the definition of data source, data preparation, machine learning algorithms, and visualization. The Experimenter is used mainly for comparison of the performance of different algorithms on the same dataset. Knowledge flow is akin to RapidMiner's operator paradigm in a sense that it allows one to specify the dataflow using appropriately connected visual components. Although not as visually appealing and extendable as RapidMiner, Weka's Knowledge flow still does the job.

Weka supports many model evaluation procedures and metrics, but lacks many data survey and visualization methods. It is also more oriented towards classification and regression problems and less towards descriptive statistics and clustering methods, although some improvements were made recently with respect to clustering. The support for big data, text mining, and semi-supervised learning is currently limited, while deep learning methods are still not considered.

C. R

The open-source tool and programming language of choice for statisticians, R, is also a strong option for DM tasks. R has been in development for the last 15 years and is the successor of S, a statistical language originally developed by Bell Labs in 1970s. The source code of R is written in C++, Fortran, and in R itself. It is an interpreted language and is mostly optimized for matrix based calculations, comparable in performance to commercially available Matlab and freely available GNU Octave.

The main language is extended by a myriad collection of packages for all sorts of computational tasks. Some of the packages are listed in Table II in parentheses. The tool offers only a simple GUI with command-line shell for input. It is certainly not a user-friendly environment because all commands need to be entered in the R language. The learning curve is steep, and although simple tasks such as drawing graphs and descriptive statistics can be learned rather easy, the language's full potential is difficult to master.

Some advanced users sometimes offer helpful reference cards with the list of the most significant functions [9]. From DM user's perspective, R offers very fast implementations of many machine learning algorithms, comparable in number to RapidMiner and Weka (from which a large number of algorithms is borrowed), and also the full prospect of statistical data visualizations methods. It has specific data types for handling big data, supports parallelization, data streams, web mining, graph mining, spatial mining, and many other advanced tasks, including a limited support for deep learning methods.

R's main problem is its language, which, although highly extendable, is also a difficult one to learn thoroughly enough to become productive in DM. Advancement for DM tasks in that direction is the Rattle package (author Dr. Graham Williams and other contributors) that offers a decent GUI for R. Rattle, which is in development from 2006, is similar to Weka's Explorer in the sense of user-friendliness. It loads separate packages from R upon request for a specific analysis. Rattle uses some of the R's standard implementations of DM methods and also additional packages. The only problem with Rattle is that it cannot use all of the R's algorithms or Weka's DM implementations. Nevertheless, Rattle is user-friendly and quite popular in DM community.

D. Orange

Orange is a Python-based tool for DM being developed at the Bioinformatics Laboratory of the Faculty of Computer and Information Science at the University of Ljubljana. It can be used either through Python scripting as a Python plug-in, or through visual programming. Its visual programming interface, Orange Canvas, offers a structured view of supported functionalities grouped into nine categories: data operations, visualization, classification, regression, evaluation, unsupervised learning, association, visualization using Qt, and prototype implementations.

Functionalities are visually represented by different widgets (e.g. read file, discretize, train SVM classifier etc). A short description of each widget is available within the interface. Programming is performed by placing

widgets on the canvas and connecting their inputs and outputs. The interface is very polished and visually appealing, offering a pleasant user experience.

One apparent downside of Orange is that the number of available widgets seems limited when compared to other tools such as RapidMiner or KNIME, especially because of the lack of integration with Weka. Still, the coverage of standard data mining techniques is quite good, as can be seen from Table II. Furthermore, there are a number of interesting widgets currently in development that can be found in the "Prototype" category, so it is reasonable to expect that the feature set will be expanded in the future.

E. scikit-learn

scikit-learn is a free package in Python that extends the functionality of NumPy and SciPy packages with numerous DM algorithms. It also uses the matplotlib package for plotting charts. The package keeps improving by accepting valuable contributions from many contributors and is supported by both INRIA and Google Summer of Code. One of its main strong points is a well-written online documentation for all of the implemented algorithms. Well-written documentation is a requirement for any contributor and is valued more than a lot of poorly documented algorithm implementations.

The package supports most of the core DM algorithms. However, several significant DM algorithm groups have been omitted currently, including classification rules and association rules. On the other hand, the package is strong in function-based methods including many general linear models and various types of SVM implementations. It is also quite fast despite being written in an interpreted language. This is mainly because the contributors are asked to optimize the code in various aspects, such as calling array based NumPy number crunching algorithm or writing wrappers for existing C/C++ implementations in Cython.

Despite its advantages, the use of scikit-learn still requires that one is a skilled programmer in Python because of its command-line interface. This will detract almost anyone not versed in this language because there are other tools that do not have this assumption.

F. KNIME

KNIME (Konstanz Information Miner) is a general-purpose DM tool based on the Eclipse platform, developed and maintained by the Swiss company KNIME.com AG. Its development started in 2004 at the University of Konstanz, Germany, and the initial version was released in 2006. KNIME is open-source, though commercial licenses exist for companies requiring professional technical support. According to the official website, KNIME is used by over 3000 organizations in more than 60 countries, and there seems to be a considerable community support.

The tool adheres to the visual programming paradigm present in most DM tools, where building blocks are placed on a canvas and connected to obtain a visual program. In KNIME, these building blocks are called nodes, and according to the official website, more than 1000 nodes are available through the core installation and various extensions. Nodes are organized in a hierarchy and can be searched by name within an intuitive interface. Each node is documented in detail, and the documentation is automatically shown within the interface once the node is selected.

A large repository of example workflows is available to facilitate quicker learning of the tool. One of the greatest strengths of KNIME is the integration with Weka and R. Although extensions have to be installed to enable the integration, the installation itself is trivial. Weka integration enables using almost all the functionality available in Weka as KNIME nodes, while R integration enables running R code as a step in the workflow, opening R views and learning models within R. Several other interesting free extensions are also available, e.g. JFreeChart extension that enables advanced charting, OpenStreetMap extension that enables working with geographical data, etc. There are also commercial extensions for more specific functionalities. Overall, KNIME seems to be one of the best choices for a user interested in a purely visual programming paradigm with a need for a large variety of nodes.

IV. CONCLUSION

Several DM tools were presented in this work. Overall conclusion is that there is no single best tool. Each tool has its strong points and weaknesses. Nevertheless, RapidMiner, R, Weka, and KNIME have most of the desired characteristics for a fully-functional DM platform and therefore their use can be recommended for most of the DM tasks.

Abstract – MAS (Multi Agent Systems), belong to the field of AI (Artificial Intelligence), the study addressing the methods of construction of complex systems using a large number of agents and adjusting their behavior to a particular problem. MAS can be defined as groups of entities (agents) working together to solve problems not solvable by their individual skills and know-how. Business decisions are based on extraction of useful knowledge from different data sources. Those data sources, usually called the big data, might be huge digital data sets such as an internal data warehouse or external sources like the web. In order to process the big data, one needs to have smart solutions, analytics services, programming tools and applications. Intelligent agents can perform certain tasks such as big data processing, information retrieval and the creation of OLAP (On-Line Analytical Processing) cubes which represent multidimensional data. Given that volumes of data grow continuously, insurance companies have to be able manage them. The agent technology has the potential to become the key technology for management of ever-increasing amount of information. This paper describes how to develop MAS in order to gather useful knowledge from the data source and automate the specific process for better business decision.

Keywords: Multi Agent Systems, Artificial Intelligence, On-Line Analytical Processing, Decision Support, Big Data, Business Intelligence, JADE, OLAP, MAS, BI

I. INTRODUCTION

In the second half of the last century information sciences focused on data in general, and in particular on data collection, storage, transfer, sharing, analysis and, last but not least, data usage. Data volume increases on a daily level and we have become unable to store and analyze such amount. According to the Gartner's analysis, the amount of data grows by 50% every year. Gartner's analysis proves that information has become one of the most valuable assets that organizations have. Investors know how valuable information-centered businesses are and new information-based revenue streams are becoming a mainstream process across different industries. The "Big Data" technology innovation is challenging the existing information infrastructure. Information management is a top priority for organizations around the world. [1]

The term "Big Data" is used to describe large volumes of both unstructured and structured data, so big and complex that practically no one can use them with traditional management tools and applications for analysis. Text archive files, images, videos, social networks, e-commerce, medicine, the military, internet indexing, searching etc. account for the enormous data increase. Moreover, the information industry shifts to mobile computing, provision of cloud and it relies on analysis of large volumes of data.

Modern trends pose serious difficulties in management of large data volumes, and this is especially true of business analytics data because standard techniques cannot support it. New requirements expect from organizations to discover knowledge from their internal or external data sources which can help organizations to make better business decisions. The process of knowledge discovery is an integral part of the Business Intelligence (BI) technology approach that has been used increasingly, especially in last few decades, when a lot of new applications on that can help organization to improve business process and make better business decisions appeared on the market.

In order to improve their decision making process, organizations have created the right environment to respond to these new challenges. The environment which enables organizations to extract and store extracted information is called the Data Warehouse (DW). The DW covers a group of technologies and techniques which help employees to handle data more easily. The Figure 1 below shows typical architecture for supporting business decision systems within the organization. In order to have an effective system, appropriate methods have to be developed, which will gather and process data from multiple different data sources and in different data formats, such as the web, text documents, binary, etc. Such data should be cleansed and should be stored in the organization's data warehouse. Also, the data contained in the DW needs to be cataloged, maintained and corrected. Furthermore, the data warehouse needs to be updated as the new data comes in, for example, last month's sales. [2]

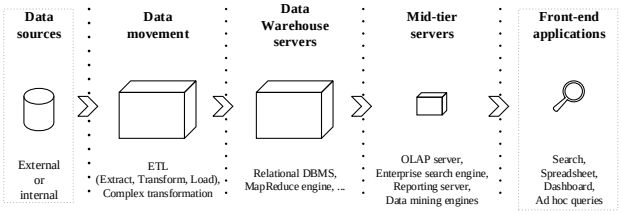

Figure 1 Typical decision support architecture

This paper presents information exchange between agents using a set of communication rules known as ontologies. The term "ontology" applies to business terms and rules that enable people to manipulate the real business problems and make business decisions based on intelligent agents. Introducing intelligent agents into big data processing, especially for business decision support, can reduce human workload. This is mainly due to agents'

independence, i.e. autonomous properties, which enable agents to act on behalf of humans in a business process, especially in the field of data acquisition and collection.

The following sections present an overview of the decision making technology process and agent-oriented technology programming approach using the JADE [1] technology (Java Agent Development Framework). The last section provides a simple example of exchange of business information between two agents that help the staff in an organization to make better business decision.

II. DECISION-MAKING TECHNOLOGY OVERVIEW

The Figure 1 presents typical architecture for supporting BI and knowledge discovery. The data comes from different sources, structured or unstructured. Data sources might be of different quality and in different formats. Sometime, the data might even be inconsistent. Problems of integrating, cleaning and standardizing such data are challenging but imperative because the necessary, successful environment exists.

The first step in establishment of architecture for a successful BI system as a basis for knowledge discovery and business decisions is collection of data from its source. The so-called ETL (Extract, Transform, Load) methods present the crucial procedure in the data gathering process. These methods help to establish and correct problems in data quality. They also facilitate efficient loading of large data volumes to the Data Warehouse (DW). [2]

The DW is a collection of data and collection of decision support technologies that assist an employee with sufficient knowledge (executive, manager and analyst) to make better and faster decisions. Data can be stored in many different types of databases; however, the data in DW is stored on a single site. In order to create a DW, data should be extracted from the source, cleansed (free of errors), transformed (summarized) and loaded into a data store – DW (ETL). DW servers are divided from operational databases and they have their own database which is used only for decision support. Data stored in a DW share the following characteristics: *Subject oriented* – data is logically organized around the main item, e.g. customers, sales, etc., *Integrated* – all of the data organized around such an item is combined and can be analyzed together, *Time variant* – historical data is maintained in historical form and *Nonvolatile* – data is read-only, not updated or changed by users. [3]

Once data is ready for querying, i.e. cleansed, filtered and corrected, employees should be able to query and perceive it from multiple dimensions. The Online Analytical Processing (OLAP) enables operations like filtering, aggregation, pivoting, rollup and drill-down of multidimensional data. The main difference between DWs and the OLAP is a different data view. DWs are based on relational technology while OLAP uses a multidimensional view of aggregated data. Use of a multidimensional view provides quick access to further analysis. A data analyst, manager or executive can analyze data from different views, in a fast and interactive way. The OLAP systems have the ability to answer to the "*who?*" and "*what?*", but it is their ability to answer the "*what if?*" and "*why?*" questions that sets them apart from Data Warehouses. The OLAP, with its capabilities, transforms the DW into strategic information, moving data access from information to knowledge. All the applications that use the OLAP have to be able to deliver information just-in-time. [4] The OLAP systems work with very large databases, up to petabytes, and thanks to that feature, the OLAP can be appropriate for intensive workloads. In addition, it is more tolerant to ACID[2] design philosophies [5]. The OLAP is nothing else but the *multidimensional* view of data in the DW. In multidimensional models a set of *numeric measures* exist that are subject to analysis. Such measures include sales, the budget, inventory etc. *Dimensions* represent the context for the measure. Examples of dimensions associated with the sale amount include the city, product name, date, etc. All dimensions uniquely determine the measure. Each dimension is further described by a set of attributes. For example, the *Product* dimension has the category of attributes and the industry of the product. The Figure 2 depicts the multidimensional view of the data.

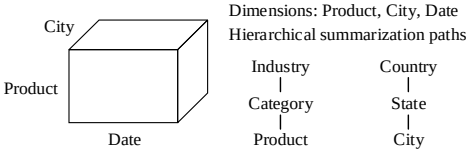

Figure 2 Multidimensional data

The OLAP conceptual model has features such as *aggregation* of measures by one or more dimensions. This feature is one of the key features in the OLAP. Computing and ranking of the total sales of a policy by a broker or within a city can be examples of aggregation. Another popular operation in the OLAP is *comparison* between two measures – for example, the sales and budget aggregated by certain dimensions. One of the most important dimensions in the decision support analysis is time, for example, the trend analysis. [7]

III. MULTI-AGENT SYSTEMS

The Agent Oriented Programming (AOP) is a software paradigm that brings concepts from the artificial intelligence theory to the center of the distributed systems. The AOP essentially shapes the applications as collections of components called agents, characterized as autonomous, with the possibility of communication. Being autonomous as they are, they have the capability to handle complex tasks. Agents must be able to communicate, negotiate and

[1] JADE is distributed agent platform created according to FIPA standards. It is developed in the programming language Java (J2SE), and it is being distributed via „Telecom Italia“, available as an open source platform with LGPL license. Source: http://jade.tilab.com/

[2] ACID represents design philosophies which focus on consistency and it is traditional approach of databases. ACID means: A-Atomicity, C-Consistency, I-Isolation and D-Durability. [6]

cooperate in "open" environment. Given that they have the ability of communication, they are able to interact with other entities, work for their own agenda and for agendas of other agents. The architecture of agent-oriented applications is exclusively peer-to-peer, implying that every agent is capable to initiate communication and to reply to requests at any time. A number of independent issues must be resolved when adopting an Agent system to solve specific domain problems - for example communication between agents. Multi Agent Systems should be on the top of agent-oriented infrastructure as independent, allowing developers to focus on the business logic. [8]

A. The JADE architecture

Applications developed on the JADE platform are comprised of a set of components called „*Agents*", each bearing a different name. Agents perform tasks and they communicate via message exchange. Agents live at the top of the platform that provides the basic information, such as message delivery. Just as the methods, objects etc., the programming agents represent one form of programming abstractions. The difference between an agent and object is the fact that the object is a programming abstraction describing the methods and attributes of the programming component, while the agent is a software abstraction at an even higher level of abstraction, enabling the simple and powerful tool for construction of complex programming entities. Unlike objects defined by attributes and methods, the programming agent is defined by its behavior. This fact is very significant because it reduces the programming of agent systems to the specification of the certain agents' behavior.

The JADE is completely developed in the Java programming language. It simplifies the implementation of Multi Agent Systems respecting the FIPA[3] (Foundation for Intelligent Physical Agents) rules, and via the graphical tools, it supports the development and testing phases. The agent platform can be distributed to several computers being controlled via graphical interface implemented in the JADE Framework. The programming agent needs to be: autonomous, mobile, purposeful, stabile, communicative and capable of learning. The JADE programming platform includes one or more containers. Containers can be executed on different hosts (computers, mobile devices etc.) making a distributed platform. Each container may contain one or more agents. Figure 3 [9] represents the basic elements of the JADE architecture. [8]

The Main container is a special form of container, capable of containing agents, but still very much different from other containers because the Main container is a place at which other agents register and it includes two different agents: the AMS (Agent Management System) represents an authoritative agent, the only one that is able to start and stop the platform, and the DF (Directory Facilitator) represents the "Yellow Pages", as we might call it, a place used by agents to advertise their services, that the other agents can browse through to search for information, depending on their needs [9]. The JADE platform may contain multiple containers like Container 1, on the Host 3, which contains the Agents A2 and A3.

Agents can communicate transparently, depending on their location; for example A2 or A3 can communicate; as well as A1 and A2 and although they belong to different containers, they are on the same platform. Communication is possible between A1 and A5, even though they belong to different platforms. Communication is based on asynchronous passage of messages. The message format is determined by the ACL (Agent Communication Language), a language defined by the FIPA (Figure 4 [11]). [9]

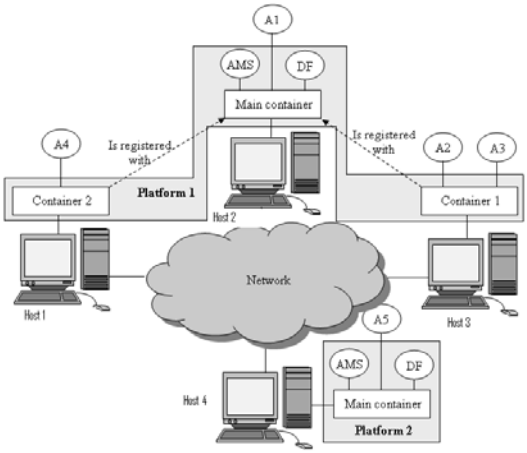

Figure 3 JADE architecture

A FIPA message includes the following data: the *Sender agent* - sending the message, the *Receiver agent* – receiving the message and the *Message* itself - intended for communication acts representing the sender's intention. For example, when the agent sends the INFORM message, it wants to inform the receiver of the fact (e.g. INFORM "It's raining today"). When the agent sends the REQUEST message, it demands an action from the receiver. The FIPA differentiates between 22 possible communication acts, covering 95% (it does not support the remaining 5%) of the possible situations. Content represents information contained in the message. [9]

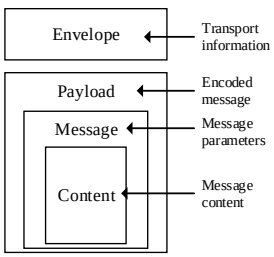

Figure 4 FIPA Message Structure

[3] FIPA (Foundation for Intelligent Physical Agents) is a nonprofit standardization organization dealing with the standardization of the programming agents and agent platforms. FIPA standardizes the architecture of agent systems, agent management, their communication etc.

An example of the FIPA-ACL (Agent Communication Language) message with the REQUEST performative:

```
(REQUEST
        :sender (agent-identifier :name Ivan)
        :receiver (agent-identifier :name Mark)
        :ontology travel-assistant
        :language FIPA-SL
        :protocol fipa-request
        :content
        ""((action
                (agent-identifier
                        :name Ivan)
                (book-hotel
                         :arrival 15/10/2006
                        :departure 05/07/2002 ... )
        ))""
)
```

[Part of code from [8]]

```
(PROPOSE
        :sender (agent-identifier
                :name Main@MY_IP/JADE
                :addresses (sequence MY_URL/acc ))
        :receiver (set
                (agent-identifier :name Seller@MY_IP/JADE
                :addresses (sequence MY_URL/acc )) )
                :content  "MAIN:
                        Number of policies: 8
                        Premium: 2900.0
                :reply-with
                        Seller@MY_IP/JADE136
                        :conversation-id  policy
)
```

[a part of the code from insurance example presented in the paper]

When a certain object is additionally described by a set of complex information, it is necessary to define the syntax for the receiver to be able to read the message content in order to obtain the necessary information. Ontologies represent abstract concepts and a relation for a specific domain. They can be shared and used many times across the internet by knowledge representation languages such as the Resource Description Framework (RDF) or Web Ontology Language (OWL).

According to the FIPA terminology, this syntax is known as the content language. The FIPA does not enforce these standards; they are recommendations how to communicate with AMS and DF agents –most significant in the JADE architecture.

An example of the content language recommended by the FIPA:

(Policy :number 123456 :seller Ivan :insured Mark)

When the agent receives this string, it has to be able to convert the string in the appropriate format to understand the information contained in the string. It also has to be able to share the meaning with the sender of the string and symbol concept („Policy, number, seller, insured") used for the structure expression. This set of concepts and symbols is known as ontology. The ontology is independent and inherently related to the corresponding research domain. Ontology-supported work makes the JADE capable for complex content operation. Software developers can choose to work with JADE classes, JAVA serialization, XML, or with some other technology, depending on their needs. The classification offered by the FIPA is the one separating the ACL message into two sections: *predicates* and *terms*, as indicated in the Figure 5. [8]

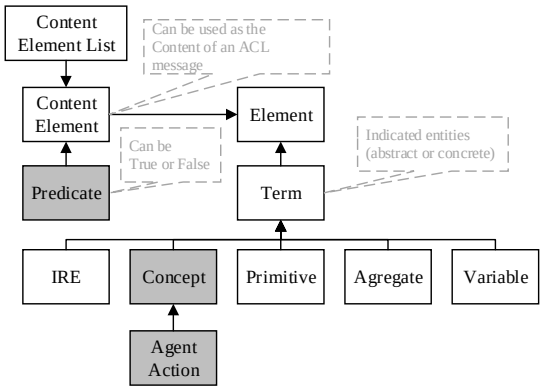

Figure 5 Reference model

Predicates are expressions describing the status of a certain object and they can be true or false:

(Insured (Person :name Ivan) (Municipality :name Split))

Description of the insured person, "person named Ivan" from "the Municipality of Split".

Predicates are used for the INFORM or QUERY-IF message content exchange, e.g. if two agents want to exchange some facts.

Terms are expressions identifying entities that exist in the real world. They can be abstract or concrete. They are classified into:

- Primitives – entities such as string and integers
- Concepts – entities with complex structure

(Person :name Ivan :Age 30)

Concepts are referred to inside predicates:

(Policy :number 1234 :insured(Person :name Ivan))

- Agents' actions: are special concepts that indicate action that can be perform by some agents.

(IssuingPolicy (Policy :number 12345) (Insured :name Ivan))

- Aggregations are entities or groups of other entities

(Sequence (Person :name Ivan) (Person :name Mark))

- IRE (Identifying referential expressions) are expressions that identify the entity (or entities) for which a given predicate is true
- Variables are terms frequently used in queries.

Agents have to be able to perform several competing tasks to respond to different requests. For this purpose, every agent has the possibility to implement different behavior types, ranging from those simple ones, performed only once to those performed until a certain condition is fulfilled, unless otherwise specified. The Figure 6 shows the JADE framework behavior hierarchy. [8] The behavioral state has to be contained in corresponding agents. Every agent cares about its behavioral state, such as the action completion and the action blockage.

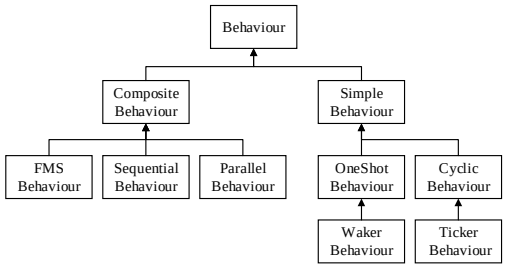

Figure 6 The Jade behavior hierarchy

The FIPA has specified interaction protocol stacks used for inter-agent communication. For every conversion, the JADE differentiates between the roles of the *initiator* and the agent replying (*Responder*) to the messages. The Figure 7 shows inter-agent communication structure. The Initiator sends the message, and the responder may reply with the message "not understood", refuse to reply with the message "refuse" or agree with the message via "agree". If the agent replies with "agree", the message is sent so quickly that it can be considered as an unnecessary burden. [10]

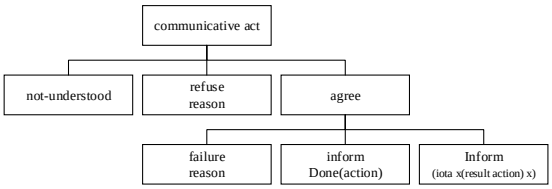

Figure 7 The Interaction Protocol Homogeneous Structure

IV. INSURANCE MAS EXAMPLE

This example comes from the Insurance domain and describes one of many situations in which employees need information to make a decision about their business actions. This is a problem not only for employees working in headquarters or static workers in other offices, but also for mobile employees. As the number of mobile and online users in the world continues to grow, so do the ways in which mobile users can gather the right information. All employees, ranging from a CEO to a seller, can request and obtain, automatically or on demand, a critical alert or information that is important for their business operations to their mobile phone or a smart phone. Every mobile phone equipped with appropriate software becomes a mobile agent capable of imitating communication with the headquarter agent who will respond to their queries.

To demonstrate this, we have developed two agents with different roles using the JADE architecture. One of them has a double role and represents the most important agent in the process since it discovers knowledge and upon discovering it, it sends it as information to mobile agents. Mobile agent is the second agent that only initiates communication.

The database includes two tables: one, titled "Policies" includes the concluded policies, and the second, titled "Persons" that contains data of the policy holders. The Figure 8 indicates the database structure:

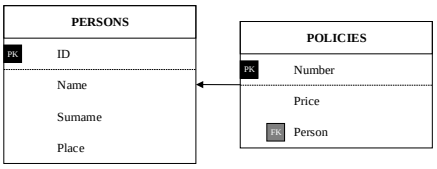

Figure 8 Database structure

The Agent that discovers knowledge, called the "Main" agent, obtains the statistical figures regarding the number of issued insurance policies and the realized premium. When the "Main" agent finds the right information it sends it to mobile agents, known as the "Seller" agents. The Main agent offers to the Seller agent available information that it has and offers the Seller agent to accept or refuse it, depending on the Seller's needs. The Seller agent performs the "Seller"behavior, sending the query on the schedule time passing through the corresponding communication steps (Figure 9). Every step requires corresponding behavior, depending on the message type.

The next code snippet covers a part of communication between the Main agent and the Seller agent.

```
if (messageRecieve.getPerformative() ==
ACLMessage.CFP){
messageAnswer.setPerformative(ACLMessage.INFORM);
messageAnswer.setConversationId("policy");
messageAnswer.setContent("MAIN: Available ...");
//Sent message
myAgent.send(messageAnswer);
} else if
(messageRecieve.getPerformative() ==
ACLMessage.ACCEPT_PROPOSAL){
messageAnswer.setPerformative(ACLMessage.PROPOSE);
messageAnswer.setConversationId("policy");
messageAnswer.setContent("MAIN: Number …");
//Send message
myAgent.send(messageAnswer);}
```

In the first step, the Seller agent sends the CFP (Call for Proposal) request for the available statistics. The behavior defining the CFP message is „SendCfpRequest". The Main agent grasps that this is a CFP message and sends back the INFORM message, informing the Seller agent about the available statistics.

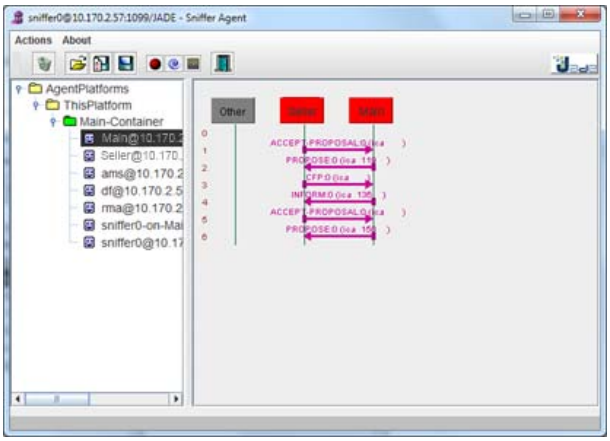

Figure 9 JADE Communication between Seller and Main Agent

The Seller agent accepts the proposal from the Main agent via "ReceiveCfpRequest" behavior and returns the message ACCEPT_PROPOSAL. The behavior defining the proposal is "CofirmRequest", whereby the Main agent, using the appropriate methods, contacts the distributed databases and, by performing the queries (SQL select), the Main agent sends the corresponding information via the message PROPOSE. Then, the Seller agent accepts the statistics via the "AcceptStatistics" behavior and prints them to the console.

After running the application, the console displays the following:

```
------------------------------------------------------------------------
Agent container Main-Container@10.170.2.57 is ready.
------------------------------------------------------------
SELLER: Request for statistic?
MAIN: Available statistics are number of sold policies and
premium!
SELLER: Accept! Give me all statistics.
MAIN:
        Number of sold policies: 8
        Premium: 2900.0
**************************************
```

V. CONCLUSION

Due to the large amount of information, intelligent software agents organized in the Multi Agent Systems represent a solution to the problem of gathering, processing and using information. Intelligent software agents are a collection of technology that ensure development of advanced services because it enables creation of intelligent services, tailor-made to the needs of a user. By using software agents, certain tasks, otherwise performed independently by users, can now be automated. Intelligent software agents support business processes due to their great potential, especially in terms of processing and maintenance of large amounts of information stored in heterogeneous, dislocated information sources. Implementation of a business process solution through the Multi Agent System based on the JADE framework, such as the one presented in the paper, is straightforward and intuitive. With the development and spread of new mobile hardware, problems such as detection of individual system entities and users and their communication are entering into a new phase. New trends and increase in the number of users of smart devices result in larger number of services these devices can provide. The fact that each user has a smart device in his/her immediate vicinity and that he/she can store new data at any moment, indicates the need to synchronize this data with other systems, as well as the need for various data access.

***Abstract*—Nowadays, by help of tourist trip planners, in many travel destinations, the trip itinerary could be prepared automatically. The trip planners enable customization of trip itinerary based on tourist preferences, available time and budget, where the itinerary is optimized by using optimization techniques from the field of metaheuristics. In this paper, we present a new approach based on simulated annealing algorithm for solving the tourist trip planning problem. The hard constraints include limited trip duration, working hours of points of interest (POIs) and tourist budget, while tourist preferences and traveling time comprise the soft constraints, which take part in a two component function for evaluation of quality of solutions. The search space is explored by using three types of operators, namely *insert*, *swap* and *shake*. The algorithm is tested against some real test data for the city of Prishtina in Kosova. In addition to fine tuning the values of algorithm parameters, further experiments are made for exploring different approaches of construction of initial solution, time duration of algorithm execution for various trip lengths, and influence of *shake* operator into the solution quality.**

I. Introduction

A tourist trip itinerary is plan for visiting a number of POIs in city (or a wider geographic region) during a limited period of time. In general, the itinerary contains a list of visits to POIs that are ordered based on the time of visit, where each visit might be annotated with a starting and ending time, visit duration, a short description of POI, etc. In addition, a trip itinerary might include a map with navigational information for traversing between individual POIs.

Usually, in a touristic city/region there might a high number of POIs which could be potentially visited, nevertheless the trip duration is usually limited to few days, and as result, only a subset of them can be actually visited. In addition, often it happens that the tourists preferences about types (e.g. monument, castle, statue, etc.) and categories (e.g. architecture, archeology, nature, etc.) of POIs are such that require visiting POIs that are located far from each other. Therefore, it is a complex task for the tourist to manually prepare the trip itinerary that would include the POIs that are the most preferred to her/him.

In general, the tourist trip planning problem is known as Tourist Trip Design Problem (TTDP) [1]. Given a number of POIs in a city/region, the goal is to prepare an itinerary that includes visits to POIs that meet, to a great extent, the preferences of the tourist. Depending on the kinds of features or constraints being considered for the problem, different problem modelings from the literature could be used to model the tourist trip planning problem. The Orienteering Problem (OP) [2] and the Team Orienteering Problem (TOP) [3] are used to model single and multiple day itineraries, respectively. The OP with Time Windows (OPTW) [4] and TOP with Time Windows (TOPTW) [5] enable modeling working hours of POIs, whereas Multi Constraint TOPTW (MCTOPTW) [6] allows enforcing additional constraints for the itinerary, such as maximum budget to spent, or maximum number of POIs of certain type (e.g. statue, castle, etc.) to be visited. The OP with Hotel Selection (OPHS) [7] enables selection of a hotel at the end of the trip of each tour.

Golden et al. [8] prove that OP is a NP hard problem, therefore many researcher tackle OP and its deriving extensions by using various approaches from the field of metaheuristics. Vansteenwegen et al. [9] discuss the most effective approaches that solve OP and its respective extensions.

In the process of trip itinerary planning, a method that estimates the interest of the tourist about POIs is required [10]. A such a method would consider the preferences of the tourist and features of the POIs, and based on their reciprocal match, it would generate the estimated satisfaction factors of the tourist with each POI. Nevertheless, introducing a new such a method is out of scope of this paper, hence, a method from the literature is used for that purpose.

The goal of this paper is to present a new algorithm that plans the tourist trip itinerary by considering multiple day tours, tourist budget, working hours of POIs and breaks during the trip of a day. In comparison to existing modelings in the literature for the trip planning problem, where optimization is done by only maximizing the satisfaction factor of a tourist with POIs, in our case, the optimization includes a second component, that is minimization of the total traveling time of the tourist.

The remaining of this paper is organized as follows: Section II discusses the state of the art algorithms, Section III presents the mathematical modeling of the problem, Section IV presents the proposed solution, Section V gives the computational experiments and Section VI outlines the main conclusions of the paper.

II. State of The Art

Vansteenwegen et al. [5] are the first to model TTDP as TOPTW problem. As result, they develop an approach based on the Iterated Local Search (ILS) framework. The neighborhood structure of the algorithm comprises of an insert step (for inserting new POIs) and a shake step (for escaping from local optima). The insert step adds consecutively new

points into the tours. The shake step removes one or more visits from each tour. The computation time of this algorithm is, with a factor several hundred, faster than the other presented approaches in the literature for TOPTW problem. This feature makes the algorithm suitable for application in the domain of tourist trip planning. Later, Garcia et al. [6] extend ILS to solve the Multi Constraint TOPTW, which allows modeling the constraints about maximum allowed budget to be spent and maximum allowed POIs of certain type or category to be visited.

Gavalas et al. [11] solve TOPTW by using two analogous approaches from cluster-based heuristics named as Cluster Search Cluster Ratio (CSCRatio) and Cluster Search Cluster Routes (CSCRoutes). The presented approaches aim at encouraging visits to dense areas that consist of a high density of "good" points (with high satisfaction factors). Both heuristics employ a clustering procedure to organize points into clusters based on distance from dense areas. This increases the probability that more visits would to take place inside individual clusters, and as result, two positive effects would be achieved, the decrease of duration of tours and minimization of number of transfers between different clusters. In terms of quality of solutions, this approach performs better than ILS [5], while the computation time remains in comparable level.

Garcia et al. [12] solve a variant of OPTW problem called Time Dependent Orienteering Problem with Time Windows (TDOPTW), which models the variability of traveling time between POIs. The TDOPTW is used to model different modes of traveling between any two POIs, such as walking, bicycle, public transportation or car. The ILS algorithm [5] is hybridized with Dijkstras Shortest Path algorithm to solve the TDOPTW problem. The Dijkstras algorithm is used to calculate the average travel times between all points available. Due to the constraint for a real time computation, the traveling times are calculated in an off-line-mode and saved for letter use by the ILS algorithm. The computation experiments performed with the data of city of San Sebastian in Spain, prove that the approach is able to generate valid routes in real time.

Souffriau et al. [13] extend MCTOPTW problem to the MCTOP with Multiple Time Windows (MCTOPMTW), where multiple working shifts of POIs can be modeled. The proposed approach for solving MCTOPMTW is a hybridization between ILS and Gready Randomized Adaptive Search Procedure (GRASP) algorithms. This approach is also based on the ILS approach of Vansteenwegen et al. [5] for TOPTW. The ILS-GRASP approach outperforms the approach of Garcia et al. [6].

In [14], we presented a tabu search method for solving the MCTOPTW problem. Oppositely to the approach of Garcia et al. [6] that tackles the same problem, we enforced an additional constraint to the problem that forbids any waiting time between consecutive visits. The method was shown to be competitive to the state of the art algorithms for solving the MCTOPTW problem.

Further, in [15], we extended MCTOPTW problem to MC Multiple TOPTW (MCMTOPTW) to model the trip itinerary for a group of tourists. Then, we solved the problem by devising an algorithm that is built on top of the approach presented in [14], which is used for construction of the starting solution. The proposed algorithm was again implemented under the framework of tabu search meta heuristic with a neighborhood structure that relays on three operators, namely *Separate* (a tourist from the group), *Join* (two tourists from two different subgroups) and *Insert* (a new POI into the trip of a tourist). The solution that is returned by the algorithm creates personalized itineraries for each tourist in the group, by allowing them to switch the company with different tourists during the trip, in accordance to their preferences.

III. Mathematical Modeling

We suppose that there are *N* POIs available in a city or region. Each POI *i* is characterized with a set of attributes, such as: coordinates (x_i, y_i), visit duration t_i, tourist satisfaction factor S_i, opening time o_i, closing time c_i and entry fee e_i. In addition, we suppose that traveling time t_{ij} between POI *i* and POI *j* is symmetric and it is known for all *m=1, ..., N* and *j=1, ..., N*, given that $i \neq j$. On the other hand, the tourists trip details, include: number of tours *M*, budget for the complete trip (all tours) B_{max} and duration of tour T_m, where *i=1, ..., M*. In general, individual tours can have different starting and ending times. Further, we assume that for each tour *m*, POI *1* and POI *N* are the starting and ending points, respectively. In practice, the starting and ending point could be the same, where in most cases that is a hotel (accommodation).

Next, based on [16], we formulate the envisioned trip planning problem as an integer programing problem, where we make use of two decision variables, namely x_{ijm} and y_{im} that are defined as in following. In addition, the starting time of a visit to POI *i* in tour *m* is denoted as s_{im}.

$$x_{ijm} = \begin{cases} 1, & \text{if visited point } i \text{ is followed with a visit to point } j \text{ in tour } m \\ 0, & \text{otherwise} \end{cases}$$

$$y_{im} = \begin{cases} 1, & \text{if point } i \text{ is visited in tour } m \\ 0, & \text{otherwise} \end{cases}$$

$$Max \sum_{m=1}^{M} \sum_{i=2}^{N-1} S_i y_{im}, \tag{1}$$

$$Min \sum_{m=1}^{M} \sum_{i=1}^{N} \sum_{\substack{j=1 \\ j \neq i}}^{N} t_{ij} x_{ijm}, \tag{2}$$

$$\sum_{m=1}^{M} \sum_{i=2}^{N-1} e_i y_{im} \leq B_{max}, \tag{3}$$

$$\sum_{m=1}^{M} \sum_{i=2}^{N-1} y_{im} \leq 1, \tag{4}$$

$$(y_{im} = 1) \implies (o_i \leq s_{im} \wedge s_{im} + t_i \leq c_i), \quad \forall i = 2, ..., N-1, \ \forall m = 1, ..., M \tag{5}$$

$$\sum_{i=1}^{N-1} \left(t_i y_{im} + \sum_{j=2}^{N} t_{ij} x_{ijm} \right) \leq T_m; \ \forall m = 1, ..., M \tag{6}$$

The first two constraints take part in a two component objective function for the envisioned problem, where Constraint (1) aims at maximizing the total collected score for tourist (by visiting POIs with the highest satisfaction factor), whereas Constraint (2) aims at reducing the total traveling time for the tourist throughout all tours. Constraint (3) limits the overall cost of all tours to the specified maximum budget B_{max}, whereas Constraint (4) makes sure that no POI is visited more then once. Constraint (5) ensures that the visits to individual POIs occur only during their respective opening hours. Finally, Constraint (6) limits the duration of individual tours to the respective maximal allowed durations.

The envisioned problem deviates from the original TOPTW problem [5] in two aspects: (1) it considers the entry fee of POIs by limiting the maximum allowed budget to a specified limit, and (2) it optimizes the solution not only based on the overall tourist satisfaction factor, but also based on the overall tourist traveling time.

IV. Solution Approach

The Simulated Annealing (SA) is a metaheuristic that is based on theories from thermodynamics where creation of the structure of crystals depends merely on the cooling function, which should neither be so quick or so slow, as defects in the crystal might appear. Analogical, in the field of optimization, SA uses a cooling function to determine whether the algorithm should also be able to select random solutions that might be worse then the current solution, or it should only accept better solutions, and thus act more as a hill climber. This feature enables SA algorithm to avoid premature convolution, thus it is able to escape from getting stuck in local optimum. The SA algorithm was initially presented by Kirkpatrick et al. in [17]. Recently, the SA algorithm was used by Lin & Yu [18] to successfully solve the related problem of TOPTW.

A. Solution Representation

The representation of a given current solution (denoted as S_c) is done by using an array of M members, where each member is a list, which itself contains the sequence of POIs that are part of a single tour (day). In addition, the POIs that are not included in any of the tours, are kept in separate list called "QueueList". Considering an example of a tourist visiting a city that has $N = 10$ POIs for a duration of $M = 2$ tours, an arbitrary candidate solution might be represented as in following:

$$S_c = \{[1, 8, 2, 5], [9, 7, 10]\}$$
$$QueueList = [3, 4, 6]$$

B. Neighborhood Exploration

There is a number of operators in the literature that could be used to solve the proposed problem. The *insert* operator [5] is used for insertion of new POIs in the itinerary, or *remove* operator to remove one or more POIs from the itinerary. In addition, the *swap/exchange* operator can be used to exchange POIs inside the itinerary with POIs outside of the itinerary, or also it can be applied to exchange POIs within itinerary itself (cross-exchange) [19].

In this implementation, the structure of the neighborhood exploration procedure consists of three operators, namely *insert*, *swap* and *shake*. The *swap* operator is only implemented to exchange POIs in the itinerary with POIs outside of the itinerary. Nevertheless, the cross exchange between the POIs within the itinerary occurs indirectly through *swap* operator, since when a POI goes outside of the itinerary at a given iteration, it has the chance of going back to the itinerary at a later iteration, and there exist probability that the same POI would go to some other position in the tour than it has been at the time when it was lastly removed.

C. Evaluation Function

The evaluation (fitness) of the solutions to the problem at hand are done by using a function that consists of two components, as given by Equation (7). The first component E_s represent the overall normalized satisfaction factor of the tourist with the POIs included into the itinerary, whereas the second component E_t represents the overall normalized satisfaction of the tourist with the overall traveling time during the tours. Both components are multiplied with their corresponding wight coefficients w_s and w_t, respectively, which are used to make a trade off between finding itineraries that include POIs with high satisfaction factors, or in finding itineraries with less travel time. In this implementation, the values of the weight coefficients are assumed to be set by the user, whereas in the future work, we aim to automatize them by taking a multi-objective approach, such as for instance the method of *Pareto front* of the space of candidate solutions.

In reference to Constraint (1) and Constraint (2), note that in order to have a maximizing fitness function, where both its components would have a maximization nature, the second component of Equation (7) needs to consider the complementary value of the normalized traveling time, since its original aim is to minimize the traveling time.

In order to make sure that individual components of the evaluation function do not predominate each other, their respective values need to be normalized based on their maximal possible values. In regard to the component of satisfaction factor with POIs, the normalization (Equation (9) is made by supposing a maximum number of POIs (denoted as τ) that can be visited during a tour (day), and by considering the satisfaction value of the POI with the highest satisfaction factor (denoted as ω). On the other hand, the normalization of the traveling time component is done by considering the total duration of all tours.

$$E(S) = w_s E_{s_{norm}} + w_t(1 - E_{t_{norm}}) \tag{7}$$

$$E_{s_{norm}} = \frac{\sum_{m=1}^{M} \sum_{i=2}^{N-1} S_i y_{im}}{M * \tau * \omega} \tag{8}$$

$$E_{t_{norm}} = \frac{\sum_{m=1}^{M} \sum_{i=1}^{N-1} \left(t_i y_{im} + \sum_{j=2}^{N} t_{ij} x_{ijm} \right)}{\sum_{m=1}^{M} T_m} \tag{9}$$

TABLE I. ALGORITHM PARAMETERS

Symbol	Description
α	Specifies the proportion of temperature decrease
β	Maximal temperature used to commence the search process
γ	Minimal temperature used to end the search process
δ	Maximal number of iterations without improvement
ϵ	Number of POIs to remove during the Shake step
ζ	Specifies one of the modes for generation of the initial solution

D. Simulated Annealing Implementation

The proposed SA algorithm can be fine tuned by using six different parameters. Table I gives more details about the utilized parameters, where the first column presents the respective symbols, whereas the second column explains the purpose for using the envisioned parameters.

As shown in the pseudo code (Figure 1), the parameters can be used to fine tune different mechanism within the algorithm. The ζ parameter sets one of five possible modes for generation of the initial solution, as described in following:

- *Mode 1* - inserts POIs into the itinerary in a random order
- *Mode 2* - initially orders POIs based on their satisfaction factor and then inserts them into the itinerary in a descending order, where POIs with highest satisfaction are inserted first
- *Mode 3* - orders POIs as *Mode 2*, except that it inserts them into the itinerary in a ascending order, where POIs with lowest satisfaction are considered first
- *Mode 4* - calculates the average distance of each POI with all other POIs, and then inserts them into the itinerary by giving priority to the POIs that have shorter average distance to the others
- *Mode 5* - inserts POIs into the itinerary by giving priority to POIs that have a shorter visit duration

The evaluation function described earlier (Subsection IV-C) is used to evaluate the candidate solutions during the search process, such as the initial solution at the start, and the neighbor solutions later. The iterative part of the algorithm depends on its main loop, which is controlled by the initial temperature, which, at the start, is set to its maximal value (parameter β), the temperature decreasing ratio (parameter α), the minimal temperature (parameter γ), and the cooling function. In this implementation, the cooling function follows a decreasing exponential law, which depends on current iteration t and parameter α. At a given iteration t, the temperature T_t is calculated by using Equation 10, where T_{t-1} represent the temperature in previous iteration.

$$T_t = T_{t-1} e^{-\alpha * t} \tag{10}$$

In a given iteration t, the neighborhood of a current solution consists of all neighbors (candidate solutions) that yield as results of trying to swap every POI p that is off the itinerary with every POI q that is currently in the itinerary. There are two mechanisms that are applied priory to evaluating the fitness of the neighbors. The first is elimination of non feasible

```

42: end procedure
```

Fig. 1. The SA algorithm for generation of trip itinerary

neighbors, which do no meet the hard constraints, such as maximum budget, at most one visit to a POI and limited duration of the tours, whereas the second mechanism is about filling empty spaces in the itinerary that might have come out due to application of the envisioned operators. Depending on the size of the empty space, additional non included POIs are inserted into the itinerary.

This implementation follows the general guidelines of SA algorithm in reference to adaption of a neighbor solution as a next current solution. Therefore, a neighbor is always accepted as a next current solution when it is better then the actual current solution. Nevertheless, if a neighbor is worse then the actual current solution, it can still be accepted, with a certain probability, as next current solution. The probability of acceptance is higher if the corresponding quality of the

neighbor is not that worse then the quality of actual current solution, and if the running temperature is higher (this is usually the case in the early iterations of the SA algorithm when it undergoes its exploitative phase). In the pseudocode, variable a gets a random number between 0 and 1, whereas variable b also gets a value between 0 and 1 through the expression in Line 25. If the value of a happens to be smaller then the value of b, then the neighbor solution would be accepted as the next current solution.

If the algorithm undergoes a consecutive number of iterations without improvement (as defined by parameter δ) then the *shake* operator will be applied. Considering the ϵ parameter, the *shake* operator removes a number of POIs from the itinerary. Afterwards, at first, the POIs are reordered by being shifted as much as possible towards the beginning of the tours, so that the empty spaces are gathered at the end of the tours, then the mechanism for filling up the empty spaces (described above) is put into function, and lastly the modified solution is adapted as next current solution. The application of *shake* operator might be important as it might help the SA algorithm to escape from getting caught into the local optimum.

V. Computational Experiments

The algorithm is developed by using Java 1.7. The experiments are conducted by using a machine with an Intel Core Duo 2.5 GHz processor with a Windows 7 operating system and 3GB of RAM memory. In the following subsection, we describe the test set, and then in Subsection V-B, we present the experimental results.

A. Test Set

The test set is made of fifteen instances, where eleven of them consist of two tours (days), while the remaining four have 1, 3, 4 and 5 tours, respectively. In addition, the tourist interest about types (e.g. monument, park, castle, etc.) and categories (e.g. archeology, architecture, religious art, etc.) of POIs is modeled by using the mechanism of random number generation of Java programming language. Further, all fifteen instances of the test set are executed against fifty real POIs in city of Prishtina in Kosova. Each POI, besides its name and description, is also characterized with its estimated tourist satisfaction/interest factor, coordinates, opening and closing time, visit duration and entry fee. In addition, each of the fifteen instances is associated with an additional point (e.g. hotel, bus station, city down town, etc.), which serves, both as a starting and ending point for the tours. The distance between individual POIs is expressed in the unit of minutes.

The first ten instances, except for the tourist satisfaction factor, are characterized with same attribute values, as it follows: 2 tours, each tour starts at 08:00 hrs and ends at 17:00 hrs, break time 30 minutes, wight for satisfaction factor 60% and weight for travel time 40%. The other five instances have diverse attribute values.

B. Experimental results

The values of the algorithm parameters (except ζ) have been fine tuned through some preliminary experiments that have been conducted by using the complete test set. The fine tuned values are: $\alpha = 0.005, \beta = 4000, \gamma = 80, \delta = 210, \epsilon = 6$.

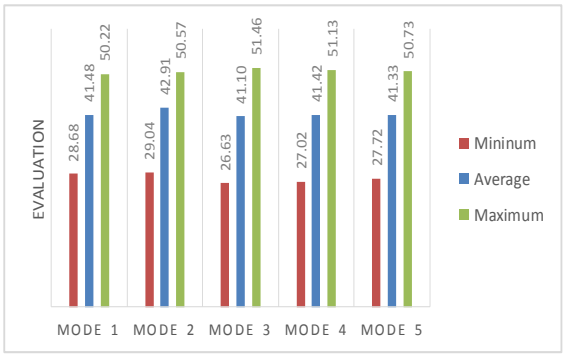

Fig. 2. Algorithm performance for different modes of initial solution

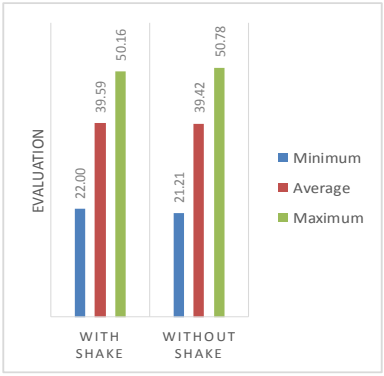

Fig. 3. Algorithm performance when *shake* operator is applied

In the following, we present the results about four types of experiments, such as: the performance of different modes of initial solution, the effect of *shake* operator into the search process, the variations between different executions of a given instance, and the time needed to execute instances with different number of tours. Each experiment includes ten executions for each instance of the test set. Therefore, the results presented below are averaged over the ten executions of individual instances.

Figure 2 shows that, in average, *Mode 2* of initial solution, where POIs with higher satisfaction factor are more common, performs better than the other considered modes. This result can be explained based on the indication that *Mode 2* of initial solution is more diverse, since most of its POIs have high satisfaction factor, hence they get more prone in being subject of exploration operators, and therefore make the algorithm more exploratory.

The diagram in Figure 3 depicts the averaged results over the complete test set, where the performance of the algorithm is presented in variance to the application of *shake* operator. By considering the average results, it can be noted down that the *shake* operator helps the algorithm to achieve only a slight improvement in the overall quality of solutions.

Figure 4 presents the variance in time over ten different executions of *Instance 12*, which consists of two tours. In terms of quality of solutions, for this particular instance, it is evident

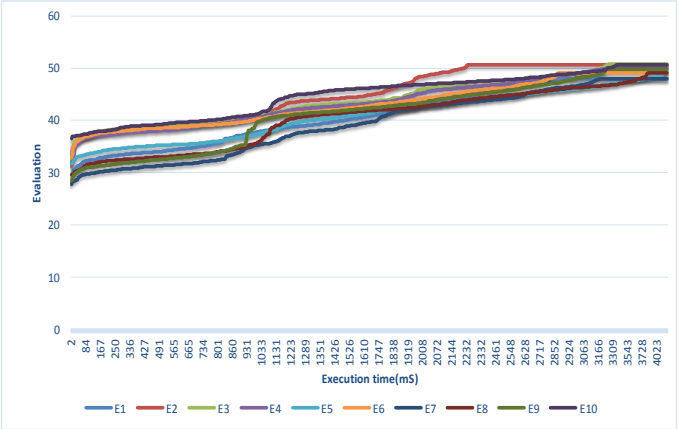

Fig. 4. Variations between different executions for instance *Instance 12*

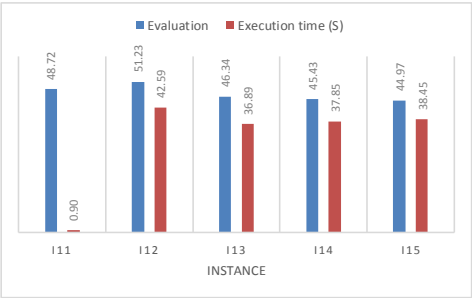

Fig. 5. Computation time for different number of tours

that the difference between different executions is at most a little less than 3 points, whereas the computation time, in the worst case scenario is a little less than 4 seconds. In addition, it can be noted down that, although, in some executions, the starting solutions are much worse, at the end of executions the algorithm manages to produce solutions with comparable quality to the cases where initial solution is better.

Figure 5 shows the performance of the algorithm when executed for instances 11 until 15, which consist of 1 to 5 tours, respectively. In terms of evaluation, the algorithm produces comparable results for all five considered instances, whereas the computation time for *Instance 11* (with one tour) is a little less than 1 second, and for other instances it is much higher.

The particular trip planning problem tackled in this paper differs from the related problems in the literature, therefore the results of the proposed algorithm can not be experimentally compared with the results of the state of the art algorithms.

VI. Conclusions

In this paper, we presented a new approach based on simulated annealing for planning the tourist trip itinerary. The computation time for itineraries with one tour is quite short, whereas for itineraries with two tours and more the average computation time is about 39 seconds. Although, the algorithm works slightly better by using *Mode 2* of initial solution (where POIs with higher satisfaction are given priority for insertion), we can conclude that the difference by using other modes is quite small. Despite our expectations, the application of *shake* operator does not prove to be very successful in improving the quality of solutions. Therefor, it remains an open question to investigate application of other operators that might be helpful in further improvement of the results.

Abstract - Recent research efforts in data stream management systems (DSMS) focus mainly on processing continuous queries over traditional data streams, and only a few addressed spatio-temporal continuous queries. OCEANUS presents an effort to extend TelegraphCQ DSMS with spatial support providing a platform for spatio-temporal streaming applications. Data type system that represents the formal basis for modeling moving objects in data streams, as well as an approach for managing moving objects in spatio-temporal data streams based on user-defined aggregate functions (UDAF) are presented. In this paper we are concerned with improving proposed approach for extracting moving objects out of spatio-temporal data streams based on UDAF. It is based on two methods for detecting static locations on trajectories of moving objects and for reducing total number of units in sliced representation by introducing trajectory buffer. First method leads to more precise results of certain operations over moving objects such as retrieving information about speed and direction, but also enables introduction of few new operations such as retrieving static locations and overall stoppage time on moving object's trajectory. Second method leads to better memory usage during processing spatio-temporal continuous queries in DSMS.

I. INTRODUCTION

Moving objects databases actually represent spatio-temporal databases that manage spatial objects with continuously changing location and/or geometry and they represent relatively intense research area in recent years. These databases are overloaded with frequent updates of moving objects positions, and new approach of considering trajectory of a moving object as a continuous data stream which carries information about object's position at any instant has been proposed. To manage this data, several DSMSs have been developed, that support the management of data streams and standard relations as well. Mainly based on relational paradigm, they have very rudimentary support for spatio-temporal data types and operations that would enabled efficient management of moving objects.

The majority of published research has focused on moving objects databases or data streams separately, while only a few attempts to combine these two areas. The goal of our previous research [1][2] was to examine the possibility of combining data models and associated algebras developed for traditional spatio-temporal database management systems (DBMS) with spatio-temporal data streams in order to efficiently manage moving objects. We have proposed an approach for spatio-temporal data stream management based on extending relational-based DSMS with a full-fledged set of spatio-temporal data types and associated operations. Formal specification of operations for moving objects in the context of data streams is presented by using a conceptual framework of many sorted algebra consisting of data types and operations needed to support spatio-temporal data in data streams. Implementation of abstract data model at discrete level, including spatio-temporal predicates and operations, is based on the concept of extracting moving objects out of data streams using UDAFs.

Extracted moving object is formed of unit types each consisting of a time interval and a value describing simple function on the unit time interval as it is presented in [1][2]. The unit type that describes movement of a corresponding moving object as a linear function of time is created by using two successive spatio-temporal data stream elements with spatio-temporal references consisting of successive locations and time instants. Complete sliced representation presents a moving object as a set of temporal units whose time intervals are disjoint and, if adjacent, their values are different. Assembling unit types into a moving object based on the spatio-temporal references of data stream elements is achieved by using UDAFs.

In this paper we are concerned with improving proposed method for creating temporal units in sliced representation of a moving object. It consists of two extensions that would enable more precise results of certain operations over moving objects (such as *speed* and *mdirection*) and an optimization of memory usage during processing spatio-temporal continuous queries. First extension implies detecting locations on moving object's trajectory when it actually doesn't move (such as stations, semaphores, etc.). Second extension introduces trajectory buffer with required accuracy which at the end leads to reducing number of temporal units in sliced representation of a moving object.

II. RELATED WORK

The upgrade of DBMSs with the ability to manage moving objects, but also data streams and their DSMSs, are of great interest for scientific-research community in last two decades. However, researches done within these two areas were usually conducted separately, especially in their initial phase, and only recently they are trying to combine.

In [3] authors consider moving objects databases from the location based perspective and introduce model of trajectory of a moving object as a polyline in three-dimensional space, where two dimensions refer to space and third dimension to time. This model takes into account the temporal and regional uncertainty of moving objects by associating uncertainty threshold with each line segment of the trajectory. They also consider querying moving objects with uncertainty given by their trajectories and introduce the set of most essential operators for doing this.

Model of a trajectory presented in [4] captures the inherent parameter of uncertainty of the moving objects location, which impacts both the semantics of spatio-temporal queries and the algorithms for their processing. The operators which capture the spatial, temporal and uncertainty aspects of a moving object are implemented as UDAFs on top of existing object-relational DBMS and can be used for answering queries and generating notification triggers. Proposed model is implemented in DOMINO project.

Inherent imprecision of the information about moving objects location at a given time in moving objects databases is also addressed in [5]. This work deals with the issues of constructing, representing and querying the trajectories of moving objects. Uncertain trajectory is modelled as 3D cylindrical body and set of novel but natural spatio-temporal operators which capture the uncertainty is presented.

The geometry of the uncertain trajectories of the objects with movement constrained to networks and the interaction between such objects in terms of operations is presented in [6]. It is based on the framework in [7] which is extended with data types and operations supporting uncertainty.

Work presented in [8] introduces a flexible trajectory modelling approach that takes into account model-inferred actual positions, time-varying uncertainty, and nondeterministic uncertainty ranges. It also presents an efficient mechanism to evaluate probabilistic range queries on those evolving-density trajectories, as well as estimators that effectively infer evolving densities of trajectory data.

Method for trajectory segmentation and sampling based on the representativeness of the (sub)trajectories in the moving objects databases is presented in [9]. Most representative subtrajectories are find based on local density and trajectory similarity information of each segment of the trajectory.

Work presented in [10] introduces term trajectory stream for point objects and several new types of window operators that would enable more efficient management of those trajectories. As a result, TSV (Trajectory Stream Visualizer) based on TelegraphCQ and Java that enables posing and visualization of queries on moving objects trajectories is created. However, it has significant limitations in terms of supporting spatio-temporal data, since it only uses built in spatial data types and operations inherited from TelegraphCQ.

Our approach for generating spatio-temporal streaming trajectories is similar to one presented in [3], [4] and [5] in sense of inherited uncertainty but is based on actual location of moving object contained in data stream element rather than expected one calculated using motion vector. We should also keep in mind that our approach extracts moving object out of data stream using UDAF in terms of spatio-temporal data type, and that *trajectory* is one of supported operations over this data type that yields trajectory made by moving point as a line in 2D space. For this reason, our model of trajectory for point objects is closed to one presented in [10] but overcomes limitations of supporting spatio-temporal data with supporting data type system presented in [1].

III. MODELING MOVING OBJECTS IN DATA STREAM SYSTEMS

In next section we will introduce extensions of an abstract algorithm for iterative function used in UDAF for extracting moving objects out of data stream. These extensions use spatio-temporal data types for representing moving objects presented in our approach for modelling moving objects in data stream systems [1]. It is based on a system of data types on abstract level supporting historical and current queries, defined using many-sorted algebra and second-order signature, and build upon work presented in [11][12] and [13].

Modelling on abstract level allows us to make definitions in terms of infinite sets, without fixing any finite representations of these sets. Although the abstract level is the conceptual model we are interested in, it should be noted that it is not directly implementable and that additional step of fixing a concrete, finite representation is needed. To ensure support for spatio-temporal data in DSMS, in [1] we have defined abstract data types by extending abstract data type system introduced in [12], [13] and [3].

New sorts representing attribute in a relation or data stream that represent a basis for building spatio-temporal DBMS in extensible DBMS environment, such as SECONDO [14], with the goal to support modelling and querying history of movement, are presented. We have also approached modelling data streams by adding new sorts and type constructors with two significant differences compared to the corresponding sorts and type constructors for modelling relations:

- Relation tuple may contain data of temporal types, while for data stream tuple that is not the case. We consider that data stream tuple may contain data about current location or extent of moving object, but not the moving object entirely.

- Each data stream tuple must implicitly contain timestamp that represents time when it is generated at data source.

Based on two approaches for modelling moving objects, the one presented in [1] and the one presented in [3], it is obvious that in the context of spatio-temporal data streams data types obtained by using type constructors *moving* and *streaming* try to model similar phenomena from the real world, and that is unit of data that changes over time. However, there are important differences:

- Data types obtained with type constructor *moving* do not change without explicit intervention of user, while data types obtained with type constructor *streaming* change under the influence of external data source.
- Implementation of data types obtained with type constructor *moving* can be done in different ways, and sliced representation with different ways of interpolation between slices. On the other hand, data types obtained with type constructor *streaming* have discrete sliced representation, in which one value holds until next one arrives.

Since both sets of data types are related to the same moving objects from a real world, the most of operations that are defined for data types obtained with type constructor *moving* can also be applied to data types obtained with type constructor *streaming*. This is also introduced in our previous work [1].

IV. IMPROVING UDAF FOR EXTRACTING MOVING OBJECTS OUT OF DATA STREAMS

Spatio-temporal data stream encapsulate information about successive locations of moving objects that represent their sources, i.e. information on how these objects move around in space. A main task in extracting this information is that every single moving object that sends data into spatio-temporal data streams is presented in a form of sliced representation based on the spatio-temporal references of data stream elements (*intime*(*point*) type). If we consider spatio-temporal references of two successive data stream elements generated at same data source, it is easy to calculate a linear function that describes movement of a corresponding source between two points presented with spatial stamps during time interval presented with timestamps of data stream elements. If $p_1(x_{p1}, y_{p1})$ denotes spatial stamp of first data stream element and t_1 its timestamp, and $p_2(x_{p2}, y_{p2})$ denotes spatial stamp of second data stream element and t_2 its timestamp, linear movement of a point moving object along x and y axes can be presented with following equations:

$$\begin{aligned} x_0 &= (-t_1)(x_{p2} - x_{p1})/(t_2 - t_1) + x_{p1} . \\ x_1 &= (x_{p2} - x_{p1})/(t_2 - t_1) . \\ y_0 &= (-t_1)(y_{p2} - y_{p1})/(t_2 - t_1) + y_{p1} . \\ y_1 &= (y_{p2} - y_{p1})/(t_2 - t_1) . \end{aligned} \quad (1)$$

The coefficients x_0, x_1, y_0 and y_1 represent the value *MPoint* which describes the movement of a point 2D object as a linear function of time, i.e. its meaning is [3]:

$$f((x_0, x_1, y_0, y_1), t) = (x_0 + x_1 t, y_0 + y_1 t) . \quad (2)$$

To define the unit of sliced representation (*unit*(*point*) type), it is necessary to assign a time interval with a function presented with *MPoint* during which it holds. This time interval is defined with timestamps t_1 and t_2 of two data stream elements used for unit creation. To create moving object in a form of sliced representation (*moving*(*point*) type) it is necessary to assemble units obtained with procedure described above. And as we have already mentioned previously, assembling unit types into a moving object based on the spatio-temporal references of data stream elements can be achieved using UDAFs, as we presented in our previous research [1][2]. This method of adding new unit to the moving object can be represented by an abstract algorithm we introduced in [15]. In this algorithm we use *mpoint, upoint,* and *ipoint* to denote data types *moving*(*point*), *unit*(*point*) and *intime*(*point*), respectively.

A function that is used in iterative operation in UDAF implements presented abstract algorithm and is called once for each value aggregated, i.e. for each spatio-temporal reference of new data stream element generated at the same source.

A. Detecting static locations on moving object's trajectory

Static locations on a trajectory of moving object are the places where moving object stops for one short period of time. For vehicles moving on the road network these locations can be traffic lights or traffic congestions, for the buses are bus stations, and for taxis are places for entry and exit of passengers, etc. During these short stops, moving objects that represent data sources continue to send information into data stream, even though they represent the same spatial data. This means that a number of successive data stream elements have identical spatial references.

If we consider creating a new unit of sliced representation when such spatial stamp is arriving, this would mean that the linear function that describes the movement of a moving object during last unit will be the same, only the time interval of that unit during which the function is valid will be changed. However, this approach of defining units of a moving object would lead us to have incorrect results when applying specific operations on a moving object. For example, the *speed* operation would result with a lower value than the actual speed of a moving object during one unit, and the *mdirection* operation would result with a certain direction even though the moving object is not moving.

In order to avoid the occurrence of such incorrect results, static locations of a moving object need to be represented as separate units in a sliced representation. Creation of such unit begins when the spatial reference of a new arriving data stream element coincides with the moving object's location on the right end of the last unit's time interval. When data stream element whose spatial reference is different from static location presented in the last unit of sliced representation arrives, creation of that

unit ends and creation of a new unit of sliced representation begins.

These changes should be considered when creating linear function for new unit of a moving object presented with equations (2). Abstract algorithm for function performing creation of linear function is given in Fig. 1. Function call should be embedded into abstract algorithm for iterative function used in UDAF for extracting moving objects out of data stream in a fallowing way:

- If function call returns *null*, there is no need for creating new unit of sliced representation, since right end of time interval in last unit is set to time reference of new arriving data stream element (line 6 in abstract algorithm).
- Otherwise, new unit of sliced representation is created with linear function set to returned value of function call.

In [1] we have presented a subset of operations defined specifically for moving data types that are appropriate for streaming data types. With presented approach and changes made in UDAF for extracting moving objects out of data stream it is possible to extend this set of operations over moving objects. Here we introduce two new functions with signatures:

locations: *streaming*(*point*) → *points*

stoptime: *streaming*(*point*) → *int*

Function *locations* applied over type *streaming*(*point*) returns a set of points in which each element presents one static location on a trajectory of a moving object. This function simply scans sliced representation of a moving object and for each slice with $x_1 = 0$ and $y_1 = 0$ adds new point into resulting point set. Function *stoptime* returns a overall stoppage time of a moving object on its trajectory expressed in seconds. It simply summarizes time intervals of all slices (units) with $x_1 = 0$ and $y_1 = 0$.

B. Trajectory buffer

Total number of units in a sliced representation of a moving object can be reduced depending on the accuracy requested for representing moving objects. As we can see from a method for crating moving objects in form of sliced representation and method for detecting static locations of a moving object presented previously, the new unit of sliced representation of a moving object is not created with the arrival of each new data stream element. If the spatial reference of data stream element is lying in the same direction as the direction of trajectory segment obtained with projection of the last unit on the x-y plane, we just need to change the right end of the last unit's time interval. The same approach applies if data stream elements with the same spatial references are arriving.

If data stream elements arrive with high frequency, it often happens in practice that the spatial reference of new data stream element deviates very little from the direction of trajectory segment previously mentioned. Depending on the permitted deviation from the actual trajectory of a moving object, and on the required accuracy for presenting moving objects, we can introduce a *threshold* which represents the distance from the trajectory and which when exceeded implies a creation of a new unit of sliced representation. As long as the deviation is less than this threshold, already introduced approach of changing the right end of last unit's time interval applies.

In this way, we introduce the concept of *trajectory buffer*, which presents a wrapper around the trajectory of a moving object inside which moving object can be found in practice. Radius of a trajectory buffer around each trajectory segment has value of a requested accuracy threshold. This approach is illustrated on Fig. 2.

Since the most of aggregate functions in DSMSs does not support two parameters, the accuracy threshold should be defined in another way. As it now presents a feature of created moving object, the best way is to store that value into moving object itself. In this way, when using operations on moving objects you can also get information about result deviation from the actual value. Proposed method for creation a unit of sliced representation can also be embedded into abstract algorithm for iterative function used in UDAF, in a way to call function that implements abstract algorithm given in Fig. 3. If this function returns *true*, right end of time interval in last unit is set to time reference of new arriving data stream element. Otherwise, new unit of sliced representation is created.

We should keep in mind that the actual movement of a moving object is already approximated by a linear function between two spatio-temporal references of data stream, and that this approach represents an additional approximation of the movement. This concept is similar to the concept of uncertainty of moving object's trajectory presented in various works. Since it is related directly to

```
algorithm newMpoint(mp,ip)
input: moving object of type mpoint, new arriving spatio-temporal reference of type ipoint
output: linear function Mp of type MPoint for new unit of moving object
1: Mp = ∅
2: n := no_units(mp)
3: ip1 := atinstant(mp, mp.un.p.end)
4: if val(ip) = val(ip1) then
5:         if mp.upn.Mp.x1 = 0 and mp.upn.Mp.y1 = 0 then
6:                 mp.un.p.end := inst(ip)
7:         else
8:                 Mp := val(ip)
9:                 p.s := p.e := inst(ip)
10:                p.lc := true, p.rc := true
11:        end if
12: else
13:        compute linear function Mp between spatio-temporal references ip1 and ip by
           using equations (1)
14: end if
15: return Mp
end
```

6: **if** $up.Mp = mp.u_n.Mp$ **or** $d < mp.th$ **then**
7: **return** *true*
8: **else**
9: **return** *false*
10: **end if**
end

Figure 3. Abstract algorithm for testing whether new spatial stamp is lying within permitted accuracy threshold

moving objects presented in a form of sliced representation it implies not only to operation *trajectory*, but also to other operations on moving objects. Defining new set of operations on moving objects that take into account this uncertainty is beyond scope of this work and one should use standard set of operations on moving objects but also be aware of this inherited uncertainty.

For this reason, it is necessary to determine very carefully the applications in which this approximation is allowed and appropriate, and also when it certainly should not be used. For example, it would not be appropriate for the movement of vehicles on the road network, but perhaps with certain accuracy it would be appropriate for the movement of ships at sea.

C. *Query examples and experimental results*

As we have already introduced in previous section, proposed method for detecting static locations enables introduction of two new functions: *locations* and *stoptime*. These two functions has been embedded into CSQL, an SQL-like query language that supports continuous queries over spatio-temporal data streams. Beside set of queries presented in our previous works [1][2] and [15] now we can pose additional queries that illustrate proposed approach and usage of aforementioned functions.

Q1: *For each taxi find all places on its trajectory when it was not moving during last hour.*

```
SELECT id, locations(moving(geometry))
FROM carStream <PAST '1 hour'>
WHERE carType = 'taxi'
GROUP BY id
```

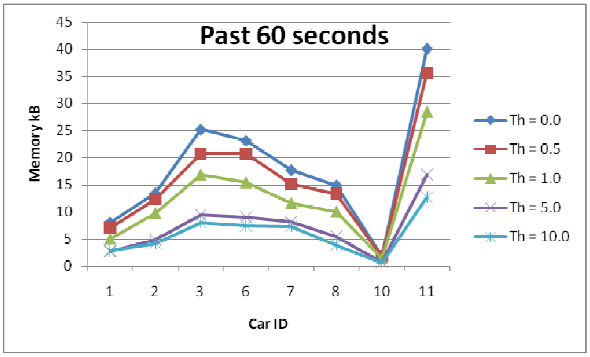

Figure 6. Memory usage in continuous query with past window of 60 seconds and different values of accuracy threshold

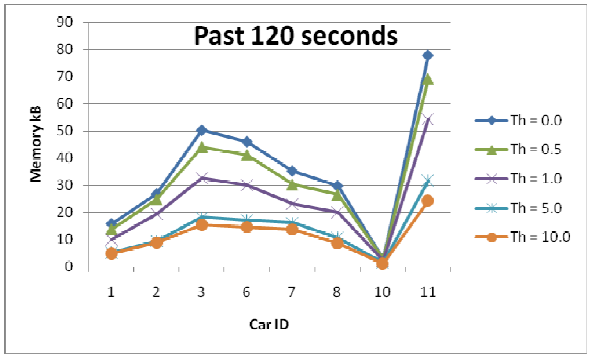

Figure 5. Memory usage in continuous query with past window of 120 seconds and different values of accuracy threshold

Q2: *Find each police car and its driver that didn't move for more than 10 minutes during last 90 minutes.*

```
SELECT id, driver
FROM carStream <PAST '90 minutes'>
WHERE carType = 'police'
GROUP BY id, driver
HAVING stoptime(moving(geometry)) > 600
```

Q3: *Find each bus and its driver that was staying at a particular location sometimes during last half an hour.*

```
SELECT id, driver
FROM carStream <PAST '30 minutes>
WHERE carType = 'bus'
GROUP BY id, driver
HAVING
ST_Contains(locations(moving(geometry)),
ST_GeomFromText('POINT(557234      322701)',
25832))
```

None of these queries were possible with existing set of functions supported in OCEANUS prototype. For example, it was possible to determine did some vehicle passed some location of interests (using function *passes*), but it wouldn't give as an answer whether it was staying at this location for one short period of time. These query examples illustrate improvements gained with proposed method for detecting static locations on moving object's trajectory.

Generating moving objects with trajectory buffer approach enables better memory usage during processing spatio-temporal continuous queries which can be illustrated through few simple experiments shown on Fig. 4 and Fig. 5. Both figures illustrate memory usage in continuous query with two different size of window *past* and accuracy threshold in range of 0.5 to 10 meters. Fragment of INFATI data set [16] consisting of around 4500 tuples was used in both experiments.

As one can see from both figures, memory saving is significant as the threshold value is higher, even for this relatively small set of data stream elements. For example, for car with id=11 it ranges from 11% with threshold value of 0.5 meter to 68% with threshold value of 10 meters. This saving also increases with window size since number of units reduced in each sliding window is higher when window size is larger. This is also illustrated with Fig. 5 representing results of window size two time bigger than the one on Fig. 4. With these experiments, we have

shown that careful and appropriate choice of accuracy threshold in combination with windows size can lead to significant memory saving during processing spatio-temporal continuous queries on moving objects.

V. CONCLUSIONS AND FUTURE WORK

In our previous work we have introduced a formal framework for managing moving objects in data streams, consisting of data types and operations needed to support spatio-temporal data in data streams. Implementation approach is based on UDAF for extracting moving objects out of spatio-temporal data streams and in this work we propose two methods for its extension. With first method we are able to detect all static locations on moving object's trajectory and also to get more precise results when using certain functions on moving objects such as *speed* and *mdirection*. Detecting static locations also enables introduction of new functions, such as *locations* and *stoptime*, that enable posing quite a new range of continuous queries some of which were illustrated in last section. Second method enables better memory usage in a case when data arrives in system with high frequency and accuracy of moving object's trajectory is not a priority. We introduce two new terms, trajectory buffer and accuracy threshold, which leads into concept of uncertainty when applying functions such as *trajectory* on moving objects.

Focus of our future work will be on defining new set of operations on moving objects that would consider uncertainty inherited with proposed approach. This operations should produce results with information about probability that moving object has been in the given range. They should take into account the temporal uncertainty and the regional uncertainty of moving objects as it has been proposed in [3].

***Abstract*—Automated grading of multiple-choice exams is of great interest in university courses with a large number of students. We consider an existing system in which exams are automatically graded using simple answer sheets that are annotated by the student. A sheet consists of a series of circles representing possible answers. As annotation errors are possible, a student is permitted to alter the annotated answer by annotating the"error" circle and handwriting the letter of the correct answer next to the appropriate row. During the scanning process, if an annotated"error" circle is detected, the system raises an alarm and requires intervention from a human operator to determine which answer to consider valid. We propose rather simple and effecive computer vision algorithm which enables automated reading of a limited set of handwritten answers and minimizes the need for a human intervention in the scanning process. We test our algorithm on a large dataset of real scanned answer sheets, and report encouraging performance rates.**

I. Introduction

Automated grading of multiple choice exams is a necessity in modern university courses taken by a large number of students (e.g. a few hundreds). Although in recent years there has been a notable shift towards taking multiple choice exams on computers [1], [2], written exams are still inevitable when the number of students taking the exam surpasses the number of computers the university can provide at a given point in time. Manually grading hundreds of multiple choice exams is tedious work prone to errors, and a task more suitable for a machine than for a human. Using automated grading saves time, enables faster processing of exams and reduces the probability for grading errors. If exams are graded by a machine, the results of an exam can be known in as little as a few hours after the exam has finished, with very little human effort, hence offering a considerable benefit both for students and for course staff.

In this paper, we consider an existing system for automated exam grading [3], [4] currently in use at the Faculty of Electrical Engineering and Computing, University of Zagreb, Croatia. The system operates by scanning and recognizing answer sheets of a predefined format on which the desired answers are annotated by the student. Although offering a fair amount of automation, the system is not yet fully automated, as it requires operator input in cases when the student makes an annotation error, i.e. decides to change an already annotated answer. In these cases, the student is expected to annotate a special error column (or annotate more than one answer where only a single answer is expected) and handwrite the letter corresponding to the appropriate answer in a dedicated rectangle. When the system detects that more than one answer or the error column had been annotated, a prompt is raised to the human operator, who is required to read the handwritten letter and input it back into the system. Hence, a certain amount of supervision is required during the automated grading process. We address this problem by proposing a computer vision technique for handwritten letter recognition suitable for use in the context of automated exam grading. The recognition task is constrained, as a limited number of letters need to be supported, given that multiple choice exams rarely offer more than six choices. Still, the relative simplicity of the task balances itself with high performance requirements: the recognition should be as fast as possible and as reliable as possible, and generalize well over a large number of different handwritings. Errors are highly undesirable, so the recognition module should be able to assess its own certainty in the recognition result. For uncertain recognitions, human input should be requested.

II. Related work

Character recognition has been a subject of intensive research for a long period of time. While recognition of printed text is today mostly considered a solved problem, recognition of handwritten text remains a challenging task, primarily due to high variability in handwriting among different people. A large number of methods have been proposed for handwritten text recognition. These methods can generally be categorized either as online or offline. Online recognition involves the automatic and real-time conversion of a text as it is written on a special digitizing device, where a sensor tracks the movements of the pen and an algorithm processes this information, while offline methods start from a static image usually obtained by scanning a document. An overview focused on offline handwritten character recognition methods can be found in [5].

The task of character recognition generally involves the following processing steps [5], [6]:

(i) Preprocessing (for instance including size normalization, image binarization, etc.),
(ii) Feature extraction,
(iii) Classification.

It is presumed that an adequate method for character localization has been previously applied, in order to find parts of the image containing each of the characters.

The key step in the process is the selection of an appropriate feature extraction method (or representation), since features must at the same time be sufficiently discriminative among the

character classes, but also invariant to the expected variations inside the class. Furthermore, the size of feature vectors should be relatively small in order to reduce computational complexity and therefore the time needed to perform the classification. A variety of different feature representations have been proposed in the literature. A standard survey can be found in [7]. Commonly used feature representations can be classified in three broad classes [5], [7]:

(i) *Statistical representations*, that represent a character image by a statistical distibution of points. This class includes methods such as analyzing densities of points or other features in different regions of an image (zoning), projection histograms, counting the number of crossings of an image contour with line segments in specified directions, and distances of line segments from given boundaries.

(ii) *Structural representations*, based on geometrical and topological properties, such as aspect ratio, distances between characteristic points or strokes, cusps, openings in different directions, chain codes, graph and tree representations, etc. These kinds of features encode some knowledge of the structure of the character, i.e. what sort of components it is made of.

(iii) *Representations obtained by global transformations*, that describe an image by a linear combination of a series of simpler well-defined functions. The features are then formed by coefficients of a such linear combination. Fourier transforms, Gabor transforms, wavelets, moments, Karhunen-Loeve expansion, etc., can be counted in this category.

As already stated, using distances of the image elements from the predefined boundaries has been used and described in the literature. Kim et al. [8] used distances of image pixels from the minimum bounding box of a whole word, along a certain number of horizontal and vertical scan-lines, in combination with several other feature types combined in 120-dimensional feature vector, applied to much harder problem of recognition of a limited set of handwritten cursive words. By using a heterogeneous classifier consisting of two multi-layer perceptrons and a hidden Markov model, they achieved recognition rate of 92.7% for 32 classes of legal words. Similarly, Mohamed [9] represented cursive handwritten word images by computing the location and number of transitions from background to foreground pixels along vertical lines (image columns). Hidden Markov model was used for classification. The obtained recognition rate was 83.9% (for the first ranked class). Surinta et al. [10] use the distance values between the closest black pixels and predefined hotspots in four or eight different directions to represent characters. They report the recognition rate of 90.1%.

In this paper, we adhere to the general idea of using image distances, and propose an offline character recognition method particulary suitable for recognizing a limited set of characters in the context of automated grading. In contrast to previously described methods, our method is specifically optimized to the set of supported characters, i.e. it can be said that it incorporates a degree of prior knowledge. It is designed so as to maximize separability between supported character classes by measuring specific properties characteristic to individual classes (e.g. it assumes that the existence or absence of the middle dash is an important classification cue).

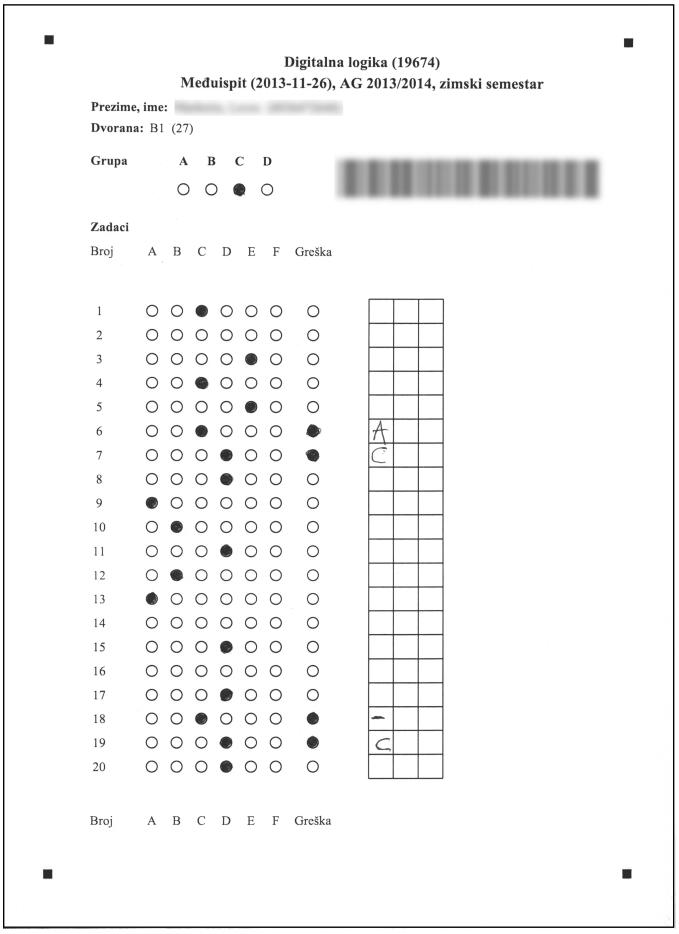

Fig. 1. An example of a standardized answer sheet.

III. THE EXISTING SYSTEM

The first step in developing any automated grading system is to introduce a standardized answer sheet that can be machine-processed. In this paper, we consider an automated grading system called *FreeFormReader*, currently in use at the Faculty of Electical Enginnering and Computing at University of Zagreb. An example of a standardized answer sheet that can be processed by the system is shown in Fig. 1. The answers are annotated by the student in an answer matrix that consists of an appropriate number of rows of empty circles. Each row corresponds to a single question, and each column to a single answer. To annotate an answer, the student darkens the appropriate circle. It is often the case that a student annotates an answer and later changes his mind. If that happens, the student is expected to annotate the "Error" cell ("Greska" in Croatian, as shown in Fig. 1) in the appropriate row or darken the correct answer in the same row, and write the letter corresponding to the final answer in the rectangle near the appropriate row, also illustrated in Fig. 1. When the system detects that the "Error" cell is marked, or that two or more answers are marked, an alarm is raised and a human operator must inspect and manually enter the correct answer.

Given that many exams at our university are graded in a way that wrong choices add negative points to the exam score

(usually -0.25 points), it sometimes happens that a student wishes to revoke his answer to a particular question, and leave the question unanswered. In that case, the same procedure is followed, except that instead of handwriting the letter of the appropriate answer, the student is expected to write the dash symbol ("-"). On the other hand, if the student is confident that for a certain question none of the offered answers are correct, or that there is more than one correct answer, the student is allowed to annotate the "Error" column in the corresponding row and write the letter X in the appropriate rectangle. This situation can occur when there has been a mistake in forming the exam. If an X is detected, the human operator should manually inspect the student's solution.

Currently, the system supports exams with up to 23 answer choices. However, the most frequent case are questions with four to six answers and for these cases we are trying to further automate the recognition process. Our practical experiences suggest that errors in annotation happen in about 20% of exams. The process of manually correcting annotation errors is tedious and it is easy to make a mistake, given the repetitive nature of the task.

IV. Representing and Classifying the Characters

In devising an appropriate representation and classification method for handwritten characters that could be used within our exisiting system, we adhere to the following requirements.

(i) The required computations for representation and classification should be very fast, so that current processing speed of the system is retained.
(ii) It can be assumed that the set of supported characters is limited to six answer letters (A, B, C, D, E, F) and two characters for revoking the answer and signaling a mistake in the question (dash and X).
(iii) The classification framework should be able to output confidence level. Predictions with low confidence level should be presented to the human operator.

In the following section we describe the method that we propose for the character recognition.

A. The edge distance representation

After scanning the document, an approximate location of the table containing the handwritten correction answers is manually annotated by the human operator. This has to be done only for the first exam sheet, since the approximate position of the table remains the same for all the other sheets. Then the precise location of the table and the locations of individual cells must be found. This can be done either by finding lines using Hough transform (and finding individual cells by finding their corners defined by intersections of found lines), or using a method described in [4], or any other. Currently, for experimentation purposes, we use (slow) Hough transform.

Once the individual cells have been found, a procedure for finding a minimal character bounding box is performed. Then the corresponding part of the image is further preprocessed by reducing its dimensions to 24×32 pixels, since we expect that in this resolution the distinguishing features of characters are still preserved. We then perform binarization by simple histogram-based adaptive thresholding. The result is a 24×32 binary image in which the character extends from top to bottom and from left to right margin of the image. The size normalization is essential, since the proposed features will only have low variability in case of size normalized images, thus lending themselves to character recognition.

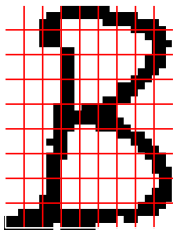

Fig. 2. The grid of $M \times N$ horizontal and vertical scan-lines

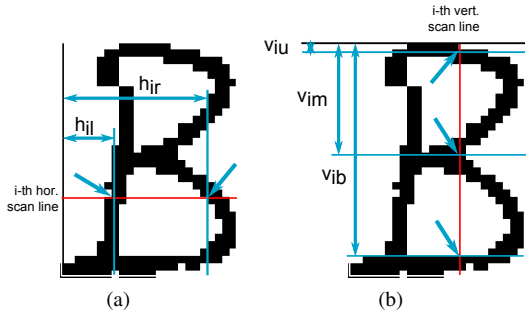

Fig. 3. The definition of features: (a) horizontal features; (b) vertical features

To facilitate the recognition, we propose a simple but effective feature extraction method resulting in an *edge distance* representation of characters (Figs. 2 and 3). In the image, M horizontal and N vertical equidistant scan-lines are defined (in our experiments, $M = N = 8$), as shown in Fig. 2. On each horizontal scan-line i, two features are defined (Fig. 3(a)): the relative distance of the leftmost black image pixel on that line from the left margin of the image (h_{il}) and the relative distance of the righmost black image pixel on the same line again from the left image margin (h_{ir}). On each vertical scan-line, however, three features are defined (Fig. 3(b)): the relative distance of the uppermost black pixel on the $i-th$ vertical scan-line from the upper image border (v_{iu}), the relative distance of the bottom-most black pixel on the same line from the top of the image (v_{ib}), and finally, the third feature (v_{im}) intended to reflect the position of the "middle stroke" that exists in some letters (such as B and E), i.e. the relative distance of the pixels of this "middle stroke" crossing the $i-th$ vertical line from the top of the image, if the "middle stroke" exists. More precisely, v_{im} is defined as the relative distance from the top of the image to the black pixel below the uppermost pixel that is at the same time disconnected both from the uppermost and from the bottommost pixels and is closest to the center of the letter. If it does not exist, i.e. if there are no pixels on the $i-th$ vertical scan-line disconnected from uppermost and bottommost black pixels, the feature v_{im} is set to 0. The described representation results in a feature vector of dimension $2M+3N$ (in our case the dimension was $2 \times 8 + 3 \times 8 = 40$).

Intuitively, the features defined in the described way should be sufficiently discriminative for characters belonging to dis-

tinct classes, while maintaining a relatively low variability inside a class, regardless of different handwriting styles. We emphasize here that our goal is not to define rotation invariant features, since we do not expect hanadwritten characters to have any larger degree of rotation. The features (h_{il}), (h_{il}), (v_{iu}) and (v_{ib}) describe in a rough way the outer shape of the letter, while (v_{im}) enables easier distinguishing between letters that could have similar outer shape in some handwritings (i.e. C and E; B and D).

B. Selecting the classifier

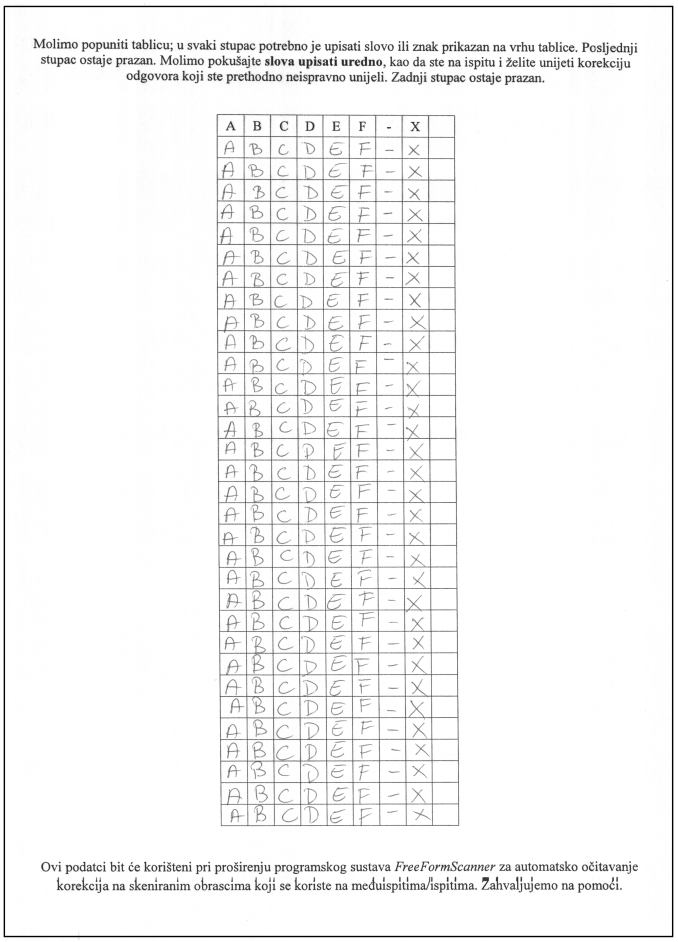
Given the desired performance requirements, we opted to use the random forest classifier proposed by Breiman [11]. The random forest classifier is reasonably fast to train, the classification results are fast to compute, and it offers performance comparable [12] to other popular classifiers such as support vector machines [13]. The main idea of the random forest approach is combining randomized decision trees into ensembles. When building a decision tree within a random forest, for each split at inner tree nodes, the algorithm randomly selects a subset of m attributes and then performs the split by the best attribute from the selected subset, based on the Gini impurity index. In contrast to SVM, which is posed as a binary classification algorithm, random forests inherently support multiple classes. Given a sample, each of the trees of the classifier casts a vote for one of the classes, and the final class of the sample is determined by the majority of votes. Tunable parameters of the random forest algorithm are the number of trees, the number of top candidates to consider (m), and the allowed depth of individual decision tree.

V. Experiments

For experimental validation of the proposed procedure, we collected two datasets. The training dataset contains handwriting samples from 289 individuals, and the test-dataset contains samples from 15 individuals. Each individual was asked to write all the considered characters (A, B, C, D, E, F, X, -) 32 times, using a specialized sheet as illustrated in Fig. 4. Hence, for each individual we collected a total of 264 samples plus the eight printed samples from the table header, resulting in the training dataset size of 76296 samples and the test set size of 3960 samples. There is no mixing of samples from the training and the test set, i.e. individuals contributing to the training set were not a part of the second group that contributed to the test set. Multiple samples per person were collected with the goal of improved learning, given the inevitable variations that occur within different instances of the same handwriting.

The edge distance representation was implemented in Java in a straightforward way, according to the described algorithm. For each scanned image, the table containing the handwritten letters was located using Hough transform; then the cells were located using intersections of appropriate border lines. The procedure for the minimum letter bounding box described in [4] was then applied, and the character image was extracted and further binarized. On the binarized image, the edge distance features were extracted.

For testing classification performance of the random forest classifier, we used the open source data mining tool Weka [14]. Weka offers a graphical user interface for experimenting



Molimo popuniti tablicu; u svaki stupac potrebno je upisati slovo ili znak prikazan na vrhu tablice. Posljednji stupac ostaje prazan. Molimo pokušajte **slova upisati uredno**, kao da ste na ispitu i želite unijeti korekciju odgovora koji ste prethodno neispravno unijeli. Zadnji stupac ostaje prazan.

A	B	C	D	E	F	-	X	

Ovi podatci bit će korišteni pri proširenju programskog sustava *FreeFormScanner* za automatsko očitavanje korekcija na skeniranim obrascima koji se koriste na međuispitima/ispitima. Zahvaljujemo na pomoći.

Fig. 4. An example of an annotation sheet used to collect handwritten character samples.

with various classifiers, but it is also available as a standalone Java library. Given that the existing automated grading system is written in Java, we expect that using Weka will ensure a seamless integration of the final classifier with the existing code.

A. Classification results

We experimented with several parameter settings, and found that the best performance is obtained by using a forest of 100 trees, considering $m = 6$ random attributes in each split, and not limiting the tree depth. Using this setup, the random forest classifier was able to correctly classify 96.5% of samples from the test set (3821 of 3960). The confusion matrix is shown in Table I. It can be seen that, as expected, most confusion occurs between visually similar letters. For example, 20 instances of the letter E were classified as C, although only four C's were classified as E's. It seems more common for the letter E to lack a middle dash, making it similar to C, than for the letter C to contain an additional dash that would make it similar to E. Other notable confusions include 18 instances of the letter B being classified as E, 16 instances of the letter E being classified as B, etc.

In order to better illustrate the amount of confusion among different classes, a visualization of the confusion matrix is

TABLE I. THE CONFUSION TABLE FOR THE TESTING SET. ROWS CORRESPOND TO CORRECT LABELS, AND COLUMNS TO THE NUMBER OF CLASSIFICATIONS AS A GIVEN SYMBOL OUTPUT BY THE RANDOM FOREST.

	A	B	C	D	E	F	-	X
A	483	2	1	5	0	1	3	0
B	5	454	0	14	18	3	0	1

D	1	9	3	479	1	0	2	0
E	1	16	20	0	454	3	0	1
F	2	2	0	0	2	489	0	0
-	0	0	0	0	0	1	493	1
X	11	0	1	0	0	0	1	482

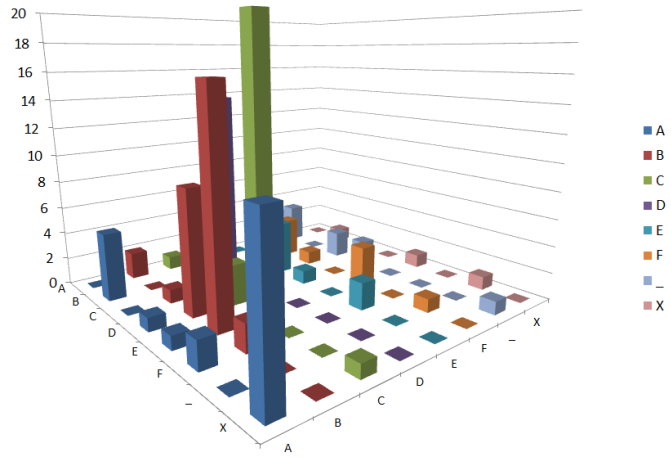

Fig. 5. Visualization of the confusion matrix without diagonal elements

(a) (b) (c) (d) (e) (f) (g)

Fig. 6. Examples of misclassifications. From left to right: A classified as B, B classified as D, C classified as E, D classified as B, E classified as B, F classified as E and X classified as A.

shown in Fig. 5. In order to emphasize misclassifications, we removed the bars corresponding to correctly classified examples so that only misclassifications are left. The height of each bar corresponds to the number of misclassified examples at the corresponding location of the confusion matrix.

A few misclassified samples from the test dataset are shown in Fig. 6. The correct labels from left to right are A, B, C, D, E, F, X. Note that most of these examples are hard to classify even for a human. For example, the examplified letter B reminds of a heart symbol and in a certain way to letter D, the letter E looks like a G, the letter F could easily be confused for an E, and the character X reminds of the Greek letter λ.

B. Varying the decision threshold

As discussed before, the proposed system should provide a confidence measure of the predicted label, so that labels with low confidence can be presented to the human operator. In order to find the optimal classification certainty threshold below which manual operator intervention will be required, we have considered two facts:

(i) The classifier will inevitably produce a certain number of misclassifications that will be misclassified with a certainty greater than the confidence threshold; these will initially pass undetected and will require later intervention based on student complaints.

(ii) There will be some correctly classified letters for which the system will ask the operator to manually confirm the classification, because the classification certainty will be smaller than the confidence threshold; this scenario costs operator time.

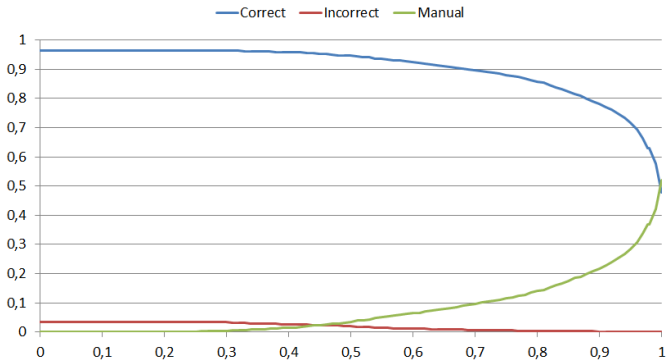

Fig. 7. The percentage of correct classifications, misclassifications and uncertain classifications requiring manual input, depending on confidence-level threshold (for the first method; for the second method the diagram is similar). X-axis corresponds to confidence-level thresholds, while y-axis represents the percentage of correct, incorrect and uncertain classifications.

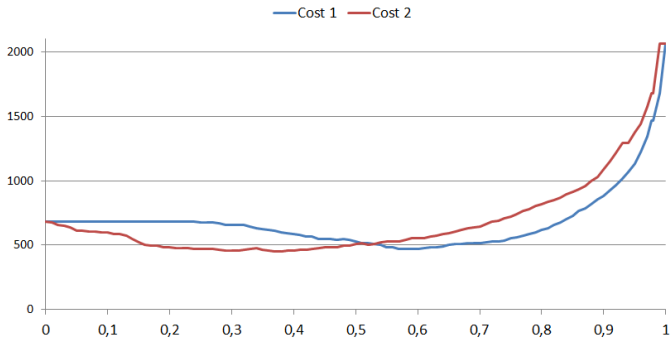

Fig. 8. Performance of penalty function. X-axis corresponds to confidence-level thresholds, while y-axis represents values of penalty functions for the two proposed approaches (less is better). *Cost 1* corresponds to method (i) and *Cost 2* to method (ii).

To tackle these two situations, we observe that it takes more time for course staff to manually inspect and correct missclasifications upon receiving a complaint by a student than at the time of sheet proccesing. Therefore, we define the following cost function: for each classification with insufficient confidence level we add a penalty of 1 point; for each undetected misclassification (misclassification with a confidence level greater than the threshold) we add a penalty of 5 points. Given this penalty function, we define two approaches to solving the problem of selecting the optimal threshold.

(i) In this approach we require that the absolute value of confidence for the predicted character class must be greater than θ. We evaluated the clasification performance for each distinct θ in $[0, 1]$ which occured as confidence of prediction for any character. With the change of threshold, the number of correct classifications, misclas-

sifications and uncertain classifications changes, and is illustrated in Fig. 7. The performance of penalty function is presented in Fig. 8. As can be seen, for this case the optimal certainty-level threshold is 0.59 at which we have 92.8% correct classifications, 1.2% misclassifications and 6.1% manual interventions.

(ii) In this approach we require that the relative value of confidence for the predicted character class must be greater than θ. This means that the difference between the probability of the most probable class and the second most probable class must be greater than θ. We evaluated the clasification for each distinct θ in $[0, 1]$ which occured as confidence of prediction for any character. With the change of threshold, the number of correct classifications, misclassifications and uncertain classifications changes, and is similar to the one illustrated in Fig. 7. The performance of the penalty function is presented in Fig. 8. As can be seen, for this case the optimal certainty-level threshold is 0.37 at which we have 92.6% correct classifications, 1.0% misclassifications and 6.4% manual interventions.

VI. Conclusion and outlook

We have presented a technique based on edge distances and random forest classifier that can be used to improve an existing automated grading system by machine-based recognition of handwritten characters. In the existing setup, these characters represent answer alterations in case a student annotates an answer in a predefined answer matrix and then changes his mind. Extensive experiments were performed on a large dataset containing samples of eight supported characters. Experiments indicate that by introducing the proposed technique into the existing automated grading system, more than 92% of such answers could be machine-read, hence saving valuable operator time and further improving the automated grading process.

Abstract - The paper proposed the method for the language identification according to texture analysis. First, the algorithm encrypted the text given in different languages to the cipher based on the baseline status of each script element in text. Then, the cipher was subjected to the texture analysis. The aim of this analysis was the extraction of texture features. Obtained texture features showed significant diversity between languages. Hence, they were suitable for creating the discrimination and identification criteria between languages. The proposed method was tested on Serbian and Slovenian documents from custom oriented database. The experiments gave encouraging results.

I. INTRODUCTION

Language identification is defined as a task of determining the language in a certain document. It represents a preprocessing step, which is commonly included in the optical character recognition (OCR) systems, information retrieval systems (IRS) or web page encoding [1]. That's why, it used to be an initial step in a text processing system [2].

Language identification has become more and more important, as more and more textual data are present on the Internet. In recent years, the number of web pages and languages has increased tremendously. Currently, the number of languages which has been implemented in Google is around 150 [3].

Many studies of language identification on written text have been reported in the past [4-11]. They achieved a good accuracy. Consequently, a comparative survey of language identification methods for written text was reported in [12]. However, text from the Web is considerably different [13]. The difficulties presented by the Web domain are generally related to the noisier nature of the text, including things like spelling errors, small amounts of text or multilingual documents.

Two major stages in language recognition systems can be identified [14]: (i) the language modeling stage, where the distinctive features of languages are determined and stored in models, and (ii) the classification stage, in which the model of the (partial) input document is compared to the reference language models.

This work was partially supported by the Grant of the Ministry of Science from Republic of Serbia, as a part of the project TR33037 and III43011 within the framework of Technological development program.

The language model most similar to the input document represents the language of the document. As a basis for document modeling, we employ cryptography [15]. Cryptography converts data from a readable to an unreadable state. Readable data is called a plain text, while unreadable data represent a cipher [16]. This process is realized with a cryptographic algorithm. It is used to encrypt and/or decrypt data. Although there exist three different types of cryptographic algorithms, we used a hash algorithm (HF) which performs a one-way encryption. It means that once the data has been encrypted, there is no path to retrieve the original data [17]. However, the decryption process is an unessential for further texture processing.

The modeling is based on the baseline characteristics of each letter. This way, we perform the task of grouping a set of objects in such a way that objects in the same group are more similar to each other than to those in other groups. Due to clustering the number of the active variables has been reduced. Then, the obtained model is replaced with the cipher [15]. Cipher is used as appropriate criteria for further texture analysis. From the above, it is clear the such a model greatly reduces the computation costs. Furthermore, the cipher text is subjected to the feature extraction. The gray level co-occurrence matrix (GLCM) is used as a basis for feature extraction [18-19]. Then, the obtained texture features are classified. According to these results, it is possible to make a strong margin in some feature characteristics, which can be used as criteria for characterization of the certain language as well as for distinction and dissemination between languages.

The rest of the paper is organized as follows. Section 2 describes the proposed algorithm, which is based on the extraction of texture features from the cipher text. Section 3 describes the elements of the experiment. Section 4 shows the results of the experiment. Furthermore, it discusses the obtained results and establishes the decision-making criteria for the language discrimination in web pages. Section 5 gives the conclusion with the future research plans.

II. PROPOSED ALGORITHM

The algorithm consists of the following stages:

- Cipher modeling,

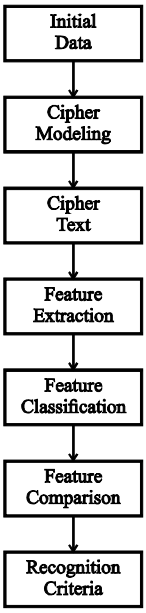

Figure 1. The flow of the proposed algorithm

- Feature extraction,
- Feature classification,
- Feature comparison, and
- Recognition criteria.

Figure 1 shows the flow of the proposed algorithm.

A. *Cipher Modeling*

Cipher modeling converted different scripts by HF according to the text-line structure definition. It is based on the assumption that each text-line in printed documents contains following three vertical zones [20]: (i) the upper zone, (ii) the middle zone, and (iii) the lower zone.

All letters, diacritics, ligatures or signs represent the constituents of any script. They are classified according to the zones herein. Figure 2 (a) shows the script characteristics in accordance to vertical zones. The base letter **a**, which occupies the middle zone, is mapped to B. The ascender letter **b** occupies both the upper and middle zones. It is mapped to A. The descender letter **p** occupies the lower and middle zones. It is mapped to D. Finally, the full letter **Lj** enlarges among the upper, middle and lower zones. It is mapped to F. Hence, the model is based on the following elements {B,A,D,F}. For further texture analysis, above set is encrypted to cipher set {0,1,2,3}, respectively. It is shown in Figure 2 (b).

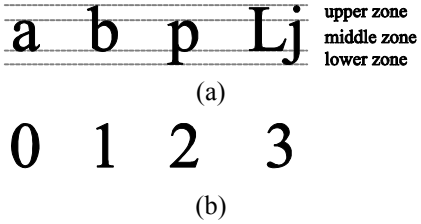

Figure 2. Illustration of the cipher modeling

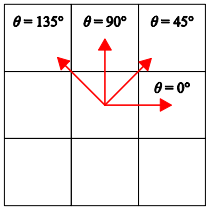

Figure 3. Illustration of the window of interest (the four directions of adjacency for calculating the Haralick texture features with $d = 1$).

B. *Feature extraction*

In our approach, the features extraction is established with texture analysis of the cipher text. Due to text characteristics the cipher text represents 1-D image given with vector **A** featuring M rows (in this special case $M = 1$) and N columns. Furthermore, the number of gray levels G is determined by the number of the levels in cipher text, which is set to 4 (using into account the elements from the set {0, 1, 2, 3}).

The method begins at the top left corner of the image **A** and counts the occurrences of each reference pixel in reference to neighbor pixel relationship, i.e. in the window of the interest (WOI). Each element (i, j) of GLCM represents the sum of the times the pixel with the value i was located at some distance d and angle θ from the pixel of intensity j. Accordingly, the element (i, j) gives the number how many times the gray levels i and j appears as a sequence of two neighbor pixels located at a defined distance d along a chosen direction θ. Figure 3 illustrated the WOI.

The GLCM for an image $A(x, y)$ featuring M rows and N columns is parameterized by the offset $(\Delta x, \Delta y)$. It is:

$$C(i,j) = \sum_{x=1}^{M}\sum_{y=1}^{N}\begin{cases}1, & \text{if } A(x,y) = i \wedge A(x+\Delta x, y+\Delta y)\\ 0, & \text{otherwise}\end{cases} \quad (1)$$

The offset $(\Delta x, \Delta y)$ represents the pixel displacement d and the orientation θ for which the co-occurrence matrix is calculated. Consequently, the feasible values of the parameters d and θ are narrowed to 1 and θ (for the 1-D image), respectively. The probability version of GLCM is:

$$P(i,j) = \frac{C(i,j)}{\sum_{i=1}^{M}\sum_{j=1}^{N} C(i,j)}. \quad (2)$$

Figure 4 shows the values of probability GLCM **P** for the Serbian and Slovenian language.

0.4105	0.2057	0.0694	0.0033

0.0054	0	0.0009	0

(b)

Figure 4. The probability GLCM **P**: (a) for Serbian, (b) for Slovenian

C. Feature classification

The extracted fourteen texture features [18] can be used for the classification. In our case, the three features only can be used for dissemination between Serbian and Slovenian language. It is reasonable because both languages belong to the same group of South Slavic languages sharing similar characteristics like the corresponding dialect [21]. Hence, the Energy, Maximum (probability), and Entropy are the only features which can distinguish both languages.

Energy is a measure of textural uniformity of an image under consideration. It is defined as:

$$Energy = \sum_{i=1}^{M}\sum_{j=1}^{N} P^2(i,j). \quad (3)$$

Energy reaches its highest value when gray level distribution has either a constant or a periodic form. In contrast, if the image contains a large number of small entries, the energy will receive smaller value.

Maximum (probability) determines the most predominant pixel pair in the image. It is defined as:

$$Maximum = \max_{i,j} P(i,j). \quad (4)$$

Entropy is a feature which measures the randomness of gray level distribution of the image. It is defined as:

$$Entropy = \sum_{i=1}^{M}\sum_{j=1}^{N} P(i,j)\log P(i,j). \quad (5)$$

Entropy measures the disorder of an image. It achieves its smallest value when the image has mainly uniform level. However, when the image is not texturally uniform many GLCM elements have very small values, which imply that entropy is very large.

D. Feature comparison

All texture features (proposed in [18]) are unique for each language. To identify any of the languages, their comparison is mandatory. If two languages are compared, then the texture feature ratios is a solid way to start with. In our case, three texture feature ratios are of the interest:

- Energy ratio,
- Maximum ratio, and
- Entropy ratio.

E. Recognition criteria

To establish recognition criteria between two languages, the texture feature ratios are used to create a logical relation, which can be used for language distinction. This logical equation is the aim of the recognition process given by the proposed algorithm.

III. EXPERIMENTS

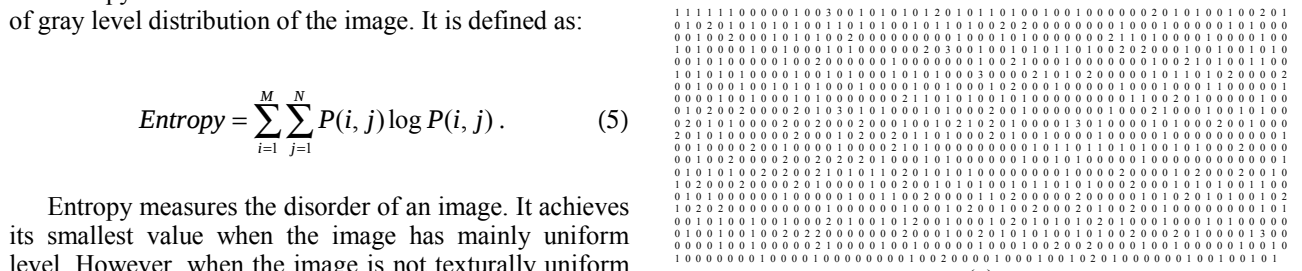
For the sake of the experiment, a custom-oriented database is created. It consists mainly of short texts which are extracted from different web sites. However, it includes few longer texts from PDF documents. The database includes 100 documents. This number of samples represents so-called "rule of 100", which can be used as rule of thumb in factor analysis [22].

The smallest document represents the text which length is roughly 500 characters only, while the longest one contains around 5000 characters. Figure 5 illustrates the initial data from document given in Serbian and Slovenian as well as the appropriate ciphers.

IV. RESULTS AND DISCUSSION

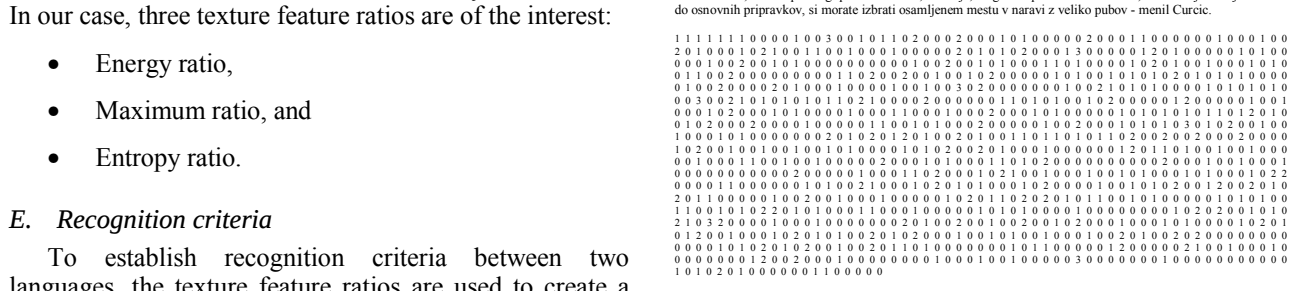
The obtained results can be divided into following categories: (i) texture features for Serbian text, (ii) texture features for Slovenian text, and (iii) texture features ratios between Serbian and Slovenian text.

LONDON, 30. novembar, (Njuz) – Nekadašnji fudbaler Partizana i pobednik rijalitija „Veliki brat“ Saša Ćurčić dobio je poziv menadžera Arsenala Arsena Vengera da do kraja sezone vodi omladince ovog kluba u nočne izlaske širom Londona.
Kako saznaje Njuz, bivši fudbaler je pristao da mlade nade Arsenala upozna sa čarima noćnog života, za mesečnu platu od 4.000 funti, koliko smatra da će mu biti dovoljno za plaćanje cena koktela, piva i garderobe u lokalima širom britanske prestonice.
Prvi čovek Arsenala smatra da omladinci ovog kluba treba da na vreme otkriju čari izlazaka, jer je mnogo bolje da kroz tu fazu prođu u ranom tinejdžerskom dobu, nego kada zaigraju za prvi tim Topdžija.
- Razmišljali smo ko bi mogao da im pokaže sve najznačajnije klubove po Londonu, a da im istovremeno za šankom ispriča i neku anegdotu vezanu za fudbal. Saša Ćurčić nam je svima bio prva opcija, pogotovu kada smo na Youtube na nekim snimcima videli kako sjajno pleše, što je takođe veoma važno za posao koji mu predstoji – izjavio je Arsen Venger.
Saša Ćurčić kaže da mu je velika čast da omladincima Arsenala otkrije ono što njemu nije imao ko da pokaže, zbog čega je morao sam da se snalazi.
- Najvažnije mi je da igrači na vreme dođu u dobru kondiciju. Poslednja stvar koju želite je da vaši omladinci već nakon drugog piva ne mogu više i požele da idu da spavaju. Razmišljao sam i da odemo negde van Londona na bazične pripreme, treba samo da odaberemo neko izolovano mesto u prirodi sa dosta pabova – smatra Ćurčić.



(a)

LONDON, 30. November (Njuz) - Nekdanji nogometaš in zmagovalka resničnostnega šova "Big Brother" Sasa Curcic je bila povabljena, vodja Arsenala Arsene Wenger do konca sezone traja mlade iz kluba v noči po Londonu.
Kako odkrije novice, nekdanji igralec dogovorili, da mladi hopefuls Arsenala spoznajo čarobno nočno življenje, za mesečno plačo 4.000 £, da misli, da bo dovolj za plačilo koktajli cen, pivo in oblačila v trgovinah po vsem britanski prestolnici.
Prvi človek verjame, da Arsenal mladi ta klub potrebuje za pravočasno odkrili čare gre ven, ker je veliko bolje, da gredo skozi to fazo, v svojih zgodnjih najstniških letih, ko pa igrajo za prvo ekipo strelec.
- Mislila sva, ki bi jim pokazati vse večje klube v Londonu, in da se hkrati v baru in povedal anekdoto, povezano z nogometom. Sasa Curcic vse nas prva možnost, še posebej, če ste na YouTubu videti nekaj posnetkov na velikem plesu, ki je tudi zelo pomembno delo pred njim - je dejal Arsene Wenger.
Sasa Curcic dejal, da je počaščen, da Arsenal mladi odkrili, kaj je bilo, nihče ne bi naredil vtis, zato sem moral spopasti.
- Najbolj pomembna stvar se mi je, da igralci pridejo na čas v dobrem stanju. Zadnja stvar, ki jo želim je, da je vaša mladost, vendar po drugi piva ne morem, in želijo, da gredo spat. Zato sem mislil, da se nekje zunaj Londona do osnovnih pripravkov, si morate izbrati osamljenem mestu v naravi z veliko pubov - menil Curcic.



(b)

Figure 5. Initial document from database and cipher text: (a) Serbian, (b) Slovenian

Table I shows the texture features obtained from the Serbian text.

TABLE I. TEXTURE FEATURES FOR SERBIAN TEXT

Serbian	*Energy*	*Entropy*	*Maxi*
Min	0.2444	-1.6801	0.3754
Max	0.2856	-1.5006	0.4441
Mean	0.2633	-1.5921	0.4156

From Table I the Serbian text is characterized with energy between 0.2444 and 0.2856, entropy between -1.6801 and -1.5006 and maximum between 0.3754 and 0.4441. Table II shows the texture features obtained from the Slovenian text.

TABLE II. TEXTURE FEATURES FOR SLOVENIAN TEXT

Slovenian	*Energy*	*Entropy*	*Maxi*
Min	0.2239	-1.7199	0.3341
Max	0.2755	-1.5701	0.4388
Mean	0.2422	-1.6556	0.3843

From Table II the Slovenian text is characterized with energy between 0.2239 and 0.2755, entropy between -1.7199 and -1.5701 and maximum between 0.3341 and 0.4388. Table III shows the texture feature ratios obtained from the Serbian/Slovenian texture feature ratios.

TABLE III. TEXTURE FEATURE RATIOS

Serbian/ Slovenian	*Energy Ratio*	*Entropy Ratio*	*Maxi Ratio*
Min	0.9781	0.9109	0.9699
Max	1.1821	0.9959	1.2501
Mean	1.0821	0.9566	1.0921
Criteria	> **1** (99%)	< **1** (100%)	> **1** (99%)

From Table III the comparison between Serbian and Slovenian text is characterized with energy ratio between 0.9781 and 1.1821, entropy ratio between 0.9109 and 0.9959 and maximum ratio between 0.9699 and 1.2501. Such close values are reasonable due to the language similarities [21]. However, the energy ratio > 1 as well as the maximum ratio > 1 are obtained in 99%. Furthermore, entropy ratio < 1 is obtained in all cases. Accordingly, this texture feature ratio can be used as a solid criteria in discrimination process between Serbian and Slovenian language. Hence, the logical equation that can be used for language recognition between Serbian and Slovenian language is given as `Energy ratio < 1`.

The proposed approach is characterized as computationally non-intensive. The algorithm is coded in Matlab without any programming parallelism. Testing shows that typical processing time is as low as 0.1 second per text including 2000 characters. Furthermore, the algorithm doesn't need any prior training like n-gram approach. At the end, it is suitable for short text samples of 300-400 characters.

V. CONCLUSIONS

The manuscript proposed a new approach to the language distinction between different languages. This approach establishes a model based on the baseline status of each letter in text. Then, it is encrypted making a cipher, which is subjected to the texture analysis. The analysis extracts the texture features of the cipher text. Obtained texture features showed significant diversity between languages. Accordingly, they are a starting point in the process of creating the language discrimination and identification criteria. The proposed method was tested on documents from custom oriented database. The algorithm achieved a good accuracy. At the end, it is manifested as computationally non-intensive algorithm.

Future research plans include the creating of database languages that can distinguish them mutually. Furthermore, the proposed algorithm will be accustomed to be used effectively in OCR.

***Abstract*—The efficiency of any character recognition technique is directly dependent on the accuracy of the generated feature set which could uniquely represent a character and hence correctly recognize it. This paper proposes a hybrid approach combining the structural features of the character and a mathematical model of curve fitting to simulate the best features of a character. As a preprocessing step the character is binarized and transformed to a thinned skeleton and the spurious edges are removed. Then, a combination of structural features of the character like number of end points, loops and intersection points are calculated. Further, the thinned character image is statistically zoned into partitions and quadratic curve fitting model is applied on each partition forming a feature vector of coefficients of the curve. This vector is combined with the spatial distribution of the foreground pixels for each zone and hence script independent feature representation. The approach has been evaluated experimentally on English and Hindi scripts. The algorithm achieves as average recognition accuracy of 89% for any script without incorporating any script specific features.**

I. Introduction

In the field of pattern recognition, character recognition is regarded as one of the most interesting and challenging steps for script processing. Handwritten character recognition (HCR), a tool to recognize and convert scanned text script images into digitized form broadly consists of 3 major stages, i.e. preprocessing, segmentation and recognition. HCR initializes with pre-processing that includes binarization, skew and slant normalization of text document. In further steps preprocessed text image is divided into lines, lines into words and finally each word is partitioned into individual character. In the simplest case this character is fed to the recognition algorithm, however to avoid complexity of the recognition system, a set of features is extracted for each character in order to reduce its dimensionality and this reduced representation of character is fed into the recognition phase to classify the character into its appropriate class. To make this feature set extraction task more effective and refined a new preprocessing step applied on individual character named thinning has been introduced in this paper. Since feature vector is the direct input to the recognition step, accuracy of the system depends on the effectiveness of the feature vector obtained. A number of approaches are introduced earlier to simulate the feature extraction like character moment based [1], direction based[2], neural network based[3] and transform based [4]. In most of the approaches either structural features are estimated or spacial and statistical features are calculated. In this paper we have proposed an approach based on both structure and spacial distribution. The paper comprises of the details of proposed approaches in Section II. Section III defines the neural network

classifier applied. Results and conclusions are appended in Section IV and V respectively.

II. Proposed Approach

A. THINNING- a step further in preprocessing, a refinement

Before applying any feature extraction mechanism, as a preprocessing step, thinning has been introduced. Thinning is an image processing operation that refines a binary valued character image by approximating the center skeleton of the character. This step reduces chaos in the structural elements of the character and retains their generality more effectively. It is usually required that the resulting image after thinning is connected so as to infer the shape and topology of the original image. The algorithm for thinning is summarized in Algorithm 1.

The algorithm for thinning has been tested on several Devanagari and English script characters with the results presented in Table I.

B. Structural Feature Set Extraction

Structural features are used to acquire the topological information of the characters, assuring minimal affect of shape/font/size variation on the feature set. The proposed technique captures the endpoint(EndPts), intersection point(IntersectPts) and presence of hole(HasLoop) in the character image as shown in Fig. 1(a)-(c). EndPts and IntersectPts are composed of the number of pixels with single and three or more neighborhood respectively. The HasLoop feature is true if the character contains one/more closed loop or hole is/are present in the character image. The procedure for computing Structural Features is Procedure 2.

C. Statistical Feature Set Extraction

To derive the enhanced features from the character image that can significantly capture the trend of foreground pixel distribution, as a statistical measure in a processed image, a

Algorithm 1: Algorithm for thinning character image.

Input: 2-Dimensional binary segmented character I.

Output: Thinned character image.

1 Calculate the minimum stroke width *W* of character to be used as threshold of non-spurious edges.

2 Compute skeleton of the input character image using standard mechanism defined in terms of the hit-or-miss transform as described in (1).

$$I \oslash B = I - (I \otimes B) = I \cap (I \otimes B)^c \qquad (1)$$

$$B = \begin{bmatrix} 1 & 1 & 1 \\ 1 & x & 1 \\ 1 & 1 & 1 \end{bmatrix}$$

where B is the structuring element.

3 The resulting character matrix consist of single element edge irregularities leading to distortion and spurious edges. Repeat steps 4-7 to remove such edges.

4 Find the end-point pixels with 1-neighborhood depicted by N_1.

5 Traverse the connecting pixels in clockwise direction using 8-neighborhood until the pixel with 3 or more neighborhood is found depicted by N_3.

6 Calculate the distance *D* between N_1 and N_3.

7 If $D < W$ Remove the edge as it is a spurious edge.

Procedure StructuralFeatures(Image).

1 Compute number of neighbors, *N*, in Image by using 8-connectivity mechanism.

2 For each foreground pixel (i,j) do

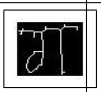
$$\text{if} N_{(i,j)} = \begin{cases} 1 & EndPts = EndPts + 1, \\ > 2 & IntersectPts = IntersectPts + 1, \\ else & \text{do nothing.} \end{cases}$$

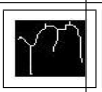
Set binary variable HasLoop=1 if exists holes exists in the Image using Flood Fill Algorithm [5].

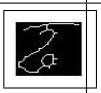
3 **return** *[EndPts IntersectPts HasLoop]*

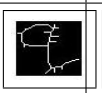
TABLE I. RESULT OF THINNING ALGORITHM.

Input Character	Skeleton	Thinned Character	Input Character	Skeleton	Thinned Character
					
					
					
					









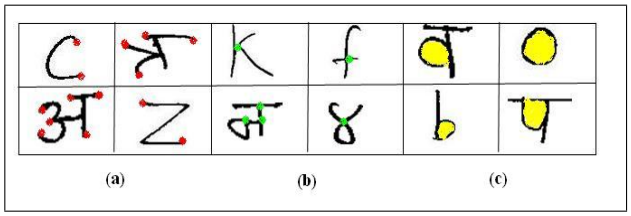


Fig. 1. (a) End points (b) Intersection points (c) Loop.

two way method is applied. First fit a curve on the character and determine the coefficients of the curve equation as features, secondly a count of the number of foreground pixels is used as a direct measure of distribution. To further improve the resolution of process output we have segmented the character image into fixed small blocks of size 5x5. Each such block will derive a curve and count of foreground pixels.

Curve fitting is defined as a way to capture the trend of spatial distribution of pixels by assigning a single function across the entire range possibly subject to constraints. Each constraint can be a point, angle, or curvature. To fit a curve on the specified skeleton pixels we postulate a function form f(x) (2), a polynomial function of 2nd order to describe the general trend in the data. Fig. 2 shows the results of quadratic curve fitting with the co-efficients labeled along.

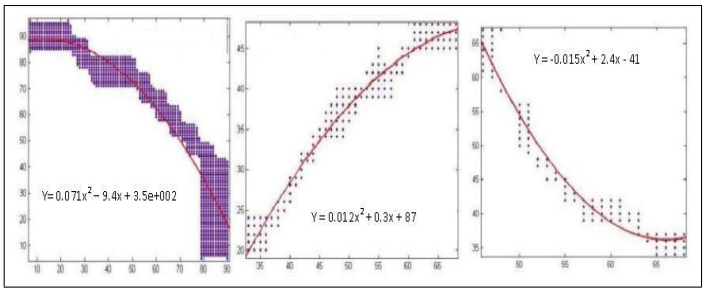

Fig. 2. Quadratic curve fitting along with the resulting polynomial equation.

$$f(x) = ax^2 + bx + c \tag{2}$$

While fitting the curve f(x) over the data pixels there will be inevitable measurement errors. Hence the best we can try to capture the trend of curve is to choose the parameters of the function as such that the curve fits as close as possible to the pixel distribution so as to minimize the fitting error. So ultimate goal of the algorithm is to minimize the Residuals r_i (3), difference between the observed y value and the value corresponding to fitted curve.

$$r_i = y_i - f(x_i) \quad \text{for 1= 1,2,3....n} \tag{3}$$

Equation (4) is used to calculate the standard measured error, i.e. mean square error(MSE), for all points. Hence by an iterative method we can minimize the residual r until it reaches a global minimum by adjusting the parameters a,b,c. The evolution of the normalized mean of the squares of the errors for a sample curve is shown in Fig. 3.

$$\begin{aligned} MSE &= (\frac{1}{\sqrt{n}})||r||_2 \\ &= \sqrt{(\frac{1}{n}\sum_{i=1}^{n}(r_i)^2)} \\ &= \sqrt{(\frac{1}{n}\sum_{i=1}^{n}(y_i - f(x_i))^2)} \end{aligned} \tag{4}$$

D. Complete Approach

Feature set generation is the method of converting highly redundant, variable and diverse data to a small size, robust,

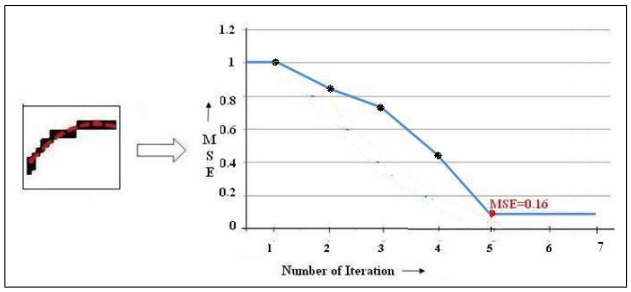

Fig. 3. Evolution of mse for a sample curve

Procedure StaisticalFeatures(Zone$_i$).

1 Find Sum$_i$, (5)the number of dark pixels for Zone$_i$. It constitutes 1 feature for each input zone.

$$Sum_i = Sum_i + Zone_{ij} \qquad \text{for all } \mathbf{Zone_{ij} = 1} \quad (5)$$

2 Using curve fitting mechanism over the skeleton of character to generate a quadratic polynomial QuadPolyCoeff$_i$ using (6).

$$f(x) = a_0 + a_1 x + a_2 x^2. \quad (6)$$

Using a_0, a_1 and a_2 compute standard error(4) and iterate until MSE$_j \approx MSE_{j+1}$.

3 Polynomial generated in previous step gives 3 values of corresponding coefficients $(a_0, a_1$ and $a_2)$ constituting 3 entries in the feature vector.

4 **return** *[Sum$_i$ QuadPolyCoeff$_i$]*

abstract and complete set that conveys all features of the original data. Generally data with greater size increases complexity and becomes time consuming for applications to process. Hence mapping to a corresponding small set of data makes task easier.

In character recognition task extracting those features that are essential to differentiate among characters is a tedious task. A simple method that generates most appropriate and complete set of features is always needed. In this paper we have tried to fabricate a simple mathematical approach Algorithm 2 based on a combination of Statistical and

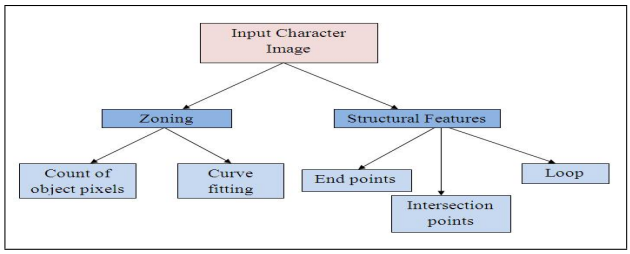

Fig. 4. Block diagram for the proposed Feature Extraction Approach

structural feature extraction techniques. The approach can also be represented by a block diagram as shown in Fig. 4. Fig. 5(a)-(d) presents the results of implementing Algorithm 2 on sample character images.

Algorithm 2: Algorithm to extract feature vector.

Input: 2-Dimensional binary segmented character.

Output: Feature vector consisting of 125 features to be fed to the neural network for further classification.

1 Apply thinning on the input image using Algorithm 1 to deduce a 1-pixel wide character skeleton.

2 Call Procedure StructuralFeatures() to compute structural features of Input Character resulting in a vector of 3 features. Re-size input image Img to dimensions 100x100 and partition Img in 5x5 block using equal partitioning, thus resulting in 25 blocks each of size 20x20.

3 Repeat Procedure StatisticalFeatures() for each zone.

4 Hence a complete feature vector consists of ((1*25) +(3*25)+3) i.e. 103 entries that give a wide range of features to differentiate among characters.

5 Finally this feature vector can be fed as input to the neutral network for training and for testing as well.

III. Neural Network Classifier

The classification stage uses the feature vector generated in the feature extraction stage to identify the text image. Classification is accomplished by a single layer feed forward neural

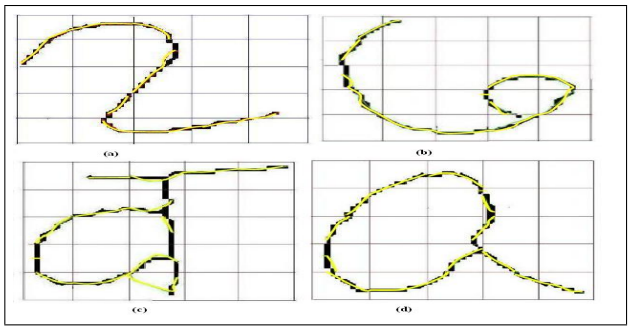

Fig. 5. Implementation of Algorithm 2

network with back propagation learning. The topology of the classifier consists of an input and output layers with neurons determined by the length of feature vector and number of classes respectively. The network employs gradient descendent rule in attempt to minimize the squared error between the network output values and the target values for these outputs. The trained network is used to test a input character image entered by the user and the classifier maps any input pattern to a number of classifications. The probability density function (pdf) of each of the class is generated, then an unknown image, X, belongs to class i if: $f_i(X) > f_j(X)$, $\forall j \neq i$, where f_k is the pdf for class k.

IV. Experimental Results

The proposed feature set generation technique has been trained and tested on $9,500$ scanned and standard data-set samples. The samples comprise of handwritten Hindi numeral, and character open source database *"Devanagari numeral and character database for offline handwritten character recognition"* [6] and a database obtained by CVPR Unit, ISI Kolkata [7]. Also a database of English numeral and characters is generated by scanning handwritten images written by 100 users. The results for testing has been summarized in Table II. Equation 7 and 8 presents the accuracy and error measure of the proposed method which achieves an average accuracy of 89% and false ratio of 10.29%. Also the accuracy of validation i.e. the ratio of correctly classified characters is 86% approximately.

$$Accuracy = \frac{^1TP + ^2TN}{TP + TN + ^3FP + ^4FN} \quad (7)$$

$$Errorratio = \frac{FP + FN}{TP + TN + FP + FN} \quad (8)$$

V. Conclusions

This paper proposes a novel and efficient feature set extraction technique using statistical and structural features of the text image for script independent character recognition. Results generated by the experiments on the test bed images conform to the greater level of efficiency with respect to the size of feature set, time utilized to train the network and its complexity. The approach of Quadratic Polynomial Curve Fitting used for generating feature set has been experimentally derived by testing various feature extraction approaches. For n data points the complexity of the algorithm is $O(kn)$, where k is the number of iterations. As the image is divided into 25 zones, hence the complexity achieves O(25*kn) $\approx$ O(kn). Whereas, the algorithms to compute transform [4] takes O(nlogn) and fuzzy model [8] has exponentially growing computational complexity. As a measure of statistical comparison, proposed approach gives accuracy of 89% in established test bed environment compared to the quoted accuracy of 80% and 83.5% in manuscripts of [2] and [3] respectively. These results uphold the application of the approach to generate feature vector.

***Abstract*—Handwritten document analysis is a persistent research area nowadays. It has large applications in various image processing domain as human computer interaction, machine translation and automation of reading various scanned images for handwritten fields in forms, postal address on envelopes and amounts in banks checks. The main factor which influence the performance of handwritten text recognition is the selection of an appropriate set of features for representing input samples. In this paper, we propose a efficient feature vector for handwritten character recognition, using a hybrid of the statistical and structural properties of a character to represent the particular character class. Experiments have been performed on standard database of handwritten digits and letters. The recognition accuracy is tested on a Neural Network classifier with different parameters. The results have been compared with existing features extraction algorithms. The comparative results shows the effectiveness of our approach.**

***Keywords*-Handwritten text segmentation; Connectivity strength parameter; Offline text Recognition;**

I. Introduction

Handwritten Text Recognition systems transform the handwritten documents into its electronic form for further transformation. Nowadays, although recognition of printed isolated characters is performed with high accuracy, recognition of cursive handwritten characters still remains an open problem in the research area and to increase the character recognition accuracy, novel features extraction techniques are indispensible [19].

Handwritten Text Recognition system involve several steps: preprocessing, segmentation, feature extraction and classification. In this paper, we address the feature extraction step.

Feature extraction step plays one of the most important roles in recognition system. In simplest case, the binary images are fed to a recognizer and a template matching is done. However, in most of the recognition system, in order to avoid extra complexity and to increase the accuracy of algorithms a more compact representation is required. For this purpose, a set of feature is extracted for each class that helps distinguish it from other classes.

So we can say that in this step of recognition, we extract discriminant information from an image of a segmented character and reduce its dimension of representation and produce a vector of feature to represent the character. Such suitable compact representation of the image by means of a vector of features is used for classification to classify the character efficiently.

A good survey on feature extraction methods for character recognition can be found in [2]. In the following, hundreds of documents image features extraction approaches are categorized in three major groups: a) statistical, b) structural and c) transformations based features.

The statistical features include histograms, moments and direction features. The structural features include registration, line element features, Fourier descriptors, topological features, and so on. The transformation methods include principal component analysis (PCA), linear discriminant analysis (LDA), kernel PCA, and so on.

A feature extraction algorithm must be robust enough such that for a variety of instances of the same symbol, similar feature sets are generated, thereby making the subsequent classification task less difficult [2].

The most common statistical features used for character representation are: a) zoning, where the character is divided into several zones and features are extracted from the densities in each zone [7] or from measuring the direction of the contour of the character by computing histograms of chain codes in each zone [10], b) projections [12] and c) crossings and distances [14].

In paper [11], dimensional features are extracted for isolated Greek handwritten character recognition based on efficient feature extraction followed by a suitable feature vector dimensionality reduction scheme. Extracted features are based on (i) horizontal and vertical zones, (ii) the projections of the character profiles, (iii) distances from the character boundaries and (iv) profiles from the character edges. The combination of these types of features leads to a 325-dimensional feature vector.

Structural features are based on topological and geometrical properties of the character, such as loops present in the character image, maxima and minima, reference lines, ascenders, descenders, cusps above and below a threshold, cross points, branch points, strokes and their directions, inflection between two points, horizontal curves at top or bottom, etc .

The structural approach for recognizing Greek handwritten characters is introduced in [15].They extracted a 280-dimensional vector consisting of histograms and profiles. The horizontal and vertical histograms are used

in combination with the radial histogram, out-in radial and in-out radial profiles.

Due to the fact that a continuous signal contains more information than needed representing this signal by a linear combination of a series of simpler well defined functions is easier. The coefficients of the linear combination provide a compact encoding known as transformation. Fourier Transforms (FT) is most popular among global transformation. Since the first n coefficients of the FT can be used in order to reconstruct the image [16], then these n coefficients are considered to be a n-dimensional feature vector that represents the character. Other transformations used are the Discrete Cosine Transform (DCT) [17], moments [18] etc.

Cursive characters present high variability in shapes, a feature extractor should have negligible sensitivity to local shifts and distortions. Therefore feature extractors that perform local averaging are more appropriate than others that yield an exact reconstruction of the pattern (e.g. Zernike polynomials, moments). The feature extractor, fed with the binary image of an isolated cursive character, generates local and global features.

The remaining of the paper is organized as follows. In Section II the proposed methodology is presented as preprocessing and feature extraction. Section III describes the configuration of the experimental data set and the classifier parameters. Experimental results are discussed in Section IV and finally conclusions are drawn in Section V.

II. Proposed Methodology

For uniformity of feature representation we first normalize all binary characters images to a $N \times N$ matrix with respect to the original aspect ratio. As we are interested in the relative positions of the strokes in the pattern but not in the size of the pattern we transform the character image into its skeleton using thinning operation. A skeleton shows the general shape of a pattern, and some important feature can be extracted from it. There are many approaches to find the skeleton of an object [3].

After finding the skeleton we divide the image into 5×5 zones as shown in Figure 4.

A. Feature Extraction

In our proposed approach, we employ three types of features. The first and second set of features are local features and are based on zoning. The image is divided into horizontal and vertical zones. In the first set of features we calculate the area of characters in each zone.

In second type of features, the curve fitting, also known as regression analysis is used to find the best fit curves for series of foreground pixels in each zone. We use the least square method of curve fitting which minimizes the square of the error between original data and the values predicted by the equation. It is a statistical method of fitting a function to a data set. There are five types of least squares fitting approaches such as Linear, Polynomial, Exponential, Logarithmic and Power. In term of

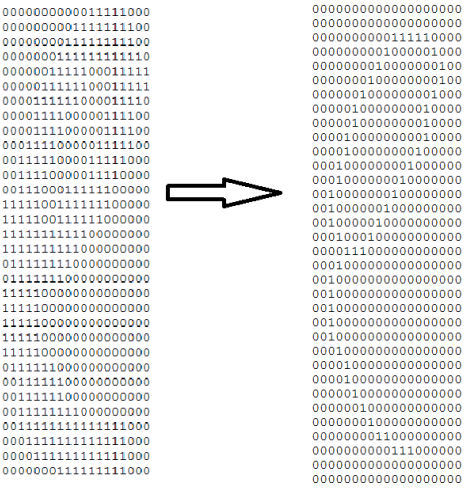

Figure 1. (a) Example matrix format of a handwritten character, (b) The corresponding skeleton matrix of the character.

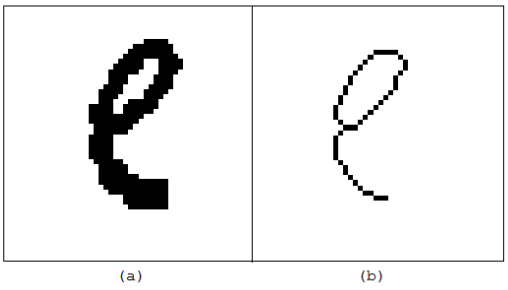

Figure 2. (a) Image of the handwritten character shown in 1, (b) The corresponding skeleton image.

required computing complexity and appearance of curve in character images , we use the second order polynomial function for best fitting. Quadratic polynomial functions are a reasonable choice owing to their low degree of complexity and enough flexibility to encode free hand curve in a small area (zone). The parametric representation of a polynomial of second order is given as

$$P(t) = c_0 + c_1 t + c_2 t^2$$

where $t \in [0, 1]$, is the parameter and the polynomial $P(t)$ goes through the points which satisfies $P(t)$.

Thus, compute $P(x_i, y_i)$ for $i = 1, 2, 3, ..., n$

$$c_0 + c_1 x_i + c_2 {x_i}^2$$

where coefficients c_0, c_1 and c_2 are the n unknowns, while the x_i and y_i are known as foreground pixels in the respective zone.

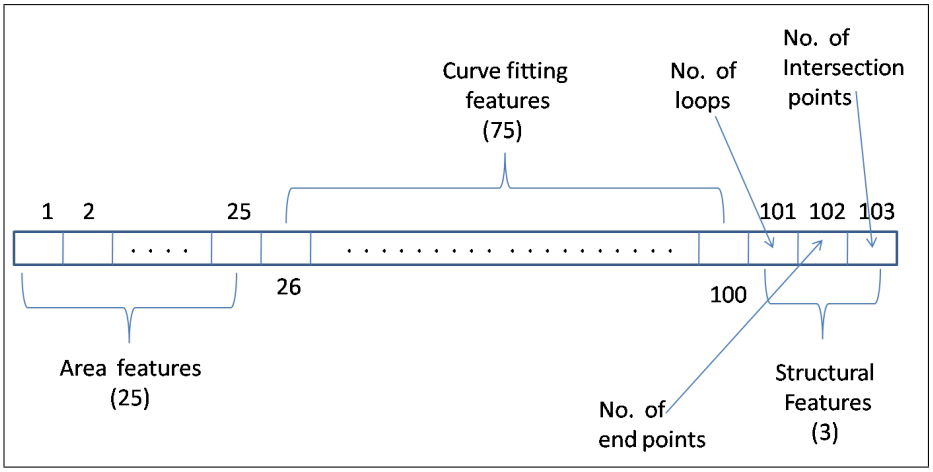

Figure 3. Structure of the proposed feature vector for character representation. It is a hybrid of features like: statistical (area), coefficients of a polynomial, and structural features like end points, intersections and loops.

$$\begin{bmatrix} 1 & x_1 & {x_1}^2 \\ 1 & x_2 & {x_2}^2 \\ 1 & x_3 & {x_3}^2 \end{bmatrix} \begin{bmatrix} c_0 \\ c_1 \\ c_2 \end{bmatrix} = \begin{bmatrix} P_1 \\ P_2 \\ P_3 \end{bmatrix}$$

We find the polynomial coefficients c_0, c_1, and c_2 and use them as features. Thus for each zone, three features are generated.

The third feature set is a global feature set and uses the structural information of characters like number of loops, end points and intersection points present in the character as shown in Figure 4.

The extraction of such global and structural features, is done by testing a 3x3 neighborhood of every foreground pixel of the skeleton. The following cases are determined.

- An end point is identified if there is only one foreground pixel in a 3×3 neighbourhood.
- An intersection point has more than two neighbours.
- Loop detection is based on the presence of circular or elliptical shapes within the character using the flood fill algorithm [6].

The complete features of our technique are shown as feature vector (FV) in Figure 3. Corresponding to (every character) 5×5 zones we have 25 area features listed at index $FV[1]$ to $FV[25]$. Every zone has three coefficients of the parametric curve, hence 75 quadratic curve coefficients listed at index $FV[26]$ to $FV[100]$, followed by the three structural features: end points, intersection point and loop; at $FV[101]$to $FV[103]$.

III. Experimental Design

For performance testing of our approach we have focused on universality and robustness. We attempt to be objective by using a database which covers maximum syntactic variations and fluctuations in cursive handwriting. For this, the test set is designed by people from diverse academic backgrounds and from different geographical areas.

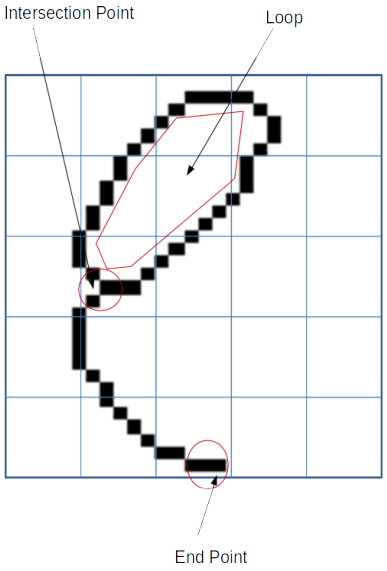

Figure 4. The example showing the three structural features of a character.

For robustness of our classifier extensive tests are conducted with different network training parameters like: varying the range of instances with different number of epochs and activation functions ranges with various thresholds of Mean square error range.

A. Organization of the database

As the cursive handwritten data set is not available, the database used for our experiments was generated with 100 writers from different academic background (primary school to UG college) and from different geographical regions (rural to urban). We have used the 10 digits, 26 lowercase and 26 uppercase English cursive characters. This concluded in 62 classes each one containing 100 patterns. The database has $62 \times 100 = 6200$ characters. Complete bifurcation of dataset in terms of number of

Table I
DATABASE USED IN OUR EXPERIMENTS.

	Number of classes	Training Size	Test size
Numerals	10	700	300
English capital letters	26	1820	780
English small letters	26	1820	780

training and testing instances is shown in Table I.

B. Configuration of NN classifier

The selection of a suitable classifier is an important part of any recognition system, because it highly affects the accuracy of results and speed. A well known classifier, feed forward neural network is designed for testing our proposed approach. The neural network was implemented using well known feed forward training algorithm with the mean square error function.

A constant learning rate 0.2, is used. The input samples are fed after shuffling their order at every epoch. The number of hidden layers is two times the number of output nodes. After initiating the training, we monitor the mean square error MSE at the output layer for every instance in order to determine the termination of training. The initial values of epochs taken is 500. The termination of training is done if the MSE is less than a MSE threshold or when the number of epochs exceeds the initial value of epochs.

Determination of the initial value of epochs and MSE threshold is not easy because the MSE changes among the character set. We setup their values so that the actual recognition rate for the training set reaches a stable point with no further increase.

Three separate neural networks were trained for digits, lowercase and uppercase characters. The number of outputs considered for digit was 10 and for both upper and lower case characters was 26 each. Moreover, 70% of each class was used for training and 30% for testing for each network.

IV. RESULTS ANALYSIS AND COMPARISON

For performance testing of the proposed approach, we have used the predictive analytically parameters, which is a table of confusion also known as confusion matrix, having two rows and two columns that reports the number of false positives (FP), false negatives (FN), true positives (TP), and true negatives (TN) present in the experiment. Total size of dataset will be the sum of all as

$$Total = \{TP + TN + FP + FN\}$$

Such parameters allows more detailed analysis than mere proportion of correct accuracy and error ratio. The accuracy rate (AR) and error ratio (ER) is calculated as

$$AR = \frac{TP + TN}{Total}$$

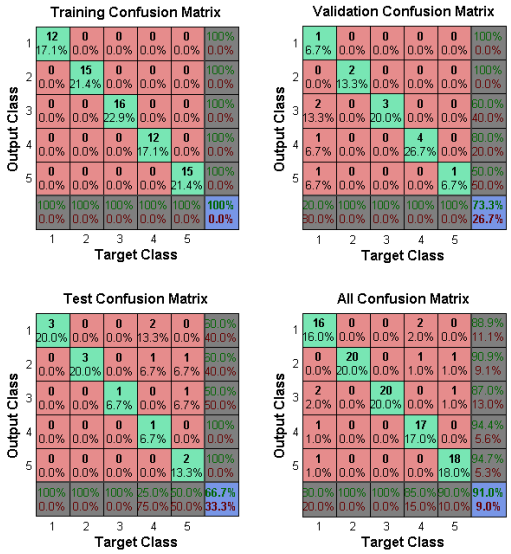

Figure 5. Confusion matrix for numerals.

$$ER = \frac{FP + FN}{Total}$$

For illustration of confusion matrices for digits, we have used five classes of digits which were selected randomly. The confusion matrix in various phases are shown in Figure 5. The performance in different phase of classifier as training, validation and testing is also depicted in Figure 6 for the same. The experimental results for 10 digit class achieved an overall accuracy rate AR and error ratio ER as 93.9% and 6.1% respectively as shown in Table II .

For illustration of confusion matrices for characters, we have used ten classes of characters five from lower case and five for upper case, which were selected randomly. The confusion matrices in various phases are shown in Figure 7. The performance at different stages of classifier like training, validation and testing is also depicted in Figure 8 for the same.

The complement experiments for 26 uppercase characters achieved an accuracy rate AR of 86.19% and error ratio as 13.81% and for 26 lower case characters we achieved an accuracy rate AR of 89.61% and error ratio as 10.39%.)
The complete experimental results with all three datasets is shown in Table II.

A. Results Comparison

It is always a difficult task to compare results for handwritten character recognition with other researchers in the literature. The results vary due to differences in experimental methodology, different experimental settings and difference in the handwriting database used.

In [8], they used the standard transition feature, as proposed by author of [9] and produced results of 70.31%

Table II
RECOGNITION RATE BASED ON NEURAL NETWORK.

Data	Size	True Positive (TP)	False Positive (FP)	True Negative (TN)	False Negative (FN)	Accuracy in %	Error Ratio
Numerals	1000	207	39	732	22	93.9	6.1%
English capital letters	2600	472	307	1769	52	86.19	13.81%
English small letters	2600	543	322	1787	48	89.61	10.39%

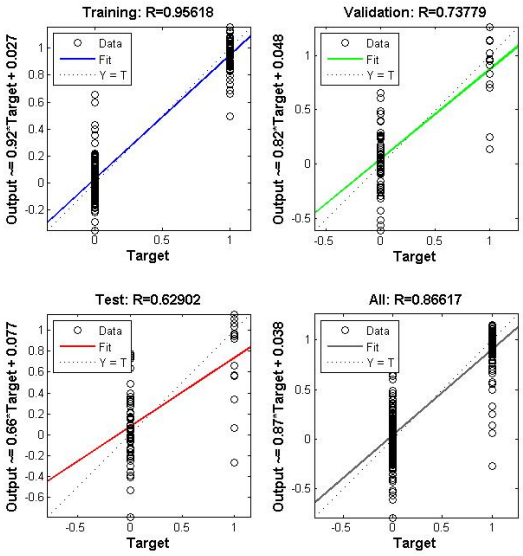

Figure 6. Regression curve for numerals.

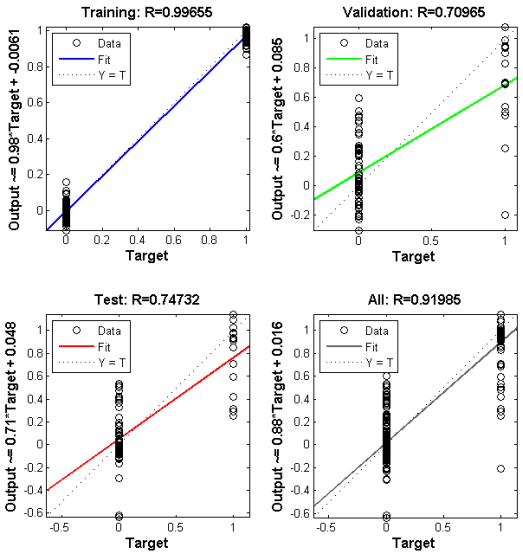

Figure 8. Regression curve of five class of characters.

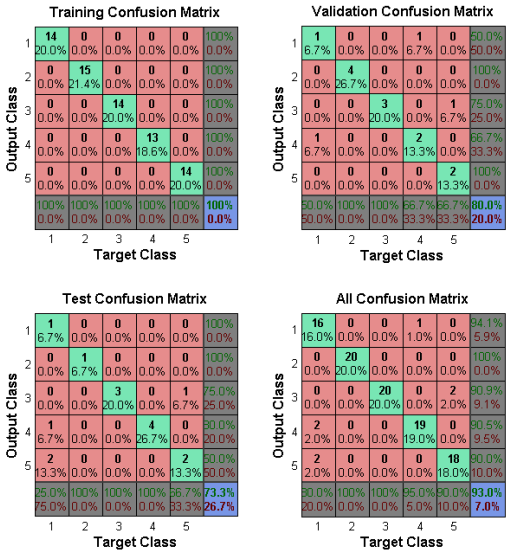

Figure 7. Confusion matrix of five class of characters.

and 79.23% for lowercase and uppercase characters respectively.

A complete state of art and critical analysis of neural network for document image is discussed in [19]. In this literature, reviewers emphasis that all existing preprocessing techniques have some inherent problems. They also provide the comparison of existing feature extraction techniques. All are only suitable for specific predefined condition and for the cursive characters the low accuracy with high computation demand was reviewed.

Additionally, some techniques need training/training data and in most of the cases typical training data is unavailable. Our experiment results are higher in accuracy than those described in above and It also must be noted that our technique requires less processing as the feature vector is a combination of statistical and structural features so it captures both kind of variations. Also a quadratic polynomial is used for encoding the character which is efficient compared to template matching, zoning and direction features as done in various techniques enumerated in [5].

V. CONCLUSIONS

In this paper, we proposed a feature extraction methodology for offline cursive character recognition using both statistical and structural features. This improve the recognition accuracy due to use extensive features and improves the efficiency due to novel curve fitting encoding of character features.

Abstract - For linguistics related research on a language there is always a need for a large collection of database which includes all features of a language such as grammatical information, style of writing, syntax etc. Corpus provides a platform for investigation on a natural language. As compared to other languages very limited research work is done on Urdu language due to its segmentation dilemma and difficult character shape. Very less number of editable printed text data is available in Urdu language, most of the data is available in graphical or picture format. To increase Natural Language Processing research work on Urdu language there is a need for a large database which contains a range of variance in annotated Urdu handwritten as well as printed text. In our work we purpose a large database of Urdu text including 1000 handwritten text images written by 500 different writers. Each image would be four to six lines of Urdu text having 60 - 80 words per line the estimated number of words would be around .35 million. Selection of words would be done from six different categories so that maximum number of distinct words can be included. Corpus would be annotated for line as well as word segmentation where a word may be an individual character or component. The corpus would be a benchmark for quantitative analysis of Handwritten Text Recognition techniques for Urdu language such as text line extraction, word segmentation and character recognition etc., and for linguistic research in Part of Speech, writer identification, dictionary etc.

Keywords:
Urdu language; Corpus annotation; Urdu corpus; Corpus creation; Urdu handwritten image database

I. INTRODUCTION

In the recent era corpus linguistics has a big role for research and development activities on any particular language. Corpus is a large collection of text data, which is stored in a scientific and systematic manner to represent a hypothesis about a language. This provides a platform for detail investigation on a language. In short form corpus is a big collection of smaller text, where Genre of text may be in printed text, handwritten text or spoken text. According to nature of corpus it is mainly divided into two parts raw corpus and annotated corpus. Raw corpus is just collection of text without any description or labelling of text. Annotated corpus is annotation of text in a systematic and scientific manner according to use of corpus.

Annotation of corpus is done according to the Corpus Encoding Standard (CES). The Layers of Linguistics Annotation is as follows:

- Syntax: - Combination of words to make sentence.
- Semantics: - Relation between words and what they are being used to represent.
- Morphology: - The study of units of meanings in a language.
- Lexicon: - The study of words and phrases used in a language.
- Discourse Analysis: - The study of the flow of information across sentence boundaries.
- Pragmatics: - The study of the context of text affects the meaning of expression.
- Text structures Analysis: - The studies of textual styles are constructed.

Corpus linguistics has good potentials to exhibit most of the features of a natural language with the large collection of empirical databases. Corpus linguistics approach has been used in a number of research areas such as:

- To empirical analysis and study about language based on large collections of text samples.
- Information about all the properties and components used in a language such as grammatical and functional information of letters.
- To build up an intelligent computer system that will be able to make efficient linguistic interaction with human.
- It is a way of collecting literary and non-literary data of a language for language related research and development activities.
- Extra linguistic information relating to time, place, situation, and social cultural backgrounds of linguistic.

According to use of corpus there are different types of corpus design annotations.

- General Corpus: General Corpus (e.g., LOB Corpus) is a simple random collection of texts

belonging to different categories. Selection of text is finite in number, but according to availability of new data it will grow over time.

- Special Corpus: Special Corpus is designed according to certain properties of investigation or demand of researchers. It varies in size and composition according to purpose. Collection of data for this type of corpus is mainly dependent upon the research requirements (e.g., literary Corpus: used for survey on literature collection of data available according to time span).
- Sample Corpus: Sample Corpus is a special type of corpus made with a sample containing sufficient number of text. Selection of text is made with utmost care because once a corpus is developed it will not change later to prevent any kind of imbalance.
- Multilingual Corpus: Corpus in a variety of languages.
- Parallel Corpus: texts are translations of each other (e.g., Hindi to Urdu).

Corpus linguistics use modern computer technology to store big collection of language data, and methods for pre-processing and information retrieval from this database.

As compared to other languages very limited research work has been done in Urdu due its word and character segmentation dilemma and the shape of the character. In our proposed work we design a standard annotated Urdu corpus of handwritten text images, which contains a dataset of 1000 forms of handwritten text image written by 500 writers belonging to distributed geographical region. For ground truth purposed corpus would be labelled in Unicode text file for both line and word according to previously described layers of linguistics annotation.

The paper is organized as: in the next Section 2, we describe literature survey and level of annotation on available corpus. Section 3 is concerned with the motivation and importance of Urdu language and proposed methodology to develop corpus. Section 4 further describes the characteristics of annotation and procedure for data storage and information retrieval. Finally some conclusions are presented in Section 5.

II. LITERATURE SURVEY

Since the 1990s, the corpus methodology has become a revolutionized in all branches of linguistics or language.

[1] Johansson, S., Atwell, E., Garside, R., and Leech, developed Lancaster Oslo/Bergen Corpus (LOB) is the first computer-readable general corpus of texts prepared for linguistic research on modern English. The collection of text in this corpus is in printed (Electronic) form. First version of this corpus was without annotation in which they include raw data as a plain text without labelling of text, but later version of corpus was released in annotated form. The structure of first version corpus released is as follows:

- 500 samples of English language
- 11827 sentences
- 134740 words

[2] Christian, P. Michel, Stefan and Philippe, IRESTE dual handwritten database of French and English. Instead of full length sentences corpus contain isolated words and characters. Corpus was just collection of text without any labelling of words. Corpus was designed for both off-line as well as on-line handwritten recognition. Structure of this multilingual corpus is as follows:

- 28657 words from French language
- 7689 words from English language

U. Marti and H. Bunke., [3, 4] Designed an IAM off-line handwritten database which is first available corpus consisting of full English sentences. The structure of the database is available in both printing and handwritten image format as well as in Unicode format. The segmentation and annotation was done for both line and words according to annotation layers. Due to proper segmentation and annotation the database can be used for English language linguistics research purpose and also for retrieval and information detection. Structure of database is as follows:

- 250 handwritten forms by different writers
- 4751 words
- 4881 lines
- 6625 different word

Lecun et al., MNIST [5] is a database of handwritten digits (Image) in which 60,000 samples of isolated digits handwritten image, is collected from 500 different writers.

M. Waqas, C. Lei, N. Nobile, and C. Y. Suen, (2009) design [6] CENPARMI is a first Urdu handwritten corpus which includes isolated digits and characters of Urdu language. Corpus is available in scanned image format without any annotation. Structure of corpus is as follows:

- 343 handwritten form with different writer
- 44 isolated characters
- 57 isolated words
- Collection of date in different Urdu format

Sarkar, N. Das, S. Basu, M. Kundu, M. Nasipuri and D. Basu, [7] CMATER is a database of unconstrained handwritten Bangla and English mixed script document image. Corpus is available in scanned handwritten image format without any annotation. Structure of the corpus is as follows:

- 150 handwritten form with different writer
- 100 form is pure Bangla language
- 50 forms is mixed of both Bangla and English

Hussain, S., (2008) CRULP [8] corpus is a large collection of Urdu text in Unicode format from Jang news and BBC Urdu services. The corpus has not been made publicly available. In this corpus manually POS tagging is done. The corpus is available in printed not handwritten form. Structure of the corpus is as follows:

- 1,83,08,616 words
- 50635 distinct words
- 1,10,098 annotated words

A. Raza, I. Siddiqi, A. Abidi, and F. Arif, (2012) [9] CENIP-UCCP is the only available corpus of Urdu Handwritten text image with full sentences. The database is labelled with coordinates of each of text for both printed and handwritten text. Manual segmentation is done in this corpus for lines. Data base could be used for handwriting task, but for benchmarking purpose corpus should be annotated for line and words. It was not considered for description of words such as grammatical and segmentation information. Structure of corpus is as follows:

- 396 handwritten forms with 200 different writers
- 2051 lines with 23833 words

Examples of some other widely used databases in the field of handwriting recognition are CEDAR [10], NIST [11], ETL9 (Japan) [12], and PE92 (Korea) [13].

From literature survey it was found that sufficient number of corpus is available for English language in printed and handwritten format. The researcher's community seems anxious to move forward fast in research of South Asian languages and mostly in Urdu language [14], but cannot because a standard corpora is required, which include big collection of linguistics information about a language.

III. MOTIVATION

Urdu is historically associated with the Muslim region of Hindustan. It is the national language of Pakistan, and one of the 22 scheduled languages in the Constitution of India. Also an official language of five Indian states: Uttar Pradesh, Bihar, Andhra Pradesh, Jammu & Kashmir and New Delhi. The population of Hindi-Urdu speakers is the fourth largest of the languages of the world, after Mandarin Chinese, English and Spanish. According to Govt. of India [15] census 2001 around more than 50 million person speaks Urdu in India as shown in Table 1.

Language	Persons who returned the language as their mother tongue			
	1971	1981	1991	2001
Urdu	28,620,895	34,941,435	43,406,932	51,536,111

TABLE 1: URDU SPEAKING POPULATION IN INDIA

Although Persian was the dominant and "official" language of the Mughal Empire, the language of the elite later evolved into a form known as Urdu. History of Mughal Empire (Shahan-e-Mogul) is written in Urdu. Urdu is written in Nastaleeq style using Arabic Script. In recent time the Unicode provides almost complete support for Urdu. Urdu uses the 0600–06FF Unicode range for its characters.

Application of Urdu corpus:

- Corpus is always a strong cognitive and linguistic motivation to envisage how we communicate through language across time and space.
- To build up an intelligent computer system that will be able to make efficient linguistic interaction with humans who know Urdu very well.
- Used to develop systems that contribute for the benefit and advancement of the whole mankind. Such as Machine Translation, Information Extraction, Language Understanding, Speech Understanding, Computer-Aided language teaching, etc.
- To understand empirically the natural languages adorned with all their regular and rare features (e.g., Urdu NLP research).

1. Proposed corpus structure

Our Proposed methodology to design and develop Urdu corpus consists of full Urdu text sentences.

Statistics of the Urdu corpus is as follows:

- Database will consists of about 1000 handwritten text forms. Each form having around 5 to 6 lines and 60 to 80 words.
- To captures the maximum syntactic variations, forms will be filled up by 500 different writers having diverse background and belonging to different geographical locations.
- Number of words in this corpus will be around .35 million.
- In the first phase of corpus development we will collect data in Unicode format as a plain text from various sources.
- Unfortunately there are very few repositories of Urdu text in Unicode format. Most of Urdu source text is present text in graphical form. To cover maximum number of words we will convert graphical image of text to plain text.
- Urdu language has a huge vocabulary because it is used from the time of the Mughal Empire (early 16th century) in India. According to time span each language is constantly evolving by adding some new words instead of existing words. The conversion of the graphical Urdu text to Unicode will make corpus sufficient in quantity term with large vocabulary.
- Database will be completely markup according to hierarchical level of indexing. Markup is done on the basis of multilevel indexing. It will start from handwritten text form, than for segmented lines where line is again segmented into words.
- Proposed corpus would provide facilities to further add more words by same procedure of markup where all annotation information will be entered manually during the insertion of new handwritten text form.

2. Category wise distribution of proposed data collection

To cater to a huge vocabulary the domain of the corpus would be a data collection of six different categories: Art and Literature, History, Science, News, Medicine and Sports. List of category along with some of their subcategory is as follows:

- Art and Literature (Poetry, Shyari, Ghazals)
- History (According to time span) and Architecture
- Science and Technology (Innovations and practices)
- News (News, articles and blogs)
- Medicine (Disease, medicine, procedures)
- Sports (Sports articles, Information about different sports)

The corpus development would start from the collection of raw text and end with the appropriate tagging or labelling of the collected text in the database. Figure 1 shows the complete process in step by step manner to develop the corpus.

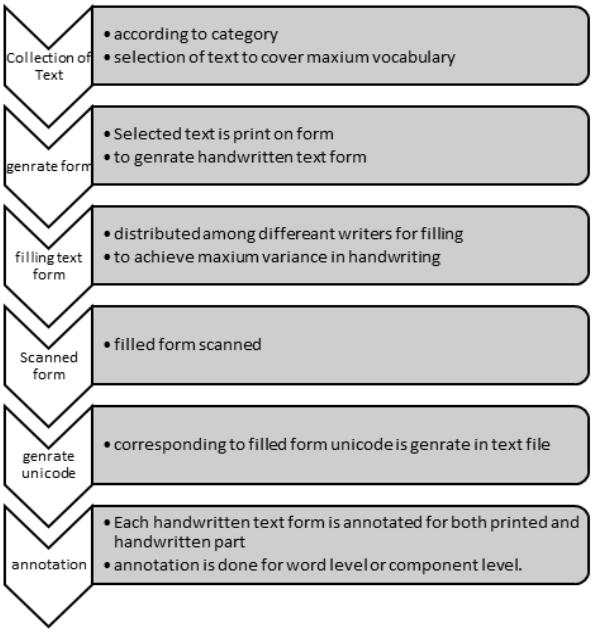

Figure 1. Process of corpus development

IV. OUR CONTRIBUTION

For collection of handwritten Urdu text a form is generated as shown in Figure 2. The design and structure of the form is split into four parts, each part is separated from each other with a horizontal line.

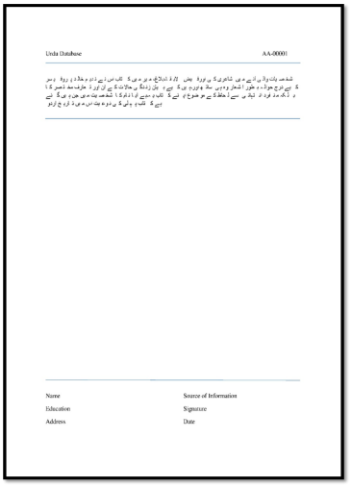

Figure 2. Layout of handwritten text form

Part 1: The first part comprises the title "Urdu Dataset" and a unique identification number of form. For example AA-00001, in which first letter A denotes the category of the form. Each category assigns a particular letter and combination of the first two letters denotes the subcategory (if A denotes category Art and Literature than AA denotes subcategory Poetry and AB denotes Shyari etc.) and 00001 specifies unique identification of form with its category and form number.

Part 2: Second part of the form consists of 4 to 6 lines of printed text which is collected from various sources. Each line having number of words around 60 to 70.

Part 3: Third part of the form is left blank where the writers replicate the printed text in his/her natural handwriting.

Part 4: Fourth part of the form having six attributes: Name, Education, Address, Source of Information, Signature and date of form filling, writers can optionally provide this information.

Sample Corpus Design

The filled form is to be scanned at the resolution of 300 dpi at a grey-level resolution of 8 bits. The images are saved in TIFF-format with LZW compression. Each form is completely scanned, including both the printed and handwritten text. In addition to quantitative tests for image processing and segmentation operations, it can also be used for experiments on machine-printed text and handwritten text separation.

Annotation (labeling) of text in a corpus is prerequisite for any corpus development process, because this task is time consuming and error prone it requires utmost care. Apart from pure text annotation corpus provide some additional linguistics information about data. To create the annotation and markup of handwritten image, the text of a form is copied twice into Unicode, once for the machine-printed text and once for the handwritten text.

Figure 3.Home page of corpus

Figure 3 shows the home page of the proposed corpus. The homepage gives the details of corpus and provide option for access and to update corpus with new data. Handwritten image are distributed according to category, on clicking a category its shows its subcategory and the list of unique-id number of forms stores in this category.

Figure 4. Display of form with annotated information

Along with annotation information the form also shows some additional information as shown in Figure 4. The detail description of handwritten text form contains:

- Unicode corresponding to handwritten text.
- Category and subcategory of form.
- Skew of page.
- Number of handwritten line in the form.
- Each handwritten line is segmented and assigned a unique-id with their Unicode text.
- Name of writer.

A sample display of segmented line and annotated information of line is shown in figure 5. This shows the segmented line separately which is segmented from handwritten text form. The Unicode of the segmented line corresponding to handwritten text line. Each line has a unique id which is extension of form id for example if form id is AA-00001 than it is extended to AA-00001-00 for first line and AA-00001-01 for subsequent line.

For evaluation of handwriting recognition systems, the ground truth data corresponding to the actual transcription of each line of text is stored in Unicode format.

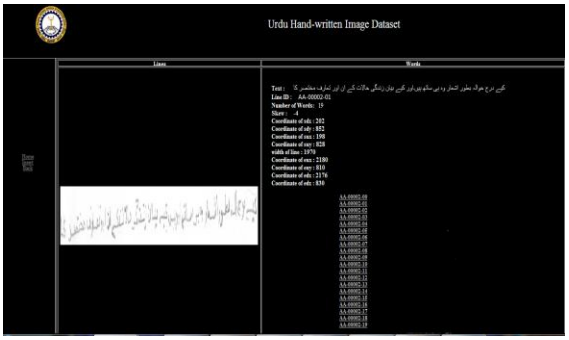

Figure 5. Display of line with its annotated information

Each segmented line of handwritten text form is further mark-up with the detail description which contains:

- Unicode of segmented text line corresponding to handwritten text line.
- Unique identification number of line.
- The x and y coordinates with respect to bounding extent of the line.
- Starting top and bottom pixel.
- Ending top and bottom pixel.
- width and height of the line.
- Skew of the line.
- Number of words in line.

The ground truth data of segmented line with detail description is stored in Unicode format will be useful for benchmarking of handwritten text recognition algorithms.

The segmented line is again segment into words. Each of the segmented word having unique id number:

- Each word has unique id which is extension of line id for example if line id is AA-00001-00 than it is extend to AA-00001-00-00 for first word and AA-00001-00-01 for subsequent word.
- Each word in handwritten text line is segmented and annotated separately.

The segmented word is further mark-up with the information as shown in figure 6 which includes the detailed descriptions:

- Unicode of segmented word or component.
- The x and y coordinates extents with respect to each component.
- width and height of word.
- Skew of word.
- Each word of line is annotated with noun, pronoun, adjective, verb, preposition etc.

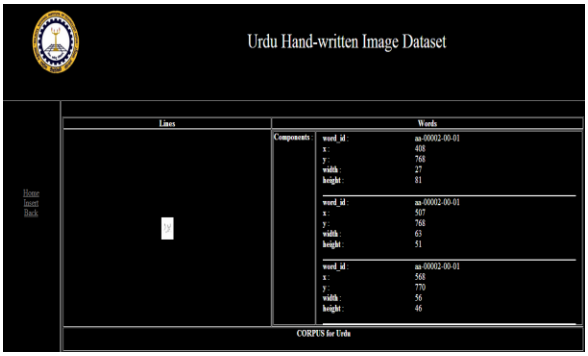

Figure 6. Display of Word with its Annotated information

To retrieve list of words according to alphabetical order we annotated each word's first character with a label according to Urdu alphabet. This will be useful to generate ligature and dictionary searching of Urdu words. Since we are also storing the writer's identity, it could also be used for hand-writer identification detection techniques.

The corpus provides facilities such as benchmarking of handwritten text recognition algorithm. To maintain accuracy in benchmarking, the corpus would be annotated and segmented manually. For benchmarking of handwritten algorithm all the annotated information of line as well as word is stored in Unicode format. These Unicode will be match with algorithm output to check the accuracy.

V. CONCLUSIONS

The proposed corpus includes a very large scale of database with distinct number of words belonging to six different categories to maintain equality and quantity features in the corpus. Annotation of corpus is done for both printed and handwritten format. Database would be useful for linguistics related research on Urdu language. Corpus consists around 1000 Urdu handwritten forms of 500 different writers and each form consists 4 to 6 lines having 60 to 80 words. Information of text will be in both printed and Unicode. Corpus will be completely markup according to hierarchical level of indexing. Markup is done on the basis of multilevel indexing. It will start from handwritten text form, followed with the segmented line where line is again segmented into words. Segmented word may be individual character or unit. Corpus will also provide facilities to further add modify a word. Corpus would be useful for both linguistics related research and benchmarking purpose.

Non-Standard Words as Features for Text Categorization

Slobodan Beliga, Sanda Martinčić-Ipšić
Department of Informatics
University of Rijeka
Radmile Matejčić 2, 51000 Rijeka, Croatia
{sbeliga, smarti}@inf.uniri.hr

Abstract - This paper presents categorization of Croatian texts using Non-Standard Words (NSW) as features. Non-Standard Words are: numbers, dates, acronyms, abbreviations, currency, etc. NSWs in Croatian language are determined according to Croatian NSW taxonomy. For the purpose of this research, 390 text documents were collected and formed the SKIPEZ collection with 6 classes: official, literary, informative, popular, educational and scientific. Text categorization experiment was conducted on three different representations of the SKIPEZ collection: in the first representation, the frequencies of NSWs are used as features; in the second representation, the statistic measures of NSWs (variance, coefficient of variation, standard deviation, etc.) are used as features; while the third representation combines the first two feature sets. Naive Bayes, CN2, C4.5, kNN, Classification Trees and Random Forest algorithms were used in text categorization experiments. The best categorization results are achieved using the first feature set (NSW frequencies) with the categorization accuracy of 87%. This suggests that the NSWs should be considered as features in highly inflectional languages, such as Croatian. NSW based features reduce the dimensionality of the feature space without standard lemmatization procedures, and therefore the bag-of-NSWs should be considered for further Croatian texts categorization experiments.

Keywords: text categorization, non-standard words, collection representation, features, accuracy

I. INTRODUCTION

Categorization or classification is tasked to classify a given data instance into a pre-specified set of categories. In the domain of text categorization, the task is called text categorization (TC) – given a set of categories (subjects) and a collection of text documents, the process of finding the correct topics for each document [1]. Typically, texts are represented with vectors of word's frequencies in the bag-of-words model. The problem with this approach is the dimensionality of the features vectors, which is equal to the number of different words in the collection [1, 2].

One of the solutions for the dimensionality problem is **Feature Selection** which can be: heuristic, guided by linguistic and domain knowledge, or statistical [3].

In linguistically guided approach, the dimensionality of the features vector is reduced with stop words (*a*, *an*, *the*, *of*, etc.) omission and lemmatization. Lemmatization changes each inflected word form with its lemma (*walked*, *walks*, *walking* – with lemma *walk*) and therefore reduces the dimensionality of feature vectors, which is of essence in morphologically rich languages such as Croatian. Some feature selection approaches ignore terms that are too frequent or too rare according to empirically chosen thresholds [3]. As data sets become more complex, heuristics are usually not sufficient. Therefore, another solution is to use measures such as Information Gain and Chi-Squere, to define relevance of each feature [4].

Another approach to dimensionality problem is **Dimensionality Reduction by Feature Extraction**. It implies a much smaller set of synthetic features from the original feature set, using synthetic features rather than naturally occurring words. This will avoid the problems inherited from natural language (polysemy, homonymy, etc.). Using word groups, instead of individual words as features, with a high degree of semantic relatedness, proved to be justified in clustering [1]. Systematic approach - Latent Semantic Indexing (LSI) is based on this principle [1].

In this paper we propose opposed approach based on Non-Standard Words (NSWs) as features. Instead of bag-of-words, we construct the bag-of-NSWs, and use them to train different text classifiers. The peculiarity of proposed approach is in using NSWs which would usually be omitted from the text during the text cleaning procedures. Non-standard words are: numbers, dates, time, abbreviations, acronyms, currency, measurement units, etc. Text normalization transforms NSWs in their extended form: the abbreviation */dr./* into */doctor/* or acronym */SMS/* into */Short Message Service/*.

The motivation for this work rises from an idea that discarded characters and numbers are sufficient for discrimination of classification of the text categories, reducing the feature vector dimensionality at the same time [2].

The paper is organized as follows: Section II. presents methodology of text normalization and categorization, Section III. presents the data collection, NSW features extraction procedures and training of classification models. The results are presented in the end of Section III. The paper concludes with discussion and some future work considerations.

This research is partially supported by the grant 13.13.2.2.07 of University of Rijeka.

II. METODOLOGY AND RELATED WORK

A. NSW extraction

Traditionally, in the field of natural language processing (NLP), normalization is the process of transforming the unit into its normal form (i.e. lemma). Normalization is also the first step in the text pre-processing of Text-to-Speech (TTS) systems. It is performed in the normalization module, which is responsible to identify a NSW token and to transform it into its expanded form [5, 6]. Text Normalization for Croatian Speech Synthesis is described in [7]. In this work, the Croatian NSW taxonomy driven rule based approach was used for NSWs extraction [7, 8].

Module for normalization initially detects the NSW and separates it from standard words. Then, detected NSW is transformed into its expanded form, suitable for the TTS system. In this experiment, the process of transforming NSW to expanded form is not required. Instead, we detect each NSW and determine its NSW type as is suggested in taxonomy for classification of non-standard words in Croatian language [8]. In addition, every occurrence of NSW for each NSW type is counted. Our approach identifies NSWs and then normalizes detected NSWs following the taxonomy of Croatian NSWs by combining programmed rules and the lookup dictionary.

B. Text categorization

Text categorization is tasked with assigning one of predefined classes to a document. Usually text categorization is performed using a bag-of-words model borrowed from information retrieval (IR), and most often based on TF-IDF model [1-3]. Documents are represented as feature vectors, which are, according to the bag-of-words model, unordered list of words with the frequency of their occurrence in a document. Inverse document frequency is used to model the rareness of terms in a document collection. Feature vectors are used to train the classifier, usually Bayesian classifier, k-nearest neighbor (kNN), classification tree or support vector machines (SVM), etc. [1, 3, 9]. Some of the techniques for the vector dimensionality or the feature space reduction are: *stop words* and NSW removal [10], lemmatization or morphological normalization [11] - NLP based principles; selecting the most discriminative subset of features (document frequency, information gain, mutual information, odds ratio, etc.) – called feature selection [4, 12] - or deriving new smaller set calculated from original features – called feature extraction [13].

Our approach is presented in Figure 1.: in the first step - we detect all NSWs from the text; in the second step – for detected NSWs we assign its type (number, abbreviation, date, etc.); in the third step – we construct the bag-of-NSWs; in the fourth step – we train the classifiers. Finally, as a result of the text categorization we obtain the texts which are organized as categorized collection of texts – every text is associated with one of the possible categories.

III. NSW BASED TEXT CATEGORIZATION

A. Data (SKIPEZ)

For the purposes of normalization and categorization tasks we prepared the collection of texts in Croatian language – SKIPEZ (Službeno, Književno, Informativno, Popularno, Edukativno, Znanstveno). SKIPEZ contains 390 texts organized in 6 predefined classes: official, literature, informative, popular, educational and scientific. The distribution of text over classes is balanced so each class contains exactly 65 texts. Texts were selected according to their relevance to the class and according to the % of contained NSWs, because we needed a balance between both aspects in order to train a classifier. SKIPEZ statistics is shown in Table I., and additional details about SKIPEZ are in [14].

The content of texts in each subclass was carefully selected, in order to capture as many different and representative text in each class used and contain representative set of NSWs, in order to compile the exhausted list of Croatian NSWs is shown in Table II.

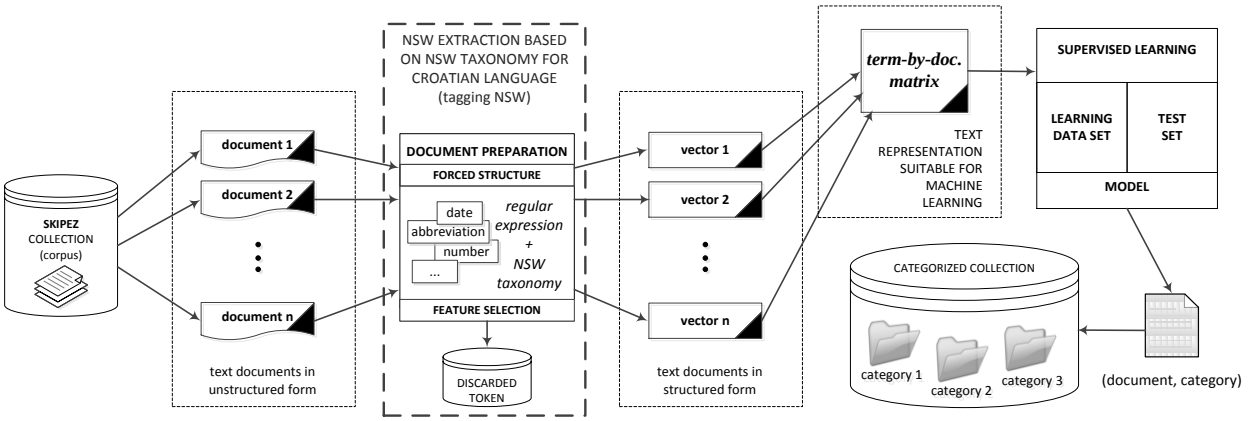

Figure 1. Shematic representation of NSW based text categorization

TABLE I. NUMBER OF TOKENS* AND NON-STANDARD WORDS IN SKIPEZ CORPUS SHOWN PER 6 CATEGORY

B. NSW Extraction Procedure

The NSWs were extracted from the SKIPEZ text collection according to the approach presented in [7, 8]. Here, we only detected NSWs types according to this taxonomy, resulting in feature vectors consisting of NSWs types frequencies for each document in the collection. A feature vector for each text document in collection contains 85 values (calculated from NSW types frequencies):

- STRING part - 15 values: ordinal and nominal roman numbers, simple or compound abbreviations, abbreviations without full stop, chemical elements, measurement units, currency an monetary units, acronyms, inflected and special acronyms, symbols, emoticons and suffixes.
- NUMBER part - 21 values: numeric format date, time period, time, proportion, dimensions, short references, short and long telephone number, interval, positive and negative decimal numbers, decimal interval, positive and negative fractions, exponents, ordinal and nominal numbers, ordinal and nominal intervals, positive and negative nominal numbers, ISDN/UDK numbers.
- COMBINED part - 20 values: 3 different date formats, geographical coordinates, long references, biblical references, enumerations of tables, figures and titles, road designation, TV show label, traffic abbreviations, compound measurement units, vitamins, house numbers, chemical and mathematical formulas, program code, registration number, argo-emoticons, domain specific NSWs, and NSWs of unknown type.
- DERIVED part - 29 values: total of NSWs in the number class, total of NSWs in the string class, total of NSWs in combined class, total of NSWs in text, total of words in text, number of different NSW types, number of empty NSW types, ratio between filled features and subclasses, ratio between filled and empty NSW types, coefficient as number of NSW divided with number of words in text. Moreover, there are also features that summarize the total number of instances of certain NSWs subclasses that are inter-related and can be classified in the same superclass. These are respectively: total of full date, total of incomplete date, total of references, total of numeration, total telephone numbers, total of range, total of decimal numbers, total number of fractions, total number of road designations, total number of electronic addresses, total of ordinal numbers, total of nominal numbers, total of roman numbers, total number of abbreviations, total number of measurement units, total number of acronyms, total number of office designation, total number of formulas and total number of jargon terms.

