up, refrigeration marker and timers are reset, and defrosting period marker M04 and timer T04 are set. When timer T04 counts up, cycle repeats itself according to comparison CP01 of counter block C01 implemented to count number of cycles by setting marker M01 in ON stage again.

Times stored in timers may also be variable, since they are stored as data in particular memory location selected by process programmer. On fig. 5 two different types of timers are shown.

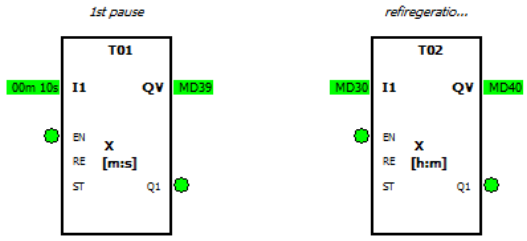

Fig. 8 On-delayed timer function blocks for fixed and variable time setpoint

First timer, used for pause period has time setpoint I1 fixed and set to 10 seconds. Second timer, used for refrigeration period, has a variable setpoint located in particular memory location in microcontroller memory (MD30). Actual inputs of both timers are set to two different memory locations (MD39, MD40) allowing program process designer or end user (optionally via SCADA or some other visualization device) to monitor time elapsed on each period of current cycle. Other inputs on timer block are enable bit (EN): digital signal used to start the timer, reset bit (RE) and stop bit (ST). Output Q1 is used as on-delayed switching contact.

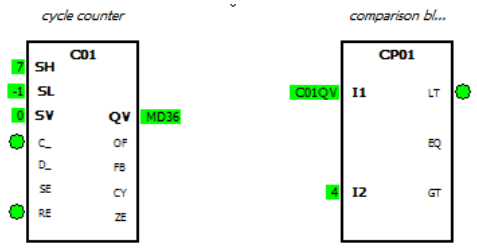

Fig. 9 Counter and comparison function blocks with fixed and variable setpoints

When setting cycle number, counter block needs to be defined. More important signals SH, SL and SV present upper, lower setpoint and preset value. Bit C_ presents count coil that counts on every rising edge. Bit D_ defines count direction. Actual value of the counter is set in QV output. Comparison block takes two values (I1, I2) and transfers their comparison as digital signal to three types of switching contacts defined as bit outputs in comparison block definition: LT (lower than), EQ (equal), GT (greater than). These function blocks are used to define number of cycles and condition if current cycle has reached that limit. Variability of all mentioned values can be easily obtained by using SCADA/HMI systems, therefore giving accessibility to end user.

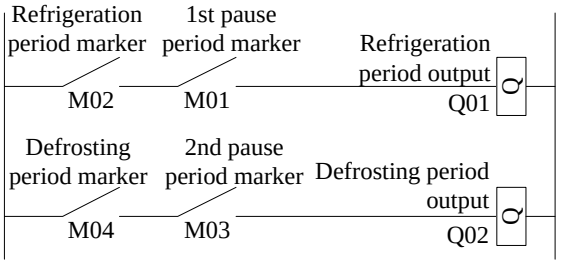

Fig. 10 LADDER diagram for refrigeration control and defrosting period outputs

Digital outputs are set to ON state when current period and previous pause period markers are set on. When proceeding to next pause period, previous pause period marker is reset, setting the output bit to zero. Logic of described output switching process is shown in fig. 10 and fig. 5, 6 and 7 respectively.

V. COMPLEX COOLING PROCESS IN FREEZING TUNNEL

Individual quick freezing process in freezing tunnel is observed as a practical approach to the problem of complex cooling. Goods that are frozen in this type of process behave in same manner as mentioned in first chapter of the paper, such as raising level of humidity in freezing tunnel's space.

Measurements were taken from the cooling system consisting of three freezing tunnels with different carrying capacities (two smaller tunnels have capacity of 15 tons of fresh fish and one large tunnel has capacity of 30 tons of fresh fish). Every tunnel works in four or six cycles, depending on the type and freshness of fish to be frozen. All cycles have fixed time presets, varying from first to last cycle. Refrigeration periods within each cycle are fixed but different in each cycle. Defrost periods are fixed and same in all cycles, as well as pause periods are too.

Automatic temperature control is realized with Carel's MPXPRO® electronic regulators which control evaporator fans in refrigeration periods, and evaporator electric heaters in defrosting periods. These regulators have one digital input reserved for starting signal of defrosting period which enables electric heating of evaporator section in coordination with evaporator temperature probe. In

refrigeration period evaporator fans are switched on according to signal from room temperature probe.

Automatic pressure control of compressor and condenser units is performed by Carel's microcontroller unit pRACK® that has one digital input reserved for starting signal from superior microcontroller device EASY 820-DC-RC® performing time cycle control. When in refrigeration period, EASY relay gives signal (by setting Q01 output to ON stage) to pRACK unit to start with pressure control. Suction line's pressure is used to control compressor, and discharge line's pressure is used to control condenser fans. In this particular approach compressor and condenser fans switching states are not observed, because temperature control and monitoring in freezing tunnels is more interesting from the aspect of HACCP (Hazard Analysis Critical Control Points) inspection, since food storing and freezing has to satisfy certain number of regulations concerning food quality.

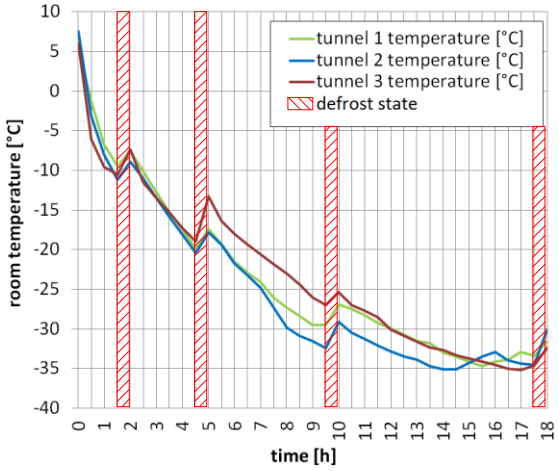

Fig. 11 Time-temperature graph of complex cooling process in three freezing tunnels loaded with 120% carrying capacity

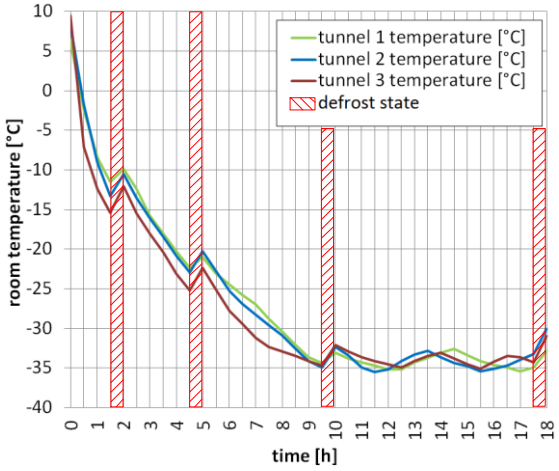

Fig. 12 Time-temperature graph of complex cooling process in three freezing tunnels loaded with 100% carrying capacity

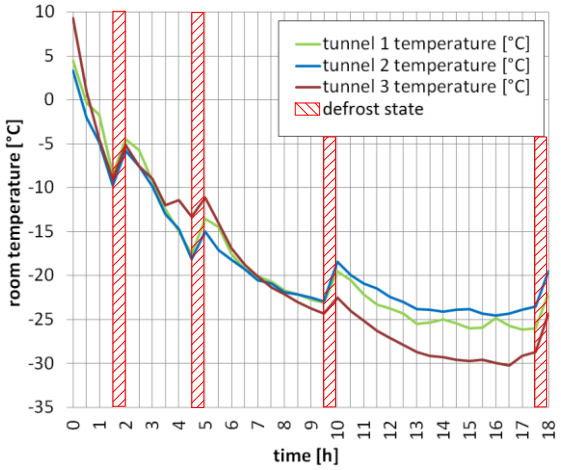

Fig. 13 Time-temperature graph of complex cooling process in three freezing tunnels loaded with 200% carrying capacity

Graphs of temperature measurements are shown on fig.11, 12 and 13. Measurements were taken from four cycle cooling processes with tunnels carrying 120%, 100% and 200% of fresh fish capacity, with 30 minutes sample time. Observed four cycle process lasts for 18 hours. Device used for generating HACCP inspection reports was Carel's PlantWatch PRO®. This device has minimum sample time of 30 minutes when observing room temperature in creating HACCP report.

Working conditions and setpoints were same for all three freezing tunnels. Temperature setpoints of all three tunnels has been set to -35°C, with temperature difference set to 2°C, meaning that in refrigeration period evaporator fans switch from -33°C to -35°C.

With process in defrosting period heaters are switched on until evaporator section temperature reaches 20°C, with temperature difference set to 2°C. Due to pretty long sample rate of data acquisition from the measuring system and short fixed period of defrost period, switching states of defrosting elements are almost impossible to monitor. On temperature/switching state graphs it can only be seen that defrosting elements are switched on when defrosting period takes place in observed process.

With process in refrigeration period, one can observe and conclude from these measurements how the effect of overload can affect directly to the electrical supply system, with all electrical components working continuously. Switching states of evaporator elements have been observed for different conditions of tunnel loading. Load equal to carrying capacity (100%) shows that in last cycle automatic temperature regulator switches fans off, as the goods have reached desired temperature, with their quality preserved (fig.15).

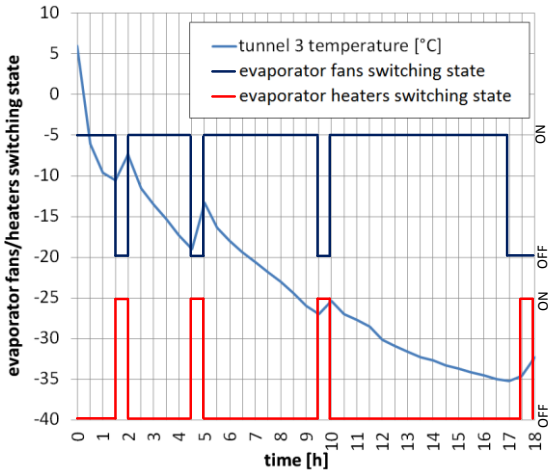

Fig. 14 Switching states during four cycle complex cooling process in largest freezing tunnel loaded with 120% carrying capacity

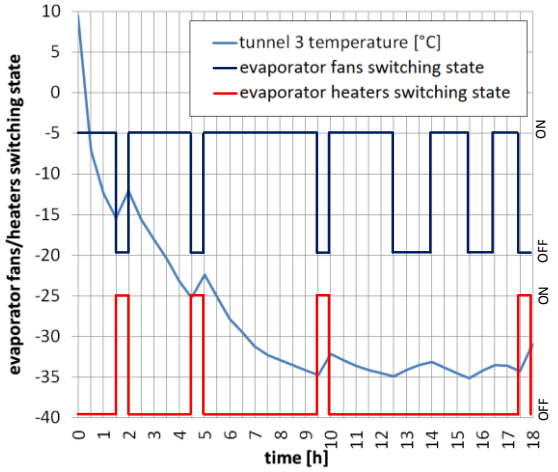

Fig. 15 Switching states during four cycle complex cooling process in largest freezing tunnel loaded with 100% carrying capacity

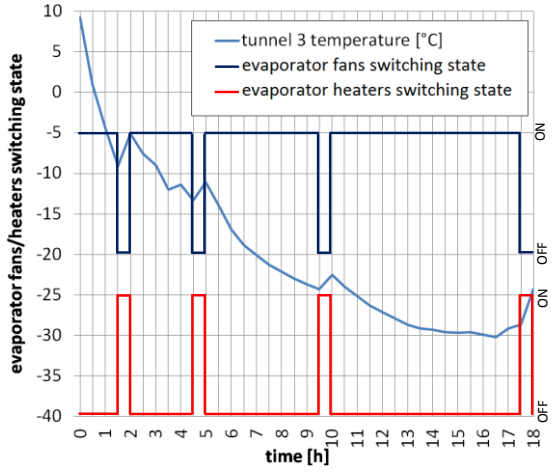

Fig. 16 Switching states during four cycle complex cooling process in largest freezing tunnel loaded with 200% carrying capacity

Switching states/temperature graph (fig. 14) for slightly larger overload above rated shows continuous operation of all elements included in refrigeration period, but also reaching the desired temperature with satisfying quality of frozen goods, while in heavily overloaded freezing tunnel room temperature never reaches default temperature setpoint, making goods' quality questionable.

VI. CONCLUSION

Temperature regulation for simple cooling process is commonly used in food storage and quick freezing, and used as one cycle cooling process. But with more demandable cooling processes of specific goods, such as various types of fish, it's complexity needs to be expanded. Various durations of cooling cycles consisted of refrigeration and optional defrost period, demanded for successful processing of goods, require more complex process design than the one described as simple process with automatic temperature/pressure regulation only.

Most affordable and optimal design lies in microcontroller coordinating with electronic temperature and pressure regulators. Possibilities for end user to control complex processes are numerous (with optional SCADA/HMI systems) and at the same time having possibility to preserve administrating of the system for service and parameter change purposes.

Described results in last chapter of this paper show that this type of control design is successful in operation and with its low-cost equipment acceptable for end user. It's simple core consisting of microcontroller driven by LADDER program and automatic regulation devices for specific purposes (such as temperature and pressure control) and possibility of control elements expansion (SCADA/HMI systems, microcontroller networking) is also an advantage of this type control design.

Abstract - This paper describes the application of Internet and wireless communications in the monitoring and control of production processes in the metallurgical company RTB Bor, Serbia. A special attention is paid to the presentation of the software solutions. Implemented distributed control systems have shown remarkable reliability in practical work, low cost of maintenance and investment in their expansion. The described solution is applicable for monitoring and control of processes with the control system response time of about a minute or longer.

I. INTRODUCTION

Our previously presented works describes the development of the PLC based on microcontroller (Motorola MC68HC11) [1, 2] and applications for monitoring and control of industrial processes [3-6]. Such monitoring systems are implemented at all key production lines in the Copper Mining and Smelting Complex Bor (RTB Company).

The RTB Company is engaged in excavation and processing of copper ore (mines, flotation, copper smelting and refining facilities) [2]. The process equipment in almost all production units in the RTB Company was very old with the basic local process control systems. As an investor the RTB Company has always demanded low cost monitoring systems. For these purposes the specific process control systems have been designed and developed [2-5]. Monitoring and control of process parameters in many production units in the RTB Company include interaction with the process from remote locations. For that reason, the individual control systems were interconnected in a large industrial network [3].

Dynamic development of new communication technologies provides new ways for remote monitoring and control of industrial processes. For that reason, the realized monitoring and control systems are constantly upgraded and improved until nowadays, both in terms of hardware and software. In this paper we describe the use of programs for data exchange and synchronization over the Internet and wireless networks with the aim of remote monitoring and control of industrial processes in the RTB Company.

II. OVERVIEW OF REMOTE MONITORING OF INDUSTRIAL PROCESSES IN THE RTB COMPANY

Remote monitoring and control in the RTB Company in previously realized monitoring systems was achieved over remote workstations. The workstations were connected using base-band modems via leased lines with a number of PLCs [2]. Communication protocol, BSCP (Binary Synchronous Communication Protocol) was specially designed and applied in order to support real-time data transfer between all network nodes [7]. That was costly because of the large amounts of time required for development of communication software and hardware.

In the past decade, carefully planned and realized industrial computer network was realized in the RTB Company. It consists of several LAN segments connected in a single network [3, 4]. Connection of distant LAN segments is achieved either with conventional telephone copper wires and the appropriate modems, or with wireless access points (AP). Wherever it was possible, wireless connection is applied. 'Point to point' mode is used for wireless AP operation. For short distances, connection between the network nodes is provided by using the UTP cables. In some cases the connection between the nodes or LAN segments is established using the mobile phone network services with GPRS data modems, HCP SHARK Quad-band GSM/GPRS [8].

The special SCADA real-time application named Process Control Program (PCP) [9] was developed in order to support PLC functions and to perform data transfer, analyses and real-time result interpretation. The PC which is directly connected to a PLC, running the PCP, acts as data server in the network configuration. Remote workstations execute Remote Control Program (RCP), a passive version of PCP. RCP is used for distant monitoring only. RCP can access the databases stored on the server and retrieve the new data. Each production unit has the server entity that consists of the PLC and PC workstation, as shown in Figure 1.

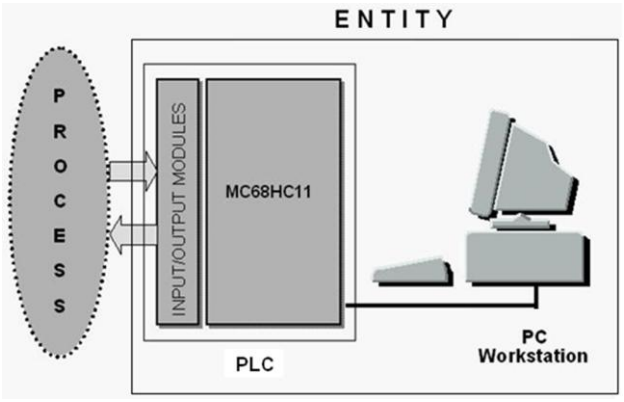

Figure 1. Diagram of a simple control system (entity)

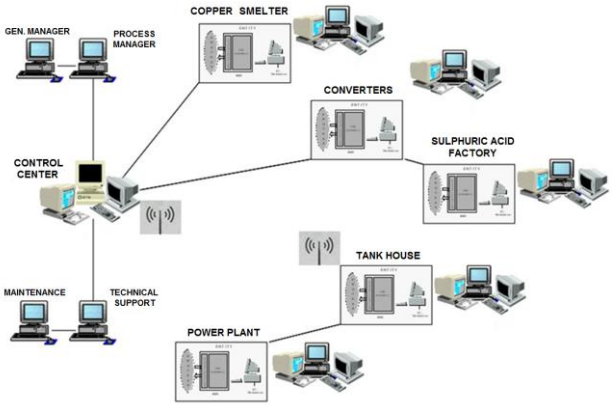

Figure 2. Block diagram of realized industrial network structure

The realized industrial network consists of several sub-networks with a number of clients for remote monitoring as shown in Figure 2. Smelting of copper concentrates is such process in which the majority of the process parameters change slowly over time (temperatures, pressures, and flow rates). Slow change of process parameters was the main reason for adoption that PCP provides data for RCP on every minute. PCP generates very short text files (ASCII), with the size of few KB, which contains actual information about monitored process parameters. The workstations that execute RCP simply download these files over LAN. From a technical point of view, this is a low-cost solution having in mind that distant LAN segments are mostly connected over conventional telephone copper wires (RTB Company owns private telephone lines inside and between the most of its facilities).

III. THE NEW WAYS OF REMOTE MONITORING AND CONTROL OF INDUSTRIAL PROCESSES

The constant evolution of the Internet and information technologies brings new methods for remote monitoring and control of the industrial processes and equipment. The Internet technologies provide low cost mechanisms for connecting computers anywhere in the world. One such technology is digital subscriber line (DSL) where computers have a permanent connection to the Internet. RTB Company uses DSL technology to lower remote monitoring costs. The most of remote monitoring implementations in the RTB Company uses simple file transfer protocols (FTP) to transfer data between two distant locations. This requires software to transfer and view data. For that purpose Gbridge software is used.

Gbridge is free software that is used to synchronize folders at remote computers with the folders on host computer [10]. Gbridge automatically forms a collaborative, encrypted VPN (Virtual Private Network) that connects computers directly and securely [11]. It allows users to remotely control a Windows host, transfer files, share folders, and automatically synchronize files between PCs. Also, Gbridge does not require any modifications to the network firewall. It creates a soft VPN between host and remote PCs using the gbridge.com website [10] and a Gmail account to login in. This VPN is fully meshed so that multiple clients can see one another and participate in file transfers, remote control, and shared file locations. Thus, Gbridge provides many-to-many connectivity instead of a one-to-one link as with most remote control utilities [12]. SecureShare is the Gbridge feature built in VPN that enables sharing files or folders on one computer, to all other participants of VPN.

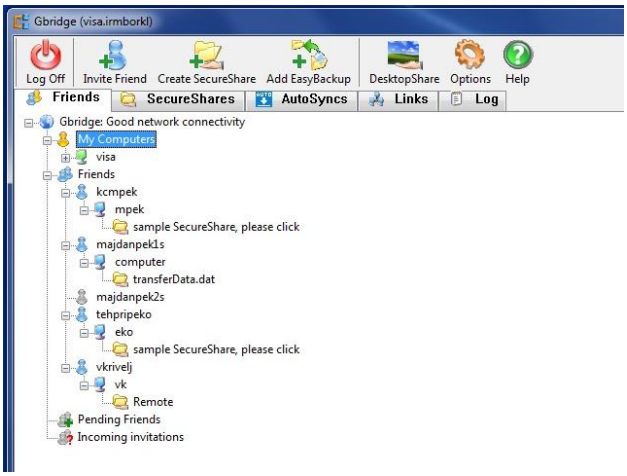

Figure 3. Gbridge Friends tab with SecureShare folders provided on 'friend' (host) computers

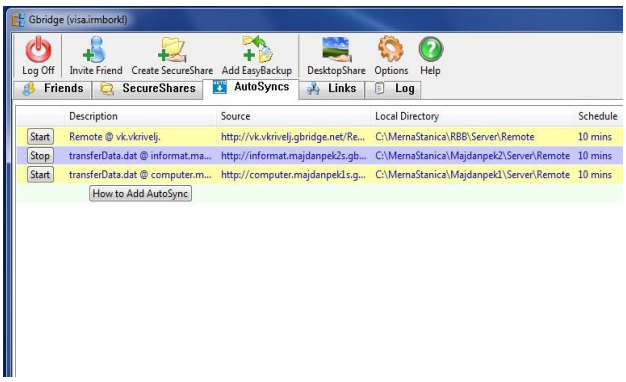

Figure 4. Gbridge AutoSyncs tab with a number of tasks running

Gbridge AutoSync feature typically involves two computers: one as the source, which provides the SecureShare, and the other is the destination which actually does the automatic synchronization copying data from SecureShare to a local folder. The feature needs to be invoked by first navigating to the "friends" tab (as shown in Figure 3) and find SecureShares created on those source computers, then one can click on these SecureShares to start the auto sync task.

For the purpose of remote monitoring of industrial processes we always need to get the latest copy of files generated by PCP. This requires creating the AutoSync tasks as shown in Figure 4. The destination computer always tries to synchronize the contents of the "Source" SecureShare according to a predefined schedule. AutoSync performs smart scan on the source directory and would only send the difference over, so it uses a negligible amount of data when the two folders are already synchronized. If AutoSync misses a scheduled synchronization due to the source or destination computer being offline, it will resume the synchronization as soon as both computers are available [10].

With Gbridge we can track parameters of industrial processes from any place in the world that has Internet access. RCP reads current information on the state of industrial process parameters from a local folder on the same computer that executes RCP. Particularly useful option is using a wireless connection on a laptop computer to monitor the industrial processes.

When the process control must be performed from a remote location (for example, when a manager wants to change the process parameters of a control loop from his home) TeamViewer software is used.

TeamViewer is a software package for remote control and file transfer between computers [13]. TeamViewer has to be running on both host and client computers. Once installed it generates a partner ID and password as shown in Figure 5. To establish a connection from a local client to a remote host, the host ID and password must be entered into the local TeamViewer window (shown in Figure 5).

Figure 5. TeamViewer common window with local ID and password (on the left) and partner ID (on the right)

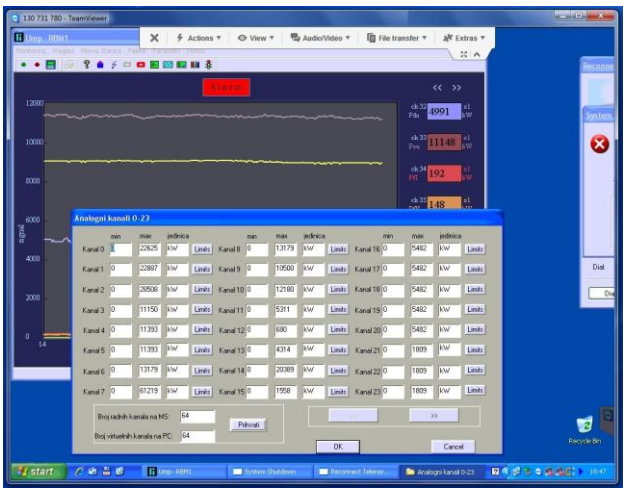

Figure 6. Example of remote control of PCP parameters using TeamViewer

Example of TeamViewer usage for changing the parameters of a PCP is shown in Figure 6. TeamViewer is also very suitable for transferring large files between the two computers because there are no file size limits as is the case when e-mail is used. Although TeamViewer can also be used just for monitoring of control computer (observing its desktop) we didn't use this option.

CONCLUSION

In this paper we describe solutions for monitoring and control of industrial processes using the Internet and wireless communications. Presented solutions were applied in practice for monitoring using Gbridge and control processes using TeamViewer in the metallurgy of copper. The main benefit of given solutions is their ease of use, low price, and its applicability in the different combinations of operating systems and hardware. The described solutions are applied in our environment for control of processes with the control system response time of about a minute or longer.

Furthermore, proposed approach has another benefit – the existing SCADA applications (PCP and RCP) didn't require any modifications at all. In this way, the new communication technologies with described software solutions provide new possibilities for monitoring and control of the production processes with minimal investment.

***Abstract*—Real world networks often have community structure. It is characteristic that the groups of nodes are connected denser within themselves and rarely with each other. The Girvan-Newman method for the detection and analysis of community structure is based on the iterative elimination of edges with the highest number of the shortest paths that go through them. By eliminating edges the network breaks down into smaller networks, i.e. communities. This paper introduces improved Girvan-Newman method where multi-edge removal is allowed, and presents the results of the application of both methods to the existing real social network (Zachary karate club), the computer-generated network and the tumor genes and their mutations network. The improved algorithm in practice reduces the number of operations, but retains the same computational complexity, so it cannot be applied to networks with a very large number of nodes. The most important feature of our improvement is that the result is graph-theoretical invariant, while original algorithm depends on the vertex labeling.**

***Index Terms*—Girvan-Newman, complex networks algorithms, edge betweenness**

I. Introduction

A network is a set of nodes and links connecting them. Studying network properties belongs into graph theory area which is a part of discrete mathematics. With the development of computers that can perform operations on very large amounts of data, modeling and analysis of network performance is extended to other scientific disciplines and becomes an interdisciplinary topic.

In mathematics, network is represented with a graph, where nodes are *vertices* and links *edges*. *Graph* is ordered pair $G = (V, E)$, where $\varnothing \neq V = V(G)$ is set of vertices, $E = E(G)$ is set of edges such that every $e \in E$ connects two vertices $u, v \in V$ called *endpoints* of e. Two connected vertices are *adjacent* vertices and we say that the edge and its endpoint are *incident*. A *loop* is an edge that connects a vertex to itself. The number of edges incident to a given vertex is the *degree* of that vertex, where every loop is counted twice. A graph is *regular* if all its vertices have the same degree.

In the real world, complex systems in different disciplines form networks such as social networks, World Wide Web, transport networks, citation network, metabolic networks, protein interaction networks, and gene regulatory network. Network exist in almost every area of human existence, from neuroscience to sociology, from economy to information technology. Those networks are called *complex networks* or *real-world networks*. Although graph theory is almost 300 years old (Euler solution for Könisberg bridges problem in 1736. is considered as the birth of the graph theory), the study of complex networks is a young discipline, only a little more than a decade old.

Unlike random (Erdos-Renyi model) and regular graphs, which were the focus of the graph theory before the Erdos-Renyi model, most real world networks are not random nor regular and have common topological properties. Some of them are small world effect, scale-free property, clustering or network transitivity, and community structure.

The property of complex networks that nodes are divided into groups or communities in which the links connecting nodes within the community are dense and the connections between nodes from different communities are sparse is the focus of this study. The possibility of detecting communities in networks can have practical applications. Communities in social networks could represent people with similar preferences or interests. The epidemiology could use the results to recognize the communities and the connections between people in order to prevent the spread of disease [1]. Kininmonth et al. [2] used the community detection methods to analyze genetic information exchange among the coral reefs through transport larvae. Communities on the Internet could be pages with similar content. From these examples, it is clear that the detection of communities in complex networks has broad application in a variety of scientific disciplines.

The rest of the paper is organized as follows. In Section 2 we present methods used for community structure detection in complex networks. Section 3 describes the Girvan-Newman method and our improvement of the method. In Section 4 we introduce modularity, a qualitative measure of network decomposition. Section 5 presents and discusses results achieved with our modification, and finally, Section 6 concludes the article.

II. Methods for community structure detection in complex networks

Main methods for finding communities in a network are variants of hierarchical clustering methods used in social network analysis [3]. Hierarchical clustering could be agglomerative or divisive, depending on decision to start from

empty network and add the edges to form communities, or to start with complete network and remove edges until the communities are formed. In both cases, the process could be represented with *dendrogram*, which is a hierarchical tree with clusters as a nodes in tree, and single nodes as leaves. In agglomerative process, dendrogram is built from leaves to the root, and in divisible process from root to the leaves (Fig. 3a).

A. Agglomerative methods.

The traditional hierarchical agglomerative clustering algorithm starts with empty graph which consist of nodes of original graph without edges. In every step of the algorithm edges are added, starting from "stronger" to "weaker" links.

Edge weight can be calculated in different ways. For example, edge weight could be the number of node-independent or edge-independent paths between vertices. Two paths are node-independent if they share no other vertices than the path endpoints. Similarily, they are edge-independent if they share no edges. The number of those paths represents the number of vertices (or edges) which should be removed from the graph in order to disconnect path endpoints [4].

New communities are formed in the consecutive steps of the algorithm. Iterative algorithm process could be stopped at any iteration, but usually, it is done until all the edges are added to the graph. In the end, all the nodes and edges form one community.

B. Divisive methods.

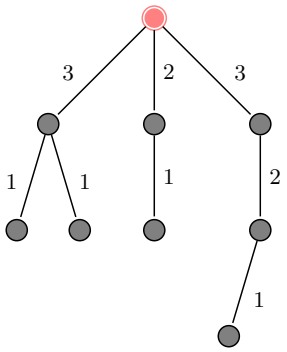
Opposite of agglomerative methods, divisive methods start from the complete graph and, in every iteration, remove the edges with the highest weight. In every step weight calculation is repeated, since the weight of remaining edges changes with edge removal. The Girvan-Newman algorithm, which will be described in detail in the next section, is an example of divisive algorithm. In that algorithm, the order of removal of the edges with the highest weight is not defined, so it could produce different results depending on implementation. Modifications of that algorithm exist in which the community structure is built for every possible order of highest weight edge removal.

III. Girvan-Newman method

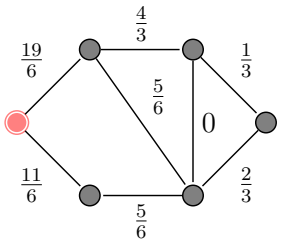
Girvan-Newman method is divisive method where edge weight is the number of shortest paths passing through the edge. That value is called *edge betweenness* and it is a generalization of central vertex betweenness which determines vertex influence on other vertices in network. Vertex betweennes is the number of shortest paths passing through the vertex, therefore, edge betweenness is the number of shortest paths passing through the endpoints of the edge.

We can describe Girvan-Newman algorithm in the following way:

1) Calculate edge betweenness for every edge in the graph.



(a) A tree



(b) Not a tree

Figure 1: The number of shortest paths in a graph: a) In a tree there is unique path from source to every vertex. b) If graph is not a tree there is more than one path to every vertex. Each edge has weight which is fraction of the paths flow through the edge.

2) Remove the edge with highest edge betweenness.
3) Calculate edge betweenness for remaining edges.
4) Repeat steps 2-4 until all edges are removed.

In order to calculate edge betweenness it is necessary to find all shortest paths in the graph. The algorithm starts with one vertex, calculates edge weights for paths going through that vertex, and then repeats it for every vertex in the graph and sums the weights for every edge.

Let us choose source vertex $s \in V$ in a graph. In the most simple case graph is a tree (Fig. 1a) and there exists only one shortest path from the source vertex to any other vertex. Starting from the leaves we assign the value 1 to the edges that connect leaves with the rest of the tree (because there is only one shortest path to s passing through that edge). Moving upwards in the tree we assign edge value as a sum of values assigned to the edges directly below it, increased by 1. The number of shortest paths in the tree from source vertex to every other vertex passing through particular edge is that edge weight value. By repeating the process for every vertex and calculating the sum of weight values for every edge, we calculate edge betweenness for every edge.

If a graph is not a tree (Fig. 1b), it is possible that more than one shortest path connects source vertex with some other vertex. In that case, value $\frac{k}{l}$ is assigned to the edge on shortest path to source vertex, where k is the number of shortest paths to source vertex from the endpoint of the edge that is closer to source and l is the number of shortest paths from source vertex to other endpoint of the edge, and multiplied by the

number of shortest paths from source that pass through edges below farther vertex incresed by one. Assignment starts from the edge that has maximum distance from source vertex.

The algorithm for calculating edge betweenness is performed in two parts. In the first part of the algorithm, using breadth-first search, distance from source is assigned for every vertex and also the number of shortest paths from source to vertices. In the second part, starting from edge incident to the vertex with maximum distance from the source vertex as endpoint (the last vertex visited in the first part on the algorithm), the numbers of shortest paths passing through edges are calculated for every edge. For every vertex $i \in V$ the triple (d_i, w_i, b_i) is calculated, where d_i is the distance from the source vertex, w_i is the number of shortest paths from source vertex to vertex i, and b_i is the number of shortest paths between source vertex to any vertex in graph that pass through vertex i.

For this algorithm we denote $Adj(v)$ as the set of all vertices adjacent to $v \in V$.

The first part of the algorithm for vertex marking:

1) For initial vertex $s \in V$ let $d_s = 0$, $w_s = 1$, $b_i = 0$.
2) Let $d_v = \inf$, $w_v = 0$, $b_v = 1$ for all $v \neq s \in V$.
3) Create queue Q, $Q \leftarrow \{s\}$. Create list L, $L \leftarrow \{s\}$.
4) While Q is not empty:
   a) Dequeue $i \leftarrow Q$.
   b) For each vertex $j \in Adj(i)$:
      i) If $d_j = \inf$ then $d_j = d_i + 1$, $w_j = w_i$. Enqueue $j \rightarrow Q$. Push $j \rightarrow L$.
      ii) If $d_j \neq \inf$ and $d_j = d_i + 1$ then $w_j += w_i$.
      iii) If $d_j \neq \inf$ and $d_j < d_i + 1$, do nothing.

Efficient implementation of this part of the algorithm could be done by using abstract data type queue.

The second part of the algorithm starts from the vertex that was last marked in the first part of the algorithm and visits vertices in reverse order than they were visited in the first part of the algorithm. Only one shortest path from source passes through the last marked vertex.

The second part of the algorithm for edge betweenness calculation:

1) While L is not empty:
   a) Pop $i \leftarrow L$.
   b) For each vertex $j \in Adj(i)$:
      i) If $d_i < d_j$ then $b_i = 1 + \sum_j \sigma_{ij}$.
      ii) If $d_i > d_j$ then $\sigma_{ij} = \frac{w_j}{w_i} * b_i$.

Both parts of the algorithm are performed for all source vertices s and edge betweeness for every edge is calculated as a sum of the edge betweennesses calculated in every step.

The computational complexity of this part of algorithm is $O(mn)$, where m is the number of edges and n is the number of vertices. After each edge betweenness calculation, the edge with highest edge betweenness is removed and the algorithm is repeated until there is no remaining edge. The algorithm complexity is therefore $O(m^2n)$.

In complex networks it is often the case that more edges have the same highest edge betweenness. Since the recalculation of edge betweenness has $O(mn)$ complexity, in order to reduce the number of calculations we could remove all edges with the highest edge betweenness in the same step. On the other side, Girvan-Newman algorithm does not say anything about the order of removal for those edges leaving that detail to implementation.

Consequently, we introduce modification of the Girvan-Newman algorithm:

1) Calculate edge betweenness for every edge in the graph.
2) Remove all edges with highest edge betweenness.
3) Recalculate edge betweennes for remaining edges.
4) Repeat 2-4 until graph becames empty.

Worst-case time complexity is still $O(m^2n)$, but in networks with strong community structure the number of calculations could be significantly reduced.

The main problem of Girvan-Newman algorithm is the fact that it is not really an algorithm that has a graph as input and community structure as output. Namely, if the labeling of the vertices of the graph is rearranged, than the result of Girvan-Newman algorithm may change. Hence, there is no unique output for a given input (which should be a property of any algorithm). Our modification amends this shortcoming of the Girvan-Newman algorithm. Namely, our community structure indeed does not depend on the labeling of the vertices of the graph.

Also, this modification may reduce the number of operations of the algorithm. However, this strongly depends on the observed graph. There are graphs for which no improvement will be obtained and there are graphs for which significant improvement will be obtained. The most drastic example may be edge-transitive graphs (i.e. graphs such that for each two edges e and f there is the automorphism that maps e to f). Standard Girvan-Newman algorithm has complexity $O(m^2n)$ on this graphs also, while our algorithm does not repeat calculation for each edge, but does everything in a single step reducing complexity to $O(mn)$.

IV. Modularity

The algorithms used for community structure detection in networks give an overview of possible communities. Simulation of decomposition done by Girvan-Newman method gives more information of network structure. Knowing network structure, it is possible to predict critical connections in the network, and therefore, control the network. For example, in the electricity distribution network detecting critical connections could be a method to prevent the collapse of the system that has occurred in the United States in 1965, 1996, and in September 2011.

However, the question is when an optimal decomposition of a network into communities is reached. To answer that ques-

tion it is not necessary to decompose network in communities of the size one. Qualitative measure of network decomposition is called **modularity** [5].

For a particular partition of a network into k communities, let us define $k \times k$ matrix E such that e_{ij} is the fraction of number of edges that connect vertices between community i to community j in the total edge number. Then on the diagonal of the matrix E is the fraction of edges that are located within the same community, so the trace of the matrix $tr(E)$ is the fraction of edges that will not be removed in process of removing edges. A good partition is the partition with high value of the trace. However, that number will be the highest in the case where all the vertices are in the same community, so it does not always give necessary information about the structure of the communities.

We define modularity:

$$Q = \sum_i (e_{ii} - a_i)^2 = tr(e) - \|E^2\|,$$

where $\|\|$ is the sum of matrix elements, as the fraction of edges that connect vertices within communities decreased with the expected fraction of edges within partition in random graph [6]. When the fraction of edges within the communities is higher than it is in random graph, the value is $Q = 0$. As Q is approaching the value 1, the community structure in network is better. In most cases, the value of Q is between 0.3 and 0.7 [5].

Value Q is calculated in every step of divisible algorithms. The maximum value q gives us the best partition of the graph.

V. Results

We tested the Girvan-Newman algorithm with the single edge removal and modified algorithm with the multiple edges removal on three different complex networks. The first, Zachary's karate club; the second, computer generated random network; and the third, network of cancer genes with co-occurring and anti-co-occurring mutations.

A. Zachary's Karate Club

Zachary's karate club is the example of the real-world network for which it is known how the network was split in reality. Fig. 2 shows the friendship network between 34 members of a karate club at a US university observed by an anthropologist Wayne Zachary for a period of three years, from 1970 to 1972 [7].

At the beginning of the study there was a conflict between the club president (node 34) and the karate instructor (node 1). During the study club was divided into two parts and has become the most frequently tested dataset in the network communities detection area. The Girvan-Newman algorithm divides the network into two communities with an accuracy of 97% (which is also Zachary's accuracy) with wrong classification of the node 3 (in Zachary's study the node 9 was wrongly classified). Fig. 3a shows the dendrogram generated using the Girvan-Newman algorithm, while Fig. 3b shows the dendrogram generated using implementation of modified method with multiple edge removal. It is clear that our method leads to faster separation of the communities i.e. reduced number of operations (Fig. 4). The algorithm modularity values are high when the network is divided into two communities which is expected concerning the nature of community and the process of the separation. However, modularity is the largest in the network partition to the three communities. On Fig. 2 we can see that there exists a community of five nodes (5, 6, 7, 11, 17) with high number of links within community and small number of links to other communities.

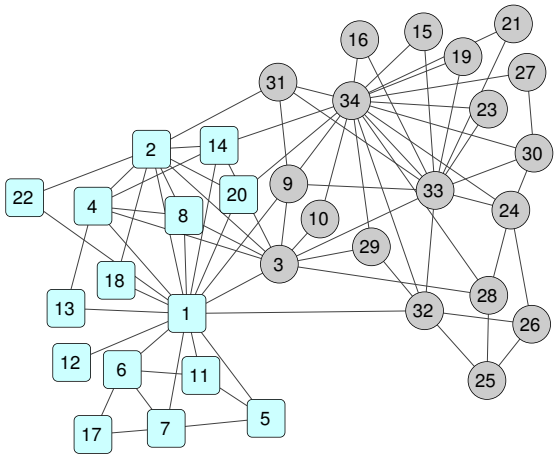


Figure 2: Zachary karate klub

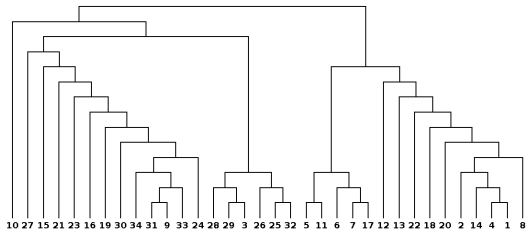
B. Computer generated network

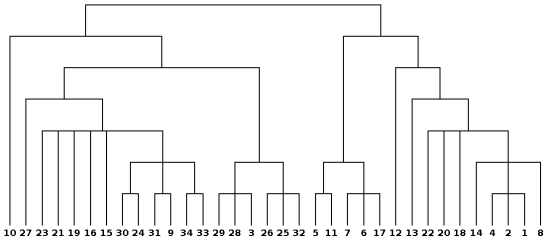
In addition to real-world examples we analysed computer-generated network with strong community structure. For this purpose, network with 48 vertices divided into communities of 16 vertices is generated with probability p_{in} that edge is within community and p_{out} that edge is between communities. Fig. 5 presents the modularity values for Girvan-Newman algorithm and for our multiple-edge-removal modification of the algorithm. The modularity function maximum is reached in both algorithms when the network is divided in three communities, but needed fewer steps to complete calculation in the latter case. Both algorithms correctly classify all nodes.

C. The network of cancer genes with co-occurring and anti-co-occurring mutations

The network of cancer genes with co-occurring and anti-co-occurring mutations (CCA network) is presented in [8]. CCA networks are studied in order to better understand the development of cancer and community detection in such networks is an important property. The cancer genes are nodes and co-occurring and anti-co-occurring mutations are links between them. The tested network has 306 nodes and 1366

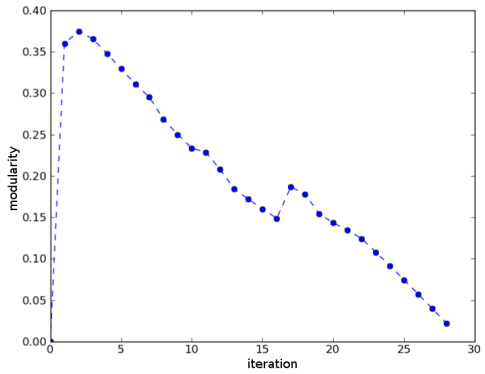


(a) Single edge removal



(b) Multiple edge removal

Figure 3: Zachary's karate club



(a) Single edge removal

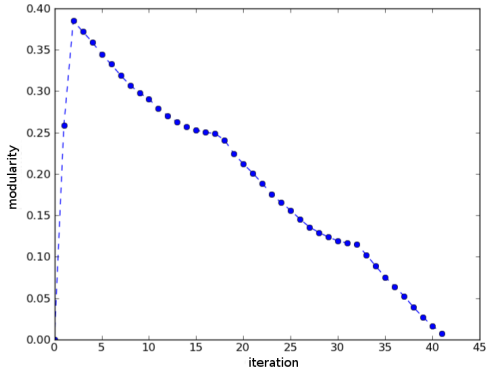
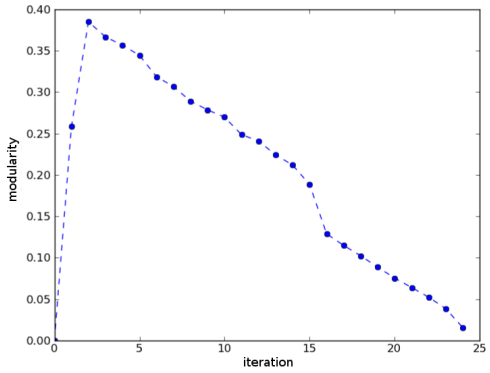
edges, of which 1355 are co-occuring and 11 are anti-co-occuring.

The number of iterations in this example needed to divide



(a) Single edge removal



(b) Multiple edge removal

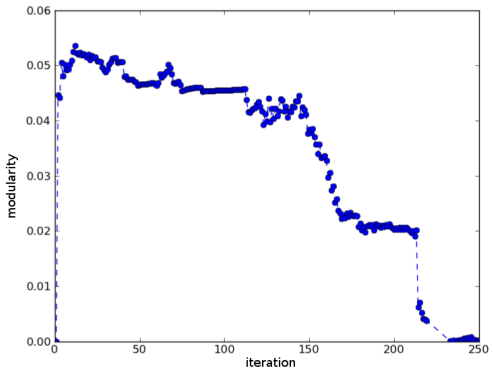
Figure 5: Computer generated network modularity

the network into communities with modularity 0 is much smaller when multiple edge removal is done. Both algorithms correctly classify all the nodes.

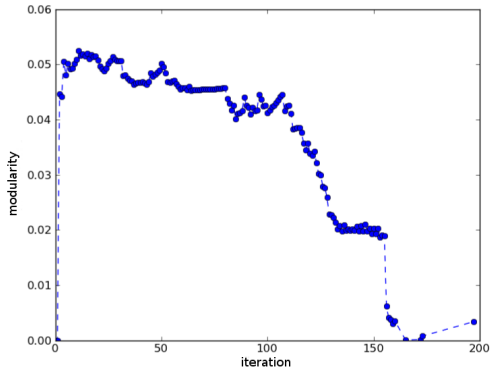
VI. Conclusion

Community detection in networks is important for different scientific and practical areas. It is not a surprise that in this article we refer to articles of physicists, sociologists, mathematicians, biologists, epidemiologists, etc. Complex network research is young discipline and with its rapid development reflects the flourishing of interdisciplinary research. Graph theory is widely used in various applications in different areas. Some of them are mentioned in this article. The robustness of a network and analysis of system collapse due to the elimination of nodes or links between nodes is of great importance in the study of networks. How can we stop the propagation of diseases? How can we determine the most important airlines or highways? Algorithms decribed in this article help us to experience the world around us.

Girvan-Newman algorithm is one of the first algorithms that deals with detecting communities in networks and as such suffers from certain "childhood diseases". Number of operations is proportional to m^2n, or n^3 for sparse networks, which limits performance on networks with up to tens of



(a) Single edge removal



(b) Multiple edge removal

Figure 6: A network of cancer genes with co-occurring and anti-co-occurring mutations modularity

thousands of nodes. Methods based on modularity, [6] [9] [10], the use of the eigenvectors of matrices [11], and greedy algorithms [12] give us smaller complexity than Girvan-Newman method. Regardless, in this article we focused on the Girvan-Newman method and its improvement, as a starting point for any subsequent methods. This small algorithm improvement reduces the number of operations, but still not enough to apply it on large complex networks. But on smaller networks it has a high percentage of correct classification of nodes and it is independent of vertex labeling, which puts it ahead of other methods.

Performance Evaluation of Websocket Protocol for Implementation of Full-Duplex Web Streams

D. Skvorc, M. Horvat, and S. Srbljic
University of Zagreb/School of Electrical Engineering and Computing, Zagreb, Croatia
dejan.skvorc@fer.hr, matijah@acm.org, sinisa.srbljic@fer.hr

Abstract – Besides traditional synchronous HTTP request-response communication paradigm that was used on the Web for decades, modern Web services require more flexible communication system that enables asynchronous messaging between clients and servers, as well as server-initiated data delivery. Among several Web-based asynchronous communication paradigms emerged recently, the *Websocket* protocol and corresponding *Websocket* API are accepted as a pivotal framework for implementation of full-duplex asynchronous Web streams.

In this paper, we evaluate the performance of the *Websocket* protocol with respect to underlying TCP protocol. We compare the two against the latency and amount of generated network traffic. The results show that, except a small overhead imposed due to initial handshaking, *Websocket*-based communication does not consume any more network traffic than plain TCP based communication. However, it is still slightly inferior in terms of latency.

I. INTRODUCTION

Since its announcement in the early 1990's, the HTTP protocol is the primary communication protocol for the World Wide Web [1, 2]. HTTP is an application-level protocol built on top of the TCP/IP protocol stack. It was designed to operate in client-server settings with strict separation of concerns between clients and servers. Client is responsible to ask for data or service from a server by sending an HTTP request. On the other hand, server responds with an HTTP response, carrying the results of execution of the action required by the client. Server hosted data and services are delivered to the clients upon their requests only, rather than being delivered autonomously when they become available on the server. Request-response paradigm of the HTTP protocol dictates a synchronous operation of the communication parties, which means that every HTTP request from a client is followed by an HTTP response sent by server. This prevents or at least diminishes the application of the protocol in modern Web-based environments that require more sophisticated and flexible communication models.

Recent research in the field of real-time Web tried to overcome the limitations of the HTTP protocol by upgrading the natively non-asynchronous communication paradigm and tuning it to operate in asynchronous settings. That resulted in various conceptual models, such as HTTP-based polling and long polling [3], and technologies, such as *Comet* [4] and *BOSH* [5]. However, each of these technologies either provides only a subset of the required functionalities or tradeoffs the system's simplicity, scalability, and performance for the sake of functionality. For example, *Comet* and *BOSH* only simulate the asynchronous communication between client and server by maintaining two TCP connections, one for upstream, and another one for downstream communication. Recently introduced *Websocket* protocol [6, 7] and *Websocket* API [6, 8], developed as part of the HTML 5 standard [9], are currently the only true asynchronous full-duplex communication framework for the Web. *Websocket* protocol and *Websocket* API bring the expressiveness and flexibility of the TCP sockets to the Web applications, where access to the raw TCP sockets is otherwise not allowed. *Websocket* technology is now natively supported in all major Web browsers and Web servers, while *Websocket* API libraries are available for almost any programming language used in Web development [10, 11, 12, 13, 14, 15].

Many discussions and written reports have been published so far comparing the performance of the *Websocket* and related technologies [16, 17, 18]. All of them highlight the *Websocket* as a breakthrough technology for implementation of asynchronous full-duplex real-time Web streams. However, little is known about the performance degradation this high-level protocol imposes over a plain TCP socket based communication, which still remains an underlying transport mechanism.

In this paper, we compare the *Websocket* and the TCP protocol against two performance-related dimensions: latency and amount of generated network traffic. Although both protocols provide similar communication capabilities, in general they should not be considered as alternatives to each other since they operate at different levels of the Internet protocol stack. While native applications may directly access the raw TCP protocol through the sockets API, until recently Web applications were limited to the HTTP protocol and its synchronous request-response communication paradigm. The *Websocket* protocol is an application-level protocol built on top of the TCP and specifically designed to expose TCP-like communication capabilities to Web applications, which do not have access to the raw TCP sockets. Thus, the goal of our research was to determine the amount of inevitable performance loss if full-duplex asynchronous communication system operates within the limitations of Web settings.

The rest of this paper is organized as follows. Section 2 outlines the most important characteristics of the *Websocket* protocol and shortly describes the *Websocket* API. We emphasize the *Websocket* handshake and *Websocket* frame as key factors used during the evaluation. In Section 3, we describe the evaluation procedure, the experiments for benchmarking the performance of the *Websocket* protocol, and the results gained from these experiments. Section 4 concludes the paper.

II. WEBSOCKET PROTOCOL AND WEBSOCKET API

The *Websocket* protocol [6, 7] is an application-level protocol built on top of the TCP. It enables bidirectional data transport in Web sessions, and is considered as a viable alternative to HTTP polling techniques [3], which are implemented as tradeoffs between functionality, efficiency, and reliability. As such, the *Websocket* protocol is suitable for Web-based near real-time traffic required in games, chats, stock exchange information systems, multimedia systems, remotely controlled systems, etc.

Although similar in functionalities to the regular TCP protocol, the *Websocket* protocol is backward compatible with the existing Web infrastructure. The *Websocket* handshake is compliant with the HTTP 1.1 specification. Furthermore, *Websocket*-based communication inherits all the benefits of the existing Web infrastructure, such as

- native support in Web browsers, including origin-based security model
- proxy and firewall traversal
- URL-based endpoints which enable multiple, and potentially unlimited number of services running on a single TCP port
- elimination of length limits imposed by plain TCP protocol

Fig. 1 shows a sequence diagram of a *Websocket* session and emphasizes the communication overhead the *Websocket* protocol requires over the plain TCP protocol. Since the *Websocket* is a TCP-based protocol, it requires a TCP connection to be established between client and server before any *Websocket*-based interaction can occur. Handshaking a TCP connection requires three messages to be exchanged between client and server. At this point, two peers that have direct access to the plain TCP protocol can start sending application-specific payload data to each other. However, for *Websocket*-based communication, a *Websocket* session should be established first.

To establish a session, client sends a *Websocket Upgrade Request* to the server, upon which server responds with a *Websocket Upgrade Response*. From this point forward, even the Web-based client and server can send data back and forth in asynchronous full-duplex mode.

A. Protocol Handshake

The *Websocket* handshake takes the advantage of the HTTP protocol in the session establishing phase. The *Websocket Upgrade Request* is a regular HTTP GET request with session endpoint specified as a request URI component. HTTP headers `Upgrade` and `Connection` are indication to the server that the client wants to switch from regular HTTP to the *Websocket* protocol for the rest of the session. Other fields enable negotiation of additional *Websocket* options, such as protocol version, subprotocol indication, and security-related parameters, such as script origin and *Websocket* key used to confirm the connection acceptance.

```
GET /chat HTTP/1.1
Host: server.example.com
Upgrade: websocket
Connection: Upgrade
Sec-WebSocket-Key: dGhlIHNhbXBsZSBub25jZQ==
Origin: http://example.com
Sec-WebSocket-Protocol: chat, superchat
Sec-WebSocket-Version: 13
```

If the server supports the *Websocket* protocol, it replies with an HTTP response with a status code set to `101 Switching Protocols`. From this point forward, the HTTP-based communication is finished and all further communication is based on *Websocket* frames.

```
HTTP/1.1 101 Switching Protocols
Upgrade: websocket
Connection: Upgrade
Sec-WebSocket-Accept: s3pPLMBiTxaQ9kYGzzhZRbK+xOo=
Sec-WebSocket-Protocol: chat
```

B. Data Framing

Units of data transfer in the *Websocket* session are called *Websocket* frames. The *Websocket* protocol supports binary data frames, textual UTF-8 encoded data frames, and control frames for protocol-level signaling. Minimal framing information is added to each payload data, as shown in Fig. 2.

Each *Websocket* frame begins with at least 2 bytes long header prepended to the payload data. Depending on the length of the payload data and the direction of the communication, the length of the header may increase up to 14 bytes.

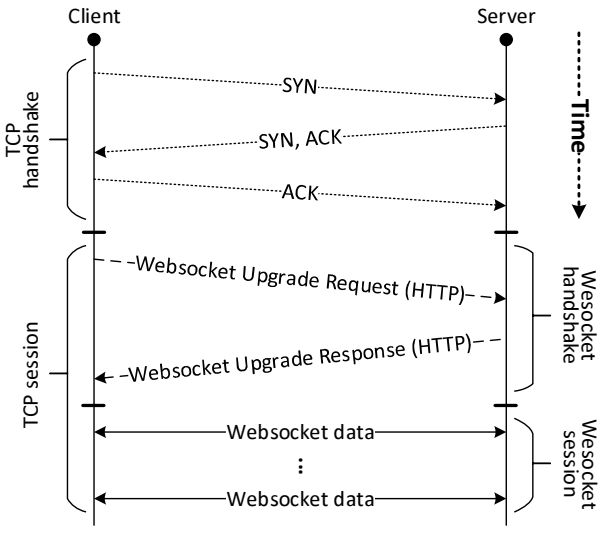

Figure 1. *Websocket*-over-TCP sequence diagram

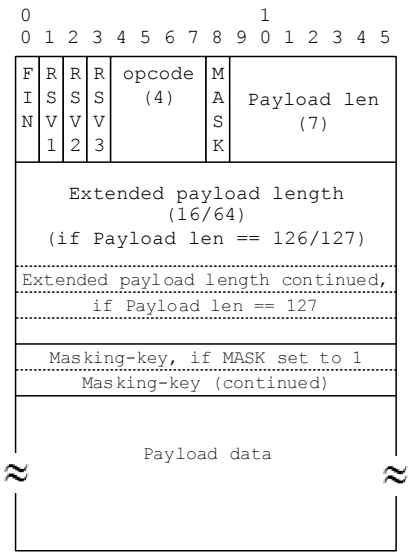

Figure 2. *Websocket* frame structure

First byte contains control bits and 4-bit operation code `opcode`, which defines whether the payload data should be interpreted as binary data, textual data, or protocol-level signaling. Next bit is a `MASK`, which if set to 0 signals that the payload data are transferred in clear form, and obfuscated otherwise. Following 7 bits are used to indicate payload data length. If payload data length is up to 125 bytes, this value is directly specified in `Payload len` field. If payload length is between 126 and 65535 bytes, the `Payload len` field is set to 126, and two additional bytes are added to specify the actual payload data length. Finally, if payload data are longer than 65535 bytes, the `Payload len` field is set to 127, and 8 additional bytes are added to specify the actual payload data length.

Client-originated frames must additionally be obfuscated with a 32-bit `Masking key`, specified in the following 4 bytes of the frame header. This is required to disable the unwanted payload processing performed by the network intermediaries that may discover patterns of HTTP traffic in *Websocket* frames. For example, if a *Websocket* frame contains a pattern of HTTP traffic, an HTTP proxy may accidentally decide to cache the data as if they were regular HTTP traffic. This is a security vulnerability known as HTTP proxy cache poisoning [19, 20]. For frames sent from server to the client, this masking is not necessary, thus 4 bytes containing a `Masking key` are omitted in server-originated frames. The *Websocket* frame ends with payload data of specified length.

Table 1. Event-driven *Websocket* API

Callback	Description
`onopen`	invoked when *Websocket* session is established, signalizes that the protocol is ready to transfer payload data
`onerror`	invoked whenever an error occurs
`onclose`	invoked when one of the peers has terminated the session
`onmessage`	invoked when an incoming message from another peer has arrived

C. *Websocket API*

Besides the protocol itself, *Websocket* specification also defines the API to interact with the protocol [6, 8]. The *Websocket* API is defined by its states of readiness, responses to a networking or messaging event, and message types available for data transfer between client and server. Table 1 summarizes the protocol events exposed to applications through an event-driven callback-based API.

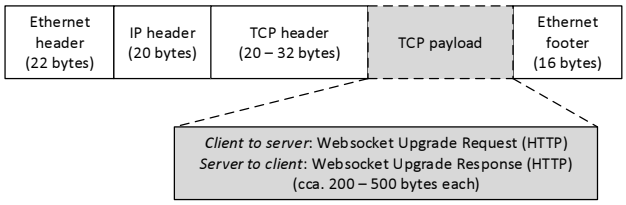
III. PERFORMANCE EVALUATION

Performance evaluation of the *Websocket* and the TCP protocol we present in this paper consists of comparison of the network traffic and data transfer time these two protocols consume to transfer given amount of data between client and server. Since the size of data frames in both protocols depends solely on the size of the payload data, we evaluate the protocols' efficiency from the network traffic perspective analytically, using the protocol specifications defined in *Websocket* RFC [7] and TCP RFC [21], respectively. On the other hand, data transfer time is evaluated experimentally in a laboratory test bed.

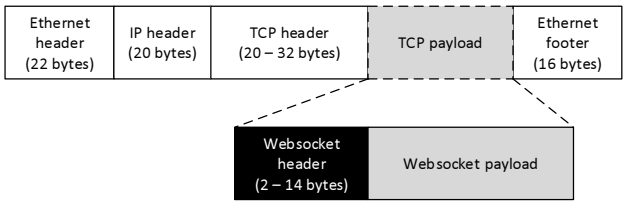
A. *Analitical Evaluation of Network Traffic*

Fig. 3 shows the embedding of the protocol fields in the Internet protocol stack. Regardless of whether the two peers communicate directly via TCP or through the *Websocket* protocol, lower level protocol fields, including the TCP header, are always present in all network packets. Thus, our analysis takes into account only the overhead the *Websocket*-based communication incurs over the plain TCP-based communication. This overhead includes two HTTP messages transferred during the *Websocket* handshake, as well as *Websocket* frame headers for each frame transferred during the session.

The overhead of the *Websocket* handshake is fixed in length and typically counts few hundreds of bytes. Since this handshake is performed once per session, its significance decreases with each new *Websocket* frame carrying payload data. Thus, the rest of our evaluation is focused on long-running sessions, where the impact of the



a) Network packet structure during the *Websocket* handshake



b) Network packet structure during the *Websocket* session

Figure 3. Protocol relationship in the Internet protocol stack

initial handshake is diminished and the only observable traffic overhead is caused by the *Websocket* data framing.

When given amount of payload data are transferred using plain TCP protocol, these data are directly embedded as TCP payload. However, when transferred as a *Websocket* frame, then the TCP payload consists of both payload data and a *Websocket* frame header, as shown in Fig. 3b. This relation is given in (1), where *data* is the length of the payload data, P_{TCP} is the length of the TCP payload when these data are transferred as a TCP payload, P_{WS} is the length of the TCP payload when the same data are transferred as a *Websocket* payload, while H_C is the length of the *Websocket* frame header for client-originated frames.

$$\begin{aligned} P_{TCP} &= data \\ P_{WS} &= data + H_C \end{aligned} \tag{1}$$

As shown in Fig. 2 and described in Section 2, the *Websocket* protocol uses variable frame header length that depends on the size of the payload data. The *Websocket* framing scheme is given in (2), where *data* is the length of the payload data, H_S is the length of the frame header for server-originated frames, while H_C is the length of the frame header for client-originated frames. As described in Section 2, masking of client-originated frames requires 4 additional header bytes in relation to server-originated frames.

$$\begin{aligned} H_S &= \begin{cases} 2, & 0 \le data \le 125 \\ 4, & 126 \le data \le 65535 \\ 10, & data \ge 65536 \end{cases} \\ H_C &= H_S + 4 \end{aligned} \tag{2}$$

The network traffic overhead O_P a *Websocket*-based communication incurs over a plain TCP-based communication is given in (3). The dependence of this overhead on the size of the payload data is given in Fig. 4. The graph shows a worse case, with a client-to-server directed communication only, where each *Websocket* frame is prepended with 4 additional bytes carrying a masking key.

$$O_P = \frac{P_{WS} - P_{TCP}}{P_{TCP}} \cdot 100\% \tag{3}$$

Significant difference in performance of the two protocols occurs only for tiny messages of just few bytes in size. In this range, the *Websocket* protocol generates almost an order of magnitude more network traffic than the TCP. However, even with this additional traffic, the total overhead is no more than six bytes, as defined in (2). For bigger messages, the *Websocket* frame size converges very fast towards the non-framed TCP payload size. For messages bigger than 1 kB, the overhead is less than 1 %. The relation shown graphically is given for small range of payload data sizes only, where the difference in the behavior of the two protocols is significant. We intentionally omitted the rest of the graph, where this relation asymptotically approaches to 0.

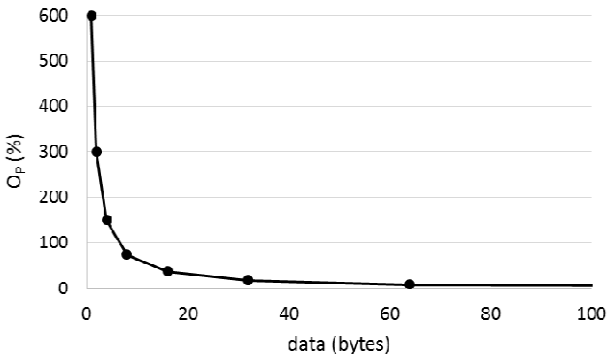


Figure 4. Network traffic overhead of the *Websocket* protocol in relation to the TCP protocol

Except the initial handshaking performed through one HTTP round trip at the beginning of the session, the amount of network traffic generated by the *Websocket* protocol is comparable to that generated by the plain TCP. With a carefully designed framing scheme, which gradually decreases the amount of framing information as the payload data decrease in size, the *Websocket* protocol generates negligibly more network traffic than plain TCP, even for the smallest amounts of data.

B. Experimental Evaluation of Data Transfer Time

Experimental environment for measuring data transfer time consists of two host machines, one playing the role of a server, while other being a client. Hardware and software configuration of these host machines are given in Table 2.

Both protocols are similar in terms that they both require particular form of negotiating the protocol parameters between communicating parties, prior to be able to transfer actual data through the network. Thus, we separately measure the time required to negotiate a connection and the time required to transfer a chunk of payload data from one side to the other.

In our first experiment, we measure the time required for client and server to establish a TCP connection and a *Websocket* session, respectively. Results are given in Fig. 5.

Table 2. Experimental environment configuration

	Client	**Server**
Hardware	CPU: AMD Turion II P520 RAM: 6 GB	CPU: AMD Athlon X2 5000+ RAM: 5 GB
OS	Windows 8 64-bit	Windows 8 64-bit
Network	1000BASE-T (Gigabit Ethernet, host machines directly connected using UTP Cat5 Ethernet cable)	
TCP implementation	*java.net.Socket* (Java JDK 1.7)	*java.net.Socket* (Java JDK 1.7)
Websocket implementation	*org.eclipse.jetty.websocket.**client**.** (Jetty 9.1.0)	*org.eclipse.jetty.websocket.**servlet**.** (Jetty 9.1.0)

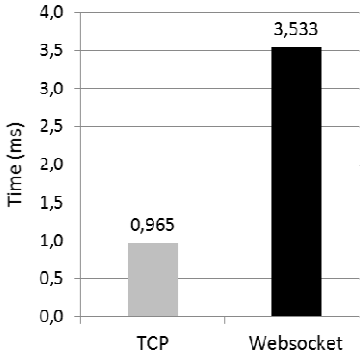

Figure 5. Comparison of TCP and *Websocket* handshake duration

In our laboratory environment with client and server being directly connected with a Gigabit Ethernet cable, establishing a *Websocket* session lasts 3.7 times longer than establishing a TCP connection. The reason for such a slow performance of the *Websocket* protocol is the fact that the *Websocket* protocol is not a real transport protocol, but rather an application-level protocol built on top of the TCP. This means that each *Websocket* session requires a TCP connection to be established first, as shown in Fig. 1. Thus, setting up a *Websocket* session includes all the actions required for setting up a TCP connection, plus an additional HTTP round trip for a *Websocket* handshake. Besides the time required to transfer two HTTP messages through the network, this additional handshake also includes the time necessary for client and server to allocate the necessary resources and initialize the *Websocket* API callbacks required to perform a *Websocket*-based communication in the rest of the session.

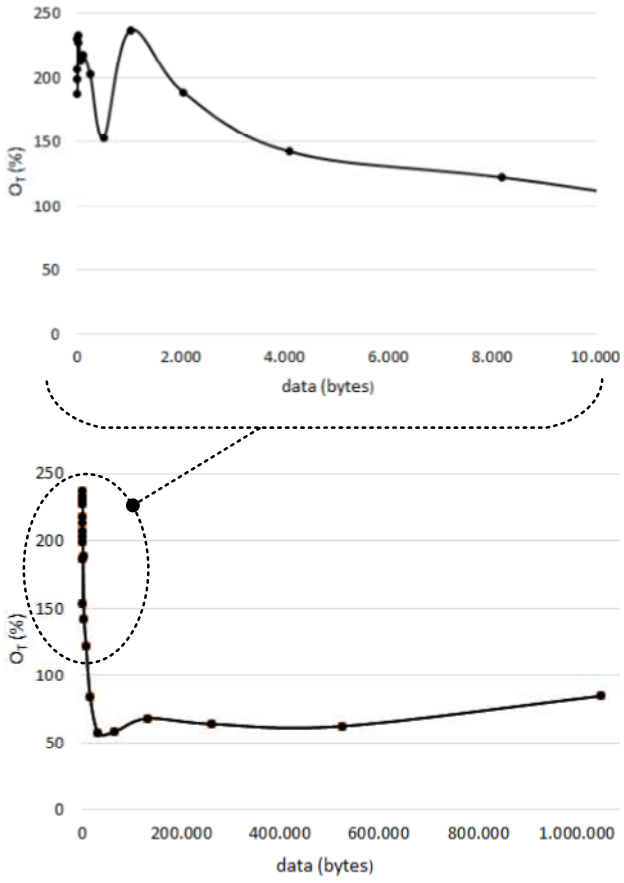

Figure 6. Data transfer time overhead of the *Websocket* protocol in relation to the TCP protocol

In our second experiment, we measure the data transfer time between client and server once the TCP connection and the *Websocket* session have been established. Client generates a given amount of payload data and sends them to the server. Upon receiving all the data, server echoes the same data back to the client. Client measures a round trip time. Results are given in Fig. 6. On vertical axis, we show a relative time overhead O_T a *Websocket*-based communication incurs over a plain TCP-based communication. This overhead is calculated by (4), where T_{TCP} is the time required to transfer the data using plain TCP protocol, while T_{WS} the time required to transfer the same amount of data using the *Websocket* protocol.

$$O_T = \frac{T_{WS} - T_{TCP}}{T_{TCP}} \cdot 100\% \quad (4)$$

Here we notice that, despite of the negligible difference in the overall amount of data being transferred (payload + *Websocket* frame headers), the *Websocket* protocol performs significantly slower than the TCP through the whole spectrum of the test cases. The performance drop is more significant for small messages and gets better as message size increases. The overhead of the *Websocket*-based communication fluctuates between 150 % and 250 % for very small messages. For bigger messages, as message size becomes more and more dominant factor in data processing and data transfer, the overhead gets stable at roughly 60-70 %.

There are several factors that impact the performance of the *Websocket* protocol. First reason is the relationship of the TCP and the *Websocket* protocols in the Internet protocol stack. The *Websocket* operates at a higher level of the stack and consumes more computational resources that deliver the data from the TCP layer to the upper layers. Second, opposed to TCP, the *Websocket* protocol uses an event-driven callback-based API to deliver data to Web applications, which requires additional application-level data handling. Third, every message sent from a client to a server requires additional processing to mask the data with a 32-bit masking key on a client, and to unmask them on a server. One more reason, yet unconfirmed in our experiments, might be the implementation of the protocol itself. While TCP protocol is intensively used for decades and highly optimized libraries are available for almost any programming language, the *Websocket* protocol emerged just a few years ago, with little production systems deployed so far, and with early implementations not yet verified by wide research and developer community.

IV. CONLUSION

In this paper, we have analytically and experimentally compared the *Websocket* and the TCP protocol against two performance-related dimensions: amount of generated

network traffic and data transfer time. As expected, TCP protocol slightly outperforms the *Websocket* protocol in both of these dimensions because the *Websocket* operates at the application layer and uses the underlying TCP as a transport layer protocol. While the difference in the amount of generated network traffic is minimal and negligible for any practical use, the degradation in data transfer time is still remarkable due to operation at a higher level of the Internet protocol stack, data masking, and event-driven callback-based interface to applications. However, the advantage of the *Websocket* protocol is its alignment with the existing Web infrastructure, where low-level TCP protocol is not directly applicable.

Since the *Websocket* protocol augments the Web with a TCP socket-like communication capabilities that were not available or were only inefficiently simulated in HTTP-based applications, slight drop in performance in relation to the plain TCP protocol still makes it a powerful mechanism for implementation of full-duplex asynchronous Web-based data streams. If used as intended, in long-running Web sessions, where data are continuously streaming between client and server, the cost of initial HTTP handshaking is split over the large number of optimized payload transfers and gets negligible even after few client-server interactions.

Improving thread scheduling by thread grouping in heavily loaded many-core processor systems

Luka Milić* and Leonardo Jelenković**

**University of Zagreb, Faculty of Electrical Engineering and Computing, Zagreb, Croatia
luka.milic@foi.hr, leonardo.jelenkovic@fer.hr

Abstract – Basic scheduling techniques currently employed in operating systems usually don't account for hierarchy of processors cores and caches resulting in suboptimal system efficiency, especially on heavy loaded systems. In this paper we explore possible improvements in scheduling for such heavy loaded many-core systems. Basic idea is to group threads of the same process as close as possible, preferably even on the same processor. We expect that doing so may improve efficiency of processor's cache usage, resulting in better overall performance. The idea is tested by adapting the Linux's simplest scheduler (in code) – a round-robin scheduler. Achieved results are presented in this paper.

I. INTRODUCTION

Today's operating systems schedulers mostly do not differentiate multiprocessor system where every processor is simple (one core) from many core system where many cores are coupled on single processor sharing its caches and connections to system busses. Virtual cores (hyper-threading) are also usually treated the same (as regular processor). That is not really a problem until there are not many cores/processors in the system. In the future that is very likely going to change as most computers working non-trivial jobs will have many cores [1].

Architectures of multi and many core systems are various. Most personal computer systems (and some smart phones and tablets) have a single multi core processor. Workstations and servers that require more computing power may have several multi core processors. In the future multi core processors (up to 8 cores) will probably be replaced by many core processors (from 8 cores and up). Computing power of many core processor systems is not relaying only on raw processor's core capabilities and number of cores but also on data acquisition. Cores in many core processor are usually arranged in local groups that share local cache memory. Although any core can fetch data from anywhere (local cache, non-local cache, main memory), delay such fetch operation request will be lesser if data is closer.

Thread scheduling algorithm should take thread's properties and inter-thread interactions into account for achieving more efficient use of processor's cache and thus improve overall system performance [2][3]. Usually, threads of the same process operate on shared data and have high level of interactions. We will call such threads as connected threads (co-threads). Although threads from different processes can also be connected (i.e. use same shared resources), that is rarely, more exception than a rule.

Scheduling algorithm should be aware of connected threads as well as processor's core architecture where those threads are to be placed.

In systems in which the average number of ready threads is not much greater than the number of processor cores, scheduling procedures should keep connected threads as close as possible, on cores that share same caches (L2/L3).

In heavier loaded systems (at least twice as much threads than cores) different way of scheduling may be appropriate. Considering that it is more difficult to achieve a synchronous work of interconnected threads on multiple cores, which may be the optimal scheduling for those jobs (and maybe generally), the alternative could be to collect such threads on the same core. The advantage of this approach is in efficient use of the cache of such cores because it is expected that such interconnected threads will use the shared data probably already present in cache. In this way we will lose potential for parallel execution, but on heavy loaded system probability for such parallelism might be very small, and efficient use of cache could prove more beneficial.

Since schedulers don't differentiate simple single core processor from one core of multi/many processor, when describing existing schedulers we use term processor as synonym for both. In same context, term multiprocessor is used for describing systems that have more processor cores, standalone ones or in multi core package.

For testing such hypothesis a rather simple scheduler `SCHED_RR` from the Linux operating system is used and adapted. Primary reason for choosing `SCHED_RR` even if its real-time scheduler over `SCHED_OTHER` default scheduler for general thread is in source code simplicity. `SCHED_OTHER` that implements Completely Fair Scheduling algorithm is far more complex and hard to adapt. If proposed adaptation don't give positive results for `SCHED_RR` (using threads with same priority, which de facto turns off any real-time properties of scheduler) there is no reason for going into adapting `SCHED_OTHER`.

In section II we first describe scheduler `SCHED_RR`. Section III describes our modification of `SCHED_RR` scheduler, and section IV presents simulation environment and achieved results.

II. LINUX SCHED_RR SCHEDULER

Linux, like most operating systems use different scheduling policies for different types of threads, particularly differentiate normal from real time threads.

A. Linux scheduling policies

Currently, for normal threads Linux supports scheduling policies `SCHED_OTHER`, `SCHED_BATCH` and `SCHED_IDLE`. Those scheduling policies are based on a completely fair distribution of the virtual processor time. This virtual time is a rather complex function of the fair thread priority, real time and the processor consumption by fair threads [4].

Real time scheduling policies `SCHED_FIFO` and `SCHED_RR` are priority based schedulers. Thread with highest priority is always scheduled first. Difference between `SCHED_FIFO` and `SCHED_RR` policies are in scheduling of more than one highest priority threads.

For example if we have ready threads A and B with same highest priority, `SCHED_FIFO` will pick one that become ready first and execute it until it finished or block itself voluntarily. `SCHED_RR` will alternate threads A and B on processor, giving each a time interval before switching to next. On multiprocessor system (or multi/many core) both threads will be running in parallel, each thread on its processor.

On multiprocessors, real time thread scheduling is based on a system-wide strict priority scheduling. Since we use this mechanism to adapt scheduling, system-wide strict priority scheduling is detailed in next subsection.

B. Push-pull algorithm

Strict priority scheduling in a multiprocessor system with *N* processors must ensure that *N* highest priority threads are always chosen as active on those processors (one thread per processor) [5].

The priorities of real time threads are in range from 1 to 99, where higher number represent higher priority. For each processor there is separate data structure containing 99 thread queues, one thread queue per priority. Every ready real time thread is placed into one thread queue, one that matches thread's priority. Active thread for each processor is chosen from its ready queues (thread from highest non-empty queue), and then removed from that queue and marked as active.

System-wide strict real-time priority scheduling is implemented by using *push-pull algorithm* on overloaded thread queues. A real time thread queue is considered to be *overloaded* if it holds at least one another thread (besides currently active) which could be migrated to another processor according to that thread's processor affinity mask.

Push part of the algorithm is performed on processor which uses overloaded thread queues. Its purpose is to push overloaded threads to other processors that will immediately execute them. Such processors must be acceptable by such threads (they must be in thread affinity mask) and currently running lesser priority threads.

More precisely, push algorithm is activated on particular processors only after events:

1. active real time thread is changed (replaced with higher priority thread or its priority is lowered);
2. a new real time thread is created on current processor;
3. a real time thread is waked on current processor.

The push algorithm splits into three algorithms: *pushing*, *finding* and *searching*.

The *pushing* algorithm is activated when a queue on a given (current) processor is overloaded. Highest-priority thread from overloaded queue is then passed to *finding* algorithm which might find a processor where migrate such thread.

The *finding* algorithm use *search* algorithm to find a processor on which the thread will be migrated. Algorithm is repeat up to three times because of scheduling data structures locking semantics [6].

The *searching* algorithm looks processors that are in observed thread's processor affinity map. From that set of processors algorithm search for a lowest priority subset of processors, i.e. processors that currently run threads with currently lowest priority in system. If there are more processors in this subset, choose processor on which thread was run last time. If there is not such processor in subset, then choose one of the closest to processor on which thread was run last time (by scheduling domains).

Similarly to push algorithm, *pull* algorithm is activated when a thread on single processor is finished or blocked or its priority is lowered. Pull algorithm looks at ready queues of other processors (overloaded queues) and if it finds a real time thread with higher priority than the highest priority thread in his queues, it pulls such thread to this processor where such thread will immediately become active. Only threads that can be migrated to current processor are observed. If there are more such threads, only one with highest priority is chosen and pulled.

III. ADAPTING SCHED_RR

The goal of adaptations was to try to group threads of the same process (here called co-threads). The solution was implemented by four ideas, i.e. changes, for push-pull algorithm.

Push algorithm, i.e. its searching algorithm is modified as follows.

1. First try to find a processor on which are threads that belong to the same process (co-threads) but only if there are none on current processor. If such processor is found push thread to its thread queue.
2. If processor where thread was last executed is in thread's available processor subset push thread there.
3. Search for processor closest (by scheduling domains) to processor with co-threads (processor

that is not thread's available processor subset). If one is found push thread there.

4. Search for processor closest (by scheduling domains) to processor where thread was last executed.
5. Return any processor from thread's available processor subset.

In the pull algorithm, pull is additionally performed in situations when remote thread has the same priority as top priority local one if this remote thread has co-threads here and not on remote processor.

The scheduling of real-time threads is not actually changed with this adaptations – system-wide strict real-time priority scheduling is preserved.

Adaptations in Linux source code was done by adding a new scheduling policy `SCHED_RR2` based on `SCHED_RR`. Since changes to `SCHED_RR` are minimal, adaptations (additions) are preformed in same code.

Files included in adaptations (modified files) are:

- `include/linux/sched.h`
- `kernel/sched/sched.h`
- `kernel/sched/core.c`
- `kernel/sched/cpupri.c`
- `kernel/sched/rt.c`.

In kernel code, modifications regarding `SCHED_RR2` scheduling (in respect to vanilla `SCHED_RR`) are protected with a macro. To use `SCHED_RR2` macro must be set. Otherwise, when macro is not set vanilla `SCHED_RR` is used (all modifications for `SCHED_RR2` are not compiled). Experiments were performed on both kernel: one compiled with defined macro (using proposed modifications, i.e. `SCHED_RR2` scheduler) and one without macro (vanilla `SCHED_RR` scheduler).

IV. Experimental results

The processor on which experiments are performed has Intel's processor of *Sandy Bridge* architecture, namely the model *i7-2670QM*. This processor has four hyper-threaded cores (8 logical cores) from which every physical core has 32 kB L1 cache and 256 kB L2 cache. All cores share 6144 kB L3 cache. The processor itself runs on a frequency of 2.2 GHz. The kernel version used in experiments was Linux 3.3.0-rc7 [7].

Test program constructed for evaluation of adapted scheduler try to mimic general multithreaded program whose threads usually operate on shared data. Program first spawns given number of processes. Each spawned process further creates given number of threads producing large number of threads that simulate heavy loaded system. Since our test system has only four physical cores, size of shared data is kept small to amplify cache utilization in achieved improvements.

Test program was executed on unmodified version of kernel using `SCHED_RR` policy, and on modified kernel using adapted `SCHED_RR2` policy. Each run was timed to 10 seconds when progress was printed (number of predefined operations on shared data). Tests are performed many times and average results are presented in Table I.

TABLE I. Experimental results

Test No.	*Processes per program*	*Threads per process*	*Shared data size*	*Efficiency Improvement*
1	7	1	small	0.37%
2	11	5	small	16.02%
3	9	3	small	14.29%
4	9	3	medium	12.15%
5	9	3	larger	9.93%

Results are surprisingly good. Of course, this is synthetic test and maybe not a real measure for real application, but improvements of 10% and more are encouraging. As expected, when there are small number of threads (test no. 1) our adaptation didn't change performance (0.37% may be counted as statistical error). But when the number of threads is significantly greater than number of processors (all other tests) expected improvements did happen and surpass our expectations. Those improvements are greater with more threads and smaller shared data. As shared data grows, less cache utilization is achieved, lesser improvement is obtained.

Once again we must say that used scheduler is adaptation of real time scheduler and we compare obtained results by original real time scheduler. Real time scheduler is not concerned with fairness and maximal resource utilization. Therefore, we expect that if same ideas of grouping were implemented in scheduler for normal threads (policy `SCHED_OTHER`), improvements, if any, will be much lower since that scheduler uses more sophisticated load balancing algorithms. However, on heavily loaded many core systems we still expect that improvements in efficiency with proposed thread grouping should grow as number of cores grows.

V. Conlusion

This paper presents an idea to improve scheduler for many core systems when such systems are heavy loaded with lots threads. Idea is to group threads of same processes on same processor and improve efficiency of processor's local caches. In simulated environment adaptation to simple round robin scheduler (using `SCHED_RR` on Linux) show significant improvements up to 15%, which encourage further research in this direction. Further research should be oriented to adapting more complex schedulers, e.g. ones that are used for scheduling of normal threads. Furthermore, test program could also be improved to better mimic variety of real multithreaded applications.

Raspberry Pi as a Wireless Sensor Node: Performances and Constraints

Vladimir Vujović* and Mirjana Maksimović*
* Faculty of Electrical Engineering, East Sarajevo, Bosnia and Herzegovina
vladimir_vujovich@yahoo.com, mirjana@etf.unssa.rs.ba

Abstract - The main building block of Wireless Sensor Network (WSN) is sensor node consisted of four basic elements: the sensor unit, processing unit, communication and power units. In this paper we propose the Raspberry Pi, cheap, flexible, fully customizable and programmable small computer board and abilities of its usage as WSN node and SensorWeb node. The Raspberry Pi brings the advantages of a PC to the domain of sensor network, what makes it the perfect platform for interfacing with wide variety of external peripherals. Comparative analysis of its key elements and performances with some of current existing wireless sensor nodes have shown that despite few disadvantages, the Raspberry Pi remains an inexpensive computer with its very successfully usage in sensor network domain and diverse range of research applications.

I. INTRODUCTION

A wireless sensor network (WSN) is composed of spatially distributed nodes equipped with sensing devices to monitor and to measure characteristics of the physical environment at different locations. WSNs are designed and deployed for different purposes by various organizations. WSN based monitoring applications range from simple data gathering, to complex Internet-based information systems. In other words, the observations obtained from sensor networks may be helpful in many software applications like environmental, industrial and meteorological monitoring, building and home automation, medicine, urban sensor networks, intelligent transportation, security, military defense, etc [1].

Sensor nodes, as building blocks of WSN, are consisted of four basic elements shown in Fig. 1: the sensor unit, processing unit, communication and power units.

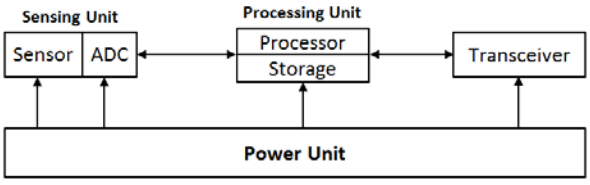

Figure 1. Typical sensor node architecture

Sensor nodes are the small, low power single board computers with a radio for wireless communication. Number and types of sensors depends on the applications. Sensor nodes collect and transfer data using four stages: collecting the data, processing the data, packaging the data and communicating the data [2].

Currently in the market there are many commercially available sensor node platforms. In this work emphasis will be on Raspberry Pi computer making a comparative study of its performances and constraints with current popular wireless sensor nodes presented in [2, 3]. The main goal of this research is to define and present advantages and disadvantages of Raspberry Pi and abilities of its usage as a sensor node.

The rest of this paper is organized as follows. The basic information about Raspberry Pi and literature review of its usage in sensor networks are presented in Section 2. Raspberry Pi's performances, constraints and abilities of its usage as a wireless sensor node and SensorWeb node are shown in Section 3. Finally, Section 4 provides conclusion remarks and outlines directions for future work.

II. WHAT IS RASPBERRY PI ?

Raspberry Pi is a small, powerful, cheap, hackable and education-oriented computer board introduced in 2012 (Fig. 2). This credit card-sized computer with many performances and affordable for 25-35$ is perfect platform for interfacing with many devices.

Figure 2. Raspberry Pi

The Raspberry Pi board contains a processor and graphics chip, program memory (RAM) and various interfaces and connectors for external devices (Fig. 2). Some of these devices are essential, others are optional but all Raspberry Pi models have the same CPU named BCM2835 which is cheap, powerful, and it does not consume a lot of power [4]. Raspberry Pi operates in the same way as a standard PC, requiring a keyboard for command entry, a display unit and a power supply. SD

Flash memory card normally used in digital cameras is configured in such a way to 'look like' a hard drive to Raspberry Pi's processor. The unit is powered via the micro USB connector. Internet connectivity may be via an Ethernet/LAN cable or via an USB dongle (WiFi connectivity) [5, 6].

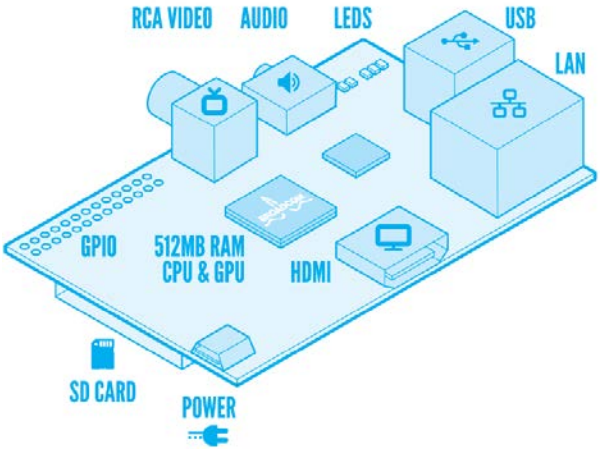

Figure 3. Raspberry Pi components [13]

Like any other computer, the Raspberry Pi also uses an operating system and the "stock" OS is a flavor of Linux called Raspbian. Linux, as a free and open source program, is a great match for Raspberry Pi. On one hand, it keeps the price of the platform low, and on the other, it makes it more hackable. There are also a few non-Linux OS options available [5]. The additional hardware and software requirements can be achieved by already existing hardware modules and open source software.

One of the great things about the Raspberry Pi is that it has a wide range of usage. Numerous recipes of Raspberry Pi usage with sensors, displays and motors is given in [7]. In the workshop [8] a Raspberry Pi is used to read sensors (inputs), store their vales in a database for historical trending and turn relays (outputs) on and off when a sensor value goes outside of a certain range. In other words, a system that turn on a light if the door is open or motion is detected in an area is built. In [9] is stated that wireless sensors and a Raspberry Pi open up a world of possibilities. Author of [10] also state that sensor networks are just one example of how these small, powerful, and inexpensive components can be used. On the example of XBee–ZigBee Mesh network author shows how to with a moderate skill build own sensor network. The possibility to use Raspberry Pi board as a ZigBee home automation server, which can be set up to support a range of tasks, including remote controlled air conditioning and lighting, and checking whether doors are open or closed is presented in [11]. Works [7, 12-16] propose combining the Raspberry Pi with the power of the open source Arduino platform, and present numerous home automation and sensor networks projects.

The performances and constraints of Raspberry Pi will be described in rest of the paper.

III. THE RASPBERRY PI'S PERFORMANCES AND CONSTRAINTS

The Raspberry Pi performances will be compared with following wireless sensor nodes [2, 3]:

- MicaZ – is based on the Atmel ATmega128L which is a low-power microcontroller and runs MoteWorks from its internal flash memory. The MICAz (MPR2400) IEEE 802.15.4 radio offers both high speed (250 kbps) and hardware security (AES-128).
- TelosB - bundles all the essentials for lab studies into a single platform including: USB programming capability, an IEEE 802.15.4 radio with integrated antenna, a low-power MCU with extended memory and an optional sensor suite. This platform delivers low power consumption allowing for long battery life as well as fast wakeup from sleep state.
- Iris – is used for enabling low power WSN. Iris provides users a wide variety of custom sensing applications providing up to three times improved radio range and twice the program memory over previous generations of MICA Motes.
- Cricket - is a location aware version of the popular MICA2 low-power Processor/Radio module. The Cricket Mote includes all of the standard MICA2 hardware and an ultrasound transmitter and receiver.
- Lotus - is based on the NXP LPC1758, 32-bit ARM Cortex-M3 based microcontroller. A single processor board can be configured to run sensor application/processing and the network/radio communications stack simultaneously. Lotus, as all previously mentioned sensor node platforms, has the data rate of 250 kb/s.

A. Size & Cost

The physical size and cost of each individual sensor node has a significant and direct impact on the ease and cost of deployment. Physical size impacts the ease of network deployment because smaller nodes can be placed in more locations and used in more scenarios. One of the main goals of every network is to collect data from as many locations as possible without exceeding fixed budget. A reduction in per-node cost will result in the ability to purchase more nodes, to deploy a collection network with higher density, and to collect more data [17]. The comparison of size, weight and cost of basic models of Raspberry Pi and above mentioned wireless sensor nodes is given in Table I (the smaller values are better).

TABLE I. THE COMPARISON OF SIZE, WEIGHT AND COST

Name	Size (mm)	Weight (g)	Cost per node US$
Raspberry Pi	85.6*53.98*17	45	**25-35**
MicaZ	**58*32*7**	**18**	99
TelosB	65*31*6	23	99
Iris	**58*32*7**	**18**	115
Cricket	**58*32*7**	**18**	225
Lotus	76*34*7	**18**	300

The values presented in Table I show that Raspberry Pi's advantage against other systems lies in its smallest per unit price.

B. Power and Memory

To meet the multiyear application requirements individual sensor nodes must be incredibly low-power. The average power consumption of WSN nodes should be measured in micro amps. Ultra-low-power operation can only be achieved by combining both low-power hardware components and low duty-cycle operation techniques. Also, algorithms and protocols must be developed to reduce radio activity whenever possible. This can be achieved by using localized computation to reduce the streams of data being generated by sensors and through application specific protocols. One of the solutions is to combine together events from multiple sensor nodes by a local group of nodes and then transmit a single result across the sensor network [17].

The CPU is the main component of the Raspberry Pi, responsible for carrying out the instructions of a computer program via mathematical and logical operations. The processor of Raspberry Pi is a 32 bit, 700 MHz System on a Chip (SoC), which is built on the ARM11 architecture and can be overclocked for more power. ARM chips come in a variety of architectures with different cores configured to provide different capabilities at different price points. This means that the vast majority of the system's components – its central and graphics processing units, audio and communications hardware along with 256 – 512 MB memory chip, are built onto single component. The ARM-based BCM2835 is the reason why the Raspberry Pi is able to operate on just the 5V 1A power supply provided by the onboard micro USB port. The Raspberry Pi for operating requires up to 700mA [18]. The unit of Raspberry Pi can be powered using a range of power sources (assuming they are able to provide enough current ~700mA) like [6]:

- Computer USB Port or powered USB hub (will depend on power output),
- Special wall warts with USB ports,
- Mobile Phone Backup Battery (will depend on power output),
- Alkaline batteries (six rechargeable AA batteries and a voltage regulator [7] or high capacity rechargeable batteries depending of Raspberry Pi power needs),
- Solar cells system (for outdoor usage).

The Raspberry Pi has four distinct power modes [19]:

- The run mode - the CPU and all functionality of the ARM11 core are available and powered up.
- The standby mode - the main core clocks are shut down (the parts of the CPU that process instructions are no longer running) although the power circuits on the core are still active. In this mode the core can be quickly woken up by a process generating a special call to the CPU called an interrupt. This interrupt will stop any current processing and do what the calling process has asked for. This mode is known as Wait for Interrupt, or WFI.
- The shutdown mode - there is no power.
- The dormant mode - the core is powered down and all caches are left powered on.

The two approaches of powering Raspberry Pi with batteries are discussed in [7]. The both approaches use the small capacity batteries which power Raspberry Pi model B and ensure Raspberry Pi working time of approximately 2 hours (depends of attached peripherals). Depending on power modes and active modules, power consumption can vary from 700 mA to 1 A. The Raspberry Pi's biggest limitation regarding the power supply is that no external device should draw more than 100 mA from any of its USB ports [4].

It is important to note there's no hard drive on the Raspberry Pi; everything is stored on a Secure Digital (SD) Card. Although large SD cards holding 32 GB, 64 GB or more are available, they are often prohibitively expensive, but the minimum required size of SD card is 2 GB depending on the distribution demands of the operating system. If possible, it is necessary to use the SD card class 10. This storage can be expanded by using devices that provide an additional hard drive upon using the USB ports. Known as USB Mass Storage (UMS) devices, these can be physical hard drives, solid-state drives (SSDs) or even portable pocket-sized flash drives [18] (Table II).

TABLE II. THE COMPARISON OF CPU AND MEMORY *

Name	Processor	RAM	External memory
Raspberry Pi	ARM BCM2835	**256-512 M**	**2-64 G**
MicaZ	ATMEGA128	4 K	128 K
TelosB	TI MSP430	10 K	48 K
Iris	ATMEGA1281	8 K	128 K
Cricket	ATMEL128L	4 K	512 K
Lotus	ARM NXP LPC1758	64 K	512 K

*(The higher value is better)

It is also important to note that the Raspberry Pi Model A has 256MB of RAM while the Model B has 512MB. Compared to other considered systems Raspberry Pi has the largest amount of memory (Table II) what generally leads to improved overall systems' performances.

C. Flexibility

For a wide range of usage scenarios WSN architecture must be flexible and adaptive. Each application scenario demands a slightly different mix of lifetime, sample rate, response time and in-network processing. Additionally, for cost reasons each device will have only the hardware and software it actually needs for considered application. The architecture must make it easy to assemble just the right set of software and hardware components. Thus, these devices require an unusual degree of hardware and software modularity while simultaneously maintaining efficiency [17].

One of the great things about the Raspberry Pi is that it is very flexible and there's no single way to use it. For

example, it can be used for: general purpose computing, learning to program or integrate it with electronics projects [5]. The following core components enable the wide range of its usage [20]:

- Two USB 2.0 ports allows connecting peripherals and storage devices while one micro USB serve for powering device.
- The 3.5mm analog audio jack allows connecting headphones and speakers to the Raspberry Pi what is especially useful for audio and media player based projects.
- Composite RCA port for attaching the yellow video cable from TV allows using TV as a monitor.
- The High Definition Multi-media Interface (HDMI) port allows the Raspberry Pi to be hooked up to high-definition televisions and monitors that support the technology. It is also used for streaming video and audio from the web to TV.
- Support for DSI (Display Serial Interface) - Raspberry Pi can be expanded with display.
- Support for CSI (Camera Serial Interface) - Raspberry Pi can be expanded using camera.
- The GPIO (general purpose input and output) pins on the Raspberry Pi are the main way of connecting with other electronic boards. It consists of 26 pins arranged in two rows containing 13 pins each. The left row contains the even-numbered pins, and the right row contains the odd-numbered pins (Fig. 4). The GPIO pins on the Raspberry Pi are the main way of connecting with other electronic boards. In other words, the GPIO pins can accept input and output commands and thus can be programmed on the Raspberry Pi. It is important to note that there is a certain difference between GPIO pins schedule among model A and model B of the Raspberry Pi. GPIO pins can be accessed for controlling hardware such as LEDs, motors, and relays, which are all examples of outputs. As for inputs, Raspberry Pi can read the status of buttons, switches, and dials, or it can read sensors like temperature, light, motion, or proximity sensors (among many others) [4]. Some of GPIO pins can be used as digital inputs/outputs and as interfaces for embedded protocols. Two most important protocols based on their widespread are:
  - I^2C – low-speed interface – Inter-Integrated Circuit (I^2C) is a serial bus interface which supports multiple devices and only requires two wires for communication. It's work on relatively low speeds [21].
  - SPI – Serial Peripheral Interface Bus (SPI) is a synchronous full-duplex (two way) serial connection [22].
- Extended GPIO – in addition to standard GPIO port, Raspberry Pi Model B Rev 2 has an expanded set of connectors. It is important to mention P5 header which is made up of 8 pins (+3.3 V, +5 V, two ground pins and four GPIO pins that can provide the second I^2C protocol) and P6 header with two pins – their short circuiting provides soft reset of BCM2835.

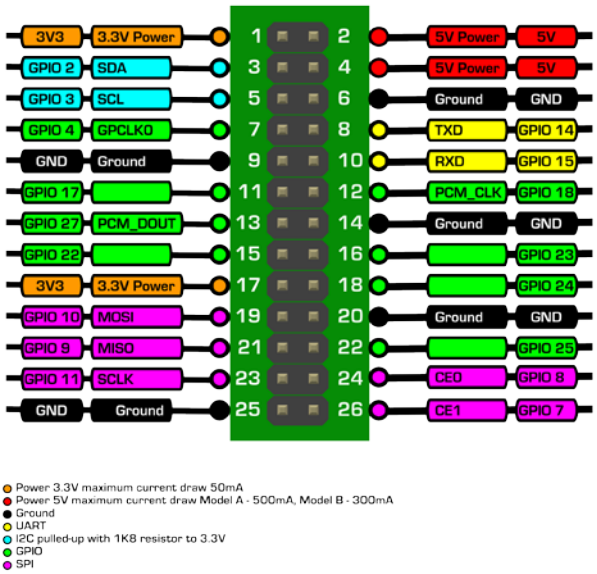

Figure 4. Raspberry Pi Model B Rev2 – GPIO connectors [20]

Analysis of the Raspberry Pi has shown that it, as above mentioned wireless sensor nodes, has expansion connector which supports Analog Inputs, Digital I/O, I^2C, SPI and UART what make easy their connection to a wide variety of external peripherals.

D. Communication

A key evaluation metric for any WSN is its communication rate, power consumption, and range. In order to create an interconnected network, nodes can not be placed too far apart. Most application scenarios according to desired sensing have natural node densities. If the radio communications range demands a higher node density, additional nodes must be added to the system in to increase node density to a tolerable level. The communication rate also has a significant impact on node performance. Higher communication rates mean less transmissions time and lower network power consumption. However, an increase in radio bit rate is often accompanied by an increase in radio power consumption. All things being equal, a higher transmission bit rate will result in higher system performance. But an increase in the communication bit rate has a significant impact on the power consumption and computational requirement of the node [17].

The Ethernet port is the Raspberry Pi's main gateway for communication with other devices and the Internet. The model B has a standard RJ45 Ethernet port while model A doesn't, but can be connected to a wired network by an USB Ethernet adapter. The Raspberry Pi's Ethernet port is auto-sensing which means that it may be connected to a router or directly to another computer (without the need for a crossover cable) [5, 6]. USB Ethernet adapter has two-speed mode, 10 Mb/s and 100 Mb/s. With a cable connected, the Raspberry Pi will automatically receive the details it needs to access the Internet when it loads its operating system through the

Dynamic Host Configuration Protocol (DHCP). This assigns the Raspberry Pi an Internet Protocol (IP) address on network, and tells it the gateway it needs to use to access the Internet (typically the IP address of router or modem). Internet connectivity of Raspberry Pi besides an Ethernet/LAN cable (standard RJ45 connector) may be via an USB WiFi adapter. Using such a device, the Raspberry Pi can be used for creating ad-hoc networks or to connect to a wide range of wireless networks, including those running on the latest 802.11n high speed standard [18].

Raspberry Pi can serve as static websites, but it can also generate dynamic content using databases and web applications. In addition, it can even provide access to its GPIO ports via web technologies. Also, Raspberry Pi can be used as SensorWeb node by connecting it to a network so it can be accessed from other computers. On the other side, the administration of Raspberry Pi can be done over Secure Shell (SSH), a network protocol for secure data communication [4].

E. Operating systems

Sensor nodes run embedded software that samples the physical environment, load data, aggregates and communicate with higher level (peers or gateways). Regardless of the hierarchical approach each sensor node still needs a program, and the most common approaches to programming each sensor node, is to either program it using some form of operating system or to choose a higher level of abstraction. The operating systems vary from traditional operating systems in terms of goals and technique and each system differs substantially in the approach to memory protection, dynamic reprogramming, thread model, real-time features, etc. [17].

Like every computer, the Raspberry Pi needs an operating system, and the preferred one for the Raspberry Pi is Linux distribution. That's partly because it's free, but mainly it's because it runs on the Raspberry Pi's ARM processor [4]. There are several distribution of Linux ported to the Raspberry Pi's BCM2835 chip, including Debian, Fedora Remix and Arch Linux [19]. The Raspberry Pi uses an operating system called Raspbian (Table III) based on Linux but there are also a few non-Linux OS options available.

TABLE III. THE COMPARASION OF USED OPERATING SYSTEMS

Name	Operating system
Raspberry Pi	RASPBIAN
MicaZ	TINY OS,MOTE RUNNER
TelosB	TINY OS,SOS,MANTISOS
Iris	TINY OS,MOTE RUNNER
Cricket	TINY OS
Lotus	RTOS,TINY OS

There are several reasons for deciding to go with the Raspbian operating system [19]:

- Raspbian has a desktop environment similar to Windows and Mac called Lightweight X11 Desktop Environment (LXDE), so it provides an easy transition for those not familiar with Linux command line.
- It comes pre-installed with software useful for writing codes.
- The operating system has been tailored to run on the Raspberry Pi. The code compilation is optimized for on-chip floating-point calculations (hard-float) rather than a slower software-based method.
- There is wide spread community support for the operating system.

F. Advantages

After analysis above performed, general conclusions about the Raspberry Pi advantages can be stated.

- First of all, it is important to mention that Raspberry Pi is a small independent computer that runs on the Linux operating system and can be programmed as needed.
- It has a very large working memory (many other sensor nodes do not have).
- It has expandable memory to store the data.
- It works on processor which supports a large set of instructions.
- It operates at speeds from 700 MHz to 1000 MHz.
- It has support for USB 2.0 which allows its expansion with a large number of peripherals.
- Depending of the needs it is possible to expand the Raspberry Pi with WiFi and Bluetooth adapters (power and range can be changed by changing the adapter).
- Expansion and communication with network devices over a LAN adapter are possible.
- It is possible to form an expandable system with various electronic components (sensors and electronic circuits) using digital inputs and outputs, I^2C or SPI protocols (most of today's devices use one of these methods of communication).

G. Disadvantages

Based on the above mentioned it can be noted that for small amount of money the Raspberry Pi comes with a lot of nice things, but it also lacks some useful features. The main disadvantages of Raspberry Pi are [4]:

- It does not have a real-time clock (RTC) with a backup battery. The fact of missing clock can be workarounded using a network time server, and most operating systems do this automatically.
- The Raspberry Pi always boots from an SD card. It means that even a perfectly valid installation of an operating system is available on a USB stick or an external hard drive, it can't be booted. In other words, external storage devices can be used but can't be used to boot the Raspberry Pi.
- It does not support Bluetooth or WiFi out of the box but these supports can be added by USB dongles.

- Unfortunately, most Linux distributions are still a bit picky about their hardware, so it should be first checked whether flavor of Linux supports particular device.
- It doesn't have built-in an Analog to Digital converter. External component must be used for AD conversion.
- Its power consumption varies depending on how busy Raspberry Pi is and what peripherals are connected. Typically, the model B uses between 700-1000 mA depending on what peripherals are connected, and the model A can use as little as 500 mA with no peripherals attached. Thus, it is necessary to provide a power supply that can provide enough current to power the device plus any connected peripherals.

IV. CONCLUSION

Based on the comparison of Raspberry Pi's key elements and performances with presented current existing wireless sensor nodes it is possible to summarize Raspberry Pi's pros and cons against to other systems:

- pros: processing power, memory, connectivity, multipurpose usage (USB), Linux,
- cons: power consumption.

The analysis above performed has shown that beside the power consumption issue, Raspberry Pi is ultra-cheap-yet-serviceable computer board. With support for a large number of input and output peripherals, and network communication it makes the perfect platform for interfacing with many different devices and using in wide range of applications. By coupling it with WiFi it can communicate remotely what the Raspberry Pi makes very suitable for the construction of wireless sensor nodes and SensorWeb nodes. Moreover, Raspberry Pi can be used as processing node in WSN networks, not just as sensor node but also as controller. In addition, data processing and decision making can be based on artificial intelligence.

Further, The Linux operating system usage provides additional advantages of using Raspberry Pi as a SensorWeb node. Programming in high-level languages such as C, C++, Python, or Java, solution implementation is quite simple and it is enabled to a large number of users, opposed to micro controller programming which usually depends of development kit.

By installing the Web Server on the unit and providing access to the Internet, Raspberry Pi becomes complete and ideal system (hardware and software) for building SensorWeb nodes. One of the possible Raspberry Pi usage scenarios, which is already implemented, is creation of hardware device that has implemented sensor units and communicate with Raspberry Pi via peripheral devices or via GPIO (I^2C) interface. The developed Raspberry Pi prototype SensorWeb node is based on RESTful services and created in order to build the infrastructure that supports fast critical event signaling and remote access to sensor data via the Internet (the detection of critical events is performed using fuzzy logic). The final evaluation of this prototype and Raspberry Pi usage as wireless sensor node and SensorWeb is planned to be performed by its implementing in home automation and Internet of things projects what are directions of our future work.

Abstract - In this work, we present the architecture of firmware software update infrastructure, which uses a centralized server to distribute adequate firmware updates to a large number of embedded devices. These updates enable transparent proactive management of everyday bugs and other vulnerabilities inherent in software-based systems, as well as embedded system evolution. Presented firmware update mechanism utilizes a network connectivity nowadays already presented in a wide range of embedded systems.

I. INTRODUCTION

Ubiquity of embedded computer systems in every pore of human life gets the credits from flexibility and faster product development from an idea to the final product. Technological development of microcontrollers is focused on specialization to different type of embedded systems. One of the goals is fast and flexible replacement of embedded software also called firmware [1]. Due to this fact that firmware within the embedded system is largely defining product's role, capabilities and its functionality, it shortens time of a development from idea to the final product. In such environment the hardware can be designed as final product in early stages of this development bringing it faster to final stage, as software would in the end define this final product functionality. This creates another problem, as a very little time is left for detailed testing of a product and very often companies place mini batch of products on market which have not been thoroughly tested. In such cases end users become beta testers of the product. In such environment we need to provide an improved level of flexibility in automated and transparent firmware changes in the embedded system already installed at end users, to enable transparent and straightforward software update to prevent possible malfunctions.

Rising trend of wide spreading use of GSM and GPRS technology and its price drop opens possibility to affordably equip embedded computers with appropriate components to enable self-maintenance at any place. Presuming such environment, embedded system could achieve access to Internet and straight connection to the device manufacturer for maintenance purpose or dynamic replacement of a firmware [2].

In following section an algorithm for automatic software or firmware upgrade is described. Third section presents developed and implemented firmware upgrade algorithms. Forth section presents test environment and performance comparison.

II. RELATED WORK

The possibility of embedded system to upgrade running firmware over the Internet, also called FOTA [3] (Firmware Over The Air) is well known and widely used on very powerful embedded systems running ARM processors and operating system. However, this paper analyzes the use and the specifics of software agents in the process of upgrading software of the smaller embedded computer without operating system. Given the limitations of memory, it analyses the advantages and disadvantages of software agents with direct entry into the program memory and agents with the use of additional memory resources.

Implementation of the system software upgrade is based on software agents to enter directly into the program memory, and on-board computer was built in the system based on ATMEL processor [4] equipped with self-modifying program memory. Connectivity to the Internet was done with GPRS module that enables communication with the server. It describes the implementation of software algorithms, software agents, in detail. It evaluates the implementation process of dynamic upgrades of software described by a series of measurements that give insight into the properties and characteristics of deviation. Applications of dynamic software upgrade by software agents is also suitable for implementation in a limited region of embedded computer systems of limited resources.

III. FIRMWARE UPGRADE ALGORITHM

In first case we used embedded computer based on AVR family of micro-processors made by Atmel and GSM/GPRS module Wismo228 [5]. This case represents embedded systems where communication module doesn't contain memory for temporal storage, Figure 1. In this environment an algorithm for automatic software or firmware upgrade (called Agent) used an Intel HEX file format for transferring of the new software that was supposed to replace existing ones. In this case the binary

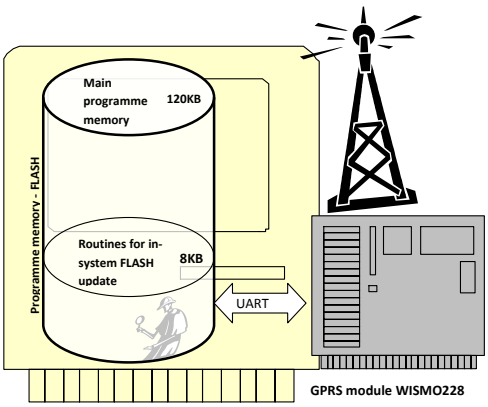

Figure 1. ATmega128 and communication module without memory buffer

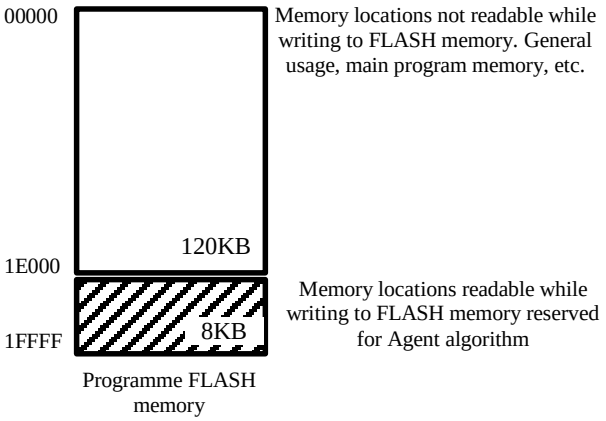

Figure 2. Flash update agent without memory buffer

firmware was packed into Intel Hex file format and downloaded from the server using Hyper Text Terminal Protocol. As used micro-processor ATmega128 is fairly small and inexpensive, but built on AVR core with strong processing capabilities and a lot of integrated features and interfaces, it is often used in industry for production of consumer electronics and other embedded systems. Since this was an extremely undemanding embedded computer without any additional memory, Agent downloaded and upgraded main software in segments sized 2KB, while main program and embedded system functions were stopped and the product in which computer is embedded in was put out of operation. Figure 2 presents memory organization for algorithm in case when there is not available memory buffer. Entire flash update agent without memory buffer is presented in Figure 3.

Replacing transferring format of new software into customized base64 encryption and storing it in segments of 2KB, where each has basic checksum, the file that is transferred via GPRS connection generally was reduced in size, almost halved. A binary segment of the 2048B (2KB) packed in Intel Hex format increased the binary to 5325B (5.2KB) while the same in customized Base64 format was reduced to 2735B (2.67KB).

The Agent itself occupies 8KB of program memory (FLASH memory) reserved for in system FLASH updating algorithm routines presented on Figure 6, and 120KB of program memory remains for the main software or firmware (from 128KB of FLASH which ATmega128 has). Although the processor has built in self changing FLASH memory with program routines inside the same FLASH, it has one limitation. 120KB of FLASH memory is not readable while calling FLASH writing routines. Only upper part of the FLASH program memory reserved for Agent routines is always readable and Agent program can run normally while writing FLASH.

Another advancement of an Agent was achieved by replacing GSM/GPRS module model WISMO228 with GSM/GPRS module model SIM908 [6] made by SimCom. This new GPRS module has built in http client engine and by using this integrated HTTP protocol with buffer memory of 160KB within a GPRS module; it became possible to download the entire new firmware, the main software at once without the segmentation, presented on Figure 8.

Also, it is now possible to initiate download within the main software while embedded computer and device performs main functions of the product in which it is built-in. Once new software was downloaded via GPRS and Internet network and stored in memory buffer of the SIM908 module, downloaded Base64 packed file would be checked segment by segment with checksum calculations for correct download of the new main software. Checking of a downloaded Base64 file takes

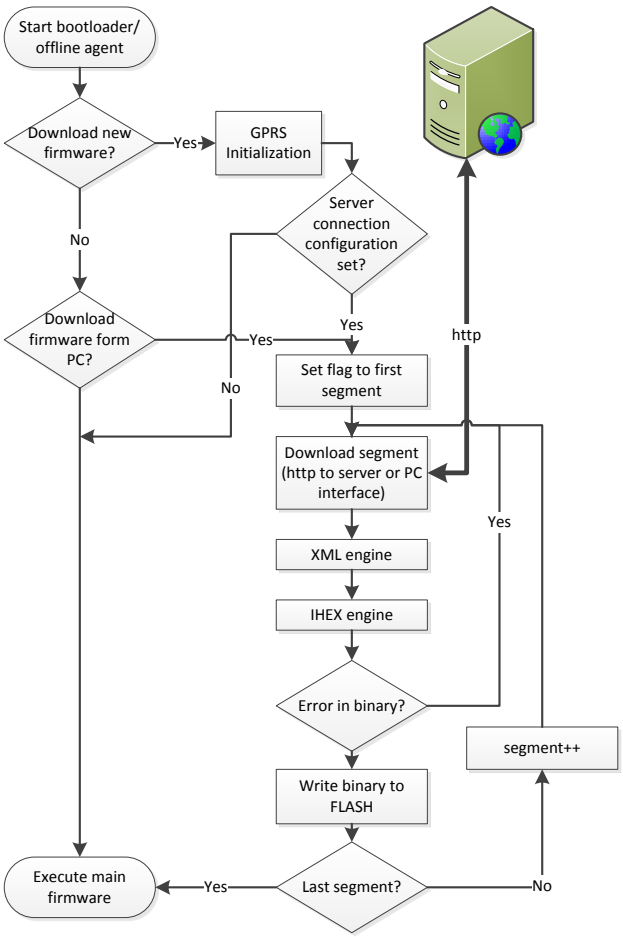

Figure 3. Flash update agent without memory buffer

about 23 seconds every time over local 64Kbps connection, and it doesn't depend on GPRS and network connection. This is just another precaution that takes a small amount of time and makes an Agent more robust and the software upgrade routines more transparent and reliable.

In a case when new downloaded software packed in Base64 is correct, the main program stops and calls stand-alone Agent routines to make program memory (FLASH) upgrade from a buffer which takes about 25 seconds over local 64Kbps connection that is a bit increased with a write FLASH time.

So it is known in advance exactly how much system would be out of operation (25 seconds for nearly the biggest program that fits FLASH) and it no longer depends on the effects of availability of GSM and GPRS networks and internet once the new software packed Base64 file is downloaded in SIM908 buffer.

Selected test embedded computer is normally built into the GNSS system for tracking, securing of vehicle from grand theft auto and remote engine start, called SMS Commander Genie made by Globis presented at Figure 4. This embedded system is quite flexible and used in a broad of applications. Embedded System is based on ATmega128 micro-processor by Atmel, GSM/GPRS/GPS Module model SIM908 by SimCom, switching power stabilizer for voltage regulation at 5V based MP1591 integrated circuit made by Monolithic Power Systems, 3V linear regulator for micro-processor based on TPS76930 by Texas Instruments, crystal oscillator of 7.37MHz frequency for micro-processors clock, MEMS motion sensor based on ADXL343 by Analog Devices, Lithium Polymer 3.7V backup battery, outside world outputs based on ULN2003D made by Texas Instruments, outside high power P-channel MOSFET outputs based on ZXMP6A18K made by ZETEX Semiconductors, CANBUS interface controller and logic converter based on MCP2515 and MCP2551 by Microchip, and other glue logic and interface to the outside world, which is the vehicle. As the embedded system operates 24/7 and it is supplied primarily from vehicle battery, maximum attention is dedicated to the smaller dimensions (108x54mm), and small energy consumption. To gain small energy consumption micro-processor is powered by 3V and MEMS motion sensor is used to disable GPS functions in GPS module SIM908 when the vehicle is not moving as the biggest power consumer is GPS function on the embedded system.

For testing and validating thesis of this paper only a micro-processor, oscillator, GPRS module and power supply circuit are needed and the electrical schematic for such embedded system is presented on the Figure 1.

IV. TESTING AND COMPARISON

Testing environment is presented at Figure 5, for live testing in a real world environment. Embedded system is equipped with an Agent. Tested embedded systems is additionally modified to enable a continuous 24 hour testing downloads. The real environment includes exploits commercial GPRS network and Internet, and as well on the other side server computer running Linux with Apache http service and PHP with MySQL database. Server is a real time production server used for embedded systems made by Globis, and it is only altered in a way to record starting and ending times of new firmware download. This way it recorded sample times of each download.

To test the new upgraded Agent versus previous work and results measurements from before, to compare upgraded Agent to the old one, the test was conducted using a new software binary sized 110KB just as the first test. But there is a big difference. The old Agent was working with binary files packed in Intel Hex format and the new Agent is working on binary files packed with customized Base64 format. So now the size of new file being transferred over the network is almost halved, and expected download time would be smaller. What goes in favor of the new upgraded Agent is a new way of downloading as it is no longer downloaded in segments, because of a memory buffer inside GPRS device. In this case download speeds could reach the theoretical maximum of GPRS connection class 10 which is 80Kbps for download and 20Kbps for upload.

Figure 4. GNSS capabale selected testing embedded system.

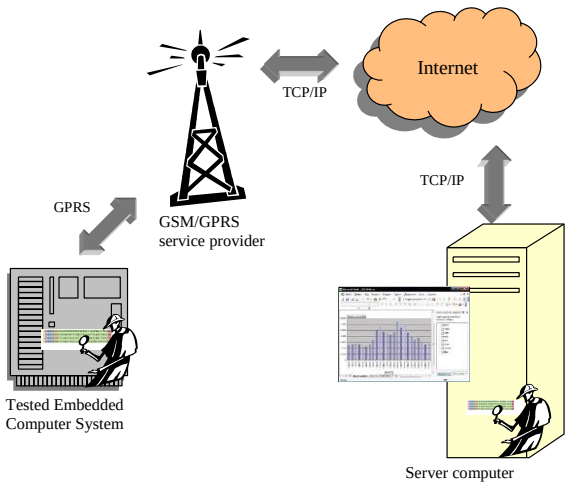

Figure 5. Recording data environment for testing embedded system Agent firmware download times.

TABLE I. FIRMWARE PACKAGE DOWNLOAD TIMES

Firmware package format	*Intel Hex*	*Base64*
Segment size:	2KB	N/A [a]
Firmware packed size (binary 110KB)[b]:	282KB	147KB
Theoretical download time (60/40kbps)[c]:	48.3s	25.1s
Theoretical download time (80/20kbps)[d]:	**25.5s**	**18.8s**
Best achieved download time:	**84.0s**	**19.0s**
Average achieved download time:	103.8s	36.9s
Worst download time:	1335s	219s
Number of tested samples:	624	313
Number of samples with retries:	86	N/A
Number of retries:	182	N/A

a. Because new embedded system uses GPRS module with internal buffer memory the software is transferred at once without segmentation

b. Binary size of a new software is 110KB but the packed size for Intel Hex and Base64 is different

c. Theoretical link speed of GPRS connection class 10 in normal mode

d. Theoretical link speed of GPRS connection class 10 in big files download mode

The standard GPRS connection class 10 uses 60Kbps for download and 40Kbps for upload, but it switches automatically to 80/20 mode in a case of transmission of bigger file. It is noticed that the old way of downloading files in segments, GPRS would never switch to 80/20 mode for faster download. So in comparison of times of older and upgraded Agent, not only the halved of firmware size would make the advantage. Also the switched 80/20 mode would make some difference in download times.

Testing samples were gathered by infinite loop calling an Agent to make download and starting and ending times were recorded in database. These downloads were conducted through 24 hours to check if a time of a day influence on the results because of the network bandwidth congestion. We can notice there are certain times of a day when the GPRS network is more utilized and therefore the spikes are recorded in tested samples. Figure 6 is showing segmented download times of firmware packed in Intel Hex format, while the figure 7 shows the same data, but downloaded at once in customized Base64 format.

In table I. the numbers of recorded samples are

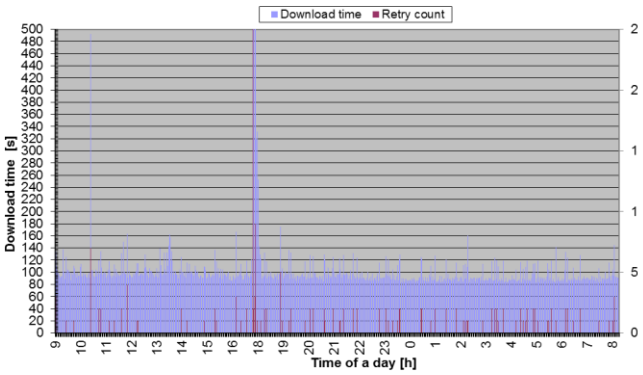

Figure 6. Recorded download times in a time of a day for Intel Hex packed binary firmware file originaly sized 110KB.

TABLE II. AGENT FUNCTIONS EXECUTION TIMES

Main firmware function:	*Agent time:*	*Intel Hex*	*Base64*
Online Agent Time [a]:	Best:		19.0s
	Average:		**36.9s**
	Worst:		219s
	Firmware check [c]:		23s
Offline Agent time (flash update)[b]:	Best:	84.0s	
	Average:	**103.8s**	
	Worst:	1335s	
	Flash write [d]:		**25s**

a. Main embedded system's firmware is running and Agent is working in parallel with the main firmware

b. Main embedded system's firmware and functions are down. Only the Agent is running.

c. After downloading the new firmware in a memory buffer built in SIM908, it is checked for errors before starting the Agent in an offline mode while the main process is stopped.

d. Flash is written from local buffer in new Agent with Base64 and SimCom, while on the old Agent, Flash is written while downloading segment by segment.

presented. There were 624 recorded samples for Intel Hex format and 313 recorded samples for Base64 format. There is a noticeable difference in download times because of the halved file in size in favor the new upgraded Agent, packed in customized Base64 format. But as it is presented in Table II, download time for not segmented file almost reached theoretically best possible download time for this type of a GPRS connection. While there is no possibility to achieve this kind of theoretical speeds in a segmented way of downloads. The best possible download time for Base64 packed file is 18.8 seconds, achieved 19.0 seconds. The best possible download time for old packed files are 25.5 seconds, but only achieved 84.0 seconds in the past. The difference is great. Also for average and worst download times, the new upgraded Agent is in noticeable advantage.

Also, there was no record of a retries in download for the upgraded Agent, because the GPRS module built in HTTP engine was taking care of this. So, if the retries did exist, they would manifest them self in a bit longer download time recorded.

The second advantage of the new agent over the old one is added local buffer memory inside the GPRS

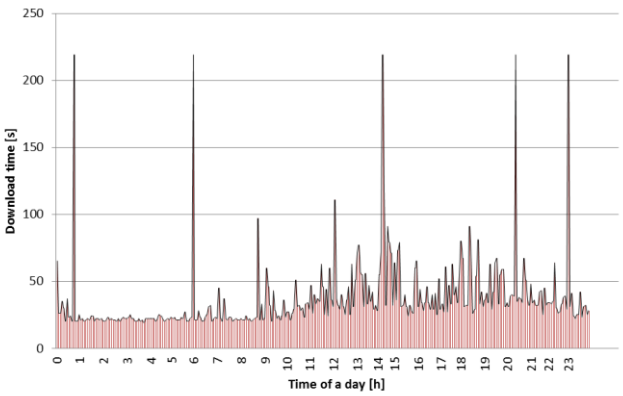

Figure 7. Download times in a time of a day for customized Base64 packed binary firmware file originaly sized 110KB.

module. This makes entire concept of the automated software upgrades more transparent, robust and reliable. As presented on the table I. the worst case scenario is very worrying. The main function of the embedded system, in this case a security against a grand theft auto was shut down for whole 1335 seconds or calculated in minutes, it is over 22 minutes. This is not acceptable in reliability sense. Therefore the new agent with local memory buffer wouldn't shut down the main process until it would made sure that the new firmware is correctly downloaded, and shut down time would always be exactly 25 seconds during the FLASH upgrade.

After the new agents receives a notification from GPRS SIM908 module that the HTTP download of a new firmware is completed, it would check it, that would take 23 seconds on 65Kbps connection, and shut down the main process and start up the offline Agent algorithm. The main process would be up and again running in 25 seconds with an upgraded firmware.

V. Conclusion and Future Work

The paper considered the possibility to upgrade software of an embedded system using the Internet to gain self-maintained software. Connectivity to the Internet was in our case is realized using GPRS module. Two software agents are presented: one with possibility of direct access into the program memory and agents with the use of additional memory resources. Considering the memory limitations, and processing power of the embedded system it is analyzed the advantages and disadvantages of.

Implementation of the system software upgrade is based on software agents to enter directly into the program memory, and on-board computer was built in the system based on ATMEL processor equipped with self-modifying program FLASH memory.

The paper compares implementation of the Agent without additional memory buffer for temporary saving the new firmware and the newer implemented Agent with additional memory buffer.

Although a compared embedded system mostly differs on built in GPRS module (with and without http engine and built in memory buffer) there was significant improvement in Agent algorithm implementation exploding different binary file packaging format. The simplest, easy to implement and most common data transferring format is Hyper Text Terminal Protocol, on the server side and client side. So, that is the reason for using HTTP protocol, as the client side was software implemented in Agents algorithms. But it has limitations and binary files transferred without controlling signals were not an option for Agent implementation. Instead, ASCII type file packaging was used.

On the older implementation of the Agent, Intel Hex file format was well known and already used for the micro-processor program memory upgrades. It has built in checksum In this case the segmented download and upgrade was only option due the lack of additional memory resources essential for temporarily saving downloaded firmware.

In second case advanced GPRS module with built in http engine and memory buffer used to store downloaded http page with a limited size of 160KB. In this case we exploited another way of packaging firmware files in a smaller and more compressed way. The decision favored base64 packaging format, as it used only ASCII signs and with addition of checksum and file segmentation with segments sized 2KB, it enabled both segmented and not segmented downloads on new software almost halved in size in comparison to Intel Hex file format.

Implemented Agent engine for parsing customized base64 file format is almost the same in size as implemented XML engine and Intel Hex parser.

The new upgraded embedded system with upgraded Agent algorithm is not only faster, but is more reliable and only fixed amount of time main process is down when upgrading program memory. Download is done as the background process in GPRS module and doesn't affect main process and embedded system in any way. This way updating FLASH time while the main program and routines are down is not affected in any way by GPRS and network bandwidth.

In conclusion, achieved solution is more advanced in hardware and algorithm of the software Agent. Achieved solution for dynamic upgrades of software described in this paper is faster, more robust and reliable which was presented by a series of measurements that give insight into the properties and characteristics of deviation.

Applications of dynamic software upgrade by software agents are also suitable for implementation in a limited region of embedded computer systems built on limited resources. The future work would be extending Agents with compression algorithm implementation. Since Agent has size limitation we will examine several possible candidates and its optimizations due to available program size and main memory required. Also, another there is possible improvement would be in improving program availability

Abstract - Trade-off between execution time and resource occupation arise in all kinds of digital system designs. Here we present such relation for FPGA-based custom processor design. Usually, the optimal tradeoff is directed by device sizing on all scales of the design, but for FPGA device, as predefined hardware platform, it is more focused on comparison of existing platforms organizations. The customization of processor architecture as a point of design performance improvement is usually focused on selection of parameter set that governs the most the design characteristics.

In this paper, the focus is on processor architecture datapath with predefined design template and relationship of its structure to final FPGA implementation it maps to. For purpose of evaluation of multiple design at the same time, the appropriate software flow is applied to construct the design space based on constraining of datapath functional units operation types. The data are collected throughout the whole design flow starting from input control and data flow characteristics of the application and ending with FPGA implementation data. The analysis of the design flow showed dependence of final implementation on datapath structure and its components complexities.

I. INTRODUCTION

As Moore's law is predicting for over a 50 years now, the miniaturization of electronic devices is constant, [1]. During this period great improvement in performance, i.e. speed, is achieved also, but lately the system designers community turned to finding other possibilities for future design advances. Multiprocessor System-on-Chip (MPSoC) became a paradigm in embedded system world for distributed cooperation of existing hardware cores since increase in single core speeds appeared to be more demanding task to accomplish in short period, [2]. During advances in submicron scales the phenomena as parasitic capacitances and inductances had always been an open issue to describe and neutralize during very large scale chip integration, [3, 4]. The tradeoff between system size and performance was always actual challenge to handle during system design, independent of design methodology and level of abstraction the designer had been looking. It arises in everyday embedded system design that is trying to satisfy design functionality in all kinds of environment usually with exact sizing and performance goals. It is valid not only for isolated hardware components the system is composed off, but also for their communication and interface to human what includes software and communication protocols embodied within the system. From the point of system-level design, that is motivated by controlling the whole design process from a high level perspective and targeting specific functionalities under strict design constraints, describing the expected tradeoff means even a harder task of predicting system behavior in earlier design phases.

Our previous work coped with processor based custom design. Especially our development corresponds to hardware synthesis or high level synthesis (HLS) as a one of system level design topics, [5]. High level synthesis usually assumes specification in programming language that is not of specialized type, but familiar to more potential users. C code is usual choice because of its acceptances in computer engineering community and easiness in presentation of application control and data flow, [6, 7].

Previous work in high level synthesis field, as in custom processor design we assumed, shows this task as very acceptable when trying to minimize overall design time. Also, the fact of coping with many questions that direct the final solution appeared to be very challenging, especially in early development phases. Every such design process was, besides the specification itself, governed with some kind of directives and constraints that describe target platform and execution environment features. The common goals are design minimization and performance maximization. As these goals are in contraposition for practically every digital design, the design space exploration takes place as natural assumption and consequence of research that governs the design process.

The foundation of custom processor assumed in this paper is the *No-Instruction-Set Computer* (NISC) concept, where datapath of processor architecture is fully customizable according to needs and wishes of the corresponding toolset user, [8, 9]. Since application specification assumed C coded algorithm our and some previous work effort was on automation of datapath design out of arbitrary C code written by user, [10-12]. During corresponding research the appropriate design

This work was supported by research grant No. 036-0362980-1929 from the Ministry of Science, Education and Sports of the Republic of Croatia.

flow was developed with several transformations of input C code until final FPGA implementation is achieved. The idea behind such development was in automation of the design that shortens design cycle time and eases the overall designer's work as are the light motives of Electronic Design Automation (EDA) approach. It assumes all kinds of software support for digital system design starting from high level specification to low level phenomena description. Development of software that supports embedded system design became dominant in designer's effort during last decade, [13].

One of the usual steps towards design size optimization that was recognized in HLS, and also in our approach, was in reducing the interconnect complexity by reduction of global interconnect seen through reduction of multiplexer inputs, [14].

FPGA device is the target hardware platform for many HLS tools and for our approach. It proved itself as appropriate platform for diverse design domains and development flows, [15]. The exploration of FPGA area-delay tradeoffs is however a specific task as many families of such devices are available at the market today. In fully custom hardware design the device sizing impact is the key characteristic that affects the signal delay because of electrical effects, while FPGA is predefined device to work with. Therefore, the comparison and choice of the appropriate device is the specific task when having different architecture organization, transistor and LUT sizing, [16].

In this paper the exploration of the design space does not have an approach of devices or components sizing variations, but variations from the point of processor datapath structure when mapped to the predefined hardware platform. On the side of processor customization, predicting the best design tradeoff primarily has a meaning of selecting the set of most meaningful design parameters [17], and here we vary the functional unit types as a base of datapath design.

In Section II the background of design space exploration is given, and in Section III the motivational example for examining occupation-performance tradeoff is presented. Section IV describes the principle of forming and analyzing the solution space and the results are illustrated in Section V. Section VI gives final conclusions.

II. BACKGROUND

The foundation for design space exploration is in processor datapath design algorithm, [12]. It is situated as the central point of the design flow where C code specification is conducted to FPGA implementation.