The first representation of SKIPEZ collection is a feature set composed from NSW type frequencies. For each document the features vector contains 85 values (as listed above).

The second representation of text, based on the NSW frequencies, represents the base from which the values of the features are derived. In this case, the statistics serves as a tool for obtaining metadata from the previously calculated frequency of NSW occurrence. For each element of the population, therefore each vector, we calculate some of its numerical characteristics called statistical features [15, 16]. The main idea when choosing a feature vector is utilizing the basic statistical features, which can describe the dispersion of identified patterns of NSW in a particular text.

The statistical characteristics of each population (each vector) were counted. We observed the vector elements as a sequence of elements and determined the individual values of absolute and relative measures of dispersion: the arithmetic mean, the range of variation, standard deviation, variance, coefficient of variation, and also a measure of flatness and a measure of asymmetry. We then calculated the statistical characteristics exclusively for superclasses (string, number, and string + number) – higher classes from taxonomy (Figure 2.). This second group of calculations observes dispersion patterns within the superclass, i.e. numerically describes the statistical characteristics of the NSW dispersion in three superclasses. We calculated the following characteristics: the arithmetic mean of superclass, interquartile q3, interquartile q1, interquartile Iq, coefficient of quartile deviation and coefficient of variation.

The third representation of texts is formed as a union from the features of the first and second representations, therefore includes all their values. Through the combination of features, we try to take advantage of the knowledge that was previously extracted from all the texts, on the principle "the more, the better".

In experiments with all 3 feature sets we conduct an iterative process of adding the created vectors for each text, we gradually form a bag-of-NSWs model (*term-by-document matrix*) - see Figure 1. Since we used supervised machine learning, during the bag-of-NSWs construction to each feature vector we assign its actual category (see Table II.).

C. Categorization Results

We trained the Naive Bayes, Classification Tree, kNN, CN2, C4.5, and Random Forest using the Orange [17] toolkit. As the measure of classification performance we used accuracy (1) [9].

$$\text{Accuracy} = \frac{Number\ of\ correct\ classifications}{Total\ number\ of\ test\ cases} \qquad (1)$$

where a correct classification means that the learned model predicts the same class as the original class of the test case.

The results of trained classifiers (Naïve Bayes, Classification Tree, kNN, CN2, C4.5 and Random Fortest) are obtained for three different feature representations using 5 fold cross-validation. The text categorization results using the first feature set - NSW frequencies are shown in Table III.; using statistical features in Table IV. and for combination of features in Table V.

TABLE III. RESULTS OF TEXT CATEGORISATION WHERE TEXTS ARE REPRESENTED BY FREQUENCIES OF NSWS

CLASSIFIER	*#tokens*	*Accuracy [%]*
Naïve Bayes	263	67,44
Classification Tree	305	78,21
kNN	296	75,90
CN2	306	78,46
C4.5	309	79,23
Random Forest	**335**	**86,15**
The mean score of all classifiers:		77,56

TABLE IV. RESULTS OF TEXT CATEGORISATION WHERE TEXTS ARE REPRESENTED STATISTICAL FEATURES

CLASSIFIER	*#tokens*	*Accuracy [%]*
Naïve Bayes	176	45,13
Classification Tree	223	57,18
kNN	220	56,41
CN2	212	54,36
C4.5	229	58,72
Random Forest	**260**	**67,95**
The mean score of all classifiers:		56,62

TABLE V. RESULTS OF TEXT CATEGORISATION WHERE TEXTS ARE REPRESENTED BY UNION OF NSWS FREQUENCIES AND STATISTICAL FEATURES

CLASSIFIER	*#tokens*	*Accuracy [%]*
Naïve Bayes	176	62,05
Classification Tree	223	76,92
kNN	220	70,00
CN2	212	74,62
C4.5	229	78,97
Random Forest	**260**	**86,92**
The mean score of all classifiers:		74,91

The experimental results can be analyzed twofold: by accuracy of different classifiers and by accuracy with respect to different types of representations in collection - Figure 3. Random Forest achieves the highest accuracy and Naïve Bayes the lowest in all representation of the collection. The accuracy of all classifiers with statistical features is generally worse than the frequency features

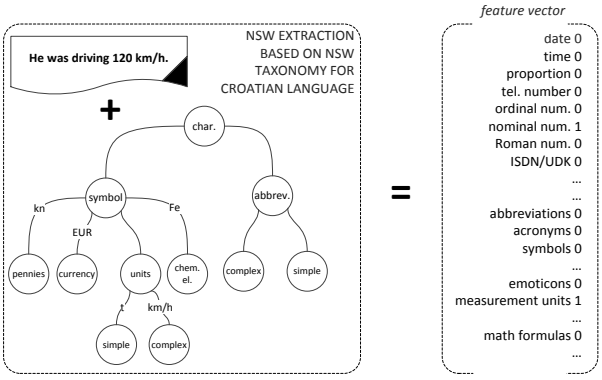

Figure 2. Forming a feature vector in Bag-of-NSWs

(Table IV.). With statistical features, Random Forest achieved a slightly higher accuracy (increase less than 1%). Chakrabarti, Yang and Pedersen in [4] state that numerous techniques of selection of features improve the performance of the classifier only marginally. This was confirmed also with our experiment, although the selection of features used non-standard features of the vector.

Experimental results can be analyzed according to text categories as well. Comparison of text categorization accuracy, only using Random Forest, is presented in Table VI. The highest accuracy was achieved for the class of informative texts, while the worst was achieved in the class of scientific and educational texts. The obtained results of classification leave room for discussion about the possibility of unification or reduction of scientific and educational domains because in this 2 categories is the highest number of misclassified texts. The science and education are closely related and they share the division of the subareas, fields and branches.

The worst scores for educational and scientific domain can be explained as an error that is probably caused by the fact that the educational and scientific texts are equally distributed in the scientific and artistic areas, fields and branches as required by the National Council for Science, and for Republic of Croatia Ministry of Science, Education and Sports, available at [18]. On the basis of this criterion texts are selected for SKIPEZ collection. Classifier failed to recognize the scientific style of writing. Encyclopedic texts, journals, articles and dissertations are apparently very similar to school textbooks, teaching materials and manuals through the NSW perspective.

TABLE VI. COMPARISON OF CATEGORIZATION ACCURACY WITH RESPECT TO 3 DIFFERENT FEATURE REPRESENTATIONS FOR RANDOM FOREST ALGORITHM

CATEGORY	ACCURACY [%]			AVG [%]:
	NSWs freq.	*Statistics*	*NSWs freq. & Stat.*	
official	76,92	66,15	81,54	74,87
literature	98,46	67,69	93,85	86,67
informative	100	83,08	100	**94,36**
Popular	100	66,15	92,31	86,15
educational	72,31	64,62	76,92	**71,28**
scientific	69,23	60,00	76,92	**68,72**
AVG [%]:	86,15	67,95	**86,92**	

IV. DISCUSSION AND CONCLUSION

This paper presents categorization of Croatian texts using Non-Standard Words (NSW) as features. Results suggest that non-standard word forms can be used as features for representation of texts in text categorization. The associated NSW taxonomy is suitable form of background knowledge on the basis of which NSW can be automatically extracted from texts. It has been shown that the NSWs carry enough information about the nature of text, which is suitable for further classification. With this approach, it is possible to significantly reduce the dimensionality of feature vectors (space) and at the same time achieve good text categorization results. Using NSWs feature, the feature vectors have several times lower dimensions then the original ones and this way reduces the problem of sparse data.

Bag-of-NSWs approach is suitable for inflectional languages because extremely reduced dimensionality (only 85 features) which can avoid the procedure of lemmatization of words or morphological normalization.

Obtain results should be compared with standard TF-IDF classification method. Since the literature presents the support vector machine as successful, it would be appropriate to examine whether a classification using SVM provides better results than the Random Forest algorithm. In further work we plan to extend our work to the field of micro texts classification, since SMS and twitter texts contain a lot of NSWs.

{ivan.budiselic, goran.delac, klemo.vladimir}@fer.hr

Abstract - The aim of this paper is to show that an accurate and efficient text classifier for relatively simple problem domains can be created in only a few hours of development time. The motivating example discussed in the paper is a recent *HackerRank* competition problem that tasked competitors with creating a classifier for questions from the popular question and answer platform *StackExchange*. The paper describes the key components of one solution to this problem, and briefly overviews the naive Bayes classifier that is the basis of the solution. The discussion is focused on feature selection and example representation which were the key challenges to be addressed during the development of this classifier. We also analyze the effect of the number of features on accuracy, training and classification time and the size of the resulting classifier and the representation of the training examples which were all important characteristics for the competition. The described classifier achieved slightly over 89% accuracy on the hidden question set, while the winning submission achieved around 92%.

I. INTRODUCTION

Text classification is a process in which pieces of text, often called *documents*, are assigned to one or more predefined classes or categories. Up until the late 1980s, automatic text classification was based on predefined rules encoding expert knowledge about the problem domain [1]. This approach to text classification requires a high level of expertise, both in understanding the problem domain in which classification is being employed, and in choosing and encoding appropriate rules for classification. However, since then, automatic text classification has shifted towards machine learning techniques where, in some sense, the computer is tasked not only with classification itself, but also with choosing classification rules within a certain model based on a set of already classified examples. This development makes it possible to quickly create useful text classifiers with minimal domain knowledge and prior experience with text classification technology.

This paper is motivated by the September 2013 edition of the *HackerRank* [1] *20/20* online programming competition, where competitors were tasked with creating a classifier for questions from the popular question and answer platform *StackExchange* [2]. We present one classifier developed for this competition.

A competition context presents several specific challenges in designing and developing a text classifier. First, the classifier needs to be developed in a short amount of time, and the classifier described in this paper was developed in around five hours during the course of one day. Second, the evaluation environment of an online competition imposes strict limitations on the training and classification time of the system. The goal of the paper is to describe how these challenges were successfully addressed, and ultimately show that an accurate classifier for this problem can be developed quickly.

The rest of the paper is organized as follows. Section II precisely defines the *StackExchange* question classification problem. Section III describes the key components of the presented solution to the problem. Section IV discusses some key implementation details that were necessary to address the strict efficiency requirements for the classifier, and analyzes the impact of the number of features on several key properties of the classifier. Finally, the paper is concluded in Section V.

II. STACKEXCHANGE QUESTION CLASSIFICATION PROBLEM DEFFINITION

The *StackExchange* platform powers a continually growing number of 112 different question and answer sites spanning various topics, from religion to physics and biology. The objective of the *HackerRank* competition task was to develop a *StackExchange* question classifier. Given the title and the text body of an example question, the classifier should produce the topic in which the question had been asked.

To keep the training and test datasets sufficiently small, the problem was restricted to only these ten topics: *android*, *apple*, *electronics*, *gis*, *mathematica*, *photo*, *scifi*, *security*, *unix* and *wordpress*. Note that there is some overlap between these topics. For example, the *Mac OS X* operating system for Apple computers is based on the Unix operating system. Therefore, some questions could have legitimately been asked on either the *apple* or the *unix StackExchange* site, and even a human expert would not be able to always guess the actual class of the question. A similar overlap exists between any of the *android*, *apple* or *unix* topics and the *security* topic.

[1] http://www.hackerrank.com
[2] http://www.stackexchange.com

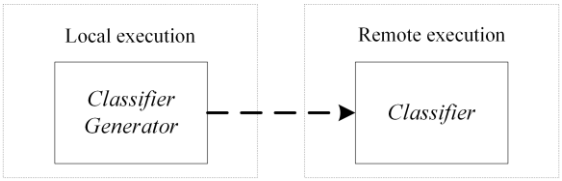

Figure 1. The two programs of the presented solution to the *StackExchange* question classification problem.

Competitors were given a training set of 20209 questions with correct topic labels. The number of questions per topic in the training dataset was between 1369 questions for the *mathematica* topic and 2383 questions for *gis*. This training file was also made available in the evaluation environment.

The problem statement also defined that the hidden question set used for evaluation would contain 22000 questions. This is significant because solutions must label all the questions in the evaluation set within a fixed small amount of time that varies with programming language. For example, C++ solutions are allowed only three seconds of run time. The solution presented in this paper was developed in Python, where solutions are allowed to run for up to 16 seconds. This large difference in allotted processor time is due to the fact that programs in these competitions are typically computationally intensive and the CPython implementation of Python is significantly slower than C++ for such tasks [2][3].

Another significant part of the problem specification is that solutions are submitted in the form of a single file of source code. This solution organization restricts the classifier training process to two options. First, the classifier can be trained offline and the submitted solution can then somehow reconstruct the trained classifier before classifying test examples. Second, the solution can train the classifier during evaluation using the training file available in the evaluation environment. With both options, the time required to either reconstruct or train the classifier must be carefully considered as it is also counted towards the execution time limit. This is an unusual requirement as this process of initializing a classifier is usually done once before the classifier is used for a longer period of time, and only classification time is critically important while longer training times can be tolerated. This issue is discussed in more detail in the next section.

Finally, in addition to the standard Python library, Python solutions to *HackrRank* problems can use the *Natural Language Toolkit* (NLTK)[3] [4][5]. NLTK is a suite of open source Python modules for natural language processing. The solution presented in this paper used the implementation of the naive Bayes classifier found in NLTK.

III. Solution Architecture

The presented solution to the *StackExchange* question classification problem consists of two separate programs shown in Fig. 1. The *Classifier Generator* (called simply the *Generator* in the remainder of the paper) is executed locally and generates the source code of the *Classifier*.

[3] http://nltk.org

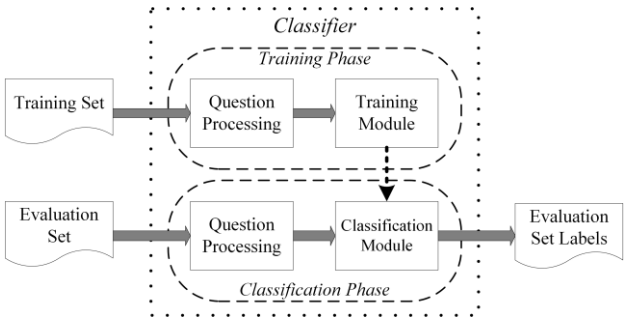

Figure 2. The architecture of the *Classifier*.

The *Classifier* is then submitted to the *HackerRank* server for preliminary evaluation where it is executed on a small question set to make sure that it can run within the evaluation environment.

This organization of the solution allows quick exploration of different options in question processing and representation with frequent submissions for preliminary evaluation. This is essential as it provides feedback on the exact effect of changes in the classifier on the classifier's execution time in the actual evaluation environment.

The architecture and the roles of the *Classifier* and the *Generator* are discussed in detail in the next two subsections. As the *Classifier* is significantly simpler, it is discussed first.

A. Classifier Architecture

The architecture of the *Classifier* program is shown in Fig. 2. Of the two classifier training options mentioned in Section II, the solution presented in this paper is based on the latter option in which the classifier is trained in the evaluation environment. Therefore, the operation of the *Classifier* can be divided into two phases shown with dashed ovals in the figure: the *training phase* and the *classification phase*.

The common process in both phases is *question processing*. Questions are represented in the classifier with a *bag of words* model, which is frequently used in text classification and text processing in general [6]. A bag of words model removes the notion of sequence order from a piece of text, focusing instead only on the word content.

The process of converting the classifier input into this model can conceptually be decomposed into four steps. First, as both training and evaluation questions are given to the classifier in *JavaScript Object Notation* (JSON), they are parsed into an internal format. Second, the question title and body text are merged into a single string that is normalized by replacing punctuation and other special characters with spaces and by converting all letters to lower case. Third, the resulting string is split into *words*, where a word is defined as a continuous sequence of non-whitespace characters.

Finally, in the fourth step, the word list is filtered to only include words that were selected as *features* which is then the final question representation. As the set of features is chosen in the *Generator*, this final step is discussed in greater detail in Subsection III.B.

Question processing is intentionally kept simple to increase efficiency as the classifier must process a large number of questions in a short amount of time. Specifically, neither *stemming* [7] nor *lemmatization* [6] are used. Stemming typically removes affixes from words to create a stem that might not be a word itself, while lemmatization attempts to reduce all of the morphologically different instances of a word to one canonical word. An attempt to use the lemmatizer that is part of NLTK increased the question processing time almost threefold so it was removed from the solution early in the development process.

In the training phase, the processed questions with the given correct topic label are given to the *training module* which generates the *classification module*, as indicated by the dashed arrow in the figure. In the classification phase, the processed questions are given to the classification module which assigns a topic label to each question.

The interface of the *Classifier* is shown with a dotted square in Fig. 2. The *Classifier* takes two input files containing the training question set and the evaluation question set and outputs the topics for the questions in the evaluation set.

The training and classification modules are based on the *naive Bayes classifier* that is briefly described in the remainder of this subsection. Although a more complex classifier model like *Support Vector Machines* (SVM) would potentially yield higher accuracy [8], the training time of such models is typically significantly higher [9][10] and requires more tuning to achieve peak accuracy than the naive Bayes classifier. Both of these characteristics significantly contributed to the choice of naive Bayes, and as it performed well and due to time constraints, other models were not tried.

1) Naive Bayes Classifier

The naive Bayes classifier [11] is based on the idea that training examples can be used to estimate the probability that an example belongs to a certain class. Given an example to classify, the classifier then selects the class that is estimated as the most likely to contain the example.

Examples are encoded with a tuple of values of predefined *features*, where each feature can have some value drawn from a finite set. In the context of text classification, features are words from the text.

It is important to note that *equality* is the only relation defined on the value set of a feature. Specifically, no two values of a feature are more different than any other pair of values. Therefore, the intuitive word frequency value set has the problem that a piece of text with 50 occurrences of a word is modeled as equally different from a piece of text with 49 occurrences of that word and one with no occurrences of that word.

Due to this fact, the solution presented in this paper is based on the bag of words model where features are words from the questions and their values are binary. Specifically, a particular feature has the value one if and only if that word occurs in the question at least once and possibly many times, and otherwise has the value zero.

Let the set of question classes be C, and C_i be the ith class in some fixed order over C. Similarly, let the feature set be F with F_i denoting the ith feature. Examples are then represented with an n-tuple $(v_1, v_2, ..., v_n)$ where v_i is the value of feature F_i and n is the cardinality of the feature set.

When classifying an example, we would like to determine which class attains the maximum conditional probability $P(C_i \mid v_1, v_2, ..., v_n)$, where the condition is a conjunction of events that the example either contains a word or it doesn't. Formally, the given example $(v_1, v_2, ..., v_n)$ would be classified in the class

$$c = \text{argmax}_{Ci}\, P(C_i \mid v_1, v_2, ..., v_n). \quad (1)$$

The naive Bayes classifier introduces a strong assumption that feature values are independent given the class. Using this independence assumption and Bayes' rule, (1) can be rewritten into

$$c = \text{argmax}_{\text{Ci}}\, P(C_i)\prod_j P(v_j \mid C_i). \quad (2)$$

The $|C|$ prior probabilities $P(C_i)$ and the $n|C|$ likelihood parameters $P(v_j \mid C_i)$ can be estimated from the labeled training data. The intuitive maximum likelihood estimator which would assign the ratio of the number of training examples from class C_i that have the feature value v_j and of the total number of examples in class C_i to $P(v_j \mid C_i)$ overfits the training data. Specifically, the fact that a certain feature value never appears in a class in the training data is made universal by assigning the value zero to the corresponding parameter of the classifier. Consequently, no example with that feature value can ever be classified into that particular class.

A simple way to address this limitation is to introduce *smoothing*. The NLTK implementation of the naive Bayes classifier uses *Laplace smoothing* which can be thought of as the maximum likelihood estimator in a training set that is extended with one example for each possible feature value and class pair.

Finally, in practical computer implementations, (2) is replaced with

$$c = \text{argmax}_{\text{Ci}} \left[\log P(C_i) + \sum_j \log P(v_j \mid C_i) \right]. \quad (3)$$

This transformation is done primarily to avoid working with very small real numbers that result from multiplying many potentially small likelihoods which can cause precision issues and even floating point underflow.

B. Generator Architecture

The logical organization of the *Generator* is shown in Fig. 3. The *Generator* takes two question sets as input: the *feature selection set* and the previously discussed *training set*. The output of the *Generator* is the source code of the *Classifier* that can immediately be submitted for evaluation on the competition server.

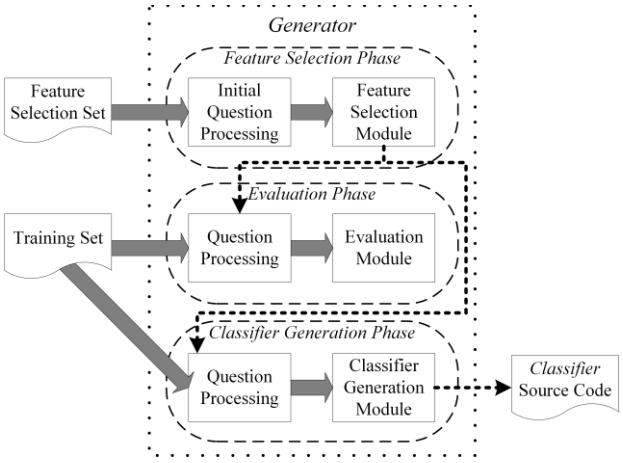

Figure 3. The architecture of the *Generator*.

As shown in the figure, the functionality of the *Generator* can be grouped into three phases which are described in the remainder of this subsection.

1) Feature Selection Phase

In the simplest implementation of a naive Bayes text classifier, all the words appearing in examples could be used as features. However, this choice would lead to two significant limitations. First, by observing (3), it is obvious that the time complexity of example classification scales linearly with both the number of features and the number of classes. Furthermore, the number of parameters that need to be estimated in the classifier training phase similarly increases linearly with the number of features and classes. As the number of classes is typically a parameter of the problem and can't be changed, choosing a smaller number of features is the only way to increase classifier computational efficiency in this model.

Second, many words that appear often in natural language are completely independent of the class to which some text belongs. Typical examples of such words are pronouns and conjunctions. Including such words as features only makes the classification problem harder as they decrease the relative differences between the computed probabilities for each class.

When selecting words as features, we would ideally like to select words that make it possible to distinguish examples from different classes in the general problem domain and not only in the training set. Choosing features that might provide very high accuracy on the training set but fail to generalize to other examples in the problem domain is an instance of the *overfitting problem* [12].

Avoiding overfitting is especially challenging when the training set is small. While there are techniques that successfully deal with this challenge even for small data sets, it is typically better to get more data if possible. As *StackExchange* publishes the whole question set on a quarterly basis, getting more examples is easy.

Therefore, the feature selection question set was generated from the two latest quarterly sets of questions covering the first half of 2013 [4]. From the total downloaded question set, 160 thousand questions were selected at random while preserving the relative frequency of topics to be approximately equal to that of the training set provided in the problem statement. The selected question set was further partitioned into 120 thousand questions for training during feature selection and 40 thousand questions for evaluating the classifier with the selected feature set.

The feature selection phase of the *Generator* consists of *initial question processing* and the actual *feature selection*. Initial question processing in the feature selection phase differs from question processing in the *Classifier* and other phases of the *Generator* in that words can't be filtered as the features have not yet been chosen. Instead, after the question has been split into words, the generator eliminates *stop words* from the question representation. Stop words are ideally words that frequently appear in language and don't help the classification process. In total, 519 words were chosen as stop words using an iterative semiautomated process where the most frequent remaining words were displayed and suggested for removal.

After stop word removal, the remaining least frequent words in the whole set of 120 thousand questions was removed from question representations so that the feature set was reduced to 150 thousand words. With 150 thousand features and 120 thousand training examples, the *Generator* took up to several minutes to train the naive Bayes classifier which is acceptable as this is done locally. This step is essential for feature selection as the resulting *Classifier* needs to use a significantly smaller feature set to meet the efficiency limits of the evaluation environment.

NLTK provides a method *most_useful_features(n)* on a trained naive Bayes classifier which returns the *n* feature values that are estimated to be the most useful for classification given the training set. The usefulness of the feature value v_j is estimated as

$$\frac{\max_{Ci} P(v_j \mid C_i)}{\min_{Ci} P(v_j \mid C_i)}. \qquad (4)$$

In words, the usefulness of the feature value v_j is equated with the ratio of the maximum and minimum likelihood that this feature value appears in any class. If this ratio is large, the feature value v_j is useful for discriminating between examples in the two classes in which the maximum and minimum likelihoods occur.

When features are binary, the usefulness estimate of the two possible values are inverses of each other because the class in which the maximum likelihood is achieved will have the minimum likelihood of the opposite value and vice versa. Therefore, to identify the most useful features, it is sufficient to simply ignore the value of the features returned by the NLTK method. For example, the five most useful features identified by this measure were *squared, code, pre, validity* and *data*.

The chosen set of features is then used in question processing in the remaining phases of the *Generator*. This

[4] http://www.clearbits.net/creators/146-stack-exchange-data-dump

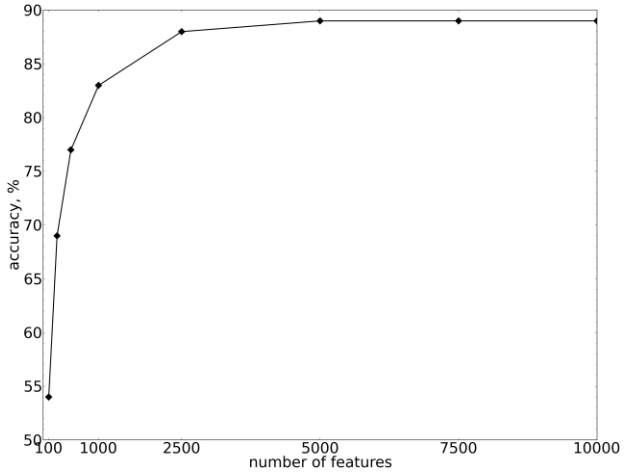

Figure 4. The effect of the number of features on the accuracy of the classifier trained on a set of 16000 questions and evaluated on a set of 4000 questions.

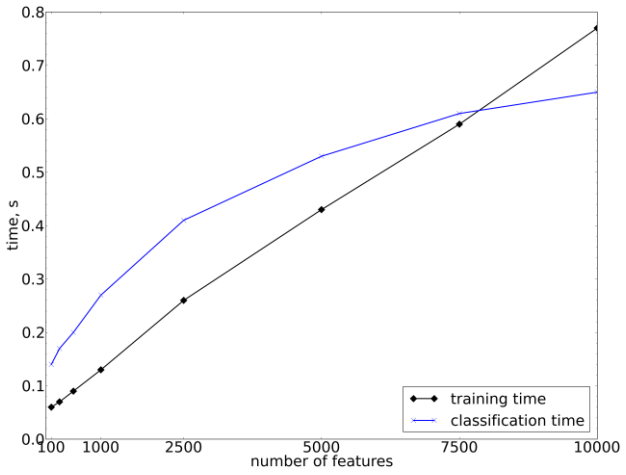

Figure 5. The effect of the number of features on the training time and classification time of the classifier trained on a set of 16000 questions and evaluated on a set of 4000 questions.

transfer of information is shown with dashed arrows entering the question processing modules in Fig. 3.

2) Evaluation Phase

Once a smaller set of features is selected in the feature selection phase, the classifier is retrained and evaluated on the set of 40 thousand evaluation questions. Through about ten iterations of this process, the final number of features was set to 5000. The effect of the number of features on several key properties of the *Classifier* is analyzed in Section IV.

Additionally, although the large feature selection question set significantly reduces the threat of overfitting, it is necessary to check if the selected features actually work well for the question set given to the contestants as part of the problem statement. This is important as questions in several topics are very time dependent and features selected for one time period might not perform well in another time period. To actually estimate the accuracy that the classifier will achieve on the hidden evaluation question set in the evaluation environment, the selected feature set is therefore evaluated using the question set provided in the problem statement.

Specifically, the provided question set is split randomly into 16000 training questions and 4000 evaluation questions. A new classifier is then trained using the selected features and evaluated on the evaluation set.

3) Classifier Generation Phase

The final task of the *Generator* is to actually create the source code of the *Classifier* that can be submitted for evaluation. To enable question processing, the *Classifier* needs the set of features selected in the feature selection phase. The feature set is inserted into the *Classifier* source code using the *pickle* serialization module in Python. Specifically, the data structure representing the feature set is serialized into a string that is compressed and *base64* encoded into the source file. The *Classifier* undoes this process during initialization.

A similar approach can, in theory, be applied to the trained classifier object itself to avoid the training phase during evaluation. However, this was not practical as the serialized and compressed classifier object was large (slightly under 2MB) and its decompression and deserialization took longer than actually training the classifier.

To further optimize the training phase of the *Classifier*, the processed training questions are also serialized into the generated source code. This basically eliminates the question processing step in the training phase described in the previous subsection.

IV. Implementation Details and Evaluation

In this section, we analyze the effect of the number of features on the accuracy and efficiency of the *Classifier*, and discuss some implementation details that were important for achieving the required performance. The analysis was done on the training file provided by *HackerRank* split into a set of 16000 training questions and 4000 evaluation questions. Feature selection was done in the *Generator* using the much larger question set, as described in the previous section.

The effect of the number of features on classifier accuracy is shown in Fig. 4. With a hundred features, classification accuracy is only 54% and grows quickly up to 88% with 2500 features. With 5000 features, the accuracy increases further by 1% and remains constant if more features are used. This graph is a clear indication that 5000 features was an appropriate choice for this problem and classifier model in terms of peak accuracy.

The efficiency of the *Classifier* is significantly impacted by several implementation details. Using the *cProfile* Python profiler on the *Classifier*, we found that almost 30% of run time in the initial implementation was being spent on string processing and manipulation. The simplest way to represent both features and classes in the classifier is to use strings, and this is also the suggested representation in NLTK's tutorials. However, this representation is inefficient both in terms of run time and in terms of the size of the trained classifier. This issue was addressing by mapping all strings to numbers that were then used throughout the *Classifier*. This is a particular

implementation of the general idea of *string interning*. With this change, the execution time of the *Classifier* decreased by around three times and the size of the serialized features and examples decreased up to five times. This ultimately made it possible to increase the number of features from 1000 to 5000 which corresponds to an increase in accuracy of more than 10%.

The change of the training and classification time with different feature set sizes is shown in Fig. 5. The graphs show the mean of five experiments for each data point. Only relative changes should be considered as the actual times on the y-axis were measured for a smaller set of questions than the actual hidden evaluation set, and all experiments were done locally and not on the evaluation server.

As the naive Bayes classifier needs to estimate $n|C|$ parameters during training, the nearly perfect linear dependence of training time with the number of features n is expected. However, the fact that classification time grows sublinearly is surprising as by (3) the naive Bayes classifier needs to add $\Theta(n|C|)$ logarithms which is clearly linearly dependent on the feature count n.

The explanation for this behavior stems from the interplay between the used example representation and the implementation of the naive Bayes classifier in NLTK. As the *Classifier* needs to prepare over 20 thousand training examples, it is impossible to represent every example with all 5000 features. NLTK expects examples to be represented with a feature-value map (a *dict* in Python) which is very inefficient for binary features. Due to this fact, questions were represented with a map that contained only those features with the value 1, i.e. only those feature words that were actually found in the question. However, when classifying examples, the naive Bayes classifier in NLTK simply ignores those features that are not present in the map, and therefore only adds the log-likelihoods of 1-value features. Features added beyond the first 2500 or so are rare words that are therefore not frequently found in example representations and this causes classification time to grow sublinearly.

A similar effect of increasing the number of features can be observed on the sizes of the serialized and compressed feature set (which grows linearly) and processed training question set (which grows sublinearly).

V. Conlusion

In this paper, we've described one solution to the *StackExchange* question classification problem posed in an online competition hosted by *HackerRank*. As the classifier was developed in a competition environment, special attention was given to efficiency, both in the training and the classification phase. The final version of the classifier with 5000 features took 13 seconds to process the evaluation set which fit comfortably within the 16 second time limit.

In terms of accuracy, the classifier took 8th place out of 44 solutions in the competition with 89.46% accuracy on the hidden evaluation set, while the winning solution achieved 92.13%. By using a custom implementation of the naive Bayes classifier it would be possible to significantly reduce the classifier's run time by using a more efficient representation of examples with binary features. This would free up processor time for other improvements, primarily for correctly computing topic assignment probabilities without disregarding 0-value features. Additionally, the method used for feature selection is fairly simplistic, and better feature selection algorithms could be used to potentially increase accuracy or decrease the number of features required for peak accuracy.

A more detailed analysis of accuracy shows that the classifier underperforms on questions in the *apple* (79%), *mathematica* (82%) and *unix* (82%) topics. Searching for features that might increase accuracy for these topics is the most likely avenue for improving the classifier's accuracy with the least amount of additional effort.

Based on the described experience with this classification problem, it can be concluded that it is possible to develop an accurate and efficient text classifier for nontrivial problem domains in only several hours of development time.

Abstract - Knowledge representation is one of the areas covered by artificial intelligence. One of the methods for graphical representation of text expressed knowledge is the method NOK (Nodes Of Knowledge). NOK method enables transformation of text expressed knowledge into a graphical network of words and group of words. In this paper application of NOK method is presented. This application is based on sentences from an Aesop's Fable in Croatian ("Golden eggs in the chicken") and English ("The Goose with the golden eggs") version. In this way the applicability of this method on two natural human languages is presented, and similarities and differences that are partially conditioned by freedom of translators, and not only by differences in the syntax of the two languages, are observed.

Key words: Node Of Knowledge, Text-based knowledge representation, Network-based knowledge representation.

I. INTRODUCTION

AI studies computational modelling of human intelligence. Intelligent behaviour is conditioned by knowledge – human act based on what they know (or believe) about the world [1], [2]. One of the fields of interest of AI is knowledge representation and reasoning, which is suitable for reaching artificially intelligent behaviour. Many methods of converting knowledge into a form that can be encoded on a computer have been developed and they are applicable to different types of knowledge [3], [4].

Graphical method Nodes Of Knowledge designed for the presentation of sentences written in natural language is applied in this paper [5]. The formalization of this method is shown in [6]. The possibility of its application has been demonstrated on one text in Croatian and English. By analyzing produced graphic presentations answers to the following questions were obtained: Is there a difference in the complexity of making diagrams, which model is more complex, can answers to the same questions be read from both diagrams, regardless of differences in translation, are there any questions applicable on one model only and how can this problem be solved.

II. REVIEW OF RELEVANT PUBLICATION

In the field of artificial intelligence different approaches to knowledge representation formalisms are defined [2], [3], [7]. Conceptual graphs [8], [9], [10], semantic networks [11], frames [12] and predicate logic [13] are traditional formalisms that eventually produced numerous other formalisms and methods for knowledge representation. Ontologies have had a significant impact in the field of knowledge representation in the past twenty years [14], [15], [16]. They emphasize the semantic components of knowledge and language [17]. Furthermore, the field of computer analysis of natural language (NLP) is also involved in the formalization of knowledge expressed in language and text [18], [19], [20], [21], [22], [23], [24], [25], [26], [27].

There are two approaches to the formalisation of text-expressed knowledge: declarative and procedural. Examples of declarative approaches are: BG (Basic Conceptual Graphs) [28], MULTINET (Multi-layered extended semantic networks) [29], HSF (Hierarchical Semantic Form) [30], RDF (Resource Description Framework) [31], and other methods based on the first order predicate calculus (FOPC). The result of the procedural approach is a rule system.

III. RESEARCH MOTIVATION

Text as a knowledge carrier is not suitable for computer-supported knowledge dynamics (changes, paraphrasing, distribution, use, generation of new knowledge, abandonment, etc.). It should be specially formatted - formalised - in order to enable a computer to perform mathematical/logical operations. Nodes of Knowledge (NOK) method is a new method by which sentences written in natural language can be modelled. The purpose of graphical modelling sentences with NOK method is the creation of models (formal representation) of different forms of sentences (declarative, interrogatory, simple, complex, etc.) in order to verify the basic concepts of the method. Designed models and their verification represent the basis for the development of mathematical formalism for knowledge representation and reasoning based on a NOK method - first formalism is shown in [6].

The aim of this paper is to model the same text in two languages, English and Croatian, compare derived models and notice similarities and differences in the model that are conditioned by the freedom of translators.

IV. NODES OF KNOWLEDGE

NOK method belongs to a group of semantic networks [11] where knowledge is represented as a graph [32]. Its

aim is to present textual knowledge as a network of knowledge [29].

NOK is a method for modelling by which textual knowledge is represented graphically in the form of a diagram DNOK (Diagram Nodes Of Knowledge) [33]. Sentences written in human language are converted to graphical model from which it is possible to interpret the meaning because this model kept it. NOK method consists of nodes (node, processing node and linker) and connections between them which contains the role identifier and they together form a network of knowledge.

Characteristics of the NOK method are [5]:

- simplicity – it has only three elements: nodes, links and the role identification in link
- expressiveness – ability to represent different levels of abstraction
- simplicity of reading – it is possible to start reading knowledge from any node

A. *Nodes*

Node represents a word or group of words in a sentence that has some meaning. For example, in the sentence "The toy is very old." nodes are: The toy, is, very, old. Graphical representation of nodes and concepts in the NOK method is given in Table I.

Node name is an attribute of node and it gives it semantic meaning. The name may also consist of several words that have a meaning. To implement the method it is necessary to appoint a node name that clearly identifies it in the network. Homonyms and synonyms can be used [32], [35] but should be linked to their originals on contextual level of knowledge.

We can distinguish between [34], [35], [36]:

- Node – ordinary, static, entity, concept, term
- Context node – node of a higher degree of abstraction (group, sort, class, type)
- Data node – place where data are kept
- Process node – node that connects other nodes (using links) and with them creates a more complex presentation of knowledge. It presents knowledge that cannot be displayed by ordinary node such as connections between multiple nodes. The most common types of words in the names of process nodes are verbs.

B. *Links*

Links connect the nodes in the network of knowledge. They do not have names, but may have role identifications that belong to the nodes [35]. The names of role identifications are questions which connect two adjacent nodes. This link is represented with line, with or without arrows. Arrows are used when connecting nodes on different levels of abstraction [33] or for direct connection of process nodes.

The cardinality of a link is always (1, 1) (1, 1) [35].

TABLE I. SYMBOLS OF NOK METHOD

Simbol	Concept
goose	NODE - part of the knowledge in the reality or minds
1. going	PROCESSING NODE - action, event, occurrence
to	LINKER – complex sentence of more parts
What?	LINK (one-way) and QUESTION (role indentifier) – connecting nodes

V. MODELLING OF SENTENCES

Using the NOK method sentences of natural language can be displayed by using nodes and links between them. From the resulting model, without access to the original text, answers to asked questions can be obtained. The applicability of NOK method will be shown in Croatian and English language on the example of the same Aesop's[1] fable „Zlatna jaja u kokoši“ [37]. The fable is titled "The Goose with the golden egg" in English [38].

For modelling sentences from the fables the symbols shown in Table I were used. Specifying the nodes, processing nodes and linkers, when there was a need for them, and connecting with links which were assigned the role and the meaning of nodes with questions in sentence, both graphic representation were constructed, in Croatian (Figure 1.) and in English (Figure 2.).

Fable „Zlatna jaja u kokoši“ in Croatian has the following 4 sentences:

1. „Neki gospodar imao je među mnogim svojim kokošima i jednu takovu koja je nesla zlatna jaja.
2. On je mislio, da joj u trbuhu mora biti mnogo zlata, pa je, ne razmišljajući mnogo, zakolje.
3. Ali se ljuto prevario, ne našavši u njoj ništa drugo nego li i u ostalim kokošima.
4. Tad se uzalud sam korio što je bio lud, da se polakomio za mnogim blagom, pa tako izgubio i ono što je imao.“

The same fable, "The Goose with the golden egg", in English according to [38] has sentences as follows:

1. „One day a countryman going to the nest of his Goose found there an egg all yellow and glittering.
2. When he took it up it was as heavy as lead and he was going to throw it away, because he thought a trick had been played upon him.

[1] Aesop (620 - 560. BC.), slave and storyteller who lived in Ancient Greece

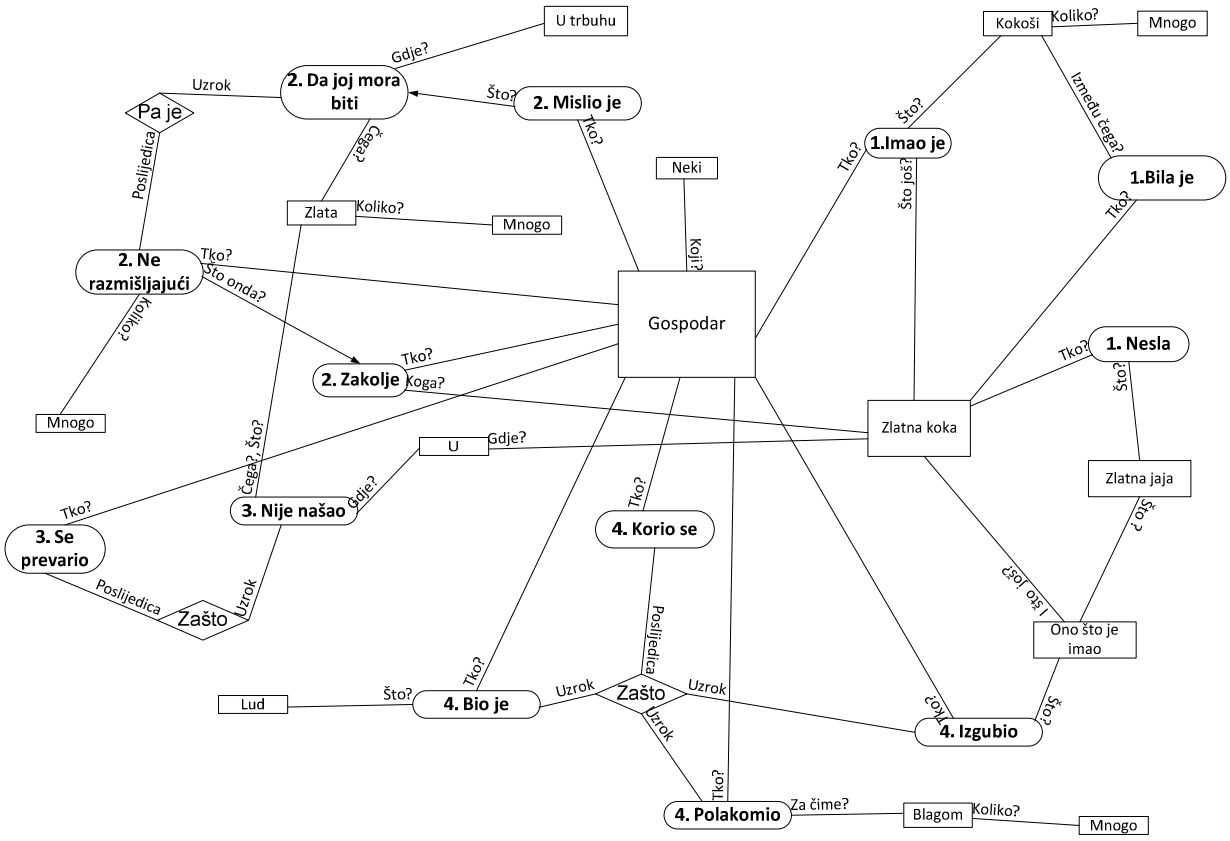

Figure 1. Representation of the fable “Zlatna jaja u kokoši” by NOK method

3. But he took it home on second thoughts, and soon found to his delight that it was an egg of pure gold.
4. Every morning the same thing occurred, and he soon became rich by selling his eggs.
5. As he grew rich he grew greedy; and thinking to get at once all the gold the Goose could give, he killed it and opened it only to find nothing.“

From the number of sentences, or words and groups of words in them, it is obvious that it will be more complex to make diagrams of the English version of the fable as it will consist of more nodes and connections between them.

In complex sentences, and between several separate clauses occurs causal - consequence relationship between certain parts that is displayed by using a linker node "why" which connects the causes and consequences. There is a possibility of multiple causes and / or consequences which determines the complexity of the model.

C. *Interpretation rules*

In the sentence modelling the following rules are applied:

- Each noun becomes a node
- Each verb becomes a processing node
- Each node represents a single term that can consist of a group of words (eg. „zlatna jaja“, „was going to throw“)
- Each node must be linked to at least one node
- Process node is numbered by the number of sentence from which it was taken
- Pronouns are eliminated and the related network is connected with the noun to which eliminated pronouns refer.
- Related actions are connected with a rhombus, and this connection represents cause-and-effect relation.
- Node relationships are identified by questions that determine the semantic connections between nodes.

D. *Comparison*

At first sight it is evident, by comparing the texts of the fable, that there is a difference in the translation which is determined by customs, folk tradition and the environment for which it is intended and, naturally, by the autonomy of translators. The title itself reveals a difference in choosing the animal which lays the golden eggs: it is a hen in the Croatian version and a goose in the English one.

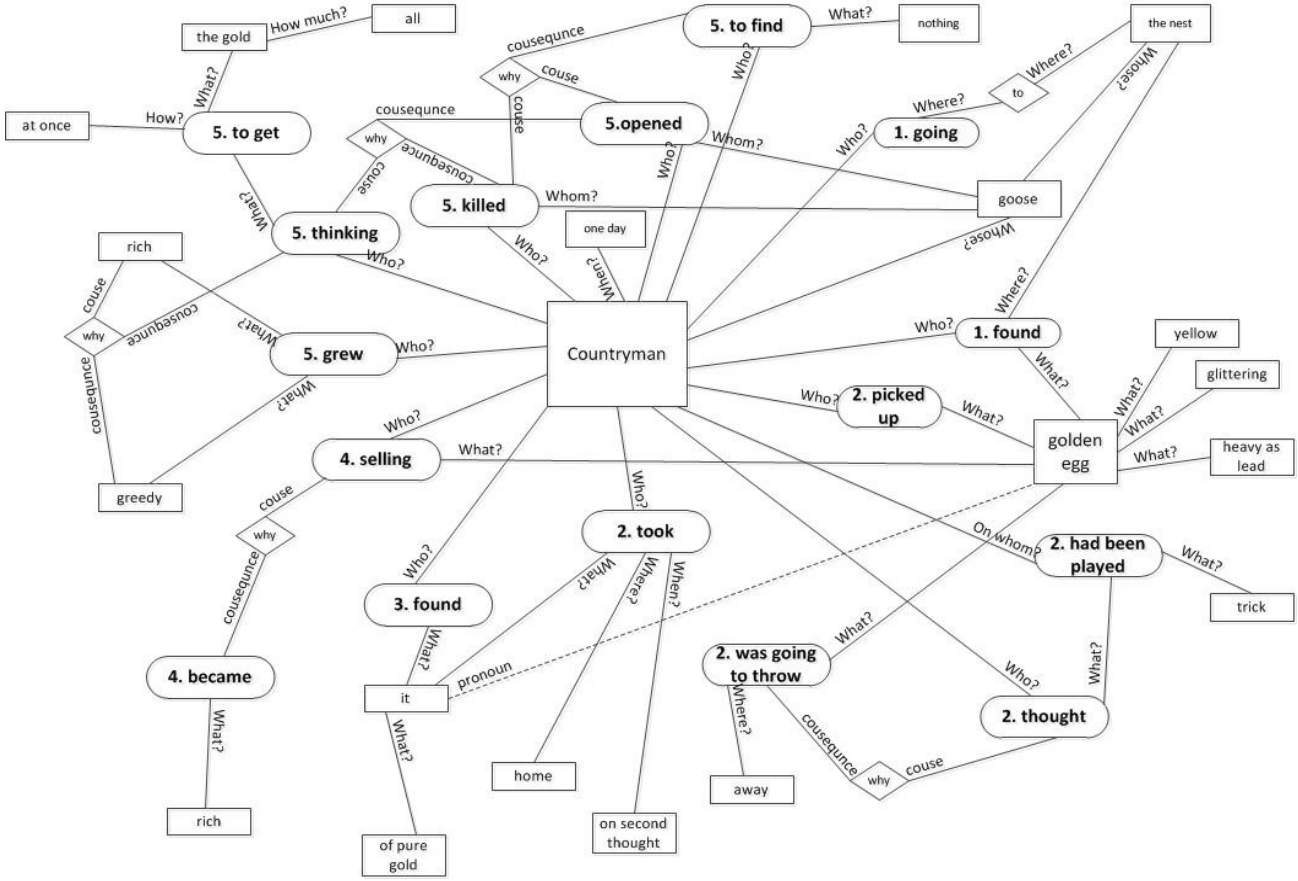

Figure 2. Representation of the fable “The Goose with the golden egg” by NOK method

From this we can conclude that translation is not a mathematically rigorous mapping of terms in one language in the same terms in other language. Also, two different translators will not translate the same text in the same way. Therefore translation does not provide a single best solution. Translators believe that their translation preserves the message and knowledge that the author wanted to convey to the reader.

Despite this, the fable has the same moral and is told in a similar way. This means that the knowledge on the high level of abstraction contained in the fable can be stored in both languages in a different way. This brings us to the conclusion that it is possible to keep text-based representation of the knowledge in a variety of models.

The diagram (Figure 1. and 2.) shows a difference in the presentation. Difference in the complexity of its construction is also evident. English translation of the fable is more complex in terms of the number of nodes and links that are displayed. The English version consists of five, and Croatian version of four sentences. Depending on the number of verbs, ie process nodes, each of these sentences can be divided into simple sentences in which difference becomes even greater. This is evident by the numbering of process nodes on the diagrams (Figure 1. and 2.) that indicate the number of the sentence where the node is.

What is significant for NOK method is getting answers to questions from the both created model. If we ignore the hen/goose difference in translation, we can get similar or the same answers to the same questions from the model, even though the arrangement of nodes in each model is different: for example, who laid the golden eggs?, who was greedy? (Figure 3.), who butchered the hen / goose? etc. On the other hand, there are questions applicable to one model only (for example, English version: who found the golden egg?, who is going to the nest?; Croatian version: who laid the golden egg?, who lost what he had?).

In the graphical representations of fables with NOK method contextual connections between the terms in the text are also recorded. In both versions, there are sentences without explicitly listed content-related terms. For example, in the following part of sentence "he killed it and opened it only to find nothing," one concludes from the context that this refers to the countryman and the goose, and the diagram supports that because the connections between nodes 5. killed, countryman and goose preserved it (Figure 2).

VI. Conclusion

In this paper the same fable in two languages translated by two different authors was presented. For these translations a knowledge network was made, by using the NOK method.

NOK method is applicable to the modelling of a sentence written in a variety of natural human languages.

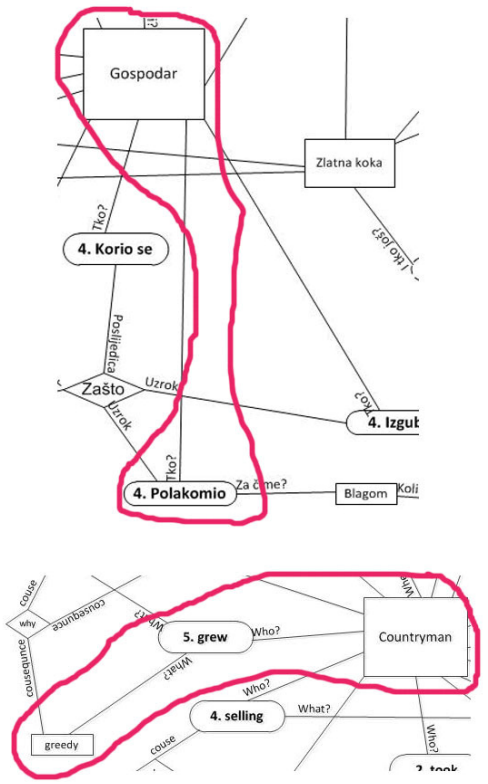

Figure 3. Answer to the question "Who grew greedy?"

Regarding the translator's autonomy, some parts of the model remain similar, but in some parts there are differences in the same story and in the same sentences.

By translating and merging of different models, not just by modelling of translation, we can get the model in different language from which it is possible to get the same meanings.

Choosing texts that are more similarly translated could provide a model with greater overlapping. Furthermore, it is possible to measure the difference in models and translations by a number of used concepts and words. It is possible to explore how NOK method can be used to translate texts and improve the process of translating one language in the DNOK and vice versa. NOK method is a new method for knowledge representation and it yet remains to investigate how it keeps knowledge and what its potential in building a computer system is.

ACKNOWLEDGMENT

The research has been conducted under the project "Extending the information system development methodology with artificial intelligence methods" (reference number 13.13.1.2.01.) supported by University of Rijeka (Croatia).

Abstract— **With the development of internet technologies and communication services, message transmissions over the internet still have to face all kinds of security problems. Hence, how to protect secret messages during transmission becomes a challenging issue for most of the researchers. It is worth mentioning that many applications in computer science and other related fields rely on steganography and watermarking techniques to ensure information safety during communication. In this paper, we propose a new steganographic method to embed the secret data inside a cover image based on least-significant-bit (LSB) replacement method. The embedding process predominantly concentrates on distributing the secret message inside one share of a color image to appear like a 3D geometric shape. The dimensions of the geometric shape are variable pursuant to the size of secret message. Data distribution process makes our method to be of a great interest as of being so difficult for the hackers or intruders to reconstruct the shape from stego-images, thereby the security is improved. Furthermore, we compare the performance of our approach with two other relevant approaches in terms of peak signal-to-noise ratio (PSNR). The contribution of our approach was immensely impressive.**

Index Terms— **Cover image, stego-image, geometric shape, least-significant-bit (LSB), security, imperceptibility**

I. INTRODUCTION

Due to the fast growth of internet applications, digitized data becomes very prevailing bearing in mind that the internet does not use secure links. Hence, data needs to be transmitted may be vulnerable to interception as well. As indicators of its importance, intruders may not only reveal transmitted data to others, but also modify it to give a false idea of an individual or organization or even use it to launch attacks. Owing to the easiness of digital duplication and tampering, data security becomes a challenging matter for most of researchers nowadays. One of great interest solutions is the use of information hiding which encompasses many sub-disciplines, out of which steganography and watermarking [1-7].

There are many watermarking techniques proposed in the spatial domain [8-23]. Among these implemented watermarking techniques, the following are some of interesting and relevant schemes: Pixel-value differencing (PVD) and PVD cascaded with least-significant-bit (LSB). In PVD approach [8], the cover image is simply portioned into non-overlapping two-pixel blocks. The difference between each two consecutive pixels of any block determines how much data can be embedded. In other words, small and large differences denote for working at pixels located in smooth and edge image regions and tolerate small and large changes in their values, respectively. The authors proposed a range table that contains all possible differences in the whole image region in which the selection replies on the sensitivity of human vision to gray value variations. The main goal of doing this is to keep the resulting stego-images unnoticeable. For interested readers, further details can be found in [8]. In [9], both PVD and LSB substitution method have been cascaded for the reason of obtaining more hiding capacity. After embedding using PVD approach, the idea proposed in [9] simply encompasses embedding using LSB method in the first pixel of each pixel pair (block). The distortion, made by LSB method, is then adjusted through modifying the second pixel of that block in a way that the difference between pixels, calculated from PDV approach, is kept.

Taking advantage of LSB scheme, we propose, in this paper, a very efficient watermarking approach. In this approach, the watermark is constructed on the form of a geometric shape that appears like a 3D house in which its dimensions are variable and depend on the size of secret data. The media used is colored images. To the best of our knowledge, this is brand new idea and no prior work similar to ours. However, the house geometric shape is divided into four areas where all are included in the embedding process as will be discussed shortly. For comparison purposes, the red share is used each time to embed the data according to the pixel area bearing into consideration that our approach is flexible to accept incorporating all shares in the embedding process. It is noteworthy to mention that our approach fulfills the security watermarking evaluation objective. In other words, the house geometric shape makes the emission of the attacker harder due to the endless effort needed to find the equations of the house required to find the watermark. The secret bits per pixel (embedding depth) are chosen up to five bits and this is to

conserve the transparency and capacity evaluation objectives. Apart from that, our scheme falls within spatial domain category. Hence, the payload (hiding capacity) is considered to be high compared to those schemes proposed in either transform or quantization domains. Due to changing only one share byte of the pixel at a time and having the size of the house variable pursuant to the size of watermark, the imperceptibility (i.e., the closeness of visual quality between the original and watermarked images) is achieved. As no need, in our watermarking approach, to convert the image into different domains (frequency/quantization) or different spaces (e.g., gray-scale) and there is no heavy computational operations such as multiplication and division required on pixels, the computational time is low. Furthermore, since there is no need for the original image or its features to be present in the exaction phase, our watermarking technique is blind. Additionally, our watermarking technique is a standalone since it is not combined with another transform- or quantization-based watermarking algorithm which makes it easier to improve and modify.

The remainder of the paper is organized as follows. The proposed watermarking approach is elucidated in Section II. Experimental results along with observations and necessary discussions are presented in Section III. The paper is summarized in Section IV.

II. Proposed Approach

The secret data is embedded in color images in the guise of a 3D geometric shape. The embedding occurs in the least significant bits of the red share. The size of this geometric shape is variable according to the secret data size and embedding depth which represents the number of secret bits that need to be inserted and is chosen to be five to maintain the imperceptibility. In order to have a variable shape of the watermark inside a digital image, we should be aware of the following points:

1. Finding the number of pixels needed, which is equal to the ceiling of watermark size (in bits) divided by the embedding depth,
2. Finding the areas entailed to hide the watermark where the overall area indicates the number of needed pixels found in point 1. As seen in Fig. 1, the variable shape is divided into four different areas where each area is calculated with respect to $Area_1$ as the following: $Area_2 = 0.25 * Area_1$, $Area_3 = 0.25 * Area_1$, as well as $Area_4 = 0.125 * Area_1$. It is important to mention that the factors of $Area_1$ (i.e., 0.25, 0.25 and 0.125) are selected according to a specific engineering model that takes into consideration maximizing most of performance objectives, mentioned previously, required for evaluation. Consequently, we can embed in $Area_1$ up to (8/13) times the number of pixels required.

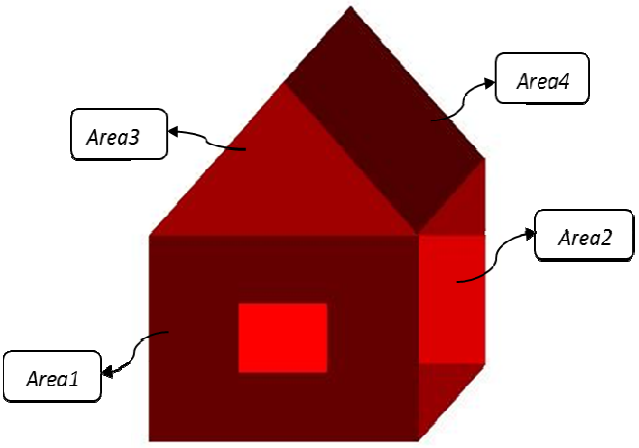

Figure 1. The geometric shape of proposed approach

A. The embedding procedure

On account of being easily applied for gray-scale images and comparing its performance with other pertinent proposed watermarking algorithms, we consider in our work embedding in just one share of the image which is settled on red bearing in mind that involving all images shares may be better for enhancing the security objective. However, Fig. 2 describes the strides entailed to construct the geometric shape that professes to be the watermark. Interestingly, the pixels located in $Area_2$ and $Area_4$ will involve embedding in the semblance of a parallelogram. Similarly, the shapes of triangle and rectangle will be formed if the pixels located in $Area_3$ and small and big windows of $Area_1$, respectively. To improve the security, we start embedding the secret data in the small window and the rest will be resumed in the big window but in the opposite direction. After that, the embedding will recommence in $Area_2$, $Area_3$, and $Area_4$ in sequence. It is good to stress on the point made to improve the imperceptibility that if the secret data is embedded in any pixel of the red share, then the same pixel at the corresponding positions of the other shares will not be affected (immutable). However, after embedding the secret data, the resulting shape will look like a 3D house as shown down in Fig.2. However, the geometric shape is invisible in the watermarked image.

III. Results and Discussions

Our experiments have been conducted using Matlab version 2010R on a PC with an Intel Core i5-2400 CPU working at 3.1 GHz with a 4MB cache and 4 GB RAM. In our experiments, five cover images, which include *Lena*, *Peppers*, *House*, *Couple*, and *Baboon*, were used, each with a size of 512x512. To evaluate the performance of our proposed watermarking scheme to be then compared with what are closely connected in the literature, namely PVD and PVD

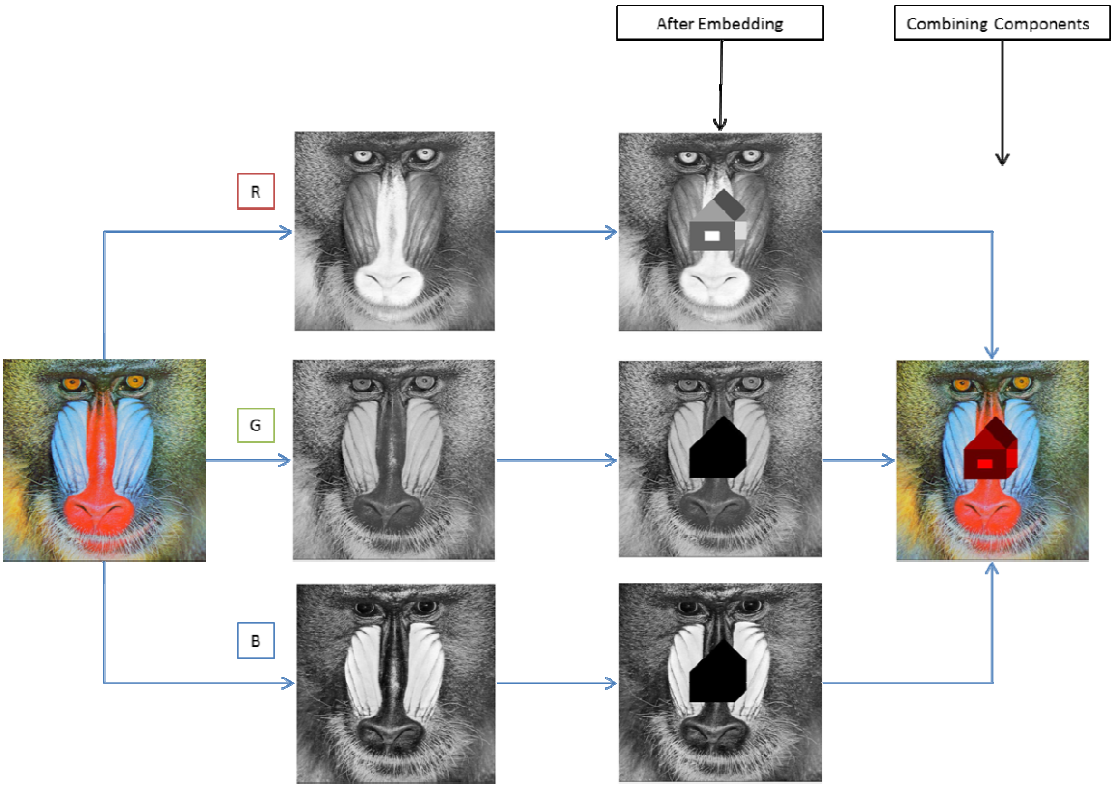

Figure 2. Embedding using the proposed geometric shape

cascaded with LSB, we consider peak signal-to-noise ratio (PSNR) performance metric. It deserves disclosing that for the reason of having a fair comparison, we implement the former approaches on the red share of color images precisely as described. However, PSNR is a very popular function for evaluating the imperceptibility or visual quality of the watermarked result [8, 21].

Fig. 3 shows the results of PSNR performance metric versus different watermark lengths when experimenting (simulating) our proposed approach and two other popular approaches, that is to say, PVD [8] and PVD cascaded with LSB [9]. The host image used is *Couple*. It is worth stating that higher obtained values of PSNR indicate having better results. In other words, as the difference between original and stego-image gets closer and closer, the PSNR gets higher and higher. As seen in this figure, the PSNR values decrease as the watermark size increases. This is to be expected since the number of characters embedded increases. Unlike other proposed approaches, our proposed approach achieves higher values of PSNR for all described watermark lengths. With reference to what are mentioned about PVD and PVD cascaded with LSB in Section I, it is noteworthy to realize and conclude that these approaches may affect the stego-images more than our approach. To show its consistent contribution over other standard test images, Fig. 4 shows the PSNR results for a different cover image (i.e., *Baboon*). It is worth noting that the PSNR values for PVD are higher than those for PVD cascaded with LSB and these completely comply with what are reported in [9].

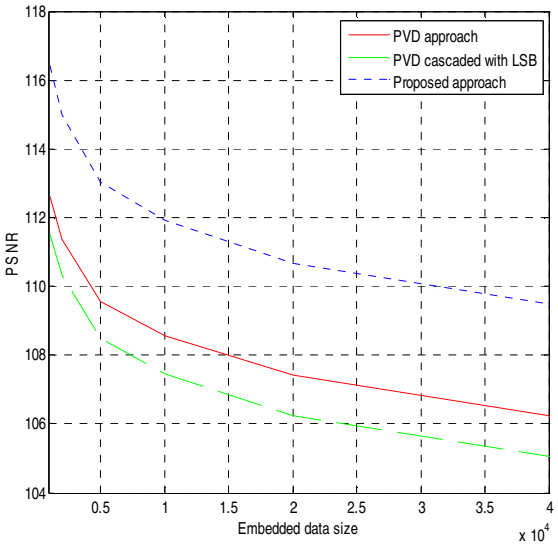

Figure 3. PSNR versus watermark size (in bytes) for different watermarking methods using cover image "*Couple*"

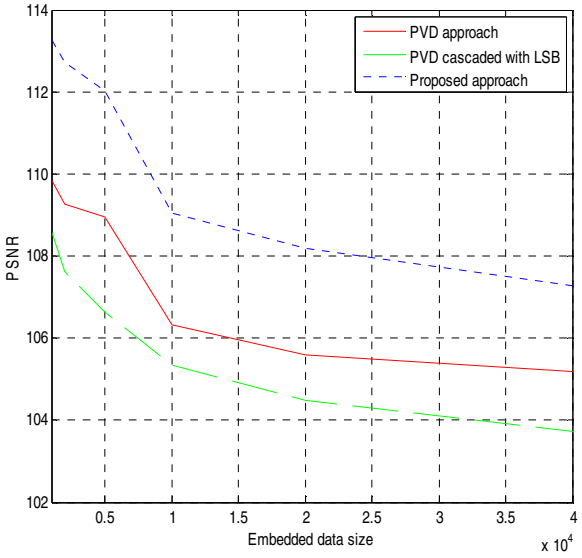

Figure 4. PSNR versus watermark size (in bytes) for different watermarking methods using cover image "*Baboon*"

IV. Conclusion

As the digital technologies over the internet increasingly evolving, the need for digital watermarking to protect the owner's right becomes urgent. In this paper, we propose an efficient watermarking approach based on least significant bits replacement method. Our approach mainly embeds any secret data into a cover image on the form of a geometric shape which looks to observers as a 3D house. This shape is divided into different areas where each has various dimensions and embedding policy. The importance of our approach comes in improving the security and coding time watermarking evaluation objectives. The security is enhanced since too much effort is required to break our algorithm and extract the watermark. Furthermore, its computational complexity causes as little burden on the overall system since no arithmetic operations or translations are required for image pixels. Our proposed approach does not stop to this extent, but rather it improves the imperceptibility and capacity watermarking evaluation requirements. The closeness between cover and stego-images was extremely impressive. Two former algorithms (PVD and PVD cascaded with LSB approaches) were implemented and evaluated to be compared with our approach in terms of PSNR metric. Genuinely, our approach outperforms both of them.

Abstract— **The use of user identification technology has become increasingly in demand in today's society. Biometrics have been capitalized upon for this purpose. The human iris in particular is one of the most unique and intriguing biometrics available to use in the identification of an individual. The process of recognizing a human iris is split into four major steps. These steps are segmentation, normalization, feature extraction, and matching. In this paper, two new methods are introduced to implement feature extraction. Both methods use a sliding-window technique and different mathematical operations on the pixels to produce feature vectors. Experimental results of the methods produced relatively small feature vectors of size 5x120 and 5x130. A small feature vector is valuable as it contributes to the efficiency and speed of the overall recognition system. In addition, a step was included in both methods to minimize the effect of varying light intensity. This reduces the time needed to acquire an image with suitable lighting, which in turn contributes to the speed of the system as well. Analysis of our methods was done by considering various performance metrics such as the False Acceptance Rate (FAR), False Rejection Rate (FRR), and Recognition Rate (RR). Both proposed methods achieved a recognition rate of about 98.3264%.**

I. INTRODUCTION

A biometric is a trait or characteristic of the human body that can be used to uniquely identify a person [1]. Biometrics have been put into practice for a variety of applications. The most common ones used include fingerprints, voice patterns, DNA (deoxyribonucleic acid), or iris patterns [2]. The objective of a biometric system is to be able to represent this unique trait or characteristic into a template. The template is then compared with others in order to identify a match or an imposter [3]. Biometrics systems are further classified into either "Identification Systems" or "Verification Systems". An identification system is one that blindly takes the generated template of a biometric and tries to identify the person it belongs to [4]. A verification system is one that requires an additional input such as a username. The username is linked to a specific template with which the input template is compared to [2, 4].

In security, biometrics are favored over traditional security methods such as keys, PINs (personal identification numbers), and passwords, because for many reasons. Biometrics are robust with time and are always available to a person to use unlike keys or passwords which can be lost or forgotten. Imposters also have an easier time of creating copies of keys or cracking passwords than they would trying to mimic a biometric.

In this paper, two methods for extracting features from the human iris are introduced. The advantages of using the human iris lead its selection over other biometrics. The iris is a thin, colored, circular structure in the eye [5]. The textural details of the iris are unique to every human being and they remain stable throughout a person's life. The function of the iris is to manipulate the diameter and size of the pupil to control the amount of light that passes through to the retina. The iris responds to light by contracting or dilating muscles attached to the aperture at the center of the iris, known as the pupil [5, 6]. Analysis of the iris can be done by acquiring a high resolution image of the iris. DNA, on the other hand, would introduce greater difficulty to analyze and would require more time to do so [7]. Asking a person for a picture is also a more user friendly approach than asking for a saliva swab or blood sample to analyze DNA. Voice patterns have been shown to be less robust with time than other biometrics as a person ages [8].

One of the goals of our feature extraction methods was to create small feature vectors. The reason for this is because small feature vectors contribute to a faster overall system. It also reduces the amount of memory needed to save these vectors in a database. Another problem tackled by our methods was variable light intensity. It is difficult to maintain the same levels of light intensity when acquiring the images for iris recognition. Rather than setting up hardware to solve this problem, we have solved it in our algorithms. This solution contributes to the accuracy of identification.

The remainder of the paper is organized as follows: Section II provides the related work. The proposed methods are elucidated in Section III. Experimental results along with observations and necessary discussions are presented in Section IV. The paper is summarized in Section V.

II. Literature Review

Iris recognition began with Dr. John Daugman, who created the first algorithm to be used to extract features of the human iris [9]. Daugman observed that 2D Gabor filters showed similar frequency and orientation to those of the human visual system [10, 11]. He used them as bandpass filters [12] and modulated them using an elliptical Gaussian function [11] in order to implement his iris recognition algorithm. Other work in iris recognition showed the value of working on individual signal frequency components. Wavelets are used to decompose a continuous-time signal into a set of signals with different resolution levels [13]. Haar wavelets [4, 14] and the zero-crossings of 1-D wavelets are examples of wavelets that have been used in iris recognition. Haar wavelets take the iris image and decompose it into 4 subimages by using 4 different combinations of high and low pass filters [3]. The images are then encoded into binary feature vectors. Zero-crossings of the 1D wavelet are extracted when a signal is decomposed into a set of signals [15]. They are represented using sets of complex numbers to create a feature vector. There has also been work in the time domain to extract features, by working with filters directly on an image and using the resulting values as feature vectors [16]. A method called the difference conversion to complex numbers presented in [17] operates on the pixels in the time domain and presents their values in a form that can be encoded into feature vectors.

III. Proposed Approaches

To create feature vectors, mathematical operations are performed on the input image and the results are used to create the template. A feature extraction method's performance is judged based on how well it can uniquely represent each individual's iris patterns. If every person's iris can be mapped into their own specific feature vector values, this will lead to a highly accurate and fast matching process.

A feature vector needs to be compared to the database of a system in order to identify to whom it belongs to. This database contains the feature vectors of the people allowed access to the system. The type of comparison a system can make is split into two categories: identification and verification. An identification system requires only the input image. It uses this image to compare it with each saved template in the database in order to find a match. A verification system on the other hand does a more specific search. It requires the additional input of a username or something similar in order to specify which part of the database it will search through. For example if a username of "John" is entered along with the iris image, only feature vectors belonging to user "John" are compared with the input image to verify that this person is indeed "John". A good matching algorithm applies both identification and verification, making it more robust and applicable in different situations.

The feature extraction process is done once the image of the iris is normalized. In our methods, the top right part of the iris is used when the iris image is unwrapped using Daugman's Rubber Sheet model for normalization [11]. The differences between pixels were operated on rather than direct operations on the pixels. This is to account for any light intensity changes when the images of the iris were acquired. The proposed methods use "sliding windows." A sliding window means the algorithm is repeatedly applied per pixel and uses the adjacent pixels that fall within the perimeter of this "window." The algorithm is blind to any pixel outside of the window and only sees them once the window is shifted to the next pixel.

A. Method 1: Mean Thresholding

The normalized image section taken is 5x130. A 1x11 sliding window is used on each row, beginning with column 6 up to column 125. The procedure of performing this method includes the following steps in sequence:

1. Center the window at column 6 in the first row.
2. Take the 5 preceding pixels and 5 succeeding pixels.
3. Find the mean value of these pixels and set as the threshold.
4. Test the centered pixel. If the value of the pixel is greater or equal to the threshold, set the pixel as 1, else set it to 0.
5. Repeat the steps until column 125.

The size of the resulting binary feature vector is 5x120.

B. Method 2: Mean-by-Median Thresholding

The section taken from the normalized image is 5x130. A 1x25 sliding window is used from the first column to the last. The following steps summarize how this method precisely works:

1. Center the window at the first pixel in the first row.
2. The last 12 columns from the original normalized iris image are concatenated to the beginning of the section taken.
3. Calculate the mean of the 12 preceding and succeeding pixels.
4. Calculate their median.
5. Calculate the threshold using the equation:

$$Threshold = \sqrt{mean \times median}. \quad (1)$$

6. If the centered pixel is greater than the threshold, set it as 1, else set it as 0.
7. Shift the window to the next pixel and repeat steps 3 through 7 until pixel 130 is reached in the row.
8. Concatenate the first 12 columns from the original normalized iris image to the end of the section taken.
9. Repeat steps 3 through 6 for the pixel.

10. Begin with the next row and repeat steps 2 through 9 until all rows are complete.

The resulting binary feature vector size is 5x130.

Both methods produce binary feature vectors. The Hamming distance matching technique was chosen because it operates best with binary templates. It defines the "dissimilarity" between biometric templates. This means it finds the number of corresponding bits that differ between to templates. Comparison of iris templates was split into two categories:

1. Intra-class comparisons: comparing the input image with templates belonging to a certain person.
2. Inter-class comparisons: comparing the input image with the entire database of users.

During image acquisition, the iris may not be positioned properly and experience rotation. This was accounted for by creating 8 circularly rotated templates of the input image. A total of 9 templates are then compared with the database. This was achieved by circular shifting template columns 4 times to the right and 4 times to the left. With the 9 templates, 9 matching ratios are produced using the Hamming distance formula. The largest matching ratio is the only one taken from among the 9. Once the matching ratio for intra-class and inter-class are calculated, they are used to find the threshold between the two distributions.

IV. Results and Discussions

Two separate codes were constructed with identical segmentation, normalization, and matching techniques, only differing in the feature extraction method. These codes were written using MATLAB® software and the database used for iris images was the CASIA version 1.0 database. Only a subset of 693 images (99 classes) was used from the CASIA database to test our methods. The codes implemented both identification and verification. In the identification mode, the input image was compared with every iris template in the database. The comparison that yielded the highest matching ratio was chosen to be assigned to that person. In verification mode, the pattern that is verified is only matched against a certain user's saved templates or his "class". Matching ratios are generated and the maximum is chosen for that person. To prevent imposters from passing through the system, a minimum level was set for the matching ratio. If the maximum matching ratio found did not exceed this level, it is rejected and no match is found.

Table I compares the recognition rates achieved by our methods with other methods. It shows that the results achieved by our methods are of high accuracy. Our recognition rate for both methods was 98.3264%. The recognition rate is defined as the ratio of the number of input images being correctly recognized to the total number of input images entered into the system.

Our methods produced accurate with a vector of size 600 pixels (5x120) and 650 pixels (5x130). A smaller feature vector contributes to the speed of the system and reduces the amount of memory needed to store them. Table II shows a comparison between the vector sizes of our templates with other methods published. The contribution of our proposed methods is undeniable and very magnificent.

The False Rejection Rate (FRR), or type I error, measures the probability that an individual who has been registered into the system is not identified by the system. FRR can be calculated by:

$$FRR = \frac{\int_T^1 P_{intra}(x)dx}{\int_0^1 P_{intra}(x)\,dx}, \tag{2}$$

where, $P_{intra}(x)$ and T represent the distribution of the intra-class comparisons and threshold between intra- and inter-class distributions, respectively.

The False Acceptance Rate (FAR), or type II error, measures the probability that an individual who may or may not have been registered into the system is identified as another individual. FAR can be calculated by:

$$FAR = \frac{\int_0^T P_{inter}(x)dx}{\int_0^1 P_{inter}(x)\,dx}, \tag{3}$$

where, $P_{inter}(x)$ represents the distribution of the inter-class comparisons.

The intra- and inter- class distributions of method 1 are shown in Fig. 1. Fig. 2 shows the distributions of method 2. The thresholds T were determined experimentally by finding FAR and FRR and choosing the T that minimizes these metrics for each method. Table III shows the thresholds found for our methods.

TABLE I. Recognition Rate Comparison

Method	Recognition Rate
Mean Thresholding	98.3264 %
Mean-by-Median Thresholding	98.3264 %

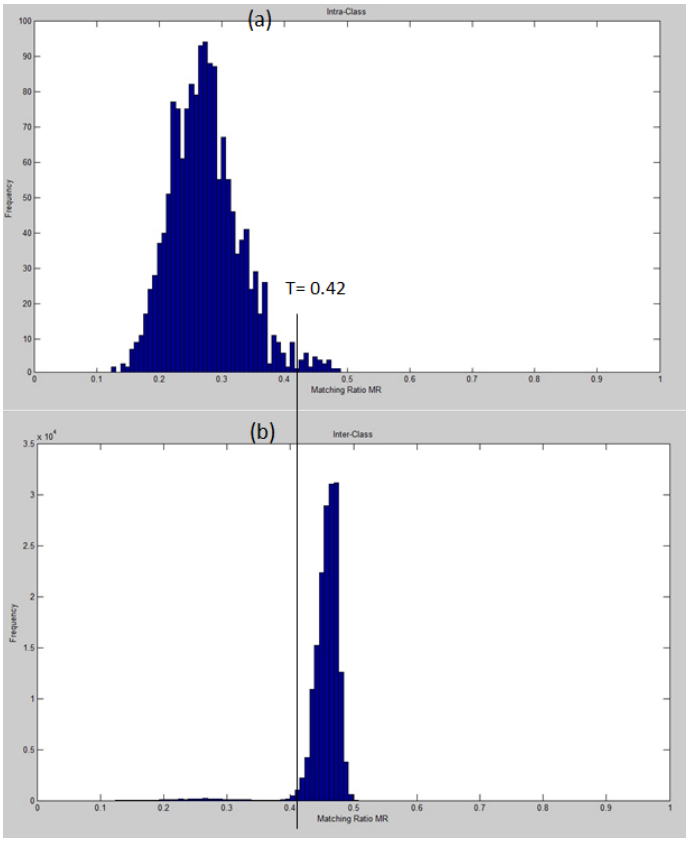

Figure 1: Method 1 distributions: (a) Intra-class distribution (b) Inter-class distribution

TABLE III. THRESHOLDS CHOSEN THAT MINIMIZE FRR AND FAR

Method	**FRR %**	**FAR %**	**Threshold**
Mean Thresholding	0.322	0.039	0.42
Mean-by-Median Thresholding	0.281	0.0389	0.42

V. CONCLUSION

Two different approaches have been introduced to extract features from the human iris. Both have shown to have created small templates. Small templates improve the overall speed and reduce the amount of memory needed to save the templates produced. The effect of light intensity was eliminated during the process of feature extraction so that additional hardware to fix this problem is no longer needed. The methods also achieved high recognition rates. We can conclude from this that our implementation is practical and that an accurate iris recognition system can be created using these methods.

***Abstract*—The problem of visual object detection, the goal of which is to predict the locations and sizes of all objects of a given visual category (e.g., cars) in a given set of images, is often based on a possibly large set of local features, only a few of which might actually be useful for the given detection setup. Feature selection is concerned with finding a 'useful' subset of features. In this paper, we compare two approaches to feature selection in a visual object detection setup. One of them selects features based on their individual utility scores alone, regardless of possible interdependence with other features. The other approach employs the AdaBoost framework and hence implicitly deals with interdependence. Using two feature extraction methods and several image datasets, we experimentally confirm the significance of feature interdependence: features that perform well individually do not necessarily perform well as a group.**

I. Introduction

Many object detection methods begin with extracting a potentially large set of local features from a given set of training images. The extracted features may be immediately used as building blocks in the detection model of the given visual category [1]. However, it is often beneficial to reduce the number of features before constructing the detection model. Besides the computational reasons, a properly selected set of features might lead to a better detection performance than the original set, since the selection process may be able to remove the 'useless' or 'harmful' features.

A viable feature selection method has to assess the utility of individual features for the given object detection problem. A feature is 'useful' if it is both distinctive (it often occurs in images depicting objects of the given category and rarely in other images) and predictive (it consistently occurs at similar relative locations within images of objects). For the 'Cars' category, for instance, an example of a 'useful' feature is one that captures a tire, since tires tend to be visually distinctive for cars and to occur at similar relative positions in a majority of car images.

The primary contribution of this paper is the comparison of two methods for selecting a favorable (in terms of detection performance) subset of T features out of the initial set of N features. Both methods use the same measure for the utility of individual features. However, while one approach simply selects the T best features according to the individual utility scores, the other embeds the scoring mechanism into an AdaBoost framework [2], thereby considering interdependence of features [3] in addition to their individual scores. Informally, AdaBoost seeks features that work well as a group rather than just individually. We experimentally show that feature interdependence has to be considered in a feature selection process. As the secondary contribution, this paper compares two feature extraction and representation methods, namely that of Fidler *et al.* [4] and that of Ferrari *et al.* [5]. Both comparisons are evaluated on five real-world image datasets.

In this paper, we use the feature selection approach due to Fürst *et al.* [6]. Viola and Jones [7] proposed a highly successful AdaBoost-based method for selecting features for face detection. Both approaches formulate detection as a classification problem. However, while Viola and Jones use a similar classification approach in both the learning and the test stage, Fuerst *et al.* use classification only to select features in the learning stage. Many other AdaBoost-based object detection approaches have been proposed [8], [9], [10].

The rest of this paper is structured as follows: In Sect. II, we present both feature selection approaches. Section III describes the detection algorithm used for both feature selection and experimental validation. Section IV gives a brief overview of both feature extraction methods. Section V presents and discusses the results of experimental validation. Section VI concludes the paper.

II. Feature Selection

In this section, we present both feature selection approaches. For the sake of clarity, we first present the AdaBoost-based approach, since the approach that searches for the individually best features is actually its simplification.

A. AdaBoost-based Approach

The AdaBoost-based feature selection approach proposed by Fürst *et al.* [6] takes into account both the properties of individual features (distinctiveness and predictiveness) and their interdependence. Originally, AdaBoost [2] is an approach for constructing classifiers in binary classification problems. Given a set of 'weak', threshold-based classifiers, a set of training samples, and a set of weights assigned to individual samples, each iteration of AdaBoost selects the classifier that yields the highest classification accuracy on the sample set with respect to the current values of the weights. After

selecting the current classifier, the weights of the samples misclassified by that classifier are enlarged so that the next iteration will be likely to select a classifier complementary to the one just selected. In this way, AdaBoost will implicitly deal with interdependence in the set of weak classifiers.

We shall now present how to adapt the AdaBoost framework to the problem of selecting features for object detection. Let us assume the existence of an object detection algorithm that accepts an image I and a set of features $\mathcal{G}$ and returns a set of detection hypotheses predicting the locations and sizes of individual objects in the image I, with the additional restriction that I can be represented only by the features from $\mathcal{G}$. Each returned hypothesis H is assumed to be equipped with a positive number $s(H)$ designating its strength. An example of such a detection algorithm is described in Sect. III, but the presented selection approach would work with any algorithm fulfilling the stated requirements.

The AdaBoost-based feature selection process due to Fürst *et al.* requires a set of images that depict various objects of the given visual category on a uniform background (positive training images, $\mathcal{I}_+$) and a set of images depicting anything but objects of the given category (negative training images, $\mathcal{I}_-$). Let $\mathcal{I} = \mathcal{I}_+ \cup \mathcal{I}_-$ denote the entire set of training images, and let $\mathbf{w} = (w_I)_{I\in\mathcal{I}}$ denote a vector of weights assigned to individual images such that $\sum_{I\in\mathcal{I}} w_I = 1$. At the beginning of the AdaBoost algorithm, we have $\mathbf{w} = \mathbf{w}^{[1]}$, where $w_I^{[1]} = 1/(2|\mathcal{I}_+|)$ for all $I \in \mathcal{I}_+$ and $w_I^{[1]} = 1/(2|\mathcal{I}_-|)$ for all $I \in \mathcal{I}_-$. During the algorithm, the weights are iteratively updated.

To apply the classification-oriented AdaBoost framework to our detection-oriented feature selection setup, the problem of detecting objects in the training images is transformed into that of classifying training images themselves, and a threshold-based classifier is constructed for every feature. Let us first define a function $S\colon \mathcal{F}\times\mathcal{I}\to\mathbb{R}$ as

$$S(F,I) = \begin{cases} s(H^*(I \mid F)) & \text{if } I \in \mathcal{I}_+ \text{ and } H^*(I) \text{ is correct;} \\ s(H^*(I \mid F)) & \text{if } I \in \mathcal{I}_-; \\ 0 & \text{otherwise,} \end{cases} \tag{1}$$

where $H^*(I \mid F)$ denotes the strongest detection hypothesis on the image I provided that I is represented solely by the feature F. For a feature F and a threshold $\theta \in \mathbb{R}$, let us define a classifier $d_{F,\theta}\colon \mathcal{I}\to\{0,1\}$ that classifies a given training image as positive (output 1) or negative (output 0) according to the following rule:

$$d_{F,\theta}(I) = \begin{cases} 1 & \text{if } S(F,I) \geq \theta; \\ 0 & \text{if } S(F,I) < \theta. \end{cases} \tag{2}$$

If y_I denotes the actual class of the image I ($y_I = 1$ for all $I \in \mathcal{I}_+$ and $y_I = 0$ for all $I \in \mathcal{I}_-$), the classifier's error on the entire training set can be computed as

$$\epsilon(F,\theta;\mathbf{w}) = \sum_{I\in\mathcal{I}} w_I |d_{F,\theta}(I) - y_I|. \tag{3}$$

Let $\theta^*(F;\mathbf{w})$ be a threshold at which the classifier's error is minimal:

$$\theta^*(F;\mathbf{w}) = \arg\min_{\theta} \epsilon(F,\theta;\mathbf{w}) \tag{4}$$

The classifier $d_F^* = d_{F,\theta^*(F;\mathbf{w})}$ attains the smallest classification error and will thus be called the *optimal* classifier. The *utility* of a feature F is defined as

$$u(F;\mathbf{w}) = 1 - \epsilon(F,\theta^*(F;\mathbf{w});\mathbf{w}) \tag{5}$$

For a feature F that is both distinctive and predictive, $S(F,I)$ is large for many positive training images and small for many negative ones. Under the initial weight vector, the optimal classifier for such a feature F attains a low classification error, since a threshold θ^* can be found such that most of the values $\{S(F,I)\}_{I\in\mathcal{I}_+}$ are above θ^* and most of the values $\{S(F,I)\}_{I\in\mathcal{I}_-}$ are below θ^*. The feature F has therefore a high utility. Conversely, if a feature F is non-distinctive, the values of $S(F,I)$ tend to be random, whereas if F is non-predictive, $S(F,I)$ is zero for many positive images. In both cases, even the optimal classifier produces a high classification error, and so F has a low utility.

The AdaBoost-based feature selection method is shown as Algorithm 1. In each iteration, the algorithm selects the feature having the highest utility with respect to the current weight vector and decreases the weights of the training images correctly classified by the optimal classifier for the selected feature. In the next iteration, the misclassified images have higher relative weights, which encourages the selection of a feature complementary to the feature selected in the previous iteration.

B. Static Approach

In the static approach, features are selected by decreasing values of $u(F;\mathbf{w}^{[1]})$. Features are thus selected by individual utility, but their interdependence is not considered.

III. Object Detection

We employed an object detection approach due to Leibe *et al.* [1]. For now, let us assume that all objects are approximately the same size; an extension to arbitrary sizes will be briefly described later. In the training stage, the method of Leibe *et al.* learns the so-called Implicit Shape Model (ISM) from a set of training images depicting different objects of the given visual category on a uniform background. In the test stage, the learned model is used to form detection hypotheses for a given real-world image depicting an unknown number of objects of the given category.

To learn the ISM for a given category, every training image is first represented by the given set of features. For a feature F located at the coordinates $\mathbf{y}$ in an image I, the learning algorithm stores a pair $(F, \mathbf{x}-\mathbf{y})$, where $\mathbf{x}$ denotes the location of the object's centroid in I. Informally, the ISM is thus a collection of the relative locations of individual features with respect to the object centroid. The test stage begins with the representation of a given test image by the feature set. Each feature then 'votes' for all locations of the object centroid based on its ISM entries. Specifically, if a feature F is located

Algorithm 1 The AdaBoost-based feature selection method.

Require:

(a) A set of training images $\mathcal{I}$ with class membership labels y_I (1: positive; 0: negative)

(b) A set of features, $\mathcal{F}$.

(c) The number of iterations, T.

Ensure: A sequence of selected features $\langle F^{[1]}, \ldots, F^{[T]} \rangle$.

Process:

1: $\mathcal{F}' := \mathcal{F}$; // $\mathcal{F}'$: *the set of not-yet selected features*

2: $w_I^{[1]} := 1/(2|\mathcal{I}_+|)$ for all $I \in \mathcal{I}_+$

3: $w_I^{[1]} := 1/(2|\mathcal{I}_-|)$ for all $I \in \mathcal{I}_-$

4: **for** $t := 1$ **to** T **do**

5: Normalize the weights such that their sum becomes 1:

$$w_I^{[t]} := w_I^{[t]} / \sum_{J \in \mathcal{I}} w_J^{[t]} \text{ for all } I \in \mathcal{I}. \quad (6)$$

6: Select the feature with the highest score $u(F; \mathbf{w})$ with respect to the current weights:

$$F^{[t]} = \arg\max_{F \in \mathcal{F}'} u(F; \mathbf{w}). \quad (7)$$

7: Let $\theta^{[t]} = \theta^*(F^{[t]}; \mathbf{w}^{[t]})$, $d^{[t]} = d_{F^{[t]},\theta^{[t]}}$, and $\epsilon^{[t]} = \epsilon(F^{[t]}, \theta^{[t]}; \mathbf{w}^{[t]}) = 1 - u(F^{[t]}; \mathbf{w}^{[t]})$.

8: $\mathcal{F}' := \mathcal{F}' \setminus \{F^{[t]}\}$.

9: Update the weights:

$$w_I^{[t+1]} = \begin{cases} \frac{\epsilon^{[t]}}{1-\epsilon^{[t]}} w_I^{[t]}, & \text{if } d^{[t]}(I) = y_I; \\ w_I^{[t]} & \text{otherwise.} \end{cases} \quad (8)$$

10: **end for**

at the coordinates $\mathbf{q}$ in the test image and if the ISM entries for F are $(F, \mathbf{r}_1), \ldots, (F, \mathbf{r}_k)$, then F votes for the coordinates $\mathbf{q} + \mathbf{r}_1, \ldots, \mathbf{q} + \mathbf{r}_k$. The votes are weighted: the method of Leibe *et al.* considers both the possibility that a given local structure is represented by several features, each with a certain probability, and the possibility that a given feature votes for several object centroid candidates, each with a certain probability.

The output of the voting algorithm is a probability map that, for each pixel of the test image, specifies the probability that the object centroid is located at the coordinates of that pixel. To obtain a small set of robust detection hypotheses, the probability map is smoothed by a Gaussian filter. The locations of the maxima in the smoothed map are taken as individual detection hypotheses. The strength of a hypothesis H, $s(H)$, is defined to be the value of the corresponding maximum.

A single feature may cast votes for many different object centroids, often giving rise to strong secondary hypotheses. Such hypotheses may be suppressed by a greedy MDL-based algorithm [11]. In each iteration, this algorithm selects the currently strongest hypothesis and greedily assigns to it all of its support, i.e., all probabilistic votes that it gathered in the voting process. The competing hypotheses thereby lose part of their support and hence strength. This scheme has been experimentally shown to significantly improve detection performance.

The described training and detection process can also be adapted to multiscale detection. At least two approaches exist: (1) single-scale learning, multiscale detection; (2) multiscale learning, single-scale detection. In the first approach, the training stage is the same as in the single-scale case, but the test-stage voting algorithm is applied to several rescaled versions of the test image. The second approach only works with scale-covariant features (such a feature can be detected at multiple scales, and each of its occurrences provides information about the scale of the corresponding local structure). The learned ISM contains both the offset and the scale of each feature, relative to the position and the size of the object. In the test stage, the features cast votes in a 3-dimensional space. Each feature votes not only for candidate object centroid locations but also for candidate object sizes. The detection algorithm thus produces hypotheses about both the centroids and the sizes of individual objects.

IV. Feature Extraction and Representation

We tested two feature extraction and representation methods: that of Fidler *et al.* [4] and that of Ferrari *et al.* [5]. Features of Fidler *et al.* are arranged into layers according to the 'parts composed of parts' paradigm. The first layer contains only a single feature; this is the kernel of the Gabor filter in the orientation 0°. Each feature of a layer $n > 1$ is a composition of rotated copies of features of layer $n - 1$. In particular, a layer-n feature F_i^n can be represented as $\{(F_{j_1}^{n-1}, \alpha_1, \mu_1, \mathbf{\Sigma}_1), \ldots, (F_{j_s}^{n-1}, \alpha_s, \mu_s, \mathbf{\Sigma}_s)\}$, where for each $k \in \{1, \ldots, s\}$, α_k is the discretized orientation of the k-th component of feature F_i^n (relative to the orientation of the first component), whereas μ_k and $\mathbf{\Sigma}_k$ denote the mean and the covariance matrix of the Gaussian distribution that models the variability of the position of the k-th component (relative to the position of the first component). To represent an image with a set of features, the features are matched against the Gabor-filter representation of the image in a layer-by-layer fashion. The result of the representation is a set of triples $(F_i^n, (x, y), \beta)$, where F_i^n is a layer-n feature, (x, y) is the position of an occurrence of F_i^n in the image, and β is the discretized orientation in which the feature occurs at that position.

Features of Ferrari *et al.* [5] are obtained by a multi-step procedure. First, an edge detector is used to obtain edge elements, i.e., image points at directed intensity transitions. After that, each group of edge elements that form an approximately straight line is taken as a separate 'segment'. In the next step, the extraction procedure builds groups of k segments that touch or almost touch each other. If $k = 2$, for example, such groups include segment pairs in the shape of the letters L and T. Groups of k adjacent segments are then clustered by their visual similarity. Finally, each cluster is taken as a Ferrari *et al.* feature. Features are described in a rotation- and scale-invariant manner. To represent a given image by a given set of features, the image is first processed so as to obtain a set of groups of k adjacent segments. After that, the features are

matched against the groups in the image, giving a set of triples $(\mathbf{r}(G), t(G), \mathcal{R}(G))$, where G is a k-adjacent-segments group, $\mathbf{r}(G)$ and $t(G)$ are its location and size, and $\mathcal{R}(G) = \{(F, r(F,G)), \ldots\}$ is a set of features that can be matched against the group G, equipped with an estimate of the reliability of the match.

V. Experimental Results

Before presenting the results, let us describe how individual experiments were evaluated. The output of the detection algorithm for a given image is a set of detection hypotheses together with their strengths. A hypothesis is a prediction of the bounding box of an object in the image. Let (x_H, y_H, w_H, h_H) denote the image coordinates of the centroid (x_H and y_H) and the width and the height (w_H and h_H) of the bounding box predicted by a hypothesis H, and let (x_O, y_O, w_O, h_O) define the true bounding box of a depicted object. The hypothesis H is proclaimed to be correct if the following three conditions are met [1]:

1) $\sqrt{(2(x_H - x_O)/w_O)^2 + (2(y_H - y_O)/h_O)^2} \leq 0.5$.
2) The predicted bounding box covers at least 50% of the area of the true bounding box.
3) The true bounding box covers at least 50% of the area of the predicted bounding box.

If the above conditions are fulfilled by multiple hypotheses for the *same* object, only one of those hypotheses is considered correct; all others are regarded as false positives.

The detection performance on a given image set is estimated by the following measure:

$$F_{\max} = \max_{\tau} \frac{2 \times \text{recall}(\tau) \times \text{precision}(\tau)}{\text{recall}(\tau) + \text{precision}(\tau)}. \quad (9)$$

The $F_{\max}$ measure ranges from 0 to 1, with 0 being the worst and 1 being the best possible detection performance. The recall and precision at a given threshold τ are computed as follows:

$$\text{recall}(\tau) = \text{TP}(\tau)/\text{OBJ}; \quad (10)$$

$$\text{precision}(\tau) = \text{TP}(\tau)/(\text{TP}(\tau) + \text{FP}(\tau)). \quad (11)$$

Here, OBJ denotes the number of all depictions of objects of the given visual category in the image set, $\text{TP}(\tau)$ ('true positives') is the number of correct hypotheses H with $s(H) \geq \tau$, and $\text{FP}(\tau)$ ('false positives') is the number of incorrect hypotheses H with $s(H) \geq \tau$.

Each combination of feature extraction and feature selection method was tested on five test image datasets, some information about which is provided in Table I. To extract and select features and to learn the detection model for individual categories, we used category-specific training image sets obtained from various sources. All training sets were completely disjoint from the corresponding test sets.

For each combination of feature extraction method, feature selection method, and image dataset, we extracted all features (their number is given in Table II), selected the first T features (where T varied from 1 to 50), and learned and tested the detection model using the T selected features. Fig. 1 shows the $F_{\max}$ values for all experiments.

TABLE I: Test image datasets.

Horses	896	398
Mugs	912	314

The AdaBoost-based approach significantly outperforms the static feature selection approach. The reason for such a behavior is the redundancy of the extracted feature set. Many extracted features react to similar local structures and hence attain similar utility scores. Consequently, a feature set selected solely by the utility of individual features is likely to contain many similar features. By contrast, AdaBoost favors features that correctly classify the images misclassified by the already selected features. Tables III and IV list the first 10 selected features for the categories 'Cars' and 'Mugs'. The feature sets selected by the static approach are clearly redundant. As shown in Fig. 1, a much greater number of features selected by the static approach is required to attain a detection performance comparable to AdaBoost-selected features.

For each of the first 10 AdaBoost-selected Fidler *et al.* features for the 'Mugs' category, Table V shows its rank in the decreasing sequence of $u(F; \mathbf{w}^{[1]})$ values. The third selected feature, for instance, appears at a rank as low as 156 out of 912, but it represents the best complement to the first two selected features, at least with respect to the employed training image set.

The features obtained by the method of Fidler *et al.* led to substantially more favorable detection results than those of

Ferrari *et al.*. For instance, the most distinctive and predictive features for the 'Cars' category are those that capture tires, a few examples of which are shown in Table III. While the method of Fidler *et al.* is able to extract such features, this is not the case with the method of Ferrari *et al.*, which builds features from straight segments. These features are therefore unable to capture small circular or semi-circular structures. In addition, although Fidler *et al.* features tend to be fairly indistinctive (with the possible exception of wheel-like features), they occur on equivalent local structures much more consistently than Ferrari *et al.* ones. Fig. 2 shows the first AdaBoost-selected Fidler *et al.* features for the categories 'Cars' and 'Mugs', their respective ISM probability maps (the probability of the object centroid location relative to the location of the feature), and a few occurrences in test images.

VI. CONCLUSION

We have compared an AdaBoost-based feature selection approach with a simplified, 'static' approach that does not pay regard to feature interdependence. Using two feature extraction methods and five real-world image datasets, we showed that for a fixed target number of selected features, the AdaBoost-based method considerably outperforms the simplified selection method. The main reason is that many extracted features tend to be visually similar and hence attain similar utility scores. The resulting feature sets therefore contain much redundancy. AdaBoost, by contrast, selects features so that they complement each other and thus tends to achieve a comparable detection performance using much fewer features than the static approach.

We assumed that the number of selected features is fixed and known in advance. A natural extension of the presented selection approaches is therefore the automatic determination of the most appropriate number of features with respect to both detection performance and computational burden. Another interesting research direction is feature selection for the multiclass detection setting, where the goal is to find all objects of several categories simultaneously [10].

Movie Posters Classification into Genres Based on Low-level Features

Marina Ivasic-Kos, Miran Pobar, Luka Mikec
Department of Informatics
University of Rijeka
Rijeka, Croatia
{ marinai, mpobar}@uniri.hr

Abstract— **A person can quickly grasp the genre (drama, comedy, cartoons, etc.) from a movie poster, regardless of visual clutter and the level of details. Bearing this in mind, it can be assumed that simple properties of a movie poster should play a significant role in automated detection of movie genres. Therefore, low-level features based on colors and edges are extracted from poster images and used for poster classification into genres.**

In this paper, poster classification is modeled as a multi-label classification task, where a single movie may belong to more than one class (genre). To simplify and solve the multi-label problem, two methods for multi-label data transformation are described and evaluated given the classification results obtained by distance ranking, Naïve Bayes and RAKEL.

Experiments are conducted on a set of 1500 posters with 6 movie genres. Results provide insights into the properties of the discussed algorithms and features.

Keywords—multi-label classification, data transformation method, movie poster

I. INTRODUCTION

With just a glance at a movie poster, a person can comprehend a variety of perceptual and semantic information. Capturing essential information about the movie at once, regardless of the visual complexity, can be experienced while driving around town and spotting a billboard or walking around the shopping center and cursorily glancing at an advertisement for a film. A person can grasp the genre (drama, comedy, cartoons, etc.) from a poster independently of the short observation time, clutter and the variety of details.

The same phenomenon has already been observed in complex real-world scenes, where persons can promptly recognize the basic-level category of the scene (e.g., a street) [1], its spatial layout (e.g., a street with tall vertical blocks on both sides) [2], as well as other global structural information (e.g., a large volume in perspective).

Assuming that one of the goals of the poster is to convey the information about the film (genre, etc.) to potential moviegoers without them paying a lot of attention, the important information for determining the genre might be contained in global low-level features such as dominant color of the whole poster, texture or color histogram. We thus wanted to develop a method to automatically determine the genres of movies using mostly visual low-level features of their posters. The task is made more complex by the fact that most movies belong to more than one genre, for example „Titanic“ belongs to Action, Disaster, Drama and Romance genres, and „Back to the Future“ belongs to Adventure, Comedy, Sci-Fi and Family genres, according to TMDB [3]

Film genre classification from additional supporting promotional material (trailers) has recently received some attention. In paper [4] low-level visual features extracted from movie trailers have been used to classify 100 movies into 4 genres (drama, action, comedy, horror). In [5] GIST, CENTRIST and W-CENTRIST scene features were applied to a collection of temporally-ordered static key frames to yield a feature representation. These features are used as visual vocabulary for genre classification and tested on 1239 movie trailers.

In [6] the same visual features were used as in [4]. Movies were classified into three genres (action, drama, and thriller) which were selected because of their frequency among movies that were played in Taiwan from 2004 to 2006. Some additional genres were grouped together and presented as those three (e.g. drama included comedy and romance while thriller included horror). All these approaches [4-6] simplify the problem considering only single genre per movie and deal with only single label classification problem.

In our approach, multi-label poster classification is proposed. In Section II two kinds of data transformation methods are explained. A set of low-level features, classification methods used for poster classification into movie genres and evaluation of described data transformation methods are presented in Section III. The paper ends with description of experimental setup, experimental results with discussion and directions for future work.

II. DATA TRANSFORMATION METHODS

The goal of classification is to assign class labels from the set of class labels C to examples from the set of samples E. In many problems, an example belongs to a

single class (single-label classification). In binary classification, an example e is classified in one of two possible classes from C, $C = \{C_1, C_2\}$ as in spam classification where a mail message is declared as either spam or not-spam. In multi-class classification an example is classified into one of more classes {C1, C2 … Ck}, for example a cloud can be classified as nimbus, cumulus, cirrus, etc. However, there are many problems where an example e_j should be classified into more than one class, as in our experiment. This is the case of multi-label classification which can be formally expressed as:

$$\exists\, e_j \in E : \varphi(e_j) = \{C_l, C_m\} \cup Z,\ Z \subseteq \cup_{i=1}^{k} C_i,\ l, m \in 1..k, l \neq m \text{ and } \varphi: E \to C.$$

Thus, in the set of examples E, an example e_j exists that the classifier φ maps into at least two classes C_l and C_m.

If a hierarchical structure exists among some of the classes in C so that one class can be inferred from another, then it is the case of hierarchical multi-label classification. For instance in scene classification, if a scene can be classified as beach, outdoor scene and natural scene, the parent class – outdoor scene will be inferred from the child class – beach.

Where the parent-child relationship does not exist between classes, the problem is known as flat multi-label classification. In case of e.g. classifying songs into moods and genres, one class label cannot be inferred from the other, because there is no parent-child relationship between them. For example, the song Paperback Writer by The Beatles can be classified into mood carefree and genre pop while the song Sabotage from Beastie Boys can be classified into mood brash and genre hip-hop according to [7]. The same problem exists in many different applications like in text classification where an article could belong to crime and sports classes, in medical diagnosis, information retrieval etc.

The multi-label classification problem cannot be directly solved by most classification methods which are designed for single-label classification. One approach to tackle a multi-label classification problem is to transform the data so it fits a series of single-label classification [8]. The other approach contains methods that extend specific learning algorithms in order to handle multi-label data directly.

In this paper, a multi-label classification problem is transformed into single-label classification, in two ways.

In the first, each of the examples that had two or more class labels was transformed into a set of ordered pairs. The first element of each pair is the example and the second one is the class label. Thus, if an example $e_j \in E$ can be classified into $Y_j = \{C_l, C_m, \dots, C_r\}$, $Y_j \subseteq C$ then we replace that example with $|Y_j|$ ordered pairs $(e_j, C_l), (e_j, C_m) \dots (e_j, C_r)$. For instance, the movie „Top Gun“ belongs to Action, Romance and War genres, and would be transformed into the set of ordered pairs containing individual genres: {(Top Gun, Action), (Top Gun, Romance), (Top Gun, War)}.

Now, model that maps first element of the ordered pair (example) to the second element of the pair (class label) can be defined. If the classifier assigns a confidence value to each class label, classes whose confidence scores are greater than a set threshold will be assigned to the example. A related approach is ranking, where classes are ranked according to their confidence scores, and top n are mapped to the example. In the following, this data transformation method is referred to as M1.

In the second case each set of class labels $Y_j = \{C_l, C_m, \dots, C_r\}$ is transformed into a new combined class $C_{l,m,\dots,r}$ that is assigned to the example e_j. In that way we create the new set $C' \supseteq C$, by adding the new combined classes into the set C'. Using this problem transformation method "The Top Gun" example would be transformed into the ordered pair containing one combined genre (Top Gun, Action&Romance&War). This data transformation method is hereinafter referred to as M2.

Both problem transformation methods are algorithm independent, so any classification method appropriate for the single-label classification can be used to map the examples to the new class.

III. EXPERIMENTS

In this section we present our experiments conducted on posters and metadata obtained from the TMDB. Our goal is to automatically determine the genres of movies using visual features of their posters.

A. Data and Preprocessing Step

We have used 1500 posters of movies dated from 1990 onwards, selected so that 6 chosen genres (Drama, Action, Animated, Comedy, War and Horror) had 250 examples each. Since each movie can have multiple genres, additional genre labels (e.g. Mystery, Crime, Family, and Romance) were present in the data. These genres were transformed into the chosen 6 and only two labels per movie were kept. The following rules were used to transform the original genre labels that were present in the data into genre labels that were used for classification (Table I):

TABLE I. TRANSFORMATION RULES

Original genre labels	Genre class label
Action, Disaster, Fantasy, Western	Action
Animation	Animation
Comedy	Comedy
Crime, Drama, Romance, Thriller	Drama
Horror	Horror
War, History	War

We applied this preprocessing step to prevent data scarcity, caused by too many genre labels in C' with too few examples. After the mapping, the resulting number of movies of each genre differs from the initial 250.

From 1500 collected posters, 1000 were used for training and 500 for testing.

After the preprocessing step, the genre labels in method M1 correspond to individual genres, and are from the set

$$C = \text{Drama, Action, Animated, Comedy, War, Horror}\}.$$

In the method M2 the genre labels except labels of individual genres include combined genre labels, and are from the set:

$$C' = C \cup \{\text{Drama\&Action, Drama\&Comedy,..., War\&Horror}\}.$$

B. *Features*

Motivated by the way people glance at billboards and still capture enough information about the film we wanted to see if only simple low-level features are enough for automatic poster classification into movie genres.

Intuitively it can be assumed that the variance of color has a strong correlation with respect to genres, so we used more low-level color features and experimentally tested their discriminate ability in terms of genre classification. Before the low-level features were extracted, each poster was proportionally scaled to 200 pixel width and converted to HSV color space. The relationship between the hues with maximal saturation in HSV color space with their corresponding RGB coordinates is illustrated in Fig. 1.

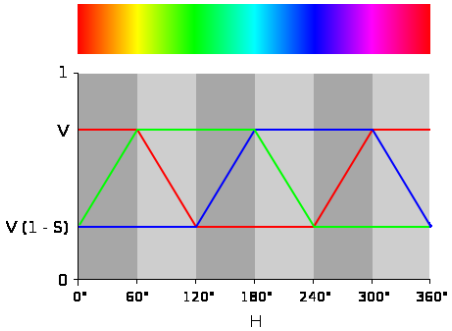

Fig. 1. The relationship between the hue of colors with maximal saturation in HSV color space with their corresponding RGB coordinates [9]

First, the image color histogram was calculated on hue (H) and saturation (S) channels of the whole image. We used 50 bins for the H channel and 60 bins for the S channel. The value (V) channel was not used. The idea was to keep the number of features low enough to emphasize the information that is relevant for classification and adequately train the classifier, especially in approach M2, where the number of classes is increased.

To test if color layout has an important role in classification, we computed 6 local H-S histograms on images divided into 3x2 grids, and one H-S histogram computed on the central part of the image. The central part was of the same proportions as the whole image, but 1/3 of the diagonal size. The arrangement of image grid from which the local color histograms were computed is given in Fig. 2.

Fig. 2. The arrangement of image grid from which the local color histograms were computed

Alternatively, we defined a set of features F which includes dominant colors, features based on edges and the number of faces. Dominant colors correspond to the histogram bins with the highest values and are defined according to [10]. We have used different numbers of dominant colors (3, 6, 8, 12, 16, 24 and 36) and have experimentally determined that 12 dominant colors yield the best classification results in our task.

The edge based feature was computed by first blurring the value (V) channel of each image with the 3 by 3 Gaussian filter, convolving the result with an edge detection mask and counting the number of pixels exceeding the set threshold. Experimentally we selected the value (V) channel of HSV color model and set the threshold to 0.5. We used the Sobel edge detector.

The number of faces in the poster was detected by the OpenCV [11] implementation of Viola-Jones face detector on images blurred with 3 by 3 Gaussian filter. Given that posters are images that are artistically styled, face detection for frontal faces was successful in 66%, while the profiles had significantly worse results, both less than expected for unprocessed images.

C. *Classification Methods*

We used the distance ranking (DR), k-NN and Naïve Bayes classifiers on data adapted with both data transformation methods, and compared the results with the random k-label sets (RAKEL) [12] method which has been shown to be effective in multi-label classification tasks.

For both data transformation methods M1 and M2, we used the same procedure to define representative feature values for the genre labels. For each genre label, we defined a number of representative vectors for each feature except for the number of faces for which the average number was used. The representative values were determined using k-means clustering algorithm. Experimentally, we selected up to 3 representative H-S histograms, 12 dominant colors and 3 centroids of edge based feature values.

For genres that have few movies for one centroids value, less than 3 representative H-S histograms are created. Otherwise genres would be represented with histograms based on too few examples to be relevant. For example, the Horror genre has two representative H-S histograms indicated in the Fig. 3 and Fig. 4, while the Action genre has three representative H-S histograms.

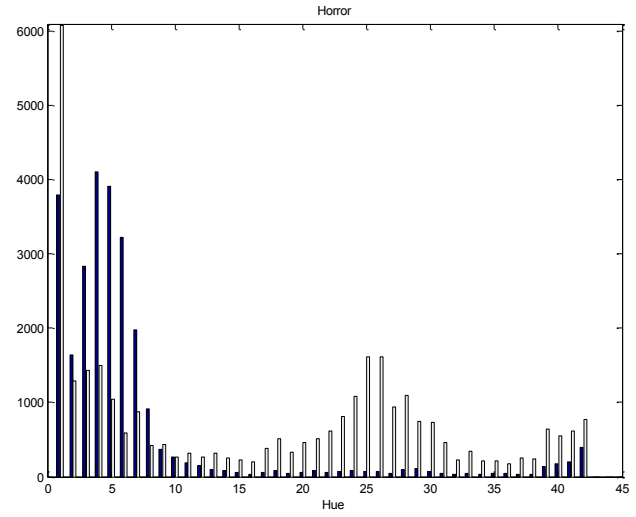

Fig. 3. Representative hue histograms for the Horror genre.

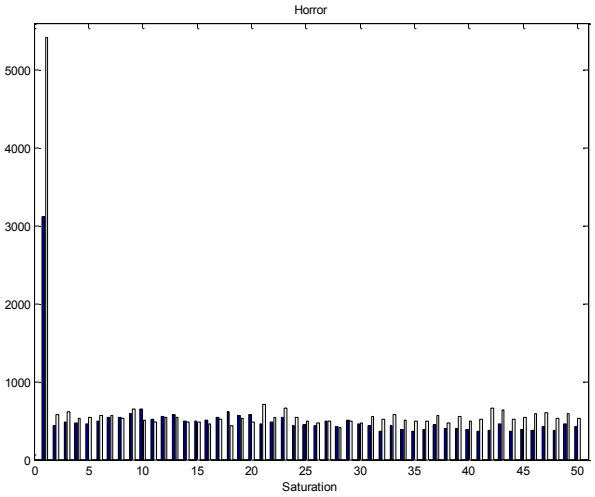

Fig. 4. Representative saturation histograms for the Horror genre.

To determine distance between H-S histograms computed on the poster images, the Chi-Square distance was used (1):

$$d(H_1, H_2) = \sum_I \frac{\left(H_1(I) - H_2(I)\right)^2}{H_1(I)} \qquad (1)$$

where H1, H2 are normalized H-S histograms, I is a histogram bin and d(H1, H2) distance used to express how well both histograms match. For the features from the set F we used the Euclidean distance.

Figures 5 and 6 show the hue and the saturation histograms of Action and Comedy genres. It can be seen for example, that Action posters typically have many more black/gray pixels than Comedy posters, as presented on the saturation histogram. The hue histogram shows the different distribution of colors, e.g. Action genre has more pure red (Hue histogram bin 0) values, while Comedy genre has more orange values (Hue histogram bin 4). Note that hue values range from 0-50 and saturation ranges from 0 to 60.

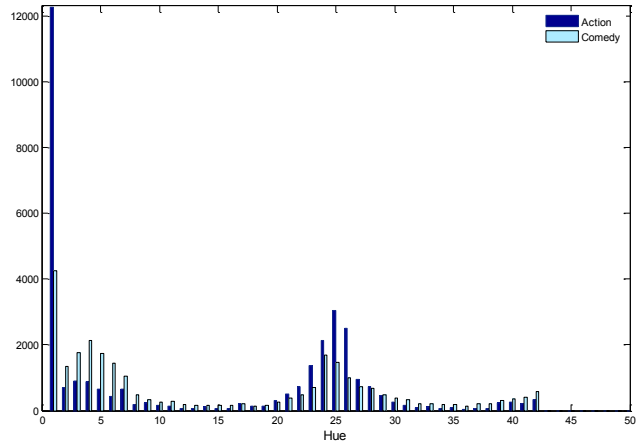

Fig. 5. Action and Comedy hue histograms.

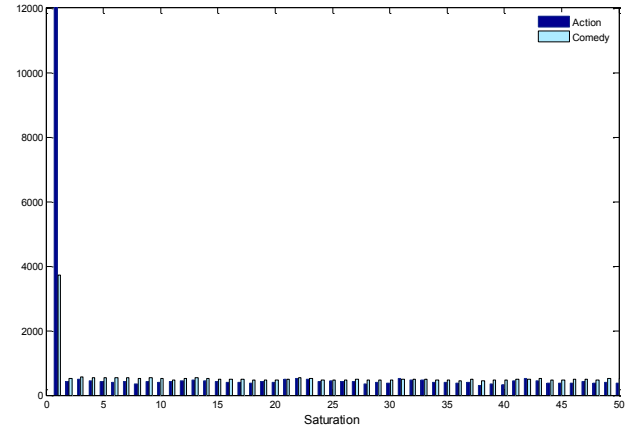

Fig. 6. Action and Comedy saturation histograms.

Moreover, the correlation among dominant colors and movie genres has been experimentally determined. For instance, Animation and Comedy tend to have a large variety of colors (hues), whereas War and Horror films often adopt few dominant colors (hues).

A new unknown movie poster is classified into genres using distance ranking (DR), Naïve Bayes (NB) and RAKEL classification methods.

In the case of DR, the distances of genre centroids and of the feature values extracted from a movie poster are calculated using (1) when histograms are used and Euclidean distance for the features from the set F. The genres are ranked according to the distance of their centroids to the poster features and the top two are selected as classification results.

When using Naïve Bayes, each feature vector x_{e_j} of poster e_j is classified into one of the genre labels according to the maximum posterior probability c_{MAP} (2):

$$c_{MAP} = \text{argmax}_{C_i \in C} P\left(\boldsymbol{x}_{e_j} \middle| C_i\right) P(C_i) \qquad (2)$$

The probability $P(C_i)$ is estimated from relative frequency of label C_i in the training data. To determine the second genre we pick the class with the second highest probability score $P(x_{e_j}|C_i)$.

RAKEL was run using the nearest neighbor (1-NN) classifier based on the Bhattacharyya distance (3),

$$d_B(p,p') = \sum_{i=1}^{N} \sqrt{p(i)p'(i)}, \qquad (3)$$

where p and p' are histograms and N is the number of bins.

The RAKEL subset size was 3 and the number of models was 12.

IV. EXPERIMENTAL RESULTS

All experiments were run using 5 runs of 5-fold cross-validation. The following results were obtained as an average of those runs.

The Table II shows the classification results for the test set of 500 posters using the data transformation approach in which classes correspond to single genres (M1). The presented results are obtained using distance ranking and Naïve Bayes classifier. The results of distance ranking are obtained based on H-S histograms (DR1), local H-S histograms (DR2) or features from the set F (DR3) explained in the Section II. In the Tables II and III, rows marked as "2/2" show the percentage of movies for which both movie genres were correctly recognized and rows marked "1/2" show the percentage of movies for which at least one of the two genres was correct. The best results are obtained using distance ranking based on features from the set F in cases 2/2 and 1/2.Similar results are obtained by Naïve Bayes. Comparing the data, the contribution of color seems to be most important for classification.

TABLE II. CLASSIFICATION RESULTS FOR DATA TRANSFORMATION METHOD M1.

No. correct labels/top ranked labels	DR 1	DR2	DR3	NB
2/2	8.97%	10.10%	**12.1%**	11.2%
1/2	59.72%	54.85%	**66.58%**	62.21%

The results of classification on the same set using the data transformation method with combined genre labels (M2) is presented in the Table III in the similar fashion. In this case, RAKEL method was additionally used.

TABLE III. CLASSIFICATION RESULTS FOR DATA TRANSFORMATION METHOD M2.

No. correct labels/top ranked labels	DR 1	DR 2	DR 3	NB	RAKEL
2/2	**13.61%**	8.90%	10.51%	8.93%	13.24%
1/2	57.69%	58.44%	62.08%	61.24%	**62.54%**

The best results are obtained using distance ranking based on histogram, if all labels need to be correctly classified (2/2). If one correct label should be obtained among the two top ranked (1/2), then RAKEL is the best solution.

Distance ranking based on global H-S histograms used with data transformation method M2 performs best when both genre labels need to be correctly classified. If we allow one incorrect label among the top two ranked, the distance ranking and data transformation method M1 used with the features from the set F (DR3), performed best on test data.

Perhaps surprisingly, results obtained by local H-S histograms are worse in the case of the M2 approach.

The large differences between classification results for cases 2/2 and 1/2 are expected because of the difference in the baseline, where expected random score for 2/2 is 6.7% and for 1/2 is 33%. In both cases, automatic classification performed about twice as good.

The results suggest that both data transformation methods perform similarly regardless of the tested classification method. Consequently, we expect that new features should be extracted from posters to improve the classification.

A few examples of correctly and incorrectly classified posters obtained using DR1 and M2 transformation method are presented in Table IV. Presented movie posters give some insight into the complexity of the problem.

TABLE IV. EXAMPLES OF CORRECTLY AND INCORRECTLY CLASSIFIED POSTERS

Movie poster	No. correct labels/ top ranked labels	Correct labels	Top 3 predicted labels
	2/2	Animation, Comedy	Animation, Comedy, Action
	1/2	Action, War	Action, Horror, Comedy
	0/2	Animation, Comedy	War, Horror, Action

V. Conclusion And Future Work

In this paper, automated detection of movie genres from posters was modeled as a multi-label classification task, where a single movie may belong to more than one genre. The multi-label classification problem was transformed into single-label classification by two kinds of data transformation methods. The first one transforms examples with multiple labels into multiple ordered pairs that are suitable for single label classification. The second extends the set of genre labels by forming combined labels. Both data transformation methods are algorithm independent and were tested with Naive Bayes and distance ranking classifiers and have performed comparably on the test set of 500 movie posters. A well-known multi-label classification algorithm RAKEL was also used with similar results.

The features used in the classification were low-level features based on color and edge combined with the number of detected faces on posters.

The best results were about 14% for two out of two correctly detected labels and 67% for at least one of two correctly detected labels. Since the results were similar using all the tested classification algorithms, we expect that the improvement in classification should primarily come from finding better image features that capture the relevant information about genres in posters. In the future work, we plan to test the dense SURF [13], GIST [14] and other visual low-level features used for scene representation [10] as well as features for text recognition. We also plan to test the classification on a much larger dataset with larger set of genres.

A subjective test will be conducted to determine human ability to detect genres from poster images, and the results will be used for comparison with automatic detection.

Detection of Roadside Vegetation Using Features from the Visible Spectrum

I. Harbaš and M. Subašić
Faculty of Electrical Engineering and Computing, Zagreb, Croatia
iva.harbas@fer.hr

Abstract – Detection of vegetation in images is a common procedure in remote sensing and is commonly applied to satellite and aerial images. Recently it has been applied to images recorded from within ground vehicles for autonomous navigation in outdoor environments. In this paper we present a method for roadside vegetation detection intended for traffic safety and infrastructure maintenance. While many published methods for vegetation detection are using Near Infrared images which are particularly suitable for vegetation detection, our method uses image features from the visible spectrum allowing the use of common on-board color cameras. Our feature set consists of color features and texture features. One of our specific goals was to identify a useful texture feature set for the problem of vegetation detection. Based on the feature set, the detection is implemented using a Support Vector Machine algorithm. For training and testing purposes we recorded our own image database consisting of different images containing roadside vegetation in various conditions. We are presenting promising experimental results and a discussion of specific problems experienced or expected in real-world application of the method.

Keywords **- image analysis, image processing, vegetation detection, traffic safety.**

I. INTRODUCTION

Detection and analysis of the state of vegetation from images is considered very important in the field of remote sensing where it is used for detecting green areas on Earth and detecting changes caused by urbanization. Detection of stressed vegetation [2], [10], [5] and other similar applications are aimed at raising environmental awareness and improving our ecological footprint.

Vegetation detection in other areas besides remote sensing, e.g., in robotics, is very young and unexplored. The need for detecting vegetation in this area arose when autonomous vehicles were used for forest exploration. Vegetation is not a static obstacle and all of vegetation-like obstacles don't need to be avoided (i.e. a vehicle can go over tall grass) [9]. Hence, it was necessary to detect vegetation and decide if the vehicle can drive over that obstacle or should it be avoided. Increased use of autonomous vehicles for off-road navigation is the main reason for new research efforts in detection and classification of vegetation [1], [3], [6], [7], [8].

In this paper we present a pixel-based method for roadside vegetation detection from within a moving vehicle intended for traffic safety and infrastructure maintenance (e.g., mowing the grass along the road).

Many published methods for vegetation detection are using Near Infrared (NIR) images where vegetation has distinctive properties. Our method uses image features from the visible spectrum, imitating how people detect vegetation using color and texture features and allowing us the use of a common on-board color camera. The benefit of this approach is that the same camera can be used for other computer vision tasks which require color images recorded from within a moving vehicle. It should be made clear that many publications mentioning successful vegetation detection often indicate some very specific species of vegetation or a very limited dataset. And these approaches are then just used for robots operating in a specific environment or for satellite images but not for roadside vegetation detection using a camera mounted on a vehicle. Due to different goals, those methods cannot be directly compared to our method for detection of vegetation.

A brief overview of some proposed methods for vegetation detection is given in the second section of this paper. Our approach is introduced in the third section where feature selection and classifier training is described. Our methods results will be presented in the fourth section. Conclusions and future work are presented in the last section of this paper.

II. RELATED WORK

People easily detect vegetation on the basis of typical visual characteristics such as color, texture and shape. Often researchers try to mimic the human visual system when developing methods for automatic detection of vegetation. Studies have shown that there is valuable information for vegetation detection in the spectrum invisible to the human eye and therefore, systems for detecting vegetation can be divided into two groups:

- Systems based on the visible spectrum
- Systems based on the invisible spectrum.

Systems based on visible spectrum use color and/or texture features. Using only color as a feature can give good results but objects of the same color as vegetation (e.g., green car) are falsely detected. Such objects can be distinguished from vegetation using additional texture features. A green car does not have a strong texture while the texture of vegetation is unstructured and turbulent.

This research has been partially supported by the European Union from the European Regional Development Fund by the project IPA2007/HR/16IPO/001-040514 VISTA - Computer Vision Innovations for Safe Traffic.

Some researchers use LiDAR (*Light Detection And Ranging*) sensors which give information about the 3D structure of the scene for calculating texture features. Nguyen et al. use a sliding cube across the 3D-point cloud in space to capture the local point statistics features. For every sliding cube they calculate a positive definite covariance matrix and extract the principle components (eigenvalues and eigenvectors) of that matrix. The relative differences of the three eigenvalues indicate a spatial structure. They segment the 3D-point cloud into three classes: surfaces, linear structures and porous volumes (foliage grass, tree canopy) [6], [9]. It can be argued that using only 3D-data can't result in a robust detection of vegetation because no color information is used. Therefore, Nguyen et al. address the 2D-3D fusion approach which combines 2D-3D information for vegetation detection [6]. For 2D features they use mean and standard deviation of brightness and color, and the difference of histograms [6]. These features are used to train a SVM (*Support Vector Machine*). The problem with this approach is mapping the 2D and 3D information because they are obtained by two different sensors. For this in [6] they use a coarse calibration method. This approach is time consuming and it should be used when time is not a criteria [9]. Liu et al., in a similar way, are using a combination of 2D and 3D features. The feature vector consists of the height calculated from the 3D space obtained with LiDAR, and the H and S components obtained by converting RGB (*Red, Green, Blue*) to HSV (*Hue, Saturation, Value*) color space [3].

Except for navigation, detection of vegetation is also used to improve the quality of video, or TV images. In [4] and [11] authors used texture features and color components from the YUV color space as color features. After detection of grass in video sequences they enhance the image by changing the color or brightness of pixels in that segment.

Using features from the visible spectrum has some problems (leaves change color, green cars, different illumination scenes, etc.) and that is why researchers started using features from the invisible spectrum. This idea was present for many years in remote sensing where researchers found that chlorophyll rich vegetation has a high reflectance in NIR part of the spectrum and can clearly be distinguished from the sky and other objects. Using this property of vegetation many different features can be calculated which are called Vegetation Indices. Mostly used is NDVI (*Normalized Difference Vegetation Index*) [8].

Although NDVI has been successfully used in remote sensing the work of Bradley et al. [1] has shown that there is a drastic difference between the view-points of a satellite and an autonomous ground vehicle where there are more problems typical for on-ground recordings such as shadow, shining and underexposure effects. Taking that into consideration and wanting to avoid time consumption needed for calibration and LiDAR scanning Nguyen et al. developed a modified vegetation index MNDVI [9] which they use as a feature for vegetation detection and all they need is NIR intensity and color information. In [8] a combination of vegetation indices with color and texture features is used for vegetation detection. First, by setting a threshold for NDVI and MNDVI they obtain pixels rich in chlorophyll. These pixels are seeds for spreading algorithm that follows. For each seed pixel distance in color and texture between the seed pixel and his neighbors is calculated.

Systems based on invisible spectrum require equipment for recording NIR images and systems based on visible spectrum that use LiDAR for feature extraction need an additional 3D scanner.

We require no additional sensors but a single color camera for data acquisition so the features that will be used for detection are from the visible spectrum only.

III. METHODOLGY

In this section we describe our method for detecting roadside vegetation using only features from the visible spectrum which does not require any additional equipment except a common color camera mounted onboard. Our method for vegetation detection comprises of three steps:

1. extraction of selected features,
2. pixel-based classification and
3. postprocessing.

To the best of our knowledge there is no publicly available database that could be used for our application. That is the reason we made our own database for testing and all results presented in this paper were obtained using this database. The database was recorded using a High Definition Camcorder Canon XF100 from a moving vehicle. The videos have been recorded in daylight at different times of the day to include different lighting conditions. The database includes different traffic scenarios including roadside vegetation in various conditions. Currently our database contains 270 images extracted from the recorded video sequences, each having 1920x1080 resolution. These images were manually segmented into vegetation and non-vegetation regions.

The intended use of our method requires that exact contours of each vegetation region are detected so we perform per-pixel classification into vegetation or non-vegetation classes.

A. Feature extraction

Features that we extract from color images to detect vegetation are color and texture features.

1) Color features

Human perception of color is one of the most important visual elements which help us visually recognize different objects. Color is an important descriptor of vegetation because vegetation doesn't have a specific shape but is usually represented by green, orange or yellow color. Transferring this human ability to a computer algorithm is far from simple. One major problem is the change in intensity and color in different

light conditions. This usually doesn't pose a problem for the human visual system but a change in luminance can cause a significant change in image features.

Some authors consider using different color spaces for color features (e.g., HSV [3], YUV [4], [11]), while others take into account the mean and standard variation values of intensity and color [6]. In [3] they use only H and S components, ignoring the luminance component V so their feature set would be less sensitive to light changes in the scene.

Taking this into account the first step was deciding which color features would be most suitable for our problem. Three color spaces commonly used in published vegetation detection methods were used in our test: RGB, HSV and CieLAB. We didn't test YUV color space because YUV is used for a specific analog encoding of color information in television systems and the only reason it is used in [4] and [11] is because they used it for TV image enhancement. CieLAB was added for testing because it is designed to mimic human perception of color. Additionally, we tested only the H and S components excluding the lightness from HSV and only A and B components excluding the *L* component from CieLAB.

We used five different feature vectors containing different color features to train a SVM classifier with linear kernel. This classifier was used only in this stage of testing to evaluate how appropriate each feature vector is for our problem.

To properly evaluate how each of our color features will generalize to an independent data set we use 10-fold cross-validation to measure the performance and to validate our results. The results are shown in Table I.

From these results we conclude that excluding the lightness component from the feature set does not affect the results drastically. Slightly better performance can be seen when using the lightness component with color information, i.e., better accuracy is achieved using HSV and LAB then HS and AB features respectively. The second conclusion we draw from Table I. is that RGB and LAB color spaces perform similarly and are giving better results compared to HSV. Vegetation color should theoretically be green in HSV color space under most different environment conditions. In reality, this is not always true for scenes containing sky or varying lighting conditions (shades, overexposure, and underexposure). Low intensity of the value V in HSV color space tends to turn the color of image to red, red brown, etc [6]. And that is why using HSV color space has more false positive errors where red objects in scenes are detected as vegetation. On the basis of conclusions previously presented, we decided to use RGB color components as color features.

2) Texture features

TABLE I. COMPARISON OF DIFFERENT COLOR SPACES USED FOR VEGETATION DETECTION

	Feature vector				
	RGB	***LAB***	***HSV***	***HS***	***AB***
Accuracy	92,6873	92,767	87,3196	87,1123	91,1518

Simple color features lack discriminative power required for our problem where non-vegetation objects may have colors similar to vegetation like illustrated in **Fig. 2 b.**. Additionally when dry vegetation, which takes on shades of yellow and red, is added to the training set, the number of falsely detected objects increases. To solve this problem we added texture features to the feature vector.

There are many different methods for calculating texture features in images and choosing one is a difficult task. Knowing that vegetation is diverse and that vegetation regions in images contain more information than homogeneous surfaces, we decided to use entropy as a texture feature. Entropy is a statistical measure of randomness and it can be described as a measure of the amount of disorder in a system. For images it can be expressed as a spread of states (gray levels) which the individual pixel can adopt. If pixels in an image, or in a block of an image, have the same values the entropy is zero and if an image (or a block) contains pixels changing in unexpected ways the entropy is high. We expect that vegetation region in an image have high entropy.

The entropy *H* of an image is defined as [12]:

$$H = -\sum_{k=0}^{M-1} p_k \log_2 p_k \qquad (1)$$

Where *M* is the number of gray levels and p_k is the probability associated with gray level *k*.

B. Feature ranking

Using the entropy of the grayscale image did not yield better performance so calculating entropy in different color spaces was considered. Color spaces taken into consideration were the same ones used for testing color features. There are a lot of possible combinations of color features and entropy in different color spaces that we could use as a feature vector for testing. To find the best one we used feature ranking as a filtering method where all these features are ranked, and based on the calculated rank we choose the best one.

To understand the influence of features on the system or even if the number of features is to large feature ranking is a good method to get baseline results and to assess features individually [13]. We created a feature vector that contains our selected three color features and 9 texture features that are entropy calculated for R, G, B, H, S, V, L, A and B components of the corresponding color space models. Total number of features is 12. Twelve features is not too much to handle for any kind of feature selection, but feature ranking is a good filter method and a good preprocessing step independent of the choice of the predictor [13]. The goal of using any kind of filtering of features is to eliminate possible outliers. Ranking was done using Wilcoxon rank sum test which is a nonparametric test for equality of population medians of two independent samples [14]. A nonparametric test was used because they don't assume normal distributed classes and our samples were tested and showed that they are not normally distributed.

Variable ranking makes use of a scoring function computed from the input variables (calculated features) and output variables (class assignment). For this test the scoring function is the rank sum statistic calculated for every feature in the feature vector. By convention, we assume that a high score is indicative of a valuable variable [13].

This test was repeated 10 times so that statistical significance can be established. For each of the ten different iterations, R, G and B features were always the three top ranking features followed by entropy calculated for saturation (S component of HSV color space). This is the only entropy that was mostly top ranked while others varied drastically from test to test. For this reason we added only this entropy to our feature vector.

C. Training the classifier

SVM is a well known supervised learning algorithm used for classification and in this paper it is used to discriminate vegetation and non-vegetation. An SVM is trained with a set of training examples each marked as belonging to one of two classes, in this case, vegetation and non-vegetation. Positive training examples were selected randomly from hand segmented vegetation regions in images and negative examples were also selected randomly but we made sure that different problematic objects (green, red, and yellow cars, green T-shirt of a pedestrian, yellow stripes on the road, etc.) are present in the negative set so the classifier would be trained on these examples too.

Selecting the training data is a very important step because all further classification is dependent on the trained model. Using only green vegetation for training makes a classifier that detects green vegetation but doesn't detect vegetation that is yellow or red (dry vegetation) (**Fig. 1.**) or different species of vegetation. Adding dry vegetation to the training set makes a classifier that detects dry vegetation but it detects more false objects as vegetation including yellow and red objects (and not only green objects).

After training examples are selected the SVM training algorithm builds a model that assigns new examples into one category or the other [15].

Our database contains 270 images of resolution 1920x1080 which presents 1920*1080*270 pixels available for training and testing the classifier. A smaller sample needs to be selected because training an SVM with a large number of samples can lead to overfitting and a very complex model can be built which can be time consuming during classification.

There are various recipes for calculating the required sample size which require knowledge of the variance or proportion in the population, the maximum desirable error, as well as the acceptable Type I error risk (confidence level).

It is possible to construct a table [16] that suggests the optimal sample size – given a population size, a specific margin of error and a desired confidence interval. Based on the table from [16] we found that the best sample size is 4000 (2000 samples representing vegetation and 2000 samples representing non-vegetation). These 4000 samples are chosen randomly. We have tested the algorithm using a greater number of samples but it only increased the computational time and it didn't improve accuracy.

a) b)

Fig. 1. Detection using: a) only green vegetation for training, b) all vegetation for training

D. Postprocessing

Classification is done for every pixel in an image. The resulting image with two classes marked often has some pixels marked as vegetation inside a non-vegetation region and non-vegetation pixels inside a vegetation region. It is safe to assume that pixels, or groups of pixels surrounded by vegetation also belong to vegetation. Also, solitary pixels or small groups of pixels surrounded by non-vegetation is often non-vegetation but is misclassified because it is too similar to underexposed vegetation (shadows under cars or parts of asphalt) or it has yellow reflectance (dry vegetation is mostly yellow). These gaps and solitary pixels can be removed after classification using a combination of morphological operations on the image.

In the postprocessing stage of our method we use morphological opening. The morphological open operation is an erosion followed by a dilation, using the same structuring element for both operations [17]. After opening further improvement was done by additionally removing solitary groups of pixels of certain size (for which we presume that are misclassified non-vegetation pixels) followed by filling up patches of certain size misclassified as non-vegetation (surrounded by vegetation).

IV. Experiments and Results

To find the optimal parameters for our method we tested several options for every aspect and choose the ones that gave the best accuracy.

Entropy is calculated for every pixel taking into account its neighborhood. The neighborhood size is a changeable variable. We tested four block sizes: 7x7, 9x9, 11x11, and 13x13. Experiments showed that the optimal neighborhood size is 9x9 (the smaller one showed worse accuracy, while the bigger ones did not improve accuracy). For training and classification, beside the linear kernel, we tested quadratic and radial kernels to take advantage of SVMs kernel trick and Cover's theorem. The best classification accuracy was obtained using radial basis SVM. For postprocessing, three variables have to be set: the structuring element, size of patches to remove, and size of patches to fill. We have used a circular structuring element with 5 pixel radius. At this step we presume that vegetation parts of an image are well connected and those parts in the image are large so

we remove the ones that are less than 3000 pixels and filling was done for patches less than 500 pixels big. The small value of 500 was used because there are parts of roadside vegetation that have utility shafts that are small and any bigger size of 500 would misclassify these parts as vegetation (**Fig. 2 b.** and **c.**, **Fig. 3 b.** and **c.**).

Adding texture features improved detection in problematic images. With these features the green objects in **Fig. 2 a.** are much better classified as non-vegetation seen in **Fig. 2 c.** compared to **Fig. 2 b.** where only color features were used. Also, the yellow stripes on the road were falsely detected as vegetation when only color is used as a feature (**Fig. 2 b.**) but adding texture improved detection (**Fig. 2 c.**). In **Fig. 2 c.** misclassified solitary pixels and groups of pixels can be seen which we improve using postprocessing (**Fig. 2.d.**).

For final testing of our method we divided our database into training and testing set. Training set consists of 180 images which is 2/3 of the total number of images in the database, and from this set we are randomly choosing 4000 pixel samples for training. The remaining 90 images were the testing set, and all their pixels were testing samples. Because we select our training samples from the training set randomly we must repeat the selection process to exclude the possibility of choosing "the perfect" training samples and presenting statistically insignificant accuracy. We ran 10 iterations of training and testing, every time randomly selecting the training set and achieved average accuracy of pixel classification is 94.995%. We used high definition images in our training and testing and because of that the classification is somewhat time consuming but at this stage of our research that is not a concern for us as we are not focused on real-time performance.

Some results of vegetation detection using the method presented in this paper are shown in **Fig. 3**. In **Fig. 3 a.** and **b**. more examples of green objects in scenes correctly

Fig 2. Results of vegetation detection for problem images

detected as non-vegetation can be seen. In **Fig. 3 c. – e.** we see good detection in different traffic scenes, while good performance in detecting vegetation in shade can be seen in **Fig. 3 f. - h.** Also good detection is presented in underexposure and overexposure conditions (**Fig. 3 i.** and **j.** respectively). In **Fig 3 k.** and **j.** we can see poorer detection results. In **Fig 3 k.** parts of the yellow car are still detected as vegetation even though we included these examples in the training set. This color is too similar to dry vegetation examples in the training set and because entropy is high over the edges the classifier decided that this is vegetation. In image **Fig 3 j.** vegetation that is far from the camera is not detected due to a lack of details in that part of the image, combined with a color deviating from green. Parts of the parked dark car are also detected as vegetation due to green reflections on its hull.

V. CONCLUSION

In this paper we present our method for detecting roadside vegetation using only features from the visible spectrum. This approach allows us to use common multi-purpose color cameras, and we are using both color and texture features. Based on our experiments, RGB color space proved to be the optimal choice for our color features. In the similar manner, we have selected entropy as our texture feature. We require a texture feature because color features alone were insufficient to solve problems with common situations where green non-vegetation objects occur in images. Entropy has mostly solved the problem of false positive green objects, but to further improve detection results we have implemented a post-processing step based on morphological operations. We have compiled our own data set for training and testing, with special attention paid to the training data set. It was compiled from random images and from several especially problematic images. The classifier we have used is SVM with radial kernel. We have obtained promising experimental results, and for our future work we plan to implement complex texture features from the frequency domain to increase accuracy. Real-time execution was not in the focus of presented research so current version of our vegetation detection method is not optimized for speed.

Abstract – In order to optimally control the energy flow in the microgrid, consist of several renewable energy sources, including solar photo electric system and storage system, it is essential to know availability of the specific energy source. So, it is necessary to determine the exact moment of the Sun shading the by clouds as well as shadow duration. These parameters could be obtained by cloud movement tracking system. The cloud movement tracking system is based on the detection of cloud edges and determining angular velocity vector which describes the speed and direction of cloud movements. As clouds change their shapes, directions and speeds, the position of every cloud is determined according to his centroid. This paper deals with cloud recognition and movements analysis based on video stream obtained by camera with resolution 1920x1080 pixels and refresh rate of 25 frames per second. The clouds detection is based on the HSV (Hue-Saturation-Value) color model in combination with mathematical morphological operations of erosion and dilation. Video and image processing was performed by application developed in Java programming language using the JavaCV library that offers the functionalities of computer vision.

Keywords – renewable energy sources, cloud movement prediction, Sun cover duration, centroid, HSV

I. INTRODUCTION

Environmental requirements as well as increased demands for energy cause increased share of renewable energy sources in electric power production. On the other hand, increased share of renewable based on solar and wind power increases challenge of maintaining power grid stability, due to their stochastic nature. In order to maintain the desired level of availability it is essential to use different energy storage system in the microgrid and virtual power plants. One of the crucial data in optimizing microgrid power flow is prediction of the availability of the specific power source. The main uncertainty source of the solar irradiance for solar energy sources are clouds and their movement. Predicting the instant of the shading of photo panels, as well as duration of the shading, allows more effective management of the microgrid. As weather forecasts mostly obtain irradiance prediction at the hourly level it is crucial to obtain short term cloud movement prediction [1], [3].

This paper deals with reduction of the cloud movement prediction sampling period to only a few seconds using cloud movement tracking by video stream processing. The camera frame rate was set to 25 frames per second and by processing every 100th or 300th image, it is possible to set the sampling frequency to four seconds (25 x 4 = 100) or to 12 seconds (25 x 12 = 300), etc.

After detecting the cloud edges or contours that accurately determine the position of the clouds on the image being processed, it is necessary to also determine the movement direction and velocity of clouds in the cylindrical coordinate system expressed in radians per second. As the reference point between two cloud positions, the centroid was chosen. Using that information it is possible to estimate the moment when the nearest edge of the cloud will reach the Sun surface and begin to block the Sun. In a similar way it is possible to determine how long the shadow will last.

In the following chapters the principles used to detect the edge of the clouds were presented, based on HSV (Hue-Saturation-Value) color model and morphological operation of erosion and dilation. Every processing step is picture illustrated and the final results of cloud edge detection are shown.

II. HSV COLOR MODEL

In contrast to the commonly used RGB (Red-Green-Blue) color model, which is based on creating different shades of color by adding different intensities of red, green and blue (ranging from 0 to 255), in this paper the HSV color model is used. The HSV color model is based on three parameters: hue, saturation and value. Hue defines the color, saturation defines the amount of color, and value defines the level of brightness in color, or the amount of black added to the color. Instead of the Cartesian coordinate system that is used in the case of the RGB color model, HSV uses a cylindrical coordinate system (Figure 1). [4]

Hue specifies angles from the red color, which is at 0˚, from the yellow color, which is at 60˚, from the green color, which is at 120˚, from the cyan color, which is at 180˚, from the blue color, which is at 240˚ and from the magenta, which is at 300˚. Saturation with value of 1.0 result with the maximum of color amount, and the lower values that 1.0 result in a color that is closer to white color. In case of the saturation value of 0.0, the shade of gray color occurs, and that depends on the level of parameter values of HSV color model. For example, if the color is set to red, saturation and value are set to 1.0, resulting color is pure red. In the case of reducing the saturation red color becomes lighter and eventually

becomes pink, and with additional reduction of the saturation becomes white. [4]

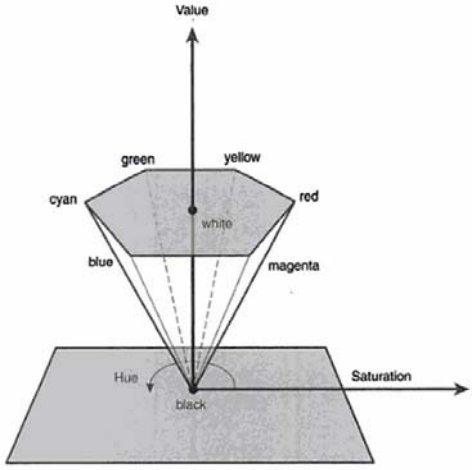

Figure 1. The cylindrical coordinate system of the HSV color model [4]

The conversion of RGB component values to the HSV color model begins by assigning a maximum RGB component value to value parameter of the HSV color model. The value of saturation parameter is determined by calculating the difference between the maximum and minimum values of the RGB components, and this difference must be divided with the highest value among RGB components. The first special case represent RGB values set to 0, which represents the black color, and the HSV parameters saturation and value also have the value 0 (in this case the value of hue parameter has no effect on the resulting color). The second special case represent all RGB values as equal, which represents the shade of gray color, and means that the saturation value is 0. The hue parameter in the HSV color model is determined by one of the methods shown in the following terms, depending on the values of the RGB components. The complete algorithm for determining the HSV values is shown below (1). [4]

$$\max_RGB = \max(R, G, B)$$

$$\min_RGB = \min(R, G, B)$$

$$d = \max_RGB - \min_RGB$$

$$V = m_RGB$$

$$S = \begin{cases} 0, d = 0 \\ \dfrac{d}{\max_RGB}, d \neq 0 \end{cases}$$

$$H = \begin{cases} nedefiniran, S = 0 \\ 60° \times \left(\dfrac{G - B}{d} \bmod 6 \right), R = m_RGB \\ 60° \times \left(\dfrac{B - R}{d} + 2 \right), G = m_RGB \\ 60° \times \left(\dfrac{R - G}{d} + 4 \right), B = m_RGB \end{cases} \quad (1)$$

III. CLOUD EDGE DETECTION

Cloud edge detection consists of several steps: image conversion from RGB to HSV color model, the execution of basic morphological operations of erosion, dilation and detection of the contours that represent the edges of the clouds.

Figure 2. Initial cloud image in RGB color model

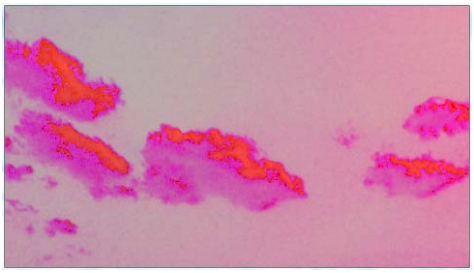

Figure 3. Converted cloud image to BGR and afterwards to HSV color model

A. CONVERSION FROM RGB TO HSV COLOR MODEL

According to the rules for converting the image from RGB to HSV color model described by (1), the transformation results with the same output – the appearance of the initial picture remains unchanged (Figure 2). OpenCV library and thus JavaCV by default use a little different color model called BGR (Blue-Green-Red), which is very similar to RGB, with only difference in the color component order (R and B switch places). Using BGR color model the initial cloud image (Figure 2) is converted to image with predominantly red colors instead of blue colors (Figure 3).

After the conversion to BGR and HSV color model, it is necessary to perform morphological operations of erosion and dilation. Morphological operations use structural elements of the given size and shape based on the values of neighboring pixel perform transformations in the input image. The most basic morphological operations are erosion and dilation. Before performing these operations, the cloud images must be converted to black and white.

B. EROSION

Erosion is used to remove the pixels at the edges of cloud contours within the image. According to [9], erosion is morphological transformation which combines two sets using vector subtraction of set elements. If A and

B are sets in Euclidean *N*-space (E^N), then the erosion of *A* by *B* is set of all elements *x* for which $x+b \in A$ for every $b \in B$. The erosion of *A* by *B* is denoted by $A \ominus B$ and is defined by

$$A \ominus B = \left\{ x \in E^N \,\middle|\, x+b \in A \text{ for every } b \in B \right\} \quad (2)$$

If equation (2) uses the expression for difference of elements *a* and *b* and sets *A* i *B* respectively, the equation (2) becomes:

$$A \ominus B = \left\{ x \in E^N \,\middle|\, \text{for every } b \in B \text{, there exist an } a \in A \text{ such that } x = a - b \right\} \quad (3)$$

According to [9], the utility of the erosion transformation is better appreciated when the erosion of is expressed in a different form. The erosion of an image *A* by structuring element *B* is the set of all elements *x* of E^N, for which *B* translated *x* is contained in *A*:

$$A \ominus B = \left\{ x \in E^N \,\middle|\, (B)_x \subseteq A \right\} \quad (4)$$

Thus the structuring element *B* may be visualized as a probe which slides across the image *A*, testing the spatial nature of *A* at every point. Where *B* translated to *x* can be contained in *A* (by placing the origin of *B* at *x*), then *x* belongs to the erosion $A \ominus B$.

According to [9], erosion of an image *A* by a structuring element *B* is the intersection of all translations of *A* by the points –*b*, where $b \in B$:

$$A \ominus B = \bigcap_{b \in B} (A)_{-b} \quad (5)$$

Erosion rule can be in the case of binary images and sets represented by *X* and *Y* coordinates of pixels shown in Figure 4 interpreted as follows: the value of the output pixel is the minimum value of all neighboring pixels covered by the structuring element. In case of detecting edges of clouds with that operation the more precise contours are produced.

As a structural element which performs erosion operation, the matrix of dimensions [3, 3] is used, wherein for the central pixel (surrounded by the checked adjacent pixels) the pixel with coordinates (1,1) is chosen. The result of executing erosion operation of black and white image (Figure 3) is shown in Figure 4.

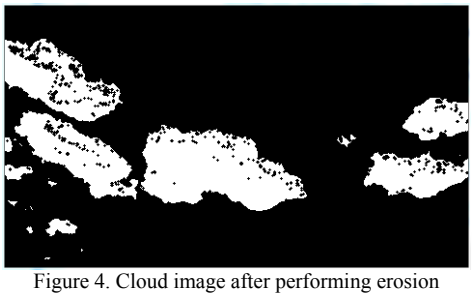

Figure 4. Cloud image after performing erosion operation

In Figure 4. it can be noticed that the edges of the clouds are precisely determined, but on the cloud surfaces black spots are visible – they are undesirable effects of erosion operation. To be able to determine precise contours of each cloud on the image, performing morphological operation of dilation can solve the problem of black spots caused by erosion operation.

C. DILATION

Dilation is used to add pixels to the edges of an object within image. According to [9], dilation is the morphological transformation which combines two sets using vector addition of set elements. If *A* and *B* are sets in Euclidean N-space (E^N) with elements *a* and *b*, respectively, $a = (a_1, \cdots, a_n)$ and $b = (b_1, \cdots, b_n)$ being *N*-tuples of element coordinates, then the dilation of *A* by *B* is the set of all possible vector sums of pairs of elements, one coming from *A* and one coming from *B*. According to [9], assuming that *A* and *B* are subsets of E^N, the dilation of *A* by *B* is denoted by $A \oplus B$ and is defined by

$$A \oplus B = \left\{ c \in E^N \,\middle|\, c = a + b \text{ for some } a \in A \text{ and } b \in B \right\} \quad (5)$$

Furthermore, assuming that *A* is a subset of E^N and $x \in E^N$ then the translation of *A* by *x* is denoted by $(A)_x$ and is defined by [9]:

$$(A)_x = \left\{ c \in E^N \,\middle|\, c = a + x \text{ for some } a \in A \right\} \quad (6)$$

According to [9], the dilation of *A* by *B* can be computed as the union of translations of *A* by the elements of *B*:

$$A \oplus B = \bigcup_{b \in B} (A)_b \quad (7)$$

Dilation rule can be in the case of binary images and sets represented by *X* and *Y* coordinates of pixels shown in Figure 5 interpreted as follows: the value of the output pixel is the maximum value of all neighboring pixels covered by the structuring element.

Dilation operation solves the problem of black spots that appeared on cloud surfaces after erosion operation, thus the image is ready for detecting contours and edges of clouds.

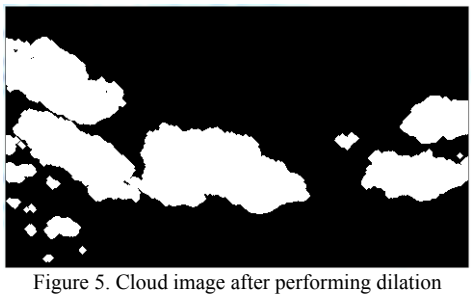

Figure 5. Cloud image after performing dilation operation

Figure 5. shows minimized amount of black points on the surfaces of clouds, while the edges are more rounded than showed in Figure 4. As a structural element that performs

dilation operations, the matrix with dimensions [3, 3] is used, wherein as for the central pixel (surrounded by the checked adjacent pixels) the pixel with coordinates (1,1) is chosen, as in the erosion operation.

D. CLOUD EDGE DETECTION

After performing the dilation operation, in Figure 5 the cloud shapes are clearly visible, which facilitates the detection of edges or contours of the clouds. The contour of the object is represented by a list of points at the edge of the object. [6]

Figure 6. Detected cloud edges

In order to find contours corresponding to the edges of the clouds, the Suzuki contour tracing algorithm [7] was used. Only the outer contours that represent clouds were used. The resulting contours were drawn to Figure 1 and Figure 6 was the final result.

After finding the edges of the cloud it is necessary to determine the direction and velocity of the clouds in order to predict the location of clouds at a certain point in the future, and thus to predict the moment when a cloud reaches the Sun. Regarding how clouds in motion very often change their shape, their edges cannot be used as movement reference points. In this paper, as a reference point for determining the movement of clouds, the centroid of every closed contour (or clouds) was chosen. Also, very small clouds were ignored and the centroid calculation was not performed.

IV. DETERMINING THE ANGULAR VELOCITY VECTOR OF CLOUDS

To determine the direction and velocity of cloud movement, the centroid of every cloud is used to track its position in each image processing cycle. In order to measure the movement, time interval between the measurements must be large enough. Since every 300th image of the video was processed, which means that the interval of cloud position analysis was performed every 12 seconds (300 frames / 25 frames per second = 12s).

Figure 7. Directions of cloud movements

In order to determine velocity and direction of cloud movement, the spherical coordinate system is used. For every cloud the angular velocity vector is determined by analyzing change of the centroid location from the start position $T_0(x_0, y_0)$ to the new position $T_1(x_1, y_1)$.

Figure 7. shows how to determine the direction and movement velocity of clouds. The black point on the cloud surface indicates the new location of centroid after movement, and the red line indicates a change of the centroid position from initial to final position within the analysis cycle (12 seconds). Only clouds with considerable area are taken into consideration.

Angular velocity of each cloud is determined by changes of two components: azimuth and elevation. Azimuth is the angle formed between the North and the observation angle (in range between 0 and 360 °), and elevation is the angle between the horizon and the height of the object being observed (in range between 0 i 90°). Figure 8 shows an example of the object in the sky with azimuth of 156° and elevation of 38°. When determining the azimuth and elevation of objects on the images processed from video, the zenith (the point in the sky above the observer) is placed on the horizontal center of the image (if the image resolution is 1920x1080, the zenith is placed at 960th horizontal pixel so the location of the observer is set on location with coordinates X = 960 and Y = 1080). According to the location of the observer, the angle measured between initial and final centroid points of one measurement interval is calculated and thus determine the first component of angular velocity. Elevation angle is determined by the height of the image (1080 pixels) divided by the maximum elevation angle (90°) and therefore determines the amount of elevation: vertical shift of cloud centroid in pixels multiplied by the quotient of the vertical resolution of the image and the amount in degrees. Taking into account the time interval in which the shift occurred, the second component of angular velocity can be determined.

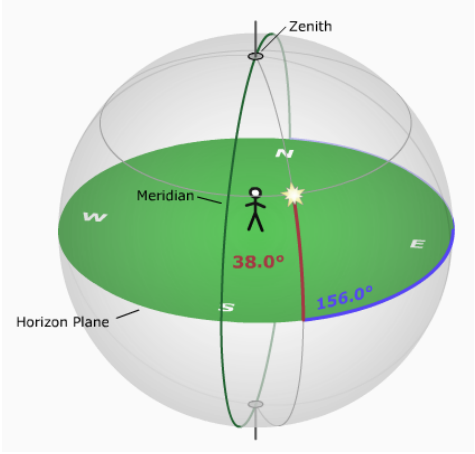

Figure 8. Azimuth and elevation of object on the sky (source: [8])

Figure 9. shows an example of cloud movement, where the centroid as reference point and the observer point is set on coordinated 960x1080. In the analysis of the first image, initial position of cloud centroid was on point

$T_0(x_0, y_0)$, and after 12 seconds (300 frames interval), centroid has moved to point $T_1(x_1, y_1)$ and changed the angle by $\Delta\varphi$. The shift resulted with the change of centroid location, but also the change of azimuth and elevation. According to Figure 10 it is possible to determine the difference between points $T_0(x_0, y_0)$ i $T_1(x_1, y_1)$, consisting of the components Δx i Δy:

$$\Delta x = x_2 - x_1 \tag{8}$$

$$\Delta y = y_2 - y_1 \tag{9}$$

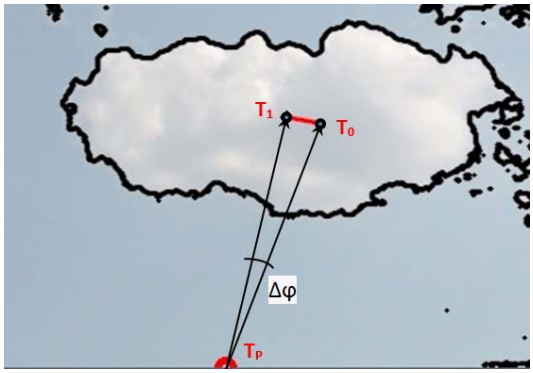

Figure 9. Shift of the cloud (centroid) from the start point T_0 to the final point T_1 from the observer point of view T_P

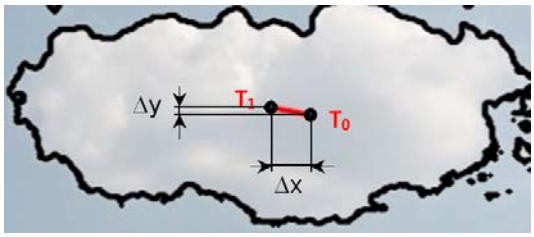

Figure 10. Coordinates change from the start point T_0 to the final point T_1

Assuming that the point $T_P(x_P, y_P)$ is the location of the observer, it is possible to determine the change of the angle $\Delta\varphi$ using simple trigonometric expressions by determining the initial angle at point $T_0(x_0, y_0)$ and afterwards the angle at point $T_1(x_1, y_1)$. The difference between those angles is:

$$\varphi_0 = \arctan\frac{y_P - y_0}{x_P - x_0} \tag{10}$$

Similar to that, it is possible to determine the angle φ_1 of the point $T_1(x_1, y_1)$ and then calculate the change of the angle:

$$\Delta\varphi = \varphi_1 - \varphi_0 \tag{11}$$

To determine the scalar azimuthal angular velocity following expression can be used:

$$\omega_A = \frac{d\varphi}{dt} = \frac{\Delta\varphi}{\Delta t} \tag{12}$$

For calculation of the angle change the expression (12) can be used, and the time interval is defined by the frequency of processing images from video. For example, if every 300th video image is processed, the video quality is set to 25 fps, the time interval is 12 seconds (300 / 25 = 12). After conversion of degrees to radians and use of vector calculus the expression for angular velocity vector is as follows:

$$\vec{\omega}_A = \vec{\omega}_{A1}\omega_A\frac{\pi}{180} \tag{13}$$

where $\vec{\omega}_{A1}$ is a unit azimuth vector with horizontal direction, and ω_A scalar azimuth velocity from the expression (12).

After determining the azimuthal angular velocity, it is necessary to determine the elevation angular velocity, to be able to sum these two vectors and calculate resultant angular velocity. As the elevation is in range between 0 i 90° and vertical resolution of the image is 1080 pixels, the shift of the cloud by 12 pixels (1080 pixels / 90°) corresponds to the shift of one degree of the elevation. According to Figure 10, the vertical shift of the cloud centroid Δy can be determined and according to that shift it is possible to calculate the scalar value of the elevation angular velocity by using following expression:

$$\omega_E = \frac{dy}{dt} = \frac{\Delta y}{\Delta t} \tag{14}$$

where Δt is defined by the frequency of image processing from video. After conversion of degrees to radians and use of vector calculus the expression for angular velocity vector is as follows:

$$\vec{\omega}_E = \vec{\omega}_{E1}\omega_E\frac{\pi}{180} \tag{15}$$

where $\vec{\omega}_{E1}$ is a unit elevation vector with vertical direction, and a ω_E scalar elevation velocity from the expression (15).

The resultant velocity vector can be calculated by the sum of azimuth and elevation angular velocity:

$$\vec{\omega}_R = \vec{\omega}_A + \vec{\omega}_E \tag{16}$$

V. PREDICTION OF CLOUD MOVEMENTS AND SUN COVER DURATION

To accurately predict the duration of Sun cover with clouds, an approximation shapes of ellipse and rectangle were used (Figure 11 shows one cloud whose shape is approximated with ellipse and rectangle). With using these shapes, determining the contours is much simplified and it is easier to describe shapes with mathematical

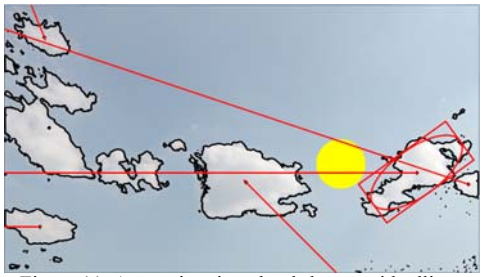

Figure 11. Approximation cloud shapes with ellipse and rectangle

expressions. In addition, Figure 11 shows the movement directions of clouds (marked red), beginning with centroid points to the edges of area covered with camera (image). Simulation the location of the Sun is performed by drawing a yellow filled circle at a given location in the image.

With taking the cloud contour into consideration approximated with ellipse or rectangle and movement direction of the cloud, it is possible to precisely determine the moment of creating the shadow on the Sun and the duration of the shadow. Table 1 shows the results comparison between the approximated cloud shapes and the real cloud contours. Firstly, the starting reference point in time was set. From that point by using approximation of the ellipse and the rectangle, and taking into account the direction of movement of clouds, it is determined the exact moments when the cloud starts to cover the Sun and when the area of cloud finally stops with Sun covering. These results were compared with the real situation and therefore the error rate is shown in Table 1.

TABLE I. RESULTS OF PREDICTING THE MOMENT OF COVERING THE SUN BY APPROXIMATING THE SHAPE OF CLOUDS AND THE REAL CLOUD CONTOURS

Measure ment	**Type of approximation**	**Error in prediction**	
		Start of covering	***End of covering***
1.	Ellipse	16,7%	1,3%
	Rectangle	16,7%	16,7%
2.	Ellipse	115,6%	0,7%
	Rectangle	102,1%	4,39%

VI. EXPERIMENTAL RESULTS

Table 1 shows the results of predicting the moment of cloud covering the Sun using ellipse and rectangle approximation, and determining the error compared to real cloud contours without approximation.

Measurements were performed using various cloud sizes and different movement directions. The most significant impact on error rate had the sudden change of cloud shape and their "connecting" with other clouds. In cases where the data calculation on which the prediction was based is performed more frequently with shorter time intervals, it is possible to significantly reduce the error.

VII. CONCLUSION

The forecast of photo panel shading technique is obtained in this paper in order to decrease uncertainty in prediction of power production which is necessary for effective microgrid control. The paper deals with the photo panel shading caused by clouds. The prediction of shading is based on the clouds movement prediction technique which uses rectangular and ellipsoidal cloud shape approximation and centroid position movement calculation from video stream. Erosion and dilation operations are crucial in recognizing and detecting clouds while the direction and speed of the cloud are calculated according to centroid shift between two measurements.

Developed technique allows precise and frequent short-term shading prediction useful for increasing accuracy of the commercial hourly weather forecast.

***Abstract*—The main objective of this paper is producing an intelligent virtual teacher who will be able to predict the students' final grades at the end of the semester. Our approach is based on continual observation of the student's activities on the particular course during the semester. In order to achieve realistic modelling of the students' devotion to the given lectures and also the degree of how much the student has learned from the given lecture, we take into account both the e-Learning and the e-Assessment results through the semester. In our previous work we did an intelligent students' Profiling to classify the students into a pass, or, fail category. In this paper we go deeper into the problem, achieving more precise modelling according to which we will be able to determine the student's most likely final grade, using multi classification methodology. The advantage of our model is in its ability to take into account all the assessments during the semester, not relying only on the results from the last student's assessment. It can be a good indicator whether the teacher needs to perform additional testing of the student's knowledge in order to derive an overall conclusion on the most appropriate grade.**

***Index Terms*—e-Learning, e-Assessment, Machine Learning**

I. Introduction

E-Learning, or Computer Assisted Learning, refers to the learning by using sophisticated information and communication technologies, whereas, the e-Assessment, or Computer Assisted Assessment, aims to assess the learner's knowledge. Vonderwell et al. [1] make a clear distinction between assessment of learning (assessment for the purposes of grading and reporting with its own established procedures) and assessment for learning (assessment whose purpose is to enable students, through effective feedback, to fully understand their own learning and the goals they are aiming for). A good overview of e-Assessment systems is presented by Gusev and Armenski [2]. In our research the assessment for learning is referred to as e-Learning and the assessment of learning is referred to as e-Assessment.

Rovai [3] in his research on online and traditional learning identifies the major principles of general assessment theory, examines how these principles can be applied to an online environment, and identifies and describes several assessment issues that have special significance in a virtual classroom. Practical suggestions are included to assist both first-time and experienced online instructors develop assessment components for their online courses.

Various conflicting attitudes about distance learning have been discussed by Hannay et al. [4] in order to present the perceptions of both the students and the teachers. Sun et al. [5] developed an integrated model with six dimensions: learners, instructors, courses, technology, design, and environment to investigate the critical factors affecting learners' satisfaction in e-Learning. The results showed that learners' computer anxiety, instructors' attitude toward e-Learning, e-Learning course flexibility, e-Learning course quality, perceived usefulness, perceived ease of use, and diversity in assessments are the critical factors affecting learners' perceived satisfaction.

The research that we conduct in this paper is a result of a long term e-Learning and e-Assessment process during the course on Computer Architecture and Organization (CAO). We believe that besides the benefit of the intelligent prognosis of the students' final grades, the results will be a useful indicator for the teachers of whether the given lectures for the e-Learning process are well formed and represent the real students' knowledge, and also whether the students have adapted to this kind of learning a can fully express their knowledge.

Beside the surveys on the students' satisfaction, universities have been given a lot of advices to turn their interests towards cloud computing, since the cloud offers good resources flexibility and scalability, storage, computational requirements, network access, reduced power consumption and lower costs [6], [7], [8]. As an upgrade to the e-Learning and e-Assessment system that we use in this paper, Ristov et al. [9] propose a SOA architecture of a cloud hosted e-Assessment system which uses scalability and elasticity in order to achieve sustainable performance. Their solution reduces the overall costs since it uses minimum resources utilized only during the e-Assessment.

However, the focus of this research is not to analyse the existing system's performance and cost, but to introduce an intelligence in the e-Learning and e-Assessment processes which will result in producing an intelligent grading agent (IGA) whose decisions will be as similar as possible to the teacher's opinion on the student's final grades. For that purpose we use the results from the online learning system that has been implemented at our university since 2002. Based on 10 years of e-Learning and e-Assessment experience, we have developed a strategy by which we proved that the student has achieved all learning objectives (LOs) by providing correct answers for relevant knowledge items during the online learning process. During the strategy development we confronted issues of guessing the correct answers in a random manner,

which we solved by introducing negative scoring for wrong answers. This is how we expect the students to answers the given questions only when they know the correct answer. During the development of the strategy, we also determined the minimal number of questions the system should ask to get relevant assessment of student's knowledge. After analysing several strategies, we agreed that the least vulnerable strategy that offers satisfactory results is 3R (three correct answers in a row). The probability analysis showed that the probability to randomly choose three consequently correct answers is smaller than the probability to choose any three correct answers from a given set. The overall contribution of this research is that we developed strategy by which the students are asked as minimum questions as 3 and expect 3 correct answers in a row, in order to allow them to continue the online learning process. This strategy somehow confirms the student's knowledge on a particular learning objective.

Therefore, the resulting online learning system is with the following features:

- *Corrective measure* - whenever the student gives a wrong answer the system suggests corrections.
- *Adaptive learning path* - better students can move faster towards the more complex learning objectives.
- *Clear objectives and goals* - the navigation explains what else has left to be learned.

However, this approach does not estimate the final grade of the e-Assessments, nor evaluates the student efficiency, and this is the motivation to conduct a research whose results are reported in this paper.

The work reported in this paper is based on our previous research [10] where we achieved modelling of the students overall work during the semester, taking into account the results from both the e-Learning and the e-Assessment, to determine whether the student will pass or fail the CAO course. We believe that this kind of grading that depends on the students' overall work through the whole course will additionally motivate them to work continuously during the semester and present their real knowledge during the e-Learning process, since it directly affects their final grade.

Our research mainly consists of two parts. At first we verify the existing methodology for classifying the students into a pass or fail class where we use most common Support Vector Machines (SVM) kernels. The second part of the research reported in this paper focuses on building an IGA able to estimate the students' final grade.

Figure 1 presents the interaction between the online learning system and our intelligent agent. As depicted, the online learning system continuously assigns e-Learning exams from the current LOs that have to be learned before the student proceeds to the next learning level. The results from the e-Learning are then stored into the online learning system. Periodically, on teacher's request, the system assigns e-Assessment to the students in order to test their knowledge. All the results are again saved by the online learning system. As soon as the course is finished, the IGA collects all students e-Learning data which then it uses to create individual students' Profiles. The Profiles refer to the students' manner of passing the learning objectives of the particular lecture. On the other hand, the e-Assessment results are used to update those Profiles. After that, the Profiles are used in the ML process, i.e. the SVMs to produce a classifier able to determine the students' final grades. Since the teacher is allowed to monitor the results and each student's knowledge background, the IGA's decision is verified by a human factor. Hereupon, we propose a system that simulates a real teacher and is able to estimate the real achievements of its students.

The rest of the paper is organized as follows. In Section II we present the use of machine learning (ML) methods in education. Our methodology for multi-class classification of the students' knowledge is presented in Section III. In Section IV we present the experiments and the results from the presented approach and we derive a conclusion and present the plans for future work in Section V.

II. Related Work

In this section we give a review of the latest ML methods used for educational problems.

Castro et al. [11] aim to provide an up-to-date snapshot of the current state of research and applications of Data Mining methods in e-learning. They provide a taxonomy of e-learning problems to which Data Mining techniques have been applied, including: students' classification based on their learning performance, detection of irregular learning behaviours, e-learning system navigation and interaction optimization, clustering according to similar e-learning system usage and systems' adaptability to students' requirements and capacities.

Zaiane et al. [12] in their paper suggests the use of web mining techniques to build an agent that could recommend on-line learning activities or shortcuts in a course web site based on learners' access history to improve course material navigation as well as assist the online learning process. These techniques are considered integrated web mining as opposed to off-line web mining used by expert users to discover on-line access patterns.

The paper by Fei et al. [13] describes their work in exploring automatic question classification tests which can be used in e-learning system. Such tests can take the form of multiple-choice tests, as well as fill-in-the-blank and short-answer tests. They proposed a text categorization model using an artificial neural network trained by the backpropagation learning algorithm as the text classifier. Their test results showed that the system achieved the performance of nearly 78%.

Chang et al. [14] state that with the growing demand in e-learning, numerous research indicated that adaptive learning is a critical requirement for promoting the learning performance of students. The first step for achieving adaptive learning environments is to identify students' learning styles. Therefore, in their paper they propose a learning style classification mechanism to classify and then identify students' learning styles. The proposed mechanism improves k-nearest neighbour classification and combines it with genetic algorithms. To demonstrate the viability of the proposed mechanism, the

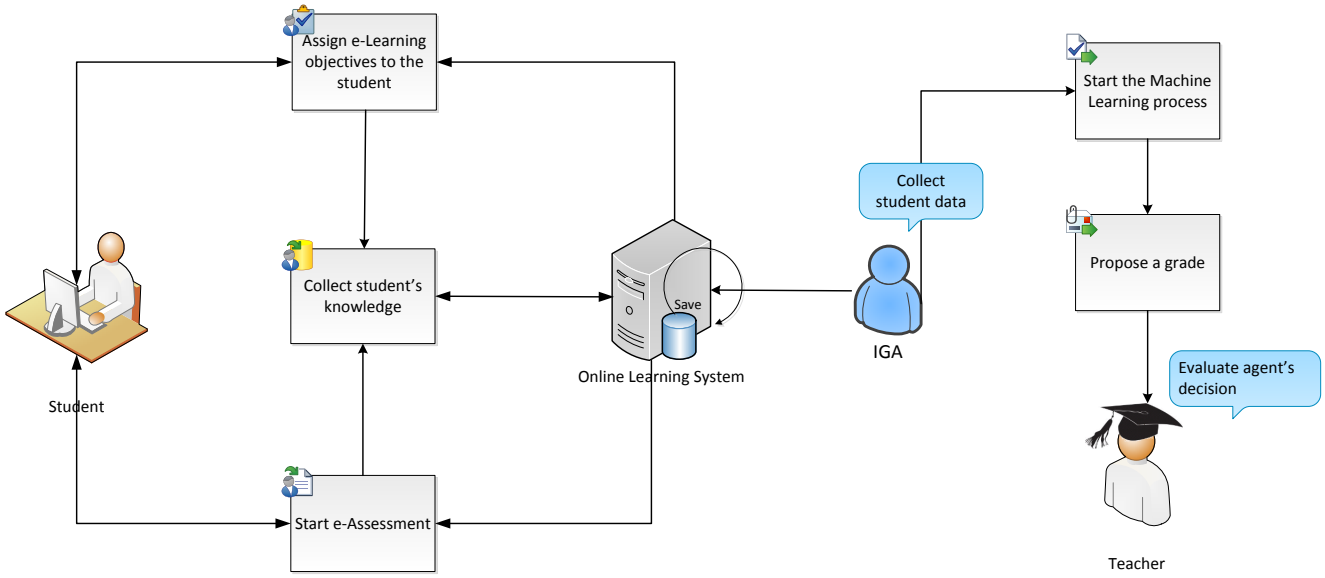

Fig. 1. Interaction between different roles in the machine learning process

proposed mechanism is implemented on an open-learning management system. The experimental results indicate that the proposed classification mechanism can effectively classify and identify students' learning styles.

Applying intelligence in e-Learning services has been the focus of several recent research projects and papers, and with the explosive growth of information sources available on the World Wide Web, the existing e-Learning services requires pedagogical overhauling for keeping pace with the trends in e-Learning. One of several possibilities can be its application to Online Assessment. In this Paper, we present the system architecture for applying intelligent methodologies to online assessment that adapts to the examinee's ability level and the other side we describe that web mining can be applied to Learning Content Management Systems to build knowledge about e-Learning and has potential to help and improve learner's performance.

The design of online assessment tools has been in the focus recently [15], [16], as well as applying intelligence in e-Learning services. For example, Uday et al. [17] present a system architecture for applying intelligent methodologies to online assessment that adapts to the examinee's ability level and the other side we describe that web mining can be applied to Learning Content Management Systems to build knowledge about e-Learning and has potential to help and improve learner's performance.

III. Methods and Methodology

In this section we present the methods and the methodology that we developed for building the students' individual Profiles as well as the classification process itself.

A. Online Learning System's Structure

Before we describe the students' Profiling, we must discuss the structure of the online learning system. The knowledge database for each course can be described in a tree-like manner. If we assume that one course represents the root of the tree, than the course lectures are its branches, and the learning objectives are branches' branches. Each learning objective consists of few questions for which there is one, or, several correct answers. In order to make the 3R strategy applicable for any learning objective, there are at least five questions provided.

B. Student's Profiling

In order to show how the results from the long term e-Assessment of a particular student can affect the previous e-Learning impression, we must provide each student an individual Profile, which can be described as follows.

The first step is extracting their knowledge from the online learning process in a n-dimensional vector, where n is the number of LOs. The students knowledge of a particular LO is represented as a number of trials to pass the given LO and the number of questions answered before the 3R pattern occurred in the passing trial. In order to express the student's efficiency for each LO that has been assigned, we proposed new metric in (1) to measure the student's *Initial Success*, IS. In the beginning, the IS for every student enrolled in the course is a null vector. The dimensionality of the IS vector is the same as the number of all LOs in the knowledge database. Therefore, $IS_i = (LO_1, LO_2, ..., LOj)$, where the highest value of i is the total number of students and j is the total number of LOs in the database. Considering the fact that the students are assigned each week with new questions from the LOs, the IS is calculated as sum of the number of trials (NT) necessary for

the student to pass the given LO, and the product of the scalar 0.01 and the number of questions (NQ) in the last trial. We use the value 0.01 in order to scale the number of questions in range $0.03 \leq NQ < 1$, since the maximum number of answered questions per learning objective is a double digit number. Therefore, the lower the IS score is, the more the student has learned the taught lectures.

$$IS_{ij} = NT_{ij} + (0.01 * NQ_{ij}) \quad (1)$$

Once we built the IS vector, our IGA uses them to conceive preliminary impression on the students' devotion to the course. However, taking into account only the ISs is not enough to derive conclusion of the students' most probable final grade. Therefore, we propose another approach which takes into consideration the students' e-Assessment results before concluding the grade. Thus, the students' success is revised every time the student has taken an e-Assessment. By introducing this approach, we simulate a real surroundings where the teacher evaluates the students' activities during the whole course to determine their grades. Hereupon, we calculate the *Revised Success*, RS, as:

1) *Punishment:*

$$RS_{ij} = IS_{ij} + 1 \quad (2)$$

2) *Reward:*

$$RS_{ij} = IS_{ij} - 1 \quad (3)$$

where i denotes the currently analyzed student and j denotes the particular LO.

The RS fully depends on the student's result from answering the questions from the e-Assessment. If the student's answer on a question from a particular LO is $false$, then the student is punished with adding one more trial on his IS of the particular LO from the e-Learning knowledge background. On the opposite, when the student's answer on a question from a particular LO is $true$, the student is rewarded with reducing the number of trials by 1 in the e-Learning history. That is how we use the e-Assessment results to affect the student's impression during the semester.

C. Machine Learning Analysis

After creating the students' individual Profiles, in this section we show how to use them to train a SVM classifier to perform multi-grade classification. We consider SVM to be an appropriate classification technique since we know the desired outputs during the training process. In order to obtain the best training, we compared the performance of three types of kernels: linear kernel (LK), polynomial kernel (PK) and radial basis function (RBF). In order to avoid overfitting in the process of training the classifier, we used hold-out cross-validation technique which does not permit overlap between training data and test data, yielding a more accurate estimate for the generalization performance of the algorithm [18].

The SVM technique is mainly used for binary classification problems. Since, we want to adapt it to classify the students into six classes, we need to organize the classification across a multiple-machines strategy. Before we discuss the training procedure, we must describe the classes we want our IGA to learn from:

- C_{fail} - contains all the students who have failed the course, i.e., the average score from their e-Assessments is $\leq$ 50%;
- C_6 - contains the students with on average 51 - 60% success;
- C_7 - contains the students with on average 61 - 70% success;
- C_8 - contains the students with on average 71 - 80% success;
- C_9 - contains the students with on average 81 - 90% success;
- C_{10} - contains the students with on average 91 - 100% success;

Considering the classes, we defined two test cases for the training process:

- *Training Case 1*: In the first training case we organize the students Profiles into 2 classes; the first contains the Profiles from C_{fail} and the second contains the Profiles in the remaining $C_{6:10}$ classes. Thus, the first SVM machine will assume that $C_1 = C_{fail}$ and $C_2 = C_{6:10} = C_{pass}$. Hereafter, we need to train the classifier to recognize each grade distinctively. Therefore, we defined five additional SVM classifying machines (CM). The training process is performed in 5 iterations, which means that in each iteration we set the class C_1 to be the class C_i for $i = 6 : 10$, and the class C_2 to be a set from the classes $C_{6:10} \setminus C_i$. The whole process is depicted in Figure 2.
- *Training Case 2*: In the second training case, instead of excluding the Profiles that have failed the course when determining the correct grade, we assume $C_{fail} = C_5$. Thus, the training process is developed as follows. We define six SVM machines and each of them sets the class $C_1 = C_i$ for $i = 5 : 10$, and the class $C_2 = C_{5:10} \setminus C_i$. Figure 3 visually explains the process.

In order to evaluate the classifier's performance we use $Precision$ (4) and $Recall$ (5) measures. The classifier's $Precision$ is a measure of true positives (TP) among all Profiles classified as positive (C_1), which include the true positives and the false positives (FP). The classifier's $Recall$ is a measure of its ability to select the Profiles that are positive from all the Profiles in the positive class.

$$Precision = \frac{TP}{TP + FP} \quad (4)$$

$$Recall = \frac{TP}{TP + FN} \quad (5)$$

The experiments and the results from the analyses are presented in Section IV.

IV. Experiments and Results

In this section we present the results from the methodology described in Section III.