Basically, the datapath is designed with integration of application control flow blocks into unique solution. Before that, every block of the control flow is processes by its data dependencies to form appropriate datapath that enters the final integration into unique datapath. The Control and Data Flow Graph (CDFG) is used as the intermediate representation that exposes those two aspects of every application, [18]. The datapaths that belong to control flow blocks consist of functional units performing operations of every block and registers encapsulated within register files holding variables for those operations. Therefore, the integration of blocks contributions relies on their functional units. The functional units are added to the final datapath along with register files they interconnect. During this process, multiplexers are instanced at functional units and register files input ports if more than one connection enters any of those ports.

TABLE I. COMPARISON OF DESIGNS

Characteristic		Cnt1	CntMax	NoCnt
Datapath	# Adders	1	1	14
	# Subtractors	1	1	1
	# Shifters	1	1	5
	# ANDs	1	2	4
	# ORs	1	2	7
	# XORs	1	1	3
	# NOTs	1	1	1
	# Comparators	1	1	6
	# Assigns	1	1	10
	# RFs	26	27	47
	RFs by register count	10-6-6-2-1-1	11-6-7-1-1-1	44-0-0-1-1-1
	# Muxes	35	41	61
	Mux widths	6-10-13-5-1	8-18-10-3-2	23-23-14-1-0
	# Interconnect lines	235	248	354
Implementation	DM depth	202	198	198
	CW width	217	224	242
	# Exec. cycles	3850	3770	3770
	RAM36_EXPs	11	11	13
	Slices	753	856	1097
	Slice Registers	310	343	1149
	Slice LUTs	2797	3072	3910
	Min. period	15.2 ns	14.0 ns	10.5 ns
	Max. frequency	65.9 MHz	71.7 MHz	95.0 MHz

During the final datapath integration the designer can interfere with setting the top numbers of functional units per operation types allowed in the final datapath. When new functional unit is fetched from the processed block datapath it is firstly tested if its operation type count in the final datapath exceeds the limit set by the designer. If it does not exceed this limit a new functional unit is instanced into the final datapath, otherwise not. Thus the diverse datapaths can be produced for same application what naturally reflects in different end implementations.

III. MOTIVATIONAL EXAMPLES

Comparison of diverse resulting designs is presented in Table I as motivational design example. The application beneath is SHA-1 encryption algorithm, [19, 20]. The C code of this algorithm is not very long but has quite

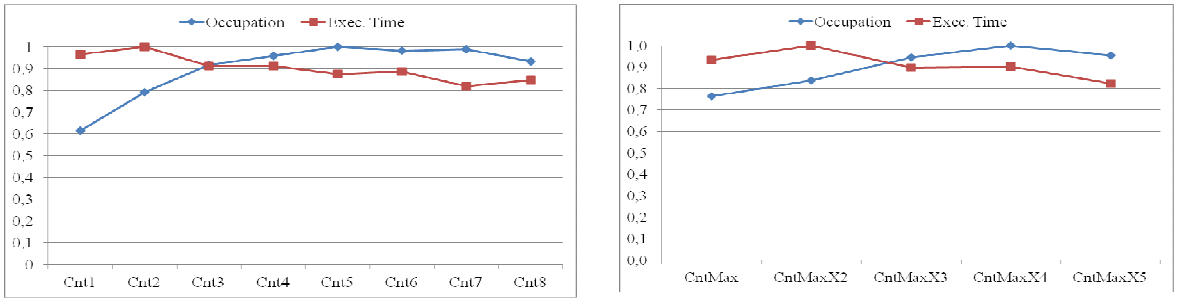
complex control flow consisting of 31 blocks. Moreover, it consists of nine different operation types: addition (ADD), subtraction (SUB), shifting (SHIFT), logical operations AND, OR, XOR and NOT, comparing (COMP) and assignment of values (ASSIGN). We examine its datapath design with some "milestones" defined by different operation type constraining styles:

- *Cnt1* as the design with limit of only one instance of every operation type.
- *CntMax* as the design with limits set to values calculated after analysis of all basic block schedules. Those values represent minimum numbers of all operation types needed to allow the full execution parallelism within blocks. For SHA-1 those values are two for logical operations AND and OR, and one for all others.
- *NoCnt* as the design without imposed limits on any operation type.

The designs in Table I are evaluated according to datapath and FPGA implementation features. The first nine rows of correspond to functional units instances of all operation types. For first two constraining cases they clearly correspond to set limits on allowed operation types, while for third they actually show the summed numbers of all blocks functional units. For last column there are no reuse of any functional unit or register, i.e. there is much redundancy in the datapath. There are much more functional units and register files and, consequently, multiplexers and interconnect lines. The first row below that describing register files count (*RFs*) shows distribution of registers across register files. Thus, there are 10 single registers (or "register file with single register"), six register files with two and three registers (each), two register files with four registers and one register file with five and six registers (each) for *Cnt1*, and even 44 single registers for *NoCnt* case. The row *Mux widths* shows the numbers of multiplexers per widths in format *Mux2-Mux4-Mux8-Mux16-Mux32*. As expected, the datapaths with less components use multiplexers with more inputs (in average) than those with more component redundancy. On the side of implementation the slices occupations of the first two are 20-30% smaller than the last one, but they are 30-45% slower than this last one.

Elaboration that is started by *Table I* data is further extended by establishing a set of constraints with clear tendency of increasing datapath sizes. Fig. 1 shows outcomes of two such constraining approaches. First, in Fig 1a is extension of *Cnt1* constraining style where *Cnt2* to *Cnt8* denote limiting the operation types to two to eight instances of every type. The second approach in Fig. 2 extends the *CntMax* constraining style where *CntMaxX2* to *CntMaxX5* denote limiting the operation types to double, triple, quadruple and quintuple numbers of every type compared to *CntMax* numbers. Graphs in Fig. 1 display existence of tendencies of rising occupations and performance looking from left to right.

Therefore, to investigate if such tendencies will be, and in what extent, recognized as common relation for our processor based design we implemented the software support that will in short time produce a range of diverse



(a) (b)

Figure 1. Correlation between occupation area and execution time under simple constraining variations

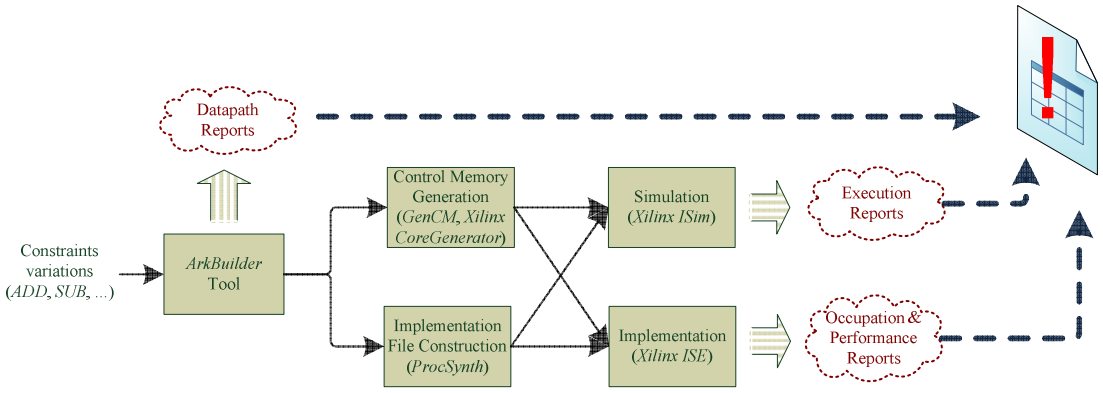


Figure 2. Design Space Exploration Flow

solutions for analysis.

IV. Design Space Exploration Principle

The design flow presented in [12] is supported with several scripts that automate generation of diverse final implementations, Fig. 1. Variations of allowed operation types numbers are generated for running datapath generation tool *ArkBuilder*. This is followed by control memory generation with *GenCM* and *Xilinx* CoreGenerator tools and Verilog implementation file construction with *ProcSynth* tool. Generated control memory cores and implementation file are then used to synthesize and simulate the final FPGA implementation. This flow is covered with several report types that serve as sources for deeper design analysis. Those are reports on:

- Datapath.
- Execution
- Occupation & Performance

Datapath reports include data on components and interconnect that form the datapath. Components data include data on component types: functional units, registers, register files, multiplexers, data memory, control unit. Functional units can be of 11 different types what is determined by operation type they perform. Register files can consist of any number of registers and registers can store any number of variables. Multiplexers can be of different widths (2, 4, 8, 16, etc.), while interconnect lines connect different components.

Execution report is generated during design simulation and has information on execution cycle count.

Occupation and performance reports assume files generated from *Xilinx ISE* implementation. Those include place and route (*.par* file), timing (*.twr* file) and power (*.pwr* file) data.

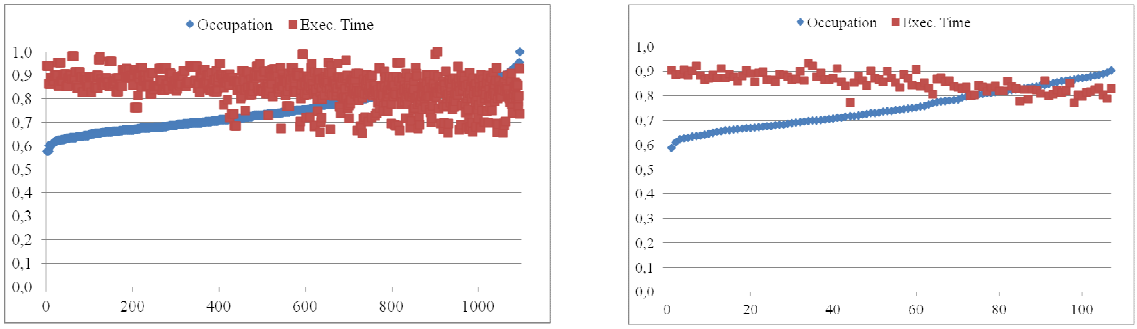
Therefore, all further analysis is based on those three report types.

V. Results

We generate three groups of cases according to different constraining levels:

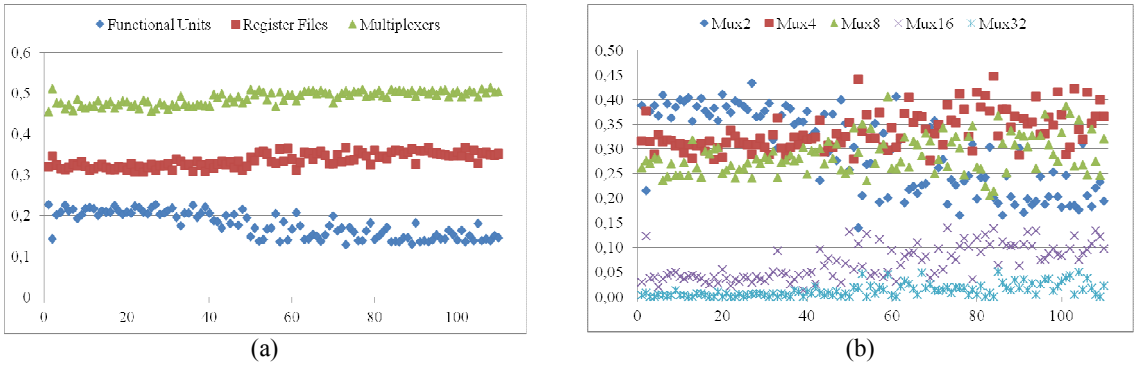
- *ordered12* resulting from variations of every operation type constraint between one and two. As there are nine different operation types, this set consists of 512 cases.
- *random14* as randomly generated 64 cases of constraints with minimum of one and maximum of four allowed instances of all operation types.
- *random17* as randomly generated 520 cases of constraints with minimum of one and maximum of seven allowed instances of all operation types.

Therefore, the complete solution set consists of 1096 datapaths and implementations, and Fig. 3a shows the relationship between occupation (in FPGA slices) and execution time for the complete set. The data are sorted by increasing occupation and show tendency of performance improvement with greater occupations, however with significant variations. This tendency is more emphasized



(a) (b)

Figure 3. Tradeoff between occupation area and execution time: (a) without grouping, and (b) when grouped by 10 constrained cases



(a) (b)

Figure 4. Dependence of execution time on: (a) component types shares (b) multiplexer widths shares

when solutions are grouped by 10 as in Fig. 3b. The same relationship between occupation and execution time when looked for constituents of the data set, i.e. separated *ordered12*, *random14* and *random17* groups, appears to differs only in steep of rising occupation points. It is steeper for cases with more relaxed constraints, i.e. *random14* and *random17* (not presented because of limited space).

Fig. 4 illustrates the solution space data grouped by 10 solutions where solutions are sorted by rising execution time. Starting points assume lower and ending points assume greater execution times, i.e. left sides of the graphs represent solutions with better performance (not explicitly drawn because of the illustrations clarity). Fig. 4a shows dependence of the execution time on component types, functional units, register files and multiplexers, shares in total component numbers. It can be noted that more functional units allow better performance as it is the main datapath design constituent allowing higher level of parallelism. However, it is not the only point of influence on execution time that is noticed. Greater number of functional units, even when having some redundancy, is better for performance when analyzing timing relationships between designs. The designs with more functional unit instances have more other component types also, i.e. register files and multiplexers. Their total count is greater, but their structures are simpler, i.e. register files have (in average) less registers and multiplexers use fewer inputs. Fig. 4b illustrates the execution times dependency on number of multiplexers per width showing their shares in total multiplexers count. The most significant in this graph is the drop of *Mux2* share that is happening along with performance drop. Reciprocally the other multiplexer widths types shares are greater when moving to the right of the graph what confirms the conclusion that components simplicity significantly influence the performance.

During system design it is usual to employ the concept of resource sharing not only by reuse of registers, but also the by use of functional units that can accomplish different operation types. Using such combined functional units reduces their overall number and numbers of other components that serve them by providing and storing data. Consequently it reflects in area occupation reduction. Therefore, the parallel solution space for *ordered12* solution set is formed by allowing combinations of different operation types within the same functional unit. Fig. 5. illustrates the relationships of area occupations (a) and execution times (b) between the cases with different functional unit sharing policies. With respect of area occupation it is noticed that in 92,5% of cases occupation is smaller when functional units sharing is allowed, but in 100% of such cases the execution speed is worse. This also leads to conclusion that complexity of datapath components is an important parameter for optimality of solution space as more complex units, i.e. combined functional units, have negative impact on timing and, consequently, design execution time.

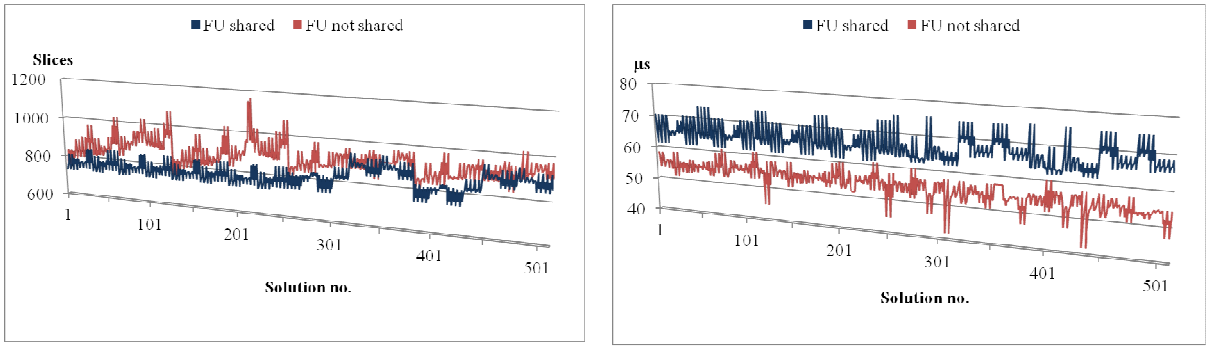
The simulation and implementation were accomplished in Xilinx ISE 14.3 Design Suite for Virtex XC5VSX50T device, [21, 22].

VI. CONCLUSIONS

The tradeoff between digital system occupied area and performance is open issue in every design process. Here we examined the design space evaluation for custom processor design that is based on automated C code algorithmic specification. This task is highly dependable on the quality of target hardware platform description and its correspondence with early design phases. The knowledge of implementation optimization principles is the to final solution occupation and performance estimation. Quality design space exploration and precise prediction of area-performance behavior depends on many parameters. Here we used control over functional units types to form the design space.

As the part of the overall custom processor design flow, we used proprietary IP tools for achieving FPGA device implementation so we could direct the design focus between area and performance only partially. However, we established the structure for design space exploration of custom processor design based development by constraining the functional unit component instantiation as a base datapath design component. Design space data collecting and reporting time was primarily dependable on particular tools run times and did not introduce noticeable time overhead.

We noticed that examined tradeoff is only partially impacted by execution cycles counts, but more on complexity of components.



(a) (b)

Figure 5. Comparisons of: (a) occupation area, and (b) execution time data with dependence on functional units sharing for *ordered12* set

Future work will be on exploiting established solution space to find best performance solution within strict occupation area constraint. Also, another point of future research interest is datapath interconnect reduction based on reduction of multiplexers widths to move the occupation-performance tradeoff focus closer to optimality within the solution space.

Critical Path Method Based Heuristics for Mapping Application Software onto Heterogeneous MPSoCs

Nikolina Frid and Vlado Sruk
University of Zagreb, Faculty of Electrical Engineering and Computing, Zagreb, Croatia
nikolina.frid@fer.hr, vlado.sruk@fer.hr

Abstract – In this paper the authors propose new heuristics for automation of software partitioning and mapping onto heterogeneous multiprocessor System-on-Chip (MPSoC) platform – Longest Parallel Path mapping algorithm (LPP). In contrast with traditional approach to solving this NP-complete problem – the Integer Linear Programming (ILP), our method uses a modified version of Critical Path Method with additional heuristics that rely on greedy approach. The algorithm performs one-to-many mapping of application to platform with minimizing the overall execution time of the application as the main objective. Our experiments with generic application model and several different platform layouts show that the proposed algorithm provides an efficient mapping scheme enabling significant execution speedup. In addition, the comparison with another greedy mapping algorithm shows that LPP algorithm exploits available task level parallelism better.

Keywords: Design Space Exploration, Software partitioning and mapping, Task scheduling, Critical Path Method

I. INTRODUCTION

Modern embedded systems are above all ubiquitous: they are found everywhere - from simple electronic products, communication and entertainment devices to expensive and complex systems (car, plane). They are getting more and more complex, and have to be able to perform advanced computation and meet special requirements: real-time response, maximum performance, minimum size and weight, low power consumption. This leads to development of new generation of embedded systems – MPSoCs which must often be very heterogeneous to meet all requirements with minimal cost.

Designing this type of systems is a challenging and time consuming task. Automation of design process would significantly lower cost and time-to-market. However, because of MPSoC versatility and heterogeneity, this is easier said than done. Many different approaches exist and many algorithms have been developed but this issue is far from being solved yet.

Scheduling and mapping software to hardware on heterogeneous platforms is NP – complete problem, and finding near optimal solution in reasonable amount of time is challenging [8].

Traditionally this problem is solved using Linear Programming model [4], but high complexity of this approach and extremely high computational requirements significantly increase design time. There have been several attempts to solve this problem, including greedy deterministic [7][6] and evolutionary non-deterministic approaches [11]. Greedy approach is the most common approach and delivers the final mapping solution much faster than evolutionary approach but always gives a suboptimal solution.

The Longest Parallel Path Mapping Algorithm (LPP), proposed in this paper, aims to present another possible approach to solving task mapping problem on heterogeneous MPSoC architectures.

II. DESIGN SPACE EXPLORATION

Design Space Exploration (DSE) is a process to find out near-optimal system architectures for a given application, considering the design constraints and objectives. It involves task partitioning and mapping, architecture and processing element selection, and performance estimation before a hardware prototype is built [2]. The process starts with application specified using a model of computation, description of architecture instance and a set of constraints for the overall system. Those inputs are fed to mapping engine which performs partitioning and mapping of software to hardware. Finally, a performance analysis is conducted to determine whether the output design meets given constraints. If the result is positive the production phase begins, if not modifications to application and/or architecture are made

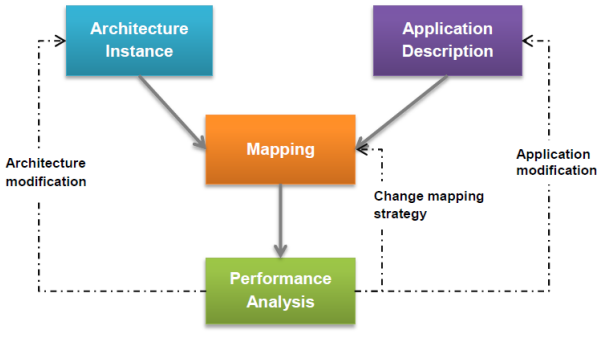

Figure 1. Design Space Exploration Flow

and the whole process is repeated. It is also possible to alter the mapping strategy and check if it produces better outcome. Figure 1 illustrates the described DSE flow.

A. *Related Work*

There is no commercial tool available to automate the whole DSE process. However, a tool is regarded as a DSE tool if it enables the system designer to alter the target architecture and task mapping easily, and it provides the estimated performance. Several tools exist that provide a general modelling and mapping framework to allow DSE [2]. Most prominent is a commercial solution - CoFluent Studio from CoFluent Design, a SystemC-based system-level design tool that supports DSE through Y-chart modelling. The designer specifies separate models for the application and the platform and combines them at the mapping stage. Then, the resultant design is evaluated by simulating the transactional SystemC code that is automatically generated. VisualSim from Mirabilis Design is a system-level design tool that supports diverse simulation capabilities in a single framework. Both algorithm simulation and architecture simulation can be performed at various abstraction levels. By changing the mapping information and architecture parameters, the user can explore the design space efficiently. However, in each of these tools task mapping must be performed manually.

Most prominent non commercial DSE tools include The Modular Performance Analysis (MPA) toolbox from ETH Zurich, which is a performance analysis tool based on real-time calculus, and Daedalus framework from University of Amsterdam, which has the capability of automatic mapping but the process takes several hours to finish [13]. However, much effort is put into further research and development of these tools and it is reasonable to expect that future improvement will resolve current issues.

B. *Task partitioning and mapping*

The key step in design space exploration process is partitioning application software into separate tasks and deciding where to allocate each task on the target platform. Due to heterogeneity of both application and platform this problem requires an NP-complete class algorithm to find the optimal solution. This means that the solution cannot be reached in polynomial amount of time. A faster alternative is using some form of specialized heuristics based on greedy strategy. This way a suboptimal solution is obtained much faster, but heuristics are usually rather specialized and are applicable to a smaller set of problems.

III. PROBLEM DEFINTION

The main problem can be summarized as: finding the near optimal solution to mapping of a generic type of embedded application to a heterogeneous multiprocessor platform in a reasonable amount of time.

The rest of this chapter gives a more detailed problem specification.

A. *Application Model*

Due to versatility of embedded systems, embedded applications come in a wide variety of forms. For the purpose of evaluation of the proposed algorithm a generic application model is constructed with certain assumptions and constraints in mind.

First, it is assumed that application has a flow from a single point of entry to a single point of exit and inside the application flow there are no cycles at all. However, the application as a whole can be cyclic, meaning that after exit point it starts all over again from start. Second, some level of functional parallelism in application is implied because otherwise the discussion about mapping parts of application to different processors is pointless, unless a certain task requires a certain type of special HW accelerator.

The application is modelled using a parallel model of computation and represented as a Directed Acyclic Graph (DAG), $G = (T, E)$. For each vertex $t \in T$ which represents one task, we define set of edges $E_t \subseteq E$ connected to t that represent communication between tasks. Figure 2 depicts an example application graph.

Vertex weight, given by a weight function:

$$w_t : T \to \mathbb{R} \tag{1}$$

stands for the number of operations executed in the process (in Mops) and the edge weight, given by a weight function:

$$w_e : E \to \mathbb{R} \tag{2}$$

is the amount of data transacted (in KB), both as reported by a profiler.

B. *Architecture Model*

The MPSoC hardware platform is also modelled as a directed graph $H = (P, F)$, each vertex $p \in P$ represents a processing element. Vertex weight is the computation

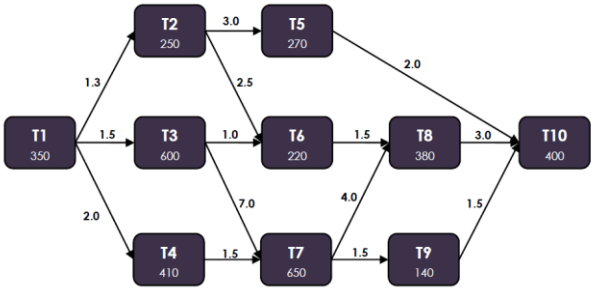

Figure 2. Application representation

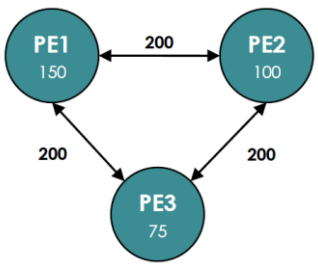

Figure 3. MPSoC platform representation

speed in Mops/s and is given by a weight function:

$$u_p : P \rightarrow \mathbb{R} \quad (3)$$

Each edge represents connection between PEs and weight is the throughput in kBps given by a function:

$$u_f : F \rightarrow \mathbb{R} \quad (4)$$

Figure 3 depicts an example platform graph with three different processing units.

In this model, processing elements differ from each other strictly by raw computational power, i.e. it is assumed that each PE is capable of performing all types of operations equally efficient.

It is also assumed that each processing element has its own private memory and communicate via interconnect network.

C. Mapping Problem

Given the application and architecture models, the mapping problem can be defined as assigning application components - tasks to architecture components in a way that the overall execution time required to execute the application is minimized. The final solution has to be found under the constraints that all the tasks are assigned a PE and one task is assigned only to one PE.

For n tasks (n=|T|) and m processing elements (m=|P|), where $n \geq m$, the cost of mapping of task $i := t_i$ to processing element $k := p_k$ can be defined as the time required to complete all of required computation and communication.

$$T = T_{comp} + T_{comm} \quad (5)$$

Computation time is calculated as:

$$T_{comp}(i,k) = \frac{w(t_i)}{u(p_k)} \quad (6)$$

Communication time is the sum of duration of communication between task i and all predecessor tasks mapped to a processing element different that k (communication cost between two tasks on the same PE is zero). The cost of communication between two tasks i and j mapped to processors k and l respectively is expressed in (7).

$$T_{comm}(i,j) = \frac{w(t_i, t_j)}{u(p_k, p_l)} \quad (7)$$

In order for a task to begin execution, all its predecessors must finish execution. After the predecessor j finishes execution, it would take $T_{comm}(i,j)$ time before the task i can use the results. This has to be calculated for all predecessors of task i and the maximum such value is the time when task i can start execution. The time the task i takes to execute $T_{comp}(i)$ depends on the PE it is assigned to.

IV. Longest Parallel Path Mapping Algorithm

In order to solve this resource allocation problem, a static scheduling algorithm [14] has been developed based on Critical Path Method [5] with additional modifications to develop fast and efficient heuristics. This algorithm's objective is to minimize the overall execution time of the application.

For each task the earliest and the latest possible start time governed by data dependencies can be defined. If both times for a certain process are equal that process is a *critical process.* A set of critical nodes (processes) and edges between them from source to finish form a *critical path.*

The mapping process, as shown on Figure 4, consists of four stages. In the first stage, first of all processing elements are sorted descending by their computation speed. Afterwards, using a modified version of Dijkstra algorithm [12], the longest path is identified and mapped to the fastest processor. As long as there are free PEs, the algorithm identifies the second critical path, the third etc. and maps all tasks in the path to the fastest free PE. Thus, communication costs between tasks on the same path are minimized.

Next, a preliminary schedule is made for mapped tasks, which enables the search for free gaps in PE task list where unmapped tasks will be mapped in stage 3.

Stage 3 comes in two versions. In the first one, mapping of remaining tasks starts with PEs *sorted ascending* by computation speed. For each unmapped task a time frame is calculated - it begins when all of task's mapped predecessors have finished and ends before the first mapped successor has to start. Starting with the slowest PE, mapper checks if it is free during time frame and fast enough to compute the task in time; if

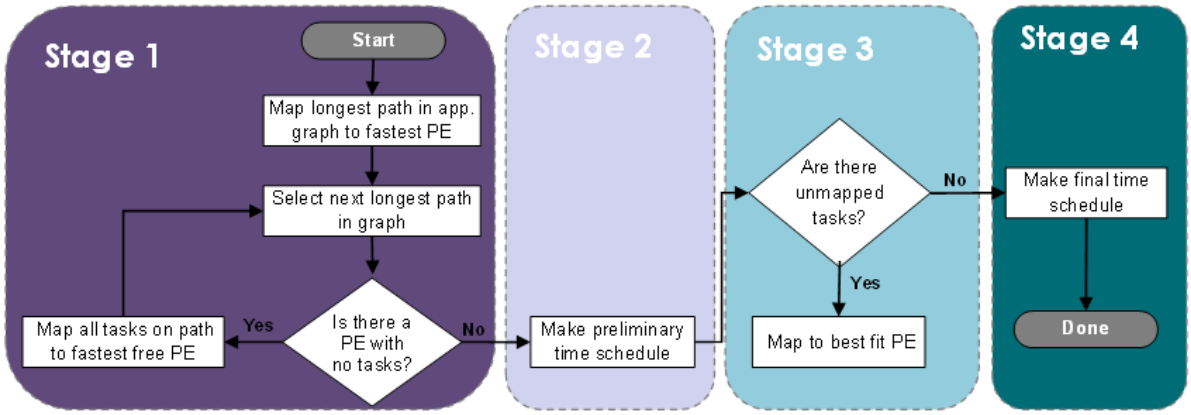

Figure 4. Longest Parallel Path algortihm flow

it is not, the overflow for that task and that PE (expressed as time) is stored for later evaluation.

In the second version, PEs are *sorted descending* by computation speed thus search for candidate PE starts with fastest processor.

When the fit PE is found the task is mapped to that PE – a perfect fit, and in case when there is no perfect fit the task is mapped to PE with least overflow.

The rationale behind the first version of Stage 3 mapping is that it is hardest to find a task that can be mapped to slowest PEs without disrupting entire schedule. On the other hand, mapping one task to slow PE usually means that it will consume the most of the available time frame and leave little chunks of free processor time that are not big enough for any other task to fit in. On the contrary, fast processors require much less time to finish the computation and it is probable that when a task is assigned in a free time frame, enough room will be left for at least one more task to be fitted in the same time frame.

The final schedule is calculated in the last stage of the mapping process.

Based on the algorithm discussed above, Automatic Mapping Tool has been developed in Java programming language and preliminary results of conducted simulations are discussed in the next chapter.

V. Experimental Results & Future Work

In this chapter we present the results of performance testing of LPP algorithm, make comparison with results obtained by using another greedy algorithm – LPT [7] and propose directions for future development.

A. Case Study

The performance of proposed mapping algorithm, in terms of total execution time estimation, was examined on nine different platform configurations for two generic applications. The configuration for each test case is described in Table 1. The numbers represent PE speed in Mops, and in each case communication costs between two processes on different PEs are the same.

1) The LPP algorithm was tested for both versions of Stage 3 (ascending and descending order). The execution times estimation of mapping generic application, represented by a DAG on Figure 2, are shown on chart on Figure 5. In the same figure we compare to the results obtained using LPT algorithm. LPP – ascending version results

TABLE I. Platform configurations for test cases

	1PE [Mops]	2PE [Mops]	3PE [Mops]
Configuration 1	150	150, 150	150, 150, 150
Configuration 2	100	150, 100	150, 100, 100
Configuration 3	75	150, 75	150, 100, 75

In all nine test cases LPP outperforms LPT by up to 130 percent. It is also important to note that LPP algorithm, in case of platform with two fast PEs (both 150 Mops), reaches optimal solution: total duration is equal to critical path duration, and LPT can never reach that situation. In that case LPP algorithm provides speedup of 1.56 times compared to a sequential solution. Even more interesting is that in Configuration 3, when two fast PEs (both 150Mops) are replaced by a set of PEs by a third and a half slower ('3PE' in Table 1) the speedup is still high - 1.5 times compared to sequential solution.

It is also important to note that time complexity of LPP algorithm is $T(n) = O(n \log n)$ which is a significant improvement compared to complexity of LPT algorithm which is $T(n) = O(n^3)$ [7].

2) LPP – descending version results

The results for the second version of LPP (Stage 3 PE search in descending order) are exactly the same as in the previous case. A possible explanation for this is that other features of the algorithm govern task scheduling in later stages. For example, the first stage of the algorithm works in a way that it puts most load to fastest processors which later have little room to host additional tasks. On the other hand slower processors are left with much more idle time after the preliminary scheduling and have a higher

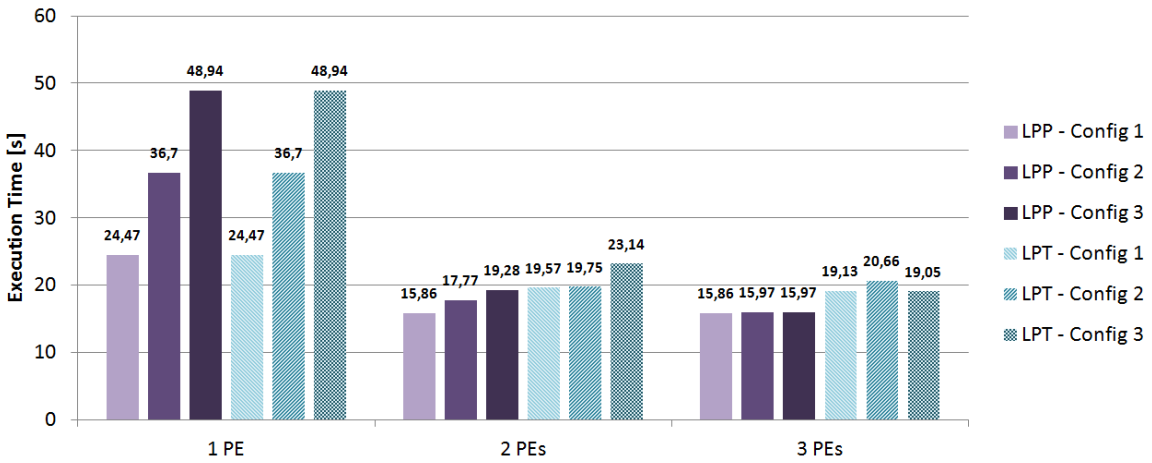

Figure 5. Total execution time comparison

possibility to contain a gap in scheduling that is big enough to fit a new task without overflow. Another possible reason for this, in case when all processors are left "crowded" after the preliminary scheduling, and overflow is almost iminent, is that faster processors will have less overflow (can compute the task faster) and will be filled with new incoming tasks first, regardless of the order of processor list traversal.

B. *Future development*

In future research, the LPP algorithm should be improved so it could tackle the following two issues: support for application with loops and recursions, and support for MPSoC platforms that have a more specialised type of components which are more suitable for a certain type of operation (e.g. floating point operations) – *mapping affinity problem.*

Another direction of development could address DSE from another point – giving recommendation for the platform architecture by selecting the most suitable configuration from a set of available components.

VI. CONCLUSION

In this paper we have given a short overview of Design Space Exploration, as a vital concept for modern heterogeneous multiprocessor embedded system, and related work. Further, we have addressed the issue of lack of quality mapping algorithms – crucial for automation of the entire DSE process by presenting new greedy strategy based on critical path method.

The presented LPP algorithm provides efficient automatic mapping strategy which exploits available task level parallelism in the given application. Conducted case study shows that the algorithm is able to schedule tasks on heterogeneous platforms with variable processor performance and achieve speedup very close to optimal solution in polynomial amount of time. In comparison to another acknowledged greedy strategy, LPP algorithm shows significant performance improvement – up to 130 percent. However, some issues concerning exploiting data level parallelism available in application and higher level of "platform awareness" remain and will be dealt in future research.

Event Calendar for Internet Data Sources

P. Rantanen* and P. Sillberg*
* Tampere University of Technology/Pori Unit, Pori, Finland
{petri.rantanen,pekka.sillberg}@tut.fi

Abstract – Several nations in Europe have released formerly closed data sources collected by government agencies and municipalities. These open data initiatives have enabled new and innovative services. The research presented in this paper is funded by the European Union Regional Fund as part of the Satakunta Regional Centre for Economic Development, Traffic and Environment funding program, and by the City of Pori. One of the goals of the research is to study how open data can be utilized technically. This paper presents technologies found useful for the implementation of a service utilizing open data. These technologies are presented in this paper as part of an event calendar service that uses open data sources available in the region of Satakunta, Finland. The overall architecture of the service is described briefly, and the paper focuses on the open source components used to implement the user interface, front-end service, and database. Despite the use of region-specific data sources, the utilized solutions i.e. hybrid databases, search platforms, and HTML5 technologies can be exploited in the design of other services.

I. INTRODUCTION

The research presented in this paper is part of the AVARAS project. AVARAS is an Open Data Project in the Satakunta Region in Western Finland conducted by Tampere University of Technology, Pori Unit. The idea of it is to study and implement business opportunities related to Open Data. It is a regional activity with close connections to more than ten SME-sized software companies that are used to guide and direct the project activities. The project is funded by the European Union Regional Fund as part of the Satakunta Regional Centre for Economic Development, Traffic and Environment funding program. [1]

One of the main goals of the project is to study how open data sources can be utilized technically. The research is conducted using pilot applications, which will be openly available for public use. Their purpose is especially to publish interfacing technologies and interface specifications, which can be re-used in new applications. Similar activities are taking place in other regions in Finland [2], [3]. This paper presents one of the pilot applications designed in the AVARAS project.

The application presented in this paper is an event calendar service, which utilizes event data available on the public Internet. The service does not require any input from the event publishers, and can be set to crawl any number of sources automatically. There are many event calendars available on the Internet and the idea of an event calendar is in no way a new one, even though one could argue that there are not that many calendars that can list external events without some kind of input from the event publisher or event provider. Nevertheless, the main reason for choosing an event calendar application in particular was the type of container it provides. Basically any data can be thought of as "an event": the daily weather forecast, road accident reports, sports events, or movie showtimes – which are used as an example case in Section V of this paper. In a way, the idea of an event calendar can be generalized to contain almost any kind data. This paper does not go into too much detail when describing the basic calendar functionalities, but attempts to illustrate how the chosen technologies could be used both in this use case and perhaps in a more general way outside the event calendar context by describing the advantages and disadvantages of the chosen technological solutions.

As mentioned above, the example shown in Section V uses details of movies from the local cinema as a data source, though any other data source could have been chosen as well. The other sections of this paper are as follows: Section II gives a short overall presentation of the chosen system architecture; Section III describes the chosen database solution; Section IV explains the designed REST interface; Section VI discusses some of the issues related to the application; and finally, Section VII summarizes the paper.

II. SYSTEM OVERVIEW

The system introduced in this paper is an effort to utilize publicly available data in the region of Satakunta, Finland, and also test the usability of open source software components and libraries. The selection was made partly by suggestions from the steering committee of the project, and partly guided by academic ambitions. Fig. 1 illustrates the basic organization of the system. There are three distinct components: data storage, front-end service, and client, which are described in more detail in Sections III, IV and V, respectively.

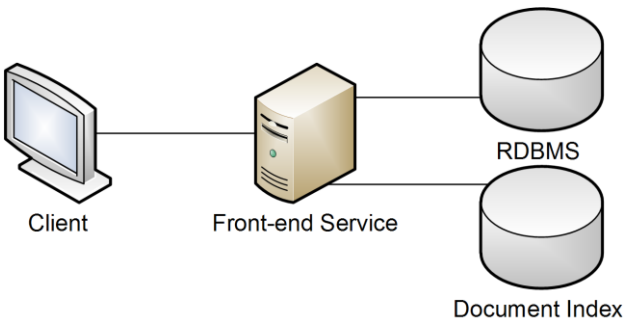

Figure 1. System overview

The *Client* is in principle an HTML web page, which accesses the *Front-end Service's* RESTful (e.g. [4], [5]) interface to retrieve data, and then visualizes this data in a calendar view. The client allows the user to narrow down the dataset by entering filtering terms such as date, time, keywords and also free text searches.

The *Front-end Service* is an access point to the features of the system. It provides user authentication, RESTful API for data in XML format, and adapts the data sources to make them suitable for indexing and storing. The service is written in Java and the main open source components it utilizes are Apache Tomcat [6] and Spring Framework [7].

Our database solution includes features from both the traditional RDBMS and NoSQL [8] approaches. The *Document Index* uses the Apache Solr [9] search platform as it is specialized in indexing and searching, while the *RDBMS* is based on MySQL [10] and is used to store the document relationships and basic structural information such as user credentials.

III. DATABASE

The searching and indexing of data provided by open data sources is the key point of the system. The database solution must have good search capabilities, but it also must be able to handle loosely structured data. Different data sources are often provided in various formats, thus it may be difficult to parse the same data from them all. For example, one source could simply list the names of the performers while another source may contain performer names, email addresses, and groups they belong to.

The SQL approach with its well-defined table-column structure was considered too rigid for the data we might encounter. Of course, we could define all possible columns and leave them null if not available, but that would not be very practical. From the NoSQL approach we found a solution, Apache Solr, which had the capability to index and store the data, as well as sophisticated text search features.

The most interesting feature of Solr is its ability to index any kind of text in various ways. With relatively small changes and additions to the Solr core's basic setup, it is possible to enable request handlers such as full text search, "more like this," and auto completion [11]. As a security measure, the database section in our system is behind the front-end service. This means that the client cannot access features of the database directly. A simple call through API was implemented on the front-end service to handle requests.

There is often a need for storing relationships between documents, and implementing this feature was cumbersome with Solr alone. For storing simple data types, such as strings, texts, dates, or a list of strings, Solr can manage with no problems. Issues arise if there is a need to store complex and denormalized data within the same document. For example, take the situation where there is an event involving many performers in it, and for every performer we need to store a name, email address and URL for the website. There are several possible approaches on how to solve the issue:

1. Store performer data in synchronized lists inside the same event document. This requires some extra effort in marshalling objects, but Solr can still index the document effectively. Maintenance of the document or parts of it suffers from the denormalized data format and from the way Solr handles updates (complete overwrite, i.e. no partial updates).
2. Store performer data in another Solr core as separate documents, and store the relationship (i.e. performer ID) in the original event document. This approach allows easier maintenance and is closer to the traditional relational approach. Solr cannot handle joins as fluently as SQL does, so extra lookups and queries are required. Extra work is required for fully utilizing search and indexing in the Solr multi-core setup.
3. Store performer data in another Solr core as separate documents, but store the relationship (i.e. performer ID and event ID) in another database (e.g. MySQL). If the only task of this other database is mapping of relationships, a graph database (e.g. [12], [13]) might be an alternative choice for a SQL database. This hybrid – or polyglot [8] – approach is much like the previous case, but the handling of relationships might be easier. This increases complexity due to the use of another database technology.
4. Store both the event data and the performer data in the same Solr core, but store the relationship (i.e. performer ID and event ID) in a separate database. Use of a single Solr core simplifies indexing and searching. Storing of multiple types of documents in a Solr core can be achieved as Solr allows dynamic field assignments. The type of document must be known when the data is marshaled. Compared to the first case, maintenance of these smaller documents may be easier.

A combination of multiple databases is called the polyglot persistence model by reference [8]. Together they may create an ecosystem that is more powerful than the sum of its parts [8]. In theory, one could choose any combination of database techniques if using them together generates more benefits than drawbacks (e.g. code complexity, time to develop).

We chose the hybrid approach (3) for the event calendar implementation. In our use case the main event details and minor event details are stored in separate Solr cores, and the relationships are stored in a MySQL database. The minor event details can contain information such as event location and event organizer, or sub events which belong to the main event. In principle the minor event details could be stored directly to relational database, but this would prevent using Solr's text indexing and search functionality. On the other hand, the details could be merged with the main event details, and stored in a single core as described in the approach 1 above. In practice this would require flattening of very complex objects to key-value pair lists, which is more difficult than separating the less important data into individual cores.

Naturally, dividing the data between multiple cores will have an effect on the complexity of search queries and the search performance if the queries need to be targeted to multiple cores. In addition to a performance gain, in our use case there is also an additional advantage achieved by flattening certain important data with the main event details, which is perhaps not immediately evident. Event details often contain various performer details, such as description of a band, movie studio or names of the artists. These descriptions generally vary depending on the data source and analyzing the details to form a single combined entity is difficult. A simple solution to this problems is to ignore the performer-event relations altogether and flatten the data into a single core. This will cause all details to be duplicated and appear slightly different for each event, but it will also enable the use of Solr's text search features when querying for the event details. From the text indexer's point of view these minor differences in the descriptions are irrelevant.

IV. FRONT-END SERVICE

The front-end service implements interfaces for three kinds of functionality: user management, suggestions, and search. In our demo implementation the user management is limited to basic functionality, i.e. creating a new user and modifying user details (such as password and email address). User authentication is provided using the Spring Security [14] framework and in principle supports all features supported by the framework. The reason for implementing only a minimal set of user authentication and authorization features is the nature of the processed data, which consists of publicly available content. There is no need to check user authorization when accessing the content. Of course, the service could be extended with the possibility to add user-created content, but this would complicate the implementation and is not the focus of our current demo implementation. The user management could also be utilized for personalized calendars, but this functionality is not currently implemented.

The suggestion API provides the user with search suggestions. It is implemented using the text indexing features found on Solr and works similarly to the functionality found on many search engines. For example, if the user types "Hobb", based on the indexed content the system may suggest search terms "Hobby" or "Hobbit".

The search API provides the functionality required for content queries and offers features such as free-text search, content filtering, sorting, and paging. Many of the currently available open source databases directly offer interfaces for the aforesaid features [15], [9], which can be easily used over HTTP by using GET or POST. In this case content filtering refers to filtering by values (e.g. only return events taking place between January 1st and January 10th), though similar functionality could also be used to implement filtering for improper content (e.g. do not show adult content to anonymous users or to children).

Depending on the use case, these interfaces might be all that is necessary. The limitations of the APIs are not so much on the basic functionality, but more on the user management. The NoSQL database APIs often do not enforce – or even provide only a very limited – user authentication. In a way this is a shame, as in many cases the REST interface provided by the NoSQL databases could be all that is needed for the query operations. Then again, perhaps the idea is, that it is not the task of the NoSQL database to perform user authentication. Of course, in many cases this does not matter so much as it is often the case with web applications, that the user authentication is performed by the front-end service or by some kind of mediator interface, and the user does not directly interact with the database. The similar approach is possible with Solr and with any other NoSQL database. If a complex authentication scheme is required it might be better to implement a front-end service with interfaces combined with user authentication and authorization. The demo implementation presented in this paper uses the aforementioned design pattern by providing a separate REST interface for query operations, which in turn will delegate the requests to the database when appropriate.

Another advantage received from implementing a separate front-end service is the additional control gained over the requests. This enables simplifying the search queries or limiting the set of available search filters or even resolving the XML element (or JSON object) names given in a query to database field names to be used for sorting and filtering. In particular, mapping element names to database fields is often required when the actual field names defined in the database are hidden to end users or developers using the API. As document databases generally offer output in the form of XML or JSON, it is possible to use the field names defined in the document directly in the response returned to the user, but this is generally not a good practice – it is much easier to change the internal implementation when the fields defined in the database layer are not directly being used by the users of the service API. Also, defining separate field names and XML element names is often a minor task, for example by using annotations in Java. Both the Solr Java implementation (SolrJ) [16] and Spring Data framework [17] provide annotation support for defining Solr field names for Java objects, and the annotations can be combined with Java Architecture for XML Binding (JAXB) [18] or Google GSON [19] to provide XML and JSON responses. This way the response Java objects that are deserialized from Solr query responses can be directly serialized to XML or JSON for external service API responses.

On Solr, database queries cannot modify the database content and thus the risk of code injection can be mitigated by rejecting all other user requests except queries. In our use case, there is no risk of users retrieving content they are not authorized to view by running a malicious query, as all of the content is publicly available. Also, it should be noted that implementing user preferences does not necessarily require user authentication. For example, if the user always wants to see the latest events or only events of a certain type (such as sports), the preferences can be stored on the client software or in local storage [20] on a web browser and from these preferences the required filter parameters can be generated and appended to the queries.

V. CLIENT

Fig. 2 illustrates a calendar with events retrieved from XML API [21] provided by a local cinema in the City of Pori. The calendar view could include any events indexed by the front-end service, but for simplicity only movie events are shown in this example. The view in the figure is a screenshot from a web browser. The main page layout is created using the w2ui JavaScript UI Library [22], which consists of plugin extensions for the popular jQuery library [23] and the calendar view itself is an embedded component created with the FullCalendar jQuery plugin [24]. There are many open source alternatives that can be used to implement web user interfaces (e.g. [25], [26]) and calendars (e.g. [27], [28]), and it is possible to implement a new user interface from scratch using basic JavaScript or jQuery, but in many cases the pre-made plugins and libraries provide a better starting point. The choice between the various alternatives is partly use case-specific as not all libraries provide similar functionality, and partly based on the developer's preference or pre-knowledge of a particular library. In this use case we use movie details from the local cinema.

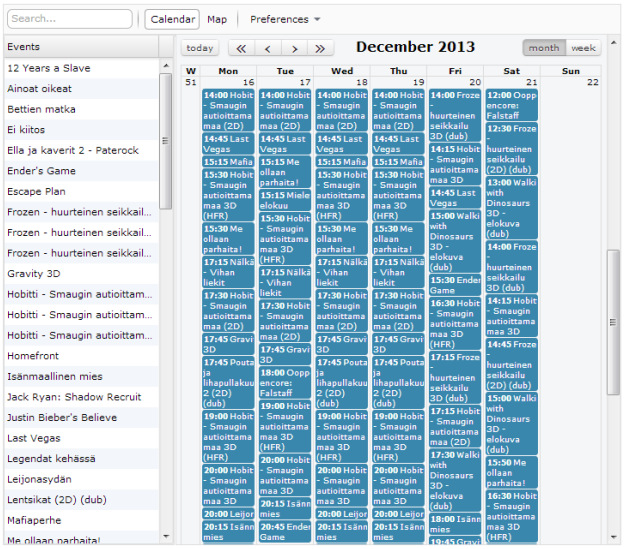

Figure 2. Calendar view

The calendar view in Fig. 2 shows all events currently listed in the events panel on the left. In the example case, no search terms have been given and thus all movie events known by the system are shown. The search field at the top left accepts both free text search and the basic query syntax of the Solr query parser. The Solr query syntax is based on the Lucene Query Parser syntax, which can be somewhat cryptic for end users. There are alternatives for the default parser such as the Extended DisMax Parser [21], which can provide better usability. However, in general, users will most likely prefer free text search over syntax-based queries, and it is better to create filter parameters and additional search terms programmatically and append them to the search query given by the user. The additional parameters can originate from, for example, checkbox selections or user preference options.

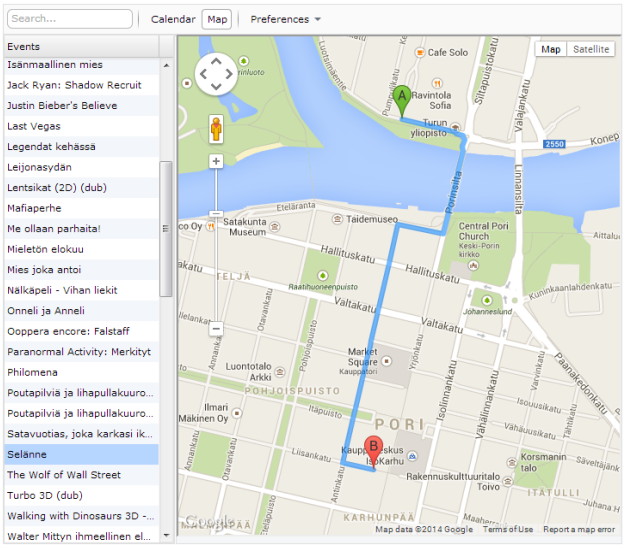

Figure 3. Map view

Fig. 3 shows the location of a selected event on a map using the Google Maps API [30] embedded in a w2ui panel. Showing a map and directions is often quite simple, but they can provide a lot of additional value for the end user. Most of the online map services provide JavaScript APIs, which can be used to show a location on a map and provide guidance to the location from the user's current location [31] on foot, by car or by public transportation. Unfortunately, in most cases the directions are not turn-by-turn capable and cannot as such be used to navigate directly to the target location except by continuously re-calling the mapping service, which can be very resource-intensive. To enable turn-by-turn navigation, the use of a native map application found on a mobile device is often required. If more complex map operations are required, the use of a native map application may be a better choice than a web-based client. In addition to extended functionality, native applications generally perform much better on mobile devices when compared to JavaScript web applications with similar functionality.

VI. DISCUSSION

This paper presented an event calendar service, which can be used to show data retrieved from various data sources, and provided some technological insight on how to implement the aforesaid service. Nevertheless, there remain several problems with the current implementation, and these problems are not strictly related only to the application in question. As mentioned above, the newer database technologies have not yet been fully utilized, and because of this it is often hard to find ready-made solutions for the problems. This is especially true when compared to traditional relational databases – several good books have been written and best practices developed to solve various implementation problems related to relational databases. The lack of best practices naturally creates problems for adapting new technologies, but on the other hand it makes the subject an excellent research topic. When adapting to a new technology, there is also a great temptation to abandon the old models and use new technology for every use case – even when it is not appropriate to do so. For example, it is possible to use a

key-value database or document database to map relationships, even though that is not what they are designed for, while a relational database would be a more appropriate choice.

Another problem is finding the event sources from the Internet. It is relatively easy to find listings (e.g. [32]) of usable event APIs by using a simple web search, but utilizing the sources requires implementing parsers for each of the various APIs. Implementing a parser is generally a straight forward task, but it does require one to study the API documentation and perform some programming work. Another option is to search events from popular web pages such as Facebook or Google Calendar – or use the APIs provided. The availability of events is dependent on the services used, and extracting the events may require special permissions from the publishers of the events whether they are the users of the service or the service operators. In practice it may be better to use the service APIs directly instead of crawling the web in hope of finding up-to-date event details in sensible format is difficult. Also, in many cases the online calendar applications are dynamically populated with, for example, JavaScript, and can be very challenging to parse. Extracting content from dynamically created web pages has been researched by e.g. [33] and [34].

In addition to purely technical problems, there are also other issues related to implementation and usage. In many cases it is often difficult to figure out whether the data in question is actually *open* data or merely *openly* available [35], [36]. This can be illustrated by using the example chosen in this paper. If the cinema does not show copyright notices or present license agreements on its web page nor are there any present in the provided data, does that mean that the data is truly open and free to use? Should permission be asked from the cinema owner, or maybe from the company who made the movies, or even from the company who made the local translations of the movie descriptions? In our use case one might assume that showing the movie details and showtimes on a public calendar is only good publicity for the cinema and a way to advertise in a way the cinema did not think of, but legally this may not be the case.

Also, many open data sources do offer data freely, but with certain limitations. The user may have to register first, or maybe the data cannot be shown openly and freely in all possible use cases. Finding these license agreements is not always a simple task. The service presented in this paper mostly ignores these issues by being a technology demo, but when designing an actual implementation, which will be a publicly available service, one should be careful to check that the apparently free and open data is truly free and open.

VII. SUMMARY

This paper presented an event calendar service, which can be used to visualize open data. The overview of the service was presented, and the chosen technical solutions were explained. The issues encountered while implementing the service were also dealt with briefly. The pilot application proved that the chosen technologies were promising candidates for future studies. In the future, our research will continue to focus on the new database technologies. We will also continue to improve the calendar implementation, with a possibility of running a user trial on a local summer festival. It was also found that there is a need for a separate study on the issues concerning the licensing of open data.

Simulation Library for Resource Constrained Project Scheduling with Uncertain Activity Durations

Mario Brčić* and Nikica Hlupić *
* Faculty of Electrical Engineering and Computing, Zagreb, Croatia

Abstract – Stochastic Resource Constrained Project Scheduling (SRCPS) is among the hardest combinatorial problems. Exact calculations of interesting measures, such as expected project duration and the probability of satisfying the deadline, using known probabilities are in #P even for relaxed instances of the problem where resource constraints are ignored. The most common approach is to use substantial simulation to evaluate candidate solutions. All of the work so far uses ad-hoc developed simulation environments with prevalent use of a priori generated activity duration scenarios. This paper describes the discrete-time simulation library aimed to support the creation of simulation-based algorithms for solving SRCPS problems with known probability distributions of activity durations. The library is designed, in the first instance, with shared memory parallelization of simulation, using OpenMP. Runtime parallelized generation of random activity duration scenarios is supported and we deal with "inconveniences" that are otherwise elegantly avoided using a priori generated activity duration scenarios. However, in some approaches that is not feasible and runtime scenario generation has to be used. We propose modular organization of simulators that enables better reuse of basic intrinsic project scheduling functionality.

I. INTRODUCTION

Stochastic Resource Constrained Project Scheduling Problem (SRCPSP) is a relevant generalization of previously well-researched deterministic problem [1]. The model and its variants are general enough to model real-life projects. It uses random variables with known probability distributions to model uncertain elements.

The solution for deterministic variant of the problem is a schedule calculated offline, before the project start, that is executed exactly as planned using the trivial policy that starts activities according to the schedule. This is not the case for stochastic variant. Instead, the solution is a strategy, i.e. policy, that guides creation of schedules using the information that becomes available during the project execution – a form of contingency planning is necessary.

Unfortunately, these problems are computationally very hard and evaluation of candidate solutions is much harder than evaluation of candidate solutions for the deterministic variant where it is in low polynomial complexity. It has been shown in [2] that, even in the case of project with no resource constraints and discrete activity duration distributions with just two values in the support, the exact calculation of expected project makespan is #P-complete. Simulation is used as a way of obtaining evaluations of measures of interest such as: objective function, execution statistics, etc. Of course, depending on the problem, each simulation-obtained estimate is noisy due to the simulation error. When using simulation for evaluation and choosing among several options through comparisons, we are trying to achieve as precise estimates as possible for each pairwise difference between the estimates in order to make a selection. Due to the mathematical properties of variance of the difference of random variables and based on assumptions that the estimate errors of are positively correlated [3], using the identical set of scenarios for simulation of each option reduces the variance of differences between the estimates for options. This is the basis for using the a priori generated scenarios for all the simulations where the procedure permits. Also, these scenarios are usually generated in serial mode because the cost of generating them is much smaller than the simulation cost which has to be parallelized. In serial mode, all the benefits of existing pseudo-random number generators and their mathematical properties are reaped.

There has been substantial work in the area of SRCPSP with uncertain activity durations. Three basic types of solving procedures have been applied: predictive, proactive, and reactive scheduling. Predictive scheduling ignores uncertainty and uses point estimates in calculation of the schedule. There are two types of reactive methods: completely online and schedule repair. Online methods create schedule in steps without using baseline schedule. Schedule repair methods use the baseline schedule and perform the rescheduling when the baseline is made infeasible due to random events. Both reactive procedures search for policies that govern the runtime decisions depending on the current project situation. Proactive methods try to create schedules that are robust with respect to some measure of robustness. Most commonly used measures of robustness are quality and stability robustness. Although protected against some uncertainty, proactive schedules, just as predictive ones, can be yielded infeasible due to unfavorable activity duration scenarios. In all cases, a scheduling policy is a necessary component of the solution that makes project execution possible and

ensures project termination. Theory of solving these problems is based on stochastic dynamic programming [4] and, due to the "curses of dimensionality", the solving efforts usually steer to suboptimal methods [5]. One approach is to define policy families, their parameterization, and use some search method to find good enough solution inside that family. Other approach is to work with the value function approximations.

Of existing works in SRCPSP that used simulation, Stork in his PhD thesis [6] used simulation in branch and bound procedure to evaluate objective value of nodes in the search tree. Van de Vonder et al. in [7] used the simulation in improvement procedure over initial buffered schedule obtained by Starting Time Criticality (STC). Deblaere et al. in [8] used simulation based descent to search the family of proactive resource-based policies with release times. Ashtiani et al. in [9] defined PP-policies and searched the policy space using the two-phase genetic algorithm and simulation. Authors in [10] used simulation with electromagnetic heuristic. In the related field of machine scheduling, authors in [11] used genetic programming and evolutionary algorithms in order to search complex policy space. Additionally, authors in [12] used support vector regression in value function approach for finding good rescheduling policies with pre-generated scenarios. But, all these works used simulators made specifically for the problem at hand where certain number of scenarios is generated a priori, before the optimization, and later used for all evaluations. Csaji and Monostori in [13] used fitted Q-learning to find good dispatching policies for machine scheduling. They also used distributed sampling, but didn't specify the used random sampling mechanism in their ad-hoc approach.

In order to make the future developments on dynamic optimization of SRCPSP with activity duration uncertainties, the area of SRCPSP research that withstood the greatest developments, we propose a simulation library that can be used as a basis of future research as well as the applications of the existing work in practice.

Contributions of this paper are: general-use simulation library for dynamic optimization of SRCPSP with uncertain activity durations, runtime parallelized scenario generation that enables sampling from the conditional discrete distributions, model separation of simulator into the simulator/sub-simulator components, and the MDP model builder in order to measure the optimality gap for small toy problems.

This paper is organized as follows. General structure of the library is given in the section 2, with detailed description of components in the subsections. Section 3 gives basic performance measurements. Finally, conclusion is made in the section 4.

II. LIBRARY STRUCTURE

The library consists of several important components:

- *Project scheduling problems* – contains the basic project scheduling problems
- *Pseudo-random number generators (PRNG) and probability distributions*
- *Simulators* – simulate the project execution with defined simulator-dependent state space and action space
- *Controllers* – implement the policies, i.e. make decisions based on the current project state
- *Experiments* – contains facilities for the most commonly used parallelized simulations
- *Optimization algorithms* – basic collection of algorithms that can be used as basis for new algorithms or for comparisons with them
- *Model builder* – builds Markov Decision Process (MDP) model from certain types of simulators that have factored project state representations

As in many cases simulations are easily parallelizable, the library is designed to support shared memory parallelization through OpenMP. The library takes care to support parallel random number generation based on the existing work in literature. In one typical application scenario, there can be more than one levels of parallelization, but for performance purposes nested parallelization is by default disabled. The first prototype of the proposed library was implemented in Python with the basic multithreading supported by the language. The prototype is implemented in C++11 for better performance and all of the components except optimization algorithm SBD and model builder are re-implemented with the letter components in plan for the near future work. Due to constrained space, UML diagrams contain only the parts relevant for the exposition.

A. Project Scheduling Problems

SRCPSP is a tuple *(V, E, p, R, B, D, c)*, where *V* is the set of activities, *E* defines the precedence relation, *p* is the joint probability distribution of activity durations, *R* is the set of resources, *B* is the vector of resource availabilities, *D* the matrix of activity-resource demands, and *c* is the objective function, usually the expected makespan. For more details on the formal definition, check [1].

The library holds definitions for the deterministic RCPSP, SRCPSP, and proactive variant where the objective function depends on deviations of realized and predicted baseline activity start times. All problems are realized in accordance to the formal model with a class hierarchy as shown in Fig. 1, where only parts of the classes pertinent to our exposition are displayed. Input data for test problems is available in benchmarks. Standard benchmark data is available for deterministic

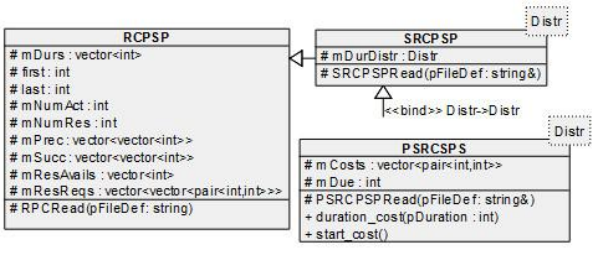

Figure 1. Project problem classes

variant, mostly in the Patterson format. The most commonly used benchmarks are PSPLIB [14] and the newer dataset RG300 [15], both in Patterson format. The simulator library enables reading and parsing the input files. Also, we define an extension on Patterson format to include the data about probability distributions and various costs for more complex SRCPSP variants, such as proactive ones that include costs for activity start deviations with respect to the baseline schedule. In order to obtain test instances for specific problems, the input data for deterministic instances can be "enriched" with the rest of the necessary data for more general instances. The library provides the option of instance enrichment using random data. Enriched problem instances can be saved in the extended form for later usage.

The described project scheduling problem classes are complex and have a big memory footprint. The most of the data is constant and immutable during the project execution. The only data that can change during the project execution is the realized activity duration vector, due to revealing actual activity durations, and in some applications the activity duration joint probability distribution, due to the conditioning on the available data. For that reason, in order to reduce the copying overhead of project scheduling problem definitions when creating new instances of simulators, one project description is shared among the all using objects. All evolvable/mutable structures are isolated into special classes. *EvolvableDuration* class holds and tracks the data on evolution of the activity duration vector. Objects of this class have small memory footprint relative to the project definition objects and the gains in speed are considerable when simulators use them, as is demonstrated in the measurements section.

B. PRNGs and probability distributions

As mentioned earlier, most of the existing work in the area of SRCPSP uses pre-generated random scenarios during the whole simulation and optimization process. In that case we can generate all the scenarios in the main thread and use the generated data in parallel simulations. However, when we have to generate random numbers during parallel simulations, as several works warn [16, 17], we have to be careful which PRNGs we use and how we initialize them. In parallel simulations, in order to avoid bottlenecks if we were using the singleton thread-safe random number generator, we need to generate random variates from several streams. The problem with the most of existing, conventional, PRNGs is their serial nature, as they operate in a sequential fashion through the states in the state space where the next state depends on the process history that contains visited states. There are several options to achieve that with conventional PRNGs in a way that each random stream would be as independent as possible: random seeding, parameterization, block splitting, and leapfrogging [18]. The former two are multi-stream, while the latter two are sub-stream approaches. Random seeding of PRNG seeds, although the easiest, is a procedure without any theoretical guarantees on independence of different streams and is feasible only for PRNGs with very long periods. Parameterization approach uses as many PRNGs of the same type as needed and all of them have carefully chosen parameters, but theoretical guarantees for this approach are not strong. Block splitting splits one stream of random numbers into consecutive blocks of a priori known and set length. Leapfrogging also uses one stream of random numbers which is split into sub-streams in the way that k-th sub-stream gets each k-th number from the main stream.

In the library, we have implemented support for the two types of parallel PRNGs (Fig. 2) using publicly available implementations: Mersenne twister with carefully constructed parameterizations of all streams as presented in [19] and yarn PRNG that uses leapfrogging as presented in [18]. In future we intend to implement several other parallel RNGs. L'Ecuyer et al. in [20] presented a solution to create multiple long streams and substreams using combined multiple recursive generator that can be used in parallel. Salmon et al. in [21] present a very different and promising approach to conventional PRNGs, introducing counter-based PRNGs which can be easily parallelized in both multi-stream and sub-stream modes. This library follows the design choices present in libraries GNU Scientific Library (GSL) and Boost where the pseudo-random number generator is decoupled from the transformation algorithms necessary for getting variates from variety of probability distributions. This enables the easy validation of results using different PRNGs.

In order to enable modeling of heterogeneous joint probability distributions, we have modeled probability distributions inside the class hierarchy with the top class Distribution as is visible in Fig. 3. The univariate probability distributions in the library are designed using adapter pattern around probability distributions in other libraries and expose functionalities both for pseudo-number generation transformations and statistical tests. This enables uniform behavior even if using different support libraries in the background. The library, at this moment, has implementations of the following univariate distributions: beta, general discrete, triangular, uniform continuous, and uniform discrete. Also, the library has several classes of independent joint distributions which are important for modeling activity durations. *JointIndepDistribution* is the class of independent joint distributions in which independent component distributions do not necessarily belong to the same distribution family. *JointIndepIdentDistribution* is, on the other hand, the template class of independent joint distribution with all independent component distributions belonging to the same distribution family. Among the

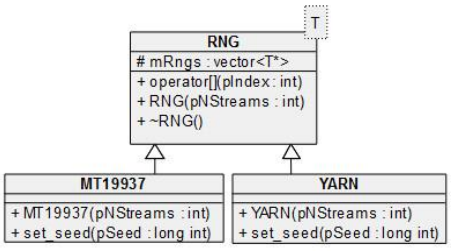

Figure 2. Supported PRNGs

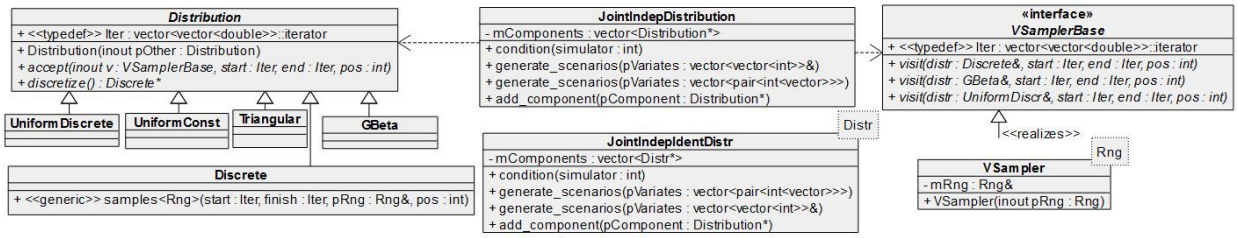

Figure 3. Probability distributions and related classes in the library

latter ones, the joint independent distributions of general discrete distributions as components is the most important for our purposes as, by the definition of SRCPSP, the activity duration distributions are discrete with the support in N_0.

All the existing probability distributions are discretizable so that they can be transformed to the general discrete distribution and used in homogeneous joint distribution for the simulation. Joint distributions can be conditioned on the simulator state. In the case of joint independent distributions, that means that each component for currently running activities can be conditioned on the time elapsed since the activity start, i.e. can get truncated. Truncation at the moment is supported only for general discrete probability distribution, as that was the priority for SRCPSP. For other distributions either rejection sampling or Markov chain Monte Carlo (MCMC) methods can be implemented in the future. In order to enable random sample generation from heterogeneous joint distributions using different PRNGs, a variant of Visitor pattern is used. A template member function *samples* is added to all classes in the hierarchy of basic probability distribution classes except the *Distribution*. Class *VSamplerBase* and class template *VSampler* are part of the pattern. *VSampler*, together with its purpose to implement double dispatch, also decides on which stream of the PRNG object to use in sample generation. The thread ID is used as an index of the stream.

C. Simulators

The specific feature of this simulation library is separation of the simulation engine into sub-components. The library contains basic simulators concerned only with the basic scheduling and schedule book-keeping – very specific and common project scheduling functionality dealing with resource and precedence constraints. These basic simulators can be used as sub-simulators in more complex simulators that have specific features needed for supporting complex project scheduling decision making problems. In the view of the project as a multistage decision making process [4], decisions are made in successive timepoints. This inevitably leads to the fact that complex simulators will use as sub-simulators various variants of parallel schedule generation scheme (SGS). Examples of such simulators are given in Fig. 4.

SerialSimulator and *TPSimulator* are the most basic simulators implemented in the library. The former is the simulator that supports serial SGS and inserts activities in the first feasible timepoint in the existing partial schedule. The latter is transactional parallel simulator and supports

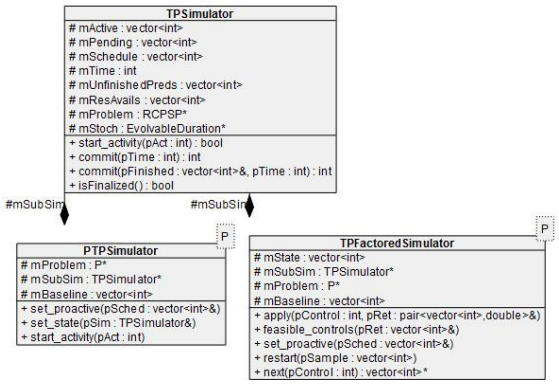

Figure 4. Parallel simulators

making decisions on starting activities in series of increasing timepoints. The decisions in each timepoint have to be committed in order to jump to the next decision timepoint. Both basic simulators have set-based representation of their states.

The complex simulator *TPFactoredSimulator* is the built on the top of *TPSimulator* and has a factored state representation, i.e. the state is represented by a tuple. That simulator also calculates costs for transitions between the states and it is suitable for value function approaches as this state representation is tailored for the value function approximation. *PTPSimulator* is the proactive extension of *TPSimulator* with the calculation of tardiness-earliness costs after each applied control.

Other simulators implemented in future can include more complex control space that is the superset of its sub-simulator's control space, inclusion of the baseline schedule in predictive/proactive-reactive approaches, use of different objective measures, etc.

D. Controllers

Controllers embody policies and in the given state they provide the next control for the decision making process, as well as apply the control to the simulator. The library, at the moment, contains three basic controllers: parallel schedule generation scheme (SGS) using activity priority list (in Fig. 5), serial SGS using activity priority lists, and parallel SGS using resource-based policies with release times. Each controller at each decision timepoint gets, as the input, the whole simulator that is the holder of the project state. It is up to the controller to choose if it will be non-anticipative, as it could also see some future data available in the simulator and that can be useful if modeling problems with objective functions in the form of regret. This unconstrained access to the simulator leaves to the policy to define which conditions and

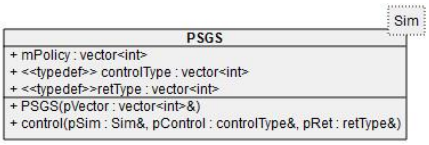

Figure 5. Parallel SGS controller

constraints it will satisfy. The parallel SGS variants are the basis of stochastic scheduling where policies satisfy non-anticipativity and non-retroactiveness, which is in accordance with scheduling decision making in real-world projects. Basic serial SGS does not satisfy non-retroactiveness nor non-anticipativity. The latter is mainly used in deterministic scheduling as it has been shown in [22] that in deterministic RCPSP, unlike serial SGS, greedy parallel SGS is sometimes unable to reach an optimal solution.

E. Experiments

Experiments embed simulations undertaken to estimate some measure of interest. This is the part that is highly parallelizable, and the rest of the library is realized as a support for the parallelization purposes here. Each experiment uses pre-generated set of scenarios as an input. This enables us to choose if and when to run the experiments with the same scenarios. By embedding experiments within each-other we can implement runtime random number generation. Although experiments can be written on case-by-case basis, we have modeled integrated approach to experiments. The experiments are modeled through a static template member method *experiment* in the utility class *Experiments*. The body of that template method has a basic skeleton which uses blocking parallelization. It runs the project evaluations using the controller leaving to the experiment policies to define the necessary data recording. Two experiment policies have been implemented: *ExperimentStartsPol* and *ExperimentAvgPol*. The former records start times of all activities, while the latter evaluates the average project duration under policy defined by the controller. The pseudocode of the experiment body is given below:

```
Experiment(simul,controller,ExpPolicy,scenarios,num_repeats,
num_threads)
    ExpPolicy.init(result)
    Parallel block
        Calculate the task block;
        ExpPolicy pol;
        For each task in block
            Create simulator sim with unused scenario;
            While sim not finished
               Control,cost=Controller.control(sim);
               pol.update1(sim,control,cost,result, taskID);
            pol.update2(sim, result, taskID);
        critical section
           pol.update3(result,task_block data);
    ExpPolicy.post_process(result);
    return
result;
```

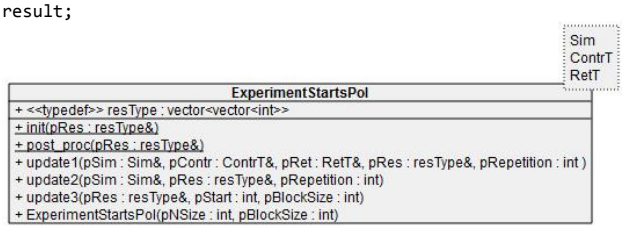

Figure 6. Experiment policy class example

F. Optimization algorithms

The input to the algorithm is a project definition and the output is a controller with good performance. The library, at the moment, contains *GADet* and *SBD*. *GADet* is class that implements the VanHoucke-Debels bi-population genetic algorithm for solving deterministic RCPSP as described in [15]. Many algorithms for solving SRCPSP need the deterministic schedule as an input [8, 23] and this algorithm finds high quality solutions to big problem instances. *SBD* was mentioned in the introduction. It searches for the good enough policy in the family of resource-based policies with release times in order to minimize expected stability and project earliness-tardiness costs in proactive-reactive scheduling problems.

G. Model Builder

For very small problems exact model can be built using *ModelBuilder* as a Markov Decision Process (MDP) represented by the class *MDPModel*. This component uses the explicit state-based simulator (for example *TPFactoredSimulator*), the data about activity duration joint probability distribution, Bayes' theorem, and the depth first search in order to build state indexes, the transition table, and the cost vector. The created MDP model can be solved exactly in order to compare the performance of simulation based approaches relative to the optimum. Possible solving methods are: generalized policy iteration, value iteration, and linear programming (LP) [24]. Former two methods work directly with the MDP model. For the linear programming, there is *LPModeler* class that takes MDP model as the input and creates the linear program that can be solved using some of available LP solvers. This component is implemented in the python prototype library and is planned to be implemented in C++ in the future work.

III. COMPUTATIONAL RESULTS

There are two relevant types of errors in simulation based optimization; model error, which depends on discrepancies between reality and the used model and data, and simulation error. The former is under control of project modeler, and this library supplies several general models with the possibility of extension. The latter can be reduced by increasing the number of experiment replications and parallelization helps in that regard. For the test setting we used all 600 PSPLIB instances with 120 activities enriched with the stochastic data in identical way as in [8]. The program code was written in C++ and all time-measurement results were obtained on a laptop equipped with Intel i7-2670QM quad-core processor. In order to examine the performance and the benefits of parallelization, we have made measurements on simulator that uses *EvolvableDuration* and shared project descriptions (labeled 'Evolvable' in Fig. 7), and the simulator variant that works directly with the project definitions (labeled 'Project' in Fig. 7). The trivial priority vector was constructed and the resulting parallel SGS policy was evaluated using *ExperimentStartsPol* with 1000 scenarios on each project. The graph in Fig. 7 shows experiment runtimes, without experiment setup, averaged over 600 projects with different experiment settings. It is evident that simulators that isolate mutable

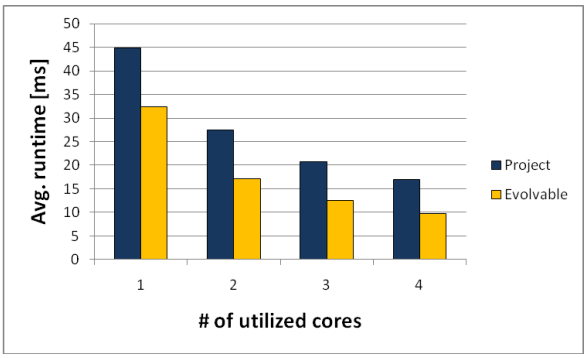

Figure 7. Average runtimes versus the number of utilized cores

structures have better performance. The speedup is close to linear with respect to the number of utilized cores.

IV. CONCLUSION

The general simulator library for SRCPSP has been presented. As the most of the work so far focused only on ad-hoc approaches to simulation, this brings an approach that makes possible and easy to work on future simulation based optimization algorithms without having to "reinvent the wheel". Parallelization is very important issue in simulation, where measures of interest are calculated through averaging many samples. The most common approach is to generate scenarios a priori, before the simulation and, due to favorable mathematical properties of variance reduction of comparisons, compare candidate solutions only with samples based on these scenarios. However, in some approaches samples have to be generated during the runtime, and if the scenario generation is done in parallel there are potential problems with correlated random number streams. We proposed inclusion of several different solutions into our library to circumvent the potential issues. We presented a modular organization of simulators where more complex simulators build on simpler ones, and that enables better reuse of common project scheduling functionalities.

Future work includes empirical data on performance of the library using newly developed as well as existing algorithms. Other models of parallelization in heterogeneous ways using Message Passing Interface (MPI), General purpose computing on graphical processing units (GPGPU), and combinations of approaches could be tried out and used. It would be interesting to see if it is opportune to use GPGPU for calculations of this type because relatively big data structures could hinder the opportunities for the speed-up. Research into the effects of using different PRNGs in parallel simulations might provide interesting insights and recommendations for the practical usage.

Abstract - Information system dependability reflects the user's degree of confidence in the system. Today's ICT allows connections between information systems in different applications and in different geographic locations. These information systems are called dependable because connections between them cause certain events in one information system to be reflected in the other. Therefore, it is important to have a method for the estimation of information system dependability that will be used in the information system development phase. This estimation will provide arguments for a possible modification of information systems before their final commissioning. The purpose of this paper is to provide an overview of the methods and software for the estimation of information system dependability. Five qualitative and two quantitative methods for estimation of information system dependability are presented. A list of ten estimation software it has been made and five of them are presented in detail.

I. INTRODUCTION

The protection and survival of complex information systems that provide services for the infrastructure of advanced society has become a national and world-wide concern of the highest priority. [30]

Real-time systems are used in the critical applications such as space flight, nuclear technology, aviation, etc. Failure of such systems can lead to major damage, loss of life and environmental impact. The common denominator of these types of failure in organizations is the loss of value in the capital market. Research in [3] states that a failure of information systems can cause a 2% decrease share values for a period of two days.

On the basis of functions and scope of the failure of the system in real time, there are three types of systems:

The first is *Safety-critical* systems required to ensure the safety of EUC (equipment under control), people and environment. Examples of such systems are: shutdown of the nuclear reactor, digital aircraft flight control, etc. [1]

A second type is *Mission-critical* systems whose failure results in failure of the mission. For example, control and coding unit (CCU) of an avionic navigation system or spacecraft, etc. [1]

The third type is *Economically-critical* systems whose failure results in the unavailability of EUC (equipment under control) or a failure such as a server or communications equipment in a business environment (system control reactor nuclear power plant, unavailability of servers in the banking sector due to a fault on the router etc.). [1]

The purpose of this paper is to present methods and software for estimation of information system dependability and to present short review of several important concepts relevant to the understanding of term dependability. Such concepts to be reviewed are the concept of dependability and terminological structure that is published by Jean-Claude Laprie in his work "Dependability: Basic Concepts and Terminology". [15] Other concepts are methods for estimation dependability with emphasis on Markov chains, methods for estimation reliability, availability, maintainability and safety, and software to support these estimation methods.

II. INFORMATION SYSTEM DEPENDABILITY

Dependability of an information system is the ability to deliver service that can justifiably be trusted. [5] There is also an alternative definition by which dependability is defined as the ability of the system to avoid frequent and severe inaccessibility of services than what is acceptable.

Dependability studies two or more systems which interact in a dependent relationship, or how an event in one system affects the operation of other systems and the overall system. Evolution of the concept of dependability through four decades is resulted on terminology that is presented by Jean-Claude Laprie.[15]

The three basic elements of observation are: attributes, threats and methods for achieving dependability.

A. Attributes

Information system dependability is a complex information system characteristic which consists of the following attributes:

- *Availability* is the system's ability to deliver the correct service. [5], [4], [2], [14]
- *Reliability* is the system's ability to continually deliver the correct service. [5], [4], [2], [14]

- *Safety* is the system's ability to operate without catastrophic consequences on the user and environment. [5], [12], [7], [2], [14]
- *Confidentiality* is the system's ability to not permit unauthorized disclosure of information. [5], [4], [2], [14]
- *Integrity* is the system's ability to prevent improper modification of the system. [5], [4], [14]
- *Maintainability* is the system's ability to be easily repaired and maintained. [5], [4], [2], [14]
- *Security* is the system's ability to protect itself from accidental or deliberate attack (is formed by combining the attributes of availability, confidentiality and integrity). [19], [2], [14]

B. Threats

Threats of the information system dependability are:

- *Fault* is improper deviation of at least one characteristics of the system. [21], [14]
- *Error* is the state of the system that can cause *failure*. Errors can be latent or detected [5], [4], [14]
- *Failure* is the permanent cessation of the system's ability to perform a required function. [21], [14]

C. Methods for achieving dependability

There are four basic methods for achieving dependability:

- *Fault prevention* is to prevent the occurrence of a fault, and achieves the quality control during the design and production of hardware and software. [5], [4], [14]
- *Fault tolerance* refers to information systems that deliver the right service due to the existence of an active fault and have well-developed immunity to malfunction. This technique is commonly used for error detection and subsequent system recovery. [5], [4], [2], [14]
- *Fault forecasting* is performed by estimating the behaviour of the system with respect to the occurrence of a failure. It is estimated the current situation, future failures and the consequences of failure [5], [4], [14]
- *Fault removal* is applied in the development and working phase of information systems. The development phase includes testing, diagnosis and repair, while the working phase includes corrective and preventive maintenance. [5], [4], [14]

III. METHODS FOR ESTIMATION OF INFORMATION SYSTEM DEPENDABILITY

These methods perform estimations of the current state of the probabilities of failure and estimations of the probability of the consequences of failure. Using these methods it is possible to estimate the degree of confidence on the ability of the system to meet specific goals. These methods are used to [19]:

- compare possible solutions
- estimate level of system resistance in the work
- estimate system confidence, required resources and costs

Estimations of system dependability can be observed through two approaches:

- *Qualitative* or *ordinal approach*, wherein the identification and classification of the system failure or combination of events which cause system failure is performed [4]
- *Quantitative* or *probabilistic approach* involves estimation of the probability to what extent measured attributes meet requirements. An important component of this approach is the measurement of attribute. [4]

A. Qualitative (ordinal) estimation methods

The following methods are shown: FMECA method, Reliability block diagram (RBD), Fault tree, Attacks tree.

a) FMECA method

FMECA or Failure Modes, Effects, and Criticality Analysis is method that was intended to be used for modelling hardware, but subsequently began to be applied on software (SEEA: Software Error Effect Analysis). Originally FMECA was developed in the '40s for the U.S. military under the standard name MIL-P-1629th. [26]

In the early 60's this method was adopted by NASA to develop space programs such as Viking, Voyager, Magellan and Galileo. [20]

Soon after, the method was extended to civil aviation and auto industries.

The method is used to identify each component or function, discovering ways in which failure occurs and what are the consequences caused by the system. It is possible to make estimations of any possible case of failure and based on the weight of the consequences caused by failure to recognize and execute a prioritization. FMECA process recognizes the critical failure modes and thus enhances the formal recognition of risk for the project and provides an incentive to change the design of the system. [19]

b) Reliability block diagram (RBD)

Reliability Block Diagram executes analysis of reliability and availability of large and complex systems using block diagrams to show network connection. The method was developed by the U.S. military under the standard name MIL STD-756B.

Graphical method consists of two types of components: blocks (representing system components) and dummy nodes (for connections between the components). Graphic topology describes how the reliability of individual components affects the reliability of the system. Dependability of blocks and nodes models is dependent on the condition of its components. The system is considered operational if the ultimate dummy nodes are connected at any point of time. If it does not, the system is considered to be faulty. Serial systems are considered not redundant while parallel systems are considered redundant systems. [9]

c) Fault tree

This method was developed by H.A. Watson from Bell Laboratories in cooperation with the U.S. Air Force, and

later, this method was extended to the field of civil aviation. [8] A model presents a graphical representation of a combination of events that cause the occurrence of the event. Tree can be used for modelling of hardware and software failures, human errors, errors in system maintenance and environmental impact on the system. The model identifies the relationships between undesired events in the system and failure of subsystems that contributes to failure of the entire system. A model for estimation of the reliability is developed by "top-down" principle, and the method can be applied at each stage of system design. The method provides qualitative and quantitative estimations of the reliability of the system. Fault tree represents an acyclic graph with internal nodes (having logic gates such as AND or OR), external nodes (leaves or basic events, which are the components of the system) and edges that represent the flow of information failure in terms of Boolean entities (TRUE or FALSE, 0 or 1). The links that are connected to the edges define the operational dependence on the system components. At any point of time, the logic value of the root node determines whether the system will be operational. [9]

d) Attacks tree

Attacks tree is based on modelling with the help of graphical and mathematical methods. This method was in its original form developed for intelligence agency and for the first time the idea of logic trees threats appeared in the literature in the late 80s. Later, B. Schneier published the concept of attack tree [6].

The method of attack tree is closely related to the concept of the idea of fault tree method because it describes a set of events that can lead to system failure. This tree can be used for modelling of all possible attacks on the system, which provide a formal, methodical way to describe the security system that is based on the different types of attacks. Attacks on the system are displayed in a tree structure, where the roots are nodes of attack targets, and methods of attacking are the leaf nodes. Safety of large systems can be modelled with a set of attack trees, where the root of each tree is an attack that can significantly damage the system. In the outline view, a tree is shown with two types of nodes (logical AND or OR). Attacks tree provides a systematic description of security vulnerabilities, thus making it possible to assess the risks and make safety decisions. [9] [25]

B. Quantitative (probabilistic) estimation methods

The big disadvantage of the above-described qualitative estimation methods is assumption of stochastic independence between components in a system which has resulted in the inability of its applications in complex systems. [17]

For this purpose the quantitative (probabilistic) estimations methods are used. These methods are based on the state space e.g. Continuous Time Markov chain, Markov reward models, Petri nets, etc.

Markov chain is a discrete stochastic process that is commonly referred to as the state transition diagram. Markov "law" says that the next step depends only on the current situation, which can be represented by the following equation (1):

$$P(X_{n+1}|X_1, X_2, ..., X_n) = P(X_{n+1}|X_n) \quad (1)$$

Markov chains know the following space states: initial, transitional and final.

Continuous time Markov Chain (CTMC) is a mathematical model that allows the state change in any moment in time. Transition matrix (describe transitions between the state) expresses transition rates instead of probabilities. Description of the condition of continuous time Markov chain can be explicitly used to monitor the status of components and subsystems for observed system. Each state represents particular error state, while transition represents component failure rate. States show the number of failures of components over time. CTMC is time homogeneous process in the way that events such as failures and repairs are independent of each other. [10]

Discrete time Markov chain (DTMC) is a mathematical model that executes a change of state of the system after a specified time. The transition to the next state depends on the transition probabilities in the transition matrix. Each row of transition matrix represents an output from the state, and each column represents the input to the state. This model is used to predict the probabilities of hardware failure. [10]

Petri Nets is a graphical form of the formal logical description of the interaction between the components or the flow of activities in a complex system. The original Petri Nets have no time dimension. For the study of dependability is necessary to introduce the duration of events associated with transient conditions. Petri Nets can be extended with the transition duration which results in depicting temporal dimension. A special case of time Petri Nets are Stochastic Petri Nets (SPN) where the trigger time is considered random variables. SPN can be automatically converted to the basic Markov model. SPN in graphic terms consists of two types of nodes - places and transitions. Places typically represent conditions in the system while transitions represent events that cause changes in system conditions. Tokens are points associated with the place and represent the status of the place. Arcs connect places and transitions. The places from which an arc runs to a transition are called the input places of the transition. The places to which arcs run from a transition are called the output places of the transition. [16]

a) Markov chains in estimation of information system dependability

Markov chains are used to estimate the availability and reliability of complex hardware systems. This probabilistic method is applied also for modelling software reliability. Approach is suitable for predicting the reliability already at the design phase of the information system, even before a "black boxes" models and real components or software subsystems become available.

Markov models can serve as a basis for Markov Reward Models (MRM), which is used to estimate the reliability of the system. It allows "rewarding" the system for time spent in states that represents readiness of the system. [13]

b) Stochastic Petri Nets in estimation of information system dependability

Stochastic Petri Nets (SPM) provides a valuable tool for describing and analyzing the system. Since the beginning of its application, this method is used to solve problems in the estimations of reliability, availability, performance and analysis of software and hardware systems. [17]

In [28] is described Stochastic Activity Networks (SAN) that is based on Stochastic Petri Nets. This method is used to estimate reliability and availability. The main concept is activities (transition in Petri nets) that have impact to the system's ability to perform. Estimation is based on the analysis of which activities are enabled in a certain state of the system, and what is the next state of the system upon completion of activities.

IV. SOFTWARE FOR ESTIMATION OF INFORMATION SYSTEM DEPENDABILITY

There are several software packages for modelling dependability. Some of them are: SURF-2, GREAT-SPN, Ultra SAN, Möbius, Sharp, DrawNet ++, SPNP, Deem, TimeNeto, DSPNexpress, adviser, ARIES, CARE III, METFAC, SAVE, SURE, ASSIST, HARP, etc. Table 1 shows some software for modelling and estimation of dependability.

A. SURF-2

Surf 2 is a tool for estimation of hardware and software systems dependability. It is based on a strict construction, validation and numerical solving of Markov models. The software was developed in the laboratory LAAS, France 1996. The system behaviour is modelled with Markov chains and Stochastic Petri Nets. The main idea of the software is to have a simple method that compares the reliability of various system architectures. [24]

B. Great-SPN

GreatSPN is a tool that supports the design and the qualitative and quantitative analysis of Stochastic Petri Nets and Stochastic Well-Formed Networks (SWN). GreatSPN appeared in the late 80s of the last century. Since then, several different versions of this tool have been developed.

GreatSPN2.0 package consists of different software that collaborates in the construction and analysis of PN models. Using the capabilities of communication networks, it is possible to perform various analyzes on different machines in a distributed computing environment. GreatSPN2.0 modular structure enables the addition of new modules for the analysis, as well as new research results. All modules are written in the C programming language, which ensures portability and efficiency on various UNIX machines. [11], [22]

TABLE I. SOME SOFTWARE FOR ESTIMATION OF INFORMATION SYSTEM DEPENDABILITY [19]

Software name	Used methods	Designer
SURF-2	GSPN, Markov chain	LAAS, France
Great-SPN	GSPN, SWN	Torino, Italy
UltraSAN	SAN	UIUC, USA
Möbius	SAN, Markov chain …	UIUC, USA

C. UltraSAN

UltraSAN is a software tool used for evaluation of the system based on the Stochastic Active Networks (SAN). SAN has the characteristics of Stochastic Petri Nets and queuing models. Using a variety of analytical and simulation modules, it is possible to determine following: efficiency, maintainability and feasibility. UltaSAN enables the graphical presentation of the results. To determine the valid model, it is necessary to specify a set of subnets using SAN editor and classify them according to the hierarchy. UltraSAN offers six analytical techniques for solving transient and steady state. [29]

Three techniques that allow solving the steady state are: direct steady-state, iterative steady state, and iterative deterministic steady state. To resolve transients state, transient instant of time method, PDF interval-of-time and expected interval-of-time techniques is used. [27]

D. Möbius

Möbius (Model-Based Environment for Validation of System Reliability, Availability, Performance and Security) is a software tool for modelling behaviour of complex systems. The tool was designed at the University of Illinois, USA, and was originally designed to study the reliability, availability and efficiency of computer and network systems. Its flexible approach allows engineers and scientists to present their systems in a language model appropriate to their problem area, and then accurately and efficiently solve systems using solving techniques that best suit the size and complexity of the problem. The tool supports Stochastic Petri Nets, Markov chains and Stochastic Process algebra. Models are presented numerically and graphically, and are made with the right level of detail, and have the possibility to adapt to the behaviour of the system of interest. This tool can build detailed mathematical expressions that measure the correct information about the system (e.g., reliability, availability, performance and security). Measurement can be carried out at certain points of time (some time period or time when the system reaches a steady state). [18]

E. SHARPE

SHARPE (Symbolic Hierarchical Automated Reliability and Performance Evaluator) is a tool that provides a specification and solution methods for the most commonly used type of estimation model for performance, reliability and feasibility. Models that are present in the SHARPE are Fault Tree, Model Queuing and State Model (Markov chains, semi Markov chain with reward and Stochastic Petri Nets). For each model SHARPE has preferred analytical algorithms. This tool allows measurement of models that can be used as a parameter to another model. Therefore it is considered to be a hierarchy oriented tool. The user interface supports command-line and graphical user interface that is made in Java. SHARPE is developed at Duke University, USA. [23]

V. CONCLUSION

The term dependability is relatively new and is based on the real needs of reliable and available information system that is easily maintained, has protected confidential information, is secure from external and internal threats and is safe for environment.

First estimation methods for information system dependability are developed for the needs of mission and safety critical systems in the space programs of NASA, ESA and in the military industry. These methods are now customized for use in economically-critical systems.

The fact that the failure of information system in economically-critical systems may result in significant costs, has led to a need to estimate dependability before information system is implemented. For this purpose, there is a space for development of a new methods and appropriate software for estimation of information system dependability in economically-critical systems.

***Abstract*—Internet of things (IoT) will connect a huge amount of devices to the Internet. There will also be many applications that will use the generated data to provide a service to end-user. This presents a problem in situations when the application owner is not the device owner. Application owner needs to find and contact the owners of the devices that provide the data he needs. When done by a human, this process lasts a long time and costs a lot of money. In this paper, we propose a middleware architecture that connects the appropriate devices and applications. It is based on software agents representing devices and applications negotiating between each other on the terms by which the data can be used.**

I. Introduction

Internet of things market can be divided in two basic areas. The device owners and the application owners. Although this distinction is still in its nascent stages, it will grow only more important in future. The device owners are people who go to the store and buy an Internet connected thermometer, pollution sensor, heart rate tracker or any other kind of Internet connected device. Application owners are the people who want to use data from these devices to create new applications. For example, a pharmaceutical company could want to build an application that tracks the average heart rate of the people in a city and publish it in real time on the web. This could be a part of their marketing efforts, they could advertise it as "The heart rate of Los Angeles".

There are a couple of reasons for creating an Internet of things cloud platform. One of them is to overcome the problem of each device speaking it's own language. That way, the cloud can speak all languages, and allow applications to access all of the devices using a unique interface.

Also, the cloud platform can aggregate the data, store it for later retrieval, perform complex operations on that data and enable device and data discovery. These problems are already being solved by the emerging internet of things cloud solutions and numerous startup companies, examples of which are given in section II.

However, there is another service the cloud platform could provide, and that is the mediation between application and device owners. In this context, mediation is used for finding the conditions of data provision that both device and application owners find acceptable. For example, a person could create an IoT application similar to the city heart rate monitor described above. But, for that to work, the application needs a lot of devices to provide it data. Deploying new devices for this specific purpose is not financially viable, and personally contacting many device owners to find the ones interested in exposing the data and then negotiating with them on the price, schedule and other conditions is tiresome and unscalable. Creating a mediation framework that connects the compatible devices and applications and performs the negotiation automatically would ease this process significantly, and could create many new economically viable use cases for the IoT. This paper presents one approach for implementing this kind of service.

The remainder of this paper is organized as follows. Section II examines the previous research done on this and similar subjects. A platform that is used to connect IoT applications with devices is presented in section III.

More details on the actual negotiation process between applications and devices are given in section IV. Section V proposes directions for future work, and concluding remarks are given in section VI.

II. Previous Research

This paper deals with a number of topics from various research areas - including IoT middleware platforms, software agents, agent negotiation protocols, semantics of IoT devices, etc. This section will give a brief overview of existing IoT platforms while the specifics of agent negotiation will be presented in a separate section.

There are a lot of startup companies creating IoT platforms enabling the cloud management of IoT data. Some of these platforms are: Axeda[1], Carriots[2], Evrythng[3], GroveStreams[4], Device Cloud by Etherios[5], Nimbits[6], One Platform by Exosite[7], Xively (Pachube)[8], SensorCloud[9], etc.

These platforms usually enable remote control, management and monitoring of IoT devices. They allow device owners to connect their devices to cloud and then do various operations with incoming data. Usually, they can make the data public so IoT application owners can use that data in their applications. However, they don't allow automatic negotiation on various aspects of the data the device provides to applications.

In [1] authors propose an agent based negotiation strategy for service provision in IoT domain. However, the purpose and

[8] https://xively.com/
[9] http://www.sensorcloud.com/

domain area are a bit different than in our case. The authors are mostly concerned with provisioning optimized services to mobile devices users. Agents and negotiation are used to overcome the possible semantic communication differences between various devices. Also, there are two other differences. The service provider and service consumer agent in [1] share a common goal, while in our problem, goals are often conflicting. The other difference is that in [1] the negotiation is of a bilateral type, where service consumer negotiates directly with the service provider in order to achieve the optimal service. In the case of IoT mediator, the application agent is negotiating with many device agents at the same time, and the outcome of each one of those negotiations can impact the other.

Global Sensor Network (GSN) [2] is a platform which provides a scalable infrastructure for integrating heterogeneous sensor network technologies using a small set of powerful abstractions. It supports the integration and discovery of sensor networks and sensor data, provides distributed querying, filtering, and combination of sensor data, and supports the dynamic adaption of the system configuration during operation through a declarative XML-based language. The sensor services are published through a peer-to-peer directory and searched based on their properties. Applications can discover sensor networks using the registry and subsequently access sensor networks by using a standard data access interface. However, in GSN it is assumed that sensor networks that produce data share it freely with all interested members of the network. This is different than IoT mediator, where the applications need to negotiate with sensor services on the conditions under which the sensors will provide data.

Hourglass [3] is an Internet-based infrastructure for connecting a wide range of sensors, services, and applications in a robust fashion. The infrastructure consists of an overlay network of well-connected dedicated machines that provide service registration, discovery, and routing of data streams from sensors to client applications. In addition, Hourglass supports a set of in-network services such as filtering, aggregation, compression, and buffering stream data between source and destination. When a service (sensor) announces itself to the Hourglass system, it affiliates with one or more topics and further describes itself using a set of predicates. These predicates are used to match services against application queries. More than one service may match the set of predicates and topics. In this case, it is up to the Hourglass system to decide which service to use. It makes this decision based on a pre-scripted behavior (e.g. trying to accomplish load balancing, pick a geographically close server, etc.), and unlike IoT mediator, there is no negotiation going on between the applications and devices (services) on which device is willing to offer the best usage terms.

III. IoT Mediator Platform

A prototype platform was created to solve the problem presented in the introductory section. Applications and devices can communicate with the platform through an HTTP interface. The basic use case is when the application asks for the appropriate devices, the platform returns a list of contracts with the specific devices from which the application can get the data it needs.

Platform architecture is presented in figure 1. The platform exposes an HTTP interface that applications and devices can use for registration, device discovery, contract making and data retrieval.

When a device is registered, all of the important details such as the type of data it provides, or the negotiation strategy used by the device agents are specified in an xml file. An example of this xml is given in figure 2. Negotiation strategy selection is particularly important. Owners can select from a list of template strategies, and change their configuration to best suit their needs. In the example in figure 2, a minprice strategy is used. This means that the device agent will provide the data only if the price is higher than the specified limit.

Once a device is registered, the platform saves the details in the database for later use. When an application requests the discovery of devices that match it's criteria, a negotiation module is utilized. This module consists of two submodules: Preselection and JADE Container. Preselection module first selects all of the devices that could potentially provide the data that the application needs. The purpose of this step is to speed up the actual negotiation process. Preselection is done to eliminate all of the devices that are outside the desired location, measure different properties than requested, or can be excluded from the negotiation process for any other reason. After the preselection step, there is a small number of potential devices remaining, and it is now only needed to select the ones that can give the best terms to the requesting application. This is done using autonomous agents. A JADE container is created and populated with a single agent for every device and application. This agents then negotiate to determine which devices will provide the data and at what conditions.

Typically, a separate container is created for each negotiation. Thus, there will usually be only one application agent and multiple device agents per container. Agents use negotiation algorithms and other constraints that were specified at the time that applications/devices were registered. Application agents have goals such as "find as much consistent data as possible given a limited budget" or "find all of the needed data using an unlimited budget". Device agents have goals such as "conserve as much device battery as possible", "achieve the highest possible price for the data", etc.

Applications search for the devices that are able to provide the appropriate Schedule, Location and Data descriptions.

Schedule is a single point in time, or a recurring event. The application agent can leave a schedule field blank, specify a time range, a list of possible schedules, or require an exact schedule.

Location is a geographical area containing all acceptable places for deployed devices. This can be irrelevant for some applications, in which case the agent would simply leave this field blank.

Data description is a description of data that the device should provide. This is usually not open to negotiation since most devices have a predefined type of data they provide. Although this field is named "data description", it contains everything related to sensors, their parameters and the properties they measure.

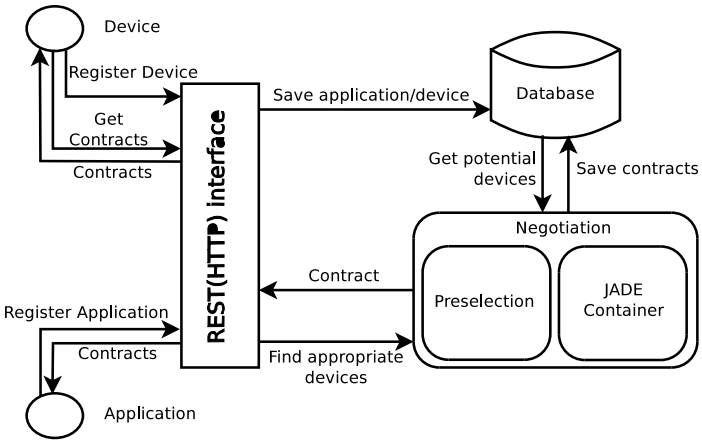

Fig. 1. Architecture overview

```
<device>
    <name>kitchen_thermometer</name>
    <type>HUMIDITY</type>
    <location>
        <latitude>45.8167</latitude>
        <longitude>15.9833</longitude>
        <elevation>1.2</elevation>
    </location>
    <algorithm type="minPrice">
        <minPrice>22.85</minPrice>
    </algorithm>
</device>
```

Fig. 2. Device registration xml example

Agents negotiate on several properties: data pricing, reading schedule, and in some cases, the reading locations (for devices that are mobile). Once the negotiation is finished, if both application and device agent are satisfied, the platform creates a contract between each device and application. The contract defines at what times will the device provide data, what is the price, and all the other relevant parameters. A copy of the contract is sent to both the device and the application. Once the contract is made, the device is obliged to provide the agreed data to the application respecting the contract terms. Application (i.e. application owner) is obliged to pay the agreed compensation for the provided data.

An example of a contract is given in figure 3.

Once contract is made, devices (i.e. device owners) are obliged to send the data to the platform at the times that were specified in the contract. Applications can use the HTTP interface to retrieve the generated data. Although it would be possible for devices to send data directly to applications, platform proxy is necessary so that the mediator platform would be able to determine if some applications or devices are not holding to their end of the contract.

IV. Agent Negotiation

Autonomous agents are a well researched area and are well suited for the problem of negotiation [4]–[6]. An architecture overview, describing how autonomous agents are used to reach

```
<contract>
   <application-id>126</application-id>
   <device-id>1121</device-id>
   <location type="exact-location">
      <coordinates>
         <lat>45.8167</lat>
         <lon>15.9833</lon>
      </coordinates>
   </location>
   <schedule>
      <repeating>
         <start>1376863200000</start>
         <period>3600000</period>
         <repeat-count>20</repeat-count>
      </repeating>
   </schedule>
   <data-type>temperature</data-type>
   <price type="per-measurement">
      <amount>0.5</amount>
      <currency>USD</currency>
   </price>
</contract>
```

Fig. 3. Contract example

agreements between applications and devices in IoT mediator platform, is given in figure 4.

By considering the complexity of negotiation environments, agent negotiation can be classified into three levels, which are the Bilateral Negotiation Level, the Multilateral Negotiation Level, and the Multiple Related Negotiation Level [7]. Application-device negotiation is an instance of Multiple Related Negotiation Level so it will be described further. This level represents a situation in which an agent needs to perform several negotiations in order to reach a global goal, and relationships between these negotiations are somehow related [7].

In device-application negotiation, the agents need to perform more than one negotiation with different opponents for different goals at the same time. These goals are often not independent, and these multiple negotiations are somehow related. For instance, a device agent could be involved in negotiations with multiple application agents, but the actual device might not have enough battery power to satisfy all of the applications. Or, a device might be interested in serving all of the requests at the same point in time, because in that case it needs to activate less often and thus can conserve battery power.

Most existing approaches to agent negotiation [8]–[10] separate the related negotiations and treat each of them individually. IoT mediator platform also uses this technique to simplify the overall negotiation process. The exact algorithm is described in the rest of this section, and a diagram can be found in figure 5.

The application has a list of measurement requirements. Each of these represents a separate requirement, for example, in an application that correlates current weather data to citizens heart rates, one measurement requirement is to get the weather data, and the other is to get the current average citizens heart

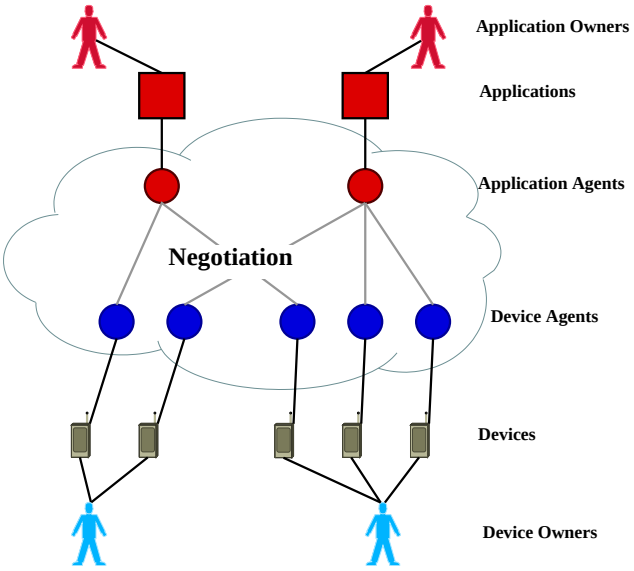

Fig. 4. Negotiation agents in M2M communication

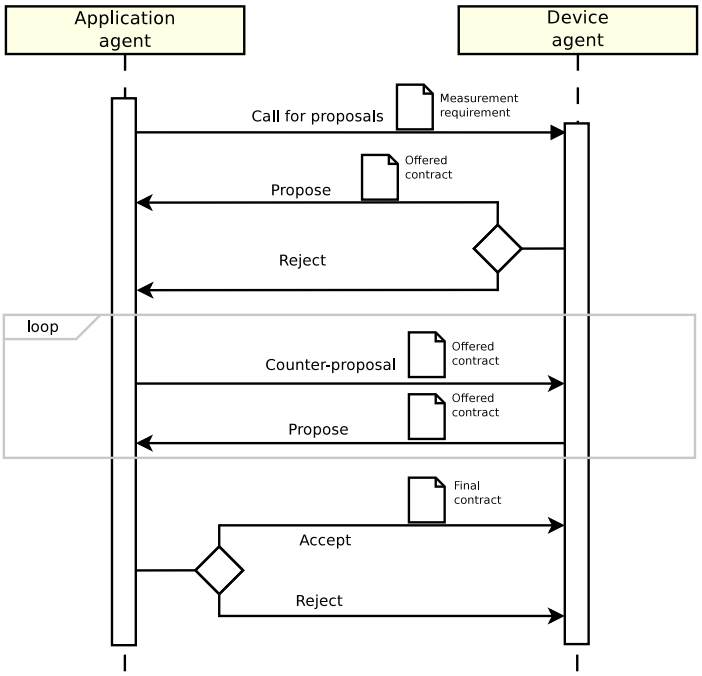

Fig. 5. Negotiation protocol

rate.

Negotiation for each of these measurement requirements is conducted separately, and if successful, temporary agreements are made. Once all of the measurement requirements are satisfied, temporary agreements are turned into obligatory contracts.

First, the application agent sends a call for proposal to all agents providing the appropriate data. This message contains the range of values that the application agent finds acceptable. For example, it contains the geographical area, a list of possible timestamps when the device should provide the data, acceptable price ranges, etc.

The devices respond with offered contracts. Each response contains the exact timings, locations, and prices at which the device is prepared to provide the data. At this point, the application can accept the proposal, reject it, or make a counter-proposal. This process can repeat until the device and application agents agree, or find out that the deal isn't possible.

Once the application has made all of the temporary agreements it needs to satisfy all of it's measurement requirements, the temporary agreements are turned into obligatory contracts. If the device has made temporary agreements for some measurement requirements, but isn't able to fulfill other requirements, it can cancel the temporary agreements. This situation could happen, for example, in an application that correlates average heart rate of citizens with current weather data. If this application creates temporary agreements for weather data, but is unable to find the appropriate providers of heart rate data, it can cancel the agreement on weather data because this data alone holds no value to the application.

The actual agent negotiation module was implemented as a multi-agent system using JADE (*Java Agent Development Framework*) agent platform [11]. Agents communicate by exchanging ACL (*Agent Communication Language*) messages [12].

V. Future Research

The data description is currently given as a simple enumeration of all allowed data types. So, a device owner selects if his device measures temperature, humidity, heart rate, etc. This could be refined so that data could be described using a standardized ontology, most convenient of which is the one created by the W3C Semantic Sensor Network Group [13].

Recognizing devices and applications that are not holding to their contract obligations would be very important in a real-world scenario. There are some existing approaches based on Web Service Level Agreements (WSLA) [14], but a more lightweight approach based on rating the credibility of the device/application owners might be more suitable. A similar mechanism is successfully implemented in online marketplaces such as ebay. Thus, application agents will favor devices with high credibility and vice versa.

Currently, application and device owners define all of the details about their devices/applications in an xml file. This xml is then sent to the platform when the device/application is registered. This is not suitable for technically inexperienced users. Thus, it would be useful to create a web based application that would give the users an intuitive graphical interface for registering devices and applications.

Platform distribution across multiple servers is also an interesting problem, and would become even more significant if the number of connected devices increases. How would the described mechanism of agent negotiation function on a distributed platform is an open question.

Currently, the mediator platform focuses mostly on sensors, but in the future it could be used just as well to accommodate actuators. Addition of actuator support would open up a whole range of new possibilities. One example of an interesting

actuator device is the electronic billboard that could connect and negotiate with different companies about showing their ads. They could negotiate on the times when the ad will be shown, pricing, etc. Interesting use cases could emerge, for example, companies will be willing to pay more if there are a lot of people standing in front of the ad, ice-cream companies would be prepared to pay more to show their ad on a hot day, etc.

VI. Conclusion

Creating a framework for automatically connecting applications with appropriate devices creates new use cases for the IoT. It provides a financial incentive for the end users to buy and connect more devices with the final goal of making a profit by the data these devices provide. It also creates possibilities for the application owners to get the necessary data without the need to purchase new devices, but instead to reuse the already available data. This could hopefully help create a feedback loop where more devices make the applications more interesting which in turn gives the financial reason for the device owners to buy even more devices.

The prototype implementation described in this article provides one way of implementing this service. It uses autonomous agents to implement the actual negotiation between devices and applications, which allows us to use a wealth of research done on agent negotiation. It also uses standard protocols and simple data descriptions to make the usage of platform as easy as possible.

Abstract - Availability and increased hardware performance of handheld devices with high resolution screens encourage users to exploit them as the second screen while watching television. Second screen is a term that refers to an additional screen of a handheld device such as a tablet or a smart phone, with an operating system capable of running desired installed applications. Desire to make additional DTV information available to the user which can be presented on the second screen tends to push the limit of digital television in that direction. This paper presents a framework to distribute and present both premium and free-to-air television content. The framework is based on server/client architecture and includes: TV remote control, streaming of television services, additional content (Electronic Program Guide, reminders...), data protection of streamed services to client devices. The system architecture consists of a media server and its clients. Media server is a Set-Top box with Android OS. Main duty of media server is to receive and process DTV content received from broadcasters and distribute the content to clients (second screen devices). Client application is developed on various OS/Platforms: Android and iOS. Multimedia content can be streamed using supported protocols: HTTP, RTP/RTSP, and adaptive streaming protocols (HLS and MPEG-DASH). Streamed content is protected using DTCP-IP. The main objective of the paper is to describe the utilization of before mentioned standards in a framework to use the DTV data and functions beyond the scope of the main TV screen. The client application also implements the remote controller GUI in order to use one device to control the TV.

I. INTRODUCTION

During people's leisure time, television (TV) is primary media source. With the expansion of new technologies (social services, handheld devices) and their integration with the TV, watching TV is drastically changed. Connection through the internet and using social networks allows people to be more connected than ever. Participation and involvement with media is possible through various platforms [1]. TV is easier to access over different devices, and usage of additional devices during the TV watching has become an usual habit [2]. Even media consumption which is relevant to the watched TV service has changed [3]. New technologies allow for personalized and more flexible media consumption [4]. Forms of media and associated devices are widespread in domestic settings. They alter the types of entertainment and information-centric activities that people engage within the domestic media environment, with multiple media appliances in their homes (laptops, smartphones, tablets) [5]. These media devices can be used as a second screen in the second screen TV environment.

Second screen allows television audience to interact with the content they are consuming such as TV shows, music or video games. While watching the TV, data which would have not been shown otherwise (teletext, electronic program guide (EPG), etc.) can be shown on the second screen. Without any interference with other users which are viewing the TV on the main screen, applications for second screen can integrate interactive television (iTV) services and TV-centric applications [6] on the second screen. In the research presented in [7] it has been concluded that TV watchers frequently use their laptop to surf the web, check their e-mail or shop online while watching the TV. In that same research it has been said that there is a priority to have access to different services on multiple screens, rather than putting all the information on one shared screen.

Remote controllers which are more flexible and have more capabilities will help viewers to become more active in the iTV environment, changing the traditional way of watching the TV, as it is highlighted in the studies [6,7,8]. In [8] it has been shown that remote controllers are often considered less useful. Furthermore, results indicate that flexibility of portable devices can be used as remote controllers and to offer more advanced features. From [6] it has been concluded that more sophisticated form of control is needed to be presented for iTV to gain its full potential.

The idea for using a second screen in the television environment is not new. One of the first systems where handheld devices were used for interacting with the television is presented in [9]. Research study [10] shows that staggering 77% of TV viewers is using an additional screen while watching TV. Such results undoubtedly imply that future development of DTV will promote second screen environment even further. In order to improve second screens' functionality majority of features are transferred from set-top-box (STB) to second screen device [11]. A widely accepted way of connecting different devices in home network is through the use of Digital Living Network Alliance (DLNA) protocol.

The most important feature of second screen concept is the security of the audio and video content. Since the signal is Digital Video Broadcasting (DVB) signal,

regulated by DVB standards, therefore security is provided by Conditional Access Module (CAM) which uses Conditional Access techniques presented in [12,13,14]. As DVB signal can be broadcasted through various mediums, different DVB standards are applied. We can distinguish two different phases in content protection: acquisition and post-acquisition as it was stated in [15]. While the content security during the acquisition phase is regulated by DVB standards through CAM, it is up to developer to provide content protection in post-acquisition phase in order to stream premium content to second screen [16].

This paper presents a framework to distribute and present both premium and free-to-air television content. The framework is based on server/client architecture and includes: TV remote control, streaming of television services, additional content (Electronic Program Guide, reminders...), data protection of streamed services to client devices, and various second screen concepts.

II. System Architecture

A second screen environment implies that there are more than one visualization devices that are served with content by a primary (source) device. Therefore, server-client architecture is necessary. It is presented in fig. 1.

Figure 1. Server/Client architecture

Because of the recent development, tablets represent a convenient solution for target device on client side. Server receives broadcasted DVB content and passes it through to clients when all security conditions have been met. Server is a set-top box device based on Android OS [17] that has a DTV service server and provides all of the content for its clients. Clients are second screen devices in form of a tablet or smartphone.

In our system CAM is an integral part of host, as it is in fact a piece of hardware which is usually integrated in STB. In order to control the CAM, Common Interface Plus (CI+) stack is used. Streamed content between server and client is protected using Digital Transmission Content Protection (DTCP-IP) when it is needed. DTCP-IP was chosen because it is widely accepted and it is part of DLNA protocol that is supported by majority of second screen devices. Moreover, CI standard encourages the use of DTCP-IP for protection of streamed content.

III. Second Screen TV and Mulitmedia Playback

Live TV can be watched on the second screen device independently from the main screen. Channels watched on the second and the main can be different or duplicated (same channel on both screens). On the second screen, while watching live TV, user can switch channels, control volume, view services provided by the watched channel and all of that without interfering with the main screen. Some controls like channel zapping and volume control are possible with finger gestures. For example, swiping left or right zaps to the next or the previous channel.

In order to watch the live TV on the second screen, player had to be implemented. That player supports both premium and free-to-air TV content. TV channels are streamed from the server for the clients. The solution for problem of content protection for premium content is presented in fig. 2.

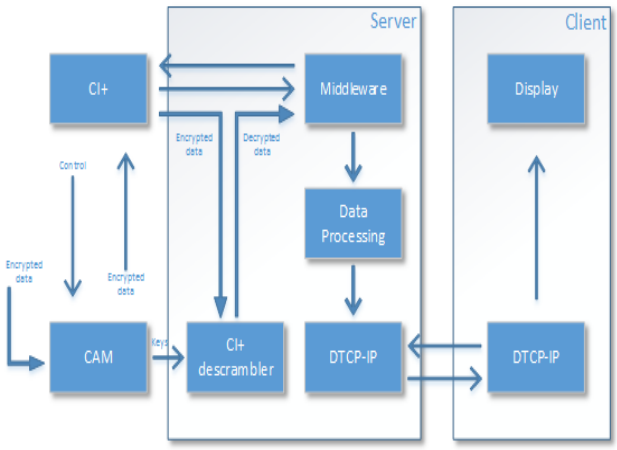

Figure 2. Content Protection

This solution provides the user with a significant amount of freedom regarding the format of streamed content, due to the fact that all the processing and descrambling is done on the server side. After the data is descrambled, all wanted alterations can be done regarding the format of the content. The codec of audio and video data could be changed in order to make it suitable for particular second screen device, for example. That allows for greater system flexibility. This solution is compliant with practically all second screen devices, as the data format can always be changed on the host side. However, this solution requires more processing on host side that uses host's bandwidth. As a consequence a powerful hardware is needed.

Multimedia content is streamed over HTTP, RTP/RTSP and adaptive streaming protocols such as HLS or MPEG-DASH. All of the videos or music on the server could be streamed to the second screen device. User can browse through the set-top-box's music and video library and play the content he or she desires.

IV. Additional Content

Multiple examples of additional content are presented in this section. Some of the use cases can be seen in figure 3.

A. Electronic Program Guide

For any channel available, the user can view EPG on the second screen. User can select and preview info about any channel's current, past or future event while browsing EPG. From the EPG presentation channels can be changed or added to the favourites list. Details on any EPG event can be viewed by selecting desired event. Selected EPG event and EPG in the background can be seen in fig. 4.

Figure 3. Second Screen use cases

Because it does not have to be the channel currently viewed on the main screen, it enables personal EPG browsing without interfering with other TV watchers or with the main screen of the DTV. EPG can be activated from the Remote Controller for the main screen, or from the mosaic and live TV on the second screen. From the EPG user can also set the reminders on both main and the second screen for pop-up reminder to remind user to watch some channel later. The reminder will pop on both main screen and the second screen when the show is about to start.

Figure 4. EPG with deatiled view of an EPG event

B. *DLNA Multimedia Browser*

From their second screen device, users can browse DLNA servers using the DLNA browser implemented in the second screen application. If user chooses, browsed media content (pictures, audio and video) can be reproduced on the second screen. Also, multimedia content on the TV set can be browsed and reproduced including videos recorded with PVR (Personal Video Control). The user can choose whether to reproduce multimedia content on the second screen or main screen.

C. *Personal Video Control*

It is possible to browse and watch previously recorded content on the second screen or previously recorded content on media server and control it. If the recording is activated on the second screen device, the user can designate amount of memory which can be used for storing the data. Controlling the content includes play, pause, stop, rewind and fast forward functions. These controls can be used to time shift live TV channels. Personal Video Control (PVR) is done via remote controller module of the second screen application.

Figure 5. Remote Controller modules

D. *Remote Controller*

Second screen application offers remote controller UI and can act as a secondary remote controller for the set-top box. The idea is that remote controller on the second screen becomes a lot more flexible as it is a software application and can be used to control more than the TV set. Remote controller is used simultaneously with classic remote controller which comes with the TV, but considering that all of the other options are present on the second screen, software remote controller is accepted with ease. By using the Controller unit, it is possible to use the application on Android powered set-top boxes. Remote Controller consists of three modules: Keyboard, Touchpad and Remote Controller which can be seen in figure 5. Touchpad and keyboard modules are used for browsing content on the Android part of the set-top box. Remote Controller is used in a classic way of interacting with the TV and it consists of three modules: Navigation, Numbers and Classic Remote Controller.

V. CONLUSION

In this paper second screen framework for live TV is presented. The framework includes additional data such as EPG, reminders, PVR control. Second screen live TV which supports both premium and free-to-air TV is the key part of the solution for the problem of content protection for second screens. Future work is planned on

expanding additional second screen features and fully implementing SAT>IP and ChromeCast in the second screen environment. Also, connecting second screen application with social networks in order to connect second screen users is planned thus making this second screen environment even more user friendly.

Abstract – Providing access to devices via Internet is a growing trend allowing consumers to monitor and control their home appliances, heating, air conditioning and multimedia devices remotely from their tablets or laptops. Increasing number of "anywhere access" applications emerged to provide the users with cutting edge monitoring and control possibilities, including scheduling, event linking or even in-depth behavior scenarios definition. In this paper a device cloud platform architecture and a pilot implementation is presented. The device cloud allows arbitrary web, mobile or PC applications to connect to devices over the internet, to monitor and control their behavior and upgrade their firmware. It is also allowed to compose scripts and define cross-device and cross-event scenarios, which are maintained and executed within the cloud, thus allowing unprecedented level of automation and intelligent control. Main contributions of the presented device cloud are the interoperability with devices based on open technologies (TR-069), dynamic adaptation to device types, dynamic API layer towards user applications, intelligent bandwidth preservation and modular and scalable in-cloud scripting engine.

I. INTRODUCTION

With the increase of number of "smart" home devices, and with the increase of internet bandwidth and ubiquity of internet access, the need to control this ecosystem seamlessly has appeared. The establishment of a platform for device-user interaction regardless of user location would allow the development of "anywhere access" applications. Open technologies for application implementation (e.g. HTML-5 with Javascript), together with the ubiquity of the devices which are able to show applications (PCs, tablets, smart phones), would allow the clear leverage with the seamless API implementation provided by the Device Cloud platform. This platform builds upon the concept of Internet of Things (IoT), which envisages the possibility of unique identification and access to each device over the Internet. In recent years there is an increase in Device Cloud platform providers, which offer means of connectivity between devices, cloud and user applications.

In this paper a concept, architecture, implementation and demonstration use cases of a novel Device Cloud platform, called *Insight,* are given. The proposed device cloud tackles some of the most daunting problems in this area. Its architecture is adaptive so that it can accommodate any type of device with any data model specification, which maps directly to the cloud API and is accessible by apps in a semantically expectable manner. The connection of the device and the cloud is facilitated by the provision of cloud agents in various convenient forms, such as Android service, Linux daemon or pure-C software library which use IP connection for cloud access using open technologies, such as TR-069. Alternatively, low-performance devices can be connected to the cloud through an easy-to-install gateway supporting Zigbee and ZWave protocols. The device shadow continues to exist in the cloud even in the case the device is temporarily offline. Support for load balancing is designed in, so that all the device communication can be throttled if necessary and thus preserve bandwidth.

II. RELATED WORK

Since it was first coined in 1999, term Internet of Things was a promising paradigm that would resolve many problems of protocol convergence and ubiquitous access to all physical entities in the world [1]. The problem focus has recently shifted from wireless sensing network architectures (WSN) and device accessibility from the global network, towards the creation of cloud-centric frameworks for IoT usage and management. Gubbi et al. recently proposed a conceptual cloud framework for IoT access implemented as Aneka, which allows the creation of Sensor Applications which dynamically assigns computational resources and provides sensing data from the ubiquitous sensors [2]. However, this framework is sensing-centric, disregarding aspects such as configuration and maintainability of physical device ecosystem. The proposal of common application layer with thin server architecture pushing the operation logic and device accessibility to the cloud, was given by Kovatsch et al. [3]. However, this solution does not address security concerns, nor does it provide access to device nodes which may not be operational when requested by an application.

Commercial platforms related to the proposed device cloud are growing in number. Etherios (formerly iDigi) provides a hosted device cloud solution which enables apps creation which can control devices in real time, schedule operations and configure alarms [4]. Each device is exposed to the cloud through Cloud Connector libraries for Android or embedded systems. Many startups are also offering less mature M2M interfaces and cloud services such as Arkessa [5], Axeda [6], Carriots [7], Xively [8], Control4 Anywhere Access [9], etc. To the best of our knowledge, these solutions provide limited or no support for device identification, device model adaptability and device "shadow" image, which are issues handled in the proposed device cloud.

Motorola EDGE Manager [11] supports monitoring and configuration script written in JavaScript execution, however automatic script execution is allowed only for simple events in the system, where more complex events require operator management. This solution uses TR-069 Connection Request mechanism which does not exploit all TR-069 possibilities, especially data synchronization between end devices and monitoring platform.

III. DEVICE CLOUD ARCHITECTURE

Top level architecture of the proposed device cloud - Insight Device Cloud (IDC), is shown in **Figure 1**.

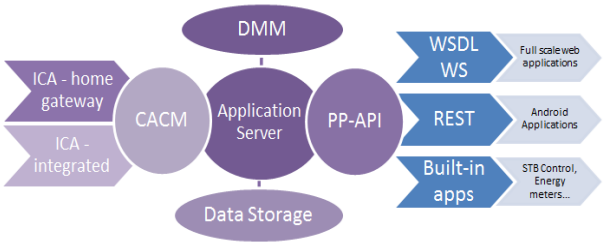

Figure 1. Top level architecture.

The *Application Server* is a scalable core of the IDC, providing the runtime environment for the *Data Manipulation Module* (DMM) and provides access to *Data Storage*. The *Cloud Agents Communication Module* (CACM) maintains the communication with the physical devices, supporting various device types and parameter sets through the concept of XML-based data model and dynamic API. *Insight Cloud Agent* (ICA) implements the device side of communication with IDC, available as Android service, Linux deamon or C library. The communication between CACM and ICA is based on TR-069 protocol. DMM controls end-to-end information flow while load-balancing access to storage units (database/cache). IDC exposes *Post-Processing APIs* (PP-API) for third party application development using standardized communication web-based interfaces such as web services based on web service description language (WSDL) or REST.

Several novel approaches are within the IDC architecture and functionality. Each device is represented by its *data model*, which is essentially a tree describing all device parameters, command hooks, objects etc (**Figure 2**). ICA adapts to this data model both in compile-time and run-time, making the device semantically close to the target application use cases. Based on the data model obtained by CACM, DMM dynamically adapts PP-API using WSDL to expose the API as close as possible to the device type and its functionalities.

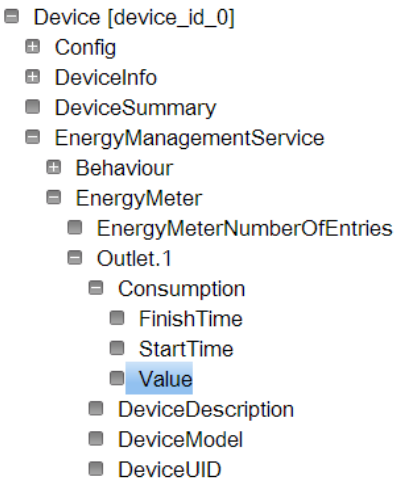

Figure 2 Example of data model specification

PP-API uses *security mechanisms* and reputation-based trust management to secure public domain data flow. Security in Cloud environment is a big issue, so messages on both ends are secured. Communication layers, towards ICA and third-party applications integrate HTTPS/SSL as the industry standard. WSDL based web-services endorse Web Service-Secure (WSS) protocol for message encryption. Federated Identity Management (FIdM) is integrated with Pluggable Authentication Module (PAM). This mechanism enables different high level application controllers with different access privileges. Besides specific security, IDC is applying Cloud-specific security through mechanisms through corrective and detective controls. *Load balancing* is provided by measuring the average duration of communication session with each device. If the threshold duration is reached, load is balanced by adjusting the interval between two consecutive Inform messages. Inform is a basic inter-entity message in TR-069 protocol. To trigger Inform asynchronously when immediate access to a device is required, ICA supports the use of STUN or XMPP to connection-request the device.

Each device is represented by its *cloud shadow;* this concept encompasses the usage of object-relational mapping libraries. Once the device is connected to the IDC, its shadow is created based on its data model. Cloud shadow provides advance features such as full device backup to mitigate risks of failure and device reconfiguration on start-up.

IDC allows automatic execution of Lua scripts through separate connected application. *Script Executor* (SE) interprets user defined scripts and executes actions based on device properties or events occurred in the system. Communication between IDC and SE is HTTP. Top level architecture of SE and IDC is shown in **Figure 3**.

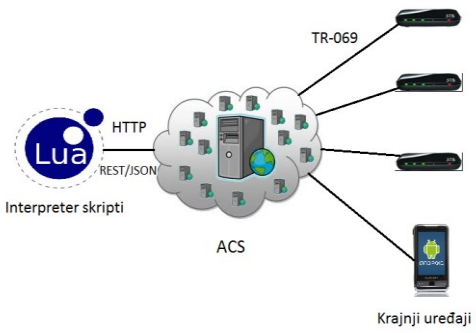

Figure 3. Script Executor and IDC top-level architecture.

IV. USE CASES AND EVALUATION

Evaluation was performed by the development of several web front-end applications using PP-API to provide monitoring and control of specific devices – set-top-boxes (STBs), home gateways, energy meters and light controls. Additionally, cross-device application for audience monitoring in TV networks was developed.

STB dashboard application (**Figure 4**) allows the user or service personnel to monitor current state of device, including active frontend connection, streaming protocols used, performance indicators (CPU load, memory consumption), user activity (currently watched channel/show) etc. Users are able to configure their device, perform channel scanning or even zap to a desired channel. The application can be accessed from web browser.

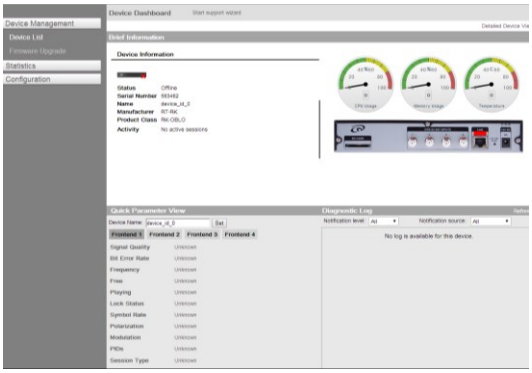

Figure 4 STB dashboard application

Energy meter dashboard application (**Figure 5**) shows the power usage statistics within a household. Power consumption can be disaggregated to specific consumption devices, such as power outlet and dimmer switches. Additionally, users are able to control lights or toggle devices within the home remotely.