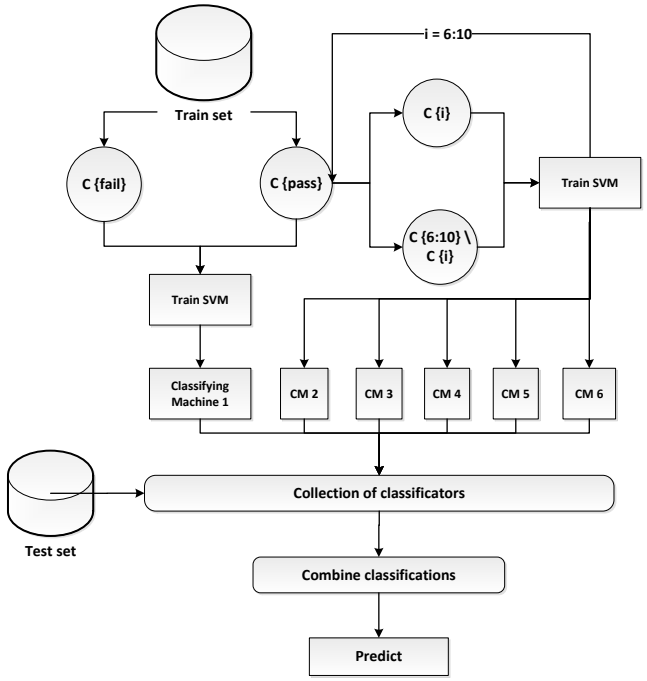

Fig. 2. Training Case 1

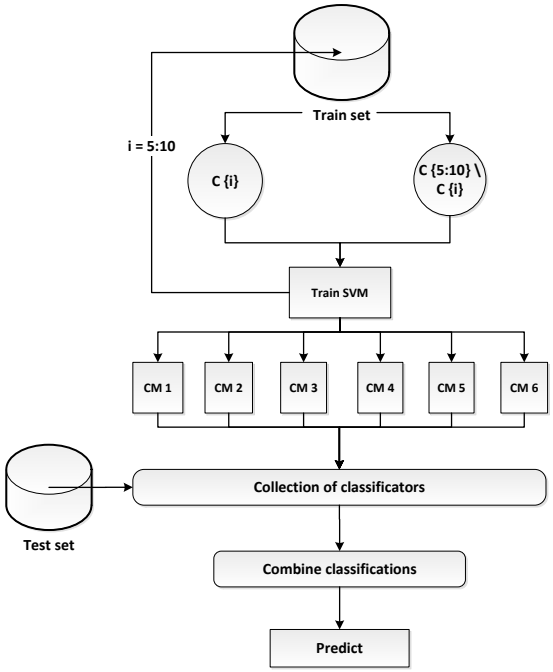

Fig. 3. Training Case 2

In order to obtain reliable results, we analysed the Profiles of 1273 randomly selected students that have attended the CAO course in the past years. The analyses were performed according to the training cases described in Section III-C, by using the *SVMlight* [19] tool. Since the results from the RBF were not promising, we present only the results from the classification with LK and PK.

Considering the fact that in both training cases, the training and the classification procedure is the same for the class of Profiles that have failed the course, $C_{fail} = C_5$, at first we describe the classification results from this analysis. Thus, in order to train the classifier to recognize the Profiles categorized as failed, we created two classes:

- C_5 which contains 629 Profiles that have failed
- $C_{6:10}$ which contains 644 Profiles that have passed

However, the initial results from the classification were not satisfying and we decided to use the bootstrapping method in order to obtain increased number of Profiles that have failed and passed the course. The method resulted in a 1000 Profiles in each class. The results from the binary classification are presented in Table I.

TABLE I
RESULTS FROM THE BINARY CLASSIFICATION

SVM Results	LK		PK	
Class	Precision	Recall	Precision	Recall
C_5 vs $C_{6:10}$	100%	100%	100%	100%

Since there are variable number of Profiles in each of the classes, we also used the bootstrapping method to enlarge the data in the first class so the number of Profiles will be the same as in the second class. Therefore, the number of Profiles before and after applying the bootstrapping method in each Training Case 1 and 2 are presented in Table II.

TABLE II
NUMBER OF PROFILES BEFORE AND AFTER THE BOOTSTRAPPING METHOD

Number of Profiles	Before	Training Case 1	Training Case 2
C_6	247	324	956
C_7	192	379	1011
C_8	101	470	1102
C_9	30	541	1173
C_{10}	1	570	1199

The preparation of the Training Case 1 and 2 according to the methodology defined in Section III-C produced the classification results in tables III and IV.

TABLE III
RESULTS FROM TRAINING CASE 1

SVM Results	LK		PK	
Class	Precision	Recall	Precision	Recall
C_6 vs $C_{6:10} \setminus C_{5,6}$	99.39%	100%	98.18%	100%
C_7 vs $C_{6:10} \setminus C_{5,7}$	99.47%	100%	98.95%	100%
C_8 vs $C_{6:10} \setminus C_{5,8}$	99.16%	100%	98.74%	100%
C_9 vs $C_{6:10} \setminus C_{5,9}$	100%	100%	100%	100%
C_{10} vs $C_{6:10} \setminus C_{5,10}$	100%	100%	98.96%	100%

The analyses from the both training cases showed that the Training Case 2 produced barely improved results, but both of

TABLE IV
RESULTS FROM TRAINING CASE 2

SVM Results	LK		PK	
Class	Precision	Recall	Precision	Recall
C_6 vs $C_{5:10} \setminus C_6$	99.58%	100%	98.96%	100%
C_7 vs $C_{5:10} \setminus C_7$	99.61%	100%	99.02%	100%
C_8 vs $C_{5:10} \setminus C_8$	100%	100%	99.46%	100%
C_9 vs $C_{5:10} \setminus C_9$	100%	100%	99.49%	100%
C_{10} vs $C_{5:10} \setminus C_{10}$	100%	100%	98.36%	100%

them resulted in very accurate and promising classifiers, which confirmed that the methodology we defined in Section III is reliable.

V. CONCLUSION AND FUTURE WORK

In this research we analyse e-Learning and e-Assessment data from the Computer Architecture and Organization course at our faculty. The data is collected from various years between 2002 (when the online learning system was implemented) and 2012.

The purpose of the analysis is creating an intelligent agent which based on the previous students knowledge will be able to determine the students' final grades. Therefore, we proposed a methodology that included modelling students' Profiles based on their activities in the e-Learning and e-Assessment processes during the course. The Profiles are then used in a two types of SVM training processes with multiple kernels, and each of them produced 6 classification machines.

The experiments and the results proved the reliability of the methodology we defined by showing that both training cases are capable of producing very accurate classifiers which is very important for our future research.

We believe that this model is essential and of great advantage for both the students, since they will stay highly motivated to successfully finish their exams until the end of the course, and for the teachers, since it can be a good indicator whether there is a need of additional testing of the student's knowledge in order to derive an overall conclusion on the most appropriate grade.

In our future work we will aim to develop different strategies for determining the final grades which will be based on the students' individual manners for passing the given learning objectives.

ACKNOWLEDGEMENT

This work was partially financed by the CodEval (Evaluating performances of program codes and educational processes using ML methods) project at Faculty of Computer Science and Engineering at the "Ss. Cyril and Methodius University", Skopje, Macedonia.

Predicting the success of students is a topic which has been studied for a long time in different scientific fields. Evaluation of importance of the features used in the prediction and their subsequent selection is an immensely important step in the process of classification and data mining. This paper presents a study on the importance of student demographic features in the process of predicting. The study and performed analyses used the demographic data collected from the Information System for Higher Education (ISVU). For determining the importance of demographic features in the study the following methods have been used: Information Gain (IG), Gain Ratio (GR), Sequential Backward Selection (SBS), Sequential Forward Selection (SFS). The results show the features rank, their importance weight in the prediction and comparison of the results and the use of different methods. Two classification algorithms for evaluating the impact of ranking features to the quality of prediction are used: Naive Bayes i Support Vector Machine (SVM). Final results provide guidelines for the development of a new prediction model.

I. INTRODUCTION

Predicting the success of students has long been a topic which is being studied in various scientific communities. So far they have conducted various studies and analyses related to success in learning, finding the answer to the question how to achieve better results, and the relation regarding student properties and their impact on studying success. Predicting the success of students is closely associated with the concept of data mining and machine learning. In the research various techniques of learning and classification algorithms were used [1],[2]. Demographic data are an integral part of each classification that includes information about people, users, students, etc. For the purposes of the research in this article, we used Information System of Higher Education Institutions (ISVU), the data from Medimurje University of Applied Sciences in Cakovec, Croatia.

Data mining and machine learning are the scientific fields in which the concept of prediction has been explored, various algorithms have been developed in order to achieve better prediction accuracy [3],[4]. When mentioning prediction, it primarily refers to classification of data to determine their membership depending on their features. If the prediction is determined on the basis of input data and achieved results, then we are taking about Supervised Learning [5].

The amount of data, the number of features, data dimensions, vary depending on the prediction purpose. Multi-dimensionality of data and large number of features increase the complexity of algorithms which use in prediction and has an influence on the extension of time for prediction and consumption computer resources. Due to the large number of features that are included in the prediction model and to accelerate the prediction process, some models use algorithms to determine the importance of individual features for the final score prediction. In order to achieve better performance of prediction, it is necessary to pre-process the data. Pre-processing is the process of preparing the data before it is sent to the model of prediction, transforming data suitable for the prediction model. Data pre-processing methods are divided into four activities: data cleaning, data integration, data transformation and data reduction. Data reduction refers to reducing the number of dimensions and features, determining the subset of features [6],[7]. Feature subset selection is the process of identifying and removing irrelevant and redundant information.

Generally, selection algorithms are distinguished between filter algorithms and wrapper algorithms [8],[9]. In evaluation filter algorithm only considers data reduction but does not take into account feature activities. Filters ranked features based on certain statistical criteria. Features with highest ranking values are selected on a subset. In the wrapper approach, feature selection is "wrapped" in a learning algorithm. Wrappers use the learning algorithm itself to evaluate the usefulness of the features. The filter algorithms that are widely used are: Information Gain (IG), Document Frequency (DF), χ^2statistic (CHI), Expected cross entropy (ECE), Weight of evidence for text (WET), Odds ratio (ODD). Selection of algorithm largely depends on the property of multidimensional data and the selected machine learning technique [10]. Wrapper algorithms like Sequential backward selection (SBS), Sequential forward selection (SFS), Plus-L minus-R selection (LRS), Genetic algorithms (GA)[11,12] can be grouped into two categories: greedy algorithms and random / stochastic algorithms [13]. These algorithms typically give better results than filter algorithms, but they are much slower and need to be repeated every time when any changes in the data structure happen, as well as the changes at machine learning algorithm [14].

This article presents the evaluation of selection algorithms on the base of the same data. During the study a prediction over a different set of input features was conducted. Analysis and comparison of results show the achieved accuracy.

II. OBJECTIVES OF RESEARCH

The main objective of this study was to determine the importance and influence of certain demographic features of students in the process of prediction, to rank the features in order of importance and determine the rank threshold where the feature has an impact on the final score of prediction and compare several algorithms selection of features, evaluate the results and determine algorithm that provide the best results.

To predict the student success two techniques of machine learning were used: Naive Bayes and Support Vector Machine (SVM). The prediction was achieved with binary classes: successful and unsuccessful student. The results of prediction were determined by two classes: successful and unsuccessful student.

III. DATA SOURCE

The data used in this study are part of a national database of Information System of Higher Education Institutions (ISVU) [15].The database contains a large number of different data about students organised into several groups: personal demographic information, demographic information about the parents and the type of residence, information on passed exams, data on high school achievement, information about the current student status, social status of student, student grants for food. For a description of one student the system uses more than 60 features. Prediction of student success is focused on determining the success in first year of the study. In addition to demographic data, which are the basis of this research, student high school grades were added to the input data, which is one of the categories in the application to the study.

For training and test data, the data of the students enrolled in the program in the last three academic years 2010- 2012 have been used. As the target data ECTS (European Credit Transfer and Accumulation System) credits which the student achieved at the end of the academic year have been used. For success in the first year of study a student must achieve at least 42 ECTS credits. These students were classified in the "successful students" class, other students in the "unsuccessful students" class.

Cleaning and adjustment of the data was performed before the feature selection and prediction. By removing irrelevant and redundant data (ID number, address, phone number, name of high school, job title ...) a collection of 15 demographic features remained. Each student is described with the following demographic data, shown in Table 1:

TABLE I.
LIST OF STUDENT DEMOGRAPHIC DATA

No	Feature description
1.	Sex - male / female
2.	Place of birth - city post code or the birth place of student
3.	Nationality (Croatian) – Yes / No
4.	Completed secondary school - the name of the secondary school that the student has completed
5.	Vocation - vocation which the student completed at the secondary school
6.	Duration of education - The number of years of education in secondary school
7.	Programme (curriculum) - designation of the curriculum in secondary school
8.	Profession - finished profession in secondary school
9.	Student rights - designation of student rights and subventions
10.	Marital status - married / unmarried
11.	Status of residence – subtenant, lives with his/her parents, his/her own flat/house
12.	Education level of mother - the system defined six levels of education
13.	Mother's profession - the current workplace
14.	Education level of father - the system defined six levels of education
15.	Father's profession - the current workplace

IV. CLASSIFICATION ALGORITHMS

In evaluation of quality of prediction two learning techniques were used: Naive Bayes and Support Vector Machine (SVM).For both of the two learning techniques during forming the model a k-fold Cross-validation method was used, by which the input data are divided into k equal subsets. In k-fold Cross-validation, the training sample is partitioned into k-folds as equally as possible and each fold is left out of the learning process and used as a testing set, k-1 folds used as a training set [16],[17].

A. Support Vector Machine (SVM)

SVM is a machine learning techniques used in the field of data mining. SVM algorithm is based on statistical learning theory developed by Vapnik (1995). The algorithm is defined as a supervised learning algorithm which solves linear and nonlinear binary classification problem. The SVM training algorithm aims to find a hyperplane that separates the multidimensional training data into a discrete predefined number of classes, usual binary class. The operation of the SVM algorithm is based on finding the hyperplane that gives the largest minimum distance to the training examples. Determining the direction and position of the hyperplane where the distance between the training data, both two-class, and hyperplane will be maximised. The hypeplane divides multidimensional training data into two sets: the positive and negative class. Lines that pass the data vector that is closest to the hypeplane are called margins. The training data that lie on the margins, called support vectors, are the only ones that define the hyperplane of maximum margin [18],[19]. SVM ensures maximum distance between the margins throughout the length of the hyperplane.

B. Naive Bayes (NB)

Naive Bayes is a linear classifier based on Bayesian theorem [20]. The algorithm analyses the relations

between features and classes. The algorithm calculates the conditional probability for relations between the values of the features and classes. Features $\{x_1, ...,x_k\}$ represent a vector x, vector x belongs to class c. During training, the algorithm determines the probability of each class. Probability is computed by counting how many times it occurs in the training dataset. This is called the prior probability P(C=c). The algorithm also calculates the probability that the instance x belongs to class c, shown in equation (1)[17]

$$P(C = c \mid X = x) = \frac{P(C = c)\prod_i P(X_i \mid C = c)}{P(X = x)}. \quad (1)$$

In the denominator there is a scalar coefficient, which is calculated as the sum of all the associated probability, shown in equation (2)

$$P(X = x) = \sum_j P(C_j)P(X = x \mid C_j). \quad (2)$$

This algorithm carried out a quality prediction over a small amount of training data, enables the use of multiple output class, but is sensitive to pre-processing of data and prediction over nominal data [21].

V. FEATURE SELECTION

The features selection is performed in order to optimise the operation of the classifier. Prediction is often performed over multi-dimensional data with a large number of features. In order to achieve a simpler and faster classification, some systems reduce the number of input features and determine the features which have a significant role in classification. Features get ranked and determine a features subset which is sent to the prediction model. Selection methods which have been used for the purposes of this article:

A. Info Gain (IG)

Info Gain method calculates the value of the features information taking into account the class to which they belong, thereby determining the entropy. IG uses the following expression for the calculation:

Info Gain (Klasa, Atribut)=H (Klasa) – H(Klasa|Atribut),

where H is the entropy, which is defined by using the following equation (3)

$$Entropy(S) = -\sum_{j=1}^{m} p_j \log_2 p_j, \quad (3)$$

where p is the probability, for which a particular value occurs in the sample space S.

Entropy value ranges from 0 to 1. Value 0 means that all instances of the variables have the same value, value 1 equals the number of instances of each value. Entropy shows how the attribute values are distributed and indicates "purity" of attributes. High entropy indicates the uniform distribution of attributes. Opposite to that, low entropy indicates distribution which is concentrated around the point [22].

B. Gain Ratio (GR)

The Gain Ratio method is a normalized version of Information Gain. Normalization is accomplished by dividing the information gain with the entropy of the attribute with respect to the class. The result of this approach is reduced bias from the information obtained by the algorithm. The formula used by the GR is represented by Eq. (4)[22]

$$GR(Klasa, Atribut) = \frac{(H(Klasa) - H(Klasa \mid Atribut))}{H(Atribut)}. \quad (4)$$

C. Sequential forward selection (SFS)

Sequential forward selection is a simple greedy search algorithm which is trying to determine the optimal set of features. The algorithm uses a special list in which the optimal features are recorded. At the beginning the list is empty. The algorithm adds in the list feature x^+ whose objective function J ($Y_k + x^+$) gives the best result when combined with the feature Y_k which has been selected and is on the list.

Algorithm pseudocode [23]:

1. Start with the empty set, initialise the feature set Y0={Ø}; k=0
2. Select the next best feature x^+=argmax[J(Y_k+x)]; x¢Y_k
3. Update the feature set $Y_{k+1}=Y_k+ x^+$;
4. While k < d
   k=k+1
   Go to Step 2

D. Sequential backward selection (SBS)

Sequential backward selection is an algorithm that is similar to the SFS algorithm, but it works in the opposite direction. Initially, the algorithm in its optimal list has all the features of X from set D. Algorithm removes a single feature that improves (or minimally worsens) an objective function to obtain the best subset of features. The algorithm uses the objective function J (Yx^-) and determines for which attribute function the minimum value is returned. This attribute is permanently removed from the list and increases the value of the target function. J ($Y_k- x^-$) > J (Y_k).

VI. EXPERIMENTAL RESULTS

A. Features ranking

For each student in the database approximately 62 demographic features are located. The original data contained a large number of missing, redundant and irrelevant data. Before the pre-processing of input data and reducing the number of features, feature selection and calculation of the prediction of student success was performed over the "raw" data, all in order to enable later results evaluation, to enable defending individual impact of features in achievement of prediction accuracy.

For the classification of raw data and features ranking we used the Information Gain method and SVM classifier. The study achieved "interesting" results of ranging

features and very poor prediction accuracy. Table 2 shows the results of ranking top 10 features.

TABLE II.
RATING LIST OF FEATURE – RAW DATA

Ranked attributes	
0.94142	1 Student surname
0.86595	2 Date of birth
0.86595	3 Citizenship
0.77155	4 Address
0.71501	5 Average grade
0.71001	6 Mother's name
0.70076	7 Student name
0.41789	9 City
0.41789	8 Place of residence
0.40975	10 Father's name
0.30528	11 Student rights
. . .	

In the classification, input data were divided into 10-fold Cross-validation. The following results were obtained:

Correctly Classified Instances	***56.6038 %***
Incorrectly Classified Instances	***43.3962 %***
Kappa statistic	*0.0225*
Mean absolute error	*0.434*
Root mean squared error	*0.6588*
Relative absolute error	*93.8619 %*
Root relative squared error	*137.1311 %*

Results show a low level of prediction accuracy, with only 56.6% correctly classified instances. The analysis of input data showed a significant number of incomplete data which certainly had an impact on prediction accuracy.

After classification, original data were pre-processed, irrelevant data and redundant features removed. The results of the analysis separated 15 demographic features, features that were used in further process of prediction determination. Ranking using all four methods was conducted on the selected demographic features. Table 3 shows the results of the ranking depending on the chosen selection method.

The results are somewhat different than we expected at the beginning of the studies. All used ranking methods have highlighted "Average grade" feature as the most important, more than any demographic features. This is somehow logical because various demographic data such as situation in the family, type of curriculum, etc. have the impact on the final secondary school grades. Secondary school results are a strong indicator of success / failure of the newly enrolled students.

From the ranked demographic attributes, the analysis highlighted the curriculum that the student completed in secondary school as one of the more important for prediction. According to the rank results, the curriculum that the student learned in high school has significant influences on the success during the study. The second demographic feature that has an impact on the prediction is "Student rights". The feature belongs to a group of motivating features in order to keep the acquired rights that successful students have(cheaper food, transport, students' service, etc.).

TABLE III.
RATING LIST OF SELECTED FEATURE

Rating	
Info Gain (IG)	Ranked feature: 0.74982 1 Average grade 0.29000 2 Programme (curriculum) 0.15111 3 Completed secondary school 0.14609 4 Secondary vocation 0.1079 5 Student rights 0.08909 6 Education level of the father 0.08285 7 Place of birth 0.08262 8 Education level of the mother 0.05238 9 Duration of education 0.04683 10 Mother's profession 0.03954 11 Father's profession 0.03700 12 Status of residence 0.02160 13 Marital status 0.01381 14 Nationality 0.00497 15 Sex
Gain Ratio (GR)	Ranked feature: 0.16713 13 Marital status 0.11926 1 Average grade 0.08177 12 Status of residence 0.07612 2 Programme (curriculum) 0.06896 5 Student rights 0.05782 6 Education level of the father 0.05516 3 Completed secondary school 0.04679 8 Education level of the mother 0.04674 4 Profession 0.04071 9 Duration of education 0.03897 7 Place of birth 0.01885 14 Nationality 0.0139 10 Mother's profession 0.01272 11 Father's profession 0.00561 15 Sex
SFS/ SBS	Ranked feature: 0.206 1 Average grade 0.179 5 Student rights 0.177 2 Programme (curriculum) 0.176 12 Status of residence 0.172 13 Marital status 0.168 6 Education level of the father 0.166 3 Completed secondary school 0.163 9 Duration of education 0.158 8 Education level of the mother 0.154 7 Place of birth 0.150 4 Profession 0.145 14 Nationality 0.138 10 Mother's profession 0.132 11 Father's profession 0.127 15 Sex

Selective methods have also underlined the parents' education as an important element in predicting the student success. According to the character of data, father's education has a significant role compared with mother's education. All methods have determined that the gender of students is ranked the lowest. This information

leads to the conclusion that this attribute should have the least impact on the data classification. This could be due to relatively small number of female population that is enrolled in the study of computing engineering.

B. Features impact

With specifying the individual impact of each attribute, a features selection process can be improved and a more accurate classification provided. After implementing the feature selection, classifications were performed with both techniques, NB and SVM. Table 4 shows the results of classification.

TABLE IV.
CLASSIFICATION RESULTS

Classification summary	**Naive Bayes**	**SVM**
Correctly Classified	61.607%	70.53 %
Incorrectly Classified	38.39 %	29.46%
Kappa statistic	0.2287	0.4027
Mean absolute error	0.4128	0.2946
Root mean squared error	0.5268	0.5428

The results show that the SVM classifier achieved significantly better prediction than NB classifier. SVM also achieved better results with all demographic attributes involved. After measuring, the classification additional analysis of the feature impact on classification accuracywas performed. In testing the prediction, some target features were blocked and after that the accuracy using SVM technique was measured. The obtained results are shown in Table 5.

TABLE V.
FEATURES IMPACTED TO THE RESULT OF CLASSIFICATION

Feature	**Accuracy**	**Impact**
Average grade	66.96	-5%
Programme (curriculum)	64.28	-9%
Completed secondary school	62.50	-11%
Secondary vocation	69.64	-1%
Student rights	55.34	-22%
Education level of father	69.64	-1%
Place of birth	73.21	+4%
Education level of mother	73.21	+4%
Duration of education	65.17	-8%
Mother's profession	71.42	+1%
Father's profession	69.64	-1%
Status of residence	71.42	+1%
Marital status	70.73	0%
Nationality	69.64	-1%
Sex	68.75	-3%

In the table, the column "Impact", shows the impact of each feature on the prediction accuracy expressed as a percentage. A negative value indicates the percentage of accuracy reduction if a specific feature is not taken into consideration during classification. Positive value has the opposite effect on the prediction. In other words, the assumption is that the separation of particular feature from a set of input features would increase the accuracy of prediction.

Such a classification and analysis of the results showed the interesting results. The biggest impact of the features has been calculated for "Student rights" feature. As mentioned in the previous section, this feature indicates the students motive to keep student status and achieve some benefits. Very often some of the students try to maintain their status due to the difficult economic situation or heavy employment. The second ranked feature by impact on prediction is "Completed secondary school" feature.The years of my experience justify this result. This feature is the most significant at the study programmeswhich belong to the area of technical sciences. For the purpose of this research the students come from three types of secondary schools: technical school, high school and school of economics. By comparing the data about their ECTS, it is evident that significantly better results were achieved by the students from technical schools. In Table 5, four features that have shown positive Impact factorwere indicated, which means that they have no significant impact on the accuracy of prediction. To evaluate this assumption a classification was carried out in a way that the indicated features were removed from the input set. After extracting the attribute classification with both techniques better accuracy of prediction, for approximately 5%,was achieved. Table 6 shows the evaluation results:

TABLE VI.
THE CLASSIFICATION WITH REDUCED SET OF FEATURES

Classification technique
Naive Bayes Correctly Classified ***65.1786 %*** Incorrectly Classified 34.8214 % Kappa statistic 0.3004 Mean absolute error 0.3876 Root mean squared error 0.5013 **Classification Improvement ca. 6%**
Support Vector Machine Correctly Classified ***73.2143 %*** Incorrectly Classified 26,7857 % Kappa statistic 0.4582 Mean absolute error 0.2679 Root mean squared error 0.5175 **Classification Improvement ca. 4%**

VII. CONCLUSION

Evaluation of the results definitely has proved that quality pre-processing is a requirement for obtaining good results of classification, in this case the prediction of student success. In the study of selection and ranking features four relatively commonly used methods are used: Information Gain (IG), Gain Ratio (GR), Sequential

Backward Selection (SBS), Sequential Forward Selection (SFS). None of the methods showed identical results of ranking features.It can be concluded that in the selection of attributes and determination of their importance in predicting it is necessary to include additional verification and empirical methods.

Evaluation results of ranking have shown three features that have a significant impact on the success of the study: Average grade, Completed secondary school and Student rights. The analysis of results offers a conclusion that the completed secondary school and the curriculum are very important for success in the first year of the study. Students with poor professional prior knowledge adapt harder to the requirements of the technical study, which in some way justifies the faculties when emphasising that future students should pass some specific courses. In addition to the list of courses, faculties also give great importance to final secondary schoolgrades.

Two other demographic features have a different meaning. Students who come from technical schools, in this case, they can easily adapt on study demands because they have necessary background knowledge which is required for technical studies. In this way some students have reduced the impact of lower grades from the high school. Other demographic feature acts as a motivational factor in education, as previously explained. We conducted a ranking of features with four different methods. Each method has estimated slightly different order of features importance. In estimating the impact of demographic features on the prediction accuracy, analysis was pointed out that feature "Student rights" had the greatest impact. The results of analysis have shown that “Place of birth”, “Education level of mother”, “Mother profession” and “Status of residence” are four features who do not have a significant impact on the classification. After determining the impact of features, four features with the least impact were removed from the input set. After reducing the number features, with new classification was achieved about 5% better results. The obtained results indicate the need for involving additional control in the features selection process. One of possible solutions is to introduce a hybrid model of prediction. Model that with additional algorithms would increase the accuracy of prediction. This assumption gives a scope for further research in the field of classification and prediction of students success.

Abstract - With the development of ICT the need for automated question-answering systems is becoming increasingly important. Question-answering systems are still under development and experimentation. This paper is an overview of the research area that deals with question-answering systems; it explains the concept of question-answering systems and points out the problems that occur during their development. It also refers to a complex assessment techniques that are necessary when designing such systems. The system described is a real system and so are the test results.

Keywords: question-answering systems, artificial intelligence, technology assessment question-answering systems

I. INTRODUCTION

Along with the development of ICT grows a need for systems that allow the user to ask questions using everyday language and getting fast answers with the smallest quantity of context that is necessary for confirming the answer.

The solution to this problem are question - answering systems (QA systems) (Hirschman et al., 2001). QA systems are a method of retrieving information that answer questions asked in spoken language (Tomljanović et al., 2014).

The success in this field was achieved as part of the Text Retrieval Conference (TREC) (Ittycheriah et al., 2000) which is a series of workshops the mission of which is to retrieve as many information as possible from different fields of research and to backup the research in the field of QA systems.

To answer the question, the system has first to analyze the problem using the context. It finds one or more possible answers offered by the Internet source and offers an answer in an appropriate form. In most cases it is the supporting material that makes the answer understandable to the user or provides some further explanations regarding the answer.

In 1999 TREC started with the evaluation of QA systems that answer the factual questions by consulting the documents contained in TREC collections. A large number of systems successfully combine information retrieval and natural language processing techniques.

One of the groups of methods for knowledge representation is a graphical method for representing knowledge. These methods first transform knowledge into the model, then search knowledge by the model, and then are able to answer the questions. The NOK method (Jakupović et al., 2013), (Pavlić et al., 2013a), (Pavlić et al., 2013b), (Pavlić et al., 2013c) belongs to this group.

This paper will cover the methods which use the existing sources of knowledge registered in different texts.

II. COMPLEXITY ASSESSMENT TECHNIQUES QA SYSTEM

There are two critical research questions in development of QA systems: resources and evaluation. These two questions are closely related; developers need tools to build the system and they need assessment methods (exercises and tests) to evaluate the effectiveness of their system. The introduction of a general evaluation, such as TREC, has created associations interested in the area, and speeded up the research process as well. This is the evaluation with the special emphasis on methods for automatic evaluation.

A. Collection of questions and answers

In order to build a system that answers the questions, scientists need a stream of questions and answers. Ideally, such groups would be often occurring questions, and their answers would be contained in a large collection of documents. Kupiec uses a trivial search for questions as a source of question - answer pairs, as well as the Internet encyclopedia as a collection where to seek the answers (Kupiec, 1993).

A much larger collection is required for efficient use of machine learning and statistical techniques. For example, the syntax of questions and statements is different, and a large collection that explains or narrates usually contains very few questions, so without special settings, the rules based on the collection, will not work for the analysis of questions. The proper analysis of questions requires a large collection of questions and related short answers in order to develop premium features for speech tagging, parsing and questions input. For example, Mann used 2 collections of trivial questions with short answers (Mann, 2001). Auxiliary systems on the Internet include access to the most frequently asked questions as sources of question - answer sets, which are particularly useful in the development of QA systems specialized in certain areas. The number of QA websites is increasing. Good examples are sites that provide tests for foreign languages learning or contain quizzes based on actual events (Roever, 2001; Ushida, 2005).

Additional work in finding and collecting such collections on the Internet would accelerate the progress of the QA systems. The most common source of question - answer sets are multiple choice questions. Such questions are used in standardized tests. MCQs are not as natural as short-answer questions because they are designed to make the evaluation easier. Since the designing of tests is rather expensive, it is difficult to get a collection of materials for research or evaluation.

B. Expansion model

Any collection that contains question - answer sets may be useful. Some types of questions are much easier to be dealt with than the others. Previous researches have focused mainly on simpler questions. At the beginning of TREC assessment, questions were limited to simple factual questions that had the answer in the associated collection of documents. The result showed that the best assessment strategy was a ranked list of proposed correct answers.

The following assessment has increased the complexity of the questions in two dimensions: it allows questions that have no answers and questions with a list of answers (Ittycheriah et al., 2001). This further complexity requires changes in the assessment of the answer and in the construction of the system. To deal with questions that have no answers in the separate collection, systems themselves must measure their reliability regarding the answer.

Questions that require an answer sheet (e.g. a list of countries bordering Croatia) will need to choose an answer from more sentences comprised in one document, or even merge the answer from more documents. Both the former and the latter require the extension of a simple model to simple finding of sentences or parts of the document that give the best answer.

C. Evaluating response problems

The first problem that arises in the assessment is the choice of criteria to be used to assess the answer. *How to evaluate your question answering system every day . . . and still get real work done* (Breck, et al., 2000) calls for six following criteria:

- *relevance:* the answer should answer a given question
- *correctness:* the answer should be factually correct
- *conciseness:* the answer should not contain extraneous or irrelevant information
- *completeness:* the answer should be complete, i.e. partial answer should not get full credit
- *coherence:* the answer should be coherent, so that the questioner can read it easy
- *justification:* the answer should be supplied with sufficient context to allow a reader to determine why this was chosen as an answer to the question

Previous evaluations focused mainly on relevance, although today TREC - QA assessment requires that the answer must be justified by the context and that the size of the answer must be limited (in bytes). This is the first step towards conciseness. Optimization of a single criterion affects the quality of the other. For example, the justification of answers can reduce conciseness. This is exactly why the assessment criteria must depend on the purpose of use, the type of the user who searches for an answer, as well as on the interface.

After the criteria, the assessment procedures occupy the second important position. Experiments carried out during The Eighth TREC Conference introduced human evaluators to read and evaluate each answer. The results obtained showed that the human evaluator was consistent enough to preserve the relative ranking system, which implies that it is actually possible to have only one evaluator.

This has significantly reduced costs, but since there is a need for a human hand, this method does not support the systematic repetition of tests for machine learning. It is always useful to have a human subject dealing with evaluation, and therefore, tests that assess reading comprehension are ideal. In case of using multiple-choice tests, a human evaluator is not required.

D. Automated assessment techniques

Automated grading methods are under development and experimentation. For evaluation of short answers, it is possible to automate the comparison of answers, regardless of whether the answers are provided by the system or by a person, e.g. a student, with answers from the key provided by an expert. Such an assessment is described by Hirschman, Breck, Light,

Burger and Ferro in their book "Automated grading of short answer tests" (Hirschman et al., 2000). Such comparisons, though not as precise as those by human evaluators, nevertheless provide reasonably good results, 93-95 % according to human evaluators, which was good enough for machine learning.

Automated answers and evaluation are of great importance for testing the educational community. Despite the fact that the tests with short answers and essays are better, the multiple choice tests continue to be widely used. Tests where the person himself / herself writes the answers (either short answers or essays) are considered to be too subjective to be used for standardized testing. Recent research in this area (Kukich, 2000) have demonstrated the feasibility of automated methods of assessment, sometimes in combination with only one human evaluator. These results indicate that the automated grading systems are approaching human evaluators. We can already encounter automated assessments and e–learning systems throughout the Internet.

III. EXAMPLES QA SYSTEMS

1. *IBM's statistic system*

Operation of the system that answers the questions is explained using the example of IBM's statistic system that answers the questions (Ittycheriah et al., 2000). The architecture of the system is built around 4 major components, as shown in Figure 1:

- QA Type Classification
- Query expansion/Information Retrieval
- Named Entity Marking
- Answer Selection

The question is input that is classified, as asking for an answer belonging to one of the named entity classes. In addition, the question is presented to the IR engine for query expansion and document retrieval. This engine, given the query, looks at the data base of documents and outputs the best documents or passages annotated with the named entities. The final stage is to select the particular answer, given the answer class and the top scoring passages.

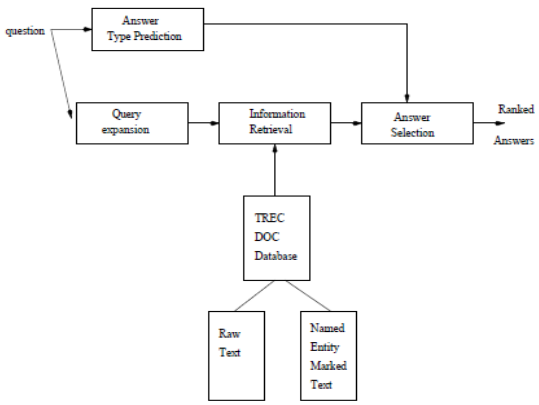

FIGURE 2. QUESTION ANSWERING ARCHITECTURE

A. *QA Type Classification*

The classification refers to the classification of questions and answers. In classifying the type of answer the problem is to label a question with the label of the named entity that the question seeks. These labels are the standard MUC (Chinchor, 1997) categories with the addition of PHRASE (P), which presents all the answers that cannot be put in standard categories. In standard categories we have REASON (R) category, which is tied to *why* questions. Processing of REASON and PHRASE is the same in this IBM system, interpreting it as desiring a clause which has a NOUN PHRASE (NP) imbedded in it.

Ittycheriah, Franz, Zhu, Ratnaparkhi, and Mammone created 1900 questions by presenting a human subject a randomly selected document and having read a portion of the document , a question was phrased, the answer and a document number noted in addition. They also used 1400 questions from a trivia database (Hallmarks, 1999), annotated in a similar way.

Each feature type expands to the property above it. The "Expanded Hierarchy" feature uses WordNet (Miller, 1990) in order to expand words from a question words up to those including noun predicate. The "Mark Question Word" feature identifies the question words and labels them as occurring in the beginning of a question, i.e. bqw, in the middle of a question, i.e. mdw or at end of a question, i.e. eqw.

N- gram language models are used as the method for language modeling. Regarding the length, N-grams can be unigrams (n =1), bigrams (n = 2), trigrams (n = 3)... (Gaspic, 2012).

Table 1 shows the classification of the QA type on the example question *"What year did World War II start?"* First, each word is classified into one of the word classes. WP is *wh* - pronoun such as *who, what, which, how, how many* ... NP refers to a noun phrase, VP verb phrase, NN singular noun, after English noun number, VBD verb in the past tense.

Table 1 shows that *what* is marked as an interrogative pronoun, while *year* is annotated as a noun. Expanding the features of the question pronouns up to those that contain the nominal predicate , i.e. we link *what* to *year*, we can conclude that the *wh* pronoun *what* and a noun predicate *year* require a certain time or a certain time period. Subsequently, we determine

TABLE I. FEATURES USED IN THE ANSWER CLASSIFICATION EXPERIMENTS

Unigrams	What year did World War II start?
Morphed,Part-Of-Speech	what{WP} year{NN} do{VBD} World{NP} War{NP} II{NP} start{NN}
Bigrams	what{wp} what{wp}_year{nn} what{wp}_do{vbd} what{wp}_world{np} ...
Expanded Hierarchy	what{WP} year time_period measure abstraction year{NN} do{VBD} ...
Mark Question Word	what_bqw year time_period measure abstraction year{NN} do{VBD} ...

TABLE II. RETRIEVAL RESULT

	MRR
pass1, TREC	0.4605
pass2, TREC	0.4824
pass2, encyclopedia	0.5031

the position of a question word within a question; in this case it is the beginning of the question, as shown in Table 1.

B. Information Retrieval

The purpose of the IR module is to search the database to select passages of the text, containing information relevant to the query. The IBM IR system uses a two-pass approach. In the first pass, the encyclopedia database is searched. The highest scoring passages are then used to create expanded queries, applied in the second pass. The scoring is based on unigram and bigram features extracted from the text data using tokenization, part-of-speech tagging and a morphological analyzer. (Merialdo, 1990).

In the first pass, Ittycheriah et al. modified the Okapi formula [1] (Robertson, Walker, Jones, Hancock - Beaulieu, Gatford, 1995) in order to score passages extracted from the encyclopedia documents, then converted all the encyclopedia articles into 82 277 overlapping passages, each containing about 100 non-stop words. Based on the first passage ranking, they constructed expanded queries. In the second passage they used extended queries and scored 2 632 807 passages based on the TREC-9 corpus. The passages contained about 200 non-stop words. Table 2 summarizes the Information Retrieval (IR) results on tests (Sparck Jones and Willett, 1997).

The performance is measured by the MRR[2] or Mean Reciprocal Rank. The first line of the Table 2 shows the result of the first pass scoring; the second line shows the result of the second pass scoring, and the third line shows the result corresponding to the system applied by the IBM as an example, with queries expanded using the encyclopedia database.

C. Named Entity Marking

Named entity annotation refers to a markup of the text with the class information. As mentioned above, classes correspond to the standard MUC classes.

Windows of + or - words, morphs, part-of-speech tags and flags raised by pattern grammars (DATE, MONEY, CARD, MEASURE, PERCENT, TIME, DURATION). The window for predicting the tag (0) is shown in Table 3.

Each stream has a fixed vocabulary. N-grams from this vocabulary form the features of the maximum entropy model.

[1] In IR is a ranking function used by search engines to rank matching documents according to their relevance to a given search query.

[2] MRR(Q) = $\frac{1}{|Q|} \cdot \sum_{i=1}^{|Q|} \frac{1}{r(d_{i,rel})}$

TABLE III. FEATURES USED IN THE NAMED ENTITY MODEL FOR PREDICTING TAG(0)

Words	w(-) w(-) | w(0) | w(+) w(+)
Morphs	m(-) m(-) | m(0) | m(+) m(+)
Part-of-Speech	p(-2) p(-1) | p(0) | p(1) p(2)
Grammar Flags	f(-2) f(-1) | f(0) | f(1) f(2)
Previous Tags	t(-2).t(-1) t(-1) |

The training data is arranged to indicate a special category for beginning of each named entity, for example BeginPERSON to find the boundaries of the named entity.

The system explores multiple NE hypotheses in parallel and keeps only those only those with high probability. It proceeds with the algorithm to find the most likely part for the whole sentence.

D. Answer Selection

In this phase we have a question, a class of the answer that the question seeks and a ranked set of passages annotated with the MUC classes. We are searching now the optimal sentence that will contain the answer. The TREC length constraints of 250 byte and 50 byte are then applied on the sentence. The algorithm used in this module is listed here:

1) Each passage is split into sentences.
2) A window is formed around each sentence.
3) The following features are computed:
   a) *Matching Words* (the sum of the number of words that matched identically in the morphed space (+)),
   b) *Aligning the Terms* (the sum of the number of words that are synonyms (+))
   c) *Mis-Match Words* (the sum of the number of question content words that did not match in this answer (-))
   d) *Dispersion* (the number of words in the candidate sentence that occurred between matching question words (-))
   e) *Cluster Words* (the number of words in the candidate sentence that occurred adjacently in both the question and answer candidate (+))
4) The location or absence of desired entities is noted in the score.
5) Each of these distances are weighted, the sentences ranked and the top 5 sentences are then output.

Each of the above distances has its own weight and the corresponding sign shown above to attach to it. The score for an answer is the sum of distances and the top 5 sentences are then output.

In order to select the 250 or 50 byte answer from these sentences, the system identifies the longest mismatched pieces between the answer and the question. It then analyses the answer and the question to find where the center of the match is and using a

subject-verb-object assumptions of the sentence, it takes the question as either desiring the subject or the object, whichever has the least matches with the question.

E. Testing

Testing this IBM example, the authors came to the conclusion that the selection of the answer is still the hugest problem in QA systems. In 24.7 % of cases, their 250B system showed an error when selecting answers, while at 50B system the percentage reaches even 35.6 %.

The method used in the IBM QA system is a complex search that is not trying to get to the semantics of the text, but introduces a number of measures to calculate the overlapping of the content and the answer.

2. DeepQA Project

IBM Research undertook a challenge to build a computer system that could compete at the human champion level in real time on the American TV quiz show, Jeopardy. The Jeopardy Challenge helped to address requirements that led to the design of the DeepQA architecture (Figure 2.) and the implementation of Watson. The goals of IBM Research are to advance computer science by exploring new ways for computer technology to affect science, business, and society. The Jeopardy Challenge requires advancing and incorporating a variety of QA technologies including parsing, question classification, question decomposition, automatic source acquisition and evaluation, entity and relation detection, logical form generation, and knowledge representation and reasoning. Baseline performance is the QA system called Practical Intelligent Question Answering Technology (PIQUANT) (Prager, Chu-Carroll, and Czuba 2004), which had been under development at IBM Research by a four-person team for 6 years prior to taking on theJeopardy Challenge. At the time it was among the top three to five Text Retrieval Conference (TREC) QA systems. PIQUANT was a classic QA pipeline with state-of-the-art techniques aimed largely at the TREC QA evaluation (Voorhees and Dang 2005). PIQUANT performed in the 33 percent accuracy range in TREC evaluations. While the TREC QA evaluation allowed the use of the web, PIQUANT focused on question answering using local resources. A similar baseline experiment was performed in collaboration with Carnegie Mellon University (CMU) using OpenEphyra, an open-source QA framework developed primarily at CMU. The framework is based on the Ephyra system, which was designed for answering TREC questions. In these experiments on TREC 2002 data, OpenEphyra answered 45 percent of the questions correctly using a live web search. Minimal effort was spent in adapting OpenEphyra, but like PIQUANT, its performance on *Jeopardy* clues was below 15 percent accuracy.

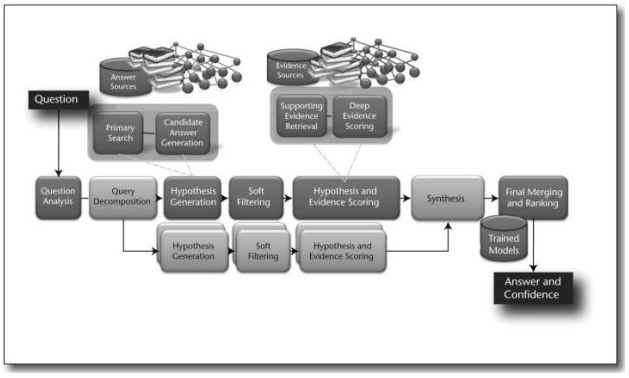

FIGURE 2. DEEPQA ARCHITECTURE

A system called DeepQA, still continuing to develop, is a massively parallel probabilistic evidence-based architecture. DeepQA is an architecture with an accompanying methodology. DeepQA has successfully been applied to both the *Jeopardy* and TREC QA task. It was first adapted to different business applications and additionally to exploratory challenge problems including medicine, enterprise search, and gaming.

The overarching principles in DeepQA are massive parallelism, many experts, pervasive confidence estimation, and integration of shallow and deep knowledge.

Massive parallelism: Exploit massive parallelism in the consideration of multiple interpretations and hypotheses.

Many experts: Facilitate the integration, application, and contextual evaluation of a wide range of loosely coupled probabilistic question and content analytics.

Pervasive confidence estimation: No component commits to an answer; all components produce features and associated confidences, scoring different question and content interpretations. An underlying confidence-processing substrate learns how to stack and combine the scores.

Integrate shallow and deep knowledge: Balance the use of strict semantics and shallow semantics, leveraging many loosely formed ontologies (Ferrucci at al., 2010).

The authors believe that in the future more methods will focus on detecting semantics and propose pretreatment of the texts and their recording in the network of knowledge to be used for asking questions and searching answers. It is planned to do such a research by using the NOK method.

IV. CONCLUSION

The complexity of technical evaluation of QA systems indicates resources and evaluation as two critical issues in their development.

Standardized tests use multiple-choice questions.

The selection of the evaluation criteria presents the problems in assessing the answer. The evaluation criteria are: relevance, correctness, conciseness, completeness, coherence and justification.

Today's QA evaluation of TREC requires the answer to be justified by the context as well as the limitation of the answer (in bytes), which is the first step towards brevity.

Evaluation criteria must depend on the purpose of use, the type of user who searches for an answer and on the interface.

Regarding the short answers, it is possible to automate the comparison of answers. Comparisons that are not accurate, as those by human evaluator, nevertheless provide good results (93-95 %).

Tests where the person himself / herself writes the answers (either short answers or an essay) are considered to be too subjective for standardized testing.

An automated method of evaluation, sometimes in combination with only one evaluator has proven to be worthwhile, which indicates that the automated grading systems are approaching human evaluators.

The IBM, which has played a leading role in the development of information technology, has developed QA systems whose results show an error in 30 % of cases.

They are constantly seeking an algorithm (method, model, procedure) to solve the selection of a short and concise answer.

QA systems are still unreliable, do not always provide good results, require a lot of sources, can't make conclusions, do not solve the context problem, etc.

Further research will go towards the development of QA systems using the NOK.

ACKNOWLEDGMENT

The research has been conducted under the project "Extending the information system development methodology with artificial intelligence methods" (reference number 13.13.1.2.01.) supported by University of Rijeka (Croatia).

Inteligentni sustav upravljanja tunelskom rasvjetom

Zdenko Balaž, Krešimir Meštrović, Petar Jandrlić i Marko Čaržavec
Tehničko veleučilište Zagreb/Elektrotehnički Odjel, Zagreb, Hrvatska
zbalaz@tvz.hr, kmestrovic@tvz.hr, pjandrlic@tvz.hr, mcarzavec@tvz.hr

Sažetak - Moguća racionalizacija svakog projekta rasvjete tunela počiva na njegovim utvrđenim eksploatacijskim parametrima. Obradom parametara rasvjete s pozicije ekspertnih sustava, naročito dugačkih tunela, ukazuje da su moguće značajne uštede kako u potrošnji električne energije tako i u održavanju. Raspoložive baze podataka i baze znanja, te manipulacija znanjem tijekom višegodišnje eksploatacije tunelskih rasvjeta rezultirale su kreacijom inteligentnog sustava za upravljanje tunelskom rasvjetom na način drugačiji od uniformno prihvaćenog i oslonjenog na dosadašnje legislative. Tunelska je rasvjeta kao sustav sačinjena od više međusobno povezanih i zavisnih dijelova rasvjete. Ona u prvom redu pridonosi sigurnosti prometa kroz tunel i stoga je bitno voditi računa o problematici prilagodbe i akceptiranja svih relevantnih parametara luminancije. Inteligentni je sustav zadužen da upravlja rasvjetom, na način da vodi računa o vizualnoj prilagodbi ali uzimajući u obzir prosječnu luminanciju okoline, samog tunela, predportalnih građevina i prometnice, kao i dnevnog svjetla, neba koje je podložno promjenama kako atmosferskih prilika tako i ekliptike. Za tako velik broj utjecajnih parametara razrađene su aktuatorske i perceptorske mogućnosti oslonjene na nove tehnologije opreme, s kojom su studenti Tehničkog veleučilišta u Zagrebu kroz kolegij, Umjetna inteligencija – Espertni sustavi na III. Semestru specijalističkog studija provodili ispitivanja. Dobiveni rezultati i prikupljeni podaci u bazama znanja sintetizirani inteligentnim sustavom su potvrdili opravdanost novog pristupa projektiranju i izvedbi upravljanja tunelske rasvjete.

I. Uvod

Tunel kao objekt autoceste, sa svojom rasvjetom, je bitan tehnički čimbenik u funkciji sigurnosti prometa. Prilaz tunelu, predstavlja dio prometnice autoceste prije samoga ulaza u tunel i za njega se projektira dio tunelske rasvjete nazvan rasvjeta prilazne zone. Nakon ulaza u tunel projektira se dio sustava tunelske rasvjeta nazvan rasvjeta prijelazne zone koja sadrži zonu ulaza i zonu praga, što predstavlja najveću koncentraciju rasvjetnih tijela od ukupno projektiranog sustava rasvjete tunela. Sustav rasvjete tunela sastavljen je od osam podsustava, [1], i tijekom velikog projekta hrvatske izgradnje autocesta zadnjih petnaest godina, zbog nepostojanja domaće legislative u projektima rasvjete tunela, koristila se austrijska i njemačka, [2], [3] i [4].

Problematika upravljanja rasvjetom tunela obrađivala se samo u razvojnim projektima, [5] i [6]. Oni su poslužili kao osnova prikupljanja baza podataka i baza znanja a kroz [7] i kao gradivo za edukaciju. Kroz taj angažman inteligentni sustav, (IS), je poslužio kao izazov i osnova studentima koji su svojim radovima ukazali da ima još prostora za racionalizaciju, [8] i [9], što je namjera prikaza u ovom radu.

Kod vozača prilikom nailaska na tunel, prostorna i vremenska prilagodba uvjetima vožnje, može izazvati osjećaj nelagode i nesigurnosti. Prilikom nailaska, odnosno ulaska i izlaska iz tunela, vrijeme prilagodbe može biti kritičan čimbenik koji utječe na sigurnost prometa.

Promjena sadržaja u vidnom polju vozača, tijekom vizualne prilagodbe pri približavanju ulaza u tunel, ili izlaza, povezana je sa subjektivnim osjećajem percepcije luminiscencije, [1]. Izraz luminiscencija odabran prema [10], ukazuje na svijetljenje, odnosno stvaranje izvora svjetlosti kojeg u prvom redu promatramo od stanja dnevnog svjetla. Iz tih sadržaja bitno je prepoznati i druge parametre prema kojima bi se projektirala rasvjeta tunela jer stvaranje svjetlosti, one dnevne, podložno je klimatskim uvjetima.

Među parametrima moguće je izdvojiti osim svijetle površine neba - svijetli sloj atmosfere između položaja vozača i ulaza u tunel, površinu kolnika dionice ceste ispred vozača, okolicu oko ulaza u tunel, okolicu ceste ispred vozača, otvor i portalne građevine tunela.

II. Novi parametri utjecaja na rasvjetu tunela

A. Ekliptički parametri

Svijetla površina neba, svijetli sloj atmosfere posljedica je položaja Sunca. U svakom trenutku visina i azimut jednostavno opisuju njegovo kretanje. Globalnim sustavima za utvrđivanje pozicije moguće je vrlo precizno pratiti ekliptičke promjene, Tablica 1.

Kretanje sunca po nebu, Sunčev dijagram, prikazuje se u cilindričnim ili polarnim koordinatama. Podaci su dostupni i od izuzetne su važnosti u istraživanjima za fotonaponsko iskorištavanje sunčeve energije, [11]. Rezultati tih istraživanja su korišteni za slaganje algoritama prema kojima funkcioniraju mjerni članova za utvrđivanje trenutnih, ekliptičkih parametara dnevnog svjetla sunca odabranih i u IS. Prema njima su se simulirale matrice potrebnih intenziteta rasvjete ulazne odnosno izlazne zone tunela kako bi bile najbliže trenutnom dominantnom dnevnom svjetlu.

Promjenu dnevnog svjetla prati promjena scenarija prema kojem se odabire referentna veličina za upravljanje intenzitetom rasvjete preko agentskog sustava.

TABLICA I. EKLIPTIKA –RAZLIKA UNUTAR ČETIRI GODINE

Red. broj	Datumi i vremena solsticija i ravnodnevnica		
	Ravnodnevnica	*Ljetni solsticij*	*Zimski solsticij*
2012	20. III.-06:14	21. VI.-00:09	21. IX.-12:11
2013	20. III.-12:02.	21. VI.-06:04	21. IX.-18:11
2014	20. III.- 17:57	21. VI.- 11:51	22. IX.- 00:03
2015	20. III. -23:45	21. VI. -17:38	22. IX. -05:48

B. Klimatski parametri

U svim ekliptičkim stanjima luminiscencija Sunca na nebu kao izvor dnevnog svjetla podložna je klimatskim utjecajima, magla, kiša, oblaci i snijeg. Analizirani su eksploatacijski podaci i sintetizirani s rezultatima dobivenim mjerenjem koja su simulirala određene uvjete. Mjerenja su se dosta vjerno približavala simuliranim rezultatima, što je omogućilo korištenje istih ulaznih parametara za generiranje referentne veličine kao i kod ekliptičkih parametara samo uvođenjem određenih prigušnih faktora, f_{pm}, f_{pk}, f_{po} i f_{ps}.

C. Parametri doba dana

Za analizu dnevnih parametara korišteni su rezultati istraživanja prema [12]. FAA - Savezna je uprava za civilno zrakoplovstvo, koja kao agencija američkog Ministarstva prometa nadležna za reguliranje i nadziranje svih aspekata civilnog zračnog prometa u SAD-u, predlaže promjene legislative. Tako je bio slučaj s dijelom sustava svjetlosne signalizacije u funkciji sigurnosti zračnog prometa za koji je utvrđeno da su najvažniji parametri, koji utječu na rezultate vidljivosti pojedinih svjetlosnih sustava, prijelazi od jutarnjih do večernjih perioda u danu. Prosjek rezultata koji su dobiveni od 42 nezavisna subjekta direktno involvirana u procedure istraživanja, provedena od siječnja do rujna 2004. godine, prikazuje Tablica 1.

TABLICA II. REZULTATI VIDLJIVOSTI SVJETLOSNIH SUSTAVA

Svjetlosni sustav	Parametri, DP-1, 2, 3 i 4			
	Zora /Jutro (m)	*Dnevno svjetlo (m)*	*Sumrak /Večer (m)*	*Mrkla noć (m)*
Svjetlosni znakovi (SIGN)	146	142	122	120
Sustav zaštitnih svjetala (RGL-elevated)	237	95	260	255
Sustav zaštitnih svjetala (RGL-inset)	146	68	243	213
Sustav zaštitnih svjetala „T-con“ (RGL-inset)	76	55	121	127
Oznake bojom (MARK)	63	91	48	48

Tablica se odnosi na tri različita svjetlosna sustava:

- Svjetlosne znakove naredbi, koji su dio obvezne opreme aerodroma prema ICAO i FAA legislativi, [12] i [13]. (engl. Mandatory Instruction Signs). Ugrađuju se sa svake strane manevarske površine. Znakovi su oblika panela visine ispod jednog metra, bijele su boje na crvenoj podlozi.
- Sustav zaštitnih svjetala uzletno-sletne staze koji su podignuti iznad tla, (engl. Elevated Runway Guard Lights). Ugrađuju se sa svake strane manevarske površine. Svaka jedinica ima par svjetala koja naizmjenično svijetle s frekvencijom bljeska nešto kraćeg od jedne sekunde.
- Sustav zaštitnih svjetala uzletno-sletne staze koja su ugrađena u manevarsku površinu, okomito kao zaustavna prečka i sa svake strane, (engl. In-pavement Runway Guard Lights). Jedinice sinkronizirano svijetle s frekvencijom bljeska oko jedne sekunde. Ovaj tip sustava svjetala izveden je u dvije varijante s tim što druga varijanta ima još i par svjetala ispred za „T“ konfiguraciju, (engl. Alert Zone Lighting).

Osim svjetlosnih sustava u tablici je naveden i rezultat za oznake na mjestu čekanja, na manevarskim površinama oslikane bojom, (engl. Runway Hold Position Markings). Ti su podaci korišteni u IS za donošenje odluke o uporabi određenih scenarija upravljanja rasvjetom koji rezultiraju određenom racionalizacijom, baš oslonjeno na analizirana četiri trenutka 24-satnog trajanja dana.

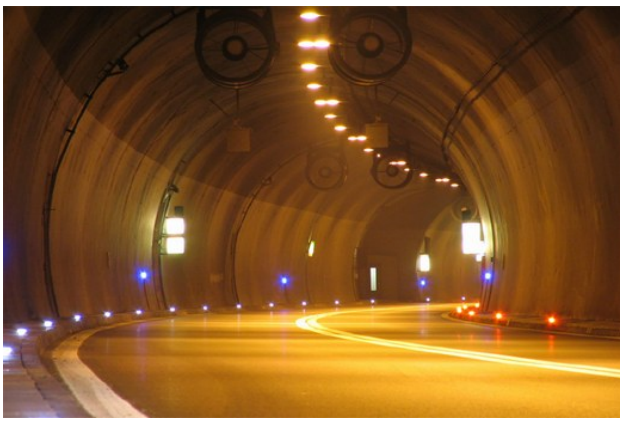
D. Manipulacije parametrima

Manipulacija raspoloživim parametrima ukazivala je na disproporciju rasvjete u pogonu od one koju bi angažirao inteligentni sustav. Za potvrdu dobivenog zaključka pristupilo se novoj analizi baziranoj na fotografskom dokumentiranju stanja. Fotografski snimci rasvjete najčešće ulazne i izlazne zone odabirani su prema kriterijima rezultata američkih istraživanja navedenih u [12]. Snimanja su provedena istom opremom za sve tunele. Iz baza podataka IS, izdvojene su raspoložive fotografije za usporedbu istih dijelova rasvjete u istim uvjetima za dva različita tunela, slika 1. i slika 2.

Slika 1. Ulazna zona jednog hrvatskog tunela na autocesti A1 s pripadajućim dijelom sustava rasvjete za parametre DP-3

Slika 2. Ulazna zona jednog francuskog tunela s pripadajućim dijelom sustava rasvjete uz identične parametre DP-3, kao na slici 1.

Za primjer su odabrani i parametri prijelazne zone tunelske rasvjete, koji su isti za DP-1-4, prema Tablici I. u usporedbi hrvatskog i talijanskog tunela, slike 3. i 4.

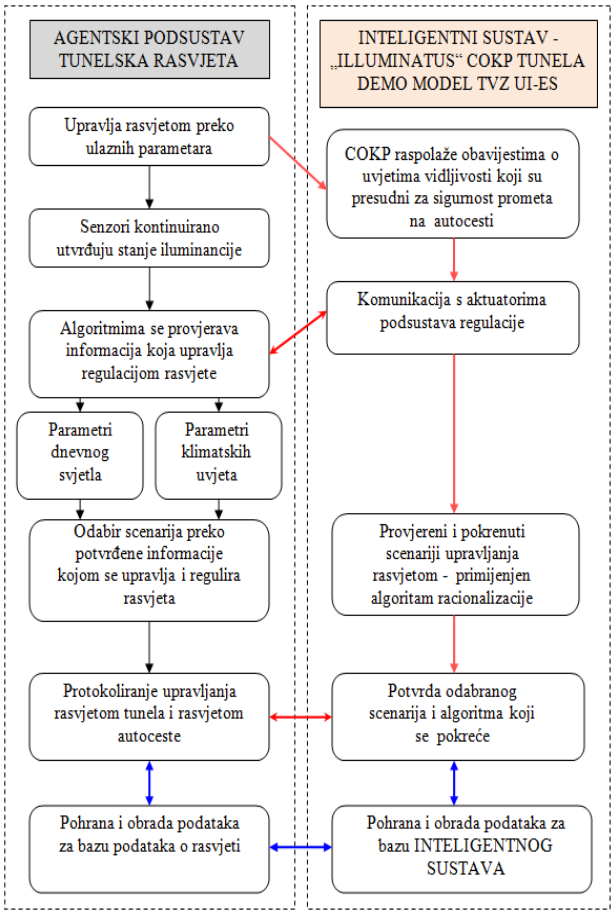


Slika 3. Prijelazna zona tunelske rasvjete hrvatskog tunela na autocesti A1, identična za sve parametre DP-1-4

Slika 4. Prijelazna zona tunelske rasvjete talijanskog tunela, identična za sve parametre DP-1-4

E. Mehanizmi zaključivanja - upravljanje rasvjetom

U razvoju IS su uzete u obzir sve specifičnosti koje unosi odabrani tip rasvjetnih tijela ovisno, o tome kako je tunelska rasvjeta projektirana, evidentne razlike sa slika 3. i 4. To je posebna baza podataka, obogaćena bazom znanja koje je znanje eksperata potvrđeno u eksploataciji. Razradu za provedbu algoritama i scenarija IS za upravljanje rasvjetom prikazuje dijagram, slika 5.



Slika 5. Dijagram provedbe algoritama i scenarija upravljanja rasvjetom tunela

F. Učenje iz inteligentnog sustava

Kreacija baza znanja i baza podataka u IS je posebno interesantna s aspekta planiranja održavanja. Ti podaci i znanja mogu se koristiti odmah, jer djeluju na korekcije ili potvrde odabranih scenarija, čime se direktno može utjecati na racionalizaciju, što je i cilj razvoja inteligentnog sustava. Gledano kroz eksploataciju tunela moguće je vrlo jednostavno sumu troška za održavanje, (ΣT), promatrati kao zbroj troškove preventivnog i interventnog održavanja, ($T_{\pi io}$), i troškova za utrošenu električnu energiju, ($T_{\varepsilon\lambda}$), "(1)".

$$T_{\pi io} + T_{\varepsilon\lambda} = \Sigma T. \qquad (1)$$

U troškovima plaćene električne energije za pogon tunela dominantna je stavka, rasvjeta, [14]. Kao što je eksploatacijskom kreacijom baza znanja i baza podataka IS uočeno, postoji više mogućnosti utjecaja na upravljanje rasvjetom tunela. Mogućnosti pružaju prvenstveno nove tehnologije i aktualna legislativa, ali i empirijska i heuristička znanja eksperata, [15] i [16]. Spoznaja da je ekspert stručnjak odnosno specijalist postavlja ga u poziciju vrsnog poučavatelja koji ne predstavlja nadmoćnu instituciju, instancu za posljednje odluke. Već kao što u korijenu riječi stoji, (lat. experientia docet – iskustvo poučava), skupljanje i posjedovanje iskustva, nije zvanje, ali pohranjeno u IS posreduje u praksi i na taj način IS zamjenjuje eksperta.

G. Rezultati

Odabrani parametri još do sada kako je poznato autorima ovoga rada nisu valorizirani u scenarijima upravljanja na način kako je razrađeno. Rasvjeta u pogonu hrvatskih tunela u velikom broju slučajeva, snimljena i izmjerena na licu mjesta u velikom broju slučajeva bila je i za 50 % veća od one koju bi angažirao inteligentni sustav, a koja se u 80% slučajeva poklapala sa snimljenom rasvjetom nekih europskih tunela, [5] i [6]. Najveća odstupanja u luminiscenciji, (zatečena – generirana od IS), uočena su prilikom obrade dnevnih parametara, DP-1, (svitanje/zora) i DP-3, (predvečer/suton). Ti su se rezultati poklapali sa stanjem koje je bilo posljedica primjene prigušnih faktora, f_{pm}, f_{pk}, f_{po} i f_{ps}. Faktori prigušenja zbog magle, f_{pm}, kao i zbog snijega, f_{ps}, nisu utjecali na luminiscenciju kao što je utjecao faktor prigušenja dnevne svjetlosti zbog naoblake, f_{po}, čiji je efekt najbliži parametru DP-3. Dobiveni su rezultati korišteni za simulaciju novog upravljanja tunelske rasvjete i izračunati su troškovi za potrebnu električnu energiju rasvjete na referentnom tunelu, [17]. Izračunata ušteda električne energije za rasvjetu svih hrvatskih tunela iznosi 8%.

Rezultati provedenih istraživanja razvojem IS, uspoređivani su prema [17], i izdvojen je zaključak koji prezentira drugi pristup troškovne analize izrađene za investitora s 5 različitih scenarija u periodu od 15 godina, što je životni vijek sustava rasvjete. Analize su obuhvatile pet varijanti, od kojih niti jedna ne obrađuje sustav upravljanja, a sve upućuje na zaključak s povećanjem troškova održavanja i troškova za električnu energiju za 2% godišnje, u što je uključen očekivani rast cijena električne energije i inflaciju?

III. ZAKLJUČAK

Inteligentni sustav, (IS), koji se koristi na Tehničkom veleučilištu u Zagrebu, (TVZ), u izbornom kolegiju služi studentima za stjecanje znanja iz područja umjetne inteligencije. Uključivanjem u njegovu izgradnju i razvoj kroz seminarske radove dobivene su konkretne spoznaje i utvrđeni i drugačiji parametri koji upućuju na novi pristup u projektiranju upravljačkih dijelova sustava rasvjete. Karakteristike i efikasnost agentskog podsustava, za upravljanje rasvjetom tunela ovise osim o povezanosti s ekspertnim sustavom za nadzor i upravljanje u centru za održavanje i kontrolu prometa, kojeg predstavlja demo IS za edukaciju na TVZ-u i o novim parametrima. Formiranim bazama znanja i podataka o stanju sustava rasvjete složeni su algoritmi za upravljanje koji su uzeli u obzir nove parametre koji još do sada nisu bili u projektima sustava tunelske rasvjete. Analogijom primjene novih tehnologija i metoda ispitivanja fotonaponskog iskorištavanja sunčeve energije utvrđeni su ekliptički parametri. Istraživačkim projektima u zrakoplovstvu postavljeni su dominantni parametri dnevnog svjetla povezani s prigušnim parametrima zbog klimatskih uvjeta koji su iskorišteni i u demo IS. Prema algoritmima su složeni scenariji kojima se postiže racionalnije korištenje sustava tunelske rasvjete, bez narušavanja sigurnosti prometa, jer su dobiveni rezultati potvrđeni u usporedbama s nekim europskim tunelima. Iako demo IS, studenti na njemu uče konkretne primjere iz prakse i promišljaju na način kojim umjetna inteligencija poučava. Studenti TVZ-a, specijalističkog studija Elektrotehničkog odjela na izbornom kolegiju kroz IS uče i svojim ga znanjem, kako onim kroz seminarski rad, tako i onim iz obrade pretraga, nadograđuju. Raspoloživa znanja iz baza kao i kompetencije koje studenti stječu mogu pomoći u kreiranju planova održavanja.

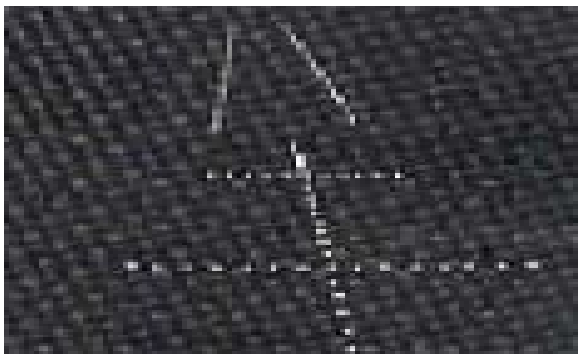
Sažetak - Aerodromski sustavi svjetlosne signalizacije su konfigurirani serijskim krugovima s konstantnim izvorom struje. Važan parametar koji ukazuje na funkcionalnost takvog strujnog kruga je otpor izolacije primarnih kabela serijskih strujnih krugova napajanih iz regulatora konstantne struje. Regulator je opremljen modulima koji nadziru i upravljaju rasvjetom. Raspoloživi parametri se nadziru i arhiviraju u računalo službe održavanja. Kreacijom baza znanja i baza podataka te manipulacijom znanjem postiže se efikasnije održavanje. Inteligentni sustav pomaže u procedurama preventivnog i prediktivnog održavanja i služi za učenje. Stečeno znanje ukazuje na moguće racionalizacije i na unapređenja prilikom revitalizacije ili zamjene postojećih sustava. Razvijenim inteligentnim sustavom koji se koristi u programu edukacije za stjecanje licence aerodromskih specijalista na održavanju sustava svjetlosne signalizacije, dobiveni su konkretni podaci o karakteristikama i efikasnosti pojedinih podsustava. Između ostalih to je sustav za nadzor stanja izolacije serijskih strujnih krugova koji pomaže u podizanju kvalitete izolacije. Kontinuiranim praćenjem i stvaranjem baza podataka o stanju izolacije složeni su algoritmi za predviđanje mogućih kvarova a samim tim i za racionalnije održavanje uz visoku pogonsku pouzdanost.

I. UVOD

Svjetlosna signalizacija na zračnim lukama u početku svoje primjene služila je isključivo za vizualno navođenje zrakoplova u procedurama slijetanja i polijetanja, Slika 1.



Slika 1. Svjetlosna signalizacija aerodroma Heathrow 1957. godine

Danas je to složeni sustav s množinom opreme koja osim sustava svjetlosne signalizacije, obuhvaća sustave sigurne opskrbe električnom energijom s osnovnim i sekundarnim izvorima, sustave upravljanja kretanja zrakoplova po manevarskim površinama i sustave za navođenje zrakoplova na parkirne pozicije, Slika 2.

Slika 2. Aerodromski sustavi svjetlosne signalizacije CAT IIIB

U zrakoplovnoj terminologiji to se naziva kategorija zračne luke, (CAT) i predstavlja ukupnu razinu tehničke i tehnološke opremljenosti što uz stroge procedure i osposobljene, (licencirane) djelatnike, garantira pružanje kvalitetne usluga prihvata i otpreme zrakoplova – sigurnosti zračne plovidbe na zračnoj luci. Svi navedni specijalistički tehnički podsustavi povezuju se u ekspertni sustav s bazom podataka, bazom znanja i mehanizmima zaključivanja, koji se nalaze u aerodromskoj službi elektroodržavanja, engl. Airport Electrical Maintenance, (AEM).

U ovom radu bit će prezentirana iskustva stečena kroz realizaciju projekata aplikativne problematike, [1]-[4]. Stupanjem na snagu nove legislative, [5], pokrenuti su programi cjeloživotnog obrazovanja, (AERO TVZ), [6] i opremljen je praktikum za izvođenje vježbi i uvođenje znanstveno-istraživačkog rada, [7]. Uz programe edukacije razvija se inteligentni sustav koji se koristi formiranim bazama znanja i bazama podataka aerodromskih sustava svjetlosne signalizacije. Kreirani algoritmi ukazuju na karakteristike i efikasnosti pojedine opreme i podsustava, što se može vrlo kvalitetno primijeniti u poslovanju za unaprijed planirane zadatke. U edukacijama se koristi pristup kojim su japanski radnici zahvaljujući metodama osposobljavanja kroz kontrolu kvalitete provodili racionalizacije, unapređenja i procjenjivali svoje učinke, kao u [8] i "neobjavljen" [9].

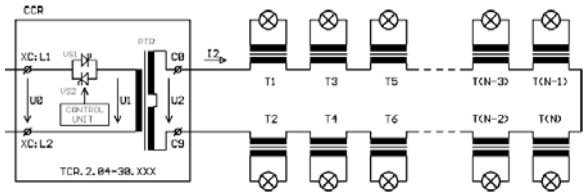
Uporaba informacijsko komunikacijskih tehnologija, (ICT), nameće informatizaciju samog posla. Potencijalno dostupne informacije i parametri mogu se uporabljivati u realnom vremenu te se s njima može manipulirati u smislu potreba odlučivanja, [10]. Inteligentni sustav, (IS), razvijen i instaliran kao demo model sustava svjetlosne signalizacije, uz [6], ima sve realne mogućnosti kao nadzorno upravljački aerodromski sustav. IS ima svoj hardver i softver i omogućava funkcije upravljanja koje se

u stvarnosti na zračnoj luci provode upravljačkom jedinicom na aerodromskom tornju, (TWR). Sve funkcije se nadziru lokalno na samoj opremi kao u AEM-u.

II. AERODROMSKI SUSTAV SVJETLOSNE SIGNALIZACIJE

A. *Koncepcija strujnih krugova aerodromske rasvjete*

Sustav svjetlosne signalizacije, engl. Airfield Lighting System, (ALS), koncipiran je serijskim strujnim krugovima, [11], koji su napajani iz izvora konstantne struje, regulatora, engl. Constant Current Regulator, (CCR). Svako rasvjetno tijelo, svjetiljka ili svjetlosna oznaka, u serijskom strujnom krugu je priključeno preko svog izolacijskog transformatora, (T_1-$T_{(N)}$), Slika 3.

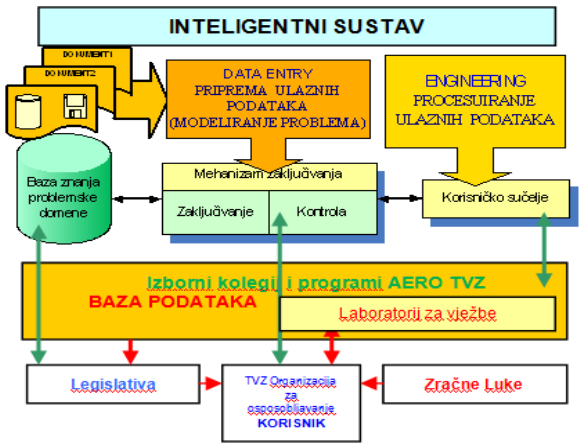


Slika 3. Serijski strujni krug sustava svjetlosne signalizacije

B. *Laboratorijska oprema ALS*

Kompletna oprema za laboratorijski model serijskog strujnog kruga ALS je dobivena zaslugom sponzora[1]. Primarni krug je sastavljen od CCR-a, primarnih kabelskih vodova s primarnim konektorima i izolacijskim strujnim transformatorima. Krug je opremljen senzorima, perceptorima i aktuatorima u modularnoj izvedbe i sve je ugrađeno u ormar CCR. Kao hardver IS sastoji se od modula napajanja, modula upravljačko procesorske jedinice, komunikacijskog modula, modula regulacije CCR-a, modula za nadzor stanja otpora izolacije i modula za kontrolu broja pregorjelih žarulja u serijskom strujnom krugu, sve integrirano operabilnim softverom.

Inteligentni sustav, (IS), je predstavljen računalom s aplikacijskom programskom podrškom kao mehanizmom zaključivanja, bazom znanja i bazom podataka, Slika 4.



Slika 4. Inteligentni sustav laboratorijskog modela aerodromskog sustava svjetlosne signalizacije

[1]-TRANSCON, Electronic Systems,www.transcon.eu. (sponzor)

C. *Inteligentni sustav za učenje i poučavanje*

Baze podataka i znanja, procesuiranje ulaznih podataka i modeliranje problema, kroz IS koriste se za učenje, znanstveno istraživački rad i programe edukacije na Tehničkom veleučilištu Zagreb, (TVZ), i to:

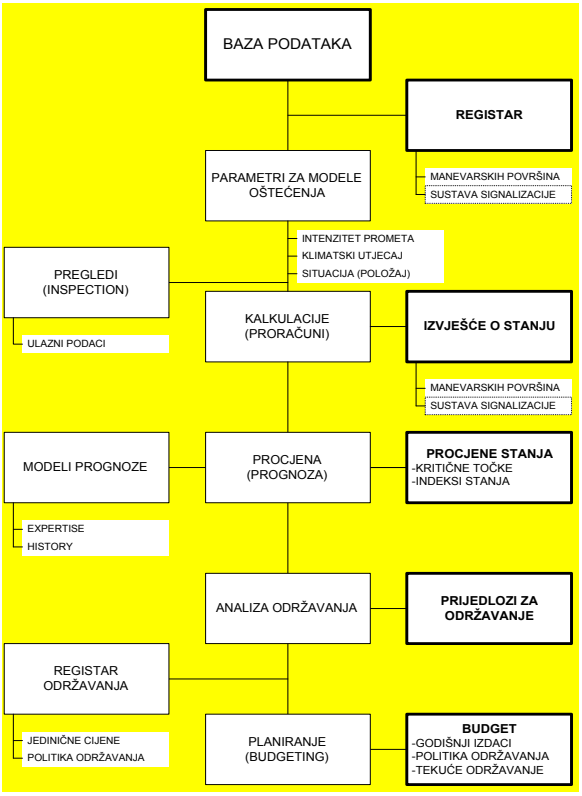
- Kroz teorijska predavanja izbornog kolegija Umjetna inteligencija, (UI) – Ekspertni sustavi, (ES), [7], studenti se uvode u problematiku IS, te kroz interaktivni rad otkrivaju i pronalaze mogućnosti djelovanja. Kroz spoznaje o UI i razvoj ES, studenti osim aplikativne primjene, stječu i usputni pozitivne učinke jer se kroz kolegij težište stavljaju na izučavanje s ciljem boljeg razumijevanja ljudske inteligencije i olakšavanje komunikacije ljudi sa strojem. Klasična UI, usko je vezana s pojmom znanja, njegovog prikupljanja, pohrane i primjene pri rješavanju složenih zadataka. Zbog tih se razloga kroz kolegij potiču razmišljanja o UI naše stvarnosti, odnosno konkretnih praktičnih problema primjera iz prakse, o domenama znanja koje se usvaja kroz kognitivne složenosti i kontekst znanja,"neobjavljen" [9].
- Kroz laboratorijske vježbe izbornog kolegija UI-ES, sintetiziraju se spoznaje do kojih se dolazi pretraživanjima baza znanja, uz pomoć ES. Na taj se način profiliraju stavovi, mišljenja i ekspertiza o znanju i naukovanju i potiče hermeneutičko promišljanje na način da se svjesno dopušta izmak uvjeta njegove ograničenosti kako za poučavatelja tako i za poučavanog,"neobjavljen" [9].
- Kroz specijalističke programe cjeloživotnog obrazovanja na TVZ-u, u skladu s [5], specijalistička znanja su podloga za stručnjake od kojih se očekuje stručnjačko rješavanje problema na razini ekspertize, a za što je neophodno razumijevanje**.** Za potvrdu razumijevanja koriste su raspoložive baze podataka, stvarni eksploatacijski rezultati te uspoređuju s rezultatima dobivenim pretragama. Na taj se način ekspertu "Otkriva mogućnost razumijevanja koje nije nemislivo unaprijed", [12]. Na specijalističkim edukacijama kandidate se upoznaju s djelovanjem eksperta, odnosno specijalista. Promatra ga se s pozicije vrsnog poučavatelja, što je i cilja kojem teže poučavani. U konačno dosegnutom statusu izobrazbe on ne predstavlja nadmoćnu instituciju, instancu za posljednje odluke, jer skupljanje i posjedovanje iskustva, nije zvanje. Ali zvanjem postaje kada posreduje svojim znanjem u stručnoj praksi. Očekuje se, da se njegova uloga odlikuje izrazom expertus, što se osamostalilo iz čitave velike rijeke iskustava stečenog u praksi i potvrđenog na edukaciji. Iz tih su razloga i predviđeni specijalistički programi koji se razlikuju, radili se o stjecanju potvrde o osposobljenosti, njenom obnavljanju ili produljenju. Ekspert se nalazi između znanosti, u kojoj mora posjedovati kompetencije i društvene politike prakse, [13].

- Znanstveno istraživački rad se potiče već izradom seminarskih radova za koje se studenti odlučuju tijekom slušanja kolegija. Predavanja su kao i razrađeni specijalistički programi usmjereni na konkretne probleme koji se rješavaju, pa je tako dostupno u bazi znanja dovoljno gradiva za odabir kvalitetnog završnog rada. Ovaj rad rezultat je rada mentora i studenta koji je započeo seminarskim a bit će finaliziran kroz završni, diplomski rad studenta trećeg koautora.

Iz raspoloživih baza znanja i podataka analiziraju su problemi vezani na konkretne serijske strujne krugove odabranih zračnih luka s učestalim smetnjama koje narušavaju operabilnost sustava svjetlosne signalizacije. Uzrokovani kvarovi na izolaciji primarnih kabelskih veza modeliraju problem i njegovo rješavanje korištenjem svih spoznaja koje se profilirale tijekom svih provedenih edukacijskih programa. Uspoređivanjem rezultata iz prakse sa zračnih luka, uključujući i one s najekstremnijim klimatskim uvjetima sintetiziraju se rješavanja, [14].

III. ODRŽAVANJE AERODROMSKIH SPECIJALISTIČKIH SUSTAVA I OPREME

Održavanje specijalističkih aerodromskih sustava pomoću računala započelo je još sredinom prošlog stoljeća uvođenjem računalne opreme i aplikacijskih programskih podrški oslonjenih najviše na građevinsko održavanje manevarskih površina zračnih luka, [15]. Sustav za gospodarenje kolnika (PMS), koji je prvotno razvila američka vojska doživio je čitav niz prilagodbi, između ostalog i nadogradnju za praćenje stanja sustava svjetlosne signalizacije. Bio je prvenstveno namijenjen za planiranje strategije održavanja, a korišten je i u razvoju edukacijskog modela IS, Slika 5.



Slika 5. Blok dijagram sustava za gospodarenje kolnika

A. *Održavanje sustava svjetlosne signalizacije*

Prema [11], način održavanja sustava svjetlosne signalizacije precizno je propisan. On obuhvaća građevinsko i elektro održavanje. U ovom je radu izložen model održavanja elektro opreme, ALS u AEM. Dvije su veličine kao karakteristike kvalitete ALS-a određene kao referentne. Prva je vezana na kvalitetu luminiscencije i definirana je postotnom vrijednošću intenziteta svakog pojedinačnog rasvjetnog tijela. Druga je vezana na kvalitetu izolacijskih svojstava primarnih kabelskih vodova i definirana je graničnom vrijednošću otpora izolacije kompletnog strujnog kruga. Procedure održavanja striktno su propisane i obuhvaćaju dnevne, tjedne, mjesečne i periodičke preglede. Osim pregleda propisane su i procedure ispitivanja i mjerenja, [11].

B. *Otpor izolacije serijskih strujnih krugova*

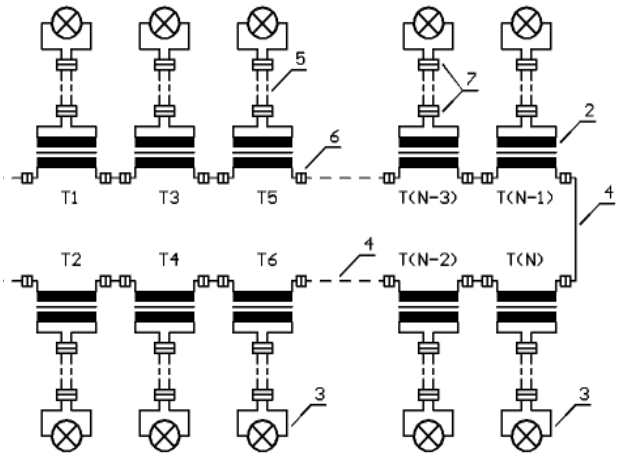
Vrijednosti otpora izolacije serijskih strujnih krugova, (SSK), Tablica I., za aerodromski sustav svjetlosne signalizacije, (primarni krugovi), prema referentnoj dokumentaciji[a], zavisna je o njihovim dužinama. U primarnim krugovima koriste se jednožilni kabeli, različitih tipova izolacije presjeka vodiča od šest kvadratnih milimetara za ukupni napon u krugu od pet kilovolta, kojima su povezani izolacijski transformatori.

TABLICA I. OTPOR IZOLACIJE SERIJSKIH KRUGOVA - ALS

Red.br.	Referentni dokument: MAINTENANCE OF AIRPORT VISUAL AID FACILITIES[a]		
	Dužina serijskog kruga(m)	*(MΩ)* [a]	*(MΩ)*
1	3000 ili manje	50	50
2	3000 - 6000	40	50
3	6000 ili više	30	50

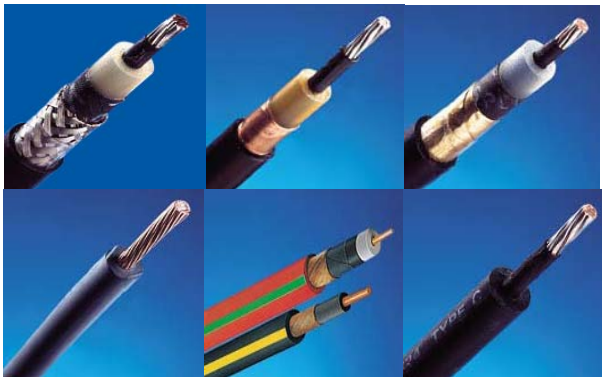
[a] FAA- Federal Aviation Administration AC No: 150/5340-26A, Initiated by: AAS-100

Prema slici 6. u serijskom krugu ALS, segmenti primarnih kabela, (4), povezuju transformatore, (2), primarnim konektorima, (6). Na svakom izolacijskom strujnom transformatoru preko sekundarnih kabela, (5) i konektora, (7), spojena je lampa, (3).



Slika 6. Primarni, serijski strujni krug sustava svjetlosne signalizacije

Izolacijski strujni transformatori u serijskom strujnom krugu bez obzira na pogonsko stanje sekundara, a koje može biti prazni hod, kratki spoj ili radno trošilo – žarulja, ne utječu na stanje otpora izolacije primarnog strujnog kruga. Iz tih razloga utvrđivanje stanje otpora izolacije primarnih strujnih krugova svodi se samo na ispitivanje kruga koji je sastavljen od primarnih kabela, Slika 7., primara izolacijskih strujnih transformatora, Slika 8. i primarnih konektora, Slika 9.



Slika 7. Tipovi primarnih kabela serijskog strujnog kruga sustava svjetlosne signalizacije

Slika 8. Tipovi izolacijskih strujnih transformatora serijskog strujnog kruga sustava svjetlosne signalizacije

Slika 9. Primarni i sekundarni konektori strujnih krugova ALS

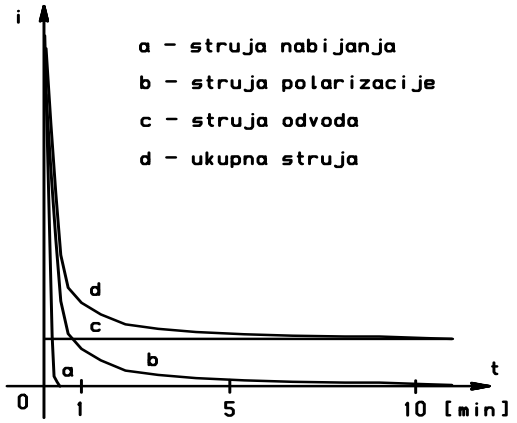
C. Mjerenje i prijenosna mjerila otpora izolacije

Za mjerenje otpora izolacije najčešće se primjenjuje U-I metoda. Koristi se istosmjerni napon, koji priključen na izolaciju u prvom trenutku propusti veliku struju nabijanja koja brzo opadne. Održava se polarizacijska struja koja opada sporije. Tek nakon nekoliko minuta ostane samo struja odvoda kroz izolaciju koja određuje istosmjerni statički otpor izolacije, Slika 10. Zato je bitno da se prilikom mjerenja čeka s očitanjem dok se struja kroz izolaciju približi stacionarnoj vrijednosti i ustali pokazivanje instrumenta kojim se mjeri.

Za provedbu mjerenje bitno je koliki je istosmjerni napon i temperatura jer o tome ovisi vrijednost izmjerenog izolacijskog otpora. Na temelju mjerenja otpora izolacije može se procijeniti stanje izolacije. Naročito, ako se mjerenje otpora izolacije provodi u određenim vremenskim intervalima. Može se na temelju kretanja vrijednosti otpora izolacije dobro zaključivati o stanju izolacije i očekivanim promjenama jer je za takvu ocjenu često važnije praćenje vremenske relativne promjene otpora izolacije nego apsolutni iznos otpora izolacije.

Ove spoznaje oko mjerila i mjerenja otpora izolacije rezultirale su punjenjem baze znanja. Utvrđene su razlike između mjerenje otpora izolacije i kontrole otpora izolacije. U samom početku uvođenja ispitivanja na ALS, za kontrolu izolacijskog otpora u pogonskim uvjetima su se koristili induktorski megaommetar. To su bili istosmjerni generatori s instrumentom s križnim svicima. U novije vrijeme se koriste baterijski uređaji koji daju konstantni istosmjerni mjerni napon uobičajenih vrijednosti 250, 500, 1000 ili 5000V. Preciznost mjerenja u početku nije bila propisana a danas uporabna pogreška mjerila, za mjerno područje ili mjerna područja koja je odredio proizvođač i za nazivne propisane uporabne zahtjeve ne smije biti veća od ± 30%. Za mjerila je potrebno provodi tipska ispitivanja koja se provode na osnovi dokumentacije i/ili rezultata laboratorijskih ispitivanja, [16].

Prema usvojenoj legislativi u Hrvatskoj je na snazi propis koji striktno definira način mjerenja otpora izolacije svih primarnih strujnih krugova sustava rasvjete operativnih površina i prilazne rasvjete. Otpor izolacije kabela nove i postojeće instalacije mora biti najmanje 50 MΩ, prema Tablici I., četvrta kolona nije definirana zavisnost o dužini primarnog kruga. Legislativa navodi, ako se prilikom kontrole mjerenja pokaže da otpor izolacije pada, provjeru otpora izolacije potrebno je obavljati češće s utvrđivanjem uzroka pada. Za ispitni napon se preporuča vrijednost od pet kV. Odstupanje od propisanog minimuma otpora izolacije je dozvoljeno do vrijednosti dobivene izračunom otpora izolacije za svaki strujni krug. Minimalni dozvoljeni otpor izolacije izražen u MΩ može se izračunati na temelju napona ispitivanja i dozvoljene struje odvoda. Proračun otpora izolacije i mjerenje izoliranosti kabela za napajanje električnom energijom i kabelima za signalizaciju i upravljanje provode se u skladu s legislativom, [11].



Slika 10. Struje kroz izolaciju

D. Ugradni moduli za mjerenje otpora izolacije

Spoznaje o postupcima mjerenja kao i procedure ispitivanja otpora izolacije pridonijele su razvoju i primjeni uređaji za kontinuirano praćenje stanja otpora izolacije serijskih strujnih krugova, koji se kao standardna oprema SSK ugrađuje uz CCR opremu ALS jer se pokazalo kako kontinuirani ispitni napon narinut na primarne krugove pridonosi poboljšanju narušenog otpora izolacije zbog vlage, jer se izolacija suši i poboljšava.

Poznato je da prijenosna mjerila otpora izolacije, zbog primjene visokih mjernih napona moraju imati takva konstrukcijska svojstva koja će omogućiti da se njima rukuje sigurno. Također uz svako mjerilo mora biti na raspolaganju odgovarajući visokonaponski kabel koji je za to namijenjen. Ako se k tome doda i nužna obučenost rukovatelja kao i periodično ispitivanje mjerila, prednosti stacionarnih uređaja, kao standardne opreme za kontinuirano praćenje stanja otpora izolacije SSK, i te kako su opravdane, [17].

Analizirani rezultati ispitivanja otpora izolacije nekih karakterističnih SSK, [18], prikupljeni u bazi podataka IS, poslužili su za algoritme održavanja, Tablica II.

IV. ZAKLJUČAK

Razvijenim inteligentnim sustavom, (IS), koji se koristi u programima edukacije na TVZ, kako u izbornom kolegiju tako i za stjecanje licence aerodromskih specijalista na održavanju svjetlosne signalizacije, dobiveni su konkretni parametri koji upućuju na karakteristike i efikasnosti pojedinih podsustava. Između ostalih, implementirani modularni sustav za nadzor stanja izolacije serijskih strujnih krugova pridonosi podizanju kvalitete izolacije. Formiranim bazama znanja i podataka o stanju izolacije složeni su algoritmi za predviđanje mogućih kvarova ili za odgađanje sanacije zbog poboljšanja koje je uzrokovano primjenom novih metoda ispitivanja. Samim tim se postiže racionalnije održavanje uz visoku pogonsku pouzdanost.

Kandidati uključeni u specijalističke edukacije i studenti izbornog kolegija kroz IS uče i svojim ga znanjem, kako onim empirijskim tako i onim iz obrade pretraga, nadograđuju. Stečena znanja kao kompetencije educiranim specijalistima pomažu u kreiranju planova održavanja.

ZAHVALA

Za kompletno opremanje laboratorija serijskim strujnim krugom ALS, koji je korišten kao IS i u ovom radu, zahvaljujemo se svojem sponzoru[1], TRANSCON ELECTRONIC SYSTEMS, spol. s r.o., Kvapilova 2133, 738 01 Frýdek-Místek, CZ,, www.transcon.eu

Mobilni uređaji u funkciji racionalizacije upravljanja udaljenim računalima emuliranjem računalnog miša

Dimitrij Vukelić*, Marino Franušić**, Ivan Grakalić**,
* Gradsko kazalište lutaka Rijeka – mitja.vukelic@gmail.com
** Veleučilište u Rijeci, Rijeka – marino.franusic@veleri.hr, ivan.grakalic@veleri.hr

Sažetak - S obzirom na razvijenost mobilnih operacijskih sustava i podršku sklopovlju za povezivanje u bežične mreže, pri razvoju aplikacija za mobilne uređaje može se iskorištavati sve aspekte računalnih mreža. Osim mobilnog prijenosa podataka za spajanje na internet mobilnom mrežom, uz pomoć integriranih mrežnih kartica mobilni uređaji spajaju se i u bežične lokalne mreže. Povezivanjem u lokalnu mrežu ostvaruje se komunikacija s ostalim uređajima spojenim u istu mrežu, a time se otvara cijeli niz mogućnosti korištenja tih uređaja putem mobilnog uređaja. Cilj ovog rada je iskoristiti mobilni uređaj u svrhu upravljanja udaljenim računalom uz pomoć pokreta mobilnog uređaja detektiranog ugrađenim akcelerometrom. U radu se definira koncept upravljanja spajanjem mobilnog uređaja i udaljenog računala u bežičnu lokalnu mrežu. Spajanje se odvija u klijent – server arhitekturi putem protokola UDP. Radom je pokazana mogućnost upravljanja emuliranjem rada računalnog miša i dan je pregled mogućih primjena. Moguće primjene sustava temelje se na sve većoj popularizaciji „pametnih" mobilnih uređaja opremljenih svim potrebnim elementima za rad ovog sustava. Testirana funkcionalnost na više platformi dokaz je valjanosti koncepta i iskoristivosti.

I. UVOD

Sredinom devedesetih godina dvadesetog stoljeća na tržištu su se pojavili mobilni uređaji s vlastitim operacijskim sustavom. Početak razvoja pokrenula je tvrtka IBM s uređajem IBM Simon, mobilnim telefonom i dlanovnikom u jednom. Otvaranjem novog tržišta pokreće se intenzivniji razvoj mobilnih uređaja s operacijskim sustavima te se pojavljuju operacijski sustavi PalmOS, Windows CE za mobilne uređaje, Nokia S40, Symbian i Blackberry OS kao najistaknutiji. No pravi porast razvoja i veći ulazak na tržište pokreće tvrtka Apple plasiranjem svojeg iPhone mobilnog telefona. Od tog trenutka, zbog velikog porasta tržišta i prihvaćenosti u korisnika, pametni mobilni telefoni (engl. smartphone) i njihovi operacijski sustavi postaju vrlo zanimljivi kompanijama

Tehnološki napredak uređaja zahtijeva i vrlo brz razvoj mobilnih operacijskih sustava koji ih pokreću. Mobilni operacijski sustavi, za razliku od klasičnih, prilagođavaju se posebnostima platforme za koju se razvijaju. Tako je potrebno razmatrati potrošnju električne energije zbog ograničenog napajanja, veličinu ekrana, manju količinu raspoložive memorije i procesorske snage. Konstantno poboljšanje tehničkih karakteristika uređaja omogućuje i sve veće mogućnosti mobilnih operacijskih sustava, te se otvara prostor za sve veći broj primjena u područjima za koja oni nisu temeljno namijenjeni te se ranije za njih nisu ni koristili.

Jedan od temelja popularizacije svakako je i velika količina dostupnih aplikacija za mobilne uređaje, te mogućnost razvijanja i prodaje korisnicima. S obzirom na razvijenost mobilnih operacijskih sustava, aplikacije mogu poprimati visoke razine kompleksnosti, te pružaju mogućnosti usporedive sa stolnim računalima. Aplikacije mogu na jednostavan način iskorištavati i posebne mogućnosti koje pružaju mobilni uređaji, kao što su korištenje mobilnog pristupa internetu, spajanje na bežične lokalne mreže, korištenje dodatnih senzora (kamera, GPS (engl. global positioning system), akcelerometar, žiroskop, mikrofon).

Mobilni uređaji mogu se povezati s drugim uređajima koristeći nekoliko metoda komunikacije kao što su IrDA (engl. infrared data association), Bluetooth, SMS (engl. short message service), NFC (engl. near field communication) ili Ethernetom. Povezivanje mobilnih uređaja na računalne mreže pruža sve mogućnosti komunikacije među uređajima, kao da se radi o spajanju s klasičnim računalom. Spajanje na računalnu mrežu neovisno je o mobilnom operacijskom sustavu i uređaju s kojeg se spaja. Pri uključenju u neku lokalnu mrežu otvara se cijeli spektar mogućnosti slanja ili primanja podataka s drugih računala i uređaja spojenih na mrežu. Jedan od mogućih aspekata povezivanja mobilnog uređaja u računalnu mrežu je upravljanje udaljenim računalom putem mobilnog uređaja i/ili upravljanje mobilnog uređaja putem udaljenog računala.

Komunikacija između mobilnog uređaja i udaljenog računala odvija se putem aplikacija koje se razvijaju u nekoj komunikacijskoj arhitekturi, primjerice klijent - server arhitekturi ili komunikacija putem oblaka (engl. cloud). Putem aplikacije mobilni uređaj može primati podatke koje šalje aplikacija na udaljenom računalu, te može slati podatke aplikaciji na udaljenom računalu. Prema primljenim podacima, bilo na mobilnom uređaju ili računalom programiraju se određene akcije koje uređaj mora izvršiti. Tako je moguće upravljati udaljenim računalom putem mobilnog uređaja u svrhu jednostavnijeg i slobodnijeg rada s jednostavnim zadaćama na računalu.

Cilj ovog rada je prikaz povezivosti računala i mobilnog uređaja te kontrola računala. Cilj je racionalizirati upravljanje računalom tako da mobilni uređaj emulira rad računalnog miša gestama, odnosno pomicanjem mobilnog uređaja. Rad je koncipiran tako da su prvo prezentirani slični radovi iz područja upravljanja udaljenog računala s mobilnim uređajem. Zatim je prikazana metodologija izrade ovog projekta te objašnjeni razlozi za korištenje pojedinih elemenata. U posljednjem dijelu dan je prikaz razvijenih aplikacija i opisan je njihov rad. Potom se daje pregled mogućih primjena ovakvog koncepta upravljanja.

II. KRATKI PREGLED ZNAČAJNIH SLIČNIH RADOVA

Raniji radovi na području upravljanja udaljenim uređajima putem mobilnog uređaja koristeći M2M (engl. machine to machine) komunikaciju većinom su se bazirali na upravljanju GSM mrežom (engl. global system for mobile communications) mreže. Koristi se zaseban kontroler koji prima naredbe bilo pozivom (glasovno, automat upravljanje ili DTMF (engl. dual-tone multi-frequency)) ili SMS-om. Ovakve primjene najčešće se nalaze u upravljanju kućnom automatizacijom [1], [2]. Putem GSM-a i SMS-a mobilni uređaj se koristi i za reguliranje potrošnje električne energije [3]. Za upravljanje kućnom automatizacijom koristi se i sustav DTMF [4].

Za povezivanje s mobilnim uređajem koristi se i bežična tehnologija Bluetooth jer je većina danas aktualnih mobilnih uređaja opremljena je modulom Bluetooth. Ovaj način povezivanja najčešće se koristi kad su uređaji u neposrednoj blizini i ostvaruje se komunikacija jedan na jedan. Primjene komunikacije i upravljanja tehnologijom Bluetooth nalaze se u raznim područjima. U [5] bave se prikupljanjem medicinskih podataka i nadzora zdravlja računalom i mobilnim uređajem. U [6] se opisuju implementirani sustav kontrole pristupa u zgradi preko mobilnog uređaja. U [7] prikazuju se upravljanje mobilnim robotom.

S obzirom na činjenicu da je sve veći broj mobilnih uređaja opremljen karticama za pristup bežičnim lokalnim mrežama i činjenicu da većina modernih mobilnih uređaja ima pristup internetu, u tom se smjeru većinom razvija moderna komunikacija između računala i mobilnih uređaja. Radovi [8], [9] i [10] bave se korištenjem mobilnih uređaja spojenih bežičnom lokalnom mrežom na udaljeno računalo za kontrolu kućne automatizacije. U [11] mobilnim uređajem spojenim na bežičnu mrežu spajaju se na računalo koje upravlja robotom, prema određenim radnjama koje se mogu izvršiti povlačenjem prsta po ekranu mobilnog uređaja. Radovi vrlo slični ovom radu u užem smislu načina funkcioniranja i bave se prepoznavanjem pokreta i gesti putem akcelerometra u svrhu upravljanja kućnom automatizacijom [12] ili za emuliranje touchpada korištenog na prijenosnim računalima putem ekrana mobilnog uređaja [13].

Upravljanje mobilnim uređajem većim brojem udaljenih jedinica koje su povezane u ZigBee mrežu te preko modula spojene na bežičnu računalnu mrežu, kojom mogu komunicirati s mobilnim uređajem, bave se u radu koji analizira prikupljanje podataka s udaljenih senzora [14].

Osim znanstvenih i stručnih radova sličnu tematiku su obradili i proizvođači mobilnih aplikacija koje su objavljene i na Google Play dućanu i na Apple Appstoreu. Radi se o aplikacijama Ultimate Mouse Lite [15], Remote Mouse [16] i Mobile Mouse Pro [17].

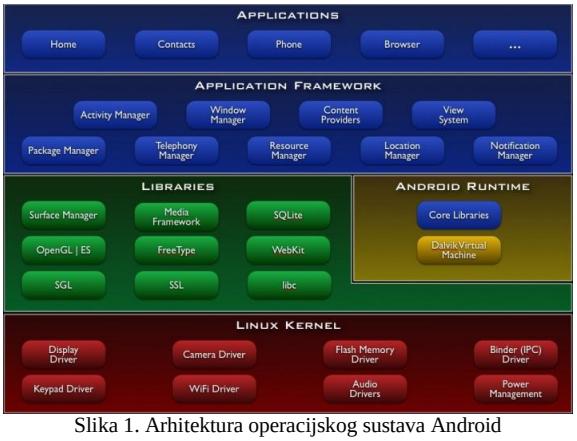
III. KONCEPT ANALITIČKOG DIJELA RADA

Kao temelj analize povezivanja i upravljanja udaljenim računalom putem mobilnog uređaja odabrani su mobilni uređaji na platformi Android. Razlog odabira prvenstveno je mogućnost razvoja i testiranja aplikacija potpuno besplatno, što na drugim mobilnim operacijskim sustavima nije moguće bez značajnijih preinaka. Osim toga, operacijski sustav Android za mobilne uređaje trenutno je najraširenij na tržištu te i dalje ima najveći godišnji rast.

Mobilni operacijski sustav Android baziran je na jezgri (kernel) Linux 2.6 i ima arhitekturu koju je moguće promatrati kao stog koji se sastoji od više razina (grafički prikaz na slici 1):

- Linux jezgra – upravljački programi i međuprocesna komunikacija
- Knjižnice pisane u C/C++ programskom jeziku
- Android Runtime – pokretanje aplikacija ima dva dijela:
    - knjižnice jezgre – core library za Javu
    - Dalvik virtualni stroj – pokreće aplikacije kao zasebne instance
- Aplikacijski sloj – application framework
    - upotreba API-ja
- Aplikacije

S obzirom na to da se razvoj za operacijski sustav Android standardno radi u programskom jeziku Java, i u ovom je radu Java odabrani programski jezik za mobilnu i za aplikaciju na računalu. Zbog otvorenog sustava jednostavno je pisati aplikacije koje koriste hardver uređaja uz pomoć besplatne inačice razvojnog paketa Android – ADK (engl. android development kit) i virtualnog stroja Android - ADT (engl. android development tools) u skladu s Eclipse IDE-om (engl. integrated development enviroment) koji je korišten pri izradi ovog rada.

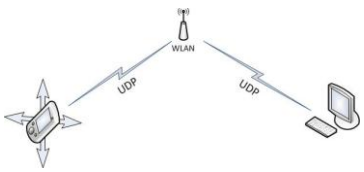


Slika 1. Arhitektura operacijskog sustava Android

Za operacijski sustav na računalu odabran je Microsoft Windows operacijski sustav koji je korišten i za razvoj aplikacija. Ovaj operacijski sustav odabran je prvenstveno zbog činjenice da se na njemu odvija razvoj aplikacija, a potom i zbog činjenice najveće raširenosti i korištenja upravo tog operacijskog sustava. S obzirom na činjenicu da se razvoj vrši u programskom jeziku Java u radu se testira funkcionalnost na više platformi, odnosno na Linux operacijskom sustavu Ubuntu distribucije te na Raspberry Pi, ARM baziranom ugradbenom računalu s Raspbian distribucijom operacijskog sustava Linux.

Za ostvarivanje komunikacije odabrana je klijent – server arhitektura aplikacije. Aplikacija na računalu predstavljat će server na koji se spaja klijentska aplikacija s mobilnog uređaja. Za komunikacijski protokol odabran je protokol UDP (engl. user datagram protocol). Konkretni protokol odabran je zbog svoje brzine i neosjetljivosti procesa na povremeni gubitak paketa. Ovaj posljednji faktor uzet je kao bitan kako bi se aplikacija mogla izvesti bez provjere dospijeća paketa. Razlog tome je pojednostavljivanje aplikacije za potrebe istraživanja i smanjivanje opterećenja na mobilni uređaj u svrhu štednje resursa kao što su memorija, baterija i procesorsko vrijeme. Prikaz arhitekture sustava vidljiv je na slici 2.

Zamišljena metoda upravljanja bazira se na emuliranju pokreta računalnog miša pokretanjem mobilnog uređaja. Dakle, nagibom udesno želi se pomicati pokazivač miša na ekranu udesno, nagibom ulijevo – pomak ulijevo. Slično je i s pomakom gore dolje po ekranu, samo se sad radi o nagibu mobilnog uređaja gore – dolje. Za ovu primjenu potrebno je koristiti očitanja s akcelerometra ugrađenog u mobilni uređaj. Premda se najčešće nalazi troosni akcelerometar, za ovu primjenu dovoljno je promatrati dvije osi (X – horizontalnu i Y – vertikalnu). Emuliranje pritiska tipki računalnog miša zamišljeno je pritiskom na ekran mobilnog uređaja. Zbog definiranja dvosmjerne komunikacije uvodi se i povratna informacija s računala pri prelasku pokazivača miša preko određenih segmenata serverske aplikacije.



Slika 2. Prikaz arhitekture sustava

IV. KRATKI PREGLED ZNAČAJNIH SLIČNIH RADOVA

Server aplikacija razvijana je u alatu Eclipse IDE metodom Model – View – Controller (MVC). Prednost metode MVC je logičko odvajanje modula aplikacije radi olakšanog daljnjeg razvoja, jer se strogo odvajaju programske cjeline.

Aplikaciju se lakše razvija i održava ako se zna da, na primjer, u View klasi postoje isključivo klase za prikaz podataka ili grafike na zaslonu.

Aplikacija Android razvijena u ovom projektu nema Model klasu, već se View klasa dijeli na datoteku XML (engl. extensible markup language) koja definira izgled i kontroler View, koji definira akcije na zaslonu i kontrolu hardvera. Pri razvoju aplikacije za Android povezuju se podaci iz datoteke XML s definiranjem objekata i dodavanjem koda koji se izvršava za svaki objekt, odnosno kontrolu.

Aplikacija na Android platformi zamišljena je i realizirana tako da putem protokola UDP šalje podatke o kutu nagiba mobilnog uređaja s ugrađenog akcelerometra. U samoj aplikaciji na mobilnom uređaju potrebno je omogućiti tipke za simuliranje lijeve i desne tipke miša, te polje za unos IP adrese računala s kojim se želi upravljati odnosno računala na kojem se nalazi serverska aplikacija. Grafičko sučelje aplikacije prikazano je slikom 5 i prikazuje sve glavne elemente od kojih se sastoji aplikacija na mobilnom uređaju.

Otvorenost sustava Android olakšava izradu aplikacija koje koriste specifičan hardver uređaja, kompas, kameru, GPS ili u ovom slučaju akcelerometar. Komunikacija s hardverom, dakle čitanje podataka s njega ili pisanje podataka na njega, svodi se na pozivanje metoda. Metode se pozivaju na objektu koji referencira na hardver, odnosno senzor s kojim se želi komunicirati. Stvaranje instance senzora vrši se putem klase SensorManager koja omogućuje pristup senzorima na mobilnom uređaju. Čitanje podataka s akcelerometra vrši se iz SensorListener objekta onSensorChanged. Ta funkcija se poziva pri promjeni podataka na bilo kojem senzoru mobilnog uređaja te se unutar nje programira čitanje podataka samo u slučaju kada podaci dolaze s akcelerometra, što je moguće jer podatak koji stiže sadrži i informaciju o tipu uređaja s kojeg je stigao.

Slika 3. Grafičko sučelje aplikacije na mobilnom uređaju s elementima

Funkcija prosljeđuje klasu event koja je tipa Sensor te sadrži podatke o tipu senzora i njegovih vrijednosti. Za potrebe ove aplikacije čitaju se dvije osi akcelerometra, X i Y, u svrhu mjerenja kuta nagiba mobilnog uređaja. Pri određivanju kuta uređaja uzima se da akceleracija od ± 1 g referencira kut od ± 90º. Izmjerena akceleracija prosljeđuje se serverskoj aplikaciji koja ne temelju te vrijednosti povećava, odnosno smanjuje vrijednost X i Y pozicije pokazivača miša na ekranu. Držeći mobilni uređaj u ruci korisnik ga naginje u lijevu ili desnu stranu te tako pomiče pokazivač miša na upravljanom računalu u lijevo ili desno. Naginjanjem mobilnog uređaja naprijed ili nazad pomiče se pokazivač miša gore odnosno dolje na ekranu upravljanog računala.

Kontroler klasa u aplikaciji je komunikacijska klasa koja se koristi za UDP povezivanje s udaljenim računalom. Kako bi se ostvarila istovremena dvosmjerna (engl. full duplex) komunikacija koristiti se dva kanala (porta). Jedan kanal koristi se za primanje podataka i jedan za slanje podataka. Metode komunikacijske klase koriste se i u Android i u serverskoj aplikaciji u vrlo malo promijenjenom obliku. Naime, one rade u „cross“ modu, odnosno metoda za slanje podataka iz aplikacije Android koristi kanal koji serverska aplikacija koristi za primanje podataka. Unutar metode za slanje podataka kreira se paket podataka te se šalje na IP adresu koja je definirana kao adresa serverske aplikacije. Paket koji se šalje formira se od podataka s X i Y osi akcelerometra, statusa pritisnutosti lijeve i desne tipke simuliranog miša, te kontrolnog paketa kojim serverska aplikacija provjerava je li primljeni podatak upravo njoj namijenjen.

Metoda za primanje podataka unutar serverske aplikacije raspakirava podatke te provjerava jesu li podaci njoj namijenjeni. Ako jesu, podaci se raspakiravaju i uz pomoć Robot klase upravlja se pokazivačem miša. Operacijski sustav ima prednost u kontroli pokazivačem ispred ulaznih jedinica te se uz pomoć metoda koje se nalaze u Robot klasi može upravljati pokazivačem miša, prosljeđivati pritiske tipki miša ili tipki na tipkovnici.

Serverska aplikacija izrađena je korištenjem alata Swing za izradu grafičkog sučelja. Taj alat koristi se kako bi se ostvarila kompatibilnost s različitim operacijskim sustavima bez potrebe za instaliranjem dodatnih knjižnica. Kako bi se ostvarila i demonstrirala povratna veza, odnosno dvosmjerna komunikacija, serverska aplikacija sadrži nekolicinu tekstualnih objekata preko kojih kad se prijeđe pokazivačem miša mobilni uređaj vibrira. Ovo je realizirano korištenjem metode Listener koja prima podatke kad pokazivač uđe u područje tekstualnog objekta. Pri tome se formira paket koji se šalje na mobilni uređaj slično kao i kad se paket šalje s mobilnog uređaja na serversku aplikaciju, s time da je podatak znatno kraći jer se samo šalje podatak o tome da se aktivira vibracija koja traje 500 milisekundi.

Pokazivač miša na upravljanom računalu pomiče se preko cijelog ekrana i može upravljati u potpunosti operacijskim sustavom na kojem se serverska aplikacija izvodi. Serverska aplikacija izvedena je kao grafička aplikacija za potrebe demonstracije te se za punu učinkovitost planira izvesti kao aplikacija koja će se izvoditi u pozadini (Windows servis ili Linux daemon).

Aplikacija je uspješno testirana na mobilnim uređajima s operacijskim sustavima Android 2.3.6 i 4.0. Povezivanja su testirana s Microsoft Windows 7 (32-bit i 64-bit), Microsoft Windows XP, Ubuntu Linux 12.10 i operacijskim sustavima Raspbian Linux. Testiranja su vršena na više različitih računala te tipova računala, kao što su stolna računala, prijenosna računala i Raspberry Pi ugradbeno računalo. Osim toga, testirano je u raznim konfiguracijama bežičnih mreža bez da su pokazani nedostaci. Trenutnu inačicu aplikacije testiralo je 30 korisnika na svojim mobilnim uređajima u kućnim i poslovnim mrežama.

V. PREGLED MOGUĆIH PRIMJENA

Po razvijenom projektu i dokazanoj valjanosti koncepta otvara se pitanje mogućih primjena ovog načina racionalizacije upravljanja udaljenim računalom. Za punu primjenu ovakvog koncepta upravljanja mobilnoj aplikaciji potrebno je nadodati mogućnost korištenja tipkovnice za prosljeđivanje tipki na udaljeno računalo i otklanjanje potrebe za tipkovnicom na udaljenom računalu.

Trenutni razvoj potrošačke elektronike i razvijenost mikrokontrolera doveli su do razvoja minijaturnih računala koja se mogu spojiti direktno na monitor ili televizor te se koristiti za prikaz multimedijalnih sadržaja ili pretraživanje interneta. Osim toga pokrenut je i razvoj „pametnih“ televizora koji već imaju ugrađeno mikro računalo te se putem samog televizora, spojenog na lokalnu mrežu, može spajati na internet i koristiti aplikacije, slično kao na „pametnim“ mobilnim uređajima, kao što su mobilni telefon ili tablet računalo. Za upravljanje tim uređajima potrebno je spojiti dodatne uređaje kao što su miš ili tipkovnica. Uz pomoć koncepta upravljanja prikazanog u ovom radu moguće je putem vlastitog mobilnog uređaja upravljati tim računalima, pretraživati internet i upravljati multimedijskim sadržajima bez potrebe za dodatnim upravljačkim uređajima. S obzirom na to da su takva računala i televizori pogonjeni operacijskim sustavom baziranom na Linuxu, serverska aplikacija Java na njima može raditi, kao što je i testirano u ovom radu. Razvoj aplikacija za „pametne“ televizore ima sličan proces kao i razvoj aplikacija za „pametne“ mobilne telefone uz razliku korištenja drugog razvojnog paketa (kao što je na primjer SmartTV SDK [18]).

U vrijeme ugrađivanja „pameti“ u veliki broj uređaja, započet je i razvoj „pametnih“ kuća. Kućna automatizacija, kao segment automatizacije u zgradarstvu, podrazumijeva upravljanje rasvjetom, grijanjem i klimatizacijom, kućnim sigurnosnim sustavima, motoriziranim roletama na prozorima i upravljanje bilo kojim uređajem u kući. Sustavi kućne automatizacije, bilo da su pogonjeni nekim namjenskim sustavom ili izvedeni uz pomoć klasičnih ili ugradbenih računala, mogu se spojiti na računalo koje će upravljati cijelim sustavom putem nekog korisničkog sučelja. Premda sustavi kućne automatizacije, naravno, imaju svoje kontrolne ploče i daljinske upravljače, to je uvođenje još jednog dodatnog upravljača za onoga koji posjeduje i koristi takav sustav. Ovakav koncept upravljanja omogućuje korisnicima da svojim mobilnim telefonom upravljaju računalom koje

prosljeđuje naredbe sustavu kućne automatizacije. Ako se isto računalo koristi i za prethodno opisano korištenje spajanja na televizor i za spajanje na sustav kućne automatizacije, tada se putem televizora i mobilnog uređaja pružaju sve mogućnosti upravljanja tim uređajima. Osim predloženog koncepta upravljanja, uz modifikacije programskog koda za čitanje podataka s akcelerometra i interpretaciju podataka na serveru, jednostavno je izvesti i prepoznavanje gesti pomicanja mobilnog uređaja (Kühnel et al., 2011). Pročitani podaci s akcelerometra prosljeđuju se na serversku aplikaciju te se tamo interpretiraju kao skup podataka i pokušava se odrediti i prepoznati uzorak odrađene geste. Prema prepoznatoj gesti serverska aplikacija može izvršavati programirane radnje.

Koncept upravljanja udaljenim računalom putem mobilnog uređaja primjenjiv je i u aspektu računalne sigurnosti. Upravljanje poslužiteljskim računalima najčešće se ograničava tako da na sama računala nisu priključeni ulazne jedinice kao tipkovnica i miš. U prostorijama s poslužiteljskim računalima obično se nalazi jedan komplet ulaznih jedinica koji se spajaju na ono računalo na kojem se radi. No i taj jedan komplet može predstavljati sigurnosni problem. Primjenom koncepta upravljanja mobilnim uređajem otklonila bi se potreba za spajanjem ulaznih jedinica te dodatno smanjila mogućnost korištenja tih računala od strane neautoriziranih osoba. Slično se može primijeniti i na ugradbena računala koja se koriste kao uređaji za prikupljanje i analiziranje podataka s raznih mjernih uređaja s obzirom na to da se i takva računala najčešće ostavljaju bez ulaznih jedinica.

VI. ZAKLJUČAK

Temelj razrade koncepta upravljanja udaljenog računala mobilnim uređajem razrađen u ovom radu temelji se na jednostavnoj arhitekturi i dokazu koncepta mogućnosti upravljanja i primanja povratnih informacija. Cilj samog rada ostvaren je i dokazan testiranjem na većem broju mobilnih uređaja (mobilnih telefona i tableta) u kombinaciji s nekoliko različitih operacijskih sustava kao što su Windows XP i 7, Ubuntu Linux i Raspbian Linux.

Za potpunu funkcionalnost i iskoristivost ovog koncepta upravljanja u mobilnoj aplikaciji bi trebalo dodati mogućnost korištenja tipkovnice. Shodno tome aplikacija na udaljenom računalu trebala bi očekivati pakete s proslijeđenim tipkama s mobilnog uređaja te ih emulirati u operacijskom sustavu na kojem radi. Tako se može ostvariti potpuna funkcionalnost racionalnijeg upravljanja udaljenim računalom i drugim sličnim uređajima putem mobilnog uređaja.

Abstract - REST protokol je akronim za *Representational state transfer* protokol koji omogućuje komunikaciju na Internetu pomoću svih najpoznatijih programskih jezika kao što su C/C++, C#, Jave, Ruby, PHP i sličnih kao i preko najpoznatijih operacijskih sustava poput Microsoft Windowsa, Mac OSa, Linuxa itd. Zahvaljujući odličnom radu nad velikim brojem klijenata (engl. *scalability*), mogućnosti primjene ovog protokola na mnoge programerske probleme kao što su dohvaćanje podataka na serveru, dodavanje, promjena ili brisanje postojećih podatka te neovisnosti o tehnologiji, razlog je zašto baš ovaj protokol koriste mnoge velike tvrtke kao što su Google (GoogleMaps[1], GoogleSearch[2]), Microsoft (Azure[3], Shrepoint[4]) za komunikaciju između tehnologija na Internetu. Mogućnosti biranja tehnologije odgovora (JSON, XML, HTML itd.), mogućnost slanja filtera podataka direktno serveru i kreiranje odgovora u ovisnosti o poslanim HTTP metodama je ono što čini ovaj protokol naprednijim i boljim od bilo koje druge alternative[5].

I. UVOD

Jedan od najvećih problema Interneta danas je komunikacija među različitim tehnologijama koje se mijenjaju svakodnevno i čiji su standardni masivni i dosta često nedorečeni. Rješenja poput SOAP protokola su često puno teže implementirana i zahtijevaju puno više resursa. [6] Nadalje, rješenja koja su do sada pokazala veliku brzinu su većinom razne binarne standardizacije gdje ne dolazi do parsiranja između teksta i podataka. Takva standardizacija je puno teža za implementaciju od klasičnih rješenja, traženje pogreške i preglednost odgovora (*engl. human readable*) [7]. Trenutno najbolje rješenje je REST protokol koji omogućuje jednostavnu implementaciju, komunikaciju između tehnologija, kao i jedan od najbitnijih aspekata Interneta, a to je sigurnost[8].

II.KORIŠTENJE POSTOJEĆIH PROTOKOLA

Za rad REST protokola nije trebalo izraditi potpuno nove protokole za komunikaciju nego su iskorišteni postojeći. Jedan od iskorištenih protokola je poznati HTTP protokol. Roy Fielding, osoba koja je sudjelovaja u izradi HTTP protokola je napravila i REST protokol.[9]

II.I. HTTP PROTOKOL

HTTP protokol [10] je aplikacijski protokol na čijem se radu zasniva cijeli WWW (*engl. World Wide Web*), točnije na verziji 1.1. Srž rada ovog protokola se zasniva na stvaranju upita i odgovora. Svaki upit i odgovor ima HTTP zaglavlja. Zaglavlje se sastoji od više elemenata među kojima su najpoznatiji: Request URL, Request Method, Status Code, Accept, Host. [11]

Request URL – puna adresa gdje se šalje upit.

Request Method – jedna od HTTP metoda (najčešće GET ili POST).

Status Code – HTTP status kod (najpoznatiji 404 Not Found). [12]

Accept – što server ili klijent prihvaća kao odgovor (json, pdf, sliku itd.).

Host – naziv računala i TCP port na kojem računalo "sluša".

II.II. XML STANDARD

XML (engl. Extensible Markup Language) je jezik za označavanje podataka. Ideja je bila stvoriti jezik koji će biti jednostavno čitljiv i ljudima i računalima.

Jedna od najvećih prednosti XMLa je jednostavnost [13]. Podaci se odvajaju tzv. tagovima ili oznakama (otvorenim i zatvorenim). Oznake mogu imati atribute koji dodatno opisuju podatke.

```xml
<?xml version="1.0" ?>
<Osoba spol="M">
    <Ime>Davor</Ime>
    <Prezime>Lozić</Prezime>
</Osoba>
```

Slika 1 - primjer XML dokumenta

II.III. JSON

JSON (engl. Javascript Object Notation) je otvoreni standard za prikaz podataka kao alternativa XML standardu [14]. Prednost JSONa nad XMLom je što JSON zauzima puno manje prostora tako da je JSON pogodniji za prijenos većih količina podataka, a XML za konfiguracijske datoteke ili kada je potrebna XSLT tehnologija.

```json
{
    "Osoba": {
        "Ime": "Davor",
        "Prezime": "Lozić",
        "Spol": "M"
    }
}
```

Slika 2 - primjer JSON dokumenta

III.RJEŠENJA PRIJE REST PROTOKOLA

III.I. SOAP PROTOKOL

SOAP protokol je baziran na XMLu [15] što ga čini jednostavnim za čitanje (engl. *human readable*). Budući da su poruke koje se šalju između pošiljatelja (klijenta) i primatelja (poslužitelja) zapravo čisti i relativno razumljivi tekst, jednostavno ih je pratiti, ispravljati pogreške i razumjeti što se događa.

Još jedna velika prednost SOAP protokola je mogućnost primjene na različita područja poslovne inteligencije (engl. *extensibility*) [16]. Stvar je implementacije što će određena funkcija raditi, SOAP poruke služe samo za poziv i slanje rezultata obrade.

SOAP je neutralan (engl. *neutrality*) [17]. Jezici kao što su C/C++, C#, Python, PHP itd. imaju biblioteke koje rade s ovim protokolom te nije ograničen niti na operacijske sustave. Ono što je bitno je da se ti jezici drže pravila i standarda te će te poruke moći razumjeti bilo koji operacijski sustavi s bilo kojim programskim jezikom. SOAP protkol koristi najčešće HTTP(S), ali je kompatibilan i s asinkronim protokolima kao što su FTP ili SMTP [18].

```xml
<env:Envelope
  xmlns:env="http://www.w3.org/2003/05/soap-envelope">
  ...
</env:Envelope>
```

Slika 3 - SOAP omotnica

Protokol, kao glavni element, sadrži omotnicu (engl. *envelope*). Unutar omotnice postoji zaglavlje (engl. *header*) koje je opcionalno. Zaglavlje može sadržavati vrijeme, api ključeve (engl. *api keys*), podatke za pristup (engl. *login credentials*) i slično [19].

Unutar protokola mora postojati tijelo omotnice (engl. *body*). Unutar tijela omotnice se najčešće nalazi ime funkcije koje želimo pozvati, zajedno s parametrima funkcije. Opis funkcija, parametara, tipova podataka i slično se nalazi unutar WSDL dokumenta (Web Service Definition Language).

```xml
<env:Body xmlns:m="http://www.primjer.com">
  <m:DohvatiKorisnika
    <m:IdKorisnika>5</m:IdKorisnika>
  </m:DohvatiKorisnika>
</env:Body>
```

Slika 4 - SOAP primjer poziva

Jedan od nedostataka SOAP protokola je relativna kompliciranost, posebno kod implementacije sigurnosti. Specifikacije ne nalažu puno stvari vezane uz sigurnost pa se većinom koriste i ne toliko standardni načini sigurne komunikacije [20].

Drugi nedostatak je što je SOAP relativno velik dokument i za male podatke [20], ali je to više problem XML jezika nego samog SOAP protokola što je prikazano slikom (Slika 5), gdje za običan odgovor s imenom i prezimenom zapravo dobijemo relativno puno teksta.

```xml
<soap:Body xmlns:m="http://www.primjer.com">
  <m:DohvatiKorisnikaOdgovor>
    <m:Korisnik>
        <m:Ime>Davor</m:Ime>
        <m:Prezime>Lozić</m:Prezime>
    </m:Korisnik>
  </m:DohvatiKorisnikaOdgovor>
</soap:Body>
```

Slika 5 - SOAP primjer odgovora

IV. REST PROTOKOL

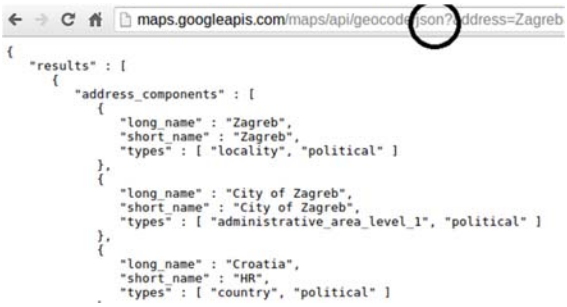
Trenutno najbolje rješenje za komunikaciju između tehnologija je REST (Representational

state transfer) protokol. REST je preuzeo dobre stvari iz SOAP protokola kao što su neutralnost tj. mogućnost programskih jezika kao što su C/C++, C#, Java i slični da komuniciraju ili neovisnost o operacijskom sustavu (MS Windows obitelj, Linux itd.). Također je preuzeta i mogućnost primjene protokola na bilo koji aspekt poslovne inteligencije.

IV.I. PREDNOSTI NAD SOAPOM

REST protokol može koristiti više različitih odgovora (XML, JSON itd.). REST servisi daju dobra privremena skladišta (engl. *cache*) pri korištenju GET poziva [21] što pokazuju Slika 6 i Slika 7.

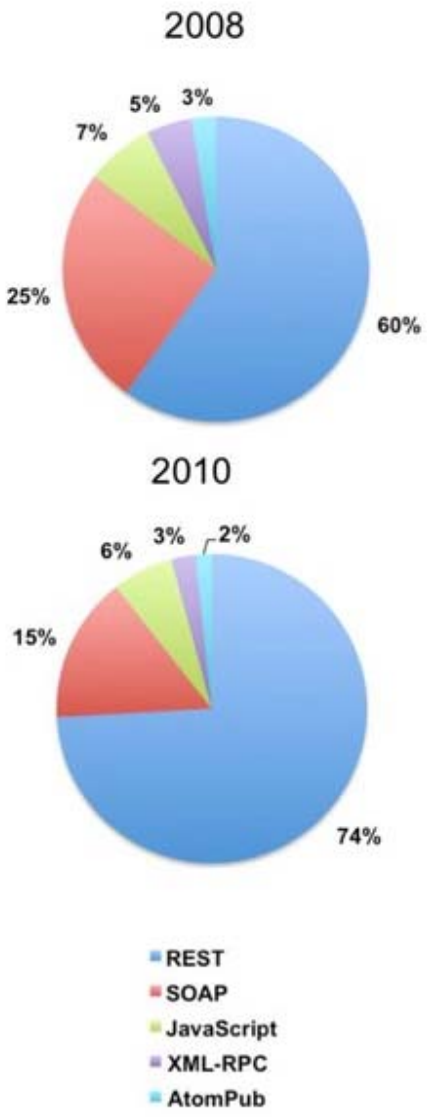
Slika 6 - REST preko XMLa



Slika 7 - REST preko JSONa

IV.II. PODRŠKA REST PROTOKOLA

Jedan od najvećih zagovornika REST protokola je Google. Servisi kao što su Google Translate API [22], Google Earth API [23], Google Maps API [24] itd. Microsoft također koristi REST servise kao što Locations API [25], Traffic API [26] i slični te se tako ti servisi mogu koristiti i u privatnim aplikacijama.



Slika 8 - Sve veći prelazak servisa na REST protokol [28]

IV.III. REST I HTTP

REST protokol je usko povezan s HTTP protokolom, točnije, građen je na njemu. REST, kao i HTTP, može slati GET, POST, PUT i DELETE metode prema serveru. Već se tu može vidjeti povećana sigurnost jer, ako je GET samo dohvaćanje podataka, onda klijent ne može tom REST porukom mijenjati nikakve podatke.

Tablica 1 - REST metode

Metoda	Značenje
GET	Dohvaćanje podataka
POST	Dodavanje podataka
PUT ili PATCH	Promjena podataka
DELETE	Brisanje podataka

REST sintaksa, pravila i ostali dijelovi standarda velikim dijelom ovise o servisu. Najčešći standard je proslijeđivanje parametara kroz URL serveru kao što to koristi Google Maps API [27].

Google Maps url:

http://maps.googleapis.com/maps/api/staticmap?center=Zagreb&zoom=13&size=300x300&sensor=false

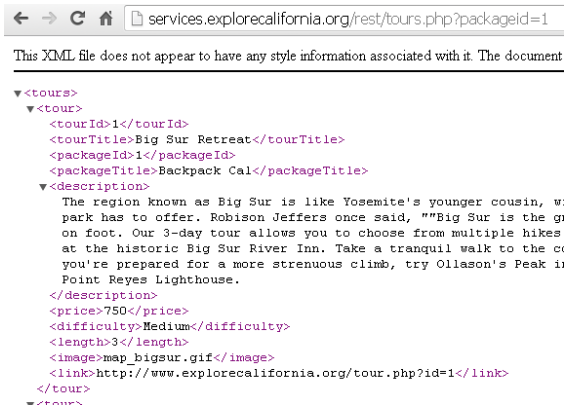
Možemo putem URLa proslijediti Google Mapsu koju sliku želimo s mape. Atributi poput center, zoom, size itd. su samo neki koje možemo specificirati. Svaki servis ima svoja pravila i načine korištenja.

Slika 9 - Google Maps Zagreb

Podatke preko IDa možemo zatražiti također preko URLa.

http://services.explorecalifornia.org/rest/tours.php?packageid=1

Kao rezultat dobijemo XML:

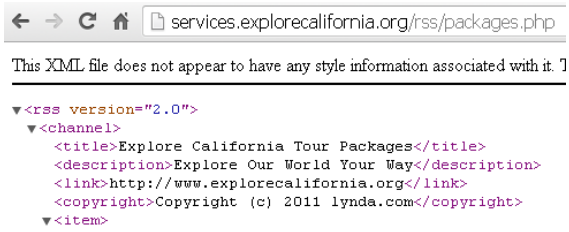


Slika 10 - dohvaćanje preko IDa

Još jedan od formata podataka je RSS.

http://services.explorecalifornia.org/rss/packages.php

Kao rezultat imamo RSS:



Slika 11 - dohvaćanje RSSa

IV.IV. SIGURNOST REST PROTOKOLA

Podaci se mogu slati preko zaštićene HTTP verzije koja ide preko SSL/TLS protokola, tzv. HTTPS protokola. Drugi način je unos podataka za pristup u sam URL:

https://username:password@www.domena.com/webservis

Korisničko ime i lozinka se mogu kodirati pomoću base64 algoritma. Još jedan način je imati neki znakovni niz od više znakova koje je teško pogoditi i poslati ga na server. Server usporedi sa listom znakova koju već ima i ako u bazi postoji taj znakovni niz, dopusti pristup samom servisu.

V.ZAKLJUČAK

Zbog svoje jednostavne implementacije na različite probleme, radom nad HTTP prokolom, interoperabilnosti te primjenjivosti na sve poznate operacijske sustave i programske jezike je razlog zašto je REST protokol danas najpoznatiji način za među-servisnu komunikaciju na Internetu. Lagana primjena GET, POST, PUT i DELETE metoda čini ovaj protokol jednostavnim za implementaciju mnogih rješenja. Sama mogućnost biranja izlaza

(XML, JSON, HTML, RSS) kao i relativno visoka sigurnost je uvelike utjecala na ogromni skok ove tehnologije u komunikaciji na Internetu.

PAPERS

Password security – no change in 35 years?

Viktor Taneski*, Marjan Heričko* and Boštjan Brumen*
* University of Maribor, Faculty of electrical engineering and computer science/Institute of Informatics, Maribor, Slovenia
viktor.taneski@uni-mb.si, marjan.heričko@uni-mb.si, bostjan.brumen@uni-mb.si

Abstract - BACKGROUND: Textual passwords were first identified as a weak point in information system's security by Morris and Thompson in 1979. They found that 86% of the passwords were weak: being too short, containing lowercase letters only, digits only or a combination of the two, being easily found in dictionaries. OBJECTIVE: Despite the importance of passwords as the first line of defense in most information systems, little attention has been given to the characteristics of their actual use. Thus, the objective of this paper is to identify any problems that may arise in creating and using textual passwords. METHOD: A systematic literature review of studies in the area of password use and password security. Our research is restricted to articles in journals and conference papers written in English and published between 1979 and 2014. The search is conducted through IEEEXplore, ScienceDirect, Springer Link and ACM Digital Library. RESULTS: The computer community has not made a very much-needed shift in password management for more than 35 years. Users and their passwords are still considered the main weakness in any password system, because users often choose easily guessable passwords: words, names, birthdates, etc., because they are easy to remember. CONCLUSION: Password policies and password checkers can help users create strong and easy-to-remember passwords. This work will serve as a starting point for our further research in this area where we want to determine whether these password policies are useful to the users, and whether the users can easily apply them.

I. INTRODUCTION

Typically, a user is authenticated based on one of the three underlying principles: "what you know" (e.g. textual or graphical passwords), "what you are" (e.g. retina, iris, voice and fingerprint scans) and "what you have" (e.g. smart cards or other tokens). The passwords that fall under the category of "what you know" can be divided into textual passwords and graphical passwords [24][29]–[31][45]. In this study, we focus particularly on the textual passwords and their security simply because they are still the most common method for authentication.

More than 30 years ago, Morris and Thompson [3] identified textual passwords as a weak point in information system's security. They found out that majority of users' passwords (87% of them) were short, contained only lowercase letters or digits or were easily found in dictionaries. Because the use of passwords has always been, and continues to be, one of the most common control mechanisms for authenticating users of computerized information systems, it was expected that Morris and Thompson would have raised the awareness of system users about the consequences of how they choose their passwords. However, despite the widespread use of passwords and their importance as the first line of defense in most information systems, little attention has been given to the characteristics of their actual use.

The objective of this paper is to perform a systematic literature review of studies in the area of textual passwords and textual passwords security. We conduct our review following the guidelines proposed in [1]. The rationale for conducting the review is threefold. The first reason is to identify any problems that may arise in creating and using textual passwords. Secondly, to appraise the current situation of passwords with respect to the passwords strength, password management and password memorability. Thirdly, to find out what is the relationship between users and the textual passwords they use (are the users still "the weakest link?").

The reminder of this paper is organized as follows: the research method is described in Section II, while Section III represent the review results and the answers to our research questions. Section IV concludes the paper and presents plans for future work.

II. RESEARCH METHOD

A. Research Questions

We use the PICOC (Population, Intervention, Comparison, Outcomes, Context) [2] structure for formulating the research questions. Table 1 represents the selected criteria for the PICOC structure. Considering the three parts in Table 1, we formulate the following research questions:

- **RQ1**: What are the major problems with creating and managing textual passwords?
- **RQ2**: What is the current situation of textual passwords with respect to password strength, password management and password memorability?
- **RQ3**: What is the relationship between users and textual passwords? Are the users still "the weakest link"?

Our population represents the textual passwords, while the intervention are the different techniques and technologies used for creating and manipulating textual passwords. We do not compare textual passwords with other types of passwords, since our subject of interest are strictly textual passwords. The outcomes refer to the

TABLE I. THE PICOC STRUCTURE

Population	Textual passwords
Intervention	Techniques and technologies for creating and managing textual passwords
Comparison	/
Outcome	Problems when creating and managing textual passwords
Context	/

problems that may arise in creating and using (or manipulating) textual passwords.

B. Search Strategy

Our literature search strategy is organized in two phases*: initial search* and *reference search*.

The initial search for relevant studies is performed over electronic data sources – digital libraries. When selecting the digital libraries, we took into account the recommendations from the literature [1] and also our knowledge and practical experience and the fact that we do not have access to all the digital databases. This initial search is conducted through the digital databases IEEEXplore, ScienceDirect, SpringerLink and ACM Digital Library.

We composed a search string by deriving major search terms from our research questions and by using Boolean OR to link the major search terms:

("password security" OR "password strength" OR "password memorability" OR "password cracking" OR "password management")

The search of the electronic databases is restricted to articles in journals, conference papers and book chapters written in English and published since 1979, i.e. this is the year when the first article in the area of password security was published.

The reference search is conducted by reviewing the reference lists of primary studies and the review articles addressing the password security [3], [4] and [5].

C. Selection Criteria

The search is performed by using the search string and the search result is a set of documents in which the search string appears partially or entirely. However, in some cases, the search string outputs a study whose topic is in a different field of study. Because of such cases, we also performed a subsequent semantic checking by reading the titles and abstracts of these documents and selecting the documents that are consistent with our research area. This selection is carried out in an objective manner, using inclusion and exclusion criteria. In order to select the relevant documents, we define the following inclusion and exclusion criteria:

Inclusion – a study focuses on textual passwords only ("what you know"):

- the study focuses on password security or presents method(s) for password creation
- the study deals with issues or problems with password use, password management or password memorability

Exclusion – a study is not peer-reviewed, or the study deals with computer security in general, cryptography, graphical passwords or any other type of user authentication (biometrics, tokes or smart cards etc.).

Because the titles and abstracts of the documents are not always extensive, we do not always have a clear indication if the document meets the specified criteria. If this is the case, we take a further step and read the whole document to determine whether the data meet the inclusion and exclusion criteria.

III. RESULTS

Table 2 lists the results from the initial search. The search into 4 electronic databases found **58** relevant primary studies. The third column in the table represents the number of studies that are duplicates, i.e. studies that have already occurred in another digital database. We can see from the table that the ACM Digital Library contributed the largest number of documents (42) and also the largest number of duplicates (20). The column "Total relevant studies" shows the total number of documents from each source, but in this case documents that have already appeared in the a previous source are not included. The review of the references of the primary studies found additional 9 documents that were not found by the initial search of the electronic databases, thereby increasing the number of total relevant documents to **67.**

Next, we present the results of our review and the answers to the research questions.

RQ1*: What are the major problems with creating and managing textual passwords?*

We observe that 17 ([3]-[18][68]) out of 67 studies, address the issue of password security, password use or re-use, and are suitable for answering the first research question.

As already mentioned earlier, Morris and Thompson [3] were the first authors that addressed the issue of password security in 1979. They observed problems regarding to the accessibility and availability of the password file in the UNIX system. They also conducted experiments in order to determine typical users' habits about the choice of passwords and noticed that users of the system chose passwords that are **short**, **simple** and from a **restricted character set** (e.g. alphanumeric password with all lower-case letters). Ten years later authors in [4] concluded that, in order to maximize the difficulty of password cracking and to prevent the fast, simple attacks, systems should implement passwords policies that will require the passwords to contain certain amount of entropy.

On the other hand, higher entropy makes a password more difficult for a user to memorize [13]. Further research has shown that despite password policies' recommendations and the efforts by information system professionals to educate users about secure password policies, users still tend to choose passwords that are

TABLE II. SUMMARY OF FOUND AND SELECTED STUDIES

Electronic database	Found studies	Relevant studies	Duplicates found elsewhere	Total relevant studies
IEEEXplore	89	15	0	**15**
ScienceDirect	76	6	0	**6**
SpringerLink	847	15	0	**15**
ACM Digital Library	1203	42	20	**22**
Total	**2215**	**78**	**20**	**58**

simple and easy to remember [5]. This particular study [5] showed that user-created passwords are still based on user's personal data or a combination of meaningful details. Adams and Sasse [7] conducted a study of password related user behaviors, including password construction, frequency of use, password recall and work practices. They concluded that their participants lacked security motivation and understanding of password policies, and tended to circumvent password restrictions for the sake of convenience.

Because of the rapid growth of the popularity of Internet technology and e-commerce and the increased number of online services requiring password based authentication, users have to maintain many different accounts [15]. Different passwords should be used for every account so that no single password cracking will lead to compromising the other accounts [10], thus users have to remember **multiple passwords**.

In order to provide better password security i.e. to ensure that a stolen password will become unusable more or less quickly, some password security mechanisms and password policies include forced password change (**password aging**). This results with the user having many different accounts to maintain and many different passwords to remember that are changing frequently because of password security mechanisms. Password aging is a very serious problem, because of the lack of warning users receive before their password is about to expire. If the system insist on users changing their password during the login procedure, denies them the time to think about choosing a good one [6]. Forcing password change too frequently may make the user to quickly **forget** the password [5][13], or to **write it down** [5][8][9][14], which is another "bad habit" noted in the literature regarding to password security.

One of the most common vulnerability, which is also most frequently cited in the literature, associated with password security is the **password re-use** (using the same password, or a very similar one, for more than one secure item) [9][10][11][12][14][15][16][17][18]. The results of studies [9][17] show that duplicating passwords is a very common practice. In such an environment, where one password is used for authentication for several different accounts (an average user has about 25 different password accounts [12]), password re-use can cause serious damage, if the password is successfully cracked, for a single (not-so-important) account. Information may be revealed that will aid the hackers in infiltrating other systems, potentially leading to the fall of many other systems (including the ones that are far more secure that the first one) [10]. Users must lower their overall password quality, in order to cope with the password overload [68]. According to [11], duplicating passwords is more likely to become more problematic in the future as password reuse rates are increasing because people are accumulating more accounts but are not creating more passwords.

***RQ2**: What is the current situation of textual passwords with respect to password strength, password management and password memorability?*

From all collected documents, we can observe that in the period of 35 years different methods and approaches for creating and easily memorizing and managing textual passwords were developed ([19]-[58][64]-[67][69] 45 out of 67 studies).

The earliest approach that deals with the problem of creating passwords that are memorable and difficult to guess, is the use of **cognitive passwords**. Cognitive passwords represent a dialog between a user and a system. The dialog is a actually a rotating set of randomly chosen questions out of a set of predefined questions, previously selected by the user [20]. Cognitive passwords are more readily recalled than conventional passwords and are also more difficult to guess [20][21][23]. The only possible issues are the issue of time needed for authentication of user access and that remembering many cognitive passwords may be harder for the user [20][21].

Similar to cognitive passwords are **associative passwords**. This alternative is based on a single-word cue and a one-word response, instead of whole questions and answers [21]. Just like with cognitive passwords, the only possible problem is that a user would likely not remember many associative passwords [21][54].

Passphrases and **mnemonic-based passwords** are another alternative for conventional passwords. A passphrase is basically an extended password, which consists of a meaningful sequence of words. It is designed to form a compromise between ease of memorability and difficulty of guessing it [21]. It turned out that passphrases are no harder to remember and are more resistant to brute-force attacks than conventional passwords [35][21]. But [35] also found out that passphrase users initially experienced a significantly higher number of login failures due to typographical errors, which can be one downside of passphrases. Mnemonic-based passwords present an alternative for passphrases and are also one of the earliest approaches [19]. They are basically a short passphrase where a character (often the first letter) is used to represent each word of the passphrase (e.g. "I love to ski at Seven Springs!" transforms into "Ilts@7S!") [32]. They are difficult to guess, but are also almost equally safe as the random passwords, and equally easy to remember as the naively selected passwords [27][43]. The only downside of mnemonic-based passwords is that users often select phrases from music lyrics, movies, literature, or television shows, which are often available on the internet. This opens the possibility that a dictionary of mnemonic passwords can be built, so authors in [32] conclude that mnemonic passwords should not be treated

as a solution for the problems mentioned earlier in this section.

We mentioned **password policies** earlier as a mechanism for encouraging users to create and use strong and easy to crack passwords. But the literature shows that users do not comply with such recommendations and policies [28][33][47][51][53]. This usually happens because password policies are too inflexible to match users' capabilities, and the tasks and contexts in which they operate [47][66]. So, other studies conclude that password policies should be adjusted for different focus groups and should be more aware of the increasing burden users have managing passwords [39][57][67]. If we start to enforce stricter password policies without a thorough explanation and user training, this has almost no effect [57][64]. This can create a conflict between users' perception and the enforced practice – we can only ran into some of the already mentioned problems regarding to password security [47][52].

Some authors even propose that administrators should pro-actively attempt to crack passwords in their systems, in order to estimate the risk of password-guessing attacks, such as [69]. Password breaking mechanisms may also be used for data recovery purposes, as suggested in [69].

A proactive **password checker** is one possible solution to prevent users from creating easily guessed passwords and to also encourage them to adhere to password policies. Password checkers are proposed in some of the studies we analyze, including [22][25][26] [44][65]. But password security is not a problem that can be solved only by technical means. Human factors are also very important (which is basically the problem with password policies) [25]. A further research is needed in order to find out how to create password policies that are acceptable to users and that can create secure passwords.

A few studies propose a technique of **"persuading"** users to choose better passwords, rather than to instruct them or impose new password schemes, because they believe that improved instructions and new password schemes may not be the solution [36][40].

Passfaces and **graphical passwords** are not originally our subject of interest but, since they are potential substitute for textual passwords, we decided to include only those studies where the security of graphical passwords is discussed. Studies [24][29]–[31][45] show that passfaces and graphical passwords actually provide a better security than textual passwords. The only downside with graphical password is that the password registration and log-in process take very long and the authentication procedure is different than that using textual passwords. This requires redesign of the existing software.

It seems that users are more aware about password security and the importance of creating strong and hard to guess passwords [48]. The results indicate that, according to the amount of characters, passwords became little more secure over time (a study in Greece shows that the average password length is slightly less than 7 characters) [49][56]. Despite that, users still tend to use less secure passwords (which are composed only of lowercase letters, uppercase letters or numbers), to write their passwords down or to share them with their friends and they also rarely change their passwords [34][38][46]. Password requirements may have something to do with this, since [42] found out that the majority of the websites that have passwords requirements, do not keep pace with the progress in the area of password security and rarely change od update their passwords requirements. In the following years we can expect that the security of any system that is based on passwords will be equivalent to the availability of the material for passwords disclosure and not how random and strong passwords are [58]. Therefore, stronger passwords may not be necessary (especially for smaller institutions with hundreds rather than millions of users), as long as the security protocols are well designed (e.g. three unsuccessful logins freezes the account for a time) [37]. Users can also be encouraged to design strong passwords, using elements associated with a given service, together with a personal factor [55]. The growth of web-based services will demand memorizing even more passwords in the future, so some other usable alternatives to textual passwords may have to be found [41][56]. Due to the widespread use of the World Wide Web and the increased number of Web accounts that a user has to maintain, we still encounter with the majority of the already discussed problems [34][50].

***RQ3**: What is the relationship between users and their textual passwords? Are the users still "the weakest link"?*

The rest of the studies (5 out of 67) address the issue of the user as the weakest link in password security [59][60][61][62][63]. From the studies that we have already analyzed, we can observe that the user behavior is a very common issue in the area of password security and many security departments treat users as a security risk that needs to be controlled. Authors in [59] and [60] argue that the usability of the security mechanism has rarely been investigated. Users usually are not aware about the security threats and the importance of security and password mechanism are currently badly matched to users' capabilities and their tasks. These are the challenges arising from the lack of communication between users and organizations (or their security services), which leads to the development of useless security mechanisms [59][60]. Therefore it is maybe necessary for password mechanisms to apply a user-centric approach for designing "usable security" (i.e. human factors should be given priority over technological factors) [62][63]. On the other hand, authors in [61] claim that users are the enemies of the system (willingly or unwillingly) and security policies should be applied appropriately according to the user's type. They argue that ignorant users have to be educated about security mechanisms, and non-copliant users have to be persuaded to follow the security best practices.

According to this, we can not conclude if the users are still the enemy of a system and we aggree that a further research in this area is needed.

IV. CONLUSION

The results of our review show that the computer community has not made a very much-needed shift in password management for more than 35 years. It seems nothing has changed since Morris and Thompson

addressed the issue of password security and published their results in 1979. For example, an average user has 8.5 different Web accounts, 6.5 passwords (each of which is shared across 3.9 different websites), resulting in users to very often forget their passwords or write them down [12][34][50]. Besides that, users still tend to create passwords based on their personal characteristics. Users and their passwords are still considered the weakest link – the main weakness in any password system is that users often choose easily guessable passwords: words, names, birthdates, etc., because they are easy to remember. One way to decrease password guessability is to restrict the passwords accepted from the user by using a system (e.g., a password checker) that filters out easily guessed passwords. Password checkers require that passwords have certain characteristics (usually defined in a password policy) before they are accepted by the system when the user enters a password. Password policies and password checkers can help users create strong and easy-to-remember passwords. However, despite password policy advice, users still tend towards creating weak and easy-to-guess passwords. This work will serve as a starting point for our further research in this area where we want to determine whether these password policies are useful to the users, and whether the users can easily apply them or the policies cause them problems when creating and using passwords.

Brute Force Analysis of PsychoPass-generated Passwords

B. Brumen* and A. Černezel*
* University of Maribor, Faculty of Electrical Engineering and Computer Science, Smetanova 17, Si-2000 Maribor, Slovenia
bostjan.brumen@uni-mb.si

Abstract - Background: Recently, Cipresso et al proposed a novel method for generating textual passwords. The PsychoPass password can be created, memorized and recalled by thinking of an action sequence instead of a string of characters.

Objective: The objective of this paper is to analyze how and when the PsychoPass passwords are resilient to brute force attacks and how they compare to randomly generated ones.

Methods: The PsychoPass method was studied analytically. The number of possible different passwords that can be created using PsychoPass method was calculated for different possible settings.

Results: The PsychoPass generates passwords that are resilient to brute force attacks with password lengths comparable to those generated randomly. A PsychoPass-generated password with 18 characters is as strong as a completely randomly generated password of length 11 characters with mixed upper and lowercase letters, numbers and symbols, but can easily be remembered.

Conclusion: The PsychoPass method is an alternative to the existing passwords and is resilient to brute force attack. There is no known dictionary to enable the dictionary attack. The PsychoPass passwords look like random ones, eg. »aEy|dX%7Tu]6hJ«, but a user can easily remember it based on the action sequence instead of remembering its characters.

I. INTRODUCTION

The ability to authenticate the identity of a user via passwords continues to be basic and the most relied-upon security mechanism in information systems. Weak passwords have led to very serious breaches, exposing millions of users and/or causing billions in damages. The history of password-related problems pre-dates the seminal paper written by Morris and Thompson in 1979 [1] – it goes way back to mid-1960s and to the CTSS operating system exposing all the passwords as a daily welcome message [2]. A comprehensive list of breaches since 2005 can be found at [3].

A typical survey evaluating the generation and use of passwords revealed that users have several password uses and the average password has more than one application. Two thirds of passwords are designed around one's personal characteristics, with most of the remainder relating to relatives, friends or lovers. Proper names and birthdays are the primary information used in constructing passwords, accounting for about half of all password constructions. Almost all respondents reuse passwords, and about two thirds of password uses are duplications. Passwords have been forgotten by a third of respondents, and over half keep a written record of them [4].

It seems that nothing has been learnt and changed in the course of almost 50 years – users and their passwords remain the weakest link [5-13], although the basic and the most relied-upon security mechanism in information systems continues to be the ability to authenticate the identity of a user. The passwords used to be [14-16] and still are the main method of authentication [17-19], although research continues on more sophisticated methods of authentication, see e.g. [20-29]. Some novel solutions are even improvements of concepts well known to the automobile industry (i.e. car keys) [30].

II. BACKGROUND ON PASSWORD STRENGTH – WHY ARE GOOD PASSWORDS SO HARD TO REMEMBER?

The general rule is that passwords strength is proportional to their length and the size of the symbols space – i.e. the pool from where the password characters can be used from. This is true only if the process of the character selection is truly random [31]!

The number of possible combinations can be expressed by $s=b^{le}$, where s is the total number of combinations, b is the total number of symbols in a domain and le is the length of the password in number of characters. Typically, the pool size is taken to be 75 (upper and lower case characters, digits, symbols). If n characters are used for a password, there is a total of $s=b^1+b^2+b^3+\ldots+b^n=b^{n+1}-1$. Today, the reported speeds (v) for restoring a plaintext password from a given (unsalted) hash value are in the range of $v=10^9$ combinations/second [32-35], up to 10^{12} combinations/second [31]. Due to the Moore's Law [36] still in effect, the computing power doubles roughly every 18 months. In 10 years, we can expect the speeds to be 100-times of today's (only taking into the account the Moore's Law and no other improvements in the field, e.g. quantum computing [37] or improvements in hash computations [38]). Table I lists the number of all possible combinations for passwords of length from 7 up to 11 characters for the size of 75 character in a pool (letters, numbers and special symbols) and the time required to check all possible combinations at today's speeds and the time it will take in 10 years from now due to speed improvements.

TABLE I. WORST CASE TIME TO CRACK RANDOM PASSWORDS NOW AND IN 10 YEARS FOR DIFFERENT PASSWORD LENGTHS (BASE=75 CHARACTERS; CHARACTERS RANDOMLY DRAWN)

Pwd length	*Number of combinations*	*Time to crack now*	*Time to crack in 10 years from now*
7	1,00113E+15	11 days, 14 hours	2 hours, 46 minutes
8	7,50847E+16	2 years, 139 days	8 days, 16 hours
9	5,63135E+18	178 years, 207 days	1 year, 286 days
10	4,22351E+20	13392 years	133 years, 338 days
11	3,16764E+22	1.004.450 years	10.044 years

The table shows that what is safe today will not be safe tomorrow [31], this especially holds true for off-line files which will remain unchanged for years, containing interesting medical data about an important person. The breach of privacy of data in such a file has a timelessness property [39] – no matter when in the lifetime of data the breach happens, it poses a problem.

A user, when creating a password, needs to observe one the following principle: (1) a password is considered secure if the cost of breaking it exceeds the value of the protected information, or (2) the time required to break the password exceeds the lifetime of the protected data [31]. Today, we cannot rely on the costs because the ratio of bits processed per unit of currency is continuously sinking making the password cracking machine affordable [32, 34, 35]. One can only increase the time required. Thus let us assume a typical 60-year time span of usefulness of stored information [40-44]. In other words, a safe password today (in 2014) would be made of at least nine characters from upper and lowercase letters, numbers and symbols, but it would not be safe in 10 years from now. Thus, 10-character passwords are required today to be safe tomorrow as well, confirming findings by Egelman et al [18]. Today, a typical password has (only) 8 characters [45-47].

When we come to the 10 (or more) characters to remember, they constitute a much larger corpus than is the capacity of human memory, the well-known 7±2 principle [48]. Human memory in addition is temporally limited (short-term) when it comes to memorizing sequences [49] and has a limited capacity with a fixed final error rate [50-52]. For this reason good passwords that are consisting of an abundant number of randomly selected characters are doomed: the users will either forget them [53] or write them down, or both [54-56]. What are the alternatives?

III. RELATED WORK

Typically, a user is authenticated based on one of the three underlying principles (or combinations thereof): "what you know", "what you are" and "what you have" [31, 57]. "What you know" is based on secrecy known only to authorized user, "what you are" is based on user's physical characteristics (e.g. retina image, fingerprint) and is better known by the term biometrics, whereas "what you have" is based on smart cards or other tokens.

The passwords that are generated based on "what you know" principle can be divided into textual passwords and graphical passwords [58, 59]. In our contribution we focus on textual passwords as graphical ones require a different user interface for entering passwords [59] and are thus not directly comparable to our study. In addition they require a redesign of user interface for entering a password [59].

There are several alternatives to (nearly) random long textual password.

First, a password can be based on personal data or characteristics (e.g. birthdate, names, pets, addresses, etc.). They are easy to be cracked [1, 60] and their use is strongly discouraged [61].

Second, cognitive password authentication schemes require user to answer a randomly selected set of personal questions which only an authorized user can answer correctly. They have a high recall rate, but are susceptible to guesses by family and friends [20]. To prevent reuse, each system would require a unique set of questions [62].

Third, pass-sentences and pass-phrases are passwords composed of long, grammatically correct phrases [63]. They are memorable and software-cracking resistant, but their length makes them useless for repeated use [62].

Fourth, randomly generated but pronounceable passwords made up of concatenated pronounceable syllables are resistant to standard dictionary or brute-force attacks [64], but the algorithm is vulnerable to a special dictionary attack [65].

Fifth, mnemonic passwords are those where a user chooses a memorable phrase and uses a character – often the first letter – to represent each word in the phrase, or vice versa, for a given (random) passphrase a system generates a grammatically correct phrase that the user can remember. They were endorsed in the past [16], but were found vulnerable and will even be more vulnerable in the future [20].

Orthogonal to the works on different textual password generating techniques are contributions that deal with password metrics, principally meters that show users how strong their password might be [18, 47, 66]. It was shown empirically [47] and mathematically [67] that Shannon entropy value is not useful when determining the strength of a password creation policy, and other policies need to be used. Common advices on minimum password length and character set requirements provide against online attacks [47]. Yet, by observing these requirements, users tend to forget passwords and/or write them down, usually in an insecure location [60]. Writing down a password is not a bad practice itself, as pointed out by Bruce Schneier: "*…if only users wrote [a password] down on a small piece of paper, and keep it with their other valuable small pieces of paper: in their wallet*" [68].

Orthogonal to our work are also contributions dealing with users' compliance to different password creation policies [5, 6, 8, 69]. General observation is that users tend to choose bad passwords due to inexistent policies or try to comply to them with minimal effort [9, 45, 47, 70]. All users need is a sound piece of advice and an explanation why passwords need to be strong and how to achieve it [8, 71].

A. *PsychoPass Method*

Cipresso et al [72] have proposed a novel method for generating textual passwords: the method was improved by Brumen et al [40]. The proposed improved method is, in our modest opinion, a novelty in producing strong passwords that was not seen for years, maybe ever since the invention of graphical passwords in 1990s [73, 74]. "*The idea of PsychoPass is that a password can be created, memorized and recalled by just thinking of an action sequence instead of a word or string of characters*" [72]. With PsychoPass method, a user creates a password based on visual location of keys, not the key values themselves. Figure 1 depicts a visual circle and a square (actually a rhombus) on the keyboard using blue numbered dots. The keys that draw the circle are A-W-E-D-X-Y, and the keys that draw the square are 5-6-7-T-U-G-H-J.

Figure 1. A circle and a square on keyboard producing a strong password

However, the improved PsychoPass method requires the use of SHIFT and ALT-GR keys and that the keys that are not always adjacent to each other in the sequence.

Suppose that key #1 is pressed without SHIFT or ALT-GR, key #2 is pressed in combination with shift key, and so on, as given in Table II (please note that SI-Slovenian keyboard layout is used).

The password representing the circle and the square in Figure 1 would read »aEy|dX%7Tu]6hJ«, as presented in Figure 2 and Table II.

TABLE II. PASSWORD RESULT OF THE VISUAL REPRESENTATION FROM FIGURE 1 USING PSYCHOPASS

Seq. #:	1	2	3	4	5	6	7	8	9	10	11	12	13	14
SH/AGR[a] :		s		a		s	s		s		a			s
Result :	**a**	**E**	**y**	**|**	**d**	**X**	**%**	**7**	**T**	**u**	**]**	**6**	**h**	**j**

a. S=shift used, A=ALT-GR used

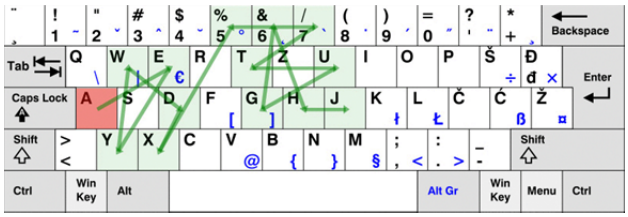

Figure 2. A representation of password »aEy|dX%7Tu]6hJ«

Interestingly, the very same shapes, if shifted one key to the right on a keyboard, would yield another password, namely »sRxefC&8Zih7jK«, as shown in Table III and Figure 3.

TABLE III. PASSWORD RESULT OF THE VISUAL REPRESENTATION FROM FIGURE 1 USING PSYCHOPASS, SHIFTED ONE TO THE RIGHT

Seq. #:	1	2	3	4	5	6	7	8	9	10	11	12	13	14
SH/AGR[a]:		s		a		s	s		s		a			s
Result :	**s**	**R**	**x**	**e**	**f**	**C**	**&**	**8**	**Z**	**i**	**h**	**7**	**j**	**K**

a. S=shift used, A=ALT-GR used

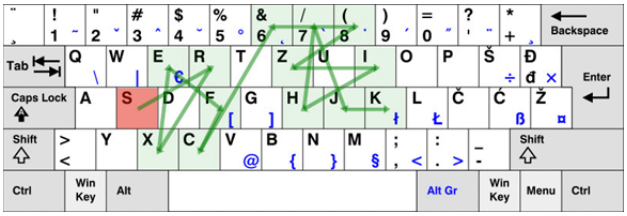

Figure 3. A representation of password »sRxefC&8Zih7jK«

The representations of passwords »aEy|dX%7Tu]6hJ« and »sRxefC&8Zih7jK« are shown in Figure 2 and Figure 3, respectively.

The user thus memorizes a password based on its visual representation (action sequence) and additionally when to press SHIFT or ALT-GR.

It may seem that the password produced (e.g. »aEy|dX%7Tu]6hJ«) is totally random (with 75^{14}= 178.179.480.135.440.826.416.015.625 =1,78e26 different combinations, and the brute force attack would take some 5,6e9 years. However, the Psychopass generated passwords are not random, and the question is, how such passwords are resilient to brute force attacks.

B. *The contribution*

The aim of the present work is to present the findings of the brute force analysis of the improved PsychoPass method.

IV. BRUTE FORCE ANALYSIS OF PSYCHOPASS METHOD

The PsychoPass method was studied analytically. The number of possible different passwords that can be created using PsychoPass method was calculated.

Let us represent a keyboard as an undirected graph, G = (V, E), comprising a set V of vertices together with a set E of edges. Each key capable of producing a character represents a vertex of the graph. Each vertex is weighted; weight 2 denotes keys that can produce 2 or less characters (typically in combination with SHIFT) and weight 3 denotes keys that can produce 3 or less characters (additionally in combination with ALT-GR). Each vertex is connected to the other ones based on the key adjacency on the keyboard of length up to 2, e.g. the "D" key has the following 1-adjacent keys: "SERFCX", and 2-adjacent keys "VYAW345". Additionally, key "D" is adjacent to itself since a password can contain a subset like "dd" or "DD".

Let us represent the graph G by matrix A of dimension *n* x *n*:

$$A = [a_{i,j}] \qquad (1)$$

where

$a_{i,j} =$

$\begin{cases} 0; \text{ if keys } i \text{ and } j \text{ are not adjacent} \\ w_j;\ w_j \text{ is the weight of key } j \text{ if keys } i \text{ and } j \text{ are adjacent or } i = j. \end{cases}$

Since we are interested in all possible combination of passwords of length l, we calculate the $(l\text{-}1)^{\text{th}}$ power of matrix A:

$$B = A^{l-1} \tag{2}$$

To calculate the total number of all possible combinations, we first multiply the ith row with the weight of ith key.

$$C = [c_{i,j}]; c_{i,j} = b_{i,j} * w_i \tag{3}$$

The total number of all possible combinations (s) is the sum of all elements in the resulting matrix:

$$s = \sum_{i=1}^{n} \sum_{j}^{n} c_{i,j} \tag{4}$$

The numbers of all possible combinations for specific l and for Slovenian-SI keyboard layout were calculated and are given in Table 4. Additionally, the table 4 lists the time needed for a brute-force attack with today's computing power and in 10 years from now.

TABLE IV. NUMBER OF POSSIBLE PASSWORD COMBINATIONS FOR GIVEN *L*, AND BRUTE FORCE ATTACK TIMES (NOW / 10 YEARS)

Password length	*Number of combinations*	*Time to crack now*	*Time to crack in 10 years from now*
1	123	0 sec	0 sec
2	1763	0 sec	0 sec
…	…	…	…
10	5,09386E+12	1 hour 24 minutes	51 seconds
11	7,79683E+13	21 hours 39 minutes	13 minutes
12	1,19364E+15	13 days 19 hours	3 hours 18 minutes
13	1,82766E+16	211 days 12 hours	2 days 2 hours
14	2,79886E+17	8 years 319 days	32 days 9 hours
15	4,28669E+18	135 years 339 days	1 years 131 days
16	6,56618E+19	2.082 years	20 years 299 days
17	1,00589E+21	31.896 years	318 years 352 days
18	1,54109E+22	488.675 years	4.886 years

V. RESULTS

From Table IV it can be concluded that passwords generated by PsychoPass method need to be at least 15 characters long to be resilient to today's brute force attacks and 17 to resist those in 10 years from now.

The comparison of strength of PsychoPass passwords and randomly generated is shown in Table V.

TABLE V. COMPARISON OF PSYCHOPASS AND RANDOM PASSWORDS RESILLIENCE TO BRUTE FORCE ATTACKS

Psychopass password length	*Random password length*	*Number of combinations*[a]	*Time to crack now*[a]	*Time to crack in 10 years from now*[a]
12	7	E+15	~10s days	~ hours
13	8	E+16	~100s days	~days
14		E+17	~ years	~10s days
15	9	E+18	~100s years	~years
16		E+19	~1.000s years	~10s years
17	10	E+21	~10.000s years	~100s years
18	11	E+22	~100.000s years	~1.000s years

a. Approximation only

The results show that for comparable password strength the PsychoPass passwords need to be from 5 to 7 characters longer than randomly generated ones.

VI. CONLUSION

In this paper we presented an analysis of brute-force resilience of passwords generated with a novel PsychoPass method that is an alternative to the existing passwords schemes. The idea of PsychoPass is that a password can be created, memorized and recalled by just thinking of an action sequence instead of a word or string of characters.

The results show that psychopass-generated passwords are resilient to today's brute force attacks if their length exceeds 14 characters and are considered safe at lengths exceeding 16 characters when taking into the account the expected increase in the computing power in the next 10 years.

The required length of psychopass-generated passwords exceeds the randomly generated ones for a comparable resilience; however, they are much easier to remember. The length of a randomly generated password constitutes a much larger corpus than the capacity of an average human memory.

Additionally, there is no known dictionary to enable the dictionary attack. The PsychoPass passwords look like random ones, eg. »aEy|dX%7Tu]6hJ«, so the attacker cannot easily prove that the particular password was created using the PsychoPass method instead of being randomly generated.

An additional advantage is that the same action sequence can produce completely different passwords so the popular password reuse is supported in a safe way.

A disadvantage of the proposed method is that it is bound to a specific keyboard layout and the usage in mobile devices is somehow limited.

***Abstract*—Three approaches exist for a company to migrate its services in the cloud. The first is select the most appropriate commercial cloud provider, such as Microsoft, Amazon, Google or SalesForce, and to rent their resources and deploy its services. These cloud service providers The second approach is to build a private cloud with some of the open source cloud frameworks like Eucalyptus, OpenStack, OpenNebula or CloudStack. Finally, the third option is to build a hybrid cloud, i.e., to split the services and to migrate the confidential and private services in its own private cloud, which could be open source, while the public and non confidential services and data to migrate in some public commercial cloud. Commercial cloud providers encash for their resources as a service, but offer and guarantee secured resources and huge availability of minimum 99.9% through a SLAs (Service Level Agreements). On the other hand, building an open source private cloud is the lowest starting investment, which does not guarantee neither security nor availability. Therefore, it is important for a company to assess the security of the open source cloud frameworks, especially their web management interface since it is the front end application, through which a user can get an unauthorized access to the company's data or applications.**

Eucalyptus is one of the most common open source cloud frameworks for building IaaS (Infrastructure as a Service) private or hybrid clouds, which also has its own web management interface to manage the cloud resources. In this paper, we assess the security of the cloud framework web management interface of the newest version of the Eucalyptus cloud. The results of the security assessment analysis show that the cloud web management interface is vulnerable. We assess the security vulnerabilities and propose measures how to secure them.

I. Introduction

Migrating the services from on-premise to a public cloud reduces the company's cost, but leverages the security risks. If the security is more important than elasticity for a given company, then the solution is to build a private cloud. This can be based either on a commercial cloud solution, such as IBM or VMware, or on one of the most common open source cloud softwares, such as OpenStack [1], Eucalyptus [2], OpenNebula [3], CloudStack [4] etc. However, the security of cloud platform is not guaranteed. For example, Dabrowski and Mills [5] demonstrated that open-source clouds can be attacked to degrade the availability of virtual machines.

Open source cloud is more and more used as a framework for building a private or public cloud. Eucalyptus is one of the major open source cloud software platforms designed to be a counterpart to commercial Amazon's EC2 cloud [6], [7].

All open source cloud frameworks have different purposes. For example, Eucalyptus fits well to build public cloud services (IaaS) with homogeneous pool of hypervisors, while OpenNebula [3] fits well for building private/hybrid cloud with heterogeneous virtualization platforms [6]. Voras et al. [8] devise a set of criteria to evaluate and compare the most common open source IaaS cloud solutions. Mahjoub et al. [9] compare the open source technologies to help customers to choose the best cloud offer of open source technologies.

In this paper, we assess the vulnerabilities of the Eucalyptus web graphical interface for administration, i.e., its dashboards. The rest of the paper is organized as follows. Section II presents the related work in the area of open source cloud security. In Section III, we briefly describe the Eucalyptus cloud architecture, its components and services, while in Section IV we present the assessment environment and the tool that is used for the assessment. The security assessment analysis of Eucalyptus administration service vulnerabilities are presented and discussed in Section V. Finally, Section VI concludes the work and presents future work.

II. Related Work

Virtualization and multitenancy generate additional security challenges and vulnerabilities in the cloud compared to the on-premise solutions. Grobauer et al. [10] define indicators if a particular vulnerability is cloud specific to distinguish general security issues from cloud-specific security issues.

Several papers propose methodologies and evaluate the security of cloud solutions and service layers. Chen and Yoon [11] propose a framework of checklist of IT auditing to secure the cloud. However, third party auditor should not bring new vulnerabilities towards data privacy [12]. Ristov et al. [13] evaluate ISO 27001 [14] control objective importance for on-premise and the cloud service layers IaaS, PaaS (Platform as a Service) and SaaS (Software as a Service).

The security of open source cloud frameworks is also assessed. Gusev et al. [15] analyzed the security vulnerabilities of Eucalyptus cloud from inside and outside and determine that the Eucalyptus server nodes are more vulnerable from inside, rather than from outside of the cloud, while the virtual

machine instances have the same security vulnerability risks both from inside and outside.

Ristov et al. [16] assessed the security vulnerabilities of OpenStack using one network configuration. They proved that OpenStack cloud multi-tenant environment raises new security vulnerability risks from inside the cloud, both for the tenants and the OpenStack cloud provider. Donevski et al. [17] evaluated that segregating the networks in OpenStack cloud rises new security risks, but only for CSP from inside, which need to be patched by the cloud software vendor. The vulnerabilities remain the same for the tenants.

The security of the commercial clouds is also analyzed. Tajadod et al. [18] compared the security of Microsoft's Azure platform and Amazon's Elastic Compute (EC2) cloud architectures and determined that both CSPs have significant security issues, with Microsoft offering a better level of data security than Amazon does.

In this paper we are focused on the security of Eucalyptus' dashboard on the application layer.

III. Eucalyptus Cloud Architecture

Open source clouds have similar architecture [19]. Although the architecture designs consist of several different parts, they are based on two main parts: *Cloud controller* and *Cloud node*. The former controls the system and network, schedules the execution of instances and offers a web interface for management of the whole cloud, while the latter hosts the instances of VMIs. In this section, we briefly describe the Eucalyptus cloud architecture, its components and services.

Eucalyptus is an open source cloud software that allows the users to build public, private and hybrid clouds. The Eucalyptus cloud software platform is developed to support highly scalable, modular and distributed platforms. It offers the customers a possibility to manage VMIs, volumes and snapshots. Nurmi et al. [20] outline the basic principles and important operational aspects of the Eucalyptus cloud solution.

Figure 1 presents the architecture of the Eucalyptus cloud. It consists of six components (five essential and one optional component), separated in three logical tiers:

- *Cloud Tier* - which consists of the following two components:
  - *Cloud Controller (CLC)* - acts as front point of the cloud which offers the web administrative interface for managing the whole cloud and EC2-compatible SOAP and Query interfaces. Also, the CLC makes high-level resource-scheduling decisions, makes requests to all of the available Cluster Controllers (CCs) and is responsible for exposing and managing the underlying virtualized resources (servers, network and storage). This component handles the authentication, accounting, reporting and quota management and communicates with all other cloud components except the Node Controllers (NCs);
  - *Walrus* - offers a persistent storage to all of the installed VMIs in the cloud. This component can contain images of VMIs, volume snapshots, application and user data, and can be used as a Storage-as-a-Service solution;
- *Cluster Tier* - which consists of the following two mandatory and one optional components:
  - *CC* - schedules a certain VMIs execution on specific node and manages the networks. This component communicates with the CLC, SCs and NCs;
  - *Storage Controller (SC)* - offers an option for managing the EBS (Elastic Block Store) volumes and snapshots of VMIs in the cloud. This component functions as Amazon's EBS [21]. It communicates with the CC and NCs;
  - *VMware Broker* - is an optional Eucalyptus component and is out of the scope of this paper. It is activated only in versions of Eucalyptus with VMware support which enables Eucalyptus to deploy VMIs on VMware infrastructure elements;
- *Node Tier* - which consists of the following component:
  - *NC* - controls activities of VMIs and manages the virtual network endpoint. This component communicates only with the CC and interacts with the host OS and the installed hypervisor..

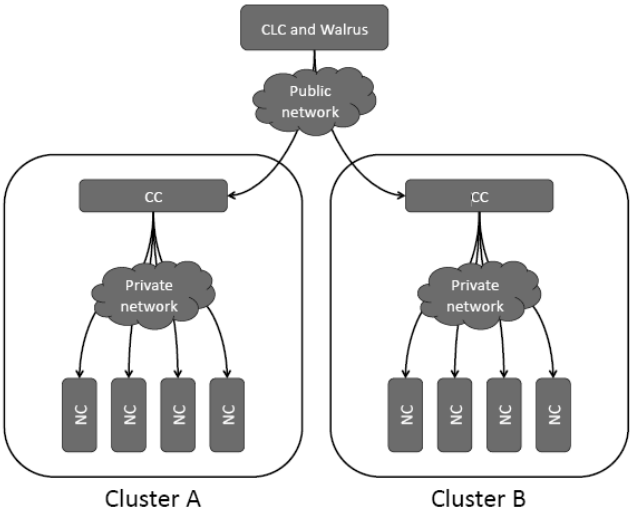

Fig. 1. The Eucalyptus Network [20]

Each component is a stand-alone web service and the communication between the cloud components are based on the SOAP protocol with WS-security extension to add end-to-end security.

The goal of this paper is the security assessment of the web management interface, which is depicted in Figure 2. It allows the administrators to monitor the activated instances, create key pairs, manage the images, etc.

IV. Assessment Environment and Tool

This section presents the assessment environment and tool used in the assessment, that is, the practical deployment

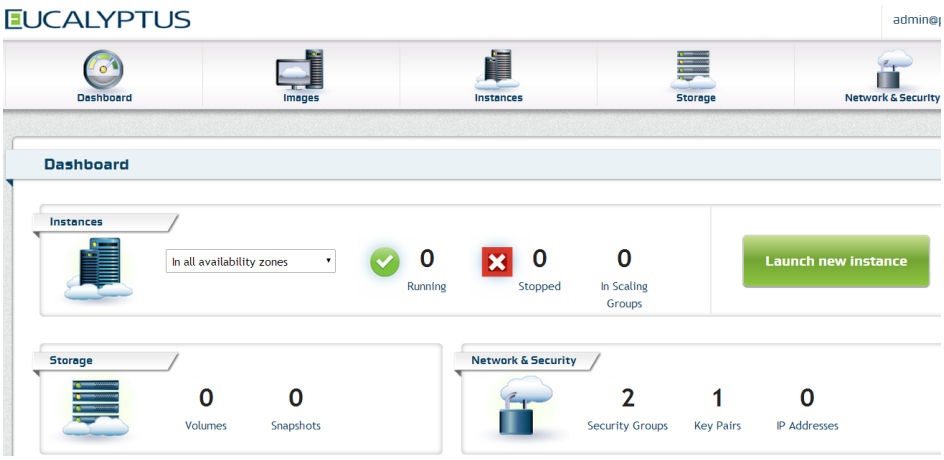

Fig. 2. The Eucalyptus web management interface

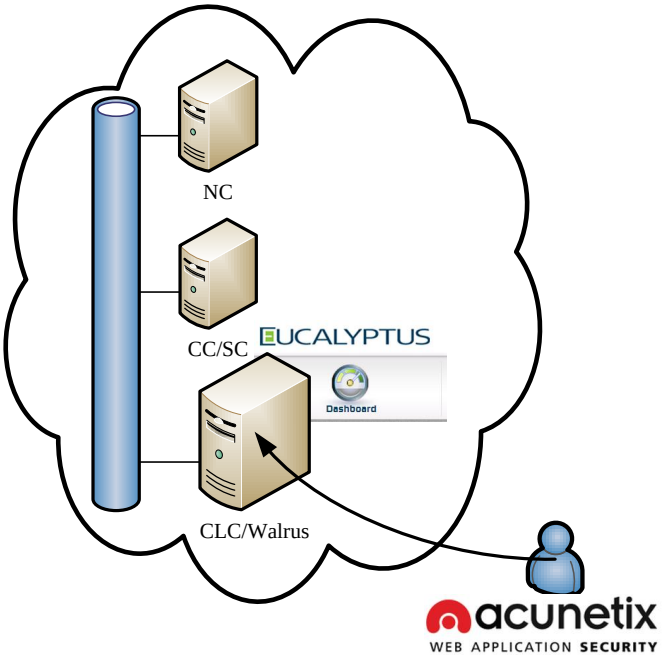

Fig. 3. The assessment environment

of Eucalyptus cloud. The research is based on assessing the security vulnerabilities of web management interface of the Eucalyptus' cloud framework, i.e., the Eucalyptus' User Console.

A. Assessment Environment

The Eucalyptus cloud deployed on three physical servers, as depicted in Figure 3. Each server is installed with Ubuntu Server 12.04 operating system. The web management interface is installed on the the cloud controller.

B. Assessment Tool

The security of cloud framework is assessed using the Acunetix Web Vulnerability Scanner [22] version 8.0. Acunetix scanner is pioneer, worldwide leader and one of the most advanced penetration tools for testing the web application security. Each vulnerability is rated as high-, medium- and low-severity type vulnerability. High-severity vulnerabilities are categorized as the most dangerous, which put a site at maximum risk for hacking and data theft [23]. Medium-severity vulnerabilities are caused by server misconfiguration and site-coding flaws, which facilitate server disruption and intrusion [23]. Low-severity vulnerabilities are derived from lack of encryption of data traffic, or directory path disclosures [23].

Acunetix checks the vulnerability realizing multiple pre-defined checks for the following vulnerabilities: Application Error Message Checks, File Inclusion, Blind SQL injection, Full Path Disclosure, CGI Testing, LDAP Injection, Code Execution, PHP Code Injection, Cookie Manipulation, Remote XSL inclusion, CRLF Injection, SQL Injection, Cross Frame Scripting (XFS), Script Source Code Disclosure, Cross-Site Scripting (XSS), URL Redirection checks, CSRF Injection, XPath Injection, Directory Traversal, and Directory File Checks. It is also a port scanner and enumerates the discovered open services for well-known vulnerabilities.

V. The Results of the Security Assessment

In this section, we present the results of the security assessments made on the Eucalyptus cloud services.

The security assessment of Eucalyptus detected 4 high-severity, 4 medium-severity and 4 low-severity type vulnerabilities.

XSS vulnerability is detected on 4 pages which allows an attacker to send malicious code (Javascript, VBScript, ActiveX HTML or Flash) to another user. The Eucalyptus developers must redevelop the vulnerable pages to filter metacharacters from user input.

Table I summarizes the medium-severity type vulnerabilities. 3 Eucalyptus directories display the list of files, but this is a false positive vulnerability. An attacker can inject plain text into the protocol stream which could allow him to issue

TABLE I
DETECTED MEDIUM-SEVERITY EUCALYPTUS' WEB MANAGEMENT INTERFACE VULNERABILITIES

Vulnerability Type	Assessed Vulnerabilities
Directory Listing	3
TLS1/SSLv3 Renegotiation Vulnerability	1
Total	**4**

TABLE II
DETECTED LOW-SEVERITY EUCALYPTUS' WEB MANAGEMENT INTERFACE VULNERABILITIES

Vulnerability Type	Assessed Vulnerabilities
OPTIONS method is enabled	1
Login page password-guessing attack	1
Password field submitted using GET method	1
Sensitive page could be cached	1
Total	**4**

HTTP requests. The Eucalyptus developer should patch this vulnerability in future version.

Low-severity type vulnerabilities are summarized in Table II.

The OPTIONS method is also false positive since it depends on the web server configuration, and not on the developed software. The Eucalyptus is also unprotected by password-guessing attack. The password field is submitted through GET instead of POST method. Finally, caching should be prevented. The three latter vulnerabilities must be patched by the Eucalyptus' developers.

VI. CONCLUSION AND FUTURE WORK

We assessed the security of Eucalyptus' web management interface using web vulnerability scanner. The experiments addressed the security vulnerabilities of web site administration. The assessment detected some false positive vulnerabilities which depend on web server configuration rather than cloud softwares.

The results of the assessments show that the Eucalyptus' cloud software is vulnerable. That is, we detected 4 high-, 4 medium- and 4 low-severity vulnerabilities. Although some of the detected Eucalyptus' web management interface vulnerabilities are false positive, all 4 high-, 1 medium- and 3 low-severity must be redeveloped by the Eucalyptus' developers.

In this paper we assess the vulnerability of Eucalyptus' cloud web management interfaces. Our future work will be focused on analyzing the other internal cloud services of Eucalyptus, as well as other open source clouds in order to help the clients to evaluate the security of the most common open source cloud frameworks, and select the most appropriate cloud framework to build their private or hybrid IaaS cloud.

Abstract - In this paper we present our approach to fast flux detection called CROFlux that relies on the passive DNS replication method. The presented model can significantly reduce the number of false positive detections, and can detect other suspicious domains that are used for fast flux. This algorithm is used and implemented in Advanced Cyber Defense Centre – a European project co-funded by the European Commission.

I. INTRODUCTION

Nowadays information systems are threatened by various types of attacks. If we look at the most popular threats in information security like distributed denial-of-service, malware distribution and spam, we can notice that they can be conducted using botnets. Botnets are networks of infected computers that are usually managed from a central point also called command and control center (C&C). These networks use various techniques for hiding their presence or amplifying the damage of their attacks. One commonly used technique is fast flux which abuses DNS (Domain Name System). DNS records of flux domains are frequently changed; in such a way that authoritative DNS returns different bots in various time intervals. Flux domains are usually used for hiding botnet command and controls servers, hosting malware delivery sites or for hosting phishing pages. Fast flux facilitates load balancing and proxy redirection that make malicious servers more resistant against detection or takedown attempts.

There are two different types of fast-flux: single-flux and double-flux. Single fast-flux is a technique where multiple bots, within the botnet, are registered and deregistered in a DNS A record for a single fully qualified domain. In combination with round robin DNS algorithm that has very short TTL values (e.g. 3 minutes), this technique produces a constantly changing list of destination IP addresses for the same domain. Resolved bots act as proxies for malware or phishing delivery sites, these sites are popularly called "mothership" nodes.

Double-flux technique, unlike the single flux, provides an additional layer of redundancy. Specifically, in double flux, both the DNS A record and authoritative name server (NS) record are changed. The used authoritative name server administers a fast-flux DNS zone, with all domains and subdomains in it.