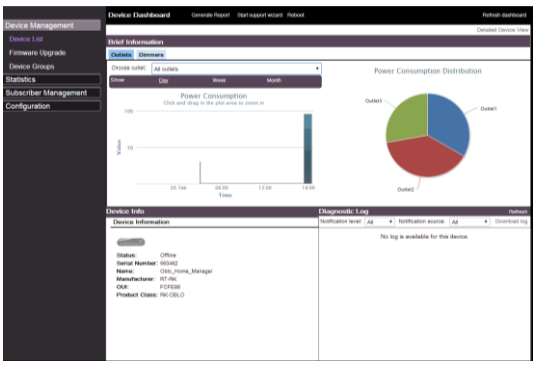

Figure 5 Energy meter dashboard application

Cross-device application for audience monitoring (**Figure 6**) uses PP-API to gather information about user behavior (channel watching statistics) from a group of STB devices. Application is implemented as a server enterprise back-end communicating via WSDL with the IDC. Front-end web application fetches aggregated statistics from the back-end part and populates the graphs accordingly.

The main selected evaluation metric was *response time.* Response time was measured for the following cases: (1) response to channel zapping in STB dashboard application split into (a) the time needed to process the request in the cloud, (b) the time needed for propagation through the Internet and (c) the time needed to perform actual zapping; and (2) response to light switch toggling in energy meter dashboard application when (a) instructed through IDC and (b) instructed through a Control4 Anywhere Access [9].

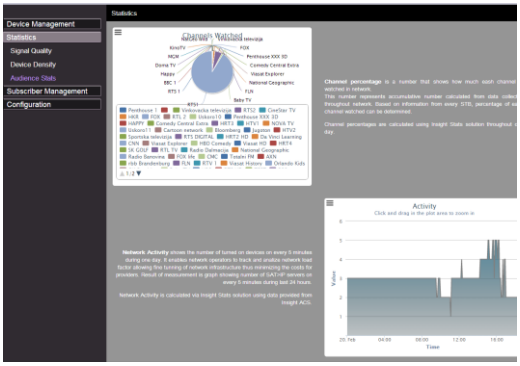

Figure 6. Cross-device application for audience monitoring

Figure 7 shows evaluation response in seconds for the test case 1. The time needed to perform the processing within the cloud is considerably smaller (~6%) when compared to propagation time and channel zapping time. For most applications, this overhead is not expected to be a drawback.

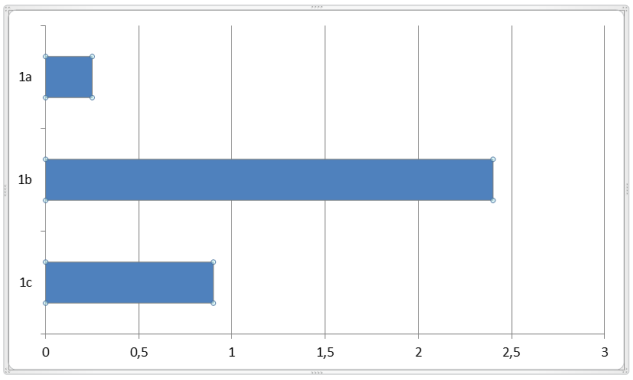

Figure 7. Test case 1: Average response time to channel zapping, time in seconds; (1a) processing the request in the cloud – IDC overhead; (1b) propagation through the Internet and (1c) actual zapping time on the STB.

Figure 8 shows evaluation response in seconds for the test case 2. Note that the actual dimmer device used when instructed both through the IDC and the Control4 Anywhere Access was the same (Oblo Smart Dimmer Switch [10]). The response time of IDC-based application (~2.9s) is lower than the response time of Control4 Anywhere Access (~3.4s). This shows that the proposed solution has comparable or better performance while keeping the architectural advantages that were introduced.

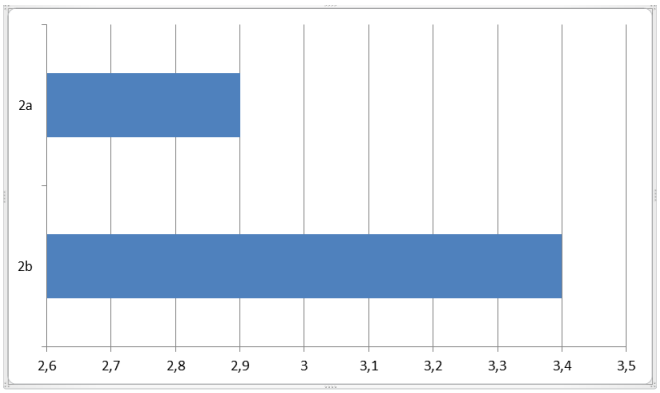

Figure 8. Test case 2: Response time in light switch toggling; (2a) using Insight Device Cloud, (2b) using Control4 Anywhere Access

Another evaluation was conducted using Script Executor web front-end application shown in **Figure 9** and comparing its speed and possibilities against a similar JavaScript based solution [11].

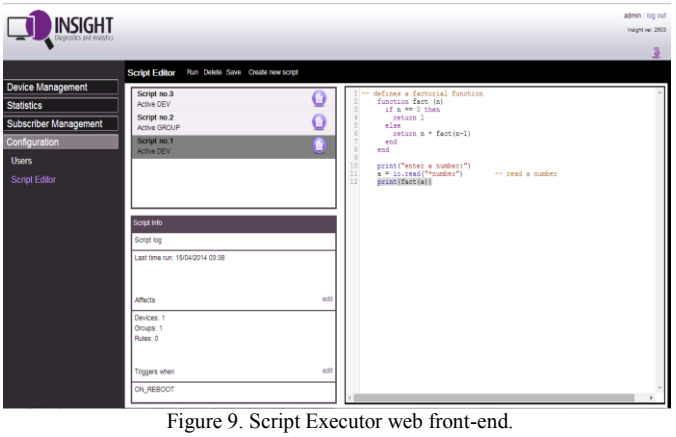

Figure 9. Script Executor web front-end.

Measurement results are shown in **Figure 10**.

	Lua	JavaScript
Memory consumption of interpreter	336 kB	739 kB
Script response time	268 msec	13 msec
Reaction to discreet events	Supported	Not supported
Complex event handling	Supported	Not supported
Configuration for a single device	Supported	Supported
Configuration for groups	Supported	Supported
Configuration according to certain criteria	Supported	Not supported
Stopping scripts	Supported	Not supported

Figure 10. Script measurement results.

V. CONCLUSION

Proposed device cloud brings several contributions to the state-of-the-art, including the ability to automatically identify new devices, adapt API dynamically, use automatic script execution and provide device representation in the cloud (*device shadow*) as long as it is required by applications, regardless of the device actual connection state. The overhead when using the proposed cloud is up to 200 ms what is acceptable for Internet of Things applications for device monitoring and control. Our initial evaluation shows that overall response time outperforms similar cloud solutions both in communication with Cloud Agents and in script execution. Future work will include proliferation of the proposed device cloud with the goal to increase the number of applications for various new devices.

Sound quality assessment in VOIP environment

Darko Lukša[1], Siniša Fajt[2], Miljenko Krhen[2]

[1]Polytechnic of Zagreb, Zagreb, Croatia
[2]Faculty of Electrical Engineering and Computing, University of Zagreb
e-mail address: darko.luksa@tvz.hr

Abstract

The need for measuring the sound quality in VOIP environment is a basic requirement of modern multimedia communication systems due to technical, commercial and legislative reasons. Measuring the sound quality using objective methods is not standardized up till now. Expected measurement results should be in correlation with subjective tests of sound quality. The usage of application for measurement of acoustic qualities of the space is explored, with an emphasis on evaluating speech intelligibility as the main parameter. In this work we present measurement method and influence of codec choice on different hardware platforms. Objectively measured small differences showed possibility to evaluate the sound quality of voice internet protocol.

I. INTRODUCTION

Nowadays, Voice Over IP (VoIP), IP telephony, audio streaming and videoconferencing becomes familiar for a wide range of users. Due to the nature of Internet communication there are still challenges to be overwhelmed to provide the end user with acceptable levels of service quality, especially because of unreliable connections quality and unexpected propagation delays. In the second chapter we presents main characteristic of main components in VOIP systems. Third chapter depicts test environment and methods, and discuss measured results.

II. THE OBJECTIVE OF THE PAPER

Assessing the quality of interactive VoIP streams is a difficult task which than that of assessing the quality of one-way streams. In this case more parameters need to be considered, such as the delay and jitter and various software configurations.

The VoIP tool employed is called Elastix [7], which is based on open-source tool Asterisk. Asterisk is the Open Source software PBX that's widely used in business telephony. It runs on Linux and provides a full-featured approach to voice and data transport over TDM, switched, and Ethernet architectures. Additionally, as one of the fastest growing Internet technologies, Voice over IP can provide a number of specific services compared to traditional telephony such as conferencing, events notification, presence notification, text-to-speech, instant messaging, video telephony and various multimedia transmissions. It could be expected that open source IP telephony products will replace a number of proprietary hardware and software with standard Linux servers and open call control over the coming decade.

Recent advances in embedded systems development qualify them for implementation of Asterisk based system. Such implementation could be found in small IP enabled embedded system boards such as Raspberry PI and various home routers.

Nowadays the most extended protocols for VoIP are SIP [4] and IAX protocol [5]. SIP protocol is widely used and represents the most popular standard until now in many VoIP applications. Before the apparition of IAX, the functionalities of call signaling and multimedia transport were implemented by different protocols acting in parallel (H.323 and SIP for signaling and RTP for the transport). However, IAX as a new concept in VoIP combines both functions in the same protocol. Thus IAX conveys all the signaling and multimedia information for the management of the voice streams into the same session which improves performance. Additionally, IAX also provides the possibility of using Trunk connections for several calls. Using this option, all the protocol overhead is common for all the calls between two IAX nodes, which clearly reduce the bandwidth usage.

During this conversation phase, SIP protocol rely the multimedia transport on Real-time Transport Protocol - RTP. On the other hand, IAX performs multimedia transport in a very different manner. Instead of use the services of RTP, IAX sends multimedia traffic into the one IAX session. Although this leads to the different impact on multimedia transport in this work we are focused on superior impact on bandwidth requirement by codec type choice.

At the transmitter side, the encoder takes an analog voice signal from an input such as a microphone and transforms the signal into a digital format that can be appended as the payload of an RTP packet. On the receiver, the decoder takes that payload content of the RTP packet and converts it back to an analog signal for play out to the receiving user. The broadest division among speech coding algorithms is between waveform quantization and parametric quantization, where the first group represents the signal by the time samples quantization. Second group denotes the signal by a binary representation of a speech model or spectral parameters.

The simplest nonparametric coding technique is Pulse Code Modulation (PCM), which is simply a quantizer of sampled amplitudes. ITU T Recommendation G.711 standardizes the u Law and A Law compression

algorithms, used in the United States and Europe, respectively. These algorithms use logarithmic scale quantization and are considered both uncompressed and reference for quality comparison with other algorithms. To enable uses in VOIP environment, ITU T recommendation G.711 incorporated Packet Loss Concealment and Discontinuous Transmission mechanisms for the G.711 codec.

Parametric codecs characteristically involve an analysis and synthesis method. In the analysis phase, speech is represented by a compact set of parameters that are encoded efficiently. At the synthesis phase, these parameters are decoded, and used in conjunction with a reconstruction algorithm to recreate a speech signal. The analysis phase can be open loop or closed loop. In the case of close loop analysis, the parameters are extracted by minimizing an objective metric, typically the square of the error between the original signal and the reconstructed speech. Due to the fact that close loop analysis usually involves the reconstructed speech, it is also called analysis by synthesis.

Some of the most commonly used codecs in the industry today which use Linear Prediction Coefficients are for the representation of the speech signals, and construct the signal using the analysis by synthesis ITU T G.729, ITU T G.723.1 and iLBC. For example, in the case of G.729 codec the autocorrelation coefficients are computed on 10 ms windows, and then converted to LPC coefficients.

Generally, packet networks have some inherent unsuitability with the transport of real time services, such as voice or video. The total delay on the network is compounded by several independent sources, which can be broadly divided in two categories: fixed delay components and variable delay components.
Variable delay are commonly referenced as delay jitter or simply jitter, is caused by the queuing that occurs in the different egress trunks that interface the Local Area Networks (LANs) to the Wide Area Networks (WANs), and add a variable and unpredictable amount of delay.

Coder delay refers to the time taken by the processor to compress a block of sound sample. This factor is manifestly affected by the processing capability of the device performing the selected compression algorithm, and the number of concurrent processes this device should handle. In this process the greatest importance has the algorithmic complexity and the frame size of the coder.

There are two other important factors that add to the overall delay are the decompression delay and the algorithmic delay. Although decompression delay is roughly 10% of the compression delay, but it should be noticed that it is multiplied by the number of frames sent in an RTP packet. Algorithmic delay refers to the unavoidable delay that some coders required in order to acquire future samples of the signal and depends on the number of future frames the coder or decoder needs to look ahead for proper operation.

Unavoidable packetization delay represents the time it takes to accumulate sufficient frames as needed by the designed number of frames in a single RTP packet. This delay is the product of the window size chosen for the compression algorithm (in ms) and the number of frames included in each RTP packet.

Queuing delay is a variable delay which depends on the trunk speed and the state of the queue in the router. It refers specifically to the queue inside the transmitting endpoint or gateway, and should not be mixed up with the propagation or network switching delay.

Network Switching Delay represents the propagation portion of the switching delay which results from the physical distance that needs to be traveled by the transmitted packets. Network congestion may adjust the number of hops required to reach the destination points, consequently the physical distance can vary from packet to packet, making packets arrive in an order different to which they were transmitted.

Specifically, we used Elastix as a unified communication platform that combines many popular sets of software available for Asterisk-based PBXs into a single interface. As a result, Elastix provides a highly user-friendly configuration of different VOIP parameters, especially for those users who are not familiar with Linux and complicated VOIP protocols implemented in Asterisk.

In exploitation it is important to clearly specify all the parameters consuming the VOIP PBX's resources CPU, RAM and hard disk. These parameters include the number of concurrent calls, type of codec used for different trunks, call features such as voice mail, music on hold and call conference to be supported. Even though it is very difficult to specify how much each of these parameters consume the VOIP-PBX resources, this information can benefit us to approximately determine the specification of the hardware for developing the VOIP-PBX. Table 1 presents required resources for main functionality. Due to the nature of different end point devices VOIP PBX an important assignment is converting different coding between them, which is processor and memory consuming task.

Commonly, in practice are used two types of phone for VoIP system: (1) Softphone and (2) specialized VoIP phone. They share the common purpose of making and receiving phone calls that are routed over the Internet, but are quite different in various aspects.

Softphone refers to software that can be installed in a computer device such as PC, notebook, smartphone, or tablet and utilizes its resources. Nowadays, there are plentiful softphones available to download, for example, X-lite, 3CX, Zoiper and many more which could be

Table 1 VOIP functionality and its resource consumption

Functionality	CPU	RAM	Hard disk
Concurrent calls	x	x	
Transcoding	**x**	**x**	
Voice mail, Call log, Backup			x

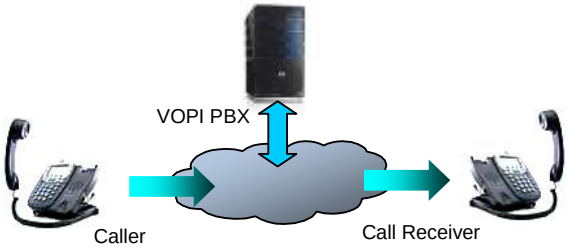

Figure 1 System diagram

Table 2 Codec properties

Codec	Bit rate [kbps]	Frame size [ms]	Data size per frame [bytes]
g.711 (A Law)	**64**	**20**	**160**
g.726	32	20	80
gsm	**13**	**20**	**33**
lpc10	2.4	22.5	7

found in different versions. The call features they provide typically are more flexible when comparing with what VOIP phones can offer.

On the other hand, VOIP hard phone refers to physical equipment that is devoted for telephony services. It is usually implemented using dedicated SOC processors for networking a wide variety of voice coders, jitter buffer management and packet loss concealment techniques, and a library of standard telephony algorithms required for IP phone operations. Comparing with the use of softphone, it is considered to be more user-friendly and due to usage of dedicated speaker and microphone provides better voice quality.

In our study we analyses influence of codec choice on different hardware devices ranging from small embedded systems to high performance computer systems.

III. DESCRIPTION OF SYSTEM

The functional diagram of the system deployed for the purpose of sound quality assessment is presented in Fig. 1. It basically includes three components: an Asterisk server, a Caller, and a Call Receiver.

For the Asterisk server we have used Elastix 2.4 with CentOS 64-bit Linux system on a Pentium 4 (2.4 GHz) with 2 GB RAM Memory. Used engine is Asterisk 1.8.20 using a standard configuration.

Asterisk server support different codec type for transcoding in a case of when receiving endpoints doesn't support used codec.

As a Caller and Call Receiver softphone was used. Choice of softphone over hard phone provides a flexibility of controlling and choosing codec on both endpoint sides. In our test environment free Zoiper softphone was used [6]. In Table 2 are presented main properties of exploited codecs.

III. THE MATERIALS AND RESULTS OF RESEACH

To determine the quality of a VoIP system, it is necessary to perform a number of objective measurements ("classical" methods for signal distortion and SNR) and subjective tests (overall quality score - user opinions).

In this study the performance and quality of a VoIP system dependent on a variety of codecs and parameters was measured, with the emphasis on the objective measurements. Measurements were performed in an anechoic chamber. The measurement system is shown in Fig. 2.

Asterisk were managed through Elastix interface. The software package Easera Pro (Electronic & Acoustic System Evaluation & Response Analysis) installed on Lenovo ThinkPad L512, Windows 7 Professional SP1 64 bit was used

Through Elastix interface more extensions or user (receiver and transmitter) were created. To place the call using the software IP phone (Softphone) ZoIPer. ZoIPer

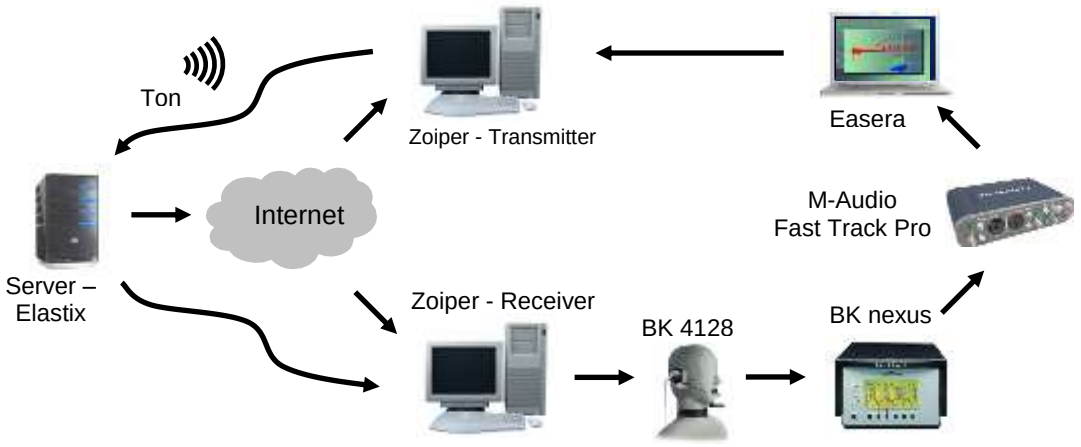

Figure 2 The Measurement System

Table 3 Speech intelligibility

Parameter	gsm_gsm default	gsm_alaw default	alaw_alaw default
STI	0,77	0,78	0,804
AlCons (%)	2,624	2,492	2,18
STI (male)	0,776	0,778	0,807
STI (female)	0,753	0,759	0,792
RASTI	0,855	0,828	0,855
equv. STIPa (male)	0,791	0,781	0,811
equv. STIPa (female)	0,77	0,765	0,8

is a software IP phone that supports both SIP and IAX2 signaling protocols and is the most commonly used software with Asterisk VoIP telephone switchboard. ZoIPer comes in several versions: free, business and OEM. The program has a built-in following audio codecs:

- G.711 μlaw
- G.711 alaw
- GSM
- Speex
- iLBC 20
- iLBC 30
- G.729 (at extra charge)

In this research the parameters by default mode were used or with the included parameters Echo cancellation, AGC and noise suppression for different combinations of codecs such as alaw - alaw, GSM - GSM and alaw - GSM. The amplitude frequency response is measured broadband with the followind codec combinations: alaw - alaw, GSM - GSM and alaw – GSM. It is noticed that there was a difference in the characteristics which can be seen in Figures 3-5.

However, in speech intelligibility by changing combinations of codecs differences were not observed. STI (Speech Transmission Index) during the measurements is ranged from 0.70 to 0.90. Index of speech intelligibility STI is a parameter for the objective evaluation of the quality of voice transmission (Table 3).

However, although in speech intelligibility differences were not observed, subjectively are perceived differences in quality. Specifically in order to examine how the system behaves by octaves, 1/48 octave analysis was made. The review of octave analysis and octave analysis of amplitude characteristics of the combination of codecs a fundamental difference in the color tone or sound is spotted. Octave amplitude characteristics of the combination of codecs GSM-GSM, GSM-alaw and alaw alaw is shown in Figure 6.

IV. CONCLUSIONS

On the basis of measurements it can be concluded that there is no objectively influence the choice of codec and their combinations on the intelligibility of voice, but it was objectively confirmed subjective aural impression of sound color change depending on the combination used codecs.

Automatic Interpretation of Aircraft Piston Engine Monitor Log

Dubravko Miljković
Hrvatska elektroprivreda, Zagreb, Croatia
dubravko.miljkovic@hep.hr

Abstract - Digital engine monitor during each flight produces large amount of data containing numerous engine parameters. These logs can be later downloaded to a personal computer and graphically presented with accompanying specialized software as sets of curves in a time domain. Potential problems are spotted when parameters exceed specified predetermined operating limits and when conditions for a particular diagnostic pattern are fulfilled. Catalogued diagnostic patterns consisting of EGT-CHT bars, one for each cylinder, are complex and are not easily detected from representation in form of curves on a display. Rule based pattern recognition of catalogued graphic engine fault patterns can provide necessary fault detection and isolation functions.

I. INTRODUCTION

Engine monitor is an advanced instrument for monitoring of piston engine parameters and produces sizable engine logs after each flight. After the flight logs can be downloaded to a PC where engine parameters can be presented in a graphical form suitable for the analysis by the maintenance personnel. Aside from spotting large deviations of a particular engine parameter, spotting of most diagnostic patterns corresponding to potential fault conditions is not so easy and requires considerable experience. By the automatic interpretation of data contained in the aircraft piston engine monitor log this process can be accomplished even with the less experienced personnel (possibly even the owner) and with greater speed.

II. ENGINE MONITOR

Engine monitor, called also Graphic Engine Monitor (GEM) or Engine Data Management (EDM) system is advanced and accurate piston engine-monitoring instrument that helps the pilots at managing of engine operation, [1-3]. Digital bar graph and numeric display is capable of displaying simultaneously exact Exhaust Gas Temperature (EGT) and Cylinder Head Temperature (CHT) temperature for each cylinder with the addition of Turbine Inlet Temperature (TIT) on turbocharged engines as vertical bars on the engine monitor's display. These bars form various EGT-CHT patterns that change during engine operation and may help detect abnormal engine conditions, [1-8]. Depending on engine monitor type the same bar can be used for both EGT and CHT (missing segment of a bar depicting CHT value), or, as is common on newer products, there are separate bars for EGT and CHT values, Fig. 1.

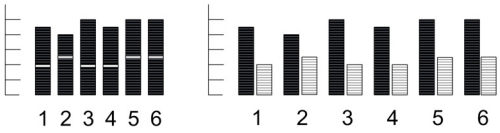

Figure 1. CHT-EGT values shown on the same and separate bars

III. ENGINE MONITOR LOG

Typical engine monitor records and stores all engine parameters to a log once every six seconds (default value) or at a user selected rate. After the flight, at a later time, this data can be transferred to a laptop PC. Engine parameters recorded by the one popular engine monitor (JPI EDM830) are shown in Table I. Logging of important engine temperature data (EGT, CHT, TITT) on a regular basis allows the creation of a engine-operation history. It remains a detailed record documenting each hour of an engine's operating life. Example of part of one engine log is shown in Fig. 2. After the record number, time data following by engine parameters and (optional) GPS data if a GPS receiver is connected to the engine monitor. If during a flight the pilot notices something unusual, it is possible to closely examine the log file belonging to that flight later.

TABLE I. MONITORED ENGINE PARAMETERS

Parameter	Description
EGT	Exhaust Gas Temperature
CHT	Cylinder Head temperature
OIL TEMP	Oil Temperature [1]
OIL PRES	Oil Pressure [1]
TIT 1	Turbine Inlet Temperature 1 [1]
TIT 2	Turbine Inlet Temperature 2 [1]
OAT	Outside Air Temperature
CDT	Compressor Discharge Temperature [1]
IAT	Intercooler Air Temperature [1]
CRB	Carburetor Air Temperature [1]
CDT - IAT	Intercooler cooling
RPM	Rotations Per Minute
MAP	Manifold Pressure
% HP	% Horse Power
CLD	CHT Cooling Rate [2]
DIF	EGT Span [3]
FF	Fuel Flow [1]

[1]optional, [2]fastest cooling cylinder, [3]difference between the hottest and coolest *EGT*

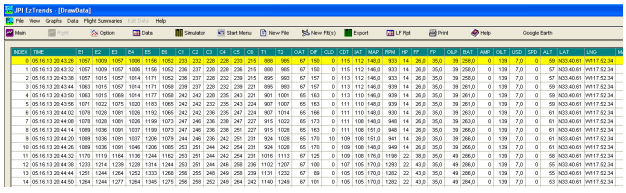

Figure 2. Example from the engine monitor log, include engine parameters and GPS data

IV. GRAPHICAL ANALYSIS SOFTWARE

EzTrends is the utility program that accompanies JPI engine monitors and enables the transfer of compressed data from the Engine Data Management (EDM) system to a personal computer (PC) for further detailed analysis, [9]. After decompression of the data software can plot the data on the screen as the graph where various engine parameters are presented as curves in different colors. EzTrends software allows great flexibility in how one can display engine monitor data. Graphs can present main and optional parameters either together, as shown in a Fig. 3, or separately, as in Figs. 4 and 5.

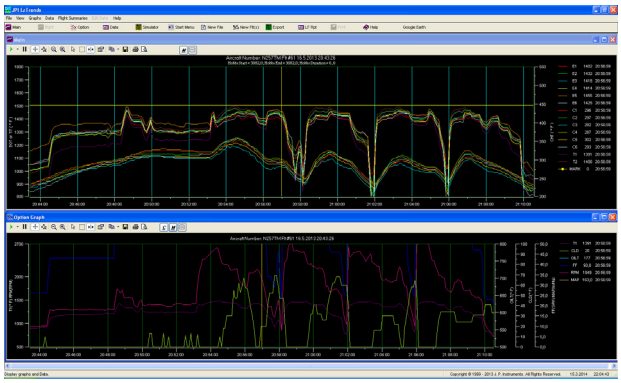

Figure 3. Main and optional parameters on the same screen

A. *Main Parameters*

Main parameters are Exhaust Gas Temperatures (EGTs) and Cylinder Head Temperatures (CHTs), The top six lines in the graph shown are EGTs (with the temperature scale on the left) and the bottom six lines show CHTs (with the temperature scale on the right), as shown in a Fig. 5.

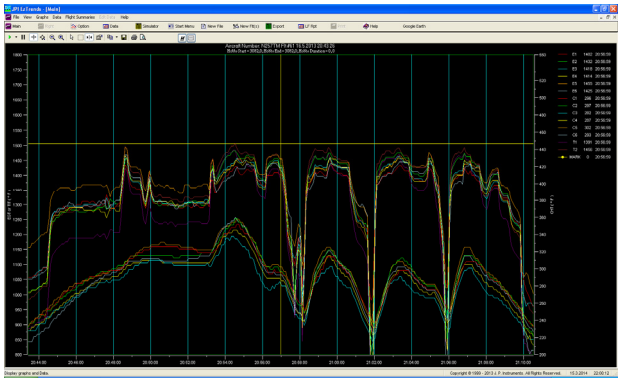

Figure 4. Main parameters (EGT, CHT, TIT)

Please note that the CHTs always lag behind the EGTs.

B. *Optional Parameters*

Optional parameters include Turbocharger Inlet Temperatures TIT1, (TIT2 if available), oil temperature OILT, fuel flow FF, engine speed RPM and manifold pressure MAP, Fig. 6.

C. *Flight Summary*

In a flight summary, Fig. 6, a schematic diagram of the engine is shown as small squares representing cylinders and connecting pipes representing exhaust pipes. Deviations from averages, for all cylinders, are color coded with the legend on the right side of the page. Operating the engine too hot is very damaging, [6,7].

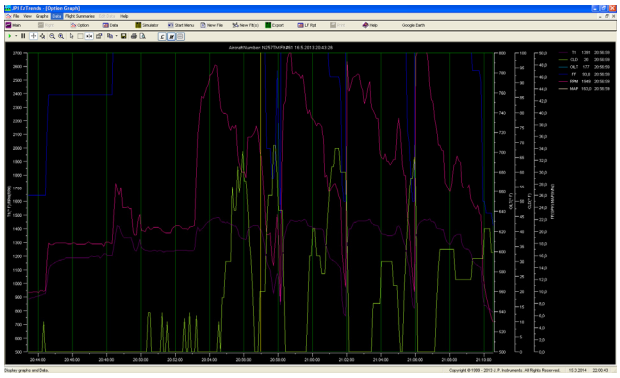

Figure 5. Optional parameters (CLD, OILT, FF, RPM, MAP)

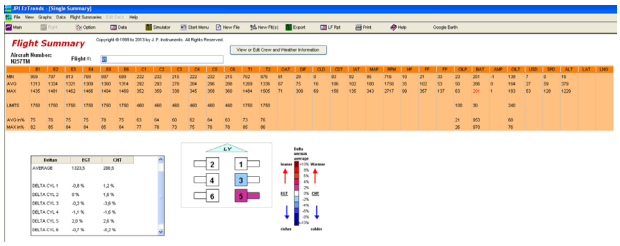

Figure 6. Flight summary as expressed by EzTrends software

The engine metal starts to soften when its temperature gets above 400°F. Hence, 450°F is chosen as the limit for engine CHTs. Serious damage to the engine may occur if CHTs rise above that value. Many turbochargers are limited to maximum turbine inlet temperature of 1650 °F. Exceeding that value may result in catastrophic failure of the turbocharger, [1]. When operating an engine one should respect limits listed in Table II, [2,3].

TABLE II. DEFAULT ENGINE MONITOR ALARM LIMITS

Measurement	Default Low Limit	Default High Limit
CHT		450 °F 230 °C
EGT [1]		1550 °F 843 °C [2]
OIL	90 °F 32 °C	230 °F 110 °C
TIT		1650 °F 900 °C
CLD		-60 °F/min -33 °C/min
DIF		500 °F 280 °C

[1]many engine monitors (e.g. JPI) don't have EGT alarm limit but DIF alarm limit instead, upper normal EGT value shown here, [2]on high performance aircraft, 1350 °F (732 °C) engines with less than 200 HP

As can be seen from previous description this software is graphically displaying log data together with some simple flight summary containing extreme values of engine parameters logged in previous flights. Maintenance personnel must carefully watch presented curve and with hindsight of experience spot abnormal engine behavior. By looking into parameters curves it is not difficult to spot large temperature deviations from default engine monitor alarm limits. However spotting fault patterns from curves is practically impossible. To spot fault patterns it is necessary to activate display simulator option, Fig. 7, showing CHTs and EGTs as vertical bars (showing patters while parsing a log). Again, one must remember and be proficient with various fault patterns.

Figure 7. Engine monitor display simulator for later log analysis

V. FAULT DETECTION AND ISOLATION

Fault detection is determination of faults present in a system and time of detection, [11]. On the other hand fault isolation is determination of kind, location and time of detection of a fault. Fault isolation follows the fault detection. Fault detection and isolation is identifying when a fault has occurred, and pinpointing the type of fault and its location, Fig. 8. Once the fault has been detected and isolated it is possible to advise appropriate corrective action. By elimination of the causes of a problem, it is possible to prevent its recurrence.

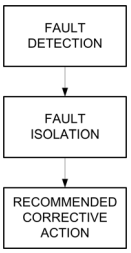

Figure 8. Fault detection, isolation and corrective action

For the automatic interpretation of engine monitor log files, limit checking is used for severe fault detection and pattern recognition of fault patterns is used for detection and isolation of various faults.

A. Limit Checkers for Engine Parameters

Limit checkers are very basic fault detection technique that can be applied using default engine alarm limits from table II. These limits contain allowable extreme EGTs (many monitors use DIF limit), CHTs, TITs and OIL temperatures during engine operation. Temperature extremes pose very wide limits that are suitable for detection of severe engine problems (1).

$$L_{L,i} < p_i < L_{H,i} \tag{1}$$

where

$L_{L,i}$ is low limit for parameter p_i
$L_{H,i}$ is high limit for parameter p_i
p_i is engine parameter i

EGTs, CHTs, TITs and OILT are primary parameters that should be considered for limit checking. Considering only upper limits for EGTs, CHTs, TITs, and both lower and upper limit for OILT (due to oil viscosity) following relations should be fulfilled, (2)-(5):

$$E_i < E_{MAX} \tag{2}$$

$$C_i < C_{MAX} \tag{3}$$

$$T_i < T_{MAX} \tag{4}$$

$$O_{MIN} < O < O_{MAX} \tag{5}$$

where

E_i is EGT of cylinder i i=1, …, N_c
C_i is CHT of cylinder i i=1, …, N_c
T_i is TIT of turbocharger i i = 1, 2
O is OILT
E_{MAX} is the maximal permissible value for E_i
C_{MAX} is the maximal permissible value for C_i
T_{MAX} is the maximal permissible value for T_i
O_{MIN} is the minimal permissible value for O
O_{MAX} is the maximal permissible value for O
Nc is the number of cylinders in engine

Despite the fact that limits from Table II consider only the extreme temperatures encountered in normal engine operation, these values are well known and documented in most piston engine and engine monitor documentation, i.e. one deals with well established facts, [1-3,10].

B. Recognition of Fault Patterns

Engine monitor is capable of displaying EGT-CHT patterns suitable for the fault detection. Patterns consist of bar graphs, darker bars represent EGT and lighter (or missing) bars CHT values. Each pattern corresponds to one or more engine problems. In pattern recognition it is possible to differentiate two classes of patterns:

1) Static Patterns

Static patterns don't change with time. There is no time evolution of pattern that depends of previous values from previous moments in time, Fig. 9. Such patterns can be described by one feature vector from a given moment.

Figure 9. Static pattern described with feature vector of parameters at a particular moment

2) Dynamic Patterns

Dynamic patterns incorporates temporal dimension (evolution of parameters through the time). To detect such patterns it is necessary to consider values from the past. Dynamic patterns can be represented by more features vectors in the neighborhood that represent evolution of that pattern through the time, Fig. 10.

Figure 10. Dynamic pattern described with feature vector of parameters in the neighborhood of the particular moment (e.g. from a recent past)

In most simple case these patterns could be described by introduction of the simple rate of change of parameters that are elements of feature vector. This way it is also possible to avoid large feature vectors.

$$\Delta p_i = p_{i,t+1} - p_{i,t} \tag{6}$$

where

$p_{i,t}$ is the value of parameter p_i at the moment t
$p_{i,t+1}$ is the value of parameter p_i at the moment t+1

Rate of change may sometimes in engine monitor documentation be described in vague linguistic form. Terms like slow change and fast change require further clarification.

C. Integration Into the Method

For automatic parsing of engine logs limit checking is integrated with the pattern recognition for the recognition of engine fault patterns, Fig. 11.

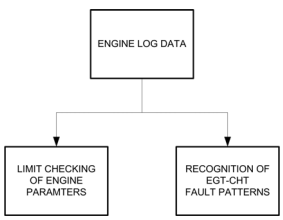

Figure 11. Log data analysis using engine parameters limits and recognition of various fault patterns

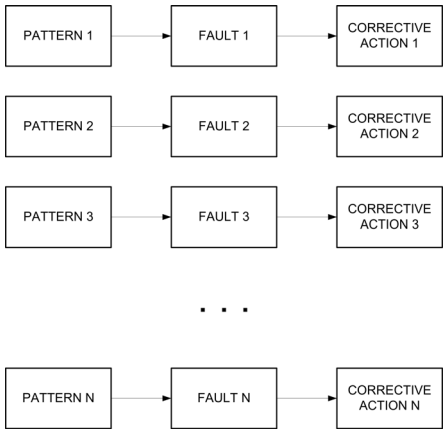

Figure 12. Fault pattern recognition for various faults

Limit checking is used for checking if engine parameters exceeded documented allowable extremes and pattern recognition for detection and isolation of various faults described by corresponding EGT-CHT fault patterns.

When using limit checking, there exists a possibility of using additional regime dependent limits based on engine speed - RPM, % of calculated maximal horse power - % HP or using flight phases, [12]. However, such limits are not widely discussed in comparison to use of limits corresponding to extreme values from Table II that practically represent common knowledge.

In a similar way measures for engine roughness and parameter fluctuations could be introduced in form of standard deviations of parameters in a recent period, however, no referent values are present in literature.

VI. RULE-BASED FAULT PATTERN RECOGNITION

Proposed pattern recognition technique employed in this method is rule based. This is due to rather precise fault pattern descriptions available in pilot's guides that accompany engine monitors, [1-3, 8]. There is also a lack of necessary numerous real world fault patterns that would otherwise justify use of some statistical pattern recognition techniques. Pattern recognition for the set of fault patterns is illustrated in Fig. 12.

A. Statistical Pattern Recognition

In statistical pattern recognition, a pattern is represented by a set of features, or attributes, viewed as a multidimensional feature vector. Various approaches in statistical pattern recognition are presented in [13]. Statistical pattern recognition requires large sample of normal and abnormal (faulty) patterns, Fig. 13, that are still difficult to acquire due to very reliable aircraft engine operation (MTBF values of an order of 5,000-30,000 hours) and consequently limited number of available recorded engine faults (and particularly various types of faults). For reliable pattern recognition each fault should be represented with at least several fault samples. It is not impossible to collect large sample base of this faults, but this would require collaboration of large owner base of aircrafts equipped with engine monitors willing to share such data. Producers of piston engines don't disclose engine failure data and statistics.

B. Rule Based Pattern Recognition

Rule based classifier represent the model as a set of

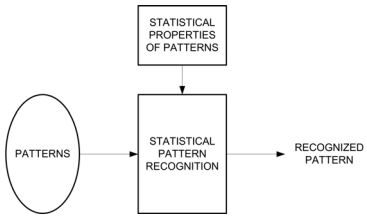

Figure 13. Statistical pattern recognition

IF-THEN rules. A rule covers a pattern x if the antecedent is satisfied (the rule is said to be triggered), [14].

Rule n: IF condition THEN conclusion (7)

A rule set may be not exhaustive (existence of patterns not covered by any rule) and may not be mutually exclusive (several rules may be triggered by the same pattern).

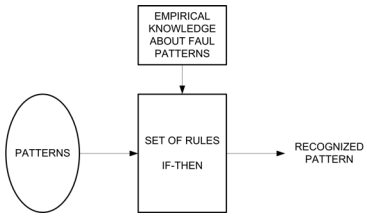

Figure 14. Rule based pattern recognition with knowledge coded into set of IF-THEN rules

Rule based pattern recognition, Fig. 14, as a kind of syntactic pattern recognition can be used instead of statistical pattern recognition if there is clear structure in the patterns. However, the development of a rule base can take great effort to complete. Mathematical descriptions for most fault patterns are produced from linguistic descriptions and expert opinion. Such mathematical descriptions in terms of necessary conditions for patterns are suitable for the rule-based pattern recognition.

Empirical knowledge about fault patterns is used for creation of simple rules for detection of numerous faults. Original rules intended for maintenance personnel are defined as descriptions in English language, usually in just one sentence and catalogued in manuals, [2, 3].

For detection of patterns it is necessary to know EGTs, CHTs, MAP, RPM and rate of change for EGT and CHT, (8) and (9):

$$\Delta E_i = E_{i,t+1} - E_{i,t} \tag{8}$$

$$\Delta C_i = C_{i,t+1} - C_{i,t} \tag{9}$$

where $E_{i,t}$, $E_{i,t+1}$, C_i, $C_{i,t+1}$ are values of E_i and C_i at moments t and t+1. Extreme values E_{max}, C_{max} that are maximal EGT and CHT values within particular record in a log are also needed, (10)-(11):

$$E_{\max} = \max\left(E_1,...,E_{N_C}\right) \tag{10}$$

$$C_{\max} = \max\left(C_1,...,C_{N_C}\right) \tag{11}$$

Beside EGTs and CHTs, the prerequisite for some patterns is previous ignition maintenance (before current flight) and GPS altitude h_{GPS}. Hence, the flag is introduced, F_{Maint} - recent ignition maintenance (before the flight). On installation with no available GPS data altitude information is not present and detection of particular pattern is omitted.

IF (recent ignition maintenance) F_{Maint}=1, else F_{Maint}=0 (12)

Following parameters are used in pattern recognition:

$$E_i,\ E_{max},\ \Delta E_i,\ C_i\ ,\ C_{max},\ \Delta C_i,\ \Delta E_{SPAN},\ M,\ R,\ F_{Maint},\ h_{GPS}$$

ΔE_{SPAN} denotes EGT span (DIFF)
M denotes manifold pressure (MAP)
R denotes engine speed (RPM)

The engine is normally operated with a slightly richer mixture. During leaning process, [1-4,8], EGTs could (temporarily) rise above limits from Table II. Leaning process may interfere with the fault detection producing false alerts. Hopefully leaning is performed only during very short periods in comparison with the duration of total flight and hence this is not a great disadvantage.

C. *Fault Patterns and Rules for Detection*

Total of 17 patterns are considered for inclusion and based on its description in [2,3] appropriate rules are formulated. Patterns in Fig. 15-29 are shown both for same and separate bars versions of CHT-EGT display. Probable causes are also described in more detail in [2,3]. Rules for detection of patterns are upgraded and revised version of rules from [12] that now include temporal changes. Bellow is the list of catalogued patterns (six cylinder engine, N_c=6), but now with derived simple mathematical description (conditions) suitable for program implementation. Resulting conditions are described in (13)-(27). "For one" means "for just one".

1. 75° to 100° EGT rise for one cylinder during flight
   - faulty spark plug, plug, wire or distributor

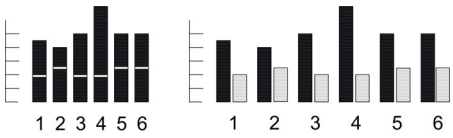

Figure 15. Pattern 1

$$\text{IF } (((E_{max}\text{-}E_i) > 75) \text{ AND } (R > 1500)) \quad \text{for one } i, \quad i=1,...,N_c \quad (13)$$

RPM greater of 1500 (as in cruise flight) is introduce to differ from Pattern 6.

2. EGT increase or decrease after ignition system maintenance
   - improper timing

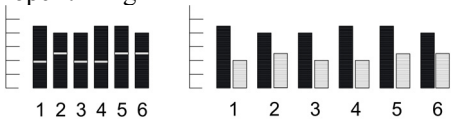

Figure 16. Pattern 2

$$\text{IF } ((F_{Maint}=1) \text{ AND } (M>20) \text{ AND } (((E_i>600) \text{ AND } (E_i<1000)) \text{ OR } (E_i>1500))) \quad \text{for all } i, \quad i=1,...,N_c \quad (14)$$

3. Loss of EGT for one cylinder
   - stuck valve

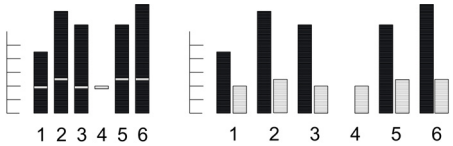

Figure 17. Pattern 3

$$\text{IF } ((M>20) \text{ AND } (E_i>0) \text{ AND } (E_i<600)) \quad \text{for one } i, \ i=1,...,N_c \quad (15)$$

EGT greater of 0 is introduced to differ from pattern 4.

4. Loss of EGT for one cylinder; no digital EGT
   - failed probe or wire harness

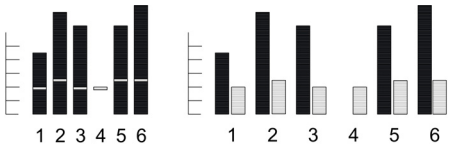

Figure 18. Pattern 4 (same as 3)

$$\text{IF } (E_i = 0) \text{ for any } i, \ i=1,\ldots, N_c \quad (16)$$

5. Decrease of EGT for one cylinder
   - faulty valve lifter

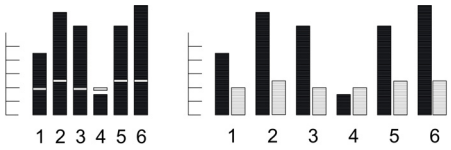

Figure 19. Pattern 5

$$\text{IF } ((M>20) \text{ AND } (E_i>600) \text{ AND } (E_i<1000)) \text{ for one } i, \ i=1,\ldots,N_c \quad (17)$$

6. Decrease of EGT for one cylinder at low RPM
   - low compression

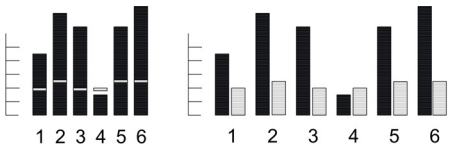

Figure 20. Pattern 6

$$\text{IF } (((E_{max}\text{-}E_i)>500) \text{ AND } (R<1500)) \text{ for one } i, \quad i=1,\ldots, N_c \quad (18)$$

7. EGT and CHT not uniform (injection engines only)
   - dirty fuel injector or fouled plugs

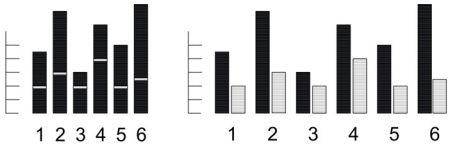

Figure 21. Pattern 7

Degree of uniformity is determined from the E_i/C_i ratio

$$\text{IF } ((E_i/C_i)<3 \text{ OR } (E_i/C_i)>6) \quad \text{for any } i, \quad i=1,\ldots, N_c \quad (19)$$

8. Decrease in EGT for all cylinders
   - decreased airflow into the induction system (ice?!)

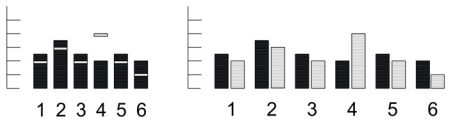

Figure 22. Pattern 8

$$\text{IF } ((M>24) \text{ AND } (E_i>1000) \text{ AND } (E_i<1200)) \text{ for all } i, \ i=1,\ldots,N_c \quad (20)$$

9. Slow rise in EGT, low CHT
   - burned exhaust valve

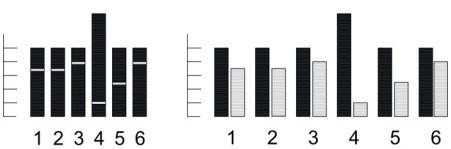

Figure 23. Pattern 9

$$\text{IF } ((E_i > 1550) \text{ AND } (C_i < 300)) \text{ for one } i, \ i=1,\ldots, N_c \quad (21)$$

Introduction of ΔE_i is not quite appropriate as rule refers to very slow change (trend) in large number of logs from successive flights

10. High CHT on cylinders on one side of engine
    - obstruction under the cowling

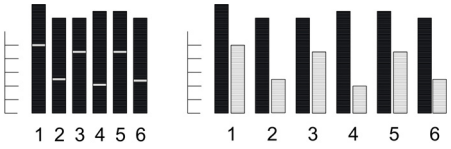

Figure 24. Pattern 10

$$\text{IF } (\text{abs}(C_{\text{left}} - C_{\text{right}}) > 100) \qquad \textit{left}=2n \ \textit{right}=2n+1, \ n=0,1,2 \quad (22)$$

Cylinders on the left side of the engine are even numbered, and on right side are odd numbered.

11. Rapid rise in EGT/CHT of one cylinder
    - detonation

With the introduction of ΔC_i it is expected that C_i rise rapidly with temperature gradient greater than 5 °F/s (30 °F in six seconds – default record time separation).

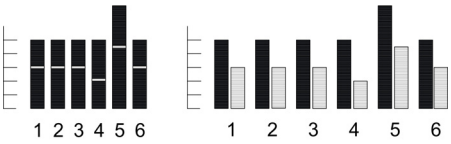

Figure 25. Pattern 11

$$\text{IF } (((E_i > 1550) \text{ AND } (C_i > 450)) \text{ OR } ((C_i > 350) \text{ AND } (\Delta C_i > 30))) \quad \text{for one i, } i=1,\ldots,N_c \quad (23)$$

12. Sudden off scale rise for any or all cylinders
    - preignition or failed probe

With the introduction of ΔE_i it is expected that E_i rise rapidly with temperature gradient greater than 10 °F/s (60 °F in six seconds – default record time separation).

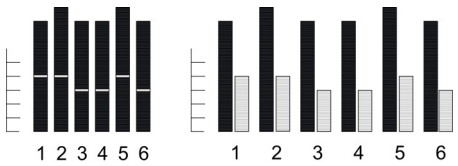

Figure 26. Pattern 12

$$\text{IF } ((E_i > 1550) \text{ OR } ((E_i > 1400) \text{ AND } (\Delta E_i > 60)) \text{ for any } i, \ i=1,\ldots, N_c \quad (24)$$

13. Loss of peak EGT-not implemented, leaning process
14. Decrease in peak or flat EGT response to leaning process-not implemented, leaning process (mixt. adj.)
15. Bellow 10,000 ft full throttle causes EGTs to rise
    - defective mechanical fuel pump

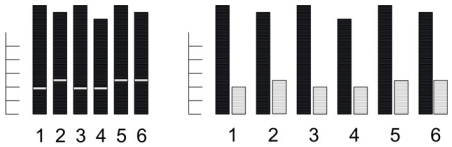

Figure 27. Pattern 15

$$\text{IF } (((h_{GPS} < 10000) \text{ AND } (M > 29)) \text{ AND } (((E_i > 1550) \text{ AND } (C_i < 450)) \text{ OR } ((E_i > 1400) \text{ AND } (\Delta E_i > 30))) \quad \text{for all } i, \quad i=1,\ldots,N_c \quad (25)$$

Manifold pressure MAP>29 due to full throttle requirement.

16. CHT more than 500º, EGT normal. Adjacent EGT may be low
    - leaking exhaust gasket to CHT probe

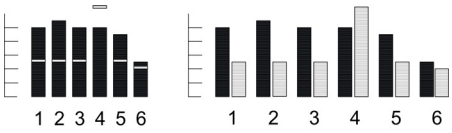

Figure 28. Pattern 16

$$\text{IF } ((C_{max} > 500) \text{ AND } (E_{max} < 1550)) \quad (26)$$

17. Large DIFF at low RPM
    - blow by in cylinder rings

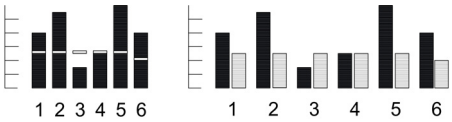

Figure 29. Pattern 17

$$\text{IF } ((\Delta E_{SPAN} > 500) \text{ AND } (R < 1500)) \quad (27)$$

D. *Parsing the Log File*

All records ($N_{records}$) in the log are checked for fault patterns ($N_{patterns}$) using procedure and derived rules:

```
for record=1 to N_records
{
 find E_i, E_max, ΔE_i, C_i, C_max, ΔC_i, ΔE_span, M, R, h_GPS, F_Maint
 for i = 1 to N_patterns
   check rule for pattern(i)
}
```

VII. CONCLUSION

Method for automatic interpretation of engine monitor log is proposed. It parses a log and is watching for engine parameter exceedances and potential fault patterns. Fault pattern recognition is realized using rule based pattern recognition where to each fault pattern correspond one or more rules. Such rules are developed by carefully analyzing decryptions of fault patterns intended for maintenance personnel and expressed in normal English language. Some rules are considered only below the particular altitude (acquire from GPS altitude if available in log) or after recent ignition maintenance and additional maintenance flag is manually determined before pattern recognition. This simple but effective approach may provide significant help to maintenance personnel.

Regime Dependent Aircraft Piston Engine Monitoring

Dubravko Miljković
Hrvatska elektroprivreda, Zagreb, Croatia
dubravko.miljkovic@hep.hr

Abstract - Modern digital engine monitors with separate probes for each cylinder provide useful diagnostic information that precedes large class of engine problems. Limits for alarm alerts in such monitors are set to encompass all phases of engine operation. Method for monitoring engine parameters that considers multiple engine regimes corresponding to a current flight phase (engine run-up, taxi, take-off, climb, cruise and descent) and individual cylinder differences is proposed. Engine operation is presented graphically on the engine monitor display as patterns consisting of CHT/EGT bars. They can be compared to previously stored patterns corresponding to a particular flight phase possibly indicating deviations from previous flights. Flight phases are determined from engine RPM parameter together with speed and vertical speed derived from geometric altitude present in GPS data.

I. INTRODUCTION

Most of general aviation aircrafts (popularly known as small private airplanes) with the exception of turboprop and business jet aircrafts are powered by gasoline (Avgas) piston engines. Piston engine is a heat engine designed to convert energy contained in fuel into mechanical energy. It uses reciprocating pistons to convert pressure into a rotating motion. Aircraft piston engine is not very efficient at converting energy contained in a fuel to a physical motion. Only about one third of energy from fuel is converted to mechanical energy, [1]. Monitoring of engine temperatures make it possible to asses the efficiency of combustion process and indirectly detect most of engine problems, [2]. The main source of engine information traditionally available to pilot are several traditional gauges indicating cylinder head temperature (CHT), exhaust gas temperature (EGT), engine rotational speed (RPM, tachometer), fuel flow, oil temperature and oil pressure, [1,3]. These classical gauges give very basic information about engine condition. A single CHT and EGT gauge gives an average of each cylinder's head and exhaust gas temperature. Graphic engine monitor, [3-6], replaces this older method of viewing of one temperature with precise multi-cylinder engine monitoring of EGT and CHT temperatures plus myriad of other parameters. Piston engines used in general aviation aircrafts have a MTBF (considering total loss of power) in a range of 5000-30000 hours depending on engine complexity, operation and maintenance. With monitoring of engine parameters it is possible to detect impending engine problems and increase engine operational reliability. Engine monitors usually have one set of parameter limits for all flight phases that when exceeded issue an alarm. Introduction of separate parameter limits for various flight phases may improve fault detection capability of engine monitor.

II. ENGINE MONITOR

Engine monitor is advanced and accurate piston engine-monitoring instrument that monitors engine parameters and assist the pilot to operate engine in correct and optimal way, [1-6]. Temperatures are shown graphically as bars on the display of an engine monitor, Fig. 1. Each column in the bar on the display is composed of a stack of segments. The total height of each column represents the EGT while the missing segment in the column represents the CHT. In addition to graphically displaying EGTs and CHTs, on turbocharged engines the instrument continuously displays Turbine Inlet Temperature(s) (TIT). New products often have color display with separate columns for EGTs and CHTs, [6], Fig. 2. Engine monitors cover much more engine data then basic gauges (about dozen of parameters that are also recorded and can be downloaded and analyzed later). Various engine problems appear on the monitor's display as bar graph fault patterns, with two examples shown in Figs. 3 and 4. More examples can be found in [2,4,6].

TABLE I. MONITORED ENGINE PARAMETERS

Parameter	Description
EGT	Exhaust Gas Temperature
CHT	Cylinder Head temperature
OIL TEMP	Oil Temperature [1]
OIL PRES	Oil Pressure [1]
TIT 1	Turbine Inlet Temperature 1[1]
TIT 2	Turbine Inlet Temperature 2 [1]
OAT	Outside Air Temperature
CDT	Compressor Discharge Temperature [1]
IAT	Intercooler Air Temperature [1]
CRB	Carburetor Air Temperature [1]
CDT - IAT	Intercooler cooling
RPM	Rotations Per Minute
MAP	Manifold Pressure
% HP	% Horse Power
CLD	CHT Cooling Rate [2]
DIF	EGT Span [3]
FF	Fuel Flow [1]

[1]optional, [2]fastest cooling cylinder, [3]difference between the hottest and coolest *EGT*

Monitored engine parameters (available in JPI EDM 830) are shown in Table I. The similar set of parameters is also available in other modern engine monitors. Engine monitor automatically records engine parameters during each flight into a log, Fig. 5. New log record is typically recorded every 6 seconds giving 600 records per hour. Recorded data can be downloaded with cable, wireless connection or memory card for later analysis using software, [7], installed on a PC for sophisticated graphical analysis. Suspicious data logs can be sent to a mechanic or engine manufacturer for further clarification.

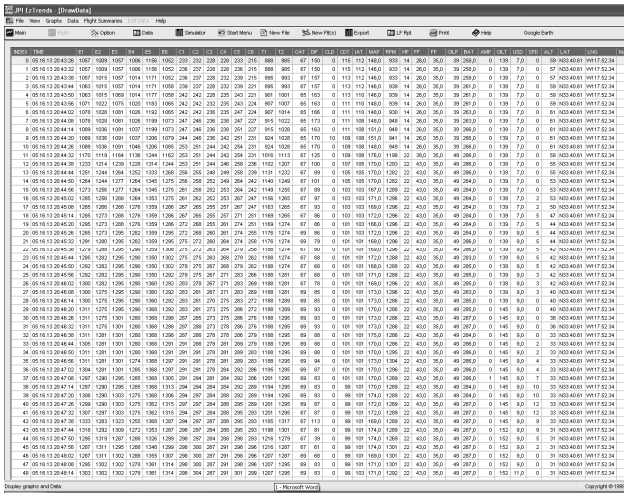

Figure 5. Example from engine monitor log, include engine parameters and GPS data

III. ENGINE PARAMETERS STATISTICS

Graphical representations of the probability distributions of key engine parameters CHT, EGT and TIT in form of frequency histograms are shown in Figs. 6-8, [8]. As can be seen in figures, the probability distributions have several peaks and as such are too complicated for simple application of common mathematical distributions. One solution to this problem is use of the statistical summary in form of percentiles, [8,9]. Percentile is the value of a variable below which a certain percent of observations fall. The 99th percentile is the value below which 99% of the observations may be found. Statistical analysis was performed on three engine log files supplied with the EzTrends2 software, [7],

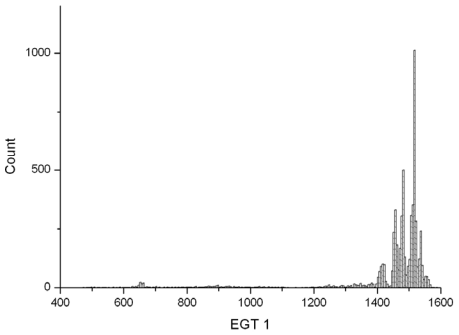

Figure 6. EGT 1 histogram

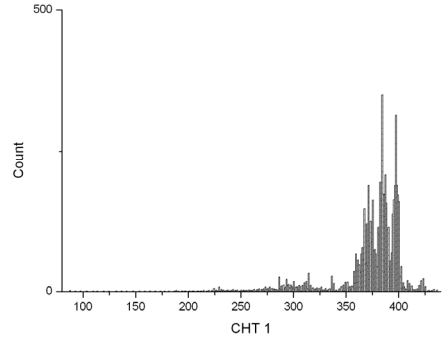

Figure 7. CHT1 histogram

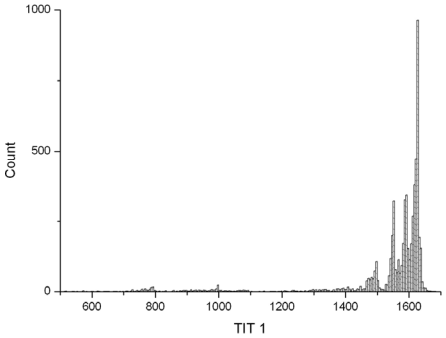

Figure 8. TIT 1 histogram

Flt#49 of duration 2.57 hours, Flt#56 of duration 0.43 hours and Flt#61 of duration 0.45 hours, belonging to a six cylinder, 280 HP turbonormalized Continental engine TSIO-550-G, from 2007 Mooney M20TN Acclaim aircraft, N257TM, with no known faults present. Resulting statistical summary of engine parameters encompassing all engine regimes is shown in form of Box-Wiskers plots in Fig. 9 with corresponding data given in Table II. Engine operation during a whole flight could be additionally summarized with flight summary generated by EzTrends2 software (average, max, min value of engine parameters) as shown in Fig. 10. Temperature deviations form average (see color legend) for each cylinder are shown in small picture. As can be seen, extreme values (minimums and maximums) of engine parameters during normal operation for the period of whole flight, shown in Table II and Fig. 10, are

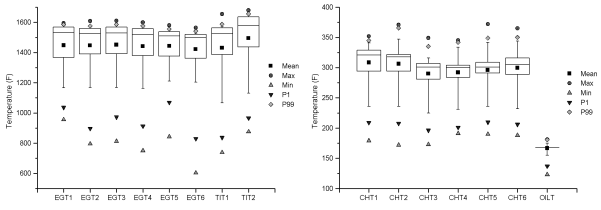

Figure 9. EGT1-6, TIT1, TIT2, CHT1-6 and OILT for all engine operating regimes

TABLE II. STATISTICAL SUMMARY OF SELECTED ENGINE PARAMETERS (TEMPERATURES) ENCOMPASSING ALL ENGINE REGIMES (LIMITS USEFUL FOR ALERTS ARE SHADED)

Param.	Mean μ	Std.Dev.σ	Min	Max	P_1	P_{99}
EGT1	1447,5	143,9	956	1595	1036,6	1586
EGT2	1446,8	149,0	796	1608	897	1576,2
EGT3	1451,3	148,0	813	1610	972	1586,2
EGT4	1441,4	150,6	751	1599	912,8	1577
EGT5	1443,3	118,6	843	1580	1069	1556
EGT6	1422,2	134,6	604	1564	829,2	1542,2

CHT3	290,0	28,0	173	349	196,4	335,2
CHT4	292,0	27,7	191	345	201	342
CHT5	296,0	27,5	190	372	209,6	349
CHT6	299,4	29,9	188	365	206	350,2
OILT	166,7	7,43	123	181	137	181

close to the default (but adjustable) engine monitor alarm limits shown in Table III, [6]. Alarm values are quite close match for EGTs (many monitors use DIF alarm limit instead) and TITs, and somewhat higher for CHTs.

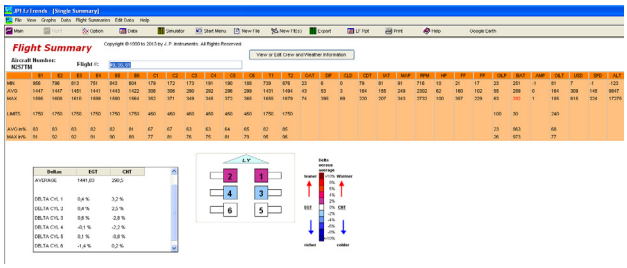

Figure 10. Flight summary as generated by EzTrends2 software

TABLE III. DEFAULT ENGINE MONITOR ALARM LIMITS

Measurement	Default Low Limit	Default High Limit
CHT		450 °F 230 °C
EGT [1]		1550 °F 843 °C [2]
OIL	90 °F 32 °C	230 °F 110 °C
TIT		1650 °F 900 °C
CLD		-60 °F/min -33 °C/min
DIF		500 °F 280 °C

[1]many engine monitors (e.g. JPI) don't have EGT alarm limit but DIF alarm limit instead, upper normal EGT value shown here, [2]on high performance aircraft, 1350 °F (732 °C) engines with less than 200 HP

IV. FLIGHT PHASE DEPENDENT REGIMES

During a flight engine operates through various regimes. In aircraft with a constant speed propeller engine is controlled with the throttle and prop lever. The throttle lever controls the target manifold pressure (MAP) while the prop lever controls the desired rotation speed at the propeller governor expressed in Revolutions Per Minute (RPM). The mixture lever control manages the richness of mixture. Table IV lists several regimes of engine operation corresponding to various phases of flight. Engine parameters during a particular regime fall within a narrower range compared to a wider range corresponding to all regimes, [8,9]. This way one can detect minor deviations for a particular regime. Separating engine operation in regimes can be done in many ways. Some of them are proposed bellow.

A. *Revolutions Per Minute - RPM*

Separation based on the engine operating speed expressed in Revolutions Per Minute (RPM) is quite simple solution, but it has some shortcomings. It doesn't consider altitude, load and manifold pressure (MAP).

TABLE IV. REGIME DETERMINATION FOR CONSTANT SPEED PROPELLER

Phase	Speed kn	Alt.ft QFE[1]	Vertical speed ft/min	RPM	MAP[3]
Engine run-up	0[2]	0[2]	0[2]	800-1000	
Taxi	< 20	0[2]	0[2]	800-1500	
Take-off	<45	0[2]	0[2]	2300+	
Climb	> 45	> 0	> 200	2000+	33-35
Cruise	> 45	> 0	>-200,<200	1800-1500	32
Descent	> 45	> 0	VS <-200	< 1800	18-24
Landing	< 45	0[2]	0[2]	< 1200	

[1]height above a specific aerodrome or ground level, [2]in practical considerations some tolerance must be allowed instead of precise value of 0, [3]approximative values

Same RPM has different meaning in term of engine load during climb, cruise and descent. Relation between the speed, altitude and RPM is shown in Fig. 11. High RPM is present booth in climb and cruise. Engine load is generally much greater during a climb. Example of regime switching variable r that separates operating regimes in 20% RPM brackets is defined by (1), where RPM_{MAX} is maximal value RPM can achieve (≈2850).

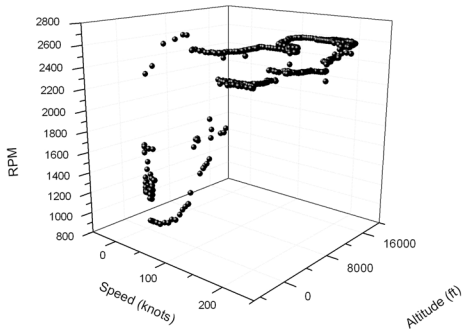

Figure 11. Figure Speed, altitude, RPM combinations during a flight

$$r = \left\lceil \frac{100RPM}{20RPM_{MAX}} \right\rceil \quad (1)$$

B. *Calculated Percent of HP - %HP*

This is more sophisticated choice that considers Revolutions Per Minute RPM, Manifold pressure MAP, fuel flow FF, outside air temperature OAT and sometimes pressure altitude. Horsepower is the product of torque (roughly proportional to MAP) and RPM. At a given torque, HP is directly proportional to RPM. % HP as a function of RPM and MAP is shown in Fig. 12. Regime switching variable r that separates operating regimes in 20% brackets is given with (2), [8,9].

$$r = \left\lceil \frac{\%HP}{20} \right\rceil \quad (2)$$

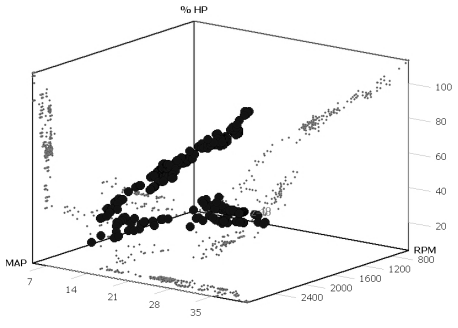

Figure 12. % HP as a function of RPM and MAP (manifold pressure)

C. Flight Phase

Full glass cockpit is still rare in general aviation aircraft. However, GPS receiver is commonly available. Many engine monitors can accept GPS data, Fig. 13. By incorporating GPS speed, GPS geometric altitude and calculated vertical speed to engine monitor RPM parameter it is possible to determine actual flight phase.