A query that has been sent by client's stub DNS resolver is received by DNS recursor (caching DNS server) which in turn is recursively sent downwards from the root server to the last authoritative name server. The last authoritative name server is a bot used for a double flux scheme. Periodically, other bots take a role of authoritative name servers, thus the corresponding NS records are changed.

After receiving the query the authoritative name server forwards it to the mothership node requesting required information (e.g. domain's A record). The mothership node sends a response to a flux name server which forwards the response back to the DNS recursor. IP addresses in DNS responses belong to bots. Motherships are second layer C&C servers in a fast-flux botnet scheme, these nodes typically host both DNS and HTTP services to accomplish their single and double-flux scheme role.

II. RELATED WORK

Weimer [1] proposed the passive DNS replication (pDNSR) method whose purpose is to extract resource records from response packets of authoritative DNS servers. Using the paired query and response, pDNSR builds a replica of DNS zones that are available from the data. To preserve privacy pDNSR uses only queries between DNS servers. A similar approach was used by Zdrnja and his colleagues [2]; they deployed a custom solution for collecting domains. Analyzed data contained: misspelled domains, fast flux domains and spam related domains.

Holz et al [3] proposed a Flux score to differentiate malicious domains from benign ones. Flux score uses features derived from active DNS queries. These features are: number of unique A records in DNS lookups, number of name servers in lookups and number of unique autonomous numbers (ASN) from type A records. Their system sends several active queries to collect relevant data about domains. After the first query system waits for TTL to expire, and then it sends another query. Using popular spam domains they obtained an optimal hyper plane that separates flux domains from benign ones.

Fast flux domains are classified using Flux score as following:

$$1.32 \cdot \text{numIP} + 18.54 \cdot \text{numASN} + 0.0 \cdot \text{numNS} > 142.38 \quad (1)$$

Where the parameters are:

- *numIPs* – number of distinct IP addresses
- *numASN* – number of unique autonomous system numbers of IP addresses
- *numNS* – number of used name servers for the given domain (ignored because of the zero coefficient in the Equation 1)

Holz et al also realized that Fast-Flux domains have similar characteristics like content delivery networks (CDN) or round robin DNS's that are used to increase website availability. Thus, CDNs are usually classified from the aforementioned algorithm as false positive flux domains. A handful implementation of the algorithm can be found on GitHub [9].

Fluxy [4] uses a similar approach; their authors implemented an adapted equation to compute the Fast-Flux score. In addition to previously mentioned Holz et al method, Fluxy uses reverse DNS queries to detect dynamic IP addresses probably belonging to infected end-users.

EXSPOSURE [5] is a system based on a passive DNS replication. Used data was provided from Security Information Exchange (SIE), which contained response data from authoritative servers from North America and Europe. From this vast amount of data, approximately 4.8 million domains collected through 2.5 months, they extracted time based features of collected domains and analyzed them with a change point detection algorithm CUMSUM. CUMSUM is used to detect short lived domains and domains with repeating patterns. Their classification model was built using a C4.5 decision tree classifier and was trained with features of popular malicious domains. Beside the time related features, they used other groups of features based on: DNS answers, TTL values and domain name characteristics. An extensive list of features can be found in the paper.

Fluxbuster [6] is another system which uses passive DNS replication. Fluxbuster prunes the collected domains based on conservative criteria and outputs candidate domains; pruning procedure is based on data returned in responses (TTL values and diversity of servers' networks). After that, candidate domains are clustered using a hierarchical clustering algorithm. Classification of these domains is based on features collected by the passive analysis. They introduced some novel features like growth ratio of IP addresses and networks. Given clusters are classified using a decision tree classifier. The used training set was obtained using a semi-manual process, where authors combined known malware domains and manual corrections in labeling.

III. CROFLUX

A. System Architecture

The developed system CroFlux uses a Farsight's SIE framework [1]for DNS data collection. The framework is similar to the solution proposed by Weimar [1] which reconstructs a partial zone replica preserving users' privacy.

The SIE sensor, as shown in Fig. 1, captures DNS messages from the connected authoritative DNS server.

Processing stage returns queried domains and IP addresses from a particular time interval. We can look at those results as aggregated responses to specific domains. SIE outputs the processed DNS messages in NMSG format. NMSG is a wire format optimized for storing and transmitting binaries over UDP [10]. NMSG stores the following information: domain name, DNS query type, name server that sent the query, authoritative name server that answered the query, IP addresses pointing to domain, record class and record type.

B. Fast Flux Detection

One limitation of designing a fast flux detection algorithm is the passive nature of DNS data collecting. So the classification process needs to rely on data gathered by completely unpredictable timing of DNS queries sent by various users. This posed a problem, since we need as many as possible resolved IP addresses of fast flux domains which enhance the detection result. We did not use any active DNS data checking like described in [3] and [4], because we wanted to avoid potential exposure to botnet operators. This limitation may become negligible if passive DNS replication method is installed on a big network with many users.

Another problem that may occur is detection of benign domains as flux (false positives). False negatives, i.e. fail to detect fast flux domain, are of a less pertinence. As the result of fast-flux detection algorithm is considered to be a part of public services and actions, false positive results may produce certain inconvenience, distortion of reputation or legal issues. Thus false positive elimination presents a problem of current fast flux detection solutions [8].

CROFlux algorithm runs through three phases. Namely, as shown on Figure 1:

(a) Prefiltering/pruning of collected domains
(b) Candidate domains clustering
(c) Detection of fast flux clusters

a) Prefiltering fast flux candidates

SIE outputs NMSG files that contain captured domains which are later filtered. This filtering stage is similar to the pre-filtering stage proposed by Perdisci [6]. On Figure 1 this step is called domain list pruning procedure.

[1] Farsight SIE framework is available at https://archive.farsightsecurity.com/

Selected candidate domains must meet the following requirements:

- Domain's time to live (TTL) should be below 3 hours (TTL<=3600 s)
- Minimum number of resolved IP addresses for the following domain |RS|>= 3, or if RS requirement is not met take only domains with a small TTL<=30 seconds. The number of the resolved IP addresses is aggregated from various DNS queries and depends on cache timeout setup on the SIE sensor.
- Diversity of networks for a domain should be div(RS)>0.333. To be a part of the same network, resolved IP addresses must have the same /16 prefix. Diversity is calculated as entropy of /16 networks of resolved IPs for a given domain.

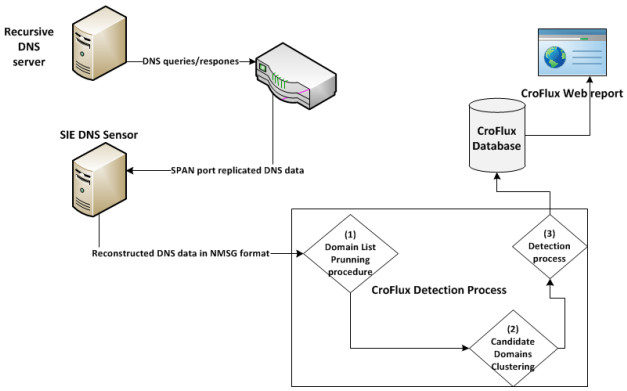

Figure 1. – Overview of CroFlux architecture

After the pruning procedure we have a dictionary with candidate flux domains, where domain names are keys and discovered IP addresses are values. Periodically, measured in time of few minutes, all dictionary records are added to a global dataset. Candidate domains from the global dataset are evaluated from: number of distinct IP addresses, number of distinct AS origins of those addresses and number of estimated dynamic IP addresses of those domains.

Behind flux domains are infected computers or bots which are spread across multiple ISP networks over the world, mostly linked with a broadband connection. The following method is used to mark domain as fast flux candidate [4]:

$$\text{Fluxy Score} = 1.32 * \text{numIPs} + 40.0 * \text{numSPLink} + 20.0 * \text{numASNs} \quad (2)$$

Where the parameters are:

- *numIPs* – number of distinct IP addresses
- *numSPLink* – number of dynamic IP addresses
- *numASNs* – number of distinct autonomous systems

We used a conservative threshold score of 450 for marking domain as a fast flux candidate. For comparison, Fluxy authors and Holz and colleagues used a lower threshold score 142.38 [3] [4].

b) Clustering

Domain clustering is a process in which we group domains that are operated in the same network. As we may expect, hosting providers, content delivery networks (CDN) and botnets that use fast flux are those types of networks. In this step we try to target more closely fast flux domains. Number of common IP addresses is used as clustering criteria. This number of overlapping IP addresses is empirically tuned. Every week clusters are expanded or new ones are created, based on newly collected DNS data.

c) Determining fast flux clusters

The final step is to determine fast flux clusters from all candidate clusters. Fast flux domains are often used for malware delivery or hosting phishing domains so we can say that they act as proxies. The way to determine fast flux cluster is to compare candidates' clusters against publicly available and private malware lists collected by internally used tools. Based on the number of malicious domains in cluster we label that cluster as fast flux cluster. Otherwise, cluster is labeled as some other type (CDN, hosting providers etc.). We use a minimum number of malicious domains to classify a candidate cluster as fast flux. This number is tunable and is found empirically. Aforementioned blacklists are available via multiple online services [11] [12] [13] [14] [15] [16] [17]

IV. RESULTS

DNS data has been replicated from August 2013 till January 2014, using a CARNet recursor. CroFlux has collected 427.502 de-duplicated second level domains. From these domains we have near 265 malware domains with flux characteristics. In Figure 2 we can see the distribution of top level domains with flux characteristics. Collected flux domains are primarily from Russia (.ru) and Soviet Union (.su) domain which is still used.

In Figure 3 are presented calculated Flux scores of CroFlux's detected flux domains. Scores are shown on logarithmic axes, and as we can see collected flux domains mostly have higher Flux scores. The bright dashed line represents the Fluxy's threshold for flux domains. Also, we can notice that detected flux domains tend to have higher flux scores.

Fluxy score, similarly to Holz score, generates many false positive results [9], i.e. benign domains labeled wrongly as flux. It is also useful to note that given classification hyperplane weights (calculated in [3] and [4]) are trained on elder flux domains - from circa 2008.

Many collected legitimate sites have a high score. They also have similar characteristics to flux domains like: short TTL, many IP addresses scattered through geographically distant autonomous systems etc. Examples of these sites are: content delivery networks like Akamai, cloud services like Amazon AWS, sites used for time synchronization NTP and video streaming services like Netflix and Hulu.

Similarly, distributed peer to peer networks like Bitcoin use fallback nodes hardcoded in Bitcoin miner applications that use a short TTL (60 seconds) and contain many peer nodes with dynamic IP addresses.

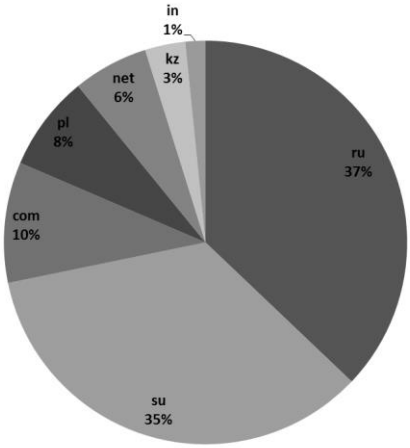

Figure 2 – TLD Distribution of detected flux domains

Using our data we recalculated the Fluxy separating hyperplane. Because of the difference between active querying and passive replication we used the last two inserts (of the specific domain) for calculating feature weights.
On a dataset with 9300 benign domains and 100 flux domains we performed a 10-fold cross validation, like in [3]. We obtained feature weights using the Support Vector Machine method with a linear kernel.
This resulted with an optimal hyperplane for flux domains:

$$-0.2853 \cdot \text{numIPs} + 0.4076 \cdot \text{numASNs} + 0.1837 \cdot \text{numSPLink} > 1.5704 \quad (3)$$

Benign domains were classified with a precision of 99% and flux domains with a precision around 91%.
Detected flux domains contained many double flux domains which rotate name servers and IP addresses in responses.
An example of double flux is the following:

Ns1.nulled-db.com
Ns2.nulled-db.com
…
NsXX.nulled-db.com

We also noted multiple level flux domains, like mentioned in [8]. These domains have multiple levels of name servers, where there is an overlap between the existing IP addresses.
An interesting type of domains are domains with a short TTL (less than 10 seconds), that rotate several IP addresses in every query. Usually, they return a single IP address. These domains tend to evade popular approaches to flux detection.

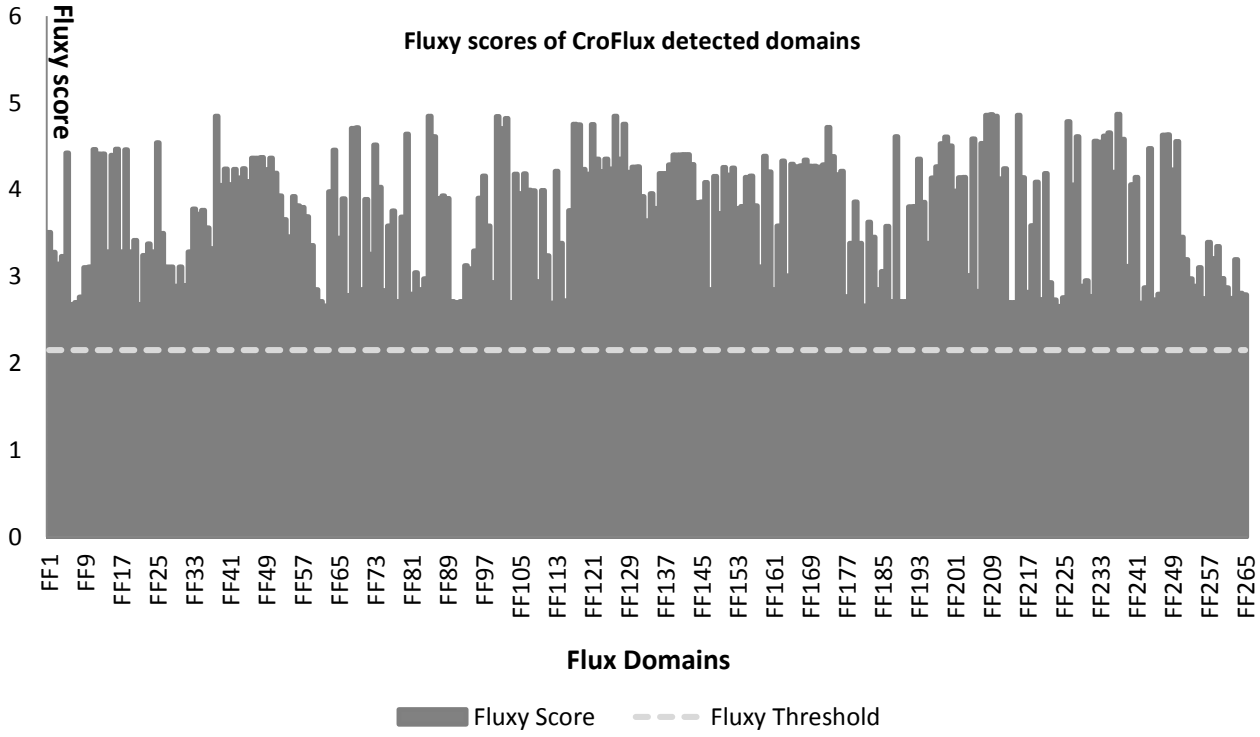

Figure 3 – Fluxy scores of collected Fast Flux domains

V. CONLUSION

In this paper we introduced CROFlux, a method for detecting fast flux domains in the wild. Our approach leverages on publicly available knowledge about malicious delivery sites.

Our system can continuously detect unknown fast flux domains with an advantage that reduces false positives, relaying on detected domains with flux characteristics which are usually used for sharing malware.

With our conservative approach we get a list of real flux domains, and we avoid reporting benign domains with similar characteristics.

We also have similar lists of malicious domains that are collected using other systems developed in house and used in an EU funded project - Advanced Cyber Defence Centre (ACDC). CroFlux has been developed within the ACDC project, and temporally is tested on one DNS recursor hosted in our network. We have plans to expand the number of monitored DNS servers, in order to gain more flux domains. At the moment information about detected flux domains is sent to a centralized ACDC database called central clearing house. Further actions like domain takedown will be done in collaboration with law enforcement agencies and domain registrars with the aim of reducing botnets' damage.

As we can see from the results, botnet operators constantly work on new techniques to avoid detection and takedown of malicious domains. In order to have an updated classification, we updated the classifier using newly collected domains. Edge cases like small TTL domains with one IP address in response cannot be detected using an active querying approach, but passive replication helps on aggregating resolved IP addresses if this type of domains is queried enough times.

ACKNOWLEDGMENT

Writing of this paper is funded by the European Commission. The views and opinions expressed in this paper are those of the authors and do not necessarily reflect the opinions and views of the European Union.

Also, we would like to thank anonymous reviewers whose comments helped us to improve this article.

Sarajevo, Bosnia and Herzegovina
E-mails: mk14746@etf.una.ba , ddonko@etf.unsa.ba

Abstract—Software security is becoming highly important for universal acceptance of applications for many kinds of transactions. Automated code analyzers can be utilized to detect security vulnerabilities during the development phase. This paper is aimed to provide a survey on Static code analysis and how it can be used to detect security vulnerabilities. The most recent findings and publications are summarized and presented in this paper. This paper provides an overview of the gains, flows and algorithms of static code analyzers. It can be considered a stepping stone for further research in this domain.

Keywords—static code analysis; security; vulnerability; survey;

I. INTRODUCTION

Millions of users accomplish their daily tasks using web and desktop applications on different electronic devices. The prevalence of software enforces the software industry to think of how to build quality in. Most aspects of software quality are related to the skills and knowledge of the development team [1]. Unfortunately, developers make mistakes that lead to vulnerable and defect software. Exploited security vulnerabilities lead to unreliable software that can become harmful for the user and software provider.

The CWE (Common Weakness Enumerations) initiative provides a unified, measurable set of software weaknesses which can lead to serious security vulnerabilities [2].The top 25 vulnerabilities list contains the most widespread and critical errors that can lead to security vulnerabilities that can be easy exploited by an attacker. Table I presents an overview and description of the most common and harmful attacks. CWE has documented more than 680 software weaknesses that can lead to impacts like modified data, read data, denial of service (DOS) attacks, resource consumption, execution of unauthorized code, gain of privileges, protection bypass or the hiding of activities.

Many security focused methodologies like the Open Software Assurance Maturity Model (Open SAMM) [3],The Building Security In Maturity Model (BSIMM) [4], or Microsoft's Security Development Lifecycle (SDL) [5] are designed to enforce developers to build security in. Still, the research provided by Cenzic showed that 99% of all reviewed applications in 2012 had at least one serious security vulnerability [6].Conveniently, tools that are able to scan millions of lines of source code and detect defects and vulnerabilities in relatively short time are improving rapidly. A variety of such utilities is now available as commercial or free tools that can be used either as a standalone tool or as a plug-in for a development framework. Automated code analysis tools can be utilized during the development phase and as part of the build process. The detection of defects in such an early phase can reduce costs significantly.

The main characteristics of static code analysis tools, their gains and flows are outlined in section II. Section II also provides information on how to measure the contribution of static analysis to vulnerabilities detection. Section III presents the techniques and algorithms static code analysis is based on. This section contains an overview of the most recent work and a summary of related researches. The Conclusion is presented in section IV.

Table I. Top 5 security attacks [2]

Name	*Description*	*Effects*
SQL injection	SQL – Injection is one of the major threats for data rich software. Every non validated textbox that utilizes user input and uses it in a SQL context can be used by an attacker to inject SQL commands.	Attackers use the commands to bypass authentication mechanisms or insert tainted data into the database.
OS command injection	Applications are considered vulnerable to the OS command injection attack if they utilize non validated user input in a system level command what can lead to the invocation of scripts injected by the attacker.	Attackers attempt to execute system level commands in order to achieve the desired goal.
Buffer overflow	Buffer overflows is an anomaly where a program, while writing data to a buffer, overruns the buffer's boundary and overwrites adjacent memory. It can be triggered by non-validated inputs that are designed to execute code.	Buffer overflow may result in erratic program behavior, including memory access errors, incorrect results, a crash, or a breach of system security.
Cross-site scripting	Cross-site scripting is typically found in Web applications and it enables attackers to inject client-side scripts into Web pages viewed by other users.	Attackers use it to bypass access controls, steal user sessions or to redirect users to a different website.
Missing authentication	Missing authentication is a security vulnerability that occurs in software that does not perform any authentication for functionalities that require a provable user identity or consume a significant amount of resources.	Exposing critical functionality. Provides an attacker with the privilege level of that functionality.

II. STATIC CODE ANALYSIS

Every software application has its business context, environment and purpose. Potential risks and threats should be defined in regards to the protected values, and the weaknesses prioritized accordingly. The Common Weakness Risk Analysis Framework (CWRAF) [7] and the Common Weakness Scoring System (CWSS) [8] help the community to focus on its risk-reduction activities. CWRAF supports the automatic selection and prioritization of relevant weaknesses, customized to the specific needs of the organization's business or mission. Such initiatives help developers and consumers introduce more robust and resilient software into their operational environments [9]. Once the business value has been linked with weaknesses it is easier to detect and fix the security vulnerabilities important for the application domain. Since manual code reviews are costly, automated tools seem to be a good solution. Automated tools can perform static or dynamic code analysis.

Static analysis tools detect vulnerabilities by scanning the applications source code and examining all possible execution paths and variable values without executing the application. This makes the process fast, repeatable and not dependent on the fact whether the program can be executed. Static code analysis can be applied during the development phase which can help programmers to find and fix defects and security lapses early. Static code analysis is related to the source code examination which makes it dependent on the programming language. One of the major roadblocks to the wide use of automated code analyzing tools is the fact that such tools tend to report false positives and false negatives [10]. False positives refer to results that report non existing security bugs, similar to false negatives which occur when tools don't report existing bugs. Unfortunately, false positives and false negatives seem inevitable if a reasonable amount of resources should be used for the analysis. Although, there is a theoretical possibility to create a tool that has almost no false negatives, close to zero false positives and that works for many plausible programs. Such tool would find errors by systematically exploring all possible program states with all possible inputs and looking for error states. In theory, this is possible because digital computers are ultimately finite state machines, but the number of states is so vast that such a tool would take an unreasonable amount of time to complete [11]. Since such a tool doesn't exist, the main goal is to achieve a tolerable false positive and false negatives rate and a satisfying execution time. Most static analysis tools are configurable; they allow users to define the set of vulnerabilities to search for. Static analysis tools present a list of warnings that have to be inspected manually, and classified as true weaknesses or false alarm – this process is known as *triaging* [10].

Dynamic analysis tools require an installed and configured application. The vulnerabilities detection is based on test scenarios and the findings are related to the current configured environment. Dynamic analysis tools are susceptible to false positives and false negatives also. However, such tools are agnostics in terms of the used programming language because they are utilized on object code, which makes them preferable in some situations.

The common known shortcomings of static code analysis often led to discussions about the benefit of such tools. The most effective tool is one that strikes the right balance among false positives, false negatives, and performance. The benefit of a static analysis tool can be measured in regards to the weaknesses reported.

Recall is defined as the probability that a tool will find a real defect [11].

$$R = \frac{TP}{TP + FN} \tag{1}$$

Precision is defined as the probability that a result corresponds to a real defect [11].

$$P = \frac{TP}{TP + FP} \tag{2}$$

TP represents the number of true positives found by a tool;*FN* represents the number of false negatives and *FP* the number of false positives reported by a tool.

Once the reports have been triaged and the true positives sorted out it is easy to calculate the precision measuring, but it is difficult to measure the recall value since it relies on the number of false negatives which cannot be determined accurately. Also, a tool can be very effective in finding one kind of vulnerabilities but it doesn't mean that it will have a satisfying recall and precision value for other types of vulnerabilities. There is a general understanding that the real measure of a static-analysis tool's usefulness is whether it can find a reasonable number of important defects in a program without overwhelming the user with useless reports or using an unreasonable amount of computing resources.

A step forward in improving user experience is a well-structured and intuitive UI that groups related defects. This could reduce the number of reports and suppresses repeated defect reports that can be addressed with one common fix. Some tools like Parfait provide an easy way to store and share defects [12]. Such reports can be reviewed by other team members or used for further bug prediction. Some results might be misjudged or discarded because of way they were presented. Distinguishing a true positive from a false positive takes some care, time and experience. Tools have to be intuitive, easy to install and forthcoming in the way they present the results or they won't be used, no matter how precise or fast they are.

III. HOW STATIC CODE ANALYSIS WORKS

Static code analysis is performed on a model of the code to be analyzed. The model usually consists of a set of intermediate representations such as symbol tables, abstract syntax trees, control-flow graphs, and the program call graph. This model is queried using different mechanisms like simple searches of data structures to very sophisticated algorithms based on advanced concepts such as dataflow analysis,

symbolic execution, abstract interpretation, or model checking [11]. Since the analyzing mechanisms aren't applied directly on the program but on a model of the program, false positives and false negatives arise because the model is almost never exact. The model of the program is most often either an over- or under-approximation. An exact model or over-approximation is often referred to as *sound* because it captures all possible aspects of the program's behavior. Such models will most likely find the majority of true positives but they will also tend to report false positives. An under-approximation is a model that fails to capture some relevant aspect of the program, and therefore a variety of false negatives are possible.

There are various techniques and mechanisms developed to detect security vulnerabilities in a program model. Table II presents the most common vulnerabilities and their classification based on the source of the security vulnerability. The following subsections outline in more detail the techniques and mechanisms that static code analysis is based on for the tree identified vulnerability classes.

Table II. Vulnerability classification[13]

Access Control Vulnerabilities	***Information Flow Vulnerabilities***	***API Conformance Vulnerabilities***
Broken access control	Un-validated input	Insecure storage
Broken authentication and session management	Cross-site scripting	
Application denial of service	Injection flaws	

A. Access control

The mechanisms for access control restrict access to security-sensitive resources based on a user's identity and membership in predefined groups [14]. Runtime authorization failures may result when an access control policy doesn't grant sufficient permissions to a user. Likewise, if an access control policy grants users unnecessary permissions, the system may be exposed to security attacks. There are two major approaches used in the Java and .Net Common Language Runtime platforms:

- Stack-based Access Control (SBAC)
- Role-based Access Control (RBAC)

SBAC systems ensure that only programs that satisfy a set of permission requirements gain access to restricted resources. When a program attempts to gain access to restricted resources the runtime system checks whether all callers on the thread's stack satisfy a set of permissions requirements. Therefore SBAC systems prevent a caller which is trying to gain access to restricted resources by invoking more trusted code. In SBAC systems permissions can be granted declaratively in a policy database. The permission requirements for a SBAC security policy depend of the dynamic program behavior. This can be quite complicated since several components are interacting in diverse contexts. The policy configuration can be determined through testing. Permissions are added iteratively until no failures occur. Even when all test complete successfully there is still a chance that some paths of execution were not covered which could lead to runtime authorization failures.

SBAC systems should always stick to the Principle of Least Privilege [15] without violating the functioning of the program. Fortunately SBAC systems provide *privilege asserting* [16]. During stack inspection, the runtime system must enforce that privilege-asserting code holds the necessary permissions, while the callers of the privilege-asserting code do not need to hold the permission. Although privilege-asserting code is necessary to enforce security policies, malicious clients can exploit the privilege-asserting mechanisms to introduce security holes. In order to prevent security vulnerabilities developers should verify that:

- The privilege is necessary
- The privilege is not redundant
- All security-insensitive code that can be moved out of privilege-asserting code is moved
- The privilege asserting code block does not contain more than one security sensitive operation
- The privilege asserting block must respect all integrity and confidentiality requirement concomitant with the security-sensitive operation

Papers [17]-[25]present some new concepts and algorithms related to SBAC implementation.

RBAC is a mechanism to restrict system access to authorized users. RBAC systems provide access control based on permissions and roles. Permissions represent the right to perform restricted operations. Roles represent a set of permissions that can be assigned to a user. Each user that is attempting to invoke an operation must be assigned to a role with that particular permission granted.

RBAC is an access control mechanism based on operations instead of resources, which has its challenges. In order to restrict access to sensitive data all operations accessing such data need to be identified. A resource based approach would be much more intuitive in this scenario. Also, there is no simple way of denying a user access to sensitive data. All operations that have directly or indirectly access to the particular resource must be denied for the role assigned to the user. Mapping the operations to the data they access would provide verification that the intended data based security policy does not conflict with the configured operation-based security policy [26] [27]. Another difficulty with RBAC is related to the invocation chain of an application. The invocation of an application entry point will only be successful when the user has all roles assigned that are necessary to perform all the operations transitively triggered by the application. Important is that a user shouldn't have any unnecessary roles assigned since that would be a violation of the principle of least privilege.

Papers [28]-[35] offer some interesting researches related to the implementation of RBAC mechanisms.

B. Information flow

The two main types of information flow vulnerabilities are integrity and confidentiality. The principle of noninterference dictates that no information flows from higher to lower security levels [36]. Contempt of this principle can lead to violation of the integrity and confidentiality of sensitive data. Vulnerabilities such as those caused by non-validated input and injection flaws constitute integrity violations. SQL-Injections and OS command injections are some of the most common attacks caused by using tainted data (data gathered from an untrusted source) in a trusted environment [37]. The requirement for confidentiality establishes that a value flowing out of a privilege-asserting block should remain confined inside that component unless a check has been performed to verify that the value can be safely released [13].The basic idea behind using static analysis for detecting information flow is to statically check that flow of information between variables in a program is consistent with the security labeling of variables. Each variable is labeled with a certain security level. If a variable x is used to derive, or influence, the value of another variable y, there is potential information flow from x to y. The flow is permissible under a security policy only if the policy allows the security level of x to flow to the security level of y [13].

Studies [38]-[42] present the most efficient approaches and algorithms used for the detection of information flow vulnerabilities.

C. API Conformance

Security vulnerabilities can be related to violations of API specifications. Enterprise software platforms provide a number of APIs for system security services. The misuse of such interfaces can lead to security holes. This kind of misuse can't be detected by compilers but it can be checked with trivial syntactic code scanning or by using some more complex methods. A client that wants to invoke some services from a package needs to follow API conformance rules described in the class documentation. If the client fails to follow these conformance rules, the application will receive a security-related exception.API conformance rules can be expressed as temporal safety properties in a deterministic finite state automaton, or a *typestate specification* [43]. A large number of researches are related to the implementation of such rules [44]-[51], while other papers present a purely analytical approach [52]-[60].

IV. Conclusion

Static code analysis can be utilized to detect defects and security vulnerabilities in source code. It is a fast and repeatable technique for scanning millions of lines of code during the development phase. This is a time and a cost saving way to detect vulnerabilities before an attacker has the chance to exploit them. As shown in the paper, false positives and false negatives are still a major roadblock for the acceptance and widespread use of such tools. The third section outlines that static analysis is based on powerful algorithms that are improving constantly. This indicates that static analysis is one of the most promising mechanisms that can be utilized to achieve secure and reliable software.

Abstract – We define a new non-sequential logic element: the random flip-flop. By definition it operates similarly to the conventional flip-flop except that its clock input functions with probability of 1/2 otherwise the flip-flop does nothing. We discuss several applications of that novel device.

I. INTRODUCTION

Practically all contemporary computers are constructed from deterministic logic circuits (gates, flip-flops, etc.) and are therefore equivalent to a Turing machine [1]. However, it has been realized that a more powerful notion of a computer, so called probabilistic Turing machine [2], [3], can execute *randomized algorithms* [4] which offer either greater speed or greater simplicity (or both) than their deterministic counterparts and on top of that they may be more resilient to errors which may occur during the calculation process. The price to be paid for that advantages is that a randomized algorithm have a finite, usually small and tunable probability to yield a wrong result. For example, one of the earliest known randomized algorithms, the Rabin-Miller primality test [5-6], estimates efficiently and with a high probability whether a given large number is prime or not which is useful in cryptography. This algorithm is much faster than any known deterministic algorithm [7]. Examples of use of probabilistic Turing machine include numerical simulations, Monte Carlo calculations, PSI factor research and gambling automata. And last but not least the cryptography, as one of the cornerstones of online trade and internet security, depends on local availability of freshly generated, unguessable random numbers at each communication endpoint.

Probabilistic Turing machine can be thought of as an ordinary Turing machine complemented with a random number generator and/or random decisions. Having in mind importance of random numbers or random decisions for countless applications it is quite astonishing that modern computer processors do not contain a *standardized* randomness source and a set of machine language instructions dealing with random decisions and/or random numbers. While rare attempts to include a random number generator in the microprocessor exist [8-9] they are by no means guaranteed to appear in any future processors, there are no industry standards on how to access them and are slower than a PRNG ran on the same microprocessor. Probably because of these drawbacks, developing software that would use these generators does not seem to be an appealing option to software designers. Instead, established state of the art is to use pseudo-random formulae seeded by user supplied data or with a handful of bits collected in various ways from the computer hardware (hard disc access times, internal clocks/interrupts, temperature sensors, keystrokes, etc.) in order to generate long pseudo-random numbers which are then used as a substitute for true random numbers.

Modern computers are built from deterministic sequential logic (e.g. the NAND gate) and non-sequential logic circuits (e.g. a flip-flop). Here we propose a single, new elementary non-sequential logic building block: *the random flip-flop* which can be used, among many other applications, to build a probabilistic Turing machine. Random flip-flop may be useful in many other applications such as signal processing, cryptography, laboratory equipment, analog computing, etc. In this study we will define, describe a few possible experimental realizations of the random flip-flop and discuss examples of its usage which extend over both digital and analog applications.

II. DEFINITION OF THE RANDOM FLIP-FLOP

Conventional edge-triggered D-type flip-flop (DFF) shown in Fig. 1a) is an important building element of logic circuits, microprocessors, computers etc. It is typically used as a one bit data storage or a frequency divider-by-two. The "edge-triggered" action means that flip-flop performs its action when clock pulse input (CP) changes state from LOW (logic 0) to HIGH (logic 1), that is upon the "rising edge" of the input pulse. Flip-flop does not care about pulse duration or the falling edge at the clock input (CP). In this work we will only refer to edge-triggered flip-flops and therefore this characterization will be dropped henceforth. Although there are several types of flip-flops in use (D, T, RS, JK, etc.) the D-type is universal in the sense that it can most easily mimic all other types of flip-flops. In principle, it can be realized from basic logic gates [10]. D-type flip-flop operates in the following way. With each occurrence of the rising edge at the input CP (clock pulse), the logic level present at the data input D is transferred to the output Q. The transfer takes some propagation time, usually denoted by t_{CPQ}. After the transfer is finished the value of Q is frozen i.e. becomes independent of the subsequent changes at the input D until occurrence the next rising edge at the clock input. This operation is illustrated by an example timing diagram shown in Fig. 1b). By definition, the D-type flip-flop is a *deterministic* device. It means that under the same input conditions it will always give the same output. Of course, conventional logic elements such as flip-flops, AND gates, OR gates etc. are designed specifically to behave in a deterministic fashion in order to ensure stable and predictable operation of logic circuits, computers, etc. Although in practical devices problem known as "metastability" [11] occurs with a small probability, it can be minimized by careful design of the flip-flop, by stacking flip-flops or by avoiding critical operating conditions. This elusive effect is of no interest here.

As a contrast to deterministic flip-flops we here introduce a family of *random flip-flops* (RFF). Each deterministic type of flip-flop has its random counterpart. For example, by definition, the D-type random flip-flop (DRFF) (symbol shown in Fig. 1c)), operates the same as the conventional D-type flip-flop with only difference that upon the clock pulse, state of the data input D is transferred to the output Q with probability of ½, randomly.

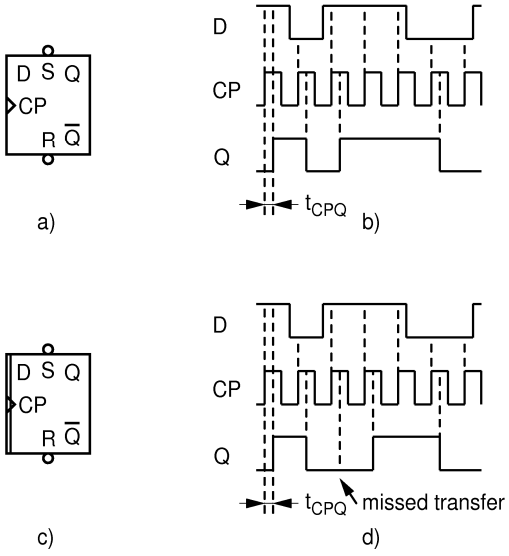

Figure 1. The conventional D-type flip-flop (DFF) symbol (a) and an example of its input-output waveforms (b). The D-type random flip-flop (DRFF) symbol (c) and an example input-output waveforms (d). The t_p is propagation delay between the clock pulse input CP and the outputs Q and $\overline{Q}$.

An example of the input-output diagram of DRFF is shown in Fig. 1d). We have adopted the usual convention that the state of the output changes with positive going edge of the clock pulse. Another type of random flip-flop of particular convenience for this presentation is T-type (TRFF). Deterministic T-type flip-flop (TFF) toggles output state with each clock if input T is held at logical 1 while if T=0 the output is left unchanged. By definition, TRFF is different from TFF only in that if T=1 then each clock pulse reverses the output state with probability ½. In both TFF and TRFF clock input is disabled while T=0. Note that the two definitions (of DRFF and TRFF) are mutually compliant in that whatever a given type of deterministic flip-flop does upon receiving a clock pulse, its random counterpart does randomly with probability of ½, and that in the same manner the definition could be extended to all other types of flip-flops. A RFF optionally features inverted output $\overline{Q}$ which is a binary complement of the output Q. Besides random action of the clock input CP, all random flip-flops optionally feature deterministic Set (S) and Reset (R) inputs or their inverted versions ($\overline{S}, \overline{R}$), which unconditionally *set* (to HIGH) or *reset* (to LOW) the output Q. Although the two random flip-flops can be emulated by each other as shown in Fig. 2, it is sometimes more convenient to realize given circuit by use of a particular type. Interestingly, the same emulation schemae are true for deterministic counterparts (DFF and TFF).

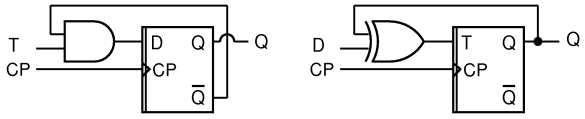

Figure 2. Emulations of DRFF and TRFF by each other. These exact same schematic diagrams hold also for deterministic counterparts.

Of course, one could consider a random flip-flop with the action probability different from 1/2 but the probability of 1/2 is the most convenient for general applications.

Random flip-flops are digital devices with logic inputs and logic outputs that are fully compatible with conventional logic circuits and can be used in mixed designs. Research on full potential of RFFs has just began. In present article we outline some of the most interesting known areas of application.

III. RANDOM NUMBER GENERATOR

Probably the simplest and most obvious application of the random flip-flop is the random bit generator (RBG), a physical device that produces one random bit upon a request. By definition of RBG, any generated bit must have no correlation with the pool of previously generated bits *and* probability of zeros p_0 must be equal to the probability of ones p_1. Figure 3 shows two equivalent random bit generators, one realized by DRFF (left) and the other by TRFF (right). Every rising edge at the CP input will trigger a generation of a fresh new random bit at the Data output synchronously with the Strobe's rising edge. By definition of RFF, the sequence of random bits is truly random and there is no correlation of any sort among bits, but of course in practice it would depend on the quality of the RFF. A random number generator that produces multiple random bits per single clock can be obtained by parallelizing a desired number of bit generators. For example by parallelizing eight RFFs one could generate a random byte in a single clock cycle.

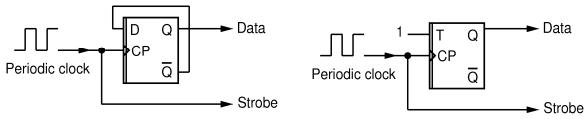

Figure 3. Stream random number generator. Shown are equivalent realizations with DRFF (left) and TRFF (right). Each rising edge of the periodic clock generates a fresh new random bit at the Data output synchronously with the Strobe's rising edge.

Having in mind possible miniaturization of RFFs to a chip level, random number generators of this sort can be particularly useful in cryptographic hardware (smart cards, password tokens, cell phones, computers,...) with a purpose of secure generation of keys, passwords,

challenge-response data, as well as basis data in quantum cryptography [24].

IV. RANDOMNESS PRESERVING FREQUENCY DIVIDERS

Dividing periodic frequency of periodic signals by a fixed integer or fractional number can be performed by various well known techniques [17-19]. For example, a single TFF will divide by two frequency of its clock signal while division by n can be made by a counter-to-n.

Let us now define a random pulse train (RPT) as a sequence of logic pulses in which waiting times between subsequent pulses follow Exponential p.d.f. RPTs are time-wise maximally random and are an important concept with many applications. Frequency of a RPT can also be divided by counters but the Exponential p.d.f. will not be preserved. Randomness preserving frequency division wasn't feasible so far. However, this can be made with random flip-flops.

A random divider by 2, shown in Fig. 4a, omits randomly on average every second clock pulse. If a RPT of average frequency f is fed to the input CP, a random pulse train of frequency two times lower will appear at the output Q. We denote the function of this circuit as $f_{OUT} = f_{IN} / 2_R$ where subscript "R" denotes "random" division action. Stacking two DRFFs as shown in Fig, 4b one achieves division by 4_R etc. A surprising possibility of dividing frequency by 4 with a single DRFF is shown in Fig 4c, but this division is composed of first dividing by 2 randomly and then by 2 deterministically, which we denote as $1/2_R/2_D$ where subscript "D" stands for "deterministic".

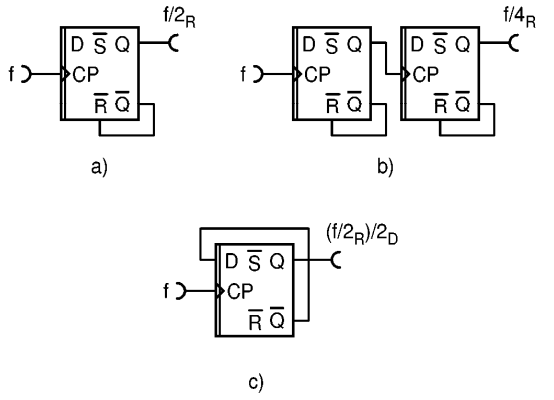

Figure 4. Basic dividers with RFFs: a) random divider by 2; b) random divider by 4; c) divider which performs random division by 2 followed by deterministic division by 2.

Although dividers in Figs. 4b) and 4c) both divide input frequency by 4 their action is not the same because the first divider preserves exponential distribution whereas the second converts exponential distribution into Erlang distribution with shape parameter n=2. Generally, a RPT with mean frequency f deterministically divided by n will result in another random pulse train with mean frequency of f/n but its distribution will be Erlang distribution with shape parameter n:

which for large n tends to the Normal distribution due to the central limit theorem. The Erlang distribution for n = 2 which corresponds to waiting times of an exponential RPT divided by 2_D is shown in Fig. 5. A random division of an Erlang(t; f=1, n=2) pulse train by factors 2_R, 4_R and 16_R (normalized to unity frequency). The conclusion is that deterministic division by n drives the output signal away from randomness and Exponential distribution whereas random division by n drives *any* initial distribution asymptotically closer to the Exponential p.d.f., that is to the highest possible time-wise randomness. In that respect random frequency division and synthesis of RPTs as well as RPT computing are stable, self-healing processes which tend to diminish effects of imperfections in hardware.

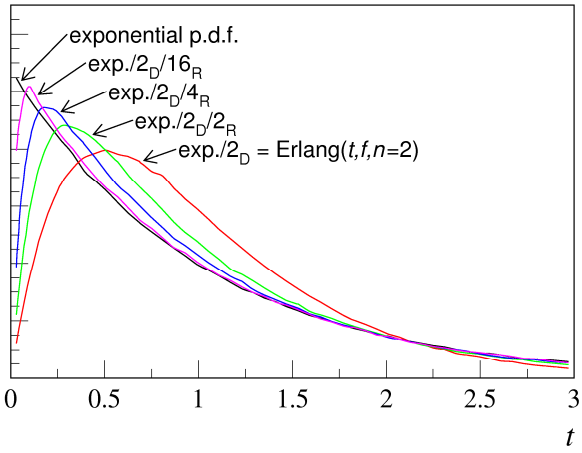

Figure 5. Waiting time distributions of an RPT (exponential) and of an RPT divided by factors: 2_D, 2_D2_R, 2_D4_R and 2_D16_R.

A complex circuits for frequency division by means of multiplication by a number smaller than 1, as well as for synthesis of an arbitrary random frequency, have been developed and presented in our earlier work [20]. Such circuits can be used to realize a paradigm of random pulse computing [21] which allows for complex, fast and reliable calculations even with slow and unreliable hardware – probably a principle used in biological systems.

V. RANDOM COUNTER

Various circuits possible with deterministic flip-flops are also realizable with RFFs but function of the random counterpart can be quite different. Building tools for systematic understanding of properties of logic circuits containing random flip-flops is an interesting open challenge.

For example the $1/2_R/2_D$ frequency divider explained above (Fig. 4c) can be considered as a single bit random counter. Indeed, usual approach to frequency division is by use of counters. To that end let us now explore an equivalent of a deterministic synchronous 4-bit counter but realized with TRFFs rather than with TFFs, as shown

in Fig. 6. This circuit has a rich set of complex properties not all of which have been explored yet.

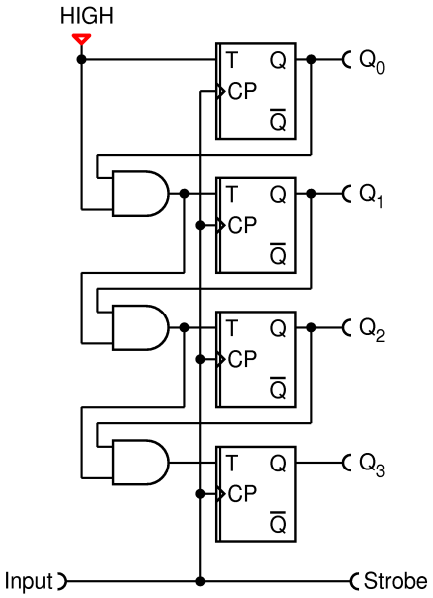

Figure 6. Synchronous 4-bit random counter. With each clock pulse the counter randomly advances up similar to random walker on a line.

The counter has 16 possible states which can be represented by a binary number $\mathbf{Q}=\{Q_3,Q_2,Q_1,Q_0\}$ whose value is in the range from 0 to 15. Unlike its deterministic counterpart which counts from 0 to 15, then folds back to 0 etc., the output value of the random counter behaves like a random walker that wonders around the mean value of 15/2. The 4-bit binary numbers **Q** behave like random draws from the Binomial distribution with n = 15 trials and trial success probability p = ½. It can be used as a generator of such values, but at the moment it is not known how to make a random counter up to an arbitrary integer number n.

When considered individually, each of the outputs Q_i (taken in synchronization with the Strobe) yields a random number sequence with zero bias but a strong autocorrelation characterized by the serial autocorrelation coefficient with a lag k (defined for example in [22]) equal to: $a_k(Q_i) = (1-2^{-i})^k$. The coefficients obey geometric law with respect to the lag k.

If the Input is fed by a random pulse train, each output Q_i gives another random pulse train. The mean frequency of i-th output (Q_i) is will be equal to the input mean frequency divided randomly by 2^{i+1} and then deterministically by 2 (in our notation: $f(Q_i) = f_{in}/(2^{i+1})_R/2_D$) but random pulse trains appearing at outputs Q_0-Q_3 are not statistically independent and cannot be combined for frequency synthesis.

VI. Random Programming Language Instructions and Probabilistic Computing

As noted in the introduction, today's computers are deterministic and cannot *per se* generate any random action which poses serious limitations. Should computer microprocessors be equipped with random logic circuits, such as random flip-flop, they would be able to generate random numbers, make random decisions and execute random instructions, for example random branching instruction. Conventional, deterministic branching instruction typically takes the following form:

```
IF {condition} THEN
 {block1}
ELSE
 {block2}
ENDIF
```

where *condition* is a Boolean-valued function, such as "A>B". If *condition* is fulfilled then program flow deterministically branches to the *block1* otherwise to *block2* after which it continues at the first instruction after ENDIF. Following the logical reversibility of computing [16] this (and in fact any) instruction can be inverted. To facilitate inversion, special universal programming languages have been formulated (e.g. R, PISA, LISP). This led to an automatic program inverter in LISP [23] capable of inverting any program written in LISP. Invertible programming is important because it promises computing with reduced power dissipation - a problem that has virtually stopped advance of clock frequency of computer processors about year 2005. Probably the most devastating practical consequence of inverse programming is that any cryptographic primitive, such as the encryption algorithm AES, could have an inverse that only needs to be "calculated" once and that could be made beforehand. Having such an "inverse" would be a great help in cryptanalysis: a single attack on a ciphertext could in principle yield both plaintext and the key. On the other hand, programming instructions relying on true randomness are non-invertible and therefore hold promise of safer cryptography, such as quantum or stochastic [24]. In those, Alice and Bob iterate via authenticated messages a certain randomized algorithm that converges to a common key with a probability arbitrary close to 1. The algorithms itself are non-invertible and use abundant quantity of random numbers. Here we give two examples of randomized instructions. A random branching instruction may have the following form:

```
RIF {prob} {condition} THEN
 {block1}
ELSE
 {block2}
ENDIF
```

where *prob* could be a real-valued probability of branching to *block1* if *condition* is TRUE, otherwise branching to *block2*. In a real-world implementation parameter *prob* could be compared to a single-precision float number which consists of 24 bit random mantissa and fixed 8 bit exponent and sign part. A 24 random flip-flop register could produce one such random number in a single processor clock – incomparably faster than any pseudo-random number algorithm executed in software, and on top of that truly random and non-invertible. A version of this would be random GOTO instruction that

would branch to any of the labels in the list with equal probability:

RGOTO label1, label2, label3, ...

Randomized algorithms [4] make use not only of random numbers but also of random decisions. In fact, computers *per se* do not compute or use numbers: they only make Boolean operations between binary values which we interpret as numbers (or letters, pictures, etc.). Even simplest numerical operations such as addition or multiplication are "higher level" operations build of very many basic logic operations. It is therefore tempting to believe that the most optimal use of randomness would be at the level of basic logic operations instead.

Another issue is the speed of random number production. In Monte Carlo programs with intensive use of random numbers their explicit production in software by mathematical operations can amount a significant portion of CPU resources. Having a specialized register consisting of random flip-flops, to generate the whole random number in a single CPU cycle, would greatly improve the CPU performance.

In order to fully grasp computational power of a randomized computer, a new type of programming language would be required which could use a standardized and efficient access to random bit registers, execute random decisions and random logic operations.

VII. GAUSSIAN WHITE NOISE GENERATOR

Gaussian white noise is a very useful resource for various techniques such as: real time speech and music synthesis, measuring and testing of audio equipment and for radio communication circuits. Random logic can be used quite elegantly for production of analog white noise with exceptionally flat power density spectrum. Circuit shown in Fig. 7, driven by the periodic oscillator of frequency f_{osc}, generates at its output Gaussian white noise whose frequency spectrum envelope is nearly flat from 0 Hz till some portion of f_{osc}. The envelope of the power density is given by:

$$\frac{dP}{df} = \left(\frac{\sin\left(\pi \frac{f}{f_{\text{clock}}}\right)}{\pi \frac{f}{f_{\text{clock}}}} \right)^2 \qquad (2)$$

The power density continuously drops down falling only -0.1dB at 0.12 f_{clock}, -1dB at 0.26 f_{clock} at and half of the power (-3dB) at 0.44 f_{clock}. If faster drop at the end of the spectrum is desired, one could pass the output through an active analog low-pass filter. In that case, the flatness of the spectrum is also affected by the transfer function of the filter. As is well known in the art, for maximum flatness in the pass region one should use the *n*-th order Butterworth filter, whereas for the maximum steepness in the stop region and minimum ripples in the pass region one should use the Chebyshev type of low-pass filter [25]. Digital filtering offers further possibilities to shape the power density virtually at will.

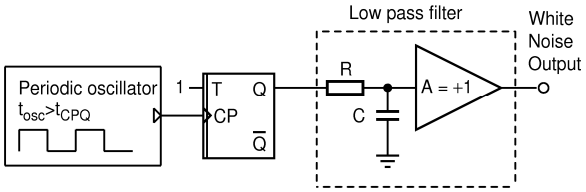

Figure 7. A practical realization of analog Gaussian white noise generator by means of a single random flip-flop.

A detailed mathematical treatment of this type of white noise generator and its spectrum is given in [26] and an improved version in [27] while suitable low-pass filters are explained for example in [25]. If the pseudorandom source was used, the spectrum would consist of equidistantly spaced spikes (excluding 0Hz) rather than being truly flat. The comb-like spikes in the pseudo-random noise come from the finite period of the pseudo-random number generator, whereas the period of a non-deterministic generator is infinite and consequently the spectrum is continuous. An interesting characteristic of the analog noise generator presented here is that the spectrum is extremely flat at the low frequency end and extends all the way to 0 Hz, which is to be contrasted to various semiconductor sources, such as Zener diodes or bipolar transistors whose spectrums suffer from 1/f rise in that region, as well as with PRNG based generators that exhibit spectral ripples and a cut-off near zero. Random flip-flops can also be used to generate other random amplitude analog signals.

VIII. SYMMETRIC BINARY CHANNEL WITH NOISE

In information-theoretic secure cryptographic protocols based on noisy channels [28-29] the crucial resource is a physical device called "symmetric binary channel with noise" (BSCN), which flips the data bit with a predetermined probability p_{err}, known also as *bit error probability*. Such a device effectively adds a precise, predetermined quantity of non-deterministic noise (entropy) to the stream of digital data bits. Circuit shown in Fig. 8 is a practical realization of a BSCN using previously described random frequency division circuit. We assume that the data bits at the Data Input appear in synchronization with the positive going edges of the Strobe. The data bits and the random sequence from the divider's output are synchronized by means of the pair of D-type flip flops and then XOR-ed to obtain a bit flip with probability $p_{err} = \lambda$.

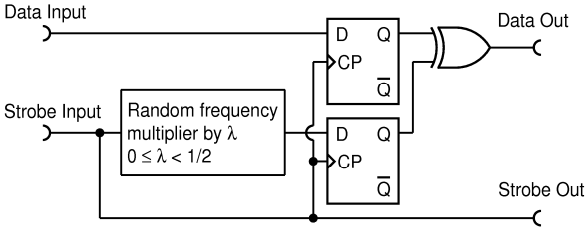

Figure 8. Realization of symmetric binary channel with noise by means of the random divider circuit. Input data bits are either copied to the output with probability (1 - λ) or inverted with the probability λ.

For binary channels with noise considered in information theory bit error probability is usually a small number, and is absolutely limited by $0 \le p_{err} < 0.5$.

IX. DICE THROWER

And finally some fun. Circuit in Fig. 9 after each request generates one random number between 1 and 6 (in binary or BCD notation) thus emulating throws of a perfectly fair dice. What happens is that upon a request signal on the input "Request" the device produces one random number in the range 0-7. If it happens to produce 0 or 7 then the periodic oscillator sends additional requests until the random number happens to fall between 1 and 6. New requests are not possible until the last one is completed which is signaled by "Ready" going HIGH. Note that this particular circuit is permutation symmetric in the three flip-flops meaning that it is irrelevant which binary value is assigned to which output. Moreover, the assignment can be changed at will and at any time - the circuit will still produce sequence of absolutely fair and uncorrelated random throws! This "dice" is unpredictable: collection of all throws made so far contains zero information about the outcome of the next throw. This example illustrates usability of RFFs in hazard games, online gambling and gaming automata.

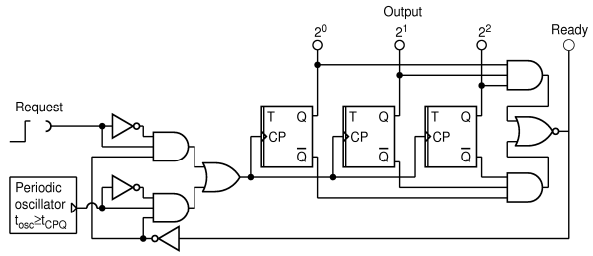

Figure 9. A random logic circuit which generates equiprobably one random binary number in the range of 1 to 6 upon each request, thus mimicking throws of a perfectly fair dice.

In a similar fashion one could create circuits to mimic any lottery game.

X. REALIZATION OF (PSEUDO) RANDOM FLIP-FLOP

Apparently, one can think of a random flip-flop as consisting of an ordinary flip-flop (of the same type) and a physical source of randomness that will be "consulted" at the time when clock pulse arrives in order to make decision of whether the clock pulse will be accepted (action) or rejected (no action). In that respect a RFF is a simplest mechanism to obtain a random bit from a physical source of randomness. Conversely, a random bit generator (RBG) can be used to build a random flip-flop. Figure 10. shows a schematic of a RFF with an internal pseudo-random bit generator (PRBG) or physical true random number generator (TRBG) .

It may seem odd to use a RBG to build RFF which can be used as a RBG (Section 3). However our point is that packaging randomness in form of a RFF rather than RBG gives much more versatility because RFF can be conveniently used for so many digital and analog applications. In that respect a random number generator is just one out of many possible applications of random flip-flop.

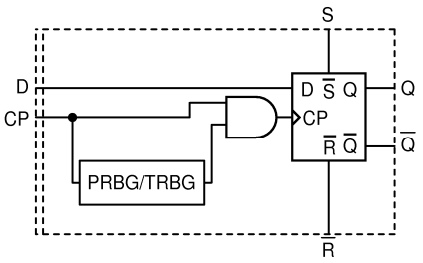

Figure 10. Random D-type flip-flop containing an internal random number generator.

It turns out that for usability of RFF should preferably have a well defined propagation delay which should be the same for all RFFs used in a given circuit. (Just as it is the case for flip-flops found on the same chip.) This is necessary for synchronization of several RFFs which is important for synchronous counters, random frequency dividers, random frequency synthesis etc.

By definition random flip-flop is a non-deterministic device. Nevertheless in some cases pseudorandom behavior can be tolerated or perhaps preferred. To that end a linear feedback shift register (LFSR) [13-14] can be used and it already features the constancy of the delay time. If nothing else, pseudo-random flip-flop (PRFF) is technically interesting because it can be built from standard logic circuits. The leftover problem of initializing a PRFF, especially in case of using many of them in a single design, can be conveniently solved by use of recently found Boolean chaos [12]. Having this, all circuitry required for realization of a PRFF can be programmed in an FPGA.

It is generally straightforward to make PRFF with a constant delay time, a feature which is highly desirable but as we shall see not easy to obtain with sources of true randomness. Additional bonus of using LFSR is that the total propagation time of the RFF is constant and independent of the length of the LFSR so highly complex LFSRs can be used at no cost in speed. The propagation time of the resulting PRFF is very small: just about twice the propagation time of the DFF employed. However one has to bare in mind that pseudo-random flip-flop is in fact deterministic device, built only from deterministic logic elements and therefore its output is predictable. This compromises its usability in cryptographic and some other applications. Therefore generally, a truly random flip-flop would be highly desirable. Quantum physics is known to allow for true randomness [15], [30] but general problem with physical random phenomena is that they either create random events at random times or at known times but with probability smaller than 1 and therefore random events might not be available at the time of request leading to non-constant propagation delay. The concept of RFF is very new and research on its possible realizations by using physical random phenomena is under way.

XI. CONCLUSION

We introduce a new non-sequential logic element, the random flip-flop, and discuss its applications in generating

random numbers, realizing random counters, randomness preserving frequency dividers, probabilistic Turing computers, analog noise generators, binary channels with noise and gambling automata. Random flip-flops feature logic inputs and outputs compatible with ordinary logic circuits and therefore can be easily combined with them. While Boolean logic allows us to predict functioning of deterministic logic circuits, building of tools for systematic understanding of properties of logic circuits that contain random flip-flops is an interesting opened challenge.

***Abstract*—Elliptic curves are gaining momentum as scientists are continuously proving their security and performance. Pairings over elliptic curves are relatively new in the world of cryptography. Researchers are coming with new cryptographic usage of pairings for over ten years. ID-based cryptography is also gaining popularity because of the certificate-less mode of work. Blind signatures are appropriate schemes when user anonymity is wanted as property. One possible type of blind signature is ID-based blind signature based on bilinear pairings. For easy computation we look into pairing-friendly elliptic curves for implementation of pairings. This paper will review state of the art ID-based blind signature schemes from pairings over elliptic curves which are suitable for building blind signatures as part of e-voting protocols. We give comparative results about the computation cost of arithmetic operations. In our knowledge, this is first paper which gives head-to-head bandwidth comparison of the interactive protocol in the signing algorithm of blind signature schemes. The results are easy to use when choosing appropriate blind signature scheme for e-voting protocols.**

***Keywords*—elliptic curves, cryptography, pairing, blind signature, e-voting**

I. Introduction

For almost thirty years scientist and practitioners are trying to come up with elegant solution which will be a substitute for traditional voting. E-Voting is relatively recent tool in the democratic processes. Many cryptographic protocols have been invented for more secure and efficient e-voting processes. These protocols are heavily burdened with the many properties that they have to fulfil.

As soon as cryptographers come up with new security mechanisms, e-voting protocols are starting to follow path. The base notion of secure protocols is the identity certification. The standard public key cryptosystem (PKC) has one private key (SK) and one public key (PK) for each user. Additionally, every user has some identification (ID) which is linked to his PK by means of certificates. Therefore, a prerequisite step of communication is to verify the certificate of the user. This additional step in communication also means that the system has to keep all certificates which leads to additional storage and computing requirements. In 1984 Shamir [1] introduced new kind of encryption and signature schemes, so-called ID-based schemes, in order to simplify the key management in standard PKC's. ID-based PKC has the property that a user's identity is his public key, and the private key can be derived by a trusted authority called private key generator (PKG).

Bilinear pairings were firstly used to attack the DLP problem and reduce DLP on some elliptic curves (or hyperelliptic curves) to the DLP of representative finite fields (MOV attack [2] and FR attack [3]). However, recently bilinear pairings have been employed in "good" light, in construction of new ID-based cryptographic primitives. In 2000 Joux [4] made one-round three party Diffie-Hellman key agreement protocol. In 2001 Boneh and Franklin [5] made ID-based encryption scheme based on bilinear pairings. Again in 2001, Boneh, Lynn and Shacham [6] made basic signature scheme (BLS signatures) using bilinear pairings which has the shortest length among all signature schemes.

Blind signature is interactive signature scheme between user and signer, devised by Chaum in 1982 [7]. Blind signature S_b is signature on a blinded message M (let us call it M_b). The signer can not deduce any information about M and anyone can verify that the signature S_b is from the signer for the message M. Blind signatures provide anonymity of users for electronic money, or in our case, for e-voting. There are more types of blind signatures, such as fair (involve third party for blindness revocation in case of dispute) or partially blind (user and signer agree on some mutually known piece of information from the message M). Horster et al. [8] divide blind signatures into four categories: hidden, weak, interactive blind and strong blind. The later categorization treats the message as (a) document and (b) signature parameters, and the four categories of blind signatures determine the knowledge of the signer about the relation of (a) and (b).

Blind signatures have found their way into many protocols. E-voting uses blind signatures to obtain votes without violating the anonymity of the voter. In this protocol, the voter usually asks for blind signature on his encrypted vote. Then the voter unveils the signature and sends the signed ballot for counting. This scenario ensures that the administrator which checks the eligibility of the voter doesn't see the plaintext vote. Further more, this means that the e-vote process can have more roles, divided among more parties for higher robustness of the system. Blind signatures have bee used in many e-voting protocols [9], [10], [11], [12]. Because ID-based cryptography has certain advantages, especially in the cheaper setup of a PKI, there are current e-voting protocols which use ID-based blind signatures [13], [14], [15]. Because blind signatures are used in the casting of every vote, it is of great importance that this operation does not become the bottleneck of the protocol. This paper reviews ID-based blind signatures and compares the

arithmetic operations for their execution. Implementors have many algorithms to choose from, depending on the needs of the protocol. This paper is just part of the bigger research in e-voting protocols for low-resource devices, such as mobile phones. If we are to implement decent e-voting protocol intended for big audiences then we have to choose the most optimal algorithms in terms of processing requirements.

This paper reviews the ID-based blind signatures in [16], [17], [18], [19], [20], [21], [22]. These blind signatures were devised in the last ten years of research papers. Here we bring the protocols under one metric and compare them. First we give detailed algorithms of each of the blind signatures scheme. With this step we can easily see the similarities and the inventions that authors found in ID-based blind signatures. The comparison includes required assumptions, security model, computational cost and bandwidth cost. We can understand the computational cost and the bandwidth cost only if we have in mind implementation of these schemes. In this paper we use the Panda project [23] for calculating the cost of each arithmetic operations and the size of the operands passed around in the interactive protocols. This is the framework under which we compare the ID-based blind signatures from bilinear pairings.

The rest of the paper is organized as follows: Section 2 covers the preliminary terms used in the blind signatures. Section 3 explains the reviewed blind signature protocols. In Section 4 we give comparative data about the cost of implementation and running of the protocols. Finally, in Section 5 we conclude the paper.

II. Preliminaries

A. Elliptic curves and pairings

Definition 1. *Let E be elliptic curve defined over a finite field F_p denoted by the equation $E : y^2 = x^3+ax+b$. Then, $E(F_p)$ is denoted as the set of solutions (x, y), $x, y \in F_p$, where x and y satisfy E. There is another element on the curve which doesn't belong to F_p, denoted as point-at-infinity $\mathcal{O}$ and acts as the neutral addition element.*

Definition 2. *Consider the map $e : G_1 \times G_2 \to G_3$ where G_1 and G_2 are additive groups, and G_3 is a multiplicative group. The function e is a bilinear pairing if it satisfies the following properties:*

1) *Bilinearity: for all $P, P^{'} \in G_1$, $Q, Q^{'} \in G_2$ $e(Q+Q^{'}, P) = e(Q, P)e(Q^{'}, P)$ and $e(Q, P+P^{'}) = e(Q, P)e(Q, P^{'})$.*
2) *Non-degeneracy: $e(Q, P) = 1$ if and only if $P = \mathcal{O}$ or $Q = \mathcal{O}$.*
3) *Computable: There exists an algorithm A which efficiently computes $e(P, Q)$ for all $P \in G_1$, $Q \in G_2$.*

For the defined bilinear function e it holds $e(aQ, bP) = e(bQ, aP) = e(abQ, P) = e(Q, abP) = e(Q, P)^{ab}$, for arbitrary $a, b \in Z_r$.

Definition 3. *Random Oracle Model (ROM): Protocols under ROM are proved secure under additional assumptions that there exist publicly available functions chosen at random. Then, concrete implementations are obtained by replacing the random oracles with cryptographic hash functions (like SHA or MD5) [24].*

Definition 4. *ID-Based Blind Signature Scheme (IBSS) consists of four algorithms: Setup, Extract, Issue and Verify. The Setup algorithm is run by trusted party called PKG which generates the public parameters and the master key. The public parameters are published and the master key is kept secret by PKG. Extract algorithm has as input the public parameters and the master key, and generates the private key D_{ID} for given ID. Issue algorithm blindly issues a signature for a message. The Verify algorithm inputs a signature, message, ID and the parameters of the scheme, outputs 1 if the signature is valid for the message and ID, or outputs 0 otherwise.*

B. Security assumptions

Next we explain the security assumptions used by the authors as difficult problems on which they rely in the creation of blind signatures.

- **Decisional Diffie-Hellman (DDH):** given P, aP, bP, cP output *yes* if $c = ab$, or output *no* otherwise.
- **Computational Diffie-Hellman (CDH):** given P, aP, bP output abP.
- **Gap Diffie-Hellman group (GDH):** Group G is GDH group if there is efficient polynomial time algorithm which solves the DDH problem and there is no polynomial time algorithm which solves the CDH problem.
- **Bilinear Diffie-Hellman (BDH):** given P, aP, bP, cP output $e(P, P)^{abc}$.
- **Decisional Bilinear Diffie-Hellman (DBDH):** given $P, aP, bP, cP, r, a, b, c$ output *yes* if $r = e(P, P)^{abc}$, or output *no* otherwise.
- **ROS problem:** Given an oracle random function $F : Z_q^l \to Z_q$, find coefficients $a_{k,i} \in Z_q$ and a solvable system of $l + 1$ distinct equations in the unknowns $c1, c2, ..., c_l$ over Z_q: $a_{k,1}c_1 + ... + a_{k,l}c_l = F(a_{k,1}, ..., a_{k,l})$, for $k = 1, 2, ..., t$.
- **Bilinear Diffie-Hellman Inversion (BDHI):** Given aP, bP, cP compute S, T s.t. $e(S, T) = e(P, P)^{abc}$.

III. Blind signatures

This section overviews the ID-based blind signature schemes in [16], [17], [18], [19], [20], [21], [22], in order of appearance in the scientific literature. Each of this schemes is explained in its own subsection.

A. ZK1 scheme [16]

This scheme is the first ID-based blind signature scheme from bilinear pairings. The IBSS scheme is given as follows:

[Setup]: Let P be a generator of GDH group G_1. PKG chooses a random $s \in Z_q^*$ and set $P_{pub} = sP$. Then two hash functions are defined as $H_1 : \{0, 1\}^* \to Z_q$ and $H_2 : \{0, 1\}^* \to G_1$. The published parameters are $\{G_1, G_2, q, P, P_{pub}, H_1, H_2\}$ and s is the master key.

[Extract]: Given identity ID, PKG calculates public key $Q_{ID} = H_2(ID)$ and returns private key $S_{ID} = sQ_{ID}$.

[Issue]: This algorithm is proposed as interactive protocol between the signer and the user:

- **Commitment:** Signer randomly chooses $r \in Z_q^*$, computes $R = rP$ and sends R to User.
- **Blinding:** User randomly chooses $a, b \in Z_q^*$, computes $c = H_1(m, e(bQ_{ID} + R + aP, P_{pub})) + b$ and sends c to Signer.
- **Signing:** Signer computes $S = cS_{ID} + rP_{pub}$ and sends S to User.
- **Unblinding:** User computes $S^{'} = S + aP_{pub}$ and $c^{'} = c - b$ and outputs $\{m, S^{'}, c^{'}\}$.

[Verify]: Verify that $c^{'} = H_1(m, e(S^{'}, P)e(Q_{ID}, P_{pub})^{-c^{'}})$.

The authors in [16] proved that the scheme is blind and that the security on the generic parallel attack depends on the ROS problem. But, Wagner in [25] claimed that ROS can be broken in subexponential time and in order to be resistant q needs to be at least 1600 bits long. This makes this scheme inefficient in a practical way.

B. ZK2 scheme [17]

The authors in [16] proposed new IBSS scheme which does not depend on the ROS problem. Their scheme is given as follows:

[Setup]: This algorithm is the same as in ZK1 scheme.

[Extract]: This algorithm is the same as in ZK1 scheme.

[Issue]: This algorithm is an interactive protocol between the signer and the user:

- **Commitment:** Signer randomly chooses $r \in Z_q^*$, computes $U = rQ_{ID}$ and sends U to User.
- **Blinding:** User randomly chooses $\alpha, \beta \in Z_q^*$, computes $U^{'}\alpha U + \alpha\beta Q_{ID}$ and $h = \alpha^{-1}H_1(m, U^{'}) + \beta$, and sends h to Signer.
- **Signing:** Signer computes $V = (r + h)S_{ID}$ and sends V to User.
- **Unblinding:** User computes $V^{'} = \alpha V$ and outputs $\{m, U^{'}, V^{'}\}$.

[Verify]: Verify that $e(V^{'}, P) = e(U^{'} + H_1(m, U^{'})Q_{ID}, P_{pub})$.

This scheme has proven the blindness property, but there is no formal proof against one-more signature forgery.

C. HCW scheme [18]

The authors in [18] attack the unforgeability claim under generic parallel attack of ZK2 scheme [17] and present new efficient IBSS scheme secure under the ROM model:

[Setup]: Let P be a generator of GDH group G_1. PKG chooses random $r \in Z_q^*$ and set $P_{pub} = sP$. Then two hash functions are defined as $H_1 : \{0,1\}^* \times G_2 \rightarrow Z_q^*$ and $H_2 : \{0,1\}^* \rightarrow G_1$. The published parameters are $\{G_1, G_2, e, q, P, P_{pub}, H_1, H_2\}$ and s is the master key.

[Extract]: Given identity ID, PKG computes $P_{ID} = H_2(ID)$ and returns private key $S_{ID} = sP_{ID}$.

[Issue]: This algorithm is an interactive protocol between the signer and the user:

- **Commitment:** Signer randomly chooses $r \in Z_q^*$, computes $R^{'} = e(P_{ID}, P_{pub})^r$ and sends $R^{'}$ to User.
- **Blinding:** User randomly chooses $t_1, t_2 \in Z_q^*$, computes $R = R^{'t_1}e(P_1, P)^{t_2}$, $h = H_1(m, R)$, $h^{'} = ht_1$ and sends $h^{'}$ to Signer.
- **Signing:** Signer computes $V^{'} = (rh^{'} + 1)S_{ID}$ and sends $V^{'}$ to User.
- **Unblinding:** User checks if $e(V^{'}, P) = R^{th^{'}}e(P_{ID}, P_{pub})$, computes $V = V^{'} + ht_2P_1$ and outputs $\{m, R, V\}$.

[Verify]: Verify that $e(V, P) = R^{H_1(m,R)}e(P_{ID}, P_{pub})$.

Authors have proven unforgeability of this scheme under ROM, but they don't give formal proof against one-more signature forgery, just like the scheme in [17].

D. GWWF1 scheme [19]

This scheme is the first IBSS that proposes optimal rounds in the interactive protocol. GWWF1 has one-round interactive protocol between the user and signer in the phase of issuing of blind signatures. The scheme is given as:

[Setup]: Let P be a generator of GDH group G_1. PKG chooses random $r \in Z_q^*$ and set $P_{pub} = sP$. Then two hash functions are defined as $H_1, H_2 : \{0,1\}^* \rightarrow G_1$. The published parameters are $\{G_1, G_2, e, q, P, P_{pub}, H_1, H_2\}$ and s is the master key.

[Extract]: Given identity ID, PKG computes $Q_{ID} = H_1(ID)$ and returns private key $D_{ID} = sQ_{ID}$.

[Issue]: This algorithm is an interactive protocol between the signer and the user:

- **Blinding:** User randomly chooses $r_1 \in Z_q^*$; computes $P_m^{'} = r_1H_2(m)$ and sends $P_m^{'}$ to Signer.
- **Signing:** Signer randomly chooses $x_{ID} \in Z_q^*$, computes $A^{'} = x_{ID}P_m^{'}$, $B^{'} = x_{ID}^{-1}D_{ID}$, $C^{'} = x_{ID}P$, and sends $A^{'}, B^{'}$ and $C^{'}$ to User.
- **Unblinding:** User verifies $e(A^{'}, P) = e(P_m^{'}, C^{'})$ and $e(Q_{ID}, P_{pub}) = e(B^{'}, C^{'})$, then chooses random $r_2 \in Z_q^*$, computes $A = r_2r_1^{-1}A^{'}$, $B = r_2^{-1}B^{'}$ and $C = r_2C^{'}$ and publishes $\{m, A, B, C\}$.

[Verify]: Compute $P_m = H_2(m)$ and verify that $e(A, P) = e(P_m, C)$ and that $e(Q_{ID}, Ppub) = e(B, C)$.

Authors have proven the blindness property and security against one-more forgery under parallel chosen message and given ID attacks. These proofs are based on one-more BDHI

assumption that authors devised in their proof (similar to the one-more RSA-inversion in [26] which proves Chaum's blind signature scheme [7]).

E. KKS scheme [20]

The KKS scheme is actually a generalization of modified ElGamal signatures which are extended to blind signatures scheme [27]. Horster [28] showed that using the general signature equation $\tilde{A} \equiv \alpha\tilde{B}+k\tilde{C} \pmod q$ one can obtain many variations of the blind signature scheme. The KKS scheme has 18 variants based on permutations of the general signature equation. Here we present just one variant of the possible permutations:

[Setup]: This algorithm is the same as the Setup algorithm in HCW scheme.

[Extract]: This algorithm is also the same as the Extract algorithm in HCW scheme.

[Issue]: This algorithm is an interactive protocol between the signer and the user:

- **Commitment:** Signer chooses random $k \in Z_q^*$, computes $\tilde{t} = e(P,P)^k$ and sends $\tilde{t}$ to User.
- **Blinding:** User chooses random $a, b \in Z_q^*$, computes $t = \tilde{t}^a e(P,P)^b$, $r = H_1(m,t)$, $\tilde{r} = a^{-1}r$ and sends $\tilde{r}$ to Signer.
- **Signing:** Signer computes $\tilde{U} = \tilde{r}S_{ID} + kP$ and sends U to User.
- **Unblinding:** User verifies that $e(\tilde{U},P)e(Q_{ID},P_{pub})^{-\tilde{r}} = \tilde{r}$, computes $U = a\tilde{U}+bP$ and outputs $\{m,r,U\}$.

[Verify]: Verify that $e(U,P)e(Q_{ID},P_{pub})^{-r} = r^m$.

The authors give proof for the blindness property, but do not give official proof against one-more signature forgery.

F. RARG scheme [21]

The RARG scheme in construction is very similar to the schemes [18] and [20] and is based on Hess ID-based signature scheme [29].

[Setup]: This algorithm is the same as the Setup algorithm in HCW scheme.

[Extract]: This algorithm is also the same as the Extract algorithm in HCW scheme.

[Issue]: This algorithm is an interactive protocol between the signer and the user:

- **Commitment:** Signer randomly chooses $k \in Z_q^*$, computes $R = e(P,P)^k$ and sends R to User.
- **Blinding:** User randomly chooses $a, b \in Z_q^*$, computes $R^{'} = e(bQ_{IDs}+aP, P_{pub})R$, $V = H_1(m,R^{'})+b$ and sends V to Signer.
- **Signing:** Signer computes $S = Vd_{IDs}+kP$ and sends S to User.
- **Unblinding:** User computes $S^{'} = S + aP_{pub}$, $V^{'} = V - b$ and outputs $\{m, S^{'}, V^{'}\}$.

[Verify]: Verify that

$$V^{'} = H_1(m, e(S^{'},P)e(Q_{IDs},P_{pub})^{-V^{'}}).$$

The authors prove the blindness property of the scheme and the unforgeability due to Hess ID-based signature [29].

G. GWWF2 scheme [22]

This scheme is an improved version of the GWWF1 scheme [19]. In [22] the authors give two versions of their scheme in [19], named IBBS-1 and IBBS-2. Both schemes are very similar to the GWWF1 scheme. We would not go into details, but will list the resulting cost of the scheme together with all the schemes reviewed in this paper.

In the next section we present comparable results of the computation and bandwidth cost of the schemes explained in this section.

TABLE II. BANDWIDTH COST OF SCHEMES: G_1 - ELEMENT FROM GROUP 1; G_P - ELEMENT FROM PAIRING GROUP; S - ELEMENT FROM THE BASE FIELD (SCALAR); C - COMMITMENT PHASE; B - BLINDING PHASE; S - SIGNING PHASE; P - SIGNATURE PUBLISH PHASE.

scheme	direction	G_1	G_p	s
ZK1	**C: S to U**	1

IV. RESULTS

The aim of this paper is to give comparative review of ID-based blind signature schemes in the scientific literature. We reviewed seven schemes [16], [17], [18], [19], [20], [21], [22] and gave detailed description of their algorithms in the previous section and the security assumptions and proofs used by the authors. In this section we present the results in several forms.

The first comparative table I is representing computation cost - it gives count of operations with elements in the base field and the group elements. For better understanding of this

TABLE I. COMPUTATIONAL COST OF SCHEMES: P - PAIRING; M - SCALAR AND GROUP 1 ELEMENT MULTIPLICATION; A - ADDITION OF TWO GROUP 1 ELEMENTS; H - HASH FUNCTION $H : \{0,1\}^* \rightarrow G_1$; M_S - MULTIPLICATION OF TWO SCALARS; A_S - ADDITION OF TWO SCALARS; I_S - INVERSION OF SCALAR; C_S - COMPARISON OF TWO SCALARS; H_S - HASH FUNCTION $H_s : \{0,1\}^* \times G_2 \rightarrow Z_q^*$; E_P - EXPONENTIATION OF PAIRING ELEMENT; M_P - MULTIPLICATION OF TWO PAIRING ELEMENTS; C_P - COMPARISON OF TWO PAIRING ELEMENTS.

scheme		P	M	A	H	M_s	A_s	I_s	C_s	H_s	E_p	M_p	C_p
ZK1	**S**		3	1									
	U	1	3	3			1			1			
	V	2						1		1	1	1	
ZK2	**S**		2				1						
	U		3	1		2	1	1		1			
	V	2	1	1						1			1
HCW	**S**	1	1				1				1		
	U	3	1	1	1	2					2	2	
	V	2			1						1	1	1
GWWF1	**S**		3					1					
	U	4	4		1	1		2					2
	V	4			1								2
KKS	**S**	1	2	1							1		
	U					1		2		1	3	2	1
	V	2						1		1	1		
RARG	**S**	1	2	1							1		
	U	1	4	2			2			1			
	V	2						1	1	1	1	1

	U	4	4		1	1		2					2
	V	4			1								2
GWWF2, IBBS-2	**S**		3	1									
	U	4	5	4	1			1					2
	V	4		1	1								2

TABLE III. BANDWIDTH COST OF SCHEMES: GIVEN BANDWIDTH NEEDED FOR EACH PHASE, AND TOTAL BANDWIDTH FOR THE SIGNING PROTOCOL. THE NUMBERS OF RESULTS ARE GIVEN IN BYTES.

scheme	direction	cost:
ZK1	**C: S to U**	**32**
	B: U to S	**32**
	S: S to U	**32**
	P: U to BB	**64**
	total:	**160**
ZK2	**C: S to U**	**32**
	B: U to S	**32**
	S: S to U	**32**
	P: U to BB	**64**
	total:	**160**
HCW	**C: S to U**	**384**
	B: U to S	**32**
	S: S to U	**32**
	P: U to BB	**416**
	total:	**864**
GWWF1	**B: U to S**	**32**
	S: S to U	**96**
	P: U to BB	**96**
	total:	**224**
KKS	**C: S to U**	**384**
	B: U to S	**32**
	S: S to U	**32**
	P: U to BB	**64**
	total:	**512**
RARG	**C: S to U**	**384**
	B: U to S	**32**
	S: S to U	**32**
	P: U to BB	**64**
	total:	**512**
GWWF1,IBBS-1	**B: U to S**	**32**
	S: S to U	**96**
	P: U to BB	**96**
	total:	**224**
GWWF1,IBBS-2	**B: U to S**	**32**
	S: S to U	**96**
	P: U to BB	**96**
	total:	**224**

table, the reader must have in mind the cost of each of these operations. This can be done by looking at the performance results of any implemented library, for example [23, Subsection 3.3].

The second comparative table II is representing bandwidth cost - it gives an overview of what is sent in the interactive protocol of signing, such as the number of group elements, pairing elements and scalars.

The third comparative table III is again about the bandwidth cost. It is depicting the spent bandwidth in each step in the interactive protocol, and the total spent bandwidth after signing algorithm. The results are calculated based on Barreto-Naehrig family of pairing friendly elliptic curves [30]. The packed size of element in G_1 is actually just the x value of the point on the curve. That size is 32 bytes. In order to retrieve the full point (or unpack) we can just solve the elliptic curve equation to get the y value. The scalar element is also 32 bytes, and the pairing element is 384 bytes. These numbers can vary in different libraries for arithmetic in elliptic curves. We refer the reader to the Panda project [23] which has implemented base field arithmetic, group field arithmetic and fast pairing implementation under Barreto-Naehrig curves.

V. CONCLUSION

This paper rounds up significant propositions for ID-based blind signatures. We can see the inner algorithms of the proposed schemes side-by-side and draw conclusions for our benefit. Further more, we have given comparative results for the cost of implementation and running of these schemes. The detailed comparison of computation cost gives number of arithmetic operations in each phase of the interactive protocol of the signing algorithm. To the best of our knowledge, this is first paper which has given detailed bandwidth comparison of the phases in the signing algorithm.

The results of this paper can be used when choosing ID-based blind signature scheme. Depending on the overall e-voting scheme, computational resources and possible bottlenecks, the reader can easily find out the right scheme. If the e-voting scenario is using powerful administrator nodes, blind signatures can be chosen s.t. the burden of the signature is with the signer. This comes very well in scenarios of computationally-weak users (internet browsers, mobile phones). In some scenarios the bandwidth may be bottleneck, for example SMS e-voting. Or maybe the number of rounds are critical because the establishment of communicational channels is hard (or expensive). All these prerequisites can be used to easily find the appropriate blind signature scheme based on our results.

***Abstract*—Since the first notions of fully homomorphic encryption more than 30 years ago, there has been numerous attempts to develop such a system. Finally, in 2009 Craig Gentry succeeded. Homomorphic encryption brings great advantages but it seems that, at least for now, it also brings many practical difficulties. Furthermore, in the last couple of years, several other fully homomorphic systems arose where each has its one advantages and drawbacks. However, with the developments in cloud computing, we need it more than ever to become practical for real-world usages. In this paper we are discussing the strengths and weaknesses of homomorphic encryption and we give a brief description of several promising fully homomorphic encryption systems. Next, we give a special attention to the homomorphic encryption systems for cloud computing. Finally, we discuss some recent developments by IBM and their open-source library for homomorphic encryption.**

I. Introduction

Today, cryptography plays important role in our lives, although many people are not fully aware of that fact. Whenever we buy something over the Internet or withdraw cash from ATM machine, cryptography protects our sensitive information.

One of the basic questions in cryptography concerns how it is possible to safely exchange information. If two parties, commonly called Alice and Bob, want to securely communicate, then they need a shared secret. This notion represents the basis of private key cryptography. In this setting Alice and Bob both have the same secret (called secret key) and they encrypt and decrypt data with it. All secure communication is limited to those that have that secret key. Of course, here we are simplifying the situation and assume that key and methods of encryption are appropriately chosen. If some third party, Eve, intercepts encrypted message it should be practically infeasible for her to decrypt it. Now, even from this abstract description, it is possible to observe one obvious drawback of private key cryptography. In order to be able to encrypt and afterwards decrypt the data, Alice and Bob must use the same key. If we add an additional condition that the key needs to be changed from time to time, question becomes, how to securely communicate (in order to exchange the key) before they can securely communicate to exchange the actual data. Almost 40 year ago, public key cryptography arose to solve that problem. In public key cryptography security relies on hard mathematical problems and each party needs a public key for encryption and a private key for decryption [1].

Additionally, Alice and Bob also wants for instance to be sure that the other party is he who says it is, and that the messages can not be changed while transmitted. For each of those constraints, appropriate solution is devised and implemented in practice. However, only a couple of months after the publication of the RSA algorithm paper [2], Rivest et al. asked the question whether it is possible to work with encrypted data, without the need for decrypting it first [3]. That question started the search for homomorphic encryption systems. It turned out that this question would pose unsolvable problem in following decades. Before going into more details about homomorphic encryption, we give a simple example why we would even need an option like that. If we have some information and we send it to the server for some additional processing, we may not want that the server can read our information. In the modern society, the need for privacy is present as never before and homomorphic encryption can help us in preserving it.

Homomorphic encryption allows us to perform operations on encrypted data without knowing the private key and without decrypting that data. When we decrypt the result of any operation, it is the same as if we carried out the calculation on the plain data. In the process of building a system with such capabilities, a plethora of systems were developed that offer partial functionalities. Those types of homomorphic encryption systems are known as partially homomorphic encryption systems. In 2009, Craig Gentry in his PhD thesis described the first fully homomorphic encryption system (FHE) [4]. From then, a number of systems were (and still are) developed that offer similar or better characteristics.

In Section 2 we give a brief introduction to the basic notions about homomorphic encryption. Several partially homomorphic encryption systems are described in Section 3. In Section 4 we describe fully homomorphic encryption as presented by Gentry and several other fully homomorphic encryption systems. Possible usages of fully homomorphic encryption with particular accent on cloud computing are discussed in Section 5. Finally, in Section 6 we give a conclusion.

II. Preliminaries

Here we give basic notions about homomorphic encryption and schemes presented. For a detailed introduction to general cryptographic notions we refer readers to [1].

A Homomorphic encryption is additive if:

$$Enc(x + y) = Enc(x) \cdot Enc(y). \quad (1)$$

A homomorphic encryption is multiplicative if:

$$Enc(x \cdot y) = Enc(x) \cdot Enc(y). \quad (2)$$

Next, we present building blocks of the homomorphic encryption system.

- Key generation is the algorithm that outputs public key P_k and secret key S_k.
- Encrypt function is the algorithm that takes public key P_k and a message m and outputs ciphertext c.
- Decrypt function is the algorithm that takes ciphertext c and a secret key S_k and outputs a message m.
- Evaluate function is an algorithm that takes evaluation key, circuit, a set of ciphertexts $c_1, ..., c_n$ and outputs a ciphertext c_e. Circuit represents a certain function realized with logical gates.

III. Partially homomorphic encryption systems

There are two different types of homomorphic encryption systems, fully homomorphic encryption systems and partially homomorphic encryption systems. Fully homomorphic encryption systems are defined over a ring and therefore support both operations, addition and multiplication. Partially homomorphic encryption systems are defined over a group and therefore support just a single operation on the encrypted data.

In last thirty or so years there have been several encryption systems that belong to the partially homomorphic encryption systems class. Those systems we can divide on a basis of the operation they support on additive homomorphic encryption systems and multiplicative homomorphic encryption systems. There are also systems that allow arbitrary many operations of one type and only a limited number (usually just one) of operations of other type.

A. Additive Homomorphic Encryption

Some well known examples of additive homomorphic encryption systems include Goldwasser-Micali system [5], Paillier system [7] and Damgard-Jurink's generalization of Paillier system [6].

The Paillier cryptosystem, invented by Pascal Paillier in 1999, is a probabilistic asymmetric algorithm for public key cryptography [7]. This cryptosystem is based on the decisional composite residuosity assumption (DCRA). DCRA assumption can be stated as the following: given a composite n ($n = p \times q$ for primes p and q) and an integer z, it is hard to decide whether z is a $n-$ residue modulo n^2 or not (i.e. it is hard to find out whether there exists y such that $z = y^n mod n^2$). Paillier cryptosystem computes encryption of $m_1 + m_2$ with public key and encryptions of m_1 and m_2. Short description of Paillier scheme is given in Algorithm 1. Implementation of that cryptosystem can be found online under the name "The Homomorphic Encryption Project" (thep) and it's main application is electronic voting where each vote is encrypted but only the sum is decrypted [8].

Suppose that we have two ciphers C_1 and C_2 such that following equations hold:

$$\begin{aligned} C_1 &= g^{m_1} \cdot r^n \ mod\ n^2, \\ C_2 &= g^{m_2} \cdot r^n mod\ n^2, \\ C_1 \cdot C_2 &= g^{m_1+m_2} \cdot (r_1 \cdot r_2)^n mod\ n^2. \end{aligned} \tag{3}$$

Algorithm 1 Paillier scheme

Key Generation KeyGen (p, q)
$Input : p, q \in P$
$Compute : n = p \cdot q, \lambda = lcm(p-1, q-1)$
$Choose : g \in Z^*_{n^2} \mid gcd(L(g^\lambda \ mod \ n^2), n) = 1 \ where \ L(u) = (u-1)/n$
$Compute : \mu = L(g^\lambda \ mod \ n^2)^{-1}$
$Output : (P_k, S_k)$
$Public \ key : P_k = (n, q)$
$Secret \ key : S_k = (\lambda, \mu)$
Encryption Enc (m, P_k)
$Input : m \in Z_n$
$Choose : r \in Z^*_n$
$Compute : c = g^m \cdot r^n \ mod \ n^2$
$Output : c \in Z_{n^2}$
Decryption Dec (c, S_k)
$Input : c \in Z_{n^2}$
$Compute : m = L(c^\lambda \ mod \ n^2) \cdot \mu \ mod \ n$
$Output : m \in Z_n$

It can be observed that Paillier cryptosystem realizes the property of additive homomorphic encryption since the product of two ciphertexts will decrypt to the sum of their corresponding plaintexts.

B. Multiplicative Homomorphic Encryption

When looking at the multiplicative homomorphic cryptosystem, good examples are previously mentioned RSA algorithm [3] and ElGamal encryption system [9]. Next we give a short description of the RSA scheme [3] as shown in Algorithm 2.

Algorithm 2 RSA scheme

Key Generation KeyGen (p, q)
$Input : p, q \in P$
$Compute : n = p \cdot q, \phi(n) = (p-1) \cdot (q-1)$
$Choose : e \mid gcd(e, \phi(n)) = 1$
$Compute : d \mid (e \cdot d) \equiv 1 \ mod \ \phi(n)$
$Output : (P_k, S_k)$
$Public \ key : P_k = (e, n)$
$Secret \ key : S_k = d$
Encryption Enc (m, P_k)
$Input : m \in Z_n$
$Compute : c = m^e \ mod \ n$
$Output : c \in Z_n$
Decryption Dec (c, S_k)
$Input : c \in Z_{n^2}$
$Compute : m = c^d \ mod \ n$
$Output : m \in Z_n$

Suppose that we have two ciphers C_1 and C_2 such that following equations hold:

$$\begin{aligned} C_1 &= m_1^e \ mod\ n, \\ C_2 &= m_2^e \ mod\ n, \\ C_1 \cdot C_2 &= (m_1 \cdot m_2)^e mod\ n. \end{aligned} \tag{4}$$

It can be observed that RSA as a homomorphic encryption system has some security weaknesses. For example, if we assume that two messages m_1 and m_2 correspond to ciphers C_1 and C_2, and if the client sends that pair (C_1, C_2) to the server, the server will perform multiplication of C_1 and C_2 and send it encrypted to the client. If the attacker intercepts ciphers C_1 and C_2 which are encrypted with the same private key, he will be able to decrypt all messages exchanged between the server and the client. This is due the homomorphic encryption multiplicativity where product of the ciphers equals cipher of the product.

C. Additive and multiplicative homomorphic cryptosystem

Each of the examples listed above allows homomorphic computation of only one operation (either addition or multiplication) on plaintexts. A step closer to the full homomorphic encryption systems represent the systems that allow arbitrary many operations of one type and limited number of operations of other type. Probably the best example of a cryptosystem which allows homomorphic computation of addition and multiplication but is not fully homomorphic systems is Boneh-Goh-Nissim cryptosystem [10] as shown in Algorithm 3. Boneh-Goh-Nissim cryptosystem supports evaluation of an unlimited number of additions but at most one multiplication. This encryption scheme is based on bilinear pairings on elliptic curves.

Algorithm 3 Boneh-Goh-Nissim scheme

Key Generation KeyGen (r)
$Input : r \in Z^+$
$Compute : \gamma(r)\ to\ obtain\ tuple\ (q_1, q_2, G, G_1, e)$
$Compute : n = p \cdot q$
$Choose : g, u \in Random$
$Compute : h = u^{q_2}$
$Output : (P_k, S_k)$
$Public\ key : P_k = (n, G, G_1, e, g, h)$
$Secret\ key : S_k = q_1$
Encryption Enc (m, P_k)
$Input : m$
$Choose : r \in Random$
$Compute : c = g^m \cdot h^r \in G$
$Output : c$
Decryption Dec (c, S_k)
$Input : c$
$Compute : m = dilog(c^{q_1})\ mod\ g^{q_1}$
$Output : m$

Here, $dilog$ represents discrete logarithm operation.

IV. Fully Homomorphic Encryption Systems

In this section we present several fully homomorphic encryption systems, starting with Gentry's systems and then covering several other constructions.

A. Gentry's FHE

The first construction of fully homomorphic scheme (based on ideal lattices which are ideals in algebraic number field) is described by Craig Gentry in 2009 [4]. This work is important not only because it represents the first fully homomorphic encryption system, but also since it served as a paradigm for later fully homomorphic encryption schemes as the one we describe in section below.

Gentry's scheme consists of several steps. First, one constructs a somewhat homomorphic encryption scheme (SWHE), which only supports a limited number of operations. In SWHE system there are usual Encrypt and Decrypt functions, but also an Evaluate function. Evaluate function conducts an operation on ciphertext where it is realized as a combinatorial circuit. However, the problem with homomorphic encryption is that ciphertext contains random noise where addition roughly doubles the noise and multiplication squares the noise. This noise becomes larger with successive homomorphic operations and only ciphertexts whose noise size remains below a certain threshold can be decrypted correctly. The origin of noise is in the probabilistic encryption process where we add some noise during the encryption, and remove that noise during the decryption. Because of this limitation, homomorphic encryption can not have arbitrary number of operations and is therefore called somewhat homomorphic encryption. Somewhat homomorphic encryption scheme is shown in Algorithm 4. To overcome this problem, Gentry devised *bootstrapping* method. In bootstrapping, Evaluate function is used to run Decrypt function. Since Evaluate works with encrypted data, the result is not the plaintext but a new encryption with reduced noise. This refreshed ciphertext can then be used in subsequent homomorphic operations. By repeated refreshing of the ciphertexts, the number of homomorphic operations becomes unlimited, and that results in a fully homomorphic encryption scheme. In order for system to work as described Decrypt function must not exceed the noise threshold. If this would not be the case, we would not be able to apply bootstrapping to the SWHE scheme. Indeed, in Gentry's original FHE scheme this condition was not satisfied. Therefore, he added a *squashing* procedure to the Decrypt function. Here, squashing means transforming SWHE scheme into one with same homomorphic capacity but with simpler Decrypt function [11]. The cost of the squashing method is that the key grows larger and more complicated.

B. FHE

After 2009 and Gentry's breakthrough result, many improvements have been made, introducing new variants, improving efficiency, and providing new features. Recently, Brakerski, Gentry and Vaikutanathan described a different framework where the ciphertext noise grows only linearly with the multiplicative level instead of exponentially, so that bootstrapping technique is no longer necessary to obtain a scheme supporting the homomorphic evaluation of any given polynomial size circuit. Currently, there are 3 main families of fully homomorphic encryption schemes:

Algorithm 4 Somewhat homomorphic encryption scheme

Key Generation KeyGen (R, B_i)
$Input : R, basis\ B_i$
$Compute : (B_{P_k}, B_{S_k}) = IdealGen\ (R, B_i)$
$Output : (P_k, S_k)$
$Public\ key : P_k = (R, B_i, B_{P_k}, S_{amp}$
$Secret\ key : S_k = B_{S_k}$

$Output : m$

- Gentry's original scheme based on ideal lattices [4].
- Van Dijk, Gentry, Halevi and Vaikuntanathan's (DGHV) scheme over the integers [12].
- Brakerski and Vaikuntanathan's scheme based on the Learning with Errors (LWE) and Ring Learning with Errors (RLWE) problems [13].

Since we already described Gentry's original scheme, now we give short descriptions of the other two schemes.

In DGHV scheme [12] a ciphertext has the form of

$$C = q \cdot p + 2 \cdot r + m, \tag{5}$$

where p is the secret-key, m is the bit plaintext (m is 0 or 1), q is a large random number and r is a small random number.

To decrypt, one calculates

$$m = (C\ mod\ p)\ mod\ 2. \tag{6}$$

It is easy to see that decryption works as long as the noise $2 * r$ is smaller than p.

Suppose that we have two ciphers C_1 and C_2 such that following equations hold:

$$\begin{aligned} C_1 &= q_1 \cdot p + 2 \cdot r_1 + m_1, \\ C_2 &= q_2 \cdot p + 2 \cdot r_2 + m_2, \\ C_1 + C_2 &= (q_1 + q_2) \cdot p + 2 \cdot (r_1 + r_2) + m_1 + m_2, \\ C_1 \cdot C_2 &= q_{12} \cdot p + 2 \cdot (2 \cdot r_1 \cdot r_2 + r_1 \cdot m_2 + r_2 \cdot m_1) \\ &\quad + m_1 + m_2. \end{aligned} \tag{7}$$

From these equations, we see that we can obtain the encryption of $m_1 + m_2$ $(mod\ = m_1 \oplus m_2)$ by computing $C_1 + C_2$. Similarly, encryption of $m_1 \cdot m_2$ can be obtained by computing $C_1 \cdot C_2$. However one gets a new ciphertext with noise roughly twice larger than in the original ciphertexts C_1 and C_2. Since the noise must remain below p, the number of permitted multiplications on ciphertexts is therefore limited. This is an example of somewhat homomorphic encryption scheme.

Scheme from Brakerski and Vaikuntanathan is known as "Fully Homomorphic Encryption without Bootstrapping" where their approach is based on Learning with Errors (LWE) and Ring Learning with Errors (RLWE) problems [13].

In RLWE problem for security parameter λ, let $f(x) = x^d + 1$ where $d = d(\lambda)$ is a power of 2. Furthermore, let $q = q(\lambda) \geq 2$ be an integer, $R = Z[x]/f(x)$ and $R_q = R/qR$. Let $\xi = \xi(\lambda)$ be a distribution over R. The RLWE problem is to distinguish two distributions, in the first distribution, one samples (a_i, b_i) uniformly from R_{q^2}. In the second distribution, one first selects $s < -R_q$ uniformly and then samples (a_i, b_i) $2R_q^2$ by sampling $a_i < -R_q q$ uniformly, $e_i < -\xi$ and setting $b_i = a_i s + e_i$. The RLWE assumption is that the RLWE problem is infeasible.

In this scheme the authors are able to obtain a direct construction of a bootstrappable encryption scheme without having to "squash the decryption circuit", and hence there is no need to apply a bootstrapping technique to achieve fully homomorphic encryption. As per Gentry's scheme, Brakerski and Vaikuntanathan started from somewhat homomorphic encryption which was constructed to work over a ring R, where R can be described as $R = Z$ for integers, or $R = Z[x]/(x^d+1)$ for polynomial ring with d being a power of 2. For integer q, R_q is used to indicate R/qR. The error distribution parameter ξ is introduced to work over the ring R, where it is set to be as small as possible. Brakerski and Vaikuntanathan somewhat homomorphic algorithms is presented in Algorithm 5.

Algorithm 5 Brakerski-Vaikuntanathan

Key Generation KeyGen (l^λ)
$Sample : S_k = s \Leftarrow R_q \mid polynomial,\ small\ coefficients \in error\ distribution\ \xi$
Encryption Enc $(S_k, \mu \in R_2)$
$Sample : a \Leftarrow R_q\ randomly, polynomiale \mid small\ coefficients \in errordistribution\ \xi$
$Compute : c = (a, a_s = 2 \cdot e + \mu)$
Decryption Dec $(c = (a, b), S_k)$
$Sample : b \Leftarrow R_q\ randomly$
$Compute : \mu' = b \cdot a_s \in R_q$
$Output : \mu = \mu' mod 2$

The key contribution of this scheme is the technique of managing noise so that it increases linearly with the multiplicative level instead of exponentially which was the case in previous FHE schemes.

V. Going to the Cloud

As Internet evolved, computing concepts changed from parallel to distributed and grid computing and recently to cloud computing. If we look for the definition of cloud computing we can find that "Cloud computing is a model for enabling convenient, on-demand network access to a shared pool od configurable computing resources that can be rapidly provisioned and released with minimal management effort or service provider interaction" [14]. Cloud computing is the most popular notion in IT today, where even an academic

report from Berkeley says “Cloud computing is likely to have the same impact on software that foundries have had on the hardware industry" [15]. They go on to recommend that “developers would be wise to design their next generation of systems to be deployed into cloud computing" [15]. Cloud computing brings many business advantages such as accessing and using configurable computing resources through sharing and virtualization techniques, and all that at a lower cost. Main disadvantages are security and privacy issues that come along with resource sharing, virtualization and possible lack of trust between business and cloud providers. Many privacy issues could be solved with using homomorphic encryption, for instance cloud user can encrypt data and store it in the cloud, where both the user and cloud provider are unable to carry on any computations on data before decrypting it. It becomes more usual even for individuals, let alone for the companies to use the computational power of cloud computing, but often they would like their data to remain private. It is not so unrealistic to envision a system that collects health information from users in real time and on a basis of that information give alerts to the users. However, in a setting like that, user privacy is important and therefore the data needs to be encrypted and the operations in the cloud must run on encrypted data. It is worth mentioning that there are many possible applications that require only a limited number of operations and therefore somewhat homomorphic encryption systems would suffice.

A. HElib

Craig Gentry was the creator of first fully homomorphic encryption scheme, which was inefficient for implementation, but in the last 4 years efficiency has rapidly improved. In 2013 IBM presented open source software library for homomorphic encryption Helib [16]. HElib is a software library that has implementation of Brakerski-Gentry-Vaikuntanathan scheme, along with many optimizations to make homomorphic evaluation faster. To be exact, in 2010 all available FHE schemes were so inefficient that they would simply not run on any hardware, for instance, at the 2012 Crypto conference Gentry, Halevi and Smart showed that it “only" takes 36 hours to evaluate AES in the encrypted domain [17]. Only one year later this was possible to do under 3 hours. HElib is written in C++ and uses NTL mathematical library, however, it does not have implementation of bootstrapping. We can say that HElib is a young library in a rather young field of cryptography.

VI. Conclusions

Homomorphic encryption systems evolved significantly in the last couple of years since the design of first fully homomorphic encryption system. However, all those systems are still to impractical for real-world applications. Nevertheless, we already know numerous practical scenarios where we could use them. Because of that, it makes it interesting problem not only from academic perspective, but also from the industrial one. This will lead to the design of more efficient homomorphic encryption systems in the following years. Naturally, since there are applications where somewhat homomorphic encryption systems would be powerful enough, it seems we are closer to that goal than it may look like.

Abstract - Security and privacy on the Internet and especially the e–mail, is becoming more and more important and crucial for the user. The requirements for the protection of e-mail include issues like tracking and privacy intrusions by hackers and commercial advertisers, intrusions by casual observers, and even spying by government agencies. In an expanding e-mail use in the digital world, Internet and mobile, the quantity and sensitivity of personal information has also tremendously expanded. Therefore, protection of data and transactions and privacy of user information is key and of interest for many users. Based on such motives, in this paper we present the design and current implementation of our secure and privacy-enhanced e-mail system. The system provides protection of e–mails, privacy of locations from which the e–mail system is accessed, and authentication of legitimate users. Differently from existing standard approaches, which are based on adding security extensions to e-mail clients, our system is based on the concept of proxy servers that provide security and privacy of users and their e-mails. It uses all required standards: S/MIME for formatting of secure letters, strong cryptographic algorithms, PKI protocols and certificates. We already have the first implementation and an instance of the system is very easy to install and to use.

Keywords—E-mail; Proxy Server; S/MIME; X.509 certificates; PKI

I. INTRODUCTION

During the last two decades, e–mail has evolved from a simple replacement of paper letters to a necessary and unavoidable means of Internet communication. It is more than common for the majority of the people to possess at least one e-mail account from completely different providers.

E-mails are not only used for communicating between users but as well between users and automated services. E–mail addresses often represent digital identities, which allow the owner to authenticate to online services, such as social networks. Moreover, accessing one's e-mail account does not occur from only one particular device, but on the contrary, often from many different ones, both in terms of capabilities and also in terms of privacy risks for the user. For example, it is very significant for someone's privacy to assure a confidential use of e-mail while moving in a public environment or with public transport, as already shown by our work [1].

The e-mail exchange became of interest for intelligent services to collect material about the user contents and activities. Such collection takes place on the server side and is not user specific [11].

In this paper we describe the design and current implementation of our secure e-mail system based on the use of a secure proxy. We explain our motivation behind this idea, describe our design, and provide details of our implementation.

In section 2 we review the relevant work in this area. In section 3 the design principles of the secure web-based e-mail system are described, while in section 4 the motivation of using a proxy server as a solution is explained. In section 5 we describe the current implementation of our secure and privacy–enhanced e–mail system, as well as the current drawbacks and potential solutions to them. Finally, in section 6 we outline conclusions and suggestions for future research and development.

II. RELEVANT WORK

The concept of using a proxy server in order to enhance security for an application or in particular for e–mail is not new. Already in 1999, Brown et. al [2] have implemented a proxy server called Enigma to add security to mail clients of that time. Their solution was using only the Post Office Protocol (POP), but more importantly, the proxy they developed was not located remotely, but was an extra component on the user's workstation. As a result, their proxy was a local application acting as an extension of an e–mail client, communicating internally with the e–mail client and over the network with the corresponding e–mail server.

Abbasi et al [4] proposed a secure e-mail system with a proxy server, which is logically located at the domain of the mail server and acts as a proxy by introducing S/MIME and other security mechanisms, such as spam filtering and address book protection. Their design is different from our implementation as it consists of two separate components, the secure e-mail server and the secure e-mail client, which both reside at the corresponding mail server. These components are responsible for performing security functions and act as a proxy on behalf of a user. Moreover, the two elements are actively interfering with the functionality of native e–mail servers in order to apply some of the extra security functionalities, to apply spam policies for example. Our implementation, on the other hand, is more flexible, i.e. it does not interfere at all with functions and operations of the native mail server, as we consider that the native mechanisms are more than capable of handling these kinds of threats. Moreover, the

mechanisms of the mail servers are updated regularly and as a result the adoption to each update would have been an important burden.

Another secure e-mail solution currently deployed and in testing phase, is Scramble [5]. Although providing end-to-end encryption to e-mails, it actually represents a new independent e-mail server and not an add-on solution. As a result, users cannot use it with their existing accounts, but would rather have to create a new, dedicated secure e-mail account. We consider that as a major obstacle for broader adoption and one of the distinguished features of our system is that users can keep their current e-mail addresses.

Jammalamadaka et al. [3] have implemented a proxy based architecture in order to enable secure browsing when using a public computer. Delegate, as their system is called, prohibits some known attacks, like hijacking, and prohibits the user of entering his/her credentials on an untrusted computer. The drawback of this implementation is the necessity of extra hardware, a mobile phone in this case. The user needs to use his/her mobile phone loaded with a specific mobile application in order to authenticate to the proxy in order to then initiate the secure communication with the untrusted computer.

Besides developing systems and designing architectures there have been also some more simple solutions, mostly focusing on a single e-mail server. For example the Gmail S/MIME [6] is a plugin for Firefox that adds S/MIME when accessing the Gmail server from the browser. The main drawback of this and other similar solutions is that the plugin is depending on the interface of the e-mail provider. As a result, when the GUI changes and functionalities are modified, the plugin is not functioning anymore.

Another example for Windows based systems is OpaqueMail [12]. This solution provides a local proxy that interacts with the mail client and provides S/MIME. The main differences with our solutions is that this solution requires local installation and thus, besides the OS requirements, needs to be installed on all users' devices.

III. SECURE E-MAIL DESIGN

When designing our secure e-mail system, we considered several important principles in terms of user–friendliness, usability, scaling, privacy of users, and security of e-mails.

The most important requirement is that all security and privacy extensions should be completely transparent to the end user. This principle is very important when designing and implementing new features, as it is common practice for users not to adopt new technologies that significantly change the way they interact with a standard service or a product. This is actually aligned with Saltzer and Schroeder's Psychological acceptability principle [7]. As they stated back in the 1970s "security mechanisms should not make the resource more difficult to access than if the security mechanisms were not present". The result of not applying this principle is that users will simply not use the extra security features.

As a result of this important aspect, in our design and implementation we have applied the above principle in two ways. First, we deploy all security extensions completely transparently to the user. Encryption and signing of e-mails, management of certificates, secure communication between the users and our proxy server, and secure communication between the proxy server and the native e-mail servers are not visible to the user at all. They are all performed automatically by our secure e-mail proxy and only appropriate indications are shown to the users as a means of informing and assuring them about the correctness and verification of the process. This approach is different from concepts like PGP where the user needs to establish the secure communication in a trusted way with each of his contacts by himself.

Second, our system is very simple to use. Our aim was not to differentiate the logic of our secure e-mail system from the current popular web-based implementations of e-mail systems. Even the login function to our system is integrated with the user credentials of the native e-mail system. So, the user needs to provide only his/her e-mail address and password of the native e-mail account and all necessary security operations are performed transparently in the background, automatically by our system.

Another important design principle that we followed was to implement the solution in such a way that no extra hardware or software is needed on the user side in order to access and use the system. As a result, the user is able to access the secure e-mail system with a computer, a mobile device or in general any device that can support a standard browser.

IV. PROXY AS A SECURITY SOLUTION

In our system, security functions are shifted from the user to the proxy server. As users are the most critical component of the entire system when it comes to security, our approach was to separate security functionalities from users and delegate them to the dedicated proxy server. Nonetheless, the user is the one that is still responsible for security, i.e. the proxy is not in the position to read any e-mails or security credentials of the user, without the input of the user's credentials. As explained in the next section, unique user's e-mail credentials represent the identifiers to generate, protect, store and use cryptographic keys, which are used for secure processing of e-mails.

By using the concept of a web proxy extra security functionalities are provided to the user. Our design and proposal can be used for other research areas, such as Internet of Things or secure m-commerce systems. Although these two areas are conceptually different, we use the same concept for both.

In our design the proxy server is responsible for establishing a secure link with the user and delegating as many interactions as possible from the user's workstation or mobile device. Our secure e-mail proxy implementation represents our first–level solution towards the use of this approach and technology and will also be used later as a paradigm for more concrete and complicated system designs.

PKCS #7 and S/MIME packaging are general mechanisms to secure e-mail systems. They can be used generally for all e-mail communications and are recommended to guarantee confidentiality and authenticity

in sensitive use cases such as the secure exchange of m-commerce objects, as described in [8].

When using a mobile device, the use of the security proxies becomes even more important. Mobile devices have limited capabilities and so a user can delegate to the trusted party the secure operations he/she would like to execute and be reassured that the contents he/she receives meet the desired security and data protection requirements. Moreover, since the proxy server functions act as a delegate for the more "heavy" computations in terms of processor and network speed, potential bottleneck on the mobile side will be avoided, especially when being in lack of network coverage (limited Internet speed) or low battery (avoid using heavy processor-related tasks).

V. IMPLEMENTATION

Our secure e-mail proxy is a Java web application using Java Server Pages (JSP) based on the PrimeFaces framework and Java Servlets. The security mechanisms are implemented with Java, using external cryptographic and e-mail security libraries. In particular, we used the Java Mail library to handle e-mail operations and OneSEC™ Java Security Platform for security functionalities [9]. Certificates are issued by the OnePKI™ Public Key Infrastructure system [10], but in principle any other PKI could also be used. The JSP pages and Java classes (the main elements of the application), along with other components of the project, are deployed in an Apache Tomcat server.

The architecture comprises two servers: the proxy server, which handles all the communication with the appropriate parties (users, CAs, e-mail servers) and the associated CA server. Users login to the proxy server using their e-mail address and password of the native e-mail account. The proxy server identifies the native e-mail server from the e-mail address and performs the authentication of the user with the native e-mail server. The protocols used are different, depending on the native e-mail server. The list of protocols and mail servers currently supported are given in Table 1.

Once the authentication is successful, the proxy fetches the list of e-mails from the native e-mail server and displays them to the user, exactly the same way as they would be displayed when using a normal web–based client. The user from this menu can have access to all normal mail functionalities, exactly as if he would use a desktop mail client. A screenshot of the secure email's inbox can be seen in Fig. 2.

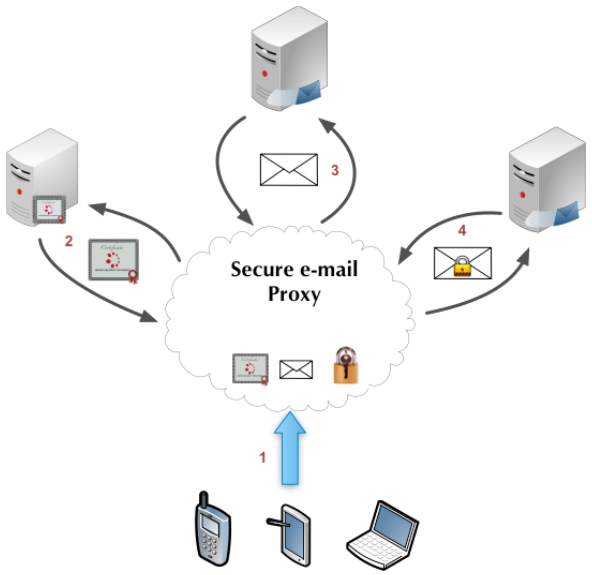

Figure 1. Secure e-mail proxy interactions

Step 1: The user logs into the secure e-mail proxy using the e-mail address and password of his/her native e-mail system; **Step 2:** For new users, the proxy generates a key pair, sends public key to the CA server, receives and stores the user's certificate; **Step 3:** The proxy fetches via IMAP the e-mails from the corresponding e-mail server. Upon double–click, each letter is cryptographically processed and displayed; **Step 4:** The user can now send signed and encrypted e-mails.

Finally, the connection between the proxy and the user is always secure. For this reason, the use of a standard SSL connection between the two parties is implemented. The architecture and the interactions between the parties in a normal workflow are shown in Fig. 1.

A. *Security Features*

When the user logs in for the first time, a RSA key-pair is automatically generated and a certificate is requested from the CA for his/her account. As the process is automated, the Common Name of the Distinguished Name (DN) is set to the user's e-mail address. They are both stored on the proxy and they are encrypted with the user's login credentials. As the standard secure e-mail approach

	Protocol	Incoming Server	Incoming Port	Outgoing Server	Outgoing Port
Gmail	imap	imap.gmail.com	993	smtp.gmail.com	465
Hotmail	pop3	pop3.live.com	995	smtp.live.com	587
Yahoo Mail	pop3	plus.pop.mail.yahoo.com	995	plus.smtp.mail.yahoo.com	465
KTH Mail	imap	webmail.kth.se	993	smtp.kth.se	465
JRC scientific Mail	imap	email.jrc.it	993	email.jrc.it	465

Table 1. Mail servers available with our secure e-mail system

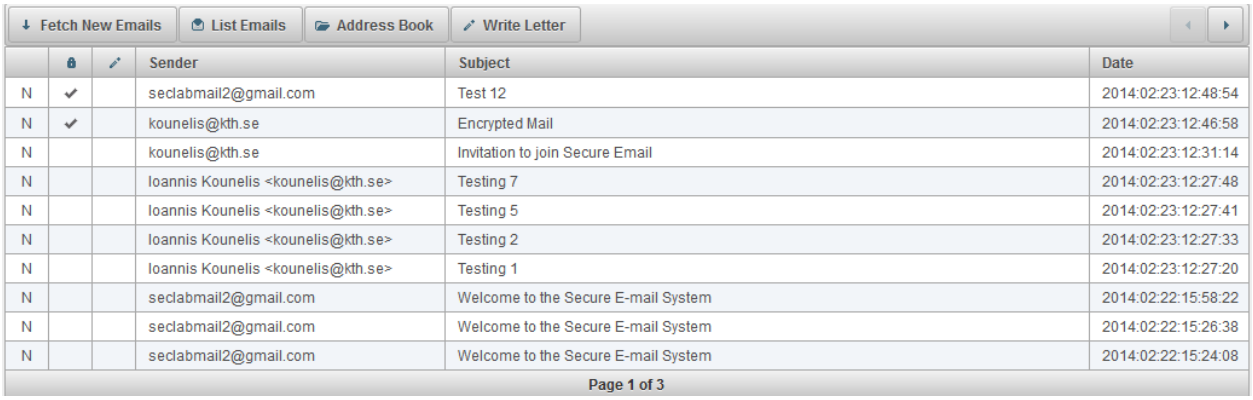

Figure 2. A screenshot of the secure email's inbox

requires, the private key is used to sign outgoing e-mails and certificates are used by recipients to verify the sender's signature.

When the user wants to send an encrypted or signed (or both) e-mail, the private key is decrypted on the fly (and kept in memory) and S/MIME formatting is per-formed with the original text of the e-mail. The user is not aware of any of these cryptographic processing details, as everything is performed transparently and by the proxy server. The user just selects, prior to sending an e-mail, the option to sign or/and encrypt the letter.

The certificate of the recipient is fetched automatically by the proxy from the local database of cryptographic keys. At that moment, the recipient(s) of the encrypted e-mail(s) must be registered in the same instance of our secure e-mail proxy, so that their certificate is available to the proxy. The e-mail address of the recipient is used as the unique identifier. As a result the recipient's certificate is found in the local database and the S/MIME packaging is performed according to the corresponding Internet standards.

When the recipient receives an encrypted e-mail, he/she will not be able to read it when fetching it and opening it directly from the native e-mail server. Instead when accessing the native e–mail server directly, he/she will just see an S/MIME attachment as a file with the standard .p7m extension and an empty body of the e-mail. However, when he/she uses the secure e-mail proxy after his/her login, the proxy will automatically understand that the e-mail is encrypted and will automatically perform decryption when the user clicks on the selected e-mail in order to read it. At the same time, he/she will see a notification that the letter is encrypted. The exact same procedure is performed with signed e-mails with the only difference being the attachment extension, which in this case is .p7s. A comparison of how an encrypted e-mail is viewed when using our secure email system and how it is viewed when accessing it directly from the native e-mail server (Gmail in this example) can be seen in Fig 3 and Fig. 4.

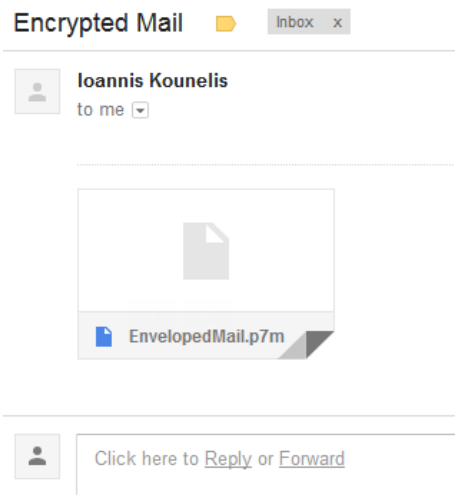

Figure 3. Encrypted e-mail when opened from the native mail server (Gmail)

Decryption is performed by recovering the encryption key packaged in the S/MIME format, using the private key of the recipient. The RSA private key of the user is already stored at the proxy encrypted with his/her password. When the user has already logged in, fetching and decryption of the private key is performed in order to be used for decrypting encryption keys contained in the incoming e-mails. A similar process is used to verify the signature of an e-mail, using the public key of the sender extracted from his/her certificate. The user should be made fully aware of the fact that the e-mail password is used as well for the encryption of the keys and as such he should be encouraged to apply a strong policy on his/her password management.

B. Drawbacks of Current Implementation and their Solutions

Besides security and privacy enhancements, which we introduced with our design and implementation, there are inevitably some minor drawbacks as well.

First, the proxy server represents a single point of failure. If it is attacked and not available to users, they will

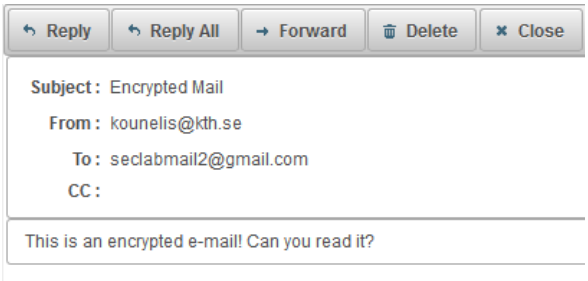

Figure 4. Encrypted e-mail as seen by using our SecureEmail

not be able to read their encrypted e-mails and verify signatures, as all the keys are stored there. As a result, even if they would be able to access their e-mails from the standard e-mail server, the non-availability of keys will not be possible to overcome. Nonetheless, a simple solution to this issue would be to have replica proxy servers that would serve as backups. All the encrypted key pairs and certificates would be saved there as well and a potential attack on the main proxy will not be able to compromise the users' keys. This solution is easily implementable in a scalable federated cloud environment.

Another implementation issue that is complicated to overcome is the native security policies of the different e-mail servers. Many of the most well-knows e-mail systems apply IP filtering specifically for each user and if they notice strange new login location such as the proxy location, they automatically block it. For example, Gmail by Google automatically blocks a user's login attempt over IMAP if it is occurring from a country that has never been previously used by the user. In this case the user will have to manually login to his/her native e-mail account and acknowledge that he/she allows the access from this third country. This security feature creates an extra burden for our implementation. As the proxy physically resides in a specific country (Sweden in our case), even if the user attempts to login from his/her country of residence to our proxy, the native e-mail server will detect the IP of the proxy and not of the user. As a result the above problem will occur.

The only way to deal with this issue is to have the user manually accept the remote access from the country where the proxy is located. An alternative would be to have proxies installed in every country, but even in this case the problem would remain when the user was travelling or when such security features would in the future not only be restricted to IPs, but also to the different devices that ask for remote e-mail access.

Moreover, a processing overhead, in terms of displaying e-mails and network traffic, is inevitable due to additional functions performed by the proxy. As all user traffic and data is deleted after the user logs off, so are all the e-mails that have been fetched from the server. As a result, each time the user logs into the secure e-mail proxy all his/her e-mails will need to be downloaded again. This issue is also present with native online mail servers and we do not consider it as an important overhead. Even more, as our intention in this phase was not to focus so much on the performance side, but rather on the security and privacy aspect of the secure e-mail proxy, we consider this aspect as an issue for future work in case our solution will be used on the market and not solely for research purposes.

Finally, it should be emphasized that encrypting an e-mail does not allow a third party to see the content of it. But, on the other hand, it also prohibits various advertisers, filters and spam tests to access the content of e-mails. As a result, malware and spam e-mail can also be encrypted and in that way bypass filtering performed by mechanisms applied on native mail servers. But this issue can be overcome by establishing security policies in which users may specify other users and mail servers from which they are willing to access e-mails.

VI. Conclusion & Future Research

In this paper we have described a secure and privacy–enhanced way to handle e-mails based on the concept of a secure proxy server. Our solution does not introduce any overhead to the user neither does it require any extra software or hardware. More importantly, all the operations are transparent to the end users, so they do not need to be concerned with any configuration or understanding of the underlying technology.

Future research will focus on improving even more user experience when using our secure e-mail proxy. We aim to create a new login layer to our platform that will allow the user with one account to handle all his/her e-mail accounts. The user will then be able to use the same certificates with all e-mail accounts that he/she chooses, instead of as today having a different certificate for each e-mail account.

Moreover, we plan to extend the system so that it provides federation of multiple proxies by distributing certificates between two or more instances of the Secure e-mail System. This means that for the next version we will introduce scalable federated architecture and utilization of the full PKI hierarchy. For example, if one proxy is deployed in Italy and the other in Sweden, a user that has already created a certificate for his/her account at the Italian proxy should not need to re-generate one if he/she uses the Swedish proxy. The two proxies should communicate and manage secure transfer of certificates in such a case.

The current system, being based on unreliable user e-mails, does not provide any assurance. One of the future extensions is to introduce versions with higher level of assurance in user identities and credentials. This will be achieved by linking the system to trusted and reliable identity and security providers and by using higher assurance authentication protocols, based on strong authentication, use of certificates, two–factor authentication and PIV smart cards.

Finally, future research will also focus on the use of secure e-mails and secure e-mail proxy in the area of m-commerce, as already described in the previous sections and on the hardening of the proxy itself, in terms of security. We aim to use the proxy technology and other security features for our future research and demo activities, by enhancing its functionality and capabilities.

Abstract - Until few years ago professional certifications were something that is good, but not necessary to have during employment process. That could be seen from the published job advertisements for variety of IT and information security professionals. In such job ads, there was first required specific experience in the subject area where no confirmation of that experience in form of professional certification was needed. Later, in addition of required experience in subject area, the possession of certain certificates was referred as advantage in job ads. Nowadays, it almost becomes the rule that the requirement for employment, in addition to having specific experience in the subject area, is also possession of a professional certificate which confirms stated experience. Professional certifications primarily demonstrate experience and knowledge in a particular area but also, due to the necessity of re-certification every few years, show commitment to professional development and constant training. The guiding principle of this study was to determine how many such certified professionals there is in Croatia and what kind of skills and competencies employers indirectly seek by requiring possession of certain certificates in job ads.

I. INTRODUCTION

With the rapid growth of information technology on a global scale, the necessary knowledge and skills required for IT professionals in different domains is constantly changing and expanding.

Today, there are significant changes in the responsibilities of IT and security professionals as expertise in one area is no longer guarantee of success in the IT profession. Moreover, employees are evaluated by their ability to perform multiple roles and it is increasingly trend that traditional business functions such as compliance, risk management and privacy compliance are assigned to such experts which means that they must master not only the technological requirements but also the business needs [1].

Assessment of the level of individuals' skills by the organizations that employ professionals in the field of information technology and security generally is based on their academic degree or professional certificate. The most important difference between academic education and professional certification is its purpose and the fact that professional certifications are focused on specific marketable skills and academic education on long-term employability and learning general theoretical model of problem solving.

II. REQUIREMENTS OF PRACTICE IN RELATION TO THE EXISTING COMPETENCIES

A. Literature review

Despite numerous frameworks and curriculum models for IT and security professionals competencies development, universities often do not provide their students with skills demanded by employers, which leads to the discrepancy between the level of skills expected by employers and the level of skills that students will have upon graduation, so many authors [2],[3],[1],[4] dealt with the issues of existing curricula and their appropriateness.

The main issue in the curriculum development is the fact that the curriculum cannot cover all potentially relevant material. Therefore, during its development one must consciously choose what will be included in the curriculum and how it will emphasize different sections, which should reflect the current needs of practice.

Curriculum models [1], [4] developed by ISACA international organizations adjust the academic community offering to the needs of professional practice and provide a framework for academic institutions and professional associations in the development of new and redesigning existing courses as they are based on the needs and expectations of the IT profession and rely on previous research of academics, practitioners, audit organizations and professional associations.

Thanks to the rapid changes and development of information systems and technology that drives them, as well as the necessary skills required, the curricula of information systems must be frequently updated to reflect the requirements of practice. For this reason, representatives of higher education should follow trends and act promptly to enhance curricula based on the industry needs, labour market statistics and defined necessary skills based on scientific research [2].

Research in which a comparison of business skills of academic and professional literature as well as those listed in the job ads was conducted [5], showed that the academic literature is lagging behind somewhat in terms of descriptions of specific technical skills, but provides the

richest understanding of the humanistic and business skills. Professional literature tends to provide views on the future of business skills, and contains the richest set of technical skills while the online job listings are fairly balanced in terms of technical, humanistic and business skills occurrences.

Many authors [5], [6], [7], [8], [9] point out that jobs within the information technology domain are becoming more strategic and business-focused and successful IT professionals today should not be satisfied with possessing just a technical or "*hard skills*" such as knowledge of hardware, software or network management, but also must have the "*soft skills*" i.e. personal, communication, organizational and interpersonal skills [7] which include good communication, leadership, interpersonal skills, motivation, negotiation skills, project and teams management, and sense for business and strategy [8]. In addition to technical and soft skills, some authors [6] points out that today's IT jobs also require "*critical skills*" that include cultural competencies and creativity.

In today's environment of constant and rapid change, a mix of different skills is essential for every IT professional and soft skills are becoming increasingly dominant. Having so far well served skills and competencies is necessary but not sufficient for successful progress [7] because all lead to a multidisciplinary approach where IT professionals are expected to specialize in two or more interconnected domains [6].

IT Managers should always have a high level of technology understanding and strengthening of core technical knowledge which remains a critical requirement for this position [10], and technical skills that are considered to be the base of the IT profession, some authors [11] split into three groups - foundational, operational and essential skills. The foundational skills group which represents the basis of this area consists of basic skills of programming, testing, support, databases, operating systems and telecommunication.

The operational skills group includes skills in operations, hosting, business continuity / disaster recovery and the mainframe / legacy area. Those skills, although specialized, commonly are not firm-specific. The third group of technical skills - essential skills group consists of skills necessary for development of IT solutions aligned with organizational goals. That includes systems analysis, systems design and IT architecture / standards [11].

On the other hand, non-technical skills can be seen as features that give professionals ability of understanding, developing and delivering effective solutions of organizational problems. Also divided into three groups those skills consist of project management skills (project leadership, project planning, project integration / program management, project risk management), problem skills (company-specific knowledge, functional area, process knowledge, industry knowledge, business process design, change management) and relationship skills (user relationship management, communications, negotiations, managing stakeholder expectations) [11].

The demand for workers with specialized skills puts considerable pressure on traditional educational strategies to ensure a skilled workforce. In response to the constant changes and advancements in the IT industry and slow response of traditional education, IT industry has established professional certifications as a preferred way of assessing skills and knowledge [12]. Thus, in the IT domain certifications become one of the criteria in hiring for many IT job roles and represent an indicator for Human Resource Managers that the condition of specific knowledge or competence has been met [13], [14]. Some authors [15] consider including IT certifications in the IT curricula as necessary while others [11] state that more important is to include basic knowledge of a defined group of technical and non-technical skills in curricula.

The reasons for IT professionals decide to gain the certification can be either self-development or career development (or both), whether it is about advancement opportunities in existing companies or to demonstrate their qualifications in terms of skills and knowledge [16] to potential new employers or clients.

As information security has become increasingly important for organizations, number of IT security certification has grown rapidly, making it difficult for stakeholders to decide which certificates to pursue or acquire [11]. There are identified four key stakeholders who have a special interest in security certificates and choices of them [14]. First of all, there are IT security professionals who are interested in getting the "best" security certificate for the purpose of employment, development expertise and income increase. Then, higher education institutions whose goal is to develop IT security education that prepares students for IT security professionals careers to whom can help a systematic approach to the assessment of IT security certificates. Third, there are employers who are looking for IT security professionals with the most relevant security certificates for their organization and finally, governments who can use a systematic approach to the evaluation of security certificates to determine the relevance of individual qualifications for accelerated immigration or regulation of the IT security profession [14].

Professional certifications, either vendor-neutral or vendor-specific, can confirm competencies and skills, but they cannot replace the experience or academic education. Education provides a broad general knowledge and skills by teaching students theoretical concepts, but there is a lack of skills for solving problems in information technology and security domain that can be reduced by acquiring professional certification from a specific domain [17]. Based on that, we can say that professional certifications, education and experience complement each other, not replace [15].

While vendor-specific certifications cover a highly specialized area, vendor-neutral certifications cover wider knowledge area, but at the same time focus on some job-specific components that are not there in formal education.

Research [18] results which included data from 299 IT professionals looking for professional certificates from various IT areas showed that the majority of professionals who are now working in IT is not certified in their field. Although there is considerable variation between different work areas of IT (from less than 14% of certified software

developers to nearly 70% of certified experts for network and security), a total of slightly less than 37% of IT professionals has certification.

On the other hand, the results of research [16] which included 240 participants (HR or IT manager) from the area of the South-eastern USA showed that hiring personnel perceive IT certification positively. Also, on question what certificate would they like their new IT employee to have over 85% of respondents chose at least one certificate from the list provided, while 14.6% put "None" and 52.1% of them reported that they would like job candidate has two or more certificates.

Professional certificates play an important role in today's IT industry mainly due to the fact they represent a standardized assessment method of knowledge and skills in a specialized field, they are globally recognized, and the certification schemes are directly mapped to defined set of required skills. Also, the benefits of the organizations that employ certified professionals are reflected in the increasing competitive advantages [12].

B. Professional certificates

There are several international organizations that provide certification of IT professionals, however authors' focus will be on two global organizations representing industry leaders in professional independent (vendor-neutral) certifications from a wide area of information technology - ISACA and $(ISC)^2$ [19], [20].

As an independent, non-profit, global organization, **ISACA** engages in the development, adoption and use of globally accepted, leading knowledge and practices for information systems. Formerly known as *Information Systems Audit and Control Association*, ISACA now uses only its acronym to emphasize a wide range of IT professionals it serves through the possibility of certification through one of the four certification programs [19]:

- *Certified Information Systems Auditor - CISA* (more than 103.000 certified professionals),
- *Certified Information Security Manager – CISM* (more than 22.500 certified professionals),
- *Certified in the Governance of Enterprise IT - CGEIT* (more than 5.600 certified professionals),
- *Certified in Risk and Information Systems Control - CRISC* (more than 16.800 certified professionals).

Obtaining the certification demonstrates that professional holds the key professional knowledge and experience in his/her profession, and each of ISACA's globally recognized certification refers to a specific area of expertise as is evident from Table I.

In order to earn ISACA's certification one must successfully pass the CISA/CISM/CGEIT/CRISC exam which consists of 200 (for CGEIT 120) multiple-choice questions in duration of 4 hours and meet the necessary requirements for specific work experience (Table I.).

ISC^2 - *International Information Systems Security Certification Consortium* with headquarters in the United States and offices in London, Hong Kong and Tokyo, is a global non-profit leader in educating and certifying professionals in information security during their careers, that currently offers the possibility of several certification programs [20] which of the most notably is the *Certified Information Systems Security Professional (CISSP)* certification. CISSP is designed for professionals in the field of information security management systems which currently holds more than 85.500 certified professionals.

In order to earn CISSP certification one must successfully pass the CISSP exam consisted of 250 multiple-choice questions in duration of 6 hours and meet the necessary requirements for work experience (Table I).

Comparative overview of observed certificates along with the minimum conditions necessary for a successful certification and profiles of professionals for which is particular certificate designed is shown in Table I.

In order to have CISA/CISM/CGEIT/CRISC/CISSP certificate in good standing it is necessary to have at least 20 hours of *Continual Professional Education – CPE* per year and 120 hours during 3-years period.

The objectives of continual education are [19], [20]:

- Maintain the competence of the individual by requesting the upgrade of existing knowledge and skills in the subject area,
- Provide the ability to distinguish between qualified certified professionals and those who did not meet the re-certification requirements,
- Provide a mechanism for monitoring the maintenance of professional competence in the subject area,
- Assist organizations in the development of valid functions of audit, control, risk management and information systems security by providing criteria for selecting quality employees.

There are numerous ways to acquire the required CPE credits from which some of them are: attending seminars as well as professional conferences, attending professional meetings and training courses either as a teacher or as a participant, publishing research papers, writing exam questions for ISACA/$(ISC)^2$ exams, reviewing books from the information technology domain, volunteering for ISACA/$(ISC)^2$ organization, etc.

III. RESEARCH

A. Methodology

After finding and analysis of relevant literature as well as previous studies on developed models of competencies management, knowledge and skills, types and characteristics of professional certificates, its comparison with formal education and other related topics in this area by using the analysis, synthesis, comparison and compilation methods and gaining some conclusions found in the literature, the authors began to collect the necessary data in order to answer the following research questions:

- Q1: How many registered certified professionals for information security (CISM, CISSP), information systems audit (CISA), IT risk (CRISC) and the management of enterprise IT (CGEIT) there is in Croatia?
- Q2: What is the certification trend in period of 10 years in Croatia in terms of certified professionals who possess the observed certificates?
- Q3: (a) To what extent organizations in Croatia are asking new employees for possession of the observed certifications when posting job ads, and (b) whether the possession of the certificate is mandatory or an advantage?
- Q4: To what extent employers in Croatia are asking for: (a) formal education, (b) technical and/or soft skills and competencies of new employees when posting job ads?

In order to find answers to research questions Q1 and Q2, professional organizations ISACA and (ISC)^2 were contacted and a request was sent by e-mail for the submission of quantitative data on the number of certified professionals over the period of 10 years in Croatia. For ISACA it was information about CISA, CISM, CGEIT and CRISC certified professionals and for ISC^2 information about CISSP certified professionals.

Simultaneously with waiting for a response from ISACA and ISC^2 to above inquiry, the authors began to collect data in order to be able to answer to research questions Q3 and Q4. This part of the research was conducted by identifying and analyzing all active job ads published on three main sites for online job searching in Croatia (job portal MojPosao - www.mojposao.net and job portal Posao.hr - www.posao.hr that also publishes jobs from the Croatian Labor Exchange - www.hzz.hr) during the period 01.07.2012 to 01.07.2013. This period was selected on purpose because that represents the last year before Croatian accession to the European Union. The first step was to identify all the jobs in IT domain advertised in reporting period, after which only those ads were filtered in which employers are seeking for security, computer, audit, information technology and other related experts in the domain of information technology, and which are related to the observed certifications. After acquiring data needed, descriptive statistics was used and results were presented in respective tables.

B. Results Analysis and Discussion

Based on the received data on the number of certified professionals in Croatia by observed certifications over the last 10 years tabular presentation was made as shown in Table II.

As seen in Table II., the answers to research questions Q1 and Q2 were partially obtained. That means that, regarding Q1, in 2012 Croatia had 90 certified professionals who possess CISA certification, 56 CISM certified professionals, 18 CGEIT certified professionals and same amount (18) of CRISC certified professionals.

TABLE I. CHARACTERISTICS AND REQUIREMENTS FOR ACQUIRING THE OBSERVED INTERNATIONAL CERTIFICATION

Certifi-cate	***Targeted audience***	***Waivers and substitutions***	***Minimum certificate requirements***
CISA[a]	IS/IT: -Auditors -Consultants -Audit Managers Security Professionals Non-IT Auditors	YES - up to 2 years based on formal education and/or work experience (working as IS or non-IT auditor or university professor)	Passed CISA exam + 3 yrs work experience in the subject area
CISM[a]	Information Security Managers Aspiring Information Security Managers IS/IT Consultants	YES - up to 2 years: • 2 years - valid CISA/ CISSP OR postgraduate degree in InfoSec or related field • 1 year – exp. in IS/ InfoSec management OR security certificates based on skills OR completed InfoSec program complied with ISACA model curricula	Passed CISM exam + 3 yrs work exp. in InfoSec mgmt in 3 or more practical business domain
CGEIT[a]	IS/IT: -Directors -Managers -Consultants -Executives IT Governance Professionals	NO - must have 5 or more years of experience managing, serving in an advisory or oversight role, and/or otherwise supporting the governance of the IT-related contribution to enterprise	Passed CGEIT exam + 5 yrs work exp. (with at least 1 yr related to frame-work for IT mgmt (CGEIT domain 1).
CRISC[b]	Professionals - in IT - in Risk - in Control - in Compliance Business analysts Project managers	NO - must have 3 or more years of cumulative work exp. performing the tasks of CRISC professional across at least 3 CRISC domains	Passed CRISC exam + 3 yrs work exp. in at least 3 CRISC domains
CISSP[a]	Security - Consultants - Managers - Auditors - Architects - Analysts - Engineers IT Managers CISOs Network Architects	YES - up to 1 year based on completing a four-year study or additional certificates (certificates of other organizations) from a list approved by the (ISC)²	Passed CISSP exam + 4 yrs direct experience working full-time in a minimum of two CISSP domains

a. 5 years of required work experience

b. 3 years of required work experience

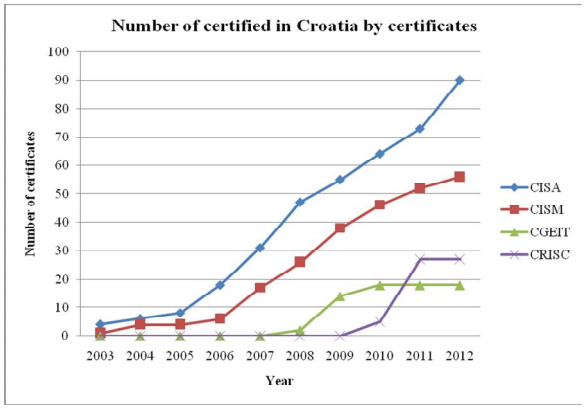

Figure 1. Number of certified professionals in Croatia by certificates

Official data for the CISSP certification was not available because ISC[2] did not provide authors with requested data with an explanation that these data are for internal use only.

Also, our data indicate a positive trend over the period of last 10 years (Q2), which one can best see from the graphical representation shown in Figure 1. of the upward trend in the number of observed certifications in Croatia in the last 10 years based on data in Table II. provided by ISACA organization.

CISA, as being the first and oldest ISACA's certificate which celebrated its 35th anniversary, is logically most represented observed certification in Croatia with the largest number of certified professionals. The next oldest certification is CISM followed by two "youngest" certifications CGEIT and CRISC. It is interesting to mention that, as one can see in Table II. and Figure 1., there has been a sudden increase of CGEIT certified professionals from 2008 to 2009 and from 2010 to 2011 for CRISC certified professionals after which the number of certified professionals becomes constant. The reason is that in the initial period for these certifications, CGEIT and CRISC certification could be obtained by the "grandfathering programs" and professionals with enough years of IT and business experience were able to apply for obtaining these certificates without taking an exam.

Results of the second part of this research related to the research questions Q3 and Q4 are as follows. In the observed period of one year on job portals MojPosao.net and Posao.hr authors found total of 30 active job ads published from which one ad was published on both portals. Of the remaining 29 ads, four ads were repeated once more in the reporting period, which brings us to a total of 25 different ads. Those ads can be grouped into seven groups as shown in Table III. The group "Other" consists of one company from catering industry and one German company for which no name nor industry or business activity was stated in published ad. Only 3 ads were published for work outside the Croatia.

If we look at the results from Table III., we can see that the observed certifications were stated in 36% of ads from which none of them as mandatory requirement, but as an advantage (Q3). The mentioned certifications were CISA, CISM, CISSP and in 1 ad CRISC. CGEIT was not mentioned in any ad probably because it is relatively new certification and it is not custom for Heads of IT in

TABLE II. NUMBER OF OBSERVED INTERNATIONAL CERTIFICATES IN CROATIA IN THE LAST 10 YEARS

Year	Number of certified in Croatia by certificates				
	CISA	*CISM*	*CGEIT*[a]	*CRISC*[b]	*CISSP*[c]
2003	4	1	-	-	N/A
2004	6	4	-	-	N/A
2005	8	4	-	-	N/A
2006	18	6	-	-	N/A
2007	31	17	-	-	N/A
2008	47	26	2	-	N/A
2009	55	38	14	-	N/A
2010	64	46	18	5	N/A
2011	73	52	18	27	N/A
2012	90	56	18	27	N/A

a. CGEIT certification program began in 2008

b. CRISC certification program began in 2010

c. (ISC)[2] organization did not provide data

Croatia. There were no bigger surprises in the results, except for the fact that the group "Audit and Advisory Services" did not ask for CISA (or any other) certification in its advertisement. However, it was ad for apprentices.

Of the total number of ads, in 20 ads (80%) in formal terms a university degree was required, in 3 ads (12%) bachelor's degree and in 2 ads (8%) there was not required any formal qualifications (Q4a). Required technical skills were listed in all 25 ads (100%), while the various soft skills were mentioned in 18 ads (72%). Top 5 requested soft skills were communication skills, responsibility, motivation, flexibility and organizational skills (Q4b).

IV. CONCLUSION

IT has become the driving force of business, and is an area in need of continuous education and training. The knowledge and skills that IT professionals gain today in a

TABLE III. PUBLISHED ADVERTISEMENTS GROUPED BY BUSINESS ACTIVITIES AND REQUIREMENTS OF CERTIFICATE POSSESSION[A]

Business activity	Number of published ads	Certification possession	
		Advantage	*Mandatory*
Production and sales	5	0	0
Consulting, development and implementation of IT solutions	12	6	0
Audit and Advisory Services	2	0	0
Banking Institutions	2	1	0
Insurance Companies	1	1	0
Government Agencies	1	1	0
Other	2	0	0
TOTAL	25	9	0

few years becomes obsolete and so professional certifications are becoming more important.

Possession of an internationally recognized industry-neutral certification certainly enhances professional recognition and credibility of IT professionals and often is accompanied with better salary than professional colleagues who do not have proper certification.

This research resulted with number of certified professionals in information security, IT audit, IT risk management and governance of enterprise IT in Croatian organizations showing the positive trend over the last 10 years. Also, there were identified and analyzed active job advertisements published during the period of the last year before the Croatian accession to the European Union. The results showed that the Croatian employers partially follow the world's trend of requiring professional certification in order to use certification to differentiate between job candidates with similar levels of education and experience. However, no organization stated in published advertisements possession of a professional certification as a mandatory condition of employment in such way like as for academic education.

The recognized limitation of this study is primarily the inability to obtain necessary data from the $(ISC)^2$ organization on the number of CISSP certified professionals in Croatia for the selected period which prevented comparison of CISSP with the other four observed certifications. Another limitation is the relatively short period of only one year to examine trends in required certifications in published job ads, and finally the lack of a sufficiently large sample of published job ads for a variety of reasons, of which the dominant are recession in Croatia and the lack of new jobs.

The possible new research could take into account the greater time span of published advertisements in order to be able to draw some useful conclusions on trends before and after the Croatian accession to the European Union. Of course, more interesting and more detailed study would be to compare current trends of professional certificates recognition with other EU countries.

Abstract - The user is still weakest link regarding information security matters, but studies on this subject are rare. The aim of this work is to develop general Users' Information Security Awareness Questionnaire (UISAQ). Development consists of selecting suitable items for which is assumed that measure the level of security awareness and testing impact of each item in measurement. Questionnaire consisted of 4 parts with total of 37 items. Results showed that first part of questionnaire, that examine the common user's risk behavior, should consist of 17 items (3 items had low factor loadings) separate in 3 subscales. Second part of questionnaire, which consisted of 6 items that measured the level of user's information security, had high internal consistency (k=6, α=0.89) and a satisfactory factor loadings. Third part of questionnaire, which consisted of 5 items that measured the level of user's beliefs about information security, should consist of 3 items (2 items significantly disrupted internal consistency) with high factor loadings and good internal consistency (α=0.76). Descriptive statistics showed that all the questions (n=6) in the fourth part of the questionnaire, which had examined the password quality and security, had a full range of answers and that normal distribution wasn't significantly violated. Although developed questionnaire requires more work and validation, first results showed that UISAQ has potential to become a good and reliable measure of users' security awareness in the future.

I. INTRODUCTION

Through the years, user of information system is still its weakest link regarding information security matters [1, 2]. Information system's user can, with his potentially risky behavior, significantly influence on overall system's security [3 - 5] and all hacker attacks usually combine social engineering with technical hacking skills [6]. However scientific studies on this subject are rare and there is need for universal measurement instruments [7, 8]. These instruments should enable measurement of user's influence on overall systems' security for state analysis and future studies.

Some previous solutions are proposed, but are partial and not universal enough [9, 10]. Actually most of the previous research on user's behavior is focused only on examining password usage and password quality and strength [11 -14].

The aim of this work was to develop reliable universal instrument which will measure level of information system's users' awareness on security matters, as general as possible, the Users' Information Security Awareness Questionnaire (UISAQ).

Development of this kind of questionnaire comprises selection of suitable items and testing impact of each item. Impact of each item which is assumed that measures the level of security awareness among users, is measured by using descriptive statistics, factor analysis and reliability analysis. Results of those analyses will exclude items with low impact and point out items with higher impact that present well defined questions [15].

With internationally validated questionnaire it should be possible to gain general conclusions about user's security awareness and potentially risky behavior. Results of those kinds of studies will enable concrete improvements of existing [16 - 18] and development of new information security solutions focused on user's education.

II. METHOD

A. Participants

Participants in this study were students (N=135) on second year of undergraduate study, from three different faculties of J.J. Strossmayer University of Osijek: Faculty of Teacher Education (N=41), Faculty of Medicine (N=51) and Faculty of Electrical Engineering (N=43). Proportion of mail students was 47.6% while proportion of female students was 52.4%. The average age of participants was 19.85 +/- 0.58 (arithmetic mean +/- SD).

B. Procedure

During regular classes students were asked to voluntarily give some general information about self (age and gender) and to fill out the UISAQ. Filling out the questionnaire lasted for approximately 30 minutes. Survey

was done on all three groups of participants during one week period.

C. Instruments

For the purpose of this research authors created UISAQ consisting of four parts with total of 37 items collected from different security guidelines and results of previous studies [19 - 24]. Each item is a question in the UISAQ presenting variable for the statistical analysis.

The four parts of UISAQ are as follows:

- First part of UISAQ consisted of 20 items measuring computer users' potentially risky behavior.
- Second part of questionnaire consisted of 6 items that measured the level of user's information security awareness.
- Third part of questionnaire consisted of 5 items which measured the level of user's beliefs about information security.
- The last part of UISAQ consisted of 6 questions that examined the quality and security of passwords.

sc4	5.8507	4.248	.417	.611
sc5	5.9925	5.060	.321	.658

The participants had to evaluate to which extend each statement refers to him/her on a scale from 1 to 5. This implies that each variable, for each examinee, can have only one value in range from 1 to 5.

Unanswered questions were not included in the statistical analysis.

III. RESULTS

Development of questionnaire consisted of selecting suitable items for which there was assumption that measure the level of potentially risky behavior of computer users, level of information security awareness, users' believes about safety or password quality issues. Using descriptive statistics, factor analysis and reliability analysis we tested if selected items were good measure of hypothesized construct.

For the first part of UISAQ Exploratory factor analysis (method principal components, oblimin rotation) was used. Analyses have shown extraction of 8 factors (using the Guttman-Kaiser criterion) with eigen values larger than 1 and explanation of 66.11 % of overall variance. Given factor structure shown only 3 dominant factors (each explained more than 10% of variance and 37.42% of overall variance) and other factors had smaller eigen

values and very small proportion (less than 7%) of explained variance. First factor explained 14.30 % of overall variance, second factor explained 12.92% of overall variance and third factor explained 10.19 % of overall variance. Than, Confirmatory factor analysis was used in order to test 3 hypnotized factors which were extracted from previous Exploratory factor analysis. The saturation (factor loadings) was defined as larger than 0.3 which interpreted the three mentioned factors.

The factor structure of the first part of UISAQ is shown in Table 1. As shown in table, 3 items had factor loading lower than 0.3 on all of three factors and they were suppressed and thereby not shown in table (items sc10, sc19 and sc20) so they were excluded from further

sc3	13.7308	17.795	.771	.858
sc4	13.9538	17.192	.806	.852
sc5	14.1692	18.064	.793	.855
sc6	13.9769	19.030	.662	.876

analysis. Final version of first part of UISAQ should consist of 17 items separate in 3 subscales: first subscale measures risky behavior of computer users (k=6), second subscale measures maintenance of computer systems (k=6), and third ones measures using other users' data (k=5). Than reliability analysis was done for three new scales (Table 2). First subscale had little bit lower internal consistency (k=6; Cronbach α=0.61), but all items contributed significantly to good internal consistency which implies that this form of subscale should be kept as finale one. Second subscale had a satisfactory internal consistency (k=6; Cronbach α=0.67), as well as third one (k=5; Cronbach α=0.66) which implies that both of these two forms of subscales should be kept as finale ones.

Results of sensitivity test of new formed questionnaire are shown in Table 3. Only 3 items did not have full range (sc3, sc13, sc14) which implies about good sensitivity of new formed scales. Distribution of results was not normal (Kolmogorov-Smirnov Statistic was significant for all items), which was expected. For first and third subscales means were at lower part of subscale (positive asymmetry) meaning less risky behavior of computer users and for second subscale means were at higher part of subscale (negative asymmetry) meaning more risky behavior of computer e.g. low level of users' maintenance of personal computer systems.

The Exploratory factor analysis (method principal

u10	.758
u11	.428

components) was also used for the second part of UISAQ, which have shown extraction of 1 factors and explanation of 64.37 % of overall variance. In table 4 is shown factor structure of the second part of UISAQ which consisted of 6 items that measured the level of user's information security awareness, and which had a satisfactory factor loadings for all items on one factor.

Reliability analysis (Table 5) had shown high internal consistency (k=6, Cronbach α=0.89) and a satisfactory factor loadings which implies that it should be kept in their original form. All items had full range of response which implies good sensitivity (Table 6) of a new formed scale. Distribution of results was not normal (Kolmogorov-Smirnov Statistic was significant for all items), which was expected. Means were at higher part of subscales (negative asymmetry) meaning low level of user's information security awareness.

For the third part of UISAQ, Exploratory factor analysis (method principal components) was also appropriate. Analysis had shown extraction of 1 factors and explanation of 45.55 % of overall variance. In table 7 is shown factor structure of the second part of UISAQ which consisted of 5 items that measured the level of user's beliefs about information security and which had a satisfactory factor loadings for all items on one factor.

Reliability analysis (Table 8) had shown lower internal consistency (k=5; Cronbach α=0.60) with two items significantly violating internal consistency (items u7 and u11) so those items were excluded from further analysis and form with 3 items which had high factor loadings and good internal consistency (k=3; Cronbach α=0.76) was kept. All items had full range of response (Table 9) which was a measure of good sensitivity of a new formed scale.

TABLE VIII. RELIABILITY ANALYSIS: ITEM - TOTAL STATISTICS FOR THE THIRD PART OF UISAQ EXTRACTION

u10	1.00	5.00	4.00	2.346	1.175	.197[a]

a. $p < 0.01$

Distribution of results was not normal (Kolmogorov-Smirnov Statistic was significant for all items), which was expected. Means were at lower part of subscale (positive asymmetry) meaning high level of user's beliefs about information insecurity.

On the last, fourth part of UISAQ was applied Descriptive statistics as this part consisted of different types of questions with different possible answers. Results (Table 10) showed that all the questions (k=6) in this part of the questionnaire, which had examined issues regarding quality and safety of passwords, had a full range of answers for all items which implies good sensitivity. Although, test of normality of distribution (Kolmogorov-Smirnov Statistic) was significant, normal distribution wasn't significantly violated (asymmetry coefficients Skewness and Kurtosis were not greater than - / + 2).

IV. CONCLUSION

Although this questionnaire requires more work, first results look promising. Results show that UISAQ has potential to become a good and reliable instrument for measurement of users' information security awareness. After validation it may become first international measurement tool of its kind as basis for ongoing professional and scientific research.

With the UISAQ IT professionals will be able to analyze information systems' users in order to identify issues with low security level, while scientists will be able to generally categorize information systems' users regarding level of their information security awareness. By analyzing enough samples of all kinds of information system's users it should be possible to gain some general

conclusions about user's potentially risky behavior, correlation with level of security awareness and identification of most insecure kinds of users.

As future work, authors will repeat collecting data analyzing them and that way improving UISAQ as many times as needed in order to develop as-good-as-possible questionnaire. The end of development process should be international validation of this questionnaire.

E-mail: kristian.skracic@fer.hr

Abstract - The aim of this paper is to analyze question based user authentication methods with regard to their potential use in commercial environments and the limitations they impose. We provide an overview of current work related to question based authentication and describe the difference between static and dynamic questions in user authentication. Additionally, we give an introduction into some common practices used in user authentication in commercial environments. Based on existing research we suggest that only dynamic questions should be used in commercial environments and propose a set of requirements a data source used for creating authentication challenges should meet. Also, we categorize the types of data that can be leveraged for authenticating users.

I. INTRODUCTION

Textual passwords present the dominant knowledge based authentication method for authenticating users. It relies on a shared secret which is known only to the user and the authenticator. Also, the method relies on users being able to recall their password during authentication. We propose that an authentication method should inherently be able to remind the user what the answer is, while at the same time it should not leek any information to third parties. Alternative authentication methods have been researched quite extensively in the past years in the hopes of replacing textual passwords [1].

Question based authentication presents a way of authenticating users by posing questions to which only a legitimate user would know the answer. However, authenticating users by allowing them to answer questions has some practical limitations. The user would have to provide answers that are private or confidential in nature and others, close to the user, may know the correct answer.

Also, the strength of the authentication process relies on the information used to construct authentication questions which could have implication on the security and integrity of the authentication process.

In this paper we give an overview of some of the existing question based authentication methods and categorize the existing types of questions available for authentication. Also, we conduct a feasibility study of their use in commercial environments based on related work and their practical limitations and weaknesses.

Question based authentication is a form of authentication that relies on a user answering a specific question which only he knows the answer to. The main premise of question based authentication is that a legitimate user will easily give the right answer to a question, while an imposter would not. However, this is rarely the case since most authentication questions are based on information that is publicly available or well known and easily guessable. In this paper we analyze the various aspects of question based authentication and propose a set of requirements that could help such authentication methods to become viable solution for commercial systems. We choose to focus our study on commercial systems since they have high security requirements. By commercial systems we mean any information system that either handles sensitive or private information or financial transactions.

II. RELATED WORK

A. Question based authentication

Question based authentication represent a way of authenticating users by posing questions to which only a legitimate user would know the answer to. It can be divided in two main groups, static and dynamic questions [2]. The main difference with static and dynamic questions is that with dynamic questions, the user is not aware of what the question will be until the login attempt is made. With static questions, the question and answer are usually chosen during registration and do not change over time unless the user wishes to change them. As described in [3], there are three types of static challenge questions: fixed, open and controlled questions. Examples of static questions are a user's mother's maiden name or the name of the street they grew up on. In contrast, a dynamic questions could be the number of calls the user made today.

In the following sections we give an overview of related work that describes the use of static and dynamic questions for user authentication.

1) Static Questions

The research in [5] proposes an additional authentication mechanism to the classical username and password. It proposes the use of a profile based authentication framework (PBAF), which is a multi-modal authentication approach, for securing online examination.

During the learning process, users are given various profile questions that are used to extend and refine the user's individual profile. In essence, the user is asked to

answer several questions such as a friends surname or a favorite academic subject. Before being allowed to attempt an online examination, the student has to provide the same answers that were given during the first questioning.

In essence, the research is based on multiple static questions. We argue that the proposed solution has the same drawbacks as solutions that only use static questions. As illustrated in [6], static questions are not immune against attacks that include automated data-mining of public records. Also, we argue that online examination has different security requirements with regards to authentication. The user (student) is more likely to want to cheat by allowing another user to take the exam in his place. This differs from e-banking systems where a user does not want another user accessing their account.

The research in [7] analyses human relationships as a basis for user authentication. More precisely, social authentication is based on the premise that a user would be able to recognize a friend or acquaintance, while a stranger could not. The research is based on an authentication method proposed by Facebook, which relies on a user recognizing his friends from various images in his album and identifying them. The research proposes that social authentication is not secure against close enemies. The paper also argues that face recognition algorithms are becoming more and more sophisticated and could be used to automate guessing attacks. Also, the data on social networks is exposed to a wide array of possible attacks and could be used to subvert such an authentication method. The paper also suggests that an attack may be derived by leveraging name statistics in challenges where a user has to name the person on a picture. Bonneau et al [8] showed that many personal knowledge questions related to names are vulnerable to trawling attacks.

The paper proposes a community-based challenge selection, in which a user is shown various pictures that come from different communities. For example, a community could be the users family, work colleagues, childhood friends etc. The result of the research paper suggests that each user has 3 to 4 communities. This does not present a viable solution for systems with medium or high security requirements. Surveys [9] and [10] show that 80% of users do not change their privacy settings from the default ones, allowing their data to be seen by various individuals. Also, a critical observation is that many attackers are usually in the user's friend circle and thus have an intimate understanding of the user.

As stated by [3], question based authentication challenges are often based on information that is already known to the user, while passwords are constructed using various rules and are often hard to memorize. Thus, question based challenges are often used for credential recovery.

The research under [11] describes a similar authentication method based on personal information available from social networks such as Facebook. The conclusion of the research is that attackers can use publicly available information to subvert some question based authentication challenges. For example, the users favorite pets name or their mother's maiden name are examples of weak authentication challenges that can be answered by using publicly available resources like search engines and social networks.

The research in [15] proposes a new authentication method called query-directed passwords (QDP). The research makes a distinction between push and pull passwords. Push passwords are standard password authentication systems where a user has to memorize a new piece of information. Pull passwords are question based authentication challenges as described in [3]. The pull type is further categorized in the following sections:

- Selectable question and selectable answer – a question based system where the system provides both the question and the answers. The user chooses both and needs to memorize them
- Selectable question and open answer – a system where the user has to select a predefined question and responds with his own answer. This present the most common type of static question authentication. This is referred to as fixed questions in [3].
- Open questions and open answer – a question based system where the user has to supply both the question and the answer. This is referred to as open questions in [3].

QDP uses a combination of selectable questions and selectable answers with selectable questions and open answers. However, the answers are restricted to numbers which is called the QDP PIN (personal identification number). When the user tries to authenticate, the PIN derived from the current answers Is compared to the stored PIN.

As stated in [15], QDP achieves optimal security results when used infrequently as there is a finite number of PIN available.

2) Dynamic questions

The research under [4] proposes an authentication method based on leveraging personal history data. The security of the proposed solution is based on the volume of information known in detail only to the authentic user and is too large for an imposter to learn, rather than relying on a shared secret.

The research proposes that the majority requirement for a trusted-third-party (TTP) authentication is the information that the user knows as it is portable and is available at a lower cost. Thus, the method relies on information stored in the user's calendar. The questions are constructed based on various appointments that are in the user's calendar. Examples of such questions are:

- On 27th of June 2003 Friday, was "DMC" scheduled at 14:00-15:00? -Where the answer is either yes or no;
- On the 21st of May 2003 Wednesday, when was it scheduled to meet "Steven". -Where

the answer is a time interval (e.g. 9:00-10:00, 12:00-13:00, 15:00-16:00).

The research results show that such a method is not suitable for real-world authentication, as stated by the authors. The reason for this is that the chosen data source (a users calendar) provides guessable data. Being a feasibility study, it does prove that such an authentication method is possible. Also, the research is focused on questions relating to events. We argue that these are not the only types of questions that can be used for authentication.

Similarly to [7], the research in [12] describes a form of question based authentication aimed at group authentication. The research is based on the work of Basu and Muylle [13], which outlined that there are systems where the affiliations with a group is more important than an individual's identity. The method outlined in this research assumes that an outsider will cause almost negligible damage in case granted access. Thus, it is not a viable solution for commercial systems. However, the work outlines a new form of data that is available and could be leveraged for authentication. The method relies on some form of initial knowledge that is formed within the group and is shared between the group members. The authentication pilot experiment assumes that the members of the group should be able to identify their group knowledge whereas an outsider would find it hard to identify group knowledge. Also, it assumes that the group knowledge accurately reflects the group characteristics.

The results of the experiment showed an almost perfect authentication score in which insiders could recognize group knowledge but outsiders could not. The experiment was also repeated for virtual groups (e.g. chat rooms) where the results were similar to the first experiment. In order to automate the question generation, the Social Network Analysis (SNA) technique is used which was developed in [14]. Using structural and relational properties provided by the SNA technique, the system can generate various types of questions asking about group norms, objectives, decision making, activities and language. For example, it could create a question based on who made a particular decision within the group and who the detractors were. In the pilot experiment, the following three questions were used to authenticate group users:

- Who is the most active member
- Which message topic has recently been sent
- Which is the latest group picture

We note that the answers to these questions change with a frequency of one week to a few months.

The research in [16] proposes the use of user's medical history as a biometric trait. The medical history data is constructed in hierarchical format and then used to construct challenges in form of questions a user must answer in order to authenticate. It relies on the premise that only the authentic user has the secret knowledge about their past medical conditions. The research is focused on solving two problems. The first is related to the speed of the authentication process. The research proposes that a quick method for extracting relevant data from medical history is needed. Secondly, the research addresses the aspect of privacy when leveraging medical data for authentication. The research suggests a solution to both problems by arranging the medical history data in a hierarchical format using h-Data and attribute value taxonomies (AVT). By abstracting the data, the challenges can guard a user's privacy, and at the same time allow for a quick traversal through the data.

The research acknowledges the possibility of using medical data in both direct and implicit questioning. An example of direct questioning would be to simply ask the user if he has a certain condition or has had a specific condition in the past. Also, an example of direct questioning would be to visually inspect the user and see if some medical condition is present. This may be less effective when a human validator is not present. An example of implicit questioning would be to ask a patient suffering from type II diabetes about his daily diet or if he experiences hyperinsulinemia.

Although direct questioning allows for a quick physical inspection of possible answers, it is argued to be inappropriate because users may feel reluctant to answer truthfully in the presence of a human validator. Instead, general questions such as lifestyle and dietary habits could be asked for authentication. The research lacks in defining how an answer, or group of answers, are to be measured for correctness. Also, one if left with the impression that all questions are fundamentally equal with regard to their guess ability and security.

Based on this research, we could conclude that data relating to medical history is related to the user in a very specific way. More precisely, the challenges created by leveraging medical history data could be different than challenges created by user's financial data. We could argue that other user specific data are equally independent and need to be viewed separately. In other words, the way a challenge is created with medical data, may differ from the way data is used with financial data.

B. Authentication in commercial environments

The paper under [17] classifies Internet banking authentication methods based on their resistance to offline and online credential-stealing attacks. Offline attacks take place on an insufficiently protected computer where an attacker may install various malware to steel sensitive and confidential information from the user. Also, attackers can poison the users local DNS cache and redirect traffic to a malicious server he controls in order to launch additional attacks, like Phishing.

Online attacks are defined as attacks that take place during the user's interaction with the target information system. An attacker tries to insert himself in the communication stream and use or steal relevant information to gain more access to the target system. The paper proposes that one-time passwords may be a viable solution for Phishing and similar attacks on user's credentials. Also, the paper proposes that all transactions should be signed by the user's private key. However, such an option relies on a PKI infrastructure and on the notion

that a user would keep their private key safe. Other research has proven that users tend to dislike such methods of authentication [18]. The research results in [18] show that users tend to prefer authentication methods that are based on a single factor. Such preferences show that users are more focused on usability than on security. This could be interpreted as a need for creating a new authentication method that will be both usable and secure.

The research under [19] proposes a new authentication method that removes the need for passwords altogether. The motivation lies in the idea that most phishing attacks could be reduced if users do not need to enter passwords during authentication. By using one-time passwords, phishing becomes much more complex since a stolen password can only be used once. Also, with time sensitive one-time passwords stolen passwords can only be used in a limited time period.

The paper under [20] describes various methods of authentication that are commonly used to authenticate users in e-banking environments. The evaluation shows that passwords are the most insecure method of authentication, while tokens that generate one-time passwords are the safest. The analysis does not include question based authentication.

Since users tend to dislike tokens [18], some approaches to one-time passwords have been focused on delivering them via SMS messages on a user's mobile phone [21]. This form of authentication greatly depends on the security of the underlying network and may include additional overhead costs. For example, in some countries it is possible to launch a SIM swap attack which could be used to attack SMS based user authentication methods.

III. USE OF QUESTION BASED AUTHENTICATION IN COMMERCIAL ENVIRONMENTS

The research in [3] provides criteria for building and evaluating question based challenges. The rules are based on three criteria: privacy, security and usability. Privacy is an important criterion as it does not limit the challenges, but the authenticator. The research proposes that in order to preserve user privacy, the authentication system should store a limited amount of information locally. The security criterion requires that the challenge is not easily guessable or observable from different sources. Usability is a well documented requirement in user authentication [18]. Thus, the usability criterion is concerned with providing a user-friendly experience with regard to applicability, memorability and repeatability. The work in [22] expands the criteria to include 25 properties that are beneficial for an authentication system. The criteria are generic and not related only to question based challenges.

From the above analysis we conclude that commercial environments tend to gravitate towards one-time passwords and two factor authentication [23]. We argue that the reason for this is the short lifespan of a credential used for authentication. Also, this presents one of the requirements outlined in [24]. We argue that in order for a question based authentication method to be a viable option in commercial environments, these requirements need to be met.

As described in [4], a crucial part of the research relevant to question based authentication is to understand how do humans remember and what are the parameters that can affect the human memory. Also, it is crucial to define the types of questions that are difficult for others to answer. In order for a question based authentication method to reach the required level of transiency, it has to use a data source with sufficient information from which the questions can be created.

The limitations of question based authentication methods for use in commercial systems are listed below.

- The questions could be answered by third parties
- Legitimate users could not provide correct answer
- Challenges and answers are known to be static in nature. They do not change over time which makes them susceptible to stealing

Based on the above analysis, we conclude that questions need to be dynamic in order to present third parties from reusing a recorded credential. Furthermore, we propose that a user must know the answer to the dynamic question with high probability. At the same time, the intruder should have a low probability of guessing the answer.

We propose that further research in question based authentication should first define a set of requirements for data sources used to construct questions. Secondly, that there is a need for categorizing information and its properties as well as define the semantic value and user relation to information. The expected outcome of such research should be a set of structures that can be used to construct questions. In the following sections we make a first step towards these goals.

A. Users relation to information

We propose that in order to leverage various types of user information, it is necessary to establish how a user is tied to the information he creates. Further research should involve analyzing how humans remember various types of information. For example, how humans remember facts, relations and values.

We suggest a categorization of user information that can be leveraged for authentication.

- Personal information - this category includes financial and medical data related to the user, as well as other personal information,
- Events - data related to various events,
- Social data - this category includes data that a user generates as part of a group of people or through social interaction,
- Habits - personal routines,
- Preferences & opinions - includes the way a user feels or thinks about a certain topic,

- User generated data - includes various sources where a user generates information that are not necessarily personal. For example, information a user has posted on a forum or group chat, or sent via email.

B. Dynamic questions

We propose that question based authentication can reach the level of security dictated by current standards, such as one-time password tokens, by leveraging large data sources and by creating dynamic questions.

IV. DATA SOURCE REQUIREMENTS

In this section we propose a set of requirements that should be met for a question based authentication method to be viable for use in commercial environments.

1) Dynamic questions

The questions should be created and evaluated on-the-fly, during a user authentication request by the system in charge of the data source. We propose that the authentication system should use its local data source and construct challenges based on its own data source. The questions should be created dynamically and should not be static in nature. This way, the challenges come as close to one-time passwords as possible.

2) Data source availability

The data source should not be publicly available in any way or form. As demonstrated by [11], public data sources are not a viable solution for creating challenges. Since attackers have the same access rights to public data sources as both the user and the authenticator, they can leverage this information for giving correct answers. We propose that a data source should be private and that no other entity should have access to it.

Furthermore, we propose that a question based on any form of user data should have this characteristic: the sum of information is large and well-known only to the individual and also that the volume is too large for imposters to learn. Then it should be possible to collate and query personal information automatically for the purposes of user authentication.

3) Data duplication

No other data source should have the information from which the question was created. Or, at least, if the secondary data source exists, it should have restricted access. If the data source is not public, there is still a possibility of an internal attacker who has access to the data source to use the available information to pose as another user. In order to minimize this threat, we propose that the data in the data source should not exist in other data sources which are publicly available.

V. CONCLUSION

This paper proposes that only dynamic questions can be used to authenticate users in commercial environments. We propose that challenges in question based authentication methods can be improved by using a data source that meets the requirements outlined in the previous section. Additionally, we suggest that legitimate users could be more likely to remember the correct answer if they are asked in a specific way. Although this paper does not provide insight into how this could be achieved, we propose that the key lies in the relationship between the user and the data used for constructing challenges. Thus, we propose a categorization of the data that can be used for authentication.

Further research should focus on dynamic questions and how they can be used in authentication systems. Also, we propose that representative data sources should be studied with the aim of defining methods for authentication question generation. With the goal of hopefully yielding configurable general purpose tools or algorithms for question generation from a variety of appropriate data sources.

Abstract - Mobile Ad-hoc Network (MANET) is a collection of communication devices or nodes that wish to communicate without any fixed infrastructure and pre-determined organization of available links. Security is a major challenge for these networks owing to their features of open medium, dynamically changing topologies. A black hole is a malicious node that falsely replies for any route requests without having active route to specified destination and drops all the receiving packets. Sometimes the black hole nodes cooperate with each other with the aim of dropping packets. These are known as cooperative black hole attack. This proposed work suggests the modification of Ad-hoc on Demand Distance Vector (AODV) routing protocol. We used a technique for detecting as well as defending against a cooperative black hole attack using True-link concept. True-link is a timing based countermeasure to the cooperative black hole attack. This paper shows the performance of MANET decreases for end-to-end delay, normalized routing overhead and increases throughput and packet delivery ratio.

I. INTRODUCTION

A Mobile Ad hoc network (MANET) is a self - configuring network [1, 2] that does not require any fixed infrastructure, which minimizes their cost as well as deployment time. As each node in this network is free to move that makes the network to change its topology continuously. These infrastructure-less mobile nodes in ad-hoc networks dynamically create routes among themselves and form own wireless network on the fly. Because of the dynamic nature, these networks are more vulnerable to attacks so security is an important as well as serious issue in MANET. One of the most critical problems in MANETs is the security vulnerabilities of the routing protocols. A set of nodes in a MANET may be compromised in such a way that it may not be possible to detect their malicious behavior easily. Such nodes can generate new routing messages to advertise non-existent links, provide incorrect link state information, and flood other nodes with routing traffic.

One of the most widely used routing protocol in MANETs is the Ad hoc on-demand distance vector (AODV) routing protocol. AODV is vulnerable [2] to the well known black hole attack. Most authors have proposed a solution to identify single black hole attack. However in their proposed solution many of them found multiple black hole nodes. Some author have suggested solution for detecting cooperative black hole attack but due to multipath routing it require more end to end delay and more routing overhead. The proposed technique works with modified AODV protocol and routing information table for searching trustful node with the help of tru-link.

This paper is organized as follows. In Section II related work for detecting cooperative black hole attack has been discussed. Section III provides AODV and its work in which discuss overview of AODV protocol with the description of black hole attack characteristics. Section IV describes the proposed solution for detecting cooperative Black hole attacks in mobile ad hoc networks and shows the working of the algorithm with the help of an example. Section V shows the simulation results of the proposed work. We conclude plan for future work in section VI.

II. RELATED WORK

In this section we will discuss research work has been done by various authors.

J. Sen, S. Koilakonda and A. Ukil [3] proposed a mechanism for defending against a cooperative black hole attack. The mechanism modifies the AODV protocol by introducing two concepts, (I) data routing information (DRI) table and (II) cross checking. In the DRI scheme, two bits of additional information are sent by the nodes which respond to the RREQ message of a source node during route discovery process. Each node maintains an additional data routing information (DRI) table. In the DRI table, the bit 1 stands for "true" and the bit 0 stands for "false". The first bit "From" stands for the information on routing data packet from the node (in the Node filed), while the second bit "Through" stands for information on routing data packet through the node. The process of cross checking the intermediate nodes is a one-time procedure which should be affordable for security. The cost of crosschecking the nodes can be minimized by allowing the nodes to share the DRI table of their trusted nodes with each other.

J. Eriksson, S. V. Krishnamurthy, M. Faloutsos [4] proposed an algorithm to detect a wormhole attack by

using True-link concept. True-link is a timing based countermeasure to the wormhole attack. Using True-link, a node can verify the existence of a direct link to an apparent neighbor. Verification of a link operates in two phases. In the rendezvous phase, the nodes exchange nonce. This is done with tight timing constraints, within which it is impossible for attackers to forward the exchange between distant nodes. In the authentication phase, i and j transmit a signed message, mutually authenticating themselves as the originator of their respective nonce. True-link is meant to be used together with a secure routing protocol. True-link is virtually independent of the routing protocol used. This work shows that True-link provides competent protection against potentially devastating wormhole attacks.

S. Banerjee [5] proposed a mechanism capable of detecting and removing the malicious nodes launching these two types of attacks. Their approach consists of an algorithm which works as follows. Instead of sending the total data traffic at a time we divide the total traffic into some small sized blocks. So that malicious nodes can be detected and removed in between the transmission of two such blocks by ensuring an end-to-end checking. Source node sends a prelude message to the destination node before start of the sending any block to alert it about the incoming data block. Flow of the traffic is monitored by the neighbors of the each node in the route.

L. Tamilselvan and V. Sankar Narayana [6] proposed a solution with the enhancement of the AODV protocol which avoids multiple black holes in the group. A technique is used to identify multiple black holes that are cooperating with each other and discover the safe route. It was assumed in the solution that nodes are already authenticated and therefore can participate in the communication. It uses fidelity table where every node that is participating is given a fidelity level that will provide to that node. Any node having 0 value is considered as malicious node and is eliminated.

H. Weerasinghe [7] proposed the solution which discovers the secure route between source and destination by identifying and isolating cooperative black hole nodes. This solution adds on some changes in the solution proposed by the Ramaswamy to improve the accuracy. This algorithm uses a methodology to identify multiple black hole nodes working collaboratively as a group to initiate cooperative black hole attacks. This protocol is slightly modified version of AODV protocol by introducing Data Routing Information (DRI) table and cross checking using Further Request (FREQ) and Further Reply (RREP).

C. Wu Yu, Tung-Kung, W. ReiHeng, Cheng and S. Chao Chang [8] proposed a distributed and cooperative procedure to detect black hole node. In this each node detect local anomalies. It collects information to construct an estimation table which is maintained by each node containing information regarding nodes within power range. This scheme is initiated by the initial detection node which first broadcast and then it notifies all one-hop neighbors of the possible suspicious node. They cooperatively decide that the node is suspicious node.

III. AODV AND ITS SECURITY PROBLEMS

A. AODV and Black Hole Attack

1. Overview of Ad hoc On Demand Distance Vector (AODV)

AODV is a reactive [9,10] routing protocol that does not require maintenance of routes to destination nodes. As its name indicates AODV is an on-demand routing protocol that discovers a route only when there is demand from mobile node.

2. Cooperative Black Hole Attacks

A black hole attack is a kind of Denial of service (DoS) attack in mobile ad hoc networks. In this attack [11], a malicious node sends a fake RREP packet to the source node that has initiated a route discovery, in order to show itself as a destination node or an intermediate node to the actual destination node. In such a case the source node would send all of its data packets to the malicious node. The malicious node then absorbs all the packets and drops them fully or sometimes partially. As a result source and destination node will not be able to communicate with each other as shown in figure 1.

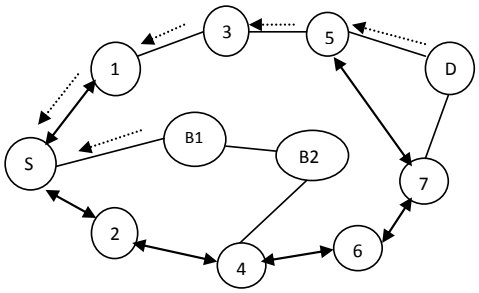

Figure 1. Detection of cooperative black hole attack

Consider the case where S is the source node, D is the destination node and B1 is the malicious node, here node S starts with the route discovery process then the node B1 advertises itself as having a valid shortest route to the destination, here the route is false with the purpose of intercepting packets. Moreover a malicious node does not need to check its routing table when sending a false message; its response is more likely to reach the source node first. This makes the source node think that the route discovery process is complete, ignore all other reply messages and begin to send data packets. As a result, all the packets through the malicious node are simply absorbed discarded and then lost. The malicious node could be said to form a black hole in the network. Sometimes these malicious nodes cooperate with each other with the same aim of dropping packets, these are known as cooperative black hole nodes and the attack is known as cooperative black hole attack.

IV. THE PROPOSED WORK

We propose a methodology for identifying multiple black hole nodes cooperating as a group with slightly

modified AODV protocol by introducing Data Routing Information (DRI) Table and Cross Checking with True-link concept shows in the system architecture of figure 2.

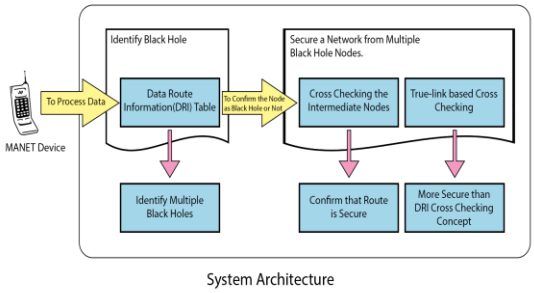

Figure 2. System Architecture

A. Data Routing Information Table

Figure 1 shows the cooperative black hole attack. Figure 1 illustrates this topology where black hole node B1 and B2 are malicious and cooperate with each other. They are attracting intermediate nodes (IN) for shortest path towards a destination and drop the packets.

The solution to identify multiple black hole nodes acting in cooperation involves two bits of additional information from the nodes responding to the RREQ of source node S. The first bit "From" stands for Information on routing data packet from the node (in the Node field) while the second bit "Through" stands for information on routing data packet through the node (in the Node field). Each node maintains an additional Data Routing Information (DRI) table. In the DRI table I, 1 stands for 'true' and 0 for 'false'.

TABLE I ADDITIONAL TABLE OF DATA ROUTED FROM, AND ROUTED TO NODES MAINTAINED BY NODE 4.

Node	**Data Routing Information**	
	From	***Through***
5	1	0
6	1	1
B2	0	0
2	1	1

Consider DRI table I which is maintained for node 4 in which the entry 1 0 for node 5 shows that node 4 has routed data packets from 5, but has not routed any data packets through 5 (before node 5 moved away from 4). The entry 1 1 for node 6 shows that, node 4 has successfully routed data packets from and through node 6. The entry 0 0 for node B2 shows that, node 4 has NOT routed any data packets from or through B2. As an example, let's consider the network in figure 3.

When node B1 responds to source node S with RREP message, it provides its next hop node B2 and DRI for the next hop (i.e. if B1 has routed data packets through B2). Here the black hole node lies about using the path by replying with the DRI value equal to 0 1. Upon receiving RREP message from B1, the source node S will check its own DRI table to see whether B1 is a reliable node. Since S has never sent any data through B1 before, B1 is not a reliable node to S. Therefore, *S* sends further request to *B2* via alternative path *S*-5-6-*B2* and asks *B2* about three things: if B2 has routed any data from B1, who is B2's next hop, and if B2 has routed data packets through B2's next hop. Since B2 is collaborating with B1, it replies positively to all the three requests and gives node 6 (randomly) as its next hop. When the source node contacts node 6 via alternative path S-5-6-D to cross check the claims of node B2, node 6 responds negatively. Since node 6 has neither a route to node B2 nor has received data packets from node B2, the DRI value corresponding to B2 is equal to 0 0 as shown in figure 4. Based on this information, node S can infer that B2 is a black hole node. If node B1 was supposed to have routed data packets through node B2, it should have validated the node before sending it. Now, since node B2 is invalidated through node 6, node B1 must cooperate with node B2. Hence both nodes B1 and B2 are marked as black hole nodes and this information is propagated through the network leading to their listing as black holes, and revocation of their certificates. Further, S discards any further responses from B1 or B2 and looks for a valid alternative route to D.

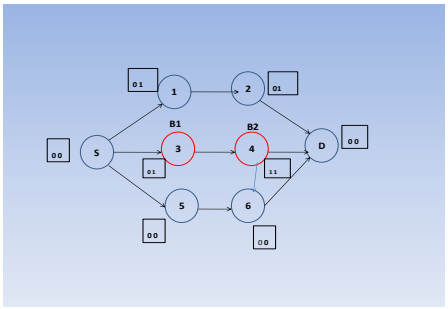

Figure 3. Detection of cooperative black hole attack by using DRI table

B. Cross Checking with True-link

Crosschecking-True-link is a timing based mechanism (time-based approach) against cooperative black hole attacks. Black hole enters mostly through network layer. So, we include Mac layer with the network layer integration (i.e cross layer) attacker will be confused that which node having the data and direction of forwarding the data. This assumption will helpful for detecting multiple black holes. By using this True-link we are integrating DRI table information with True-link concept. First we collect the black hole information using DRI table after that make list of malicious nodes and checking malicious nodes using true-link concept. True-link consists of rendezvous phase. The rendezvous phase is similar to RTS-CTS-DATA-ACK exchange, here nodes a and b will exchange two randomly generated numbers, called values. The assumption is that the IEEE 802.11 standard makes it extremely difficult for an attacker to successfully relay the exchanged frames. In the

authentication phase, i and j each transmit a signed message (α_i, β_j) mutually authenticating themselves as the originator of their respective values.

To verify the existence of a link, i initiate a link verification exchange. The exchange can be done using rendezvous phase. The rendezvous phase is managed by strict timing constraints, making it extremely difficult for an attacker to fake a link. The rendezvous phase is implemented as a single RTS-CTS-DATA-ACK exchange. We describe the operation of the protocol for each of these frames. The rendezvous operation includes following steps:

Request to Send (RTS) : Node i called initiator, calls init ( ). Node i sends an RTS to node j.

Clear to Send (CTS (α_j)): After receiving the RTS, node j calls HandleRTS ( ). A locally generated value α_j is included in the CTS, which is sent after a delay of one Short Interframe Space (*SIFS*), is the small time interval between the data frame and its acknowledgment.

DATA (βi): Having received the CTS, i generate value β_i. After a SIFS delay, the nonce is sent as the packet payload, together with a header, identifying the packet as a rendezvous packet.

ACK: When node j receives the payload packet containing values β_i, the HandleRTS ( ) function sends the ACK frame, after a SIFS delay. The received packet and the locally generated values α_j are handed to the upper layer for processing. When node i receives the ACK, the init () function at i returns the pair (α_j , β_i) to its caller.

RREQ: Route request packet
RREP: Route reply packet
SN:Source node
DN: Destination node
IN: Intermediate node
α,β: nonce key
DRI: Data Routing Information
Step 1: SN broadcasts the RREQ packet
Step 2: SN receives RREP
Step 3: if RREP is from any IN then
Step 4: SN verify the RREP of the node which sends RREP
Step 5: SN verify updates entry of DRI value of the intermediate node that initialized RREP
Step 6.then sendRTS();
Step 7.# recvCTS() times out after $t_{timeout}$ = SIFS
Step 8.α=recvCTS();
Step 9.if α != nil then
Step 10.β->nonce();
Step 11: # success = true if ACK received
Do reactive Link verification and routing method
Step 12 success=sendPacket([VerifyLink,β]);
Step 13.if success == true then
Step 14: Consider the route to be safe and start routing the data packets
Step 15: else
Step 16: Mark the node as malicious node and build a blackhole list
Step 17: end if

Figure 4. Proposed algorithm with True-link concept

The authentication phase does not have any strong timing constraints. Nodes send the authentication messages as soon as they have finished computing the cryptographic signature. Node i sends the message (α_j , β_i)i (signed by i) to j, thereby proving that it was the one sending the nonce β_i and that it received the correct α_j. This proves the existence of the link i to j to node j. Similarly, node j sends the message (α_j , β_i)j to i. This proves the existence of the link to node i.

C. Link Verification Maintenance and Routing

Verifying the existence of a link is important in itself, but in a dynamic network, this knowledge needs to be maintained and properly updated as the topology changes. We present two methods of link verification maintenance with True-link.

1. Proactive Link Verification

With this method, a node periodically transmits beacon messages to find its' current apparent neighbor set. It maintains knowledge about the actual neighbor set by periodically probing each neighbor with a link verification exchange. The proactive method is well suited to proactive routing protocols, or reactive protocols with local hello-messages. With these protocols, periodic beaconing maintains a consistent record of the apparent neighbors of a node, and it requires moderate extra effort to verify the links to each of these neighbors. When a new neighbor is found, a link verification exchange is initiated before the routing layer is notified of the neighbor discovery. Moreover, after an expiry period expiry interval has passed, each link is re-verified, to ensure that it still exists. The value of expiry interval is flexible, but should not be smaller than the beaconing interval.

2. Reactive link verification

Nodes using this method perform no link verification until the use of a link is needed. The reactive method is best suited to reactive routing protocols. As in the proactive case, a cache of recently verified neighbors is maintained, with an expiry interval (texp). In the reactive link-verification process for a broadcast route request a node waits until it receives a broadcast packet across a previously unverified link. At this time, it initiates a link verification exchange with the sender of the packet. To avoid a potential "implosion" effect, where many receivers try to initiate an exchange at the same time, the receiver waits for a small randomly selected time interval before initiating the link verification exchange.

D. Overhead vs. Security Tradeoff:

During the time interval expiry interval, a node may believe that it has a link with a neighbor, when in fact the neighbor has moved away. This provides a window of opportunity for a black hole attack faking the previously existing link. Thus, the value of expiry interval provides a tradeoff between high overhead due to frequent verifications and attack vulnerability, due to potentially obsolete information. In our simulations, we use expiry interval values between 10 and 120 seconds, with 30 seconds being the standard choice.

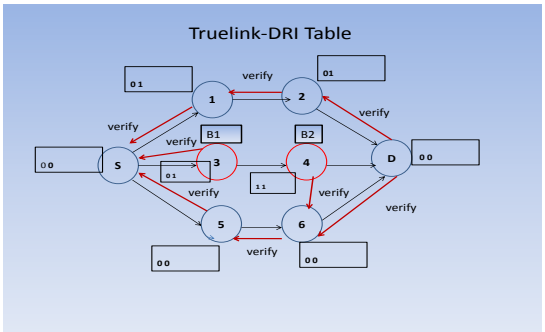

Figure 5. True-link with DRI table

V. SIMULATION RESULTS

The proposed algorithm has been carried out using the network simulator *ns-2* [12]. The 802.11 MAC layer implemented in ns-2 is used for simulation. We have used improved version of random waypoint model. Performances of the three protocols are evaluated: (I) standard AODV protocol, (II) AODV with two malicious nodes cooperating in a black hole attack, and (III) AODV with the proposed algorithm. The scenarios developed to carry out the tests using two parameters: (I) the mobility of the nodes and (II) the number of node in the network. The chosen parameters for simulation are shown in Table II. Following metrics are chosen to evaluate the impact of the black hole attack on the simulated network: (I) Throughput (II) Packet delivery ratio (III) Normalized Routing overhead and (IV) Average end-to-end delay. By using these metrics we are going to check the performance of the proposed scheme as compared to previous scheme.

TABLE II SIMULATION PARAMETERS

Sr. No.	Parameter	Value
1	Simulator	NS 2.35
2	DoS Attack	Black hole
3.	Channel Type	Wireless channel
4	Antenna Type	Omni directional
5	Protocol used	AODV
6	Underlying MAC Protocol	IEEE 802.11
7	Propagation Model	Two-ray ground
8	Mobility Model	Random way point
9	Queue	Droptail/Priqueue
10	Area(meter square)	1000*1000
11	Simulation time	200 sec
12	Pause time	1.0 sec
13	Speed(mps)	1,5,10,15,20,25,30
14	Traffic Type	CBR
15	MAC type	802.11
16	Link layer type	LL
17	CBR rate	1pkt/sec
18	Packet Size	512 bytes/packet
19	Number of sources/Destination connections	3
20	Number of Nodes	50
21	Number of malicious node detected	Two or more nodes which cooperate each other for dropping packet

Effects of node mobility vs performance metrics

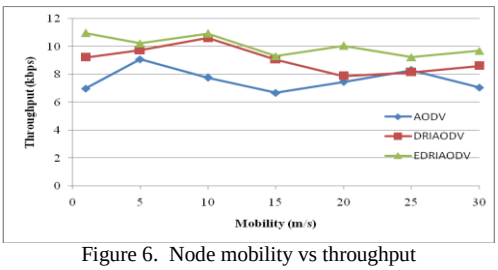

Figure 6. Node mobility vs throughput

Figure 6 to figure 9 shows the effects of mobility vs performance metrics like throughput, packet delivery ratio, normalized routing overhead and average end-to-end delay.

Figure 6 shows simulation result of node mobility vs throughput. Green color line shows proposed work in which we have achieved high throughput when node mobility is increasing as compared to AODV and DRIAODV means it improves the performance of proposed algorithm.

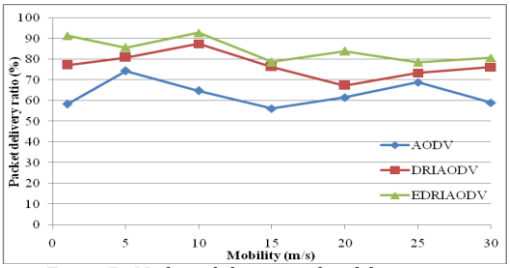

Figure 7. Node mobility vs packet delivery ratio

Figure 7, the metric packet delivery ratio is plotted against the node mobility. As the total number of mobile nodes in the network is 50, the node mobility is 1 to 30 mps. It achieves maximum delivery ratio. This is improvement over previous mechanism. It is observed that AODV performs better for lower node mobility rates. The delivery rate starts dropping with increasing mobility of the nodes. The proposed algorithm increases the delivery ratio to 72%.

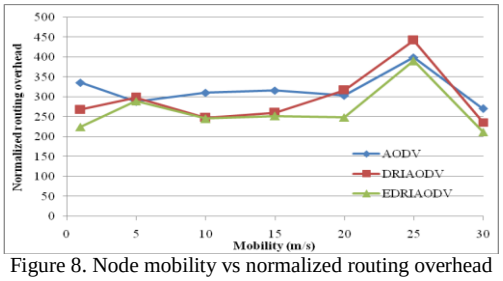

Figure 8. Node mobility vs normalized routing overhead

Figure 8 shows the simulation result with respect to Node mobility vs Normalized routing overhead. It achieves less normalized routing overhead. When mobility is high at that time routing overhead is also high but if we compare with normal AODV protocol it is 50% less. This proposed work achieves higher performance as compared to existing work.

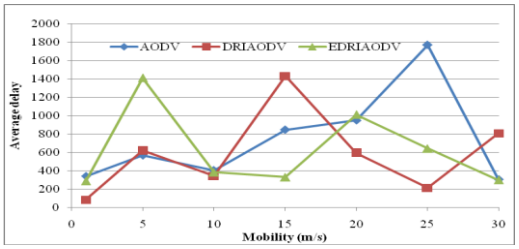

Figure 9. Node mobility vs average end-to-end delay

Above figure shows the node mobility vs average end-to-end Delay. Average delay should be less while achieving performance of AODV. In this, delay is 25% less as compared to existing system because of link verification is performed while sending packet on the network.

Effects of number of nodes vs performance metrics

Figure 10 to figure 13 shows throughput, packet delivery ratio, normalized routing overhead and average end-to-end delay.

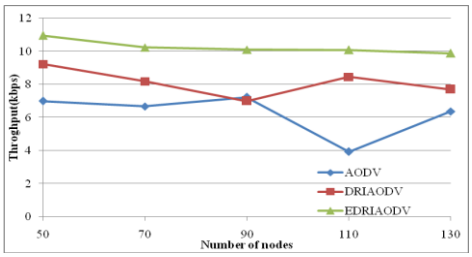

Figure 10. Number of nodes vs throughput

Figure 10 shows that when the number of nodes increases, the throughput increases for EDRIAODV protocols since source nodes can find more and more routes to destinations which can avoid black hole nodes (some normal nodes can reply before the black hole nodes).

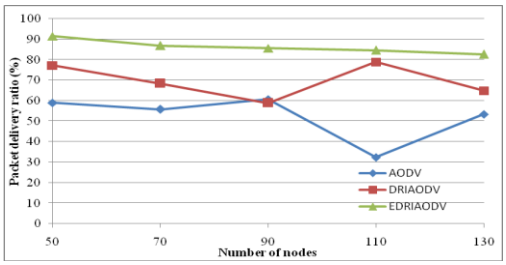

Figure 11. Number of nodes vs packet delivery ratio

Figure 11 shows that Packet delivery ratio is high as compared to other protocol. Because true-link performs link verification on selected black hole node means it will take less time as compared to other protocol when number of nodes are more. The delivery rate starts dropping with decreasing number of nodes.

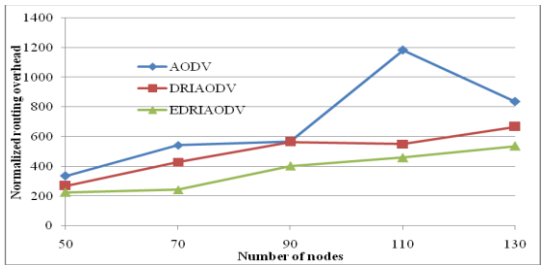

Figure 12. Number of nodes vs normalized routing overhead

Figure 12 shows that normalized routing overhead is less as compared to other protocol. Because AODV makes the lowest overhead when black holes are present since AODV uses less route request when black hole reply quickly for route request.

Figure 13 shows the impact of the number of nodes on the end-to-end delay. First, the end-to-end delay does not depict much difference when the number of nodes increases because the source and destination pairs of all CBR applications are the same for each scenario regardless of the number of nodes. But for less number of nodes, all protocols take more time since alternative routes are limited. Second, our protocol has little bit of more end-to-end delay than others since it takes more time to find out a secure route.

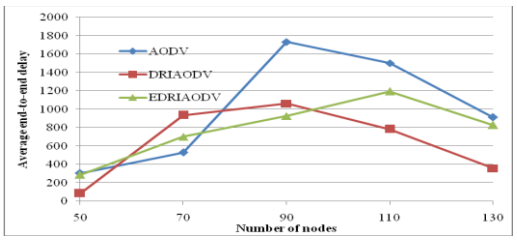

Figure 13. Number of nodes vs average end-to-end delay

VI. CONCLUSION

In this proposed work, the issue of cooperative black hole attack and its affect on the AODV-based routing protocol has been discussed. The route discovery process in the AODV is susceptible to Cooperative black hole attack and therefore, it is vital to have an efficient security method built into the AODV protocol in order to mitigate the effect of such attacks. True-link-crosschecking method is designed to isolate and mitigate the effect of black hole attacks in MANET. True-link-

crosschecking enhances AODV protocol to improve the network performance by improving routing update condition. The enhancement only involves a minimum modification in DRI based cross checking with True-link rendezvous phase by changing the existing AODV protocol scheme. This solution reduces routing overhead and delay. It achieves maximum throughput when number of nodes and pause time more. In proposed work we have reduced end to end delay as well as routing overhead. In future work, we are planning to reduce routing overhead by making nonce more secure and timestamp in link verification.

Abstract - Building a system for the detection and prevention of intrusions into computer networks is a major challenge. Huge amounts of network traffic that process these systems are characterized by diversity and the data are described by a number of attributes. In addition, input data are often changing in a relatively short period of time, creating a completely new traffic patterns. This significantly complicates the identification of potentially unwanted network traffic. The aim of this paper is to present and analyze the effects of combined application of Self Organizing Map (SOM), Adaptive Neuro Fuzzy Inference System (ANFIS), Subtractive Clustering (SC) and Voting Mechanism (VM) in building systems for intrusion detection in computer networks in order to maintain an acceptable level of efficiency of data processing and increased system adaptivity.

Keywords: Self Organizing Map, Adaptive Neuro Fuzzy Inference System, Subtractive Clustering, Voting Mechanism, Intrusion Detection and Prevention.

I. INTRODUCTION

The development of information technology in the field of processing, collection and distribution of data is further accelerated by the needs of modern business. Modern business is increasingly based on various forms of electronic commerce, which is further stimulated by the expansion of the Internet. This way of doing business brings new risks to the security of information systems. New threats appear daily by individuals and organizations who attack and abuse information systems. Accordingly, for the achievement of business goals of the company it is essential to ensure the availability and proper functioning of computer networks and to ensure that information systems are provided with information when they are needed. This creates the conditions for proper decision-making at all levels of management and decision-making system. One of the main requirements for the designers of computer networks in the past was to enable their fast and efficient work. One of the main objectives today is to prevent intrusions into computer networks through preventive action, or detect them when they happened. There is a trend in the world to theoretically and practically explore ways of detecting and preventing intrusions in computer networks [3]. The research in this paper is based on the use of SOM (neural network based on competitive learning), ANFIS, SC and VM in process of intrusion detection in computer networks. This paper is organized as follows. Section II presents related work in past several years. Section III presents data set that was used for system development, training and testing. Section IV present architecture of system describing its components using block diagrams and mathematical expressions. Section V presents proposed algorithm and reasons for combining SOM, ANFIS and SC. Section VI presents and discuss experimental result of algorithm execution. Section VII concludes the paper.

II. RELATED WORK

The researchers have been widely used SOM for data clustering [4]. However, SOM have some drawbacks. For instance, the network architecture of SOM has to be established in advance and it requires knowledge about the problem domain [5]. That kind of knowledge is difficult to achieve, especially with data of high dimensionality as it is case with intrusion detection and prevention data set [3]. Moreover, the hierarchical relations among input data are difficult to represent.

Several dynamic algorithms were proposed to overcome those drawbacks. The growing hierarchical SOM (GHSOM) is one algorithm that tries to face these problems. It is an neural network which consists of independent growing SOM arranged in layers [7]. The next is Enhanced Dynamic SOM (EDSOM). EDSOM is based on GHSOM. It is a dynamic node growth structure, but instead of using rectangular grid, a closed circle structure is applied for outpout node structure [6]. A Large Scale Memory Storage and Retrieval (LAMSTAR) network is another approach that is used for intrusion detection by combining SOM modules and statistical decision tools. It was specifically developed for application problems involving very large memory that relates to many different attributes [5]. The logistic regression model is used for data analysis concerned with describing the relationship between a response variable and one or more predictor variables. A logistic regression model with a binary response variable is a particular case of the general multinomial logistic regression model. Its dependent variable can have more than two choices that are coded categorically and in that case, one of the categories is taken as the reference category. A study on KDD CUP 99 that was published [3] identified predictors that are statistically significantly associated with the response variable.

III. KDD CUP 99 DATASET

Comparing various Intrusion Detection Systems (IDS) is extremely difficult because it is hard to find publicly avaliable data set. Fear of violating privacy is one of the main reasons why most companies are unwilling to provide their data to other institutions. Even if some of those data are available, it is very difficult to denote data as normal or as those signifying attack, since this would require the participation of a large number of experts in this area, and also a significant amount of time. Constant changes of network traffic include also new types of cyber attacks. It also brings a new definition of "normal" behavior. Because of that, it is no surprise that only a small number of shared data sets are available. IDS researchers have mostly used the KDD CUP 99 dataset in their work, thus the same data set was used in this research. It is composed of basic attributes, such as connection duration, protocol type, service type, status indicator, total bytes sent, total bytes received, whether the source and target address are same or not, number of wrong fragments, and number of urgent packages. In addition to these attributes, each connection is described by further thirty-two attributes that may be classified into the following three categories: contents attributes, time-based traffic attributes and host traffic based attributes. Each entry is composed of forty-one attributes plus target value. The target value represents the type of attack. The number of records was 4898430. 972780 records represented normal traffic, and the remaining records were attacks, with the following distribution: DoS (Denial of Service) 3883370, testing 41102, compromising attacks 1178 with 52 in relation to U2R (User to Root), and 1126 R2L (Root to Local). Duplicate records were removed from the dataset. After deleting duplicate records, the traffic was distributed as it is shown in Table 1.

TABLE 1. AN OVERVIEW OF TRAFFIC DISTRIBUTION

TRAFFIC	records	percentage	records	percentage
normal	812813	75,611	60593	19,481
probe	13860	1,289	4166	1,339
DoS	247267	23,002	229853	73,901
U2R	52	0,005	228	0,0733
R2l	999	0,093	16189	5,205
Total:	1074991	100	311029	100

Most of classification methods are not able to process the data in such a format. It is therefore necessary to perform pre-processing the data into a format acceptable by the classification algorithms. Examples of records from the KDD CUP 99 data set before pre-processing of data are as follows:

a) 0 tcp other S0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 130 13 1.00 1.00 0.00 0.00 0.10 0.05 0.00 255 13 0.05 0.05 0.00 0.00 1.00 1.00 0.00 0.00 neptune.

b) 0 udp private SF 105 147 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 1 1 0.00 0.00 0.00 0.00 1.00 0.00 0.00 255 253 0.99 0.01 0.00 0.00 0.00 0.00 0.00 0.00 normal.

For the purposes of this research attributes that describe each record used in the training and test data are labeled with the following symbols: $A_1, A_2, A_3, A_4, A_5, A_6, A_7, A_8, A_9, A_{10}, A_{11}, A_{12}, A_{13}, A_{14}, A_{15}, A_{16}, A_{17}, A_{18}, A_{19}, A_{20}, A_{21}, A_{22}, A_{23}, A_{24}, A_{25}, A_{26}, A_{27}, A_{28}, A_{29}, A_{30}, A_{31}, A_{32}, A_{33}, A_{34}, A_{35}, A_{36}, A_{37}, A_{38}, A_{39}, A_{40}, A_{41}, A_{42}$ a refer to the value of: DURATION, PROTOCOL TYPE, SERVICE, FLAG, SRC BYTES, DST BYTES, LAND, WRONG FRAGMENT, URGENT, HOT, NUM FAILED LOGINS, LOGGED IN, NUM COMPROMISED, ROOT SHELL, SU ATTEMPTED, NUM ROOT, NUM FILE CREATIONS, NUM SHELLS, NUM ACCESS FILES, NUM OUTBOUND CMDS, IS HOST LOGIN, IS GUEST LOGIN, COUNT, SRV COUNT, SERROR RATE, SRV SERROR RATE, RERROR RATE, SRV RERROR RATE, SAME SRV RATE, DIFF SRV RATE, SRV DIFF HOST RATE, DST HOST COUNT, DST HOST SRV COUNT, DST HOST SAME SRV RATE, DST HOST DIFF SRV RATE, DST HOST SAME SRC PORT RATE, DST HOST SRV DIFF HOST RATE, DST HOST SERROR RATE, DST HOST SRV SERROR RATE, DST HOST RERROR RATE, DST HOST SRV RERROR RATE and ATTACK TYPE respectively.

IV. SYSTEM ARCHITECTURE

Building a system that is used in this work was being done in phases using multiple components (Fig. 1). Each component has its own role and responsibilities in process of intrusion detection in computer networks. Components are as follows:

1) Component for data pre-processing
2) Component for forming a training and test data sets

3) Compoment for data attribute selection (SC Voting Mechanism)
4) ANFIS component
5) SOM component

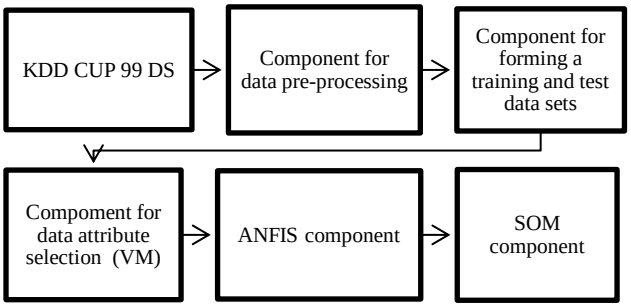

Figure 1. System architecture

Purpose of the component for data pre-processing is to prepare input data (training and test data set) for next component. This activity is performed in a manner to carry out the conversion of the symbolic value into numerical data and it is necessery to perform normalization on it (Fig. 2). This means that it is necessary to perform data pre-processing to obtain a format acceptable to classification algorithms [2]. Symbol attributes, such as the attack type (twenty-three symbols), protocol type (three symbols), service (seventy symbols), and flag (eleven symbols) are expressed as numeric values (whole numbers) with the range of (0-(N-1)), where N is the number of symbols. Each of the symbols thus expressed were scaled linearly into the following range: [0.0,1.0] using following equation:

$$B = A / \max(A) \quad (1)$$

where A is original symbol value, and B is the result of scaling. Then, all attributes with whole number fields, with a narrow value range were scaled linearly into [0,1] interval. It was not necessary to scale the remaining attributes, that are Boolean, or within the [0,1] range. Attributes with the wide vale range (0-1.3 billion) were scaled logarithmically:

$$B = 9.14 \times \log(A) / \log(\max(A)) \quad (2)$$

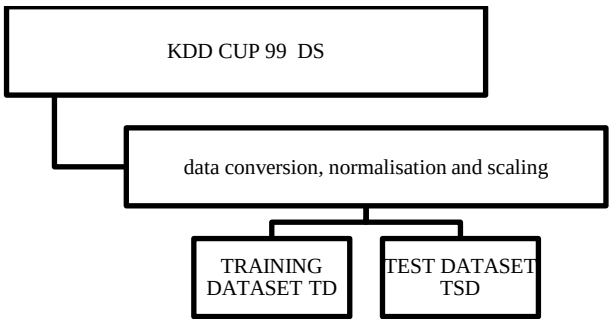

Figure 2. Training and testing data set conversion, normalisation and scalling

The fact that processing of data (the training and test data sets) is time and performance consuming process [4], it was challenge to made component of the system for forming a training and test data sets [5]. The objective of this component is to form smaller groups of training and test data sets (Fig. 3, and 4.), which are used in the construction of the system and later testing. The number and size of these data sets is determined based on the following steps:

- number of rows = size of training and test matrix
- random chosen rows= permutation (number of rows) (3)
- training and test matrix = random chosen rows (1:1000);

Figure 3. Building training data set group

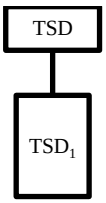

Figure 4. Building test data set group

Component for data attribute selection for each attribute of the input training data sets using the SC determines whether the attribute should participate in building the ANFIS module. The criterion according to which selection of attribute is done is the number of clusters. If the number of clusters for the attributes in the input training data is greater than one, then that attribute will participate in the construction of the module (Fig. 5). Otherwise, the attribute is not taken into consideration.

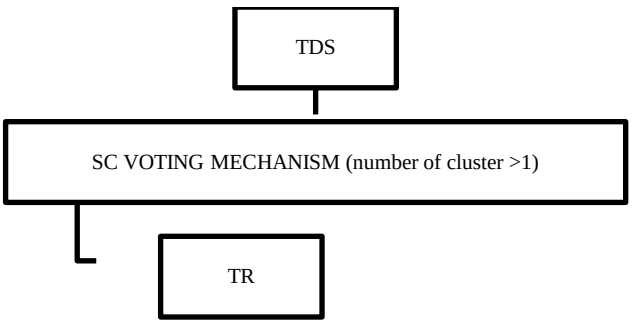

Figure 5. SC voting mechanism

Thus, for the selected training data sets attributes verifiyng is done using SC Voting Mechanism, according to previously described condition.

The result of these activities is the creation of a training matrix TR_1, TR_2, .., TR_n with reduced number of attributes. In other words the dimensionality of the input data is reduced (Fig. 6).

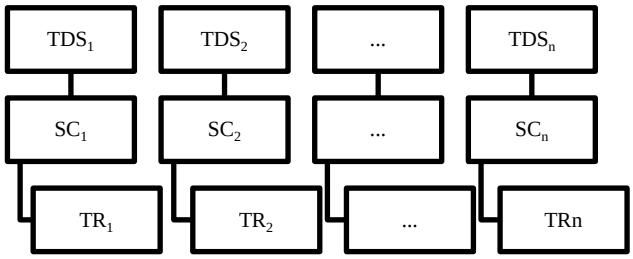

Figure 6. Training matrix dimensionality reduction

ANFIS modules are then trained with training groups of data, so that AN_1 modul is trained with TDS_1 training data group which is processed with SC_1 (TR_1), AN_1 modul with training data group TDS_2 which is processed with SC_2 (TR_n), and all remaining ANFIS modules including AN_n (TRN) (Fig. 7).

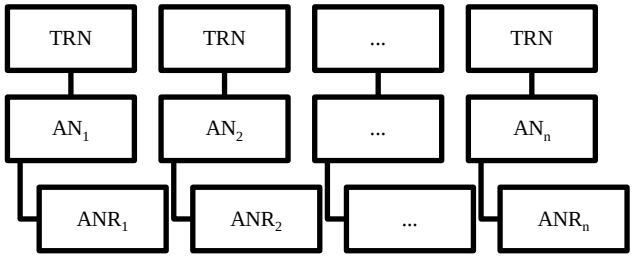

Figure 7. ANFIS module evaluation with new training data set

As input for prepared ANFIS modules (AN_1, AN_2,..., AN_n) we introduce second training data group (matrix TRN). Attributes that are marked in previous step are selected for every module from this new training group (i.e. those attributes that were involved in ANFIS module building The results obtained in this phase ANR_1, ANR_2, ..., AN_n are the input SOM component of system (Fig. 8).

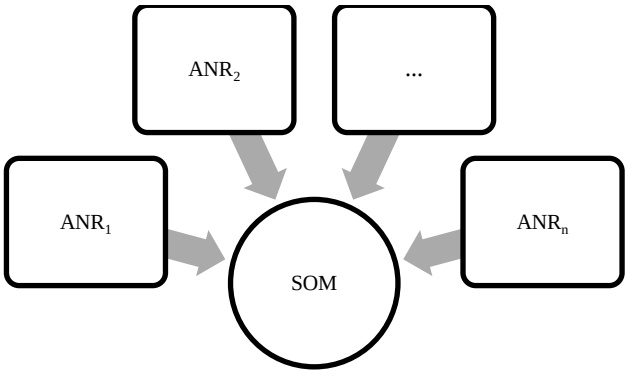

Figure 8. SOM training

SOM component of the system is then trained with these data by building a network with five neurons.

V. ALGORITHM PROPOSAL

Each of the methods and techniques that were used in the construction of the system has certain advantages that are used in the proposed algorithm [1]. Thus, the SC is used in the process of voting to reduce the dimensionality of the training and test data. ANFIS is used to build the module because the expected output for the training data is already known. And because of the fact that the random sample is taken from a small percentage of the training data of SOM is used for clustering the results obtained simultaneously by ANFIS modules and final classification of test data set.

The proposed algorithm is shown below:

1) Loading and processing KDD CUP 99 dataset training and test data in the training *TRD* matrix and test matrix *TSD* respectively

2) The formation of input training matrix TDS_k ($k=1,..,3$) with dimension [m,n] that contains data generated from training data where $m=1000$ and $n=42$. Matrix are formed as a random selection of rows from the training matrix *TRD*.

3) Applying SC on all attributes ($A_1, A_2, ..., A_{n-1}$) for each of training matrix t_k and determination of number of clusters for all matrix attributes. If the number of clusters is equal to one, this attribute is not taken into consideration when building the ANFIS module AN_k. That is how new training matrix TR_k are formed .

4) ANFIS modul AN_k training using new training matrix TR_k .

5) The formation of new *TRN* training matrix with dimension [a,b] that contains data generated form training data set where $a=1000$ and $b=41$.

6) ANFIS modul evaluation AN_k taking into consideration those matrix attributes positions TRN_k that where participated in the making of these modules respectively

7) The formation TSD_1 test matrix with dimension [c,d] that contains randomly generated data from test matrix *TSD* where $c=1000$ and $r=41$.

8) TSD_1 evaluation using the previosly described model. In other words, using ANFIS modul (for attributes defined in step 3.) and using results from ANR_k as input for SOM modul.

VI. EXPERIMENT RESULTS AND DISCUSSION

For the purpose of performing the experiments Matlab software was used. All simulations were performed on HP Compaq 6710b with Intel Core2 Duo T7100 1,8 GHz and 2048 MB RAM. During training and testing main parameters values were: for SC a range of influence of 0,5 is specified for all data dimensions, for ANFIS module SC is used for generating FIS and for SOM module five neurons for network size were used.

The following training matrices are generated: TDS_1, TDS_2, TDS_3 i TRN. All these matrix are generated from the training data set. Distribution of data in a matrices is as shown in Table 2.:

TABLE 2. AN OVERVIEW OF TRAINING DATA DISTRIBUTION

-	normal	Probe	DoS	U2R	R2L	Total
TDS_1	750	10	239	0	1	1000
TDS_2	771	15	211	0	3	1000
TDS_3	793	14	192	0	1	1000
TRN	765	6	228	0	1	1000

Applying SC Voting Mechanism on TDS_1, TDS_2, TDS_3 matrix attributes that satisfy the criterion (that is the number of clusters is larger than one) are separeted. Using these attributes new training matrix TR_1, TR_2, TR_3 are generated.

These matrices had significantly reduced dimensionality, so that the new training matrix, TR_1, TR_2 were formed with thirteen attributes (instead of the previous forty-one), while the matrix TR_3 is formed with twelve attributes.

The following table (Table 3.) is a representation of the attributes used in the new training matrix.

TABLE 3. ATTRIBUTE LIST FOR TRAINING DATA AFTER SC VOTING

Training matrix	Featured attributes of the matrix training group - TDS_k
TR_1	$A_3, A_4, A_5, A_6, A_{12}, A_{25}, A_{26}, A_{29}, A_{32}, A_{33}, A_{34} A_{38}, A_{39}$
TR_2	$A_3, A_4, A_5, A_6, A_{12}, A_{25}, A_{26}, A_{29}, A_{32}, A_{33}, A_{34} A_{38}, A_{39}$
TR_3	$A_3, A_4, A_5, A_{12}, A_{25}, A_{26}, A_{29}, A_{32}, A_{33}, A_{34} A_{38}, A_{39}$

Matrices TR_1, TR_2, TR_3 are used for training of ANFIS modules i.e. building AN_1, AN_2, AN_3. Next figure (Fig. 9) represent surface for AN_3.

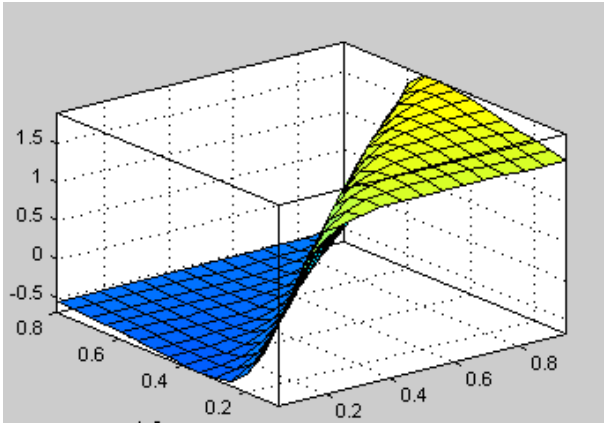

Figure 9. AN_3 surface

After completed training of ANFIS modules as their inputs TRN attributes were brought - new training matrix that is generated from the training data set. Output from this modules were used as inputs for training SOM network with five neurons.

This trained network is then used to classify the data from the test data group. Test data group TSD_1 s then brought as input data for the system, in order to carry out the evaluation. Data classification result for TSD_1 that are output from the last component of system (SOM) is graphically represented on next figure (Fig. 10).

Figure 10. SOM data classification result

The following table (Table 4.) shows the results that are obtained together with the expected results of the classification in order to perform a comparison of the results.

TABLE 4. EXPERIMENT RESULTS

	normal	Probe	DoS	U2R	R2L	1000
SC, ANFIS, SOM	859	48	91	0	2	1000
TSD_1	924	18	56	0	2	1000

The results shown that the portion of traffic that is actually classified as a normal is classified as Probe and DoS. This generates false alarms. One reason for this is the fact that volume of sample data used for training and testing is not so big and traffic is not distributed equally. On the other side, experiment shown the possibilities of the proposed algorithm on a smaller sample of data.

The comparation to other research (Table 5.) shown that proposed algorithm can give acceptable level of the intrusion detection accuracy even using this small data sample.

TABLE 5. EXPERIMENT RESULTS COMPARATION TO OTHER RESEARCH

	normal	Probe	DoS	U2R	R2L
GAUSSIAN MIXTURE [4]	98,97	93,03	88,24	22,80	9,60
RBF IDS [4]	99,07	91,31	75,10	7,01	5,6
SOM [4]	93,98	64,30	96,10	21,49	11,70

EDSOM [6]	95,20	92,30	96,20	38,40	43,60
SC, ANFIS, SOM	92,66	100,00	100,00	-	100

VII. CONCLUSION

This paper demonstrates the effects of combined application SOM, ANFIS, SC and Voting Mechanism in detecting intrusions in computer networks. This was done by comparing the results of execution of the ANFIS, SC and SOM implemented in the same software package Matlab on KDD CUP 99 data that were processed using various methods. Pre-processing of KDD CUP 99 dataset included removing duplicated data from training and testing data. This paper proposes algorithm which combines the previously listed methods and techniques, in order to take full advantage of them. Thus, the proposed algorithm has effect of reducing the complexity of the input data by reducing the number of attributes involved in the construction of ANFIS models. with no significant lost on its efficiency. For the selected amount of data, ANFIS module with parallel execution contributes in increasing the speed of execution of this algorithm. The presented algorithm will be modified in the further research by adding one more parameter. It will be the distance between clusters (in the case when the number of clusters is larger than one). In addition, the algorithm will be further tested with higher number of training samples taking the advantage of parallel execution. The proposed algorithm result in this paper shows that combining different methods (SOM, ANFIS, SC and Voting Mechanism) can give acceptable level of the intrusion detection accuracy.

Customer and User education as a tool to increase security level

Ivan Sedinić, Zrinka Lovrić, Tamara Perušić
Croatian Telecom, Cyber & Data Security Work Unit
ivan.sedinic@t.ht.hr, zrinka.lovric@t.ht.hr, tamara.perusic@t.ht.hr

Abstract - In activities to assure security of IT/NT systems and Data, where there is increasing number of attacks and where are more and more sophisticated cyber criminals, with all modern technical protection solutions in place, people are still the weakest link in the chain. And unless policy, education and training, awareness, and technology are properly employed to prevent people from accidentally or intentionally damaging or losing information, they will remain the weakest link. In case of telecom operators this are not only company employees but also employees of vendors and partners, as well as customers. To improve such situation, education is a cornerstone of activities. In this paper will be discussed different ways how to educate each of mentioned groups, what prerequisites for such education are and how technology could help in educating people. Additionally, based on examples from telecom operator, results of such approach will be shown.

Introduction

"Security policy is one thing but reality is another." These words are used very often by employees in organizations worldwide to describe everyday situation. Such statement indicates that in the certain organization a culture of security is underdeveloped. Security culture cannot be created or installed as software, but intentionally shaped and directed through mindset of people who are part of an organization and those who cooperate with organization: customers, vendors, partners, other stakeholders and the society at large. That kind of culture must be "implanted", nurtured and accepted gradually with changes in mindset, the outlook and attitudes of the people. Changes could be led by company management but cannot be imposed on people. Anyhow, senior management is the key component and the vital force for a successful implementation of an information security program [5]. Ways to achieve such changes are education, training, awareness campaigns and communication about security in general. With those activities different type of security cultures, in sense how strict it will be, could be build. There are some organizations as national intelligence agencies or banks which require strict security culture and other where alignment with the business as a whole will require less strict security culture [7]. According to ISO 27001:2013 the following control objectives are crucial [6]:

A5: Information security policies

A6: Organization of information security

A7: Human resource security

A8: Asset management

A9: Access control

A10: Cryptography

A11: Physical and environmental security

A12: Operations security

A13: Communications security

A14: System acquisition, development and maintenance

A15: Supplier relationships

A16: Information security incident management

A17: Information security aspects of business continuity management

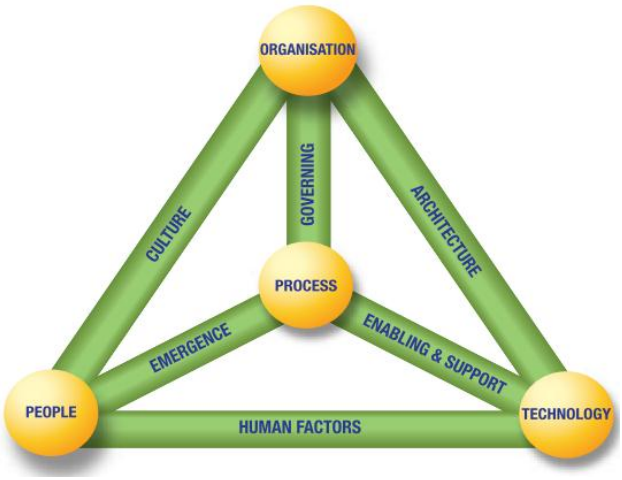
A18: Compliance

In this article focus will be on the control "A.7.2.2. Information security awareness, education and training" described with control "All employees of organization, and where relevant, contractors shall receive appropriate awareness education and training and regular updates in organizational policies and procedures, as relevant for their job function" [7]. This paper is based on the experience in Telco industry and customers are also included since they are integral part of information security.

Position of education in security

When we are talking about security in this article we have in mind certain business model for information security as shown in figure 1 [1].

Figure 1. Business Model for Information Security



Source: ISACA, The Business Model for Information Security, USA 2010

In a model presented above, it is visible that people are one of model cornerstones. When we have in mind the nature of human being, it is also clear that this cornerstone needs additional set of tools to be able to perform its designed role. Those tools could be obtained through education, training, awareness and motivation that are regular part of Information Security Process Model as it is shown in Figure 2. In this model, mentioned activities are included in group of "Run Processes", subgroup: "Interaction Processes", activities: "Communications and Relationship Management" [2].

Figure 2. Gartner Information Security Process Portfolio Model

Source: Gartner, Creating a Security Process Catalog, USA 2013

Communications and relationship management — The activities that ensure everyone knows what is allowed and what is forbidden under current security policies, and why. It includes reporting on current state, performance and proposed changes regarding security (organization, policy, processes, technology, and so on) to all relevant parties. The potential target audience includes executives, business unit management, IT staff, end users, contractors, consultants, service providers, vendors and customers. Specific subprocesses include [2]:

- Security awareness marketing, culture building and training
- Security metrics and measurement
- Security service-level measurement and reporting
- Relationship management with external service providers.

Security education is everything we do to enable people to successfully carry out their roles in security processes and it happens all the time, in all sorts of settings and ways. We also need to have in mind that education and awareness is not the same thing. People could be aware of something but may not be enough educated to take proper action. Education is this foundation on which people can plan and execute most proper action in certain circumstances.

Definition of education groups

Technical controls are very important to the information security program, and are necessary to address the aspects such as antivirus, encryption, firewalls, security mechanisms, physical security, authentication, and monitoring, but given that technical controls cannot fully address the end-user behaviors, security awareness training must be in place to reduce the risk [4].

Without organization's investment in personnel and personal involvement and commitment by people, an organization's information security management capability will be very limited in its ability to provide proper support to business goals.

Information security in general is not only the responsibility of security practitioners but of all employees. Security education is also responsibility of each individual involved in process which needs to be secured. To ensure a proper influence of security education, it needs to be tailored to specific need of certain people group and overall security program. Additionally, education needs to be continuous. Education frequency needs to be developed based on organization's areas of concern, having in mind potential threats and vulnerabilities, local, regional and worldwide news with impact on organization security, and employee's personal duties and responsibilities with impact on security. In general, security education could be grouped in [3]:

- Initial: minimal education for everyone included
- Periodical/Refresher: renewal of initial education with new content and additional topics
- Specific: extended education on specific topics needed just for certain group of people.

Methods to deliver security education could vary from standard to innovative: formal trainings, briefings, conferences, videos, e-learning, bulletins, desktop instructional materials, posters, flyers, etc. Relationship between quality and cost for different education methods is shown in figure 3, based on experience in Telco organization. Quality of one particular method is defined in comparison with other methods and possible outcomes are: High, Medium and Low. Cost parameter was defined in the same way.

Figure 3. Different education methods

Method	Quality	Cost
Training	High	High
Briefing	Medium	Medium
Conference	Medium	High
Video	Medium	Low
E-learning	High	Low
Web Portal	Medium	Low
E-mail	Low	Low
Bulletin	Low	Medium
Instructional materials	Low	Medium
Posters	Low	Medium
Flyers	Low	Medium

Each security education is supposed to do the following [3]:

- Advise: advise a personnel of effect that can result from unauthorized data disclosure
- Indoctrinate: indoctrinate personnel in the ways for protection of information
- Familiarize: familiarize personnel with procedure to ensure that security implications are considered before decision is taken
- Inform: inform personnel about techniques to exploit security weakness, obligation to report such attempts and consequences of violation security regulation
- Instruct: instruct personnel about obligations of data owners and data users.

During education we need to be careful to avoid trap of using fear, uncertainty and doubt as methodology to reach our goals. While this could give us short-term gains, the long-term outcome typically results in security personnel being avoided and mistrusted. Instead, other techniques should be used. One of them is presenting threat and vulnerability analysis. This allows the intended audience to have a better understanding of why a concern exists and possibility to form their own opinion on problem.

Based on all mentioned before, there are several groups of people for which education tailored according to their specific needs should be provided:

- Managers
- Security practitioners
- IT/NT experts
- Partners
- Regular employees
- Contracted workers
- Customers

For each of these groups messages in education need to be prepared in different format as shown in figure 4.

Figure 4. Education format for different groups

Group	Format
Managers	Brief, to-the-point, strategic, graphic
Security practitioners	Detailed, strategic and tactical, benefits
IT/NT experts	Thorough, tactical, showing benefits
Partners	Thorough, showing benefits
Regular employees	Graphic, explanatory, showing benefits
Contracted workers	Graphic, explanatory, obligations
Customers	Graphic, personal, little explanation

EXECUTION OF EDUCATION

First point when starting execution of education is to define areas which will be covered. These are:

- Physical and Personal Security
- Technology Security, Data Protection, Classified Information
- Fraud, Incident, Crisis Management, Compliance
- Business Continuity, Risk and Insurance Management

The next step is to recognize appropriate approach in which education can be delivered:

- Web
- E-mail
- Paper
- Human interaction.

The most important thing is to define the content for planned education.

In the next part few examples how education is established and which main topics should be covered in an organization will be shown.

A. Initial education:

Participants: all new employees

- Topics: Security organization and responsibilities, compliance, anticorruption, role of security in processes and services, security policies and requirements, practical advices and basic security rules, social engineering, security incidents, "security by design" process, contact information
- Method: Briefing

Participants: Partners

- Topics: Security policies and requirements, security incidents, contact information

- Method: Instructional materials

Participants: Customers

- Topics: Basic security rules and obligations
- Method: Instructional materials , Flyers

B. Periodical education:

Participants: Managers, Security practitioners, IT/NT experts, Regular employees, Contracted workers

- Topics: Security portal with most important information on security issues (strategy, security organization, policies, requirements, procedures, guidelines, other documentation, key projects, trainings, e-learnings), Security Department's current activities, Basic security principles, Physical security, IT/NT security, Security in contact centers, Social Media security, "Card of the Month" campaign - one security topic is presented every month
- Method: Web Portal, E-learning

Participants: Partners

- Topics: Changes in Security policies and Security Requirements
- Method: E-mail

Participants: Customers

- Topics: Short, easy to understand practical guide for using services in secure way: PC Safety and Basic Protection, Choosing a Safe Password, Online Shopping, Using Smartphones Safely, Using Apps Safely, Leaving No Traces on the Net, Phishing, Social Engineering, The Safety Barometer, Smart Use of Social Networks, Cloud Computing,
- Method: Web Portal

C. Specific education:

Participants: Security practitioners, IT/NT experts,

- Topics: Security incident management and CERT, Privacy and Security by Design
- Method: E-learning, Training

Participants: Managers

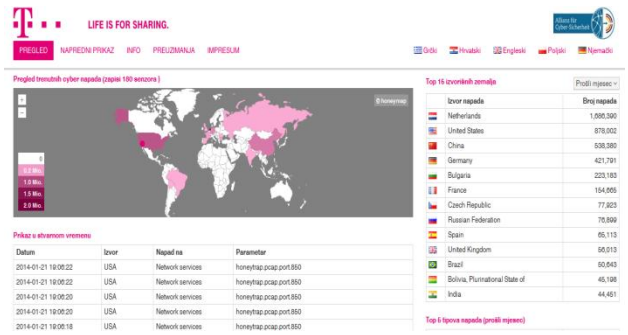
- Topics: Security trends, activities and plans
- Method: Briefing

It was recognized that most efficient and cost effective ways for security educations are e-learning and Web Portal, so they are most used for this purpose. Except for education, Security Portal is also used for awareness campaign and publishing of different security information such as shown in following figures:

Figure 5. DT Strategic Threat Radar

Source: DT AG, Data Privacy and Data Security Report 2013, Germany 2014 [8]

Figure 6. DT honeypot map – cyber-attacks on HT



Source: http://www.sicherheitstacho.eu/

Conclusion

Security is all around. It accompanies people from the very first minute every day at work. It is not only about procedure but also about way people act at work. Procedures, application and systems cannot work without people. Every single person is responsible for security.

Everyone is security.

Every person needs to understand and to apply security policies, requirements, procedures and instructions. Everyone should understand role of security in his/hers company. At the end everyone is responsible for risks and security in his area of work. And to be able to take this responsibility, education of each person is crucial.

From table in figure 3 it is clear that most cost efficient education method is e-learning with following advantages:

- Easy access for everyone

- Easy way to verify security knowledge among employees
- Interactive mode of education
- Student could choose time of education according to personal preferences
- Education could be done in few different time slots
- Education could be done from own office or even from home
- No travel and similar expenses.

To make e-learning even more efficient it is recommended to apply the following rules:

- Don't use long topics, divide one big in few smaller
- Keep descriptions short
- Describe it in interesting way using real life examples
- Be graphical
- Make knowledge verification at the end and provide explanation for answers
- Provide links to more detailed explanations for those interested in

With proper education of all employees in organization it is possible to reach status that security is integral part of product development process and is built in "by design" in products and services. In case which is subject of this paper, security organization was involved in early development phase of 100% of security relevant projects and formal confirmation of security requirements fulfillment was done for 99% of projects. Also, by educating customers, it could be achieved that most of them have perception that security is important or very important. Market research "Security and Data Protection" organized by HT in December 2013 shows that 85% of customers consider data privacy and data security very important or important. And in telecommunication industry with such customers' approach it is easier to improve security of overall telecommunication network and services.

Izradba zaštitnog profila pomoću ISO 27k kontrola

Z. Kummer*, V. Lebinac**
* Financijska agencija, Zagreb, Hrvatska
** Veleučilište Velika Gorica, Hrvatska

Sažetak - Svaki proizvod prije korištenja treba biti provjeren sa sigurnosnog stajališta i izrađen njegov zaštitni profil. Zaštitni profil se koristi kao dio procesa certiciranja proizvoda. Utvrđivanje sigurnosti proizvoda uključuje provjeru rada samog proizvoda i njegov utjecaj na sustav u kojem radi. Standardno se zaštitni profil izrađuje pomoću Općih kriterija (*Common Criteria*). U radu se za izradbu zaštitnog profila sustava za centralizirano upravljanje korisnicima koristi standard ISO 27k. Sustav za centralizirano upravljanje korisnicima izrađen je s *openssh*, *openssl* paketima uz dodatni softver. ISO 27k standard je izabran radi njegove implementacije u cijelom sustavu.

I. UVOD

Početak rada na računalu započinje predstavljanjem identiteta registriranog korisnika u sustavu. Provjera identiteta vrši se u slijedećem koraku kada korisnik s tajnom (lozinkom) potvrđuje taj identitet. Nakon pozitivne provjere identiteta, korisnik je potvrđen, dodjeljuju mu se ovlasti, aktivira se sjednica i korisnik može započeti rad na sustavu. Dodjela ovlasti vrši se u skladu s implementiranom politikom.

Standardni protokol za rad koji koriste prvenstveno administratori, za sigurnu uspostavu konekcije i sigurni rad na udaljenim sustavima je ssh protokol. Programska podrška koju koristi ssh protokol (korisnički i poslužiteljski dio) postoji praktički na svim platformama i dostupna je kao komercijalna i kao slobodna i jednostavna je za uspostavu i korištenje.

Registracija korisnika na računalu sastoji se od određivanja UID-a (*User Identication Number*) i GID-a (*Group Identification Number*) korisnika. Vrijednosti UID-a i GID-a zapisuju se u sistemske tablice s čime je korisnik poznat sustavu. Na različitim sustavima isti korisnik ne mora imati isti UID i GID. To omogućuje da se na aplikativnoj i globalnoj razini barata imenom korisnika, a na sustavnoj, odnosno lokalnoj razini s UID i GID aktiviranog korisnika.

Korisnički profil uz UID i GID sadrži još minimalno lozinku i ovlasti. Korisnik je uspostavljen na sustavu kada se on može predstaviti tom sustavu, provjeriti se njegovo postojanje, mogu mu se dodijeliti ovlasti, može raditi i može se pratiti njegov rad na tom istom sustavu.

Postojanje više računala u domeni i veći broj korisnika koji mogu raditi na njima, dovodi do problema održavanja korisničkih profila. Korisnik može raditi samo na dijelu računala iz domene i na svakom računalu imati drugačije ovlasti. Radi toga korisnik mora biti prepoznat na svakom računalu pojedinačno i na svakom od njih se po želji može prijaviti na rad i aktivirati. Kao problem ističe se: kako održavati korisničke profile.

Zahtjevi održavanja korisnika trebaju ispuniti da se korisnik samo jednom registrira, a sva ostala manipulacija s korisnikom obavlja se na jednom mjestu i postaje poznata i aktivna na svim sustavima na kojima korisnik želi raditi.

Svi navedeni postupci su kritični u funkcioniranju sustava, jer ako imaju slabosti mogu dovesti do neovlaštenog rada na sustavu. Pri izradbi rješenja, provjera rješenja vrši se usklađivanjem s standardom. Za to se uobičajeno koriste opći kriteriji (Common criteria) [1]. U radu će biti prikazano kako se za usklađivanje može koristiti ISO 27k standard [2].

Pri projektiranju sustava kreće se od mehanizama koji implementiraju kontrole koje zahtjeva politika (od dolje prema gore). Kontrola može zahtijevati neki mehanizam, ali ga ne definira dovoljno određeno što znači da svaki mehanizam treba biti usklađen s kontrolom ili kontrolama i imovinom na koju se odnosi. Tek tada je sustav usklađen s standardom čije smo kontrole odbrali. Nakon toga možemo odrediti (napisati) politiku [3].

Zaštita je proces koji treba osigurati sigurnost, odnosno stanje u kojem je sustav siguran [4].

Rad je strukturiran kako slijedi. U poglavlju II opisan je motiv za izradbu programskog rješenja za centralizirano upravljanje korisnicima koji koriste za rad ssh protokol. Poglavlje III opisuje poteškoće koje mogu nastati u radu distribuiranog sustava radi lokalne uspostave korisnika na svakom od sustava gdje korisnik želi raditi. Poglavlje IV opisuje korisnički račun kao središnji objekt potreban za I&A i uspostavu korisnika na računalu. Poglavlje V prikazuje konceptualni model rješenja. Poglavlje VI prikazuje pretpostavljene slabosti sustava s posljedicama. Poglavlje VII pokazuje korelaciju kontrola ISO27K standarda i potrebnih i ostvarenih mehanizama koji podupiru navedena kontrole.

II. MOTIV I DISTRIBUIRANI SUSTAVI

Najvažnije stanje (postupka) u procesu rada korisnika na sustavu je autentikacija, odnosno provjera identiteta. Za autentikaciju se može koristiti lozinka koja je lokalno definirana na svakom sustavu pojedinačno. Motiv za stvaranje sustava za centralizirano upravljanje korisnicima je mogućnost jednostavnog i sigurnog održavanja korisnika. Praktički se postupak svodi na održavanje identiteta i autentifikatora korisnika. Dok je identitet lokalno definiran, autentifikator je definiran globalno za cijelu domenu.

Korisnici koriste za rad na računalu ssh protokol koji omogućuje da korisnik radi u tekstualnom i grafičkom načinu rada.

Centralno upravljanje korisnicima (CUM - *Centalized User Management*) mora biti usklađeno sa sustavom za upravljanje informacijskom sigurnošću (ISMS - *Information Security Management System*). ISMS možemo definirati kao[5]:

- Skup politika i procedura za sustavno upravljanje osjetljivim podacima.
- Skup politika, procesa i sustava koje organizacija oblikuje, izrađuje, implementira i održava.

Distribuirani sustavi sastoje se od kooperativnih računala na kojima su registrirani korisnici. Korisnici se moraju prijaviti za rad na svakom od računala gdje žele obaviti neki posao i koristiti računalnu opremu. U standardnoj distribuciji poslužitelja, korisnik se uvijek registrira lokalno i po prijavi je poznat samo na tom računalu. Korisnik se po želji može prijaviti na određeni broj računala.

Poteškoće nastupaju kada imamo više računala jer održavanje korisnika i sinkronizacija stanja u kojim se oni nalaze na svakom od računala postaje složena. Poteškoće i zahtjevi u radu takovog sustava su slijedeće:

- Postoji veliki broja nepovezanih poslužitelja koje koristi isto tako veliki broj korisnika koji ne moraju biti svi registrirani na svakom računalu.
- Računala održava relativno mali broj administratora.
- Administratori su privilegirani korisnici čija prijava se mora nadzirati, pratiti i analizirati.
- Administrator mora biti uspostavljen na svakom računalu pojedinačno radi dodjele ovlasti korisnika i održavanja poslužitelja.
- Administratori koriste sekundarne komunikacijske kanale, odnosno komunikacijske kanale koje ne koriste regularni ili produkcijski korisnici.

- Uspostava administratora na velikom broju računala je nespretna, a u slučaju distribuiranih sustava jako otežana.
- Postupak autentikacije mora biti sto je moguće jednostavniji i standardiziran.
- Postupak autentikacije mora biti pod kontrolom vlasnika sustava. Razina kontrole podrazumijeva da vlasnik ima potpuni uvid u izvorni kod rješenja iz kojeg se može stvoriti samostalno produkcijsko rješenje.
- Vlasnik sustava mora po potrebi moći provjeriti rješenje.
- Nepovjerenje u zatvorena rješenje radi sumnje u postojanje „stražnjih vrata“, prikrivenih kanala, mogućnosti komunikacije s nepoznatim odredištima i postojanja „*snake oil*“ kripto zaštitnih algoritama.
- Potreba za robusnim postupcima provjere identiteta koji koriste isto tako jake zaštitne mehanizme.
- Potreba usklađenosti rješenja s standardima za sigurnost.
- Korištenje i održavanje rješenja mora biti sto je moguće jednostavnije.
- Rješenje se može oblikovati, izraditi i uspostaviti s pristupačnim alatima, po mogućnosti „otvorenim“.
- Rješenje ne treba zahtijevati posebno specijalističko obrazovanje, dovoljna su standardna znanja.
- Rješenje se mora moći jednostavno i efikasno koristiti i održavati.

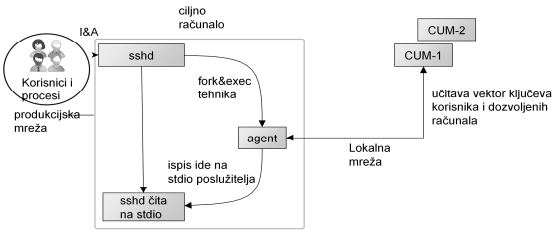
III. KORISNIČKI RAČUN

Osnovni objekt koji se koristi u fazi identifikacije i autentikacije je korisnički račun čiji sastavni dio je korisnički profil. Kreiranje računa je upis korisnika u sustavne tablice. Pri tome se korisniku daje obično sustavno određen UID i GID. Nakon toga, korisnik je poznat sustavu. Račun može biti u slijedećim stanjima:

- Registracija korisnika na računalu kreira račun kojem su pridruženi sustavni resursi. Registracija je zapis korisničkog imena koje se koristi u fazi identifikacije. Račun je još onemogućen i ne može se koristiti.
- Uspostava lozinke omogućuje autentikaciju sustavu poznatog identiteta korisnika i aktiviranje računa. Aktiviran račun dodjeljuje ovlasti i uspostavlja sjednicu za taj račun i u korist korisniku koji ga koristi.
- Račun može biti suspendiran. Korisnik je poznat sustavu. Korisnik ne zna lozinku i ne može provesti autentikaciju.
- Račun može biti opozvan. Sustav ne pozna korisnika i ne može se provesti identifikacija.
- Korisnik može sam mijenjati svoju lozinku kada to zaželi.
- Ako se koristi drugi mehanizam i podaci za autentikaciju, promjenu podataka za autentikaciju korisnika, može vršiti samo ovlaštena osoba.

Centralizirano upravljanje modificira gore navedeni postupak na slijedeći način:

- Registracija korisnika na računalu kreira račun i dodjeljuje sustavne resurse. Registracija korisnika je zapis korisničkog imena koje se koristi u fazi identifikacije. Račun je još onemogućen i ne može se koristiti.
- Registracija korisnika u CUM-u. Pri tome se upisuje javni ključ, korisnički identitet i lista računala na koje se korisnik može prijaviti. Korisnik se može prijaviti za rad samo na računala koja su navedena u listi odobrenih računala.
- Račun može biti suspendiran. Korisnik postoji na lokalnom računalu i CUM-u. Javni ključ je modificiran tako da se ne može obaviti postupak uparivanja s privatnim ključem.
- Račun je opozvan. Korisnik postoji na lokalnom računalu, a na CUM-u je obrisan. Javni ključ ne postoji i ne može se obaviti postupak uparivanja s privatnim ključem. Račun se mora ponovno kreirati na CUM-u da bi se mogao koristiti
- Korisnik ne može sam mijenjati zapise u CUM-u, nego to radi ovlaštena osoba



Slika 1. Konceptualni model

Preduvjet: korisnički račun nema lozinku. Korisnik ne može mijenjati lozinku i ne može se uspostaviti novi mehanizam i materijal za autentikaciju osim ovlaštenog.

IV. MODEL I POTEŠKOĆE ZAŠTITE SUSTAVA

Poslovni zahtjevi na sustav mogu se odrediti slijedećim pravilima:

- Korisnik za prijavu za rad na računalu mora obaviti I&A (I&A - identifikacija i autentikacija).
- Korisnik se mora moći prijaviti na svako računalo na kojem je registriran. Za autentikaciju korisnik može koristi lozinku ili neki drugi materijal koji ili zna ili ima. Veću razinu zaštite (povjerljivosti) imamo kada koristimo token na kojem je materijal za autentikaciju. Uobičajeno se koristi token (USB token koji koristi čip kao pametna kartica). Token dozvoljava korištenje i brani uvid u povjerljivi materijal.
- Prijava za rad mora biti kontrolirana i moguća samo registriranim korisnicima.
- Prijava mora biti preventivna kontrola koja brani neovlašten pristup vrijednostima korisnika. Uobičajeno je u ISMS-u koristiti pojam imovina. Ona opisuje vrijednost i njenog vlasnika pa ćemo u značenju imovine koristiti samo njenu vrijednost.
- Ovlasti po prijavi korisnik dobiva u skladu s politikom.

Sustav se sastoji od ssh poslužitelja na ciljnom računalu i korisnika koji se mogu prijaviti na njega radi uspostave sjednice. Svi korisnici trebaju biti prethodno registrirani kako bi se mogla provesti identifikacija koju provodi ssh poslužitelj. Za provedbu autentikacije, ssh poslužitelj koristi lokalnog agenta kojeg on pokreće u izvođenje s standardnom sustavnom naredbom. Argument u naredbi je ime korisnika ili ime korisnika u čiju korist se pokreće neki od pomoćnih programa (scp). Agent je standardni program čiji se integritet provjerava prije pokretanja u izvođenje. Tako je zajamčena izvornost programa i izbjegnuto podmetanje zlćudnog koda. Ovlast za pokretanje u izvođenje agenta ima samo server i onemogućeno je neovlašteno pokretanje agenta od strane bilo kojeg korisnika ili drugog procesa.

Za dohvat javnih ključeva može se koristiti bilo koji protokol za dohvat tereta. U primjeru se javni ključevi dohvaćaju pomoću http protokola. Zapis s javnim ključevima ima dodan naziv korisnika kojem pripada javni ključ i vektor hostova na koje se korisnik prijaviti. Na svakom od tih hostova korisnik može prethodno biti registriran. Moguća je anonimizacija da ime korisnika ne bude ime realnog korisnika nego neko od generičkih imena (admin0, admin1, ...) koja se dodjeljuju realnom korisniku i tako simuliraju uloge. Registracija inicijalnih korisnika može se obaviti u fazi instalacije sustava. Svaki korisnik ne smije imati lozinku i ne smije koristiti program za upravljanje lozinkama i tako neovlašteno uspostaviti lozinku. Za prijavu korisnika ne koristi se lozinka nego digitalni certfikat koji je spremljen na tokenu. Pristup tokenu i aktiviranje/korištenje certifikata je lokalno zaštićeno, odnosno omogućeno s PIN-om (PIN - *Personal Identification Number*).

U slučaju korištenja pomoćnih programa sustav javno/privatnih ključeva je također razdvojen tako da korisnik ima samo jedan od ključeva dok je drugi zaštićen i nedostupan. To je osigurano tako da ssh server dozvoljava pristup korisniku i provodi I&A sam. Materijal za I&A server dobiva od korisnika i agenta, odnosno iz dva razdvojena

izvora s čime je osigurana separacija. Poslužitelj (ssh demon) na obradu dobiva samo javni ključ korisnika koji treba obaviti I&A, dok su mu javni ključevi ostalih korisnika nedostupni.

Svaki IT sustav treba biti dostupan kada treba, pouzdan i siguran (vrijedan povjerenja)[6]. To se može osigurati preko tri osnovna načela koja sustav treba ispuniti kao siguran sustav. On mora biti povjerljiv, cjelovit i dostupan. Cjelovitost se mora proširiti uz teret i na način manipulacije. Tada je definicija cjelovitosti uz ovlaštena promjenu vrijednosti proširena i na ovlašteni način.

Slabosti su sastavni dio IT sustava. Njih napadač koristi kao ranjivosti za vrijeme napada i tako nanosi štetu vrijednostima sustava[7]. Narušavanje povjerljivosti, cjelovitosti i dostupnosti odnosi se i na prijetnje koje se žele otkloniti. Standardne prijetnje koje narušavaju osnovna načela sigurnosti su:

- Neovlašteni uvid što narušava povjerljivost.
- Prekidanje odvijanja, što narušava dostupnost i integritet. Ako se prekine neka transakcije može doći do nesigurnog i neovlaštenog odvijanja transakcije. Isto se događa ako se obriše neki objekt sustava s čime se narušava dostupnost i integritet sustava.
- Promjena postojećeg ili podmetanje novog sadržaja što narušava najprije integritet i nakon toga povjerljivost, jer imamo podmetnutu neistinu kojoj vjerujemo sa svim posljedicama toga. Posebno je opasno ako je cilj napada dnevnik sustava.

Da bi se otklonile slabosti a s time i ranjivosti sustava mora se zadovoljiti slijedeće pravilo:

„Sustav je zaštićen i siguran samo ako su inicijalna stanje sigurna i prijelaz iz jednog stanja u drugo stanje siguran, s time da je stanje u kojem se nalazi sustav sigurno i stanju u koje prelazi sustav isti tako sigurno. U početnom stanju sustav može biti samo jednom."

Da bi osigurali sustav trebamo definirati zaštitnu politiku i mehanizme koji politiku podupiru. Politika se može opisati kao niz zahtjeva, a mehanizmi kao ostvaritelji i osiguravatelji zahtjeva. Zaštitni profil pokazuje da li sustav omogućuje zaštitnu politiku s podupirućim mehanizmima.

Bitni zaštitni mehanizmi za CUM su:

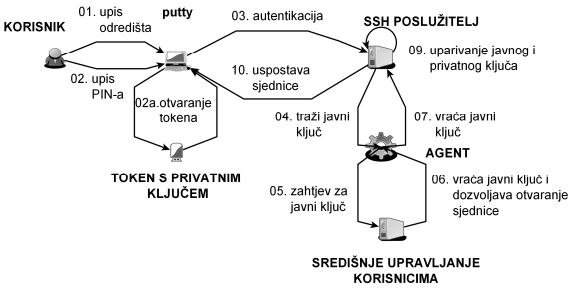
- Enkripcija što osigurava povjerljivosti i pomaže integritet sustava.
- Identifikacija i autentikacija što osigurava inicijalno sigurno stanje.
- Nadzor i praćenje što osigurava brzu detekcija eventualnog nesigurnog stanja i minimiziranje štete.

Prijetnje sustavu za središnje upravljanje korisnicima dane su u slijedećoj tablici 1.

TABLICA 1. VRIJEDNOSTI SUSTAVA I POSLJEDICE

Vrijednosti sustava	Posljedice narušavanja zaštite
Kompromitiranje vrijednosti	Neovlašteno narušavanje povjerljivosti i integriteta vrijednosti. Posljedica napada ili nestabilnosti sustava. Ništa nije detektirano, šteta je učinjena.
Zaobilaženje sigurnosne funkcije	Mogu se prevariti čvorovi (računala) i ostvariti I&A, prevariti komunikacijski protokoli i podmetnuti lažni teret (informacijski podaci).
Dohvat sistemskih tablica	Može se dohvatiti podatke koje koristi CUM i utjecati na njihov integritet, povjerljivost i zloupotrijebiti ih.
Loše priređen token	Priprema tokena može biti loša, tako da se može zloupotrijebiti KZ funkcija tokena i par ključeva koji su isto tako loši.
Fizički prodor	Neovlašteni korisnik može fizički doći do poslužitelja, CUM-a i promijeniti pravila za I&A.
Lažno predstavljanje	Neovlašteni korisnik može se lažno predstaviti kao regularni korisnik.
Upis u sistemske tablice	Može se zloupotrijebiti komunikacijski kanal za održavanje sustava ili produkciju, upisati neovlaštene informacije koje dozvoljavaju narušavanje sheme I&A, registrirati korisnika na poslužitelju i CUM-u, importirati ključ korisnika na CUM, importirati podatke koji narušavaju funkciju I&A i aktiviraju nestabilno/neodređeno) stanje i dozvoljavaju neovlašteni I&A.
Nesigurno stanje sustava	Poslužitelj, agent i CUM mogu doći u nesigurno stanje i producirati krivi rezultat ili otkazati rad.
Presretanje podataka	Neovlašteni korisnik može presresti povjerljivu komunikaciju između poslužitelja i CUM-a.
Loše (zloćudno) funkcioniranje	Agent i poslužitelj mogu biti modificirani i pretvoreni u zloćudni kod.
Promjena sistemskih podataka	Može se modificirati javni ključ i prouzročiti postavljanje poslužitelja u neodređeno stanje koje može prouzročiti štetu.
Neovlašteno kreiranje korisnika	Može se kreirati neovlašteni korisnik s nepoznatim ovlastima što neminovno omogućuje napad/štetu.
Otkrivanje informacija potrebnih za I&A	Neovlašteni korisnik može dostupiti do poslužitelja tako da ga napadne i dobije podatke potrebne za I&A.
Opovrgavanje	Korisnik može opovrgnuti I&A i maskirati praćenje, nadzor i pregled.
Rezidualni sistemski podaci	Sve informacije koje se koriste za I&A su u stanju potrebe zaštićene od neovlaštenog dostupa i sačuvan je njihov integritet i povjerljivost. Odmah po korištenju su sve informacije obrisane i s time nedostupne.
Neovlašteni dostup do agenta	Neovlašteni dostup do ssh-agenta i zapisa koje koristi CUM. CUM kao SPOF mora biti uvijek dostupan. (Dostupnost CUM-a osigurava se dovoljnim kapacitetom i prostornom raspodjelom - više CUM-ova koji se raspodijeljeni u prostoru).
Lažno predstavljanje	Može se poslati krivi (lažni) javni ključ koji se prihvaća kao pravovaljani. Zloćudni kôd može preko komunikacije neovlašteno doći do vrijednosti (objekata subjekata) i narušiti CIA cijelog sustav. Prijava neovlaštenog korisnika čiji identitet je lažan (sustav ga prepoznaje, ali identitet koji je prijavljen ne pripada realnom korisniku).

V. REALIZIRANI MODEL



Slika 2. Ostvareni model

Opća pravila koja se ne mijenjaju u vremenu i prostoru:

- Sustav radi kao transakcijski sustav.
- Svi podaci u prijenosu, obradi i pohrani su zaštićeni i osigurana je povjerljivost, cjelovitost i dostupnost.

- Krajnji korisnik može jedini za prijavu na ssh poslužitelj koristiti token na kojem je privatni ključ.
- ssh poslužitelj uparuje korisnikov javni i privatni ključ za provjeru izvornosti identiteta korisnika.
- Korisnik mora biti registriran na svakom poslužitelju na koji se želi prijaviti za rad.
- Korisnik mora biti registriran na CUM-u.
- Registraciju korisnika vrši ovlaštena osoba.
- UID i GID korisnika određuje sustav pri registraciji korisnika.
- Postupke instalacije i održavanja softvera (ssh poslužitelj, ssh-agent, CUM) vrši ovlaštena osoba.
- Instalacija, održavanje i korištenje softvera pripada ulogama koje mogu izvršiti samo djelomične postupke (onaj tko može registrirati i aktivirati korisnika ne smije biti korisnik koji koristi sustav radi separacije dužnosti).
- Osjetljivim materijalom (naziv korisnika, javni ključ) rukuju samo ovlaštene osobe.
- Ovlasti koje dobiva korisnik po prijavi određene su Politikom ovlasti koja se aktivira nakon obavljene I&A i nije predmet ovog rada.

VI. USKLAĐENOST S ISO 27K STANDARDOM

Usklađenost s ISO 27k treba osigurati da zaštita djeluje s mehanizmima na vrijednosti sustava koje se sastoje od objekata i subjekata. Objekti, subjekti i pripadajuće ISO 27k kontrole su navedeni su slijedećim tablicama:

TABLICA 2. OBJEKTI (VRIJEDNOSTI) SUSTAVA

Objekt sustava	Funkcije i namjena
PIN	Identifikator koji pozna samo korisnik. PIN je ekvivalent lozinke. Utječe na povjerljivost i dostupnost.
Identitet korisnika	Identitet korisnika zabilježen je u identifikatoru korisnika na svakom računalu gdje se korisnik želi prijaviti za rad. Utječe na integritet.
Privatni ključ	Privatni ključ uparuje se s javnim ključem. Privatni ključ nalazi se na tokenu i nikada nije izravno vidljiv. Utječe na integritet i dostupnost.
Javni ključ	Javni ključ služi za uparivanje s privatnim ključem. Javni ključ se nalazi na CUM-u. Služi za uspostavu sjednice i aktiviranje ovlasti korisnika. Utječe na integritet i dostupnost.
Lista računala gdje korisnik smije raditi	Lista računala povezana je s javnim ključem korisnika. U slučaju podudarnosti poslužitelj uspostavlja sjednicu s korisnikom. Utječe na dostupnost i integritet.

TABLICA 3. MEHANIZMI

Cjeline i kontrole	Funkcije i namjena
Korisnički SW	SW rješenje za prijavu korisnik na poslužitelja. Ima biblioteke koje koristi token.
Token A.11.3.1* A.15.1.2 A.11.5.2	Uređaj na kojem je generiran par javni/privatni ključ i spremljen x.509 certifikat. Služi u postupku identifikacija i autentikacije korisnika pri njegovoj prijavi za rad na računalu. Utječe na povjerljivost i dostupnost. Token je komercijalni produkt koji ima autorski zaštićene pripadajuće biblioteka (pkcs#11) i koje se ne smiju neovlašteno diseminirati i koristiti.
ssh poslužitelj	ssh poslužitelj. Provodi I&A korisnika i korištenjem agenta i vlastitog koda.
Agent A.10.1.3 A.12.2.1 A.12.2.2 A.12.2.3 A.12.2.4	Agent služi za komunikaciju između poslužitelja na koji se spajaju korisnici i CUM-a. Razdvajanje poslužitelja kojeg vidi korisnik i CUM-a kojeg ne vidi korisnik smanjuje moguću štetu na CUM-u Agent kontrolira dozvoljeni format i teret ulazne poruke.
CUM A.10.9.2	U ostvarenom rješenju koristi se http protokol s pripadajućim poslužiteljem.

* *Oznake A.xx.xx.xx odnose se na kontrole 27k standarda*

TABLICA 4. KORISNICI I POSLOVI

Korisnik i kontrole	Sto radi
Krajnji korisnik	Koristi token za I&A (prijavu) na poslužitelj.
Administrator ssh poslužitelja A.11.4.4	Administrira ssh poslužitelj. Registrira korisnika na poslužitelju. Onemogućuje njegov račun, tako da se ne može prijaviti ni na jedna drugi način osim s tokenom. Za administriranje poslužitelja koristi se poseban povjerljivi put s pripadajućim portom. Administratorski i produkcijski komunikacijski put su razdvojeni i ne mogu se koristi ni na koji drugi način osim dozvoljenog.
Administrator CUM-a A.11.4.4	Administrira CUM. Registrira korisnika na CUM-u. Koristi povjerljivi put.
Administrator tokena	Generira par javni/privatni ključ i PIN.

TABLICA 5. FIZIČKE PRETPOSTAVKE

Subjekti i kontrole	Uvjeti
CUM, ssh A.9.1.5 A.9.2.1 A.11.3.2	CUM i poslužitelj na koji se prijavljuje korisnik, su fizički odvojeni od korisnika i nalaze se u štićenom prostoru u koji mogu ući samo ovlaštene osobe. Svi poslovi na CUM-u moraju se raditi u štićenom prostoru.

TABLICA 6. PRETPOSTAVKE RADA SUSTAVA

Kontrole	Pretpostavke uvjeta i načina rada
A.10.9.2	Sustav radi kao transakcijski sustav (upućuje upit na koji očekuje odgovor). Izvorište mora sigurno znati da je upit postavljen željenom odredištu, došao do njega i da je pripadajuću odgovor isto tako došao od tog odredišta. Sav teret koji se prenosi od izvorišta do odredišta i obratno mora imati sačuvanu povjerljivost i integritet.
A.8.1.1	U sustavu moraju biti definirane uloge koje se dodjeljuju korisnicima ili procesima koji rade u korist korisnika.
A.10.1.3	Dužnosti/funkcije svake uloge moraju biti razdvojene i ne smiju se preklapati radi mogućnosti uspostave neovlaštene funkcije s čime bi se mogla narušiti povjerljivost, integritet i dostupnost sustava.
A.11.2.2	Svaka uloga mora imati pripadajuće ovlasti potrebne za obavljanje posla.
A.11.4.5	Poslovi za koje su korisnici ovlašteni, određeni su ulogom koju oni obnašaju u sustavu.
A.11.5.4	Sustavni programi koje može koristiti korisnik ovise o ovlasti koja je korisniku dodijeljena. Potrebno je obratiti pozornost na separaciju dužnosti radi onemogućavanja neovlaštenog korištenja sustavnih programa i narušavanja povjerljivosti, integriteta i dostupnosti.
A.12.5.4	Sustav ne smije dozvoliti curenje informacija, odnosno narušavanje povjerljivosti.

TABLICA 7. KRIPTO ZAŠTITA

Kontrole	Uređaj
A.12.3.1 A.12.3.2	Token koristi kriptografske funkcije kod uparivanja ključeva i korištenja privatnog ključa. Kripto zaštita mora biti određena politikom i ne može se proizvoljno koristiti. Manipulacija s ključevima (generiranje, promjena) vrsi ovlaštena osoba u strogo kontroliranim uvjetima i odvojeno od produkcijskog sustava.

TABLICA 8. KOMUNIKACIJA

Kontrole	Uvjeti i način rada
A.10.6.1 A.10.6.2	Identifikacija uređaja koji podupiru komunikaciju mora biti uspostavljena. Usmjeravanje mora biti vjerodostojno i ne smije doći do narušavanja ruta. Svi podaci u prijenosu moraju imati sačuvanu povjerljivosti i cjelovitost. Mrežni servisi moraju imati osiguranu dostupnost i kontrolu ovlaštenosti dostupa i korištenja.

TABLICA 9. PRAĆENJE I BILJEŽENJE

Kontrole	Postupci
A.10.10.6	Sve aktivnosti se bilježe u dnevnike sustava i moraju imati vjerodostojni vremenski atribut (točno vrijeme kada su nastale). Svaka zabilješka mora biti zabilježena u realnom vremenu.
A.15.3.1 A.15.3.2	Sustav sistemskih zabilješki treba biti osiguran od neovlaštenog dostupa, promjene zapisa i korištenja alata za pregled sistemskih dnevnika.

VII. ZAKLJUČAK

Projektiranje zaštite je postupak identičan postupku koji se provodi pri projektiranju sustava. Razlika u pristupu je jako velika. Projektiranje funkcije sustava uzima u obzir da se ništa loše neće dogoditi, dok projektiranje zaštite mora osigurati da se ništa loše ne smije dogoditi i ako se dogodi, da je funkcija sustava osigurana i nenarušena.

Zaštitu, radi njenog utjecaja na funkcioniranje sustava je najpovoljnije početi projektirati istovremeno s oblikovanjem funkcije sustava. Svaka druga faza u razvoju sustava samo otežava implementaciju zaštite. ISO 27k standard je postao praktički opće prihvaćen i usklađenost s njime podrazumijeva da je je sustav zaštićen i s time siguran.

Rad je pokušaj projektiranja zaštite istovremeno s oblikovanjem sustava i pokazao je svoju opravdanost. U radu su prikazani odgovori na prvo pitanje „što treba napraviti“. Detaljniji tehnički dio koji nije predmet rada dao bi odgovore na pitanje „kako treba napraviti“.

Rad je pokazao da je metoda od dna prema vrhu povoljnija od obratne [8][9]. Ako bi se oslonili pri odabiru kontrola samo na zakonske i ostale propise i najbolju praksu rezultat bi bio općenit. Drugi put od razvoja i izradbe rješenja koje mora biti vrlo konkretno, obuhvaća veliku sliku od potreba, mehanizama do usklađivanja. To znaci da je postupak od definiranje sigurnosne politike do tehničkih kontrola nepovoljniji od obrnutog puta. Nakon što je određeno „što treba napraviti“ s „kako treba napraviti“ i međusobno usklađeno moguće je puno jednostavnije napisati sigurnosnu politiku koja je vršni dokument zaštite.

Djela protiv intelektualnog vlasništva, kod kojih se kao sredstvo izvršenja krivičnih djela javljaju računari, računarske mreže, kao i njihovi proizvodi

Sažetak - Porast upotrebe informacionih tehnologija, odnosno globalne računarske mreže, stvorile su mogućnosti novih oblika krivičnih djela u vezi napada na intelektualno vlasništvo, što je zahtjevalo da zakonodavaci iz mnogih država i međunarodnih organizacija izmjene legislativu kako bi mogli pratiti ove promjene. Unifikacija i efikasna međunarodna saradnja, osnovne su pretpostavke za bolju koordinaciju nadnacionalnih napora za suzbijanje ove vrste krivičnih djela. U radu je dat uporedni pregled sistema zaštite softvera u Sjedinjenim Američkim Državama i državama Evropske unije. Izložen je i pregled propisa koji su na pravnoj snazi u Bosni i Hercegovini, a odnose se na suzbijanje krivičnih djela u vezi napada na intelektualno vlasništvo. Ono što je neophodno u suzbijanju kršenja autorskih i njima sličnih prava i industrijskog vlasništva jeste stabilan pravni sistem sa jakom zakonskom regulativom.

I. UVOD

Razvoj informacionih tehnologija i interneta prouzrokovao je povećanje različitih oblika ugrožavanja intelektualnog vlasništva, odnosno autorskog i srodnih prava i industrijskog vlasništva. Gotovo neograničena dostupnost književnih djela, naučnih radova, muzičkih radova, video radova i drugih autorskih djela u digitalnom obliku uzdrmala je iz temelja tradicionalni koncept autorskog i srodnih prava. On je morao da doživi ograničenja i promjene pod uticajem novih koncepata: copyleft, softvera, licenci otvorenog sadržaja, slobodne razmjene informacija, itd. Bosna i Hercegovina je dio međunarodnog sistema zaštite intelektualnog vlasništva, jer je najveći broj međunarodnih konvencija o pravu intelektualnog vlasništva ratifikovala, te su odredbe tih konvencija postale dio nacionalnog prava. Takve su Bernska konvencija za zaštitu književnih i umjetničkih djela, Konvencija o izdavanju evropskih patenata, Ugovor o trgovinskim aspektima prava intelektualnog vlasništva (TRIPS) i dr.

Računarske mreže su stvorile nove oblike kriminala, koji se vrše na računaru ili kod kojih je računar sredstvo izvršenja. U krivičnopravnoj literaturi za cyber kriminal upotrebljavaju se termini kao što su: zloupotreba računara, računarski kriminal i delikti uz pomoć računara. Tipovi cyber kriminala su brojni, a najčešći su:

- djela protiv intelektualnog vlasništva, imovine i pravnog prometa kod kojih se kao objekat ili sredstvo izvršenja krivičnih djela javljaju računari, računarske mreže, računarski podaci, kao i njihovi proizvodi;
- djela gdje se računari javljaju kao sredstvo izvršenja krivičnih djela, kod zloupotreba platnih kartica na Internetu, zloupotreba u elektronskoj trgovini i bankarstvu;
- neovlašten pristup računaru, računarskoj mreži i elektronskoj obradi podataka.

II. ZLOUPOTREBE INTELEKTUALNOG VLASNIŠTVA

Kršenje autorskih prava je kopiranje i mijenjanje računarskih programa, osim:

- kada to radi sam vlasnik programa, ili
- kada se posjeduje licenca (dozvola) vlasnika prava na program.

Vrste zloupotrebe su slijedeće:

- „*warez*'' kršenje autorskih prava: „*warez*“ je sajt na Internetu koji omogućava ljudima da preuzmu ilegalne kopije. Softver će obično imati svoja „oštećenja“, pa se ona nazivaju „*warez* kopijama“. Ljudi koji prave „*warez*“ kopije, ljudi koji vode „*warez*“ sajtove i ljudi koji preuzimaju te kopije i koriste ih su prekršioci autorskih prava;

- pravljenje nezakonite kopije softvera na CD-ovima, radi davanja nekom drugom, za komercijalnu svrhu i prodavanje istih pod izgovorom da su to zakonite kopije;
- kopiranje softvera od prijatelja ili preko interneta, gde licenca ne dozvoljava ovo;
- zloupotreba dijeljenja: gde je softver licenciran „za određene svrhe“, to je kršenje autorskih prava;
- kupovina softvera za sniženu cijenu pretvarajući se da radite u obrazovnoj ustanovi.

Internet piraterija podrazumjeva upotrebu Interneta za ilegalno kopiranje i distribuciju neautorizovanog softvera. Internet može da se koristi za reklamiranje, ponudu, nabavku i distribuciju piratizovanog softvera. Međunarodna organizacija vodećih proizvođača i prodavača softvera (BSA), procjenjuje da postoji milion Internet sajtova koji prodaju nelegalni softver.

III. MEĐUNARODNA ZAŠTITA INTELEKTUALNOG VLASNIŠTVA

Međunarodna zaštita autorskog prava regulirana je Bernskom konvencijom koja je donijeta 1886. godine, i više puta je revidirana (Pariz 1896., Berlin 1908., Bern 1914., Rim 1928., Brisel 1948., Štokholm 1967. i Pariz 1979.[1] Ovom konvencijom se štite književna i umjetnička djela, uz uslov da su originalna. A kao jedan od nedostataka ove konvencije bili su njeno nereguliranje Interneta i informaciono-komunikacijskih tehnologija, što je rezultiralo osnivanjem Svjetske organizacije za intelektualno vlasništvo (World Intellectual Property Organization, WIPO) 1996. godine. Konvencija o osnivanju Svjetske organizacije za zaštitu prava intelektualnog vlasništva na snazi je od 28.10.1979. Ujedinjene nacije su svrstale ovu organizaciju kao agenciju u sastavu UN. Osnovna aktivnost WIPO je razvoj međunarodnih normativa i standarda intelektualnog vlasništva.

Svjetska trgovinska organizacija kao jedan od uslova za članstvo zahtijeva od budućih članica da usvoje odredbe Bernske konvencije koje su sastavni dio Sporazuma o trgovinskim aspektima prava intelektualnog vlasništva (TRIPS), kojim je predviđeno da se programi računara štite kao književna djela prema Bernskoj konvenciji. Efektivan od 1. januara 1995. godine, TRIPS pokriva prava kopiranja i srodna prava kao što su izvođačka prava i prava muzičkih producenata i medijskih organizacija.

Prema Bernskoj konvenciji djela su zaštićena samim činom svog stvaranja, odnosno nije potrebno vršiti njihovu registraciju kod nekog nadležnog organa, što važi i za računarski program. Pored Bernske za zaštitu intelektualnog vlasništva značajne su Rimska Konvencija za zaštitu prava izvođača, proizvođača fonograma i organizacija za radiodifuziju iz 1961. godine i Ženevska Konvencija o zaštiti proizvođača fonograma od neovlaštenog umnožavanja iz 1971. godine.

A. Zaštita autorskog djela i patentna prava

Gotovo sva nacionalna zakonodavstva propisuju pravnu zaštitu slijedećih autorskih djela:

- računarskih programa,
- književnih djela,
- muzičkih djela,
- umjetničkih djela
- fotografskih djela,
- filmskih djela, i dr.

Oblici pravne zaštite računarskog softvera su:

- zaštita autorskim pravom,
- zaštita patentnim pravom i
- zaštita ugovorom.

Patentna prava se ne stiču nastankom pronalaska ili obavještavanjem javnosti o tome. Ova prava se stiču poslije sprovedenog postupka za priznanje patenta koji se pokreće podnošenjem prijave patenta. Prava važe od datuma podnošenja prijave patenta instituciji koja je nadležna za priznavanje patentnih prava. Patent se izdaje onda kada pronalazak zadovoljava uslove patentibilnosti. Da bi mogao biti zaštićen patentom pronalazak mora predstavljati tehničko rješenje određenog problema koje je novo, koje predstavlja rezultat stvaralačkog rada. Pronalazak mora biti tehničke prirode, odnosno djelo koje se štiti autorskim pravom. Što se tiče novosti, potrebno je da pronalazak ne bude identičan onim tehničkim rješenjima koja su bila dostupna javnosti u pismenom ili usmenom obliku, ili na neki drugi način. Pronalazak se smatra primjenljivim ako ga je moguće upotrijebiti ili proizvesti.

Patent garantuje nosiocu patenta slijedeća prava:

- ako je predmet patenta proizvod: zabranu trećim osobama da bez njegove dozvole izrađuju, upotrebljavaju i nude na prodaju zaštićeni proizvod,
- ako je predmet patenta postupak: da zabrani trećim osobama da bez njegove dozvole upotrebljavaju postupak ili nude na prodaju proizvod koji je dobijen direktno tim postupkom.

Nosioci patenta imaju pravo da putem ugovora ili nasljeđivanjem prenose prava i zaključuju ugovore o licenci. Međutim, postoje pronalasci koji se ne mogu štititi patentom. Jedno od takvih izuzeća su programi računara i primjenjuje se u svim državama svijeta, uključujući i BiH.

[1] Bernska konvencija ima 166 države potpisnice.

A. *Zaštita softvera u Sjedinjenim Američkim Državama*

Zaštita softvera u Sjedinjenim Američkim Državama regulirana je Dekretom o patentima iz 1952. godine. Zavod za patente i žigove SAD je 1996. godine donio Metodologiju ispitivanja pronalazaka vezanih za računare, gdje se navodi da upotrebljivost pronalaska mora biti u oblasti tehnologije, te da pronalazak vezan za računare jeste predmet pronalaska u smislu zakona, odnosno da predstavlja pronalazak koji ima praktičnu primjenu u oblasti tehnologije i kao takav zadovoljava navedeni uslov. Međutim, iako u pojedinim stručnim krugovima nije osporena patentibilnost softvera, ipak je postavljeno pitanje novosti i inventivnosti ovakvih pronalazaka.

B. *Zaštita računarskih programa u Evropskoj Uniji*

U okviru Svjetske organizacije za intelektualno vlasništvo prihvaćen je princip po kojem računarski programi treba da budu zaštićeni autorskim pravom, dok bi postupci korišteni u računarskim softverima trebalo da budu zaštićeni patentom. Autorsko pravo štiti originalnu implementaciju i način prikaza neke ideje, izvorni i izvršni kod i dokumentacija u digitalnom ili pisanom obliku. Patentno pravo za razliku od autorskog prava koje štiti prezentaciju ideje i oblik izražavanja štiti samu ideju i matematičke postupke programa.

Da bi harmonizovala propise svojih članica koji se odnose na zaštitu računarskih programa od neovlaštenog umnožavanja, Vijeće Evrope je donijelo direktivu 91/250/EEC od 14.05.1991. godine, o pravnoj zaštiti računarskih programa. Ova direktiva obavezuje države članice da štite računarske programe putem autorskog prava kao književna djela u smislu Bernske konvencije. Računarski program se štiti ako je originalan u tom smislu da je autorova intelektualna tvorevina. Pri tome se autorom smatra pravna ili fizička osoba ili grupa fizičkih osoba koja ga je stvorila.

Autor ima prava da daje ovlaštenje trećim osobama da:

- vrše umnožavanje računarskog programa;
- prevode ili mijenjaju računarski program i
- vrše iznajmljivanje i distribuciju računarskog programa ili njegovih kopija.

Prema ovoj direktivi smatraju se kažnjivim slijedeće radnje ako ih vrši osoba koja nema ovlaštenje autora:

- stavljanje u promet nelegalne kopije računarskog programa;
- posjedovanje nelegalne kopije računarskog programa iz komercijalnih razloga i
- stavljanje u promet ili posjedovanje sredstava koja su namijenjena za uklanjanje tehničkih sredstava za zaštitu računarskog programa.

Direktivom 93/98/EEC određeno je da zaštita računarskih programa autorskim pravom traje za života autora i još 70 godina posle njegove smrti, ili ako je više autora, posle smrti poslednjeg od njih. Da bi se razumjelo koje su mogućnosti za zaštitu računarskih programa kroz patentni sistem u državama EU treba imati u vidu odredbe Konvencije o evropskom patentu. Ovom Konvencijom propisano je izuzeće od zaštite patentom. Kao jedno od izuzeća u člana 52. navode se računarski programi. Ova odredba je zasnovana na uvjerenju da računarski programi nemaju tehničku prirodu, te da kao takvi nisu patentibilni. Iz ovoga je proizašlo shvatanje da patentibilnost softvera zavisi od toga da li pronalazak koji je u vezi sa softverom ima tehničku prirodu.

Ovo je precizirano u EPO Guidelines for Examination (Metodologija ispitivanja EPO) gde se navodi da se računarski program ne može zaštititi patentom. Ovdje se navodi da se smatra da pronalazak koji karakteriše program i koji predstavlja tehnički proces ima tehnički doprinos i da je zato patentibilan. U praksi EPO su priznavani patenti za računarske programe u formi postupaka za upravljanje procesom ili uređajem. EPO priprema reviziju Evropske konvencije o patentu kojom bi se ukinula odredba kojom se računarski programi izuzimaju iz zaštite patentom. Na osnovu toga se može zaključiti da je EPO praktično prihvatio praksu Zavoda za patente i žigove SAD. Međutim, ovo je samo djelimično tačno, jer još uvek postoje razlike između njih. Najveću od njih predstavlja tretman prijava patenata za softvere namijenjene za obavljanje poslova. Naime, metode za obavljanje poslova su u skoro svim državama svijeta isključene iz zaštite patentom. Stoga bi softveri za obavljanje poslova kao takvi bili isključeni iz zaštite patentom po dva osnova. Međutim, nakon naprijed navedenih izmjena svoje regulative SAD su počele da izdaju patente i za ovakve pronalaske. Sa druge strane, stav EU se nije promijenio i ovakve prijave patenta podnijete Evropskom zavodu za patente se odbijaju. U ovom trenutku još nije jasno koji koncept će preovladati.

C. *Konvencija o cyber kriminalu*

Evropska konvencija o cyber kriminalu donesena 23.11.2001. godine u Budimpešti, pod okriljem Vijeća Evrope (u daljem tekstu Konvencija) je prvi cjelovit formalni potpisani i široko prihvaćeni multilaterarni sporazum usmjeren na probleme cyber kriminala. Konvencija o cyber kriminalu do sada je potpisalo 46 država, a ratifikovalo 30. Konvencija je prvi međunarodni ugovor kojim se sankcionišu krivična djela i druge vrste kriminala izvršene preko Interneta i drugih računarskih mreža i veoma je značajna za zaštitu intelektualnog vlasništva. Sadržajem odredaba člana 10. Konvencije svaka država potpisnica je obavezna da usvoji takve legislativne mjere, da bi

se u njenom nacionalnom pravu, kao krivično djelo, okvalifikovalo kršenje autorskih prava definisanih u zakonima te članice koji se odnose na obaveze koje je ona preuzela po Praškom aktu od 24.06.1971. godine, Konvenciji iz Berna o zaštiti književnih i umjetničkih djela, Međunarodnoj konvenciji iz Rima o zaštiti izvođača, proizvođača fonograma i emisionih organizacija, Sporazumu o aspektima prava na intelektualno vlasništvo i WIPO ugovoru o autorskim pravima.

IV. PRAVNI OKVIR KRIVIČNIH DJELA PROTIV INTELEKTUALNOG VLASNIŠTVA U BOSNI I HERCEGOVINI KOD KOJIH SE KAO SREDSTVO IZVRŠENJA JAVLJAJU RAČUNARI

A. Zakon o autorskom i srodnim pravima

Cilj Zakona o autorskom i srodnim pravima BiH je postizanje potpune usklađenosti tog propisa sa pravnim poretkom EU i važećim međunarodnim konvencijama i ugovorima koje je ratificirala BiH [Bernska konvencija o zaštiti književnih i umjetničkih djela, Međunarodna konvencija za zaštitu umjetnika izvođača, proizvođača fonograma i organizacija za radiodifuziju (Rimska konvencija), Konvencija o zaštiti proizvođača fonograma od neovlaštenog umnožavanja njihovih fonograma (Fonogramska konvencija), Konvencija o distribuciji signala satelita (Satelitska konvencija), Ugovor WIPO-a o autorskom pravu, Ugovor WIPO-a o izvođenjima i fonogramima, te sa Sporazumom STO - TRIPS-a]. Odredbama Zakona o autorskom i srodnim pravima, računarski programi su određeni kao vrsta pisanih autorskih djela, bez obzira na njihov pojavni oblik – u tom smislu je kažnjivo neovlašteno raspolagati na bilo koji način skriptom računarskog programa, kao i mehanički kopirati CD/DVD na kojem se taj program nalazi u elektronskom obliku.[2] Zakon o autorskom i srodnim pravima BiH je usklađen sa sljedećim direktivama EU:

- Direktiva o pravnoj zaštiti računarskih programa, Direktiva Vijeća 91/250/EEC od 14.05.1991.
- Direktiva o pravu davanja u zakup i na poslugu i o određenim pravima umnožavanja u području intelektualnog vlasništva, 92/100/EEC od 19.11.1992, i kodificirana verzija od 12.12.2006.
- Direktiva o pravilima autorskog i srodnih prava koja se primjenjuju na satelitsko emitiranje i kablovsko reemitiranje, 93/83/EEC od 27.09.1993.
- Direktiva o harmonizaciji rokova trajanja autorskog i srodnih prava, 93/98/EEC od 29. oktobra 1992, i kodificirana verzija od 12.12.2006.
- Direktiva o pravnoj zaštiti baza podataka, Direktiva 96/9/EC od 11.03.1996.
- Direktiva o harmonizaciji određenih aspekata autorskog i srodnih prava u informatičkom društvu, 2001/29/EC od 22.05.2001.
- Direktiva o pravu preprodaje u korist autora originalnog djela 2001/84/EC od 27.09.2001.
- Direktiva o provođenju prava intelektualnog vlasništva, 2004/48/EC od 29.04.2004.
- Direktiva o roku trajanja autorskog i određenih srodnih prava, 2006/116/EC od 12.12.2006.

A. Krivična djela protiv intelektualnog vlasništva u Krivičnim zakonima u Bosni i Hercegovini

Bosna i Hercegovina je ratificirala Konvenciju o cyber kriminalu i Dodatni protokol uz Konvenciju 2006. godine. Nakon stupanja na snagu Konvencije u odnosu na BiH slijedila je implementacija odredbi krivičnog materijalnog i procesnog prava Konvencije u državni i nedržavne krivične i krivično procesne zakone. Sadržajem odredbi Krivičnog zakona BiH za razliku od ostala tri nedržavna Krivična zakona (Federacije BiH, R Srpske i Brčko Distrikta BiH) nisu implementirane preporučene odredbe krivičnog prava već je to „dogovorno prepušteno“ u nadležnost nedržavnim krivičnim zakonima F BiH, RS i Brčko Distrikta.

Krivična djela protiv intelektualnog vlasništva, kod kojih se kao sredstvo izvršenja krivičnih djela javljaju računari i računarske mreže, regulirana su:

- Krivičnim zakonom Federacije BiH i
- Krivičnim zakonom Republike Srpske.

Krivična cyber djela uvedena su Krivičnim zakonom Federacije BiH, u Glavi 32, gdje su predviđena „krivična djela protiv sistema elektronske obrade podataka" (čl. 393-397). Krivičnim zakonom Federacije BiH u Glavi 32, propisane su sankcije za krivična djela kod oštećenja računarskih podataka i programa. U članu 393. propisuje se krivično djelo Oštećenje izmjena ili uništenje tuđih računarskih podataka ili računarskih programa, u članu 394. propisano je krivično djelo računarskog krivotvorenja, u članu 395. propisano je kazneno djelo računarske prevare, u članu 396. propisuje krivično djelo Ometanje rada sistema i mreže elektronske obrade podataka, u članu 397. propisuje krivično djelo Neovlašteno uključenje u sistem i mrežu elektronske obrade podataka. Krivično djelo iz člana 6. Konvencije odnosno člana 7. Prijedloga Direktive propisano je u odredbama člana 393.

Krivični zakon RS (2003. g.) predviđa krivično djelo upad u računarski sistem u Glavi 16. A kao „krivična djela protiv sigurnosti računarskih podataka" (čl. 186a-čl.186e).

Krivična djela koja se odnose na povredu autorskog i srodnih prava iz člana 10. Konvencije, su odredbe krivičnih djela iz člana 242. (Zloupotreba autorskih prava), člana 243

[2] Svrstavanje računarskih programa u pisana autorska djela nije originalnost bosanskohercegovačkog Zakona o autorskom i srodnim pravima – slično rješenje primijenjeno je u zakonskim rješenjima u Japanu, Nemačkoj i Francuskoj, dok je Evropska unija 1991. izdala direktivu kojom je računarske programe izjednačila sa književnim djelima u smislu Bernske konvencije.

(Nedozvoljeno korištenje autorskih prava), člana 244. (Nedozvoljeno korištenje prava proizvođaća zvučne snimke), člana 245. (Nedozvoljeno korištenje prava radiodifuzije) i člana 246. (Nedozvoljena distribucija satelitskog signala) Krivičnog zakona BiH, koje obuhvataju i krivična djela počinjena pomoću računarskog sistema.

Analizom sadržaja odredbi državnog i nedržavnih zakona se može zaključiti da se obaveza preuzeta ratifikacijom Konvencije u pogledu krivično matrijalnog prava ispoštovala i da su krivična djela predviđena Konvencijom ugrađena u odredbe nedržavnih krivičnih zakona u BiH.

V. ZAKLJUČAK

Razvoj informacionih tehnologija i njihova masovna primjena u poslovne i privatne svrhe, uslovili su napade na autorska djela i njima slična prava. S obzirom da su načini zloupotrebe informacionih tehnologija svakim danom sve složeniji i savršeniji za otkrivanje, i da je teško ići u korak sa tim kriminalnim aktivnostima, potrebno je ulagati napore u to da javnost bude svjesna sa kakvim se fenomenom današnje društvo suočava, te je potrebno konstantno raditi na što adekvatnijem odgovoru na različita kriminalna djelovanja u ovoj oblasti. Mnoge države su postale svjesne ove pojave i u svojim krivičnim zakonima su predvidjele kršenje autorskog i njima sličnih prava kao posebna krivična djela.

U svijetu su prisutna dva sistema zaštite softvera. Prvi od njih tradicionalno predstavlja autorsko pravo i prisutan je još od pojave prvih računarskih programa. Drugi od njih, koji se naknadno pojavio predstavlja zaštitu softvera patentima. U ovom radu je analizirana zaštita softvera u SAD i državama EU, te su ukazani potencijalni smijerovi razvoja u budućnosti.

Na osnovu stanja zakonodavstva u BiH, a imajući u vidu činjenicu da je napad na intelektualno vlasništvo nov oblik kriminala, možemo da konstatujemo da su država i entiteti usvajanjem odgovarajućih pravnih propisa omogučili krivični progon počinioca krivičnih djela u vezi sa napadom na autorsko i njima slična prava.

INVITED PAPER

Log-driven user-centric OLAP

***Abstract*—While OLAP (On-Line Analytical Processing) is now a mature, efficient technology, very little attention has been paid to the effectiveness of the analysis and the user-friendliness of a technology often considered tedious of use. This work summarizes various contributions to developing user-centric OLAP, focusing on the use of former queries to enhance subsequent analyses.**

We first introduce a logical model to describe and manipulate queries and logs, including a language parametrized by binary relations over analytical sessions. In particular, these relations can be specialization relations or based on similarity measures tailored for OLAP queries and sessions.

We then describe how logs can be mined for knowledge representing the user behavior. This knowledge includes simple preferences, navigational habits and discoveries made during former explorations. We show how it can be used in various query personalization or query recommendation approaches, that vary in terms of formulation effort, proactiveness, prescriptiveness and expressive power.

Finally, we remark that the models and approaches introduced can be seen as a starting point for assessing the effectiveness of analytical sessions, and bridging the gap between OLAP and exploratory search.

I. Introduction

Data warehousing and OLAP are now mature technologies, having attracted a lot of attention from the academic and industrial community, and benefiting from the maturity of relational databases. Noticeably, the major part of this attention has been devoted to the efficient implementation and querying of the warehouse, and very little attention has been paid to the quality of the analysis and the ease of use of such technologies. Recent studies showed that BI tools, although powerful, are often underused by decision makers, who frequently rely on static dashboards [1], [2] instead of using the full potential of the tools.

To answer these limitations, it is now commonly agreed that BI should benefit from a combination with Web 2.0 approaches (a focus on user empowerment, social networks, and community collaboration), a trend often referred to as BI 2.0 [3]. Achieving user empowerment without asking for too much formulation effort, while remaining proactive, can be done using approaches based on the history, i.e., the traces left by the users during former activities. Actually, it has already been pointed out the necessity to come up with flexible, powerful means for analyzing the issued queries, and decompose, store and handle them in a dedicated subsystem in order to better support any decisional task with the knowledge captured in the analytical queries [4]. Evidences of this need are given in [5], where the authors carried out tests demonstrating that browsing through past SQL query sessions helped the users by speeding up query composition. It turns out that user-centric approaches in databases, like query personalization and query recommendation, are indeed getting more and more attention. Using preferences to personalize queries has been investigated for the last ten years [6], and recommending queries [7], [8] is emerging as a promising way of supporting the user browsing large databases.

Strangely enough, although highly relevant to BI in general and OLAP in particular, user-centric approaches, especially the ones based on leveraging past user queries, have attracted relatively little attention from the BI/data warehouse community. This paper summarizes research recently led at the University of Tours to develop user-centric OLAP, focusing on the use of former queries to enhance subsequent analyses. Section II briefly surveys personalization and recommendation approaches in databases. Section III introduce the query models we use to reason about queries as well as a technique to obtain OLAP logs. Section IV illustrates how such logs can be manipulated using a simple language inspired by the relational algebra. Section V describes the user-centric approaches. Section VI concludes and draw perspectives.

II. User-centric approaches in databases

This section briefly recalls two popular user-centric approaches adopted by the database community, namely personalization and recommendation. A more detailed presentation can be found in [9].

Query personalization in databases include two types of approaches:

- The use of explicit preference operators in queries to specify profile elements. The most representative works in this category include Winnow [10], Preference SQL [11] and Skyline [12]. This type of approaches requires high formulation effort, is not prescriptive, not proactive, but is highly expressive.
- The rewriting (expansion) of regular database queries based on a profile. The most representative work is initiated in [13]. This approach requires a low formulation effort, is prescriptive, not proactive and has low expressiveness.

Note that in these two categories, the profile is only given in terms of the constants, attributes and tuples of the database. Thus, using the criteria introduced above, all the approaches are current-state approaches.

The basic definition of the operator computing dominating tuples is the following. Given a relation r with schema $sch(r)$

and a preference C over $sch(r)$ defining a preference relation $>_C$, the Winnow operator [10], denoted w_C, is defined by: $w_C(r) = \{t \in r | (\nexists t' \in r)(t' >_C t)\}$. This operator can be used to order the query answer. Indeed, the answer to a query q can be partitioned according to C, i.e., $q = w_C(q) \cup w_C(q - w_C(q)) \cup \ldots$ meaning that the answer can be presented by displaying $w_C(q)$ first, then $w_C(q - w_C(q))$, etc. This operator has been used with various syntaxes for expressing models of preferences. The work of Kiessling [11] enrich the SQL syntax with a PREFERRING clause that enables the user to specify in each query the model of preference, through the use of of specific preference constructors. Each constructor can be used to express a specific atomic preference. Preferences can be composed with Pareto or prioritization. A restricted form of Kiessling's SQL extension is the addition of the Skyline operator to SQL [12]. This is a restriction in the sense that, originally, Skyline queries feature only numerical attributes and Pareto composition.

In the absence of a dedicated preference operator, a regular user query can be processed and transformed with preferences, resulting in another regular query that is typically a subquery of the initial one. We use the work of [13] to illustrate this approach. In this work, preferences come from a user profile which is modeled as a graph of atomic quantitative preferences of the form *(selection condition, score)*, where *selection condition* is a regular selection predicate (that may be used to join two tables) and *score* is a real between 0 and 1 indicating the intensity of the preference. Atomic preferences are composed using a very simple principle: composition of preference $(s1, v1)$ with preference $(s2, v2)$ results in preference $(s1 \wedge s2, v1 \times v2)$. Query expansion is performed as follows. First, given a query, the k most relevant preferences are selected from the profile. Then the selected preferences are added as hard constraints to the query, and the query is finally executed.

Recommender systems [14] are now well established as an information filtering technology, used in a wide range of domains, from E-commerce to web search to social networks, to suggest items to users. Recently, to our knowledge, there has been only two attempts to formalize database query recommendations for exploration purpose [15], [7]. All the approaches presented below require a low formulation effort, are proactive (a query is suggested) and prescriptive (no soft constraint are added to the suggested query) and offer a low expressiveness. In [7], the authors propose two techniques to recommend queries based on the database instance and/or the current query answer. The first technique, called local analysis, analyzes the answer to the user query to discover patterns and uses these patterns to recommend. The second technique, called global analysis, extends this principle to the entire database instance. The instance would have to be analyzed off-line, for example to discover correlations among attribute values.

For [15], the problem of query recommendation is viewed as a sessions $\times$ tuples matrix. With this approach, a query is represented as a vector whose arity is the number of tuples of the database instance. The basic approach considers that each component of such a query is either a 1, if the query used the tuple, or a 0 otherwise. A session is also represented by a binary vector which is the logical OR of the vectors of the queries of the session. Consider a particular session S_c called the current session. Recommendations for S_c are computed as follows. First, sessions similar to S_c are found, using some vector similarity measures like e.g., cosine. For those sessions closest to S_c, the queries they contain are also compared to S_c using the same similarity measure. Finally, the queries of those sessions that are the most similar to S_c are recommended. In subsequent works [8], the authors focus on fragments (attributes, tables, joins and predicates) of queries and consider thus a sessions $\times$ query fragments matrix. In this work, the matrix is used column-wise in the sense that recommendation computation relies on fragment similarity instead of session similarity.

To conclude this section, we introduce the requirements for user-centric approaches in the context of OLAP analysis of data warehouses. As evidenced by e.g., [16], [17], [18] basic peculiarities of typical data warehouses can be summarized by:

1) A data warehouse is a read-mostly database and its instance has an inflationist evolution (data are added, never or very seldom deleted). It is for instance likely that a user issues periodically *similar sequences of queries* more than once, in the sense that *queries may not be fully identical*.
2) A data warehouse is a database shared by *multiple users, mostly executives, whose interests are diverse and may vary over time*. It is argued in [19], [18], [20], [21] that *user preferences are of particular importance in data warehouse exploration*. It would for instance be important to *issue recommendations computed from other users' habits* (e.g., in a collaborative filtering fashion) and at the same time *respecting the user interests*.
3) A data warehouse has a particular schema that reflects a known topology, often called the lattice of cuboids, which is systematically used for navigation [22]. *Roll-up and drill-down operations that allow to see facts at various levels of detail are very popular in this context*.
4) A typical analysis session over a data warehouse is a sequence of queries having an analytical goal, each one written based on the past results of the session. They may be expressed in a *dedicated query language (like e.g., MDX*[1]*)*, may produce *large results that are usually visualized as cross-tabs*. Moreover, *the session has a sense w.r.t. some expectations*. For instance, the user may assume a uniform distribution of the data [23], [24] or that two populations follow the same distribution [25]. Sessions (as sequences of queries) are of particular importance in this context since *with this sequence of queries, the user navigates to discover valuable insights w.r.t. her expectations or assumptions*.

III. Modeling and constructing logs

This section describes the models for queries, sessions and logs that were used in our works [19], [26], [27], [28], [29],

[1] http://msdn.microsoft.com/en-us/library/ms145506.aspx

[30], to reason about queries. In these works, three main ways are used for modeling queries. A multidimensional query can be modeled as a set of fragments (group by sets, sets of selection predicates, sets of measures), extracted from the query expression. A query can be modeled as a set of tuples, obtained with a partial evaluation of the query expression. For instance, a multidimensional query over a star schema can be evaluated only over the dimension tables, resulting in a set of references. Note that obtaining this set of references from a query expression can be computed efficiently when dimension tables fit in main memory. In that case, a query can be expressed intentionally as a tuple of sets, one set of members in each dimension. The cross-product of these sets is a set of references, which forms the query model. Finally, a query can be modeled as the set of its answer when evaluated over a database instance. It can be defined as follows: Given a cube instance and a query expression, the query models is the set of facts extracted from the data cube by the query expression.

Intuitively, these three models can be seen as three different focuses on how the user interacts with the cube, where the importance is either the way the query is written (unevaluated queries), or the part of the cube queried (partially evaluated queries), or the values retrieved (fully evaluated queries). It is also worth noting that both the effectiveness and efficiency of the user-centric approach depends on the query model used. Indeed, a trade-off exists, that can be expressed as follows. On the one hand, modeling queries as their results allows to leverage the knowledge extracted with the query, but requires important resources to store or recompute the query answer, especially in a data warehousing context. On the other hand, using only information derived from the query expression may give rise to efficient approaches, but not knowing the data extracted with the query may prevent valuable deductions, like two different query expressions lead to identical results on a given instance.

Regarding logs and sessions, OLAP logs are modeled as sets of sessions, sessions being modeled as sequences of OLAP queries. Obviously, not all query logs produced by an OLAP system, especially those based on the ROLAP technology, naturally respect this model. OLAP queries can be expressed under the form of SQL (or relational) expressions. The log may simply be a long sequence of such expressions that may not be organized as a set of sessions. And even though the queries are organized as sessions, they may not be logically connected toward the exploration of an analytical goal. Consequently, OLAP semantics must be extracted from each expression, under the form of OLAP operations, and sessions must be identified. [29] introduces a technique to obtain an OLAP log from an ordered set of SQL queries. The techniques consists of normalizing multidimensional expressions, and checking for all pairs of successive such expressions, if a small number of OLAP operations can be used to transform the output of the former into the output of the latter. If the queries are not expressed in the multidimensional algebra, they are translated into it.

IV. Manipulating and comparing logs

This section describes the manipulation language introduced in [31], that is dedicated to query logs, and stemming from the relational algebra. While the (extended) relational algebra enables the manipulation of relations, i.e., sets of tuples, that have a schema, the language presented here manipulates logs, i.e., sets of sessions, that does not have a schema. The schema can therefore not be used in the expressions formed with this language. Instead, the operations of the language are parametrized by a binary relation over sessions θ, that may for instance be used to compare sessions. In particular, θ can be a specialization or a similarity relations over sessions. A study of similarity measures for OLAP sessions can be found in [32].

For the sake of simplicity, the names and symbols of the operations are the same as the ones used in the relational algebra. The language features 5 operations. Two of them are unary operations: selection σ and group by and aggregation π. Three of them are binary: join $\bowtie$, union $\cup$ and difference $\setminus$. In what follows, let L and L' be two logs, f be a binary functions outputting a session, agg be a function aggregating a set of sessions into a session, s be a session and θ be a binary relation over sessions.

The selection operation enables to select from a log those sessions satisfying a given condition. This condition is given under the form of a relation to another session. Formally, $\sigma_{\theta,s}(L) = \{s' \in L | \theta(s, s')\}$

As logs are defined as sets of sessions, the set union and set difference operations can be used to manipulate logs. Formally, $L \cup L' = \{s \in L \text{ or } s \in L'\}$ and $L \setminus L' = \{s \in L | s \notin L'\}$.

The join operation enables to combine the sessions in two logs, that are related through a relation θ. Formally, $L \bowtie_{\theta,f} L' = \{f(s, s') | s \in L, s' \in L', \theta(s, s')\}$. Note that intersection can be simulated with the join operation.

Finally, the grouping and aggregate operator allows to group sessions that are related to one another through relation θ, and to aggregate them using an aggregation function agg. Formally, $\pi_{\theta,agg}(L) = \{agg(\{s' \in L | \theta(s, s')\}) | s \in L\}$.

This language allows to manipulate logs in a flexible way, and can be used to search, filter, compare, combine, modify logs, and express advanced manipulations like summarization or query recommendation [31]. The language is closed under composition, and is complete. The language is not minimal since σ can be simulated with $\bowtie$. It can easily be seen that removing σ makes the language minimal.

V. Log-driven user-centric analysis

This section describes informally the approaches we proposed for user-centric OLAP using query logs.

A. Extracting profile information from the log

This section describes how relevant knowledge can be extracted from an OLAP query log to subsequently support OLAP analyses. Extracted knowledge include (i) simple preferences over dimensions, members and measures [19], (ii) correlations between query fragments [30], and (iii) investigations representing what has been seen during past sessions

for a pair of cells where measures differ significantly [27]. Unsurprisingly, it can be seen that, the more precise the query model used (with respect to the database instance), the more complex the information extracted is.

We defined simple preferences over multidimensional data to be: a partial order over the dimensions, dimension-wise partial orders over members, and an order over measures. The order over dimensions is inferred from the former queries' projections, over levels or measures, and the orders over members are inferred from the former queries' selections. Note that an order over levels in a dimension can be easily computed using this principle.

A navigational habit is defined by an association rule of the form $X \rightarrow Y$, with the intuitive meaning that whenever fragment X is used in a query expression, then fragment Y tends to be present as well. Our algorithm for extracting navigational habits uses any classical association rule extractor, and adjusts automatically support and confidence thresholds [30].

If the query expressions in the log are grouped into sessions and are modeled as unevaluated queries (i.e., represented by their results), the log can be processed to discover what was the goal of the user during the analysis session. The key idea of processing the log to discover what was the goal of the user, is to detect the difference between measure values that queries investigated. More precisely, the log is examined to discover the pairs of cells whose measures differ significantly, to retain the most general ones (the most general difference pairs, $mgdp$) as well as the queries that contains them (the most general difference queries, $mgdq$). For such pairs, a structure called investigation is created that records the set of $mgdq$ and, at a lower level of detail, the queries that confirm the difference (their drill-down differences), and the queries that contradicts the difference (their exceptions).

B. Personalizing queries with a single user log

In this section, we present two approaches for personalizing multidimensional queries, one based on the use of dedicated operators and one based on query expansion. Importantly, these approaches are consistent with the requirements stated in Section II. In particular, (i) they rely on user navigational habits extracted from past analytical sessions, (ii) the profile elements used respect the multidimensional model, and (iii) they can take advantage of the user's past discoveries in the data.

The first approach [30] deduces from the log the preference constructs to be used with a user query, assuming the use of the MYMDX preference language [33]. The profile consists of navigational habits R extracted from the log. The approach consists of three steps:

1) *Rule selection*. When a user formulates an MDX query q, a subset $R_q \subseteq R$ of rules is selected. Each rule in R_q is *pertinent* w.r.t. q, meaning that its antecedent matches with q, and *effective*, meaning that the preference it would be translated into can actually induce an ordering on the facts returned by q. Then, let a positive integer *personalization degree* α be chosen by the user to express the desired preference complexity. A query F_α is generated from R_q in such a way that the final preference expression of the MYMDX statement has α base constructors, where α is user-defined.
2) *Fragment translation*. Each fragment in F_α is translated into a base constructor; the resulting base constructors are then coalesced and composed using the Pareto operator into a preference expression p.
3) *Querying*. Query q is annotated with p, translated into MYMDX, and executed. As shown in [33], the user can effectively explore query results by visually interacting with a graph-like structure that emphasizes the better-than relationships induced by p between different sets of facts. Preferred facts are then displayed in a multi-dimensional table.

The second approach uses query expansion to enrich the user query with preferences, without relying on dedicated operators. The principle is to reduce the answer to a user query by computing the preferred subquery in the classical sense of query inclusion. The principle introduced in [13] can be directly applied: the simple preferences extracted over members can be used to generate a user profile consisting of weights on selection conditions over members. This profile could be exploited using the algorithm described in [13]. Alternatively, if the profile consists in the navigational habits, the principle used in the first approach can be used. Instead of deriving preference constructors from the relevant habits, these habits are used to enforce hard constraints, or to discard group by sets.

C. Collaborative recommendations with a multi-user log

Finally, this section describes various query recommendation techniques using information extracted from an OLAP query log. They are aligned with the requirements stated in Section II, being tailored for the multidimensional model and the ways users analyze a cube. The approaches either rely on the log and on the database instance, and in that case the recommended queries indicate potential discoveries made by other users analyzing a related set of data, or they exploit past unevaluated queries only, by looking for similar user intensions or navigational habits.

The first approach [27] uses both the information extracted from the log and the current state of the database, more precisely, the content of the fully evaluated query. In this approach, the profile is a set of investigations extracted from a multi-user log. Recommendations are computed on the basis of the differences discovered in the log. The key idea is to detect the difference that the current query is investigating and to recommend the queries in the log that investigated the same difference. An investigation records the set of $mgdq$ (the most general difference queries, i.e., the queries containing a difference pair at the coarsest granularity level in the log) and, at a lower level of detail, the queries that confirm the difference (the $mgdq$'s drill-down differences), and the queries that contradicts the difference (their exceptions). Recommendations are computed online each time a current query is added to the current session by the current user. The current query is

analyzed to detect to which investigations it corresponds (this query may be itself a $mgdq$, a drill-down difference, or an exception of what is detected in the log). Then a navigation plan (a set of queries arranged in a graph) is proposed for the current user to see drill-down differences or exceptions to the $mgdq$, by using the queries of the investigations.

The next query recommendation approaches use only the history of the database, that is the unevaluated queries of the log. The second recommendation approach relies on a general framework for computing history-based recommendations [34], where a query is recommended by using both the server log, i.e., the set of sessions already posed to navigate the cube, and the sequence of queries of the current session. Note that this framework can be used whatever the query model (unevaluated, partially evaluated, fully evaluated), by adapting the similarity used for queries (and thus sessions). The framework consists in three steps: (i) Matching, i.e., searching the log for sessions related to the current session, (ii) Predicting, i.e., generating candidate recommendations by predicting what could be the next query, and (iii) Ranking, i.e., ordering the candidate recommendations to present the queries to the user in interest order. This framework is flexible in the sense that it does not lay down a specific method for matching, predicting or ranking. Instead of that, each of these steps is parametrized with functions and relations. By changing these parameters, the way recommendations are computed changes. Instantiations of this framework are given in [26].

Finally navigational habits extracted from a multi-user query log can be exploited to derive recommendations, using an approach similar to that of [30]. In this case, the set of rules is searched for pertinent rules, i.e., whose antecedent matches the user query. The main difference is that the rules need not be effective, since the goal is not to reduce the answer set. Then pertinent rules' consequents are used to derive the recommendation.

VI. Conclusion

This paper summarizes various contributions to developing user-centric OLAP, focusing on the use of former queries logged by an OLAP server to enhance subsequent analyses. Logs are modeled as sets of sessions, sessions being modeled as sequences of OLAP queries. Three main approaches are presented for modeling queries: as unevaluated collections of fragments (e.g., group by sets, sets of selection predicates, sets of measures), as sets of references obtained by partially evaluating the query over dimensions, or as query answers. Such logs can be constructed even from sets of SQL query expressions, by translating these expressions into a multidimensional algebra, and bridging the translations to detect analytical sessions. Logs can be searched, filtered, compared, combined, modified and summarized with a language inspired by the relational algebra and parametrized by binary relations over sessions. In particular, these relations can be specialization relations or based on similarity measures over queries and sessions. Logs can be mined for various hidden knowledge, that, depending on the query model used, accurately represents the user behavior extracted. This knowledge can be used for query personalization, i.e., coping with a current query too few or too many results, or query recommendation, i.e., suggesting queries to pursue an analytical session.

To assess the effectiveness of the contributions summarized here, subjective test involving users and user traces will have to be run. To conduct and simulate such tests, a perspective is the development of a platform for assessing the quality of an analytical session over a cube. Indeed, although data quality is a well studied area of data management, the quality of the querying process has not yet been investigated. Data quality is modeled according to quality dimensions (like e.g., accuracy.), each of them grouping quality factors (like e.g., semantic correction, or syntactic correction), each of them measured by various metrics [35]. A similar approach could be used to model the quality of analytical queries and the quality of analytical sessions. In addition, such a model would allow the development of a platform for assessing and validating user-centric approaches in the context of OLAP. Notably, in domains like Information Retrieval, benchmarks are used [36] to validate approaches aiming at supporting browsing and exploratory search results. In the domain of data warehousing, the existing benchmarks are exclusively focused on performance (see for instance [37]), and effectiveness of the querying process in terms of how successful the analytical session is, is simply not addressed. So far, validating personalization or recommendation approaches is based on synthetic query logs [38] or the processing of existing logs with no guarantee of being realistic [15]. A platform for assessing user-centric approaches should allow to measure to which extent approaches are effective in that answers found are relevant, the effort spent to conduct the analysis is reduced, etc. Such a platform could benefit from previous effort to develop a benchmark to validate personalization approaches in databases [39].

Finally, an even longer term perspective is extending OLAP to exploratory search. Exploratory search can be defined by an elaborated activity that goes beyond lookup and involves learning and investigating [40]. Modeling the overall decision making process under the form of exploratory search will allow to take advantage of how the user understanding of data evolves along her/his interaction with the data warehouse.

***Abstract*—Ontologies are seen by companies such as EDF[1] as an answer to the data heterogeneity problem. However the design and management of consensual and complete ontologies in new and evolving domains remain important challenges that must be tackled for the widespread adoption of this notion. In this paper we present the approach we have developed to overcome these issues in the context of a data warehouse project with EDF concerning the electric mobility development. We first propose an incremental and modular design of ontologies. Then we suggest to formalize not only the domain knowledge as an ontology but also the business processes followed to exploit this knowledge. As a result, this method allows engineers to use the ontology as an interface for manipulating heterogeneous data as well as for reusing existing business processes. Finally we report the results and benefits of our approach for the project conducted with EDF.**

Keywords*—*Domain Ontology, Business Ontology, Study Case

I. Introduction

Initially defined by Gruber as an explicit specification of a conceptualization [1], the notion of ontology has been widely studied by the research community. As a result, standard ontology languages such as RDFS [2], OWL [3] or PLIB [4] have been defined. These ontology languages are equipped with tools to edit ontologies (e.g., Protege) [5] and to manage large amount of ontology instances (e.g, Oracle Semantic Technology [6] or OntoDB [7]). Thanks to these developments, ontologies are currently spreading into the industrial world. They are considered as practical solutions to the problem of data heterogeneity which is an important challenge for companies as most of them evolve in distributed settings.

If companies such as EDF are convinced of the interest of ontologies, their usage in an industrial context raises several challenges. One of them is the design of ontologies in new and evolving domains. This is particularly the case of the electric mobility domain in which EDF is an important actor. Indeed, during the past decade there has been a huge development of the electric vehicle (EV). This evolution is closely studied by EDF, as it is an electricity producer and supplier. The electric mobility domain concerns everything linked to EV, such as infrastructures, events, equipment, partners, services, etc.

EDF is involved in multiple EV experiments, with multiples partners across Europe, which consist in using and testing various equipment. We can cite the Kleber experiment in Strasbourg with Toyota, the SAVE experiment with Renault near Paris, or the ongoing trans-boundary CROME experiment between Germany and France. The aim of EDF is to design a data warehouse to gather the data of those experiments. As the data heterogeneity is important in those experiments, it suggests to use ontologies. However, as this domain is new and evolving, reaching a consensus among the different partners is difficult. To solve this problem we propose in this paper an incremental and modular ontology design methodology. Moreover, as the same data analyses are frequently performed on the data warehouse, we propose to formalize them in a *business process ontology* to reuse this knowledge. Then, the business process ontology is linked to the domain ontology and queries are written on the business process ontology to analyze the data. The interest of our approach is shown by describing the results of our project with EDF and the benefits they have obtained from this experiment.

This paper is organized as follows. In Section 2 we present the basic notions needed to understand our proposition. We also discuss the related work and introduce a motivating example. Section 3 presents our proposed design methodology for the incremental construction of domain ontologies. Section 4 describes our approach to define the business process ontologies linked to the domain ontologies. Then section 5 details the result of our project with EDF. Finally section 6 concludes this paper and introduces future work.

II. Preliminaries

A. Ontology Notion and OntoDB/OntoQL

As an extension of the definition of Gruber, we define an ontology as a *formal and consensual dictionary of categories and properties of entities of a domain and the relationships that hold among them* [8]. This definition highlights three main characteristics of an ontology:

- *Formal:* an ontology is based on a formal theory.
- *Consensual:* an ontology is shared by a community.
- *Capability to be referenced:* each concept of an ontology has a universal identifier.

Two main types of ontology are distinguished. While *linguistic ontologies* describe a domain as the set of terms that are used in this domain and the relationships between these terms (e.g., synonymy), *conceptual ontologies* are composed of classes and properties organized in a hierarchy [4]. In our

[1]EDF: Électricité De France, the French major electricity supplier.

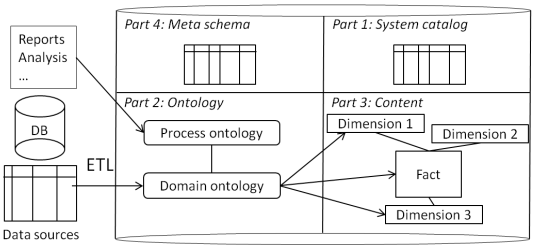

Fig. 1. Our proposition implemented on the OntoDB architecture

work we focus on conceptual ontologies that can be defined with most ontology languages such as RDFS, OWL or PLIB.

Specialized databases have been designed to store ontologies and their instances. We use OntoDB in our work [7]. Its architecture, depicted in Figure 1, is composed of four parts. Part 1 is the *system catalog*, part 2 (*ontology*) and 3 (*content*) store respectively the ontologies and their instances and part 4 (*metaschema*) records the ontology model into a reflexive meta model (description of concepts and properties, available data types, supported languages, etc.). OntoDB is equipped with the OntoQL language to manage these parts. It keeps a syntax close to SQL.

B. Related Work

In our project with EDF we had to design an ontology for the electric mobility domain. Two recent surveys have been made on ontologies construction methodologies [9], [10]. We have identified the following methods to be the closest to our needs.

The first method is the older one: a direct construction of a global ontology [11], [8]. These *global methods* require to describe the whole domain at once. As our domain is rapidly evolving, this kind of method is not adapted to our needs. Even if we proceed by an iterative process, this global method would require time to reach a consensus on new concepts and to revise the older ones.

The second closest method consists in using a common vocabulary allowing each contributors to build a local ontology on the shared vocabulary [10]. This approach permits to quickly build and work with an ontology. However its main drawback is that the shared vocabulary does not ensure that the local ontologies build on it will be compatible. As a result, some work are required to ensure the compatibility of local ontologies. Without it, the heterogeneity issue will remain.

As we can see, the proposed ontology design methodologies are not adapted to recent and evolving domains. Moreover, there are numerous work on domain ontologies but few on business process ontologies. As a consequence, we propose a method to facilitate the creation of an ontology and to make it less time consuming. Then we suggest to complete this method by building a process ontology connected to the domain ontology. With this connection the two ontologies allow engineers to capitalize knowledge efficiently in a data warehouse. Figure 1 illustrates this proposition, in part 3 the instances are stored according to the star schema.

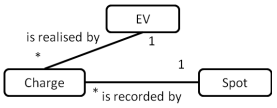

Fig. 2. Domain ontology sample

C. Motivating Example

To demonstrate the industrial interest of our method we propose a concrete case study. During an experiment involving the deployment of vehicles, EDF wants to store data generated by vehicles and charging spots. If we want to study a driver behavior, we need to record every charge done by his vehicle on any charging spot. A *charge* consists in charging the *EV*'s battery which is recorded by the charging *spot*. This description leads to the ontology depicted in Figure 2. For readability, the properties of the classes are not shown. The *charge* class is described by several dates (e.g., *connection date* or *starting and ending charge dates*), energy consumption data (e.g., *number of phases* or *charging speed*) and other information (e.g. if it is *booked*). The *EV* is mingled with its battery so we use only one class to represent it. This concept is described with several properties such as the battery's capacities or the types of charging modes accepted (fast or slow). The *spot*'s properties concern location, plugs available, etc.

The described ontology gives an extract and a high level view of the electric mobility domain. However, to define a complete ontology on this domain we need to describe precisely the different types of vehicles, charges and spots. The main difficulty is that these domains are quickly evolving and numerous vehicles, charges and spots can be added, changed and removed. Thus we have designed a particular ontology design methodology to support these changes.

III. Proposed Ontology Design Methodology

Instead of waiting for a general consensus on a domain, our methodology proposes to build a first draft of an ontology and to design the associated tools so that changes in the ontology can easily be taken into account. Moreover, as this domain is composed of different fields of expertise, we propose to decompose the ontology in several parts called *bricks* that can be switched if necessary.

A. Modularity: The Notion of Brick

A brick is a set of classes and properties that describes a field of expertise in a given domain. Each brick can be designed without reaching a consensus. Thus, several bricks can be defined on the same field of expertise by different experts. As a consequence, we view a brick as a local ontology in an integration system. Once the different bricks on the domain have been defined, they are combined to define the global domain ontology. The consensus that must be reached consists in deciding which bricks must be combined to obtain the global ontology. Then each brick can be extended or switched with another brick designed by another expert as long as it keeps the relationships with the other bricks.

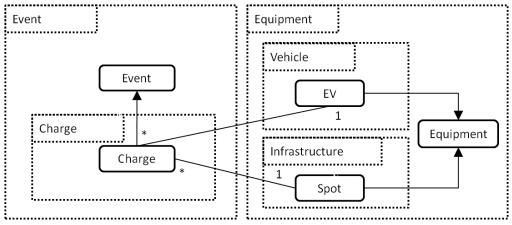

Fig. 3. Defining bricks

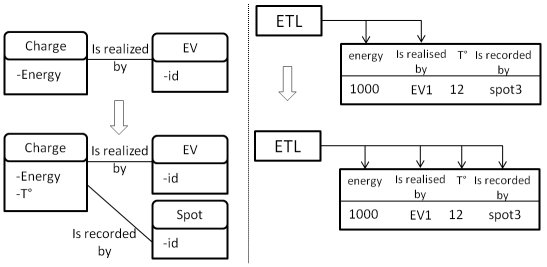

Fig. 4. ETL flexibility at work

As our objective is to be able to easily switch between different bricks on the same field of expertise, we have designed two types of bricks:

- *high level bricks* represent abstract concepts on the domain that are considered to be stable, they may contain other bricks. The link between the different fields of expertise should be done at this level if possible.
- *low level bricks* contain the most specific concepts of the ontology. The main classes of a low level brick must inherit from the classes of higher level bricks.

Example. Figure 3 presents the decomposition of our previous ontology example (see Figure 2) in several bricks. This ontology is composed of two main high level bricks: *Event* and *Equipment*. The *Event* brick defines a generic class *Event* and contains a low level brick *Charge*. The *Charge* class inherits from the class *Event*. In the same way, the *Equipment* brick defines the generic class *Equipment* superclass of *EV* and *Spot*.

In this example, the *Charge* brick is composed of a unique class. But if an equipment partner is not satisfied by our brick, he can add another concept in this brick such as *electrical properties* (e.g., *charging current* or *energy voltage*) because he may have a more precise definition of a charge. To use the rest of the ontology with his brick the only operation he has to do is to switch the actual brick with the one of his own and ensure that the connections with the other bricks are correct.

B. Brick Organization

If we consider a whole project that uses the proposed design methodology, the result is a collection of bricks. This collection should be organized regarding the domains concerned by the ontology from an engineering point of view. By combining the brick-design and the business knowledge of the domain each stakeholder of the ontology design process can propose bricks from their field of expertise. Each stakeholder can develop the bricks he needs sharing the construction only with a stakeholder that uses the same bricks. The flexibility of our design methodology relies on the fact that any brick can be either switched with an other brick or specialized if needed as long as relationships between bricks are maintained. Next section describes how we support this flexibility.

C. Supporting the Modularity

1) Ontology Consistency: Having a modular design allows experts to use a more accurate local ontology on their domains of expertise. To ensure the consistency of the ontology after modifying some bricks we propose the following mechanism. Each brick contains one main concept which defines the links with other bricks. *Vertical* links between a main brick's concept and the bricks within are ensured by using the inheritance mechanism. *Horizontal* links between distinct bricks are defined by the brick's main concept which acts like a gateway.

2) Flexible ETL Process: In order to provide a generic ETL we have designed it so that changes in the ontology are dynamically exploited: *for each mapped ontological class load the available properties* and *If a property is a relation then request the primary key*. With this process, the ontology can be changed without modifying the ETL.

To formalize the ETL process we use the algebra proposed in [12] and more precisely, the following operators.

- *Retrieve*: $Source \rightarrow RawData$. It retrieves raw data from the sources.
- *Convert & Join*: $RawData * Ontology \rightarrow Instances$. The raw data (e.g., CSV or XML files) are converted into class instances by matching the raw data properties with the ontological class properties.
- *Filter*: $Instances * Ontology \rightarrow Instances$. The instances obtained by the previous operator are filtered using the knowledge described in the business process ontology (described in section IV).
- *Store*: $Instances * Ontology \rightarrow TargetedSGBD$. This operator generates the OntoQL statements required to insert the selected instances.

As our ETL process takes as input the domain ontology, we have enriched this algebra with the operator *Retrieve meta data* to retrieve the ontology from the OntoDB platform and the source's scheme. The ETL process starts by retrieving the source's data model before retrieving the data. Then the ETL reads the ontology and stores it in its cache. Thus, the ETL process is not defined on a hard-coded ontology.

Example. Figure 4 illustrates the ETL capacities. In the first case the ETL has to read the *energy* value. *Energy* could have been a synonymous known by the ontology such as *chargedEnergy*. For the reference to an *EV*, the ETL will request the *EV*'s table for the corresponding primary key. In the second case, if we need to perform an infrastructure analysis, we add in the ontology the temperature (T) property and a reference to the spot where the charge happens. As the ETL reads the modified ontology, it can automatically retrieve the corresponding data.

IV. Business Process Ontology

A. The Need of a Business Process Ontology

In the project with EDF, the goal is not only to collect data for maintenance and supervision purposes but also to get a feedback on EV usage such as the location and period of peak demands or the reliability of the supply network. This feedback is given by engineers who perform data analyses.

By studying the current practice, we have observed that the same analyses are performed on different dataset as EDF is involved in several experiments. Moreover, as the electric mobility domain is emerging, engineers are specifying new indicators to understand and describe EV usage. Thus the knowledge used by engineers for crafting an analysis is built on personal experience and insights. As this knowledge is not recorded, engineers do not share their experience on the indicators that should be used to answer a specific business question. Yet, engineers may need to reuse indicators developed by others experts on the same sort of dataset. Moreover, there is a risk to lose this knowledge if an engineer leaves its expert role. As a solution to these problems we propose to create a business process ontology to automatize business analysis and to capitalize and share engineers personal knowledge.

B. Business Process Ontology Design

The business analyzes conducted by engineers on the electric mobility domain are rapidly expanding and evolving. As a consequence, we have adopted the same design methodology to build the business process ontology as the one used for the domain ontology. Thus the business process ontology is composed of a set of bricks. A high level brick *Knowledge* includes all the other bricks. This brick is decomposed in several sub-bricks that characterize the different forms of analyses: sorting treatments, indicators, pattern recognition, statistical reports, etc. Low level bricks describe specific analyzes tasks by defining their computation, business concepts and entities concerned by it, etc.

Example. One of the main issue of the electric mobility concept is that it contributes to the energy peak demand around 7 pm when everybody is getting home. The EV usage is a new source of energy consumption that must be added to the peak demand. Therefore, daily energy consumption is a key indicator that should be studied. To compute this indicator we had to ensure data quality, which led us to define sorting knowledge. Figure 5 illustrates this part of the knowledge brick.

The knowledge ontology is essentially used for description and sharing, the indicators are computed without the ontology with views, or batch, and loaded with the ETL. We have represented *sorting*: the physical one describes, for example, the electrical values of a charge (positive energy, mean power value, etc.) and the quality one, the relations of the charges with other concepts; the daily load curve is our main indicator built on a selection of charges (depending on the season, drivers, infrastructures, etc.). Its computation is simple, for each charge we determine the mean power: P_m used between the charge start date t_S and the charge end date t_E. Then we split a day into ten minutes intervals, and we increment the intervals between t_S and t_E by P_m.

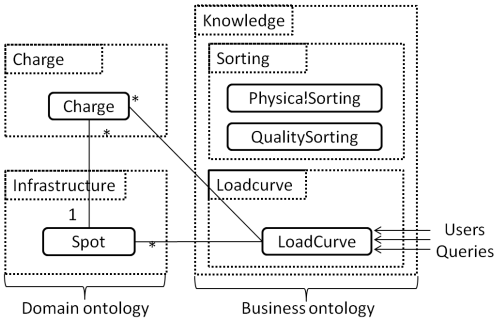

Fig. 5. Knowledge bricks sample

C. Link between Domain and Business Process Ontologies

The connection between the domain and business process ontologies is rather intuitive. The business ontology describes what is needed to generate an analysis including the data. The data needed is described by the domain ontology. So we can link the knowledge concept to the domain concepts it requires. Now the two ontologies are connected as shown in Figure 5.

In the EDF project, the domain and business process ontologies are used as follows. If an engineer identifies a useful indicator, (s)he describes it in the business process ontology and links it to the domain ontology concepts. Then anyone working on these concepts will see an annotation referring to the knowledge brick. This process permits a better knowledge sharing and it pushes engineers to formalize their knowledge. It also encourages engineers to be active contributors to the ontology, the brick design allowing them to easily integrate new indicators and/or concepts.

V. The EDF Project Experiences and Impact

A. Data Warehouse Implementation

As said previously, we have chosen the OntoDB platform for implementing our data warehouse. We have made this choice for two main reasons (1) ontologies can be stored in OntoDB and (2) the meta-schema part of OntoDB can be used to manage ontologies defined with different ontology languages. We have used OntoDB as depicted in Figure 1. The domain and business process ontologies are stored in the ontology part while the data are stored in the content part. A star schema is used in the content part where the fact tables store all the events (e.g., *EV charges* or *energy consumption*, etc.) and the dimensions are picked in the high level bricks of the ontologies (e.g, *Vehicle*, *Spot* or *Location*).

The OntoDB platform uses PostgreSQL as the underlying database management system. Thus we have been able to use SQL views to compute simple indicators defined in the business process ontology. For complex indicators, like sorting, we have implemented them with batch programs. New analysis to perform will first appear as concepts in the business process ontology. The implementation will differ depending on the

analysis: adding a dimension or a fact table with the current, or new, dimensions for a new analysis, expanding a dimension or a fact table with new properties.

B. Complete Use Case

1) Goal: EDF is an electricity supplier and charging an EV is a new electricity usage so, naturally, EDF is studying the different types of user behaviors to define new adapted contracts. The goal of this analysis is (1) to establish mean user profiles and (2) to identify the type of users that contributes the most to the consumption peak.

2) Data sources: the analysis core concerns the charges. They are extracted from monthly reports (CSV files) provided by our partners responsible for providing equipment and gathering data. These files provide several attributes for a charge such as the charge number, the charged energy, the charge starting and ending date, the vehicle id, etc.

3) Ontologies: the high level bricks of the domain ontology contain several concepts corresponding to our data sources: the charged energy, the charge starting and ending date and the vehicle id (EV concept). A 1-1 mapping is established between these concepts and the corresponding attributes in the data source. This mapping can be implicit if the attribute and the property in the ontology have synonymous names.

4) The ETL process: it reads the ontology, searches for all concepts mapped to the data sources and loads the (possibly transformed) data in the tables corresponding to these concepts. Only the attributes mapped to the ontology are loaded in the data warehouse. But we can extend the ontology. For example, if we decide to extend the definition of a charge with the property *air temperature* to study weather impact on charging speed, the ETL will automatically retrieve the corresponding data and data from older sources will be updated. Once the sources describing the EV fleet are loaded, we dispose of the necessary row data for our study.

5) Business analyzes: the main indicator for this study is the normalized mean vehicle load curve (virtual typical day). This indicator is built for each vehicle on its charges (see Figure 6 for an example) and eventually on a selection of spots.

This indicator is described in the business process ontology so the OntoDB platform automatically creates a table corresponding to it. This description includes the name of batch programs that must be launched to fill the indicator table with the new data. At the end of this batch process we have access to the indicator with a simple request: *Select * From LoadCurve*. With these data, we can draw the mean daily usage depicted Figure 6 (X axis represents a day and Y axis the charging power). This figure also displays the national electricity consumption curve from RTE[2]. Both curves are normalized for a better shape comparison.

With this knowledge, we can finally reach our goal by launching machine learning algorithms such as K-means on the indicators to identify homogeneous groups of users. The result of this step is a set of groups of users and mean profiles. These profiles and the list of users attached to it constitutes a high level indicator which will be recorded in the business intelligence brick.

[2]RTE: Réseau de Transport de l'Électricité, the French electricity distribution network operator.

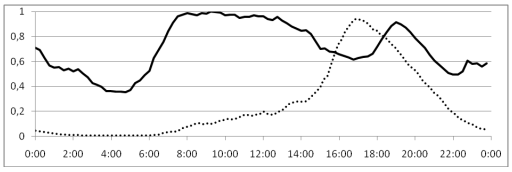

Fig. 6. Plain line: 02/14/2014 French electricity production; Dotted line: an homogeneous group of user daily load curve

An other interesting result is the identification of the groups of users that need a special focus regarding contract definition. For example in figure 6 the consumption peak occurs in a low production activity which is satisfying. But about one third of the peak surface does contribute, which can be problematic (cold weather, sudden massive energy demand...). Also, we observe that EV are fully charged around midnight. As this group is composed of companies, we can assume that EVs are not used between 12am and 6am. EDF might be able to propose a specific incentive contract to make this group use shifted charges.

6) Trans-disciplinary analyzes: EDF teams from other discipline have conducted interviews with users and fleet managers. In order to create some elements for contract creation, we cross our results with them. As we dispose of a precise list of users belonging to the 'problematic' groups, we were able to interpret the profiles we had. This interpretation gave EDF precious insights on which incentive they could propose to the users through contracts.

7) Knowledge integration: after the trans-disciplinary work we have enhanced our business intelligence bricks with more indicators to be more accurate. And we are able to generate them on every incoming data. This is possible thanks to our ontology design methodology.

C. Benefits of our Approach

1) Comparison with previous methods: before our project, EDF had several dedicated databases, one for each experiment. This situation was the result of the sources heterogeneity from one experiment to another. For example, smaller experiments used spreadsheets while bigger experiments used databases. As a result the sorting processes had to be defined and executed for each experiment. Our work helped to improve this situation. For older experiments we had to define mappings between the sources and the ontology but for the upcoming experiments, sources will comply to the ontology. Thus, our approach provides a simplified and unified data warehouse with a single flexible ETL process (see Figure 7).

The same problematic situation occurred at the business process level. The analyses conducted on data had to be developed for each experiment. This work was expensive and tiresome. Moreover, the knowledge generated during these experiments were only recorded as reports. As complete as these reports were, the re-utilization of this knowledge represented a lot of work. Using our approach, the business processes are recorded

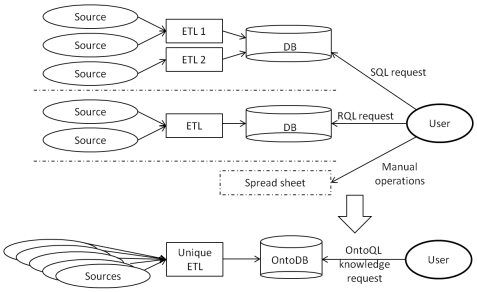

Fig. 7. Request simplification

in the data warehouse and the computation of an indicator is fully automated. Finally, the communication between research teams was not sufficient as it is not reasonable to gather all teams frequently. Therefore the cross analyzing results could not be as relevant as expected. In our approach, as every team describe their results according to the ontology, the communication between these teams is improved and it's easier to cross the results using OntoQL queries.

2) Industrial's benefits: our approach is an interesting solution for companies, like EDF, where engineers are not all familiar with database management systems. It allows several teams working on different aspects of a domain to share and capitalize knowledge and sources descriptions. In our project, several teams are working on the electric mobility domain: energy engineers, network specialists, sociologists, etc. and each of them are benefiting from the other. For example, crossing sociologists analyses with infrastructure reports showed interesting results. Some public charging spot weren't used, EV usage analysts thought that was the spots fault (plugs problems, unclear indications about the charge). In fact, people were not aware of the very existence of those charging spots.

3) Engineers' benefits: an engineer forced to re-write the same request for different logical models is a waste of time and money. Or when an engineer perform an analysis without knowing that an other already did. Moreover, the mastery of different languages and database management systems can be a burden for engineers. In our approach, the ontology is the only interface between engineers and the database. And only one requesting language is used (OntoQL). Its mastery is simplified because this language is close to SQL and because it uses the ontology terms. Thus, as the ontologies are made by engineers on their fields of expertise, they can manipulate a complex storage system with simple requests. At the current state of the project, engineers role only consists in maintaining the ontology and they can now focus on developing new knowledge and adding new data sources.

VI. Conclusion

The context of the work presented in this paper is a project with EDF aiming at designing a semantic data warehouse for the electric mobility domain. We have identified that existing ontology design methodologies are not adapted to this domain as it is rapidly evolving and expanding. As a consequence, we have designed a modular and incremental ontology design methodology. This methodology consists in decomposing the domain in several *bricks* representing specific fields of expertise. The design of a brick does not require a consensus with the other partners. The global ontology is then obtained by composing a set of bricks. The only consensus that must be reached consists in choosing the bricks, that are used knowing that the bricks can then be switched or extended if necessary. Observing that the business process analyzes are often the same, in addition to the domain ontology, our methodology suggests to design a *business process ontology*. This ontology records the different indicators used during a business analysis and their computation methods. As these indicators are also evolving, the business process ontology is defined, as the domain ontology, with a set of bricks. The link between this two ontologies consists in defining the required data for a given analysis.

The proposed methodology has been successfully applied to our project with EDF. The benefits identified during our project are: (1) to save a lot of engineer time which is a strong argument for a company (2) to ease the communication between trans-disciplinary teams by using the ontologies as an interface and (3) to be able to quickly extend or modified the ontology and (4) to simplify the exploitation of the data warehouse by using a single language that uses the terms of the ontologies. As future work, we plan to build new tools to support our design approach.

Abstract - The paper presents a coordinated set of data modeling styles relevant for data warehouse design in the context of relational databases. The scope of presented models covers: a) entity relationship models of existing relational DB sources, b) logical data vault model for integrated enterprise data warehouses as a system of records, c) dimensional fact model for analysis leading to query prototyping and dimensional models, and d) dimensional model for data marts. There is no claim of sufficiency, uniqueness, and/or universality of the selected styles set except utility. The principal contributions of the paper are: definition of data modeling styles as distinct modeling mechanisms, and initial coordination of selected complementary styles.

I. INTRODUCTION

The scope of our interest regarding data modeling in data warehouse (DW) design encompasses following practices: modeling of existing database (DB) sources, modeling enterprise data warehouse (EDW) as system of records (back-end DW tier used for compliance and for feeding presentation side of DW i.e. front-tier data marts), dimensional modeling for data marts (DM), as well as dimensional fact modeling (DFM) in user requirements driven analysis of data relationships aimed at exploring querying requirements. The last practice fills an important and frequently missing link, valuable in preparing detail star shaped models for DM.

From a general viewpoint, any system that can be described as a set of observable entities, their relationships and observable properties of those entities and relationships, can be represented by a DB organized according to system's entity relationship (ER) data model.

What is a Data Modeling Style? A data modeling style can be defined by patterns and constraints that produce models of recognizable form [18]. A style is distinct from a modeling language (and/or its visual formalism). A number of languages (notations) for entity-relationships (ER) modeling is in widespread use. Representative sources on using ER modeling in DB design/integration context are: for IDEF1X [5], for UML ([9], [24]), and for some other ER variations ([3], [25], [2], [8], [26], [27] and [28]). We do not consider notational variations to be essential in defining a data modeling style, and clearly separate modeling styles from modeling techniques [15].

Integrating modeling styles means at the minimum: keeping complementary models directly representable in common format (we selected relational DB and accomplished it by restricting IDEF1X notation), and amenable to model transformations. The paper presents complementary styles whose integration is in progress. The Figure 1 represents precedence among selected styles. The styles are intended to model: existing DB sources, integrated EDW, dimensional hierarchies in detail, and Data Marts. The three models (ER for DB, DV for EDW, and dimensional model for DM) are intended for realization using relational DB engines. The aim of the fourth model, the DFM, is to improve design, verification, and exploitation processes.

A visual observation of four kinds of models, side by side with a relational model (relational DB engines provide typical implementation of DB, EDW, and DM) provided initial motivation for considering it not only as a set of complementary representative models but as a coordinated set of modeling styles forming a grounded basis for a novel methodology of comprehensive DW design. Along the same line of observations is a longer term goal, an expectation of elaboration of formal reasoning leading to generalization and automation of transformations between such models (using relational model as an underlining basis). We expect to achieve acceleration of data integration/mapping during the user requirements analysis activities by a comprehensive model-based design using four complementary styles.

Our aim, in this paper, is to present those four complementary styles by an example that would set a stage for a fuller integration. Organization of the paper follows selected styles. The section II introduces our baseline example and an ER style for representation of existing data sources in a relational DB. The section III illustrates DV style for EDW based on integrating existing sources, the section IV introduces DFM style for conceptualization of user requirements, and section V dimensional model for DMs. The Dimensional Fact Model and the Data Vault model are relatively less known and thus will require more justification and basic illustrations.

A business case we will use in this paper deals with a DW to be designed in support of rapid introduction of 3D printing in discrete manufacturing (with a high rate of change in assembly specifications). A general expectation is that by providing analytical capabilities of DMs and a compliant permanent system of records, a desired DW solution can help with early adoption of 3D printing. Investment in technology is time sensitive and to recoup costs support from a contemporary DW system is needed.

All data model examples are shown as diagrams in the case tool ERwin 9.5 using appropriate style-related variations based on the IDEF1X (see Figures 2 to 7). Note also that even simplified examples of DBs (Figure 2) are structurally rich configurations providing an opportunity to fairly illustrate selected modeling styles as a complementary set. The rest of the paper elaborates, in a separate section, each of the four styles, all followed by a conclusion in a form of summary of research directions.

II. RELATIONAL DB ORIENTED ER STYLE

The example in Figure 2 shows a logical ER model (i.e. no data types and sizes from a source DB are shown) to simplify the analysis and design work in the paper. The example uses two data sources, a Sales DB and a fairly simplified Manufacturing Design DB. The Sales DB is a classic sale of ITEMs to CUSTOMERs placing ORDERs for multiple items (one per ORDERLINE). Probably more interesting is a DB focused on a Bill of Material (BOM). The assembly specification BOM_PART, is a resolution of a Many to Many relationship between a PART used (in assembling) and a one (to be assembled) i.e. ASSDEMBLED_PART.

To reverse engineer DB schemas closeness of IDEF1X to the relational model (RM) is an important advantage, and is also helpful in explaining models to developers. Here is a simple demonstration, just by looking at Figure 2 box-frames representing Entities, one can directly observe the intended content of every relational table. Specifically, primary key (PK) area is visually separated, all foreign keys (FK) are noted as such and traceable via relationship lines to related entities (tables). Role names for primary keys (PK) serving as FK are used only when necessary (assembledItem, instead of partID, in ASSEMBLED_PART). The redundancy of showing foreign keys (FK) as attributes is an advantage during model reviews. Subtypes are either complete or incomplete specializations, in intentional sense, i.e. one instance of a PART can be PRINTABLE or not. An incomplete case is represented by ASSEMBLED-PART and MATERIAL implying the possibility of additional sibling subtypes, and a complete case by PRINTABLE. In IDEF1X one entity type (i.e. PART) can have several independent criteria for specialization ('type' and 'printable') and all subtypes within the same specialization criteria are mutually exclusive i.e. one instance of a PART can be either an ASSEMBLED_PART or a MATERIAL, or neither. In ER modeling, as a rule, we eliminated all M:M relationships and as a result all ER IDEF1X models are directly representable in the RM (DDL prototyping using case tools is automatic). Our models use intersection entities (instead of M:M relationships) between a pair of entities, with two 1:M relationships depicted using solid lines representing identification dependencies (BOM-PART). As a pragmatic rule names of entities are shown in uppercase i.e. PART.

For each of the remaining styles a visual Template can be defined (describing relevant IDEF1X restrictions and convenient visualization conventions). In this paper we will only give some textual specification as examples models will have all visual elements displayed.

III. LOGICAL DATA VAULT MODELING STYLE

The ER style data modeling practice in a DB context (as well as dimensional modeling style in the context of DM design) are well established, but a few arguments can help make a case for the DV style now in a DW context.

First, it clearly makes sense to separate concerns and design data loading oriented EDW as a system of records for compliance (preservation of history and provenance i.e. to enable tracking the lineage of data back to the source) as logically and physically separate from the user query heavy, analysis and presentation oriented DMs.

Second, a DV approach [21],[22],[16], [10] and [23] was developed as an approach to a sustainable EDW design, and represent a style of modeling for DW that can be characterized as dependencies minimization aiming at flexibility and performance. The main advantages of DV over traditional 3NF EDW designs, in a style advocated by ([12], and [11]), are:

a) Inserts, deletes, or updates of rows are implemented only as additions (nothing ever get lost/overwritten),

b) Structural changes of and in data sources results in model expansion, principally by new links and without structural reconstruction of existing DW elements (a holy grail of architectural stability), and

c) Enable rapid parallel data loads [22].

The DV modeling style is recognizable by its major concepts i.e. Hubs, Links and Satellite entities. In terms of entity relationship models a Hub entities holds identities of lasting entities (typically business keys and their surrogates), a Link entities are representations of foreign key references (to two or more business components i.e. Hubs). A Satellite entity holds history of attributes for a related Hub or a Link. In Figure 3 we illustrate use of a DV style template, in IDEF1X, with coloring schema of: blue background for Hubs (H_CUSTOMER, H_ORDER, H_ITEM), red for Links (SAME_AS, L_BOM, L_CO, L_O-OL_I) and yellow for Satellites (S_CUST_PHONE, S_QTY, S_PRICE, S_NAME, S_BOM_EFFECTIVITY etc.). Note that all DV entities are implementable as tables. All entities are shown with standard DV metadata (a **LDT**-load date time stamp, and a **source**, a unique id for data source system- typically a DB). Note that grouping of attributes into different Satellites is driven by record data source and frequency of changes, for example S_R1 (name, creditLimit) and the S_2 are grouping attributes expected to change with different frequencies.

The source data ER models are to be lightly integrated i.e. source data mapped to a DV without a loss of information. The DV modeling starts with the identification of stable business keys representing permanent identities for major business entities, and treats

them as Hub candidates. During this modeling step a soft integration can be performed, for example PART and ITEM from the two source systems (from Figure 2) can be recognized as somehow related (if they shared the business key than they would be represented as one Hub under some generalized name). In our example where several ITEMs for sale are referring to the same product (PART) a (SAME_AS) linking needs to be explicitly established. One of the expectation from 3D printing is to offer more products while reducing the number of parts, so we decided to use PRODUCT name for current (and future) PARTs. Once Hubs are selected, we have to model Links, and in case of existing DB sources we use FK as clues. It is also very important to eliminate dependencies and deal appropriately with subtypes in DV modeling. Originally subtypes were justified in ER models when only a subset of an entity instances could possess certain attributes and/or share a relationship with other entities. Both reasons disappear in DV, restricted attributes from a subtype form Satellites (S2_ASSEMBLED, S_3D). Also, in Figure 2, (ASSEMBLED_PART) subtype associated with relationship (BOM_PART) became a role of a Hub (H_PRODUCT) in a Link (L_BOM). Such elimination of subtypes in logical and physical DV modeling results in simpler models. Any M:M relationship, which we already represented in ER style with an intersection entity is a DV Link (L_BOM). Note that a history entity (PRICE_HISTORY) is really a DV Satellite (S_PRICE) for its Hub (H_ITEM) of the base entity (ITEM). The logical DV modeling deals with composition (part of) dependencies as well, and while some authors ([22], [10], [23]) differ in their recommendations, the best option seems to be the general one of severing dependencies and treating all dependent entities as Hubs (with concatenated keys) while passing Hub key to a Link down the dependency line i.e. H_ORDER in Figure 3 where hubs H_ITEM and H_OL form a link L_OL_I_O. Note that logical DV modeling follows pragmatic and data source oriented recommendations that differ from those recommended for conceptual DV modeling [17] in situations with no existing data sources.

Using DV allows incremental integration of data sources into DW, and at the same time simplifies loading of DW from multiple sources. The primary author of architecture DW 2.0, W. Inmon, recognized DV as a DW 2.0 compliant data model. The DV approach aims at preserving history of data in a system of records manner thus leaving complex transformations for downstream processing- towards DMs. We omit discussion of additional DV design steps in data integration (related to application of common business rules) here. Authors who recommend DV approach ([21], [10], [23]) as a solution to long term flexibility and performance problems of first generation DWs also accept dimensional models for reporting oriented DMs. Note that using DFM as a stepping stone to requirements oriented DMs design makes the job of designing extract-transform-load (ETL) from DV to DMs substantially easier.

IV. DIMENSIONAL FACT MODELING STYLE

While industry leaders and authors ([19], [1]) advocate direct use of dimensional modeling for DM design, we decided to follow agile practice [6] and analyze requirements beforehand specifically using a Dimensional Fact Model (DFM) for visualization. The DFM is a conceptual model created specifically to support DM design [7] where one DFM fact schema leads to one DM star schema. Furthermore, a documented DFM provides visual representation of detailed dimensional structure helpful in verifying that standard reporting requirements are captured, is quite useful in specifying dimensions in SQL DDL, and is of lasting value in preparing complex, multidimensional SQL queries by programmers. Each DFM is showing model facts as a set of measures in the context of dimensional attributes, with explicit hierarchical relationships shown, to facilitate expression of any available granularity of potential queries. Facts model set of 'business' process events (ordering) or possibly process/state specification (assembly). Two DFM schemas are shown, in Figures 4 and 5 respectively for orders and assembly. DFMs in our example are derived each from one of the source systems from Figure 2. A requirement to track price changes in time (per ITEM) is set aside as it can be answered from ORDERED fact.

We are treating Figure 4 as a template for drawing DFM schemas in IDEF1X for convenience only i.e. using visualization as a conceptual model not to be realized directly. Detailed derivation processes can use operations such as pruning, grafting etc. [7] but those steps are not shown in the interest of brevity and to maintain the simplicity of our case.

DFM schema Template recommendation for IDEF1X representation utilizes simultaneously three levels of presentation: fully attributed Entity level (i.e. ORDERED), Entity key level (i.e. CUSTOMER), and Entity only (i.e. year). A FACT entity show in attribute view with entity name in capital letters, i.e. ORDERED. Model shows all measures as attributes in lowercase i.e. as 'quantity' and 'price' in ORDERED. Names for each dimension are represented as root entities with its grain as the key attribute, (CUSTOMER, DATE, and ITEM), lists the name of the most frequent value i.e. lowest level of granularity as a root key attribute; this means roots are shown at key level presentation in a DFM diagram. For each dimension (i.e. DATE, ITEM, CUSTOMER) represent every attribute as an entity but with names in lowercase (month, year, day, week, etc.). Whenever relationships between attributes represents a (hierarchical) identification dependency we use solid line pointing to lower level, as between state and city (1 state to M-many cities). Whenever attribute to attribute association cardinality is 1:M or 1:1 we represent such relationships using dotted line, and in cases of optional 1:1 or 1:M relationships we use dotted line with a diamond icon (holiday to date).

V. DIMENSIONAL MODELING STYLE

The Dimensional Model is practically universally used for DM design presentation [19]. Mapping of DFM into DM is almost trivial, simply collapse i.e. de-normalize all

hierarchies into corresponding dimensions, as illustrated by Figures 5 and 6. The real world complication is standardizing such dimensions into conforming dimensions used as master references for otherwise incremental development, and as such is outside the scope of this overview. The dimensional modeling style is distinguished by star schema designs where fact (set of measurement), for a lowest granularity of data needed to be tracked, is surrounded with a rich context of dimensions. In practice there are some additional complications (snow flaking of dimensions, bridge tables etc.) but because dimensional modeling is very well represented in reliable sources such as ([19], [1]) we will not elaborate.

The DV approach delays complex transformations downstream, speeding up extracting and loading of data from the sources. A soft integration based on lasting business keys (hubs) leaves to user's views to match partial requirements in DMs. Having a clearly justified DM designs (via DFM) enables incremental ETL design amenable to automation given the standard patterns of DV [22]. One point of the paper is bridging the gap between an integrated DV and individual DMs, and it is where the four styles approach converge, enabling evolving solutions for DW.

VI. CONCLUSION

In this paper we presented a set of complementary data warehouse design styles which may enable well integrated DW solutions for relational DB implementations. Furthermore, this is achieved by using a set of data modeling styles based on a common notation (IDEF1X) and in a single design tool. We are researching opportunities for further integration including elements of automation of model transformations: a) from ER to DV in a manner of extract-load and minimally transform (ELT)- with only simple and reversible transformations, b) from ER to DFM (supporting graph manipulation operations for creative i.e. essentially semi-automatable requirements analysis), c) from DFM to a dimensional model (a de-normalization by collapsing attribute hierarchies into respective dimensions), and d) from DV to DM in the classic ETL manner (including now irreversible transformations). It is worth noting that modeling redundant data aggregations i.e. materialized views (MVs) in DMs using DFM to analyze and recommend (visualize) starting set of views is easy [7], but was not treated here especially as DB engines collecting usage statistics are already recommending MV automatically. The physical design aspect as well as end-user presentation forms such as scorecards and dashboards are also outside the scope of this paper. Some of the current limitations of the approach are also research directions for future work. Specifically needed are investigations of compatible modeling for sources of semi-structured and unstructured data, formalization of models and model transformations for highly distributed environments, and development and empirical evaluation of pertinent learning aids (essential in order to support dissemination of practices proposed). Several students are already engaged inspired by work of ([13], [22], [14], [4], [20], [16] etc.).

Big Data and Sentiment Analysis using KNIME: Online Reviews vs. Social Media

Ana Mihanović, Hrvoje Gabelica, Živko Krstić
Poslovna inteligencija d.o.o., Zagreb, Croatia
{ana.mihanovic, hrvoje.gabelica, zivko.krstic}@inteligencija.com

Abstract - Text analytics and sentiment analysis can help an organization derive potentially valuable business insights from text-based content such as word documents, email and postings on social media streams like Facebook, Twitter and LinkedIn. The system described here analyses opinions about various gadgets collected from two different sources and in two different forms; online reviews and Twitter posts (tweets). Sentiment analysis can be applied to online reviews in easier and more detailed way than to the tweets. Namely, online reviews are written in clear and grammatically more accurate form, while in tweets, internet slang, sarcasm and allegory are often used. System described here explains methods of data collection, sentiment analysis process for online reviews and tweets using KNIME, gives an overview of differences and analysis possibilities in sentiment analysis for both data sources.

I. INTRODUCTION

Text mining or sentiment analysis [1] is analysis of data contained in a natural language text, which deals with the computation of opinion, sentiment and subjectivity in text. Sentiment analysis refers to the use of natural language processing, text analysis and computational linguistics to identify and extract subjective information from the text documents. Basic task of sentiment analysis is to determine the polarity of a given texts.

Tasks of dictionary making and sentiment analysis process are done by the means of KNIME [2], which is a user-friendly graphical workbench capable of entire analysis process. KNIME uses six different steps to process texts: reading and parsing documents, named entity recognition, filtering and manipulation, word counting and keyword extraction, transformation and visualization. Following workflows and tasks are developed and executed using KNIME:

- Retrieving data from database
- Dictionary development and implementation
- Review scoring

II. DATA COLLECTION

In gathering online reviews and tweets about gadgets, focus was set on few gadget manufacturers such as Apple, Samsung, Nokia, Nexus, LG and on the webpages that contain online reviews about gadgets. Total number of collected online reviews and tweets which were collected during few hours for the purposes of this paper was:

- 812176 tweets
- 419624 online reviews

The system presented here handles crawling, extracting gadget reviews and storing them for analysis. Collected unstructured text is prepared for text mining and sentiment analysis. System presented gives the analysis results for every single review or tweet.

Online reviews were crawled from webpages using Apache Nutch [3] crawler, highly extensible and scalable open source web crawler which traverses the web site starting from a given set of URLs and follows the links matching a given pattern to a certain depth. Tweets were collected with in-house developed Java package used for streaming posts from Twitter. Both online reviews and tweets were collected within few hours. Since tweets are much shorter than online reviews and collecting these posts takes less time than crawling online reviews, the number of tweets is much bigger than the number of crawled online reviews.

Crawled online reviews and tweets and stored into HBase tables on Apache Hadoop [4] server. Hadoop is an open source software project that enables the distributed processing of large data sets across clusters of commodity servers and it is popular for developing large-scale data-intensive applications. Hadoop is used as a storage environment, and HBase table, as a component of Hadoop, is used to store information about gadgets and gadgets reviews. HBase [5] is non-relational, distributed database written in Java which efficiently holds unstructured data in large tables and can be concurrently and randomly accessed. Hadoop and HBase were used because of their main functionalities, which are storage of large quantities of unstructured, textual data and their possibility of reading and writing data in the real time.

III. DATASET DESCRIPTION

Data collected into HBase tables slightly differs for online reviews and tweets.

Online reviews are described with following attributes and structured in the following way:

- Key - unique key indicator for each gadget review created before review was stored into database
- PID (Product group ID) – name of the gadget, such as Samsung Galaxy s4 or iPhone 5
- Review Date – date when online review was stored into HBase table
- Review text – text of the review about specific gadget
- Lang – language of the review text

Tweets are described with following attributes and structured in the following way:

- Key - unique key indicator for each gadget review created before tweet was stored into database
- userScreenName – Username of Twitter user
- CreationDate – date when tweet was stored into HBase table
- text – tweet text about specific gadget
- keyword – name of the gadget, such as Samsung Galaxy s4 or iPhone 5, analogous to PID field in online reviews table
- Lang – language of the tweet

Key and PID value (keyword vale for tweets) allowed aggregated analysis on the level of each review or tweet, or on the level of the specific gadget. Date values allowed aggregated analysis for the defined period of time.

Described data is loaded into KNIME with HBase Reader node and processed. In this phase, only online reviews and tweets in English language were collected. Language of the text is set to English and all texts that have different language values are filtered out, because English dictionary applied on reviews and posts written in other languages would not give results.

IV. DICTIONARY BUILDING

A. *Online reviews*

Online reviews are analyzed on the category level. Seven different categories are introduced for the gadget reviews:

- Accessibility/usage – ease of usage, availability of applications and software
- Value for money – is the price of the product reasonable or not, is the price justified by quality
- Content/composition – materials that product is made of, all hardware components, accessories (handset, bluetooth handset, keypad, etc.)
- Quality – quality of materials product is made of, quality of hardware components, manufacturer quality
- User experience – experience of the user when buying and using product (issues, would recommend, wouldn't recommend, would buy again, etc.)
- Look/appearance – physical appearance of the product (color, design, size, weight, etc.)
- Service/Support – seller's attitude and kindness, service center help support, warranty of the product

Service/support category is the category with the least number of the recognized phrases and for that reasons it is not included in chart visualizations. Redefiniton of this category is being considered.

Dictionary building for detailed sentiment analysis implies making an initial list of adjectives and nouns which are normally used when describing a specific product. Initial list is collected by analyzing existing opinions and reviews and manually extracting the words which appear the most in those reviews and opinions or those words that seem to be most important. Grade scope is defined from 0 to 5 (0 meaning extremely dissatisfied, and 5 meaning extremely satisfied). Null means no rating.

Since terms and phrases extracted from reviews need to have category and grade, nouns are holders of categories, and adjectives are holder of grades. That means that every noun on the list had to be categorized into one of seven categories, and every adjective on the list has to be graded with one grade. Once the initial list of nouns and adjectives has been collected, nouns and adjectives are used in regular expressions which bind them together and recognize complete phrases in reviews consisted of all combinations of adjectives and nouns that are in the list. Regular expressions are composed for the most used grammatical forms in English language. List of regular expressions used for dictionary development:

- Adjective + noun and negations („not“ + adjective + noun)

This form is used to detect most simple phrases of English language, such as „amazing battery“, „bad screen“ or „great apps“. For the negation detection, regular expressions are written in the form „not“ + adjective + noun.

- Noun + „to be“ + adjective and negations (noun + „not to be“ + adjective)

With these forms of regular expressions, more complicated phrases are detected, such as „battery doesn't last“, „screen is great“, or „camera is good“. To make phrases detection more accurate and successful, all forms of verb „to be“ must be included, including grammatical mistakes which are people likely to make.

- Noun + intensifier/downtoner + adjective and negations (noun + „not to be“ + intensifier/downtoner + adjective)

Intensifies or amplifiers are words in English that increase the effect of the verb and include such words as „completely“, „totally“, „undoubtedly“, „absolutely“, etc. Downtoners are words that decrease the effect of the verb

and include such words as „kind of“, „not so much“, „sort of“, and so on.

Another important feature is to correctly grade phrases that contain negations and/or modifiers because these type of words change total grade and meaning of a phrase. If phrase contains some of defined words, grade is calculated using different “if...else if” rules. These exceptions are handled as follows:

- If the phrase contains negation, the grade is reversed and replaced by its module (e.g. „camera is great“=4, „camera isn’t great“=1)
- If the phrase contains intensifier, the grade is increased by one (e.g. „good processor “=3, „really good processor“=4). If the phrase contains negations along with intensifier, the grade module is calculated (e.g. „not really good processor“ =1)
- If the phrase contains downtoner, the grade is decreased by one (e.g. „display is good“=3, „display is merely good“=2). Negations used along with downtoners are rare and therefore not analyzed

B. Twitter posts

Dictionary built for sentiment analysis of tweets contains of key words graded only as positive or negative. Scoring or sentiment analysis of tweets is done on the positive-negative level, because tweets don’t contain clear phrases such as those that can be found in online reviews. Therefore, tweets are impossible to categorize into numerous categories as online reviews, and they need to be analyzed on the word level, giving each word positive or negative polarity.

Dictionary built for sentiment analysis of social media posts consist of most used words in those posts. Because of the different structure when comparing online reviews and tweets, dictionary needs to include jargon words, internet slang, smiley icons, abbreviations, hashtags and similar. These words and symbols are of great importance, since tweets are usually not rich with useful phrases and terms. Example of such words included into dictionary are: #loveit, #horror, :-(, :-*, OMG, JK and similar.

For this task, publicly available MPQA subjectivity lexicon was used as a starting point for recognizing contextual polarity [6], which was expanded with Twitter specific words mentioned above. Existing dictionary containing of approximately 8000 words is expanded to fit the needs for gadget analysis in a way that initial portion of tweets are collected, which are separated into single words with Bag of Words processing. Unnecessary words such as symbols or web URLs are filtered out, and all useful, social media specific words are graded and added to the dictionary.

V. DATA SCORING

Sentiment analysis of online reviews and tweets differs greatly. Online reviews are easier to objectively analyze because of clearer written form and bigger amount of meaningful sentiments, but they have to be analyzed on a more detailed level than tweets.

Tweets often contain internet slang, sarcasm and allegory which are often used. It could be said that grading online reviews is easier, but the dictionary is more complicate to make, and that grading tweets is harder, but the dictionary is easier to make.

Online reviews are analyzed on the phrase and category level, giving phrase a grade for one of seven categories. Tweets are analyzed on the word level giving a positive or negative grade for each term. Text analytics of online reviews is accomplished simply with phrases counters and mean calculations, while analytics of tweets is frequency-driven.

Big quantity of reviews or posts are loaded into KNIME to be graded. Two separate wokflows are built, one for grading onine reviews based on a grade and category, and other one for positive-negative grading.

A. Online Reviews Grading

First input of sentiment analysis workflow developed in KNIME are online reviews read from the database, and second, parallel input is the dictionary made of phrases recognized with regular expressions. Phrases from the dictionary are recognized from the dictionary file and tagged in Review Texts using Dictionary Tagger node.

Online reviews are processed and graded with the term presence method [7], rather than term frequency method. Term presence method gives a binary value which simply indicates does the term or phrase occur in the text (value 1) or not (value 0). Every term or phrase has also a grade and category joined and binary values of terms are summed on the level of each review, giving term counters and grade sum for each review.

Sum of grades for every category is divided with counter number for every category, giving final grade for each online review and for each category. The results were written back to the Hadoop database (Fig. 1), and as a result of Hadoop aggregation, the average grade for every category on the level of single gadget is calculated.

"I bought this phone 5 d	4	4	3,5	3,5	3

Figure 1. Example results of analyzed online reviews

B. *Twitter Posts Grading*

Tweets are analyzed only on the positive-negative level. The result can be one of the three; positive, negative and neutral. Tweets for gadgets are not analyzed on the category level because these kind of text documents are often much shorter and not so descriptive as online reviews. Tweets are processed in similar way, but this approach uses more preprocessing steps and uses frequency-driven approach. In the preprocessing steps, various filters are applied on the text documents, such as stopwords filter, n-chars filter and punctuation erasure.

TF*IDF (Term Frequency*Inverse Document Frequency) [8] method assigns non-binary weights related on a number od occurences of a word. Weighting exploits counts from a background corpus, which is a large collection of documents; the background corpus serves as indication of how often a word may be expected to appear in an arbitrary text. TF*IDF calculation determines how relevant a given word is in a particular document [9].

Besides term frequency $f_{w,d}$ which equals the number of times word w appears in document d, size of the corpus D is also needed. Given a document collection D, a word w and an individual document $d \epsilon D$, TF*IDF value can be calculated [9]:

$$TF * IDF_w = f_{w,d} * \log \frac{D}{f_{w,d}} \quad (1)$$

Total score for each word is given by multiplying TF*IDF value with attitude of a term. Attitude can have one of three values depending on the word polarity; -1 for word with negative polarity, +1 for word with positive polarity and 0 for neutral words. Final weigths, which now represent attitude of each document , are grouped on the level of document (tweet) and binned into three bins to give one of three final results for each tweet; positive, negative or neutral (Fig. 2).

Figure 3. Analyzed online reviews results aggregated on the level of LG products

Simple tag cloud (Fig. 4) gives the overview of the most used phrases in online reviews:

Figure 4. Tag cloud for online reviews

B. *Twitter posts results*

Tweets analysis results are given in the form of positive, negative and neutral. Neutral grade can be avoided, which is easily accomplished by changing grade bins and removing a bin for neutral grade. Grade can be calculated on the level of specific post and then aggregated for all posts of one gadget product (Fig. 5). Sample of 40000 tweets were used for iPhone product analysis.

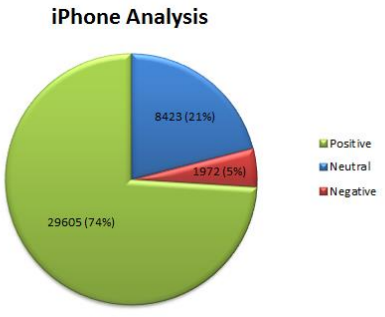

Figure 5. Analyzed tweets results aggregated on the level of gadget brand

Simple tag cloud (Fig. 6) gives the overview of the most used words in tweets:

Figure 6. Tag cloud for tweets

C. *Online reviews graded with Twitter dictionary*

When online reviews are graded with the dictionary made for analysis of tweets (Fig. 7), results are fairly good because each word is separately processed and graded. Dictionary developed for sentiment analysis of tweets is usable for the sentiment analysis of online reviews.

Figure 7. Results of online reviews graded with the Twitter dictionary

D. *Twitter posts graded with online reviews dictionary*

Tweets graded with dictionary developed for sentiment analysis of online reviews (Fig. 8) are not succesfuly analyzed because of absence of the more complicated phrases that tweets lack. Therefore, tweetscan't be graded on the detailed level, and positive-negative analysis or analysis with simple grade from 1 to 5 is most suitable for sentiment analysis of social media.

Figure 8. Results of tweets analysis graded with the online reviews dictionary

VII. CONCLUSION

Sentiment analysis of online reviews is less complicated process and gives more detailed results, but developing a dictionary for these kind of text documents takes more time and resources than for social media.

On the other side, sentiment analysis of social media posts is more complicated process, but dictionary development is less complicated task. Also, dictionary developed for sentiment analysis of social media, on a single word level, can be successfuly applied on sentiment analysis of online reviews, but vice versa situation does not give results. Social media posts are hard to analyze on the phrase or sentence level because of theirs unique structure and grammar.

Abstract - The Croatian Scientific Bibliography - CROSBI is a bibliography web site that stores information about scientific papers published in Croatia in the last 15 years. At the present, CROSBI consists of over 400,000 records and is daily accessed and updated by a large number of researchers. As the appearance and purpose of database (and hence its structure) changed over the years, some inconsistencies emerged, and existing data could not be used to its fullest potential, e.g. linking papers from the same journal or conference, or analysis of scientific activity in relation to the place of article publication. This paper explores the possibilities of improving and enriching the CROSBI database, using different techniques, from data cleaning and sanity checking, to creating links between CROSBI and similar online bibliographic databases. In order to improve data quality, book records from CROSBI were linked to the corresponding Google Books records, and using Semantic Web technologies, a number of links between CROSBI and online bibliographic databases was created. The resulting data set can be used to further improve the quality of CROSBI by creating a recommender system, or to improve and open up new possibilities in the analysis of existing data.

I. INTRODUCTION

The need to collect and organize data about scientific research in Croatia arose early after gaining independence as a country in 1992, when it was realized that data about scientific output are scattered across different index publication, subscription databases and local bibliographies. Small but regular support from the former Croatian Ministry of Science and Technology (today Ministry of Science, Education and Sports) enabled the start of the first phase of the Croatian Scientific Bibliography – CROSBI[1] development, and first release in 1997 [1]. CROSBI is designed, created and maintained at Rudjer Boskovic Institute Library in Zagreb. In the beginning, the primary goal of CROSBI was to collect the data on scientific output of the current research projects financed by the Ministry of Science and Technology and to make them publicly available [2]. The input was provided using a simple web interface, and monitoring and curation was organized by librarians. CROSBI was designed as a single entry point for various publications as books, book chapters, journal articles, conference papers, theses, reports, manuscripts, patents etc., but was also open for papers not yet published like submitted journal articles ("in press"), unpublished manuscripts, and other types of intellectual products related to the academic and research community. CROSBI served also as an Open Access (OA) repository offering free access to deposited publications long before OA movement became turning point in the scholarly publishing area. The data stored in CROSBI was used mostly for an ad-hoc insight into a comprehensive bibliography of an institution, research project or individual researcher [3].

Today, CROSBI consists of 410,000 records, about 130,000 of which are bibliographic data about journal articles, and more than 150,000 are about conference papers. Furthermore, CROSBI provides an access to 25,000 records with full-text available [4]. Authors/Researchers themselves enter the data into the database, so there is a high level of up to data.

The CROSBI system is based on open source solutions: Linux, PostgreSQL DBMS (replacing mSQL) and Apache. PostgreSQL is used for database management because it is unified database server with a single storage engine, with reliable and fast performance in complex operations, and the Perl interface used in cgi-scripts on the Web server. Apache web server is used together with SSL encryption mechanism to provide HTML content to end-users.

During the years, some inconsistencies in the database emerged, like data glitches, incomplete or missing data, missing lookup tables, etc. Since incorrect or inconsistent data could complicate database maintenance, prevent the exploitation of data to its fullest potential and lead to false conclusions, we decided to explore the possibilities of improving the quality and enriching CROSBI data, by implementing different approaches and techniques, from ETL-like procedures to the Semantic Web technologies. The goal is to enhance CROSBI from a stand-alone database of bibliographic records to a highly hyperlinked data set that can interact with other information resources on the web. Development of CROSBI will follow the principles of Linked Data, with resolvable URIs for all objects, ensuring structured RDF data. Using rich ontologies and semantic linkages data stored in CROSBI will not only be available on the web, but will really become an integral part of it.

In the future CROSBI is seen as an interoperable tool, exchanging data with others repositories, archives and databases, which will enable much easier and controlled

[1] http://bib.irb.hr/

This work was partially supported by the "Semantic integration of heterogeneous data sources" project, funded by the Croatian Ministry of Science, under grant number 036-0361983-2012.

input process and provide enriched data beyond bibliographic level. The tools and methods applied in this research and presented in this paper will enable such kind of transformation.

II. CURRENT DATABASE STRUCTURE

There are several inconsistencies and shortcomings of the current database structure, which are mainly the result of its revisions and adjustments to different needs during the years.

Some data which is a part of CROSBI is scattered over different databases. Most of bibliographic information about publications is stored in one database, but data about authors and research projects are in separate databases. Although located on the same server and within the same database management system, the fact that they are separated into different databases is an obstacle that prevents data integration and consumption of CROSBI as a whole, e.g. there are no foreign keys, and it is not possible to create advanced web services that expose data for public consumption, like RDF graph, since tools that provide these features cannot work with multiple databases at once.