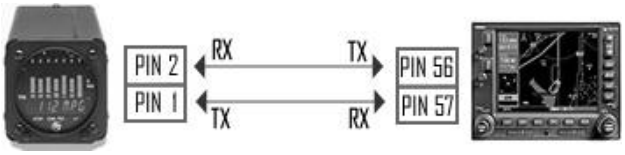

Figure 13. Communication between graphic engine monitor and GPS receiver (JPI EDM 700/80 and Garmin GNS 530) - JPI Instruments

The engine is under different load in climb, cruise and descent that sometimes can't be distinguished from engine parameters alone. The use of speed, vertical speed and engine RPM enables distinguishing of climb, cruise and descent phase. Vertical speed is determined from successive altitudes data Alt_{t1} and Alt_{t2} at t_i and t_{i+1}, (3).

$$VS = \frac{Alt_{t_{i+1}} - Alt_{t_i}}{t_{i+1} - t_i} \tag{3}$$

GPS speed is a groundspeed and in presence of very strong winds may vary significantly from indicated speed (IAS). It would be better if one could get IAS once the aircraft is aloft. Flight phase dependent regimes are particular suitable because most engine monitor documentation and literature describe potential problems in relation to the specific phase of a flight (e.g. "compare temperatures to past climbs") with readily available recommendations about engine operation and corrective actions, [2,5,6]. Speed, altitude and vertical speed during one flight are shown in Figs. 14-16.

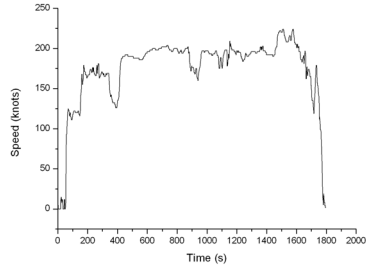

Figure 14. Speed of the aircraft during a typical flight

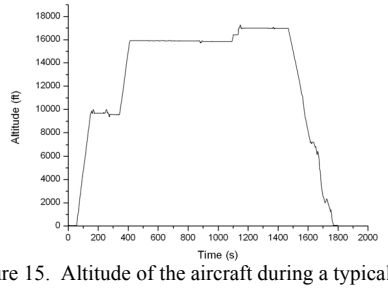

Figure 15. Altitude of the aircraft during a typical flight

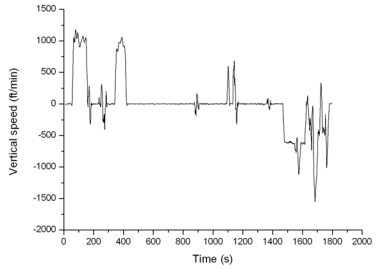

Figure 16. Vertical speed of the aircraft during a typical flight

D. Rules for Flight Phase Determination

Following flight phases are chosen: engine run-up, take-of, climb, cruise, descent. Landing is not included due to the short duration and low RPM that is not hard on the engine. Rules for the determination of the flight phase are given bellow (SPEED is GPS groundspeed, VS is calculated vertical speed from successive readings of GPS altitude and RPM is engine rotation speed):

IF SPEED < 3 AND 800 < RPM < 1700[1] Engine run-up
IF 3 < SPEED < 20 AND 30 < VS = 30[2] AND RPM < 1500 Taxi
IF 3 < SPEED < 45[3] AND 30 < VS = 30[2] AND RPM > 2300 Take-off
IF SPEED > 45[3] AND VS >200 AND RPM > 2000 (?) Climb
IF SPEED > 45[3] AND -200 < VS < 200 Cruise
IF SPEED > 45[3] AND VS < -200 Descent

[1]Recommended values for run-up are bellow 1500, value of 1700 is set after analyzing available logs, [2]In real world small margin of error (e.g. 30 ft/min due to GPS altitude error) must be allowed around value of 0 valid for ideal case, [3]Compromise value to allow for strong headwinds

With previously defined rules very small percentage of time engine parameters will not be labeled to any flight phase (≈1.5%). Disadvantage of such determination of flight phases is that it depends on availability of GPS signal. Under some rare occasions GPS data may be temporary unavailable and in that case only warning alerts not related to flight phase may be issued.

V. FLIGHT PHASE REGIME DEPENDENT STATISTICS

Statistical summaries for six previously defined engine regimes are shown in Figs. 17-22 and Table V**.** Please note that graphs vary in temperature scales (different temperature scale than used for all regimes shown in Fig. 9) and parameter spreads are smaller.

VI. FLIGHT PHASE PROTOTYPE PATTERNS

Within the engine there exist small temperature differences between cylinders due to cylinder position (different air cooling), differences in distance traveled by the air from the intake and differences among injectors. This can be seen as slightly different bar heights belonging to various cylinders. Differences also exist with the change of flight phase. It may be beneficial to compare current pattern with previously stored prototype pattern corresponding to that particular flight phase.

A. Pattern Vector

Pattern vector $\boldsymbol{v}_T$ consist of components E_i and C_i that are EGT and CHT values for cylinder i at some record, N_C is the number of cylinders, (4).

$$v_T = [E_1, \ldots, E_{Nc}, C_1, \ldots, C_{Nc}] \tag{4}$$

B. Pattern Vector Normalization

To later facilitate better pattern comparison pattern normalization is performed, removing some influence of temperature differences within a flight phase to a shape of the pattern. Normalization is performed by determining highest *EGT* among all cylinders, E_{MAX}, (5). *EGT* and *CGT* values are then divided by the E_{MAX}.

$$E_{MAX} = \max(E_i) \qquad i=1,\ldots, N_C \tag{5}$$

Normalized *EGT* values, $E_{N,i}$ are, (6):

$$E_{N,i} = \frac{E_i}{E_{MAX}} \qquad i=1,\ldots, N_C \tag{6}$$

Similarly, normalized *CHT* values, $C_{N,i}$ are, (7):

$$C_{N,i} = \frac{C_i}{E_{MAX}} \qquad i=1,\ldots, N_C \tag{7}$$

All components are within the interval [0, 1], (8),(9):

$$0 <= E_{N,i} <= 1 \qquad i=1,\ldots, N_C \tag{8}$$

$$0 <= C_{N,i} <= 1 \qquad i=1,\ldots, N_C \tag{9}$$

Normalized test pattern is now vector $\boldsymbol{v}_{N,T}$ (10).

$$v_{N,T} = [E_{N,1}, \ldots, E_{N,Nc}, C_{N,1}, \ldots, C_{N,Nc}] \tag{10}$$

C. Prototype Pattern Vector

Prototype pattern vector for flight phase r is the vector $\boldsymbol{v}_{N,P,r}$, (11), that consists of averaged normalized values $\hat{E}_{N,i,r}$ and $\hat{C}_{N,i,r}$ determined by (12) and (13).

$$v_{N,P,r} = [\hat{E}_{N,1,r}, \ldots, \hat{E}_{N,Nc,r}, \hat{C}_{N,1,r}, \ldots, \hat{C}_{N,Nc,r}] \tag{11}$$

$$\hat{E}_{Ni,r} = \sum_{k=1}^{N_r} E_{N,i,r,k} \tag{12}$$

$$\hat{C}_{Ni,r} = \sum_{k=1}^{N_r} C_{N,i,r,k} \tag{13}$$

where $E_{N,i,r,k}$ and $C_{N,i.r,k}$ are EGT and CHT values of kth record and N_r is the total number of records for the flight phase r. Components of normalized prototype vectors for each of six flight phases are shown in Table VI.

Table VI. COMPONENTS OF NORMALIZED PROTOTYPE PATTERNS FOR EACH PHASE (BASED ON AVERAGE VALUES)

Param. P_i	Regime					
	Run-up	Taxi	Take-off	Climb	Cruise	Descent
EGT1	0,9612	0,9614	0,9692	0,9792	0,9952	0,9872
EGT2	0,9518	0,9511	0,9944	0,9974	0,9931	0,9832

VII. METHOD FOR FAULT DETECTION

Previous statistics and temperature profiles for each flight phase can be integrated in a fault detection method as illustrated in Fig. 23. Limit checkers may be applied to measured engine parameters, [10].

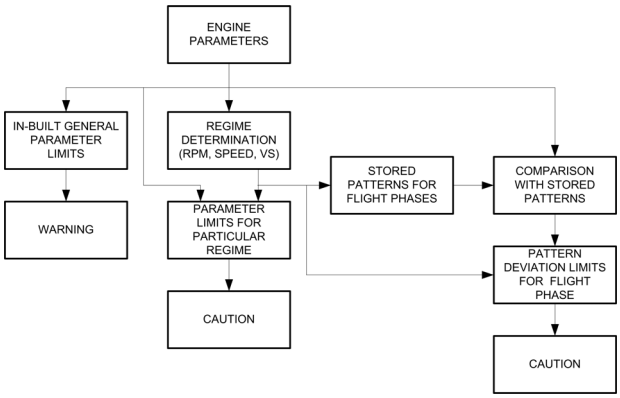

Figure 23. Integration of limit checkers with temperature profile in a method for fault detection

A. Limit Checkers for Global Limits

Limit checkers can be applied using engine parameters limits extracted from engine logs that encompass whole flights and are suitable for detection of severe engine problems issuing a warning alert, (14):

$$L_{L,i} < p_i < L_{H,i} \tag{14}$$

where

$L_{L,i}$ is low limit for parameter p_i
$L_{H,i}$ is high limit for parameter p_i
p_i is engine parameter i

B. Limit Checkers for Regime Dependent Limits

Same technique can also be applied to engine regime dependent limits, (15). This places narrower limits to engine parameters corresponding to a particular engine regime and is suitable for detection of smaller problems.

Such limits are beneficial as it may be of interest to detect smaller problems (issuing less severe caution alerts).

$$L_{L,i,r} < p_i < L_{H,i,r} \quad (15)$$

where

$L_{L,i,r}$ is low limit for regime r
$L_{H,i,r}$ is high limit for regime r

Percentiles from Table V can be used for setting limits.

C. Limit Checkers for Detection of Pattern Deviations

The Euclidian distance between vector of engine parameters represented in normalized engine pattern and stored normalized prototype pattern corresponding to current flight phase is determined. For vectors $\boldsymbol{p}$ and $\boldsymbol{q}$ the Euclidean distance between is given by (16).

$$d(p,q)=\sqrt{(p_1-q_1)^2+(p_2-q_2)^2+\ldots+(p_i-q_i)^2+\ldots+(p_n-q_n)^2} \quad (16)$$

Considering variance for EGTs and CHTs, σ^2_E and σ^2_C, weighted Euclidean distance between test vector $\boldsymbol{v}_{N,T}$ and prototype vector $\boldsymbol{v}_{N,P,r}$ is given by (17). Typical values for variances (cruise) are σ^2_E=0.000025 and σ^2_C= 0,000005.

$$d_{v_{N,T},v_{N,P,r}}=\sqrt{\frac{1}{\sigma_E^{\,2}}\sum_{i=1}^{i=N_E}\left(E_{N,i}-\hat{E}_{N,i,r}\right)^2+\frac{1}{\sigma_C^{\,2}}\sum_{i=1}^{i=N_C}\left(C_{N,i}-\hat{C}_{N,i,r}\right)^2} \quad (17)$$

Distribution of distances $d_{\boldsymbol{v}N,T,\boldsymbol{v}N,P,r}$ from all test patterns to prototype pattern for each regime r is shown in Fig. 24. Statistical summary of distance between prototype and patterns from the same regime are given in Table VII.

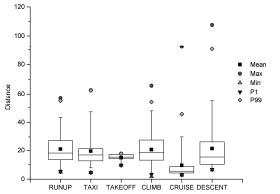

Figure 24. Difference between current and stored prototype patterns

TABLE VII. STATISTICAL SUMMARY: DISTANCES FROM PROTOTYPE

Regime	Mean μ	Std.Dev.σ	Min	Max	P_1	P_{99}
Run-up	20,87927	11,07503	4,89324	56,67822	5,2041	54,87364
Taxi	19,4386	11,36059	4,50276	62,60759	4,51575	62,50814
Take-off	14,88883	2,91856	9,60374	17,73574	9,60374	17,73574
Climb	20,49501	11,62248	1,69166	65,63849	3,2465	54,02237
Cruise	9,55232	10,01092	2,80137	92,11229	2,95024	45,60141
Descent	21,23669	16,6172	6,37109	107,54823	6,73234	90,53074

*Shaded values for P99 can be used for limits

Limit checker can be applied to distance as well, (18).

$$d_r < L_{H,r} \quad (18)$$

If distance is greater than 99th percentile limit caution is issued. This indicates that shape of a current pattern is too different from the stored prototype for a flight phase.

D. Percentiles and Detection Sensitivity

Failures in many technical systems follow a risk pyramid illustrated in Fig. 25, [8]. General idea behind this figure is that in a large sample number of minor events precede more severe and very severe events. Percentiles are fixed to 1% and 99% values, and this sensitivity may be set too high even for the smallest engine problems. Considering just upper limits of engine parameters (99th percentiles), 600 records of engine parameter per hour would translate to average of 6 caution alerts per hour

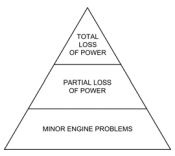

Figure 25. Pyramidal relationship of risk, tailored to engine problems

Figure 26. Permitted number of threshold exceedances within a specified time frame

for each parameter, or 72 caution alerts for all EGT and CHT values in 6 cylinder engine. To adjust the sensitivity of detection one may additionally specify the number of limit exceedances per time period (use of counter) that should be reason for concern (e.g. more than 5 exceedances per parameter in last 5 minutes). This number is adjusted to necessary fault detection sensitivity (fine tuning). Forgetting factor is needed (e.g. in form of resetting fault counter after a period of time). Combining thresholds and the number of threshold exceedances within specified time frame, Fig. 26, distinguishing between sporadic and frequent events, appropriate sensitivity could be achieved.

VIII. CONCLUSION

The graphic engine monitor is a tool for engine management that contributes to proactive maintenance. Exploiting statistical properties of engine parameters may be useful when devising acceptable parameter limits for fault detection. Statistical summary of engine parameters in forms of percentiles can be used for describing complex empirical distributions in a simple way. One fits all statistic of engine parameters acquired by analyzing the whole engine log is suitable for devising wide parameter limits for warning (severe) alert. For detection of smaller problems more precise engine parameter limits are needed that are related to a particular engine operating regime. Combining engine RPM with the additional GPS data, actual flight phase can be determined and used for separation of engine operation into regime corresponding to a flight phase. Within a particular regime engine parameters can be compared to much narrower limits, that if exceeded issue caution (less severe) alert. Use of flight phase for regime determination has an advantage of documented engine parameter values that are expected in various phases of flight. Temperature profile comparison with stored profiles (patterns) for each flight phase is included for addition detection of temperature anomalies. Percentile limits are often too sensitive for detection of potential faults; hence permitted number of threshold exceedances within a specific time period may be introduced to achieve desired fault detection sensitivity.

Konfiguriranje Profinet I/O mreže u radu sa energetskim pretvaračem

Goran Malčić, Danijel Maršić, i Julije Čučuk
Tehničko veleučilište u Zagrebu
goran.malcic@tvz.hr

Sažetak - Rad u realnom vremenu je jedan od osnovnih uvjeta koji računalna mreža mora zadovoljiti da bi bila primjenjiva u industrijskom okruženju. Upravo taj uvjet uz određene adaptacije je moguće postići sa primjenom ethernet tehnologije, te se u tom dijelu vidi najveći napredak. U ovom radu prikazan je stručni istraživački rad na implementaciji industrijske računalne mreže Profinet I/O na primjeru povezivanja pretvarača napona i frekvencije sa dvije različite izvedbe nadređenih industrijskih računala tvrtke Siemens. Konfiguracija i upravljački program su izvedeni u programskim okruženjima STEP 7 te TIA Portal V12 kako bi se uočila razlika u implementaciji. Opisan je i prikazan na primjeru način upravljanja i konfiguracije komunikacije pretvarača ACS880 (ABB) sa nadređenim PLC uređajem u dva slučaja – PLC sa integriranim Ethernet portom te PLC uređaj sa zasebnim komunikacijskim modulom.

I. UVOD

Razloge zbog kojih je ethernet mrežna tehnologija važna za industriju i zbog kojih se zadnjih desetak godina probija u područje industrijskih računalnih mreža treba tražiti u njenoj relativno jednostavnoj primjeni i sveopćoj prisutnosti u društvu. Ethernet je sigurno najrašrenija mrežna tehnologija koja se danas aktivno koristi u svijetu - relativno stabilna, vrlo razvijena te dobro poznata sklopovska i programska infrastruktura koja se svakim danom nadograđuje novim proizvodima i idejama. Osim toga, postala je u širkom smislu riječi 'svakodnevna' mrežna infrastruktura jer osim što je svugdje prisutna, za konfiguraciju takve računalne mreže nisu potrebna potrebna velika stručna znanja i zato ih posjeduje veliki broj ljudi.

Naravno, ideja jedne mrežne infrastrukture na nivou cijele tvornice, počevši od pogonske do upravljačke razine, prisutna je odavno (npr. Siemens mrežna struktura ProfiBus tehnologije PA, DP, FMS [4]). Naravno, iznad tih razina bila je uvijek prisutna ethernet tehnologija koja se neovisno razvijala u odnosu na pogonske odnosno industrijske računalne mreže. Prije desetak godina na tržištu su se pojavili prvi proizvodi koji su nudili kompletna riješenja industrijskih računalnih mreža temeljenih na ethernet sklopovlju odnosno infrastrukturi, ali sa vlastitim protokolima (npr. AllenBradley Ethernet/IP tehnologija [5]). Naime, temeljna zapreka kod razvoja etherneta na pogonskom nivou je uvjet da mreža mora raditi unutar kritičnog vremena (eng. Real time). Realno vrijeme znači da sustav procesuira vanjske događaje unutar definiranog vremena [1][2]. Definirano vrijeme odziva je uglavnom ≤ 5ms za standardne aplikacije.

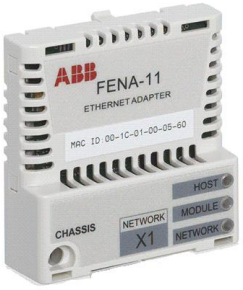
Tvrtka Siemens razvila je svoju tehnologiju Profinet (eng. *PROcess FIeld NET*) koja se bazira na Ethernet tehnologiji i na korištenju standarda. Profinet nije samo robusnija inačica Etherneta prilogođena za rad u industrijskim uvjetima. Inteligentni vanjski uređaji daju veliku količinu podataka za prijenos koja prelazi mogućnosti postojećih sabirničkih mreža i time ovoj tehnologiji čak daje prednost u odnosu na postojeće pogonske mreže. Profinet koristi optimizirani komunikacijski kanal za komunikaciju u realnom vremenu, što garantira prijenos vremensko kritičnih podataka između različitih stanica u mreži, unutar definiranog intervala. Real-time kanal može se implementirati na standardnim Ethernet kontrolerima primjenom softverskih riješenja ili u formi specijalnog hardverskog riješenja, a bazira se na 2 sloju ISO/OSI referentnog modela (Real-time protokol - RTC 1-3). Za potrebe Profinet real-time komunikacija kod procesa gdje je potrebna vrlo brza reakcija sustava upravljanja, nužan je bio razvoj ERTEC 400 i 200 (eng. *Enhanced Real Time Ethernet Controller*) ASIC procesora.

U literaturi se navodi da je rad sa Profinet tehnologijom moguć nabavom palete Siemens proizvoda te se dobiva dojam kako je to relativno zatvorena tehnologija. Zbog toga je ovom radu prikazano povezivanje pretvarača napona i frekvencije tvrtke ABB na PLC računalo serije S7-300 preko Profinet mreže. Prema uputama proizvođača ABB, takvo povezivanje i rad u realnom vremenu je moguć samo ako posjedujete PLC S7 sa integriranim Profinet komunikacijskim portom na procesoru. Takav sustav je objašnjen u prvom dijelu rada i svi problemi koji dolaze jer oprema nije od tvrtke Siemens, a ABB uputstva su bila nedostatna. Nadalje, ono što se nigdje ne navodi kao moguće, a niti se ne objašnjava slučaj kada posjedujete integrirani Profinet port na samom procesoru ili što učiniti ako već imate postojeći upravljački sustav kojemu uz procesor S7 serije dodajete zasebnu Profinet komunikacijsku karticu. Takav pristup je opisan u drugom dijelu rada i pokazuje da se može upogoniti i takav sustav.

Sustav je u oba slučaja izveden koristeći Profinet I/O komunikacijski koncept za implementaciju modularnih, distribuiranih aplikacija baziranih na industrijskom Ethernetu.

II. KOMUNIKACIJSKI MODUL FENA-11

Kako bi se pretvarač napona i frekvencije ACS 880 (ABB) mogao spojiti na ethernet mrežu potrebno je ugraditi komunikacijski modul FENA-11 za ethernet mrežu. Modul je kompatibilan s mrežnim standardima IEEE 802.3 i IEEE 802.3u i podržava tri protokola: *Modbus/TCP*, *EtherNet/IP* i *PROFINET IO*. FENA-11 modul kao medij podržava upletene parice čiji odsječak mora biti kraći od sto metara. Komunikacijski modul FENA-11 služi za slanje upravljačke riječi pretvaraču (start, stop), zadavanje reference pretvaraču, čitanje statusnih informacija i stvarne vrijednosti pretvarača te uklanjanje grešaka na pretvaraču. Komunikacijski modul podržava 10 Mb/s i 100 Mb/s brzine prijenosa podataka te automatski detektira korištenu brzinu u mreži. Na modulu se nalaze tri LED indikatora (HOST, MODULE, NETWORK) koji služe za dijagnostiku (Slika 1.).

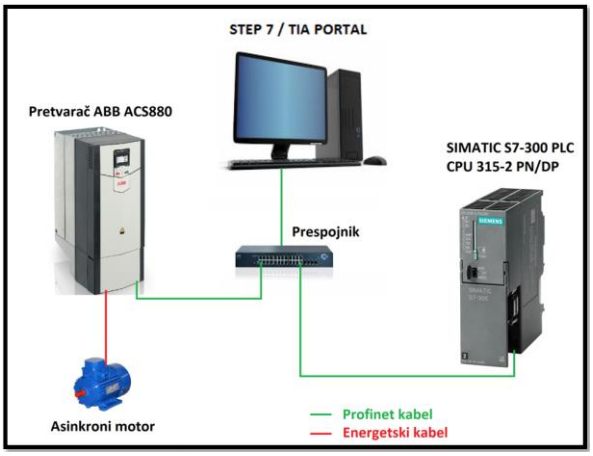


Slika 1. Komunikacijski modul FENA-11

III. S7-300 SA INTEGRIRANIM ETHERNET PORTOM

A. *Idejno rješenje*

U prvoj izvedbi sustava ostvareno je povezivanje nadređenog PLC uređaja sa integriranim Ethernet portom (CPU 315-2 PN/DP) te pretvarača napona i frekvencije ACS880 preko industrijske računalne mreže Profinet I/O. Razlog korištenja ovakve konfiguracije (CPU 315-2 PN/DP) u prvoj izvedbi sustava jest integrirani Ethernet port na samoj procesorskoj jedinici, što omogućava direktnu komunikaciju s podređenim uređajem (pretvaračem frekvencije) preko Profinet I/O protokola. To je ujedno i izvedba principa komunikacije predložena u priručniku proizvođača komunikacijskog modula FENA-11. Sve IP adrese u sustavu moraju biti statičke.



Slika 2. Idejno rješenje povezivanja prve izvedbe sustava

B. *Princip komunikacije*

Pretvarač frekvencije ACS880 može za komunikaciju sa nadređenim PLC uređajem koristiti više struktura procesnih podataka (eng. *Parameter Process data Object*, skraćeno *PPO*) definiranih prema PROFIdrive profilu 2.0. U ovom slučaju za prijenos podataka između PLC uređaja i pretvarača frekvencije koristi se *PPO Type 7* struktura podataka.

Odabrana struktura procesnih podataka (PPO) ima 12 procesnih riječi (PZD). Izlazne riječi služe za upravljanje radom, dok ulazne služe za nadgledanje statusa pretvarača frekvencije. Opis strukture procesnih podataka PPO TYPE 7 korištenih u ovoj izvedbi je prikazana na Slici 3.

	ULAZNI SMJER PODATAKA		IZLAZNI SMJER PODATAKA	
PROCESNA RIJEČ	OPIS	ADRESA	OPIS	ADRESA
PZD1	Statusna riječ	PIW256	Upravljačka riječ	PQW256
PZD2	Stvarna brzina vrtnje	PIW258	Referenca brzine	PQW258
PZD3 PZD4	Frekvencija motora	PIW262	Ne koristi se	
PZD5 PZD6	Struja motora	PIW266	Ne koristi se	
PZD7 PZD8	Moment motora	PIW270	Ne koristi se	
PZD9 PZD10	Snaga motora	PIW274	Ne koristi se	
PZD11 PZD12	Temperatura okoline	PIW278	Ne koristi se	

Slika 3. Korištena struktura procesnih podataka (PPO) Type 7

Upravljačka riječ je skupina od 16 internih binarnih signala, čija stanja određuje program PLC uređaja, koji moraju biti dostupni internoj sekvenci sustava upravljanja odnosno regulatoru pretvarača napona i frekvencije. U ovom rješenju adresa MW100 sadrži upravljačku riječ čiji pojedinačni bitovi imaju značenje prikazano na Slici 4.

Struktura upravljačke riječi PZD1				
bajt	bit	Opis značenja pojedinačnog bita	BIN	HEX
M101	0	Upravljački signal OFF1	0	E
	1	Upravljački signal OFF2	1	
	2	Upravljački signal OFF3	1	
	3	Omogući rad odabranog upravljačkog signala	1	7
	4	Omogući generiranje rampe	1	
	5	Pokreni generator rampe	1	
	6	Omogućavanje reference	1	
	7	Reset greške	0	
M100	0	Nije podržano	0	4

	3	Korisnički specificirani bitovi	0	
	4	Korisnički specificirani bitovi	0	0
	5	Korisnički specificirani bitovi	0	
	6	Korisnički specificirani bitovi	0	
	7	Korisnički specificirani bitovi	0	

Slika 4. Struktura upravljačke riječi PZD1

Za upravljanje pogonom putem Profinet I/O mreže koriste se digitalni upravljački signali OFF1 do OFF3. U ovom slučaju za pokretanje i zaustavljanje motora prema rampi koristit će se pozitivni brid upravljačkog signala ON/OFF1 što znači da je upravljačke signale OFF2 i OFF3 potrebno deaktivirati postavljanjem u logičko stanje 1. Jednako tako, potrebno je i neke od ostalih bitova upravljačke riječi postaviti u logičko 1 kako bi pretvarač bio spreman za pokretanje. Kako bi se to postiglo u upravljačku riječ mora biti upisana kombinacija $047E_{hex}$ što u stanje logičkog 1 postavlja pojedinačne bitove kako je prikazano na Slici 4.

U ovom rješenju se statusnu riječ može nadgledati i analizirati korištenjem adrese MW200 čiji pojedinačni bitovi imaju značenje prikazano na Slici 5.

Struktura ulazne statusne riječi PZD1		
bajt	bit	Opis značenja pojedinačnog bita

C. *Implementacija u STEP 7/TIA Portal V12*

Prilikom testiranja sustava utvrđeno je da ne postoje značajnije razlike u postupku implementacije programskog rješenja sustava između programskih paketa *STEP 7* i *TIA Portal V12*. Zbog toga je postupak implementacije prikazan u razvojnoj okolini *TIA Portal V12* s obzirom da se radi o novijoj generaciji programske podrške za sustave automatizacije tvrtke *Siemens*.

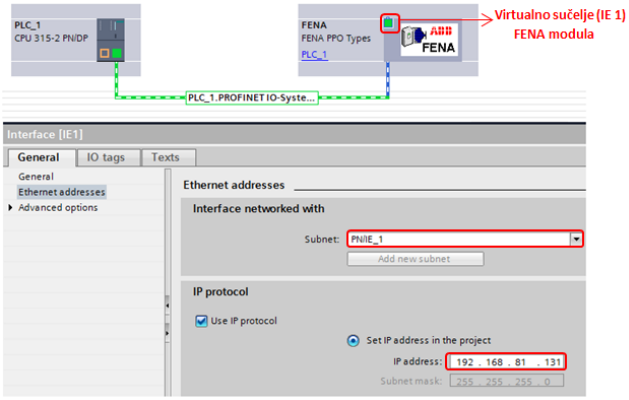
Prije izrade programske podrške u *TIA Portal-u* potrebno je prvo na energetskom pretvaraču podesiti parametre za komunikaciju preko Profinet I/O mreže. Na taj način će pretvarač biti vidljiv nadređenom PLC uređaju na mreži odnosno u upravljiv preko Profinet I/O mreže. Parametri pretvarača za mrežnu komunikaciju su podešeni sukladno uputama u priručniku proizvođača.

Nakon izrade novog projekta u *TIA Portal-u* potrebno je odabrati korištenu procesorsku jedinicu, a potom u prozoru za izradu sklopovske konfiguracije podesiti parametre ethernet porta. U ovom rješenju odabrana je IP adresa 192.168.81.130, maska podmreže 255.255.2550 i naziv uređaja na mreži *pn-io*.

Kako je PLC uređaj u stvarnosti jednim krajem spojen na (**X2**) ethernet sučelje procesorske jedinice a sa druge strane na komunikacijski modul pretvarača, potrebno je u prozoru sklopovske konfiguracije prvo definirati virtualnu Profinet I/O mrežu na koju se potom dodaje virtualni komunikacijski modul pretvarača FENA-11. Prije toga je potrebno instalirati upravljački program (GSD datoteku) za Profinet I/O komunikacijski modul FENA-01/11 preuzet od njegovog proizvođača (ABB).

Kako bi komunikacijski modul FENA-11 mogao komunicirati sa PLC uređajem potrebno je podesiti i njegove parametre. U ovom rješenju odabrana je IP adresa 192.168.81.131, maska podmreže 255.255.255 i naziv uređaja na mreži *fena*. Važno je napomenuti da IP adresa PLC uređaja i adresa komunikacijskog modula FENA-01/11 mora biti u istoj mreži, te da IP adresa u sklopovskoj konfiguraciji mora odgovarati IP adresi podešenoj u parametrima pretvarača.

Kako bi se Profinet I/O parametri dodijelili komunikacijskom modulu FENA-01/11 potrebno je pritisnuti na virtualno sučelje FENA modula (*IE 1*) te u *Ethernet addresses* postavkama odabrati izrađenu virtualnu Profinet I/O mrežu (PN/IE_1) i upisati IP adresu nadređenog kontrolera (192.168.81.130). Kao što se može primijetiti na Slici 6. maska podmreže mora biti ista kao i na procesorskoj jedinici (255.255.255.0) te se ne može mijenjati.



Slika 6. Dodjeljivanje Profinet I/O parametara modulu FENA-11

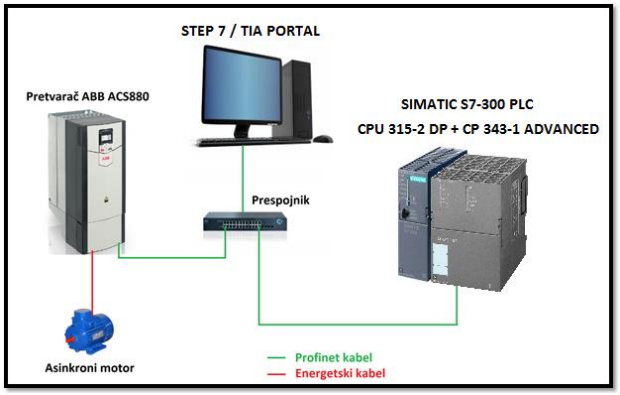
Posljednji korak u konfiguriranju pretvarača frekvencije za rad i slušanje zahtjeva sa Profinet I/O mreže je definiranje ulazno – izlaznih adresa pretvarača kojima će se slati odnosno primati poruke odabrane strukture podataka. Dvostrukim klikom na FENA modul otvara se ekran za pregled uređaja. Pomoću „povuci/ispusti“ metode umeće se već opisana PPO Type 7 struktura podataka u FENA komunikacijski modul.

Zadnji korak je izrada upravljačkog programa u organizacijskom bloku OB1. Upravljačka (PQW256) i statusna riječ (PIW256) se nalaze u perifernoj izlaznoj (PQ) odnosno ulaznoj memoriji (PI) PLC uređaja kod kojih nije moguće pristupati pojedinačnim bitovima u ladder dijagramu. Kako bi se to omogućilo, potrebno je uporabom naredbe za premještanje podataka (MOVE) prebaciti sadržaj upravljačke i statusne riječi iz periferne memorije u internu bit memoriju PLC uređaja kod koje je moguće pristupati pojedinačnim bitovima.

IV. S7-300 SA ZASEBNIM KOMUNIKACIJSKIM MODULOM

A. *Idejno rješenje*

U drugoj izvedbi sustava ostvareno je povezivanje nadređenog PLC uređaja sa zasebnim komunikacijskim modulom (CP 343-1 Advanced) i pretvarača napona i frekvencije ACS880 preko industrijske računalne mreže Profinet I/O (Slika 7.). Za centralnu procesorsku jedinicu odabran je CPU 315-2DP iz serije SIMATIC S7-300 serije koji ima integrirani PROFIBUS port. Kako bi CPU 315-2DP mogao komunicirati preko Profinet I/O mreže korišten je zasebni komunikacijski modul CP 343-1 Advanced koji služi kao Profinet I/O kontroler za operacije sa distribuiranim I/O uređajima na mreži.



Slika 7. Idejno rješenje povezivanja druge izvedbe sustava

B. *Princip komunikacije*

Kako bi PLC uređaj mogao komunicirati preko zasebnog komunikacijskog modula sa pretvaračem frekvencije potrebno je u upravljačkom programu pozvati komunikacijske blokove:

- FC11 „PNIO_SEND“ (za slanje podataka),
- FC12 „PNIO_RECV“ (za primanje podataka).

Karakteristike komunikacijskih blokova FC11 i FC12 su sljedeće:

- FC11 i FC12 su sinkroni komunikacijski blokovi,
- Za S7-300 kontrolere blokovi se nalaze u „SIMATIC_NET_CP“ biblioteci,
- Blokovi se moraju pozvati u glavnom organizacijskom bloku OB1,
- Završetak operacije prikazan je statusima „DONE“, „NDR“ ili „ERROR“

Zadaća komunikacijskoga bloka FC11 je prenositi podatke iz korisničkog programa centralne procesorske jedinice u modul CP343-1 Advanced. Blok prenosi podatke namijenjene izlaznim uređajima (eng. *IO devices*) iz zadanih izlaznih adresa CPU-a u CP modul. Kada se FC11 poziva u OB1 potrebno je unijeti parametre objašnjene na Slici 8.

Ime	Vrijednost	Komentar
CPLADDR	W#16#100	Početna izlazna adresa CP modula zapisana u hexadecimalnom obliku
MODE	B#16#0	Kako se CP modul koristi samo kao Profinet I/O kontroler MODE = 0
LEN	24	Broj bajtova koje treba poslati iz područja definiranog u varijabli SEND (**BYTE 24**)
SEND	P#**DB1**.**DBX0.0** **BYTE 24**	**DB1** – Podatkovno područje u koje se spremaju izlazne PZD riječi **DBX0.0** - Početna adresa izlaznih adresa pretvarača **BYTE 24** – Veličina izlaznih adresa pretvarača
IOCS	P#**DB2**.**DBX0.0** **BYTE 4**	**DB2** – Podatkovno područje u koje se spremaju informacije o stanju izlaznog područja **DBX0.0** – Početak adresa informacije **BYTE 4** – se dobiva iz formule (LEN/8+1)
DONE	M10.0	Bit koji prikazuje da li je slanje uspješno
ERROR	M10.1	Bit koji prikazuje da li je došlo do greške
STATUS	MW12	Statusna adresa za dijagnostiku i greške
CHECK_IOCS	M10.3	Pomoćni bit koji pokazuje treba li IOCS biti razmotren

Slika 8. Objašnjenje izrađenog komunikacijskog bloka FC11

Komunikacijski blok FC12 prima podatke iz modula CP343-1 Advanced i upisuje ih u korisnički program u CPU-u. Blok prihvaća procesne podatke ulaznih uređaja kao i informaciju o stanju od CP modula i pohranjuje u zadano ulazno područje CPU-a. Kada se FC12 poziva u OB1 potrebno je unijeti parametre objašnjene na Slici 9.

Ime	Vrijednost	Komentar
CPLADDR	W#16#100	Početna ulazna adresa CP modula zapisana u hexadecimalnom obliku
MODE	B#16#0	Kako se CP modul koristi samo kao Profinet I/O kontroler MODE = 0
LEN	24	Broj bajtova koje treba prihvatiti iz područja definiranog u varijabli RECV (**BYTE 24**)
RECV	P#**DB3**.**DBX0.0** **BYTE 24**	**DB3** – Podatkovno područje u koje se spremaju ulazne PZD riječi **DBX0.0** - Početna adresa ulaznih adresa pretvarača **BYTE 24** – Veličina ulaznih adresa pretvarača
IOPS	P#**DB4**.**DBX0.0** **BYTE 4**	**DB4** – Podatkovno područje u koje se spremaju informacije o stanju izlaznog područja **DBX0.0** – Početak adresa informacije **BYTE 4** – se dobiva iz formule (LEN/8+1)
NDR	M14.0	Bit koji prikazuje da li je slanje uspješno
ERROR	M14.1	Bit koji prikazuje da li je došlo do greške

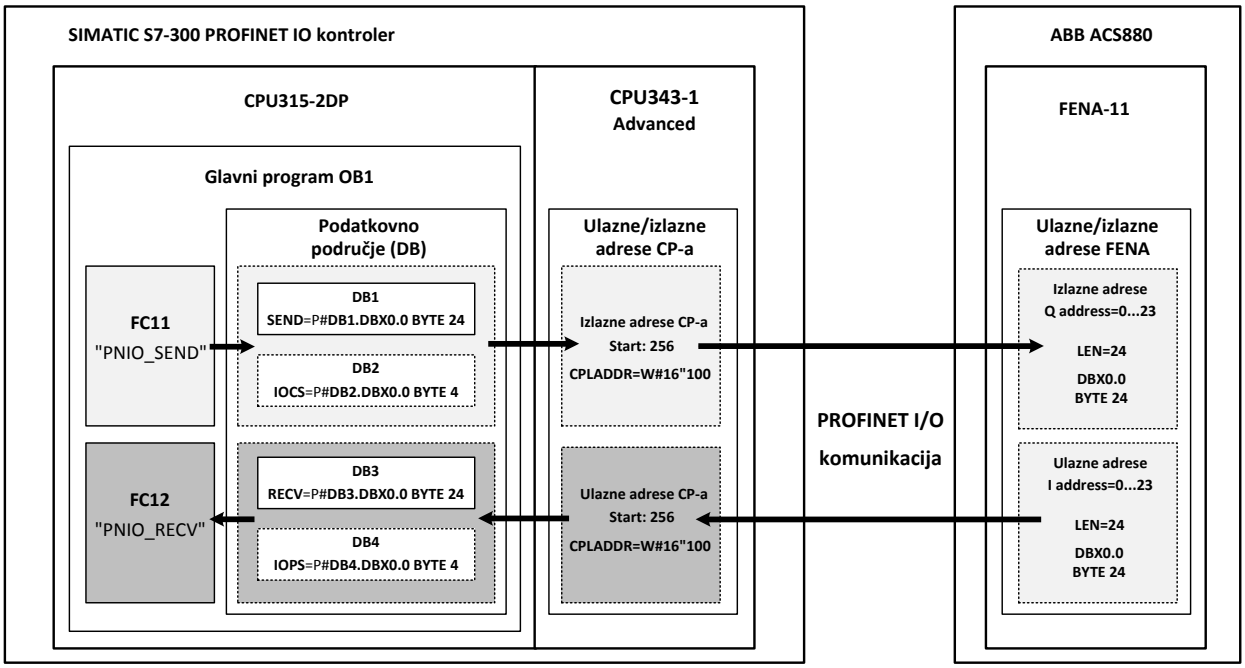
CHECK_IOPS	M14.2	Pomoćni bit koji pokazuje treba li IOPS biti razmotren
ADD_INFO	MW18	Dodatna dijagnostička informacijska adresa

Slika 9. Objašnjenje izrađenog FC12 komunikacijskog bloka

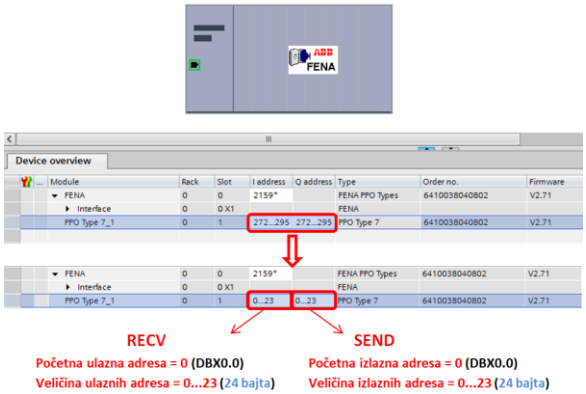
Za komunikaciju u sustavu koristi se *PPO Type 7* struktura podataka, isto kao u slučaju konfiguracije S7-300 sa integriranim portom, ali se razmjena podatka vrši preko komunikacijskih blokova FC11 i FC12 [6]. Slika 10. prikazuje principnu blok shemu PROFINET I/O komunikacije u sustavu. Kako bi pomoću komunikacijskog bloka FC11 iz glavnog programa OB1 mogli poslati podatak komunikacijskom modulu FENA-11 potrebna su dva podatkovna područja unutar procesorske jedinice. Podatkovni blok DB1 (SEND) služi za upisivanje procesnih PZD riječi dok podatkovni blok DB2 (IOCS) služi za spremanje informacija o stanju izlaznog područja. Prilikom upisivanja vrijednosti varijable SEND potrebno je definirati podatkovni blok (u ovom slučaju DB1), početak izlazne *Q* adrese FENA modula (DBX0.0) te njihovu ukupnu veličinu (BYTE 24) što se zajedno zapisuje u obliku pokazivača P#DB1.DBX0.0 BYTE 24. Komunikacijski procesor CP343-1 Advanced preuzima podatke iz podatkovnog bloka DB1 i preko svojih izlaznih adresa ih prosljeđuje FENA-11 komunikacijskom modulu pretvarača. Parametar CPLADDR označava početne izlazne adrese CP modula zapisane u heksadecimalnom obliku. Kako je početna izlazna adresa 256, potrebno ju je pretvoriti u heksadecimalni broj što se zapisuje kao W#16#100. Modul FENA-11 dobiveni podatak od strane CP modula obrađuje i šalje upravljačkoj jedinici pretvarača frekvencije ACS800. Komunikacijski blok FC12 za primanje podataka od strane CP modula djeluje na istom principu kao i FC11, jedino što se podaci šalju iz ulaznih *I* adresa FENA modula u ulazne adrese CP modula. Nakon toga se podaci prosljeđuju podatkovnom bloku (DB3) u procesorskoj jedinici, dok podatkovni blok DB4 služi samo za spremanje informacija o stanju ulaznog područja. Ostali parametri (NDR, ERROR, STATUS. Itd.) u obje funkcije služe samo nadgledanje grešaka u komunikaciji.

C. *Implementacija u STEP 7/TIA Portal V12*

Postupak sklopovske konfiguracije u programskim paketima *STEP 7/TIA Portal V12* sadrži sve korake koji su potrebni kod rada sa integriranim Profinet portom. Naravno, u ovom slučaju se sva podešenja vrše na zasebnom komunikacijskom modulu CP343-1 Advanced za koji se definira virtualna Profinet I/O mreža i dodaje virtualni komunikacijski modul pretvarača FENA-11. Kako se koristi zasebni komunikacijski modul početne ulazne i izlazne adrese pretvarača frekvencije moraju biti postavljene na način da kreću od 0 (Slika 11.).



Slika 10. Principna blok shema Profinet I/O komunikacije u sustavu



Slika 11. Definiranje ulazno – izlaznih adresa pretvarača (PPO 7)

Upravljački program sadrži komunikacijski blok FC11 koji koristi (DB1) podatkovno područje za spremanje izlaznih PZD riječi sa pretvarača veličine 24 bajta i (DB2) za spremanje informacije o stanju izlaznog područja pretvarača veličine 4 bajta. Blok FC12 blok koristi (DB3) za spremanje ulaznih PZD riječi sa pretvarača veličine 24 bajta i (DB4) za spremanje informacije o stanju ulaznog područja pretvarača veličine 4 bajta.

V. ZAKLJUČAK

S obzirom na u uvodu navedene prednosti etherneta, primjena Profinet mrežne tehnologije u izgradnji industrijske računalne mreže na pogonskom nivou trebao bi biti relativno jednostavan postupak primjenjujući norme i poštivajuću uputstva proizvođača opreme. U ovom radu je prikazano kako podrška, odnosno uputstva za rad sa ovakvim sustavima su više nego nedostatna. Zbog toga je provedeno istraživanje Profinet tehnologije i njezinog načina rada tražilo je desetke sati rada u traženju riješenja koje niti jedan proizvođač ne daje.

U prvom dijelu rada je prikazan sustav koji bi se trebao moći konfigurirati i upogoniti u vremenu od najviše par sati, što se pokazalo nemoguće. U drugom dijelu rada je prikazano koliko je za naizgled jednostavan sklop, koji se razlikuje od prvoga samo po odvojenoj jedinici za komunikaciju, potrebno uložiti vremena i znanja da bi sustav proradio. Takva rješenja bi trebala biti jednostavna, nadogradnje sustava omogućene i objašnjene od strane proizvođača opreme, no ovime se prikazalo da to nije tako. No ipak, i jedan i drugi proizvođač su izradili mrežne sklopove i programsku podršku koja je definirana Profinet normom što dokazujemo ispravnim radom sustava. Dakle poštivanje normativa neminovno mora dati riješenje, koje se na kraju pronašlo te je u radu objašnjeno. Sama primjena u budućim aplikacijama se može referencirati na ovaj rad što je naš doprinos.

Primjena SoftPLC koncepta procesnog računala prilagođene izvedbe s IEC61131-3 normom

Ivica Vlašić , Danijel Maršić i Goran Malčić
Tehničko veleučilište u Zagrebu/Elektrotehnički odjel, Zagreb, Hrvatska
ivica.vlasic@tvz.hr

Sažetak - Pristup projektiranju i izgradnji upravljačkih sustava u industriji se kontinuirano mijenja i poboljšava. Primjena IEC 61131-3 norme za programiranje PLC uređaja omogućila je razvoj novih vrsta upravljačkih sustava. Istovremeno proizvođači PLC-a prestaju s podrškom svojih starih sustava te prisiljavaju proizvođače opreme da koncepte svojih strojeva prilagođavaju novim sustavima. U radu je prikazana primjena SoftPLC rješenja tvrtke KW Software nazvano ProConOS® (eng. Programmable Controller Operating System) u tiskarskom postrojenju novije generacije. Osnovni koncept automatizacije tiskarskog postrojenja se nije mijenjao osim primjene prilagođenog (eng. custom) SoftPLC-a koji je naslijedio SIMATIC S5® sustav zadržavajući kompatibilnost u načinu primjene i održavanja.

I. UVOD

Pristup projektiranju i izgradnji upravljačkih sustava u industriji se kontinuirano mijenja i poboljšava. Paralelno s napretkom raznih tehnologija povećavaju se i dodatni zahtjevi kod razvoja upravljačkih sustava čime njihove mogućnosti postaju sve veće i veće. Kao odgovor na ove zahtjeve posljednjih dvadesetak godina je razvijeno nekoliko otvorenih međunarodnih standarda za industriju od kojih je najvažniji *IEC 61131-3* koji predstavlja skup smjernica za programiranje *PLC* (eng. ***P**rogrammable **L**ogic **C**ontroller*) uređaja. Primjena ovog standarda omogućila je razvoj novih vrsta upravljačkih sustava kao što je *SoftPLC* tehnologija.

Jedan od niza problema koji se javlja kod primjene *PLC* uređaja u industrijskim postrojenjima je nemogućnost miješanja uređaja različitih proizvođača zbog njihove međusobne nekompatibilnosti u pogledu izrade upravljačke logike. Iako su osnovne programske funkcije svih kontrolera praktički jednake, pojedine instrukcije su ipak bitno različite zbog čega se pravila pisanja programa mogu razlikovati. Ova činjenica bitno otežava razmjenu upravljačkih programa između uređaja odnosno sustava različitih proizvođača. Integratori sustava automatizacije zbog toga trebaju univerzalne alate za izgradnju svojih aplikacija da bi ih mogli koristiti na raznovrsnim PLC uređajima. Proizvođači rješenja za automatizaciju žele s jedne strane zadovoljiti potrebe kupaca (integratora sustava), dok s druge strane nastoje zadržati isplativu strukturu proizvoda u tehnološkom i poslovnom okruženju koje se mijenja iz dana u dan.

Navedeni problemi su tijekom 90-ih godina prošlog stoljeća potaknuli pojedine proizvođače programskih aplikacija na razvoj nove vrste kontrolera koji se naziva *SoftPLC*. Ovaj naziv predstavlja softver koji omogućuje izvršavanje upravljačka aplikacija u realnom vremenu na standardnoj računalnoj platformi. Pritom je upravljanje postrojenjem ostvareno preko standardiziranih modularnih *U/I* jedinica. Dakle, za implementaciju *SoftPLC* kontrolera potreban je hardver i softver kojima se postiže da standardna računalna platforma radi kao *PLC* uređaj. Osnova prednost *SoftPLC-a* je da sav potreban hardver nije ovisan o proizvođaču. Unatoč ovoj prednosti ni jedan proizvođač softvera nije uspio postaviti svoje rješenje *SoftPLC* softvera kao industrijski standard. To znači da programska podrška razvijena za jednu *SoftPLC* aplikaciju još uvijek ne može biti prenesena u *SoftPLC* nekog drugog proizvođača.

U radu je prikazan općeniti koncept *SoftPLC* tehnologije na primjeru rješenja *ProConOS* proizvođača *KW Software*. Također su prikazana višegodišnja iskustva u implementaciji i eksploataciji navedenog *SoftPLC* rješenja u tiskarskom postrojenju.

II. OSNOVE *IEC 61132-3* STANDARDA

IEC 61131-3 je naziv za prvi objavljeni globalni standard za programiranje PLC uređaja. Prvi puta je objavljen 1993. godine dok je trenutno aktualno drugo izdanje iz 2003. godine. Standardom su sažete potrebe industrijskih upravljačkih sustava kako u pogledu hardvera tako i softvera za programiranje. Smjernice i programski jezici *IEC 61131-3* standarda su primarno predviđeni za programiranje klasičnih PLC uređaja. Razvojem alternativnih rješenja industrijskih upravljačkih sustava pronašli su svoju primjenu u ugrađenim kontrolerima, programirljivim automatizacijskim kontrolerima (eng. ***P**rogrammable **A**utomation **C**ontrollers*, *PAC*) i upravljačkim sustavima baziranim na standardnim i specifičnim računalnim platformama (*SoftPLC*). Kako je standardom definiran ogroman broj detalja, od proizvođača upravljačkih sustava se ne može, u ovom trenutku, očekivati da će implementirati sve dijelove standarda, već samo određene dijelove. Dakle, standard osigurava mjerilo koje omogućuje kako proizvođačima tako i krajnjim korisnicima da procijene u kolikoj mjeri je svaki sustav za programiranje industrijskih kontrolera usklađen s *IEC 61131-3*.

Iako je većina proizvođača industrijskih upravljačkih sustava u velikoj mjeri implementirala određene smjernice *IEC* standarda, njihova hardverska i softverska rješenje se zbog komercijalnih i financijskih interesa u tolikoj mjeri razlikuju da je prijenos programa između

različitih upravljačkih platformi sve osim jednostavan. Ipak, primjenom standarda su elementi programskih jezika i struktura programa različitih proizvođača ipak postali slični što u konačnici integratorima sustava mnogo olakšava prebacivanje programa iz jednog u drugi upravljački sustav. Unatoč brojim preprekama koje stoje na putu provedbe osnovnih ciljeva *IEC 61131-3* standarda njegovim uvođenjem stvoreni su temelji za stvaranje jedinstvenog koncepta programiranja industrijskih kontrolera.

IEC 61131-3 standard se može općenito podijeliti na dva osnovna dijela:

A. *Zajednički elementi*

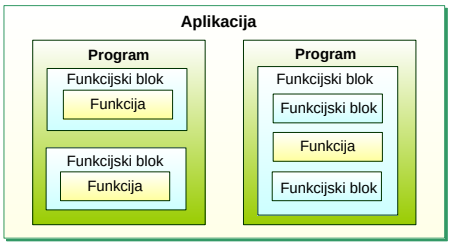
U ovom dijelu standarda su definirani sljedeći zajednički elemenati koji se mogu koristiti u svim programskim jezicima:

1) Oznake: služe za dodjeljivanje smislenih imena različitim elementima korištenih unutar IEC programskih jezika kao što su varijable, tipovi podataka, funkcijski blokovi i programi.

2) Tipovi podataka: predviđeno je nekoliko osnovnih i strukturiranih tipova podataka koje programer može definirati unutar programa.

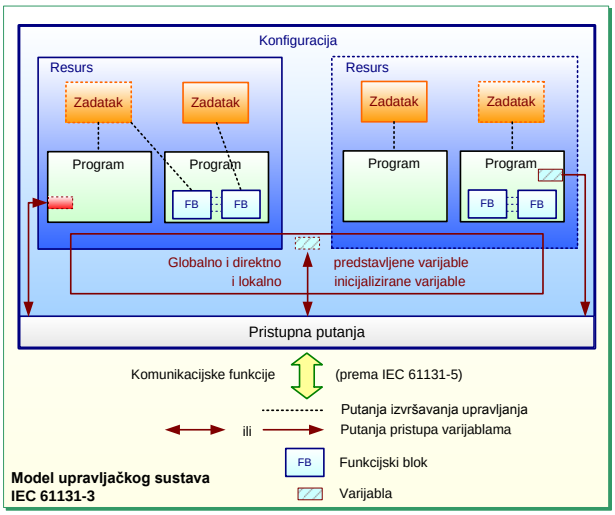
3) Varijable: su nazivi dodijeljeni podatkovnim elementima čiji se sadržaj može mijenjati tijekom izvođenja napisanog upravljačkog programa. Standardom su definirana tri tipa varijabli: lokalne, globalne i pristupne varijable.

4) Programske organizacijske jedinice: sve *IEC 61131-3* programske aplikacije se mogu razdijeliti u funkcionalne elemente nazvane organizacijske jedinice programa (eng. *Program Organisation Units, POU*) koje se mogu sastojati od funkcija, funkcijskih blokova ili cijelih programa (Slika 1.). Funkcije i funkcijski blokovi predstavljaju osnovu izgradnje kompleksnih upravljačkih programa jer sadrže strukture podataka i algoritme.



Slika 1. Primjeri upotrebe programskih organizacijskih jedinica

5) Softverski model upravljačkog sustava: je definiran kako bi se omogućilo bolje razumijevanje zajedničkih elemenata *IEC* programskih jezika (Slika 2.). Cjelokupna programska podrška koja služi za upravljanje određenim industrijskim postrojenjem se naziva konfiguracija (eng. *Configuration*). Konfiguracija je specifična za određeni upravljački uređaj jer su njezine mogućnosti temelje na njegovom hardveru o kojem ovisi brzina procesiranja, memorijske adrese ulaza i izlaza te ostale mogućnosti sustava. Unutar konfiguracije može se definirati jedan ili više resursa (eng. *Resource*) koji se mogu promatrati kao procesne jedinice sposobne izvršavati IEC programe. Svaki resurs može sadržati jedan ili više programa i/ili funkcijskih blokova koji se izvršavaju pod utjecajem upravljačkih zadataka (eng. *Tasks*). Zadatak se može izvršavati periodički ili pokretati pod utjecajem određenog okidača, primjerice uslijed pojave rastućeg brida neke varijable veličine bita. Program se može izgrađivati od niza različitih programskih elemenata napisanih u bilo kojem IEC programskom jeziku. Pristupna putanja definira simbolički naziv varijable dok direktno predstavljene varijable određuju fizičku lokaciju podataka (npr. hardverska adresa ulaznog signala) na način specifičan pojedinom proizvođaču. Globalne varijable su dostupne svugdje unutar resursa ili konfiguracije.



Slika 2. Softverski model industrijskog kontrolera

B. *Programski jezici*

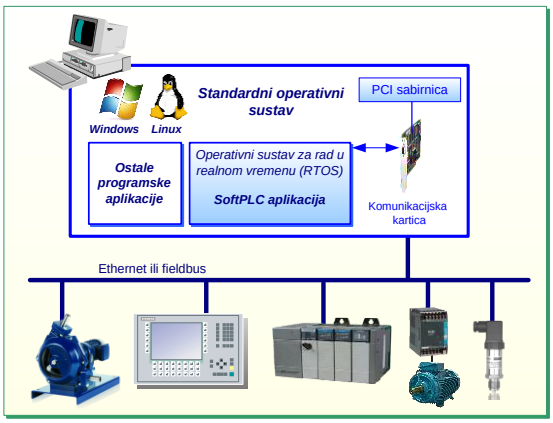
Standard podržava 5 programskih jezika što programerima PLC uređaja omogućava korištenje preferiranih jezika na osnovu prethodnih iskustava. Svaki od ovih programskih jezika ima prednosti u odnosu na ostale u specifičnim algoritmima upravljanja procesom. To su sljedeći programski jezici:

- Ljestvičasti dijagrami (eng. *Ladder Diagrams, LD*),
- Instrukcijska lista (eng. *Instruction List, IL*),
- Funkcijski blok dijagrami (eng. *Function Block Diagram, FBD*),
- Strukturirani tekst (eng. *Structured Text, ST*),
- Sekvencijalni funkcijski dijagrami (eng. *Sequential Function Charts, SFC*).

III. SOFTPLC TEHNOLOGIJA

Otvoreni standardi industrijskih upravljačkih sustava omogućili su primjenu *PC* (eng. ***P**ersonal **C**omputer*, dalje *PC*) računala za obavljanje raznih upravljačkih zadataka. U pojedinim industrijskim postrojenjima su paralelno uz primjenu klasičnih *PLC* uređaja pojavljuju koncepti upravljačkih sustava temeljenih na *PC* računalu. Rješenja takvih upravljačkih sustava razvijena su za razne operativne sustave (*Windows, Linux* i sl.) u kojima *PC* zamjenjuje klasični hardverski *PLC* uređaj. Upravljački sustavi temeljeni na *PC* računalima mogu biti izvedeni kao *SlotPLC* ili *SoftPLC*.

SoftPLC je naziv za programsku podršku kojom se postiže da standardna računalna platforma funkcionira kao *PLC* uređaj koji upravlja procesom u realnom vremenu (Slika 3.).



Slika 3. Koncept *SoftPLC* upravljačkog sustava

Komunikacija sa senzorima i aktuatorima u postrojenju je izvedena preko mreže odnosno njenih komunikacijskih sučelja spojenih na distribuiranu periferiju (fieldbus, ethernet i sl.). *SoftPLC* rješenje upravljačkog sustava je djelomično ovisno o pouzdanosti sklopovlja računala i nesmetanom funkcioniranju instaliranog operativnog sustava. *SoftPLC* aplikacija mora dijeliti resurse procesora s operativnim sustavom i eventualno s drugim instaliranim softverskim aplikacijama. Procesor PC računala mora izvršavati PLC program u realnom vremenu za što se koristi operativni sustav za rad u realnom vremenu (eng. *Real-Time Operating System, RTOS*) koji osigurava deterministički rad.

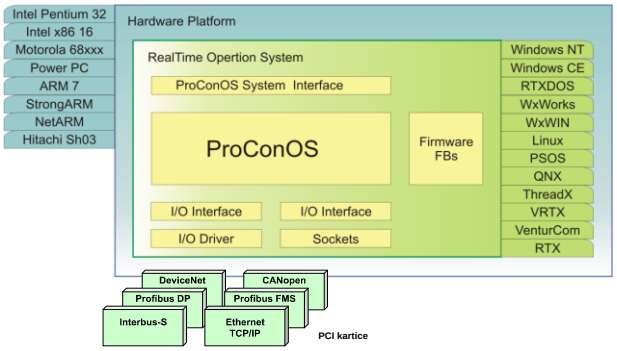
IV. *SoftPLC* RJEŠENJE *KWSoftware*

Na tržištu postoji nekoliko komercijalnih implemetacija *SoftPLC* tehnologije. Jedno od njih je prikazano rješenje *SoftPLC-a* tvrtke *Klöpper und Wiege Software*® (dalje *KW Software*) koja je razvila *PLC* operativni sustav nazvan *ProConOS*® (eng. ***Pro**grammable **Con**troller **O**perating **S**ystem*).

A. *Operativni sustav ProConOS*

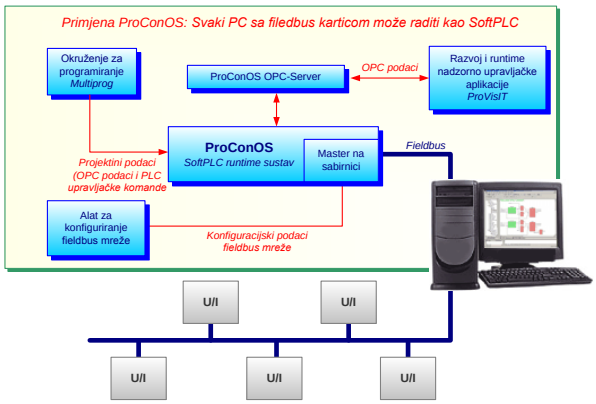
ProConOS je višezadaćni i vrlo brzi *PLC runtime*[1] sustav za kompleksne upravljačke aplikacije koji radi u realnom vremenu. Sukladan je s *IEC 61131-3* standardom i dizajniran tako da se može prilagoditi raznim standardnim ili specijalnim hardverskim platformama. Slika 4. prikazuje osnovni koncept *SoftPLC* rješenja proizvođača *KW Software*®.

KW Software® nudi samo odgovarajući *PLC runtime* softver (ProConOS®) dok je korisniku na raspolaganju velik broj hardverskih platformi na kojima može primijeniti taj softver. Dakle, posebnost ovog rješenja je u tome da korisnik može neovisno o proizvođaču softvera odabrati hardver koji će pretvoriti u softverski PLC uređaj, primjerice standardnu PC ili ugrađenu (eng. *embedded*) hardversku platformu. *ProConOS*® radi kao jedan od programa unutar jednog od mogućih operativnih sustava (npr. *Windows NT, Linux,* itd.) koji je instaliran na odabrani hardver. Kako bi *ProConOS*® mogao raditi deterministički potrebno je na operativni sustav instalirati odgovarajuću nadogradnju za rad u realnom vremenu. *KW Software* je razvio vlastita rješenja takvih dodataka kao primjerice *real-time* ekstenzija za Windows operativni sustav koja se naziva *KWRTK* (eng. *KW Realtime*[2] *Kernel*). Komunikacija s perifernim jedinicama se ostvaruje preko pripadajućih modula za podržane komunikacijske tehnologije (spojenih u PCI utore). *ProConOS*® podržava najčešće korištene sustave distribuiranih periferija kao što su *Interbus*®, *Profibus DP*®, *CANopen*®, *DeviceNet*®, *Modbus*® i sl. Otvoreno U/I sučelje nadalje omogućuje vezu preko raznih korisničko-specifičnih periferija.



Slika 4. Osnovni koncept *ProConOS* softverskog PLC-a

Slika 5. prikazuje funkcijski dijagram tipične implementacije *ProConOS*® softverskog *PLC-a* na standardnom računalu. Može se uočiti da svako računalo temeljeno na hardveru proizvođača Intel koje ima ugrađenu odgovarajuću fieldbus kraticu može raditi kao softverski PLC ako se na njega instalira *ProConOS runtime*® softver.



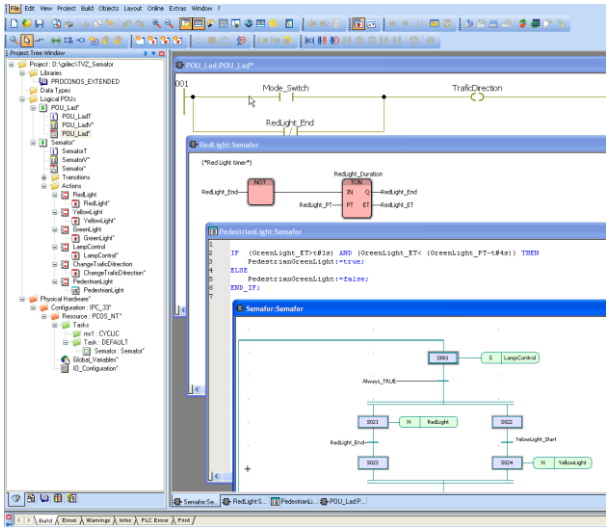
Slika 5. Primjer tipične implemetacije *ProConOS* softverskog PLC-a

Prednost ovog rješenja je u tome što se isto računalo može, osim za implementaciju softverskog PLC uređaja, koristi za ostale alate koji su obično potrebi za programiranje i rad PLC uređaja Na njemu se može nalaziti razvojno okruženje *KW Multiprog*® koje služi za razvoj i testiranje PLC programa. Jednako tako, isto

[1] *Runtime* softver koje je dizajniran kako bi podržavao izvršavanje računalnih programa napisanih u nekom programskom jeziku.

[2] eng. *Realtime* - u stvarnom vremenu

računalo može se koristi za razvoj i runtime izvođenje nadzorno upravljačkih aplikacija u programskom okruženju *ProVisIT®* koje sa softverskim PLC-om razmjenjuje podatke putem *ProConOS®* OPC Servera. Odgovarajuća fieldbus kartica (za *Profibus DP®*, *DeviceNet®* i sl.) ugrađena u PCI utore računala se konfigurira u alatu za konfiguriranje pripadajuće filedbus mreže koji se također može nalaziti unutar istog računala.



Slika 6. Izgled osnovnog ekrana okruženja *KW Multiprog*

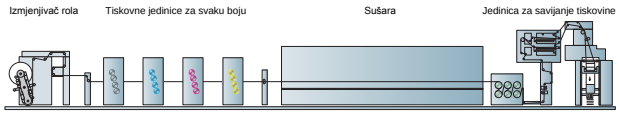
V. PRIMJENA *PROCONOS* U TISKARSKOM POSTROJENJU

A. *Zahtjevi automatizacije tiskarskog postrojenja*

Tiskarsko postrojenje *Rotoman®* za revijalni tisak je automat u koji kao sirovine ulaze papir i boja, a kao proizvod izlaze gotova tiskovina određenog tipa. U pogledu automatizacije možemo reći da se radi o kontinuiranom sustavu relativno velike brzine. Kapaciteti modernih postrojenja su od 30000 do 65000 primjeraka na sat što znači da se papirna traka prilikom tiskanja kreće brzinom od 8-15 m/s.