The database is partly denormalized, e.g. table "Proceedings_article" contains information about the papers in the conference proceedings, together with information about proceedings itself, and also with information about the related conference. Similarly, table "Journal_article" contains information about the papers in journals combined with information about journals.

Many attributes (about 70%) in the database relations are of type *character varying*, and web form fields used to enter or edit data are, or at least were, in some point in the past, simple HTML text input fields. Consequently, database columns which are mandatory and can not be skipped during the entry process, contain a lot of inaccurate data, missing data, incomplete data or typographical errors (e.g. attribute "year" contains values like "-", "not yet published", "in press", "2011/12", "2012g.", "20111" etc.). Furthermore, there are same entries written in slightly different versions (all caps, camel case, with or without Croatian diacritics). Fields that were left empty by the author were not stored into the database as null, but rather as empty string, or contain some sort of "missing data" label, presented with "-" or "n/a".

Many of these discrepancies were corrected during the years, mostly through improved web interface, data-type or range constraints, and better control of user entries, but a certain amount of data entry errors are still present in CROSBI, mostly among the old entries.

There are columns that contain non atomic values, and are in conflict with the First normal form. Place of book, proceedings publication and conference location are two most prominent cases of these fields, where users often entered more than one value, e.g. "Rijeka - Opatija" or "Zagreb, Hrvatska".

III. DATA TRANSFORMATION AND CLEANING

To clean and 'sanity' check the unstructured free-text data, a set of custom ETL procedures was prepared and executed as described in **Error! Reference source not found.**.

A copy of current CROSBI database was made, and used as a test model to explore the possibilities of improving the database content, enabling advanced search and data analysis options, increase the user experience and ease the interconnection possibilities with other similar databases.

First, the database was normalized, which resulted in creation of several new relations ("Language", "Proceedings", "Event", "Theses type", etc., and their appropriate junction or linking tables). In total, 22 new relations were created.

The next step was to load data into newly created tables. While some lookup tables were loaded from other sources (e.g. a list of universities and faculties in Croatia was loaded from ISVU[2]), most of tables were filled with data from the old denormalized tables, mainly by selecting distinct values, and then manually cleaning and separating only the relevant records.

Some tables required extra transformation effort, e.g. a relation "Place" was first loaded with distinct values from all relations containing attribute "place", then the non-atomic values were split, filtering out country names and removing the unnecessary characters (blanks, commas, semicolons). The last step was to unify alternate city names (e.g. "Beč", "Vien" and "Wienna" with "Vienna"), and repair some frequent typos, like "Zabreg" or "Zabeg" with "Zagreb".

The data about proceedings and conferences was extracted using different text similarity approaches. Database table "Proceedings_article" was split into several tables, namely "Proceedings_paper", "Proceedings" and "Event". The original table contained 146,628 records, and newly created tables have 125,779, 68,834 and 53,227 records, respectively.

TABLE I. shows comparative overview of the number of records initially loaded into newly created tables and a number of records after the different data cleansing techniques were performed.

TABLE I. A NUMBER OF RECORDS IN NEWLY CREATED TABLES BEFORE AND AFTER DATA CLEANSING

Table	***Starting noumber of records:***	***Number of records after cleansing***
Language	223	36
Proceedings	79,897	68,834
Event	86,572	53,227
Place	3,160	1,159

[2] http://www.isvu.hr/

IV. LINKING CROSBI WITH EXISTING ONLINE SOURCES

In order to further improve the quality of data in the database, records from CROSBI were matched against a number of different available datasets. Three different techniques were applied: offline matching (for datasets which were available as a whole database dump or in similar form), writing a custom (SOAP or REST) web service client, or matching using the semantic web technologies and available SPARQL endpoints.

A. OFFLINE MATCHING

Offline matching was conducted with data from Croatian Higher Education Information System (Croatian acronym: ISVU) and GeoNames[3] geographical database. Database dumps of publicly available data were obtained, and loaded into the CROSBI database. Data matching was conducted in several iterations, each iteration decreasing the number of remaining unmatched records. On the other hand, every subsequent iteration was computationally more demanding and its results contained more errors (mostly false positives).

For instance, places from CROSBI were matched against GeoNames database in the following order: at first, matching was restricted only to Croatian towns with more than 15,000 inhabitants, and the whole string was matched. Some frequent places that do not meet those criteria (like Opatija and Cavtat) were added matched manually at the same time. The remaining data was then matched against a list of big European cities, then against a list of all Croatian cities, and against the list of alternate city names in the whole World. These steps connected about 90% of cities, with very good accuracy, from around 60,000 rows in the beginning; only about 5,000 were still unmatched. The last step in a row was fuzzy string matching (matching only part of the word, Trigram[6], Levenshtein and Soundex[7] techniques), but since the unmatched data contained a lot of erroneous data (like "Unknown city" or "Whole Europe") the number of hits was small, with a lot of false positives.

B. ONLINE MATCHING - CUSTOM WEB SERVICES

1) Google Books

Google Books[4] is an online service that allows its users to search full text of more than 30 million books and magazines. In addition to web search, Google Books exposes a Representational State Transfer (REST) Web Service - Google Books API, which allows integration of third party applications with Google Books database. The custom REST Web Service client was created, and CROSBI book data was matched against Google Books database. About 1,500 records (of 10,000 in CROSBI) were matched. Since only full title was matched, the number of hits could be further improved by implementing partial matching or some other sort of fuzzy search.

2) Google Scholar

One of the biggest online resources of scientific papers is Google Scholar[5], a free web search engine that indexes the full text of scholarly literature across many disciplines and sources. Although it is free for personal use, Google Scholar does not provide an API, and use of automated data crawlers is in conflict with their usage rules. Matching of a small sample of CROSBI data against Scholar search engine yielded some very good results (around 50% of articles were successfully matched). In the future Google will hopefully include Scholar into its API, and CROSBI could be interlinked and enriched with additional data from Scholar's huge database.

3) Web of Knowledge

Another big online resource of scientific works is Web of Science[6] (WoS), academic citation indexing and search service by Thomson Reuters. There is a SOAP Web Service available to all subscribers, which allows querying their database by different criteria, and retrieving a set of basic information about discovered articles. A part of CROSBI records that had "Current Content_index" and "Science Citation Index_index" flags set, was checked against WOK database, and about 65% of records were successfully matched.

C. ONLINE MATCHING - SEMANTIC WEB TECHNOLOGIES

Online libraries and bibliographic databases like CROSBI can gain much benefit from The Semantic Web technologies, like Ontologies (specifically Web Ontology Language - OWL) and SPARQL Protocol and RDF Query Language (SPARQL)[8]. Since some of the online bibliographic databases, search engines or Web sites have a semantic version, accompanied with a SPARQL endpoint (a REST Web Service that accepts SPARQL queries and returns results in a simple XML form), a custom Semantic tool was made to match CROSBI data against different SPARQL endpoints. In our research, PubMed (Medline), DBLP, ACM, CiteSeer and Jucs.org were queried with a subset of CROSBI data. Taking into account the restrictions of endpoints, response and computation time of text similarity functions in SPARQL, only simple text search was performed on most of the endpoints. The results are shown in TABLE II.

TABLE II. DATA MATCHING AGAINST DIFFERENT SPARQL ENDPOINTS

Endpoint	*Url:*	*Matches*
PubMed	http://pubmed.bio2rdf.org/sparql	5567
DBLP	http://dblp.rkbexplorer.com/sparql/	1513
ACM	http://acm.rkbexplorer.com/sparql/	168

[5] http://scholar.google.hr/
[6] http://www.webofknowledge.com/

V. RESULTS

Different database modifications, transformations, and data matching against data from various online bibliographic and library sources were performed. The CROSBI database was normalized, most of the inconsistencies and deficiencies were removed, and data accessibility and richness was improved. Some of the results are shown in TABLE I. and TABLE II.

Since the new database tables were created, the possibilities to use or analyze data in a different way emerged. Some examples of that would be: analysis and evaluation of Croatian universities by a number and type of papers published in different journals or conferences, analysis of scientific production by region or city, and similar.

VI. CONCLUSION AND FUTURE WORK

Conducted activities improved the content of the CROSBI database and opened up new possibilities to use and analyze its data.

Links with bibliographic data on different online databases stimulates the possibilities of further data discovery and enrichment. Since the used online databases, as well as CROSBI, are being constantly updated with new data, data matching should become a regular periodical activity, so newly added records would also get interconnected and enriched.

The existence of links with other databases allows cross checking the CROSBI data with a validated data sets. Also data enhancement, by adding missing or related information, was made possible.

Although there is still a rather small number of Semantic sources available and the number of matched records is, for now, relatively small, the Semantic web technologies showed some significant advantages over the other used technologies. The Web Service Client that consumes SPARQL endpoint needs minimal adaptation to work with different endpoints, data format is open and well defined, and interconnection with other sources or inclusion of additional knowledge into existing bibliographic database is simple by using the *owl:sameAs* property.

The future work should further explore the possibilities of more advanced text comparison methods, to improve the matching efficiency and even more increase the data quality. Also, a newly discovered and collected data could be utilized in a recommender system implemented inside a CROSBI web interface, which would help and guide users in correcting and improving the data about their papers and books.

ACKNOWLEDGMENT

We would like to express our special thanks to CROSBI developer prof. Ivo Batistić, from the University of Zagreb, Faculty of Science, for creating the database system and investing a lot of hard work in the maintenance and improvements of CROSBI in last 15 years. Special thanks go also to system's librarian Alen Vodopijevec from Ruđer Bošković Institute, for continuous technical support to the CROSBI bibliography and provision of data needed for this research.

This work was partially supported by the "Semantic integration of heterogeneous data sources" project, funded by the Croatian Ministry of Science, under grant number 036-0361983-2012. The authors would like to thank the funding agency for their support.

Abstract -Demand forecasting plays a very important role in retail business. Retail information systems commonly store large amounts of data which are subsequently used by sophisticated data mining tools for building forecasting models. Quality of these models is usually measured through their predictive accuracy as their most important property, followed by other measures which consider average underestimate and overestimate costs etc. Even though the choice of data mining algorithm is usually paramount, training set cleansing and preparation has a significant influence on final model performance. This article discusses and analyses the impact of training set preparation and tailoring on a final forecasting model performance used in a real world example from the retail industry.

I. INTRODUCTION

Today's retail industry is a highly challenging and competitive business area. In Croatia, retail industry dealing with fast-moving consumer goods (FMCG) is not yet consolidated and there is strong competition between most powerful players in this field. Thus, quick adoption of new technologies and adaptation is crucial for survival on the market.

In FMCG industry effective and efficient handling of data, information, people and goods is very important. Besides experienced employees in charge, good information systems support has a crucial role in keeping this retail giants adequately running. Forecasting user demand is a key part in supply chain management process. The impact of incorrect forecasting is two-fold: overestimating can result in large storage costs, potential loss of perishable commodities and frozen capital issues, while underestimating causes loss of potential profit and decreased customer satisfaction.

Due to the recent economic situation and decline of purchasing power promotional sales have increased significantly and became an important segment of overall sales traffic. This puts further emphasis on building specific predictive models which target promotional sales in particular. Additional complexities arise due to the nature of demand of promotional goods which usually behave less predictably than regular demand, especially since promotional items tend to be offered in stores which do not hold those items as their regular selection. Consequently, building predictive models for promotional sales is a challenging yet potentially high-yielding research task.

The approach to building predictive models usually requires two important decisions: the choice of data mining algorithm and the choice of dataset on which this algorithm will be used. Nowadays, retail industry produces and centrally stores large amounts of fine-grained data, usually containing information about each individual transaction in each individual store. If this data encompasses a large enough time period (such as few years), it can be assumed that certain regularities could be inferred from the data. These regularities can be uncovered if correct data mining algorithms are chosen coupled with properly prepared training datasets.

Training set preparation is an essential part of building successful predictive models. Usually it is not wise to use all available data. In real life scenarios historical data usually contains a lot of noise and atypical examples which result from unforeseen situations. E.g. a problem with goods delivery causes absence of a product in a certain store which – if only looking at the data - may lead to a conclusion that this product was present yet wasn't sold at all in that particular store. Alternatively, a highly seasonal store can have low regular sales yet achieve great promotional sale results for only a few days a year due to holiday traffic – if a single predictive model was built on this data it would generalize very poorly. These considerations imply that before using the data for model training all potential outliers should be identified and removed. This paper deals mostly with the following step of the analysis: the issue of determining *which* data and *in what amount* should be used as input for forecasting model training to achieve the best compromise between

the efficiency of the model building process, available resources and final model performance.

The article is organized as follows: Section II presents the related work on the subject. Section III describes our evaluation methodology, while in Section IV real-life available data is presented. In Section V, the solution framework for analysis is introduced. Section VI present the details of our experiments and discuss their results. Finally, we conclude in Section VII.

II. RELATED WORK

High quality forecasting of user demand can have significant impact on the success of FMCG business. Consequently, a large volume of research has been focused on this task. For a concise overview of various approaches to this task we refer to [2]. Furthermore, as explained in [3], forecasting methods can be divided into two major groups:

- statistical models relying on modelling regularities inferred from past data
- judgment-based models relying on informed judgments about future events.

Statistical models tend to outperform judgement-based models. However, studies from [4] indicate that a hybrid approach using judgment-based adjustment of statistical model output done by a domain expert works best. Regarding promotional forecasting, [5] suggests that there are three main factors that influence promotional sales. These are promotion style, item promotion history and store promotion history. These can be analysed in various ways. An approach using intervention analysis on time series is presented in [6]. Regression style modelling using 66 variables was used to produce a very successful system in [5]. We proceed along the same lines using regression analysis. Consequently, our approach belongs in the statistical models group.

In machine learning, experience shows that training on noisy data can often produce suboptimal models. There have been many approaches to tackle this problem. In [7,8] classifiers are trained to clean up the training set for the final statistical model. Alternatively some of many uni- and multivariate statistical methods for outlier detection can be used (e.g. [9,10]). In this work we use filtering rules devised by domain experts and experiment with sampling the data in various ways.

III. MEASURES FOR MODEL EVALUATION

Decision making and planning depends heavily on reliability of forecasting models. To properly evaluate our forecasting models, we use several different yet complementary measures which are widely accepted by domain specialists [2]. These measures consider different aspects of forecasting errors made by models.

The measures we employ in this paper are as follows:

- MAPE (*Mean Absolute Percentage Error*)
- WMAPE (*Weighted Mean Absolute Percentage Error*)
- WMPE (*Weighted* M*ean Percentage Error*)

To calculate these error metrics we define:

$\mathbf{y_p}$– amount predicted
$\mathbf{y}$ – amount achieved
$\mathbf{Y}$ – total amount achieved, $\sum y = Y$

Now we calculate MAPE as follows:

$$\mathrm{MAPE}=\frac{1}{N}\sum\frac{|y_p-y|}{y} \quad (1)$$

where the absolute percentage error (APE) of a single example is given by:

$$\frac{|y_p-y|}{y}$$

While MAPE is a good indicator of model performance it assigns equal importance to all examples. In practice this is often undesirable since from an economic point of view good predictions on certain examples are more important. Such cases include products with large traffic. E.g. the APE of a predicted demand of 4 instead of 5 is considered equal to the APE of a predicted demand of 400 instead of 500. To alleviate this issue a weighted measure might be more appropriate when evaluating models used in real world applications.

We calculate WMAPE as the weighted average of APE as follows:

$$\mathrm{WMAPE}=\frac{\sum\frac{|y_p-y|}{y}\cdot y}{\sum y}=\frac{\sum|y_p-y|}{Y} \quad (2)$$

Note that we use volume (achieved amounts) as weights, giving more importance to items that sell in larger volumes. This weighing scheme reflects the requirement of model optimization from a business perspective. Alternative weighting schemes are also possible, for example taking into account the value or price of the product. E.g. revenue from selling one diving suit is much higher than the one gained from selling one matchbox, which may lead to a conclusion that the more valuable items can be considered more important, even if sold in relatively small amounts. In contrast, one may also argue that the number of customers dissatisfied with not finding the requested item can be much higher in the latter case. Since in the FMCG industry WMAPE is commonly weighted by volumes [1, 2] this is the approach adopted in this paper.

While WMAPE is the most commonly used measure in FMCG industry, it does not reveal certain properties of the model which might be considered interesting or relevant from the business perspective. For example, business users are often interested in the overall behaviour of the model when it comes to underestimating or overestimating predicted values. This is commonly referred to as a downward or upward bias, which at store-level may mean that certain store is being systematically over or under-stocked with promotional items. WMPE measure provides a way of quantifying this bias through the following formula:

$$WMPE=\frac{\sum\frac{y_p-y}{y}\cdot y}{\sum y}=\frac{\sum(y_p-y)}{Y}=\frac{\sum y_p-\sum y}{Y} \quad (3)$$

While each of these measures offers a slightly different view on model performance, for the final evaluation of models we will rely on the WMAPE measure as the most informative with respect to business goals.

IV. AVAILABLE DATA

We use a real world database containing information about promotional sales spanning a period of two and a half years. The data set was collected by one of the largest Croatian FMCG retailers. The data set we use is derived by aggregating and filtering this database.

The products we focus on are part of a predefined hierarchy of products. The highest level of the hierarchy consists of 3 product classes which we will arbitrarily denote as "A", "B" and "C". Different product classes may exhibit drastically different behaviour when considering promotional sales volumes. These differences are due to different usage and buying patterns (e.g. perishable vs. non-perishable goods). Consequently, we build individual models for each of the product classes.

To acquire satisfactory models, focusing on each of the mentioned classes is not enough. Besides filtering out outliers, certain products which demonstrate different behaviour have to be removed also. Domain experts testify that certain periods of time (e.g. holidays) also have to be modelled separately. Within research described in this paper we focused on a purified subset of our data set derived as by applying the following filters:

1. holiday seasons – promotional sales during this periods are very atypical when compared to the rest of the year due to somewhat different customer behaviour.
2. promotions without price reduction – examples of such promotions would be "buy 2 get 1 free" which are atypical and considerably less frequent in our data set.
3. special items – items that domain experts considered as highly specific exhibiting irregular behaviour compared to other items in the data set
4. other outliers – items which are extremely atypical by some criterion. Such examples are very likely the result of an error in data input or an external problem (e.g. goods could not reach a store due to transport issues). We use the following criteria:
   a. extremely low increase in sales – items where data suggests the increase in sales was miniscule (e.g. less than 1%)
   b. extremely high increase in sales – items where the increase in sales is huge (e.g. 50 times)
   c. high differences in store availability – items which change their availability in stores during promotions very drastically, making proper generalization from past data very difficult
   d. extremely high discounts – items where the relative difference between the regular and promotional price is very large
   e. items with extremely low sales
   f. items with a large number of "sibling" items within the product hierarchy

After applying a combination of the above filters we derive a purified data set for our experiments.

V. SOLUTION FRAMEWORK

Our solution framework is presented in Figure 1. More detailed explanation follows.

A realistic scenario of building predictive models for promotional sales in the FMCG industry could involve having large amounts of detailed historical data. Once the outliers are eliminated, one issue that commonly arises is whether the rule of "more data is always better" does apply at all times. First, there is an issue of algorithm complexity and scalability; available resources and timeframe assigned for model building may not be sufficient to handle the size of dataset available for training. Furthermore, even if the quality of predictive model rises with more data used, a question may arise dealing with the issue of diminishing returns. If a small

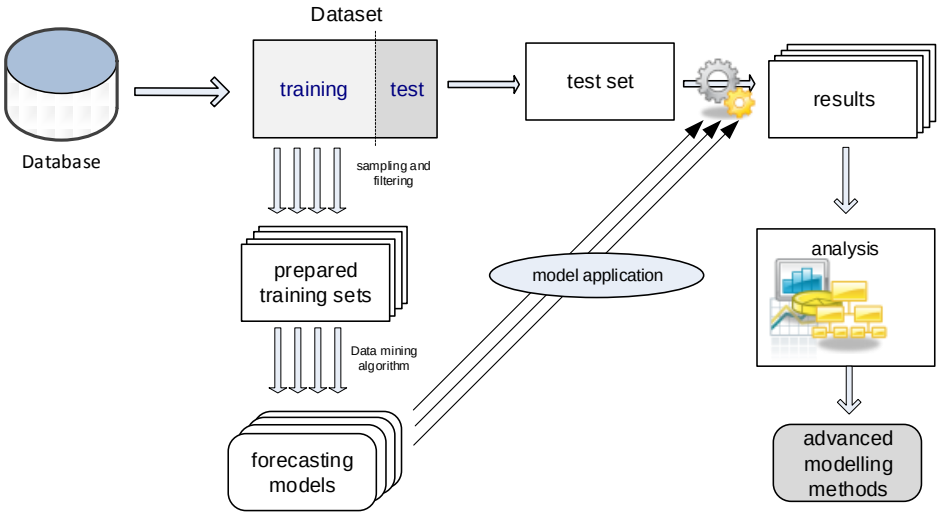

Figure 1.Graphical representation of analysis process flow

sample of available data may produce a predictive model only infinitesimally worse than the model built by using all available data, it is perhaps feasible to use less data for training to free up resources for trying out additional algorithms or approaches. In addition, customer behaviour changes over time so going further and further in the past might even start degrading the model despite increasing the amount of data used. This article deals with these issues and offers guidelines in handling similar problems.

We present a framework for efficiently determining the best method for tailoring the training set to our particular problem – forecasting promotional sale volumes.

The data set described in the previous chapter was used for building the forecasting model. The data is split into a training and test parts, statistics of which are given in Table I. We then apply various combinations of proposed filtering steps. In preliminary experiments we concluded that best results are obtained when applying all filters to both the training and test set. However, some of the filters (4a and 4b) require the value of the target variable which wouldn't be known in advance in a realistic scenario. However, analysis showed that examples which would be eliminated by these filters constitute a very small part of the whole test data set. In addition, domain experts agreed that these examples are erroneous and thus can be omitted when evaluating forecasting models. Additional optional steps are other modifications of the training set such as e.g. down sampling it to leave only the most recent data.

After preparing the training and test set we build a statistical forecasting model on the training set through the method of linear regression. The most important features used by the model include predicted baseline demand (demand in the case of no promotion), information about prices and discounts, position in the product hierarchy, and information about increased product availability during promotions. The final set of features used was determined by a "forward selection" procedure during preliminary experiments. Once the models are trained, they are used to generate predictions for examples in the test set. The performance is then evaluated on the held out dataset using the metrics described in section III

TABLE I. DATA SETS' STATISTICS

Data-set	Starting date	Ending date	No. of promotions	No. promotion/ product
training	30.8.2010.	31.12.2012	191	19186
test	1.1.2013.	20.5.2013.	20	5939

Note that instead of LR we could have used more complex models such as neural networks or support vector regression. These models, however, have considerably longer training times and are less convenient for experiments which include repeated testing with various combinations of parameters. Instead of finding optimal models the focus was placed on tailoring the training set to improve performance. It is expected that any improvements observed in these experiments will, to some extent, transfer to more complex models as well.

VI. DEPENDENCY OF MEASURES ON TAILORING OF TRAINING DATA

A. *Effects of set size*

To explore the effects of training set size on results we created subsets of the training set varying in size from 5% to 100% of the original set. The subsets were created by randomly sampling examples from a uniform distribution. Each sampled subset was used for training the linear regression model which was then tested on the prepared held out testing dataset. To account for the variance due to sampling, each experiment was repeated 30 times and the

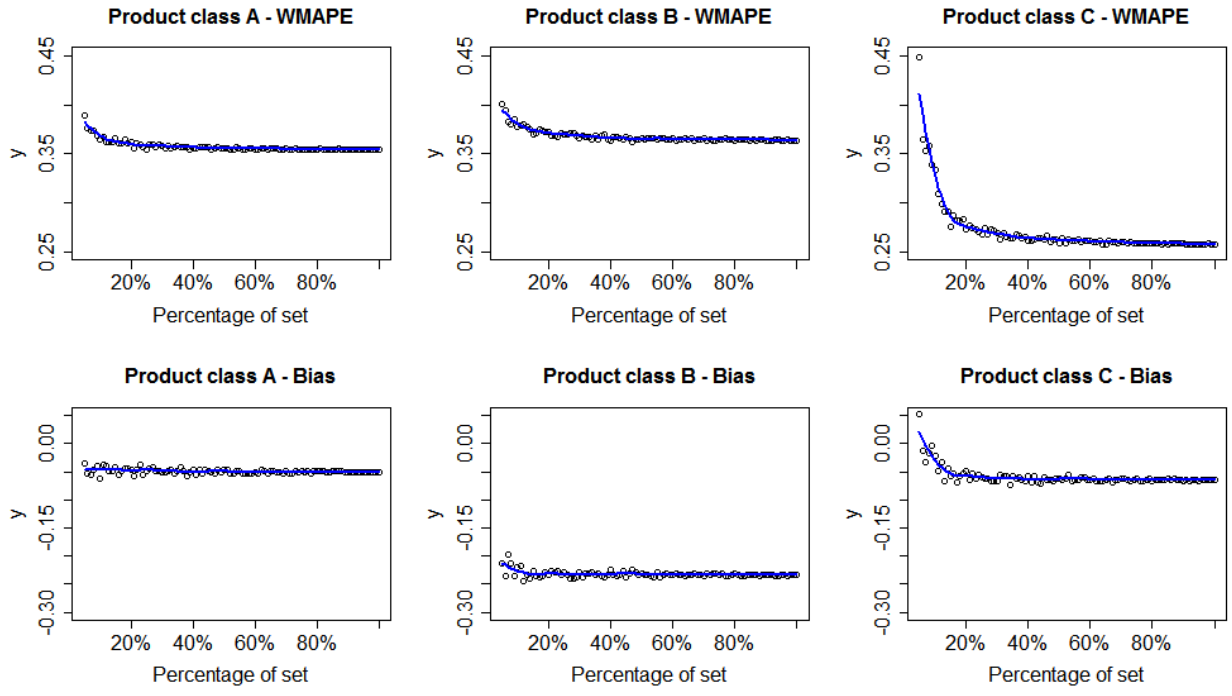

Figure 2. Evaluation measures dependency on random sampled portion of training set

average result was reported. Results are given in Figure 2.

The first row shows the WMAPE measure for product classes "A", "B", and "C" respectively. The second row provides the WMPE measure (called "Bias" here for the reasons of clarity) in the same manner. Axis ranges in each row are aligned for easier comparison.

Analysis of the graphs reveals that when considering the WMAPE measure, product class C is considerably more dependent on the amount of training data. Moreover, results on this product class are much better than on the other two. This is in line with the nature of class "C" which contains items which exhibit high regularity in customer demand. Results on other two classes also slightly improve with larger training datasets. The WMPE measure exhibits the same trends as WMAPE and remains stable for all product classes after using at least 30% of the training data.

A general observation is that all graphs tend to converge rather early. This indicates that adding more training data would not necessarily provide a significant performance boost. Furthermore, the analysis suggests that roughly 30% of the data is quite representative and could thus be used for the purposes of fine tuning more complex models which scale poorly.

B. *Effects of set size and recency*

Similarly to investigating effects of training set size we were interested in whether training set recency plays a significant role in the quality of generated models. In essence, this experiment is identical to the previous one, apart for the training set sampling method. Instead of sampling a certain number of examples *(N)* randomly, we simply take *N most recent* examples.

Note that here we investigate not only the effects of recency but the joint effects of both recency and size. *A priori* logic would dictate that an increase in either recency or size would be beneficial. However, there is a trade-off between these two dimensions. Taking more data increases the training set size but lowers recency and vice versa. To determine the optimal trade-off between these dimensions is one of the research goals in this paper.

Results are given in Figure 3. The method of display is identical as in the previous experiment. With respect to WMAPE, product class C again exhibits much better results when compared to the other classes. In contrast to the previous experiment, increasing the size does not necessarily increase the overall performance of the forecasting model. In fact, for product class B the optimal performance is achieved when using only 20% of the most recent data. Results on product class C, which previously had the most benefit from increasing size, are now quite good from the start (again roughly 20% of the most recent data), but still show modest improvement with taking more data.

Another interesting observation is that for product class A, bias improves with increasing the size of training data while for the other two product classes it slightly deteriorates.

In general, results suggest that filtering the training set chronologically can in certain cases not only reduce training times at no performance cost but can even increase the performance of the forecasting model.

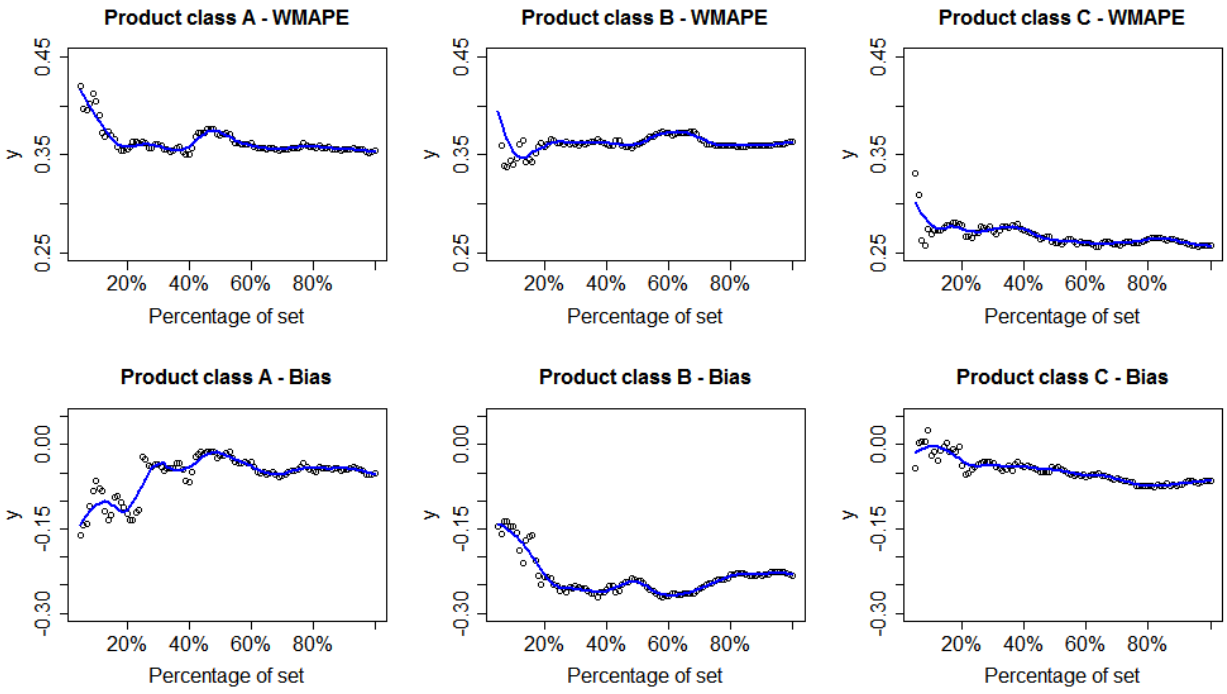

Figure 3. Evaluation measures dependency on chronologically filtered portion of training set

VII. CONCLUSION

We present a framework for optimizing promotion demand forecast model performance by filtering the training set by size or chronologically. This approach has several advantages. It allows us to reduce the amount of training data used to train the models, with little or no impact on performance. It also provides the analyst the opportunity to fine tune the more complex models before building the final forecasting model. We empirically determined good thresholds for each of the product classes present in our data set.

In future work we will focus on using more advanced yet computationally more expensive models such as neural networks or support vector regression. Another possible venue of research is using a more fine grained division of the data set, derived by a clustering procedure using measures defined in [11], [12], and training separate models for each cluster, each with an optimally tailored training set.

Abstract - Most research on network traffic prediction has been done on small datasets based on statistical methodologies. This research analyzes an internet traffic dataset spanning multiple months using the data mining process. Each data mining phase was carefully fitted to the network analysis domain and systematized in context of data mining. The second part of the paper evaluates various seasonal time series prediction models (univariate), including ANN, ARIMA, Holt Winters etc., as a data mining phase on the given dataset. The experiments have shown that in most cases ANNs are superior to other algorithms for this purpose.

I. INTRODUCTION

Network traffic prediction is a crucial part of every serious network system. Network prediction enables network administrators to strategically plan and respond to network issues such as network infrastructure scaling, testing of new protocols/devices and to deal with network problems that already happened and could occur again in the future.

The construction of such a network traffic predictor could be the fundament of a network traffic generator that could be used for precise network traffic simulation and planning.

Lelend at al.(1994) has shown and proved [1] that the Ethernet traffic in LAN networks has an self-similarity nature. In 1998 *Feldman et. Al.* writes about the fractal nature of WAN traffic [2]. Their models have been verified in several experiments as in [3,4,5] on different datasets and network domains including the internet traffic[4] as a special class of network traffic. Other network traffic properties include multiscalarity and their nonlinear nature with long rage dependence as shown in [6]. This nature of network traffic enables us to do a complex and, with the available machine learning tools, a sufficiently accurate traffic prediction.

Although there are several papers that deal with the problem of network traffic prediction [7,8,9,10,11] most of them use simple - linear statistical models for time series prediction. Also most of the papers deal with only one dimension of the network traffic mostly the data they got from the SNMP logs. The problem with SNMP logs is that they miss the packet inter-arrival time parameter that is crucial for network generators. There are less papers that use machine learning models (in most cases simple ANN models or rarely SVM). Another problem is that most research has been done on relatively short time series that span usually over a few weeks focusing on short-term or medium-term time series prediction.

II. RELATED WORK

In the literature various models have been proposed in order to model the network traffic as a prediction problem. The methods vary from strictly statistical methods based on fitting statistical distributions to specific sources, models based on auto regression and moving average (AR, ARMA, ARIMA, SARIMA, GARCH)[8] or exponential smoothing methods such as Holt Winters that showed some superiority in daily predictions and computation time. Another approach are the machine learning models especially the non-linear ANN and kernel based SVM models[9][10], ensemble methods based on ANNs that give good results for short-term time series raging from five minutes or one hour[11]. There are also hybrid methods based on the combination of ANNs and ARIMA models[7].

III. DATA MINING - TIME SERIES ANALYSIS

For the purpose of this paper a new internet traffic dataset has been created on a web server. The dataset is recorded in *PCAP* format with *tcpdump* and spans from (10.10.2013. until 22.02.2014.) and it has been made publicly available at [12].

The data analyzed in this paper spans for several months but in order to simplify the graphs a focus has been set on several weeks to analyze the different time-series properties. The dataset includes several events like weekends, state and religious holydays and the daylight saving time switch on 25.10.2013. This switch can cause issues with some algorithms and the analysis. A data mining / KDD process methodology has been used to analyze the data as described by Fayyad et.al in [13].

A. Preprocessing

This part of the process reduces the dimensions of the dataset and extracts only the data that is useful to the prediction model. This is also the step where the training/ testing/validation datasets are created. Data preprocessing may include cleaning, normalization, transformation, feature extraction/selection [14]. Also a data warehouse could be constructed as shown in [15] that is used to analyze the web logs. A similar approach could be used for network traffic.

For the purpose of the analysis the pcap file has been preprocessed: features selected, cleaned, normalized and transformed to *CSV*. Than it was imported to a *RDBMS* in order to make fast aggregations and enable filters (groupby/where/partitions) for experiment dataset generation with different parameters.

The features chosen in the feature extraction/selection process where: absolute packet arrival time, packet size, delta time (packet interarrival time) and the protocol. The delta time and protocol features have been chosen because they are needed for a proper traffic generator implementation.

B. Outlier detection

According to [16] an outlier can be defined as an observation that is significantly distanced from all the other observations. It is very important to identify all the outliers and to filter them out because in some cases they can produce massive issues when using statistical learning algorithms.

Outliers can be easily identified on a scatterplot as show in figure 1 for a multiday time series between the 10.10.2013 and 03.11.2013.

Several outlier detection algorithms have been tested including Distance Based Outlier Detection, Density outlier detection and LOF.

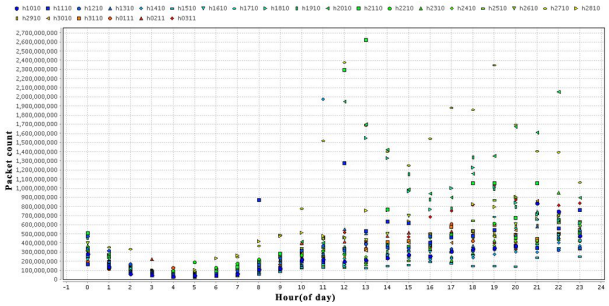

Figure 1 Outliers are visible on a time series scatterplot

Distance based outlier detection [17] searches for ***n*** outliers based on their distance from the ***k*** nearest neighbors (kNN)

Density based outlier detector DB(p,D) searches the global space for outliers. This algorithm takes an assumption that the outliers are those observations that have at least a ***p*** proportion from all other observations that are more distant than ***D***[18]. This algorithm differs from the previous one because it takes all observation into account and not just the k nearest.

The problem of this detector for this specific domain is that we have to specify the ***p*** and ***D*** parameters which is not very practical in context of the linear long time growth of network traffic and time series trends/seasonality. Although this algorithm has shown better results than the previous one by doing a global outlier detection, it is not the best choice in his plain form for this domain because of the parameter estimation problem.

Local outlier factor *(LOF)* ***algorithm*** [19] is similar to the previous ones. The LOF algorithm takes the distance from the k nearest neighbors and estimates the density.

The algorithm compares the local density of the observation with his all neighbor densities. Observations that have a much smaller density than they neighbors are considered outliers.

It's obvious that table 1 – left (distance based outlier detection) shows that there are anomalies at 11 o'clock because it's a big value(1098212) but it's hard to figure out what the anomalies are because we have to guess the number of outliers which is not very suitable for this domain.

Table 1 Left-Distance based outlier detection(with euclide distance); Middle – Density outlier detctor; Right-Local outlier factor

If we set the outlier count parameter ***n*** to 1 the algorithm will successfully detect the big number but it will leave out the others.

Table 1 – middle shows the results of applying the Density based outlier detector. The parameters distance and proportion where set to 7000 and 0.9 respectively. The results are great but the problem is how to define the distance and proportion (the distance parameter is a constant but the problem is the network traffic is growing linear over time[20]).

Table 1 – right shows the results of the LOF algorithm ordered by the outlier factor. We can clearly see that it detected the 11 o'clock anomaly successfully but there is still the threshold problem. Nevertheless it's easier to figure it out than for the previous two methods.

A graphical method could also be used to detect the daily anomalies as seen in figure 2. Its obvious that there are anomalies in the days mentioned before and identified by the outlier detector.

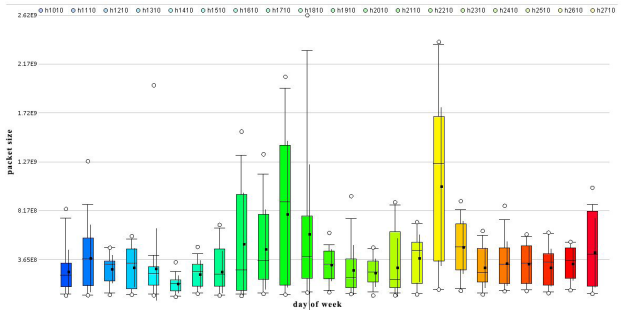

Figure 2 Quartile diagram used for anomaly detection

IV. TIME SERIES ANALYSIS OF THE DATASET

Figure 4(end of paper) shows the packet count rate of internet traffic for three and a half months on daily basis.

From figure 4 it is obvious that the traffic is similar between days and that the daily peek is from 7 till 11 PM while the off peek is from 3 to 5 AM which means that the traffic is mostly from the same time zone. It's also easy to detect the anomalies on the graph.

A. Time series components

To analyze the nature of the time series we have to decompose it to components: the trend component, seasonal component and the noise component.

In figure 5,6,7 we can see the specific components for a 10 days (240 hours) sample of the dataset. In figure 5 we see that the trend is fairly constant except the dropdown on the 100th hour (14.10.2013.) which was a day before a religious holyday (the students go home).

In figure 6 (the seasonal component) we see that the day is made of two periods. The first one from 0 to 50 has four waves, that fits to the previous observation that one day has two parts the (night) off peak and the peak period(day). In figure 7 we can clearly see the anomaly identified before.

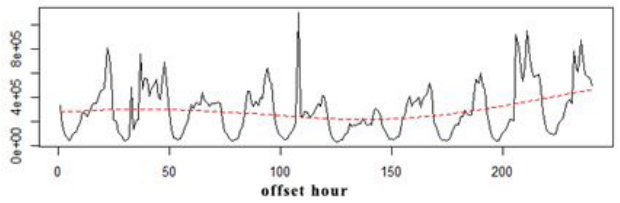

Figure 5 - The trend component

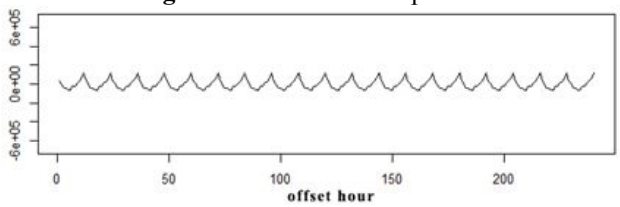

Figure 6 - The seasonal component

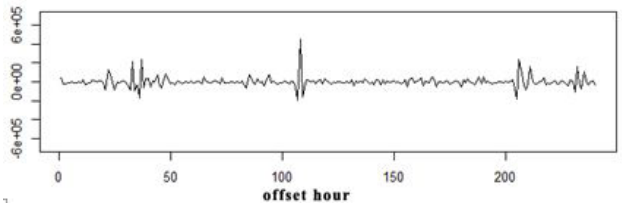

Figure 7 - The noise component

B. The Hurst parameter

By estimating the Hurst exponent we get a value that can indicate the long time memory of the time series [21] it also indicates if the time series is self-similar. An R/S analysis has been used on the given dataset to estimate the Hurst parameter. The results are given in table 2.

	Size	Delta	Count	ALL
Corrected R/ S Hurst exponent:	0.753247	0.6093524	0.7100859	0.9676726
Theoretical Hurst exponent:	0.5457227	0.5457227	0.5457227	0.5334291
Corrected empirical Hurst exponent:	0.7810718	0.4850182	0.6998232	0.9323203
Empirical Hurst exponent:	0.8152428	0.5140385	0.7312095	0.9528319

Table 2 - Hurst exponent estimation

If the Hurst parameter is smaller than 0.5(H<0.5) or greater than 0.5(H>0.5) then this is an indication that there is a trend. If the Hurst parameter is equal to 0.5 the time series is random. It's shown in [22] that time series with a greater value of the Hurst parameter give better results in ANN prediction. The results in table 2 show an H value greater than 0.5 which means there are signs of a trend.

C. Correlation between days

An interesting factor for the time series analysis is the correlation between days in a week as well as between weeks and years. A correlation matrix between days for a 10 days sample is shown in table 3 shown at the end of the paper.

It's easy to spot that the days 14, 21 and 11 (holiday) are anomalies because they have a very low correlation with all the other days.

We also see small anomalies on Friday the 25.10; 18.10 and the Saturday 12.10; 19.10 and 26.10. These are the days when most of the students go out (they are the targeted users of the websites hosted on this server).

day1	day2	corr	day1	day2	corr
h1010	h3010	0.970	h2410	h3010	0.916
h1710	h2510	0.967	h2210	h0311	0.912
h1010	h2310	0.956	h2610	h3010	0.912
h2910	h0311	0.949	h2510	h2910	0.909
h2910	h3010	0.946	h2510	h0311	0.906
h2210	h3110	0.940	h1310	h2610	0.899
h2410	h2910	0.939	h1710	h3010	0.899
h1610	h2610	0.934	h1010	h2910	0.896
h1710	h0311	0.929	h2610	h2910	0.896
h1310	h1610	0.926	h2410	h2610	0.896
h2210	h0111	0.926	h3110	h0111	0.895
h1710	h2910	0.926	h1310	h2010	0.895
h0111	h0311	0.926	h3110	h0311	0.894
h2310	h3010	0.917			

Table 4 Correlation between days sorted

An interesting thing occurred when we analyzed the most correlated days as shown in table 4. Although it's logical that the day of week should have the highest correlation with the same day next week the analysis has

shown different. The days that are near each other have the highest correlation during the week.

A correlation histogram for the days of week has been made as shown in figure 8. The histogram shows that the correlation for the sum of packet size per hour per day of week has a big value (around 0.8) and that the peaks are around the central value of 0.9. This fits a Beta(8,2) distribution.

The results have shown that the analysis for the delta parameter and packet size is very similar to the analysis made for the packet size.

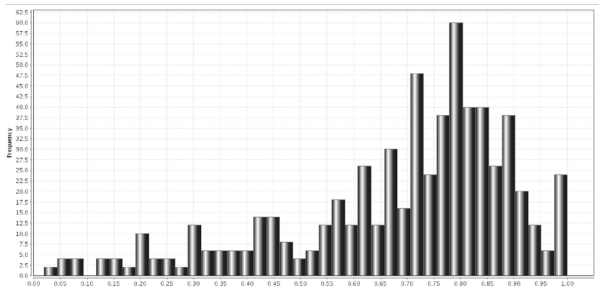

Figure 8 – Histogram - packet size correlation per hour per day per week(vertical axis frequency)

V. UNIVARIATE PREDICTION MODELS

The most popular time series prediction models are ARIMA and Holt Winer for linear prediction and ANNs for nonlinear predictions.

In this experiment we focused on a univariate time series predictions based on individual domain features.

A. Holt Winter

The Holt Winter model is a simple exponential smoothing model for TS prediction. The results of a 24 hour prediction of the time series is shown in figure 9. From the graph it's obvious that the prediction is just an average of the time series.

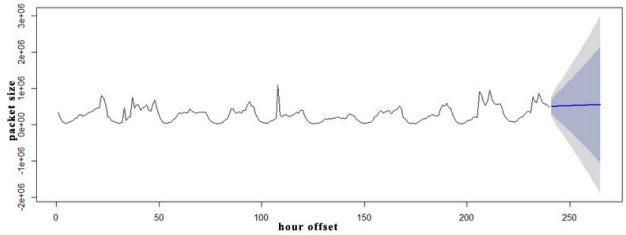

Figure 9 - 24h Time series prediction with Holt Winter

B. ARIMA

Autoregressive integrated moving average has shown good results for self-similarity internet traffic prediction[23] and with predicting time series that show a trend. During the experiment several ARIMA have been used and the model that best fitted the traffic was the ARIMA(2,0,3) model with p=2; d=0 and q=3. The 24 hour prediction on the given dataset is shown in figure 10.

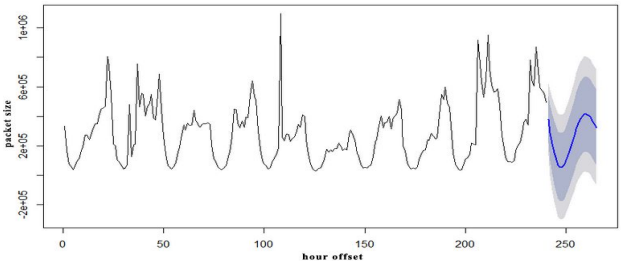

Figure 10 ARIMA(2,0,3) 24h prediction with non-zero mean

The result isn't bad but if we try to expand the prediction to five more days (120 hours) days we get the result shown in figure 11. So ARIMA in it's plain form is good for short term predictions but fails on long term predictions.

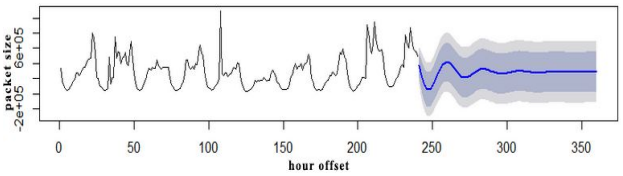

Figure 11 ARIMA(2,0,3) 5 days prediction with non-zero mean

C. ANN

Several experiments[7,11,13] have shown that the prediction with ANNs a nonlinear statistical learning model gives the best prediction results.

In order to analyze the time series a resolution of the time series sampling rate has to be chosen. The ITU rec-E.492 recommends to take a 15 min. or one hour aggregation frame [24]. Our analysis has shown that the best results for this particular dataset and the selected algorithms is a one hour frame.

An ANN with only 22 seasonal lags in the layers and with time series frequency 3 for the window has been used during the experiments. The 24h prediction can been seen in figure 12. As we can see the results are much better fitted than ARIMA so it fits better for the construction of a network traffic generator.

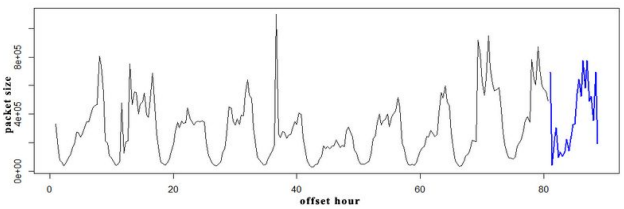

Figure 12 - ANN 24h prediction with 22 seasonal lags and frequency 3

The problem with this approach is that we use only one dimension the packet size and the neural network is adapting to that dimension. One solution is to use an ANN multivariate model in order to do a much longer prediction without the memory effect.

For the second experiment an 27 seasonal lag ANN configuration with 3 days prediction has been used as shown in figure 13.

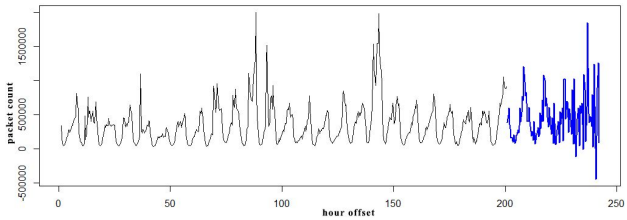

Figure 13 ANN(27,1) 3 days prediction with 27 seasonal lags and frequency 3

VI. RESULTS

A. *Fitting errors and performance*

Several error measurements have been used to evaluate the different models including ME, RMSE, MAE, MPE, MAPE, ACFI. Because of the univariate limitation of this work every dimension of the domain had to be evaluated separately. The fitting error results are shown in table 5,6,7.

	ANN	ARIMA	HoltWinter
ME	-345.6	-246.2	177387.5
RMSE	77451.7	144005.4	333465
MAE	45998.2	79901.6	217246.6
MPE	-9.8043	-17.6479	49.8455
MAPE	18.6512	31.0240	65.7479
MASE	0.25865	0.32807	1.21914
ACF1	0.059133	-0.00108	0.045426

Table 5 - Fitting errors for packet count per hour

	ANN	ARIMA	HoltWinter
ME	-205956	10955995	194601375
RMSE	125857101	226003847	417423245
MAE	65042165	11124690	24943242
MPE	-15.576	-26.010	50.054
MAPE	26.478	43.630	70.327
MASE	0.29317	0.50143	1.113607
ACF1	0.0489	0.0300	-0.0644

Table 6 - Fitting errors for packet size per hour

	ANN	ARIMA	HoltWinter
ME	1.8e-05	3.0e-05	0.00968482
RMSE	0.00403604	0.00656261	0.01967587
MAE	0.00253094	0.0045137	0.01317839
MPE	-4.489	-16.192	47.346
MAPE	16.14	33.22	73.21
MASE	0.21070	0.37578	1.096781
ACF1	-0.02278	0.006316	0.397162

Table 7 - Fitting errors for interarrival delta per hour

The results show that ANNs outperform the other models in model fitting performance but this could be also an indication for overfitting.

The indication that the model fits the data correctly is not the only factor that is important for the prediction.

Cross validation is a statistical method that could help to better evaluate the model but the method is a little bit more complex to be used on time series. A common name in the literature for time series cross validation is "forecast evaluation with rolling origin".

B. *Cross validation*

A cross validation for the time series could be constructed by splitting the dataset into several parts. One part could be the training set (in our case 80% of the dataset) and the other one the validation set (20%).

One could take 80% of the training set and then predict the next 20% and then compare the predicted ones with the real ones from the validation set that wasn't used for the training.

For the verification if the prediction was successful a correlation between the 20% predicted and the 20% validated could be done (better result would be with windowing).

The validation results cross-correlation coefficients are shown in table 8. It is obvious that ANNs outperform the ARIMA model

	Size	Count	Delta
ANN	0.6046795	0.6115911	0.7085994
ARIMA	-0.5489083	-0.3409841	0.7394064
HW	-0.6820613	0.7975048	0.6904266

Table 8 Cross validation 24 hours scope. The values are cross-correlation coefficients

It's interesting that Holt Winter outperforms the ANN and ARIMA, this is due the fact that we use cross-correlation without a time window and the result of the holt winters prediction is a straight line(avg of the time series). This shows the importance to use multiple parameters in order to evaluate the model.

VII. CONCLUSION

In this paper we show that the network traffic time series prediction fits the data mining process model. We have gone through different aspects of the analysis. This is important because most of the papers use traditional process models and small dataset while the network traffic time series prediction problem could be easily classified as a Big Data problem. It was shown that neural network outperform other linear models in the context of precision and that they could be a good model for a network traffic generator based on historical data on top of a data warehouse.

Abstract – In this paper, we propose a new conceptual model based on the visualization of data flow showing transformations of records accompanied with attribute transformations. A data warehouse development relies on the development of Extract, Transform, and Load (ETL) processes responsible for extracting data from transactional systems, data quality checks, transformation and conversion and loading data to target tables or cubes in a data warehouse. During the planning and design phases for data warehouse, the ETL conceptual model should be developed not only to show an overview of the whole process, but also to map sources, targets and necessary transformations, verify transformation logic, ensure that requirements are met and the needed structures and content exist. Once created, the conceptual model can be used for development of an ETL process, maintenance/optimization and redesign of a process due to new business requirements and database schema changes, all of which makes it a valuable addendum to data warehouse documentation.

Keywords: ETL process, data warehouse, conceptual model

I. INTRODUCTION

The need to collect, store and analyze data which can be generated through business or any other form of human activity have inspired and driven development of data warehouses. At first, data was analyzed by creating reports directly from transactional systems which were used to run business applications. But as the volume of data grew over time, so did the reporting and analysis requirements. If analytical reporting and a burst of business transactions (updating a DB) were run at the same time both tasks would suffer due to high workload. The solution was to build a special structure containing data for analysis – data warehouse.

Data warehouses (DW) are central places that contain historical data once generated on one or more transactional systems. Data can be used for analysis of past events, decision support, predicting future events and other purposes. To support specification and design of data warehouses, data models are created which differ from models used for transactional DB system.

Today, various DW modelling techniques exist, including the third normal form (3NF) model, the dimensional model [2] and the Data Vault model [4]. Different data models imply that source data must undergo a series of transformations to conform to a target structure. Also, data has to be cleansed and the quality insured so that analyses, which rely on that data, are accurate and relevant. Frequently only a portion of source data is used and modified in the process before being loaded into data warehouse.

The main goal of ETL processes is to facilitate moving and transformation of data. ETL is a collection of programs which adds significant value to data. It is far more than plumbing for getting data out of source systems and into the data warehouse. Specifically, the ETL system:

- Removes erroneous and/or corrects missing data
- Provides measures of confidence in data
- Captures the flow of transactional data for safekeeping
- Adjusts/reformat data from multiple sources to be used together
- Restructures data to fit end-user tools

The basic purpose of the ETL system is to get data out of the source and load it into the data warehouse. It is also used to clean and transform the data along the way. But the complexity of a particular implementation arises depending on data sources, business rules, existing software, and reporting applications. The challenge is to keep the focus on the simple overall mission of the ETL system [3].

Building the ETL system easily consumes up to 70 percent [1, 3] or even 80 percent of the resources needed for implementation and up to 55 percent of maintenance of a typical data warehouse [27]. Despite the fact that ETL takes up a great deal of resources and is the relevant component in the development and maintenance of a DW, there is limited literature that covers the architecture, design techniques, and methodology of data integration. Front-end business intelligence applications based on the DW provide executive dashboards with the multicolored pie and bar charts. But the processes that integrate, move, and populate the data have been largely ignored or misunderstood because it is simply hard, tedious, and highly disciplined work [1].

More challenges arise with the collection of more data, which can be structured or unstructured and comes from even more sources, often referred to as “big data.” Business users want to analyze more variables and get more insight about their business, demanding that all data

is stored and processed. ETL processes will have to handle these requests, find a way to combine sources using emerging technologies and combine structured and unstructured data in one integrated DW.

Planning and implementing the DW which fulfills the expected requirements requires extensive planning and development of ETL processes, which should start with a representation at the conceptual level as a starting point for understanding of developers and users [31]. So far, conceptual models have been developed for defining DW structure e.g. one described in [5], but the standardized method for ETL conceptual modelling has not been agreed upon yet, and researchers in the field agree that there is a relatively small amount of research literature and few approaches of ETL conceptual modelling technique exist, which may indicate more effort should be devoted to the development [12, 23, 32, 13].

The conceptual model proposed in this paper is inspired by previous work in the field and the need to present the ETL process on an abstract level. It is guided by the idea that process should be visualized to provide architects and developers with the „big picture“ of data transformations performed when moving data from source to target, thus enabling them to perform maintenance, optimization and further development of the process while keeping quality documentation.

We will concentrate on designing ETL processes which are created to run periodically (daily, weekly, monthly) to load data warehouse and data marts, with goals to ensure maximum productivity and minimum running time. Cases of special issues concerning initial batch loads and real-time and ad-hoc loads will not be covered.

Our contribution to the topic consists of:

- The proposal of a model which visualizes data flow of ETL process and separately lists attribute transformations
- The definition of a basic set of transformation elements which are used to visualize the data flow and reduce complexity of a process
- The definition of necessary information to be displayed in visualized data flows and in attribute transformation tables
- The concept of decomposing the visualization of the ETL process to a textual description using pseudo code derived from the visualization

The paper is organized as follows: In Section 2 we describe relevant work in this field. In Section 3 we present the proposition for conceptual modelling of ETL process. Section 4 presents a motivating example on which we demonstrate the model. Finally, in Section 5 we conclude the analysis and present some directions for future work.

II. RELATED WORK

There are different approaches present in the area of ETL conceptual modeling, published in research papers that propose different methods of model development. State of the art research in the area is systematically presented in [11] and [12].

In [11] a survey has been carried out covering issues concerning ETL process in DW, namely: conceptual and logical modeling of ETL processes; problems of each stage of the E-T-L; problems that pertain to the entirety of an ETL process; and review of some research prototypes of academic origin.

In [12] authors apply the method of systematic review to identify, extract and analyze the main proposals on modeling conceptual ETL processes. The main proposals are identified and compared based on the features, activities and notation of ETL processes. Questions that are considered include:

- At what level of design are ETL processes modeled?
- Does the approach define a methodology for defining the ETL process?
- Is the approach integrated with a comprehensive framework for the development of activity diagrams?
- Is the approach supported by a tool for modeling?
- What activities are described in the ETL approach?

One of the first proposals of the basis for ETL conceptual representation is described in [29]. Authors proposed a conceptual model customized for the tracing of inter-attribute relationships and the respective ETL activities. The proposed model is constructed in a customizable and extensible manner, and the authors developed a set of graphical elements for representing frequently used ETL activities.

Based on that proposal, the authors then presented a set of design steps that constitute the methodology for the design of the conceptual part of the overall ETL process. This design step includes: identification of the proper data stores; candidates and active candidates for the involved data stores; attribute mapping between the providers and consumers; and annotating the diagram with runtime constraints [28]. Further research led to the method of automatic transition from a conceptual model to a logical model [24] and responded to the need of automatic generation of program code and metadata directly from a model.

Further steps in that direction were made with the suggestion of the Entity Mapping Diagram (EMD) as a graphical model for representing ETL operations required to map data from sources to the target data warehouse or data mart [9, 32]. An improved design model and an optimization algorithm in mapping conceptual to logical models were proposed in [17]. Optimization techniques were described in [25], translation to logical models and proposal of architectural graph in [30].

Described modelling approach is based on the custom based visual representation which has been improved through time, but it does have limitations when describing

processes involving entities with large number of attributes.

Somewhat different approach is based on the Unified Modeling Language (UML). In [14] the authors define a set of UML stereotypes that represent the most common ETL tasks and use UML for the seamless integration of the design of the ETL processes with the DW conceptual schema. Further work resulted in a presentation of a disciplined framework for the modeling of relationships between sources and targets in different levels of granularity. To provide complementary views of the design artifacts in different levels of detail, the authors based their framework on a principled approach in the usage of UML packages, to allow zooming in and out the design of a scenario. The authors also extended UML to model attributes as first-class modeling elements. [13]. Additional set of modelling elements based on activity diagrams has been presented to capture dynamics of ETL processes [16]. While this approach tends to bring standards into modelling by using UML, it adds complexity to the representation. Additionally, activity diagrams visualizations would benefit from additional information about the process without adding complexity to the visualization.

An approach based on Semantic Web technologies was presented to facilitate the process of selecting relevant information from available data sources and appropriately transforming it to populate the data warehouse. The authors have used ontologies to formally and explicitly specify the semantics of the data stores' schemata, and presented possibility of automating, to a large degree, the process of the ETL workflow creation [26]. There is also another proposal of a tool called GEM [18] based on semi-automatic requirement driven design using OWL ontologies.

Authors in [7, 8] consider building ontologies a tedious task and they present model-driven framework, based on BPMN metamodel. They claim conceptual models can be straightforwardly mapped into logical models and implemented in any vendor tool, using Model-to-Text transformations. BPNM remains a choice to business-driven development of conceptual models, which can be improved by providing a new layer of abstraction that is based on a set of patterns [6]. However, BPNM is not completely suited to represent ETL, and additions are proposed also in [15] along with translation to logical and physical model.

There is another proposition of framework for modeling ETL processes named KANTARA [10] which offers a graphical working area and encapsulates the technical complexity of data.

Described proposition showcase the need and necessity to define common standardized conceptual ETL model, whether by defining new framework or adapting to existing standard. However, the most descriptive and informative model being simple enough to enter wider usage is still to be recognized.

We will also mention Data Vault modelling architecture and methodology [4] in a context of conceptual ETL modelling because it describes concept of standardization with only three types of DW tables defined and ETL code generated using repeatable patterns, which speeds up overall DW development. By loading raw data, which hasn't been transformed and/or cleansed and doing so when the data is ready and without constraining and conforming the data, it is possible to achieve very high throughput of data loading to the DW. Since there are no constraints and cleansing (business rules are enforced as far as possible downstream of the process, when building data marts from data warehouse), ETL processes don't break. This way the goals of speeding up ETL development and optimization of the processes are achieved.

III. PROPOSAL OF AN ETL CONCEPTUAL MODEL

The motivation for this proposal comes from a need to show an overview of the ETL process which was encountered through working on several data warehouse development projects. During the development, a conceptual DW model is created according to user requirements and with regard to available sources. At that time, a conceptual ETL model should also be created, which will guide developers into creating logical and physical models, respectively.

It is a realistic expectation that during the DW lifecycle the business users will request changes to the loading process, whether it were to be caused by business needs, compliance or regulatory requirements or even transaction systems changes by adding or removing functionalities. On the flip side, it is also realistic to expect that the developers who perform ETL maintenance or upgrades will change, because they will switch to other projects, change employers or there will be some other reason for workforce fluctuation.

In addition, the ETL processes are developed not only to retrieve information from various transactional system sources and load it to the DW, but also for loading specialized data marts that individual departments can use or are intended for different reporting applications. Recent developments tend to standardize the process of loading the DW by unifying types of tables and developing the method of data mapping, e.g. Data Vault model [4].

ETL can be developed by using 3GL/4GL (generation language) or visual tools. Different vendors developed different visual tools [19, 20, 21, 22] which considerably simplified the development of ETL by visualizing sources, targets and transformations. Each of these tools has a different set of predefined tools/transformations some of which are common (e.g. sorter, aggregator, joiner), but they also offer specific ones (e.g. deduplicator, rank, SQL qualifier). This situation can lead to different implementation of the same ETL concept when using different tools. Additionally, some of the tools require exact sequence or combination of transformations for some concepts to work, e.g. sorting records before joining or entering expressions to rank records before selecting the top n records. These specific rules and software requirements can add up to the complexity of visual mappings.

If the developer explores existing processes through visual data integration mappings, and tries to learn about

the concept of a process, all the necessary information cannot always be seen from the initial mapping representation. Information like join conditions in joiner or pivot setup for pivot transformation can be retrieved by opening individual transformations or additional dialog boxes. Showing details of a transformation often means showing all the fields involved in a transformation on the screen, and in cases of working with large datasets, the viewport can become filled quickly, causing the developer to lose focus. The exploration becomes even harder if the process is divided in phases through several mappings.

Consequently, we point out specific problems that may occur during the development and maintenance of the ETL:

- difficulties in communication between business users and ETL architects and developers caused by the lack of a standardized model
- time lost while maintaining the ETL process in which the developer must understand and explore the entire process in order to understand exactly what is happening with the data
- duplication of data processing and transformations caused by unawareness of all steps in the process, resulting in longer execution time and increasing complexity of data mappings, thus making maintenance more demanding - a phenomenon best described with the causal conditional "If you do not see the process, you will replicate that process" [1].
- missing the "big picture" of processing data from the transactional system source to the DW and then on to specialized data mart(s), regardless whether the process is constructed with visual mapping tools or with 3GL/4GL tools
- lack of adequate documentation which makes the ETL process harder to "read" and understand

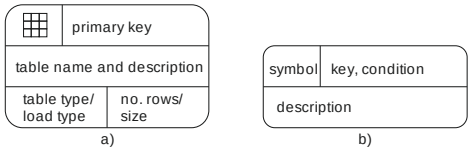

Figure 1. Visual representations of tables and record transformations

The model that we propose must fulfill the following criteria [1]:

1. Identify the major source data stores – What are the expected systems that the data will be extracted from and what is their size?
2. Document initial volumetric by source system
3. Review the data integration environment for reusable components
4. Define initial business rules and document them
5. Identify the major target data stores

The most important goal that we set up when creating the proposed conceptual model is that the model is as simple as possible and easy to read. It should be minimally affected by the complexity of the source and destination tables.

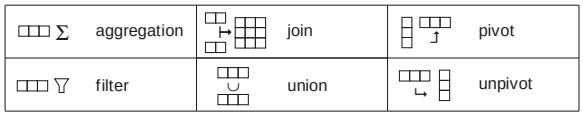

Figure 2. Transformation symbols

The ETL process is complex because there are multiple goals which have to be achieved. Currently, there are as many as 34 subsystems of ETL recognized [2]. In this paper, we propose simplification of the process in the conceptual model by separating the data flow containing records transformations only from attribute transformations. Data flow should be visualized and represent records by their keys, while the attributes will be described in accompanied table.

When creating the visual part of the model, we concentrate on the data record, as this is the main unit which is transformed. One data record is identified by the key and should have a described meaning in the model with a sentence which states the meaning of one record. We use the representation of a table (source or target) as shown on figure 1a. Elements of the visual block are:

- table type describes if it is database table or flat file
- load type denotes type of loading for the table, namely TI (truncate/insert), I (insert), U (update), M (merge) or SCDx (Slowly changing dimension where x denotes type) [2] if applicable
- no. rows/size states the projected or actual number of rows and size of the whole table in bytes.

Record based transformations are represented with visual element shown on figure 1b. Every transformation has its symbol which states what transformation takes place, key or condition by which it is performed and its description. The list of symbols is shown on figure 2.

There are different transformations defined by some vendors in ETL tools, but they can be reduced to one of mentioned transformations, e.g. splitting records can be

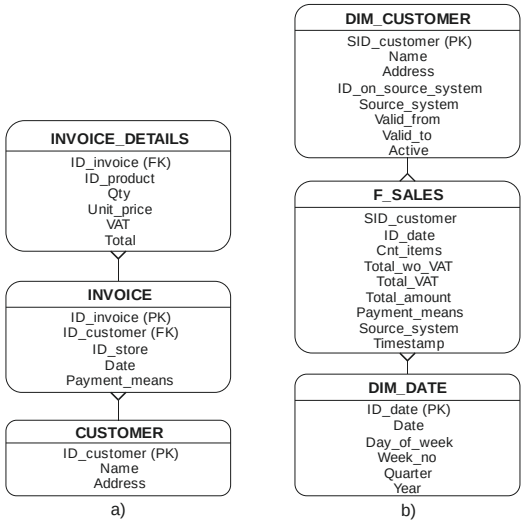

Figure 3. Model of source and target tables

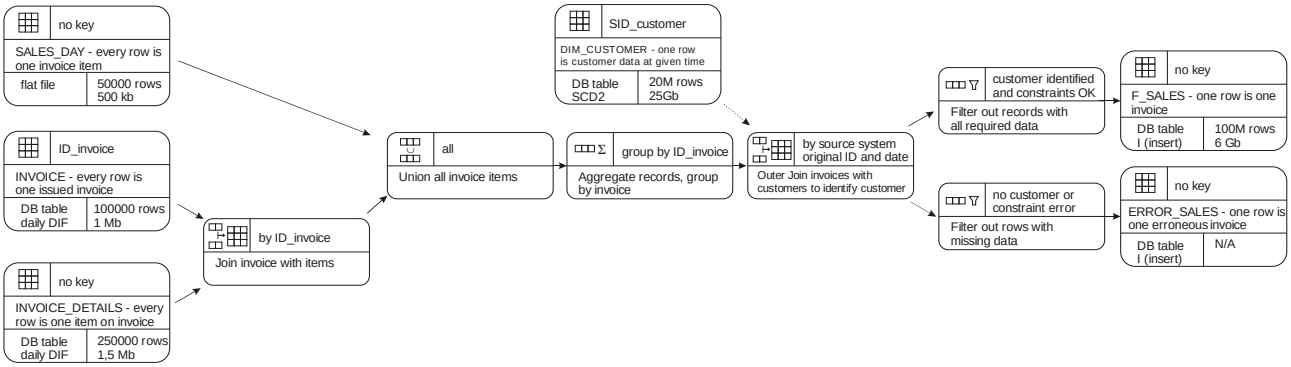

Figure 4. Visualizing the data flow of ETL process

done by series of filters and lookup can be done by outer join.

After visualizing data flow, it should be possible to decompose it to a series of sentences, going from one transformation to the other and combining the type of transformation, key and description, which combined tell a "story" of data record transformations. At that moment we have a description of the entire process which can then be communicated between ETL architects, developers, business users and other groups or individuals of interest.

During the ETL process, the transformation of attributes also takes place and should be included on the conceptual model. We propose that the attributes be shown in an additional table, so that the visualization remains simple and readable even if tables have a large number of columns. We create tables by starting from target requirements and requested data types, then map the attributes to source tables, try to describe the meaning of an attribute, describe how is it calculated and specify basic data quality rules.

IV. MOTIVATING EXAMPLE

We illustrate the usage of the proposed conceptual model through a motivating example.

Suppose we have a situation in the source system as shown in Figure 3a and we want to create a DW fact table of invoices which is connected to the customer and date dimension shown in Figure 3b. Let's assume that we get the data from two channels, sales in stores are recorded in the database system and loaded directly from it and online sales are in a flat file. Customer dimension tracks customer records and their historical values as separate rows (SCD type 2) and date dimension contains information about each date. We load the data daily, during the batch window at night.

Visualization of the process is shown on figure 4. We are able to "tell the story" about this process by constructing pseudocode sentences, for example: The process reads invoices and invoice items for the current day from the database and joins them. Those invoices with invoice items are unioned with invoices and invoice items loaded from the daily flat file and aggregated, grouped by invoice. We join every invoice to identify a customer on the invoice. Invoices which have all the required data are written to F_SALES table and invoices without a customer or missing data are written to error table.

We have described a process of record transformation with visualization, but we still need to describe attribute transformations. Steps to fill out the table include collecting requirements of the target and filling the rest of the table with data as shown in Table 1.

V. CONCLUSION

In this paper, we proposed a method for conceptual modeling of ETL processes which contributes to simplification of complex processes by showing a simple visual overview of the process. This proposal arose from recognition of diverse needs in planning, development and

TABLE I. ATTRIBUTES DESCRIPTION

Attribute	*Data type*	*Source(s)*	*Description/Meaning*	*Calculation*	*Constraint*
SID_customer	number	-	surrogate key of customer in DWH	-	not empty
ID_date	number	-	surrogate key of date in DWH	convert date to yyyymmdd format	not empty
Cnt_items	number	invoice_details, flat file	count items on invoice	count items on invoice	not empty
Total_wo_VAT	number	invoice, flat file	total amount without VAT	sum amounts without VAT	not empty
Total_VAT	number	invoice, flat file	total amount of VAT	sum VAT	not empty
Total_amount	number	invoice, flat file	total amount paid	sum total amounts	not empty
Payment_means	text	invoice, flat file	means of payment (e.g. cash, check)	-	not empty
Source_system	text	-	from what system the data arrived	-	not empty
Timestamp	date+time	-	date and time of entry in DWH	-	not empty

maintenance of ETL processes, all of which requires significant resources, time and money. It is estimated that the ETL processes take more than half of the budget for development and maintenance of data warehouses, but the standard for the ETL conceptual model has not yet been agreed upon.

The proposal meets the requirements of being able to easily present the process so it can easily be read, quickly developed, efficiently maintained and optimized according to the requirements of business users, overall ensuring minimal time is spent for understanding either new-to-be-developed or existing process. Simple and clear overview of the process supplies developers with the big picture and prevents creation of multiple processes that repeat data transformations and increase the total time required for ETL.

The key aspect of this model is that the data flow containing records transformations is separated from attribute transformations. Data flow is visualized and represents records by their keys, while the attributes are described in an additional table, so the visualization is not affected in the case of complex tables with 100 or even more attributes.

Further research on this topic may include addendums to the model in accordance with the conclusions that can arise after using the method on a higher number of ETL processes. Also, practitioners and researchers recognize a need for a way to simplify representation and exploration of the origin of data in the DW (data lineage). Conceptual model could offer a solution to that need. One of the challenges is the automatization of mapping conceptual models to logical models and maintaining the conceptual and logical models up to date and synchronized with the physical model. We believe it would be useful to develop software that would allow the design of models, as well as display of information that are of interest to all stakeholders – ETL architects, developers, business users and other stakeholders.

Abstract – UNDERSTANDER is an exploratory R&D project investigating Business Intelligence (BI) as a knowledge-gathering tool for supporting innovation processes in specific industrial domains. We develop a knowledge-based model that is grounded on the following three concepts: (i) Business Intelligence Model (BIM) developed by a Canadian project for BI technologies, (ii) taxonomy of Competitive Intelligence (CI) developed by CI practitioners, and (iii) Conceptual Dependency (CD) theory dealing with verb-oriented organization of knowledge. We also investigate whether knowledge-based models can be made adequate for the problem of gathering BI from web resources. Such a knowledge model can be used to "prime" a software agent and the agent can then search autonomously for relevant information on the Web. To express the interaction between agents, we consider "mechanism design", which is a framework for designing interaction between self-interested agents to achieve specific outcomes. A BI Seeker is a multi- agent application developed in WADE. (Workflows and Agents Development Environment). WADE is an extension of JADE, a popular Open Source framework that brings workflow mechanisms to agents. We present the design of the BI Seeker as an application in the field of Industrial Internet.

I. INTRODUCTION

Knowledge representation and understanding is a prerequisite to any form of intelligent behavior. Business Intelligence (BI) applications are expected to gather new knowledge that can be used to innovate a firm's current manufacturing process. Hence, our motivation in UNDERSTANDER is to employ the BI Seeker as a knowledge-gathering tool with the focus on improving industrial innovation processes.

In this paper, we present our approach to the design and implementation of the BI Seeker's knowledge model and its internal logic. The knowledge model is based on a controlled vocabulary and taxonomy of terms for BI and Competitive Intelligence (CI), and is organized in the form of "scripts" as envisaged in Conceptual Dependency (CD) theory. The agent has to recognize such scripts when encountering a relevant web resource.

Our motivation for the approach taken in UNDERSTANDER goes back to classical AI models and theories. Hence, we explore the core of Schank & Abelson's CD theory that deals with the verb-oriented organization of knowledge [1]. We implement our knowledge model in SWI-Prolog, which provides a stable execution environment for knowledge representations with actionable semantics. SWI-Prolog is also capable of providing Web Services, and generating HTML pages dynamically, as well as providing data for web applications (c.f. http://www.swi-prolog.org/web/).

Section II discusses related work in BI and CI. Section III presents the basic concepts of the BI Seeker's knowledge model: (i) Business Intelligence Model (BIM), (ii) a taxonomy of CI developed by practitioners, and (iii) CD theory. Section IV describes the implementation of our knowledge model through integration of its basic concepts. Section V introduces the BI Seeker's internal logic, which utilizes mechanism design and preference aggregation for agents. Section VI shows our scenario, which employs the knowledge model in the field of manufacturing of home heating systems. Section VII presents the BI Seeker and its multi-agent environment developed in WADE. Section VIII concludes the paper.

II. RELATED WORK IN BI AND CI

The term BI was introduced by Hans Luhn, IBM researcher, in [2]: *"...[business] intelligence system… utilizes data-processing machines for auto-abstracting and auto-encoding of documents and for creating interest profiles for each of the "action points" in an organization. Both incoming and internally generated documents are automatically abstracted, characterized by a word pattern, and sent automatically to appropriate action points."* In a period between 1958 and 1989, only a small number of papers on BI were published. In 1989, Howard Dresner (Gartner analyst) proposed using BI as an umbrella term to describe "*concepts and methods to improve business decision making by using fact-based support systems"*. From 1989, Gartner's definition of BI became widely used as the primary definition [3][4][5][6].

Nowadays, BI is defined as data technology that gathers and stores data, analyses data and delivers information (and knowledge), facilitates reporting, querying, and allows organization to improve decision making [7][8][9][10][11][12][5]. BI can also be defined as the process that transforms data into information, then into knowledge [13]. BI is rooted in the Decision Support Systems (DSS), but is also associated with Knowledge Management (KM) and CI [7][14][11][5][15].

The authors in [16] differentiate between three BI approaches:

- **the traditional BI approach** - it is concerned with data aggregation, business analytics, and data visualization [8][17][5].
- **the business processes approach** - it is focused on the integration of BI into business processes [18][13][5][6].
- **the adaptive BI approach** - this is concerned with BI for self-adaptive systems [9].

Novel BI tools apply semantic search and analytics technology (e.g. Oracle Social Engagement and Monitoring Cloud Service for capturing consumer "considerations and preferences" as well as insights from consumer-generated content in social media automatically [19]. Some solutions use keywords to analyze information, while others rely on Natural Language Processing (NLP) to disambiguate content. Some efforts have already resulted in standards such as OMG's Business Process Modeling Notation (BPMN) [20].

BI is closely related to CI and Knowledge Management Systems (KMS) [7][11][12][5]. Negash in [11] presents CI as a branch of BI, and refers to it as *"a systematic and ethical program for gathering, analyzing and managing external information that can affect company's plans, decisions and operations"*. CI is concerned with gathering information and analysis of the behavior of competitors on the market. The authors in [21] summarize a set of "measures of effectiveness" (MOEs) that had been previously developed and used by professionals in the commercial IT field, and reapplied those measures for the purpose of CI.

Regarding CI technology tools used so far, the authors in [22] refer to the Global Intelligence Alliance (GIA) survey given in [23] as the basic reference on CI organizations, activity areas, tools, education, and challenges. To analyze information, most companies use competitor analysis and SWOT analysis. Other tools cover financial analysis, profit and loss analysis, industry analysis, customer segmentation, etc.

Finally, the tools and methods of CI, BI, KMS, and AI need to be integrated *"to provide value-added information and knowledge toward making organizational strategic decisions", as* the authors in [14] and [16] agreed. In UNDERSTANDER, we share that view and combine several technological approaches to assess their potential synergies and economies of scale.

III. UNDERSTANDER KNOWLEDGE MODEL: BASIC CONCEPTS

The UNDERSTANDER knowledge model relies on three technology pillars: (i) BIM model, (ii) CI taxonomy, and (iii) CD theory.

The authors in [24] stated: although BI systems are widely used in many companies, data still remains trapped when it comes to their analysis and interpretation. The main reasons for that are the following: *"(i) Systems are still very technical and data-oriented, (ii) It is hard to understand what the data means, (iii) It is hard to design queries or make new reports without technical knowledge or a knowledge of the underlying data structure, (iv) There is still gap between business and IT-supplied data."* The gap between "business" and "data" is the greatest factor in the cost of applying BI technology, which remains the greatest barrier to the overall adoption of BI technology [25]. This motivated the research of Mylopoulos and his team to raise the level of abstraction of BI systems through a modeling language that emphasizes concepts more familiar to business, i.e. strategic models, business models and strategies, business processes, markets, trends and risks. The result is called the **Business Intelligence Model (BIM)**, which became a part of the Canadian BI Network project (c.f. http://bin.cs.toronto.edu/home/index.php).

In addition to BIM, we adopted **taxonomy of CI** that is being jointly developed by CI analysts. The CI taxonomy is publicly accessible from: http://www.mindmeister.com/18753652/competitive-intelligence (password: editme).

Finally, **CD theory** is a theory about verb-oriented organization of knowledge proposed in [1]. It discusses representation of the meaning of natural language sentences in a way that facilitates the drawing of inferences from the sentences. In addition, CD introduces the idea of a canonical meaning representation without duplicating information; for example, (a) different words and structures may represent the same concept, (b) CD is meant to be a language-independent representation.

Lytinen et al. in [33] give a survey of the work of Schank & Abelson, and their successors. Here we briefly summarize the main aspects of the CD theory. Lytinen's survey points out that CD assumes a richly structured knowledge base and relatively simple processing rules. Intriguingly, Tom Gruber and his colleagues, scientists in the field of ontology engineering, systems for knowledge sharing and collective intelligence, took a similar approach when developing the SIRI speech-driven assistant that is used in Apple's iPhones. *"…Perhaps the most important common thread that connects the CD family of research is the assumption that* ***intelligence is knowledge-intensive****, rather than processing-intensive. If the representations used to perform a task are rich enough, then processing strategies traditionally associated with AI programs, such as search, become less important. The result is simpler processing theories which are highly dependent on a very rich, and highly organized, knowledge base."* [33]

IV. DOMAIN VOCABULARY BUILDING

As a result of integrating the above-described concepts in UNDERSTANDER, we build our domain vocabulary by combining approaches presented in BIM and CI taxonomies and we investigate the use of CD theory for representing knowledge and reasoning. Domain vocabulary building comprises the following steps:

- implementation of core BIM concepts and its relationships;
- implementation of core CI concepts and its relationships, plus their alignment to the BIM concepts and relationships;

- implementation of core CD concepts and its relationships, and their alignment to domain vocabulary built in previous two steps

A. Implementation of the BIM Taxonomy

BIM uses several existing languages and technologies for capturing business strategy [25]: Strategy Maps and Balanced Scorecards [26], OMG's Business Motivation Model [27], Dynamic SWOT (Strength, Weakness, Opportunity, Threat) Analysis by Dealtry [28], Goal models. In addition, BIM deals with the following reasoning techniques: Goal Model Reasoning, Probabilistic Decision Analysis, Reasoning with Indicators, and Hybrid Reasoning.

Abstract concepts for describing "things" in BIM are inspired by the DOLCE foundational ontology [29]. The intentional and social concepts are further adopted from the core concepts in Goal-Oriented Requirements Engineering [30][31]. In addition, the notion of influence is adopted from influence diagrams [32], which is a recognized decision analysis technique. Concepts related to SWOT analysis [28] and others have been adopted from OMG's Business Motivation Model standard [27].

BIM language semantics incorporates Description Logic (DL). It also allows for publishing generic BIM models as ontologies on the Semantic Web [24]. For example, the BIM formal definition is implemented in Web Ontology Language (OWL), and encoded in Protégé editor in the form of the **BIM Upper Level Ontology**. BIM is also intended to support the modeling and analysis of a business organization at both a strategic and a tactical level. It provides a set of constructs for modeling and analyzing a business context including intention, situation, processes, actors, influences, key performance indicators, and more [25].

In order to make use of the BIM Upper Level Ontology [24] in UNDERSTANDER, we further encode this ontology into SWI-prolog, by defining common components of domain vocabulary such as: classes (concepts), attributes (properties, features), relations, individuals (instances), function terms, restrictions, rules, axioms, and events. Relations are ways in which concepts and individuals relate to each other. Restrictions are descriptions of what must be true in order for some assertions to be accepted as input. Rules are statements describing the logical inferences that can be drawn from an assertion in a particular form. Axioms are assertions in a logical form that together comprise the overall theory that the ontology describes in its domain of application. Events represent the changing of attributes or relations.

Figure 1 shows the core BIM concepts represented as a knowledge hierarchy. For example, `Goal` (see Figure 1) is an objective of a business; `Situation` reflects internal or external factors influencing fulfillment of goals; `Indicator` shows performance measure of strategic activities, etc.

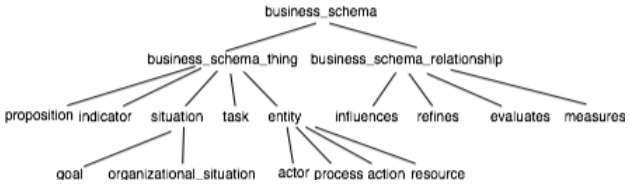

Figure 1. Knowledge hierarchy of the BIM

B. Implementation of the CI Taxonomy

The CI taxonomy consists of a "semantic cloud" of related concepts:

- **CI allied disciplines** – a list of relevant fields, e.g. market intelligence, knowledge management, etc.;
- **CI ecosystem** – considers the main elements of client/ vendor side, various organizations and associations;
- **CI decision support** – lists various decision support systems, i.e. strategy & portfolio, branding, etc.;
- **CI skills** - classifies existing approaches to applying CI e.g. researching CI or analytical CI.

Table 1 shows the alignment between the CI taxonomy and the BIM taxonomy. `CI ecosystems` classifies entities such as various clients (sales, marketing, library, etc.), vendors (small firms, major consultancies, etc.), organizations and associations. Hence, we align `CI ecosystems` (CI taxonomy) with the `Entity` class (BIM ontology). `CI allied disciplines` classifies common CI areas such as economic espionage, corporate security, market intelligence, etc. This information gives a more abstract view on previously defined entities, and can be expressed by adding to BIM, a new sub-concept of `Entity` called `EntityCategory`. In addition, `CI decision support` lists common ways of supporting CI, e.g. branding, go-to-market or customer analysis. Hence, we map this concept with the BIM's `Situation` concept. Finally, `CI skills` is the most important concept that lists various analytical tools and methods used to support enterprise, finance, evolutionary analysis, environmental analysis, etc. In order to encode this concept, we extend the BIM taxonomy by adding a new sub-concept of `BusinessSchemaRelationship`, namely `BusinessSchemaAnalyses`, which further includes sub-concepts such as `CIFinancialAnalysis`, `CIEvolutionaryAnalysis`, `CIEnvironmentalAnalysis`, `CIEnterpriseAnalysis`, `CICompetitiveAnalysis`.

TABLE I. CI AND BIM TAXONOMY ALLIGNMENT

CI Taxonomy	*BIM Taxonomy*	*Comment*
CI Ecosystem	`Entity`	
CI Allied disciplines	`BusinessSchemaThing/ Entity/ EntityCategroy`	`EntityCategory` is a newly added concept
Ci decision support	`BusinessSchemaThing/ Situation`	
CI skills	`Business Schema Relationship/ Business Schema Analyses`	`BusinessSchemaAnalyses` is a newly added concept

C. Implementation of Conceptual Dependency Theory

CD theory includes two core concepts: (i) CD primitives and (ii) CD conceptual categories. CD primitives represent semantics of possible actions, such as INGEST, EXPEL, GRASP, MOVE, PROPEL, PTRANS, ATRANS, MTRANS, MBUILD, ATTEND, and SPEAK. CD conceptual categories are *location*, *time*, *physical object*, etc. Encoding CD theory in SWI-Prolog requires defining its common components and their alignment to our domain vocabulary. The following table provides examples of the taxonomy alignment (at the schema level) between the core CD concepts and BIM taxonomy.

TABLE I. CD AND BIM TAXONOMY ALLIGNMENT

CD concepts	*BIM Taxonomy*	*Comment*
CD primitives	`BusinessSchemaThing/ Entity/ Task`	
CD conceptual categories/ PP	`BusinessSchemaThing/ Entity/ Actor`	PP stands for "picture producer", or "physical object"
CD conceptual categories/ ACT (action)	`BusinessSchemaThing/ Entity/ Action`	ACT (one of 11 primitive actions in CD)
CD conceptual categories/ LOC (location)	`BusinessSchemaThing/ Entity/ Location`	`Location` is a newly added concept
CD conceptual categories/ T (time)	`BusinessSchemaThing/ Entity/ Time`	`Time` is a newly added concept
CD conceptual categories/ AA (action aider)	`BusinessSchemaThing/ Entity/ Resource`	AA stands for "action aider"

Figure 2 shows the new BI/CI taxonomy, after merging the core concepts of BIM, CI and CD

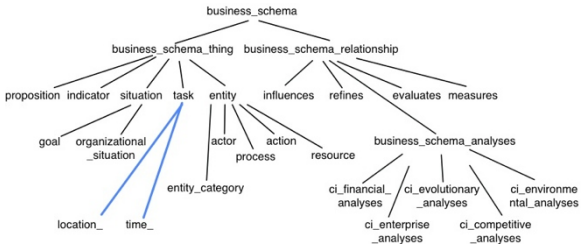

Figure 2. BI/CI concept hierarchy after merging BIM, CI and CD

The next task is to extend the generic BI/CI taxonomy by a specific domain vocabulary built e.g. for the home heating system scenario.

V. BI SEEKER – FUNCTONALITY DESIGN

Our knowledge model is to be used in an Industrial Internet application. At present, we consider two scenarios, one about 3D printing and the other about advanced home heating systems.

The BI Seeker's task is to find the most relevant business competitors and their commercial offerings. So the BI Seeker first searches for relevant web resources and then ranks them according to business criteria that can be set dynamically by making use of WADE's workflow mechanisms. In order to better assess competitors we employ an analysis technique known as mechanism design. Mechanism design looks at "*how preferences of several agents can be aggregated by a central designer"* [34]. *Note that mechanism design also addresses the issue of "strategic agents" (this means agents can even lie to others so as to maximize their individual payoffs), but we are not dealing with this case at present.* Thus, we are focused on designing preference aggregation mechanisms (ranking systems) to be employed within BI seeker, in the following real-world scenario.

VI. SCENARIO DESCRIPTION: CI FOR HOME HEATING TECHNOLOGY

We start with an introspective method to reach the following goal: *We want to know which firms are competing in the German speaking markets and what technologies they are selling. We are particularly interested in how they address the issue of integration into home automation systems. One possible approach is to first look for heater system manufacturers and then assembles a portfolio of technologies from their offerings. Another option would be to first look for technologies related to heating systems, and then look for manufacturers and their use of the technologies. The latter approach might yield more technologies than those currently on offer. Neither approach is likely to yield the specific issue of integration into home automation systems. On the contrary, we might be better off looking at pages about home automation in order to find those heating system manufacturers that are recognized as competent players in the home automation market.*

Our introspection will include the following steps:

- Step 1: Find competitors (manufacturer);
- Step 2: For each manufacturer, find types of heating systems (and relevant technology choices and developments);
- Step 3: For each manufacturer, search for offerings for home automation;
- Step 4: Find providers of home automation and what technologies and systems they are able to integrate into their solutions, and how.

VII. UNDERSTANDER MULTI AGENT ENVIRONMENT: THE APPLICATION

To perform the above steps, we develop a system of multi-agents that decide who are competitors in home heating systems technology and collect information about their technologies that are relevant for *home automation*. The question is how we can use our knowledge (domain vocabulary) to extract from the Web the information needed to compute the competences of manufacturers? How should we pool the preferences (findings) of several agents so as to best reflect the competences of competitors? To answer those questions, we employ our domain vocabulary, combining BIM, CI and CD concepts, to serve our system of multi-agents (BI seekers) as a knowledge reference.

BI seekers environment is implemented in WADE which supports the execution of tasks according to the workflow metaphor. One of the main advantages of WADE is in its workflow approach that brings the possibility of representing processes in a user-friendly graphical form. In addition, this approach utilizes the power of the Java programming language, and enables the usage of workflows for the internal logics definition that we use for the ranking of candidates.

Figure 3 shows the structure of our multi-agent system, which implements the scenario *BI Seeker for Home Heating Technology*. Here, we distinguish between two applications, namely the BI Home Heating Technology Application and the BI Ranking Application. The ***BI Home Heating Technology Application*** invokes a Web Service interface that collects the ranking results about specific companies, and/or their heating technologies, as input parameters. The ***BI Ranking Application*** finds both types of information by itself, and performs social ranking. A *Ranking Agent* is responsible for getting the user inputs and coordinating the ranking process, while a number of BI Seeker Agents correspond to the robots that retrieve the information about competitors in the field of interest (home heating systems, in our case).

All workflows that implement the relevant business logics to be executed by agents must be created in a separate module. Modules can be deployed at runtime, which allows hot-swapping of new business logics without the need to shut the system down and re-start it again.

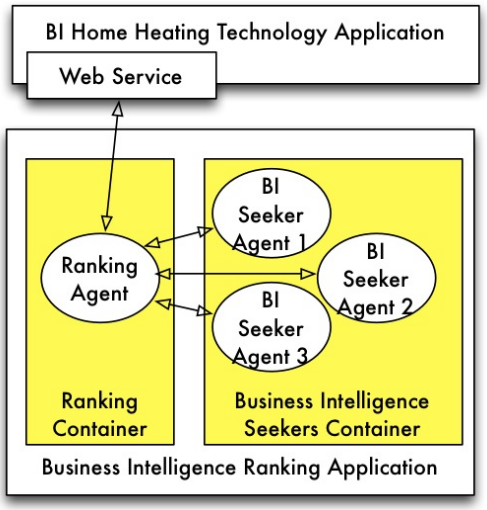

Figure 3. The structure of the BI Ranking Application

We now describe the social choice problem and its function in the context of our scenario. Let us consider a setting in which the set of agents is the same as the set of outcomes (see Figure 3 to figure out the relation between the agents and their strategies, and the outcomes).

Agents are designed as web crawlers with an internal ontology as described before (knowledge model presented in Section IV). Their task is to search for terms related to "*Heizungsanlagen*" (Heating Systems, eng.) (step 1 in the scenario). The agents are seeded with a number of web site URIs that either belongs to or point to, manufacturers of home heating systems. They gather publicly available information, which is then assessed against their ontology. In other words, we classify their technologies against an internal taxonomy of heating technologies (steps 2-4 in the scenario), and the agents then express their opinion about the importance of a particular heating technology (and manufacturer role), in order to determine a social ranking.

For the purpose of the first experimental setup, we investigate just three of the producers, one from Germany (*Buderus*), Austria (*KWB*) and Switzerland (*Elcotherm*). By firstly analyzing these three producers through humans we develop the agents' initial taxonomy of heating system technologies and components.

In order to perform ranking functionality, there exists a family of ranking algorithms. Ranking algorithms work by assigning agents numerical ranks that depend on the number of votes they have received, and breaking ties in favor of the agent who received a vote from the highest-ranked voter [13]. If this rule still yields a tie, it is applied recursively; when the recursion follows a cycle, the rank is a periodic rational number with period equal to the length of the cycle. At present, only the basic system is implemented and no performance testing has yet, taken place.

VIII. Conlusion and Future Work

In this paper we present our preliminary work on a multi-agent system that implements social choice and ranking functionality to perform BI/CI tasks in a specific manufacturing domain. More work is needed to really "understand" the nature of competitive assessment based on web resources.

Our work in UNDERSTANDER explores verb-oriented building of knowledge models as opposed to the prevalent, noun-oriented approaches. This approach has a potential to focus rather on the business service being provided, opposed to the business data being operated on. We are also aiming to provide an experimental context where our approach can be compared with and used by, Semantic Web and Linked Data technologies.

Acknowledgment

The research presented in this paper is based upon work supported by the UNDERSTANDER project (Austrian research grant 840230, awarded by FFG in the 2013 call for the "IKT der Zukunft" program).

Spend analysis systems

S. Maržić, P. Krneta and M. Pavlić
Ris d.o.o., Kastav, Croatia
{sanjin.marzic, perino.krneta, mile.pavlic}@ris.hr

Abstract – This paper introduces spend analysis, spend management and supplier management field. It describes the need for a spend analysis system, its' benefits and savings which such system can help to achieve. We present flowchart of spend analysis process in form of a dataflow diagram. We present main issues in development of a spend analysis software, and give an overview of current spend analysis systems.

I. INTRODUCTION

Usage of computers in business, development of information systems, development of programming languages and databases made businesses more efficient. Reporting is faster, richer in content, more accurate, many tasks are now automated. All of these technologies participated and are still participating in collecting large amounts of various (structured) data. There is data of company's core business, procurement, retail, human resources, revenues, spend. This data contains useful information and knowledge but to extract it one has to make various *ad-hoc* analyses over large volumes of data. Such analyses aren't feasible on transactional systems because these systems are optimized for daily work which consists of simple, predefined operations and predefined reporting. This problem was solved with data warehouses – data was periodically exported from transactional system into another database, optimized for complex analyses. In data warehouse data was additionally enriched (fulfilled) by data from other (external) sources to achieve better analyses.

During the 1980s in the USA a new need emerged – spend analysis [1]. This analysis had different requirements which couldn't be fully satisfied by data warehousing. In this analysis commodity and supplier data had to be treated differently. Spend analysis' goal is to reduce the company's expense by current expense analysis, supplier analysis, commodity analysis. Expenses are also reduced by centralizing procurement and supplier rationalization.

Spend management is a way for a company to control and optimize its expenses; it includes cutting operational costs as well as other expenses [2]. Spend management gives a company control over the money so that all business needs (manufacturing, delivering of goods and services) are satisfied in the most cost efficient way. Profit of a company is the difference between total incomes and total expenses, so profit can be augmented either by raising the income side or by reduction of expenses. In (current) period of financial crisis reduction of expenses is a common approach because the reduction of 1$ on expenses equals to raising incomes for 3$ [2].

II. SPEND ANALYSIS

Spend analysis is organization of expenses data (mostly procurement) and usage of supplier hierarchy and hierarchy of goods and services combined with amounts spent to:

(1) Find categories of expenses

(2) Find opportunities for strategic sourcing by gathering procurement requirements and supplier rationalization

(3) Reduce expenses with higher discounts (with contracts, volume discounts).

Finding categories of expenses implies categorizing goods and services (expenses) so that one can answer questions such as what was total amount spent on computer monitors. Transactional systems usually contain only data on specific purchase (e.g. specific model of computer monitor), but to answer mentioned question one should collect data of all purchases. For this kind of analysis a hierarchy of goods and services is required. This hierarchy will, for specific model of computer monitor, define that it is a monitor of specific size (e.g. 17' monitor), an LCD monitor, hardware element etc. Using such hierarchy analysis is possible inside and between categories, e.g. which category contains most expenses, how large is price range of products or services of same category. Such analysis can be used to detect corruption which can be manifested as big difference in price for products in same category. One of the existing hierarchies for categorization of products and services is UNSPSC (United Nations Standard Products and Services Code) [3]. This hierarchy was developed by United Nations and Duns & Bradstreet. In this hierarchy every product and service has a unique 8-digit code in format SS-FF-CC-DD where SS is 2-digit representation of segment, FF is family, CC class and DD commodity. Important features of UNSPSC are (1) simple drill-down and drill-up by using parts of code, (2) consistency which ensures that every element is defined in exactly one point in hierarchy, (3) completeness because all products and services that can be traded are included in hierarchy and (4) market tracking meaning that hierarchy is maintained as new products and services appear in the market.

Gathering procurement requirements enables enlargement of single procurement orders and reduction of total number of orders (by connecting smaller orders to the same supplier into larger ones or connecting orders for

similar products or services). With larger orders company can get better procurement conditions and lower prices. **Supplier rationalization** implies creating supplier hierarchy. With this hierarchy expenses and procurement data can be categorized and company can define which suppliers are preferred and which are not. Supplier hierarchy defines which suppliers (that appear in transactional system) are parts of the same company (e.g. offices of the same company or multiple records for the same company) or are connected in some other way. With supplier hierarchy the real expenses towards some supplier can be determined (in contrast to expense towards an office of a supplier). By combining supplier hierarchy with products and services hierarchy questions like "how many suppliers are supplying some product category" and "how is the expense in some product category distributed over suppliers" could be answered. With this data, available **expenses can be reduced with higher discounts** by reducing the number of suppliers for a product category. Thereby the expense towards remaining suppliers would enlarge which creates better negotiating position for getting higher discounts. By detecting undesirable (not preferred) suppliers costs with them can be lowered and transferred to other suppliers (which can lower risks and raise quality).

A. Who needs spend analysis?

Not all companies have the need for spend analysis and there are several reasons for that: spend analysis software is usually very expensive and therefore not applicable for small companies and such companies don't even have the need for spend analysis since their procurement is often centralized and not very large in volume, so it can be analyzed without software. Companies that can benefit from spend analysis are the ones that are physically dislocated, without central procurement, with multiple procurement centers. The fact that some company is physically dislocated is not enough for it to need spend analysis: e.g. a retailing company with multiple supermarkets won't be interested in spend management software because, although it has multiple supermarkets, it has central procurement and all procurement data at one place. On the other hand city administration could be interested in spend analysis because a city usually has several communal companies which are financed from the same city budget, but have independent procurement. Since each company is autonomous in procurement substantial savings can be done by gathering the procurement requests. Also, corruption can be detected by comparing the prices for similar products.

B. Savings

A question that can be asked is: what kind of savings can be expected after implementing spend analysis and in which areas of business?

Table 1 displays possible savings (in percentage) by categories. Such savings are possible with commitment to advanced purchasing methods (e.g. e-sourcing, e-auctions) [4]. All savings are achieved in one of three ways [1]:

- Strategic sourcing – finding the strategic suppliers and reduction of supplier number to achieve discounts and raise quality (quality is raised by choosing the right supplier)
- Reduction of maverick spend by choosing (contracting) suppliers and improvement of business processes (e.g. internal guidelines for procurement)
- Avoiding of spend leakage by controlling suppliers' compliance to contract terms.

TABLE I. POSSIBLE SAVINGS WITH COMMITMENT TO ADVANCED PURCHASING [4]

Category	Saving
Raw materials	2-5%
Packaging	10-20%
Indirect materials and services	10-20%
Information technology	15-30%
Professional services (including consulting, legal human resources)	8-15%
Capital projects	7-15%
Other indirects (nonproduction costs)	5-15%
Media/marketing/promotional items	10-20%
Logistics (rail, truck, barge, ocean, air)	7-15%

Third method is especially important because a part of savings that were negotiated and agreed to can be lost without control of compliance. All three points should be continuously repeated to achieve continuous savings.

Data in table 1 is relative to full amount spent per category, specific amounts can be estimated with amounts of total expenses for each category. Since savings are expressed as percentage, saving of 2% for raw materials can seem like an insignificant saving, but actually it is the largest saving for production business systems since raw materials in those systems are carrying the largest part of total expense. Larger percentage for other categories can now seem like a much smaller saving but, as figure 1 depicts, it is not always so.

Total raw materials cost	1,000,000,000
Saving 5%	50,000,000
Indirect expenses, services	500,000,000
Saving 15%	75,000,000

Figure 1. Example of possible savings [4]

C. Specific advangates of spend analysis

Spend analysis software enables its users an overview of expense data for the entire company and reduces the need for additional data processing regarding reports and trend analysis. Specific advantages:

- Visibility of all expenses of the company
- Substantial improvement of data accuracy and consistency
- Improvement of analyses quality over time
- Reduction of time required for creating ad-hoc reports from up to two weeks to almost momentarily
- Reduction of maverick spend for additional savings
- Ability to perform data cleaning and create ad-hoc reports without need for permanently employed data extraction experts

- Reduction of administrational expenses for processing and controlling of procurement orders
- Fast identification of savings opportunities
- Additional savings by selecting suppliers and larger orders
- Savings by identification of contracting opportunities
- Elimination of overpaying the supplier and guarantee of rebate realization
- Continuous improvement of compliance to contract terms and savings by tracking contracted and real prices
- Reduction of procurements' depending on IT experts for supplying the expense data
- Removal of disagreements about data quality by introducing the "single truth" for spend data.

III. SPEND ANALYSIS PROCES

Spend analysis, as a process, is similar to the data warehousing process – both processes are based on ETLA process (Extraction, Transformation, Loading and Analysis).

Data extraction is periodical fetching of data from the transactional system, as well as from other relevant data sources, to make analyses up to date. Data can be fetched from sources other than databases, like user files, internet, etc.

Data transformation is the most important part of the spend analysis process (besides the analysis itself). Quality of analysis step depends on quality of data transformation. In this step transactional data is being normalized (conversion of currencies, units of measure) and brought to the common format (e.g. putting all address data in one field with specific ordering of data elements or dividing data to multiple fields). Another important segment of data transformation step, which distinguishes it from standard transformation in data warehousing, is building the products and services hierarchy and supplier hierarchy. Supplier hierarchy means connecting naturally connected suppliers (e.g. branch offices with head office or duplicate entries) so that it is easy to determine total spend with some supplier and not with e.g. its branch offices. Products and services hierarchy is development of multilevel hierarchy which will allow analyzing spend on multiple levels. E.g. management will be interested in general spend distribution and IT department will only be interested in subcategory of IT equipment expenses and will analyze more closely its sub-categories. Duplicate entries are detected and merged, business data is being cleaned. Part of this step is also data enrichment: missing data is being filled and external sources are being used (e.g. stock market data, supplier financial data). Since there is no perfect classification algorithm (for classification of suppliers and products) there must be an option for user to correct the results of data transformation. Data of users' interference to transformation results should be used to make future transformations more precise.

Data loading is loading the transformed data into a database optimized for spend analysis.

Data analysis is step where reports are created using the transformed data. Analysis, as with data warehouse, must enable the user to perform slicing & dicing, allow multidimensional and hierarchical view on data. Visualization is very important element of analysis; it should be able to work with large set of data efficiently.

Figure 2 depicts a model of the process described. Diagram was drawn according to DFC (data flow chart) method [5, 6]. Figure 3 depicts data transformation sub process.

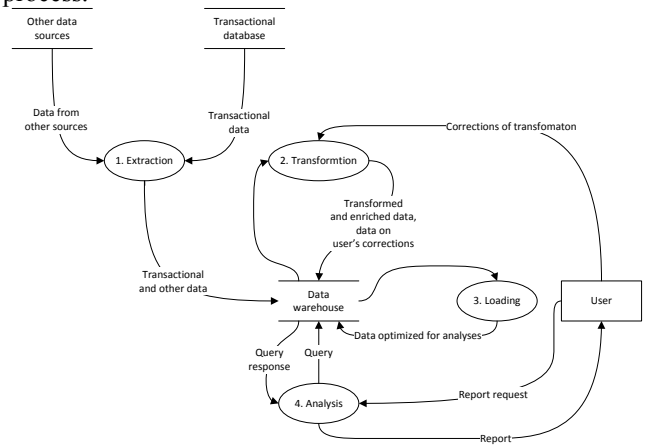

Figure 1. Spend analysis proces

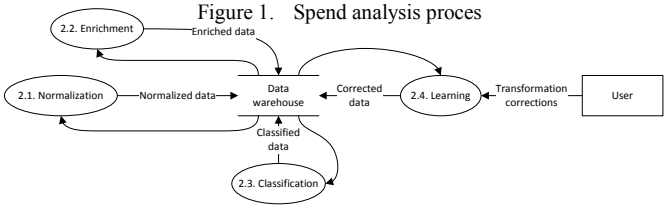

Figure 2. Data transformation process diagram

IV. SUPPLIER MANAGEMENT

Supplier management or supplier performance management is a process that consists of measuring, evaluating and controlling over suppliers' work, his business processes and habits with objective of reducing costs, lowering risk level and continuous progress [7].

Supplier management can be viewed as a business relation management for improvement of duplex understanding flow between a company and its suppliers, which especially concerns communication and negotiation about requirements and supply chain performance expectations [7]. Supplier management can include quality of delivered products and services, well-timed delivery, reliability of delivery (delivery of correct product in right amounts), adaptation to request changes, availability of required amounts of products or services when needed etc.

Supplier driven costs, or costs of poor quality (COPQ), can be divided into four groups [7]:

- Preventive expense – cost of actions that have to be performed to prevent appearance of bad products or services (work procedures, rules, planning, training)
- Evaluation expense – testing cost, evaluation or quality estimation cost
- Internal error expense – costs of low-grade products repairment (i.e. re doing the job)
- External expense – user support costs, dealing with customer complaints, loss of contracts (and reputation)

Low quality products and services costs are estimated to hold 10-25% of total sales, in that amount there is 25-75% cost produced by low supplier quality (2.5-18.75% of total sales) [7].

Low supplier quality costs are also affecting users by increasing price of company's products and services. Cost of low supplier quality rises with time needed to detect it. If problem is detected before the product is being used it can be rejected or returned to supplier which is the lowest cost; if, on the other hand, problem gets detected by the customer there are additional costs of customer service, complaint processing, returning the product, customer compensation and dealing with the returned product.

A good example of costs generated by using low quality product is cost of unusable X-ray image (table 2) [7]. Costs generated by one unusable X-ray image are paid time of technician and nurse who have to repeat the procedure, material expenses (new image, development materials, machine usage) and there is also a delay (and possible rescheduling) of the medical care that can't be given before usable X-ray image is taken. If such mistake happens five times per day and the cost of one error is evaluated to 33$ we get annual expense of 66,225$.

Information about total expense of low supplier quality is important because it helps prioritize such problems.

TABLE II. LOW SUPPLIER QUALITY EXAMPLE [7]

Element	Price
Technicians' time (30 minutes)	4$
Nurses' time (30 minutes)	9$
Film	7$
Development material	2$
Machine mainteanance	1$
Medical care delay	10$
Total price of one unusable image	**33$**
Annual expense (5 unusable imager per day, 365 days)	**66,225$**

V. SPEND MANAGEMENT SOFTWARE

First steps in spend analysis happened in 1980s, first spend management software appeared in early 2000s.

A. Properties of ideal spend analysis software [1]

In an ideal case spend analysis software would have the following elements:

1. Data selection and loading
2. Data cleaning, structuring and enrichment
3. Spend analysis
4. Knowledgebase management

Data selection and loading includes making a decision which data is going to be analyzed – what data is needed for spend analysis. With definition of necessary data, all data sources are defined [1]. Since data is fetched in a common database schema it should be brought to a compatible form, as data is arriving from heterogeneous sources. Data can be imported from different platforms, different databases, different file formats (Excel files, delimited files, etc.) [1].

Data cleaning, structuring and enrichment should have features:

1. Web oriented application with administrative and limited access – in cases where enrichment team is distributed each user should have access to specific products and services to prevent accidental (or unauthorized) change of data outside his/hers area of expertise
2. Data cleaning and enrichment – defined procedures for supplier data enrichment, classification of expenses (products, services), mechanism for conflict resolution. Expenses are classified by using rules (e.g. for supplier IBM expense is categorized as IT), these rules can be defined by an expert or by using computer learning algorithm. There can be a conflict set within set of rules (several rules with different outcome which can be activated in the same moment) so conflict resolution mechanism must be defined.
3. Defining and maintenance of hierarchies and dimensions – hierarchical schemes of products and services, supplier hierarchy, cost centers database are under continuous development so there must be one or more administrators for all these schemes, users should have limited authority over schemes and their parts to assure proper development of schemes.
4. Job scheduling – in large databases jobs can take a long time to complete, jobs should be well scheduled to assure the best system performance.
5. Import of end-user feedback – to improve system over time all feedback information should be collected to help in development of new rules based on collected information.

Spend analysis should have properties and functions:

1. Web-oriented application with administrative and limited privileges
2. Specialized data visualization tools
3. Reporting and dashboards

4. Sending feedback for changes in dimensions and hierarchies
5. Sending feedback for changes in classification
6. Immediate update of new data
7. *What-if* analyses

Knowledge base management means collecting data of user activity and to have an ability to learn upon collected data. System learns based on every action end user performs, so it should have ability to record every click of every user. Based on this information system can substantially improve its classification accuracy because it collects the data specific to user's industry. Knowledge database should have a lexicon to store data on three types of entities – concepts, instances and relations. Concepts are abstract terms (nouns, attributes, units of measure). Instances are descriptions of actual objects (e.g. "Dell 17' monitor"). Relations are structural and semantic links between concepts. Relations contain information on how concepts can be connected, which concepts are e.g. synonyms. Knowledge database is used in expense classification – the larger and more complete the lexicon is classification gets more accurate. Knowledge database management is an important task in spend analysis, there has to be a possibility to track changes in the database and to define a process for making changes, users who will have privilege of changing knowledge database.

In following sections some of the existing spend analysis applications are described.

B. Ariba

Ariba [8] is German software manufacturers founded in 1996, specialized for development of spend analysis software, contract management software, supplier management software. Their spend management application is "Ariba Spend Analysis". This application is used in software as a service model (SaaS). In 2012 Ariba was acquired by SAP.

Data imported into application is enriched with data from Dun & Bradstreet database (D&B). It is an American company that collects data on other companies to improve decision making, supplier chain management. Data is also enriched with data regarding ecology of business, company relations, and risks.

Properties of application that manufacturer points out is that it enables comparison with similar companies in the same industry; it enables predictive analyses and *what-if* analyses, classification (of products and services, suppliers) in predefined hierarchies or user defined hierarchies. Project manager is assigned by Ariba to every client.

C. Bravo Solution

Bravo Solution [9] is Italian spend management software manufacturer. The application "Bravo Solution Spend Management" is their application for spend management; as with Ariba, it is offered in SaaS model.

Properties of application that manufacturer points out is possibility to use multiple hierarchies to classify expense data, user can define their own hierarchies. Expenses are classified based on rules and classifiers trained by machine learning algorithm based on previous decisions. In supplier classification D&B database is being used as well as comparison to other available supplier attributes.

D. CVM Solutions

CVM Solutions [10] is supplier analysis software manufacturer. They are collecting supplier data so that suppliers themselves are supplying specific documents and reports, CVM Solutions are checking this data with public and closed sources and are continuously monitoring changes in supplier data. In this way they've collected a large volume of supplier data, so their service is supplier data cleaning (removing of multiple entries for same supplier, linking suppliers that are naturally connected), supplier data enrichment, analysis and control of company's suppliers and warnings in risky situations.

E. Applicability to Croatian (regional) circumstances

In Croatia and surrounding states there is not a great number of large companies which have the need for spend analysis, so spend analysis and management is not a developed field in the region. Above mentioned software is partially applicable to local companies because of several reasons: (1) D&B database and CVM Solutions database contains none or very small volume of data on regional companies so this data can't be used in supplier data cleaning; cleaning can only be done by record comparison, (2) mentioned solutions don't mention if their application interface is translated to Croatian language (or any of regional languages). In product classification some applications state that stop-words are used (words that don't contribute to the meaning of the statement and are ignored in text analysis, e.g. conjunctions, prepositions, articles), English stop-words aren't applicable to other languages so for Croatian and regional languages a research should be conducted to retrieve a list of such words. Another aspect that manufacturers aren't stating publicly is their software price. Since their customers are large corporations (they reference AT&T, Dell, Cisco, McDonalds, Mitsubishi), software price can be high because for these companies it will pay off with savings they will achieve. In region there is not very large number of large multinational companies, so their savings won't be so large; this is why software price will be a significant factor.

Existing software solutions are applicable to regional companies, but it can't be expected to give as good results as they achieve in "English speaking" companies. In Croatia a project MaxyTransparency [11] is started to develop a software solution that will be adjusted to language(s) and specific need of regional market.

VI. SPEND ANALYSIS ISSUES

In previous sections we've introduced spend analysis, requirements and causes of appearance, properties of an ideal software application and examples of existing

solutions. In development of a generic software application for spend analysis (or introduction of spend analysis to a business system) there are several issues (question) that have to be solved in different phases of the process. These issues and questions are displayed in table 3.

TABLE III. SPEND ANALYSIS ISSUES PER PHASES

Data extraction	
Refresh period	How often data extraction from transactional system has to be performed (weekly, monthly, once every quartal, yearly)? How recent analysis have to be? Should some data be imported more often?
Size of extraction	What data will be extracted/imported? Only new data or entire database will be refreshed? How to distinguish old and new data? How to recognize what data is already imported, but was changed meanwhile? Are some changes on transactional system required to optimize extractions? What data is allowed to be extracted? (important issue for demonstration of spend analysis power/ROI because real possibilities cannot be shown with missing data)
External sources	Which external sources will be used? How often? What is their price? How reliable/relevant are that sources?
Data transformation	
Product and services classification	How will products and services be classified? Which (how many) schemes will be used? How is the classification going to be performed? Which algorithms will be used?
Supplier hierarchy	How is the supplier hierarchy going to be built? How to detect/remove multiple records for the same supplier?
Data enrichment	What data will be used for data enrichment? (reliability of sources, relevance of sources, cost of this data)
Learning	How to improve future classification based on users interaction? Which algorithms will be used? How to train initial model (on what data)?
Errors	If an error is detected in data should source be corrected as well?
Data loading	
Schema	What schema (model) will be used? OLAP cubes are precalculating "answers to all questions", but for price of long refresh time and cubes are unable to give the *what-if* scenario analysis. Relational models, such as dimensional model, are faster in refresh, but queries take longer to execute.

Additional issues are present for spend analysis applications in regional circumstances. Some of reasons are language specificities (e.g. multiple word forms), writing specificities (special characters, often misuse of letters *č* and *ć*, replacements of *č* and *ć* with *c* or *đ* with *dj*). Spend analysis for companies that primary use English language can use results of numerous researches in natural language processing while in Croatian language and regional languages this research it is not possible because lack of interest for development of this area. There are no researches or tagged corpora for supplier (or products) matching model training.

Special problem is also to persuade companies that, if they are cohesive units, it is good for them to connect in unified procurement system to gather suppliers and products into a single supplier management system and usage e-supply (e.g. mutual e-auctions).

VII. CONCLUSION

In this paper we've introduced spend analysis. We've displayed expected results of spend analysis application usage and also given examples of losses, which happen without noticing, that occur when spend analysis is not applied. Process of spend analysis and supplier management is described. We've given list of features that software application for spend management should have. Also, we've analyzed usability of existing spend analysis applications on regional circumstances and identified issues that should be resolved in development of a spend analysis system.

Implementation of spend analysis system is recommended in every larger organization, public institution or private corporation, especially with large competition, lowering of income and market crisis. Spend management system can produce better results in combination with e-procurement system and supplier management system. E-procurement system helps the procurement sector; in combination with results from spend management system enables the procurement to focus on products and suppliers where most of savings can be achieved. Supplier management system holds an up-to-date supplier database, their products and services which are being used by both spend management system and e-procurement system. Such database can be created by joining several consumers and suppliers in single network: consumers can use it as an e-commerce system and suppliers as a platform for placement of their products and services.

One of suitable areas for implementation of these three systems is public sector (e.g. Republic of Croatia) and we hope that such system will be developed in near future.

ACKNOWLEDGMENT

The research has been conducted under the project "Extending the information system development methodology with artificial intelligence methods" (reference number 13.13.1.2.01.) supported by University of Rijeka (Croatia).

Poslovna inteligencija u sustavu informacijskog posrednika za elektronički račun

Danijel Matić*, Damir Kalpić**, Alan Čičak *
* InfoDom d.o.o., Zagreb, Hrvatska
** Sveučilište u Zagrebu Fakultet elektrotehnike i računarstva, Zagreb, Hrvatska
danijel.matic@infodom.hr, damir.kalpic@fer.hr, alan.cicak@infodom.hr

Sažetak - Elektroničko poslovanje je izvršavanje svih elemenata poslovnih aktivnosti ekonomskog procesa elektroničkim putem, odnosno stvaranje dodatnih vrijednosti koristeći se ICT tehnologijama. Informacijski posrednik je fizička ili pravna osoba koja u ime drugih obavlja otpremu, prijem i prijenos elektroničkih dokumenata.

U radu će biti prikazana upotreba poslovne inteligencije unutar sustava informacijskog posrednika za elektronički račun. Sustav služi za razmjenu prvenstveno elektroničkih računa, ali i za razmjenu ostalih dokumenata u elektroničkom obliku. Poslovna inteligencija je dio sustava informacijskog posrednika koji omogućava praćenje i upravljanje poslovnim procesima informacijskog posrednika. Primatelji elektroničkog računa mogu pratiti iznos troškova iz primljenih e-Računa te imaju uvid u strukturu troškova. Izdavatelji elektroničkog računa imaju uvid u uspješnost odvijanja poslovnih procesa isporuke e-Računa. Potporne službe informacijskog posrednika kroz sustav poslovne inteligencije nadziru odvijanje svih poslovnih procesa unutar sustava.

I. UVOD

Elektroničko poslovanje je oblik poslovanja koji prilikom transakcija i razmjena informacija koristi informacijske i komunikacijske tehnologije između sudionika u poslovnom procesu. Cilj je elektroničkog poslovanja automatizirati poslovne procese čime se smanjuju troškovi i povećava efikasnost. Elektroničko poslovanje pokriva poslovne procese cijelog dobavnog lanca.

Najraširenija elektronička isprava u svijetu je elektronički račun. Račun sadrži informacije koje su potrebne za fakturiranje. Podaci o računu mogu se koristiti za analizu poslovanja.

Poslovni partneri mogu u međusobnom poslovanju ugovoriti elektronički razmjenu poslovnih dokumenata. Fizička ili pravna osoba koja u ime drugih obavlja otpremu, prijem i prijenos elektroničkih dokumenata naziva se informacijski posrednik.

Informacijskim posrednicima neophodno je posjedovati pravovremene i relevantne informacije o svim aspektima poslovanja i odvijanju poslovnih procesa. Informacije je moguće brzo i jednostavno dobiti korištenjem poslovne inteligencije u sustavu informacijskog posrednika za elektronički račun.

Poslovna inteligencija (engl. Business Intelligence – BI) temelji se na podacima, koji se transformiraju u informacije potrebne za upravljanje i odlučivanje.

Sustav poslovne inteligencije u sustavu informacijskog posrednika treba osigurati da se podaci prikupljaju, transformiraju, skladište, kombiniraju, strukturiraju i čiste te treba osigurati kreiranje ključnih pokazatelja i izvještaja. Sustav poslovne inteligencije temelji se na skladištu podatka. Skladište podataka baza je podataka koja sadrži povijesne nepromjenjive podatke koji se prikupljaju i obrađuju radi potpore poslovnom odlučivanju [1].

Prema Kimballu [2] skladište je kopija transakcijskih podataka specijalno strukturirana za upite i analize. ETL (engl. *Extract, Transform, Load*) sustav je temelj skladišta podataka. Za unošenje podataka u skladište provode se ETL procesi. Dobro dizajnirani ETL sustav dohvaća podatke iz izvorišnog sustava, provjerava kvalitetu i dosljednost podataka, usklađuje podatke tako da se različiti izvori koriste zajedno i na kraju donosi podatke u prezentacijskom formatu koje pomoću aplikacija koriste krajnji korisnici za donošenje odluka [3].

Sustav informacijskog posrednika za elektronički račun sadrži važne podatke o poslovanju. Podatke je potrebno analizirati i pretvoriti u poslovne informacije koje se mogu koristiti za unapređenje i nadzor odvijanja poslovnih procesa unutar sustava informacijskog posrednika za elektronički račun.

Aplikacije koje pristupaju podacima BI sustava trebaju biti jednostavne i lake za uporabu, a informacije trebaju biti prikazane korisniku u najkraćem mogućem vremenu.

U ovom radu prikazana je upotreba poslovne inteligencije unutar sustava informacijskog posrednika za elektronički račun. U poglavlju II. opisana je generička arhitektura, funkcionalnosti sustava informacijskog posrednika i uloga sustava poslovne inteligencije unutar sustava informacijskog posrednika. U poglavlju III. izneseni su zahtjevi za implementaciju sustava poslovne inteligencije. U poglavlju IV predložen je dimenzijski model koji omogućava praćenje i upravljanje poslovnim procesima informacijskog posrednika. Izneseni su primjeri upotrebe BI sustava prilikom kreiranje izvještaja za različite korisnike sustava informacijskog posrednika.

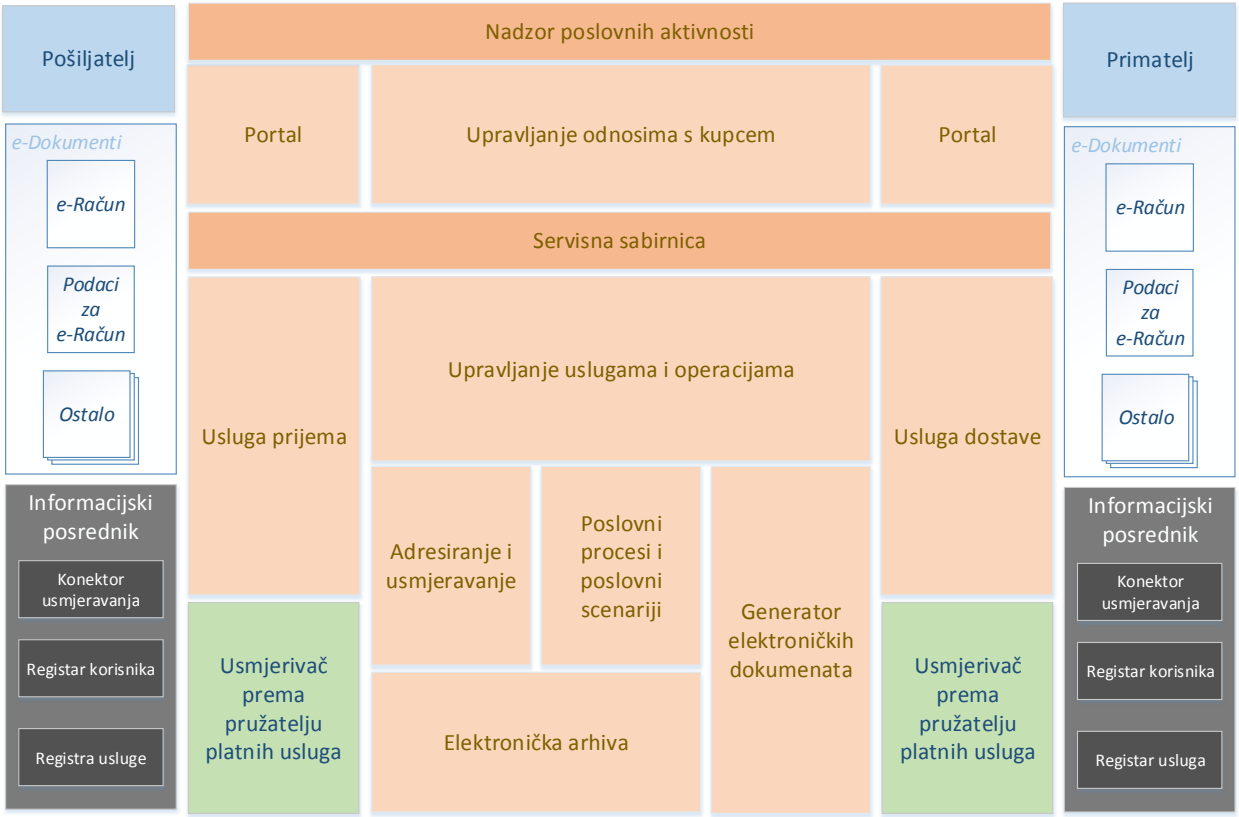
II. GENERIČKA ARHITEKTURA SUSTAVA INFORMACIJSKOG POSREDNIKA

U uvodu je spomenuto kako poslovni partneri mogu u međusobnom poslovanju ugovoriti elektroničku razmjenu poslovnih dokumenata i prilikom razmjene elektroničkih dokumenata mogu koristiti informacijske posrednike. Informacijski posrednik u ime drugih obavlja otpremu, prijem i prijenos elektroničkih dokumenata, odnosno realizira razmjenu elektroničkih poslovnih dokumenata. Informacijski posrednici osim razmjene elektroničkih dokumenta, obavljaju i funkcije elektroničke arhive, konverzije formata elektroničkih dokumenata, digitalnog potpisivanja i označavanje dokumenta elektroničkim žigom, izvještavanje korisnika, kreiranje elektroničkih dokumenata itd.

Generička funkcionalna arhitektura (slika 1.). implementira minimalni skup potrebnih funkcija za realizaciju poslovnih procesa informacijskog posrednika. Glavne funkcijske komponente sustava informacijskog posrednika za elektronički račun su:

- Nadzor poslovnih aktivnosti (engl. *Business activity monitoring* BAM) – funkcija nadzora uključuje sučelje putem kojeg se nadziru svi parametri funkcioniranja sustava od tehničke razine do razine poslovnih transakcija.
- Portal – dio sustava informacijskog posrednika čija je uloga pošiljateljima i primateljima omogućiti pristup informacijama vezanim uz proces isporuke, statusu predanih elektroničkih dokumenata, pregledu ugovorenih usluga i servisa. Funkcionalnost portala mora implementirati različite funkcije zavisno o profilu korisnika. Npr. privatni i poslovni korisnici, izdavatelji i primatelji i sl.
- Servisna sabirnica (engl. *Enterprise Service bus*) – predstavlja okosnicu sustava. Sve funkcionalne komponente koriste servisnu sabirnicu za međusobnu komunikaciju.
- Upravljanje uslugama i operacijama (engl. *Service Management & Operations*)
- Funkcija prijema elektroničkih dokumenata (engl. *Receiver Services*)
- Funkcija dostave elektroničkih dokumenata (engl. *Delivery Services*)
- Adresiranje i usmjeravanje (engl. *Addressing & Routing*)
- Poslovni procesi i poslovni scenariji (engl. *Business Processes & Scenarios*)
- Generator elektroničkih dokumenata (engl. *Electronic Document Generator*)
- Elektronička arhiva (engl. *e-Archive*)
- Usmjerivač prema pružatelju platnih usluga (engl. *Banking Gateway*)

U nastavku rada naglasak će biti na dijelove sustava koji koriste poslovnu inteligenciju.



Slika 1. Generička arhitektura informacijskog posrednika

A. *Nadzor poslovnih aktivnosti i Portal*

Potporne službe informacijskog posrednika kroz Nadzor poslovnih aktivnosti nadziru odvijanje svih poslovnih procesa unutar sustava. Nadzor poslovne aktivnosti je softver koji se temelji na poslovnoj inteligenciji i uključuje agregaciju, analizu i prezentaciju informacija u stvarnom vremenu o aktivnostima unutar sustava. Nadzor poslovnih aktivnosti pruža uvid u poslovne procese, točne informacije o stanju i rezultatima raznih operacija, procesa i transakcija. Omogućuje identifikaciju problema i rješavanja istih. Osim praćenja poslovnih procesa, Nadzor poslovnih aktivnosti može slati obavijesti koje se mogu koristiti kako bi se upozorili donositelji odluka o promjenama u poslovanju za koje je potrebno nešto poduzeti.

Na portalu se korisnicima omogućuje pregledavanje različitih unaprijed definiranih izvještaja. Portali koriste sustav poslovne inteligencije za izvještavanje tako što rade upite nad skladištem podataka.

III. ZAHTJEVI NA IMPLEMENTACIJU SUSTAVA POSLOVNE INTELIGENCIJE U SUSTAVU INFORMACIJSKOG POSREDNIKA

Sustav informacijskog posrednika za elektronički račun sadrži važne podatke o poslovanju i odvijanju poslovnih procesa. Iz tih podatka sustava može se oblikovati skladište podataka, koje čini temelj sustava poslovne inteligencije.

Prema Kimballu [2] neka od obilježja sustava poslovne inteligencije su:

- BI sustav mora omogućiti lak i brz pristup informacijama.
- BI sustav mora prezentirati informacije dosljedno.
- BI sustav mora biti prilagodljiv promjenama.
- BI sustav treba biti sigurna „utvrda“ za podatke i mora učinkovito kontrolirati pristup povjerljivim podacima.
- BI sustav mora služiti kao autoritativan i pouzdan temelj za poboljšanje odlučivanja. Skladište podataka mora imati prave podatke koji podupiru donošenje odluka.

Prije implementacije sustava poslovne inteligencije potrebno je identificirati koje informacije su potrebne korisnicima takvog sustava za analizu i donošenje odluka.

Sustav poslovne inteligencije u sustavu informacijskog posrednika mora omogućiti analiziranje osnovnih poslovnih procesa:

- proces dostave elektroničkog računa / elektroničkog dokumenta izdavatelja u sustav informacijskog posrednika
- proces isporuke elektroničkog računa krajnjem korisniku kroz različite kanale isporuke
- proces registracije i deregistracije krajnjeg korisnika za uslugu zaprimanja elektroničkog računa od izdavatelja

Iz perspektive informacijskog posrednika sustav BI treba sadržavati točne informacije o stanju i rezultatima razmjene elektroničkih dokumenata, podatke o transakcijama i dr. Potpornim službama informacijskog posrednika je potrebno osigurati informacije za praćenje rada sustava informacijskog posrednika i ključne pokazatelje uspješnosti rada sustava.

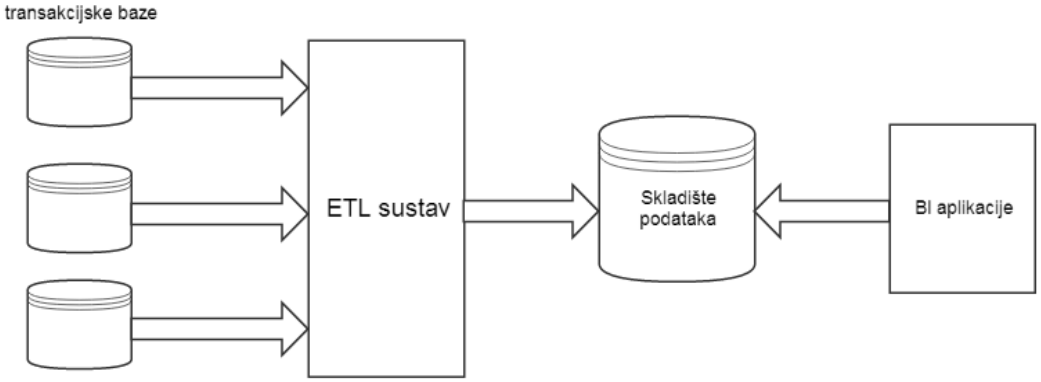
Krajnjem korisniku sustava trebale bi biti dostupne informacije o potrošnji po uslugama zaprimanja elektroničkog računa od izdavatelja. Također trebala bi mu se omogućiti statistika broja i iznosa računa po određenom izdavatelju i usluzi u određenom razdoblju.

Izdavatelji računa trebali bi imati informaciju o statusu isporuke računa i ostalih elektroničkih dokumenata krajnjim korisnicima. Izdavatelji bi htjeli imati informaciju o broju svojih korisnika koji koriste elektronički račun.

Sukladno iznesenim zahtjevima oblikovan je sustav poslovne inteligencije prikazan na Slika 2.

IV. SUSTAV POSLOVNE INTELIGENCIJA U SUSTAVU INFORMACIJSKOG POSREDNIKA

U prethodnom poglavlju izneseni su zahtjevi na implementaciju sustava poslovne inteligencije. Sustav



Slika 2. Sustav poslovne inteligencije [2]

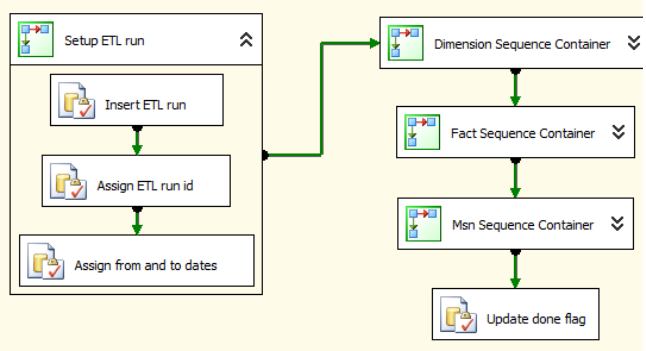
poslovne inteligencije u sustavu informacijskog posrednika za elektronički račun sastoji se od sljedećih komponenti:

- Transakcijske baze podataka – sadrže podatke iz transakcija poslovnih procesa informacijskog posrednika.
- ETL sustav – sastoji se od skupa procesa kojima se podaci dohvaćaju i čitaju iz izvorišnih transakcijskih baza podataka, transformiraju i spremaju u dimenzijski model skladišta podataka.
- Podatkovni dio BI sustava realiziran u skladu s konceptualnim (multi)dimenzijskim modelom podataka koji se implementira kao zvjezdasta shema u relacijskom modelu podataka i/ili kao nerelacijske multidimenzijske OLAP kocke, koje se kreiraju radi brže izvedbe upita.
- Aplikacije poslovne inteligencije za poslovno odlučivanje - rade upite nad skladištem podataka i/ili multidimenzijskim modelom OLAP kocki.

A. *ETL sustav*

ETL sustav uključuje sve procese između izvorišnih transakcijskih baza i skladišta podataka. Dohvaćanje podataka iz izvorišnih transakcijskih baza je prvi korak u ETL-u. Uključuje čitanje podataka iz izvorišnih sustava i kopiranje podataka u ETL sustav za daljnje manipulacije. Nakon toga slijedi niz transformacija. Ispravljaju se greške u podacima i podaci se raščlanjuju odredišne formate. Pri tome se kombiniraju podaci iz više izvora te se uklanjaju duplikati. Posljednji korak u ETL procesima je spremanje podataka u skladište podataka. Prilikom unosa podataka u skladište, ključno je zadovoljiti integritet dimenzijskog modela skladišta podataka vezan uz strukturu činjeničnih tablica i dimenzijskih tablica. Prilikom ETL-a prvo se pune dimenzijske tablice, a tek onda činjenične tablice. Budući da činjenične tablice sadrže strane ključeve dimenzijskih tablica [2], ključno je funkcijama za traženje (eng. lookup function) odijeliti ispravne vrijednosti stranih ključeva.

Slika 3 prikazuje kreirani proces ETL-a. Proces ETL-a je podijeljen u nekoliko koraka. Na početku se instancira proces i definiraju osnovne postavke procesa. Za potrebe praćenja i kontrole procesa ETL-a definirana je dodatna podatkovna struktura koju koristi ETL. Prilikom pokretanja procesa, ETL zapisuje koji paket ETL-a je pokrenut i vrijeme početka ETL-a. Zatim slijedi punjenje dimenzijskih tablica, činjeničnih tablica i mosnih tablica. Dodatno se mogu procesirati OLAP kocke. Nakon što je ETL završio, zapisuje se vrijeme završetka ETL-a i rezultat odvijanja procesa (uspješno ili neuspješno).



Slika 3. Koraci ETL procesa

Prilikom punjenja činjeničnih tablica može doći do grešaka. Primjerice funkcije za traženje ne mogu dodijeliti ispravne vrijednosti stranih ključeva iz dimenzija. Stoga je definiran mehanizam obrade grešaka. Za svaku činjeničnu tablicu u skladištu podataka definirana je njezina tablica grešaka u koju se spremaju greške prilikom ETL punjenja činjenične tablice. Jedan zapis u tablici grešaka sadrži podatke o vremenskoj oznaci greške, opisu greške, kôd greške, vrijednost pogrešnog podatka iz izvorišnog sustava i identifikator zapisa u izvorišnom sustavu.

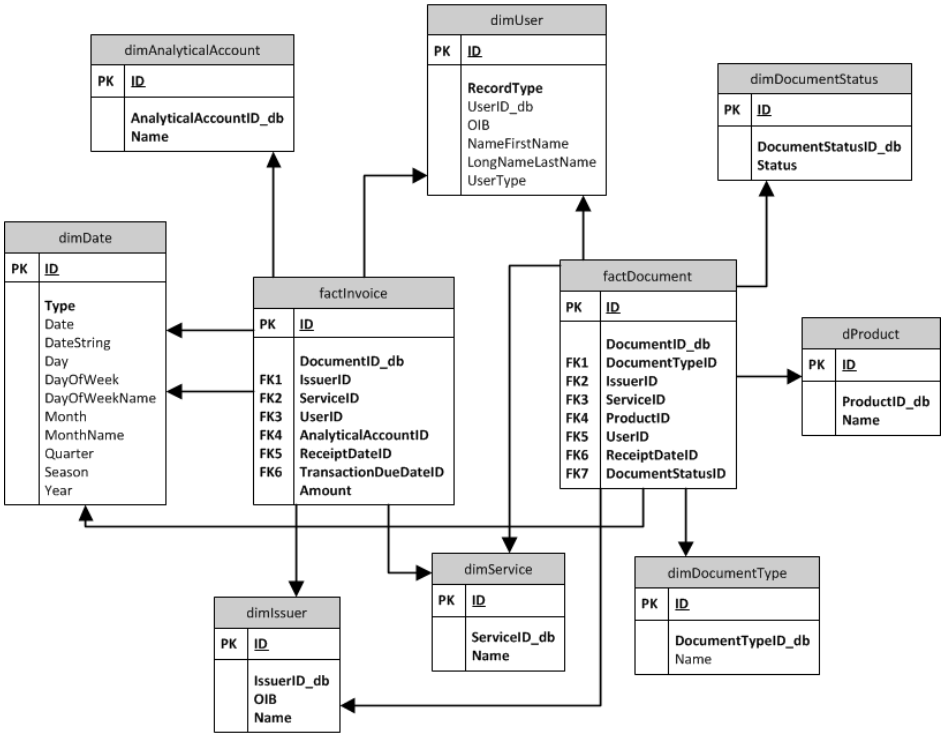
Sustav informacijskog posrednika sadrži mnogo podataka vezanih uz poslovne procese. Velika količina podataka može bitno utjecati na performansne ETL procesa. Stoga je korištenje inkrementalnog punjenja efikasnije.

B. *Model skladišta podataka*

Prilikom modeliranja skladišta analizirani su poslovni procesi navedeni u prethodnom poglavlju. U oblikovanom skladištu podataka svaki poslovni proces je predstavljen dimenzijskim modelom koji se sastoji od činjenične tablice, koja sadrži mjere događaja, i dimenzijskih tablica koje sadrže kontekst događaja. Više činjeničnih tablica dijele iste dimenzijske tablice. Činjenične tablice i njihove povezane dimenzije čine zvjezdasti model [2]. Predloženo skladište podataka informacijskog posrednika ima zvjezdasti model, a Slika 4. prikazuje dio predloženog skladišta podataka.

Nakon identifikacije koji poslovni procesi će se pratiti u skladištu podataka, potrebno je odrediti razinu granularnosti (razina detalja) podataka u skladištu podatka. Pri tome potrebno je odgovoriti na pitanje: Što znači jedan redak činjenične tablice? Za proces dostave elektroničkog računa / elektroničkog dokumenta izdavatelja u sustav informacijskog posrednika nastat će po jedan zapis u činjeničnoj tablici za svaki dokument krajnjeg korisnika koji je izdavatelj dostavio informacijskom posredniku. Prilikom procesa isporuke elektroničkog računa, činjenična tablica sadrži jedan zapis za svaki elektronički račun za uslugu izdavatelja koji je namijenjen krajnjem korisniku. U procesima registracije i deregistracije krajnjeg korisnika za uslugu zaprimanja elektroničkog računa od izdavatelja, činjenična tablica sadrži jedan zapis za svaki korisnički zahtjev za uslugom izdavatelja.

Granulacija definira primarnu dimenzionalnost činjeničnih tablica. Dimenzijske tablice sadrže tekstualni kontekst povezan s mjerljivim događajima poslovnih procesa. One opisuju "tko, što, gdje, kada, kako i zašto" je



Slika 4. Dio dimenzijskog modela skladišta

povezan s događajem. Dimenzije proizlaze iz analize poslovnog procesa i određivanje granulacije. Za procese informacijskog posrednika identificirane su sljedeće dimenzije: izdavatelj (*dimIssuer*), usluga izdavatelja (*dimService*), krajnji korisnik ili primatelj računa (*dimUser*), analitički konto korisnika u sustavu izdavatelja (*dimAnalyticalAccount*), produkt koji izdavatelj ima ugovoren u sustavu informacijskog posrednika (*dimProduct*), tip dokumenta (*dimDocumentType*), status dokumenta (*dimDocumentStatus*) itd. U procesima registracije i deregistracije krajnjeg korisnika za uslugu zaprimanja identificirane su još i dimenzije izvor zahtjeva (*dimRequestSource*), tip zahtjeva (*dimRequestType*) te status zahtjeva (*dimRequestStatus*). Nakon određivanja dimenzija potrebno je odrediti atribute dimenzija. Dimenzije imaju jednostavni surogatni ključ koji zamjenjuje ključeve izvorišnih podataka. Dimenzije dodatno sadrže i ključeve izvorišnih podataka kako bi se zadržala povratna veza na zapise u izvorišnim sustavima. Dimenzija izdavatelja računa (dimIssuer) i dimenzija krajnjeg korisnika (dimUser) sadrže osnovne matične podatke: naziv / ime i prezime i OIB. Dodatno se može proširiti s podacima o adresi. U izvorišnim sustavima podaci vremenskog tima su precizniji od razine jednog dana. Stoga oblikovano skladište sadrži vremensku dimenziju datuma (dimDate) i dimenziju koja predstavlja sekunde unutar dana (dimTime). Datumska dimenzija ima granulaciju do jednog dana. Izdavatelji računa ne izdaju račune samo na mjesečnoj bazi stoga je potreba uvesti i ostale atribute u dimenziji datuma čime se omogućava izvještavanja po danima u tjednu, mjesecima, kvartalima, godišnjim dobima i godinama. Vremenske dimenzije *dimDate* i *dimTime* inicijalno se napune vrijednostima i one se neće puniti tijekom procesa ETL.

Činjenične tablice sadrže mjere. Mjere su numerički atributi kojima se mjere procesi [2]. Zadnji korak prilikom dizajniranja skladišta podataka je određivanje mjera. U procesu dostave računa mjera je iznos računa.

Prilikom dostave elektroničkog računa od strane izdavatelja u sustav informacijskog posrednika, izdavatelj može greškom izdati račun za korisnika koji se ne nalazi u sustavu informacijskog posrednika. Informacijski posrednik može zaprimiti taj račun, ali ga ne može isporučiti korisniku. Stoga je u dimenziju korisnika dodan tip zapisa koji ima vrijednost 'Unknown' za nepoznatog korisnika.

Osim zvjezdastog modela sustav BI uključuje i multidimenzijske OLAP kocke. Online analitička obrada podataka (engl. *On-Line Analytical Processing* – OLAP) predstavlja grupu programa koji omogućavaju podršku odlučivanju i izvještavanje na temelju podataka iz skladišta podataka [4]. Pohrana podataka u multidimenzijske strukture zvane OLAP kocke [5] pruža veću brzinu izvedbe upita, mogućnosti bogatije analize i definiranje složenijih hijerarhija neodređene dubine nego pohrana u zvjezdaste sheme u relacijskom modelu. S druge strane, zvjezdasta shema pruža veći kapacitet.

C. Aplikacije poslovne inteligencije

U poglavlju II. ovog rada prikazana je generička arhitektura informacijskog posrednika. Portal je dio sustava informacijskog posrednika čija je uloga pošiljateljima i primateljima omogućiti pristup informacijama vezanim uz proces isporuke, statusu predanih elektroničkih dokumenata itd. Portali rade upite nad skladištem podataka i/ili multidimenzijskim modelom OLAP kocki. Funkcionalnost portala mora implementirati različite izvještaje zavisno o profilu korisnika: privatni i poslovni

korisnici, izdavatelji, primatelji itd. Prema zahtjevima na implementaciju sustava poslovne inteligencije u sustavu informacijskog posrednika na portalima bi trebali biti kreirani izvještaji. Krajnjem korisniku sustava trebale bi biti dostupne informacije o potrošnji, broju računa i iznos računa određenog izdavatelja u određenom razdoblju. Izdavatelji računa trebali bi imati informaciju o statusu isporuke računa i ostalih elektroničkih dokumenata krajnjim korisnicima. Potporne službe informacijskog posrednika trebale bi imati izvještaje kojima mogu pratiti odvijanje svih poslovnih procesa unutar sustava informacijskog posrednika.

V. ZAKLJUČAK

Sustav informacijskog posrednika za elektronički račun sadrži važne podatke koje je potrebno analizirati i pretvoriti u poslovne informacije. Dobivene informacije mogu se koristiti za unapređenje i nadzor odvijanja poslovnih procesa unutar sustava informacijskog posrednika. Kako bi se to omogućilo, potrebno je implementirati sustav poslovne inteligencije.

Predloženim sustavom poslovne inteligencije moguće je analizirati osnovne poslovne procese informacijskog posrednika. Sustav omogućuje lak i brz pristup informacijama. U skladištu podataka su podaci detaljno predstavljeni (niska razina granulacije) što osigurava prilagodljivost skladišta naknadnim promjenama. Predloženo skladište sadrži podatke koji su razumljivi krajnjem korisnicima, omogućuje brzo izvođenje upita i može se lako proširiti novim mjerama, dimenzijama i dimenzijskim atributima.

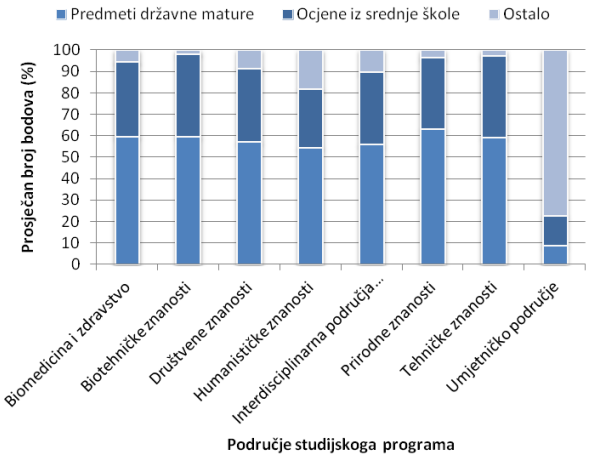
Analiza podataka u svrhu predlaganja studijskih programa u Nacionalnom informacijskom sustavu prijava na visoka učilišta

I. Budišćak*, V. Mornar* i D. Mlinarić*
* Fakultet elektrotehnike i računarstva, Sveučilište u Zagrebu, Hrvatska
ivan.budiscak@fer.hr, vedran.mornar@fer.hr, danijel.mlinaric@fer.hr

Sažetak – Nacionalni informacijski sustav prijava na visoka učilišta učenicima četvrtih razreda srednjih škola pruža mogućnost kreiranja svoje liste prioriteta najviše deset studijskih programa koje žele studirati. Neki od njih su neodlučni i ne znaju koje studijske programe odabrati. Učenicima se u sustavu prikazuje ostvareni broj bodova i plasman samo za studijske programe koji se nalaze na njihovoj listi prioriteta pa nisu u mogućnosti znati mogu li ostvariti pravo upisa na studijske programe koji nisu na njihovoj listi prioriteta. Budući da se rangiranje učenika obavlja periodički, svakih sat vremena, dodavanje i brisanje studijskih programa s liste prioriteta nije učinkovito rješenje za pronalazak studijskog programa koji odgovara učenikovim interesima i mogućnostima. U sklopu rada izradit će se model skladišta podataka za analizu ostvarenih rezultata učenika. Predložit će se postupak kojim će se neodlučnim učenicima predložiti studijski programi na temelju ocjena iz prva tri razreda srednje škole i postupak kojim će se odabrati studijski programi, koji se ne nalaze na listi prioriteta, za koje se učenicima dodatno može prikazati ostvareni broj bodova i mogući plasman.

I. UVOD

Za potrebe projekta državne mature razvili smo Nacionalni informacijski sustav prijava na visoka učilišta (NISpVU) koji objedinjuje cijeli postupak od prijava ispita državne mature i studijskih programa do rangiranja učenika za upis na studijske programe. Učenici mogu odabrati najviše deset studijskih programa koji čine njihovu listu prioriteta, a pravo upisa ostvarit će na onom studijskom programu koji se nalazi najviše na njihovoj listi prioriteta, a na čijoj se rang listi nalaze unutar upisne kvote. Slika 1. prikazuje prosječan udio bodova prema komponentama vrednovanja za sva područja studijskih programa. Najveći udio u bodovima, koji se u postupku rangiranja dodjeljuju učenicima, imaju rezultati ostvareni na ispitima državne mature i ocjene iz srednje škole. Kako bismo neodlučnim učenicima predložili studijske programe, uz ocjene koje su nam poznate za prva tri razreda srednje škole, potrebna nam je procjena rezultata ispita državne mature. Postupak za procjenu rezultata ispita državne mature opisat će se u III. poglavlju a u IV. poglavlju opisat će se postupak za predlaganje studijskih programa koji se temelji na prosječnoj ocjeni predmeta u prva tri razreda srednje škole i procijenjenom rezultatu ispita državne mature. U VI. poglavlju opisat će se model skladišta podataka iz kojega se mogu dohvatiti podatci potrebni za provedbu postupka predlaganja.



Slika 1. Prosječan udio bodova prema komponentama vrednovanja za sva područja studijskih programa

II. HRVATSKI SREDNJOŠKOLSKI SUSTAV [1]

Srednje škole, ovisno o vrsti nastavnog plana i programa koji provode, dijele se na:

- **gimnazije** - opće i specijalizirane.
- **strukovne škole** - tehničke, industrijske, obrtničke i druge, što se određuje prema vrsti nastavnog plana i programa.
- **umjetničke škole** - glazbene, plesne, likovne i druge, što se određuje prema vrsti nastavnog plana i programa.

Nastavni programi podijeljeni su u strukovna područja, a strukovna područja u obrazovne sektore.

Srednje obrazovanje učenika u gimnazijskim programima obrazovanja završava polaganjem državne mature (DM). Srednje obrazovanje učenika u strukovnim i umjetničkim programima obrazovanja, koji traju najmanje četiri godine, završava izradom i obranom završnoga rada u organizaciji i provedbi škole. Učenici četverogodišnjih strukovnih i umjetničkih srednjih škola mogu polagati i ispite državne mature, ako to žele.

Državna matura je skup ispita iz određenih nastavnih predmeta koje je učenik učio tijekom svoga najmanje četverogodišnjega srednjoškolskog obrazovanja. Cilj je državne mature provjera i vrednovanje postignutoga

znanja i sposobnosti učenika, stečenih obrazovanjem prema propisanim općeobrazovnim nastavnim planovima i programima. Na državnoj maturi učenici prijavljuju tri obvezatna predmeta (Hrvatski jezik, Matematiku i strani jezik), a od ponuđena 22 izborna predmeta učenici mogu odabrati najviše šest [2].

Sva visoka učilišta u Republici Hrvatskoj prihvatila su rezultate ispita državne mature kao jedan od uvjeta za rangiranje učenika za upis na studijske programe. Osim vrednovanja rezultata ispita državne mature, visoka učilišta vrednuju i ocjene iz srednje škole, a za pojedine studijske programe uvjetuju se i dodatne provjere posebnih znanja, vještina i sposobnosti potrebnih za uspješno studiranje. Osim toga, kod upisa na mnoge studijske programe na sveučilištima u Republici Hrvatskoj vrednuju se i neka dodatna postignuća učenika. Zbroj bodova prema svim navedenim komponentama vrednovanja je broj bodova s kojima se na kraju postupka kandidati rangiraju za upis na visoka učilišta.

III. PROCJENA REZULTATA NA ISPITU DRŽAVNE MATURE

Procjenu rezultata na ispitu državne mature moguće je učiniti na temelju ostvarenih rezultata učenika iz prethodnih generacija. Možemo reći da, s određenom vjerojatnošću, učenici s boljom prosječnom ocjenom predmeta u prva tri razreda srednje škole ostvaruju bolji rezultat na ispitu državne mature [3]. Vjerojatnost je tim veća što je veći koeficijent korelacije između prosječne ocjene predmeta u prva tri razreda srednje škole i rezultata ostvarenoga na ispitu državne mature.

Za procjenu rezultata na ispitu državne mature, na temelju prosječne ocjene predmeta u prva tri razreda srednje škole, predlaže se korištenje postupka regresije [4], [5], [6]. U postupku regresije ciljna vrijednost $y \in \mathbf{R}$ je kontinuirana, a na temelju primjera $\boldsymbol{D} = \{(\mathbf{x}^{(i)}, y^{(i)})\}$ potrebno je naučiti nepoznatu funkciju $f : \boldsymbol{X} \rightarrow \mathbf{R}$ tako da, idealno, $y^{(i)} = f(\mathbf{x}^{(i)})$, gdje $\boldsymbol{X}$ predstavlja ulazni prostor primjera. Skup svih primjera $\boldsymbol{D}$ za postupak regresije, sastoji se od prosječne ocjene predmeta u prva tri razreda srednje škole i ostvarenoga rezultata (postotka riješenosti) na ispitu državne mature, za određeni skup učenika. Skup primjera može sadržavati podatke za učenike jednoga odjeljenja, jedne škole ili učenike koji pohađaju određeni program, strukovno područje ili obrazovni sektor.

Vrijednost koeficijenta korelacije između prosječne ocjene predmeta u prva tri razreda srednje škole i rezultata ostvarenoga na ispitu državne mature razlikuje se od škole do škole. Zbog toga je potrebno razviti više regresijskih modela, primjerice za svaku školu, umjesto jednog univerzalnog regresijskog modela za sve učenike.

IV. ODABIR STUDIJSKIH PROGRAMA ZA PREDLAGANJE

Odabir studijskih programa koji će se predložili učeniku obavlja se na temelju procijenjenih rezultata ispita državne mature. Ovdje je bitno naglasiti da u izbornom dijelu učenici mogu prijaviti predmet koji nisu učili u srednjoj školi. To znači da za predmete koje učenik nije učio u srednjoj školi ne možemo napraviti procjenu rezultata na ispitu državne mature.

Postupak kojim će se učeniku predložiti studijski programi sastoji se od ovih sedam koraka:

1) Definira se skup svih studijskih programa $\boldsymbol{Q}$.
2) Odabire se skup učenika $\boldsymbol{U}$ čiji će se rezultati koristiti kao skup ulaznih primjera za učenje (50 %), provjeru (25 %) i testiranje (25 %) postupka regresije. To mogu biti učenici istoga odjeljenja, škole, programa, strukovnoga područja ili obrazovnoga sektora, koji su prethodne školske godine ostvarili upis na neki studijski program u ljetnome upisnom roku.
3) Odabire se skup predmeta $\boldsymbol{P}$. To su svi predmeti koje je učenik učio u srednjoj školi i za koje postoje rezultati ispita državne mature u prethodnoj školskoj godini za učenike iz skupa $\boldsymbol{U}$.
4) Za svaki predmet $p_i \in \boldsymbol{P}$, postupkom regresije opisanom u III. poglavlju, procjenjuje se učenikov rezultat na ispitu državne mature r_i.
5) Za svaki predmet $p_i \in \boldsymbol{P}$, odabire se skup učenika $\boldsymbol{K_i} \subseteq \boldsymbol{U}$ koji su na ispitu državne mature ostvarili rezultat u intervalu $[r_i - \varepsilon, r_i + \varepsilon]$. Na ovaj način obuhvatiti ćemo učenike koji su na ispitu ostvarili sličan rezultat, tj. rezultat koji je bolji ili lošiji za vrijednost ε. Vrijednost ε može se odrediti empirijski na podatcima prethodnih generacija učenika.
6) Za svaki predmet $p_i \in \boldsymbol{P}$, svim studijskim programima $s_j \in \boldsymbol{Q}$ određuje se postotak učenika n_i, iz skupa $\boldsymbol{K_i}$, koji su ostvarili pravo upisa.
7) Svakom studijskom programu $s_j \in \boldsymbol{Q}$ pridjeljuje se težina t_j određena medijanom vrijednosti iz skupa $\boldsymbol{M_k} = \{n_i\}$, $i \in [1, |\boldsymbol{P}|]$. Konačno rangiranje studijskih programa provodi se na temelju pridijeljene težine t_j.
8) Od tako rangiranih studijskih programa učeniku se predlaže prvih deset.

Umjesto promatranja studijskoga programa na kojemu su učenici ostvarili pravo upisa, u šestome koraku predloženoga postupka, možemo promatrati znanstveno polje ili područje studijskoga programa. Tako možemo dobiti rang-listu znanstvenih polja ili područja studijskih programa i dodatno prilagoditi predložene studijske programe. Za svako od najboljih deset znanstvenih polja ili područja studijskih programa, može se uzeti studijski program koji pripada tom znanstvenom polju ili području, a koji se nalazi najviše na rang-listi studijskih programa dobivenoj prethodno opisanim postupkom. Dodatnu prilagodbu predloženih studijskih programa može obaviti i učenik odabirom znanstvenih polja ili područja studijskih programa koji odgovaraju njegovim željama ili interesima ako ih ima.

Na temelju procijenjenih rezultata ispita državne mature i ostvarenih ocjena u prva tri razreda srednje škole, moguće je procijeniti i broj bodova za rangiranje koje će učenik ostvariti na ponuđenim studijskim programima. Usporedbom s rang-listama iz prethodnih godina, moguće je, s određenom vjerojatnošću, procijeniti učenikov plasman na ponuđenim studijskim programima a time i

hoće li ostvariti pravo upisa. Ako učenik želi studirati na nekom od ponuđenih studijskih programa na kojem s procijenjenim plasmanom ne ostvaruje pravo upisa, prikazana procjena može ga potaknuti na dodatno učenje predmeta koji se vrednuju za upis na tom studijskom programu. Dodatnim učenjem učenik bi mogao ostvariti bolje rezultate na ispitima državne mature a time i bolji plasman od procijenjenog.

V. ODABIR STUDIJSKIH PROGRAMA ZA DODATNI PRIKAZ OSTVARENIH BODOVA

Nakon što su poznati rezultati ispita državne mature u NISpVU postoje svi potrebni podatci za rangiranje učenika na svim studijskim programima. U tom trenutku promjene na rang-listama uzrokovane su isključivo izmjenama koje učenici rade na svojim listama prioriteta. Učenici koji nemaju pravo upisa na nekome od željenih studijskih programa nemaju informaciju o plasmanu na srodnim studijskim programima ako se oni ne nalaze na njihovoj listi prioriteta. Ako učenik na svoju listu prioriteta doda studijski program, mora čekati izračun bodova koji se obavlja periodički, svakih sat vremena. Brisanje prijave za studijski program na kojemu je učenik ostvario pravo upisa, ima za posljedicu da učenik koji je na tom studijskom programu bio rangiran kao prvi koji se ne nalazi unutar upisne kvote ostvaruje pravo upisa a gubi ga na studijskom programu na kojemu je imao pravo upisa prije promjene. Promjene se nastavljaju lančano, dok se ne dođe do studijskoga programa kojemu je upisna kvota veća od broja prijavljenih učenika. Dodavanje studijskoga programa na kojem učenik po broju bodova ostvaruje pravo upisa ima za posljedicu gubitak prava upisa za učenika koji je bio rangiran kao posljednji unutar upisne kvote. Slično kao i kod brisanja prijave, promjene se nastavljaju lančano. Upravo zbog toga što prijava odnosno odjava može izazvati lančanu reakciju, izračun bodova obavlja se periodički.

Nakon svakoga izračuna bodova i generiranja rang-lista može se obaviti i izračun bodova za studijske programe koji se ne nalaze na učenikovoj listi prioriteta. Izračun se može obaviti samo za one studijske programe koji pripadaju istom znanstvenom polju kao i studijski programi koji se na učenikovoj listi prioriteta nalaze na višem prioritetu nego studijski program na kojemu je ostvareno pravo upisa. Dobiveni skup studijskih programa može se smanjiti ograničavanjem na studijske programe koji se izvode u županiji u kojoj učenik ima prebivalište ili prema nekomu drugom geografskom kriteriju. Alternativno se izračun može obaviti za studijske programe koje bi odredili postupkom opisanim u IV. poglavlju ali sada sa stvarnim rezultatima koje je učenik ostvario na ispitima državne mature.

VI. SKLADIŠTE PODATAKA

Za potrebe analize nužno je izraditi skladište podataka iz kojega se mogu iščitati potrebni podatci u prethodnim školskim godinama. Za izradu modela skladišta podataka korišten je Kimballov model [7]. Skladište podataka sastoji se od triju zvjezdastih shema, a sheme su povezane uporabom zajedničkih dimenzijskih tablica. Dimenzije i tablice činjenica opisat ćemo u nastavku ovoga poglavlja.

A. *Dimenzije*

Kreirane su ove dimenzije:

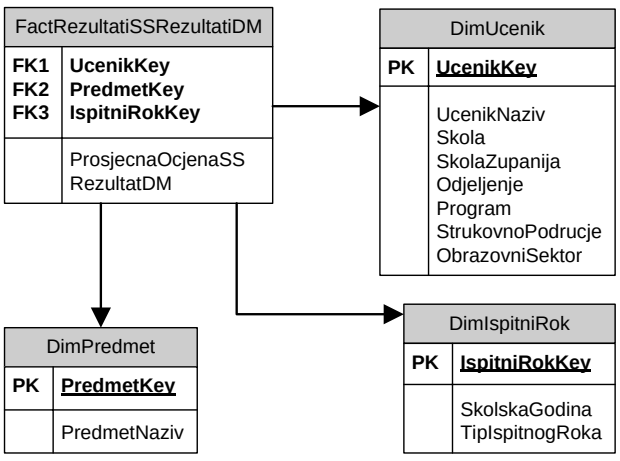
- *Učenik* – podatci o odjeljenju, školi, nastavnom programu, strukovnom području i obrazovnom sektoru
- *Predmet* – predmeti koji se polažu u sklopu državne mature
- *Studijski program* – podatci o nositelju i izvođaču, znanstvenom polju i području studijskoga programa
- *Razina ispita* – može biti viša ili osnovna
- *Ispitni rok* – školska godina i oznaka ispitnoga roka

U predloženim dimenzijama, dimenzija *Ispitni rok* može se smatrati vremenskom dimenzijom pri čemu je koristan pregled podataka prema školskim godinama ili ispitnim rokovima u jednoj školskoj godini.

B. *Tablice činjenica*

Slika 2. prikazuje tablicu činjenica koja se koristi kao izvor podataka za skup primjera za učenje, provjeru i testiranje postupka regresije opisanim u III. poglavlju. Uz tablicu činjenica prikazane su i pripadajuće joj dimenzijske tablice. Tablica činjenica sadrži ove atribute:

- *Učenik* – učenik koji polaže ispit državne mature
- *Predmet* – predmet koji se polaže ispitom državne mature
- *Ispitni rok* – ispitni rok na kojemu je proveden ispit državne mature
- *Prosječna ocjena* – prosječna ocjena u prva tri razreda srednje škole
- *Rezultat DM* – ostvareni rezultat na ispitu državne mature



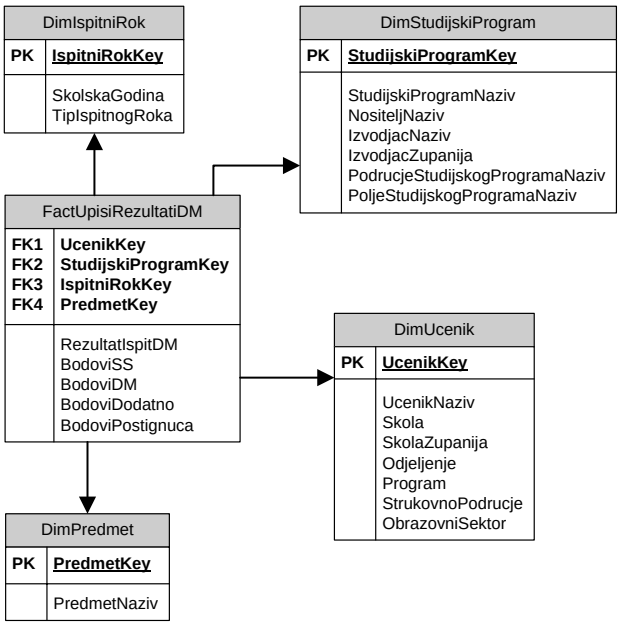
Slika 2. Tablica činjenica s pripadajućim dimenzijskim tablicama koja sadrži prosječnu ocjenu u prva tri razreda srednje škole i rezultat na ispitu državne mature za predmete koje su učenici polagali u sklopu državne mature

Podatci u tablici činjenica prikazanoj na slici 2. mogu se upotrijebiti i za određivanje korelacije između prosječnih ocjena predmeta u prva tri razreda srednje škole i rezultata ostvarenih na ispitima državne mature.

Pri izračunu rezultata ostvarenoga na ispitu državne mature valja naglasiti da se ispiti u obvezatnom dijelu državne mature polažu na dvjema razinama, osnovnoj i višoj [8]. Kako bi se rezultati ispita na osnovnoj i višoj razini mogli međusobno uspoređivati rezultat ostvaren na višoj razini množi se s faktorom 1,6 [8].

Slika 3. prikazuje tablicu činjenica koja se koristi u predloženom postupku za odabir studijskih programa za predlaganje, opisan u IV. poglavlju. Uz tablicu činjenica prikazane su i pripadajuće joj dimenzijske tablice. Tablica činjenica sadrži podatke o studijskim programima na kojima su učenici ostvarili pravo upisa i rezultate koje su učenici ostvarili na ispitima državne mature, a sadrži ove atribute:

- *Učenik* – učenik koji polaže ispit državne mature
- *Studijski program* – studijski program na kojemu je učenik ostvario pravo upisa
- *Ispitni rok* – ispitni rok na kojemu je proveden ispit državne mature i ostvareno pravo upisa na studijski program
- *Predmet* – predmet koji se polaže ispitom državne mature
- *Rezultat ispita DM* – rezultat ostvaren na ispitu državne mature
- *Bodovi DM* – broj bodova ostvaren na svim ispitima državne mature koji su vrednovani za upis na studijski program



Slika 3. Tablica činjenica s pripadajućim dimenzijskim tablicama koja sadrži podatke o studijskim programima na kojima su učenici ostvarili pravo upisa i rezultate na isptima državna mature koje su ti učenici polagali

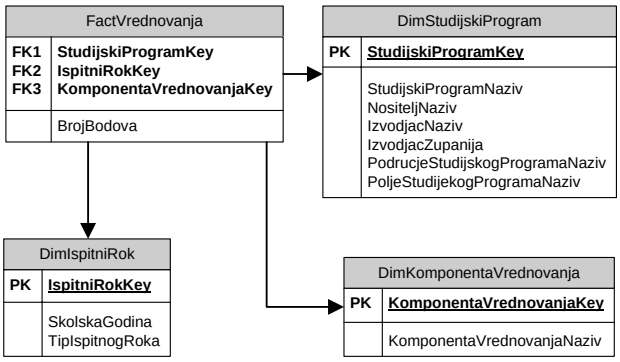
- *Bodovi SS* – broj bodova ostvaren temeljem ocjena iz srednje škole
- *Bodovi dodatno* – broj bodova ostvaren na provjerama posebnih znanja, vještina i sposobnosti
- *Bodovi postignuća* – bodovi ostvareni na temelju učenikovih dodatnih postignuća

Ovdje valja napomenuti da se prijave dvopredmetnih studija u NISpVU vode kao prijave dvaju studijskih programa pa je moguće da jedan učenik ostvari pravo upisa na dvama studijskim programima.

Iako se u predloženom postupku za odabir studijskih programa za predlaganje koristi samo rezultat ostvaren na pojedinačnim ispitima državne mature, tablica činjenica sadrži i sumarne bodove za studijski program na kojemu je učenik ostvario pravo upisa. Ti se bodovi mogu iskoristiti kako bi se dodatno ograničio skup studijskih programa koji će se predložiti učeniku. Primjerice možemo isključiti studijske programe na kojima su učenici posebnim postignućima i dodatnim provjerama ostvarili znatan broj bodova jer u tom slučaju bodovi ostvareni na ispitima državne mature nemaju jednaku težinu kao kod učenika koji te bodove nisu ostvarili.

Model podataka za opis vrednovanja studijskih programa je kompleksan i izvan okvira ovoga rada te ga ovdje nećemo opisivati. Bitno je naglasiti da se za svaku komponentu vrednovanja može odrediti maksimalan broj bodova koje učenici mogu ostvariti te da ukupan zbroj bodova iznosi 100. Slika 4. prikazuje tablicu činjenica korištenu za određivanje prosječnoga udjela bodova prema komponentama vrednovanja za sva područja studijskih programa. Uz tablicu činjenica prikazane su i pripadajuće joj dimenzijske tablice. Tablica činjenica sadrži podatke o maksimalnom broju bodova prema komponentama vrednovanja za sve studijske programe, a sadrži ove atribute:

- *Studijski program* – studijski program na kojemu je učenik ostvario pravo upisa
- *Ispitni rok* – ispitni rok za koji su definirana vrednovanja



Slika 4. Tablica činjenica s pripadajućim dimenzijskim tablicama koja sadrži maksimalan broj bodova prema komponentama vrednovanja za sve studijske programe.

- *Komponenta vrednovanja* – oznaka komponente vrednovanja
- *Broj bodova* – maksimalan broj bodova koji učenici mogu ostvariti za komponentu vrednovanja

VII. ZAKLJUČAK I PLANOVI ZA DALJNJE ISTRAŽIVANJE

Kako bismo pomogli neodlučnim učenicima koji ne znaju koje studijske programe odabrati, u III. i IV. poglavlju predložen je jednostavan postupak za odabir studijskih programa koji im se mogu predložiti. Postupak se zasniva na procjeni rezultata ispita državne mature na temelju ocjena iz prva tri razreda srednje škole. Uspješnost predloženoga postupka može se provjeriti testiranjem na podatcima u aktivnoj školskoj godini s time da se procjena temelji na podatcima iz prethodne školske godine.

Predloženi postupak uzima u obzir samo jesu li ili nisu učenici upisali studijski program no ne i jesu li ga završili i s kojim uspjehom. Kada bismo imali podatke o uspjehu na upisanom studijskom programu, imali bismo i bolju informaciju o tome jesmo li predloženim postupkom odabrali studijske programe na kojima učenik može ostvariti najbolji rezultat, tj. ostvariti svoj potencijal. Analogno sustavima za predlaganje proizvoda za kupnju kao u [9], [10], gdje je potrebno uzeti u obzir i zadovoljstvo kupaca nekim proizvodom, ovdje se na sličan način može koristiti podatak o uspjehu na upisanom studijskom programu. Smatramo da bi se korištenjem tih podataka moglo pridonijeti profesionalnoj orijentaciji učenika koji upisuju studij. Analogno, postupak bi se mogao upotrijebiti i za profesionalnu orijentaciju učenika koji upisuju srednju školu. Za takvu analizu uspjeh učenika trebalo bi se pratiti tijekom cijeloga obrazovanja, od osnovne škole do visokoga obrazovanja.

Aplikacija za uvoz podataka iz vanjskih izvora u skladište podataka

Krešo Matejčić*, Zrinko Mršo**
*IN2 d.o.o., Zagreb, Croatia, kreso.matejcic@in2.hr
**IN2 d.o.o., Zagreb, Croatia, zrinko.mrso@in2.hr

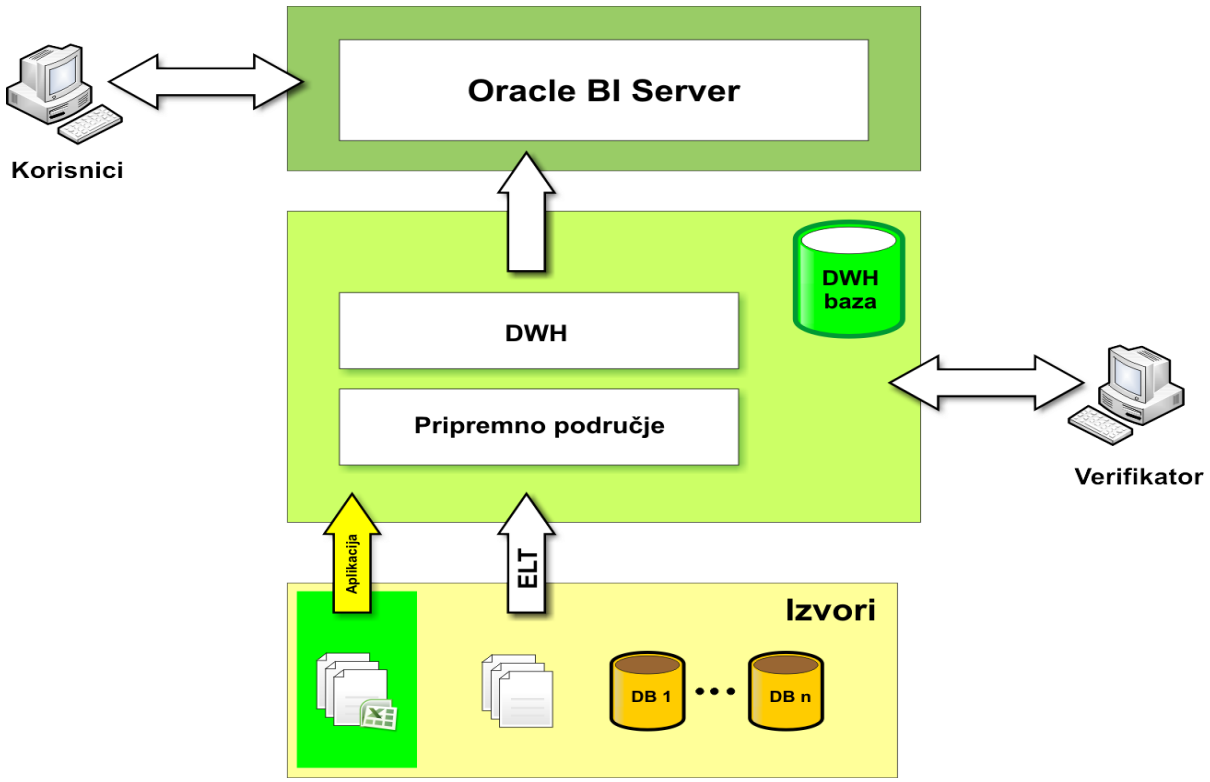
Sažetak - Aplikacija za uvoz podataka iz vanjskih izvora u skladište podataka (DWH) omogućuje korisniku da samostalno unosi vanjske podatke u sustav za potporu poslovnom odlučivanju (BI sustav). Korisnici BI sustava često imaju potrebu za podacima koji nisu obuhvaćeni redovitom ekstrakcijom podataka iz standardnih izvora (transakcijske baze podataka, ERP sustavi i sl.). Ti podaci nisu obuhvaćeni ekstrakcijom iz raznih razloga: dolaze sporadično, dolaze svaki put u drugačijem obliku, potječu iz izvora koji nisu povezani s centralnim informacijskim sustavom poduzeća. Pomoću aplikacije za uvoz podataka korisnik ima mogućnost da sam preslikava podatke iz excela (obične ili pivot tablice) na vrijednosti mjera ili dimenzija u skladištu podataka. Aplikacija se brine za konzistentnost skladišta podataka, tj. ne dozvoljava unos na nepoznate dimenzijske vrijednosti, te traži od korisnika da dimenzijske vrijednosti koje nisu u sustavu preslikava na neku dimenzijsku vrijednost. Podržana je verifikacija podataka, u smislu da uneseni podaci neće biti vidljivi korisnicima (iako su unijeti u sustav) dok verifikator ne označi podatke vidljivima. Aplikacija je bazirana na Oracle tehnologiji i integrirana je sa OBIEE izvještajnim alatom.

I. UVOD

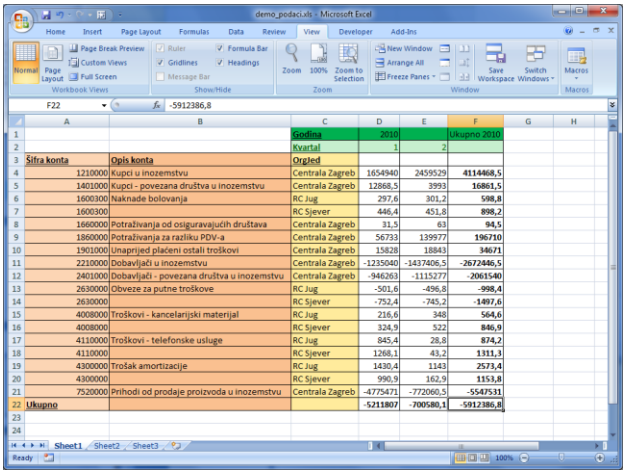
Glavni izvori za skladište podataka (DWH) su obično razne baze podataka koje postoje u poduzećima. No, vrlo često postoji potreba za uvozom podataka iz različitih vanjskih izvora. Tipičan vanjski izvor su Microsoft Excel datoteke, a može se raditi i o drugim izvorima poput raznih internih aplikacija na starijim platformama, koje nisu integrirane u novije sustave, ali se i dalje koriste za određene svrhe.

Uobičajeno je da podatke iz vanjskih izvora uvozi IT poduzeća ili implementator skladišta podataka. Samim tim je više ljudi uključeno u proces, a poslovni korisnici su ovisni o IT-ju. Posljedica te ovisnosti je vrlo često i zakašnjela dostupnost podataka iz vanjskih izvora u sustavu za podršku poslovnom odlučivanju.

IN2 aplikacija za uvoz podataka iz vanjskih izvora omogućava poslovnim korisnicima da samostalno uvoze podatke, ocjenjuju njihovu ispravnost, odnosno kontroliraju cijeli proces. Ne postoji ovisnost o IT sektoru ili implementatoru.



Slika 1. Arhitektura sustava



Slika 2. Podaci za unos

II. ARHITEKTURA SUSTAVA

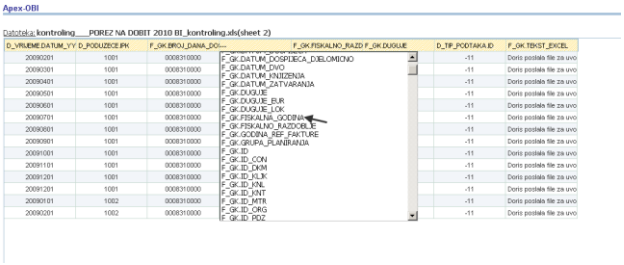
Arhitektura sustava prikazana je na slici 1. Radi se o sustavu za podršku poslovnom odlučivanju (BI) u potpunosti baziranom na Oracle tehnologiji. Front-end dio je Oracle Business Intelligence Enterprise Edition (OBIEE), koji služi kao BI server [3]. Izvor podataka za OBIEE je skladište podataka implementirano u Oracle 11gR2 bazi.

Skladište podataka puni se ELT (extract-load-transform) procesom [2], što znači da se svi podaci prvo dovedu u pripremno područje u bazi te se potom transformiraju i pune u skladišno područje (DWH), u zvjezdastu strukturu mjera i dimenzija [1].

Sama aplikacija za uvoz podataka implementirana je Oracle APEX tehnologijom [4]. Pomoću aplikacije podaci se pune u DWH, tj. aplikacija unutar sebe ima implementiran jednostavni ELT proces.

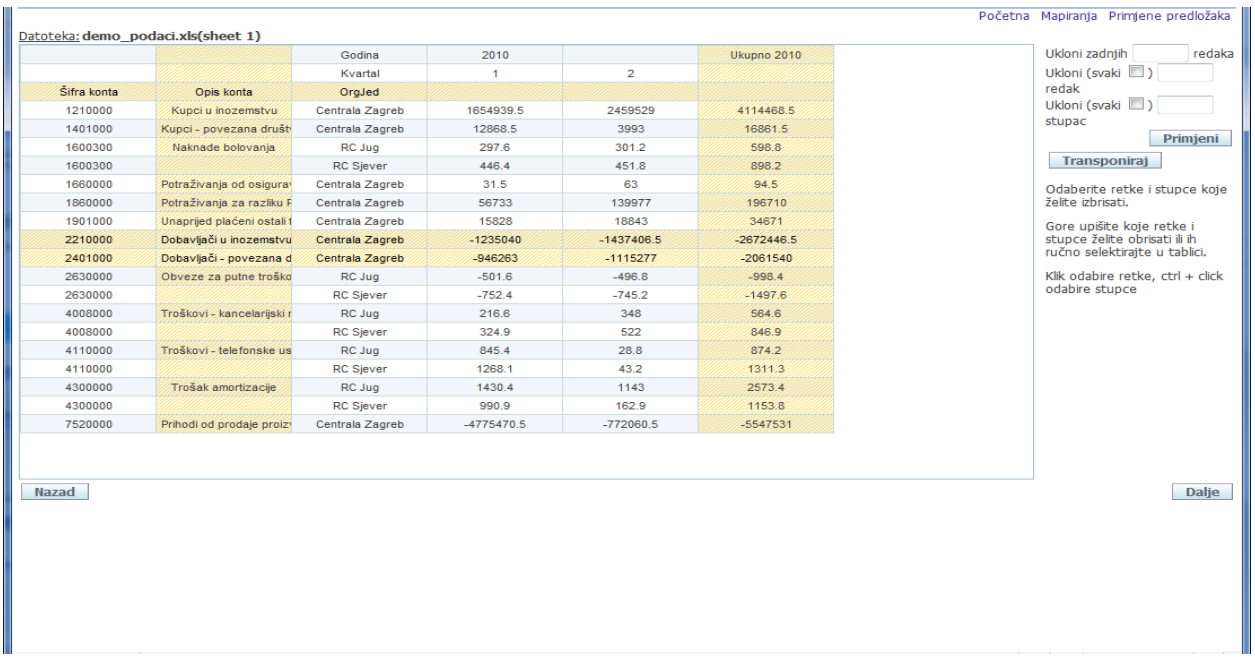
III. OPIS MOGUĆNOSTI APLIKACIJE

Svrha aplikacije je da korisniku omogući samostalan unos vanjskih podataka direktno u skladište podataka. Podaci se uvoze u tablicu mjera skladišta podataka. To znači da se barem jedan stupac iz vanjskog izvora treba moći preslikati na neku mjeru iz skladišta podataka, a ostali stupci na dimenzije koje opisuju tu mjeru. Naravno, vanjski izvor može sadržavati i više mjera, raspoređenih u više stupaca.