Slika 7. prikazuje blok shemu tiskarskog postrojenja koje se funkcionalno sastoji od sljedećih temeljnih cjelina:

- Opskrbljivač papirnom trakom (izmjenjivača rola) ima zadatak da osigura kontinuiranu opskrbu papirnom trakom tako da zamjeni istrošenu papirnu rolu novom bez zaustavljanja procesa. Dodatni zahtjevi su da se osigura varijabilna napetost papira kako bi se izbjeglo gužvanje.
- Tiskovne jedinice otiskuju sadržaj na papirnu traku i osiguravaju kvalitetu otiska koja se karakterizira kao precizan otisak pojedinačne boje (iz CYMK sustava komplementarnih boja) jedne preko druge. Osim primarnih postoje i niz sekundarnih zahtjeva kao što je opsluživanje prije tiska te zaštitni sustavi koji štite radni mehanizam od oštećenja, prilikom pucanja papira i sl., te zaštitu zdravlja i života osoblja.
- Sušara je dio postrojenja koji treba vrlo brzo osušiti boju nanesenu na papirnu traka te je isto tako brzo i kontrolirano ohladiti na izlazu. Toplinska energija se dobavlja gorenjem prirodnog plina. To podrazumijeva vrlo rigorozne zaštitne sustave budući da se razvijaju temperature od 800 ºC, a instalirana toplinska snaga je reda veličine 1 MW.
- Jedinica za savijanje (formiranje) tiskovine je sustav kompleksnih radnih mehanizama čija je zadaća da savijaju i odsijecaju papirnu traku tvoreći tako uobičajnu tiskovinu. Ovi radni mehanizmi su zbog relativno velikih brzina i složenih zahtjeva podložni pojačanom trošenju što donosi zahtjev za preciznim određivanje njihovog položaja i stanja da bi se ukupan sustav osigurao od lomova.



Slika 7. Blok shema tiskarskog stroja *Rotoman*

Zahtjevi automatizacije ovise o pojedinom segmentu postrojenja i oni se osiguravaju parcijalno dok je globalni zahtjev da se papirna traka kreće sinkronom brzinom kroz sve elemente. Ovaj zahtjev osigurava sofisticirani sustav motornog pogona kod kojeg nije samo zahtjev da se pojedini motori vrte sinkronom brzinom nego i da se osigura identični kut radnog mehanizma (eng. *Motion Control*).

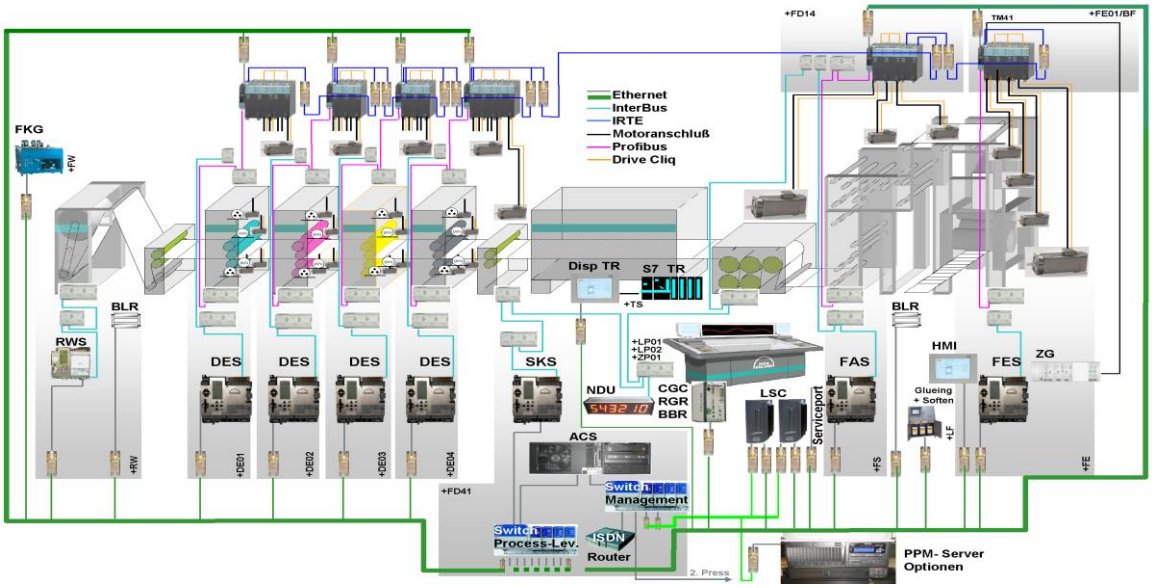
B. *Sustav automatizacije tiskarskog postrojenja*

Ako analiziramo navedene zahtjeva za automatizaciju tiskarskog postrojenja možemo kao primarne značajke primijetiti zahtjev za brzinu i preciznost te je logičan zaključak da se za ispunjenje istih primjeni sustav s više procesnih računala povezanih suvremenim industrijskim mrežama u procesnu cjelinu. Sustav automatizacije tiskarskog postrojenja *Manroland Rotoman* zadovoljava teorijske osnove modernih industrijskih mreža što se ogleda u strukturi umrežavanja na tri osnovne razine (Slika 8.).

Upravljačka razina se ostvaruje korištenjem standardne Ethernet mrežne infrastrukture koja spaja upravljačke konzole s procesnom razinom na jednoj strani te s radnom stanicom za organizaciju posla na drugoj. Ova razina omogućava implementaciju ukupnog postrojenja u informatički sustav poduzeća.

Procesna razina osigurava razmjenu podataka između bazičnih procesnih jedinica (izmjenjivač rola, tiskovne jedinice, sušara, jedinica savijanja i motorni pogon), a bazirana je na industrijskoj Ethernet mreži.

Razina polja zadužena je za procesnu sliku postrojenja. Ova razina izvedena je kao distribuirani sustav upravljanja svih aktuatora i senzora. Upotrijebljena je *Interbus-S* industrijska mreža s kojom se uspijeva osvježavati kompletna procesna slika brzinom od 500 kBd/s. *Interbus-S* je otvoreni industrijski mrežni standard koji je koncipiran kao serijski podatkovni prsten (eng. *Summation Frame Protokol*) koji radi isključivo u realnom vremenu u okviru master/slave metode kontrole prijenosa, a strukturiran je kao pozadinski posmični registar. Tijekom jednog mrežnog ciklusa serijski se isporučuju izlazni podaci članovima mreže ali se istovremeno od njih zaprimaju ulazni podaci.



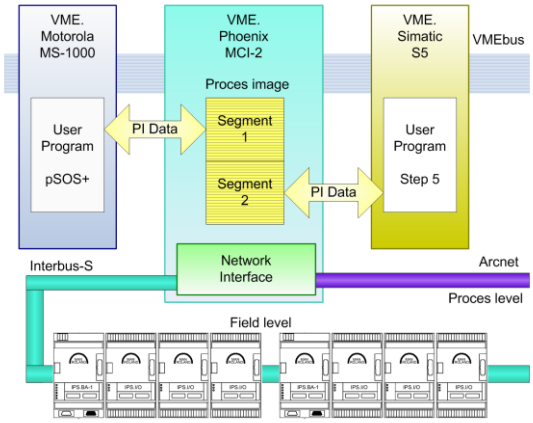
Slika 8. Industrijska mreža tiskarskog postrojenja *Rotoman*

Na kraju ciklusa svi izlazni podaci su distribuirani a ulazni upisani u ulaznu mapu slike procesa Koristeći prstenastu strukturu moguće je ostvariti istovremenu predaju i zaprimanje podataka (*full duplex*) a predvidljivo vrijeme pristupa za sve članove mreže je zajamčeno. Za potrebe svojih postrojenja tvrtka *Manroland* je konstruirala vlastite *Interbus-S®* inteligentne mrežne članove specifičnih karakteristika (*IPS-Interbus Press System*).

Motorni pogon je dosta zahtjevan dio automatiziranog tiskarskog postrojenja i izveden je korištenjem suvremenog sustava *SINAMICS*, tvrtke *Siemens*. Osnovu motornog pogona čine pretvarači frekvencije serije *SIMOTION D* koji su istovremeno i pogoni za elektromotore i posebno dizajnirana procesna računala s vlastitim programom sposobnim za održavanjem virtualne osovine tiskarskog postrojenja. S ostatkom postrojenja komuniciraju Siemensovom varijantom industrijske Ethernet mreža (***IRTE*** - ***I****socron* ***R****eal* ***T****ime* ***E****thernet*), a međusobno sustavom *Drive-CLiQ*.

C. SoftPLC rješenje modernizacije sustava

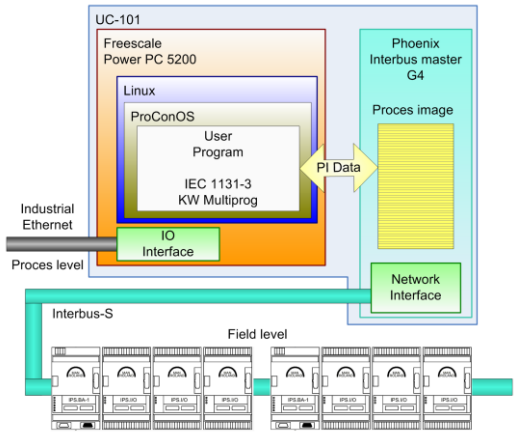
Razvoj tiskarskih strojeva u segmentima automatizacije je brži nego u području bazične mehanike radnih mehanizama što je logično gledajući tempo razvoja elektroničke industrije. Mnoga rješenja u segmentu automatizacije zastarijevaju s obzirom na performanse, ali i zbog prestanka proizvodnje i podrške osnovnih elemenata sustava automatizacije. Takav slučaj je i kod opisanog tiskarskog postrojenja čija je prethodna generacija bila automatizirana na bazi Siemensove PLC generacije *Simatic Step 5*® integriranih u VMEbus sustav sa Motorola 68000 CPU jedinicom, te *Phonix Interbus S*® kontrolerom distribuirane periferije (slika 9.). Programsko rješenje sastojalo se od dva segmenta. Prvi program upravljao je s negrafički procesnim elementima dok je drugi bio zadužen za procese grafičke obrade i sadržavao je relativne brze algoritme bazirane na matematičkim operacijama. Ovakva konfiguracija osiguravala je fleksibilna i napredna rješenje ali je problem nastao kad je obustavljana proizvodnja većine elementa.



Slika 9. Koncept procesnog računala UC-1 bazirano na VMEbus sustavu

Kako bi se zadržao kontinuitet u razvojnoj strategiji i smanjio budući utjecaj gore navedenih trendova kompanija je odlučila novu generaciju tiskarskih postrojenja automatizirati takozvanim *custom* rješenjima. Koristeći se pozitivnim efektima takvog pristupa pri razvoju vlastitih *Interbus-S*® modula odlučeno je da će se napraviti vlastito procesno računalo bazirano na otvorenom standardu. Rezultat toga je bio procesno računalo bazirano na *SoftPLC* rješenju *ProConOS*® nazvano *UnitControler UC*-101® (Slika 10.).

UC-101 je procesno računalo sklopovski koncipirano na *Power PC 5200* arhitekturi tvrtke *Freescale*® (Slika 11.). Kao *realtime* operativni sustav izabran je *Linux* kao još jedan element otvorenog koda. Ulazno-izlazni signali se kontroliraju preko *Interbus-S*® modula kao distribuirane periferije i stoga je u računalu integriran nadređeni Interbus-S član *(master)*. Računalo je smješteno u standardizirano kućište podešeno za montažu uz ostale IPS module.



Slika 10. Koncept procesno računalo UC-101 bazirano na custom SoftPLC sustavu

Programska oprema (software) uključuje *Xenomai/Linux* kao operativni sustav, *ProConOS®* kao *SoftPLC*, *KW Multiprog®* kao razvojno okruženje te *Phoenix Interbus CMD* program za konfiguriranje i dijagnostiku industrijske mreže.

Slika 11. Procesno računalo tiskarskog postrojenja UC-101

Pozitivni učinci primjene opisane tehnologije u prvom redu su, zahvaljujući konceptu distribuirane periferije, ne mijenjane osnovnog koncepta automatizacije stroja. U pogledu sklopovske implementacije dovoljna je samo zamjena procesnih računala što ne zahtijeva velike troškove redizajna sklopovske opreme. Ova činjenica ima veliki značaj kod rekonstrukcije i modernizacije postojećih tiskarskih postrojenje kada je uz cijenu vrlo bitno i vrijeme izvršenja radova.

VI. ZAKLJUČAK

SoftPLC rješenje tvrtke KW Software prikazano u radu je nazvano *ProConOS®* (**Pro**grammable **Con**troller **O**perating **S**ystem) jer predstavlja programsko bazirani PLC sustav koji se može implementirati na nizu standardnih ili specijalnih hardverskih platformi. Posebnost ovog rješenja je u tome da korisnik može neovisno o proizvođaču softvera odabrati hardver koji će pretvoriti u softverski PLC uređaj. Korisniku su, uz softverski PLC, na istoj platformi također dostupni ostali programski alati: *KW Multiprog®* za programiranje, *ProVisIT®* za izradu nadzorno-upravljačke aplikacije, softver za konfiguriranje i dijagnostiku korištene industrijske mreže, itd. U prikazanom tiskarskom postrojenju je zastarjeli PLC sustav *Simatic Step 5* zamijenjen softverskom PLC aplikacijom *ProConOS* implementiranoj na procesnom računalu sklopovske arhitekture *Power PC 5200®* firme *Freescale*. Kao realtime operativni sustav izabran je *Linux* dok se ulazno-izlazni signali kontroliraju preko Interbus-S modula kao distribuirane periferije.

PAPERS

Intelligent support used for providing a pleasant user experience

J. Kaljun*, G. Harih* and B. Dolšak*
* University of Maribor, Faculty of Mechanical Engineering, Laboratory for intelligent CAD systems, Maribor, Slovenia
jasmin.kaljun@um.si

Abstract - This paper presents a prototype of intelligent advisory system based on the aesthetic factors regarding product design, with the emphasis on appurtenant design recommendations. Aesthetics certainly belong to the more complex design factors. Although some literature can be found about the aesthetic design of consumer goods, the designer still has to amass quite a lot of experience and knowledge in the field of aesthetics, in order to choose and carry out appropriate design actions for improving the aesthetic value of the product. The aim of the paper is not to discuss aesthetics from philosophical point of view, but to present problematic of aesthetics trough eyes of the mechanical design engineer, who is responsible for outer shape of the product already in conceptual design phase, where various influential factors determine the design.

I. INTRODUCTION

Desire is the fundamental motivation of all human action (Thomas Hobbes, 1588 – 1679) [1]. When using a "desired" product, user "feels" "pleasure" and "comfort" and it can be said that user has a "pleasant user experience". Today desire is the main marketing weapon. Stimulating a desire for a certain product by conventional advertising has to be supported by products' "self-expression". With the growth and globalization of the market, the future users of the specific product, in this case consumer products (household appliances, hand tools…), increasingly search, choose and buy desired product in virtual environment e.g. online stores [2]. In such a case, when selecting the product, users rely on:

a) the description of the product or. technical system, which is usually prepared by the manufacturer,
b) the comments of existing users,
c) test reports carried out by the relevant institutions and
d) virtual product presentation. It is a virtual visual perception of the product that is crucial, as it must support the aforementioned descriptions.

Products' form has to reflect the correct combination of, for the user, important characteristics such as functionality, ergonomics, practicality, robustness, elegance... In the virtual world a visual perception of products' form is a point of contact between the product and the prospective users. On the other hand also in the real world, the prospective user, when selecting a product, among wide range of products of same category located on the shelf, primary chooses that or those, whose form most clearly express the aforementioned properties, which are important to the user [3].

The modern process of designing technical systems, including consumer products, specifically household appliances and hand tools, is a relatively well-defined and relatively well-supported by modern computer tools. Support offered by many commercial and specially developed computer tools, mainly refers to the graphic representation, simulation, engineering analysis (e.g. finite element method) and the animation of the future operation of the technical system in a virtual world. In fact, these tools do not affect the scope of defining the form or design [4].

Despite the wide range of possibilities provided by the modern computer tools, the designer has to evaluate the information, find interdependences and end up with a broad list of possible partial solutions, among which an optimum combination has to be selected. Alongside this, the designer has to take care of a very complex and to a certain degree "subjective" area of aesthetic products. For this purpose, the designer has to know all the spheres of influence, their possible overlapping or exclusions and of course all of the available design (visual) elements. With its true/false decision seriously affects the attractiveness and usefulness of the product in practice, as well as technical feasibility, lifetime, economic viability, recyclability... In taking such decisions many different experts from various areas of expertise should cooperate, which often results in difficulties in coordinating the decisions that need to be in line with sustainable development.

A. The aim of the paper

The paper will discuss a framework of intelligent support system for the definition of the relevant visual perception of the product on the basis of functional, ergonomic and technological criteria, which will be able to offer support to the designer in the decision making process of selecting the most appropriate aesthetic (design) characteristics - features for a specific product or technical system.

The aim of the paper is not to discuss aesthetics from philosophical point of view, but to present problematic of aesthetics trough eyes of the mechanical design engineer, who is responsible for outer shape of the product already in conceptual design phase, where various influential factors determine the design.

B. Exsys Corvid

One of the development tools for the construction of expert systems is also Exysy Corvid 5.2.1 [5], a tool which basically allows object-oriented build of the expert system. The end result is web based expert system.

Usage of Exsys Corvid is based on defining "variables", which, due to their different characteristics allow a wide range of applications. Variables define not only the range of possible values, but also certain parameters, which can be controlled by the developer or modify the course of decision-making (reasoning) mechanism. At the same time variables define the behavior of the user interface.

On the basis of these variables "Logical Block(s)" are built to encode the knowledge in the form of production rules. Logical blocks define the knowledge base of the system. With the help of "Command Block(s)", a developer can optimize workflow of inference engine. In real application this means that a developer can predict a forward chaining in logical block A and backward chaining in logical block B using suitable commands in a command block

User interface, of Exsys Corvid application is set in a Java environment and can act as a Java applet or Java servlet. The entire system is mounted on an appropriate server, where it can be maintained using a basic software package. Design of user interface is partly determined within Exsys Corvid, the final form can be encoded in a website where the system is implemented.

Among various types of already mentioned variables, "confidence variables" represent a powerful feature of Exsys Corvid. Along with specific recommendation, "confidence variable" includes a "confidence factor" as a level of certainty. This enables expert systems to make multiple recommendations with differing degrees of confidence to reach a "best fit" in its conclusion. While in some cases, it is possible to give a specific recommendation with absolute precision; the real world is not often so clear-cut. Often multiple recommendations are simultaneously possible and the system ranks them based on relative merit. Applying of "confidence variables" enables the emulation of the real world and gives the type of recommendations that human experts would. Exsys Corvid provides many different ways to handle and utilize confidence values among other various formulas can be used to combine the values assigned to an overall confidence for the variable.

C. Oscar

In continuation of this paper an insight to knowledge base of prototype of an intelligent advisory system Oscar [6], based on expert design knowledge management using Exsys Corvid will be presented.

Oscar covers a field of hand manipulated power tools. In the proposed frame the aesthetic appearance of the product is not considered as an influential parameter, which however is the case in our system. Oscar is namely composed out of two sub-systems (Figure 1) that can be applied in two different modes. We can use them independently from each other, or simultaneously and interdependent on the same design project.

The intelligent decision support system Oscar is still a research prototype, and as such, a subject of intensive development, especially more subjective part of the system dealing with engineering aesthetics and aesthetic ergonomics.

Basically, the intelligent advisory system Oscar is a computer system that emulates the decision-making ability of a human expert. Such intelligent systems are designed to solve complex problems by reasoning about knowledge, like a human expert, and not by following the procedure of a developer as is the case in conventional programming.

The structure of the intelligent advisory system Oscar is unique, and significantly different from traditional programs. In foundation, the system is divided into three parts. The first part is fixed, independent of the rest of the system, called the inference engine. The second part is variable, called the knowledge base. The third part, which serves as communication module is called user interface. When running Oscar, the inference engine reasons about the knowledge base like a human expert and communicates with user through user interface.

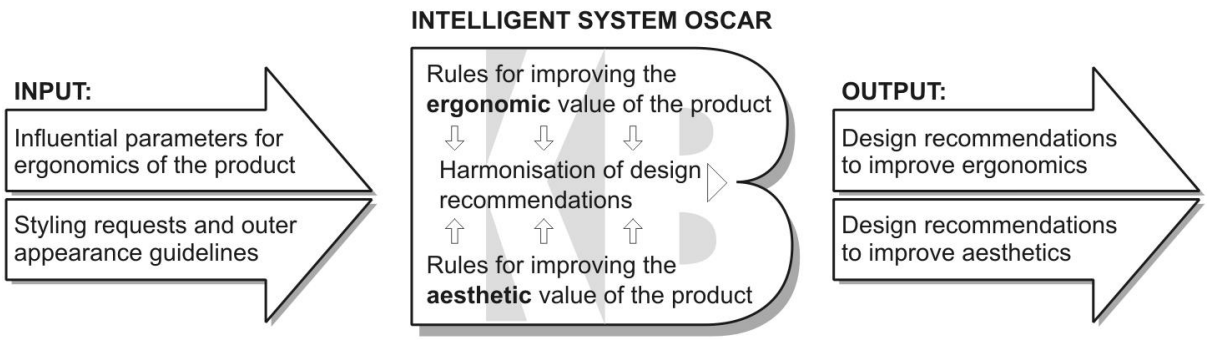

Figure 1. Basic structure of the intelligent advisory system Oscar

In the intelligent advisory system technology, knowledge base is expressed with natural language IF-THEN styled rules, called production rules.

Oscars' inference engine runs in so called conversational mode. This simply means that the inference engine requests initial data from the user at the start. Since problems are usually complex, system often cannot find a suitable solution using only initial data. Therefore the system has to find the way to solve the problem by requesting the missing data form the user.

With additional data system gradually approaches to the solution. The user feels like a participant in a dialogue led by an expert. To control a dialogue, the inference engine applies three different techniques: forward chaining, backward chaining and mixed chaining [7]. Forward chaining is a technique where the inference engine searches the solution (goal) by using specified procedure and asking questions. In backward chaining, the inference engine knows the solution and attempts to find production rules to support the solution. In mixed chaining the inference engine has an "idea" of the solution but cannot simply confirm it.

Therefore the inference engine deduces in forward chaining technique using information from previous user responses before asking the next question. So quite often the inference engine deduces the answer to the next question before asking it.

II. PRODUCT DESIGN BACKGROUND

Pleasant sensation is an accompanying product of the industrialized society and modern life and the objective fruit of the commercialization of the desire of consumption. The culture of pleasant sensation in modern life is, in reality, the demonstration of the instinctive desire of human beings. Product Design is one form of expression of this sensational culture. The product has become a carrier of the culture of pleasant sensation for people's modern material life [8].

The embodiment of pleasure culture in the design of industry goods manifests itself in two forms:

- concreteness in form, and
- symbolized metaphor.

Concreteness of the patterns of goods refers to visualized shaping of the goods, which directly incarnate some parts or organs of human body and give prominence to the shape in order to achieve physical pleasure. Symbolized metaphor means that the sexual symbol features are expressed by means of association and symbolization. Namely, the female features are represented by curvaceous-ness, tenuousness, tenderness, pink color, gentleness, while male features by linear-ness, coarseness, hardness, plain color, and dynamism.

Modern product design conveys two messages:

- rational (the function, material, and workmanship of the product), and
- sensible (the shaping, color, mentality, and way of sue), the former is the basis for the existence of the product, and the latter is more related to the formation and shaping of the product.

Apart from displaying the objectiveness of the product, the shaping of the product also reflects the cultural connotation of the product by means of some signs. Because under most circumstances, the purchasing behavior not merely involves the acquisition of the physical product itself, but also the search for something resonating with their inner desire [9].

III. THE THEORY OF AESTHETICS IN DESIGN

In the process of designing a product the aesthetic component of the product in most cases is not the main objective, as would it be in an artistic creation, which aims to achieve a high aesthetic value. The aesthetic component is a resultant of design parameters that determine the basic characteristics of the designed product [10]. The designer must develop the aesthetic component of a product included into the basic product concept through the entire creative process. Aesthetic value is formed by the elements (design solutions), which characterize the perception of the product, while challenging the subjective feelings of the user - the observer, which can be called aesthetic. The (appropriate) creation of aesthetic component is influenced by various influential factors, which can basically be divided (combined) into two major groups [11]:

- Subjective factors; the basic concept of aesthetics (philosophy) is bound to subjective perception. Subjective factors are closely linked to potential users and therefore relatively difficult to measure. They are formed by personal and cultural norms that apply in the environment originating the potential users. A large part of successful design depends on the designer's knowledge of the environment in which is the product going to be introduced. Different psychological and philosophical studies, which the designer can use in their work, can be very useful.

- Objective factors are a kind of "universal" measure of aesthetic value of each product. Objective factors dictate the aesthetic elements and relations between them, which can be called the building blocks of harmony. This group of factors includes, among others, functional factors such as clear shape, which is adapted to the main function of the product, to increase the aesthetic value of it.

A. The impact of the aesthetics to product development

Naturally, the impact of aesthetics as one of the design goals (a kind of added value) cannot be simply left to chance, but has to be considered already in the concept stage of product development. Required aesthetic value and guides to achieve these values must be, with other requirements in the areas of ergonomics, the mechanism of the structure and functions, well known and clearly defined already in the definition of development task, to allow designers to simultaneously satisfy all the requirements. Designers' task is to develop aesthetic elements in accordance with already presented factors.

The relationship between "technical" and "aesthetic" value of a product is defined by the purpose or mission of the product. The link between the technical - economic value and aesthetic - artistic value can be presented as the field of aesthetic value, which grows with the sidestepping of the basic machine elements towards consumer products, where products can be found which, together with the main function, provide even prestigious function.

IV. DEVELOPMENT OF KNOWLEDGE BASE

When analyzing the market and the anticipated requirements of customers, including estimates of the target groups regarding the developed product, the designer must have clear aims regarding the aesthetic component, and must define the semantic message of the product's visual identity. Defining the semantic forms of communication is very important, if not the key to mass produced consumer products, where the main function also complements the so-called prestigious function. The duty of the designer is to create such a product shape that best reflects the desired message, and follows the requirements of the relevant components regarding the aesthetic quality of the product. Aesthetic recommendations for the designs of products can also be an assistance and support to the designer. Aesthetic recommendations can be collected in the form of those aesthetics objectives in design, which bring together art, technical and even semantic elements. These objectives are [12]:

1. shape is consistent with the function (form follows function)
2. shape has the desired compositional consistency
3. shape reflects the planned semantic message

A. *Functionality of the product*

At the end of the 19th century, the phrase "Form follows function" was mentioned for the first time and became the 20th century leading thought in the field of industrial design. Indeed, it is in the "first plan" when developing industrially manufactured products regarding implementation of the main function, while the shape of the product mostly serves its ergonomic suitability and visual appearance. In practice this means that, the coffee grinder is intended primarily for "user friendly" coffee milling, and not decorating kitchen shelves, while expressing its identity and brand affiliation, among other things with their visual image [13].

Design recommendations in the field of aesthetics, in this case are:

- the form indicates how to use the product,
- the form of the product allows easy and safe use,
- the control areas are easily accessible,
- the use of different materials can add further functional highlight.

A representative rule in this group defines basic design goals for a tool for holding and pressing:

```
IF:
    Select the group of tools most
    suitable for tool in consideration:
    tools for holding and squeezing
THEN:
    Important safety issues are
    predicted - consider ergonomic part
    of the system.: Confidence = 5
    Shape (form) of the product should
    be consistent to products'
    function.: Confidence = 5
```

B. *Compositional consistency*

Combined with the known main function of the product, the designer has to compose a visual image of the product in such a way that it generates pleasant feelings and desires when used or merely possessed by the user, as well as the observer. The principles of visual composition are also present, in certain respects, in the designs of industrial products.

Thus, the objective compositional consistency can be archived by:

- the individual elements that constitute to the whole (in the form of a product) yet are mutually dependent so that the established rhythm, expresses the desired message (movement, resting ...).
- tendencies derived through individual elements must conform to the overall composition of the product.
- the proportions used should be in accordance with the principal function of the product:
- where possible, usage of pleasant (real) proportions is desirable,
- the use of different proportions on the different elements of one product is undesirable.

C. *Semantic consistency*

While the first two objectives of aesthetic design the care about subconsciously receiving of the product, semantic consistency carries, in concept stage already known, message of the product. Semantic message is reached with applying certain values of selected technical elements to the shape of the product. Some recommendations are presented in Table 1.

TABLE 1. DESIGN RECOMMENDATIONS FOR SEMANTIC CONSISTENCY [KALJUN ET AL. 2006]

The technical element	communication form
acceleration	aggressive, speed sports
hollow, crown	power, aggression, tension
convex, concave	tense
sharpness	tense, aggressive
tenderness	tense, natural, organic, warm
crispiness	cold, aggressive
tension	tense, wild
lead in	aggressive, threatening

Representative of production rules for semantic consistency is:

```
IF:
    How it the tool being used:
    professional use OR hobby use
AND:How to determine appropriate
    semantic meaning for the product?
    System shell derive semantic meaning
AND:Select the group of tools most
    suitable for tool in consideration:
```

```
    smashing tools
THEN:
    Tool Semantics aggression AND
    dominance
```

Presented rule recommends semantic message taking into consideration for a known usage of the product.

Different production rules are defined to translate semantic message to technical elements (Table 1). Representative rule cam be seen here:

```
IF:
    Tool Semantics aggression
THEN:
    Consider use of adequate technical
    realization of characteristic
lines.: Confidence = 5
    [Aest_Rec.ADD]  Lines/surfaces
    should express acceleration
```

V. CONLUSION

Some aspects of product design, such as aesthetics, which were in the past often unduly neglected in comparison with functional and economic efficiency of a new product, are now becoming increasingly essential.

Designers have the obligation to fashion the product to specific guidelines, regulations, standards and other elements in early developments stage, so that at the end, a product will be successful on the market. This is a difficult task for people whose job should be oriented into creative development of new goods rather than constantly studying certain rules.

Aesthetic design is a vital and complex part of product design process. In view of the complexity, multi-factors coupling and fuzziness of aesthetic knowledge, an intelligent support to aesthetic design in form of advisory decision support system is proposed.

In this context, the knowledge related to aesthetic design has be to collected, organized and encoded in form of production rules, which were found to be the most appropriate formalism due to their transparency and closeness with the human way of decision making process.

The knowledge built in the prototype of the intelligent system named Oscar is structured in form of different classes interconnected with various attributes and their values at the input side, while as the output of the system the user can expect (re)design recommendations leading to achievement of certain design goals that can improve the aesthetic value of the product being developed.

***Abstract*—Search in networks is defined as a process in which an agent hops from one network node to another by traversing network links in search for given nodes. The simplest example of network search is a random walk where the agent selects a link uniformly at random from all outgoing links of the current node. On contrary, in an informed search the agent possesses (partial) background knowledge of the network. This background knowledge steers the agent's decisions when selecting the next link to traverse. The background knowledge of the network can be represented as a similarity matrix with similarities between pairs of nodes known to an agent. This matrix can be calculated in various ways in order to model various search scenarios or to best fit needs of an application. For example, similarities based on node degrees or some external information about the nodes have been commonly used in the past. In this paper we evaluate the measures that capture regular equivalence of nodes in a network with respect to their suitability as a similarity metric to inform search in networks. In particular we are interested in the properties of Katz similarity for this task.**

I. Introduction

Search in a network is a dynamical process in which an agent moves along the links between the nodes in search for a given node or a given set of nodes. Depending on the link selection mechanism we distinguish between a random walk and an informed search. In a random walk an agent selects the next link uniformly at random from the available links (the links going out from the agent's current node). In an informed search the agent possesses some background knowledge of the network, which guides it towards selecting specific links. In other words, the agent exhibits a certain bias towards selecting some of the links – the bias is induced by the background information that the agent has about the network. Another distinction between a random walk and an informed search is the stochasticity of their link selection mechanism. By definition a random walk is a stochastic dynamical process, whereas in an informed search the link selection mechanism can be (i) either deterministic in cases where the agent e.g. acts greedy and always follows an optimal link (according to a given criterion), (ii) or stochastic in cases where the agent draws a link from a given probability distribution (induced by the background knowledge).

Various studies investigated the nature of the background knowledge in e.g. informed search in social networks. For example, in studies of human search behavior that have been inspired by the famous small-world experiment by Milgram [1] the background knowledge about the network has been represented as a hierarchy of network nodes [2], [3]. The distance of nodes in the hierarchy has been used to inform deterministic decentralized search. Another type of the background knowledge has been analyzed in [4]. In this study a deterministic search is informed by the node degree (the number of nodes adjacent to a given node), a quantity that is always available locally as compared to a node hierarchy which assumes a global knowledge about the network. In [5] the authors built on this previous work and designed a stochastic algorithm that takes into account the node degree, as well as the nodes' homophily, i.e. the tendency of nodes to connect to other similar nodes. The presented algorithm probabilistically weighted the influence of the node degree and the node homophily on the link selection probability. Moreover, the algorithm modeled a situation in which an agent does not have information on the node similarities, in which case the decision was based solely on the node degree.

Similarly to social networks search in information networks is always local, i.e. users have at their disposal only the links going out from their current Web page. Human search behavior in information networks has been investigated in the work of West and Leskovec [6]. They analyzed click paths of users playing a navigation game on Wikipedia and in their subsequent work [7] they compared decentralized search algorithms using various distance functions and benchmarked them against the human navigation paths. The authors found that automatic deterministic search strategies with a complete background knowledge typically outperform human information seeking.

One of the most interesting findings was that human navigation in information networks exhibits two phases: (i) Zoom-out phase in which the users strive to reach the network core, or a hub in the network core, e.g. an overview Wikipedia page with many links to different parts of the Wikipedia. In this first phase the humans tend to base their search decisions on the node degrees, i.e. they tend to select high-degree nodes. (ii) Zoom-in phase in which the users leave the core and close in on the topic of their interest, i.e. they dive in into a Wikipedia cluster (community) dealing with a given topic. In this second phase the humans base their decisions primarily on the similarity between network nodes such as textual similarity between Wikipedia nodes.

Thus, similarly to [5] where the authors engineered an algorithm that interchangeably bases its decisions on the node degree and the similarity between nodes West et al. [6], [7] found empirically that humans base their search decisions on

those two quantities – alternating between the node degree in the first phase and the node similarity in the second phase.

Although the previous research has identified the importance of informing search in social as well as in information networks with the node degree and the similarity between nodes not much work has been done on the analysis of various network internal similarity measures and their ability to capture those two network properties. For example, in those previous studies [5]–[7] the similarity has been calculated from the external information about the network nodes: in [5] the authors calculated standard vector-based similarity on the titles of the scientific articles in the citation networks and in [6], [7] the authors applied the same similarity measure but calculated it on the complete text of Wikipedia articles.

However, it is an interesting research question to analyze the properties of the similarity measures that are based on the internal network linking patterns since the presence of the external information is not always guaranteed and its quality may greatly vary from one network to another. Moreover, measures based on the linking patterns can in a general case capture both node properties: its degree and its similarity to other nodes in a single quantity. Therefore, it seems important to investigate if and how such measures are able to inform search in networks. Thereby, we can concentrate on the suitability of these measures to reflect e.g. the two phase process of the navigation in social and information networks, where in the first phase the node degree plays the most important role and in the second phase that role is taken by the node similarity.

In this paper, we turn our attention to the analysis of internal linking patterns to serve as a similarity measure for informing search in networks. To that end, we concentrate on simple algebraic measures that capture so-called regular equivalence and analyze the distribution of such similarities over a range of synthetic networks. In particular we concentrate on Katz similarity as an example of a measure of regular equivalence in networks. Thereby, we are interested how Katz similarity captures heterogeneity in node degrees and the existence of highly interlinked clusters of similar nodes (network communities).

The paper is organized as follows. In the next Section we give a short overview of the related work in this field. In Section III we describe our methodology and Section IV gives the details about our experiments with synthetic networks. In Section V we present the experimental results and shortly discuss them. Finally, we conclude the paper and provide directions for further research.

II. Related Work

Search has been an important concept in theoretical and empirical studies of networks. For example, in Web search the famous PageRank calculation [8], which determines the importance of Web pages is based on a random walk on the Web network. In a so-called Random Surfer model a hypothetical user navigates the Web by clicking randomly on the Web links. In the limit of large number of clicks the fraction of visits to each Web page gives its PageRank. Another example of an application of the random walk includes the problem of detecting communities (groups of highly connected and similar nodes) in networks. For example, it has been shown that designing minimal codes for encoding paths of a random walker in a network is equivalent to optimally partitioning of the network into communities [9]. Thus, we can design community detection algorithms that aim at optimally compressing a random walk paths in a network.

Research on decentralized search in social networks started with Milgram's seminal small world experiment [1] in which he aimed to study the connectedness of the US society. Milgram found that people in such a large social network are connected by short chains of acquaintances. Moreover, he found that people are able to navigate large social networks efficiently, i.e. that they are able to find those short chains even if they only possess the local knowledge of the network. In the subsequent research, Kleinberg analyzed the second result of the Milgram's experiment – the ability of humans to find a short path when there is such a path between two nodes [2], [10], [11]. Kleinberg concluded that social networks possess certain latent properties that humans are aware of. This background knowledge of network structure allows humans to find a short path between two arbitrary network nodes efficiently. Kleinberg has also investigated the nature of background knowledge that is required for efficient decentralized search algorithms. In other words: What structural properties do efficiently navigable networks possess? To that end, Kleinberg designed a number of network models such as the 2D-grid model [10], hierarchical model [11], and group model [11]. Independently, Watts [3] introduced the notion of social identity as a membership in a number of social groups organized in hierarchies and showed the existence of efficient decentralized search algorithms by simulation. Finally, Adamic [12] and others applied such a model to explain search in e.g. professional social networks.

All of these models have been based on the assumption that an agent navigating the network possesses a complete background knowledge on distances or similarities between pairs of network nodes. Contrary to that, in [4] the authors argued that distances between nodes are typically available only for some of the node pairs and that the assumption that an agent possesses a complete background knowledge is unrealistic. Thus, the authors analyzed an informed search algorithm that bases its decisions on the node degree (the number of nodes adjacent to a given node), a quantity that is always available locally. The algorithm performed better in comparison with a random walk but could not reach the performance of an agent having a complete background knowledge.

In an information network decentralized search can be used to model user navigation in an information network, e.g. the Web or Wikipedia [6]. In that model the user navigates from a Web page to a Web page by following her own intuition and her own knowledge about the topics of various Web pages.

III. METHODOLOGY

A. Node Similarity

A crucial element of an informed search is the notion of distance or similarity between the pairs of network nodes. Mathematically, we may represent the background knowledge with a distance or a similarity matrix. The rows and columns of the similarity matrix represent the network nodes and the elements of the matrix give the similarity score between corresponding network nodes. If the similarity function is symmetric we obtain a symmetric similarity matrix. Partial background knowledge may be easily represented by blank elements in the matrix for those node pairs where the agent's knowledge is missing. In this paper we denote the similarity matrix with $\boldsymbol{\sigma}$ – the element σ_{ij} of the matrix gives the similarity between nodes i and j from the network.

Different similarity measures have been previously discussed in the literature for various tasks. For example, [13] gives an overview and evaluation of various similarity measures for the link prediction task. In general, similarities in networks can be calculated from external or exogenous information about the networks (e.g. textual content in an information networks), or from internal or endogenous information (internal linking patterns). There are two possible similarity measures based on the network linking patterns: structural equivalence measures and regular equivalence measures. Structural equivalence is based on the simple idea that two nodes are similar if they share many of the same network neighbors, whereas regular equivalence between two nodes is given if they have neighbors who themselves are similar. Since absolute numbers of common neighbors are hard to interpret, this number is typically normalized. Different normalizing constants give rise to different similarity measures such as cosine similarity, Pearson correlation coefficients, or Euclidean distance ([14] gives a nice overview and comparison of various normalization methods). In contrast, regular equivalence between nodes is established when two nodes do not necessarily share same neighbors but rather they have neighbors who themselves are similar, or in a more simple case two network nodes i and j are similar if j is similar to other neighbors of i. In past, several simple algebraic measures have been developed in the past to measure regular equivalence [15], [16].

Previous research showed that node degree as well as node similarity play an important role in informed search in many networks. Therefore, we concentrate in this paper on the analysis of regular equivalence measures since structural equivalence can not capture both of these aspects in a single quantity. These measures assign a zero similarity to all nodes that do not have neighbors in common – they only capture local similarity between nodes but can not reflect any global or long range dependences between nodes. They are suitable to inform search if the agent is already in the proximity of its goal, but they can not lead that agent from a distant part of the network to the cluster or community where the target is situated. In other words, structural equivalence would not be able to instruct an agent in its zoom-out phase but only in its zoom-in phase. On the other hand, because regular equivalence measures are defined recursively over node neighbors, they are able to capture global node similarities that go beyond immediate node neighbors. They assign a non-zero similarity value to each node pair that exhibits a structural dependence in the network, e.g. the nodes are connected by at least one path in the network.

B. Katz Similarity

In this paper we concentrate on a particular measure of regular equivalence called Katz similarity [13]. Let us first introduce the basic quantities relevant for measuring this similarity. Let us denote the adjacency matrix of a graph $G(V, E)$ with $\boldsymbol{A}$:

$$A_{ij} = \begin{cases} 1 \text{ if nodes } i \text{ and } j \text{ are connected by a link} \\ 0 \text{ otherwise.} \end{cases} \quad (1)$$

We define Katz similarity recursively as [17]:

$$\sigma_{ij} = \alpha \sum_k A_{ik}\sigma_{kj} + \delta_{ij}, \quad (2)$$

where δ_{ij} is Kronecker delta ($\delta_{ij} = 1$ if and only if $i = j$, otherwise $\delta_{ij} = 0$).

The idea is that the term σ_{kj} is large if the neighbor k of i is similar to j. We then sum over all neighbors of i, which is ensured by the product $A_{ik}\sigma_{kj}$ since A_{ik} equals 1 only if i and k are neighbors. Finally, the term δ_{ij} assigns a high value of "self-similarity" of a node to itself. The constant α weights the influence of neighbors as compared to the influence of the self-similarity to the nodes similarity.

We can write the expression for the Katz similarity in the matrix form as:

$$\boldsymbol{\sigma} = \alpha \boldsymbol{A}\boldsymbol{\sigma} + \boldsymbol{I}, \quad (3)$$

where $\boldsymbol{I}$ is the identity matrix.

We can now solve this equation for $\boldsymbol{\sigma}$, which gives us the following:

$$\boldsymbol{\sigma} = (\boldsymbol{I} - \alpha \boldsymbol{A})^{-1}. \quad (4)$$

In case of large networks with e.g. millions of nodes, inverting a matrix is computationally expensive. Therefore, we may want to evaluate the Equation 3 recursively. We would typically start by assigning initial values for similarity to zero, e.g. $\boldsymbol{\sigma}^0 = 0$. We then obtain (for the first three iterations):

$$\boldsymbol{\sigma}^0 = 0, \boldsymbol{\sigma}^1 = \boldsymbol{I}, \boldsymbol{\sigma}^2 = \alpha \boldsymbol{A} + \boldsymbol{I}, \boldsymbol{\sigma}^3 = \alpha^2 \boldsymbol{A}^2 + \alpha \boldsymbol{A} + \boldsymbol{I}. \quad (5)$$

Thus, in the limit of large number of iterations m we have:

$$\boldsymbol{\sigma} = \sum_{m=0}^{\infty} \alpha^m \boldsymbol{A}^m. \quad (6)$$

The elements of matrix $\boldsymbol{A}^m$ at index i and j, i.e. $[\boldsymbol{A}^m]_{ij}$ give the total number of paths of length m between nodes i and j. The Katz similarity can be seen as a weighted count of all paths between the nodes i and j with paths of length r getting weight α^r. As long as $\alpha < 1$ longer paths obtain

less weight than shorter ones.Thus, two nodes will be similar if they are connected either by few short paths or if they are connected by many longer paths.

The inverse of $(\boldsymbol{I}-\alpha\boldsymbol{A})$ does not exist for $det(\boldsymbol{I}-\alpha\boldsymbol{A})=0$, which is exactly the characteristic equation for eigenvalues of $\boldsymbol{A}$, i.e. in the matrix form $\boldsymbol{\lambda}=\mathbf{1}/\boldsymbol{\alpha}$. Thus, the inverse does not exist whenever $1/\alpha$ equals λ_i. If we start with $\alpha=0$ and gradually increase it, we first hit the equality $1/\alpha=\lambda_i$ for the largest eigenvalue λ_1, and then again every time when we approach the next eigenvalue. Thus, if we pick an $\alpha<1/\lambda_1$ we ensure that the inverse exists (or that $\sum_{m=0}^{\infty}\alpha^m\boldsymbol{A}^m$ converges).

Therefore, we may set the value of parameter α for each network as:

$$\alpha=\frac{1}{\lambda_1}f, \tag{7}$$

where λ_1 is the largest eigenvalue of the adjacency matrix $\boldsymbol{A}$, and f is a parameter in the interval $[0.01, 0.99]$. We call f the α-parameter.

C. Synthetic networks

We carry our experiments on synthetic networks. The goal is to generate networks that structurally closely reflect a typical social or an information network. Although the real networks exhibit a wide range of interesting structural properties we concentrate on two which have been observed in the majority of networks from different domains: (i) degree heterogeneity (where we typically have only a few of high degree and mid degree nodes that keep the network connected), (ii) and modular or community structure (with various groups of nodes that are tightly connected with each other and only loosely connected to other communities – typically via high and mid degree nodes). Such networks reflect also typical search scenarios such as search for a similar node within the same community and search for a distant target node in another community. The first scenario is simpler and consists only of the zoom-in phase where an agent needs only to close in on the target node, whereas the second scenario is a more complicated one and contains both search phases: zoom-out phase where the agent exits the starting community and enters the network core and zoom-in phase where the agent enters the target community and finally closes in on the target node.

In our experiments we want to analyze if Katz similarity can capture those two phases in a search process. Thus, for a given target node i:

1) The most similar nodes to i should be the nodes from its community – this would instruct an agent that entered the i's community and is already in the proximity of its target to explore that community in its search for the target.
2) The nodes from the other communities should have low similarity to the given target node i – this would prohibit an agent to enter a distant community.
3) The nodes that keep the network connected such as high and mid degree nodes should have high to moderate similarity values to a given node i – this would guide an agent to leave a distant community in the zoom-out phase. Combined with the high similarity to the nodes from the own community it would further instruct the agent to enter the i's community and explore it until it reaches its goal.

Thus, we generate networks with injected communities and heterogeneous node degrees. A standard generative model for such networks are so-called stochastic block models, which we describe next.

D. Stochastic Block Models

Stochastic Block Models (SBM) are generative models for networks with clusters or communities [18]–[23]. They are simple extensions of the standard Erdős–Rényi [24] or Bernoulli graph model. In Bernoulli model any pair of nodes from the network is connected with a constant probability p. In addition, each link is independent on any other link in the network. This model generates networks with rather homogeneous (Poisson) degree distributions. In a stochastic block model nodes are grouped into k communities and the probability of a link between two nodes is conditioned on their membership in different communities. Thus, a stochastic block model is a mixture of k^2 Bernoulli models with different linking probabilities.

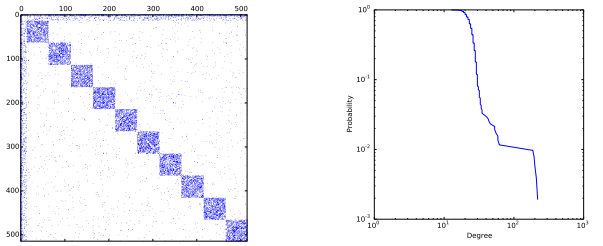
Mathematically, a stochastic block models is specified by: (i) the number of the communities k, (ii) a vector $\boldsymbol{s}$, which defines the membership of nodes in communities, and (iii) a $k\times k$ matrix $\boldsymbol{P}$, which defines probabilities of links between nodes from different groups.

The element P_{uv} of the matrix $\boldsymbol{P}$ defines the linking probability of nodes belonging to communities u and v. For the elements on the diagonal P_{uu} we obtain the linking probabilities within communities and the off-diagonal elements represent the probabilities of links that run between communities. To obtain a network with tightly connected communities with only a few links that connect the nodes from different communities we set higher probabilities in the diagonal elements P_{uu} and lower probabilities in the off-diagonal elements (see Equation 8).

To obtain a heterogeneous degree distribution we need a special community (or a couple of such communities) which are smaller than the other communities and which reverse the linking probabilities: the nodes from this community have low probability for connecting to other members of their community, but in turn they have high probability of connecting to all other communities. As a consequence these nodes obtain a larger number of links than average and thus represent high-degree or hubs in the network. The same modeling concept may be further applied to e.g. obtain mid-degree nodes, which also have a degree larger than average but still smaller than the hubs – the probabilities for connecting to the nodes from other communities should be larger than for typical nodes but smaller than the hub probabilities.

IV. Experiments

In our experiments we generate networks with 12 communities with one high-degree community and one mid-degree



(a) Adjacency matrix (b) Cumulative degree distribution

Fig. 1. **Left: Community structure.** The community structure is clearly visible in the visualization of the adjacency matrix. The thin blue line at the top and to the left of the matrix is the community of high-degree nodes. A blueish area beneath the top and to the right of the thin blue line is the mid-degree community. **Right: Heterogeneous degree distribution.** Cumulative degree distribution exhibits the existence of a small number of highly connected nodes (hubs).

community, which have 5 and 10 nodes respectively. All other 10 communities have 50 nodes. In the probability matrix for the high-degree community we assign a high probability of those nodes connecting to all other nodes from other communities. For mid-degree community we apply the same mechanism but assign smaller probabilities than for the high-degree community. All other 10 communities have a small probability of connecting to a different community (low off-diagonal entries) but a high probability of connecting to itself (high diagonal entries):

$$\boldsymbol{s} = \begin{pmatrix} 5 \\ 10 \\ 50 \\ 50 \\ \vdots \end{pmatrix} \boldsymbol{P} = \begin{pmatrix} 0.000 & 0.400 & 0.400 & 0.400 & \dots \\ 0.400 & 0.000 & 0.100 & 0.100 & \dots \\ 0.400 & 0.100 & 0.400 & 0.005 & \dots \\ 0.400 & 0.100 & 0.005 & 0.400 & \dots \\ \vdots & \vdots & \vdots & \vdots & \ddots \end{pmatrix} \tag{8}$$

A typical adjacency matrix and a cumulative degree distribution are shown in Figure 1.

Now, we are interested in the average similarity of nodes to:

1) the nodes from their own community (Own),
2) the nodes from the other communities (Other),
3) the nodes from a moderate size community of mid-degree nodes (Mid),
4) the nodes from a small size community of high-degree nodes (High).

We investigate how these average similarities change as a function of the α-parameter f from Equation 7. Thus, we iterate over the interval $[0.01, 0.99]$ in steps of 0.01 for a total of 99 different parameter settings. For each setting we generate $1,000$ random networks (for a total of $99,000$ generated networks for all parameter configurations) using a stochastic block model with the group vector $\boldsymbol{s}$ and the probability matrix $\boldsymbol{P}$ from Equation 8. For each parameter value we plot the average similarities and the standard deviation over $1,000$ generated networks.

V. Results and Discussion

Figure 2 shows the results of our experiments. For smaller values (e.g. f less than 0.1) of the α-parameter the most similar nodes to arbitrary nodes are, on average, high-degree nodes and the nodes from their own community. The mid-degree nodes have moderate average similarity and the nodes from communities other than the own community have a small average similarity. Thus, these distributions of similarity are suitable for informing search in networks. For example, these configurations can support zoom-out phase, where an agent starting in a distant community needs first to leave that community and access nodes that provide shortcuts to the target community. High-degree nodes connect different parts of the network and an agent needs to visit them first to close in on the target community. Since the high-degree nodes have a large average similarity to an arbitrary node in a network an agent following this similarity intuition would first visit one of the high-degree nodes. On the other hand, once when the agent reaches the target community the most similar nodes to the target node are the nodes from its own community – thus, an agent would enter the target community and remain within it to explore the community nodes and eventually reach its target.

For mid range of values of α-parameter (greater than 0.1 and less than 0.9) the high-degree nodes start to dominate other node types and become the most similar nodes to arbitrary nodes regardless of their community. Thus, an agent would correctly leave a distant community by visiting one of the high-degree nodes. However, the agent would remain in the network core indefinitely long. Even if the agent succeeds in reaching the target community it would in most cases try to reach the target node by leaving the target community and revisiting the high-degree nodes. The exploration of the target community would not take place at all.

For even larger values of the α-parameter (greater than 0.9) even the mid-degree nodes become more similar to arbitrary nodes than the nodes from their communities. Thus, an agent would in most cases traverse links connecting high-degree and mid-degree nodes hoping in the network core and failing even to reach the target community.

Summarizing, regular equivalence measures in general and Katz similarity in particular can provide the background knowledge and inform search in networks efficiently. They are able to capture both phases of the search process: exiting a distant community and entering the network core with many long range links to the target community, as well as the exploration of the target community. However, it is necessary to configure the parameters for calculating the regular equivalence measures appropriately. Our experiments show that the desired behavior of these measures can be only obtained by lower values of the control α-parameter, i.e. for values less than 0.1.

VI. Conclusions

In this paper we provide a short overview of various search process on structurally complex networks. We then analyze the

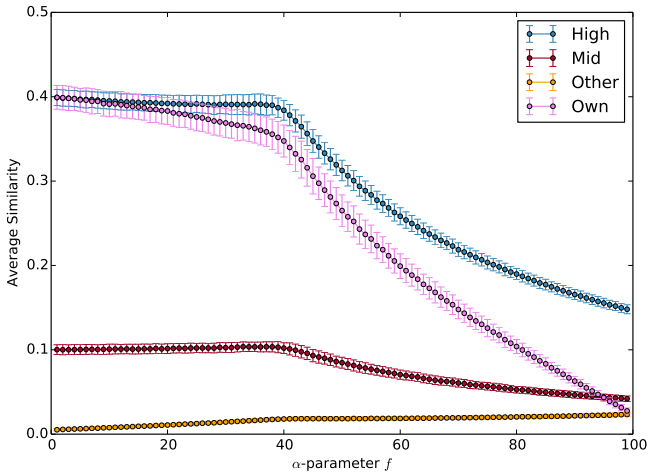


Fig. 2. **Average similarity as a function of α-parameter** For smaller values of the path weights the most similar nodes are those from the own community, closely followed by the hubs. The average similarity of the mid degrees is also significantly higher than the average similarity to nodes in the other communities. For large values of the path weights the similarity of high degree nodes dominates all other communities. The similarity to the nodes from the own community rapidly drops and for the values above 0.9 even the mid degree nodes become more similar on the average than the nodes from the own community. From the informed search point of view, the smaller values of α-parameter (i.e. values less than 0.1) are more suitable for providing guidance in both phases of search: zoom-out phase where high-degree nodes must be quickly reached, and the zoom-in phase where the nodes from the target communities need to be the most similar nodes.

suitability of regular equivalence measures to inform search in such networks. In particular, we analyze simple algebraic measures such as Katz similarity which capture several network structural properties such as node degree and node similarity into a single similarity score. Our experiments on synthetic networks with heterogeneous node degree distributions and injected community structure show that Katz similarity can efficiently inform search in networks. However, the parameters used to calculate the similarity need to be chosen with care and appropriately.

The main limitation of our work is the theoretical nature of the analysis. Specifically, we estimated the theoretical suitability of Katz similarity to inform search in networks. An experimental proof of concept would be also needed. For example, one can simulate an agent performing greedy search in networks by using the Katz similarity as the background knowledge and measure the agent's success rate and its search efficiency. Furthermore, the experiments should be repeated on empirical social and information networks that exhibit typical structural properties such as heterogeneous node degrees and community structure. However, we leave these experiments for the future work.

{daniel.domovic, tomislav.rolich, darko.grundler, slavica.bogovic}@ttf.hr

Summary - Strip-packing problem is apparent in textile industry where a set of items, i.e. cutting parts (2D convex or non-convex polygons) need to be placed on a rectangular container (fabric with an *m*×*n* area) so that cutting parts do not overlap and do not exceed the boundaries of the container. The goal is to find a placement that utilizes the area of a container. In this paper three methods (random search, greedy algorithm and genetic algorithm) are tested on sets of regular (convex polygons) and irregular (cutting parts) items. The goal is to find the optimal items placement that minimizes the cover area. In this paper a no-fit polygon (NFP) is used to assure two items touch without overlapping. NFP is constructed by rotating polygon *B* around a static polygon *A* in a way their edges always touch and never overlap. The result is a polygonal area enclosed by trajectory of rotating polygon's reference point which represents the overlapping area of *A* and *B*. Items touch if polygon *B* is placed on the NFP's border. Non-convex cutting parts are approximated with their convex hull since a NFP version for convex polygons is used in this paper.

I. INTRODUCTION

Nesting problems are a subfield of packing problems where a set of smaller elements i.e. items (convex or non-convex polygons) needs to be placed in one or more larger containers so that the following conditions are met: none of the two elements should overlap and elements need to be placed within the boundaries of a container [1].

The problem is applicable in variety of science branches and industry. That is why packing problems consist of wide variety of subproblems specifically modified according to the field of research. Two typologies have been made to systematize these problems: Dyckhoffs in 1990 which was revised by Wäsher in 2007 [2][3].

Packing problems can be researched from three perspectives. One can either try to: (1) find an optimal subset of items to pack in a container, (2) try to minimize the number of containers, or (3) try to find minimal container area/size.

In this paper a minimal container area is researched and applied on strip-packing problem commonly known as nesting problem since the cutting parts have to be closely nested to produce dense packing. Strip-packing problem is a common problem that arises in textile industry in the process of automated marker making. Problem goal is to find optimal placement i.e. optimal positions of cutting parts on material so the following conditions are met: each pair of cutting parts must not overlap and their surface area needs to be within the boundary of rectangular material area. An optimal placement that utilizes material usage needs to be created. Since material is formed in roles one dimension, usually width has a fixed size while the length needs to be minimized. In this paper, both dimensions can be various size so the goal is to find minimal area of a rectangle that serves as a bounding-box of nested cutting parts.

One of the first problems a researcher faces while nesting items is overlapping detection. Although this is a simple task for a human, computationally it is a hard problem that is getting more complex as the complexity of polygons visualization increases. The success of an overlapping detection method greatly depends on a way polygons are represented. There are several methods in the literature that are used to deal with overlapping detection: raster method, no-fit polygon, phi-functions and constraint graphs [4]. In this paper a no-fit polygon is used.

This paper is organized as follows. In section II methods and some previous research is described, including random search, greedy algorithm and genetic algorithm. In section III results of the implementation and a discussion is given. In section IV conclusions are made.

II. METHODS

A. No-fit polygon

A no-fit polygon (NFP) is a popular method for calculating an area in which two polygons will not overlap. Calculating the NFP is faster than using direct trigonometry methods and its advantage is that it allows the polygons to be represented with vertices and edges without the necessity for it to be approximated [4].

```
Define a static polygon A and a sliding polygon B
Perform initial trasformation
NFP = [first point in B]
newPoint, prevPoint = inf;
Until newPoint == prevPoint
        Calculate a touching point of A and B
        Find next start point
```

Figure 1. Algorithm for NFP construction for two convex polygons

NFP_{AB} of two polygons *A* and *B* is a resulting polygon of sliding movement of a polygon *B* around a fixed polygon *A*. During the sliding both polygons have fixed orientations. One point on polygon *B* should be chosen as a reference point. During the sliding a trajectory of a reference point represents the edges of NFP. During the sliding polygons *A* and *B* should always touch and never overlap.

To check if two polygons overlap a relationship between a reference point of polygon *B* and a NFP needs to be viewed. If a reference point is inside the NFP two polygons overlap. If a reference point is on a boundary of a NFP, two polygons touch. Finally, if a reference point is outside of NFP two polygons do not overlap.

The described NFP is an outer-fit NFP which is used when finding optimal non-overlapping position of two items. The other NFP version is an inner-fit NFP which is generated by sliding an item around the boundary of an inner side of a container. Using inner-fit NFP a set of feasible positions within a container is calculated in which a sliding polygon can be placed so that the overlap does not occur.

A no-fit polygon can be constructed using a sliding algorithm whose basic principle has been described above, using Minkowski sum and by decomposing items into star shaped or convex polygons.

Within the scope of this paper a NFP for convex polygons has been implemented in MATLAB environment based on an algorithm in [5] and is depicted in Fig. 1.

B. Convex hull

A convex hull of a planar set of points *P* is a smallest convex region enclosing *P* [6]. It can also be defined as a smallest convex set that contains *P*. The reason a polygon is approximated with a convex hull is that usually a convex hull has fewer points than an original polygon has so it becomes a simpler object to manipulate. Therefore computation is faster.

In this paper, cutting parts which are convex and non-convex polygons are approximated with their convex hulls i.e. transformed to convex polygons. All calculations are done with these approximations. Convex hull of cutting parts can be seen in Fig. 4. The yellow parts represent real shapes of cutting parts, while red parts are their convex hull approximations.

```
While maximum number of iterations is not met
    RND_perm = permutation of indexes of cutting parts
    Choose first polygon A as RND_perm[1]
    For an element i  in RND_perm
      Choose second polygon B as RND_perm[i]
      Calculate NFP of A and B
      In every point of NFP
          Calculate the area of rectangular bounding-box of
          polygon A and B
          Remeber in which point the bounding-box are is
          minimal
      Place polygon B in a point with minimal bounding-box
      area
      Set polygon A to a convex hull of polygons A and
      translated polygon B
```

Figure 2. Random search algorithm

C. Random search

One of the algoritms used in this paper is the random algorithm described in Fig. 2. Cutting parts are saved in a list therefore each cutting part can be accessed via its index. In each new iteration a new random permutation of indexes is created (RND_perm). Permutation list represents an order, i.e. polygons are taken from a list to form a placement in order their index appears in the permutation. The number of different versions of placement is *n*! where *n* is the number of cutting parts.

After two polygons are chosen, a NFP is calculated. A set of points is given in which two polygons can be placed to abut. Polygon *B* is placed in each NFP point. Then a bounding-box of a polygon *A* and *B* is calculated. A bounding-box is a minimal rectangular container that surrounds polygons, or in this case polygons *A* and *B*. For each NFP point a polygon *B* is placed in, an area of a bounding-box is recored. Final placement point for polygon *B* is chosen based on minimal bounding-box area criterium. Finally, a convex hull of polygon *A* with polygon *B* located in its best position is created. This convex hull serves as a static polygon *A* for the next iteration. A new polygon *B* is chosen form RND_perm and the procedure is continued until all cutting parts are used. Then a new iteration *i* starts.

D. Greedy algorithm

Greedy algorithm is an algorithm that builds up a solution piece by piece by choosing the currently best option that would bring immediate benefit to the solution

```
Choose initial cutting part from parts = [1,..,n]
    For each of the remaining n-1 cutting parts
      Calculate the NFP polygon points
      Calculate the bounding-box area when B is placed in
      each NFP point
      Place the polygon B in a position with minimal
      bounding box
    Place B in a NFP point that results in minimal bounding-
    box area
    Create a convex hull from A and B
    Set the convex hull as polygon A
```

Figure 3. Greedy algorithm

[7]. By creating a locally optimal solution the algorithm hopes to find the globally best solution. Although it may fail in producing an optimal solution, greedy algorithms often provide fast heuristics and are used in finding good approximations [8].

Greedy algorithms are used to solve many combinatorial optimization problems such as: Kruskal's algorithm for minimum spanning trees, Dijkstra's algorithm for a finding shortest paths etc.

In this paper a greedy algorithm for solving a 2D irregular strip-packing nesting problem has been created.

A greedy algorithm used in this paper is described in Fig. 3. An algorithm was inspired by Dijkstra's algorithm for solving the travelling salesman problem. A total of *n* iterations is calculated, and *n* different solutions are produced, where *n* is the number of cutting parts. The best one is declared the globally best solution produced by a greedy algorithm for this set of cutting parts. An iteration is equivalent to finding a shortest path from a town *i* in the travelling salesman problem (TSP).

First, an initial cutting part is chosen as a static polygon *A*. Then each of the remaining *n*-1 polygons are used as a sliding polygon *B* to test which gives a minimum bounding box area with polygon *A* while abutting in the NFP points. A position resulting in minimum bounding-box area is chosen. Optimal polygon *B* is the one with minimal bounding-box area and it is placed in a temporary solution. A convex hull is created from polygons *A* and *B*. Then a new polygon from the remaining *n-2* polygons is chosen. The procedure is continued until all polygons are used.

E. Genetic algorithm

Genetic algorithm (GA) is a heuristic algorithm based on evolutionary computation. GA mimics nature's evolution principle that describes the survival of the fittest. GA author, John H. Holland, presented the algorithm in the 1970s motivated by Darwin's theory of evolution. GA uses evolutionary methods to search the solution space in order to find a solution to the optimization problem [9].

The algorithm starts with initializing a population i.e. a set of individuals called chromosomes. Initial population is usually generated randomly within the solution space to enable searching the entire solution space. Population size depends on the type of problem, but usually the size of a few hundred to a few thousand individuals is used.

The algorithm continues with the selection process where a certain number of individuals from initial populations are selected based on their fitness to enter the reproductive process (crossover and mutation). Fitness of an individual is calculated using a fitness function *f(x)*. Good individuals are considered to pass good properties to their children in the process of crossover, and improve the quality of the population in the coming generations.

Crossover is a process of exchanging genetic material between parents. Individuals are crossing in order to maintain the good properties of the population. The higher the fitness of an individual is, the greater the likelihood of its survival and crossover. Crossover can create one or two children. The purpose is to get children chromosomes that will be just as good as or better than their parents [9].

After crossover some individuals mutate. Upon completion of the mutation, the new individuals are evaluated and copied into the population. Poor specimens are deleted from the population. The process of selection and reproduction is repeated until the termination condition is met. Termination condition may include maximum number of iteration achieved, maximum number of fitness function evaluations, the desired fitness function value has been achieved etc. [7].

1) Stochastic universal sampling

In a selection process in this paper a stochastic universal sampling is used [10]. Individuals are mapped to contiguous line segments. Size of each individual's segment corresponds to its fitness. Selection process is conducted by placing the equally spaced pointers over the line. Number of pointers corresponds to the number of individuals that need to be selected.

Consider number of individuals that need to be selected as NPointer. The distance between pointers equals to 1/NPointer. Position of a first pointer is given by a random number in the range [0, 1/NPointer].

2) Partially matching crossover

A partial matching crossover (PMX) has been used for recombination in this paper. A matrix of individuals from a current population is taken, a recombination is done on consecutive pair with a certain probability. After recombination a new population is used [11].

After two chromosomes *P* and *Q* are selected, two randomly chosen crossover points are created splitting the chromosomes to three parts: $P_1P_2P_3$ and $Q_1Q_2Q_3$. The middle labels between two cutting points are exchanged giving the new offspring: $P_1Q_2P_3$ and $Q_1P_2Q_3$. Duplicate labels may appear after the exchange. To resolve that problem it is considered that P_2 is consisted of $P_{21}P_{22}\ldots P_{2n}$ and Q_2 is consisted of $Q_{21}Q_{22}\ldots Q_{2n}$. Then, for a first child, a mapping of labels Q_{21} into P_{21}, Q_{22} into P_{22}, …, Q_{2n} into P_{2n} needs to be performed in the whole chromosome. Similar procedure is performed for the second child [12].

3) Move mutation

In this paper a move mutation has been used. A move mutation is a mutation type made for permutation/ordering/combinatorial optimization [10]. Individuals from the current population are taken, and each individual is mutated by moving variables with a given probability and afterwards returned to population [13].

III. RESULTS

A. Environment

All programs have been implemented in MATLAB environment following the algorithms in section 0. For genetic algorithm, a GEATbx (Genetic and Evolutionary Algorithms) toolbox has been used [14].

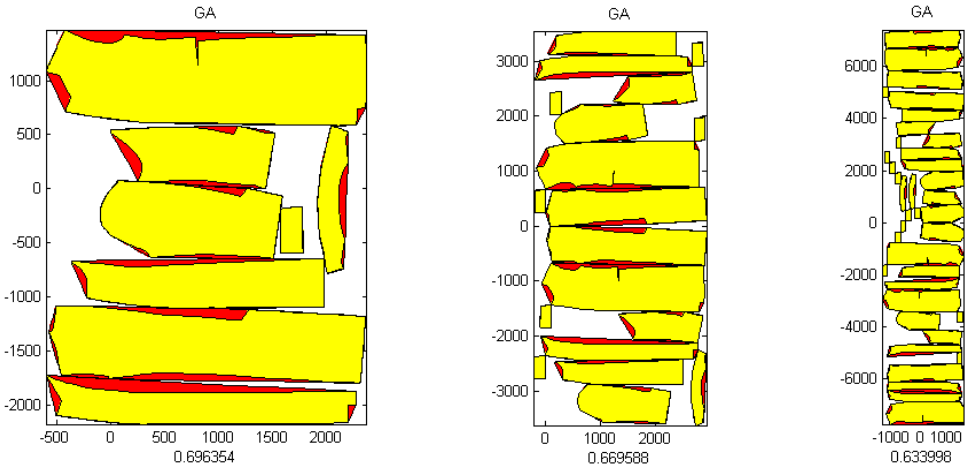

Figure 4. Best overall testing results

Additional programs have been downloaded from MATLAB Central repository and are enlisted in this section. The experiments have been run on personal computers with the following configuration: Intel Core i5-3470@3,2 GHz, 4GB DDR3, 500GB HDD.

B. Data sets

For the purpose of this research cutting parts of a male robe in garment production were used. Three sets with different number of cutting parts (8, 19 and 38) have been created.

Cutting parts were construted on paper in measure 1:5. Afterwards they were scanned and saved into bitmap format and converted to vector format using MATLAB. Since an approximate of 1200-7800 points were used to describe a polygon, using an application [15] these polygons have been simplified. Total number of points of a polygon is 1 percent of the original polygon points count (this parameter can be adjusted in [15]) which resulted in 13-78 points. The program tends to keep the aspect ratio between area and circumference as as close to 1 as possible before and after simplification.

This simplification has been done to convert curved edges of cutting parts into straight line edges. A transformation from cutting parts into convex hull has been done in the next step. Polygons created using this procedure are reffered to as version *V1*.

A different data set version *V2* is made of cutting parts from the version *V1* except *V2* is consisted of five times more points since five more points have been interpolated on a line between each two vertices of an original polygon from *V1*.

Cutting parts are saved in a list therefore each cutting part can be accessed via its index.

C. Hypothesis

The goal of this research was to find a dense packing using cutting parts aproximated with their convex hull.

Several hypothesis have been tested in the scope of this research. Hypothesis (1) included the premise that the data set version *V2* will be able to produce denser packing becauce in NFP, a sliding polygon could be placed directly on the edge of the NFP not just at the vertices which could lead to creating a convex hull of polygons *A* and *B* with a smaller area. That would mean a packing is denser.

Hypothesis (2) includes a premise that genetic algorithm is most likely to produce the best results.

In hypothesis (3) an assumption that greedy algotihm will not give the best solution.

In hypothesis (4) it is assumed that packing density depends on the number of cutting parts such that more cutting parts will produce lover cover area than less cutting parts.

D. Parameters

1) Random search parameter

In this research 10000 iterations has been used without rotation. Rotation has not been used since cutting parts in the real life techological process should not be rotated because of properties of material.

2) Greedy algorithm parameters

A total of *n* iterations has been made for greedy algorithm producing *n* different local best results since in every iteration a different cutting part has been chosen as a starting point. The solution with the best cover area has been declared as optimal.

3) Genetic algorithm parameters

Parameters described in Table I are used in the GEATbx toolbox in MATLAB. One population (parameter NumberPopulation in GEATbx) consisted of 50 individuals (parameter NumberIndividuals in GEATbx) is used in reproduction process of genetic algorithm in 200 generations. Best individual found upon this termination criterion is the best solution so far. Individuals are represented as permutations that correspond to variable format 5 in GEATbx.

TABLE I. PARAMETERS OF GENETIC ALGORITHM IN GEATBX

GA parameter		Value
Number of population		1
Number of individuals		50
Variable Format		5
Selection	Name	Selsus
	Pressure	2
	Generation Gap	1
Recombination	Name	recpm
	Rate	1
Mutation	Name	Mutmove
	Rate	1/m
Termination	Method	1
	MaxGenerations	200

In the selection process, a stochastic universal sampling method is used with pressure factor equal to 2 and generation gap parameter equal to 1. Generation gap parameter describes how many individuals will be produced in comparison to the number of individuals in the population [10]. If generation gap equals to 1, than the same amount of offspring as parents is produced and all parents are replaced with offspring.

Still the toolbox remembers the best individual found in all generations. If generation gap is less than 1, less offspring than parents is produced so parents with best solutions are able to survive to the next generation (elitism).

Partial matching crossover PMX (*recpm* in GEATbx) has been used for recombination with rate value 1.

A move mutation has been used. Mutation rate controls the number of changes per individual and equals to 1/*m* where *m* is the number of individuals.

The algorithm stops after the condition of maximum of 200 generations is met which equals to 10.000 objective function evaluations.

Fitness function is calculated using (1):

$$f(\mathrm{x}) = 1 - (areaCP / areaBB), \qquad (1)$$

where *areaCP* is the area of real non approximated cutting parts before approximation with convex hull, and *areaBB* is the area of a bounding box of two rectangles *A* and *B*. Note that, although approximations in form of convex hulls are used for nesting (so that NFP fox convex polygons can be used), real cutting parts area is used for calculating *f(x)*.

E. Discussion

The results in table II are used for hypothesis validation. Rows in table II illustrate the results for different data sets with 8 (CP8), 19 (CP19) and 38 (CP38) cutting parts. Each dataset comes in two versions: *V1* and *V2* as described in subsection Dataset. Results for cover area are shown in percentage for greedy algorithm (GRE), random search (RND) and genetic algorithm (GA). Cover area is the ratio between the area of cutting parts and minimum bounding-box of cutting parts. An average cover area of ten measurements is shown in column AVG and a standard deviation in column SD.

The results indicate that as the number of cutting parts increases cover area is getting lower for all *V2* experiments. *V2* dataset produced denser packing for 8 cutting parts using all algorithms. Only in GA *V2* gives better results than *V1* (if SD factor for CP38 is counted in). For random search algorithms *V1* always gave better results than *V2* in all datasets. Therefore, hypothesis (1) is not generally true. It is shown that datasets with less cutting parts and more points representing them will result in denser packing.

As the number of cutting parts increases genetic algorithm produces better results than the other two algorithms, because it searches the solution space diversely and with more guidance toward the best solution. Therefore, hypothesis (2) is justified. In Fig. 4 the best solutions obtained from all of the experiments are presented for 8, 19 and 38 cutting parts. All of the results have been obtained by GA. The yellow parts represent real shapes of cutting parts, while red parts are their convex hull approximations.

Greedy algorithm did not produce the best results compared to other algorithms which confirmed hypothesis (3). In the literature the results of greedy algorithm is usually used as the initial solution for some algorithms.

A relation between number of cutting parts and packing density has been detected for random search and GA for both *V1* and *V2* datasets. As number of cutting parts is increasing so is the size of the solution space. For 8 cutting parts the solution space is 8!, and for 38 cutting parts it is 38!.

TABLE II. COVER AREA

		GRE	RND		GA	
			AVG	SD	AVG	SD
CP8	**V1**	58.48	68.25	0.35	67.71	0.68
	V2	66.86	69.41	0.18	68.43	1.38
CP19	**V1**	45.16	64.7	0.82	64.81	0.9
	V2	44.58	44.54	8.02	64.89	0.62
CP38	**V1**	49.64	41.94	5.97	60.69	1.55
	V2	44.5	27.77	7.84	59.52	0.53

On the other hand, due to limiting computational resources, only 10.000 solutions for each data set is calculated in this research. This means that 24,8% of the solution space is searched for 8 cutting parts and only $5{,}23*10^{-44}$% for 38 cutting parts. The random search algorithm does not provide any guidance toward the best found solution as GA does so it produces worse results than GA for large number of cutting parts. Therefore, it can be assumed that the order in which cutting parts are nested is important and will have great influence on packing density. More points that represent a polygon do not guarantee the packing will be denser. The hypothesis (4) is valid.

It can also be noted that the shape of cutting parts influences the density of a packing because cutting parts, when optimal nesting position is found are converted to their convex hull which can lead to a lot of blank spaces that cannot be filled because a NFP for convex polygons is used.

IV. Conclusion

In this paper a research on finding dense packing using cutting parts of a male robe has been conducted. Three datasets with 8, 19 and 38 cutting parts have been used. Each data set came in two versions, one of which had five times more points representing each polygon. Experiments with random search, greedy and genetic algorithm have been performed. Results of an average of ten experiments and standard deviation have been presented in this paper.

It has been discovered that the shape and order of cutting parts influences the density of packing. If a polygon is represented with higher amount of points it does not mean the packing will be denser. Random search algorithm can produces best results for a small number of cutting parts. For large number of cutting parts it is best to use genetic algorithm.

Abstract - We consider optimal control problems solved in the process of decision support implemented as a submodule of a hybrid decision support system (HDSS). The HDSS is devoted to figure out a sustainable consumption of the forest resources in an industrial region. The proposed decision is presented to decision maker as possible scenarios of a modeled object development in the future. The scenarios are generated by a subsystem according to initial value combination obtained from various data sources. The mathematical model as an informational object representation is generated by means of automated reasoning that implements a technique of a model construction. The paper deals with the internals of the HDSS related to optimal control model implementation and its integration into the whole system. A HDSS is tested on the data of forest resources of Irkutsk Region.

I. INTRODUCTION

One of the approaches to decision support systems construction is the use of mathematical models and computer simulation to supply decision-making algorithms with additional information. This allows decision maker to manipulate more actual information and produce counterintuitive decisions. The additional information is a set of computer simulation scenarios of object under investigation and the analysis of the scenarios by means of a number of criteria. A set of Pareto-optimal scenarios is selected, and a multicriteria optimization is carried out over the set of the produced scenarios. Each stage of modeling must be supported with necessary data [1-3].

Within the above-described conceptual Hybrid approach to the Decision Support Systems (HDSS) environment and tools construction, we develop a HDSS for decision maker to support sustainable forest resource consumption [4]. The HDSS is based on computer simulation of the resource development in future according to the identified model, initial data, and a number of various scenarios of timber-harvesting and forest restoration. Identification of the model is carried out under control of a knowledge base, which constructs model state graph, identifies constants, and computes the initial conditions for the concrete scenario prescribed by a scenario generator. The user interface allows one to define criteria of a scenario assessment, initial conditions intervals for the generator and query computer simulation results as well as generated model elements. The HDSS construction environment contains also instrumental software for derivative work development.

The model construction is a creative problem due to variety of data granularity, properties of forest regions to be investigated, the structure of the object and the problem at hand. For the purpose, we use inference engine based on original Calculus of Positively Constructed Formulae (CPCF) [5-7], which have intuitionistic inferences in more broad class of formula with respect to popular resolution method of automatic theorem proving. The properties of the calculi allow us to construct logical control layers for the process of computer simulation [DSS] as well.

The HDSS environment is used to develop a prototype HDSS for management of forest resources of Irkutsk Region, Russia. Model identification algorithms are adjusted to construct a model for various source data and investigated object scales, *e.g.*, for the whole Irkutsk region and detailed forest species data, and for the set of forestry regions and raw species data. Sustainable scenarios of the forest resource development are obtained by means of computer simulation and solution of optimal control problems over the synthesized models.

Optimal control problem (OCP) for the model is defined over set of controllable variables, which in our case are amount of timber-harvesting volumes for all species (to be maximized), amount of tangible resources for forest fire protection and restoration, *etc*. In the last case, maximizing of the amount of the forest areas covered with forest to be of interest.

In this work, we use a simplified improvement procedure [8,9] for numerical solution of the OCP, which implements a second order improvement method based on the Krotov's sufficient optimality conditions. The procedure implements solving OCP of a discrete system, and it is originated from an approach for continuous systems. The procedure is still under development in the aspects of the efficiency of computation for various systems, application of nowadays methods for solving optimization tasks in the each step of improvement iteration.

Implementation of the solution of the OCP required coping with a number of technical problems such as figuring out derivatives and function compilation, result interpretation to the user with various visual diagrams, representation of the results as a digital map.

The paper describes the mathematical and software aspects of the implementation of HDSS.

II. General Design of HDSS

Decision support systems (DSS) are software components, which support decision maker with various methods (data and knowledge processing, objective and subjective models) for analysis and solution of weakly- and even nonstructured problems [4]. The idea of DSS appeared as an attempt of human behavior automation of data analysis at hand, problem solving, to elaborate a particular problem and create a decision. At present, there is no widely accepted definition of DSS, as its design sufficiently depends on a problem to be solved, available information and knowledge, and user abilities.

We suppose that DSS is a user application, which provides tools of data analysis, model identification, and computer simulation for decision maker to support his/her problems solution, make administrative and other decisions.

The main part of the DSS is Solution Generator (fig.1) that is controlled with source data on the object under investigation and the stated problem description. The generator uses knowledge based automated Reasoning Unit implemented on the base of Automatic Theorem Prover (ATP in fig.1). Reasoning Unit constructs a basic structure of the investigated object as a graph in computer

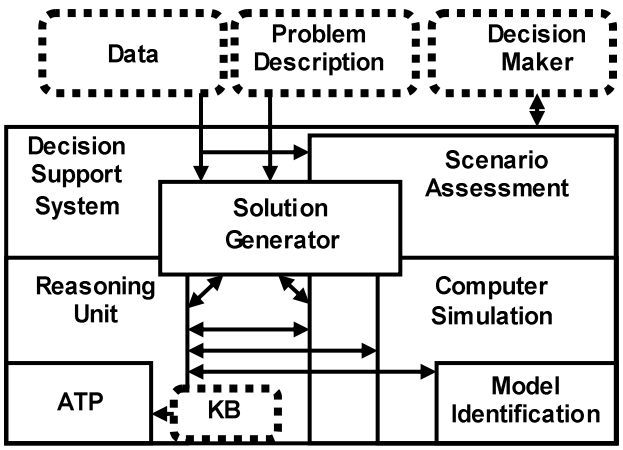

Figure 1. General design of HDSS

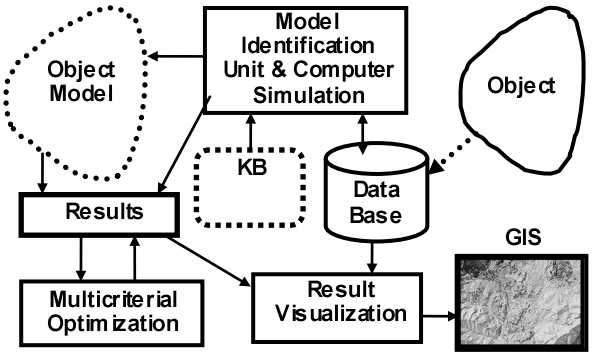

Figure 2. Information processes of HDSS

memory analyzing known data [18-asya]. Knowledge Base (KB in fig.1) includes the data about possible object change and heuristics used by mathematicians in the process of model construction; this allows us to adjust the model to particular properties of the object and the problem. Thus, the reasoning unit is used to structural and parametric model identification and assessment of the possible solutions [4].

On the identification stage of the model source data on the object under investigation is used; the data is stored in a database (DB). The data is used to figure out model parameters and initial conditions. After that, computer simulation is performed or an optimal control problem is solved. Each simulation is a scenario of forest dynamics; the scenario's condition depends on various combinations of the initial parameters controlled via user interface.

The scenarios are assessed according to a number of criteria, and, then, a multicriterial reduction of the scenario set is performed. If the results have spatial properties, they are visualized as digital map [4] (fig. 2) in a GIS module. The GIS module presents the simulation results at any time moment of the prognosis interval.

The theoretical aspect of the forest resources consumption domain is represented, in its general part, as model of forest dynamics, an optimal control problem, and a number of result assessment criteria. Let us briefly consider the representation.

III. Model of Forest Dynamics and Control

In V.B.Sochava Institute of Geography SB RAS, a system of models of forest resources has been developed [10]. A model knowledge base has been constructed, where the models are classified according to regional scale, modelled object and problem to be solved. Model coefficients identification techniques taking into account regional peculiarities has been developed [1-4]. Model of "Forest Dynamics and Control" (FDC) allows one to forecast of forest resources development of a region or a forestry for decades as proportions of forest areas of predominant species of an age group (it is described in English in [1]).

The model [1,10] corresponds to a graph structure of states (the area proportions) and edges between states, which correspond to intensities of transition of the area particles from one state to another. The graph describes forest growth, plantations, logging, burnout, and

segregation under capital construction, arable lands, reads, *etc*.

FDC is a regional-level model and uses dynamic variables. The total non-forest area S_N of the modeled territory; the total area uncovered with forest S_0; the areas covered with forest of *i*-th species predominating, including young forest of the first S_{1i} and second S_{2i} age classes, average-aged S_{3i}, maturing S_{4i}, mature S_{5i} and overmature S_{6i} forest stands. These states are all time-dependent. The dynamics of these area parcels is described by the following formulae:

$$dS_N / dt = -\lambda_{N0} S_N(t) + u_N(t); \quad dS_0 / dt =$$

$$= \lambda_{N0} S_N(t) - \lambda_{01} S_0(t) + u_L(t) + u_B(t) - u_{N0}(t) - u_C(t);$$

$$\frac{dS_{Ci}}{dt} = -\lambda_{C1i} S_{Ci}(t) + u_{Ci}(t) - u_{NCi}(t) - u_{BCi}(t);$$

$$\frac{dS_{1i}}{dt} = \lambda_{C1i} S_{Ci}(t) + \lambda_{01i} p_{0i} S_0(t) - \lambda_{12i} S_{1i}(t) - u_{L1i}(t) - u_{N1i}(t) - u_{B1i}(t);$$

$$\frac{dS_{2i}}{dt} = \lambda_{12i} S_{1i}(t) - \lambda_{23i} S_{2i}(t) - u_{L2i}(t) - u_{N2i}(t) - u_{B2i}(t);$$

$$\frac{dS_{3i}}{dt} = \lambda_{23i} S_{2i}(t) - \lambda_{34i} S_{3i}(t) - u_{L3i}(t) - u_{N3i}(t) - u_{B3i}(t) + I_i;$$

$$\frac{dS_{4i}}{dt} = \lambda_{34i} S_{3i}(t) - \lambda_{45i} S_{4i}(t) - u_{L4i}(t) - u_{N4i}(t) - u_{B4i}(t);$$

$$\frac{dS_{5i}}{dt} = \lambda_{45i} S_{4i}(t) - \lambda_{56i} S_{5i}(t) - u_{L5i}(t) - u_{N5i}(t) - u_{B5i}(t);$$

$$dS_{6i} / dt = \lambda_{56i} S_{5i}(t) - u_{L6i}(t) - u_{N6i}(t) - u_{B6i}(t) - I_i;$$

$$u_L(t) = \sum_{i,j} u_{Lji}(t); \quad u_C(t) = \sum_i u_{Ci}(t);$$

$$u_N(t) = \sum_{i,j} u_{Nji}(t) + \sum_i u_{NCi}(t) + u_{N0}(t).$$

Here, λ_{jki} is the intensity coefficients of transition of the area parcels from *j*-th category of lands or group of ages (state) to the other *k*-th forest state, with *i*-th species predominating, or to a definite category of lands (without the index *i*); p_{0i} is the share of the areas of uncovered with forest and populated with young forest of the first age group with *i*-th species predominating; $u_N(t)$ is an increase of the non-forest area due to capital construction on other categories of lands $u_{Nji}(t)$; $u_L(t)$, $u_{Li}(t)$, and $u_{Lji}(t)$, respectively, correspond to the annual area of logging as a whole, to crops of the *i*-th species, and in the forest stands of the *i*-th species and the *j*-th age group at time *t*; $u_B(t)$, $u_{Bi}(t)$, and $u_{Bji}(t)$, respectively, are the annually burnt-over areas as a whole, of crops of the *i*-th species, and forests of the *i*-th species of the *j*-th age group; I_i stands for the growth rate of the area of average-aged forests of young growth of the *i*-th species as a result of species succession, and I_i is the decrease rate of the area of overmature forests as a result of the species succession.

A. A Discrete-Time Variant of the Model

In the computer simulation we use a discrete-time variant of the model, where dynamic variables parameterized with *t*, are replaced with a discrete-time variables parameterized with the time moment number, so a general form of the forest growth equation become as follows:

$$S_{ji}^{l+1} = (\lambda_{j-1,ji} S_{j-1i}^{l} - \lambda_{jj+1i} S_{ji}^{l} + u_{ij}^{l})\Delta t.$$

Here, Δt is a differential approximation and *l* is a time moment number that varies from 0 to a finite number depending on value of Δt. If $\Delta t = 1$ the equation becomes a discrete-time vector equation (system of equations) of the following general form:

$$x(t+1) = f(t, x(t), u(t)), \quad x(t_0) = x_0,$$
$$t \in T = \{t_0, t_0 + 1, \ldots, t_1\}, \qquad (1)$$

where the function $x(t)$ takes values in the Euclidean space R^n, $u(t) \in R^m$. The function $x(t)$ is called a *state* (phase variable), $u(t)$ is called a *control*. The set of pairs $(x(t), u(t))$ satisfying (1) is called the *set of feasible pairs*, and it is denoted by *D*. *Cost function* is defined as follows:

$$I(x,u) = F(x(t_1)) + \sum_{t=t_0}^{t_1 - 1} f^0(t, x(t), u(t)) \to \min. \qquad (2)$$

The cost function realizes one of the assessment criteria. By the *optimal control problem* for discrete systems, we understand the problem of constructing a sequence $\{(x_s(t), u_s(t))\} \in D$, such that $I(x_s, u_s) \to \inf_D I$. This sequence is called a *minimizing sequence*. If for some pair $(x^*(t), u^*(t)) \in D$ the cost function $I = \inf_D I$, then $x^*(t)$ is called the *optimal trajectory* and $u^*(t)$ is called the *optimal control*.

B. An Improvement Algorithm for Discrete Systems

We will construct a minimizing sequence and an optimal control approximation by means of an iterative method. At each iteration, an improvement problem is solved. More precisely, at the beginning of iteration the pair (x^b, u^b) denotes the current feasible approximation of the optimal solution. Then, at the end of the iteration we are to obtain a new pair (x^e, u^e), such that $I(x^e, u^e) < I(x^b, u^b)$.

We use an approach implementing a second order improvement algorithm. This algorithm is obtained in [8]. Its properties of convergence and improvement have been proved in [8] as well. Iteration consists of the following steps:

Step 1. Compute $x^b(t)$ out of $u^b(t)$ from the system (1).

Step 2. Set a value of the parameter $\alpha = \alpha^b$.

Step 3. For α^b calculate $\psi(t,\alpha^b)$ and $\sigma(t,\alpha^b)$ from the system

$$\psi(t,\alpha) = -H_x^\alpha + (f_x^{'}\sigma(t+1,\alpha)f_u + H_{xu}^\alpha)\times$$
$$\times(f_u^{'}\sigma(t+1,\alpha)f_u + H_{uu}^\alpha - (1-\alpha)E)^{-1}H_u^\alpha,$$
$$\sigma(t,\alpha) = f_x^{'}\sigma(t+1,\alpha)f_x + H_{xx}^\alpha + (f_x^{'}\sigma(t+1,\alpha)f_u + H_{xu}^\alpha)\times$$
$$\times(f_u^{'}\sigma(t+1,\alpha)f_u + H_{uu}^\alpha - (1-\alpha)E)^{-1}(f_x^{'}\sigma(t+1,\alpha)f_u + H_{xu}^\alpha)^{'},$$
$$\psi(t_1,\alpha) = -\alpha F_x(x^b(t_1)), \quad \sigma(t_1,\alpha) = -\alpha F_{xx}(x^b(t_1)),$$
$$H^\alpha(t,x,\psi(\mathrm{t}+1,\alpha),u) = \psi^{'}(t+1,\alpha)f(t,x,u) - \alpha f^0(t,x,u),$$

where $\psi(t,\alpha^b)$ is a vector of n variables, $\sigma(t,\alpha^b)$ is a $n\times n$ symmetric matrix, and the derivatives of the function H^α are calculated at the point $(t,x^b(t),\psi(t+1,\alpha^b),u^b(t))$. Subscripts of H^α and other vector functions denotes the corresponding partial derivative on a vector variable, *e.g.* H_{xu}^α denotes the second order partial derivative on vector variables x, and then u. The prime sign denotes the transposition of a matrix.

Step 4. Find $\psi_\alpha(t,\alpha^b)$ and $\sigma_\alpha(t,\alpha^b)$ from

$$\psi_\alpha(t,\alpha) = H_x - (f_x^{'}\sigma_\alpha(t+1,\alpha)f_u + H_{xu})\times$$
$$\times(f_u^{'}\sigma(t+1,\alpha)f_u + H_{uu}^\alpha - (1-\alpha)E)^{-1}H_u^\alpha +$$
$$+(f_x^{'}\sigma(t+1,\alpha)f_u + H_{xu}^\alpha)(f_u^{'}\sigma(t+1,\alpha)f_u + H_{uu}^\alpha - (1-\alpha)E)^{-1}\times$$
$$\times(f_u^{'}\sigma_\alpha(t+1,\alpha)f_u + H_{uu} + E)\times$$
$$\times(f_u^{'}\sigma(t+1,\alpha)f_u + H_{uu}^\alpha - (1-\alpha)E)^{-1}H_u^\alpha -$$
$$-(f_x^{'}\sigma(t+1,\alpha)f_u + H_{xu}^\alpha)(f_u^{'}\sigma(t+1,\alpha)f_u + H_{uu}^\alpha - (1-\alpha)E)^{-1}H_u,$$
$$\sigma_\alpha(t,\alpha) = f_x^{'}\sigma_\alpha(t+1,\alpha)f_x + H_{xx} - (f_x^{'}\sigma_\alpha(t+1,\alpha)f_u +$$
$$+H_{xu}(f_u^{'}\sigma(t+1,\alpha)f_u + H_{uu}^\alpha - (1-\alpha)E)^{-1}\times$$
$$\times(f_x^{'}\sigma(t+1,\alpha)f_u + H_{xu}^\alpha)' + (f_x^{'}\sigma(t+1,\alpha)f_u + H_{xu}^\alpha)\times$$
$$\times(f_u^{'}\sigma(t+1,\alpha)f_u + H_{uu}^\alpha - (1-\alpha)E)^{-1}(f_u^{'}\sigma_\alpha(t+1,\alpha)f_u + H_{uu} + E)\times$$
$$\times(f_u^{'}\sigma(t+1,\alpha)f_u + H_{uu}^\alpha - (1-\alpha)E)^{-1}(f_x^{'}\sigma(t+1,\alpha)f_u + H_{xu}^\alpha)' -$$
$$-(f_x^{'}\sigma(t+1,\alpha)f_u + H_{xu}^\alpha)(f_u^{'}\sigma(t+1,\alpha)f_u + H_{uu}^\alpha - (1-\alpha)E)^{-1}\times$$
$$\times(f_x^{'}\sigma_\alpha(t+1,\alpha)f_u + H_{xu})',$$
$$\psi_\alpha(t_1,\alpha) = -F_x(x^b(t_1)), \quad \sigma_\alpha(t_1,\alpha) = -F_{xx}(x^b(t_1)),$$
$$H(t,x(t),\psi_\alpha(t+1,\alpha),u(t)) = \psi_\alpha^{'}(t+1,\alpha)f(t,x,u) - f^0(t,x,u).$$

The derivatives of the function H are evaluated at the point $(t,x^b(t),\psi_\alpha(t+1,\alpha^b),u^b(t))$.

Step 5. From the discrete chain

$$x(t+1) = f(t,x(t),u^b + \Delta u(t,\Delta x,\alpha)), x(t_0) = x_0,$$
$$\Delta u(t,\Delta x,\alpha) = -(f_u^{'}\sigma(t+1,\alpha)f_u + H_{uu}^\alpha - (1-\alpha)E)^{-1}\times$$
$$\times(H_u^\alpha + (H_{ux}^\alpha + f_u^{'}\sigma(t+1,\alpha)f_x)\Delta x), \quad \Delta x = x - x^b,$$

the derivatives of H^α are calculated at the point $(t,x^b(t),\psi(t+1,\alpha^b),u^b(t))$,

$$\psi(t,\alpha) = \psi(t,\alpha^b) + \psi_\alpha(t,\alpha^b)(\alpha-\alpha^b),$$
$$\sigma(t,\alpha) = \sigma(t,\alpha^b) + \sigma_\alpha(t,\alpha^b)(\alpha-\alpha^b),$$

and $x^e(t,\alpha)$ is determined, $u^e(t,\alpha) = u^b(t) + \Delta u(t,x^e(t,\alpha) - x^b(t,\alpha),\alpha)$ and the parameter α is figured out by solving the one-dimensional minimization problem over $\alpha \in 0,1$.

Step 6. If $I(x^e,u^e) < I(x^b,u^b)$, then let (x^e,u^e) be new approximation for the next iteration; otherwise, decrease α^b and repeat the process from the step 3.

The process stops if the improvement becomes less than a prescribed value.

C. Control Problem Module Implementation

Module for OCP solution has been implemented by means of Numpy, Scipy, and Simpy libraries of the Python programming language. The implementation consists of three classes: a Control Problem Base class (a stub for problem definition), and two classes corresponding to a method (the first order and the second order) of an approximation construction of the optimal solution.

To determine the model one must define a class by inheriting the stub class and defining the model f, the interval functional f^0, the terminal functional F as regular Python expressions (return values) and initial vector function of control u as the return value (an array of vectors for each discrete time moment) of a method of the class.

The model graph and its state variables are converted to vector function formula of the form (1) represented with symbols and expressions of the computer algebra library Simpy. The OCP solution implementation presumes that the formula (1) is of a general case, and no further heuristic implication asserted. Thanks to Simpy library symbolic manipulation routines, the vector function derivatives can be found, and then they are converted to a Python function of vector arguments.

The usage of the higher-order programming language and libraries instead of C or Fortran allowed us to check logical structure of the numerical methods with respect to basic matrix operations, disallowing programmer the implicit adjustment and optimizations of the algorithms "in place", *e.g.*, swapping vector dimensions in vector multiplications. As the result, we obtained shortest implementations of the algorithms that are very close to paper definitions. In further work, they can be converted (e.g., compiled) to a fast implementation on a compiled programming language with LAPACK-like libraries. The usage of Python also supplied us with higher order means of algorithms debugging, data printing, simple input-output, faster user interface implementation, integration with other modules, e.g., Matplotlib that emulates powerful graphical routines of Matlab.

The results of the computer simulation and OCP solution are stored in a database for further visualization. The visualization module allows comparing various scenarios by defining equations with simple scenario algebra.

D. The Modelling Scenarios and Multicriterial Assessment

Performing computer simulation in terms of the model, the user can access (to make relevant changes) the parameters of the main felling volume, tending fellings, burnouts and tree planting. Each of these parameters are

varied within 0% (none), 50% (a half of the volume), and 100% (total volume). Each scenario results of computer simulation are accounted using the following set of criteria:

1. $\max_j \min_i W^j(t_i)$, where $W^j(t_i)$ is standing crop (for all species and age groups) calculated in the *j*-th scenario at the year t_i (the greatest volume of felled forest);

2. $\min_j \max_i S_0^j(t_i)$, where $S_0^j(t_i)$, is the uncovered in forest area, it is calculated from *j*-th scenario in the year t_i (forest areas are better to be covered with forest);

3. $\max_j (S_5^j + S_6^j)$, where $S_5^j(t_i)$, and $S_6^j(t_i)$, respectively, correspond to the area of mature and overmature forests of all species calculated from *j*-th scenario for the forecasted period (it is better if ratios of the mature and overmature forest were greater);

4. $\min_j \max_i S_6^j(t_i)$, where $S_6^j(t_i)$ is the area of overmature forests of all species calculated from the *j*-th scenario in the year t_i (it is better if areas of the overmature forest are smaller).

Each calculated scenario is evaluated using this set of criteria. Due to the multicriteria nature of the best scenario choice problem, the principle of Edgeworth-Pareto is used to select scenarios as proposed variants to decision-making person.

In case of performing a solution of a control problem, a functional is also defined; the functional is added to the criteria or replaced one of them.

IV. APPLICATION OF CPCF IN HDSS

As we mentioned in the introduction section the logical inference in CPCF was used to deduce the model FDC graph and calculate parametric identification values of the model

The CPCF is not only machine-oriented, but it is also as a human-oriented automated reasoning method, mostly aimed at solving dynamic system control problems (DSCP), which include FDC model. The calculus has a number of properties that support the solution of DSCP. It has the only unique inference rule and simple scheme of axioms. CPCF supports modifiability of semantics of the derivative calculi (constructive, monotonic, temporal, etc.) [5,11], and, besides, it is possible to construct intuitionistic inferences of non-Horn formulas for a general class of formulas as compared to resolution method. The solemnization step is not required as CPCF supports both quantifiers. CPCF formulae can contain disjunctive branching in consequents, and the inference rule can be adjusted to control the inference branching after processing such formulae.

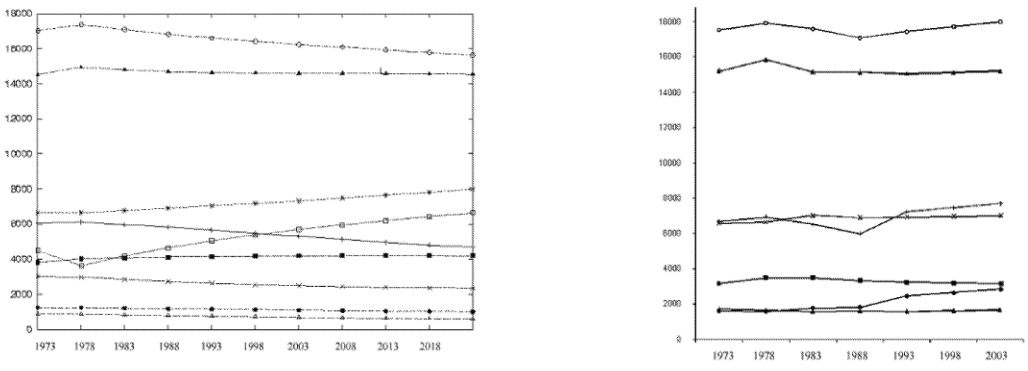
The inference of the model graph is constructed as satisfaction of a sequence of goals, which represent a general scenario of the model construction. In the process of the inference, the reasoning system issued queries to the database of forest inventory with special predicates having side effects. The results of the queries are the identified coefficients and initial values of the model. The metainformation on the database structure and attribute meanings is represented as a part of knowledge base and defined for each data source separately.

The model construction subsystem formed a basis of an experimental decision support system for sustainable resource consumption control of forest resources [8]. The usage of logical inference allowed us to raise level of generality of the model graph construction and its identifications. The expressive logical language allowed us to synthesize graphs for regional and forestry scales using the same knowledge bases but different databases and corresponding metainformation. Source data are also were processed by a special parts of the knowledge base.

The regional data is more specific and contain information on seven forest species and six age groups, whereas forestry data is more general: all species are joined to three classes (dark and light coniferous and deciduous forests). Age groups are also generalized; there are only three age groups (united young, middle-aged and maturing, and mature and overmature forest). The corresponding subset of rules reduced space of states of the graph to the sensible combinations and transition intensities are corrected in accordance.

A. Examples of Computer Simulation

The simulation software is being verified using a retrospective comparison. The year 1973 was chosen as initial time of computer simulation, as that year a reliable



a *b*

Figure 1. Verification of the Forest Dynamics and Control model

information was supplied by forest Inventory organizations.

The temporal dynamics of the forest resources (1973-2023) having regarded to natural species succession is sown in Fig. 3a., as well as fellings and burnouts (a constant increase in felling of coniferous forests is assumed), withdrawal of forests of the forest reserves as a result of capital construction, and the process of creation of forest crops and their conversion to young growth. The reference data of the verification is presented as graphics in Fig. 3b.

V. CONCLUSION

An approach to construction of hybrid decision support system on the base of integrated modules of computer simulation and optimal control problem solving has been considered in the paper. The usage of mathematical modeling in the process of decision elaboration in the HDSS allows decision maker to obtain additional objective information and produce counterintuitive decisions [1,4].

The construction of the HDSS and its environment is connected with the number of problem raging from technical to fundamental. Adaptation of the algorithms of model identification (structural and parametric) to the information at hand describing the domain and a concrete object under consideration is an example of the second case: most of the users that deal with economic domain experience difficulties in modeling and computer simulation in their unpredictable environment [12].

The support of the intermediate layer is provided by means of construction of a reasoning (inference) engine, which models the process of data analysis and model identification realized by mathematician that understands the problem domain. The engine itself is automatic theorem proving software based on original first-order calculi. The software successfully realized the process of identification of a forest resources dynamics and control model for an industrial region, namely, Irkutsk region, Russian Federation and its forestries. The usage of the logical engine allowed us, in particular, to generalize the process of database interaction by means of its metadata and to adapt general techniques of model construction to the database source data of various granularities.

Solving optimal control problems in the cycle of decision support system functioning allows decision maker to obtain more qualitative results of a criterion assessment, sacrificing the computational productivity as most of the optimal control procedures are based on iteration methods. In this case, it is necessary to develop new techniques of improvement on the base of higher order approximations and heuristic routines controlling the process of improvement.

We hope, when all will be elaborated and implemented, the usage of the HDSS will play the significant role as the decision support basis for sustainable forest resource consumption in Irkutsk and other world regions, whose ecological equilibriums depends greatly on the condition of their forest resources.

ACKNOWLEDGMENT

The research is carried on under support of Integration multidisciplinary project of Siberian Branch of Russian Academy of Sciences N 17 "Development of services and infrastructure of scientific spatial data for supporting complex multidisciplinary scientific research of Baikal nature territory" and Program of Siberian Branch of Russian Academy of Sciences IV.38.2.3. "New methods, technologies, and services for spatial and thematic data processing based on declarative specifications and knowledge". This work is also supported by Russian Foundation of Basic Research, grant No. 14-01-31449-mol-a.

***Abstract*—Genetic algorithms are used today to solve numerous difficult problems. However, it is often needed to specialize and adapt them further in order to successfully tackle some specific problem. One such example is the fault injection attack where the goal is to find a specific set of parameters that can lead to a successful cryptographic attack in a minimum amount of time. In this paper we address the process of the specialization of genetic algorithm from its standard form to the final, highly-specialized one. In this process we needed to customize crossover operator, add a mapping between the values in cryptographic domain and genetic algorithm domain and finally to adapt genetic algorithm to work on-the-fly. For the last phase of development we plan to go to the memetic algorithm by adding a local search strategy. Furthermore, we give a comparison between our algorithm and random search which is the mostly employed method for this problem at the moment. Our experiments show that our algorithm significantly outperforms the random search.**

I. Introduction

Genetic algorithms (GAs) are widely used to solve many different optimization problems. Since they are very general solvers, often it is necessary to customize the algorithm for some specific problem. Although the "No free Lunch" theorem states that when averaged over all problems all algorithms behave the same, that is true only when we posses no knowledge about the problem [1]. In this paper we start with standard genetic algorithm, and on the basis of experimental results we specialize it further to better relate to the problem at hand.

We are surrounded by small smart devices in our lives such as smart cards (contact and contactless), RFID tags, mobile phones etc. and their security is of utmost importance for a user. Considering the security and privacy of those devices there exists a special class of attacks that a malicious adversary can try, aiming at weaknesses of implementations. Those so called implementation attacks are divided into passive and active. The former explore some passive physical channel that is available while the device is processing secret data (such as power consumption or timing) and the latter is actively disturbing the computation aiming at finely tuned faults [2], [3]. The fault has to be effectively inserted such that the device does not break while an error computation will occur. This fact allows for the adversary, after inserting several "useful faults", to learn the secret key used. The famous Bellcore attack shows that having one faulty RSA signature and a correct one allows the adversary to factor the RSA modulus and hence completely break the system [4].

In this paper we consider so called glitching attacks where a sudden change in the supply voltage of a smart card can have the desired effect of a fault. However, inserting "useful faults" is considered to be very hard as there are many parameters that have to be tuned such as timing, glitch length, glitch voltage etc. The search in this multi-dimensional space is typically performed as a random search. Our work aims at improving this and deriving more efficient methods in finding the right ranges of all relevant parameters.

A. Related Work

As mentioned above, the research on fault attacks started around two decades ago with the seminal paper of Boneh, DeMillo and Lipton [4]. They showed the potential of this type of attacks assuming that they are possible. However, it took several years for a publication on an actual practical fault attack by Aumuller et al. [5]. The authors published in 2002 one of the first practical works on fault analysis, in which they describe a real-life scenario of the impact of injecting glitches in the clock and voltage lines of a cryptographic chip.

Van Woudenberg et al. describe a real attack scenario for an Optical Fault Injection attack where a laser is used to induce faults [6]. The authors also introduce the practical problem of setting the parameters for fault injection and they briefly discuss the lack of methodology.

Recently, a paper of Boix Carpi et al. [7] proposed a new algorithm that is a tailored search strategy but it is especially developed for finding the best choice of parameters for glitching. The authors also experiment with genetic algorithm and suggest investigating it further. We continue with this

recommendation aiming at setting common grounds for this new line research that could help security evaluators to assure that smart devices preserve user's privacy.

B. Our Contribution

In this paper we experiment with genetic algorithms when looking for parameters that can lead to successful fault injection. For the algorithm to behave as expected we needed to create a custom version of genetic algorithm and also interface it with a hardware-based system that inserts and evaluates fault attempts.

The rest of this paper is organized as follows: in Section 2 we present experimental setup, whereas in Section 3 we give experimental results of several search strategies as well as discussion about the results. Finally, in Section 4 we give a conclusion.

II. Experimental Setup

In this section we describe the fault injection scenario we follow, parameters of the problem and mappings between the solutions. On a more abstract level, the goal is to interface the system for injecting faults and evaluate them with the genetic algorithm framework. The role of genetic algorithm is to evolve new fault parameters and send those to the fault injection framework for an analysis. Motivation lies in the fact that finding such values is a difficult problem and there is no algorithm, except exhaustive search, that can do it. However, exhaustive search is often not a viable choice since there are constraints regarding the time that attacker has at his disposal. Furthermore, it is somewhat surprising that random search is regarded as the baseline strategy for this problem and as such is widely used.

Since random search is considered as a viable choice, that is also a pointer that research can go to the evolutionary computation area. We opted for genetic algorithms since they are directed random search method. In terms of an optimization problem, we want to minimize the time needed to find a set of parameters that can lead to the successful fault injection attack when we work in black-box scenario (no specific information about the device we attack).

A. Search Space Parameters

There are multiple parameters that need to be adjusted for a successful fault injection. Generally, they can be divided into those related with glitch shape, time and environment. In this work, we do not include environment or timing parameters in our experiments. The reason is the possibility to separate the search into two phases where in first phase we look for the adequate glitch shape and in the second phase for the correct timing periods to apply those glitches. Environmental parameters are not of interest since they can change even within the search and it is not clear how each of those changes affects the search.

Glitch shape parameters can be divided to glitch voltage [V] and glitch length [ns] parameters. With these assumptions, the goal is finding a suitable values for voltage and length that would provoke a successful fault injection. A pair of values for glitch voltage and length is considered a single point in search space (a possible solution).

B. Verdict Classes

Fault injection testing equipment and tool for the evaluation of introduced faults can output only verdict classes for each attempt. Therefore it is necessary to map each of those verdict classes to fitness values a GA can work with. There exist several possible classes for classifying a single measurement (attack attempt) [7]:

1) NORMAL: the target behaves as expected (the glitch is ignored)
2) RESET: the target resets as a result of the glitch
3) MUTE: the target stops all communication as a result of the glitch
4) CHANGING: multiple measurements in the same point yield responses that classify into different classes.
5) SUCCESS: the target response is a specific, predetermined value that does not happen under normal operation

If we define $F()$ as a function that scores the goodness of a point, and the higher $F()$ value is desired, then the formula for a single point classification is

$$F(SUCCESS) > F(CHANGING) > (F(NORMAL) == F(RESET) == F(MUTE)). \quad (1)$$

C. Interfacing Frameworks

For the fault injection (FI) framework we use Inspector program from Riscure BV. For genetic algorithms test suite we use the Evolutionary Computation Framework (ECF) [8]. ECF is a C++ framework intended for the application of any type of the evolutionary computation, developed at the University of Zagreb.

Since fault injections need to be done on the basis of the results from genetic algorithm, that makes it necessary for the fault injection system and genetic algorithm framework to communicate in real time. To be able to do that, we made an interface between those two systems.

The genetic algorithm is set to output one file for whole generation in each iteration of the evolution process. The fault injection software reads it and conducts the attacks with the values (search points) specified in the file. After each of the attacks, the FI software assigns a verdict class to each point and outputs appropriate parameter values and fitness values to a file. From that file the GA framework reads the fitness values and proceeds with the evolution.

The file system is chosen as a means of communication on the basis of the duration of candidate points evaluation; since each injection attempt can take up to several seconds, there is no need for faster process communication.

D. Target of Evaluation

We conduct all experiments with a smartcard based on an ATMega163+24C256 IC in CMOS technology. This card does not have any side-channel countermeasures or fault-injection

countermeasures. All processing on the card is performed in software, and the card is running on an external 4MHz clock frequency. The code we are attacking is the PIN authentication mechanism.

III. Search strategies and Results

Finding the correct parameter setting is a highly non-deterministic process, and countermeasures just add up to the complexity of this problem. As a result of this, security analysts usually set a value range for each parameter. Then, the fault injection setup is left testing thousands of different parameter configurations within given ranges for a-posteriori analysis. That search is typically done with strategies that involve a high search space complexity. Examples are Monte Carlo search for a successful setting within a set of value ranges, or test all possible value combinations within value ranges given a value step. Additionally, the parameter tuning (if performed) is usually done manually. As a result, the testing process can take days.

The analyst possesses some knowledge about the problem that is generally applicable, for instance, it can be assumed that two classes will always have the same relative positioning (NORMAL with low absolute values for glitch voltage/length, and RESET/MUTE class for high absolute values). It is not so interesting to search in the areas that are far from the decision boundary since it can be assumed that there are no outliers. However, there is no prior knowledge about the positions of those regions.

All the points are measured three times to enable the detection of changing behavior (the CHANGING class). Since a CHANGING class simply corresponds to different behavior in subsequent probes, a minimum of two is required for enabling detection of that class. The motivation for this lies in the fact that for some unstable protected targets more measurements per point are required to mitigate some side-effects during data acquisition.

A. Monte Carlo Search

This search strategy consists of performing measurements with randomly selected parameter combinations within the given initial search space. The random distribution for selecting values is considered to be uniform for each parameter present in the search space. This strategy is considered as the baseline search strategy.

A typical result for Monte Carlo search is given in Figure 1. All graphs are produced automatically by Inspector program and they depict only NORMAL, RESET/MUTE and SUCCESS verdict classes (CHANGING class is not shown even if found by the algorithm). Green dots represent solutions from NORMAL verdict class, BLUE represent solutions from RESET/MUTE and red dots represent solutions that belong to SUCCESS verdict class.

Two test runs are performed with the Monte Carlo strategy; a short one with 3072 measurements and a longer one with 76800 measurements. The short test completed with no SUCCESS measurement, and only a longer 76800 measurements test run produced 11 SUCCESS measurements. Because of the random nature of parameter values selection, there is also a significant number of repeating solutions.

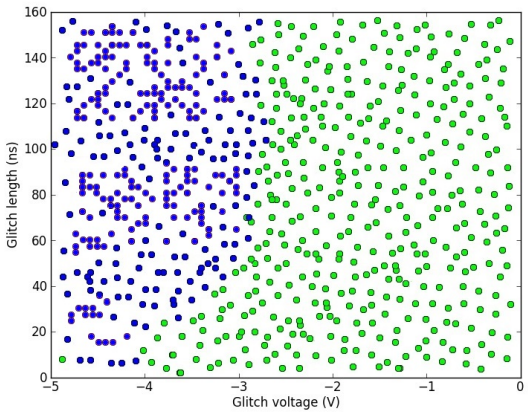

Fig. 1. Plot of measurement classification for Monte Carlo search.

TABLE I
Genetic algorithm parameters

Parameter	Parameter Value
Tournament size	3
Glitch length	[2, 150]
Glitch length resolution	2
Glitch voltage	[-5, -0.05]
Glitch voltage resolution	0.05
Population size	30
Stopping criterion	Stagnation in 10 generations
Mutation rate	0.1

B. Genetic Algorithm

For a genetic algorithm to work, we need to map verdict classes to distinct fitness values. Since we set the problem to be maximization, better classes will have higher fitness values. Mapping using in the initial version of the algorithm is NORMAL, RESET or MUTE verdict classes have value 1, CHANGING verdict class has value 8 and SUCCESS verdict class has value 10. Formally, the GA aims to find a (glitch length, glitch voltage) pair such that the fitness value F is maximal. Parameters of the search are given in Table I. Some of those values are set after the parameter tuning phase where we experimented with different population sizes and stopping criteria.

Since there are only a few different verdict classes, it means that a big portion of the search space will be impossible to differentiate. Therefore, we developed a version of tournament generational algorithm that is more appropriate for this specific problem. A single generation of the algorithm is described with the pseudocode as given in Algorithm 1.

In all the experiments, the population in the first generation is created randomly by the GA framework, where the initial fitness is zero for all individuals and then is sent to file to get the actual fitness values after the evaluation.

Algorithm 1 Genetic Algorithm - initial version

Require: count = 0, crx_count = 0
  repeat
    randomly select 3 individuals
    select best of the 3 individuals
    copy best to new population
    count = count + 1
  until $N \neq$ count
  replace old with the new generation
  repeat
    randomly select parents p_1, p_2
    $child_1$ = crossover (p_1, p_2)
    $child_2$ = crossover (p_2, p_1)
    replace p_1 with $child_1$
    replace p_2 with $child_2$
    crx_count = crx_count + 1
  until N * $p_c \neq crx_count$
  perform mutation on all individuals with p_m
  evaluate population

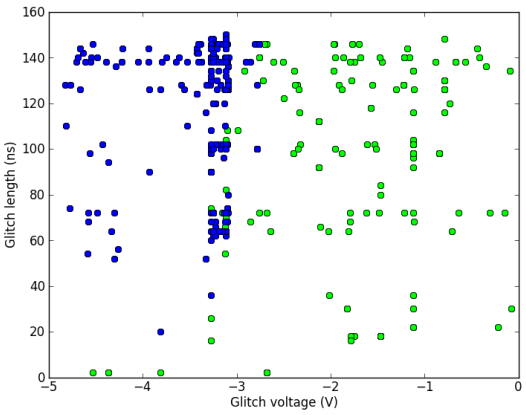

Fig. 2. Measurements for GA, initial algorithm.

Result from initial version of GA where the stopping criterion is 10 generations without improvement is depicted in Figure 2.

It can be observed that the algorithm outputs a valid point. By valid it is understood that the value is in the boundary between the two unimodal components. If speaking in terms of classifiers, the output point would be on top of the decision boundary between the two classes. The algorithm finished when no better fitness values could be found.

In Figure 3 we see a result of the same experiment but with 50 generations without improvement as a stopping criterion.

After running the first set of experiments we noticed some undesired effects. Once the algorithm finds a point with a high fitness value, it seems to fix one variable and explores the full range of the other. For this problem, spreading the search so much only in two directions is not so desirable in the sense that points too distant from each other that belong

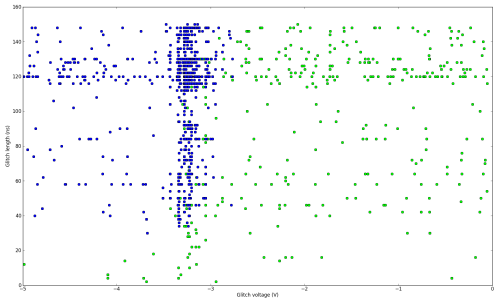

Fig. 3. Measurements for GA, initial algorithm, long run.

to the CHANGING class will likely classify to one of the low fitness valued classes (NORMAL or RESET/MUTE). To put it in other words, the decision boundary between classes will always have the same shape (convex, monotonically increasing curve and ideally it would mimic an exponential curve), so the direction that contains points belonging to the CHANGING class is not explored in depth by a vertical or horizontal line.

GA would be more successful in terms of finding more points that classify to CHANGING class by exploring the surroundings of a point that classifies into CHANGING inside a neighborhood of distance d (increasing d if needed) from it. Another effect that we observed is that once the GA finds a point belonging to the CHANGING class, the rest of the search space is ignored. This elitism is good in a sense that we want the search to be as short ass possible, but often it results in not exploring interesting parts of the search space sufficiently.

C. Improving Crossover and Parameter Tuning

Evolutionary algorithms in general (and GA in specific) do optimization by default, which means they always try to find points with a higher fitness value. The behavior of current algorithm is expected, especially with such small variances in fitness values. However, as we want to find as many points that belong to a certain class, we change the crossover operator to be more adequate.

New crossover operator crosses two points that should be of *different* classes, and it would choose a point between them that is closer to the better "parent" point. In this way we can point the algorithm to the desired region. Results for the new algorithm with improved crossover operator are shown in Figure 4. Although it may seem that the results depicted in Figure 4 are not better than those with the original algorithm, we remind that the graph does not show CHANGING class.

D. Optimization + Classification Algorithm

In a classical black-box optimization scenario, the best possible fitness value is not known in advance. The optimization algorithm will therefore always strive to find points with better values, regardless of how good the current solution is. If the best value is known, or if the goal is to find a solution of an acceptable predefined fitness value, then the algorithm is

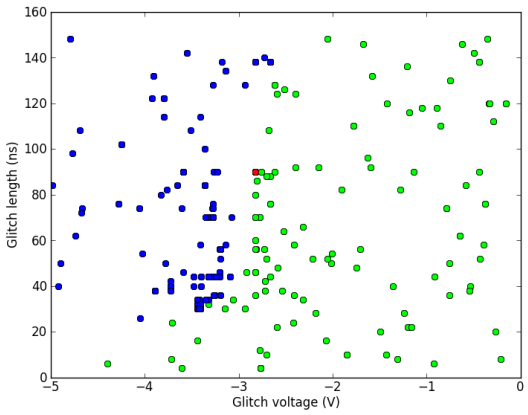

Fig. 4. Measurements for GA with modified crossover.

usually configured to stop as soon as it finds a single solution of the desired quality.

In this application we diverge from the described principle in the following ways:

1) we define a *target fitness* level where all the solutions having fitness equal or better than the target value are regarded as equally good and called *target points*;
2) instead of satisfying with a single target solution, the algorithm should find as many distinct target points as possible;
3) points worse than target value are divided into a number of *subclasses* corresponding to their fitness (we presume there is a small number of discrete fitness values).

The fitness mapping in this version is also not the same as in previous version of the algorithm, to allow distinction of different subclasses. Here we opted for a small change in values when mapping from verdict classes, so that NORMAL class retains the value of 1, RESET or MUTE classes have value 2, CHANGING class has value 8.5 and the target fitness level is set at 8. This allows the algorithm to perceive NORMAL and RESET/MUTE points as different subclasses, and all points that classify to CHANGING as target class points.

The next generation is produced in part by crossing the points from the current population of size N, and in part by selecting the better individuals by tournament selection operator. The proportion of crossover is controlled by the crossover probability (p_c), and the remaining individuals are selected with the tournament operator.

The selection of parents in the crossover operator is designed to promote diversity and explore boundaries between classes (points of different fitness values). The first parent is selected randomly from current generation; then, if the first parent is worse than the target level, the second parent is randomly selected from another class (point with a different fitness value). If, on the other hand, the first parent is of the target class, the algorithm tries to select another target class point as the second parent. If no such individual exists, a random parent is taken otherwise.

TABLE II
COMPARISON OF THE MONTE CARLO AND GA IN FINAL VERSION

Strategy	Measurements	#SUCCESS
Monte Carlo	3072	0
GA + classification	1560	8

The crossover operation also acts depending on the parent classes. If crossing points belong to different classes, the child is generated as a point between the parents in search space, but proportionally closer to the parent whose class is represented with a smaller number of individuals in current population. In this way, the search is guided towards the class that covers a smaller area of the search space. If crossing points are from the same class, the child is generated randomly between the parents in the search space.

After the crossover and tournament selection, a mutation operator is invoked on the new set of individuals, where the total number of mutations is determined with the mutation probability parameter (p_m). Algorithm 2 is a pseudocode for one iteration of the modified genetic algorithm.

Algorithm 2 Genetic Algorithm + classification

```
Require: crx_count = 0, mut_count = 0
  repeat
    select first parent
    if first parent of target class then
      try to find matching second parent
    else
      try to find second parent of different class
    end if
    perform crossover (depending on parent classes)
    copy child to new generation
    crx_count = crx_count + 1
  until p_c * N ≠ crx_count
  repeat
    select random individuals for tournament
    copy best of tournament to new generation
    mut_count = mut_count + 1
  until (1 − p_c) * N ≠ mut_count
  perform mutation on new generation with probability p_m
  evaluate population
```

A typical result of the modified GA version is shown in Figure5. In this case the algorithm succeeded in finding the most target class points in a limited number of measurements.

In Table II we give the comparison of the successfulness of Monte Carlo and genetic algorithm that uses modified crossover operator and classification.

IV. CONCLUSIONS

In this paper we explore a new option to successfully find the correct parameters for the fault injection. Currently employed methods can produce results, but are slow and often require more time than the security analyst is willing to spare.

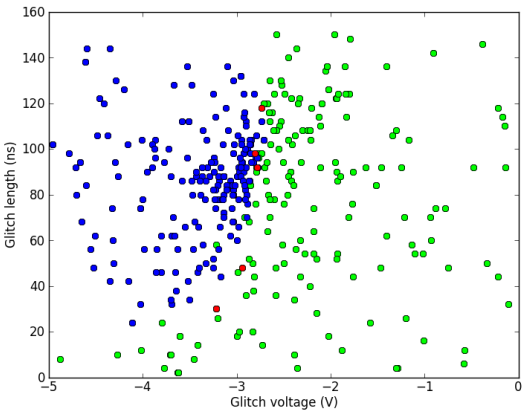

Fig. 5. Measurements for GA + classification.

We experimented with genetic algorithm where we started from its standard form and finished with a specialized algorithm. The results are promising and indicate that additional research is required in this area.

As a possible avenue for future research we plan to experiment with a memetic algorithm. That algorithm would comprise of the genetic algorithm in the last version plus an addition of a local search. When the algorithm finds a point that belongs to class INTERESTING (or better) from that point will inspect n points within distance d. If the new point belongs to a different class, the algorithm will keep that point and halve the distance value d for the next iteration of the algorithm. Additionally, since the genetic algorithm approach is working better than the baseline search strategy, it would be interesting to see how it behaves with fault injections that are based on electromagnetic radiation. The process would be similar to the scenario we describe here, only it would search for the parameters related with electromagnetic radiation.

Abstract - This expert paper describes the characteristics of six most used free software tools for general data mining that are available today: RapidMiner, R, Weka, KNIME, Orange, and scikit-learn. The goal is to provide the interested researcher with all the important pros and cons regarding the use of a particular tool. A comparison of the implemented algorithms covering all areas of data mining (classification, regression, clustering, associative rules, feature selection, evaluation criteria, visualization, etc.) is provided. In addition, the tools' support for the more advanced and specialized research topics (big data, data streams, text mining, etc.) is outlined, where applicable. The tools are also compared with respect to the community support, based on the available sources. This multidimensional overview in the form of expert paper on data mining tools emphasizes the quality of RapidMiner, R, Weka, and KNIME platforms, but also acknowledges the significant advancements made in the other tools.

I. INTRODUCTION

Data mining (DM) is the core step in knowledge discovery in datasets. It integrates all the analysis procedures that are required in order to reveal new and relevant information to an interested user. DM includes data preparation and data modeling. Datasets may be obtained from a variety of sources, including: traditional relational databases, data warehouses, web documents, or simple local textual files. It is important to prepare data in the most efficient way in order to extract as much information as possible [1]. After preparation, various models can be constructed, depending on the research goal. In order to properly interpret the models, standard evaluation and statistical procedures are pursued. The visualization of the results is also encouraged.

Free and publicly available software tools for DM have been in development for the past 20 years. The goal of these tools is to facilitate the rather complicated data analysis process and to offer all interested researchers a free alternative to commercial data analysis platforms. They do so mainly by proposing integrated environments or specialized packages on top of standard programming languages, which are often open source.

This paper focuses on the review of several such tools that have grown more efficient and useful over the years, some even comparable or better in certain aspects than their commercial counterparts. In particular, the main characteristics of RapidMiner [2], R [3], Weka [4], Orange [5], KNIME [6], and scikit-learn [7] will be outlined and compared. All of these free tools have implementations of general DM tasks. Other, more specialized tools such as Elki (clustering) or Anatella (big data), and tools with small DM community support (e.g. F#, GNU Octave) are not considered here.

The tools are compared in terms of general properties (language, license, etc.), core DM tasks (supported input, data preparation, data analysis, output), and support for some recent more advanced DM topics (big data, data streams, text mining, deep learning).

II. FREE DATA MINING TOOLS OVERVIEW

In a recent, 2013, poll published on the influential KDnuggets portal [8], regarding the use of DM tools in a real project, it is interesting to observe that in the top 5 tools there is only one commercial tool: Excel. The domination of free tools, mainly RapidMiner and R, probably stems from the maturity and availability of a large number of machine learning algorithm implementations. In Fig. 1, an adapted version of the poll is shown, with only free tools listed, for comparison.

Most of the modern DM tools are effectively software-based dataflow architectures. Some of the tools (e.g. RapidMiner, KNIME) are graphical integrated environments that enable visual component placement, connection, and dragging. The most common paradigm for such components is: pull the data in, transform, and push it further down the pipeline. The component only pulls the data in once all of its prerequisites are met. The under-the-hood implementation of such components is irrelevant for the average user, but more advanced users usually have the possibility of tackling with the code in order to improve it. Other tools (e.g. R) are just plain extensions of the underlying language in the form of specialized packages and/or GUI add-ons.

General characteristics of the six DM tools are listed in Table I. All of the tools have implementations for Windows, Linux, and Mac OS X operating systems. In the large Table II, the supported machine learning algorithms for each DM tool are summarized. The tools either implement an algorithm (+), use an external add-on (A) to support it, show some degree of support for the procedure (S), or do not implement it (-) at all. It must be noted here that the data in Table II should be considered temporary, because most of the tools are in constant state of upgrades. Nevertheless, it is important and useful to summarize their

capabilities so that interested users can choose the appropriate environment for handling their problem. The algorithms shown in Table II were selected based on their significance and presence in most of the tools. Although the tools may contain some additional algorithms, not all of them could have been listed. Some of these were put in the appropriate rows with label "others". References to the work that describe the algorithms are not provided.

Table III lists the support for some of the more specialized topics in DM such as big data, text mining, etc.

III. TOOLS DESCRIPTION

A. *RapidMiner*

RapidMiner (previously: Rapid-I, YALE) is a mature, Java-based, general DM tool currently in development by the company RapidMiner, Germany. Previous versions (v. 5 or lower) were open source. The latest one (v. 6) is proprietary for now, with several license options (Starter, Personal, Professional, Enterprise). The Starter version is free with limitations only in respect to maximum allocated memory size (1 GB) and input files (.csv, Excel). The tool has become very popular in several recent years and has a large community support.

RapidMiner offers an integrating environment with visually appealing and user-friendly GUI. Everything in RapidMiner is focused on processes that may contain sub-processes. Processes contain operators in the form of visual components. Operators are implementations of DM algorithms, data sources, and data sinks. The dataflow is constructed by drag-and-drop of operators and by connecting the inputs and outputs of corresponding operators. RapidMiner also offers the option of application wizards that construct the process automatically based on the required project goals (e.g. direct marketing, churn analysis, sentiment analysis). There are tutorials available for many specific tasks so the tool has a stable learning curve.

Although RapidMiner is quite powerful with its basic set of operators, it is the extensions that make it even more useful. Popular extensions include sets of operators for text mining, web mining, time series analysis, etc. Most of the operators from Weka are also available through extension, which increases the number of implemented DM methods (Table II). The tool has very few shortcomings. The most important one is the transition to a novel model of business. It remains to be seen whether the transition to proprietary license will limit the number of its users, but it may not be helpful. The support for deep learning methods and some of the more advanced specific machine learning algorithms (e.g. extremely randomized trees, various inductive logic programming algorithms) is currently limited. However, big data analysis via Hadoop cluster (Radoop) is supported.

B. *Weka*

Weka is a Java-based, open-source DM platform developed at the University of Waikato, New Zealand. The software is free under GNU GPL 3 for non-commercial purposes. Weka has had mostly stable

TABLE II. DATA MINING ALGORITHMS AND PROCEDURES SUPPORTED BY THE TOOLS

Category	Name	RapidMiner	R	Weka	Orange	KNIME
Data import	textual files (.txt, .csv)	+	+	+	+	+

* Own implementation of decision tree, mostly similar to C4.5 and CART

popularity over the years, which is mainly due to its user friendliness and the availability of a large number of implemented DM algorithms. It is still not as popular as RapidMiner or R, both in business and academic circles, mostly because of some slow and more resource demanding implementations of DM algorithms. Although it is not a single tool of choice in DM, Weka is still quite powerful and versatile, and has a large community support.

Weka offers four options for DM: command-line interface (CLI), Explorer, Experimenter, and Knowledge flow. The preferred option is the Explorer which allows

TABLE III. SUPPORT FOR SPECIALIZED AND ADVANCED DATA MINING TASKS

Name	RapidMiner	R	Weka	Orange	KNIME	scikit-learn
Big data	S (not free: Radoop)	A (ff, ffbase)	S (CLI, knowl. flow, distributedWekaHadoop)	-	A	S