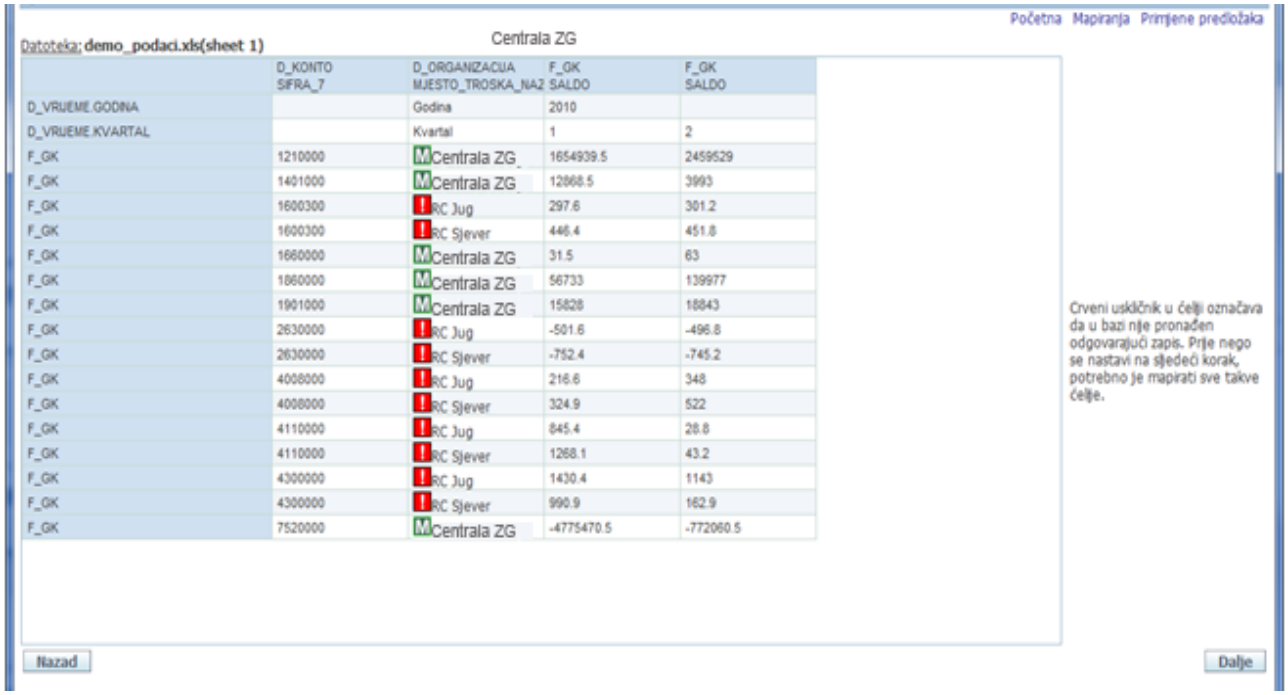


Slika 3. Preslikavanje dimenzija i mjera

Tipična je situacija da se dodatni korisnički podaci nalaze u excelu. Korisnik učitava excel kroz aplikaciju te označava stupce koji predstavljaju mjere i koje vrijednosti mjera uvozi (ne mora uvesti kompletan vanjski izvor, Excel). Zatim određuje koji stupci predstavljaju pojedine dimenzije i preslikava vrijednosti iz dimenzijskih stupaca excela na vrijednosti iz dimenzija skladišta podataka.

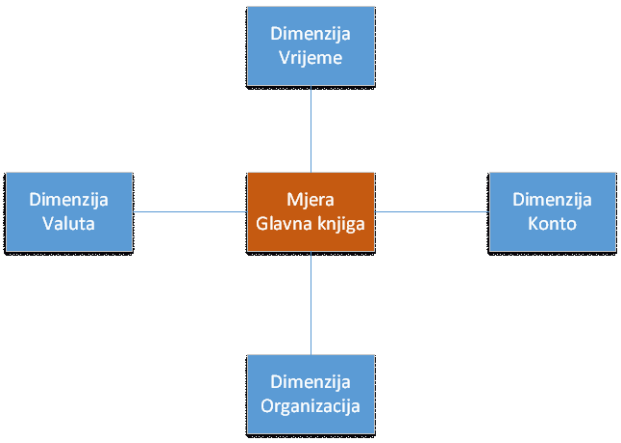


Slika 4. Odabir podataka za unos



Slika 5. Preslikavanje vrijednosti na dimenzijske vrijednosti

Za potrebe ponovnog učitavanja excel datoteke iste strukture, aplikacija podržava spremanje definiranih preslikavanja putem predložaka. Predlošci omogućavaju znatno brži uvoz svaki sljedeći put.



Slika 6. Model podataka

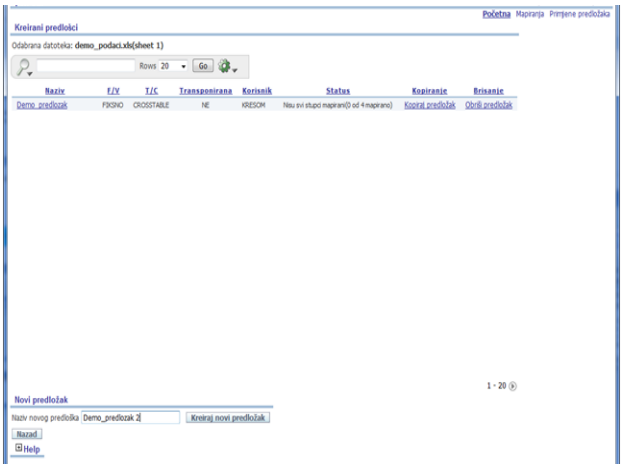
Ono što je dodatna vrijednost ove aplikacije je da omogućava uvoz excela *bilo kakve* strukture. To znači da stupci mogu svaki put biti dostavljeni u drugačijem rasporedu, pa čak i s drugim mjerama i dimenzijama. Korisnik putem aplikacije gore opisanim postupkom ponovno preslikava stupce excela na model skladišta podataka i cijeli proces se ponavlja.
Dakle, aplikacija ne uvjetuje striktnu strukturu dostavljenih podataka iz vanjskog izvora. Upotreba predložaka omogućava znatno ubrzavanje uvoza u slučaju repetitivnih dostava u istoj strukturi.

IV. PROCES UNOSA PODATAKA

Podaci koje korisnik učitava nalaze se u excel datoteci (Slika 2.), u obliku pivot ili obične tablice.
Izvorišni podaci mogu biti dostavljeni kao jednostavna tablica s vrijednostima po stupcima ili kao zaokretna (pivot) tablica. Prvi korak procesa uvoza podataka je učitavanje excel datoteke (ili drugog vanjskog izvora) u aplikaciju. Aplikacija datoteku sprema u bazu, kako bi original datoteke bio spremljen za naknadnu analizu, kontrolu ili za izvanredne okolnosti. U aplikaciji se odabiru stupci i redovi excel tablice koji će se uvesti u skladište podataka. Ako je potrebno isključiti neke stupce ili redove iz odabranog područja, treba ih samo označiti – ne treba ih brisati iz dostavljene datoteke. Aplikacija će prepoznati da ti redovi i/ili stupci nisu za prijenos u skladište podataka.
Slika 4. prikazuje proces odabira podataka za prijenos.

Nakon toga potrebno je preslikati stupce iz excela na stupce dimenzija i/ili mjera (Slika 3.).
Korisnik prvo odabire tablicu mjera na koju će se preslikavati vanjski izvor ili datoteka. Sljedeći korak je preslikavanje stupaca mjera iz datoteke na stupce (mjere) iz DWH tablice. Budući da aplikacija radi unos u zvjezdastu strukturu skladišta podataka, odabirom tablice mjere korisniku se na odabir za preslikavanje nude samo one dimenzije koje su povezane s tom tablicom mjera (Slika 6.).
Na osnovu preslikanih stupaca excel datoteke na određene dimenzijske stupce, aplikacija vrši provjeru da

li vrijednosti sadržane u tim stupcima iz excela, postoje u skladištu podataka. Ako ne postoje, aplikacija neće dozvoliti unos takvih podataka, jer bi se oni vezali na nepoznatu dimenzijsku vrijednost, već od korisnika traži da vrijednost dimenzijskog stupca preslika na neku vrijednost tog stupca iz skladišta podataka. Ako željena vrijednost ne postoji u bazi, aplikacija nudi korisniku mogućnost da unese novu vrijednost u dimenziju skladišta podataka. U praksi se pokazalo da se unos dimenzijskih vrijednosti na takav način iznimno rijetko koristi.
Slika 5. prikazuje preslikavanje vrijednosti.
Korak preslikavanja vrijednosti ključan je korak u cijeloj aplikaciji. Budući da je upravo to najkompleksniji korak prilikom unosa podataka u skladište podataka mimo ELT (ili ETL) procesa.



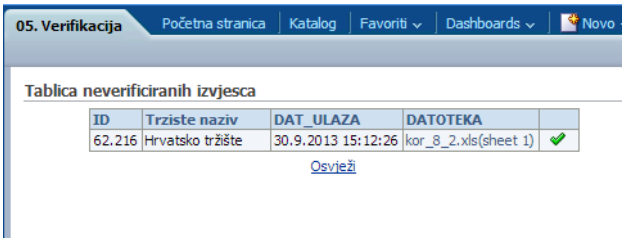
Slika 7. Rad s predlošcima

Preslikane vrijednosti pamte se u repozitoriju aplikacije tako da je dovoljno da korisnik preslikava vrijednost samo prvi kad se ona pojavi. Prilikom naknadnih uvoza, ta vrijednost će biti prepoznata kao preslikana.
Sva preslikavanja stupaca excela na stupce dimenzija i mjera bilježe se u aplikaciji u obliku predloška. Na taj način, idući puta kada korisnik želi učitati excel datoteku iste strukture može jednostavno preskočiti sva preslikavanja stupaca i aplicirati već napravljeni predložak na datoteku (Slika 7.).
Ove dvije funkcionalnosti, spremanje preslikanih vrijednosti u repozitorij i automatsko preslikavanje pri naknadnim uvozima te spremanje predložaka, značajno olakšavaju upotrebu aplikacije i ubrzavaju proces naknadnih uvoza. Jednom kad su sve vrijednosti preslikane, korisnici mogu u vrlo kratkom vremenu osvježiti skladište podataka, a sve to bez potrebe za IT stručnjacima i poznavanjem strukture baze skladišta podataka.

V. KONTROLA I POTVRDA UVOZA

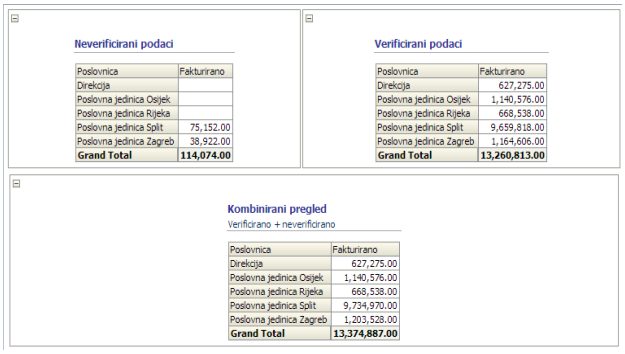
Sve učitane datoteke spremaju se u repozitorij aplikacije koji se nalazi u Oracle bazi. Na taj način uvijek je moguća kontrola i uvid u originalnu datoteku.

U skladištu podataka, na svakoj mjeri, postoji servisna dimenzija koja sadrži podatak od kuda je podatak stigao. Na taj način može se identificirati gdje su završili podaci iz pojedine excel datoteke ili drugog vanjskog izvora



Slika 8. Verifikacija podataka

Podaci učitani iz excela, neće biti vidljivi korisnicima izvještaja dok se ne verificiraju, ali će biti vidljivi verifikatoru. Na taj način verifikator ima mogućnost pregleda kompletnog sustava sa učitanim podacima, a da ih ostali korisnici ne vide (Slika 8.). Kada ih verifikator označi kao ispravne, tj. verificirane, oni će postati vidljivi svima. Aplikacija je u potpunosti integrirana sa OBI (Oracle Business Intelligence) alatom i proces verifikacije odvija se kroz OBI (Slika 9.).



Slika 9. Pregled za verifikaciju

VI. ZAKLJUČAK

Uvođenjem aplikacije za uvoz vanjskih podataka u skladište podataka korisnicima je otvorena mogućnost da sami imaju kontrolu nad uvozom takvih podataka. Povećana je učinkovitost jer više nije potrebna osoba iz informatičke podrške za taj posao. Smanjena je mogućnost greške, jer korisnik sam uvozi podatke i u načelu ih bolje razumije te prije može uočiti grešku pri unosu, ako se dogodi. Upotrebom predložaka omogućen je jednostavan i brz periodički unos datoteka iste ili slične strukture. Verifikacija podataka osigurava ispravnost izvještaja.
Aplikacija je dobro prihvaćena od strane korisnika BI sustava i koristi se u praksi.

PAPERS

Information SecurityAnd The Right To Privacy in Digital Economy– The Case Of Republic Of Croatia

Marija Boban, PhD*,
*Assistant Professor at University of Split Faculty of Law, Split, Croatia
E-mail: marija.boban@pravst.hr

Abstract - The complexity of the changes that have affected digital economy, as well as modern society in whole, is primarily reflected in the frequent use of terms such as information, data (and information) security, personal information, the right to privacy and the information society. As a result, numerous articles, studies and research are dealing with this topic. The starting point of the paper presents the concept of information, personal data, privacy and information security. Defining privacy or infringe the rights of persons (individuals) and personality (individuality) sets the basis for the protection of personal data and set up an adequate framework for information security in the Republic of Croatia. Also, in addition to the protection of data in this paper a special part presents the debate on the right to correction of information as an important part of data protection and at the same time as the way of protecting the rights of citizens in the information society - primarily in the Digital Economy and Government/Local Government/Public Services.

Key words: information, data security, information security, privacy, correction of information, Croatian law.

I. Introduction

The complexity of the social changes that have affected modern society is primarily reflected in the frequent use of terms such as information, information security, personal information, right to privacy, information society and digital economy. Numerous articles, studies and research dealing with this topic. The fundamental driver of these changes was the Internet. Of course, the primary goal of the Internet as such was ensuring that easier and faster access to information in order to be available to everyone in the network without any restrictions.[1] Although it seemed to suit the needs of the time, today it appears as one of the greatest weaknesses of the Internet , especially when it comes to the subject of data privacy and right to acces information in the public administration which especially in the area of public and local governments that include minimum investments in information security (if any!).

At this point it is important to keep in mind that first developed the technology transfer of various types of messages as well as digital form of communication , as used on the Internet now, but not the equivalents protective mechanisms which in practice lead to unwanted and quite frequent cases of abuse , which leads to the question of the status of the Internet as a global communications infrastructure. Overall, the business of the 21st century is known as the digital economy due to the fact that new knowledge and information has become the most important commodity in the market , and the Internet as a medium of exchange has imposed the same as the basic infrastructure of society that enables the exchange of data spatially very distant participants , and also those who are willing to abuse everything they available through a global network.[2]

II. Relevance of the concepts of information security and the right to privacy in the digital ECONOMY

The concept of information we encounter in the most varied situations of use in everyday life to those in specialized scientific fields. It is a basic feature of the information age, information science, technology and society itself. From the variety of meanings which owns, in this part of the processed information is one aspect of which are associated with the concept of the message as the information carrier. By definition, *information* is the result of processing, analyzing and organizing data in a way that adds a note to the recipient. In other words, it is primarily the context in which the data was obtained. Information as a concept has a variety of meanings, from the mundane to the technical use.[3]

[1] Also KOGUT, B., (ed.) „The global internet economy“, MIT Press, Massachusetts Insitute of Technology, 2004., p. 1 - 41.

[2] For more information on digital economy see MALECKI, E. J., MORISET, B., „*The digital economy: business organization, production processes, and regional developments“,* Taylor & Francis, 2008., p. 13 – 17.

[3] On the one hand, the analysis of the conceptual nature of the term of information often leads to a kind of relative historicism which reflects the constant change of meaning, and a confusing number of arbitrary definitions that do not provide the foundations of a new understanding of the term. On the other hand, the analysis by setting nature of the term information points to two problems: a large number of equivalent evidence fail to show the available information and certain personality when choosing. This presents a serious difficulty of each researcher's history one clue who wants genealogically and critical to clarify the concept of information with etymological methods. See HORIĆ, A., "Information - history of a term on Capurro understanding of the term information," Croatian Library Journal 50, 1/2 (2007), p. 98. See also

Since the data and information are often used interchangeably, it is important to distinguish these terms. Specifically, the definition of information is that this is data put into the semantic context , while the data outside of the context. According to the Law on Data Secrecy, Official Gazette . 79/2007 (hereinafter LDS) " data presents any document , or any written , amplified , drawn image , printed, filmed , photographed , magnetic , optical, electronic , or any other record of information , knowledge , measure , process , object, oral communication or information, which, given its content, has the importance of confidentiality and integrity of their owners. " (LDS Art. 1 Paragraph 1). Or in other words , the data is useless until it conveys some information . According to the definition of information is a set of characters that mean something to the recipient , or discovering something new . Information is a term with many meanings depending on the context , but as a rule closely related to such concepts as meaning, knowledge , perception, instruction , communication , and various mental processes . Simply put , the information is received and understood as the message . But above all , it is the result of processing , manipulating and organizing data in ways that they build on the knowledge the person who receives this information.

On the other hand, the message is materialized form of information. The main feature of the message is that it is informative, and that the person to whom it is intended (the recipient) provides a (new) information. Information is always about something, and in this sense, it may be true or false. To be as useful or appropriate it is important that all participants in the communication channel have a certain knowledge about the subject matter. Although theories and models that consider the recipient necessarily imply the existence of the sender and therefore do not attach importance to the idea that information can come from the environment, it should be noted that the information and the message we must look at is always strictly linguistic context, because even us and the noise that interferes with the flow communication gives specific information.

Exhaustive legal definition of personal data on the Personal Data Protection Act (Official Gazette no. 103/0, 118/06 - hereinafter PDPA), according to which personal information is any information relating to an identified natural person or a natural person who is can identify that a person whose identity can be determined directly or indirectly, in particular on the basis of one or more factors specific to his physical, physiological, mental, economic, cultural or social identity (PDPA Article 2.) However, in an attempt to define a thorough personal data the question whether the concept of distinguishes personalities from the concept of privacy was left open? If we try to primarily determine the meaning of personality in Croatian language should provide some preliminary remarks. If we were to literally translate the words used in the western countries, then we are talking about the same word or translation would be the same as the English word privacy[4], similar to the personality of the German -Croatian-English dictionary, the word privacy is translated as secrecy of trust, privacy, solitude, peace, and so on until the word Personklichkeit, or in English, personality translates as personality, identity, personality, etc.[5] Thus, the concept of personality[6] covers an area that explicitly represents a person and her personal life, and the concept of privacy encompasses a wider range of features people taken individually, do not have to have some meaning, but linked to a stable structure resulting portrait of the person, which usually only the person needs to know . Therefore, the origin of the narrower the definition of personal data as well as information specifically related to an identified natural person or a natural person or a person whose identity can be determined directly or indirectly.

Also, privacy is one of the supporting values of Western legal culture. It is based, on the one hand, the belief that every human being has value in itself, and on the other to the primal human need for the existence of a particular protected area from which everyone else was off psychologically and materially. [7] Using the phrase "right

CAPURRO, R., "Information: ein Beitrag zur etymologischen und ideengeschichtlichen Begründung des Informationsbegriffs" Saur,. Munich, in 1978., p. 116.

[4] According to the dictionary of foreign words the word " private " (derived from the word " PRIVATUS " - personal , Your) means something personal and has no official character (unofficial). Further defined as confidential, secret , private, confidential , pets , domestic , exclusive, limited, nejavan , closed. See KLAIĆ , B., Dictionary of foreign words , foreign words and loanwords , Croatian Heritage Publishing House, Zagreb, 1990. , p. 1090. The term of privacy itself has been derived from the Latin word, which originally just means those places that are not allowed access to the public. Indicated the need for the inviolability of the private sphere is sublimated in the rich tradition of human thought, especially in the writings of luminaries like Voltariea , Montesquieu , Diderot , Rousseau, Bentham , Gibbon , Hume , Adam Smith , Kant, Locke, B. Franklin , Th. Jefferson and many others. But before it was recognized as an individual right provided with adequate protection, privacy has long figured only as a moral- philosophical ideal. On this see RADIĆ , Ž. , " The genesis of the right to privacy " , Proceedings of the symposium 'Right to privacy , Novalja - Split, 2008., p. 46 See also Guardster , The Right to Privacy , "p. First available at http://www.guardster.com/?Tutorials-The_Right_to_Privacy (25th 06th 2011).

[5] The United States Supreme Court has stated that American citizens have the protection of the Fourth Amendment (freedom from search and seizure absent warrant) when there is a reasonable expectation of privacy. Without a reasonable expectation of privacy, however, there is no privacy right to protect. "Various guarantees create zones of privacy. The right of association contained in the penumbra of the First Amendment. The Third Amendment in its prohibition against the quartering of soldiers. The Fourth Amendment explicitly affirms 'the right of the people to be secure in their persons, houses, papers, effects, against unreasonable searches and seizures'. The Fifth Amendment in its Self Incrimination Clause. The Ninth Amendment provides: 'The Enumeration in the Constitution, of certain rights, shall not be construed to deny or disparage others retained by the people." Griswold v. Connecticut, 381 U.S. 479 (1965) See GUARDSTER , The Right to Privacy , "p. First available at http://www.guardster.com/?Tutorials-The_Right_to_Privacy (10. 09. 2013.).

[6] Instead of the notion of privacy as synonymous in the Croatian language uses the term "personality" since according to its content, which is determined by factors outside the person, in connection with it, is a component of "persona". Cf. Brezak, M. "The right to privacy", Croatian Heritage Publishing House,Zagreb, 1998, p. 12 by Tomislav Ladan, editor of Croatian Lexicographic Institute in Zagreb (conversation led with him on January 11, 1995)

[7] Ibid., BREZAK, M,, p.12-13.

to privacy" when determining primarily legal and safety and protection of the methodology, as well as a set of rules that should be included in the protection of all the features of the situation, the conditions and circumstances in which the individual realizes his need for inner peace, what I want and which, taking into account all social conditions, have the right, it should be clear when it comes to normative regulation.[8]

In today's busy world threats to privacy rights have the effect of violation of information personality that in the strictest sense of the word is defined as a claim of individuals, groups or institutions to independently decide when, how and what information about yourself to cede to others.[9] In a broad, generally accepted meaning of the term information personality actually defines the term information security under which implies that the individual, in terms of the information society, decide when, where, how and how much will disclose personal information, taking into account their rights and needs, but and the rights and needs of the community where the person lives.[10] Circumstances and conditions of personal rights are defined depending on different variables: depending on the culture, structure or sociological tradition of a society.[11]

In the complex environment of the digital economy modern security management information systems acknowledge that most risks cannot be completely eliminated and that they need to be managed in a cost effective manner. In information strategies, especially created for the purpose of information security is important to concentrate on the development of a methodology for the assessment and analysis of threat and vulnerabilities within the context of a security risk management.[12] It refers mostly to the threat and vulnerability assessment method developed with the needs of mobile computer systems in mind. Most of the information strategies consist of four stages: a) Assessment Scope, b) Scenario Construction & Modeling, c) Threat Agent & Vulnerability Analysis, and d) Stakeholder Evaluation. These kinds of strategies actively involve stakeholders and focuses upon a technical, socio-technical and business aspect of the system.[13]

III. The Legal Legislative In Data Privacy, inofrmation security and the right to privacy in the Republic Of Croatia

Apart from regulatory framework, the legal framework of eGovernment model in Croatia if regulated by the following legislative:

- The Constitution of Republic of Croatia; Official Gazette of Republic of Croatia, NN 56/90, 135/97, 8/98, 113/00, 124/00, 28/01, 41/01, 55/01, 76/10, 85/10
- Law on Personal Identification Number,
- Official Gazette of Republic of Croatia, No. 60/08
- Law on Protection of Personal Data, Official Gazette of Republic of Croatia 103/03
- Law on Right to Access Information, Official Gazette no. 172/03
- Law on Information Security, Official Gazette of Republic of Croatia 79/07

In this area, as one of the most questions that the information society faces in today's digital econoy is confidentiality of information, the second is availability and the third is integrity of the information. Together these three security principles form the basics of information security model which is namely intented for protection of access to information.[14], the conflicts of

[8] Also, it is important to compare the perception of personality through property relations that even possible violation of personal data is seen as a violation of people (causing mental anguish, etc.) and is not a property in the classical sense, nor of material values. See KRNETA, S., Civil law protection of the private life in European law, Yearbook of Law Faculty in Sarajevo,1970., p. 81-97. See also, Dika, M., "Protection of personal rights in litigation and enforcement", in Klaric, P. (ed.) "Responsibility for non-pecuniary damages for the infringement of personal rights, , Zagreb, 2006.,, p. 267. Also see RADOLOVIĆ, A., "The right of personality in the new Law on Obligations," Journal of Faculty of Law in Rijeka, Vol 27 no.1, p.133-134.

[9] According to WESTIN, A., Privacy and Freedom, Atheneum, New York, 1970., p.7

[10] s a basis for the definition of personal data protection is primarily defined by the concept of personal data. In accordance with the legal point of view, personal rights are defined as subjective immaterial rights legal system recognizes a person in respect of its personal, compensates personal resources and opportunities as their protection of private rights. On this definition, it is necessary to interpret the definition of personal rights as one of the key foundations of the protection of persons and personal data. With respect to protecting people and individual rights is important to distinguish the concept of protecting the physical security of the person and the protection of privacy and individual personality. Personality is , however, necessarily related to privacy, which is based on deep personal definition of each individual. Interference on the personality of violating the fundamental rights guaranteed by the legislation and the question is can you ever recover damages in this case učinjena.Cf. Brezak, M. p. 22

[11] For example, privacy in certain cultural communities is given by hiding women's faces on foundation in religion, but this is a good example of how the protection of personal rights is functioning. In the same way, in modern terms, the "chat-room-in" or talking through aliases or nicknames of people who access this website in order to protect the personality not to sign their data on the first and last name in order to prevent misuse of the same. Every person on earth is born with the need for personality, for its own framework in which to develop and prosper. On this see beyond TUCAK, I., "Rule of Law and Human Rights," Legal Life, no. 14/2007., p. 483

[12] See BÖHLEN, M. H., E-government: towards electronic democracy : international conference, TCGOV 2005 Bolzano, Italy, March 2-4, 2005 proceedings, Springer, 2005., p 122

[13] More on this approach at BOBAN, M., Building eGovernment model on the principles of new economy trends and international standards considering protection of citizen privacy and personal data, E-Society Journal Research and Applications, Volume 1, Number 2, Zrenjanin, December 2010., str. 1 – 15

[14] Refering to presentation available on the Internet KLAIĆ, A.: „EU's information security expectations", Conference Infos-week, Zagreb, 14-18. svibanj 2007., p.5. (unpublished): the first domain's property is confidentiality as the main property; the second and third domain's is privacy while in the 4th domain disclosure is not desireable but it is not harmful.

rights of access to information and protecton of personal data.[15] (as shown on Fig. 1.).

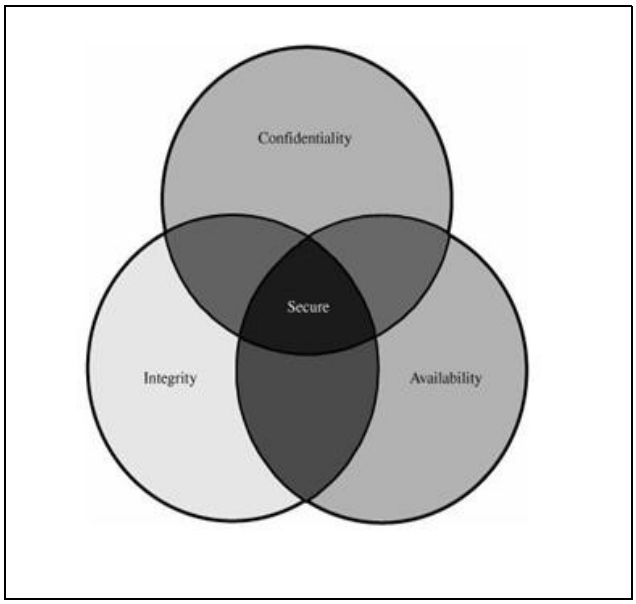

Figure 1. Three main principles of information security in digital economy

The Republic of Croatia, as the entire member states of the European Union, is also signatory of the European Convention on Human Rights and the Convention for the Protection of Individuals with regard to Automatic Processing of Personal Data, the European Commission was concerned that diverging data protection legislation would emerge and impede the free flow of data within the EU zone. Therefore the European Commission decided to harmonize data protection regulation and proposed the Directive on the protection of personal data, which member states had to transpose into law by the end of 1998. In full name, Directive 95/46/EC on the protection of individuals with regard to the processing of personal data (Official Journal L 281 , 23/11/1995 P. 0031 – 0050) and on the free movement of such data contains a number of key principles which must be complied with. Anyone processing personal data must comply with the eight enforceable principles of good practice.

In contemporary information society, information is made pursuant to the process of public information, an integral part of the democratic and political process. Information becomes an important element of freedom and the right to disseminate information to a large extent depends on the legitimacy and management capabilities of data collections. It is obvious that the process of disseminating information, its printing, publication or broadcast in the media is subject to the erroneous interpretation. Logically, one of the constitutional and distinctive means of limiting the freedom of public information for the protection of personal rights is the right of correction of information. The Constitution of Republic of Croatia ("Official Gazette" no. 56/90, 135/97, 8/98-consolidated text, 113/2000 124/2000 - consolidated text, 28/2001 and 41/2001-consolidated text, 85 / 2010-revised text - hereinafter Constitution) guarantees the right to a correction which has been determined by the Constitution and the law (Constitution Art. 38). The process of disseminating information, their printing, posting or displaying is regulated by the legal regulations governing public media. In Croatia, the information is accomplished through media that are subject to national legislation and Media Law[16] ("Official Gazette", no. 59 / 04, still-ML).

Legally, it is interesting to view the correction information is one of the logical, constitutional and differential means limiting the freedom of public information to protect the rights of personality. ML entitles legal or natural person that within 30 days of the publication of false or incomplete information from the editor requires disclosure of the correction of the notice of violating her rights and interests.[17] Correction must be published in the first, and if it arrived late, in the second program content upon receipt, without changes and additions, in the same or equivalent in the programming area, of the same or equivalent manner in which the information was published, in radio and television programs published reading in the same program and the period of time or in the same kind of identical ratings.[18] The ML also regulates rules of court proceedings if the editor refused to publish a correction or do not publish on time and in the manner prescribed by law. Considering the essence of the freedom of public information in the legal freedom of reporting, advocates of logical restrictions on the freedom of the press in the correct information, see the means to support the principle of duty of truth, i.e., transmitting only the truth in reporting. For supporters of the constitutional limitations on freedom of media boundaries of public information derived from the protection of personal honor, and the principle of equality of citizens. For the theory differing

[15] See REDDICK, C. G., Politics, democracy, and e-government: participation and service delivery, Idea Group Inc (IGI), 30. 3. 2010., p.373

[16] Media are: newspapers and other print, radio and television programs, news agencies, electronic publications, teletext and other forms of daily or periodical publishing editorial program content transmission media, voice, sound or image. The media are not books, textbooks, newsletters, catalogs or other holders disclosure intended exclusively for educational, scientific and cultural process, advertising, business communication, operation of companies, institutes and institutions, associations, political parties, religious and other organizations, school newsletters , "Official Gazette" of the Republic of Croatia, the official journal of local and territorial (regional) governments and other official announcements, posters, flyers, brochures and banners, and video sites without live images and other free information, unless this Act provides otherwise. (ML, Article 2. § 1)

[17] According to ML everyone has the right to require that the editor at no charge to publish a correction of information that they were violating the rights or interests. Have the right to correct and legal persons and other organizations and bodies, if the information was violated their rights and interests. The purpose of corrections is to correct inaccurate or incomplete informacije.Objava correction may be requested within 30 days of the publication of information. (ML Art. 40, paragraphs 1 and 2)

[18] On this see Zlatović, D., "The right to correction and response to the new Media Law," Law and Taxation, no. 3, March 2007., p. 38 - 42

demarcations of the correction of the information, its intent is to defend certain constitutional and preferential rights established by the Constitution and by the law regulations. The Croatian Constitution guarantees "the right to correction to anyone who has been violated by public news as his/hers constitutional and legal right." (Constitution Art. 38).
Through the mass media it is also exercised the constitutional right to freedom of expression. The exercise of this right requires freedom of the press and other mass media, freedom to establish any public information, the ban on censorship and the right of journalists to freedom of reporting and access to information. The Republic of Croatia guarantees the freedom of expression and freedom of the media , which includes the freedom of expression , collection , research, publication and dissemination of information, publication and dissemination of the press, the flow of information , media openness , pluralism and diversity of media , the availability of public information , production and broadcasting of radio and television broadcasting , freedom of establishment of legal persons for the performance of public information (ML Art. 3 Para 1 and 2). However, freedom of information can lead to the publication of false and derogatory information, and cause a breach of privacy. (ML Art. 7 Para 1) is therefore legally entitled to a correction and reply and the right to compensation for the damage caused.[19] On the other hand, prevent printing and distributing printed items and broadcasting is a criminal offense.

Also, the right of journalists, editors, printers and authors of published reports that refuse to give information on the source of published information or information that is intended to publish, is also protected by ML in a specific way. Specifically, the „journalistic secret" , a term that is conventional for such retention is different from the professional secret in that it is only the right , but not the obligation . So, the reporter may refuse to reveal the source of information, but there is no legal obligation to maintain the confidentiality of the data. (ML Art. 30 Paragraph 1) The court shall request for paying sources to adopt if it is necessary to protect the public interest in a particularly important and serious circumstances, and no reasonable alternative measures of disclosure of such information, and if the public interest in disclosure of the source clearly prevails over the interest of its protection.[20] According to the interpretation of the Code of Criminal Procedure (Official Gazette 62/03- still CPC), the journalist is released duty to testify about sources of information obtained in carrying out their profession , except in criminal proceedings for offenses against honor and reputation committed mass communication (CPC art. 244 § 1).[21]

In Croatia, the right to access the information is explicitly regulated by the Law on Right to Access Information – (further LRAI - Official Gazette no. 172/03). which stipulates that public authorities are public bodies, local and territorial (regional) governments, legal persons with public authorities and other persons to whom are delegated public authorities? (Article 3 paragraph 2 LRAI). The goal of LRAI is to enable and provide access to information to physical and legal persons by public action by public authorities. (Article 2 , LRAI) Also, all public authorities were required to ensure organizational, financial, technical and other requirements to implement the provisions of the Act. According to this, “the right of access to information" is defined "as the right of beneficiary to seek and receive information as well as the obligation of public authorities to provide access to the requested information, or to disclose information even when there is no special requirement for publication is their obligation to a particular law or other general regulations. "(Article 3 Paragraph 5, LRAI).
On the side of public authorities in the LRAI model, there are following assumptions: the non-existence of exceptions to the right of access; consistent application of the principle of access to information; legal action concerning a request and consistent application of measures for the realization of the right of access as well as the organization of collecting, processing and providing information. So for the availability of information it is essential to meet the specific requirements that the applicant's side, and on the side of public authorities.[22] On the information seekers: it is necessary to first know the legislation on right to access information; such content making demands that will result in the requested information; it is necessary to know the matter, within which one can find the required information and also it is an essential and status information seeker and the financial capability.

[19] See KOVAČIĆ, T., "Liability for breach of personal rights of the legal person publishing the information in the media (I)," Law and Taxation, no. 8, August 2008., p. 40-45

[20] According to art. 233 Paragraph 3 of the CPC in the criminal proceedings are not subject to seizure records of the facts that have been done by journalists and their editors in the media about the sources of information and data that they learn in the course of their occupation and who were used while editing the media, which are in their possession or the editor in which they are employed.

[21] According to Article 244 CPC obligation of testimony exempts: 1) the spouse or common-law partner accused, 2) relatives of the accused in a vertical line, relatives of the lateral line to the hird degree and relatives by marriage to the second degree, 3) an adoptee and adoptive defendant, 4) lawyers, notaries, tax consultants, doctors, dentists, pharmacists, midwives and social workers about what they are doing their jobs out of the defendant, and in Section 5) journalists and their editors in the media about the sources of information and data that they learn in the course of their occupation and who were used while editing the media, except in criminal proceedings for offenses against honor and reputation committed through the media.

[22] The law stipulates the obligation of submitting reports by public authorities on the implementation of the previous year to 31 January, and the Office submits a report to the Croatian Government to 28th February for the previous year. The Croatian Government is obliged to submit the report on the implementation until the 31st of March to the Croatian Parliament for adoption. By experience, the Central Administration Office regularly reports on the right to access information and enter it in a timely manner in the regular procedure in the Croatian Parliament. For example see report available at www.vlada.hr/hr/content/download/7052/59557/file/6%20-145.pdf (12. 03. 2014.)

Also, the main stipulation of the LRAI is public interest connected with legal, political, economic and financial interests of the Republic of Croatia – in this case. But sometimes it is not clear what the term "public interest" actually means. Often it is defined as a public benefit that may result from publication of certain information. But it is very difficult to explain what would be the benefit, because of course it depends from case to case. In this question, we should not ignore the fact that the exemption of this right to access the information as a public interest from the obligation to keep information that contain personal data of citizen's – beginning even with only a name – a secret. In this case it shouldn't no matter how the public services are motivated by public (government) interest or the right to access information of importance to the entire legal, political, economic and financial system of a country.

In this cases in the legal practice is used the test of public interest and proportionality which requires the public authority to assess whether, in each case in the public interest to allow access to the information or whether you would benefit from providing access to information was greater than any harm (proportionality between constraints and objectives to be protected). The theory emphasizes that the public interest test should be used very carefully and conscientiously as it requires a higher level of decision making between the two conflicting rights or interests. The test involves balancing the public interest and assessment in order to determine which is better for the public interest: to disclose or not disclose information. The public interest may change over time and depends on many circumstances, these changes and depends on the current situation. Public interest test requires an assessment on a case by case basis, considering the different variable factors.

IV. Conclusion

Since the information, in nowdays so called „information era" has began to rule the world, the question of the data security has becoming increasingly relevant issue in the experts discussions. Also, the question of information, data security and the personal privacy take a fundamental part of the discussion related to the personality and information security connected to the new tecnololgies. In this paper, afterwords the thorough debate, still remains the question whether indeed litigation, and the Law itself, can really undo the damage of the revelation and correction of inaccurate information? Whether the civil lawsuit can put a "price" on someone's "privacy", and whether mechanisms, so clearly laid, in the Constitution and connected laws actually function in practice? Especially in the field of Government, Local Government and Public Services? Although the litigation related to the disclosure and correction of information is laid on expedited basis - remains an open problem of compensation and protection of personal data and personal information security in order to prevent encroachment into the foundations of human rights and dignity. Furthermore, there remains the question of "irreparable" harm violating the right of personality, personal's honor, reputation, dignity, one's private and intimate sphere, the name, character or work which in Croatia in the field of public public administration – still has no legal practice in general.

E-business models for web based social networks in the Republic of Macedonia

Dimitar Jovevski*, Edvard Tijan **
* Faculty of Economics, University ss. Cyril and Methodius-Skopje, Macedonia
** University of Rijeka, Faculty of Maritime Studies, Rijeka, Croatia
djovevski@eccf.ukim.edu.mk, etijan@pfri.hr

Abstract - Since their introduction, social media sites (SMSs) such as Facebook, LinkedIn and Twitter have attracted millions of users, many of whom have integrated these sites in their daily practices. As of this writing, there are hundreds of SMSs, with various technological affordances, supporting a wide range of interests and practices.

Social media are gaining popularity and are increasingly used in regular operations of many companies, including start–ups, small, medium-sized, and large organizations. The purpose of this paper is to explore the different e-business models and organizational factors that impact the successful use of social media in companies in the Republic of Macedonia. This research will focus on the extent of impact that social media have on organizational capabilities and business performance.

From the research it could be found that successful deployment of set of external and internal factors can lead to the improvement of business performance (financial and nonfinancial) of the companies. According to the results, the successful use of web-based social networks can improve (1) CRM integration, (2) open communication within a company and (3) ICT integration.

Keywords: social media, social networks, critical success factors, e-business models

I. INTRODUCTION

The world in which we are living and the balance between companies and consumers are constantly changing. Companies need to implement new information and communication technologies (ICT) to meet the needs of consumers. Web-based social networks are included in the lifestyle of many people in the world. This fact enables the companies to have another channel to communicate with their customers through these networks. Social networks like web - based services incorporate various technologies (blog, forum, and social games).

In today's digital environment web-based social networks are important in the everyday operations of the companies. Because of its unique ability to share information between users, the web-based networking slowly but surely transformed into a powerful tool with which companies can communicate with their audience. As a result, companies increasingly seek to create fun and informative pages on social networks and to maintain their presence. Their presence directly affects their business performance.

Emerging technologies gain popularity as enabling tools for cooperation among businesses in business networks [1], [2] whereas the applications market is flourishing [3]. Companies that take advantage of the latest social media technologies seem to outperform their competitors and report benefits like lower costs and improved efficiencies [4]. In this context it is important to understand the specific impact that social media have on business performance[5]. The identification of a direct connection between the two will support the shift towards Enterprise 2.0 – a new business environment in which the companies will maximize the benefits they can obtain by integrating social media suites into their daily operations.

The subject of research in this paper is the analysis of e-business models that include the impact of various factors for successful web-based social network by organizations. This analysis involves a group of independent factors that directly or indirectly affect the success of enterprises. These groups of independent factors are: the use of ICT in organizations, organizational structure and architecture of business processes, strategy, affecting dependent variables such as increased sales and brand awareness through web-based social networking.

Empirical research includes exploratory and conclusive research with three parts. The first part is to create a conceptual model for successful use of web-based social networks, the second includes testing the relationship between various internal and external dimensions of successful use of web-based social networks and the third include testing of the relationship between individual dimensions and business performance.

Exploratory research used quantitative methods such as analysis of secondary data and interview techniques with experts. The primary data used statistical methods: structural equation modeling and confirmatory factor analysis and exploratory factor analysis.

II. E-BUSINESS MODELS FOR SOCIAL NETWORKS AND BUSINESS IMPACT

In this section we define social media as a part of Web 2.0 technologies (A), refer to the resource-based view of the firm and factors for successful use of social media and their impact on organizations (B)

A. Defining social media

The term Web 2.0 was coined in 2001 by O'Reilly [6] in a conference brainstorming session to reflect the transition from the manager generated content era to the user-generated era. O'Reilly identifies seven differences between Web 1.0 and Web 2.0: the web as a platform; the harnessing of collective intelligence; the data as the next Intel Inside; the end of the software release cycle; the lightweight programming models; the software above the level of a single device; the rich users' experience [6]. The term was widely adopted and definitions have been formulated for Web 2.0, all emphasizing collaboration and enhanced communication, as well as user involvement. Harris and Rea [7] define Web 2.0 as "a perceived second generation of Web development and design that facilitates communications and secures information sharing, interoperability, and collaboration on the Web".

Bell and Loane [8] define Web 2.0 as "a set of economic, social, and technology trends that collectively form the basis for the next generation of the Internet – a more mature, distinctive medium characterized by participation, openness and network effects".

Web 2.0 technologies share common characteristics that distinguish them from previous generations of Web development. Firstly, Web 2.0 brings about an emphasis on collaborative learning as well as on user engagement through participation. Secondly, Web 2.0 is regarded as user friendly, as it enables immediate publication and wide distribution of user generated content. The driving force behind the new wave of applications stands in their content and data management systems, as well as in their architecture of participation that encourages user contributions. Further on, the new generation of applications uses the web as a development platform. Most Web 2.0 tools are based on the Software as a Service technology [8].

Web 2.0 and social media have different meanings, but they are directly connected, and it can be said that social media derive from Web 2.0. Kaplan and Haenlein [9] define social media as "a group of Internet-based applications that build on the ideological and technological foundations of Web 2.0, and that allow the creation and exchange of user-generated content". In this paper we use Web 2.0 when we address the technology platform, but most of the time we will talk about applications that derive and use technological foundation of Web 2.0 that is social media.

Social media is a phrase that describes the platforms and other tools that connect people into social networks (of their choice) online. Some of the household social media names worldwide (other than Facebook) are MySpace, LinkedIn, Twitter, YouTube, Foursquare Google+ [10].

The individuals that make up these online networks use social media to organize themselves according to (1) their interests and (2) their preference for the way they choose to share, store and deliver information within their community (or "network") [11].

Individuals have made it clear they wish to connect with other individuals that they choose to, in the way that they choose to, and around topics and for reasons that they choose to. The individual is at the centre of the social media revolution. Companies must be present there, for sure it can be said that this is changing the way business is done.

B. E-business models for successful use of web based social networks in companies.

In the paper, the resource-based view will be pursued as a perspective on organizations to explain the impact of using web based social networks on company performance. The resource-based view states that organizations obtain a set of certain resources (like human resources or ICT infrastructure) that could be company specific. The particular combination of resources forms the basis for company's competitiveness and performance. A distinction can be made between resources and capabilities. While resources serve as basic units of analyses, capabilities are repeatable patterns of action in the use of resources to create, produce, or offer value to a market [12]. Note that resources (like Web 2.0 tools) may be obtained easily, but that it is not easy to develop business-wide capabilities to use the resources to enhance business performance. So, while any company can reach resources easily, capabilities embedded in business practice cannot be reached. We focus on Web 2.0 based capabilities, more on capabilities related to web based social networks, when a company is using them.

In the literature different models exist, describing different factors related to the use of web-based networks in companies. These different models are regarding the factors from different perspectives and views. Each of the models is defining a set of critical success factors (CSFs) that are directly connected to web based networks and responsible for improving business performance. Daniel Crain Smith [13] defines several CSFs related to social networks that are crucial for a company when using Web 2.0 technologies such as social networks. These CSFs are: age of the employees, support from the top management, organizational structure and social pressure from the environment. The main disadvantage of his model is the lack of precise and clear definition of factors that are directly connected to business performance. Colin Smith's [14] model, compared to the previous one,

succeeded in distinguishing several factors that can measure successful use of social networks in a company. Smith suggests income from sales of new products as one of the most important factors that can measure successful use of social networks. Many authors mention other CSFs that are important when one company is using social networks like: human resources, organizational culture and organizational structure. Reagans and B. McEvily [15] and Burt [16] are also defining a set of CSFs responsible for successful use of social networks in one company. According to this group of authors, the most important factors are the type and structure of the networks, demographics of the network and social capital of the organization. Multidimensionality of this model is making it complicated, besides the fact that there are factors which the company cannot influence. Another model that describes different CSFs is Philip Chen's model [17]. Is his model, Chen has defined four groups with two factors that are important for successful use of social networks. These groups are: strategy, infrastructure, openness, and collaboration. Chen clearly defines and confirms that this set of CSFs is responsible for successful use of Web 2.0 technologies to improve business performance from financial and nonfinancial perspective.

From the reviewed literature, most of the authors suggest more or less the same set of the CSFs. For our purposes, we decided to use the two groups' model (or the multistage model). The first group consists of internal factors and the second group consists of external factors. Internal factors are directly connected to every day work of a company and its capability to successfully use social networks. These factors are subsequently divided into the following subgroups: functional factors, strategy factors and technical factors. In the group of functional factors are internal integration of social networks and openness in using. Strategic factors are: alignment of business and Internet marketing strategies and alignment of Internet marketing strategy and CRM (Customer Relationship Management). The third group are technical factors like IT infrastructure and organizational structure. Second subgroup of factors are external ones related to the social pressure that one organization could have from its competitors and users in their environment. These two groups of CSFs are influencing a group of independent financial and nonfinancial factors that are directly related to business performance of a company. These independent factors are income from sales, decreasing costs, and brand recognition.

Based on the literature and the different models mentioned above, a conceptual model was created, with eight groups of factors in total.

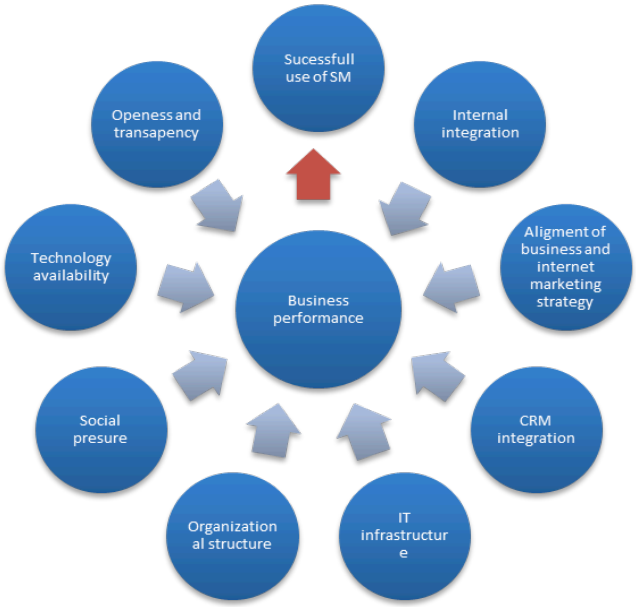

Figure 1. Conceptual model of CSFs for the successful use of social media

III. RESEARCH

For this study, a survey instrument was used. The collected data was analyzed using Structural Equation Modeling (SEM) techniques to validate, evaluate, and analyze the relationships between the specific factors (independent variables) and business performance (dependent variable).

The sample for testing consisted of 110 Macedonian companies, which actively used web-based social networks in the past year. The descriptive statistics show that 91% of the companies in the survey were from Skopje, 20% were in trading industry, 13% in software industry, 12% in telecommunication industry and 14% in media and newspapers. According to the size 40% were small companies, 26% were medium companies, 20% were micro companies and 13% were large companies.

To test the reliability, an internal consistency of this study was analyzed and reviewed using Cronbach's alpha. Construct validity is the extent to which a set of measured items actually reflects the theoretical latent construct those items are designed to measure [18], [19]. In this study, all measures were analyzed for reliability and validity using a Structural Equation Modeling (SEM) confirmatory technique. Confirmatory factor analysis (CFA) was used to construct a measurement model composed of ten constructs of this research model. The measurement model estimates each construct between latent variables (independent variables) and dependent variables using measuring items. To assess convergent

validity for construct validity, composite reliability (CR) and average variance extracted (AVE) from measures were examined [18].

Cronbach's alphas assessing the internal consistency of the study's measures are in range from 0.71 to 0.91. They were above the acceptable threshold of 0.70, suggesting adequate reliability [19].

A confirmatory factor analysis was conducted to determine the convergent and discriminant validity of the 10 constructs. As suggested by Hair [18], convergent validity was assessed by examining the factor loadings, computing the composite reliability of, and average variance extracted for the model constructs. Constructs have convergent validity when the factor loadings are statistically significant, the composite reliability exceeds the criterion of 0.70, and the average variance extracted is above 0.50. As suggested by Hair [18] and Fornell and Larcker [20], discriminant validity was assessed by comparing the squared correlations (between the constructs) and the average variance extracted for a construct. Constructs have discriminant validity when the squared correlations are lower than the average variance extracted for a construct. The fit of the measurement model was assessed using the following statistics and indices: Chi-square, the ratio of the Chi-square to the degrees of freedom (df), Comparative Fit Index (CFI), and Root Mean Squared Error (RMSEA). Chi-square/df values less than 3 indicate good model fit and between 2.0 and 5.0 is acceptable level [21]. CFI values in 0.80 to 0.90 indicate a confidence level [22]. RMSEA values less than 0.90 indicate good fit [20].

The factor loadings, composite reliabilities, and average variance extracted for the model constructs are shown in Table I. From the table it can be concluded that some of the factor loading do not fit the accepted ratios. The index GFI and AGFI are not fitting the acceptance level bellow 0.90. Also RMSEA is over the recommended level of 0.90 [19]. The index CFI is below 0.8 which is also below the recommended level. Only relative index CMIN which represent Chi-square is between 1 and 3 [23].

TABLE I. CFA TESTING WITH 10 CONSTRUCTS

χ^2	1019.429
Level of freedom	620
Level of probability	0,000
GFI	0,631
AGFI	0,56
RMSEA	0,91
CFI	0,735
CMIN	1,664

Next step in CFA is to determine the level of adequacy, by using the squared multiple standardized regressive coefficients. From the analysis, it can be concluded that 13 factors which are explaining the latent variables are below the accepted level of 0.40 [23]. Because the CFA shows that the some of the constructs in the model do not fit the factor loadings, adjustment of the model was required.

After refining and adjusting the model, a confirmatory factor analysis was conducted for the second time. The factor loadings were good, but one of the 10 constructs was left out. The factor loadings are shown in a table 2.

TABLE II. CFA TESTING WITH 9 CONSTRUCTS

χ^2	324,230
Level of freedom	216
Level of probability	0,000
GFI	0,774
AGFI	0,687
RMSEA	0,80
CFI	0,895
CMIN	1,501
PNFI	0,589

From the Table II. it can be concluded that all indexes for model fit are better then the previous model with 10 constructs. RMSEA is within the recommended value of 0.9, CFI is above recommended minimal value of 0.8. Also PNFI (Parsimony-Adjusted Measures), wich show the level of adjustment of the model is better then the first tested model. Also CMIN is in the recommended value between 1 and 3.

To evaluate the fit of the proposed model, the fit of the whole model was tested and assessed. The magnitude (i.e., statistical significance) and direction (i.e., positive or negative) of the individual parameters (i.e., the path coefficients) were assessed. Overall, the goodness-of-fit indices show that the proposed model has a good degree of fit with the data; the ratio of the Chi-square to the degrees of freedom was 3.80, a number smaller than 4.0 is considered very good, and between 2.0 and 5.0 is acceptable [18], the CFI 0.89 was within 0.8 to 0.9 confidence level [19] and the RMSEA 0.08, less than 0.1, which is considered a good fit [22].

The path coefficients and corresponding standard errors and t-values are presented in Table III

TABLE III. STANDARDIZED REGRESSION COEFFICIENTS OF SEM

			t-value	P - value
BusFin	<---	VnatInt	.070	.908
BusFin	<---	PolOtv	1.954	.008
BusFin	<---	BusIMS	.177	.775

			t-value	P - value
BusFin	<---	CRMInt	1.965	.060
BusFin	<---	ITInf	.475	.088
BusFin	<---	OrgPos	1.910	.059
BusFin	<---	NedTeh	1.935	.036
BusNFin	<---	NedTeh	1.935	.022
BusNFin	<---	OrgPos	-.574	.188
BusNFin	<---	ITInf	.335	.137
BusNFin	<---	CRMInt	1.633	.248
BusNFin	<---	BusIMS	.270	.587
BusNFin	<---	PolOtv	1.964	.018
BusNFin	<---	VnatInt	-.134	.779

*Note:*** p-value <0,01; :** p-value <0,05; :* p-value <0,10*

From the values above it can be concluded that 50% of the regression coefficients are statistically significant. Statistical significance is expected to be in the range of p-value <0.10 because of the size of the example [18]. All regressive coefficients are positive except the last one (Business non-financial and internal integration), but there is no statistical significance.

Statistical significance can be found between the next regressive coefficients: culture of open communication - financial and non-financial performance; CRM integration and financial performance; IT infrastructure and financial performance; organization structure and financial performance; availability of technology - financial performance and non-financial performance. There are 5 statistical significant relations related to financial and 2 with non-financial performance. Of all relations, the strongest is CRM integration and financial performance (t-value = 1,965), and the weakest is the availability of technology - financial performance and non-financial performance (t-value = 1.935). From here it can be concluded that seven of fourteen initial hypotheses were confirmed.

IV. CONLUSION

The subject of research in this paper was the analysis of e-business models that include the impact of various factors for successful web-based social network by organizations. This analysis involves a group of independent factors that directly or indirectly affect the success of enterprises.

The results of the conducted SEM research shows that statistical significance exists between the proposed seven critical factors and financial or non-financial performance of the companies. The results show that there is significance in the relationship with financial performance (5 links) and non-financial performance (2 links). These links are: the culture of open communication and financial performance; CRM-integration and financial performance, IT infrastructure and financial performance, organizational structure and financial performance, unavailability of technology and financial performance, unavailability of technology and non-financial performance; policy open communication and non-financial performance.

In terms of financial performance, it can be concluded that the link between CRM- integration and financial performance is the strongest. This relationship is the strongest in the overall model. Namely, if companies invest in social CRM data integration in their system, it will significantly affect and increase their sales and profits. In terms of non-financial performance the strongest link is between the policy of open communication and non-financial performance.

E-preduvjeti fiskalizacije računa u Hrvatskoj

Ivana Arbanas

Veleučilište "Nikola Tesla" u Gospiću/Poslovni i Prometni odjel, Gospić, Hrvatska
ivana.arbanas@velegs-nikolatesla.hr

Sažetak – Obveznici fiskalizacije računa moraju uz ostale prilagodbe, sukladno Zakonu o fiskalizaciji u prometu gotovinom (dalje Zakon), osigurati i određene e-preduvjete za njenu provedbu. Cilj rada je istražiti i prikazati koje e-prilagodbe za provedbu fiskalizacije trebaju izvršiti obveznici provedbe fiskalizacije računa te koliki su troškovi njihove nabave i uspostave. Zaključak istraživanja je da fiskalizacija računa utječe na povećanje troškova poslovanja svih obveznika njene provedbe, i to najviše na povećanje troškova poslovanja malih poduzeća i obrta koji nisu koristili, ili su koristili u manjoj mjeri, informacijske tehnologije i softver u poslovanju te je potrebno ukazivati i poticati na iskorištavanje mogućnosti povećanog korištenja suvremenih tehnologija uzrokovanog provedbom fiskalizacije za razvoj e-poslovanja, novih proizvoda, marketing i širenje tržišta, odnosno povećanje prihoda.

Ključne riječi: e-preduvjeti fiskalizacije računa, obveznici fiskalizacije, troškovi nabave e-preduvjeta za fiskalizaciju računa, razvoj e-poslovanja.

I. UVOD

Radi osiguravanja nadzora nad plaćanjima u gotovini, tj. smanjenja poreznih utaja pri plaćanjima gotovinom, donesen je i u primjeni je od 1. siječnja 2013. Zakon o fiskalizaciji u prometu gotovinom (NN 133/12). Ovim Zakonom propisano je tko su obveznici fiskalizacije u prometu gotovinom (dalje fiskalizacija), koji su rokovi njene provedbe, postupak i način provođenja, evidencija obveznika fiskalizacije, gotovinska plaćanja između obveznika fiskalizacije te nadzor nad provođenjem Zakona. Sam postupak provođenja fiskalizacije detaljnije je reguliran Pravilnikom o fiskalizaciji u prometu gotovinom (NN 146/12), dalje Pravilnik. Obveznici fiskalizacije koji obavljaju plaćanja u gotovini osim Zakonom propisanih obveza za sve obveznike fiskalizacije (izrade internog akta s popisom poslovnih prostora i načinom njihova označavanja, prilagođavanja elemenata računa sukladno Zakonu i ostalim poreznim propisima te postavljanja upozoravajućih naljepnica o obvezi izdavanja i uzimanja računa) moraju osigurati i određene e-preduvjete za komunikaciju s PU i provedbu fiskalizacije računa.

II. OBVEZE I E-PREDUVJETI OBVEZNIKA FISKALIZACIJE ZA PROVEDBU FISKALIZACIJE IZDAVANJA RAČUNA

Oni obveznici fiskalizacije koji obavljaju plaćanja u gotovini obveznici su i fiskalizacije računa. Npr. poduzeće koje je registrirano kao veleprodaja obveznik je fiskalizacije, ali ne nužno i fiskalizacije računa. Naime, sukladno Zakonu između ostalih obveznici fiskalizacije su i pravne i fizičke osobe obveznici poreza na dobit pa sukladno tome ukoliko poduzeće posluje kao veleprodaja, ali ako nema promete u gotovini, nego samo plaćanja općom uplatnicom na transakcijski račun ili s jednog transakcijskog računa na drugi, nije obveznik fiskalizacije računa [1], ali ako ima plaćanja u gotovini, tj. ostvaruje plaćanja novčanicama, kovanicama, čekovima, karticama ili drugim sličnim plaćanjima, obveznik je i fiskalizacije računa, osim za djelatnosti Zakonom izuzete ili oslobođene od fiskalizacije. Dok mali obveznici fiskalizacije mogu odlučiti žele li račune ispostavljati iz unaprijed u Poreznoj upravi (PU) ovjerene knjige računa ili kao svi ostali obveznici fiskalizacije računa. Obveznici fiskalizacije računa, uz sve obveze koje imaju svi obveznici fiskalizacije sukladno Zakonu, dužni su prije slanja prvog računa koji se odnosi na taj poslovni prostor, potpisati digitalnim certifikatom i putem uspostavljene elektroničke veze s PU dostaviti i poruku o poslovnim prostorima u kojima obavljaju plaćanja gotovinom, s naznakom svih podataka iz čl. 19. Zakona te račune izdavati putem elektroničkih naplatnih uređaja, softverski prilagođenih za potrebe fiskalizacije, koji im omogućavaju digitalno potpisivanje poruka i internetsku vezu s PU, tj. ovjeravanje računa jedinstvenim identifikatorom računa (JIR) od strane PU [2], [3], [4] te osigurati knjigu uvezanih računa ovjerenu u PU iz koje će ispostavljati račune u slučaju prekida elektroničke veze ili kvara elektroničkog uređaja.

Za provođenje samog postupka fiskalizacije izdavanja računa obveznici iste trebaju:

- "prilagoditi ili nabaviti naplatni uređaj sa softverom koji podržava provođenje fiskalizacije izdavanja računa
- od Financijske agencije (FINA-e) nabaviti digitalni certifikat koji se u postupku fiskalizacije koristi za elektroničko potpisivanje elemenata računa te za identifikaciju obveznika fiskalizacije prilikom elektroničke razmjene podataka
- nabaviti aplikaciju za elektroničko potpisivanje te
- povezati naplatni uređaj na Internet radi razmjene podataka s PU"[3].

U Republici Hrvatskoj (RH) primjenjuje se softverski model fiskalizacije s certifikacijskim sustavom, tj. obveznici fiskalizacije sami, sukaladno svojim poslovnim potrebama, odlučuju hoće li, tj. mogu li već postojeći naplatni uređaj (POS ili PC blagajnu) softverski prilagoditi, sukladno Zakonu [2] i Pravilniku [4] i tehničkim specifikacijama PU [5], [6], tako da im omogućava elektroničko potpisivanje podataka, internetsko povezivanje i razmjenu podataka s PU ili trebaju li nabaviti neki novi elektronički uređaj i odgovarajući softver koji im to sve omogućavaju te trebaju osigurati internetsku vezu za razmjenu podataka s PU.

III. DIGITALNI CERTIFIKATI

Za potrebe fiskalizacije FINA-a, kao jedini registrirani ovlašteni izdavatelj digitalnih certifikata (CA) u RH, izdaje dvije vrste cetifikata:

- Produkcijske aplikativne certifikate za obveznike fiskalizacije
- DEMO aplikativne certifikate za informatičke tvrtke koje će obveznicima fiskalizacije vršiti uspostavu sustava fiskalizacije.

A. Digitalni aplikativni certifikati - obveznici fiskalizacije

Osim nabave ili prilagodbe postojećeg elektroničkog naplatnog uređaja, koji mora omogućiti uporabu programske podrške za elektroničko potpisivanje elemenata računa i elektroničku vezu (Internet) za razmjenu podataka s PU, obveznik fiskalizacije računa za provedbu fiskalizacije mora nabaviti i produkcijski aplikativni digitalni certifikat FINA RDC: Fiskalx (x - redni broj certifikata izdanog za određenog obveznika fiskalizacije) koji izdaje Financijska agencija (FINA). Produkcijski aplikativni certifikat se koristi za elektroničko potpisivanje elemenata računa te za identifikaciju obveznika fiskalizacije prilikom elektroničke razmjene podataka. Ovaj certifikat nabavlja sam obveznik fiskalizacije ili njegov opunomoćenik, tj. informatička tvrtka koja obvezniku fiskalizacije obavlja uspostavu sustava fiskalizacije ne može ga nabaviti u njegovo ime, osim ako osoba ovlaštena za zastupanje obveznika fiskalizacije ne dodijeli pravo skrbnika djelatniku informatičke tvrtke, sukladno čl. 4. Pravilnika. Preduvjet za izdavanje produkcijskog aplikativnog certifikata je da obveznik fiskalizacije bude evidentiran u Registar digitalnih certifikata koji vodi FINA (Sustav PKI-Public Key Infrastructure). Ukoliko obveznik fiskalizacije već koristi neki od certifikata FINE (za neku drugu elektroničku uslugu FINA-e - Regos, PDV, ID...) već je registriran u Sustav PKI, tj. nije potrebna ponovna registracija. Registracija u sustav PKI vrši se predajom potrebne dokumentacije u nekom od Registracijskih ureda FINA-e ili elektronički putem aplikacije RDC Obrasci on-line kojoj se može pristupiti putem internetskih stranica FINA-e.

Za registraciju u sustav PKI potrebno je dostaviti sljedeću dokumentaciju:

- Rješenje o upisu u nadležni registar (tijelo koje ga je osnovalo).
- Obavijest državnog zavoda za statistiku o razvstvanju prema Nacionalnoj klasifikaciji djelatnosti (NKD-u) i matičnom broju (samo za pravne subjekte).
- Presliku osobne iskaznice osobe ovlaštene za zastupanje pravnog subjekta [7].

Za preuzimanje digitalnog aplikativnog certifikata potrebno je predati sljedeću dokumentaciju (ili presliku iste): "1. Zahtjev za izdavanje aplikativnog certifikata za fiskalizaciju – 1 primjerak, koji se može preuzeti na internetskoj stranici Financijske agencije,

2. Ugovor o obavljanju usluga certificiranja – 2 primjerka, koji se može preuzeti na internetskoj stranici Financijske agencije,

3. presliku identifikacijskog dokumenta skrbnika certifikata, te

4. dokaz o uplati naknade za izdavanje produkcijskih aplikativnih certifikata za fiskalizaciju" [7].

Nakon obrade predane dokumentacije, skrbniku certifikata, na način naznačen u Zahtjevu za izdavanje produkcijskih aplikativnih certifikata, dalje u tekstu Zahtjev, (sms-om, e-mail-om ili u Registracijskom uredu FINA-e), izdaju se referentni broj i autorizacijski kod, čijom kombinacijom može certifikat preuzeti on-line pomoću CMS Fina portala za preuzimanje certifikata, na Internet adresi https://mojcert.fina.hr/finacms/. Ako je skrbnik certifikata fizički identificiran te ako je u Zahtjevu za izdavanje produkcijskih aplikativnih certifikata naveden podatak o njegovom broju mobitela i adresi e-pošte, aktivacijske kodove skrbnik certifikata dobiva na ta dva kanala i to; referentni broj na e-mail, a autorizacijski broj putem SMS-a. Ako u Zahtjevu nije naveden broj mobitela skrbnika certifikata, aktivacijske kodove može preuzeti u Registracijskom uredu FINA-e. Rok za preuzimanje aktivacijskih podataka/kodova za preuzimanje produkcijskih aplikativnih certifikata nije određen. "Skrbnik je fizička osoba koja je zadužena za preuzimanje, uporabu, brigu i čuvanje privatnog ključa, odnosno certifikata koji je izdan za aplikaciju. Skrbnik može biti i osoba zadužena za zastupanje poslovnog subjekta" [7].

"Da bi obveznik fiskalizacije izdavanje aplikativnih certifikata za fiskalizaciju u potpunosti obavio elektronički, mora zadovoljiti sljedeće preduvjete:

- da osoba ovlaštena za zastupanje posjeduje kvalificirani digitalni certifikat izdan na FINA e-kartici/tokenu ili CoBranding kartici/tokenu banke,
- da je osoba ovlaštena za zastupanje poslovnog subjekta ujedno i skrbnik certifikata,
- da se na Zahtjevu za izdavanje certifikata naznači podatak o adresi e-pošte i broju mobitela na koje će biti isporučeni aktivacijski podaci/kodovi.

Postupak izdavanja provodi se na sljedeći način:

- osoba ovlaštena za zastupanje putem aplikacije RDC obrasci on-line popunjava elektronički obrazac Zahtjeva u kojem sebe ujedno imenuje i skrbnikom certifikata,
- na temelju podataka navedenih u certifikatu, automatski se generira Ugovor o obavljanju usluga certificiranja,
- osoba ovlaštena za zastupanje Zahtjev i Ugovor potpisuje naprednim elektroničkim potpisom,

- osoba ovlaštena za zastupanje/skrbnik zaprima par aktivacijskih podataka/kodova: referentni broj i autorizacijski kod, odvojeno; referentni broj na e-mail, a autorizacijski kod na SMS,

- kombinacijom dobivenih podataka, skrbnik vrši on-line preuzimanje certifikata" [8], pomoću CMS FINA portala za preuzimanje certifikata.

Nakon toga FINA dostavlja ovjeren i potpisan ugovor o certificiranju na adresu e-pošte navedene u Zahtjevu.

Ukoliko osoba ovlaštena za zastupanje ne posjeduje odgovarajući kvalificirani digitalni certifikat ili obveznik fiskalizacije nije evidentiran u sustav PKI, tada se Zahtjev za izdavanje certifikata može elektronički popuniti i poslati putem aplikacije RDC obrasci on-line, čime će biti automatski predbilježen u Fininoj bazi, što ubrzava proces. Istodobno je Zahtjev potrebno ispisati, potpisati i dostaviti u Finu s ostalom dokumentacijom potrebnom za izdavanje aplikativnog certifikata. Nakon obrade Zahtjeva, skrbnik certifikata dobiva aktivacijske kodove i može on-line preuzeti digitalni certifikat, na prethodno opisan način.

Pri preuzimanju produkcijskih aplikativnih certifikata, obveznici fiskalizacije računa (poslovni subjekti) trebaju se pridržavati FINA-ine Procedure za preuzimanje produkcijskih aplikativnih certifikata za fiskalizaciju. Sve detaljnije informacije, kao i sva potrebna dokumentaciju i procedure za zahtijevanje i preuzimanje produkcijskog aplikativnog certifikata mogu se pronaći na internetskoj stranici FINA-e, http://www.fina.hr/Default.aspx?sec=1543.

U Fininoj Radnoj uputi za preuzimanje digitalnog certifikata detaljno je opisan postupak rješavanja problema kad Internet Explorer i Mozilla Firefox upozoravaju na mogući sigurnosni problem prilikom pristupa stranici https://mojcert.fina.hr/finacms/, tj. prikazan je postupak prihvaćanja stranice kao sigurne u Windows ili Linux okruženju ili se za rješavanje ovog problema savjetuje, i opisuje kako, prvo obaviti postupak preuzimanja RDC CA root certifikata i njegove pohrane unutar Windows Certificate Store-a.

"Certifikati Fine su usklađeni s X.509 v3 standardom i preporukom RFC 5280 koja regulira uporabu X.509 v3 certifikata na internetu" [9]. Aplikacijski certifikati koje Fina izdaje za potrebe fiskalizacije su certifikati u soft obliku i njihovo korištenje je moguće na raznim platformama, tj. usklađeni su s međunarodnim standardima i nisu ograničeni ni na jednu specifičnu računalnu platformu i standardne su razine sigurnosti. Svrha digitalnog certifikata je autentikacija poreznog obveznika čime se on pouzdano i sigurno predstavlja PU i garantira se da je izdani račun upravo došao od tog poreznog obveznika te se njime omogućuje primjena elektroničkog potpisa, sukladno Zakonu o elektroničkom potpisu. Elektronički potpis jamči integritet i nepromjenjivost podataka na računu (potpis bi bio narušen ukoliko bi se naknadno mijenjali podaci nakon potpisa). Fina kao ovlašteni izdavatelj certifikata (CA), utvrđuje identitet i provodi registraciju svih poslovnih subjekata prije izdavanja certifikata, kako bi se ti podaci kasnije koristili unutar servisa kao jamstvo PU da je račun potpisan upravo certifikatom određenog poreznog obveznika. Aplikativni digitalni certifikati izdaju se u soft obliku pa se mogu koristiti (kopirati) na više prodajnih mjesta i više blagajni, unutar jednog poslovnog subjekta (OIB-a). Moguće je koristiti jedan certifikat na više računala kao i koristiti više certifikata na jednom računalu. Pri korištenju više certifikata na jednom računalu (vođenje poslovanja više obveznika fiskalizacije) potrebno je pri preuzimanju/pohranjivanju pojedinog certifikata voditi računa o imenovanju p12 datoteka, s obzirom da je certifikat vezan uz OIB poslovnog subjekta. [9].

Postavlja se pitanje zašto se za potpisivanje računa ne koristi napredni elektronički potpis koji ima veću razinu sigurnosti. Budući da je napredni elektronički potpis vezan uz fizičku osobu potpisnika i omogućen je primjenom kvalificiranog certifikata, koji se mora izdati na smart kartici ili USB key sa chipom (mediju-kripto uređaju koji zadovoljava određene propisane standarde) to bi značilo da bi uz nabavku uređaja i svaki djelatnik na svakoj blagajni morao posjedovati svoju karticu/key s certifikatom, dok korištenje softverskog certifikata bez potrebe za kripto uređajem pojednostavljuje izradu aplikativnih rješenja, s obzirom da se onda ona ne moraju prilagođavati tehničkim preduvjetima za primjenu smart kartice/keya, a uz to se mogu koristiti i na više blagajni, što smanjuje troškove i jedino je u aplikativnom certifikatu moguće definirati naziv aplikacije (fiskal) iz čega je vidljivo da se on koristi za potrebe fiskalizacije. Upotreba elektroničkog potpisa nema utjecaj na povećanje podatkovnog prometa, a samim time i povećanje troškova izazvanih time. Naime, obveznik fiskalizacije, sukladno Zakonu, dužan je osigurati 24 satnu internetsku vezu, koja omogućuje komunikaciju s PU, a paketi prometa koje nude operateri kreću se uglavnom od 1GB do FLAT rate (neograničenog prometa), a poruka, zajedno s potpisom, je veličine nekoliko KB (engl. Kilobyte), a potpis povećava poruku za 2 – 3 KB, odnosno potpisana poruka je oko 300 000 puta manja od najmanjeg paketa prometa iz ponude, što znači da je moguće poslati 300 000 računa unutar jednog mjeseca uz korištenje najmanjeg paketa prometa. Digitalni aplikativni certifikat vrijedi pet godina, a cijena mu je 300,00 kn + PDV [9].

B. Demo aplikativni certifikati - informatičke tvrtke

Informatičkim tvrtkama koje obveznicima vrše uspostavu sustava fiskalizacije na njihov zahtjev, isključivo za potrebe testiranja rješenja na naplatnim uređajima obveznika fiskalizacije, Fina izdaje DEMO aplikativne certifikate. Ovi certifikati su iste konstrukcije kao i produkcijski aplikativni certifikati, ne naplaćuju se, a izdaju se na razdoblje od dvije godine. Također je potrebno da poslovni subjekt bude registriran u sustav PKI. Ukoliko je već registriran tada treba samo predati dokumentaciju potrebnu za izdavanje Demo certifikata za fiskalizaciju i to:

- Zahjev za izdavanje DEMO aplikativnog cerfikata za fiskalizaciju – 1 primjerak.
- Presliku osobne iskaznice koja će biti skrbnik certifikata.

Upute "Procedura za izdavanje DEMO certifikata za fiskalizaciju", cijene licenci i ostali potrebni obrasci za izdavanje ovog certifikata mogu se pronaći na internetskim stranicama FINA-e, http://www.fina.hr/Default.aspx?sec=1542 .

Za digitalno potpisivanje poruka koje sadrže propisane elemente računa (XML-a) Fina je razvila programsku komponentu modul XmlSinger, koji je moguće integrirati u aplikativna rješenja. Poruke se potpisuju aplikativnim certifikatom za fiskalizaciju. Unutar modula nalazi se dll koji se može povezati s .NET aplikacijom, odnosno jar, za ugradnju u java aplikacije. Modul XmlSinger izdaje se za određeni poslovni subjekt, a njegov rezultat je ispravno potpisan HML računa, odnosno račun s potpisom koji će prihvatiti PU, nakon slanja putem web servisa. Računi se mogu potpisati isključivo aplikativnim certifikatom poslovnog subjekta za kojeg je i izdan modul XmlSinger. Informatička tvrtka koja će uspostavljati sustav fiskalizacije kod obveznika fiskalizacije mora za korištenje XmlSinger modula nabaviti za svakog poslovnog subjekta jednu licencu, tj. jednu ili više njih ovisno o tome kod koliko obveznika fiskalizacije uspostavlja sustav fiskalizacije. Cijenu licence/i plaća tvrtka koja je licence naručila [10].

Ako je obavljena fizička identifikacija skrbnika certifikata, tada on aktivacijske kodove može dobiti na e-mail, a ukoliko nije, tada ih može preuzeti u zaštićenoj omotnici u Fini. Aktivacijske kodove za preuzimanje ovog certifikata potrebno je aktivirati u roku od 30 dana. Ukoliko nisu aktivirani u tom roku potrebno je zatražiti izdavanje novih. Nakon preuzimanja DEMO certifikata isti je moguće koristiti/kopirati na onoliko mjesta/računala koliko je potrebno.

Korisnik je odgovoran za zaštitu lozinke kojom se pristupa privatnom ključu pripadajućeg Demo aplikacijskog certifikata, tj. ne smije zaporku zapisivati i pohranjivati u nezaštićenom obliku na računalu za fiskalizaciju.

U programsko rješenje može se ugraditi mogućnost da kod potpisivanja elemenata računa softver koristi zaštićenu pohranjenu zaporku i tako može pristupiti privatnom ključu i certifikatu za potpisivanje. Ukoliko je potrebno pronaći gdje je certifikat pohranjen na računalu treba provjeriti certificate store Windowsa (Internet Explorer->Tools->InternetOptions->Content>Certificates ili preko mmc snap in-a) [9].

IV. ANALIZA PONUDE UREĐAJA I INTERNETA ZA FISKALIZACIJU RAČUNA

Potrebno je naglasiti da vlada zabluda da je obavezno nabaviti novi hardver za potrebe fiskalizacije. Ukoliko poduzetnik posjeduje računalo ili neki drugi elektronički naplatni uređaj prosječne konfiguracije i isti omogućuje spajanje na internet i komunikaciju s PU, nije potrebno kupovati novi uređaj, već postojeći softverski prilagoditi za potrebe fiskalizacije.

U nastavku rada dat je prikaz ponuda elektroničkih uređaja, softvera i paketa interneta za potrebe fiskalizacije, do kojih se došlo slučajnim izborom, istraživanjem za stolom, tj. na temelju podataka dostupnih na internetu u trenutku pisanja rada, s tim da je dat samo prikaz tih podataka, a ne i ocjena ili izbor najboljeg rješenja, s ciljem da se korisnicima uštedi vrijeme pretraživanja ponuda i prikaže što je moguće veći broj istih, kako bi oni sami, tj. uz savjet informatičkih stručnjaka procijenili što je najbolji i istodobno najučinkovitiji izbor za njih, s obzirom na vrstu njihova poslovanja, dosadašnje korištenje ili nekorištenje elektroničkih uređaja i interneta u poslovanju.

A. Ponuda elektroničkih uređaja i softvera za fiskalizaciju

Pri izboru elektroničkih uređaja i/ili softvera za potrebe provođenja fiskalizacije, uz specifičnosti posla svakog poduzetnika pojedinačno, potrebno je skrenuti pozornost na to što se nudi u ugovoru o održavanju i prilagodljivosti programa za fiskalizaciju tipu poslovanja. Pri izboru softverskog rješenja treba obratiti pažnju na sljedeće: na koje uređaje se može implementirati, njegovu jednostavnost, mogućnost preinaka i podrške u slučaju zakonskih ili potrebnih periodičnih promjena u poslovanju. Najjeftinije niti najskuplje rješenje za fiskalizaciju ne mora nužno biti najbolji izbor, te je preporučljivo sve prethodno testirati, tj. provjeriti cjelokupnu funkcionalnost uređaja i softvera u praksi.

Kako piše Poslovni dnevnik [11] poduzetnicima se na tržištu nudi više od 300 različitih fiskalnih blagajni, tj. rješenja za fiskalizaciju, različitih „mogućnosti" i cijena. Tako se fiskalne blagajne tvrtke Fiskal 1 mogu naći i u prodavaonicama Konzuma po cijeni do 2 000 kuna, a mogu se odmah početi koristiti, podrška korisnicima se pruža kroz automatska osvježenja softvera, a hardver, odnosno Android Tablet i printer za ispis računa reklamiraju se kao i svaka druga kupljena roba. Zagrebačka tvrtka Infokom razvila je cloud rješenje koje se može koristiti i na Android tabletima, a koje se naplaćuje kroz mjesečni najam od 150 kuna na više. Tvrtka Lunacon iz Mostara razvila je vlastito rješenje softvera "Fiskalne Blagajne POS Sector", koje je usklađeno s hrvatskim zakonima, a prodaju ga kroz najam za 215 kuna mjesečno ili jednokratno za 3 550 kuna u što su uračunate eventualne zakonske izmjene.

Prema pisanju Jutarnjeg lista [12] na tržištu vlada raznolikost ponude, nesrazmjer cijena, nuđenje nepotpunih i dvojbenih usluga što dodatno zbunjuje korisnike. Prema njihovim saznanjima, do kojih su, kako pišu, došli uz savjet informatičkih stručnjaka, za manje poduzetnike koji se prvi put susreću s fiskalnim blagajnama najkvalitetnije, a istodobno financijski najpovoljnije rješenje je nabava tableta s Android sustavom, koji se može kupiti za manje od 1 500 kuna (bez PDV-a), a sadržava hardverski i softverki dio i pisač i ne zahtijeva nikakve dodatne troškove (licence za operativni sustav, antivirusni program-nema virusa i slično), jer je djelomično zasnovan na Linuxu, a može obavljati sve zadatke za potrebe fiskalizacije. Prema istom navodu, Hrvatski telekom (HT) nudi sva tri dijela za fiskalizaciju (hardver, softver i internet za komunikaciju s PU), a nudi ga putem najma. Uz HT na-

jam računala i programa za fiskalizaciju nude i drugi ponuđači, i to programski dio po cijenama od 50 do 250 kuna, a računala od 200 kuna na više. Za prodaju se programi osposobljeni za fiskalizaciju nude po cijenama od 1 200 kuna na više, a računala od 2 500 kuna na više. Također postoje i brojne ponude polovnih računala. Navodi se da većina ponuda uglavnom uključuje operativni sustav Windows, što zahtijeva dodatnu investiciju od oko 900 kuna za licencu, te još oko 200 kuna za antivirusni program, budući da se radi o sučelju sklonom prihvaćanju virusa. Također se navodi da nekoliko ponuđača nudi svoja rješenja na Linux platformi koja je besplatna i na kojoj virusi gotovo ne postoje, a čija je primjena moguća i na računalima skromnije konfiguracije što doprinosi uštedi pri nabavi računala, budući da je većina računala uglavnom presnažna tj. nepotrebno skuplja za funkciju maloprodajne blagajne. Linux rješenje je cijenama bliže klasičnim PC blagajnama srednje klase, a njihovo se programsko rješenje nudi samo kroz najam.

Kako piše na internetskim stranicama Hrvatske udruge MIPRO [13], HT je svoju ponudu obogatio Mini fiskalnom blagajnom koja korisnicima nudi najjednostavniju prilagodbu obvezama fiskalizacije, lako je prenosiva, zauzima malo prostora, jednostavna je za korištenje i instalaciju i nije potrebno ispunjavati nikakve infrastrukturne preduvjete te se zbog toga nameće kao idealno rješenje za sve obveznike fiskalizacije, a posebice za obveznike fiskalizacije koji rade na terenu. HT nudi dvije varijante ovog uređaja/blagajni: Mini prijenosnu fiskalnu blagajnu koja vezu s PU može ostvarivati putem mobilnog i/ili fiksnog interneta i Mini fiskalnu blagajnu koja se na Internet spaja putem fiksne linije.

Mini prijenosna fiskalna blagajna nameće se kao idealan izbor za obveznike fiskalizacije kao što su trgovci na tržnicama i svi ostali koji veći dio posla obavljaju na otvorenom i terenu, a Mini fiskalna blagajna svima koji pretežit dio posla obavljaju u uredima, tj. imaju mogućnost pristupa fiksnoj linii, npr. za odvjetnike, turističke djelatnike, frizere i sl. Navodi se da se izborom nekog od ovih uređaja dobiva potpuno rješenje za fiskalizaciju i da se uređaji mogu koristiti neovisno o operateru, rad na njima je jednostavan, a sadrže blagajnu (uređaj), pisač, mogućnost spajanja na internet i aplikaciju, tj. blagajnički softver, a sadrže snažnu bateriju za rad do dva dana prije nego ju je potrebno opet puniti. Korisniku su, na blagajni ili u sklopu web aplikacije, u sklopu usluge, na raspolaganju i izvještaji o izdanim računima, unošenje i ažuriranje cijena i sličnih podataka te ova rješenja za fiskalizaciju omogućuju izdavanje računa u slučaju prekida internetske veze s PU, koji će onda naknadno biti automatski poslani u trenutku uspostave veze.

Mini fiskalne blagajne moguće je nabaviti samostalno ili u paketu s internetom HT-a. Navodi se da je za poslovanje u pokretu najbolji izbor "Mini paket koji uključuje usluge Mini prijenosnu fiskalnu blagajnu i pristup internetu putem M2M (Machine to Machine) veze za 199 kuna mjesečno (cijena bez PDV-a" [13], pri čemu je sav internetski promet u mobilnoj mreži prema PU uključen u mjesečnu naknadu za mobilni Internet, tj. cijena je uvijek ista bez obzira na broj izdanih računa i korisniku je na raspolaganju 24 satna korisnička i tehnička podrška. Više o ponudi HT-a za prilagodbu fiskalizaciji dostupno je na internetskim stranicama HT-a, https://www.hrvatskitelekom.hr/poslovni/ict/poslovna-rjesenja/fiskalizacija.

Za korisnike koji posjeduju računalo s pristupom internetu i printer, kako piše na internetskim stranicama hrvatske udruge MIPRO [13], za svođenje troškova na minimum kao najbolje rješenje za fiskalizaciju nameće se Vip aplikacija za fiskalizaciju, jer u tom slučaju nisu potrebna nikakva dodatna ulaganja i aplikacija se može koristiti odmah po pokretanju, izdavanje računa je jednostavno, "a cijena kompletne usluge, koja uključuje i održavanje aplikacije i telefonsku podršku, iznosi 60 kuna + PDV mjesečno, bez ugovorne obveze"[13]. Korisnici koji instaliraju mobilni printer mogu ovu uslugu koristiti i na tabletu ili pametnom telefonu, a također se može koristiti uz vlastite uređaje i postojeći Internet. Korisnici mobilnog interneta imaju besplatan podatkovni promet za potrebe fiskalizacije. Navodi se da Vipnet uz Vip blagajnu nudi i mobilne uređaje, tablet i printere po povoljnim cijenama. Više informacije o ponudi Vipa za fiskalizaciju na http://www.vipnet.hr/poslovni/fiskalizacija.

Poslovni dnevnik, također, piše da tvtka Fiskal 1 nudi i Fiskal1 GO koje je "mobilno cjelovito rješenje koje uključuje 7" tablet, softvere Fiskal1 te Bluetooth baterijski printer. Njegova je cijena 1992 kune plus PDV". Prema istom navodu, tvrtka GRC iz Dugog sela za postojeće korisnike koji već imaju instalirana njihova softverska rješenja, nudi nadogradnju postojećeg softvera za potrebe fisklaizacije. Također se navodi da tvrtka Datalab, nudi softversko rješenje Pantheon. "Rješenje za fiskalizaciju nude gotovo svim djelatnostima, a početna cijena iznosi 999 kuna"[14].

U nastavku su navedene internetske stranice različitih ponuđača uređaja i softvera za fiskalizaciju, za potrebe različitih djelatnosti, na kojma se mogu proučiti njihove ponude, tj. obveznici fiskalizacije proučavajući iste mogu okvirno izračunati i predvidjeti troškove vezane uz potrebne e-prilagodbe za fiskalizacju. RI. POS d.o.o., Računalni inžinjering, Rijeka također nudi hardver i rješenja za fiskalizaciju. Njihova ponuda dostupna je na http://www.ri-pos.hr/software.html. Ponuda rješenja za fiskalizaciju tvrtke Fiskal1, http://www.fiskal1.hr/. Poduzeće Napredni informatički sistemi d.o.o. također nudi softversko rješenje za fiskalizaciju-Fiskalux, koje se sastoji od tableta, printera i softvera za fiskalizaciju, više o njihovoj ponudi na http://fiskalux.hr/#home. Remaris-Integralni poslovni sustavi d.o.o. također nudi rješenje za fiskalizaciju RemarisPOS fiskalne blagajne, a njihova ponuda dostupna je na http://www.remaris.com/.

Jedan od ponuđača opreme i softvera za fiskalizaciju je i tvrtka Digitron d.o.o. koja ima dugogodišnje iskustvo u proizvodnji popularnih digitrona. Paletu njihovih proiz-

voda i usluga moguće je detaljnije proučiti na internetskoj stranici http://www.digitron.hr/. Za više djelatnosti i Kigo Grupa d.o.o. u suradnji sa Symmetria d.o.o. nudi različitu opremu i programe za fiskalizaciju, a njihova ponuda se može pogledati na KigoKasa.com, http://kigokasa.com/. Neoinfo d.o.o. za informatiku, trgovinu i usluge-Moji računi, na http://moji-racuni.hr/, također nudi softver i hardver za fiskalizaciju.

Prema pisanju Poslovnog dnevnika vlada je napravila dobar potez što nije naručila licencu za fiskalne blagajne jer bi one onda bile dosta skuplje te da bi bilo upitno kako uniformirani program uklopiti u sve vrste poslovanja i koliko bi jednostavno bilo njegovo održavanje, a ovako je omogućena modernizacija na način da je iskorišten obvezan pristup internetu za smještanje programa za fiskalizaciju u "Cloud". Ovakvoj kasi se s bilo kojeg uređaja može pristupiti u bilo kojem trenutku s bilo kojeg mjesta na svijetu, s bilo kojeg uređaja koji ima pristup internetu. "Takva kasa radi na iPhone-u, iPadu, Androidu, te svim verzijama Windowsa i Linuxa" [15].

I većina ranije spomenutih tvrtki nudi cloud rješenja za fiskalizaciju, ali uz njih i sve više ostalih ponuđača nudi različita tzv. cloud rješenja za fiskalizaciju, koja se ne instaliraju na računalo korisnika nego se aplikacija za fiskalizaciju smješta u tzv. oblak, tj. premješta se na infrastrukturu drugih tvrtrki koja se iznajmljuje, tako npr. funkcioniraju Gmail ili Facebok, i često su takva rješenja besplatna i omogućavaju održavanje bez dolaska na lokaciju korisnika, tj. potrebno je imati još samo Internet preglednik novije generacije i osigurati vezu na Internet [16]. Na Fiskalna. hr (Inter-Net d.o.o) [17] također se nude slična rješenja za fiskalizaciju, njihova ponuda dostupna je na http://www.fiskalna.hr/.

Još jedna od aplikacija koja radi na sličnom principu je i internetska aplikacija KlikUred koju je razvila varaždinska informatičaka tvrtka Orion informatika. S ovom aplikacijom mali poduzetnici i obrtnici, obveznici fiskalizacije, mogu "izdavati i fiskalizairati račune samo uz notebook ili tablet koji ima pristup internetu i pisač te mjesečni izdatak niži od pretplate za mobilni telefon!"[18]. Kako piše t/portal aplikacija KlikUred je jedna od sedam startup projekata koje je Grad Varaždin nagradio iz Fonda svježih ideja kojemu je cilj potpomagati ostvarenje cjelovitih i održivih poduzetničkih zamisli mladih poduzetnika, u ovom slučaju studenata suradnika ORION informatike i djelatnika iste tvrtke. Njihov glavni cilj je bio omogućiti cjelokupno uredsko poslovanje u "oblacima", a za početni paket usluga treba mjesečno izdvojiti 49 kuna. Osim izdavanja računa, ponuda, radnih naloga i sl. tu će se nalaziti i super jeftino telefoniranje, e-mali besplatne videokonferencije te mnoge druge informatičke usluge, a imaju i projekt Mobilni KlikUred, tj. rješenje za sve one koji rade na terenu, dostavljače, terenske prodavače i sl. Jedino što je potrebno za rad je njihov Android 3G Tablet i bluetooth pisač [18], https://www.klikured.hr/. Pozitivno je i to što piše da imaju u planu otvaranje novih radnih mjesta, jer planiraju ovaj proizvod plasirati i na međunarodna tržišta, na kojima je tvrtka već prisutna. Iz tvrtke Raverus d.o.o. nude Desktop i Web rješenje za fiskalizaciju, https://www.fisoffice.hr/Default.aspx. Rep.hr. (Računalni poslovi i Internet vijesti) [19] piše da je obrt RGB-toneri ponudio besplatnu online aplikaciju za fiskalizaciju koja je namjenjena malim obrtima. O sigurnosti certifkata na serveru i mogućnostima ovog rješenja, http://www.rep.hr/vijesti/internet/ponudili-besplatnu-aplikaciju-za-fiskalizaciju/5398/ i besplatna fiskalna, online fiskalna blagajna za fiskalizaciju, http://www.besplatna-fiskalna.com. Postoji još mnogo ponuda hardvera i softverskih rješenja za fiskalizaciju i vjerojatno se s većinom ponuđača mogu dogovoriti različite kombinacije rješenja i cijena, sukladno specifičnostima i potrebama poslovanja obveznika fiskalizacije, a većina obveznika fiskalizacije i u svom susjedstvu ima malu informatičku tvrtku koja može ponuditi dobra rješenja za fiskalizaciju ili dati informatičke savjete.

Pri pisanju rada svi ponuđači hardvera i softverskih rješenja za fiskalizaciju pronađeni su slučajnim izborom, pretraživanjem njihovih ponuda dostupnih na Internetu u trenutku pisanja rada, niti jedno rješenje nije preporučeno kao najbolje i najpovoljnije. Pri eventualnoj odluci o kupnji nekog od u radu navedenih rješenja za fiskalizaciju potrebno je, najbolje uz pomoć informatičkih stručnjaka, proučiti detaljno svaku ponudu, kontaktirati detaljnije svakog izabranog ponuđača, ispitati funkcionalnost uređaja i rješenja za fiskalizaciju u praktičnom poslovanju, ispitati sigurnost podataka, pouzdanost i dostupnost usluge i podrške u budućnosti, koje se dodatne usluge nude i ocijeniti koje rješenje je najisplativije i istodobno najpraktičnije za nesmetano i efikasno poslovanje, uzimajući u obzir specifičnost svake pojedine djelatnosti.

B. Ponuda paketa interneta za fiskalizaciju

Za provođenje fiskalizacije osim potrebnog hardvera i softvera obveznici fiskalizacije trebaju osigurati i internetsku vezu putem koje će se računi slati na ovjeru u PU. Prema pisanju Poslovnog dnevnika [11] HT ima "kompletnu ponudu koja uključuje mjesečni najam PC blagajne, LCD monitora, POS printera, blagajničke aplikacije Luceed Kasa usluge i 3G mobilni Internet već od 300 kuna mjesečno." Također piše da nude pet usluga pristupa internetu u skladu s uvjetima fiskalizacije. Više o uslugama pristupa internetu na Internetskim stranicama https://www.hrvatskitelekom.hr/poslovni/internet-poslovni, https://www.hrvatskitelekom.hr/poslovni/ict.

Poslovni dnevnik [11] također piše, da Vipnet nudi tri tarife „čije se cijene kreću od 35,06 kn mjesečno", http://www.vipnet.hr/poslovni/fiskalizacija?icn=menu.Pišu i da je Tele2 ponudu za fiskalizaciju razradio u suradnji s Metronetom i da nude usluge i na optičkoj i bakrenoj mreži kao i mobilni pristup, a jedna od usluga je i SLA koja garantira da neće biti nedostupnosti više od 15 minuta mjesečno. Također navode da Optima telekom ima niz usluga za fiskalizciju, a među njim i ADSL, stalnu vezu i optičku vezu, a pišu da u H1Telekomu kažu da u svojoj ponudi imaju niz paketa pristupa Internetu koji odgovara-

ju svim poslovnim namjenama pa tako i potrebama fiskalizacije, a cijene se kreću od 49 kuna mjesečno". Detaljniji prikaz spomenutih tarifa pristupa Internetu dostupan je na linkovima u nastavku: Tele2 d.o.o., http://www.tele2.hr/poslovnikorisnici/usluge/fiskalizacija/vb60/#vise, Metronet, http://www.metronet.hr/gotovipaketi/promo-paketi/fiskalizacija/, Optima telekom d.d., http://www.optima.hr/hr/poslovni-korisnici/optimalna-rjesenja/halo-surf/, H1 Telekom d.d., http://www.h1telekom.hr/Naslovnica/tabid/54/Default.aspx., Iskon Internet d.d. također nudi različite pakete usluga za poslovne korisnike, više na http://www.iskon.hr/Za-tvrtke.

V. ZAKLJUČAK

Iz u radu prikazanih ponuda ponuđača softvera, uređaja i interneta za fiskalizaciju može se izračunati da osiguravanje e-preduvjeta za fiskalizaciju računa u prvoj godini primjene fiskalizacije povećava godišnje troškove poslovanja poduzetnika okvirno za oko 1 100 do 5 000 kuna pa i više, ovisno o prethodnom korištenju ili nekorištenju suvremenih tehnologija te veličini i specifičnosti djelatnosti poduzetnika. Fiskalizacija povećava troškove poslovanja svih njenih obveznika, a pogotovo malih obrtnika i poduzeća koji nisu ili su u manjoj mjeri koristili suvremene tehnologije u poslovanju, jer oni moraju nabaviti i uređaje i ili softver, osigurati vezu za Internet, a velika većina i prilagoditi se radu na tim uređajima i digitalni certifikat, pa imaju i znatno povećanje troškova i utrošak vremena u odnosu na njihove ionako male prihode, ali PU smatra da su ti troškovi mali i neće imati značajniji utjecaj na poslovanje obveznika fiskalizacije računa. Iako je fiskalizacija povećala troškove poslovanja pridonijet će i povećanom korištenju suvremenih tehnologija u poslovanju obrta i malih poduzeća, koji su najviše pogođeni gospodarskom krizom (pad kupovne moći, nemogućnost financiranja i sl.), a najmanje su koristili suvremene tehnologije u poslovanju. Naime, prema istraživanju koje je 2012. za Google Hrvatska provela agencija za istraživanje tržišta GfK [20], na uzorku od 700 malih i srednjih tvrtki iz cijele Hrvatske, iako 90% malih i srednjih tvrtki u RH ima pristup Internetu, a čak 99% tvrtki koje imaju više od 10 zaposlenih, samo 20% njih koristi Internet kao medij za poboljšanje prodaje svojih proizvoda, iako su svi ispitanici svjesni važnosti Interneta za poslovanje i povećanje izvoza. Tek 16% korisnika Interneta obavlja kupnju preko Interneta, a samo 13% ispitanika je imalo trening za promociju proizvoda na internetu, što ukazuje na mogućnosti razvoja e-trgovine, ali i potrebe razvoja obrazovanja i potpora poduzetnicima u ovom području kako bi povećali prihode, a pri čemu postoje znatne mogućnosti za financiranje istog iz EU fondova.

Abstract – Draft proposal of the Croatian State Information Infrastructure Act was made public in December 2013. This Act, due to be entered into legislative procedure by summer 2014, aims to regulate rights, obligations and responsibilities of the state regulatory bodies concerning establishment, development and management of the state information infrastructure system. The Act adopts a unified method of establishing and managing public registries and conditions the state information infrastructure has to implement with regard to public registries as well as using common data interchange platform within the system of state information infrastructure. The draft proposal regulates government to citizen (G2C) and government to businesses (G2B) services. The aim of the article is to analyse the current draft proposal, consider its compatibility with the European legal framework as well as with national legislative and, where current provisions fail to meet the legislative standards, to propose modifications de lege ferenda.

Keywords – information infrastructure, public sector, public registers, master register, metaregister, regulation, Croatia

I. INTRODUCTION

On the 12th of December 2013, the Public Sector Informatization Coordination Commission of the Government of the Republic of Croatia adopted the draft proposal of the State Information Infrastructure Act ("Draft Proposal") [1]. The government ministry in charge of the develepoment of the mentioned Draft Proposal is the Ministry of Public Administration.

The Draft Proposal was made available to the public on the 19th of December which marked the start of the public discussion [2]. As of the beginning of February, the official documents regarding the public discussion, received comments and criticism from experts and the general public are yet to be made available to the public.

The proposed Act, due to be entered into legislative procedure by summer 2014, aims to regulate rights, obligations and responsibilities of the government institutions and other bodies concerning establishment, development and management of the state information infrastructure system.

The Act adopts a unified method of establishing and managing public registries and conditions the state information infrastructure has to implement with regard to public registries as well as using common data interchange platform within the system of state information infrastructure. The draft proposal regulates government to citizen (G2C) and government to businesses (G2B) services as well as other users and further development of information society in the Republic of Croatia. The Act is an important step toward further integration of the Republic of Croatia into established European as well as global information networks and services.

Establishment and development of state information services is undoubtedly a challenging task considering the rapid development of information technology, information services, electronic media, privacy and other data protection issues etc. Furthermore, both from the organizational as well as financial, legal and security perspectives, establishing and managing public registries while at the same time insuring their interoperability, authenticity and information security is a daunting task even for societies far ahead of the Croatian one regarding transition into information society.

It is obvious that this complicated issue needs to be properly addressed through legislative effort - even more so in light of the facts concerning public spending on various informatization projects in the recent years. According to the publicly available state budget reports, the State and various other public sector bodies, institutions and other budget funded entities spend around billion Croatian Kuna a year on various IT projects. While budget informatization spending has been on this level for a number of years, the real question is has it had the much needed impact on the quality and speed of state administration and on the total costs of government.[3]

We feel that the Draft Proposal of the State Information Infrastructure Act suffers from numerous inconsistencies and nomotechnic defects that, proposers good intentions notwithstanding, bring the success of the legislative measures in question.

II. REASONS FOR NEW LEGISLATIVE ACTION

The published draft proposal contains an additional document with the main motives regarding the proposition to adopt measures to regulate state information infrastructure.

While correctly stating that Croatian legal framework at this time does not include a set of rules to regulate establishment, development and management of the state information infrastructure, it does describe the main problem of the current state of state information infrastructure, as well as perhaps public administration in general: "*Just like the development of the real world institutions which are developed autonomously and function autonomously, like islands, so is the development of the information systems. Connecting them into an integral sytem that can serve citizens and business entities is something delegated to the very same citizens and business entities who are burdened to carry information and documents from one institution to another, regardless of their state of informatization*".[4]

This *modus operandi* of public administration, both central as well as the one within local and regional self-government has often been underlined as one of the main antagonists in attracting significant foreign investments and businesses to the Republic of Croatia.

As a result, the citizens and businesses alike are expected to know:

1. the competences and area of jurisdiction of state institutions

2. their address and office hours

3. documentation they need to bring, along with the fact that they need to set aside significant time for each interaction with state authorities.

Both the citizens as well as business entities go through these steps each time they interact with public administration. Administration institutions relentlessly demand documents and data already available to other institutions within the administration, although the State Administration System Act [5], as well as the General Administrative Procedure Act [6] clearly state that civil servants have a duty to obtain data contained within public records established by government bodies. The document concludes that *"...currently there is no technical system in place to enact the said provisions*."

At this point, a remark needs to be made - the Draft Proposal does not only imply technical measures regarding infrastructure services, it also steps into the matter regulated by both the State Administration System Act as well as the General Administrative Procedure Act.

In order to solve the above mentioned problems the Draft Proposal:

- Establishes the central state internet portal as a unique administrative location in the virtual domain
- The National Autentification and Identification System is mandatory for all institutions
- Provides for the Public Sector institutions (see infra for clarification on "public sector") communicating with citizens through a personal electronic mailbox

These steps create legal conditions and prerequisites to enable the e-Citizens ("*e-Građani*") project.

Additionaly, the Draft Proposal describes and regulates public and master registries, authentic data, and interconnection of registries stipulating the obligation of the public sector bodies to access data from master registries without demanding the same data from citizens or business entities.

Article 47. p.2 of the Croatian General Administrative Procedure Act stipulates that "*Civil servant is required to acquire data regarding information in registers run by other administrative institutions or courts*". Its predecessor, the former federal General Administrative Procedure Act adopted 1991, that was in force until 2009. contained a very similar provision.

In general, a question arises why does a new legislative measure strive to regulate matter regulated by general principles of administrative procedure well over half a century ago instead of ensuring the application of existing provisions, just to improve what has correctly been detected as a problem - the absence of a systemic technical solution required to apply the existing provisions in the first place.

III. DRAFT PROPOSAL TERMINOLOGY

The terminology of the provisions in this Draft Proposal requires special scrutiny. Since the proposed Act, the State Information Infrastructure Act represents a general normative text, the terminology contained therein defines a number of extremely important concepts on a national level with repercussions throughout the Croatian legal system.

It has long been known that speed and efficiency of the public administration (or more precisely, lack of) present significant challanges to both the citizens and business entities in the Republic of Croatia. The main goal of this new legislative proposal is to regulate the legal framework of electronic governance in the Croatian legal system and to allow anyone with legal interest to access data harvested by the public administration and other entities performing public service.

While we can agree with the proposition that legal framework of e-government as it is in Croatian positive legal system needs additional normative effort in order to be fully effective as well as compliant to the existing normative mechanisms of (personal) data protection, right to access information, management of identity in digital environment and other aspects of what is increasingly being recognized as information law, there are certain inconsistencies and nomotechnical problems with the current draft proposal that merrit analysis.

In this chapter we shall present provisions of the draft proposal that we find inconsistent with existing legislative framework and try to offer solutions.

Article 1 of the draft proposal contains an unclear reference to "*public sector bodies responsible for establishing, developing and managing the system of the national infromation infrastructure*". The colloquial expression "*public sector bodies*" is not a legal standard. While it seems obvious that this provision actually refers to the bodies listed in the provisions of the Articles 2 and 3 of the State Administration System Act [5], the expression "public sector bodies" is referenced throughout the draft proposal including provisions in Articles 2.1.1, 2.1.4, 2.1.6., 2.1.9 etc. Furthermore, Article 2.1.20 defines "*public sector bodies as public administration bodies, state bodies and public services*".

While Croatian legal system does occasionally within a few other Acts, government Strategies and Decisions

contain the expression "*public sector bodies*", most notably the Budget Act [7]. However, this expression is not broadly accepted as a legal term that describes the range of public administration entities (central, regional and local bodies) and other legal persons with public/official authority within the Croatian legal system. Furthermore, the Budget Act in this regard provides a different definition of public sector bodies (Article 3.21 of the Budget Act defines public sector as ..." *state budget, units of local and regional selfgoverment, budget and extrabudget users of state budget and the budgets of units of local and regional selfgovernment"*). The draft proposal also contains another unclear expression - *"public services"* (2.10.) - defined as "*...public institutions and other legal persons whose means of operation are provided by the state budget"*.

It would appear more prudent to avoid usage of non-standard expressions in legal documents, especially general norms like Acts in order to avoid confusion regarding the scope and applicability of law. The proposal should instead refer to the provisions of the State Administration System Act and the Organisation and Scope of Ministries and Other Central State Administration Bodies Act (OG 150/11 and 22/12)

The Article 2 of the draft proposal contains basic expressions and concepts used throughout the proposal. Several of these warrant analysis, most notably *autentification* (2.1.2.), *electronic identity* (2.1.4.), *electronic certificate* (*"vjerodajnica"*, 2.1.5.*)*, *identification* (2.1.7), data (2.1.12), and aforementioned provision 2.1.20.

Concerning *autentification* (2.1.2) and *identification* (2.1.7), there seems to be some duplicity in terms of defining these procedures. The proposal states that "*Autentification is a formalized process of verification of users electronic public services certificates resulting in affirming/denying identity"*, whereas "*Identification is a process in which it is necessary to ascertain or recognize electronic public services users identity"*. It would be more appropriate to merge these provisions into a single provision, perhaps defining both identification and autentification as a process of establishing users identity and level of access to information system or service (public register or any other information system or service) by verifying his advanced electronic signature and qualified certificate, as defined by the Croatian Electronic Signature Act [8].

With regard to *electronic identity* (2.1.4.) and *electronic certificate* (*"vjerodajnica"*, 2.1.5.*)*, the draft proposal should be inline with the provisions of the existing Electronic Signature Act, which defines electronic signature, advanced electronic signature, certificate and qualified certificate. The draft proposal defines electronic identity as "*...a unique set of identification data regarding a certain subject (natural person, public sector body, information system) being kept in electronic form allowing for identification of related subject*". Meanwhile, the electronic certificate according to the draft proposal is "*...a set of data identifying the user of an electronic service which serves to prove electronic identity in order to allow access to electronic services"*.

At the same time, the existing Electronic Signature Act defines electronic signature (as well as advanced electronic signature, Articles 2.1 and 2.2) as "*...a set of data in electronic form associated or logically connected to other data in electronic form providing identification of user (signee) and authenticity of the signed electronic document*", and certificate (and qualified certificate) "*...as an electronic certificate that associates electronic signature verification data to a certain person thereby verifying that person's identity.*"

Furthermore, the definition of the master register ("*temeljni registar"*) is also questionable (2.1.18.). The master register is one of the fundamental notions of this Act. According to the Draft Proposal, "*a master register is a public register that collects and contains at least one authentic data item*". Evidently, almost every state register contains authentic data making this provision too broad without a clear purpose. In our opinion, master registries are in fact state registries ("*državne matice"*) and a limited number of other important registries organized and run by the state.

The question here is the relationship between electronic identity, electronic signature and electronic certificate. Seperate definitions relating to the same matter (in this context identifying users identity in an electronic environment via electronic signatures and certificates) present a challenge regarding legal interpretation, even more so when there is no clear distinction which of the conflicting norms is the more specialized one (*Lex specialis derogat legi generali*).

The solution to this situation is to adapt the draft proposal inline with the provisions of the Electronic Signature Act or add a provision to the draft proposal concerning the conflict between Electronic Signature Act and the draft proposal effectively derogating the prior law (*lex posterior derogat legi priori*).

IV. PUBLIC REGISTRIES

One of the most important parts of the Draft Proposal is the Chapter III titled "*Public Registers*". This Chapter, along with the rest of the Draft, contains several serious flaws and inconsistencies. Analyzing all of them in detail is not possible within limits of this short paper, so we shall concentrate on those we deem most important.

The Draft Proposal states that the purpose of master registries is to, through facilities of the state information infrastructure, to ensure availability of collected authentic data required to perform duties stemming from their jurisdiction to all bodies of the public sector (8.1).

Regarding this provision several questions come to mind. Why should data be made available only through facilities of the state information infrastructure, and even then why only to the bodies of public sector? Does this imply that all registers need to be based on a state controlled infrastructure, and what does this mean for the registers maintained by companies with public competences? Also, the provisions of the Right to Access Information Act allow interested parties to access data collected by the public sector bodies, under certain conditions.

Furthermore, where purpose of the proposed Act is concerned, there is no point in regulating the exact technical procedure by which the said purpose is to be achieved, especially considering the very dynamic of technological change information technology is renowned for. Since much data stored in master registries is already available to the general public, there is no point in limiting access to it by a specific norm.

Regarding the collection of authentic data, the Draft Proposal states "*authentic data is collected only once, and*

entered into the master register" (8.2). This is a classic provision stipulating that data should be entered into an electronic system only once, and henceforth should this data be required, it should be requested from said electronic system, not from citizens or other subjects.

The provision that "*the master register is established by decision of the Government of the Republic of Croatia following a proposal by the central administration body responsible for E-Croatia matters*" (8.3) also raises doubt. A decision by the Government of the Republic of Croatia by which a register is declared a master register is in essence a constitutive decison. We find that it is not necessary that Government should proclaim a register to be a master register by an individual decision (there are literally hundreds of registers!) when the definition of terminology used in the Draft Proposal already defines which register is, in fact, a master register. To illustrate, let us consider registers connected to maritime affaires - implementation regulation concerning maritime affaires contains several registers, and this is for a field of activity that is just one of more than hundred and fifty administrative areas regulated by Croatian law. [9]

Furtheremore, the following Article (9.2.) stipulates: "*Public registers are established by law or a general act of a legal person with public authority or by an international treaty, that clearly specify data to be collected, what data is authentic and who is the manager of the public register*." If a register is established by law or an international treaty then no separate decision by the Government of the Republic of Croatia is necessary. Even when a register is established by the means of a general act by a legal person with public authority, the public administration has authority and administrative mechanisms to analyze the establishment and organization of a public register (i.e. through mechanisms of administrative oversight - Article 21.1 of the State Administration System Act which grants the competent ministry adequate administrative oversight authority)

With this in mind, it is perhaps interesting to note that according to the Ordinance on Internal Organization of the Ministry of Public Administration there is no administrative oversight provided for activities administered by Directorate for e-Croatia [10]. Since the Ministry of Public Administration regulates that master registries are established following a proposal by the Directorate for E-Croatia, the Ordinance should be amended and the Directorate for E-Croatia should be provided with powers of administrative oversight.

According to the Draft Proposal, official records of the public sector bodies are established exclusively as public registers (9.1). Issue we detect here is the following - is the term "*official record*" comparable to the the term "*public register*"? Croatian nomotechnic practice has so far failed to produce a standard concerning this issue. Legislative practice itself has seen usage of distinctly different terms - registers, lists, accounts, record files etc. (registri, evidencije, upisnici, očevidnici itd.). With this in mind, even if we lack legislative standards, it may be prudent to consult theoretical division as it is currently understood in Croatian academia.

Registers or record files are statutory regulated data collections containing records on important data regarding excercising certain rights, performing duties on the grounds of administrative authority defined by law or protection of legaly defined public interest in a manner that contained records are made by a competent authority (i.e. boat register, road vehicle register, but also a land register etc.)

Inquest register or records of evidence are data collections of events and procedures established and maintained by competent authorities without regard or consent of the subject of inquiry (i.e. during a criminal investigation or a misdemeanor record).

Catalogues, inventories and other listings are data collections governed by internal rules and regulations concerning a certain activity without a formal legal grounds.

Of course, suggested division is not systemic nor formally, de lege lata, acknowledged. Current legislative practice contains various division, some rather peculiar (i.e. the one suggested by the Regulation on archive evidence records [11] which divides the archive evidence records into: books, general inventory, dossiers and evidence records (!)).

State information infrastructure Act should take advantage of this existing division, especially considering unequal and diverging legal status of the registers, records of evidence and data catalogues already in existence.

There is further evidence of terminological confusion. The Draft Proposal states: "*Public sector bodies maintaining master registers are obliged to, without delay and without asking for additional permits, to deliver (dostaviti) authentic data to a public register of another public sector body...*" (9.3). as well as: "*Establishment of public records for the purpose of collecting authentic data already being collected by other master registries is not allowed, instead data has to be taken up (preuzeti) from master registers*." Here a difference in terminology is present, however the actual meaning of these two different terms (*dostaviti, preuzeti)* is evidently the same.

Draft Proposal also iterates already present statutory obligations of the public bodies. Article 11 of the states: "*Public sector bodies maintaining master registries shall deliver without asking for additional permits data to another public sector body that uses said data within the scope of performing prescribed duties*". This provision is an exact copy of the Article 47.p.2. provision of the General Administrative Procedure Act that has the same objective. Perhaps this provision of the Draft Proposal is a reaction to the abysmal lack of compliance to this norm observable in the practice of the Croatian public administration and public sector bodies, however including the same provision into two diferent laws is not going to miraculously enable its enforcement but rather trigger further nomotechnic disorder. A proper way to ensure enforcement of this provision would be to apply existing oversight mechanisms.

Similar duplication of provisions can be also observed in the Article 15.p.2 of the Draft Proposal that states: "*Law or a general act abolishing a public register shall establish a method of continuity of further accesibility and processing of data from the abolished public register, especially an abolished master register.*" In and of itself, within the confines of this Draft Proposal, this provision seems in order. However, data from an abolished public register constitutes archive matter, as defined by the Archive and Archive Matter Act [12]. This Act defines archive matter as :" *...records or documents originated by action of legal or physical persons in performing their activities, and have lasting significance on culture, history and other sciences without regard to place and time of their origination, form or carrier medium stored on*".

When abolishing a register there may be some special circumstances that need to be defined by a competent authority (such law needs no special provisons in this regard apart from the fact that a public register is being abolished), however the lex specialis in this matter obviously exists - the Archives and Archive Matter Act - and should be applied.

Additionally, this Draft Proposal should contain specifications of longterm electronic data storage that have not been included into the Archives and Archive Matter Act, especially since Republic of Croatia has already adopted the relevant ISO 19005 standard. [13]

V. METAREGISTER

Another interesting feature of the Draft Proposal is the establishment of the Metaregister in the Article 16.

Metaregister is a public register established as a part of the state information infrastructure containing information on all public registers, specifically:

- legal grounds on establishment of the public register
- indication if the register is a master register
- indication of the kind of data collected by the public register and whether that data is authentic
- delivery of data and possible recepients of that delivery
- legal grounds of data delivery
- description of the data collection process
- overview of the manner and conditions of data utilization

Article 16. p.1 states that the purpose of establishment of the Metaregister is to ensure interoperability of all public registers, reminiscent of the Central Register implemented by the provisions of the Article 14 of the Personal Data Protection Act concerning the establishment and management of personal data collections.

In Article 16.p.2.sp.4 the Draft Proposal states "*…delivery of data and possible recepients of that delivery*" and continuing in the sp.5 "*…legal grounds of data delivery*". Meanwhile, Article 11 of the Personal Data Protection Act regulates the act of allowing a third party to receive collected and processed personal data as handing over rather than delivery (*davanje* instead of *dostava*). While both of these expressions stand for essentially the same thing, keeping them both in equivalent legal norms might needlessly incure legal uncertainty.

VI. MANAGEMENT OF THE STATE INFORMATION INFRASTRUCTURE

Finally, Articles 18 through 20 of the Draft Proposal regulate the management of the state information infrastructure.

While Article 18.p.1.sp.1 through 10 regulate the mandate of the body competent to oversee application of the State Information Infrastructure Act, Article 19 regulate the duty of that body to report to the Government of the Republic of Croatia on the progress and development of the state information infrastructure and Article 20 stipulates that the head of the competent body has duty to implement measures aimed at raising awareness regarding the activities and importance of the state information infrastructure.

Regarding this chapter of the Draft Proposal, our main concern lies within the provisions of the Article 18. More precisely, provision 18.1.10 is unclear on how this new Act relates to the provisions of Personal Data Protection Act as well as the Right to Access Information Act [14].

It is unclear what the expression "*verifies the compliance of the legal grounds and the request for access to information in public registers and authorizes the same*" actually means. However, provisions of Article 15. of the Right to Access Information Act, especially p.3 of said Article, regulate the terms and conditions how public authorities can limit access to information - these regulations do not provide for an additional level of control the Draft Proposal seems to impose.

Furthermore, this provision influences the Personal Data Protection Act as well. Article 32. and 33. of the Personal Data Protection Act regulate the competence of the Personal Data Protection Agency. The current provision in the Draft Proposal might obstruct several of the currently prescribed duties of the Agency, such as those regulated in Articles 32.1 and 32.5.

VII. CONCLUSION

The Draft Proposal, as presented to the public, is a goodhearted attempt motivated by positive and constructive intent, but falls short of the goal of facilitating effective legal framework for development of the state information infrastructure and new generation of services for citizens and businesses.

The main problem of the proposal is unnecessary and superflous mixing of technical concepts and measures within what is supposed to be a general normative text. As it is, this draft simply does not connect with the provisions of many applicable and existing laws and regulations, including but not limited to General Administrative Procedure Act, Electronic Signature Act, State Administration System Act, Archival Matter and Archives Act, Personal Data Protection Act, Right to Access Information Act as well as Office Transactions Regulation [15].

Ensuring better and more effective public administration and public sector performance is a question of well designed and implemented procedures, not merely a question of technology and technological infrastructure. Recent experiences show that major investments in information and communication technology divorced from rethinking and implementing modern business procedures in the public administration environment fails to produce an improvement in quality, availability and speed of public administration services.

In this regard, the Draft Proposal offers very little - management of state information infrastracture is again limited on management of the physical and software infrastructure, and not on the modernization and improvement of administrative procedures which should, in our opinion, represent a focus of activity for the Ministry of Public Administration.

Content Management Systems for mobile, context-dependent Augmented Reality applications

M. Lengheimer*, G. Binder ** and T. Rößler **

** evolaris next level GmbH, Graz, Austria
mario.lengheimer@avl.com

Abstract - In the last few years, the proliferation of mobile devices with internet access, especially smartphones and tablets, has grown strongly. This has also positively influenced the mobile augmented reality (AR) market and allowed AR applications to achieve a high number of users. The necessary tools and frameworks for developing such applications are numerously available. However, there is still the question how to store and manage the displayed contents of the applications in an effective way. This is true, especially if the management of user individual content is considered. This paper describes how content management systems (CMS) for mobile AR applications can be designed, in order to allow an effective and efficient management of context-dependent and personalized content. Because of the possibility to create individual AR contents for each user, with context-dependent and personalized content management an improved effect on advertising and marketing activities can be achieved. The architecture of the described system additionally considers important system characteristics, which lead to high user acceptance and high customer value.

I. INTRODUCTION

Augmented reality (AR) applications combine digital elements with the view of the reality and displays them together e.g. on a smartphone display. The basis for this combination is the captured camera video stream of the real environment, which is displayed on a screen. The digital elements are added to this view as overlay elements. First mobile AR applications focused on displaying digital content based on the location of the device. In the last few years the development more and more focused on creating frameworks and tools in order to use computer vision technologies for creating AR applications. With these frameworks and tools it is possible to create a wide range of different applications. Especially in the field of marketing these developments allow to create applications to improve the advertising effect of marketing activities. As an example, such applications can be used at the point of sale to virtually try on items of clothing or to show additional information of a product. Other applications can provide the possibility to virtually visualize the product in different contexts or to enhance 2D print media or advertising spaces with 3D or live data overlays.

To provide the possibility to achieve a higher customer value with such AR applications, this paper deals with an approach how the content, which is shown as overlay, can be created and managed individually for different users.

At the beginning this paper describes the motivation of developing and designing such an approach. Afterwards the developed approach is described in detail.

II. MOTIVATION

The motivation of this work was to further increase the marketing effect of AR applications by adapting the content of the applications. The chosen approach to achieve this is to use a form of personalized communication with the consumers. Personalized communication or personalization of content means that offers, activities and information are adapted to the individual needs of the consumer [1]. With personalization several benefits for the user can be achieved. First, since only the content which fits to the user's needs is displayed, the recognition of the benefits can be increased. If promotions are found useful, a higher acceptance of these promotions can be achieved. [2] Second, by reducing the available information to the relevant information, an information overload can be prevented [3]. Third, a higher attention for the contents of the promotions can be achieved [2].

Before designing the solution how AR content can be managed in a personalized and context dependent way, analysis of currently available system on the market were conducted. These analysis mainly covered the AR authoring tools of Wikitude, Layar, Junaio, BuildAR, Point At Me and the Feedgeorge AR Plug-In for WordPress. The research included the analysis of the provided features and where possible the technical implementation. The result showed, that the existing AR authoring tools all provide the possibility to simply create and maintain AR content without the need of having deep technical knowledge. But it also showed, that these systems do not provide the possibility to define individual contents for different users. This result reinforces our main motivation, to design an overall system architecture to combine customer relationship management (CRM)

with content management (CM) systems for content authoring for AR applications and to show which benefits can be gained out of it.

An additional motivation was the wide range of possible use cases. Especially in the field of mobile marketing several use cases can be considered. An example could be to show additional information to a scanned product and to filter these information based on the user's interests. E.g. more details if users are interested in such kind of products or showing related products which fits to the interests of the user. Additionally specific offers can be provided to a selected group of users. Another use case could be to virtually enhance magazines or print media and adapt the shown information according to the age or gender of the user resp. the current date/time/place. In the context of the described solution the use case to enhance advertisements on billboards for tourists was addressed. This use case addresses tourists or foreigners who often do not know what events or exhibitions are present, which sights have special offers or which specific activities can be done and where. All the various offers can be advertised on billboards, posters or magazines but with only rare information and not filtered according to the individual needs and interests of different viewers. This can cause an information overload at the user's side. With the described system, the user (e.g. tourist) is able to scan the advertising space with a mobile device. As a result, the mobile device displays information of events and activities which fits to the user's interests. These information could include e.g. a music event for one user and for another user an exhibition matching his interests. Videos and 3D representations of the venue or event can be used to support the advertising effect. By interacting with the displayed content, the user can e.g. request further information or book tickets. The filtering of the displayed contents according to the user's needs can be seen as the main advantage. To use various multimedia elements for visualizing the information in a more appropriate way can be seen as an additional advantages.

III. AUGMENTED REALITY

Figure 1 shows a Reality-Virtuality Continuum which defines the three areas real environment, mixed reality and virtual environment. The areas at the endpoints only use real resp. virtual elements, whereas the mixed reality area combines real and virtual elements to visualize the user's environment. Dependent on the position on the axis, more real or more virtual elements are used. [4] AR uses more real elements and can therefore be defined as the extension of the reality by digitally adding virtual information to the view of the reality [5]. The combination of real and virtual elements can be imagined as follows. The user scans the surroundings with the camera of a mobile device. This captured video stream is shown on the display of this device. Additionally, digital elements are displayed, which fully or partly overlays the real objects from the video stream. A technological independent definition of AR describes AR as the combination of real and virtual information, which provides interactions in real time and registers the elements in 3D [6][7].

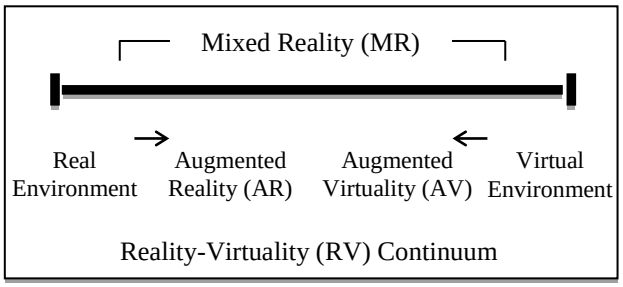

Figure 1. Cp. Simplified representation of a RV Continuum [4]

To determine which virtual information shall be shown as overlay elements, data from the reality, the real environment is used. To capture the reality either the location sensor of the device or computer vision technologies are used. With computer vision technologies specific markers on an image or the image itself can be recognized. [5][8] Based on the capured location, marker or image the virtual information can be filtered. To show the combined view, the display of mobile devices like smartphones or tablets, or head mounted displays can be used. Alternatively stationary devices with a camera and a display or devices projecting the virtual content directly onto the real object can be used. [7]

IV. CONTENT MANAGEMENT AND CUSTOMER RELATIONSHIP MANAGEMENT SYSTEMS

Content Management (CM) in general covers all necessary steps, which support the life cycle management of digital information. These steps include the creating, editing, publishing, storing, archiving and deleting of information. A CM system (CMS) assists the user when doing these steps. [9] Additionally to this requirements, a CMS must allow users with little or no programming knowledge to create and manage the content [10].

Customer Relationship Management (CRM) is the business strategy to combine the internal processes and functions with the external networks, in order to create and deliver value to the customer. To do this, high quality data about the customers, together with the information technology, is used. [11] CRM covers all steps to analyze, plan, do and check relationships with customers [12]. The purpose of CRM is the management of durable and profitable customer relationships [13].

In the area of marketing, the functionalities of CRM systems typically cover analysis and forecasting features. These are used to segment and categorize customers resp. to create forecasts for the market, purchase behavior and customer development. Additionally, this area includes features to support the campaign, territory and lead management. The campaign management deals with the planning, creation and evaluation of marketing campaign, whereas the territory management covers all features to organize marketing activities and campaigns according to specific regions. [14] In the context of this work these functionalities are combined with the features of a CMS in order to provide individual AR content to the users.

V. EXISTING SYSTEMS

To design and develop our system architecture, the architectures of existing systems were analyzed first. This

analysis mainly focused on their implementation and architectural view and mainly covered the content authoring systems from Wikitude, Layar, Junaio and BuildAR. Additionally the Vuforia platform were analyzed, which, compared to the other systems, only provides a framework for building applications and does not provide a proprietary solution to manage AR content. The analysis showed, that all systems provide the possibility to simply create AR content using a web-based user interface. Using these web applications, the user is able to upload reference images (view which shall be virtually enhanced) and to create and arrange digital overlay elements. To access this created AR content via a mobile device, proprietary mobile applications are provided by each of the manufacturers except BuildAR. BuildAR is also using the mobile application of Junaio. To create AR content and to access them with the mobile application the user doesn't need to have technical knowledge of the backend system, e.g. hosting a web service as data source for the mobile application. So this represents an easy solution for a wide range of users. Except these system characteristics, all analyzed systems are lacking of the possibility to created different AR views for the same reference image and presenting the most appropriate AR view to the user, based on the interests of the currently active user.

VI. OUR APPROACH

Focusing the addressed use case as described in section II, two different users need to be considered. The first one is the user of the backend system, which is further named as content author and represented by a marketing person who wants to create AR based commercials/advertisements. The second user is the user of the mobile application and in that use case represented by a tourist. Considering the whole scenario, this need to be split into two sub use cases, which are:

- Creating AR content for tourists with different interests or for different contexts individually (content author).
- Scanning billboards and getting individual AR content shown on a mobile device (tourist).

To provide individual AR content, the content author uploads the image of the view which shall be augmented to the backend system. This could be e.g. an image of a poster which is e.g. placed on a public billboard, in a magazine or in metro stations. If this image is uploaded, the content author creates several AR views for this single image. E.g. if there are currently several exhibition in the city the content author can create one AR view for tourists interested in arts and one for tourists more interested in technical areas. If the content author has created the different AR views, these views must be assigned to the different users/groups retrieved from the CRM system. With these steps the creation of the AR content is completed. In a second step, the tourist can scan the billboard, magazine page or poster with the mobile application and the mobile application presents the most appropriate AR view to the tourist. To do this, the tourist first needs to authenticate himself at the mobile application in order that the application knows him as the active user. Second, the mobile application requests the most appropriate AR view of the scanned billboard from the backend system in order to be able to presents this view to the user. The most appropriate AR view is one of the previously created AR views in the CMS and is selected based on matching user and contextual information. So different users, with different interests get different AR views presented. The criteria, which are used to assign AR views to users and to request the most appropriate AR view from the backend system covers the location of the device, the language which is selected on the mobile device, the gender, age and interests of the user as well as the current date, time and weekday. With these criteria a flexible assignment of AR views to different users in different contextual situations is enabled.

A. *Architecture*

Based on the analysis of the existing systems and the requirements of the use cases, the architecture of the system is designed as shown in the following figure.

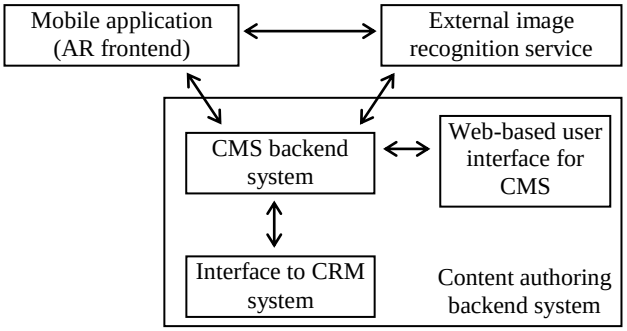

Figure 2. Overall system architecture

The overall system is basically created of three subsystems. These subsystems are the mobile AR frontend, the content authoring backend system and the backend system for image recognition. All three subsystems can be executed independently and are connected using standard web technologies. The mobile AR frontend is installed and executed on a mobile device, such as a smartphone or tablet. It is used for scanning billboards, requesting contents from the backend systems and displaying the contents for the user. Additionally this application can be used to register and authenticate users and to collect specific data about the user. The backend system for content authoring is separated into two parts. The first part is the CMS including the user interface which is used to create the AR views/content. An AR view is a collection of various virtual elements which belong together and are shown as one view to the user. Several AR views can be defined for the same billboard/image, in order to be able to create different views for different users. The second part of this backend system is the interface to the CRM system. This part is used to fetch all customer and campaign related data from the CRM system.

B. *Content authoring and image recognition backend systems*

This section describes the backend systems from a deeper technical point of view. As already mentioned before the backend systems consist of two parts, the

content authoring system and the image recognition service. The content authoring system is again divided into two parts, the CMS including the user interface and the interface to the CRM system. The CRM system itself is considered as a separate system, which is connected to the CMS by using a public interface. Therefore only the interface is drawn in the architectural overview. With this separation, the dependency between the systems can be kept as low as possible and the usage of a wide range of existing CRM systems can be enabled. Reusing existing CRM systems is important to avoid the necessity to manage customer related data multiple times (once within the existing systems and once within an AR CMS) and also because CRM systems with a huge amount of customer related data already exists in many companies. To additionally keep the mobile frontend independent from the CRM backend system, the mobile frontend only communicates with the CMS, which forwards requests to the CRM system if necessary. Requesting context-dependent and personalized content is entirely handled by the CMS.

The backend system for image recognition is used for two actions. Once to register reference images which shall be recognized by the mobile application and once to perform the recognition of the scanned billboards for the mobile application. To register reference images, the user need to create a new AR content within the CMS. The uploaded billboard image is automatically registered as a reference image at the image recognition service. To perform the image recognition for the mobile application, also the external system is used because the reference images belong to the created and active marketing campaigns and these images are changed continuously. If the image recognition would be done locally on the device, the user would have to update the mobile frontend always if the reference images are changed. To avoid this, the external service is used. Additionally the maximum amount of concurrently used reference images is limited to 100 images on several existing platforms, if the recognition is done locally in the application [15][16].

The backend systems and interfaces are implemented using standard technologies to ensure high accessibility and compatibility. The CMS is provided as web service with a browser based user interface. The interfaces between the mobile frontend and the CMS resp. the image recognition service and the CMS are implemented using the Representational State Transfer (REST) protocol.

C. Connection of CMS and CRM backend systems

Required information about users and active marketing campaigns are stored within the CRM backend system. To connect AR contents with users or user attributes, the active campaigns are used. With campaign activations, different marketing activities for different users, ages, genders, dates, times and regions can be defined. In the context of AR, the AR content/AR view represents an activity, which means that this AR content shall be shown on the mobile device if the campaign is considered as active. Since existing CRM systems shall be connectable to the CMS, the information of this assignment is stored within the CMS. The CRM system provides an interface, where the active campaigns and user data can be retrieved. If the CRM system does not provide an appropriate campaign management this can be handled by an intermediate layer between the CMS and the CRM interface. Then only the customer related data is requested from the CRM system and the campaign management is provided by the CMS user interface.

Figure 3 illustrates how the CRM and CM systems are connected using campaigns and campaign activations. Each reference image can have a list of AR views assigned. Each view can be linked with a campaign activation in order to be activated for e.g. various users or times. If the sample use case, as described in section II, is considered, this means that one reference image (the uploaded image of the poster) and two AR views (one for art-interested and one for technical-interested users) are created. Within the CRM system two marketing campaign activations are created (one for each AR view). As activation criteria once the user attributes related to arts and once the user attributes related to technical areas are set.

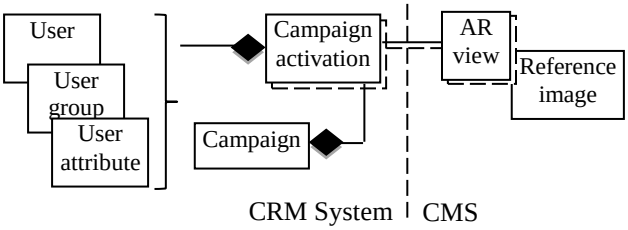

Figure 3. Connection CMS and CRM backend system

If the mobile application requests an AR view for a specific reference image, the most appropriate AR view is searched by comparing the attribute values which are set within the linked campaign activations and the attribute values which are set within the request. The following sections detailed describes how the search is done.

D. Requesting AR content

The following figure shows the communication sequence to request AR content from the backend system.

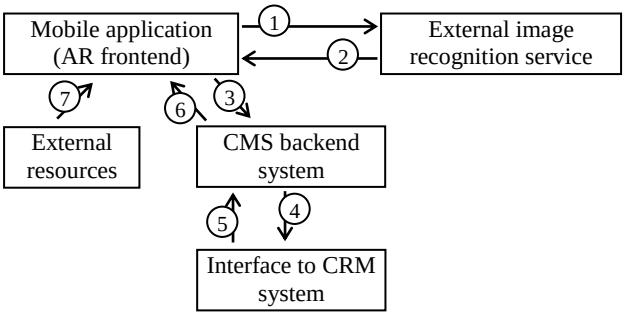

Figure 4. Communication for requesting AR content

To request AR content the mobile application first establishes a connection to the image recognition service and sends data from the captured video stream to this service (1). If the service recognizes a registered reference image within the received video stream data, the unique id of this reference image is returned to the mobile application (2). Afterwards this returned id is used, together with the user id and optionally the position and language of the mobile application, to create a HTTP GET

request to fetch the AR view from the web service of the CMS backend system (3). This request must be structured as shown in the following figure.

```
http://<base uri>/{ir_ref}/{usr_id}?lat={latitude}
                                   &lng={longitude}
                                   &alt={altitude}
                                   &lang={language}
```

Figure 5. Structure of a HTTP GET request to query AR content

Arguments which need to be set by the mobile frontend are encapsulated in brackets. Mandatory arguments are part of the URI. Optional arguments are defined as URI parameters. With the arguments `ir_ref` and `usr_id` the unique identifier returned from the image recognition service and the identifier of the currently authenticated user need to be passed. With the URI parameters `lat`, `lng` and `alt` the location of the device and with the URI parameter `lang` the present language on the mobile device can be passed. Considering the previously described sample use case only the mandatory arguments are required because the distinction between the two AR views only uses user related data which can be fetched using the user id. If the backend system receives a request, the most appropriate AR view is searched and returned. The search algorithm compares the values from the request, with the values which are set within the campaign activations. To do this, the user and campaign related information are retrieved from the CRM system (4), (5). The AR view which is assigned to the found campaign activation is returned to the mobile application (6). The values which are compared during the search cover a date range, time range and weekday selection to provide different content based on the time of day or the current weekday. Additionally the age and the gender of the user, the language and the location of the device are compared. Moreover, assigned user information are compared. These user information cover directly assigned users, user groups and user attributes. If one of these user settings match and all other compared attributes match, the campaign activation is considered as matching. If an optional URI parameter is not set, no filtering for this attribute is done and the comparison for this attribute is considered as matching. If several matching campaign activations are found, the list of matching campaign activations is ordered by a list of prioritized criteria. These criteria are:

- User is directly assigned
- At least one user attribute matches
- The user group, which is assigned to the user, is also assigned to the campaign activation
- The defined gender matches the gender of the user
- The age of the user is within the defined range

Considering the previously described sample use case the second criteria (user attributes) would be the matching one because user attributes are assigned to the campaign activations. If the content author creates a third AR view (e.g. special offer for users/tourists who often use the system) this AR view can be directly assigned to these users. Also if the user attributes match for e.g. the first AR view (interested in arts), the third AR view (special offer) is returned because directly assigned users have a higher priority. If no matching campaign activation is found, the first AR view for this reference image is returned in order to reduce the amount of returning empty views to a minimum. This approach is used, because returning a not perfectly matching content is still better, than returning an empty view or an error. Only if no contents are defined for this reference image, an error is returned. If a matching AR view is found, this is returned to the mobile frontend as a JSON formatted AR view description. If this description refers to any further external resources, these are separately downloaded by the mobile frontend (7).

VII. RESULTS

The present work shows an approach how AR content authoring tools can be designed in order to support the possibility to created different AR content for different users for the same reference image. The approach shows a flexible and extensible solution which can be either entirely implemented as described and also allows to exchange parts of the system with low effort because standard web technologies are used for inter-system communication. Additionally to the solution-design a prototype of the described system architecture was implemented in order to be able to evaluate the approach. The backend systems of the prototype is based on a Java web application running on a Tomcat web server combined with the Vuforia image recognition service. The mobile application is developed for Android and also uses Vuforia as AR engine. To further evaluate the designed system architecture, the prototype was used to carry out tests concerning response times and extensibility of the system. The following sections describes the results of the tests.

A. Response times

In order to be able to continuously update the content in the backend system without the necessity to always update the mobile application, the content as well as the image recognition service are provided by a web service. Therefore the response time of the application is related to the available speed of the mobile data connection. To evaluate that relationship, the time between the user starts scanning the environment and the AR view is displayed was measured using two different data connections. Once with a 3G connection with around 5 Mbit/s download and 3.9 Mbit/s upload. The second connection was a 2G connection with around 166 kbit/s download and 67 kbit/s upload. The tests showed, that the average response time with the fast connection was approximately 6 seconds, which can be seen as acceptable. Especially because the user interface of the mobile application changes from the image recognition view to the downloading view after about half of the time, which shows progress within the application. With the lower speed connection, the response time only for the image recognition was around 15 to 26 seconds, which can be seen as not acceptable. As a result it can be mentioned, that a high speed data connection for such a system architecture is required.

B. Extensibility

As part of this evaluation the extension of the contextual and personal criteria which are used to assign AR views to different users was considered. This showed, that criteria which addresses personal information can be easily added and removed, because these criteria are only known and handled by the content authoring backend system. The mobile application only sends the user id which is independent of the used personal criteria. The extension of contextual criteria which need to be collected by the mobile device, like the current position, is also possible but the deployment of such extension is more complex because the mobile application need to be updated as well. As a second part of this evaluation, the usage of the system with different mobile platforms were considered. Because standard web technologies are used for communication each mobile platform which supports HTTP communication and JSON or XML as data format and which is supported by the used AR engine framework can be used. Only the mobile application need to be implemented for the various platforms.

VIII. CONCLUSIONS

The described system provides the ability to create and distribute AR based commercials for different users individually. With this approach the customer needs can be fulfilled more accurately by presenting only relevant information to the user. Moreover, an information overload can be avoided. Both aspects results in a higher customer value and a higher acceptance of the system. The possibility to request further information by executing interactions with the displayed contents also results in a higher memorization and an enhanced customer loyalty [2]. On the backend system side, the complexity of the overall system can be reduced, because the linking between the AR content and campaign activations can be done by the same user interface. Low complexity is one key attribute to reach a high acceptance [17]. Additionally, personalized commercials can increase the click-through rate of an advertisement [18], which can be used as a rating for the effectiveness of the advertisement.

Because the image recognition is done remotely and the content is downloaded from a web service, the system always requires an active internet connection. This could probably prevent users from using the application, if they have no flat rate for the mobile data connection at the holiday destination. Additionally, a fast mobile data connection is required. This could prevent users from using the application in areas where the mobile data network is not well developed. Beside these two challenges there exists also another non-technical challenge for AR systems in general. This challenge focuses on the awareness for AR products in our society, which is still relatively low [19]. As a second non-technical challenge it will be necessary to convey the advantages and benefits to the user of the mobile AR applications in order to increase the usage rate.

Elektronički račun u Republici Hrvatskoj i SEPA inicijativa

Danijel Matić*, Boris Vrdoljak**, Damir Kalpić**, Alan Čičak *
* InfoDom d.o.o., Zagreb, Hrvatska
** Sveučilište u Zagrebu Fakultet elektrotehnike i računarstva, Zagreb, Hrvatska
danijel.matic@infodom.hr, boris.vrdoljak@fer.hr, damir.kalpic@fer.hr, alan.cicak@infodom.hr

Sažetak - Elektroničko poslovanje bavi se poslovnim procesima unutar područja cjelovitog dobavnog lanca. Plaćanje je završni dio procesa nabave kada kupac transferira dobavljaču novčana sredstva naznačena na računu. Elektronički nalog za plaćanje je nalog koji korisnik daje elektroničkim putem za prebacivanje sredstava sa svog računa na drugi račun i mora sadržavati sve potrebne podatke za plaćanje. SEPA (engl. Single Euro Payments Area), jest inicijativa Europske Unije s ciljem uspostave jedinstvenog sustava platnog prometa do 2016. godine. SEPA definira pravila po kojima se odvijaju transakcije. Nacionalni odbor za platni promet (NOPP) je 2013. godine donio Odluku o osnivanju radnih tijela zaduženih za implementaciju SEPA projekta u RH, odnosno o osnivanju Hrvatskog odbora za SEPA koordinaciju (HOSK-a) i Hrvatskog SEPA foruma (HSF-a). U radu se analiziraju i opisuju procesi plaćanja elektroničkih računa te se predlaže način pozicioniranja informacijskog posrednika u procesima plaćanja prema inicijativi SEPA.

U ovom radu neće se zadirati u nadležnosti navedenih tijela već će koristeći javno dostupne informacije za analizu i pripremu preslikavanja e-računa po inicijativi SEPA.

I. UVOD

Elektroničko poslovanje je oblik poslovanja koji prilikom transakcija i razmjena informacija koristi informacijske i komunikacijske tehnologije između sudionika u poslovnom procesu. Cilj elektroničkog poslovanja jest automatizirati poslovne procese čime se smanjuju troškovi i povećava efikasnost. Elektroničko poslovanje pokriva poslovne procese cijelog dobavnog lanca, a plaćanje je završni dio procesa nabave kada kupac dobavljaču prenosi novčana sredstva naznačena na računu.

Europski gospodarski prostor nastanjuje više od 500 milijuna stanovnika i godišnje se provede više od 71,5 milijardi platnih transakcija. Dio tog prostora od 1. srpnja 2013. jest i Republika Hrvatska.

The Single Euro Payments Area (SEPA), jedinstveno područje plaćanja u eurima, je nastala kao inicijativa europske bankarske industrije s ciljem osiguravanja plaćanja u eurima u Europskom gospodarskom prostoru.

Cilj SEPA-e je omogućiti potrošačima, poslovnim subjektima i tijelima javne vlasti izvršavanje i primanje plaćanja u eurima pod jednakim uvjetima, pravima i obvezama, neovisno o njihovoj lokaciji.

Pristupanjem Europskoj uniji implementacija SEPA-e je obvezujuća i za Republiku Hrvatsku. U tu svrhu, na inicijativu Nacionalnog odbora za platni promet, pokrenut je nacionalni projekt SEPA. Glavno upravljačko tijelo projekta jest Nacionalni odbor za platni promet (NOPP) u čijem radu sudjeluje Hrvatska narodna banka, Ministarstvo financija, Hrvatska gospodarska komora (Sektor za bankarstvo i druge financijske institucije) i Hrvatska udruga banaka.

Nadležnosti nad provedbom SEPA projekta u Republici Hrvatskoj su kako slijedi:

- Nacionalni odbor za platni promet (NOPP) je na sjednici 21.5.2013. donio Odluku o osnivanju radnih tijela zaduženih za implementaciju SEPA projekta u RH, odnosno o osnivanju Hrvatskog odbora za SEPA koordinaciju (HOSK-a) i Hrvatskog SEPA foruma (HSF-a).
- Članovi HOSK-a su predstavnici Hrvatske udruge banaka (dalje HUB-a), HNB-a; Ministarstva financija, Fine i HGK-a; njime predsjedava HUB, a osnovna zadaća HOSK-a je: izrada nacionalnog plana migracije na SEPA-u, izrada i provedba nacionalnih SEPA platnih shema, tj. kreditnog transfera (SCT) i izravnog terećenja (SDD) u eurima i kunama, izrada i provedba rješenja potrebnih za izvršenje kreditnih transfera i izravnih terećenja u eurima.
- HOSK je osnovao radne skupine (RS) za kreditne transfere i izravna terećenja koje imaju zadatak izradu praktičnih rješenja radi ispunjenja gore navedenih zadataka nominiranih HOSK-u. Budući da radne skupine za SCT i SDD čine predstavnici svih banaka, HOSK je osnovao i operativne grupe za SCT i SDD koje imaju za zadatak razradu formata svih poruka klijent-banka i razmjene banka-banka kao i definiranja poslovnih pravila vezano za navedene razmjene.
- Članovi HSF-a su također predstavnici HUB-a, HNB-a; Ministarstva Financija, Fine i HGK-a; njime predsjedava HGK, a osnovna zadaća HSF-a je promoviranje SEPA platnih usluga krajnjim korisnicima s posebnim osvrtom na uključivanje IT kuća i velikih izdavatelja u implementaciju SEPA platnih usluga u RH odnosno informiranje javnosti o SEPA projektu, migraciji, formatima i promjenama koje će poslovni subjekti morati ugraditi u svoje poslovne sustave migracijom RH na SEPA platne instrumente odnosno do krajnjeg roka navedenog za 31.10.2016.

Ministarstvo gospodarstva, poduzetništva i rada RH osnovalo je 2008. godine Povjerenstvo za e-račun. Ovo povjerenstvo je 2009. godine predložilo informacijski model za e-račun [14] i korištenje norme Universal Business Language (UBL) 2.0 [2]. Krajem 2013 godine objavljena je nova verzija standarda UBL 2.1 [1] kao unaprjeđenje standarda UBL 2.0.

U sklopu projekta e-račun, Radna skupina HUB-a je prema HUB1 obrascu izradila elektronički obrazac e-HUB u XML formatu. Navedeni obrazac namijenjen je sudionicima platnog prometa koji su svoje poslovanje dogovorili i proveli kroz e-poslovanje.

U trenutku kada nadležne institucije pripreme i definiraju potrebne komponente za implementaciju SEPA inicijative u Republici Hrvatskoj bit će potrebno uspostaviti jedinstveni proces, tj. povezati proces izdavanja i obrade elektroničkog računa s novim procesom plaćanja. Trenutno dostupne norme i dokumenti vezani uz inicijativu SEPA omogućuju pripremu potrebnih elemenata s ciljem osiguranja spremnosti zainteresiranih strana u procesima vezanim za elektroničko plaćanje, tj. elektronički račun.

Zainteresirane stane, naročito informacijski posrednici (Informacijski posrednik je fizička ili pravna osoba koja u ime drugih obavlja otpremu, prijem i prijenos elektroničkih dokumenata.) morat će prilagoditi informacijske sustave i podržati nove načine provedbe i iniciranja elektroničkog plaćanja.

II. PREGLED NORMI, PRAVNOG OKVIRA I SMJERNICA

Cilj elektroničkog poslovanja je automatiziranje poslovnih procesa, a preduvjet za to je definiranje formata elektroničkih dokumenata i poruka. Format i dozvoljeni sadržaj elektroničkih dokumenata definiraju se normama. Za e-račun kao najrašireniji elektronički dokument koristi se paralelno veći broj normi.

U Republici Hrvatskoj preporučeno je korištenje norme Universal Business Language (UBL) 2.0 koja je implementirana u više europskih država i u mnogim projektima u području e-poslovanja, kao što je npr. sustav za javnu nabavu PEPPOL (Pan-European Public Procurement Online), projekt u koji je uključen velik broj država članica Europske Unije.

Osim razmjene e-računa, cjelokupni dobavni lanac uključuje razmjenu mnogih drugih vrsta poslovnih dokumenata, kao što su npr. narudžbenice. Ove vrste poslovnih dokumenata logički su povezane te se podrazumijeva da će račun automatski preuzimati velik dio podataka iz narudžbenice, ako ona postoji. Za e-narudžbenicu i ostale dokumente koji se razmjenjuju unutar dobavnog lanca (otpremnica, primka i slično) je stoga preporučljivo koristiti istu normu kao i za e-račun.

Norma Universal Business Language (UBL) se temelji na konceptualnom modelu informacijskih komponenti koje predstavljaju podatkovne elemente poslovnih dokumenata. Te podatkovne komponente spajaju se u dokumente kao što su narudžba ili račun koji se prema pravilima UBL Naming and Design Rules transformiraju u XML sheme.

Norma UBL 2.0, za koju se Povjerenstvo za e-Račun odlučilo kao podlogu za izgradnju dokumenata koji se razmjenjuju u postupku naručivanja i postupku fakturiranja, sadrži niz XML shema za 31 poslovnu poruku. Od studenoga 2013. godine za UBL je postala važeća verzija 2.1 koja ima 64 vrste poslovnih poruka. Budući da verzija UBL 2.1 predstavlja nadogradnju verzije 2.0, verzija 2.1 neformalno se smatra preporučenom normom za format e-računa u Republici Hrvatskoj.

E-plaćanje predstavlja posljednji korak u automatizaciji dobavnog lanca. Na temelju ispostavljenog računa, na strani kupca se generira nalog za plaćanje. Tim dokumentom inicira se obavljanje novčane transakcije gdje kupac dobavljaču transferira novčana sredstva naznačena na računu.

SEPA kao jedinstveni prostor plaćanja u eurima omogućuje da se plaćanja u eurima, bilo u zemlji ili inozemstvu, izvršavaju prema jednakim pravilima, neovisno o tome u kojoj se državi nalaze pojedini sudionici procesa. Pristupanjem Europskoj uniji, Hrvatska je dužna prilagoditi se SEPA platnoj shemi za euro platne transakcije.

Propis (EU) No 260/2012 Europskog parlamenta i Savjeta od 14. ožujka 2012. [15] [16] postavlja tehničke i poslovne zahtjeve za prijenose odobrenja i trajnih naloga u eurima

- identifikator računa uplatitelja mora biti IBAN
- norma za format poruka mora biti ISO 20022.

Financijske institucije definirale su normu ISO 20022 za razmjenu različitih vrsta poruka u formatu XML. Poruke ISO 20022 [9] [10] [11] [12] [13] pokrivaju kompletni lanac plaćanja: od kupaca prema bankama, od banaka prema bankama te za izvješćivanje; koriste se i za naloge investicijskih fondova, izvješća o cijenama i slično.

III. PROCESI PLAĆANJA I ELEKTRONIČKO POSLOVANJE

Elektroničko poslovanje pokriva poslovne procese cijelog dobavnog lanca, a plaćanje je završni dio procesa nabave kada kupac dobavljaču prenosi novčana sredstva naznačena na izdanom računu. Dobavljač ispostavom računa s kupcem stvara dužničko-vjerovnički odnos temeljem kojeg se provodi financijska transakcija.

Procesi plaćanja po SEPA inicijativi definiraju sljedeće načine plaćanja:

- Kreditni transfer (Credit transfer).
- Izravno terećenje (Direct Debit).
- Plaćanje karticama.

U radu se razmatra kreditni transfer i izravno terećenje, dok se plaćanje karticama neće razmatrati.

A. Pozicioniranje informacijskog posrednika u procesu plaćanja

Poslovni partneri mogu u međusobnom poslovanju ugovoriti elektroničku razmjenu poslovnih dokumenata. Bilateralno ugovaranje je relativno jednostavno kada je

poslovno okruženje jednostavno u smislu postojanja nekolicine partnera s kojim je uspostavljen neki oblik poslovnog odnosa. Međutim, u trenutku kada se broj poslovnih partnera značajno poveća, ugovaranje i razmjena elektroničkih dokumenata postaje vremenski intenzivno i kompleksno. Jedno od rješenja je poslove elektroničke razmjene dokumenata prepustiti vanjskom izvršitelju, tj. informacijskom posredniku.

Korištenje informacijskih posrednika po modelu 4-strane kao u [3] omogućuje ugovornim stranama prepuštanje ugovaranja i realizacije razmjene elektroničkih poslovnih dokumenata trećima, tj. informacijskim posrednicima. Svaka poslovna, ugovorna strana sklapa sporazum s informacijskim posrednikom po vlastitom izboru (ili s istim ili s različitim).

Informacijski posrednici osim razmjene elektroničkih dokumenta, obavljaju i funkcije elektroničke arhive, konverzije formata, digitalnog potpisivanja i označavanje dokumenta elektroničkim žigom. Nadalje, temeljem elektroničkih računa mogu i trebaju generirati instrukcije za provedbu plaćanja po različitim standardima.

Glavni sudionici procesa prema inicijativi SEPA za kreditni transfer [5] dijele se po nekoliko interesnih domena:

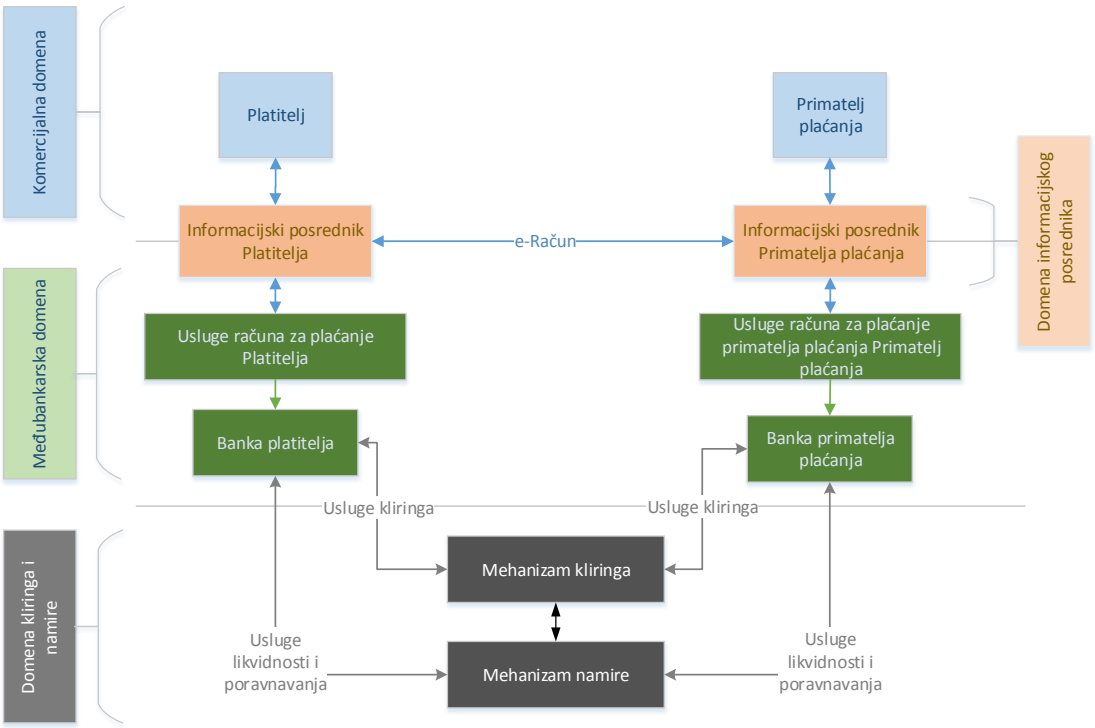
- Komercijalna domena (Commercial Space) – obuhvaća poslovne partnere generiraju financijske obaveze isporukom usluga i roba.
- Međubankarska domene (Inter-bank Space) – obuhvaća banke i potrebne servise za provedbu plaćanja i komunikaciju prema korisnicima.
- Domena kliringa i namire (Clearing & Settlement Space) –domena pokriva neophodne sudionike, procese i mehanizme za potrebe prebacivanja sredstava između banaka. Obuhvaća Clearing and Settlement Mechanism (nadalje CMS) čija je svrha pouzdana i sigurna razmjena informacija u procesima plaćanja.

Sukladno modelu 4-strane, informacijski posrednik preuzima dijelove poslovnih procesa u kojima se radi razmjena poslovnih dokumenata, u kojima je e-račun dokument kojim se stvara dužničko/vjerovnički odnos, a time i predstavlja podlogu za generiranje nalog za plaćanje. Informacijski posrednik temeljem zaprimljenog elektroničkog računa može generirati nalog za plaćanje i u ime primatelja računa pokrenuti plaćanje prema poslovnoj banci. Stoga pozicioniranje informacijskog posrednika je u procesima plaćanja između platitelja i njihovih poslovnih banaka. Na slici 2. prikazano je pozicioniranje sudionika u procesu plaćanja elektroničkog računa.

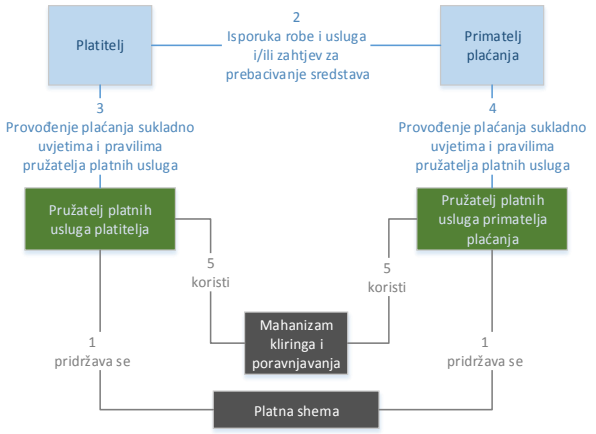
Pružatelj platnih usluga (PPU) platitelja, tj. banka u kojoj platitelj ima otvoren račun za plaćanje, mora imati sposobnost provođenja platnih transakcija prema pružatelju platnih primatelja plaćanja.

B. Proces plaćanja: Kreditni transfer

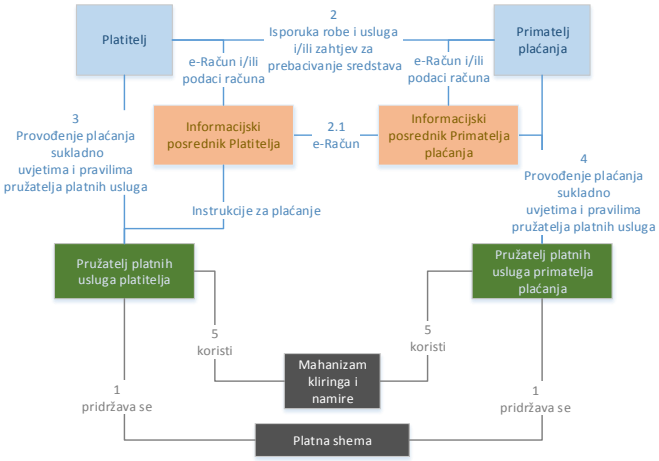
Kreditni transfer je nacionalna ili prekogranična platna usluga kojom se račun za plaćanje primatelja plaćanja odobrava za platnu transakciju ili niz platnih transakcija na teret platiteljevog računa za plaćanje od strane PPU-a kod kojeg se vodi platiteljev račun za plaćanje, na osnovi instrukcije koju daje platitelj [15] [16]. Poslovni odnos između platitelja i primatelja plaćanja je temelj kojim



Slika1. Pregled i pozicioniranje sudionika u procesu plaćanja elektroničkog poslovanja za kreditni transfer [5]



Slika 2. Kreditni transfer po modelu 4-strane [5]



Slika 3. Pozicioniranje informacijskog posrednika u virmanskom plaćanju po modelu 4-ugla

platitelj pokreće plaćanje putem izdavanja naloga za plaćanje svom pružatelju platnih usluga (engl. payment service provider, PSP). Platiteljev PPU prebacuje sredstva primateljevom PPU.

Uloge u procesu virmansko plaćanja [6]:

- Platitelj – fizička ili pravna osoba koja ima račun za plaćanje i koja da suglasnost za izvršenje nalog za plaćanje s tog računa.
- Pružatelj platnih usluga (PPU) platitelja– pružatelj platnih usluga platitelja, banka, koja zaprima naputke za plaćanje sukladno kojim u ime platitelja prebacuje sredstva u banku primatelja plaćanja, a u korist njegova bankovnog računa.
- Pružatelj platnih usluga (PPU) primatelja plaćanja – je sudionik procesa koji zaprima naputke za provođenje kreditnog transfera od PPU-a platitelja i prebacuje sredstva na bankovni račun primatelja plaćanja.
- Primatelj plaćanja - fizička ili pravna osoba koja ima račun za plaćanje i za koju su namijenjena novčana sredstva koja su predmet platne transakcije.

Isporukom roba ili usluga od strane dobavljača stvara se preduvjet za izdavanje i dostavu računa kupcu. Isporukom računa, stvara se dužničko-vjerovnički odnos između partnera sukladno [17].

U elektroničkom poslovanju dostavu računa, u ime dobavljača radi njegov informacijski posrednik. Informacijski posrednik od dobavljača može preuzeti ili već pripremljeni e-račun ili ga generirati iz dostavljenih podataka. Informacijski posrednik dobavljača dostavlja e-račun informacijskom posredniku kupca. Informacijski posrednik kupca, će zavisno od poslova koje za kupaca obavlja u kontekstu elektroničkog poslovanja, provjeriti ga (sintaksno i semantički), pohraniti u elektronsku arhivu, te dostaviti kupcu u njegov poslovni sustav.

Zaprimanjem e-Računa od strane kupca nastaje dužničko-vjerovnički odnos, kao i u klasičnom poslovanju, koji je temeljem za iniciranje plaćanja. Inicijator plaćanja je platitelj, tj. kupac. Informacijski posrednik, u ime platitelja, generira naloga za plaćanje i dostavlja ga PPU platitelja. PPU platitelja izvršava platnu transakciju prema PPU-u primatelja plaćanja. Nakon provedene platne transakcije PPU platitelja dostavlja informacijskom posredniku platitelja povratne informacije o statusu izvršenja platne transakcije. Informacijski posrednik platitelja temeljem zaprimanja statusa izvršenja transakcije informaciju dostavlja u poslovni sustav platitelja.

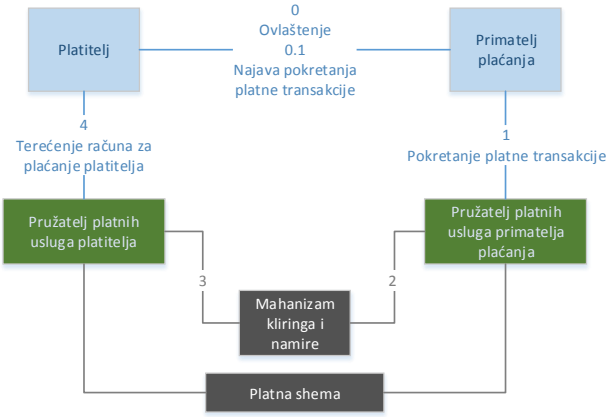
Informacijski posrednik primatelja plaćanja može zaprimiti informaciju o provedenoj platnoj transakciji. Poslovni procesi koji se pokreću zaprimanjem informacije o statusu provođenja platne transakcije ovise o ugovorenom odnosu između primatelja plaćanja i njegovog informacijskog posrednika i nisu predmet razmatranja u ovome radu.

C. Proces plaćanja: Izravno terećenje

Izravno terećenje je nacionalna ili prekogranična platna usluga za terećenje platiteljevog računa za plaćanje, kada platnu transakciju inicira primatelj plaćanja na osnovi suglasnosti platitelja [15] [16]. Platitelj daje ovlaštenje (engl. mandate) primatelju plaćanja za provedbu platne transakcije izravnim terećenjem. Primatelj plaćanja pokreće platnu transakciju izdavanjem naloga za plaćanje svom PPU. Izravno terećenje koristi se često za provođenje platnih transakcija za usluge koje se periodično isporučuju, npr. plaćanje komunalnih usluga. Također se koristiti i za jednokratne isplate. U prvom slučaju zahtijevaju ovlaštenje dok u drugom slučaju autorizaciju od strane platitelja.

Uloge u procesu plaćanje izravnim terećenjem su [8]:

- Primatelj plaćanja - prima i pohranjuje ovlaštenje za pokretanje izvršavanja izravnih terećenja. Temeljem pohranjenih ovaštenja vjerovnik može inicirati platne transakcije izravnim terećenjem.
- Pružatelj platnih usluga (PPU) primatelja plaćanja - je pružatelj platnih usluga u kojem primatelj plaćanja ima otvoren račun za plaćanje. Temeljem sporazuma s primateljem plaćanja (vjerovnikom)



Slika 4. Izravno terećenje model 4-strane [8]

prima i izvršava nalog za plaćanje. Pokreće transakciju izravnog terećenja sukladno nalogu za plaćanje prema PPU platitelja.

- Pružatelj platnih usluga (PPU) platitelja – je pružatelj platnih usluga u kojem platitelj ima otvoren račun za plaćanje. Temeljem sporazuma s platiteljem pokreće terećenje računa platitelja, prebacivanje sredstava, koje je pokrenuto procesom izravnog terećenja od strane primatelja plaćanja.
- Platitelj – Njegov račun za plaćanje se tereti temeljem naloga za plaćanje poslanih od strane primatelja plaćanja. Izdaje suglasnost primatelju plaćanja za pokretanje transakcije izravnog terećenja.

Koraci koji prethode stvaranju dužničko vjerovničkog odnosa su isti kao kod kreditnog transfera. Zaprimanjem računa od strane kupca nastaje dužničko vjerovnički odnos temeljem kojeg se inicira platna transakcija. Inicijator platne transakcije je u ovome slučaju primatelj plaćanja, tj. dobavljač.

Prije pokretanja transakcije izravnog terećenja platitelj mora ovlastiti primatelja plaćanja za izvršavanje izravnih terećenja. Ovlaštenje sadržava sve potrebne informacije koje primatelju plaćanja daju ovlasti za izvršavanje izravnog terećenja. Informacijski posrednik primatelja plaćanja nakon slanja e-računa šalje najavu pokretanja transakcije izravnog terećenja platitelju, odnosno informacijskom posredniku platitelja. SEPA definira slanje najava za plaćanje barem 14 kalendarskih dana prije dana dospijeća [8]. Ovaj rok može biti i kraći ako je isti ugovoren od strane platitelja i primatelja plaćanja. Primatelj plaćanja može poslati informacije u PPU platitelja o iznosu sredstava koje je potrebno prebaciti transakcijom izravnog terećenja. Prijenos informacija u PPU platitelja se ne smije dogoditi prije gore definiranog roka za dostavu najave za plaćanje platitelju. Informacijski posrednik u ime primatelja plaćanja generira nalog za plaćanje, čime pokreće transakciju izravnog terećenja. Informacijski posrednik primatelja plaćanja šalje nalog za plaćanje u PPU primatelja plaćanja. PPU primatelja plaćanja pokreće platnu transakciju izravnog terećenja prema PPU platitelja. Nakon provođenja platne transkacije

Slika 5. Pozicioniranje informacijskog posrednika u modelu 4-strane izravnog terećenja

izravnog terećenja, PPU primatelja plaćanja dostavlja informacijskom posredniku primatelja plaćanja povratne informacije o statusu transakcije. Informacijski posrednik primatelja plaćanja dostavlja informaciju o statutu provedene transakcije u poslovni sustav primatelja plaćanja.

IV. PRESLIKAVANJE UBL 2.1. ELEMENATA NA ISO 20022 XML PAIN PORUKE

U prethodnom poglavlju opisani su procesi plaćanja koje inicira informacijski posrednik.

Da bi se uspješno proveli procesi plaćanja elektroničkim putem, potrebno je uspostaviti semantičku interoperabilnost između normi koje se koriste s jedne stanje u razmjeni elektroničkih računa, a s druge strane u sustavima koji provede prebacivanje financijskih sredstava. Sadržaj elektroničkog računa omogućuje generiranje instrukcija za plaćanje bez obzira da li se radi o kreditnom transfer ili izravnom terećenju.

U Republici Hrvatskoj norma UBL 2.1 [1] neformalno se smatra preporučenom normom za format elektroničkog računa, a SEPA preporučuje korištenje norme ISO 20022 za implementaciju procesa plaćanja.

U budućem radu potrebno je napraviti preslikavanje određenih elemenata između normi UBL 2.1 i ISO 20022 a sukladno s [4] [7] [8].

V. MOGUĆA POBOLJŠANJA I BUDUĆI RAD

Potrebno će biti definirati sheme temeljem koje će se informacije o modelu plaćanja i pozivu na broj prenositi kao jedinstveni podatak prilikom razmjene poruka u procesima ne samo plaćanja nego i razmjene e-računa.

Sa stanovišta primjene normi objavljene su nove verzije ISO 20022 pain poruka [9] [10] [11] [12] [13] pa je neophodno donošenje naputke od strane nadležnih radnih tijela za provedbu SEPA projekta u vezi korištenja istih, te primjena tih naputaka na iznesena preslikavanja.

Nastojati će se inicirati aktivnosti kojima je nositelj Ministarstvo gospodarstva Republike Hrvatske, a vezane za elektroničko poslovanje i elektronički račun radi objave

službenog dokumenta na temu preslikavanja elementa e-računa i elemenata poruke za inicijalizaciju plaćanja sukladno inicijativi SEPA.

VI. ZAKLJUČAK

Realizacijom inicijative SEPA u Republici Hrvatskoj elektroničko plaćanje u eurima će se izvoditi na isti način na koji se izvodi na području cijele Europske unije. Bankarski sektor će implementirati neophodne protokole i poruke za provođenje procesa plaćanja prema inicijativi SEPA.

Iz perspektive e-računa kupci i dobavljači će inicijalizaciju plaćanja prema bankama prepustiti informacijskim posrednicima kao i obradu povratih informacija od strane banaka.

Plaćanja u nacionalnim valutama će se vjerojatno, nakon realizacije SEPA-e, neko vrijeme provoditi postojećim nacionalnim protokolima. Za očekivati je da će bankarski sektor i za nacionalna plaćanja uvesti iste procese, poruke i sustave kao i za plaćanja u eurima zbog smanjenja troškova održavanja paralelnih sustava kao i zbog pojednostavnjenja sučelja prema entitetima iz komercijalne domene (kupci i dobavljači) ali i iz međubankarske domene (banke). Informacijski posrednici implementirat će potrebne protokole i poruke za komunikaciju prema bankama sukladno inicijativi SEPA i preporukama Nacionalnog odbora za platni promet, Hrvatskog odbora za SEPA koordinaciju i Hrvatskog SEPA foruma. Interoperabilnost na svim razinama (pravnoj, organizacijskoj, semantičkoj i tehničkoj) će se uspostaviti među svim sudionicima elektroničkog poslovanja cijelog dobavnog lanca.

Jasna definicija i usvajanje smjernica za postizanje organizacijske, a koja uključuje procesnu, i semantičke interoperabilnosti prikazanih u ovome radu kao de facto standard za inicijalizaciju plaćanja u procesima vezanim za e-račun u Republici Hrvatskoj će značajno ubrzati tranziciju od klasičnog prema elektroničkom poslovanju na svim razinama društva.

ZAHVALE

Izražavamo našu iskrenu zahvalnost direktoru Hrvatske udruge banaka dr. sc. Zoranu Bohačeku te gospođi Sandri Ruso, savjetnici u HUB-u. Svojim konstruktivnim savjetima pomogli su nam da ispravimo neke terminološke i faktografske pogreške te da oblikujemo članak za koji se nadamo da može barem malo pomoći u unaprjeđenju elektroničkog poslovanja u Hrvatskoj.

Statistical Microdata – Production of Safe Datasets, Transparent Presentation of Contents and Advanced Services for Users through Metadata Authorization System

M. Poljičak*, H. Stančić**

** Faculty of Humanities and Social Sciences/Department of Information and Communication Sciences, Zagreb, Croatia
*poljicakm@dzs.com
**hstancic@ffzg.hr

In the European Statistical System (ESS) there are more and more generic information systems (ISs) being developed and implemented for production and dissemination of official statistics (OS) macrodata datasets. These generic systems are based on metadata repositories providing, in return, a whole set of additional functionalities and services for users of the systems. Microdata dissemination, being the youngest and least developed discipline in official statistics dataset dissemination, currently still lacks appropriate organization of business procedures and compatible generic tools for the purpose of integration of all the ESS' subsystems into one central Data Service (DS) providing microdata datasets for international users and enabling preservation of microdata datasets. The authors analyze current situation regarding statistical microdata sets acquisition and preservation in digital archives (DAs), provide valuable considerations and propose recommendations to take into account when developing repositories and systems for presentation of available microdata datasets to users. Along with that, the authors introduce the way of usage of appropriate Statistical Disclosure Control (SDC) methods for production of safe microdata outputs. Finally, the authors recommend the development of a central administrative metadata repository that could be used for users' authorization, and that could have additional services for users based on available metadata about users in the system.

I. INTRODUCTION

Protecting the confidentiality of data in statistical surveys is one of the *Fundamental Principles of Official Statistics (OS).* OS should care about secure handling, preservation and dissemination of data. Setting authorized access levels as well as not publishing any data in any way that could reveal information, protected by legal or ethical restrictions, is necessary.

When it comes to data preservation in Official Data Archives (ODAs) different situations are present, at the moment, in different European countries. Some countries have a considerable level of cooperation between National Statistical Institutes (NSIs) and ODAs, and others still haven't developed satisfying and proper levels of cooperation and legal, administrative and technical solutions to tackle these needs.

It is of great importance to maintain the trust of the public in OS, and this is accomplished by setting extra efforts in regulating ways of accessing data, with proper security measures put in place when access is granted.

The problem of setting security measures and protocols, as well as secured ways of access to data, is complex especially if one takes into account a wide range of statistical data outputs available to users. These data outputs have different confidentiality levels and disclosure risks.

Statistical Disclosure Control (SDC) methods take into account legal and administrative boundaries to assure dissemination strategy aligned to disclosure risk and management of the same disclosure risk. Usage of appropriate IT tools and technical solutions, aligned with needs of legal compliance of procedures involved in dissemination of data, is still in the development phase in some areas. In these procedures a lot of manual work is done, involving time of skilled professionals in performing SDC methods, i.e. checking data output for statistical confidentiality. The area of microdata needs a better level of automatization of procedures in order to achieve a faster and simpler channel for production of safe data outputs for research community use.

Currently, new services, aligned to the new orientation of governments across the globe for opening access to different available government datasets, are calling for the new establishment of OSs' dissemination strategies. Organizations responsible for the development of OS in countries should invest efforts in establishing better ways of communication between NSIs, ODAs and research community (universities and research institutes in countries and abroad). These organizations should receive the support of political and other influential bodies in the country, as well as all necessary resources, to implement the procedures and prepare all protocols needed to raise the level of availability of microdata. Raised availability of microdata, could be useful and contribute to better de-

cision making and policies setting for the society. In effect they could bring new and advanced environment development and decision making concerning industry, economy and all other important sectors for empowering the society. Some of the examples of interested users of OS data are economists, demographers and social science researchers, as they could benefit from using vast resources created and preserved in conducting statistical surveys. All these users can find new and advanced secondary uses of extensive and expensive material already collected [12]. However, if data are released to these users, it must be under a proper disclosure control level in place for confidential statistical data.

The broad classification of statistical outputs usually distinguishes between two categories – *macrodata* and *microdata*.

Macrodata are aggregated statistical data (sums, averages, counting units), and these data are usually publicly available. However, some macrodata sets could be restrained from dissemination to public because the sample is too revealing and therefore public could infer conclusions about individual records in the macrodata dataset.

On the other hand, *microdata* are records collected as input data for the surveys. These records are confidential, subject to law restrictions and ethical standards set in place. However, under special conditions these data could be released, with more or less content (anonymized datasets), to special groups of users. Following current regulations, the users of microdata datasets could be any person belonging to the group of university researchers or members of other research institutions in the country, or even outside of the country, if they ask for accreditation. The procedure and the level of access rights are different in each European country, as are the ways of access. In the year 2013 a new regulation by the European Commission EC 557/2013 is set in place. By that regulation the process of application for statistical microdata access is made transparent for research community. "This Regulation establishes the conditions under which access to confidential data transmitted to the Commission (Eurostat) may be granted for enabling statistical analyses for scientific purposes, and the rules of cooperation between the Commission (Eurostat) and national statistical authorities in order to facilitate such access." [6]

A lot of work is still needed for the establishment of a successful Central Remote Access Data Center (RADC) for European microdata, providing the researchers with a simple and comfortable access to microdata and transparent presentation of data available. The service is currently being developed by the Eurostat and it should provide researchers with a central RA microdata access point in Europe.

In this paper the authors draw conclusions about several issues relating to establishing RADCs.

(1) How automated SDC procedures should be developed through RADC and aligned to the disclosure risk management for microdata datasets,

(2) How available resources should be transparently shown to the users, organized and made easily searchable,

(3) How researchers' authorization levels should be managed in a way to provide users with additional services aligned to their interests and needs concerning statistical microdata.

II. Related work

In providing public, and especially research community, with valuable statistical information NSIs need to set the balance between the level of the statistical outputs released and levels of protection of confidentiality of the individual data of respondents. In order to set an appropriate SDC method in place, i.e. to choose and implement appropriate software solutions, providers of official statistics microdata (as well as aggregated data outputs) should have in mind who their users are, as well as the possible uses of the released data. Also they need to consider possible further dissemination of the released data. For dissemination of the released data a proper ways of presenting available data should be defined. Also, users of the RADC, i.e. authorized researchers, should have an easy way of authentication and authorization procedures in order to manage data retrieval and to be able to get all other advanced services needed from the system.

A. Statistical Disclosure Control

In [1] "To protect the privacy of respondents a statistical office should prevent the disclosure of sensitive information on individual respondents by an intruder. As disclosure of sensitive information is possible only after an individual has been identified, a statistical office usually tries to prevent the identification of individual respondents."

As in [3] "Statistical Disclosure Control (SDC) or Statistical Disclosure Limitation (SDL) seeks to protect statistical data in such a way that they can be released without giving away confidential information that can be linked to specific individuals or entities." Also in [3] "a disclosure occurs when a person or organization recognizes or learns something that they did not know already about another person or organization via released data." And also in [3] "statistical disclosure control techniques can be defined as the set of methods to reduce the risk of disclosing information about individuals, businesses or other organizations." SDC methods minimize the risk of disclosure to an acceptable level while releasing as much information as possible. There are two types of disclosure risks as in [3], *identity disclosure* and *attribute disclosure*. Identity disclosure occurs with the association of a respondent's identity with the disseminated data record containing confidential information. *Attribute disclosure* occurs with the association of either attribute value in the disseminated data or an estimated attribute value based on the disseminated data with the respondent.

As mentioned in [3], microdata protection methods used for generating safe datasets can be divided into two categories: *masking methods* and *synthetic data generating methods*. *Masking methods* mask the original data to protect the dataset from the risk of disclosure. *Synthetic data methods* preserve some statistical properties of the original data, but on the other hand, are difficult to implement.

There are two types of SDC masking methods [3] – *perturbative and non-perturbative methods.* Perturbative methods falsify the data before publication by introducing an element of error purposefully for confidentiality reasons. In this way, unique combinations of scores in the original dataset may disappear and new unique combinations may appear in the perturbed dataset. Such confusion is beneficial for preserving statistical confidentiality. The used perturbation method should be such that statistics computed on the perturbed dataset do not differ significantly from the statistics that would be obtained on the original dataset. On the other hand, non-perturbative methods reduce the amount of information released by suppression or aggregation of data. Global recoding, local suppression and sampling are examples of non-perturbative methods." In that sense "*global recoding* method is a method where several categories of a variable are combined into single one, and *local suppression* method is a method where a value of a variable in a record is replaced by *missing*." [1]

In [3] it is showed that "a microdata set can be viewed as a file with *n* records, where each record contains *m* variables on an individual respondent. The variables can be classified in four categories which are not necessarily disjoint:

(1) *Identifiers.* These are variables that unambiguously identify the respondent (in Croatia, the example is OIB – Personal Identification Number, author's comment).

(2) *Quasi-identifiers or key variables.* These are variables which identify the respondent with some degree of ambiguity, but they can provide unambiguous identification of the individual record. Examples are name, address, gender, telephone number, etc.

(3) *Confidential outcome variables.* These are variables that contain sensitive information on the respondent. Examples are salary, religion, political affiliation, health condition, etc.

(4) *Non-confidential outcome variables.* These are variables which do not fall in any of the categories above."

Datasets anonymization could be done by avoiding dissemination of identifiers and quasi-identifiers since some of the general conclusions about the type of data are considered highly disclosing. Besides that, in anonymization procedures usually "categories of identifying variables with too significant identifying power are commonly aggregated into a single category. (...) Geographical information is a strongly identifying variable. (...) Release of date of birth is highly discouraged." [3] Also, when dealing with business data it is very easy to find the data belonging to a largest national company in some sectors, i.e. income or turnover of the company in telecommunications or national oil and gas company, so this data should be specially protected, especially in smaller countries where there is not a lot of suppliers of some services or goods in some sectors. "Examples of identifying variables are Age, Sex, Domicile and Occupation. Although each identifying variable is generally not sufficient to identify an individual when considered separately, a combination of values of identifying variables might be sufficient. When a combination of values of identifying variables is unique, i.e. occurs only once in population, then an intruder might identify the corresponding individual. (...) For preventing disclosure it is better to avoid the occurrence of combinations of values in the microdata set that are rare in the population, instead of trying to avoid only the population-uniques in the microdata set." [1]

The rules for handling disclosure risk take into account settings of the threshold, i.e. the minimum number of occurrence of the value of variable, considered to be the minimum for allowing the variable to be released in the output microdata dataset. "In case the frequency of a particular combination is at least the prescribed threshold value then this combination is considered safe. Otherwise the combination is considered unsafe and disclosure limitation measures should be applied." [1]

Access and overall dissemination of identifiers and quasi-identifiers should be avoided, especially taking into account possibility of merging these data with other available databases and greater risk levels concerned with possible disclosure of information in that scenario. Later in this research paper we will suggest providing free access to non-confidential outcome variables, with possibility of protecting confidential variables and/or confidential sets of variables. Restricted ways of access to confidential variables using SDC methods will be analyzed.

B. Presentation of data available in RADC

The second point of interest of this paper is the presentation of available content in an easy to search and explore ways, i.e. using navigation tools in RADC with possibility of learning about available datasets.

Developing a central RADC in Europe will not be an easy task. There are many countries with their NSIs involved in collecting, processing, preserving, and disseminating statistical datasets. Many of NSIs are either in the process of implementing standards for data collecting, documenting and preserving of the collected and processed data, or they have already done it. This should ease the situation in the future and enable a better connectivity between resources from different countries. Statistical surveys are also becoming standardized in the methodology for collecting, processing and disseminating data and in data structures.

C. Authorization system using metadata repository

The third point of interest of this paper is the ways of enabling advanced services for users of RA to microdata, as well as providing authorization mechanisms according to the authorization levels of users of the system and according to the authorization level needed to perform specialized operation on a dataset. It is obvious that in this DC, enabling access to confidential data, only authorized users should have access to data. The access should be granted according to all legal, technical and other measures taken into account and set in place for the proper level of data protection. This can be achieved by using metadata repository of users. Such repository should be placed in the core of the system responsible for documenting users, their rights and prescribed services available to a specific user.

III. MICRODATA SDC

A data dissemination strategy offers many different statistical outputs covering a range of different topics for many types of users. Different outputs require different approaches to SDC and different mixture of tools for handling it.

The microdata require a high level of disclosure control in order to protect confidentiality of available datasets. Usually anonymized datasets are available to users. Users can only perform statistical analysis on data – they cannot see the real data. The produced outputs are deposited in the system's repository. These outputs are first checked by NSI staff for statistical disclosure, and only if approved, the secondary data retrieved by using microdata can be released and used by the researcher.

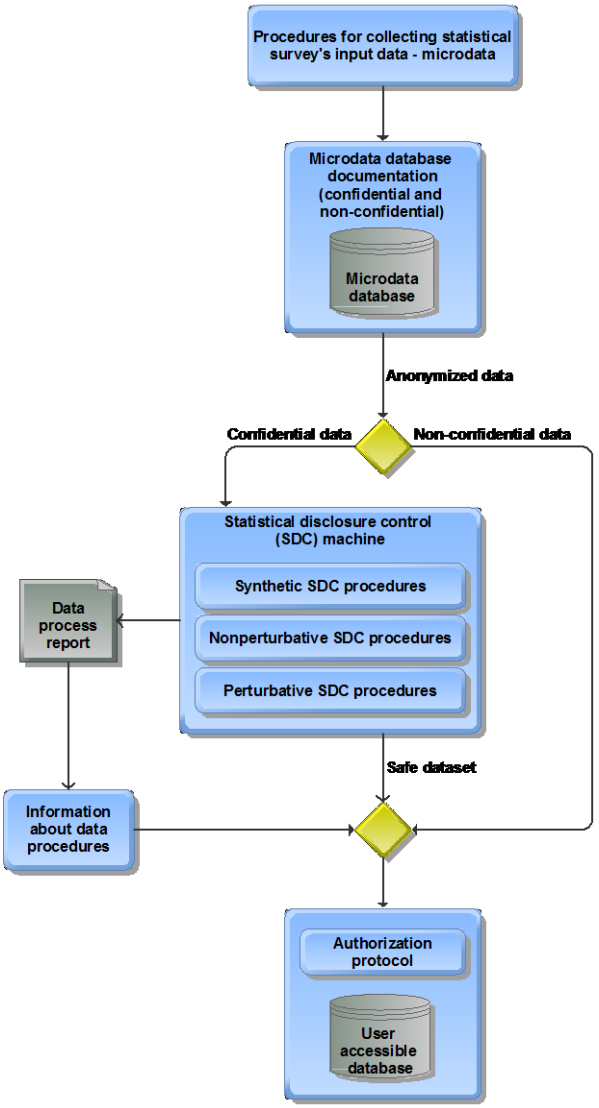
From the new Regulation introduced by the European Commission – EC 557/2013 – it can be concluded that the process of granting access to statistical microdata is becoming more transparent and procedures involved are more organized and centralized. In [6] "The Commission (Eurostat) shall publish on its website: (a) guidelines for the assessment of research entities, research proposals and access facilities; (b) the list of recognized research entities; (c) the list of accredited access facilities: (d) the list of datasets for research use with relevant documentation and the available modes of access."

However, for the NSI's staff, SDC procedures are still very time-consuming and burdening.

Therefore, we suggest building of a system for automatic creation of safe statistical outputs in the form of appropriate level of anonymization. Also, we suggest that variables and/or sets of variables considered to be revealing before being released through RADC, could be handled by development and implementation of software solution for enabling extraction of safe portions of datasets, as well as providing transparent documentation about applied SDC methods. Those datasets would then be made available to users in the form of a safe dataset with collection of non-confidential attributes and SDC protected confidential attributes which can then be used in a more user-friendly way, without creating barriers between users and the real datasets.

This system could be used for microdata dissemination strategy implementation for the research community. Accomplishing that, it is only a question of the extent of usability of the received datasets for research which are in accordance with the need for assuring the highest level of usability of data while at the same time protecting confidentiality of datasets.

However, there are, at the moment, software solutions for SDC. One example is µArgus, developed at Statistics Netherlands in 1995, using various SDC methods. The application is designed to work through several phases for ensuring production of safe data output. It works interactively with the user of the system. The metadata about data should be introduced to the system at the beginning of the process, and at the end the system produces a data process report for the data entering µArgus production of safe dataset.



Picture 1. Production of safe microdata outputs with documentation on applied SDC methods

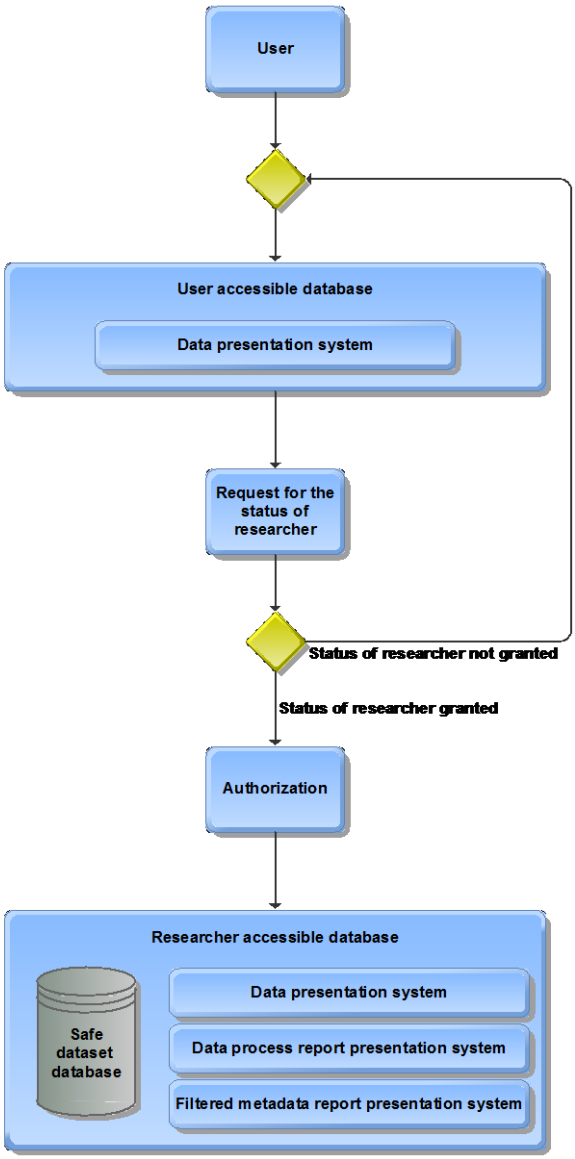
IV. TRANSPARENT PRESENTATION OF DATA IN THE USER ACCESS SYSTEM

When procedures for obtaining data collection and the documentation of the collected data in a Digital Archive (DA) become established for a statistical survey, then the same statistical survey data documentation should become available to the researchers through the DA interface that enables easy navigation and retrieval.

It is customary to use metadata repositories and semantics methodology for presentation of available resources in an interactive and easily retrievable way.

Metadata about surveys and datasets can help users learn about the available datasets and the survey methodology, and also help them to explore vast materials they are not familiar with.

The possible ways of showing the available contents are through interactive controls, like navigation trees, which should be prepared as a multilingual environment, thus enabling access and usage for possible users coming from different European countries. This goal is achievable if the system is generically built with resource-based approach to documenting all the data and metadata in a translatable repository of metadata. This repository can later be used to manage building multilingual controls for the user interface according to the available categories of data.



Picture 2. User access system

"Documentation is an essential part of any dissemination strategy both for auditing from external authorities and transparency towards users. The former may include descriptions of legal and administrative steps for a risk management policy together with the technical solutions applied. The latter is essential for a user to understand what has been changed or limited in the data because of confidentiality constraints. If a data perturbation method has been applied then, for transparency reasons, this should be clearly stated. (...) If a data reduction method has been applied with some local suppression (...) The released microdata should be obviously accompanied with all necessary metadata and information on methodologies used at various stages of the survey process (sampling, imputation, validation, etc.) together with information on magnitude of sampling errors, estimation domains, etc." [3]

V. USER AUTHORIZATION THROUGH METADATA REPOSITORY

By using a metadata repository for the purpose of building authorization system for diverse users, it is possible to develop all kinds of additional services for users, like subscribing to information about new datasets available, informing users about expiration of subscription to the data in advance, etc.

A metadata repository should hold the data about a user, surveys available to him/her to explore or use, and data released for the user exploration or additional analysis. This means that the repository will, in return, have a history of the user rights to datasets – preserved through time, and also it should be possible to record usage of the data to the user profile. This information could possibly be used in cases of confidentiality breech as well as for informing the user about some important information, or information concerning the deposit of new data and similar functions. In this way system's resources could be personalized in accordance with the users' interests and needs.

In spite of being generic and very versatile regarding available services for the user, this system should be easy to use. It should enable easy creation of new items in the database, as well as inheritance of all available modules. It should also be practical for the purposes of reuse and updating.

VI. CONCLUSION

The aim of this paper is to answer three questions important to have in mind when building either a central international RADC for statistical microdata access for researchers, or a national system for the same purpose in a national context.

Concerning the first question stated in the Introduction part of the paper, it can be concluded that SDC methods, aligned with the dissemination strategy for the data output, should be implemented through an automated system. Such a system should provide researchers with a satisfying level of data usability, and cover disclosure protection according to the level of risk of identity or attribute disclosure. This could be done by the proposed methods of anonymization and suppression of confidential values of variables where considered necessary, as well as masking of all confidential values of variables in the microdata output. Along with mentioned methods global recoding of confidential sets of variables in an automated system should be used in order to get the safe microdata dataset. Sophisticated methods, along with enabling a better level of data usability, should use perturbative methods for enabling non-disclosure scenario, because the data would be

"false", thus eliminating the disclosure risk, but at the same time "true" for obtaining exact aggregated statistical indicators.

The second question yielded a conclusion that the system providing transparent presentation of resources should be developed in a generic way, using metadata repository available in different languages, as well as using semantics methodology for building user interfaces that should enable easy exploration by users, as well as learning about the available datasets in overall transparent presentation of available resources in different languages. This system should certainly provide users with information about SDC methods used with the data before its dissemination.

Answers to the third question are in line with the usage of metadata repository for users' authorization levels implementation. They also enable the development of all kinds of advanced services for the users through personalized profile, developed on the grounds of users' metadata information. This system should be developed using a generic approach incorporating translatable metadata repository in the core of the system.

Choosing broadband access solution for modern residential buildings in densely populated urban center

Jasenko Topić, Zlatan Begić, Izudinka Kapetanović Serdarević
BH Telecom d.d. Sarajevo Direkcija Tuzla, Tuzla, Bosna i Hercegovina
jasenko.topic@bhtelecom.ba, zlatan.begic@bhtelecom.ba, izudinka.kapetanovic@bhtelecom.ba

Abstract: Broadband access today is a result of many years of growing demand and represents the best choice for telecom operators to secure telecommunications market position. Data traffic is constantly increasing and brings higher profit to operators compared to voice traffic. Newest broadband services demand next generation broadband access infrastructure. Investment in better infrastructure is key for implementing new services. Telecom operator needs to decide how complex (and expensive) should its infrastructure be in order to serve as long – term broadband solution and at the same time make profit from providing broadband services, including more and more popular triple – play.

Choice rests on multitude of factors, which include existing infrastructure quality, population density, dominant building type and geographical household distribution. This article analyzed densely populated area with dominantly residential buildings, which is a feature of urban centers and residential – business zones. It is important to say that urban centers have increased demands for broadband services, a result of larger business subjects concentration, research and educational institutions from elementary to university level.

Article goal is to give answer to rising question: which technology is the best for telecom operators from aspect of implementation speed and profitability in given area, and that can rise up to challenge of providing ever demanding broadband services and provide a way for transition to FTTH infrastructure.

Keywords: fttx, telecom, triple – play, urban, xdsl

I. INTRODUCTION

Densely populated area is an area with average household density above 1000 per km^2. Areas with dominantly residental buildings are areas with more than 70% of households in residential buildings and the rest in residential houses. Modern infrastructure residential buildings have home wiring where measured parameters on more than 50% of twisted – pair copper wires support xDSL (*x Digital Subscriber Line)* standards [1] [2] and have adequate space for telecommunications equipment.

II. EXISTING STATE

Densely populated area with dominantly residential buildings is a feature of urban centers. Objects built in last 30 years usually have adequate space for active equipment and home wiring that supports xDSL standards for providing demanding broadband services.

As an example an urban center in Tuzla is chosen, with aerial photography given in fig. 1. Broadband service is being given through ADSL2+ (*Asymmetric Digital Subscriber Line 2+*) [1] DSLAM (*Digital Subscriber Line Access Multiplexer)* equipment over copper access network. Although analyzed area is located at just about 1000 m from active equipment, households have limited bandwidth, because of which there is a large number of pending requests for broadband services that telecom operator can not process. Exact reasons will be determined after terrain survey.

Analyzed urban center has surface area of 0,15 km^2 with about 1000 households. Household density is about 6666 per km^2, which means that this area is densely populated. With more than 70% of households in residential buildings, they present the dominant type.

Urban center has great potential because of population density. More detailed analysis of access network and residential buildings infrastructure is needed in order to choose the right broadband solution.

An exact copper cable position was determined after terrain survey. Primary and secondary access network consists of copper cable too dated to be efficiently used for providing broadband services, triple – play in particular. According to previous experience, a problem was found in a cable that leads to residential buildings, which reconstruction is time consuming and presents big financial investment compared to its positive effects.

Figure 1. City center example with modern residential buildings[1]

[1] Source: Google Earth satellite photography

Access network state will be analyzed for 6 residential buildings. Prior to the measurements an ADSL2+ modem is required to be placed in a household. That modem is connected via twisted – pair copper wire to main distribution frame in telecom company building, after which there is another 10 m of copper wire leading to modem in DSLAM port. After the modems are synchronized with ADSL2+ standard, xDSL parameters can be read from surveillance system shipped by manufacturer with DSLAM. Measured values are identical to those that would be measured on a household modem. Chosen xDSL parameters are measured according to standard [1] on twisted – pair copper wires that connect analyzed residential buildings to DSLAM equipment, results of which are shown in table 1.

Results are displayed graphically in fig. 2. According to obtained results it can be seen that measured values are relatively low for twisted – pair copper wires only about 1000 m long. Access network state can be improved with a new broadband solution.

III. RECOMMENDED BROADBAND SOLUTION

Urban center with residential buildings has large household concentration in small area. Telecom operators need to act quickly to eliminate all problems in providing service to households because of the market size and strong competition. Bigger changes to access technology when it comes to replacing telecommunications infrastructure are challenging in urban centers. It is imperative to choose and quickly deploy the right broadband solution.

In urban centers telecom operators usually have cable ducts in which optical fiber can be laid down up to residential building entrances or the distance from optical fiber highway is relatively short. Copper cable access network is of bad quality for broadband services. Residential buildings provide adequate space for active equipment. House wiring is relatively good, because we analyze modern residential buildings.

Because of this FTTB (*Fiber To The Building*) is the recommended broadband solution. DSLAM is the right choice for active equipment and other services can be deployed from existing equipment at telecom premises via old copper cables.

TABLE 1. AVERAGE XDSL PARAMETERS VALUES MEASURED ON COPPER WIRE TWISTED – PAIRS IN ANALYZED RESIDENTIAL BUILDINGS

Building ID	Measured xDSL parameters		
	Signal to noise ratio [dB]	*Line attenuation [dB]*	*Bandwidth [Mbit/s]*
1	12,18	12,73	15,14
2	11,18	17,37	9,99
3	9,39	18,56	11,90
4	12,94	16,73	13,06
5	14,41	19,73	11,61
6	16,93	22,00	12,70

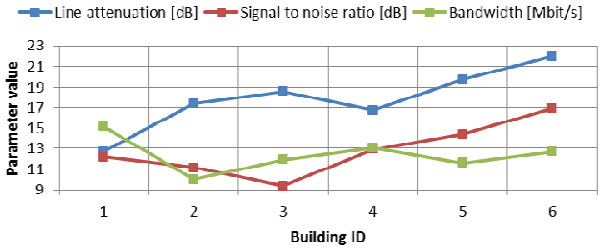

Figure 2. Graphical representation of measured xDSL parameters values

Significant improvement of xDSL line parameters is expected, because the length of twisted – pair copper wires is shortened from about 1000 m to less than 150 m of house wiring. Depending on number of households in residential buildings, telecom operators may choose FTTB DSLAM solutions for 8 – 96 households.

By using FTTB technology telecom operator eliminates copper access network entirely and leaves only copper house wiring. Telecom operator can not use existing copper access network because primary cable is dated and not adequate for xDSL broadband services. With relatively small and quick interventions telecom significantly improves broadband service quality and gains larger user base.

Compared to FTTC (*Fiber To The Cabinet*) in urban centers, FTTB has the following advantages:

- Predetermined active equipment location,
- Better elimination of copper in last mile,
- House wiring presents the only weak spot,
- Relatively short secondary copper access network length,
- Because only broadband access is changed, operator does not require MSAN (*Multi Service Access Node*) and keeps existing equipment,
- No issues with providing adequate room for active equipment and no building outdoor cabinets,
- Relatively quick optical fiber highway installation

FTTH (*Fiber To The Home*) solution compared to FTTB in urban centers is not acceptable because of:

- Complex and expensive home wiring replacement
- Telecom can always process eventual individual FTTH household requests
- optical fiber offers little advantage compared to vectorized VDSL2 (*Very-high-bit-rate Digital Subscriber Line 2*) on copper local loops under 150 m concerning bandwidth for future market demands
- FTTB is proven solution, telecom operator uses existing active equipment

House wiring in residential buildings should be adequate for deployment of bandwidth – hungry broadband services.

Telecom operator places FTTB DSLAM equipment in indoor cabinets in residential building entrances, which have enough space for active equipment, power source, optical fiber installation and copper main distribution frame. This is one of the reasons for choosing the FTTB solution. Figures 3., 4. and 5. graphically represent measured xDSL parameters values before and after deploying FTTB solution in given buildings. For comparision, before and after measurements were taken on identical ADSL2+ modems that limit bandwidth to 25 Mbit/s. It can be seen that access network is greatly improved given the previous state.

In fig. 6 are presented measured bandwidth values on VDSL2 modems [4] according to standard [2] for 9 households that use premium broadband services. This shows FTTB solution potential.

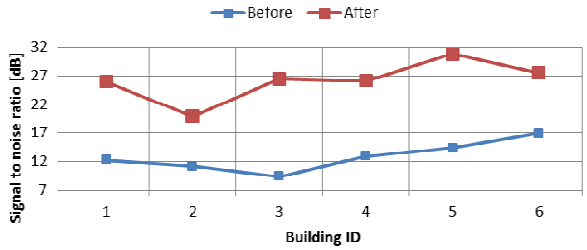

Figure 3. Before and after FTTB – signal to noise ratio

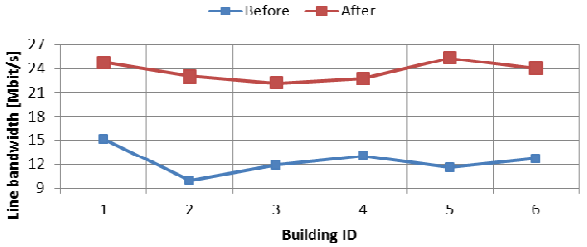

Figure 4. Before and after FTTB – line bandwidth

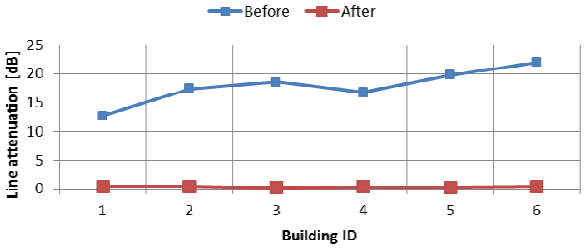

Figure 5. Before and after FTTB – line attenuation

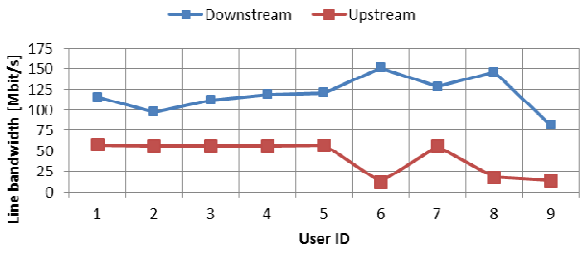

Figure 6. VDSL2 downstream and upstream line bandwidth

Copper wire downstream bandwidth is mostly above 100 Mbit/s and that is without vectoring. This bandwidth is enough for broadband services of today and in the future. For this reason operators still use copper access networks and do not go for optical fiber access networks.

Table 2. lists advantages and disadvantages of chosen FTTB solution.

Residential buildings are important to telecom operators for deploying FTTB solution because of small investment per user, high demand for broadband services and exclusivity in using home wiring thus eliminating competition.

In urban centers there is always strong competition and it is important to deploy broadband services quickly to households. Densely populated areas present large potential user base and by deploying FTTB solution, telecom operator offers better quality service compared to cable and satellite legacy services. Operator mostly uses existing infrastructure, offers technically superior solution compared to FTTC and investment – wise better than FTTH. Operator has the ability to offer 80 Mbit/s bandwidth on copper house wiring with lengths up to 150 m with VDSL2 technology [5], thus using full FTTB solution potential. According to analysis above, FTTB is recommended broadband solution.

IV. ALTERNATIVE BROADBAND SOLUTION

For FTTH solution deployment operator needs to change whole existing infrastructure. Compared to FTTB, operator needs to change house wiring from copper to optical fiber, which is more time consuming and financially challenging. FTTH solution is therefore best for greenfield locations, which have no previous copper wire broadband access network infrastructure. Cost of building optical fiber networks is currently relatively high and deployment time is also longer compared to FTTB/C solutions.

Todays household demands can be fulfilled with FTTB solution that uses line vectoring and bonding, thus achieving bandwidth up to 300 Mbit/s [5]. FTTH offers practically unlimited bandwidth, a potential unnecessary to households in the next decade.

TABLE 2. CHOSEN FTTB SOLUTION ADVANTAGES AND DISADVANTAGES

Advantages	Disadvantages
Eliminated primary copper access network	Deploying optical fiber to residential buildings
Bandwidth above 200 Mbit/s over house wiring with VDSL2 vectoring	Adaptation of building space for active equipment
Best local loop shortening	
Relatively simple deployment	
Unified technical solution	
No issues with equipment placement	

FTTC solution deployment requires good quality of existing copper access network or new copper infrastructure. Analyzed urban center has access network of poor quality, however, residential buildings in it have good quality house wiring to support demanding broadband services. FTTC solution would use primary copper network, which is of bad quality and for that reason FTTB is technically superior solution.

For an area with good quality access network located several km from active equipment FTTC can be used as recommended solution, given low household broadband demands. If longest twisted – pair copper wire would be less than 500 m, then 1 FTTC access node would be sufficient for broadband use. At that lengths operator can achieve minimum 80 Mbit/s per household [5].

Multiple FTTC nodes solution given the residential buildings have modern infrastructure is not recommended, because FTTB is technically superior and by deployment speed and cost is relatively the same. On one hand, FTTB node is more compact and can be placed in existing space indoors and on the other hand, FTTC node requires placement in outdoor cabinet and presents more expensive solution.

FTTC is recommended solution for dated residential buildings. Unpractical solution would be multiple FTTC nodes (fig. 7) and practical 1 FTTC node (fig. 8).

FTTC solution is not practical for urban centers with households in modern residential buildings. Entrances of these buildings present ideal location for active equipment (enough space for cabinet, power source and cooling). Operator shortens local loop ideally within these objects which makes VDSL2 the perfect broadband solution for deployment.

FTTC solution has longer local loop and therefore lower household bandwidth because of higher line attenuation. Multiple FTTC nodes is not recommended because of time and cost of building infrastructure for each FTTC node, which already exists in residential buildings.

V. CONCLUSION

Important factor in society informatization is telecommunications infrastructure of telecom operators that offers greater broadband connectivity with each year, improving services and building basis for development of society.

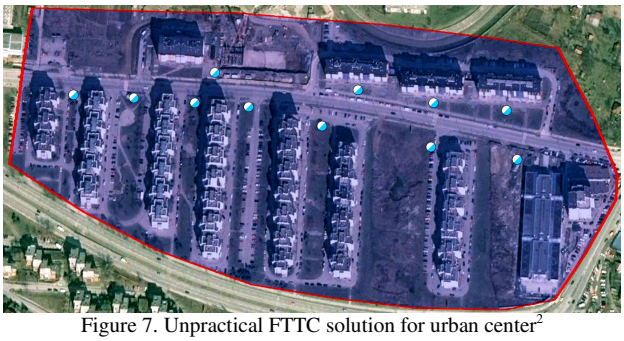

Figure 7. Unpractical FTTC solution for urban center[2]

Figure 8. Practical FTTC solution for urban center[3]

FTTB broadband solution is recommended in densely populated areas with dominantly modern residential buildings, a feature of urban centers with high informatization level. Technically and economically FTTB presents better solution compared to FTTC and in near future it is not expected for FTTH to be strong alternative. With FTTB it is possible to have *downstream* bandwidth in households up to 80 Mbit/s. Also, FTTB solution is designed for residential and other multiple – household buildings. Advantages lie in relatively quick deployment and in creating basis for later FTTH deployment when households demand more than 100 Mbit/s *downstream*.

Odabir rješenja širokopojasne pristupne tehnologije u gusto naseljenom području sa dominantno individualnim stambenim objektima

Jasenko Topić, Zlatan Begić, Izudinka Kapetanović Serdarević
BH Telecom d.d. Sarajevo Direkcija Tuzla, Tuzla, Bosna i Hercegovina
jasenko.topic@bhtelecom.ba, zlatan.begic@bhtelecom.ba, izudinka.kapetanovic@bhtelecom.ba

Sažetak – Kako je širokopojasni pristup značajan faktor društvenog razvoja, telekom operater treba temeljito razmotriti odluku koju tehnologiju implementirati uzimajući u obzir brzinu realizacije i isplativost, a koja može kvalitetno odgovoriti na rastuće zahtjeve korisnika. Za najnovije širokopojasne usluge potrebne su pristupne infrastrukture nove generacije. Ulaganje u kvalitetniju infrastrukturu otvara put razvoju novih usluga.

Operater treba donijeti odluku koliko složenu, a time i skupu tehnologiju odabrati, kako bi dugoročno riješio širokopojasni pristup, a ujedno i ostvario profit od korištenja sve popularnijih *triple – play* usluga.

Izbor ovisi o nizu faktora, koji uključuju kvalitet postojeće infrastrukture, gustinu naseljenosti, dominantni tip stambenih objekata i prostorni raspored domaćinstava. U ovom radu analizirano je gusto naseljeno područje sa dominantno individualnim stambenim objektima karakteristično za ruralne sredine, odnosno prigradska naselja.

Cilj rada je odgovoriti na pitanje koja tehnologija je perspektivna operateru sa gledišta brzine realizacije i isplativosti na predmetnom području, a koja može kvalitetno odgovoriti na rastuće zahtjeve korisnika i omogućiti postepeni prelazak prema konačnom FTTH rješenju.

Ključne riječi: fttx, ruralno, telekom, *triple – play*, xdsl

I. UVODNA RAZMATRANJA

Gusto naseljeno područje je takvo područje, koje na svojoj površini ima srednju vrijednost broja domaćinstava iznad 250 po km^2. Područja sa dominantno individualnim stambenim objektima su područja sa više od 70% domaćinstava u individualnim, a ostatkom domaćinstava u kolektivnim stambenim objektima.

II. POSTOJEĆE STANJE

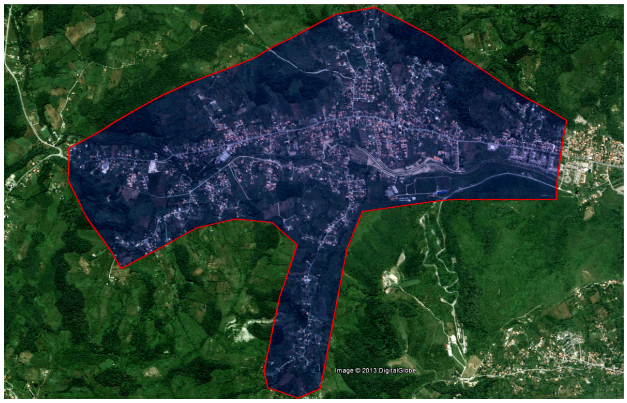
Na području sa relativno velikom dužinom parice za ADSL2+ (*Asymmetric Digital Subscriber Line 2+*) (iznad 1200 m) [1] telekom operater ima problem realizacije kvalitetne širokopojasne usluge, posebno *triple – play*. Iz tog razloga postoji velik broj smetnji kod postojećih i odbijenih zahtjeva potencijalnih korisnika zbog nepostojanja tehničke mogućnosti, problem koji operater treba riješiti.

Kao primjer ovakvog područja usvaja se naselje u Tuzli sa obuhvatom datim na sl. 1. Širokopojasna usluga realizuje se ADSL2+ tehnologijom [2] DSLAM (*Digital Subscriber Line Access Multiplexer*) uređajem po bakarnoj pristupnoj mreži.

Dati obuhvat ima površinu 3,3 km^2, a ima oko 950 domaćinstava. Gustina naseljenosti je oko 280 domaćinstava po km^2 i zaključuje se da je područje gusto naseljeno. Sa više od 70% domaćinstava u individualnim stambenim objektima, zaključuje se da je dominantni tip stambenih objekata individualni. Kablovski pravac je velike dužine. Za odabir tehničkog rješenja potrebno je izvršiti obilazak terena i ispitivanje pristupne mreže.

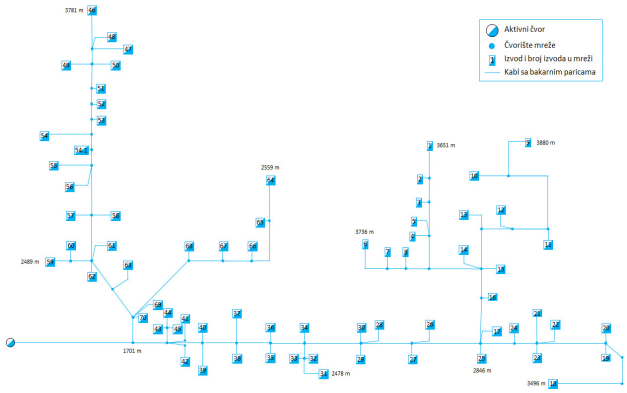
Obilaskom terena utvrđen je položaj bakarnog kablovskog pravca uz koji je postavljen i optički spojni put za spajanje pristupne aktivne opreme na distribuiranu *backbone* mrežu.

Primarni i sekundarni dio pristupne mreže sastoji se od bakarnog kabla za zahtjevne terenske uvjete. Često se za xDSL (*x Digital Subscriber Line*) usluge koristi kabl tipa TK59 GM [3]. Primjer topologije pristupne mreže dat je na sl. 2.



Slika 1. Primjer obuhvata područja sa dominantno individualnim stambenim objektima[1]

[1] Izvor: Google Earth satelitska fotografija



Slika 2. Primjer topologije pristupne mreže

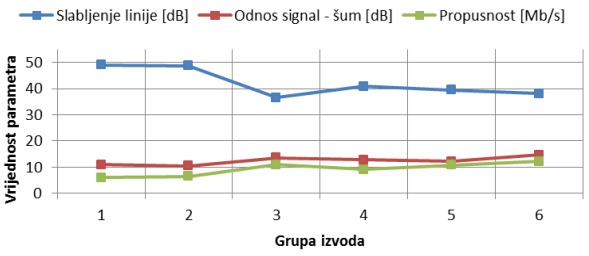
Primjer topologije pristupne mreže sadrži bakarne segmente, aktivni čvor i korisničke izvode. Mreža je podijeljena u dva segmenta približne dužine. Aktivni čvor se nalazi na početku kablovskog pravca sa dužinama parica iznad preporučenih za ADSL2+ tehnologiju [1].

Putem nadzornog sistema za DSLAM izmjereni su odabrani xDSL parametri na korisničkim portovima i izračunata je njihova prosječna vrijednost po izvodu [1]. Rezultati mjerenja prikazani su u tabeli 1. Grafički prikaz rezultata mjerenja dat je na sl. 3.

Kao što je i očekivano, najudaljeniji izvodi imaju najveće slabljenje, najmanji odnos signal – šum za datu uslugu, kao i najmanju propusnost na liniji [4]. Vrijednosti mjerenih parametara relativno su loše zbog velike dužine parica. Najveća propusnost je 12,3 Mbit/s i nije dovoljna za buduće širokopojasne usluge.[2]

TABELA 1. PROSJEK MJERENJA XDSL PARAMETARA NA BAKARNIM PARICAMA NA GRUPAMA IZVODA SMJEŠTENIM U DATOM OBUHVATU

Grupa izvoda	**Mjereni xDSL parametri**		
	Odnos signal – šum [dB]	***Slabljenje linije [dB]***	***Bitska propusnost linije [Mbit/s]***
1	11,05	49,07	6,02
2	10,56	48,78	6,53
3	13,56	36,49	11,03
4	12,80	40,81	9,15
5	12,21	39,52	10,78
6	14,75	38,06	12,29



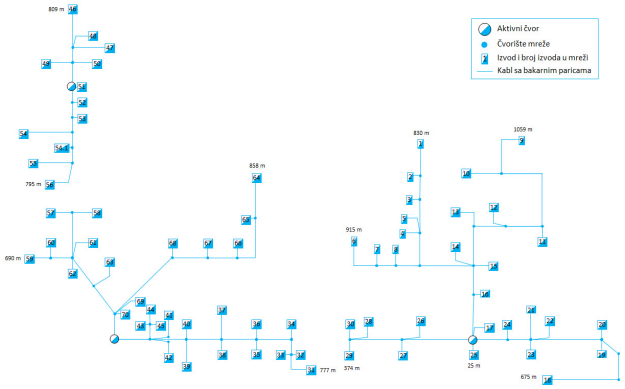
Slika 3. Grafički prikaz rezultata mjerenja xDSL parametara

[2] HD IPTV (*High Definition Internet Protocol TeleVision*) 8 Mbit/s, brzi Internet pristup 10 Mbit/s

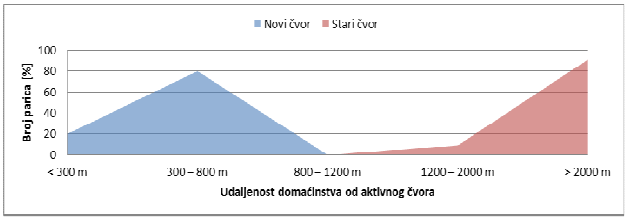
III. TEHNIČKO RJEŠENJE

Područje je gusto naseljeno domaćinstvima koja širokopojasnu uslugu ostvaruju preko parice relativno velike dužine. Ovakvo područje sa otprilike 1000 domaćinstava telekom operateru predstavlja značajnu bazu korisnika. Preporučeno je FTTC (*Fiber To The Cabinet*) rješenje sa 3 DSLAM aktivna čvora.

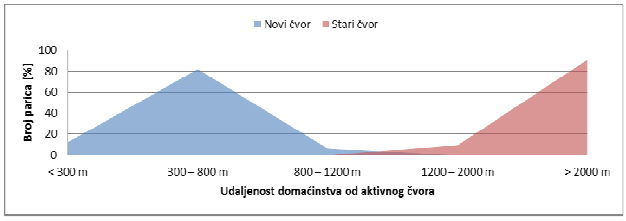
Nova topologija pristupne mreže prikazana je na sl. 4. Većina domaćinstava ima paricu kraću od 800 m. Najveća dužina parice iznosi 1059 m, pa su ostvarive brzine najmanje 30 Mbit/s za VDSL2 (*Very-high-bit-rate Digital Subscriber Line 2*) [4]. Na sl. 5, sl. 6. i sl. 7. grafički su prikazani efekti skraćenja parice izraženi u procentima broja parica u datom opsegu.



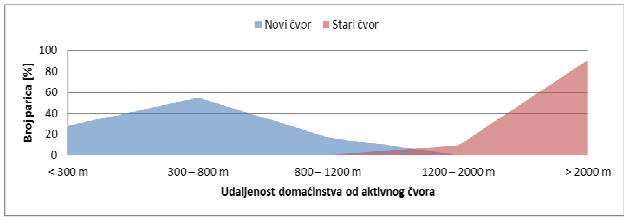
Slika 4. Nova topologija pristupne mreže



Slika 5. Efekti skraćenja parice za 1. aktivni čvor



Slika 6. Efekti skraćenja parice za 2. aktivni čvor



Slika 7. Efekti skraćenja parice za 3. aktivni čvor

Tabela 2 prikazuje prednosti i mane odabranog tehničkog rješenja.

TABELA 2. PREDNOSTI I MANE ODABRANOG FTTC TEHNIČKOG RJEŠENJA

Prednosti	Mane
Omogućena kvalitetna širokopojasna usluga cijeloj pristupnoj mreži	Udaljenija domaćinstva imaju relativno male pristupne brzine za VDSL2 tehnologiju [4]
Sa vektoriziranim VDSL2 moguće 100 Mbit/s do 400 m [4]	
Iskorišten postojeći bakarni kabl	
Uklonjene stalne smetnje na kablu	
Minimalna ulaganja	
Dokazano rješenje u praksi	

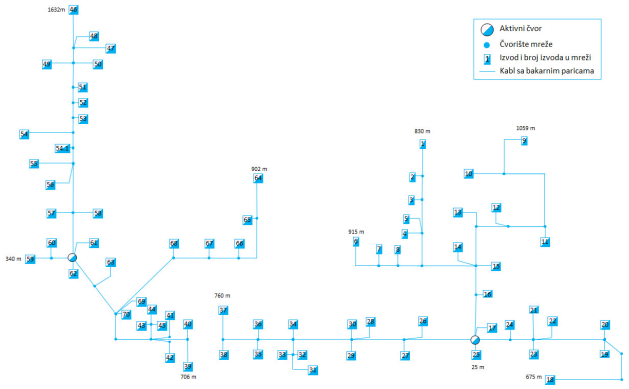
Na analiziranoj mreži do sada nije bilo tehničke mogućnosti za kvalitetnu širokopojasnu uslugu uglavnom zbog velike dužine parica. Postojeći korisnici osjetit će poboljšanje kvalitete usluge, imati veće pristupne brzine na parici, a osjetit će se i znatan porast broja korisnika širokopojasne usluge. Također će se datim tehničkim rješenjem trajno ukloniti smetnje uzrokovane velikim slabljenjem i malim odnosom signal – šum na paricama.

Implementacijom preporučenog rješenja očekuje se povećanje odnosa signal – šum iznad 20 dB za postojeće usluge, čime je moguće korištenje i zahtjevnijih širokopojasnih usluga. Očekivana slabljenja na liniji su ispod 20 dB. Najveće ostvarive pristupne brzine na parici ovisno od udaljenosti domaćinstva približit će se praktičnoj granici za ADSL2+ od 25 Mbit/s [5], a domaćinstva udaljena do 300 m od aktivnog čvora imat će pristupne brzine do 150 Mbit/s sa vektoriziranim VDSL2 [4]. Zbog gustine naseljenosti preporučuje se postavljanje više aktivnih čvorova, jer velik broj domaćinstava dobija kvalitetniju uslugu. Ne očekuje se dalja pojava smetnji uzrokovanih dužinom parice, a povećanjem zadovoljstva korisnika raste i prihod telekom operateru.

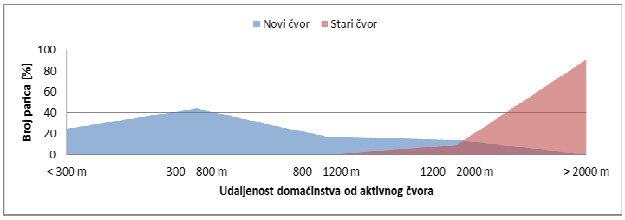
IV. ALTERNATIVNO RJEŠENJE

Za razliku od preporučenog, alternativno rješenje je FTTC sa 2 DSLAM aktivna čvora. Operater bira nove 2 lokacije za aktivne čvorove kako bi prosječne dužine parica bile što kraće. Na sl. 8 prikazana je nova topologija pristupne mreže, a na sl. 9 i sl. 10 prikazani su efekti skraćenja parice.

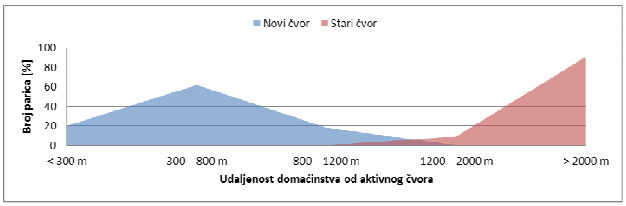
Ako se posmatraju obuhvati aktivnih čvorova, najveća dužina parice prije skraćenja iznosi oko 3800 i 3700 m, a nakon skraćenja iznosi oko 1600 i 1000 m, respektivno.



Slika 8. Nova topologija pristupne mreže – alternativno rješenje



Slika 9. Efekti skraćenja parice za 1. aktivni čvor – alternativno rješenje



Slika 10. Efekti skraćenja parice za 2. aktivni čvor – alternativno rješenje

Sa 2 aktivna čvora 75% parica u pristupnoj mreži kraće je od 800 m na kojim operater osigurava kvalitetnu širokopojasnu uslugu sa VDSL2 brzinama (najmanje 40 Mbit/s) [4]. Ostatak parica, njih 25%, duže je od 800 m, a pripada relativno malom broju domaćinstava koja će imati pristupne brzine ispod 40 Mbit/s.

Područje predmetne pristupne mreže gusto je naseljeno, gdje su bolji tehnički i ekonomski efekti postavljanja dodatnih aktivnih čvorova. Riječ je o individualnim stambenim objektima i pristupnoj mreži koju operater iskorištava FTTC rješenjem. Smanjenjem broja aktivnih čvorova u odnosu na preporučeno rješenje povećava se prosječna dužina parice, čime domaćinstva imaju lošiju tehničku mogućnost za širokopojasne usluge, a operater manja početna ulaganja. Domaćinstva imaju manje pristupne brzine u odnosu na preporučeno rješenje. Potrebno je iskoristiti potencijal ovog područja, a alternativnim rješenjem operater ne može osigurati kvalitetnu širokopojasnu uslugu, čime se ono odbacuje. Time je FTTC sa 3 DSLAM – a preporučeno rješenje.

V. ZAKLJUČAK

U gusto naseljenom području sa dominantno individualnim stambenim objektima, karakterističnim za ruralne sredine i prigradska naselja, preporučuje se FTTC rješenje za realizaciju širokopojasnog pristupa. Zbog gustine naseljenosti postavljanjem više FTTC aktivnih čvorova ostvaruje se veći potencijal korištenja zahtjevnih širokopojasnih usluga. Uglavnom se koristi postojeća bakarna pristupna mreža i za operatera sa ekonomskog gledišta predstavlja bolje rješenje u odnosu na FTTB (*Fiber To The Building*) rješenje. Ovakav tip naselja ne iskorištava puni potencijal FTTB rješenja, a FTTC rješenjem moguće je realizirati gotovo sve zahtjeve domaćinstava, jer date dužine bakarne parice omogućuju najmanje 30 Mbit/s sa VDSL2 tehnologijom [4]. U određenim slučajevima operater treba naći novo tehničko rješenje za postojeće usluge koje koriste analiziranu infrastrukturu. Iz ovog razloga bitno je vršiti najmanje moguće izmjene postojećeg stanja, a ostvariti što veće ekonomske efekte i postaviti temelje prelaska domaćinstava na FTTH rješenje u budućnosti.

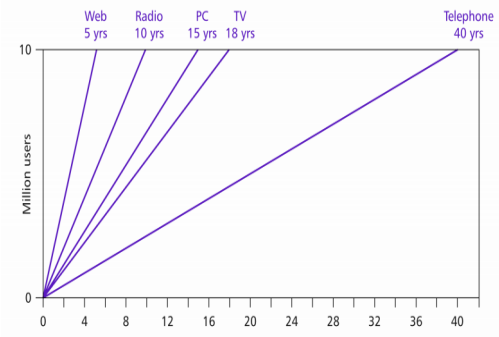
Sažetak - Danas tehnologija upravlja cjelokupnim ljudskim životom i radom. Klijenti žele pristup proizvodima i uslugama u bilo koje doba dana. Ulaganje u tehnologiju je neminovno kako bi se našao način za stvaranje novih poslovnih mogućnosti, bržem osvajanju novog tržišta. Internet danas određuje poslovnu strategiju u najvećim svjetskim kompanijama, ali i u onim malim koje su svjesne njegove prednosti, a sve to ima za cilj održivost u biznisu.
Nepostojanje razvijenog sustava za elektroničku razmjenu podataka, poslovnih informacija i transakcija predstavlja glavnu prepreku za poboljšanje poslovanja. Nužno je ulaganje u IT infrastrukturu za E-nabavu koja će pokriti sve faze procesa nabave. Uvođenjem sistema E-nabave znatno bi se uštedjelo vrijeme i novac kroz smanjenje troškova unutrašnje administracije upravljanjem postupkom kupovine putem Interneta.
Prednosti ovog pristupa su ušteda financijskih sredstava zbog pristupa velikom broju dobavljača koji se natječu za posao, te ušteda vremena u procesu nabave. Nedostatak ovog pristupa je rizik koji je sastavni dio poslovanja s nepoznatim dobavljačima, možda čak i inozemnim, pokretanje pitanja o pravnom statusu, troškovi dostave, itd.

Cilj rada je dokazati da E-poslovanje može poduzeću pružiti osjetnu prednost među konkurencijom. Pristupom E-poslovanju učvrstio bi se položaj poduzeća na tržištu, ostvarile bi se nove poslovne mogućnosti i poboljšala stopa dobiti.

I. UVOD

Elektronsko poslovanje se mijenjalo kao što se mijenjao i Internet. Kompanije su na početku Internet koristile isključivo za svoje predstavljanje, ali to danas više nije dovoljno. Nakon faze predstavljanja, počelo se razmišljati o ponudi roba i usluga, te su počele i prve narudžbe putem e-maila ili elektronskih formulara, a na kraju su se razvili B2C (*business to consumer*) i B2B (*business to business*).



Slika 1. Vrijeme potrebno različitim tehnologijama da dostignu milijun korisnika [1]

Posljednjih godina u svijetu se sve više razvijaju elektronske tržnice (*e-marketplace*) koje postavljaju nove smjernice u elektronskom poslovanju, slika 1 [1]. Elektronske tržnice omogućavaju poslovanje između kompanija virtualnom tržnicom gdje kupci, dobavljači, distributeri i prodavači pronalaze i izmjenjuju informacije o dobrima i uslugama u realnom vremenu. Prednosti E-tržnice su u pružanju bolje transparentnosti tržištu pri čemu daju uvid u dostupnost, cijenu, dostavu i uvjete plaćanja proizvoda, te pojednostavljuju način poslovanja na lokalnom, regionalnom, nacionalnom i globalnom tržištu. Kompanije sve više svoje poslovanja sele u sferu virtualnog, a tu uveliko pomažu B2B centri koji danas u svijetu okupljaju hiljade tvrtki i nude kompleksan skup usluga - posredovanje prilikom kupovine i prodaje, iznajmljivanje aplikacija, održavanje aukcija, planiranje i izvršavanje marketinških akcija, sve do prodaje informacija o konkretnoj privrednoj grani. Upravo zbog relativno velike vrijednosti pojedine narudžbine, kao i zbog mogućnosti jednostavnog spajanja kupaca i prodavca (stvaranje tržišta), B2B centri su nosioci rasta cjelokupne B2B ekonomije. Prvi oblici elektronskog poslovanja datiraju od početka sedamdesetih, kada su banke uspostavile sustave elektronskog prijenosa gotovine, dok je primjena u poslovanju i državnoj upravi počela nekoliko godina

kasnije uvođenjem sustava elektronske razmjene podataka (*Electronic Data Interchange* – EDI) bazirane na EDI normama.

II. ELEKTRONSKA DISTRIBUCIJA PODATAKA - EDI

EDI je razmjena poslovnih ili administrativnih poruka (narudžbina, faktura, obavještenja o plaćanju, stanju zalihe), između računala dva ili više poslovnih partnera uz primjenu dogovorenih normi za strukturiranje transakcija ili podataka. Analitičari ocjenjuju da trenutna vrijednost poslovanja preko mreže uporabom EDI iznosi preko 150 milijardi USD [2]. Također, očekuje se da će se ta brojka u sljedeće tri godine udvostručiti. Razlozi primjene EDI-ja su višestruki: direktna razmjena informacija, brža komunikacija, nema potrebe ponovljenog unosa podataka na strani primaoca, manje grešaka, niži troškovi. Korisnici EDI-ja su izračunali da se troškovi pripreme i izrade poslovne dokumentacije u odnosu na klasičan način smanjuju do 3% vrijednost robe u domaćem, a do čak 10% u međunarodnim okvirima. EDI tehnologiju koristi mali broj uglavnom velikih poduzeća i institucija zbog visokih troškova uvođenja (nabava podatkovno – telekomunikacijske opreme, prihvaćanje tehničkih normi, povezivanje računala između poslovnih partnera, obrazovanje korisnika i drugo). Budući da pojedine zemlje, ali ni međunarodno pravo, nisu regulirali takav način poslovanja, poslovni partneri, da bi osigurali obavezujuću snagu poslova zaključenih putem računala, sklapaju interne sporazume o upotrebi EDI-ja u međusobnom poslovanju (*Electronic Data Interchange Agreement*). EDI je zatvorena mreža, komunikacija se odvija između poznatih poslovnih partnera, pa su problemi sigurnosti manje izraženi. Masovnom primjenom Interneta, omogućena je jednostavnija i jeftinija komunikacija između poslovnih partnera, pa tako i male i srednje firme mogu koristiti prednosti elektronskog poslovanja.
Razlozi za primjenu elektronskog poslovanja su:

- niži troškovi poslovanja u području,
- nabavka roba i usluga,
- skladištenje robe,
- marketing,
- bolje usluživanje kupaca,
- prilagođavanje zemlje promjenama u svijetu što je uvjet poslovanja s inostranstvom.

III. POČETAK PRIMJENE INTERNETA U POSLOVANJU

Dolaskom Interneta elektronsko poslovanje je postalo dostupno i najmanjim domaćim firmama, što je dovelo do pravog procvata i eksponencijalnog rasta elektronskog poslovanja. Firme svih veličina sada mogu elektronskim putem komunicirati, i to preko javne mreže (Internet), preko mreža namijenjenih samo kompanijama (Intranet), tj. mreža namijenjenih kompanijama i njihovim poslovnim partnerima (Ekstranet) i preko privatnih mreža. Najvažnija područja elektronskog poslovanja su: poslovanje između kompanija (*business to business*) i firme i krajnjih kupaca (*business to consumer*). Najveći udio poslovanja između kompanija i kupaca zauzima *on-line* kupovina potaknuta stalnim rastom broja korisnika.
Elektronsko poslovanje je na Internetu do sada prošlo nekoliko faza:

- predstavljanje poduzeća na mreži,
- prikaz kataloga robe i usluga,
- prikupljanje zahtjeva kupaca,
- preuzimanje porudžbina,
- prodaja robe stanovništvu, pojedincima (B2C),
- poslovanje između firmi (B2B).

Elektronska trgovina omogućava ljudima *on-line* nabavku proizvoda i razmjenu informacija o poslovnim transakcijama. Iako je primjena Interneta kao platforme za poslovne transakcije relativno nova, Internet je svakako ostvario najzapaženiji uspjeh u odnosu na druge platforme za poslovanje prisutne u posljednjih nekoliko decenija. Elektronska trgovina omogućava kompanijama povećanu efikasnost i pouzdanost poslovnih procesa kroz automatizirane transakcije.
Jedna vrsta gotove poslovne aplikativne programske podrške jesu ERP rješenja. Proizvođači modernih ERP rješenja su uočili postojanje poslovnih funkcijskih područja koja su zajednička nekoj skupini poslovnih djelatnosti (npr. proizvodnja, uslužne djelatnosti, financijski sektor, javni sektor itd.), te su tako dobivena opća poslovna aplikativna programska rješenja primjenjiva u različitim poslovnim djelatnostima (opće ERP rješenje). No, poslovne djelatnosti, bez obzira da li pripadaju istoj ili različitim skupinama, imaju i neka specifična područja koja u općem ERP rješenju nisu podržana (tada se govori o vertikalizaciji ERP rješenja). Vertikalizacija ERP rješenja se može definirati kao postupak proširenja, dorade ili prilagodbe općeg ERP rješenja specifičnostima neke poslovne djelatnosti. Rezultat tog postupka je specijalizirano ERP rješenje koje podržava poslovne procese konkretne poslovne djelatnosti.

IV. STRATEGIJA E-POSLOVANJA

Strategija predstavlja skup aktivnosti koje upućuju kako ostvariti najočitije ciljeve poduzeća. U globalnim relacijama figuriraju se neki pojmovi koje je potrebno opisati i definirati:

A. Misija poduzeće

Predstavlja poseban, autonomni segment u okviru sustava strategijskih ciljeva poduzeća. Misija je najočitiji strategijski cilj koji prožima sve aktivnosti poduzeća na svim nivoima poslovanja. Misija nema naglašenu operativnu funkciju već određuje globalno usmjerenje i

daje odgovor o svrsi postojanja ili se ponekad naziva i vrhovnom strategijom .

B. Kredo (slogan)

Misija može biti eksplicitno izražena pomoću slogana koji osigurava prepoznatljivost poduzeća i njegovih proizvoda u okruženju. Na osnovu ispitivanja 269 japanskih poduzeća slogane su najčešće činili sljedeći pojmovi:

- dobar proizvod, razumna cijena,
- prosperitet, stalni napredak,
- razvijanje povjerenja s*takeholdera*,
- blagostanje zaposlenih.

C. Korporativna strategija

Odnosi se na cjelokupnu svrhu i obim poslovanja korporacije.

D. Strategija poslovne jedinica

Poslovna jedinica kao dio većeg sustava mora imati svoju strategiju koja daje odgovore kako se uspješno takmičiti na određenom tržištu.
Ostaje pitanje gdje je mjesto i koliki je značaj strategije elektronskog poslovanja. Postojala su gledišta da je strategija elektronskog poslovanja jedna vrsta funkcionalne strategije ili da je ona dio strategije podatkovnih sustava. Uspjeh Internet kompanija doprinijelo je da se strategija elektronskog poslovanja sve više može smatrati dijelom korporativne strategije.

V. E-POSLOVANJE U FUNKCIJI E-NABAVE

Uspješnost poslovanja i sposobnost stvaranja vrijednost u tvrtkama usko su povezani s razvojem naprednih informacijskih sustava. Osobna računala, Internet i mobilna telefonija iz temelja su promijenili životna kretanja, uključujući i način rada, obrazovanje i sve oblike interakcije. Temeljna strategija suvremenog uspješnog poslovanja je E-poslovanje (*E-business*), a unutar E-poslovanja tehnologije se nalazi E-nabava. Razmjena ideja, vizija, znanja i iskustava nikada nije bila jednostavnija, brža i jeftinija. Prednosti koje svakoj organizaciji donosi međusobno povezivanje računalne opreme čini informatičke prometnice nezamjenjivim dijelom poslovne infrastrukture. Približavanje biznisa i tehnologije uspješno je u uvjetima kada je tehnologija shvaćena kao pogonsko gorivo, a tržište kao vodilja biznisa. Tehnologija pomaže u promjeni društva. Pametna informatička mreža je funkcionalna tehnologija u službi unapređenja poslovanja, drugim riječima, inteligentna mreža je sjedište sustava koji unapređuje poslovanje. Internetska tehnologija današnjice jedno je od najmoćnijih čovjekovih dostignuća. Primjena Interneta kao poslovnog rješenja u kompanijama dovodi do toga da se one odvajaju od konkurencije i postaju vodeće na tržištu. Izazovi za implementaciju E-nabava poslovnih rješenja su:

- osigurati održivi dramatični rast poslovanja,
- osigurati visokokvalitetnu podršku korisniku,
- stvoriti i zadržati vodeću poziciju u industriji i na tržištu.

E-nabava je B2B (*business to business*) sustav izvršavanja svih elemenata poslovnih aktivnosti ekonomskog procesa elektroničkim putem. U E-nabavi dvije ili više registriranih kompanija komuniciraju web servisima kako bi se naručio proizvod bez nepotrebnih odlazaka u zastupništva kompanija, već naručivanjem preko weba. E-nabava je poslovna transformacija temeljena na:

- Udruživanju poduzeća (integracija),
- Procesu suradnje (kolaboracija),
- Globalnom mrežnom povezivanju,
- Upotrebi Interneta kao medija.

Internetsko i elektroničko poslovanje preko E-nabava sustava omogućuje:

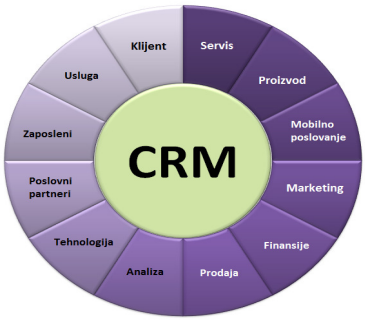
- Povezivanje dobavljača,
- Brzu, trenutnu razmjenu informacija,
- Značajno snižavanje troškova, a time i cijena.

VI. PRENOSTI I NEDOSTACI E-NABAVE

Prednost E-nabave je u tome što ono može poboljšanim marketingom povećati prodaju, kao i veličinu prodajnog programa, te smanjiti troškove vezane za upite kupca. E-poslovanje proširuje tržište poslovanja i time povećava različite mogućnosti kupovine. Kupcima su informacije o proizvodima i uslugama dostupnije, imaju veći izbor proizvoda po nižim cijenama, a kupovina im postaje praktičnija i prilagodljivija zbog dužeg radnog vremena, tj. dostupnosti proizvoda 24 sata dnevno, sedam dana u tjednu. E-nabavom smanjuju se transakcijski troškovi kojima su izloženi i kupci i proizvođači. Ono smanjuje transakcijske troškove tako da poboljšava tok informacija i poboljšava koordinaciju aktivnosti. Jednom kad je prednost E-nabave prepoznata, unutar pojedine kompanije, najvažnije što menadžeri i tehničko osoblje trebaju razmotriti jest infrastruktura internetski zasnovanog poslovanja, od pojedinačnog internetskog poslužitelja što je povoljno za manju kompaniju, pa sve do sustava informacijski intenzivne *on-line* obrade transakcija kakve grade velike zrakoplovne kompanije i turističke agencije. Nedostaci E–poslovanja i E-nabave se kriju u prebrzom mijenjanju tehnologije i međunarodnim kulturološkim i zakonskim poteškoćama. Također, neki proizvodi nisu prikladni za ovaj vid prodaje (lako kvarljivi proizvodi). E-nabava je vizija uspješnog poslovanja budućnosti. Poslovanja u kojem dominira suvremena tehnologija povezana s poslovnom strategijom kompanije koja ju implementira. Smatram da je E-nabava esencijalno za kompaniju koja želi svoje proizvode prodavati diljem svijeta i tako proširiti granice svog poslovanja bez nepotrebnih troškova.

VII. CRM

Razvoj informatičkog društva, koje se bazira na povećanju pristupačnosti znanju, informacijama i servisima putem različitih mreža i konvergenciji različitih medija, uzrokuje značajne promjene u poslovanju. Informatička i komunikativna infrastruktura ima poseban značaj za unapređenje poslovanja, jer omogućava pristup udaljenim tržištima, veliko povećanje brzine poslovnih transakcija, značajno smanjenje troškova poslovanja, kontakt s korisnicima i personalizaciju usluga. Tehnologija, informacije i znanje postali su odlučujući faktori za konkurentnost kompanija u svim sektorima poslovanja.



Slika 2. Model CRM [6]

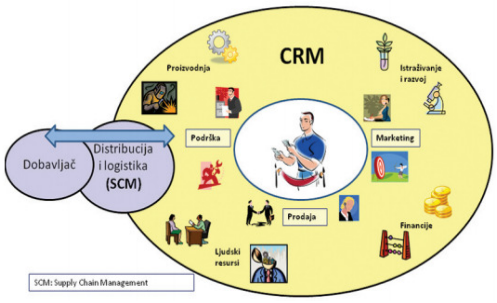
Elektronsko poslovanje omogućava povećanje efikasnosti rada kompanija, a samim tim povećava njihovu konkurentnost na tržištu. Elektronsko poslovanje također omogućava i stvaranje novih kompanija utemeljenih na suvremenoj podatkovnoj i komunikativnoj tehnologiji. Za razvoj elektronskog poslovanja potrebno je stvoriti podatkovnu i komunikativnu infrastrukturu kao i zakonske pretpostavke za elektronsko poslovanje.

Tijekom proteklog perioda, upravljanje odnosima s korisnicima (*Customer Relationship Management*) je postao jedina popularna inicijativa i visoko rangiran u procesu konzultiranja kompanija. Utvrđeno je da tri četvrtine kompanija koriste usluge CRM, odnosno uvode ili planiraju CRM rješenja. Usprkos svojoj popularnosti CRM i dalje ostaje enigma za mnoge kompanije. To je uglavnom zato što mnogi direktori kompanija, menadžeri, dobavljači software-a, industrijski analitičari i konzultanti za menadžment imaju mnoštvo pogleda na CRM, svaki oblikovan prema njihovim specifičnim stanovištima, situacijama, iskustvima i naravno, motivima. U skladu s tim, o CRM-u se može razmišljati, diskutirati, i prihvatiti ga, na tri različita nivoa: tehničkom, funkcionalnom i filozofskom.

CRM sve više stavlja na prvo mjesto analizu korisnika, a onda razrađuje neophodne funkcije u smislu podrške, bez obzira o kojem se poslovnom nivou radi. Iako je ovaj pristup bolji od onog tehnološki usmjerenog, ovaj funkcionalni pogled ne može da obuhvati suštinu CRM- a u potpunosti.

Danas je CRM uglavnom prihvaćen kao poslovna filozofija koja promatra osnovnu suštinu korisnika, ili preciznije podatke o njemu. Ona predstavlja fundamentalni preokret u načinu na koji kompanije obavljaju posao. Preokret u perspektivi je zabilježen i na globalnom planu poslovanja - prelazak s usmjerenja ka proizvodu na usmjerenje ka korisniku.

Mnoge konzultantske kompanije i industrijski analitičari zalažu se za ovu filozofsku perspektivu CRM-a. Oni reorganiziraju organizacije kako bi se ostvarila dugoročna vrijednost CRM-a da se prihvati strategija koja se odnosi na poslovanje u cjelini, a teže da se organizacija okrene pristupu na nivou kompanije. U stvari, Gartner je definirao pravi CRM kao: „ *Poslovnu strategiju koja maksimalizuje profitabilnost, zaradu i zadovoljstvo korisnika tako što se organizira oko korisničkih segmenata, njeguje ponašanje koje zadovoljava korisnika i sprovodi procese usmjerene ka korisniku.*“



Slika 3. Kupac u ishodištu svih poslovnih procesa [5]

CRM i njegova primjena, ako se gleda sa filozofskog stajališta u biti je primjenjiv i u sferi nabave, nekako bi se moglo reći po principu povratne sprege. Ovaj put kupac primjenjuje skoro isti algoritam na kategoriju dobavljača, stvarajući sebi povoljnije inpute i uvećavajući svoju konkurentnost.

VIII. CRM PROCESI U POSLOVNOM OKVIRU IT KOMPANIJE

Važan aspekt CRM-a je njegova orijentacija na korisničke procese (ili životne cikluse korisnika). Korisnički proces je niz aktivnosti koje korisnik mora da obavi da bi zadovoljio potrebu ili riješio specifičan problem. Zato, korisnički proces odlučuje koji su to potrebni proizvodi i usluge koje kompanija mora da ponudi da bi potpuno pokrila korisnički proces. Zato što najveći broj kompanija ne može potpuno da pokrije korisnički proces, ili ne želi da ga pokrije zbog fokusa na neke suštinske kompetencije, neophodna je suradnja s ostalim kompanijama koje nude komplementarne proizvode i usluge. Među njima razlikuju se tri kategorije CRM procesa:

- ***CRM procesi isporuke***: Procesi direktnog kontakta s korisnicima koji su osmišljeni tako da pokrivaju dio korisničkog procesa (upravljanje kampanjom, upravljanje prodajom, upravljanje uslugom, kontrola žalbe),

- ***CRM procesi podrške:*** Procesi direktnog kontakta s korisnicima koji nisu osmišljeni da pokriju dio korisničkog procesa, već da ispune funkcije podrške u okviru CRM konteksta. (istraživanje tržišta, kontrola lojalnosti),

- ***CRM procesi analize*****:** Procesi koji konsoliduju i analiziraju saznanja o korisnicima koja su sakupljena u okviru drugih CRM procesa.

Rezultati analize se prebacuju na CRM procese isporuke i podrške, ali se koriste i za inovaciju usluge i procese unapređenja usluge zbog efektivnosti (uvećanje broja korisnika, smjernice, profiliranje i segmentacija korisnika, povratna sprega (*feedback*) i upravljanje znanjem).

IX. ODLIKE CRM-A U IT SEKTORU

CRM predstavlja složeni skup poslovnih procesa i tehnologija za upravljanje relacijama s postojećim i potencijalnim korisnicima i poslovnim partnerima, u marketingu, prodaji i podršci, preko svih raspoloživih kanala komunikacije. Osnovni cilj CRM-a je da optimizira zahtjeve korisnika i partnera, uveća učešće na tržištu, profit i poslovnu efikasnost, gradeći što je moguće snažnije relacije na nivou organizacije.
Informatički sektor je primjenom suvremenih tehnologija stvorio novi vid poslovanja. Kompanije su stvorile poslovni model koji se sastoji od:

- načina segmentiranja i izbora korisnika,
- diferenciranja svojih ponuda,
- oblikovanja svojih resursa,
- nastupanja na tržištu i
- stvaranja vrijednosti baziranih na strateškom razumijevanju prioriteta i sklonosti korisnika.

Stvoren je strateški koncept koji omogućava top menadžmentu razumijevanje i predviđanje vrijednosti poslovanja. Prednost je razumijevanje potreba korisnika i stvaranje inovativnog poslovnog modela koji je u stanju da zadovolji te potrebe - CRM.

Korištenje prednosti CRM sustava uvjetovano je:

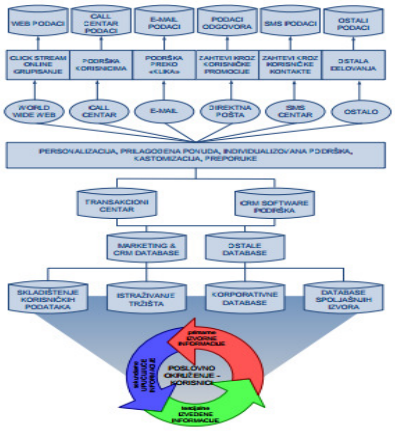
- prikupljanjem i skladištenjem podataka iz kompanije,
- analizom prikupljenih podataka i pronalaženjem pravila ponašanja korisnika,
- uspostavljanjem kontakt centara (telefon, fax, E-mail, SMS, MMS, chat, itd.) između kompanije i korisnika.

Upravljanje odnosa s korisnicima baziran na principima primjene CRM-a nalazi primjenu u mnogim kompanijama. Kompanije koje generiraju ili primaju mnoštvo podataka sigurno su one u kojima se CRM može iskazati na pravi način. Potrebno je prikupiti, skladištiti, analizirati i generirati informacije potrebne za usavršavanje proizvoda/usluga koje se pružaju korisnicima. Principi CRM-a u oblasti elektronskog poslovanja daju veliki efekt jer se svaka konekcija/transakcija odvija preko Interneta i ostavlja određene podatke koji imaju šansu da se pretvore u informaciju. Podatak postaje informacija samo ako u sebi sadrži upotrebljivost.

X. OPERATIVNI MODEL CRM STRATEGIJE

CRM sustavi se mogu klasifikovati u sljedeće tri kategorije:

- Operativni CRM sustavi unapređuju efikasnost CRM procesa isporuke i podrške. Oni obuhvaćaju solucije za marketing, prodaju i automatizaciju usluge, na primjer: sustavi i za upravljanje kampanjom i sustavi za interaktivne centre za korisnike.
- Analitički CRM sustavi skladište i vrednuju znanje o korisnicima zbog boljeg razumijevanja svakog korisnika i njegovog ponašanja. Stoga, oni pružaju podršku CRM analizi. Primjeri su skladištenje podataka, analitičko *on-line* procesuiranje (*OLAP*) i sustavi za „ rudarenje“ podataka.
- Kolaborativni (*collaborative*) CRM sustavi kontroliraju i sinhronizuju točke korisničke interakcije i kanala komunikacije. CRM sustavi suštinski procesuiraju dobro strukturirane informacije, na primjer podatke o kontaktima s korisnicima i master podatke. Suprotno tome, sustavi za upravljanje znanjem pružaju podršku zbirci manje strukturiranih informacija, razmjeni i primjeni kao što su dokumenti (eksplicitno znanje) i implicitno znanje zaposlenih. Ovo znanje je posebno neophodno u okviru CRM procesa isporuke radi zadovoljenja potreba korisnika. Na primjer, upravljanje prodajom zahtjeva detaljno znanje o dostupnim proizvodima da bi konsultovanje o ponudi prema korisnicima bila efektnija u odnosu na njihove potrebe.



Slika 4. Operativni model CRM strategije [10]

XI. ZAKLJUČAK

Zahvaljujući E-poslovanju mijenjaju se poslovni modeli, tradicionalni odnos kupac-prodavač se polako napušta, te kupci polako počinju sudjelovati u kreiranju novih roba i usluga, odnosno, počinje se koristiti interaktivnost u poslovanju. Zahvaljujući Internetu, danas se sve više i više koristi *on-line* kupovina, tako tvrtke moraju biti u korak s vremenom i pokušati naći rješenja kako zadržati kupca i kako mu omogućiti poseban osjećaj kupovine.

Povećana je brzina i reakcija tvrtki na globalne promjene zahvaljujući E-poslovanju. Globalno tržište je postalo mjesto za tržišno natjecanje, a udaljenost je prestala biti presudan faktor u poslovanju. Glavne prednosti E-poslovanja su mogućnost prodaje roba i usluga, suradnja s partnerima 24 sata na dan, te se tako omogućava veća konkurentnost na tržištu.

U Bosni i Hercegovini postoje sustavi elektronskog plaćanja koji se obavljaju preko banaka. Nedovoljna informiranost u elektronske sustave plaćanja kod građana izazivaju određeno nepovjerenje i dozu straha od prevara na globalnoj mreži.

Kada je u pitanju efikasno obavljanje većine poslovnih procesa u poduzećima potrebno je da se izvrši i njihovo planiranje. Danas u svijetu velike kompanije imaju ugrađene sustave koji im omogućavaju da planiraju i organiziraju svoje poslovne procese i da na osnovu dobre baze podataka mogu donositi i dobre poslovne odluke. Osnovna karika koja osigurava ICT podršku poslovnih procesa je upravo poslovni informacioni sustav kompanije. Primjenom E-trgovine, elektronskog sustava plaćanja i planiranja poslovnih procesa može unaprijediti uvjete poslovanja kompanija u Bosni i Hercegovini.

CRM sustav pojednostavljuje zatvorenu petlju marketinga u kojoj se podaci o korisniku transformiraju u informacije korisne za sustav. Ove informacije transformiraju se u marketing strategiju i strategiju upravljanja korisnicima. CRM strategija u informatičkom sektoru je niz aktivnosti koje se obavljaju da bi kompanija potvrdila i sprovela vlastitu korisničku strategiju, fokusiranje na identifikaciju, prioritetnost i implementaciju novih biznis mogućnosti okrenutih ka korisniku i praksi koja će poboljšati operativnost i segmente profitabilnosti. Informatički sektor uz primjenu operativnog modela CRM strategije sprovodi ciljane akcije usmjerene na zadržavanje postojećih i privlačenje novih korisnika korištenjem informacija u smjeru uobličavanja proizvoda i usluga prema potrebama raznih profila korisnika s različitim ustaljenim navikama.

Uvođenjem CRM-a u IT sektor kompanije dobivaju korporativnu prednost u odnosu na svoju konkurenciju u pogledu efikasnosti kompanije s korisnicima.

e-plaćanje u uslovima ne postojanja potpunog sistemskog rješenja e-poslovanja

Zaim Buljubašić, Nermin Buljubašić, Izudinka Kapetanović-Serdarević
BH Telecom.d.d.Sarajevo,RD Tuzla

zaim.buljubasic@bhtelecom.ba
nermin.buljubasic@bhtelecom.ba
izudinka.kapetanovic@bhtelecom.ba

Sažetak: U Bosni i Hercegovini kao i većini drugih zemalja Jugoistočne Evrope ne postoji sistemski, niti pravno oubličen sistem funkcionisanja e-poslovanja, a dinamičnost savremenih tržišta i sistema poslovanja primjenu takvog koncepta apsolutno zahtijeva. Tako dio poslovnih subjekata pogotovu onih koji su izloženi jačoj konkurenciji kako na domaćem, tako i na globalnom međunarodnom tržištu su primorani tražiti neka hibridna rješenja, koja u temelju se baziraju na uvažavanju međunarodnih standarda i preporuka usvojenim od strane kompetentnih institucija iz ove oblasti.

Elektronsko plaćanje je uvedeno u više banaka u Bosni i Hercegovini, ali ne u svim i koriste ga samo pojedini poslovni subjekti. Rješenja koja se najčešće nude su vezana za elektronsko (bankarstvo) plaćanje u 10 zemalja, uštedu vremena, veću kontrolu novčanih sredstava, jer odgovorno osoblje ima pristup računu 24 sata na dan i na taj način može kontinuirano i odmah pratiti sve prilive i odlive sa računa, smanjenje troškova (papira, tonera, goriva), pregled izvoda. Benefiti koje donosi primjena ovakvog sistema plaćanja također se odnose na: veći nivo finansijske discipline, bolju komunikaciju sa poslovnim partnerima i sl.

Ključne riječi: e-poslovanje, e-plaćanje, hibridni sistemi, standardi, ICT

Uvod:

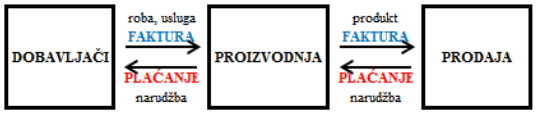
Ekonomska globalizacija sa svim svojim posljedicama, kako u organizaciji nacionalnih i internacionalnih regionalnih, svjetskih tržišta, tako i u uspostavljanju jačih, širih, i u većem broju kooperativnih proizvodnih procesa stvorila je pretpostavku primjene visokih tehnologija, kompjuterizovanih sistema proizvodnje, skraćenje životnih ciklusa proizvoda i značajnog rasta pomoćnih i uslužnih aktivnosti. Sve te promjene u ambijentu i novom načinu poslovanja zahtijevale su promjene u organizacijskoj strukturi koja je do tih vremena bila glomazno postavljena sa krutom vertikalnom hijerarhijom u menadžerskom odlučivanju.

Novi razvoj je zahtijevao fleksibilnu organizaciju sa horizontalnom strukturom odlučivanja, jer u uslovima globalne konkurencije pravovremeno se može reagirati na tržištu samo pod tim uslovima. Proizvodni sistemi koji su do tada bili pravi divovi, a nisu blagovremeno izvršili restruktuiranje svojih poslovnih procesa, vrlo brzo su počeli da na tržištu gube svoju poziciju. Restruktuiranje privrede u svim djelatnostima i na svim nivoima je nužnost, kako bi se blagovremeno moglo odgovoriti na sve prefinjenije zahtjeve potrošača. Nove informaciono komunikacijske tehnologije su sastavni dio poslovnog instrumentarija i važna osnova za kvalitetno odvijanje ovih procesa. Sa tako razvijenom organizacijom postavljenoj na znatno fleksibilnijim odnosima, uspostavljaju se odnosi kooperacije i partnerstva. Kooperacija i partnerstvo se traže i kod drugih sistema, najčešće na relaciji dobavljač-proizvođač-kupac, kako bi se na tržištu ojačale pozicije i ostvario maksimalan profit. Bez IK tehnologija to bi bilo izuzetno teško, moglo bi se reći nemoguće. Kompjuterski potpomognuta proizvodnja rezultira proizvodima različitog asortimana uz uvažavanje srodnih dizajnerskih rješenja. Vrijeme prelaska sa jednog dizajna na drugi, odnosno vrijeme podešavanja mašina je kratko i sastoji se samo od identifikacije programa.

«Svako u organizacionoj strukturi mora komunicirati i sarađivati sa svima na nivou jedne organizacione ravni, kao i između organizacionih ravni»[1]. Kooperativni odnosi se mogu razvijati između firmi iste djelatnosti ili različitih djelatnosti. Ako se govori o odnosima na relaciji proizvođač-dobavljač, onda

[1] Novičević, B.: Globalizovani poslovni ambijent i izazovi upravljačkog računovodstva, Zbornik radova, Revicon, 2003 godina, strana 29.

proizvođač zajedno sa dobavljačem želi da kreira svoje inpute u pogledu kvaliteta, mjesta i uslova nabave, cijene, vremena isporuke i sve druge značajne elemente. Takođe prodavci na tržištu najbolje znaju šta žele potrošači, pa zajedno sa proizvođačima kreiraju proizvod koji tržište prihvata.[2]



I u jednoj i u drugoj interakciji, između proizvodnje i dobavljača i proizvodnje i prodaje, javljaju se vrlo kompleksni odnosi koji svakim danom zahtijevaju saradnju i razmjenu najnovijih znanja, iskustava i informacija na velikom broju frontova. Ono što je zajedničko za obje interakcije je ispostavljanje računa (faktura) i izvršenje potrebnih plaćanja. Kako ove vrlo značajne funkcije u ukupnom sistemu poslovanja digitalizirati i po tom osnovu ostvariti konkurentske prednosti, u ovom radu će biti izvršen pokušaj davanja određenih prijedloga, pogotovu u uslovima kad koncept e-poslovanja nije sistemski zaživio. Koje su prednosti uvođenja e-računa i e-plaćanja biće prezentirano na istraživanjima u nekim kompanijama u BiH.

1.Pravni okvir za e-poslovanje, odnosno e-plaćanje

Informacione tehnologije su svojim inovacijama izvršile redefinisanje poslovnih procesa na taj način što su smanjile neefikasnost u radu unutar samih privrednih subjekata, kao i neefiksasnost u odnosima sa drugim poslovnim subjektima. U današnje vrijeme firme se suočavaju sa stalnim pritiskom da poslove obavljaju bolje, brže, jeftinije, dok održavanje visokog nivoa rezultata i dalje ostaje prioritet. U aktuelnim odnosima trgovinsko poslovnih saradnji, standardni poslovni proces je jednostavno ne adekvatan, pa je zbog toga sklapanje ugovora preko Interneta ne zaobilazan činilac za izgradnju novih i boljih poslovnih odnosa.
Međutim, ubrzan razvoj informacionih tehnologija i razvoj Interneta kao medija između subjekata u poslovnim procesima otvorio je novo pitanje kada je ugovorno poslovno pravo u pitanju. To je uslovilo donošenje Direktive od strane Evropske unije o elektronskim potpisima. Pomenuta Direktiva predstavlja pravno utemeljenje elektronskog potpisa. Na osnovu nje su donijeti zakoni o elektronskom potpisu u svim zemljama Evropske unije, kao i u većini ostalih zemalja Evrope.
Dvije najvažnije stvari koje trebaju biti istaknute u Zakonu o elektronskom potpisu su propisivanje uslova pod kojima je elektronski potpis pravno ekvivalentan svojeručnom potpisu i uslova koji moraju da ispune certifikacijska tijela koja izdaju kvalificirane certifikate za verifikaciju kvalificiranih elektronskih potpisa. Zakonom o elektronskom potpisu jasno treba biti napravljena razlika između elektronskog potpisa i kvalificiranog elektronskog potpisa što predstavlja bitno razgraničenje odlučujućih elemenata pri korišćenju ovog načina poslovne komunikacije. Ako želimo da objasnimo šta je elektronski potpis onda dolazimo do zaključka da je to skup podataka u elektronskom obliku, koji su pridruženi ili su logički povezani sa elektronskim dokumentom i oni služe za identifikaciju potpisnika, a dok je kvalificirani elektronski potpis onaj elektronski potpis kojim se pouzdano garantuje identitet potpisnika**,** integritet elektronskih dokumenata i onemogućava naknadno poricanje odgovornosti za njihov sadržaj i koji ispunjava uslove utvrđene Zakonom o elektronskom potpisu.
Tekst Zakona o elektronskom potpisu tačno navodi sve uslove koje potpis u elektronskom obliku treba da zadovolji da bi se smatrao kvalificiranim elektronskim potpisom i da bi imao isto pravno dejstvo i dokaznu snagu kao i svojeručni potpis, odnosno svojeručni potpis i pečat, u odnosu na podatke u papirnom obliku. On upućuje da je potpis povezan sa potpisnikom i da ga sa sigurnošću identifikuje.
Digitalni potpis (digital signature) je elektronska verzija potpisa, na osnovu kog se **i**dentifikuje pošiljalac i dokazuje vjerodostojnost poruke. Može se shvatiti kao način obezbjeđivanja servisa integriteta u smislu potvrde ispravnosti ili tačnosti. Baziran je na asimetričnom kriptografskom modelu ili šifrovanju sa javnim ključem**.** Osnovni dijelovi tog kriptografskog modela su šifrovanje, dešifrovanje i ključ.
Šifrovanje se sastoji od transformacije čitljivog teksta podataka u oblik nečitljiv za onoga kome taj tekst nije namijenjen, a dešifrovanje je postupak vraćanja šifrovanog teksta u čitljiv oblik. Javni ključ bi predstavljao početnu vrednost algoritma kojim se vrši šifrovanje. U ovakvom modelu šifrovanja poruke, sam postupak šifrovanja teksta može načiniti bilo ko, bitno je da tekst može pročitati ili dešifrovati jedino osoba koja ima odgovarajući privatni ključ. Jedino osoba sa privatnim ključem može digitalno potpisati neki tekst, dokument, a svako ko ima javni ključ može proveriti ispravnost potpisa. Postoji set osnovnih normativnih akata, prije svega zakona koji uređuju ovu oblast. Tako npr. R Hrvatska ima solidna

[2] Novičević, B.: Globalizovani poslovni ambijent i izazovi upravljačkog računovodstva, Zbornik radova, Revicon, 2003 godina, strana 29.

rješenja koja se očituju kroz slijedeće zakone: Zakon o elektroničkoj trgovini, Zakon o elektroničkom potpisu, Zakon o elektroničkoj ispravi, Zakon o tajnosti podataka, Zakon o informacijskoj sigurnosti, Zakon o zaštiti osobnih podataka, itd. Treba također istaći da su svi ovi zakoni u znatnoj mjeri usaglašeni sa rješenjima u EU. To je logično jer EU želi jedinstven informacijski prostor, pa se s razlogom može preporučiti i drugim zamljama koje pretenduju i streme ka članstvu u ovoj asosijaciji da blagovremeno vrše ta usaglašavanja. U čemu je onda problem? U ne dovoljnoj afirmaciji i primjeni koncepta e-poslovanja, a posebno e-plaćanja koje nudi prostor ogromnih ušteda u obavljanju ove vrlo značajne funkcije u ukupnim poslovnim procesima i propuštanju šanse ubrzavanja ovih procesa i njihove kvalitetne integracije na aplikativnom nivou sa ostalim procesima.

2. e-račun i e-nalog za plaćanje

E-fakture se iz informacionog sistema izdavaoca (ERP), putem e-banking kanala, prenose u e-banking rješenje primaoca (kupca). Primalac, bilo da je u pitanju pravno ili fizičko lice, dobija e-fakturu u svoje e-banking rješenje, što mu omogućava da samo jednim klikom prenese podatke iz e-fakture u platni nalog kojim vrši plaćanje.

Izdavalac u svom informacionom sistemu (ERP) priprema fakturu u elektronskom obliku i uvozi je u svoje e-banking rješenje. Iz e-banking programa, baš kao i platne naloge, šalje fakturu svojoj banci putem e-banking kanala.

Banka izdavaoca prima e-fakturu. Na osnovu tekućeg računa primaoca i BIC koda, koji služe kao njegova adresa, banka izdavaoca, preko e-banking kanala, šalje e-fakturu odgovarajućoj banci korisnika. Za tu svrhu nije potrebno da izdavalac i primalac imaju otvorene račune u istoj banci. Banka može, na osnovu finansijskog ugovora sa izdavaocem, zajedno sa arhivistom da proslijeđuje izdate e-fakutre u arhiv '1-2-3 U ARHIV!' .

Banka primaoca prima e-fakturu. Na osnovu tekućeg računa primaoca i BIC koda banke, banka primaoca šalje dalje fakturu u e-banking rješenje primaoca. Primalac može da sklopi sa arhivistom poslovni ugovor o elektronskom arhiviranju prenijetih e-faktura. Na taj način, slanjem e-faktura primaocu, banka istovremeno prosljeđuje fakturu i u arhivu.

Primalac prima fakture u svoje e-banking rješenje. U slučaju da su primaoci pravna lica, oni imaju mogućnost uvoza e-faktura u svoje informacione sisteme (ERP) za potrebe računovodstvenih evidencija. Osim toga, na osnovu e-fakture primaoci mogu u e-banking rješenju samo jednim klikom kreirati platni nalog sa podacima iz fakture. Platni nalog se vraća istim putem izdavaocu e-fakture, koji zajedno sa prilivom dobija ispravne i odgovarajuće podatke o uplati (referenca).

Primjer iz prakse zemlje članice EU: Jedna informatička kuća je, u saradnji sa naručiocem, razvila cjelovitu informatičku podršku za potrebe pet slovenačkih javnih preduzeća za distribuciju električne energije. Značajan dio cjelokupnog sistema je podsistem za obračun isporučene električne energije korisnicima, među kojima je 100.000 poslovnih korisnika i više od 800.000 domaćinstava. Kod tako velike količine faktura koje mjesečno šalju korisnicima veoma je značajna optimizacija postupka slanja faktura. Vlastiti sistem za pripremu, izdavanje i slanje e-faktura je veoma zahtjevna investicija. Njihov izazov bio je pronalaženje načina uvođenja što efikasnijeg sistema izdavanja faktura koji bi pojednostavio i pojeftinio proces distribucije.

Poslije razmatranja različitih mogućnosti i opcija, Informatika se odlučila za infrastrukturu e-banke sa kojom je već upoznata većina slovenačkih preduzeća. Elektronsku banku već upotrebljava oko 80% slovenačkih preduzeća, koja su ujedno i korisnici električne energije. Pored pravnih lica korisnika, elektronsku banku – u znatno manjem obimu, ali u većem broju – upotrebljavaju i domaćinstva. Postojeća sigurna i stabilna infrastruktura e-banke može da se koristi i za slanje elektronskih faktura. »Infrastruktura je već na raspolaganju, korisnici je upotrebljavaju i veoma dobro poznaju. To svakako skraćuje vrijeme i olakšava implementaciju izdavanja e-faktura. Pored toga infrastrukturu za e-bankarstvo održavaju banke i za to mi ne moramo brinuti« rekao je Franci Klauzner, stručni savjetnik direktora sektora za razvoj. Oni korisnici koji nemaju e-banku, a željeli bi uprkos tome da primaju račune za utrošenu električnu energiju u elektronskom obliku, Informatika šalje e-fakture na svoj portal e-Usluge (e-Storitve), preko koga korisnici mogu da pregledaju i mijenjaju određena mjesta. U Informatici su se za slanje e-faktura putem kanala e-banke odlučili iz više razloga. Prije nego što pošalju fakturu u elektronskom obliku, oni moraju od primaoca da dobiju saglasnost za to. Primaoci tu saglasnost mogu da daju putem portala Informatike ili svoje e-banke. Sistemom e-banke se može obezbijediti da elektronske fakture izdavača, nakon slanja primaocu, budu usmjerene u

elektronski arhiv. E-fakture, koje izdaje Informatika putem sistema e-bankarstva, su digitalno potpisane i imaju digitalni vremenski pečat pa su, time, ispunjeni svi zakonski uslovi i kao takve su spremne za arhiviranje. I kakav je postupak slanja računa? Informatika u svom sistemu priprema digitalno potpisanu e-fakturu u određenom obliku (odlučili su se za e-SLOG) i zajedno sa dokumentom u PDF formatu uvozi u sistem e-banke, koji sigurnosnu komunikaciju bazira na digitalnom potpisu. Po Zakonu o elektronskom poslovanju i elektronskom potpisu (ZEPEP) e-faktura je jednaka papirnoj ako je digitalno potpisana. Primalac prima e-fakturu u svoju e-banku i, ako je pravno lice, uvozi je direktno u svoj informacioni sistem. Svi primaoci, kako pravna lica tako i domaćinstva, nalog za plaćanje mogu pripremiti u e-banci ili automatski iz e-fakture. Primalac e-fakture je oslobođen naknadnog prekucavanja podataka, a izdavač fakture uplate prima sa pravilnim povratnim informacijama o izvršenom plaćanju. Pravilni podaci, kao što su 13-cifreni poziv na broj i iznos plaćanja su ključni pri usklađivanju primljene uplate i izdate fakture.[3]

3. Mogući efekti primjene e-plaćanja i e-računa u BiH

Analizirajući ova i druga slična rješenja u praksi, proučavajući mogućnost njihove implementacije makar kao hibridnih rješenja u realnu praksu u BiH, intervjuišući veći broj informatičkih kuća i sučeljavanju njihovih stavova, te uvažavjući principe naučne metoda analogija, došlo se do spoznaje da postoji realna mogućnost primjene ovakvih rješenja u praksi BiH, pa i drugih zemalja Jugoistočne Evrope koja nisu u cjelosti primijenila ovaj ili neki drugi koncept u svojoj praksi. Da bi se stvorila slika o mogućim efektima primjene ovih rješenja, u nastavku će biti prkazane procjene na samo jednom dijelu kompanija koje se bave uslužnim djelatnostima i čiji je država u većini slučajeva većinski vlasnik. Radi se o kompanijama (nisu sve obuhvaćene, ali značajan dio jeste) koje se bave distribucijom električne energije, telekomunikacijama, uslugama centralnog grijanja, vodosnabdijevanja i drugim komunalnim uslugama.

Godišnje ove kompanije kumulativno obrade i distribuiraju više od sto milona računa (faktura) uz prosječnu cijenu distribucije „klasičnim“ putem od ≈1€, što znači da ti troškovi iznose oko sto miliona € uz skoro iste troškove koje izaziva funkcija obrade i realizacije platnih naloga, odnosno za samo manji dio ove funkcije obzirom da su analizirani slučajevi u relativno malom broju preduzeća, koštaju preko 200 miliona €. Analizirajući oficijelne cjenovnike iz ponuda e-plaćanja od strane nekoliko banaka može se zaključiti slijedeće: Cijena distribucije e-računa i obrade platnih e-naloga u zbirnom iznosu ne prelazi cifru od 0,25-0,30 €, što pored toga što ove transakcije čine bržim, sa manje grešaka, sa 24/7/365 radnim vremenom, eliminirajući sve vremenske i prostorne razlike, čine ih i jeftinijim za 6-7 puta. Ako bi se na ovom planu napravio iskorak za barem 30-ak%, ta bi ušteda imala veći efekat nego što iznosi proračun osnovnog, srednjeg i visokog obrazovanja najmnogoljudnije županije u BiH – Tuzlanske županije.

Uzme li se u obzir da ovo čini veoma mali broj od ukupnog broja transakcija svih subjekata, a producira procijenjene ovakve efekte, s pravom se može postaviti pitanje granica efekata primjene integralnog koncepta ovih funkcija, pogotovu u zemljama sa ograničenim investicijskim resursima i uvjetima niske uposlenosti. Prema nekim istraživanja svaki subjekt koji u toku jedne godine producira barem 60.000 ovakvih transakcija u biti ima značajne efekte u njegovoj implementaciji. Treba također reći da prema istražvanjima EC pozitivni efekti od uvođena ovakvih sitema poslovanja samo u ovim funkcijama produciraju pozitivne efekte preko 300 mld. €.(Strategija razvoja e-poslovanja R Hrvatske)

Zaključak:

Ne postavlja se dilema opravdanosti implementacije ovakvih rješenja u poslovnu praksu, nego se prije nameće pitanje zašto to već odavno nije zaživjelo, pogotovu u zemljama sa oskudnim investicijskim i drugim razvojnim resursima? Mnoštvo je različitih odgovora među kojima dominiraju politički motivi svih oblika, ali se oni nisu analizirali. Realna potreba kompanija u uvjetima ne zaokruženog sistema poslovanja na principima e-poslovanja, nameće nužnost primjene hibridnih (mada to grubo zvuči) rješenja, jer unutrašnje i međunarodno tržište nije statično i ono nameće nužnost primjene ovih rješenja. Kao i svaki sistem tako i ovaj sistem će doživjeti svoju evoluciju i razvoj u svim zemljama i gospodaskim sustavima, pa tako i u analiziranim područjima Jugoistočne Europe. Što se prije sistemski i organizirano pristupi ovom poslu, to će i efekti biti brži i sa multipritirajućem dejstvu. Ono što svakako treba istaći je da infrastruktura ili postoji ili je dostupna na zavidnom nivou, pa se ne vidi niti jedan racionalan razlog za intenzivnijim započinjanjem ovog procesa.

ERP Systems in Public Sector

R. Kelemen *
* Varazdin County/County Governors Office, Varazdin, Croatia
robert.kelemen@vz.t-com.hr

Abstract - ERP systems are tended to be implemented in the public sector. In this paper the "industries" of public sector are identified which are suitable for ERP implementation. The systematic review method is used to give an overview of state of the art ERP system implementation in the public sector worldwide in the last five years as well as possible directions of future research. Finally, the critical review is given regarding potential of ERP system implementation in the public sector.

I. INTRODUCTION

The vast majority of ERP system implementation in production systems has been completed and consequently the needs of that market have been satisfied. Some other potential areas of ERP systems implementation were in focus of ERP systems manufacturers. One of the emerging markets is the public sector. Implementation of ERP systems in the public sector has already began regardless of some well-known ERP implementation problems such as enormous investment and risk of failure in implementation itself. Numerous published scientific papers deal with various aspects of ERP systems, but the number of papers regarding ERP systems implementation in the public sector is relatively small. That particular area of the public sector is becoming increasingly interesting for ERP systems manufacturers, and researchers are interested in the areas of public services where the ERP systems have already been implemented.

Vrček and Brumec [6] define ERP system as "set of logically connected programs which support organization's business processes and use central and unique database, … it is not developed for any particular organization, regarding its functions it is general but simultaneously adoptable for specific needs of majority of organizations dealing with similar activities".

International Data Corporation (IDC) [7] defines that Enterprise Application Suite must fulfill the following criteria:

1. Minimal Functionality – not less than four basic functionalities:
   a. financial accounting modules,
   b. procurement modules,
   c. order management modules,
   d. inventory management modules.
2. Integrity – design based on simple rules and use of metadata, provides users access to all functional modules using one interface, it can store and retrieve data in one common database.
3. Relatively high price per user which differentiate s it from low-end book accounting software.
4. Multiuser platform – application (program) is designed for server/host and client/server environment.

According to Tomičić-Pupek [8] the general ERP system classification has not yet been accepted, but some criteria for ERP system classification are defined:

1. According to organization's line of business (a so called industry),
2. According to the set of business activities in one industrial area (vertical industry),
3. According to the business area (e.g. Accounting, Finances, Human Resources, Sales, Procurement, etc.),
4. According to the method of implementation,
5. Accordingto the ERP system adjustment approach to the organizational needs.

Jakupović, Pavlić and Fertalj [9] recommend ERP systems classification according to 70 business operations sorted into the three basic categories (Finances and public services, Production and Services). That approach is based on analyses of commercial ERP system manufacturers' classifications compliant with Global Industry Classification Standard (GICS) and EUROSTAT classification. The authors use the IDC definition of ERP systems, explained earlier.

Classification according the business functions - "industries" is commonly used in ERP system manufacturers' offers and it is concurred with noneconomic service of public interest definition.

The second area of interest in this paper is the public sector. It is important to define which services are offered by public sector and what in fact is the public sector.

Đulabić defines public sector services [1] as activities used to satisfy public needs, whereby the fundamental values of modern democratic societies are achieved. The concepts of "Public Service" and "services of public interest" describes the principle of same activity [1]. The concept of "Public Service" is more often used in continental European countries and the same concept but under the different name as "municipal services" or "public interest" can be found elsewhere [2]. The European Parliament defines public service [2] as permanent

economic activity which is in the public interest, and which is created and controlled by some public institution and at the same time it is under certain degree of legal protection beyond the regular legislative regardless the private or public authority which provides that service.

Public services are based on following principles [2]: equality, continuity, adaptability. Privilege of founding some public service agency (founding, setup and control) are given to [2]: central government (national public services), federal states and local authorities (regions, province, municipalities).

The new standards for public services general interest are established by the new European legislative regulation. The European Union differs economic public services (e.g. network industries) and non-economic public services like social security and healthcare [3]. The economic public services are big industries and network industries like telecoms, post offices, gas distribution, electrical energy distribution, water distribution, etc [4]. The non-economic public services are: education, culture, healthcare, social services, etc, everything which is not commercially based [3].

Koprić [4] indicates that term "services of general interest" isn't used in EC Agreements, and the use of that term spread in the late 1990ties. After intensive and long public discussion, the wider and narrower terms have been defined in a series of public documents. The wider term is defined as "public services of general interest" and the narrower term is defined as "economic public services of general interest". In addition, the specificities of certain categories of public services are recognized, so the terms like "social services of general interest" or "healthcare services of general interest" are also used [4]. According to Koprić [4] the intention of European Union is to harmonize the public services using policies and legislative (White Book, Bolkestein Directive).

Based on the above facts, this research aims at non-economic public services focused on the areas shown in Table I.

In this research it is not important at which level of the government these services are provided, since the research takes into consideration all levels of government.

The research question is defined as follows:

In which direction the ERP systems in non-economic public services have been developing over the last five years.

Research method: A method of systematic literature review as described by B. Kitchenham [5].

TABLE I. NON-ECONOMIC PUBLIC SERVICES

Code	Non-economic public service
PS1	Education
PS2	Culture
PS3	Health Care
PS4	Social Services
PS5	Law Enforcement
PS6	Military – defense
PS7	Public library
PS8	Public Security
PS9	Physical Planning / Town Planning
PS10	Public sector

II. SYSTEMATIC LITERATURE REVIEW

A systematic literature review is a means of evaluating and interpreting all available research relevant to a particular research question, topic or phenomenon of interest [5].

A. Planning

The scientific databases with full text paper, and the other available scientific articles in the field of social sciences were used in the research: Academic Search Complete, Business Source Complete, Directory of Open Access Journals – DOAJ, Regional Business News, Science Direct. Springer Link, IEEE Xplore, Google schoolar, HRČAK – portal znanstvenih časopisa, http://elf.foi.hr/.

All scientific and other papers and works written in the time span from 2008 to March 2013 were taken into account in the results selection.

Based on the analysis of services of general public interest which is described in the introduction to this paper, following keywords will be used to query the database: ERP system, government, public sector, public services, public utilities, public interest, service of general economic interest, education, culture, healthcare, social services, law enforcement, military, defense, public security, physical planning and public administration.

Using the above keywords the queries in Table II. are defined.

The article selection was performed in three stages (according to Jurišić [21]):

1. selection based on the analysis of titles and keywords,
2. selection based on the analysis of the abstracts,
3. selection based on the analysis of the full text.

At all stages of the selection articles related to the areas shown in Table I were considered.

TABLE II. RESEARCH QUERIES

Code	Query
Q1	'ERP system' AND 'government'
Q2	'ERP system' AND 'public sector'
Q3	'ERP system' AND 'public services'
Q4	'ERP system' AND 'public utilities'
Q5	'ERP system' AND 'public interest'
Q6	'ERP system' AND 'service of general economic interest'
Q7	'ERP system' AND 'education'
Q8	'ERP system' AND 'culture'
Q9	'ERP system' AND 'healthcare'
Q10	'ERP system' AND 'social services'
Q11	'ERP system' AND 'law enforcement'
Q12	'ERP system' AND 'military'
Q13	'ERP system' AND 'defense'
Q14	'ERP system' AND 'public libraries'
Q15	'ERP system' AND 'public security'
Q16	'ERP system' AND 'physical planning'
Q17	'ERP system' AND 'public administration'

At each stage of selection articles that are too general or those who are not focused on the research areas listed in Table 1 were rejected.

Identical articles were identified and duplicates were discarded at each stage of selection.

B. Conduction

After rising queries with keywords in databases and other available sources, according to the strategy specified in the research plan, 1046 articles have been discovered.

Having conducted the first phase - selection based on analysis of titles and keywords from the results of the previous stage - 170 articles have been extracted.

In Phase 2, 170 abstracts of articles resulting from phase 1were analyzed and 67 articles was allocated.

In the third stage of selection, after detailed reading, 67 articles were analyzed. 36 articles of these were eliminated after the content analysis, because they were not related to the topic of research. Some of the reasons were:

- Articles describing the upgrading of the existing ERP system with some new module or a separate decision,
- Articles describing systems that have already been analyzed,
- Articles not dealing exactly with the description of ERP systems, they were related to management, organizational culture, the reasons of successful or unsuccessful implementation, evaluation of investment ...

Full text analysis resulted with a set of 31 articles, 4 of them describing research conducted over more respondents from the public sector [30], [33], [8] [42], while the other 27 refer to one specific ERP system which has been applied to an institution of the public sector. 7 articles do not relate directly to the purpose of the research but generally describe some aspects of the ERP system in the non-economic public services.

C. Results and analysis

Analysis of 31 article shows that the largest number of articles related to the introduction of ERP systems in the field of education (11), then the area of functioning of the public sector (cities, states, regions, agencies) (10), the area of defense (5) area of healthcare (3), and (2) articles describe the introduction of ERP systems in several institutions.

Analyzing separate articles regarding the country of implementation, it was found that the largest number of articles describing the implementation of ERP systems refers the U.S. - 17, an unexpectedly large number of articles describing the implementation of ERP in Croatia - four, while the ERP implementation in Italy, Egypt, Hungary, Portugal, Saudi Arabia, the Netherlands, Denmark and Finland are described with one article each. Two articles describe ERP implementation in several countries.

Regarding the ERP system manufacturer, most articles - 11 describe SAP, 6 articles describes multiple ERP systems at once, 2 articles describe Oracle, 2 articles describe Microsoft Dynamics AX, 1 article describes each of the following manufacturers: Infor, BAAN, CGI AMS, Datatel Colleague, People Soft, MADAR, MUNIS, "Ericsson Nikola Tesla alliance", Custom solution, while in one article the manufacturer is not even listed.

1) Education

According to the classification of business operations created by Jakupović Pavlic and Fertalj [9], education as part of the public services is divided into three activities: schools, higher education and research. As a result of this research related to education, there were 11 articles discovered describing the ERP modules implemented in educational organizations and they are presented in Table III. Tomicic-Pupek [8] in doctoral dissertation refers to the research of module types, manufacturers and recent clients of the ERP system implementation in higher education institutions in the U.S. where 23 of 66 higher education institutions have introduced full ERP. In the European higher education institutions such register was never found.

2) Public Sector

In the field of public sector, research has identified 10 articles from the level of the city administration up to regional, state and federal government with ERP modules implemented as shown in Table IV.

3) Defence

German army uses the ERP system called "SAP DFPS" (SAP for Defense Forces and Public Security) [16] with ERP modules stated in Table V. In the same article the Logistic information system - ISL (Information System for Logistics) of the Czech Republic Department of Defense and the Czech Republic Army is described [16] developed by Czech producers AURA with the modules presented in Table V.

U.S. Department of Defense 's (DoD - Department of Defense) uses four primary ERP systems [46] and several smaller specialized ERP systems. The largest four are: Integrated Personnel and Pay System (IPPS-A) it is a system of human resource management, the Global Combat Support System for tactical logistics (GCSS-Army), Logistics Modernization Program (LMP) of the National Logistics, General Funds Enterprise Business System (GFEBS) is a global financial system. Manufacturer of the IPPS-A is a PeopleSoft Company, SAP is a manufacturer of the other three.

In addition to the U.S. military, the ERP system was introduced in Denmark army. Christiansen et al. describes the results of the introduction of the SAP ERP system in a special unit of Danish Navy [19]. The main purpose of the system implemented in Denmark army was to meet accounting standards set by the Danish National Audit Office, and modules are presented in Table V.

Hyovnen et al. [20] describe the case of the Finnish Defense Forces. By the end of 2005, the new ERP system replaced 19 different administrative information systems.

TABLE III. PS1 - EDUCATION

Ref.	ERP Modules Implemented	ERP Manufact.
[35]	Finacial accounting, HT mgt, Material Mgt, Project Mgt, Record Mgt, Faze II: Payroll, Asset Mgt, Procurement Mgt	SAP
[36]	Financial, Human Capital, Pension, Logistics and Technical	SAP
[37]	full ERP	Datatel® Colleague®
[38]	finance, procurement, human resources, campus solution - student modules	PeopleSoft
[39]	full ERP	MADAR
[40]	human capital management, financial management and payroll processing	Munis
[41]	full ERP	Oracle
[8]	different ERP componenets or full ERP implemented in different institutions	multiple manufacturers
[12]	full ERP	proprietary developed ERP "Is_UVN"
[42]	financial system, business processes of budget execution, financial accounting	SAP
[43]	finance, human resources (HR) and student information system software	not specified

SAP R/3 system was introduced with modules specified in Table V, and it was the first major implementation of SAP R/3 system in the Finland public sector [20]. Modules project management, maintenance and human resources are planned for later introduction, the time of implementation has not been determined.

4) Healthcare

Boonstra and Govers [15] in their paper have described the implementation of SAP ERP system in the medium - sized general hospital in the western part of the Netherlands. The hospital consists of six main units: 1 clinical part, 2. outpatient, 3. medical part, 4. facilities, 5. staff, 6. IT and finance. ERP system has been implemented over 5 years and the following modules were introduced: patient management, finance, material management, human resources, laboratory system, management support system, presented in Table VI.

The management has concluded that after three years of implementation, the expected improvements in the business haven't been achieved and that the ERP system is poorly implemented. Implementers wanted, due to fixed implementation costs, to implement the system quickly and therefore they had underestimated the role and the importance of medical practice that is required to get the system set up in accordance with the existing processes of medical practice. Implementer has tried to adapt processes found in hospital system to the ERP system, instead of adapting the ERP system processes to the hospital. Due to poor implementation, the hospital has lost at least 10% of annual revenue and was very close to bankruptcy [15].

The literature review has discovered a practical example of the introduction of an integrated hospital information system (IBIS) at University Hospital "Dubrava" in Croatia.

TABLE IV. PS10 – PUBLIC SECTOR

[24]	HR	SAP
[25]	Accounting, Budgeting, Payroll, Human Resources, and Procurement	SAP R/3
[26]	Full ERP, The ERP system integrates all of the city's business functions, including procurement, payroll, finance, inventory and human resources	Oracle
[27]	financial, procurement, personnel, budget, inventory control, grants and project management wifh fully integrated document management and workflow	SAP
[29]	finance, sales	BAAN
[31]	financials, controlling, human resources, logistics. The software is to assist companies by providing support for sales, customer relationships, inventory, operations, financials and human resources.	Microsoft Dynamics Ax
[32]	budgeting solution	CGI - AMS Advantage ERP Suite
[34]	General Ledger, Purchasing and Workflow. These were complemented with Tyler's Payroll and Cashiering applications	Microsoft Dynamics AX 2012 core ERP

This example is described in two articles [44] and [14] stating that all modules are planned in an integrated hospital information system "Ericsson Nikola Tesla alliance" (company "Ericsson Nikola Tesla" from Zagreb with partners: "Grad" from Pula and "Adacta", "Samson", "HrPro" and "Vams" from Zagreb). It is expected to improve the overall system in the KBD:

- transparent monitoring of hospital operations,
- Fast and efficient invoicing costs
- Maintaining comprehensive costs under control.

The introduction of the ERP system was started in 2003 and in 2005 all modules were not introduced. Only complete system for administrative monitoring of patients has been implemented [44] presented in Table VI.. The project is currently in the phase of standstill.

Authors of the article Motivations Underlying the Adoption of ERP Systems in Healthcare Organizations: An Analysis from the "Success Stories" in their study identified 180 successfully introduced ERP systems in the field of health care in the world. From the perspective of the software manufacturer in this research, the largest market share has Oracle with 100 references , followed by SAP with 38, 37 references has Cerner, 5 references have all other manufacturers [30].

TABLE V. PS6 – MILITARY – DEFENSE

[18]	Integrated Personnel and Pay System (IPPS-A),Global Combat Support System for tactical logistics (GCSS-Army), the Logistics Modernization Program (LMP), the General Funds Enterprise Business System (GFEBS).	GFEBS - SAP, GCSS-Army - SAP, LMP - SAP R/3, IPSS-A - PeopleSoft, Navy ERP - SAP R/3, GCSS-MC - Oracle, IPPS-Navy - PeopleSoft, DEAMS - Oracle, ECSS - Oracle, AF-IPPS - PeopleSoft
[17]	GFEBS, GCSS-Army, DEAMS, ECSS	GFEBS - SAP, GCSS-Army - SAP, DEAMS - Oracle, and ECSS - Oracle
[19]	human resources, controlling, logistic	SAP R/3
[20]	material management, procurement, asset management, budget planning, payment, and financial management	SAP R/3
[16]	SAP DFPS human resources, finance, operations and business processes, module for modeling units ISL - procurement, supply, logistics, equipment maintenance and ammunition.	SAP DFPS, AURA -ISL

Successful implementation (180) relates to 31 different countries, 92 were in North America (U.S. 89), 68 in Europe (UK 17, Germany 15, Netherlands 8 - all other 28), 12 implementations in Asia, 5 in Latin America and 3 in Oceania. The study noted that the following functionalities (modules) were implemented: 145 administrative systems, clinical information systems 38, 36 clinical support systems and 22 systems for patient management. Administrative systems have modules: accounting, human resources, payroll costs to diseases, material management.

TABLE VI. PS3 – HEALTH CARE

Ref.	ERP Modules Implemented	ERP Manufact.
[30]	multiple ERP systems	multiple manufact
[15]	patient management (appointments, registration, admission, discharge andtransfer);financial management (accounts payable, accounts receivable, general ledger andfixed assets); materials management (inventory and purchase); human resource (scheduling, training and payroll);•ancillary services (dietary, laboratory and pharmacy); and management information (reporting on and providing statistics on various issues).	SAP
[14]	planned: patient management (appointments, registration, admission, discharge and transfer); ancillary services (dietary, laboratory and pharmacy); Radiolgy IS, operations, intensive care; materials management (inventory and purchase); financial management (accounts payable, accounts receivable, general ledger and fixed assets); management information (reporting on and providing) implemented: patient management	Hospital informatio n system "Ericsson Nikola Tesla alliance"

Clinical information systems have modules like emergency services, surgery, nursing services, etc. The clinical support system has modules like pharmacy, etc. The system for managing patients: patient admission, transfer and discharge of patients [30]. The research described earlier is focused on the motivation for the introduction of ERP systems in health care facilities, so that it was not possible to determine which modules were combined together from that article.

III. CONCLUSION

Based on the analysis of the articles presented, regarding the area of non-economic public services shown in Table I, it can be concluded that ERP systems have been introduced in the areas of education, health care, defense, and municipalities, regions and states to support the public administration activities. There were no articles related to non-economic public services in the field of culture, social services, justice, libraries, public safety and urban planning. With regard to the ERP systems classification prepared by the authors Jakupović Pavlic and Fertalj [9], it is evident that there is a full agreement between classifications and systems implemented in practice, and ERP systems are often introduced in the areas of education, public administration, defense and health. As seen from the analyzed articles, despite the fact that European legal regulations recognize some other non-economic public services [3], the implementation of ERP systems in those hasn't been accomplished yet. In addition, even ERP software manufacturers haven't classified such systems.

Some of the general definitions of ERP systems were described in articles [6], [7] and [8]. The articles [8], [10], [11] and [12] give a set of modules which should include ERP systems in education. Complete ERP systems in the field of health should include modules according to the authors [13], [14], [44] and [15]. ERP systems in the field of defense are described in the articles [16], [17] and [18].

Vrček and Brumec [6] in their paper display modules (functions) of ERP system and group them as business support, networking and value chain.

According to Spathis and Constantinides [51] and Spathis [52] research in organizations that have implemented ERP systems, prevalent modules were: finance and accounting, and management support systems for management and control. The authors conclude that organizations introduce ERP system beginning the modules of finance and accounting, with a desire to integrate the accounting processes.

In the field of public administration, according to the data from the articles [22], [23], [24], [25], [26], [27], [29], [31], [32] and [34] and the results obtained by the Microsoft and GFOA [28] and [33], it can be concluded that ERP systems have been introduced solely to support the business .

In the field of education, according to Tomičić-Pupek [8] 23 of the 66 higher education institutions in the United States introduced a full ERP. As seen from the articles of this research, a full ERP in the field of education is described in the articles [37], [41], [12] and [39]. ERP systems to support business operations are covered in the

articles [35], [36], [40] and [42] and it is shown that the institutions have introduced ERP to support the business. ERP systems with different modules that are in the value chain have established institutions that are described in [38], [43].

In the area of defense a full logistics and financial ERP systems were introduced, as described in the articles [17], [18], [16], [19] and [20].

In the field of healthcare according to a study by Poba-Nzaou et al., Described in the article [30] it is noted that in 180 implementations of ERP systems in 31 different country the following functionalities (modules) have been introduced: 145 administrative systems, 38 clinical information systems, 36 clinical support systems and 22 systems for patient management. The full ERP systems implementations introduced or planned in the area of healthcare were described in the articles [15] and [14].

It can be concluded that existing research shows that ERP systems in non-economic public services are generally introduced in the areas of health, education, defense and public administration.

In the area of Healthcare, the most common ERP modules were introduced to support the business processes, while a lesser extent represents modules of the value chain.

In the field of defense, exclusively full ERP systems have been introduced that cover the entire target area: logistics, human resources and finance.

Vrček and Brumec [6] define ERP system and conclude that ERP system is not intended for the implementation in one business function ("island"), but on the contrary, ERP system connects all business functions involved in performing the key processes. Justification for the introduction of the ERP system in the organization is questionable if this system does not include all the necessary modules for specific area from which the organization derives.

Based on the above, it can be concluded that in the area of non-economic public services like public sector, education, healthcare and defense, there is still some space for exploration, especially with respect to the implementation of ERP modules in the value chain of each area, taking into account the specifics with regard to the objectives of the organization and the level of development of the state.

Oslonjivost sustava e-poslovanja u oblaku

Mihael Buković, Milan Davidović, Pavle Špoljarić
VSITE – Visoka škola za informacijske tehnologije, Zagreb, Croatia
mihael.bukovic@vsite.hr, milan.davidovic@vsite.hr, pavle.spoljaric@vsite.hr

Sažetak – Utvrđivanje oslonjivosti sustava e-poslovanja (eng. *dependability*), kojom se dokazuje u kojoj se mjeri mogu dionici osloniti na njegove usluge, obuhvaća praćenje karakteristika i analizu prijetnji, te određivanje sredstava za postizanje i održavanje potrebne oslonjivosti. Oslonjivost sustava e-poslovanja u oblaku analizira se sa stanovišta davatelja i korisnika usluga, s tim da je naglasak na utvrđivanju mogućnosti koje stoje na raspolaganju korisniku glede pouzdanosti, raspoloživosti, sigurnosti, povjerljivosti i integriteta. S obzirom da je pouzdanost ključni faktor oslonjivosti sustava poslovanja predložen je pristup analizi pouzdanosti sustava e-poslovanja u oblaku.

Ključne riječi: sustav e-poslovanja, oslonjivost, pouzdanost, računalni oblak, sustav tolerantan na neispravnosti

I. UVOD

Računarstvo u oblaku (eng. *Cloud computing*) omogućit će poduzećima, posebno malim i srednjim, implementirati sustav e-poslovanja brže i uz manje troškove implementacije, pogona i održavanja u odnosu na vlastitu informacijsko-komunikacijsku infrastrukturu. Cijena programske podrške za e-poslovanje u oblaku može biti niža, jer se plaća usluga i to prema vremenu i broju korisnika koji ju koriste. Pri tom je dostupna zadnja verzija programske podrške, tako da korisnik usluge nema troškova nadogradnje i održavanja softvera (jasno, pri tom treba adoptirati dizajn procesa e-poslovanja koje podržava softver, a adaptacije softvera su nemoguće ili preskupe). Također nema direktnih troškova nabave i održavanja potrebnog hardvera i licenci, niti troškova instalacije, konfiguracije i održavanja hardvera, sistemskog softvera, softvera za baze podataka i servere elektroničke pošte i dr. U cijenu usluge je uključena i antivirusna zaštita, a kao posebna usluga može se ugovoriti pohranjivanje, te izrada i čuvanje sigurnosnih kopija određenih, za poslovanje poduzeća ključnih podataka. Pristup do resursa u računalnom oblaku je moguć samo ovlaštenom korisniku iz bilo koje lokacije koja ima pristup na Internet [1][2].

I pored svih navedenih dobrobiti nameće se pitanje u kojoj mjeri se korisnik može osloniti na sustav e-poslovanja u računalnom oblaku i koja mu sredstva stoje na raspolaganju da bi dobio ne samo jeftiniji, već i sustav e-poslovanja u koji se može pouzdati. Analizu oslonjivosti tog sustava trebalo bi provesti prije ugovaranja usluga i periodički ju provoditi nakon ugovaranja u sklopu ocjenjivanja izvršavanja ugovora. Pristup analizi oslonjivosti sustava e-poslovanja u računalnom oblaku dat je u t. II-IV.

II. KARAKTERISTIKE OSLONJIVOSTI E-POSLOVANJA U OBLAKU

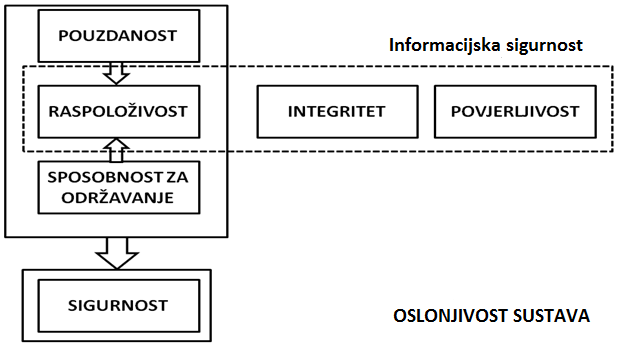
S obzirom da korisnik ovisi o uslugama informacijskog sustava, on želi znati u kojoj mjeri se može osloniti na informacijski sustav. **Oslonjivost informacijskog sustava** (eng *information system dependability*) je mjera opravdanosti korištenja informacijskih usluga. Što se aktivnosti korisnika više oslanjaju na informacijsko-komunikacijsku podršku to će korisnik biti ovisniji o informacijskom sustavu. Što je veća ovisnost (eng *dependency*) korisnika o informacijskim uslugama, to veća bi trebala biti oslonjivost informacijskog sustava [3]. Isti informacijski sustav mogu različiti korisnici ocjenjivati kao potpuno oslonjiv, manje oslonjiv ili potpuno neoslonjiv, ovisno o tome da li se u realizaciji svojih aktivnosti mogu u potpunosti ili djelomično osloniti na usluge informacijskog sustava ili se uopće ne mogu osloniti na njegove usluge [4].

Polazeći od ove definicije oslonjivosti proizlazi da će **oslonjivost sustava e-poslovanja** ovisiti o tome

- U kojoj se mjeri mogu menadžment i ostali dionici (kupci, dobavljači, zaposlenici, dioničari) u provedbi svojih aktivnosti, koje su usmjerene na povećanje sigurnosti razmjene dobara, usluga i informacija, osloniti na informacijsko-komunikacijsku potporu;
- U kojoj mjeri se menadžment može osloniti na informacijsko-komunikacijsku potporu u izgradnji novih poslovnih odnosa unutar organizacije i s poslovnim partnerima ili
- Koliki utjecaj na poslovni uspjeh imaju preustroj organizacije i redizajn poslovnih procesa koje je potrebno provesti radi djelotvornog korištenja informacijsko-komunikacijske potpore, te
- Kolika je sigurnost elektroničkih transakcija koje prate razmjenu dobara i usluga.

Kvantitativno možemo oslonjivost sustava e-poslovanja u oblaku definirati kao vjerojatnost da će sustav biti **raspoloživ** da zaprimi zahtjeve korisnika za uslugom i biti **operativan** (pouzdan) dok je usluga potrebna korisniku, što uključuje i zahtjeve kao što su **povjerljivost** ili **tajnost** (eng *confidentiality*), **cjelovitost** ili **integritet** (eng. *integrity*), **zaštita okoline** (eng. *environmental safety*) i **sposobnost održavanja** ili **popravljivost** (eng. *maintainability*). Što je veća vjerojatnost da će se sustav e-poslovanja u oblaku ponašati u skladu sa zadanim specifikacijama u zadanim uvjetima u okruženju to se korisnik može jače osloniti na njegove usluge.

Glavna obilježja oslonjivosti sustava e-poslovanja u oblaku su **pouzdanost** (eng *reliability*) i **raspoloživost** (eng *availability*). Raspoloživost određuju pouzdanost i sposobnost održavanja sustava (v. sliku 1). Računalni sustavi koji se koriste za pohranjivanje i obradu podataka, sigurnosne kontrole i komunikacijski kanali za pristup podacima u oblaku moraju biti raspoloživi da bi bili raspoloživi podaci potrebni za e-poslovanje. **Raspoloživost**, **integritet i povjerljivost podataka** tvore trijadu CIA [1] osiguravanja informacija (eng *information assurance*) koju određuje **model sigurnosti** (eng *security model*) koji primjenjuje sustav e-poslovanja u oblaku čije se usluge koriste.



Slika 1 Odnos glavnih obilježja oslonjivosti sustava
Izvor: Davidović [3]

Pouzdanost R(t) (eng. *Reliability*) je uvjetna vjerojatnost ispravnog rada sustava u zadanom vremenskom intervalu [0,t). Sustav ispravno radi ako obavlja sve zadaće u skladu sa zadanim specifikacijama u zadanim radnim uvjetima. Kao pokazatelj pouzdanosti koristi se i srednje vrijeme između kvarova (eng. *MTBF – Mean Time Between Failures*) [3][5]. Pouzdaniji sustav e-poslovanja ima veću raspoloživost i sigurnost, a time i bolju zaštitu od vanjskih napada i ostalih prijetnji (v. t. III). Da bi se postigla potpuna oslonjivost sustav e-poslovanja u oblaku trebao bi biti tolerantan na neispravnosti (v. t. IV).

Usluga sustava e-poslovanja u oblaku je **korektna** ako sustav ispravno obavlja sve zadaće potrebne za njenu realizaciju u skladu sa zahtjevima korisnika. Kod **zatajenja sustava e-poslovanja** (eng *e-business system failure*) isporučena usluga razlikuje se od ugovorom definirane korektne usluge, jer se zadaće ne obavljaju u skladu s ugovorenim specifikacijama zbog neke trajne, povremene ili prolazne **neispravnosti ili kvara** (*eng permanent, temporary, transient fault)* ili ako specifikacije sustava ne opisuju adekvatno uslugu (na primjer, neispravan dizajn) [4][5]. Sustav je **siguran** (eng *safety*) ako nema katastrofalnih posljedica zatajenja za korisnika i njegovu okolinu [4].

[1] CIA – akronim od *Confidentiality, Integrity, Availability*

Usluge neće biti korektne kad sustav nije raspoloživ zbog aktivnosti preventivnog održavanja, nadogradnje, vanjskih utjecaja i drugih razloga zbog kojih se ne može realizirati zahtjev korisnika za obavljanjem usluge iako je sustav ispravan. Usluge su nekorektne i kad sustav nema potrebne (ugovorene) performanse u trenutku zahtjeva korisnika za uslugom t. **Izvršljivost** (eng *performability*) P(I,t) je vjerojatnost da će performanse sustava u trenutku t biti iznad razine I [5]. Degradacijom performansi ispod razine I usluge postaju nekorektne, a sustav neoslonjiv.

Obnavljanje sustava (engl. *system restore*) obuhvaća otklanjanje neispravnosti i pogrešaka koje su uzrokovale zatajenje sustava ili promjenu specifikacija, redizajn funkcija i njihove tehničke izvedbe da bi sustav pružao korektnu uslugu. [3] Sustav e-poslovanja u oblaku mora posjedovati sposobnost otklanjanja skrivenih softverskih defekata koji mogu biti meta vanjskih napada ili mogu pod određenim okolnostima izazvati zatajenje sustava ili ugroziti njegovu sigurnost (v. t. III). Glavne karakteristike **sposobnosti održavanja ili popravljivosti** sustava e-poslovanja su vjerojatnost M(t) da će sustav biti obnovljen u vremenskom intervalu [0,t), intenzitet obnavljanja sustava μ [obnavljanja/h] i srednje vrijeme obnavljanja sustava MTTR (eng. *Mean Time To Repair*), MTTR=1/ μ ako je μ =konst. [3][5]

Raspoloživost sustava A(t) je vjerojatnost da će sustav biti ispravan u trenutku t ili ako je bio u intervalu [0,t) bio neispravan da će do trenutka t biti obnovljen. Kao pokazatelj oslonjivosti koristi se granična vrijednost funkcije raspoloživosti K_A ili koeficijent raspoloživosti

$$K_A = \frac{MTTF}{MTTF + MTTR} \qquad (1)$$

MTTF je srednje vrijeme do kvara (eng *Mean Time To Failure*). MTTR je srednje vrijeme obnavljanja. [3][5]

U stanju neraspoloživosti sustava e-poslovanja ne mogu se na siguran način razmjenjivati dobra, usluge i informacije, jer se ne mogu realizirati elektroničke transakcije koje ih prate, tako da su mogući vrlo visoki gubici u poslovanju zbog zatajenja i slabe sposobnosti održavanja sustava e-poslovanja. Iz (1) proizlazi da bi bili oslonjivi, sustavi e-poslovanja u oblaku moraju imati visoku pouzdanost i sposobnost održavanja.

Sigurnost oblaka utječe na percepciju oslonjivosti sustava e-poslovanja u oblaku. Problem jest što još ne postoje sigurnosni standardi za računalne oblake. Sustav e-poslovanja može se implementirati u računalnom koji ima mehanizme koji omogućavaju korisnicima da se mogu pouzdati da se u oblaku s njihovim podacima upravlja na jednako siguran način kao u standardnom IT okruženju [1]. Računalni oblak treba pružati usluge sigurnosnih kontrola prijenosa podataka i skladištenja

podataka u oblaku, zaštite od neovlaštenog pristupa podacima korisnika i druga sredstva za otklanjanje potencijalnih prijetnji.

Integritet ili cjelovitost je sposobnost sustava da spriječi neregularno ažuriranje podataka/informacija, što uključuju njihovo dodavanje, brisanje i izmjene. Pristup podacima uskladištenim u računalnom oblaku, koji se ostvaruje preko računalne mreže, podložan je vanjskim napadima. **Povjerljivost** je sposobnost sustava da podatak/informaciju otkriva samo onim korisnicima (ljudima ili drugim informacijskim sustavima i uređajima) koji imaju pravo pristupa i potrebu za informacijama/podacima. Do donošenja standarda za infrastrukturu i sigurnosnu arhitekturu računalnih oblaka potrebnih za postizanje potpune oslonjivosti sustava e-poslovanja u oblaku, povjerenje između davatelja i korisnika usluga može se uspostaviti i održavati primjenom AAA kontrola[2] i upravljačkih mehanizama za kripto ključeve kojima će se osigurati da podacima u oblaku mogu pristupiti samo autorizirani korisnici [1].

III. PRIJETNJE OSLONJIVOSTI E-POSLOVANJA U OBLAKU

Prijetnje oslonjivosti sustava e-poslovanja (eng *threat*) su neispravnosti, pogreške i zatajenja zbog kojih njegove usluge nisu korektne i korisnik se na njih više ne može osloniti. Otklanjanjem prijetnji održava se potrebna oslonjivost sustava. Utjecaj korisnika na otklanjanje prijetnji njegovom e-poslovanju u oblaku je minimalan, jer korisnik nema na raspolaganju sredstva za održavanje oslonjivosti. Samo davatelj usluga raspolaže sa sredstvima za prevenciju, predviđanje, toleriranje i otklanjanje neispravnosti aplikacija, platformi za izvođenje aplikacija i informacijsko-komunikacijske infrastrukture. Da bi se spriječilo stvaranje lanca prijetnji u oblaku između podsustava e-poslovanja, koje mogu u krajnjoj konsekvenci dovesti do prekida e-poslovanja, u računalnom oblaku treba uspostaviti sustav e-poslovanja koji je tolerantan na neispravnosti.

Kod odlučivanja o izvedbi sustava e-poslovanja u računalnom oblaku, osim dobrobiti koje donosi oblak, poduzeće treba ocijeniti i sve rizike zbog nedostupnosti podataka ili servisa, odnosno resursa računalnog oblaka. Osim poznatih prijetnji (kvarovi hardvera, pogreške i neispravnosti softvera, vanjski napadi na oblak i sl) nedostupnost podataka može biti uzrokovana i legislativom zemlje u kojima se nalaze resursi oblaka. Sve to treba regulirati u ugovoru o kvaliteti usluge (SLA – *Service Level Agreement*) između davatelja i korisnika usluga (dostupnost sigurnosnih kopija u slučaju ispada sustava, visina odštete za gubitke zbog prekida rada sustava i dr) [1]. Jasno je, da će cijena usluga biti to veća što se traži veća pouzdanost i raspoloživost sustava.

[2] eng. AAA – Authentication, authorization, accounting

IV. POUZDANOST SUSTAVA E-POSLOVANJA U OBLAKU

Sustav e-poslovanja jednog poduzeća uspostavlja se u računalnom oblaku, tako da se za odabrani aplikacijski okvir e-poslovanja osiguraju svi potrebni resursi, što smanjuje ukupne transakcijske troškove poduzeća. U slučaju stvaranja zajedničkog lanca vrijednosti dio funkcija e-poslovanja može se izdvojiti u posebne oblake (na primjer, u oblak nabave ulaze svi stalni ili povremeni dobavljači roba i usluga, a u oblak prodaje svi stalni ili povremeni kupci). Velike tvrtke će većinu svojih resursa držati u privatnom oblaku, a dio poslovnih funkcija mogu preseliti u javni oblak (e-pošta, Web maloprodaja, marketing i sl). Privatni oblak može korisniku osigurati veći stupanj kontrole performansi, prijetnji i sigurnosti sustava e-poslovanja, ali je takvo rješenje skuplje od korištenja usluga u hibridnom ili javnom oblaku [1][2].

Pouzdanost sustava e-poslovanja u oblaku je vjerojatnost

$$R(t,\tau) = R_{in}(t,\tau)\cdot R_{pl}(t,\tau)\cdot R_{sw}(t,\tau)\cdot R_{cn}(t,\tau) \qquad (2)$$

gdje su

- $R_{in}(t,\tau)$ – pouzdanost infrastrukture (hardver),
- $R_{pl}(t,\tau)$ – pouzdanost platformi aplikacija e-poslovanja,
- $R_{sw}(t,\tau)$ – pouzdanost aplikacija e-poslovanja,
- $R_{cn}(t,\tau)$ – pouzdanost mrežnih servisa,
- τ - vrijeme potrebno za elektroničku transakciju.

Relacija (2) vrijedi ako su vjerojatnosti ispravnog rada hardvera, softvera i mrežnih servisa međusobno neovisne.

Pouzdanost hardverske komponente računalnog oblaka $R_{in}(t,\tau)$ je sa stanovišta korisnika pouzdanost usluge korištenja hardvera i drugih dodatnih resursa potrebnih za realizaciju sustava e-poslovanja korisnika (virtualni strojevi i diskovi, vatrozid, virtualne lokalne mreže i dr). Korisnici u pravilu unajmljuju samo aplikacije, tako da ne vide infrastrukturu na kojoj se aplikacije izvode, tako da se $R_{in}(t,\tau)$ može uzeti kao mjera utjecaja infrastrukture na pouzdanost sustava e-poslovanja korisnika. Na isti način se tretira **pouzdanost mreže i mrežnih servisa** $R_{cn}(t,\tau)$, pa se mreža i hardver sa stanovišta korisnika mogu promatrati kao jedinstvena cjelina čiji je ukupan utjecaj na pouzdanost e-poslovanja $R_{in}(t,\tau)\cdot R_{cn}(t,\tau)$.

Pouzdanost platformi aplikacija e-poslovanja $R_{pl}(t,\tau)$ uključuje pouzdanost operacijskih sustava, baza podataka i Web poslužitelja. Pouzdanost tih usluga, napose pouzdanost baza podataka i Web poslužitelja, valja promatrati zasebno, odvojeno od aplikacija e-poslovanja. Pouzdanost softvera e-poslovanja $R_{sw}(t,\tau)$ je vjerojatnost obavljanja korektne usluge pomoću unajmljenih aplikacija e-poslovanja. Korektnost te usluge je određena s pouzdanošću softvera koja je jednaka vjerojatnosti da će softver u vremenskom periodu $(t,t+\tau)$ u zadanim radnim

uvjetima izvesti svoje zadaće u skladu sa specifikacijama bez pogreške i u skladu s ugovorenim performansama. Aplikacije e-poslovanja mogu biti sustav planiranja resursima poduzeća (ERP – *Enterprise Resource Planning System*), sustav upravljanja odnosima s kupcima (CRM – *Customer Relationship Management System*), sustav upravljanja dobavnim lancem (SCM – *Supply Chain Management System*) i dr.

Kritičan faktor oslonjivosti sustava e-poslovanja je pouzdanost softvera. To znači da u slučajevima kad se traži visoka pouzdanost i raspoloživost pojedinih aplikacija e-poslovanja nije dovoljno u oblaku osigurati rezervnu infrastrukturu i platforme na kojima se izvode te aplikacije, već treba osigurati više verzija programa. Nakon zatajenja aplikacije korisnik može koristiti druge verzije aplikacije u istom računalnom oblaku ili u drugim računalnim oblacima istog ili drugih davatelja usluga (eng *Cloud Computing Service Provider*, *CCSP*) koji se mogu nalaziti na različitim (geografskim) lokacijama.

Da bi se korisnik zaštitio od prijetnji kao što su velike prirodne katastrofe na određenom geografskom području, potrebno je osigurati i neovisan pristup do rezervnog podatkovnog centra u slučaju ispada ili zatvaranja primarnog podatkovnog centra.

Kad je sustav e-poslovanja korisnika tri-modularni redunantni TMR 3-2-1 sustav (eng *Triple Modular Redundant System*), u kojem je bar jedan sustav ispravan, njegova pouzdanost je

$$R = \binom{3}{3}p^3 + \binom{3}{2}p^2(1-p) + \binom{3}{1}p(1-p)^2$$

odnosno

$$R = p^3 - 3p^2 + 3p \qquad (3)$$

gdje je p pouzdanost sustava e-poslovanja određena prema izrazu (2) [3].

Realno je za pretpostaviti da se ovi sustavi vladaju po eksponencijalnom zakonu pouzdanosti, pa je srednje vrijeme do kvara redundantnog sustava

$$MTTF_{TMR} = \frac{1}{3\lambda} - \frac{3}{2\lambda} + \frac{3}{\lambda} = \frac{11}{6\lambda} = 1{,}83\,MTTF\,(h) \qquad (4)$$

gdje je MTTF srednje vrijeme do kvara osnovnog sustava, MTTF=1/λ [h], a λ [h^{-1}] je ukupni intenzitet kvarova osnovnog sustava [3].

Sustav e-poslovanja u računalnom oblaku s tolerancijom neispravnosti treba imati više pristupa preko različitih prijenosnih medija (eng *Transmission Media*) do davatelja internetskih usluga (eng *Internet Service Provider*) preko kojih se pristupa do računalnog oblaka davatelja usluga s kojim korisnik ima sklopljene ugovore (SLA) [1].

Predmet ugovora s davateljima usluga može biti i izvještavanje o raspoloživosti i pouzdanosti sustava u oblaku koje obuhvaća sve podatkovne centre na svim geografskim lokacijama na kojima davatelj usluga čuva podatke i izvodi aplikacije za e-poslovanje korisnika.

Pouzdanost virtualnih strojeva određuje se na temelju mjerenja vremena između uključivanja i zatajenja virtualnog stroja. Interval od ispada virtualnog stroja do podizanja novog virtualnog stroja je vrijeme obnavljanja tog čvora [6].

Pouzdanost prijenosnih sustava i sustava za pohranjivanje je razmjerno visoka zahvaljujući njihovoj izvedbi koja je tolerantna na neispravnosti [7]. No, ako se ne eliminiraju zavisni kvarovi, čiji uzrok su prirodne katastrofe i drugi vanjski utjecaji primjenom više transmisijskih medija, može doći do zatajenja sustava e-poslovanja s katastrofalnim posljedicama za poslovanje korisnika.

V. DALJNJA ISTRAŽIVANJA

Provedena analiza oslonjivosti sustava e-poslovanja u oblaku ukazala je na potrebu uspostavljanja mjerenja i praćenja oslonjivosti sustava e-poslovanja kao nove usluge koju pruža davatelj usluga pored izvođenja aplikacija e-poslovanja u oblaku tolerantnom na kvarove.

U daljnjim istraživanjima bi trebalo, s obzirom na mrežnu strukturu sustava e-poslovanja u oblaku, proširiti model pouzdanosti za primjenu u detaljnim aposteriornim analizama korektnosti usluga i pouzdanosti sustava e-poslovanja u računalnom oblaku koji će koristiti korisnici. Na temelju tog modela moglo bi se pristupiti i analiziranju odnosa performansi, troškova i oslonjivosti sustava e-poslovanja u računalnom oblaku sa stanovišta korisnika i davatelja usluga.

VI. ZAKLJUČAK

Razvoj tehnologije računalnih oblaka omogućava razvoj sustava e-poslovanja u računalnom oblaku, što je posebno zanimljivo za male i srednje tvrtke. S obzirom da korisnik, nakon uvođenja e-poslovanja, u potpunosti ovisi o informacijskoj i komunikacijskoj tehnologiji, potrebna su sredstva za praćenje oslonjivosti sustava e-poslovanja koja će obuhvatiti informacije o prijetnjama oslonjivosti sustava, pokazatelje pouzdanosti, raspoloživosti, popravljivosti i izvršljivosti, te raspoloživosti, integritetu i povjerljivosti informacija u računalnom oblaku.

Za potpunu oslonjivost sustava e-poslovanja potrebno je primijeniti metode povećanja pouzdanosti, uključivši i N modularnu redundanciju softvera, zbog čega poskupljuje

korištenje usluga sustava e-poslovanja u računalnom oblaku, ali raste i povjerenje korisnika u kvalitetu usluga. Sustavi e-poslovanja u računalnom oblaku tolerantni na neispravnosti (eng *Fault Tolerant e-Business System*), koji imaju visoku izvršljivost i osiguravaju potrebnu raspoloživost, integritet i povjerljivost podataka u oblaku, mogu osiguravati veliku vjerojatnost da će usluge obaviti korektno i tako ispuniti očekivanja svojih korisnika.

Nema jedinstvenog rješenja za oslonjivost informacijskih sustava, pa kroz razvoj oslonjivih sustava e-poslovanja u računalnom oblaku treba neprekidno prepoznavati (nove) prijetnje oslonjivosti, iznalaziti učinkovita sredstva za povećanje oslonjivosti i metode za specifikacije potrebne oslonjivosti za različite grupe korisnika, te neprekidno unapređivati metode mjerenja oslonjivosti sustava kako sa stanovišta korisnika, tako i sa stanovišta davatelja usluga.

Summary – In a digital environment that is now present in tourism and tourist transport, information and reservation systems are the basis for the realization of businesses. Besides reducing operating costs and 24-hour service availability, an additional benefit can be seen in dynamic pricing of services. Airlines first noticed the advantages of information-communication technologies (ICTs) and developed a whole new concept of business in the form of low-cost airlines (LCAs).

LCA tourists have to use information technologies in order to use LCA services, therefore it is expected that the Internet usage of low-cost airline tourists significantly differs from the Internet usage of average tourists.

Over the last several years Zadar County has strongly encouraged low-cost airlines to link its airport with as many European destinations as possible, which enabled the connection with remote outbound markets and the increase of city breaks tourism.

This paper will show the results of a research which was conducted on a sample of 900 low-cost airline (LCA) tourists and 1697 average tourists who stayed in Zadar County. Different methods of descriptive statistics were used in order to determine and compare the level of usage of information technologies of these two types of tourists.

I. INTRODUCTION

Carriers and tourism economy make up an inseparable whole. Development of means of transport resulted in the development of tourism as we know it, while the development of airlines played a key role in a creation of a global tourism market as it made any destination reachable in a short period of time. Air transport cost component had made this transport exclusive until low-cost airlines (LCAs) appeared on the market [1]. Researches show a significant positive influence LCAs have on tourism in the destination [2]. At the same time, airlines and workers in the hotel industry are among first users to recognize the advantages of the use of information-communication technologies in their business (ICTs). They see the implementation of ICTs in their business both as a new sales channel and a powerful marketing tool realizing its advantages at large scopes of target population through promotional actions of high level response, thus optimizing the use of tourism capacities. Moreover, auction system of price determination allows LCA users to see LCA advantages [3] while LCA can follow tourists' post-purchase actions.

LCA tourists are Internet usage-oriented in the purchasing process, therefore it is expected that − in gathering information and accommodation reservation in the destination – Internet usage of LCA tourists is more significant than the Internet usage of average tourists.

II. THE USE OF INFORMATION-COMMUNICATION TECHNOLOGIES IN TOURISM

Contemporary trends in tourism show a complete affirmation of ICTs in tourism business, offering different possibilities for changes and innovations. With the development of the Internet, ICTs have significantly influenced tourist offer meeting market demands as well as they enabled easier accessibility and tangibility of tourist products and services. Along with this, ICTs have changed information channels. Therefore, physical media such as brochures, tourism magazines and catalogues have partially been replaced with electronic information characterized by its easy accessibility and quality timeliness. Tourist service information has become easily verifiable with unlimited possibilities of distribution. As a result of this, today tourists are more sophisticated and more informed, with more and more complex demands and common requests for individual tourist journeys.

Gathering information is a starting point when making decision about a tourist journey. Within this process, information about tourist destination, means of transport, accommodation, cultural activities, entertainment, and other, is found and selected. Therefore, being informed presents a complex multi-stage process including one or more persons getting relevant information from different sources – gathering information depends on the composition of the group going on a journey, on presence of friends and relatives in the tourist destination to be visited, earlier staying at the destination as well as on the destination's popularity [4]. Fodness and Murray [5] point out three main factors influencing tourists' behaviour and their decision on going on a tourist journey: motivation, determinants and sources of information. Gursoy and McCleary [6] have developed a theoretical model explaining tourists' behaviour while gathering information, and certain studies have been conducted, related to tourists' sources of information, pointing out some of the categories in gathering information: informal sources, such as friends, relatives, colleagues or other tourists; earlier experience; tourist agencies or tour operators; tourist offices at the level of states, regions, or towns; various brochures, catalogues and tourism magazines; airline web sites; other web sites [7].

The Internet has changed tourism behaviour significantly [8], also stated by Buhalis and Law [9] in their retrospective review of ICTs progress and use in

tourism in their paper which stresses the development and implications of the Internet usage. Various tools, such as online reservation and online purchase, have replaced mediary services of tourist agencies and tour operators [10], and the Internet has become the basic marketing tool [9]. Certain researches show that tourists who gather information via the Internet spend more money in the destination than the tourists who gather information from other sources [11]. Global online agents, such as Lastminute.com, Expedia or Orbitz, are of great importance here. With their simple and clear web sites, they enable tourists getting all information needed, as well as making online reservation and purchase, all in one place. Low-cost airlines become more and more popular, as they provide, along with online ticket purchase, certain information about tourist destinations marked in their airlines [12]. The Internet has put a tourist into the center of planning and organization of his/her journey. However, certain researches show 55% of guests, before making a reservation of accommodation, read one to five online reviews [13]. The Internet is not an only source of information – information can be found in other electronic forms or in word-of-mouth referrals [14], and researches show tourist combine the Internet and other sources, such as brochures and catalogues [15], that is, getting information depends on online as much as on offline sources of information [16].

III. LOW-COST AIRLINES AND THEIR EFFECT ON TOURISM

During the past thirty years, there has been a significant increase and changes in the world airlines. An increase of 5.2% was reported in 2013 compared to 2012, despite high fuel prices and relatively slow economic growth. Air transport expansion is linked to economic expansion of emerging markets [17].

Although it is generally thought that low-cost airlines enabled more people to travel, the researches of Civil Aviation Authority (CAA) have shown there were no significant changes in passenger structure compared to 1990s. There was an increase in the number of passengers due to low-cost airlines, but LCA users are still mostly the ones with medium to high purchasing power, who can now travel more often and go on shorter trips [18]. The first so-called low-cost airlines occurred in the USA in 1978, after adoption of US Deregulation Act. After that, they occurred in Australia in 1990, Great Britain and Ireland in 1995, Canada and New Zealand in 1996, Japan in 1998, the EU in 1999, while in the rest of the world they occurred after 2001 [19].

Common features of the majority of low-cost airlines are: high aircraft utilization, internet booking, use of secondary airports, minimum cabin crew, lower wage scales, lower rates of unionization among employees, one class of seating thus allowing more seats per aircraft than traditional airlines, short ‘on the ground’ turn around times, no cargo carried to slow down turn around times, a simple fare structure and pricing strategy, e-ticketing, no seat allocation, passengers having to pay for food and drink, flexible working terms and conditions for employees relative to traditional airlines, point to point services and no connections [19].

An additional factor enabling cost reduction for airline companies, and thus lower ticket prices for passengers, is the fact that there is only one class of seating and therefore only one type of service; also, airline companies do not depend on travel agencies and do not pay commitment fees, telephone or online reservations can be made, point-to-point tickets are sold, no connections are possible (simplifying luggage handling and planes turnaround), no tickets are printed; there are no frequent flyer programs, and non-integration into alliances is the rule. Moreover, when a flight is cancelled or delayed, travellers usually do not get compensation. Since many low-cost airlines are not members of IATA (International Air Transport Association), they are not obliged to meet the quality standards imposed upon other airline companies [20].

Liberalization of European air transport resulted in a fast increase in the number of low-cost airlines because lower costs of air transport enabled a development of new tourist markets [21]. According to UNWTO data, more than a half of tourists (52%) in 2012 (the total number of tourists being 1.035 million) arrived in the destination by means of air transport. It is estimated that air transport will still increase, with a faster rate than land and water transport [22]. At the same time, there has been an increase in the number of young people and students who travel by air, which is an occurring trend among the young. In 2007, 16% of them travelled by air, while there was a significant increase in 2012/2013, with 26% of the young travelling by air, which was also a result of the growth in the LCA offers [23].

According to the data provided by European Low Fares Airline Association, from June 2012 to July 2013 Ryanair carried 79.9 million passengers (39%), the total number of passengers being 206.8 million carried by 10 LCAs. Second best air carrier according to the number of passengers was easyJet with 60.2 million of passengers. In June 2013 the average number of flights for Ryanair was 1600, to 180 destinations and 26 countries [24].

LCAs stimulate the development of city tourism, weekend tourism and short-break tourism as well as the development of new potential destinations [25].

A research by O'Conell and Willams has shown that LCAs attract a large number of young travellers (unlike other companies), their clients are more often groups than individuals, the self-employed, and main reasons for their travelling are visiting friends and relatives (VFR), vacation and short trips. Also, the research has shown that 31% of Ryanair's passengers stayed in hotels. The European Travel Trade explains this by stating that passengers with lower-priced tickets spend their savings on a more luxurious accommodation, such as hotel [26]. This results in an increase of various motivational factors for travelling and more common journeys for private reasons (vacation), but also in acquisition of new market niches, such as the market for cultural tourism, second home market, pensioner journeys, etc.

Competitive advantage of LCAs is seen also through the use of direct sales channels, such as web sites. Researchers have shown that passengers search available reservation channels for purchase of lower-priced tickets

even in countries with no high usage of Internet [26]. A research on the use of IT technologies in air transport from 2013 has shown that more than 90% of passengers think new technologies help them with their journeys. In 2013, 69% of passengers made an online ticket reservation, and 20% used a kiosk check-in on the day of the journey [27].

Passengers want to use IT during their journey, especially if this will make their journey easier or their costs reduced. Therefore, LCAs will definitely expand their market gradually. Along with this, it is obvious how LCAs' competition is unable to implement new technologies and IT innovations.

IV. RESEARCH METHODOLOGY

The aim of the research was to define the profile of the tourists in Zadar County and the profile of tourists using the LCA services, to compare their features as well as ways of their Internet usage for gathering information about destination and for organization of journeys. We have chosen Zadar Airport for an analysis of LCA users.

Zadar Airport and Zadar County have been chosen due to their LCA-user-oriented tourism. Zadar Airport is one of Ryanair's bases, which enabled business development of this airport. LCA started their business in Zadar Airport in 2002. Statistical data of Zadar Airport show a more significant increase in air transport only after 2007, with the occurrence of Germanwings and Ryanair.

The data available show an increase in the number of Zadar Airport passengers from 39.244 for 2001 to 472572 for 2013 (12 times larger number). There was also an increase in the number of airplanes, from 1 226 in 2001 to 4 050 in 2013 [28].

For the purpose of this research, a structural questionnaire was given to tourists (no matter which transport they used to reach to the destination) in Zadar County (including most cities and villages of the county). The research was conducted from August to September 2012, and then from May to August 2013, using random sampling including 1.697 tourists. The questionnaire was offered to tourists in eight languages. All questionnaires were filled out in the presence of a researcher.

An additional research using a structured questionnaire in English, German and Croatian was conducted on a sample of 900 LCA tourists from May to October 2013 on outbound flights at Zadar Airport. All questionnaires were filled out in the presence of a researcher.

The results obtained in the primary research were analyzed at two levels: in terms of the total number of tourists a segment of LCA tourists was also observed, and for the complete information on LCA tourists the data were obtained through an additional examination of only this segment of tourists.

The data obtained were processed in an SPSS program using methods of descriptive statistics.

V. RESEARCH RESULTS

In its strategic determinants, Zadar County has recognized the importance of LCA for its airport. Therefore, according to internal data of Zadar Airport, depending on the planned number of passengers, Zadar County invests additional financial resources of the overall tourist offer of the County in promotion of the destination on Ryanair web sites, in the form of joint marketing.

The research has shown 11.3% of total number of tourists in Zadar County chose LCAs for their air carriers on the way to their destination, while most of the tourists came to the County by car (53.4%). Average tourists (29.4%) as well as LCA users (28.1%), who chose Zadar County for their vacation, point out the main motive for doing this was enjoying the sun and the sea: with regard to the primary motive, the basic difference between these two categories is the motive of nautics. Nautics is the primary motive for travelling for only 0.7% of average tourist, while even 7.7% of LCA users point out nautics as their primary motive for travelling. Many researches [29] find that nauticians are guests with a higher purchasing power, thus, we can conclude that LCA use is not conditioned by reduced financial resources for vacation. Also, we should not neglect the fact that 3.3% of LCA tourists more than average tourists decide to go to this destination because of the favorable offer. In the framework of the research of secondary motives for the choice of destination, it is shown how even 13.3% of LCA tourists consider the destination of Zadar to be near, although the most of the respondents were from Great Britain (41.1%).

When analyzing both categories, word-of-mouth referrals present the most important channel in getting first information. Although previous researches showed LCA tourists obtained first information about the destination of Zadar mostly via Internet (50.78%) [30], today the primary source is the information obtained through relatives and friends (57.1%), while 22.6% of respondents point out the Internet as their primary source of information.

Both categories analyzed mostly obtain information about the destination via Internet. An average tourist obtained the information about Zadar County in 56.9% cases, while 76.6% of tourists using LCA services obtained the information via Internet. LCA tourists only in 4.2% cases say they needed no information about the destination, thus presenting the most informed group of tourists. Compared to this, 11.7% of tourists using land public transport believed they did not need information about the destination upon coming to the destination. Both groups mostly visited web sites of Croatian National Tourism Board at all levels (from state level to local level) (Figure 1).

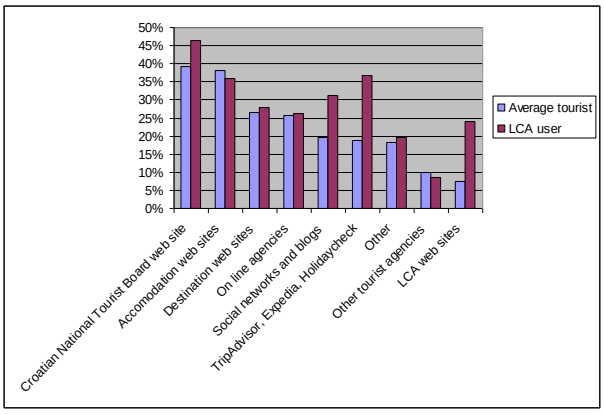

Figure 1. Web sites used for gathering information about the destination

Mostly, in the title of web sites of tourist offices there is the name of the destination, which makes tourists visit the web sites more often as these destinations are the first to appear when entering the name of the destination in Google browser, which shows other web sites visited. The data obtained are different from those from Miller's research, according to which 61% of tourists use the Internet often or always in planning their journeys, a relatively small number of tourists visit the destination's web sites, and the most visited web sites are the ones for searching accommodation in the destination [31]. Graham and Shaw [18] point out that some of the fundamental principles in LCA business are sophisticated web sites with detailed information about destination. Among all respondents, LCA tourists more often visit LCA web sites (21.5%) in order to gather information about destination compared to all other modes of transport and compared to average tourists (7.5%). Most visited LCA web sites are Ryanair's sites (77.0%), as expected because of the flight structure in Zadar Airport.

A great increase in the category of social networks and blogs during past five years has opened up new possibilities of the destination in its communication with tourists.

Among all respondents, there can be seen a significant difference in the usage of social networks and blogs in terms of modes of transport. 50.1% of LCA tourists gather information about the destination via social networks, while 20% of all users of other modes of transport (camp tourists - 8%) gather the information via social networks. An additional research among LCA tourists has shown that relatives and friends are the most important source of information about accommodation, too (53.6%), while the Internet is their second source (including digital media - 39.5%). Web sites of tourist offices are the most common source of information about accommodation here too (31.7%), followed by web sites of the airport (8.7%). The percentage of other answers (59.7%) is divided among various other web sites: booking.com, Ryanair, hostel world, hostel booking, tripadvisor, etc.

Gathering information about the destination opens up possibilities for attracting tourists or for usage of the overall tourist offer of a destination. LCA tourists have significantly higher net monthly incomes than average tourists. While monthly incomes of an average tourist visiting Zadar County are mostly (43.8%) below 1 000.00 EUR, monthly incomes of LCA tourists are mostly (27.7%) above 3 000.00 EUR.

Vacation organization has changed completely during past 30 years. While organized journeys were typical of 1980s, today the most common type of a journey is an individual journey. One of the preconditions for such a trend is definitely the development of the Internet.

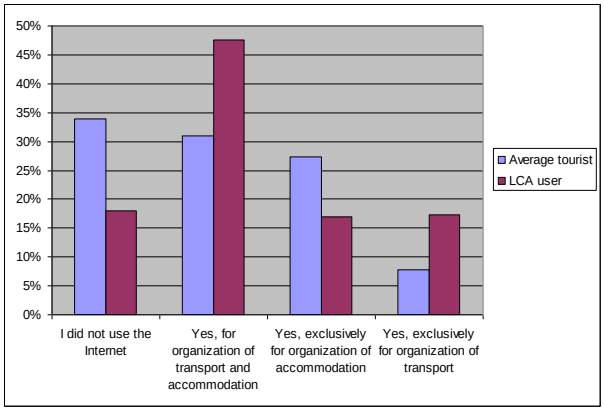

Figure 2. The usage of the internet in the organization of a vacation

As Figure 2 shows, LCA tourists use the Internet for the purpose of their vacation organization more often than average tourists. Only 18.1% of LCA tourists did not use the Internet in the organization, compared to 33.9% of average tourists not using the Internet. LCA tourists not using the Internet are not decision-makers as they are a journey accompaniment. An additional research among LCA tourists has shown that 20% of the users did not make accommodation reservation before their arrival. The largest number of the tourists (36.6%) made an online reservation via web site of accommodation objects. 16.2% of the users made an online reservation via some other web site, and 13.2% via e-mail. These data show a strong prevalence of the Internet as a distribution channel in accommodation tourism objects.

The Internet as a medium has enabled a simpler journey organization, therefore it is expected for the tourists with an Internet access to feel more satisfied with the destination, to recommend the destination and to stay loyal to it.

Table 1 shows indexes of satisfaction and desire to return to the destination according to the level of Internet usage in organizing the journeys. The significance of the differences among groups with various levels of the Internet usage in organizing accommodation and the overall satisfaction with the destination, destination recommendation and return to the destination has been verified by a variance analysis. F-ratios are significant in terms of the overall satisfaction with the destination ($F=11.178$, $p=0.000$), return to the destination ($F=5.385$; $p=0.001$), and destination recommendation ($F=38.889$; $p=0.000$). Therefore, it is concluded that there are

significant differences in terms of the desire for return to the destination and destination recommendation according to the level of Internet usage in organizing the journeys.

TABLE 1. RATIO OF SATISFACTION AND LOYALTY IN TERMS OF THE INTERNET USAGE IN ORGANIZING THE JOURNEYS

	Usage of the Internet for the organizaation	*Mean*	*Std. Deviation*	*Std. Error*
Overall satisfaction with the destination	Accommodation and transport	83.00	14.84	0.65
	Accommodation	84.37	15.16	0.71
	Transport	84.11	15.16	1.34
	I did not use it	85.15	15.81	0.66
	Total	**85.21**	**15.43**	**0.38**
Destination recommen-dation	Accommodation and transport	85.88	15.61	0.68
	Accommodation	85.06	15.53	0.73
	Transport	84.72	16.34	1.45
	I did not use it	88.66	16.73	0.70
	Total	**86.51**	**16.10**	**0.39**
Return to the destination	Accommodation and transport	42.75	29.27	1.29
	Accommodation	51.50	30.69	1.44
	Transport	44.79	33.81	2.99
	I did not use it	63.18	35.12	1.48
	Total	**52.22**	**33.18**	**0.81**

T-test analysis has shown significant differences between Internet users and non-users in organizing the journeys as well as in the categories of the overall satisfaction with the destination, desire to recommend the destination and loyalty to the destination. An analysis of the overall data shows Internet non-users are more prone to return to the destination (63.18 index points) than Internet users (46.6 index points).

Furthermore, it is expected that using a cheaper and faster air carrier makes journey easier and increases the satisfaction with staying in the destination, desire to recommend the destination and to return to the destination.

TABLE 2. AN ANALYSIS OF THE USAGE OF THE INTERNET IN ORGANIZING THE JOURNEYS AND SATISFACTION WITH AND LOYALTY TO THE DESTINATION, T-TEST

Internet usage		**Variances**		**t-test for Equality of Means**				
		F	***Sig.***	***t***	***df***	***Sig. (2-tailed)***	***Mean Differ.***	***Std. Error Differ.***
Overall satisfaction with the destination	Yes	16.18	0.00	-5.61	1645	0.00	-4.46	0.79
	No			-5.52	1082	0.00	-4.46	0.80
Destination reccomme-ndation	Yes	5.71	0.01	-3.90	1648	0.00	-3.26	0.83
	No			-3.82	1061	0.00	-.326	0.85
Return to the destination	Yes	37.09	0.00	-9.87	1645	0.00	-16.57	1.67
	No			-9.45	1000	0.00	-16.57	1.75

Table 3 shows indexes of satisfaction and desire to return to the destination in terms of modes of transport. Moreover, the significance of the differences between the groups in terms of modes of transport used to get to the destination and the overall satisfaction with the destination, destination recommendations and return to the destination has been verified by variance analysis. F-ratios are significant in terms of return to the destination (F=6.896; p=0.000) and destination recommendations (F=4.342; p=0.005), while there is no significance in terms of the overall satisfaction with the destination (F=2.199; p=0.096). Therefore, it is concluded there are significant differences in the desire for return to the destination and destination recommendation in terms of the modes of transport used to get to the destination.

TABLE 3. RATIO OF SATISFACTION AND LOYALTY IN TERMS OF MODES OF TRANSPORT TO THE DESTINATION

		Mean	*Std. Deviation*	*Std. Error*
Overall satisfaction with the destination	Own transportation	85.46	15.80	0.47
	Airplane - LCAs	86.13	11.78	0.85
	Land public transportation	82.90	16.86	1.09
	Other public transportion	85.62	14.52	1.23
	Total	**85.19**	**15.46**	**0.37**
Destination recommen-dation	Own transportation	86.35	16.30	0.49
	Airplane - LCAs	89.34	12.04	0.86
	Land public transportation	84.08	18.47	1.18
	Other public transportion	88.07	13.68	1.16
	Total	**86.51**	**16.06**	**0.39**
Return to the destination	Own transportation	55.04	33.24	0.99
	Airplane - LCAs	48.35	31.98	2.29
	Land public transportation	47.90	32.62	2.11
	Other public transportion	45.22	35.44	3.02
	Total	**52.44**	**33.37**	**0.81**

VI. CONCLUSION

LCAs have introduced significant changes in the overall market of transportation services. This has especially reflected on tourist journeys now characterized by acceptable prices of air transportation and easy accessibility of any destination. LCA business system is oriented towards Internet as a distribution channel. The research has shown that LCA tourists use the Internet more often than average tourists when it comes to gathering information about the destination. Mostly visited web sites are those of tourist offices, and LCA tourists gather information via social networks more than average tourists. LCA tourists are guests with above-average monthly incomes, and their motives for the journey are the same as the motives of average tourists, except in the segment of nautics, considered to be the main motive for LCA tourists' visit to the destination. LCA tourists make online accommodation reservations more often than average tourists. Mostly, they visit the web sites of the accommodation tourism object. Both categories analyzed point out a high level of the overall satisfaction with the destination, while in terms of destination accommodation and return there is a lower

level of agreement but more significant differences among categories of tourist coming to the destination by different modes of transport. An analysis of the level of satisfaction and loyalty of the tourists who use the Internet for the purpose of journey organization shows a significantly higher Internet non-users' level of satisfaction.

Abstract - The paper analyzes information security investments from both economic and financial points of view. Authors research special characteristics of information security investments and the difficulties which appear during the determination of input parameters of the economic analysis. Challenges in application of internal rate of return method are also analyzed. The constructed model of cash flow analysis of information security solution investments shows the feasibility of calculating the net present value, internal rate of return and the return on capital when using such an approach.

I. INTRODUCTION

Within the usual paradigm of business financing, the investment value of assets (which are owned or controlled by an enterprise and which produce certain revenue) is evaluated against the related costs (for example, maintenance, or procurement of raw materials). Assets are usually divided into material assets (machinery, buildings), non-material assets (patents, software, goodwill) and a special form of assets capable of intrinsic reproduction, called financial assets.

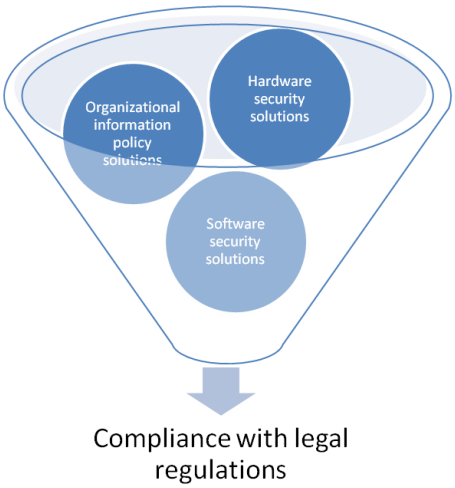
One of the tools most often used by financial managers is determining whether the Net Present Value of assets is positive by using the marginal capital cost, relevant for a certain type of business or certain type of entrepreneurial undertaking.

Information Security Management Systems, or ISMS, (technically speaking) consist of the following four components, organized in a hierarchical manner:

1. Organizational forms ensuring the compliance with legal regulations
2. Organizational information policy, or the knowledge of users and management regarding the functioning and managing of ISMS's, resulting in adequate application of risk removal techniques by using hardware, software and orgware, often formalized by security certification (e.g. ISO 27001:2005),
3. Computer hardware (servers, switches, computers, network devices, routers),
4. Computer software and applications.

The relation between the above mentioned components is shown in Figure 1.

Figure 1. Interaction between different solutions used to achieve the goals of information security



source: authors

All of the above mentioned components are related to a certain level of cost, where there is a high level of solution substitutiveness, meaning the treatment of capital investment or operative cost. Almost all modern ICT solutions, especially in complex corporate environments, can be obtained in a form which can be considered either as an investment or as operative cost [1]. For example, instead of purchasing computer applications, they could be rented or leased as a SaaS (Software as a Service) model. Instead of purchasing computer hardware, it could be rented or leased as a Cloud. Several issues can be identified while tackling difficult choice of investing in own information security assets in comparison to leasing the solution:

1. On a technical level, such divergence of possible solutions could create problems in terms of constant demands for additional education, arising from quickly changing technologies.

2. On an economic level, the total investment cost can further be obscured.

3. On an operative level, a whole set of additional costs exist, related to the setup and functioning of ISMS (application costs, ICT infrastructure etc.).

Furthermore, other costs related to information security can occur in enterprises, addressing the technical disciplines, such as the cost of training the personnel which implement information security technologies, the cost of training the employees for using the new technologies, etc. In terms of capital investments, the basic investment forms are related to security hardware, software, security telecommunication solutions, investments in ICT infrastructure, security studies and organizational blueprint implementations (among them also the applications of best practice models of ICT security).

The scope of this paper is only evaluation of the specific characteristics of the investment in ISMS, when such an investment is a part of enterprise's capital budgeting activity.

II. DIFFICULTIES IN DETERMINING THE INPUT PARAMETERS OF ECONOMIC ANALYSIS

When moving away from technical, technological and organizational aspects of ISMS and when approaching the investment aspect of such systems, a number of difficulties can arise when trying to determine the input parameters of financial analysis [2]. Some of the difficulties can be identified as follows:

1. The decisions about ISMS investments depend upon the risk assessment as a professional/specialist activity [3]. Practical risk assessment of information security is generally void of quantitative financial indicators, and is usually based on experiential assessment of the probability of unwanted occurrences and their impact on business [4], without quantifying possible damages. Risk assessment is an abstract technical assessment, providing the indicators which guide information security experts towards the fields which should be taken into special consideration in order to achieve the set business goals of information security [5]. Paradoxically, because of the lack of the detailed financial analysis (apart from the basic cost analysis), the management that deals with investments (without possessing the specific technical knowledge) often shows aversion towards the ISMS investments and implicitly takes unreasonably high levels of risks. [6] The reverse scenario is also possible, overinvesting in ISMS. This specific situation results from the traditional separation of information security, control and risk management processes from the corporate ICT management, which is generally more oriented towards the system efficiency assessment and towards ensuring the adequate return on investments [7].

2. The high level of substitutability of ISMS investments with the costs that can be considered as operative costs often complicates investment decisions. [8] Generally, such "alternative" solutions may seem acceptable, but superficial analysis often do not include numerous hidden costs, such as customer education costs, technical personnel training costs (the people which will work on solution implementation and maintenance [9]), etc.

3. Software, hardware and telecommunication solutions obtained as long-term investments by the enterprise usually imply the necessity of maintenance contracting [10]. Such contracts offer customer support through the lifetime of the purchased information security solution, but even more often it is impossible to use the solution without signing such contracts. In case that such contract has not been signed, certain hardware or software product may not be able to function properly (for example lack of security patches or similar problems which may occur during work). Regarding antivirus/antispam solutions or network devices with security characteristics, it would be impossible to receive instant definitions of certain attacks or related security profiles and definitions. Furthermore, it would be difficult to integrate a certain solution into ISMS, because its settings might not allow the integration or application to increased number of users or workplaces [11]. For that reason, when performing the initial input parameter analysis it is necessary to discern which part of the initial costs represents investments, and which part represents yearly maintenance. This should be done in order to correctly determine the total cost of implementation and exploitation of a certain ISMS.

4. It is difficult to correctly predict the real residual value of certain information security investments [12]. Some such solutions have a long lifespan (for example telecommunications and network solutions) and could be used even after being fully depreciated. The functionality of some systems might depend on the regular payments to the supplier, who is able to continuously upgrade and modernize a certain solution (which is especially applicable to software security solutions).

5. Small and medium enterprises often lack the specific knowledge necessary to adequately assess the influence of information security investments on enterprise performance [13].

III. CHARACTERISTICS OF INFORMATION SECURITY INVESTMENTS' ECONOMIC ANALYSIS

When analyzing the economic flow of ISMS solution, the structure of the source of financing is ignored (own assets or loan/financial lever) because the loan interest does not reduce the solution's economic potential, but enterprise's economic potential as a whole [14].

The classic investment economic flow analysis (or in this case the investment into information security infrastructure) calls for the initial assessment of effects reduced to market prices from the first year of the project duration [15]. Those items which reduce the economic potential of the project or solution are considered expenses. In this context, the expenses may be:

- Initial investments in information security solution or project
- Cost of project or solution maintenance
- Material expenses for using the solution (electricity, utilities)
- External services related to the solution (consulting)
- Training costs for solution implementation (permanent employees)
- Training costs for solution usage (permanent employees)
- Gross salary for employees in charge of solution implementation (reduced to full time equivalents)

When using the economic cash flow analysis of the information security solution, the problem of determining the income against determining the expenses can arise. Positive cash flow of such investments usually consists of the overall income during the solution lifetime and the estimated residual value at the end of the lifetime. [16] Such incomes can be properly defined only in enterprises who mainly provide security solutions to others, or who provide services to others and undertake the investment activity themselves.

All other enterprises do not derive income from information security solutions, but negative cash flow instances in cash flow analysis could be directly compared with the potential damage caused to the enterprise in case of occurrence of some security lapse during the usage of the security solution.

From the static point of view of such a model of modified economic flow, initially justified security investment would be the one in which the total, cumulative benefits (or the avoided cost of security problems increased by the residual value) is larger than the cost of security solution implementation [17]. Such situation is shown in Table 1.

IV. CHARACTERISTICS OF INFORMATION SECURITY INVESTMENTS' FINANCIAL ANALYSIS

Similar to the economic flow method, unmodified financial flow method [18] could also be applied to information security solution investments only if the enterprise holds such solutions as assets and leases them to other enterprises. Unlike the economic flow method, financial flow method also takes into account sources of financing [19] represented by cash inflow and obligations towards sources of financing (outgoing interest), shown in table 2.

Source: authors

The problem which appears when using the financial flow method is similar to the economic flow method – determining avoided costs. In the dynamic analysis, classical dynamic methods [20] could be used, as follows:

1. **Return on investment rate** – representing the simplest criterion of financial decisions regarding real investments. The method calculates the number of years necessary for the project (in this context, information security asset or system) to return the invested funds. In case that methodology calls for elimination of lack of incorporation of time value of money, discounted cash flow method will be used [21].
2. **Discounted period of return method** – the variant of the above method in which time value of money is incorporated in calculation.
3. **Net present value method** of investment in information security, represents the sum of present values of resultant cash flows related to the same information security solution.
4. **Internal rate of information security investment return** – representing the internal rate of return (RoR) reducing the pure cash flows of using the information security solution to the value of their investment flows [22].
5. **Profitability index** could be used as an added criterion of investment decisions. It represents the ratio of discounted pure cash flows of information security solution during its lifetime and the investment costs.

V. CHALLENGES IN APPLICATION OF INTERNAL RATE OF RETURN (RoR) METHOD

The classic analysis of the internal rate of return demands that the rate of return (leveling the investment with the pure cash flows) should be larger than the reference discount rate which is dependent on the risk level and the capital cost. [23]. Common problem with the multiple internal rates of return is usually not present in information security investments. According to the premise that the information security risks are present throughout the period of usage of the information security solution, and that the distribution of cash flows is identical (there is no change in cash flows, and last cash flow is not negative), the classic method of internal rate of return could be used.

However, when using the internal rate of return method in the analysis of information security investments, several facts should be taken into consideration [24]:

- This method could not be used when analyzing or comparing investments into multiple information security solutions, only when analyzing single investments due to the fact that the obtained results are not comparable
- The internal rate of return implies reinvesting the positive cash flow in projects or solutions that have the similar rate of return, whether it is the case of reinvesting in similar solutions or other comparable solutions. For that reason, the internal rate of return method will be used in evaluating those projects in which the reinvested cash flow is directed into projects with lesser rate of return [25]. This is especially true for security solutions or projects with high rates of return, because enterprises have difficulties in finding comparable reinvestment projects with equally attractive rates of return.

- As a rule, cash flows do not change from positive to negative and vice versa, and the last cash flow is never negative. Therefore, the problem of multiple internal rates of return should not exist.
- The internal rate of return method will only provide a relative calculation of return for a given security project or solution, not absolute.

The starting assumptions for the set model are as follows:

1. The initial investment in information security solution has been executed,
2. No opportunity costs exist,
3. Minimal residual value of the information security solution exists at the end of the solution lifetime,
4. The proportional depreciation method is being used,
5. Generated cash flow is estimated as the consequence of avoiding the occurrence of security incidents and connected direct and costs,
6. There is no tax credit,
7. Other investments related to introduction, implementation and usage of information security solution are treated as having fixed value and they are not depreciated during life time of exploitation,
8. It is estimated that variable cost exists during the lifetime of the security solution, expressed in relative terms compared to income,
9. The income tax is set as fixed during the observed period,
10. It is assumed that the working capital during the lifetime of the solution is annulled or fully depreciated (amounts to zero),
11. The discount rate is used as a direct discount rate. It is possible to calculate the discount rate within the model as it is calculated in the Capital Asset Pricing Model. [26] When doing so, risk free return rate, premium based on assumed market risk, cost of borrowing the capital and debt leverage have to be taken into account,
12. It is assumed within the model that the benefits from implementing the information security solution do not change through the years, in other words the benefits are proportionally distributed,
13. Fixed costs of solution maintenance during its lifetime do not increase; they are contained in the initial investment.

In this paper we will outline a possible practical application of the cash flow analysis in information security solution.

Input parameters of the proposed model consist of initial investment, represented by the value of investment in ICT security solution, opportunity cost of the capital, life span of the solution, scrap value, depreciation method, tax credit and non depreciated capital investments. Furthermore, required working capital is taken into consideration, so are generated cash flow, selection of the discount rate and alternative risk-free market going rate. Also, a possibility of loan and market capital borrowing rate is also anticipated - for simplicity reasons in the outlined model, investment is 100 % owned and external leverage is not used.

Finally, growth rates for implicit revenues derived from information security solution and fixed cost are set to zero, meaning they are omitted from the model. These parameters present input values of the model of cash flow analysis of information security solution investment project. The constructed model shows that by using the initial assumptions of the model it is possible to calculate the net present value, internal rate of return and the return on capital when using such a solution. Further simulations show that the internal rate of return is particularly sensible to the following input parameters [27]:

1. Time (duration) of using the information security solution,
2. Perceived (set in advance) ability of the information security solution to generate the positive cash flow during its lifetime,
3. Discount rate used.

Such model could be used in practice if the input parameters are correctly estimated. Judging from experience, the largest problem in forecasting is connected to the ability to assess the generation of the positive cash flow by avoiding costs related to the occurrence of security incidents.

VI. CONCLUSION

Enterprises and organizations which operate in the modern environment (especially in the service sector) are faced with the challenges of the modern dematerialized economy. Because of that, one of the new business functions arose in the last few decades – the business function of information security, augmented by the increased usage of networking and communication technologies. The roots of information security are in the defense sector and high technology sector, and it was firstly implemented by those enterprises which possess the advantage over their competitors because of new ideas, inventions and patents. Due to the increased number of threats, and the existence of information assets which could be compromised by those threats, even the smallest companies nowadays have to pay due attention to information security to avoid the occurrence of security incidents which could compromise the competitiveness and even the existence of such companies. Therefore, securing of the normal functioning of the enterprise by means of information security is no longer reserved for the corporate sector, it is equally important for small companies, all the way down to the level of individual entrepreneurs.

The demands for ensuring the satisfactory level of information security are also set by the legal system, trying to regulate and to positively influence the companies which have a strategic interest to the state, primarily the financial sector. Such demands are the legal requirements which those companies have to meet. As a rule, such

demands are not imposed on other companies, they have to assess themselves (according to their business plans, financial and human resources and risk assessment) the profitability of information security investments. When doing so, the benefits of information security system implementation are primarily compared to implementation and maintenance costs. According to this evaluation, investment decisions should be made. The estimation of total cost of implementation and maintenance of the information security solution is further hampered because of the different ways of achieving such goals: it can be achieved both by capital investments (real investments) in information security solutions and by presenting information security solutions as "running costs" or maintenance costs. Suppliers of information security solutions are trying to adapt the solution functionalities to fit various customer needs and their financial abilities at the given moment. In any case, information security solutions carry with them substantial maintenance costs.

The main problem when deciding about investing in information security solutions is how to decide between the two opposite investment viewpoints. The first, techno centric viewpoint, is often advocated by information security experts employed in an enterprise. Their primary focus is on risk assessment, so when trying to minimize security risks they sometimes suggest uneconomic information security investments. On the other hand, enterprise management as a rule lacks understanding of the technical aspects of information security and would prefer that such investments are avoided, because the necessary input for argumented decision making is often not presented to them, while they are concerned primarily about benefits of information security solutions for the enterprise as a whole. A key factor when investing in information security solutions is to find the balance between the techno centric and financial perspectives. In reality, the scales are usually tipped to one side, and the misbalance will either cause reduced business performance of an enterprise or implicit exposing to high levels of risk related to information security.
as shown in this paper, when deciding about information security investments, classic methods of economic and financial (cash) flow can be used. A problem of determining input parameters arises, and similar to usual models (investing into manufacturing equipment, project investments), the largest problem is determining the "income part", which can be identified as "avoided damages" in the case of security incidents which could happen if the information security solution is not implemented. Such a model has been proposed and empirically documented using proprietary data. Related data is often not publicly available, and even the specialized consulting firms do not have them, because such data is extremely dependant on the type of business and type of enterprise. It might be only partially available for financial institutions, because of legal regulations regarding financial information security. The method which could be used is a modified Internal Rate of Return, adapted to suit the information security paradigm, with the input parameters modified to specific demands of investing in information security.

Abstract - Numerous stakeholders are involved in operations of modern Port Community Systems: container terminals, customs, border police, coast guard, government ministry in charge of sea traffic and infrastructure, seaport agents, port authorities etc. Traditionally, all of these entities use separate and heterogeneous business information systems. Integration of these complex systems presents a challenge: the common goal should be the creation of one interconnected system, able to provide all vital information to various stakeholders while being efficient, financially viable and avoiding data and process duplication. In this paper, the authors will present main characteristics of existing seaport cluster information systems, their possible overlapping dependencies and initial component analysis, as a basis for decision-making related to architecture of future Port Community Systems.

I. INTRODUCTION

This paper is an introductory research into characteristics of seaport clusters, based on technologies and organization used in Republic of Croatia at the time of research (2013.). Various stakeholders (container terminals, customs control, police, port authorities, port agents etc.) utilize different ICT systems that should be thoroughly analyzed before integration into integral business information systems of the port clusters (PCS – Port Community Systems). In order to fully understand the complexity of the different systems, it is important to outline and study them [1]:

- Concession owners use heterogeneous ICT systems and their inclusion in one single system can incur elevated levels of risk imposed on information and integral security.
- Port authority and concession owners have to be organized in a way to be aligned with ISPS code (International Ship and Port Facility Security Code). ISPS code development is caused by increased number of hijackings and attacks on vessels and ports.
- Handling of dangerous cargo, its packaging, labeling, storage, separation and emergency procedures have to be in charge with IMDG code (International Maritime Dangerous Goods Code).
- Port authority is performing tasks related to safety and oversight in those segments that are related to uninterrupted traffic flow in areas of their responsibility and it is involved in search and rescue operations and inspections.
- Traffic tracking in port area is accomplished by using modern VTMS system that utilizes GPS equipment.
- Service user oversight is performed by usage of ID cards and integrated business information systems.

Integration of ICT systems in complex environments like seaports is a challenge for all subjects involved in port operations. It involves not only the creation of physical and logical networks and connections, lifeware and orgware, but also control from a single point over all delivered services, while respecting all basic principles of disaster recovery and business continuity.

II. THE PURPOSE OF SEAPORT INFORMATION SYSTEMS

Port information systems serve the following purposes [2]:

- To increase the speed of cargo loading and unloading operations.
- To adjust the duration of physical and administrative operations in order to provide services to users and to speed up the traffic and enable optimal usage of the port's infrastructure.
- To provide information systems support to stakeholders, equally for basic applications and extranet portal used by external stakeholders.
- To create relations toward external databases.
- To manage the information flow by enabling connections between stakeholders and using different information sources while ensuring information security and confidentiality.
- To manage the infrastructure by optimizing critical resources.
- To optimize cash flow by simplifying the accompanying documents.

Preliminary research has shown that the achieved level of development of port community systems in Croatia is modest in terms of their use in management of port facilities. Identified reasons for this condition are:

- The general issue of inadequate rate of ICT technology implementation in comparison with the speed of its overall development.
- Inadequate level of knowledge and adjustment ability of the entrepreneurs and the management caused by rapid scientific and technological development.

- Lack of knowledge and understanding of ICT technologies as major economic resources.
- Inadequate level of employee education and low levels of ICT investments.

However, most stakeholders inside the seaport cluster own and use information systems as part of their daily and routinely executed operations. These systems are diverse, mainly because of size of the company, operations and characteristics of the branch the company is operating in.

III. CONTAINER TERMINAL ICT SYSTEMS

Information flow and exchange in modern container terminals is complex. Cargo agents are exchanging all necessary messages with the container terminal operators, who are in turn exchanging messages with the authorities (customs, port authority). Information is accessible also to cargo haulers, trucking and railway cargo companies and other terminals the cargo will reach in the future. Information systems of container terminals are in fact systems used to operate the transport of goods stored in containers that involves computers, clients, servers and networks, with intention to collect the data about transport process, information processing, decision making, creation of messages and documents, order and document transmission and actions. In order to facilitate flawless transport process, it is necessary to understand crane and container timing and bottleneck analysis. This role is nowadays entrusted to management information systems that enhance automatization of the container terminals. Enhancement of the cargo transport inside terminals can be achieved in the following ways [3]:

- Introduction of the communication network inside terminals with a complete centralized database.
- Correct evaluation of duration of cargo transport and loading-unloading operations.
- Development of the automatic operations management (driverless vehicles, cranes without operators).
- Inclusion of the system buffers.

The most important function of ICT in the container terminal operations is creating the possibility to connect container terminals with other port community stakeholders, therefore creating an electronic community of the whole seaport system (Port Community System). Container management system that is well envisaged and possesses the proper architecture can increase terminal efficiency, with the main benefits being [4]:

- Faster container unloading and loading with increase of productivity,
- Better container storage oversight,
- Higher percentage of correct data and valid information.

Container terminals typically use TOS (Terminal Operating Systems), computerized systems used to enhance the process of cargo management. TOS basis is several decades old, but it is still in use today, even though heavily modified and modernized. Usage of the TOS system enables the terminal management to follow up individual container status (size, weight, type, content, special instructions), resources (free operative area, equipment location), limits (characteristics of the operative area and required equipment) and processes (optimal container placement and loading priorities).

ICT systems typically used in container terminals are the following [5]:

- Gate System, used to control and identify containers, perform X-ray checks and detect trucks,
- Corporate System, used for business functions, to analyze human resource deployment, create accounting and financial reports for the management,
- Engineering System, used for implementation of technological innovations on transport utilities and malfunction diagnostics,
- Anciliary System, used for management of empty areas and container repair,
- OCR Handling System, the system used for container tracking based on optical recognition and tag reding,
- Equipment Control System, follows up the equipment, current position of the cranes, controls RFID readers,
- Equipment PLC/SCADA System, used to track and control cranes and AGV (automatic guided vehicles) [6],
- Information Technologies Analysis and Design System, top-level system that manages all other elements of the hardware and software, and
- Community System that connects all stakeholders in the seaport cluster by exchanging information and electronic messages.

As a conclusion, advantages of introduction of ICT systems and electronic data exchange systems in container terminals are timely information collecting, data organization, ability to accept large amount of information, possibility of implementation even in smaller terminals, simple data disclosure, less document errors and decrease of volume of paper documents and required staff support.

IV. CUSTOMS CONTROL ICT SYSTEMS

Customs control documents were traditionally filled manually and stamped by persons in charge, resulting in slow data processing and occurrence of errors. In 1995. the customs has started importing data using magnet media (floppy disks). Since year 2000, the goods that are a part of customs procedure can be processed using electronic data exchange. The first step to implement this type of data and form management was creation of the Web application for customs declarations, that has enabled participation of importers, exporters and haulers. Every such declaration can be submitted even outside of customs working hours, and is formally and logically controlled before submission.

Further step in development of the customs informations system was completed as a part of PHARE 2005. project that has strengthened abilities of Croatian customs to achieve alignment with EU standards. Three such systems were subjects of development that ensured full compatibility and interactivity with EU information systems [7]:

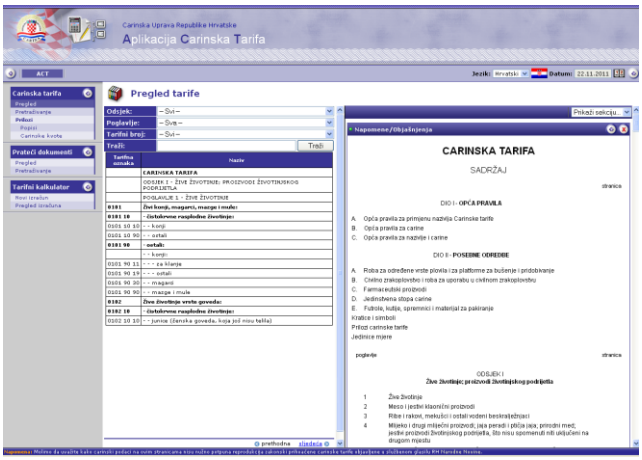
1. TARIC (acronym for French „TARif Intégré de la Communauté“) is a database of all customs fees related to imports, exports and applicable tariffs dependent on the tariff code of the goods
2. NCTS (eng. New Computerized Transit System), necessary for insurance of transit goods, and
3. EMCS (eng. Excise Movement Control System), required for efficient control of goods subjected to excises (alcohol, cigarettes, fuels and electric energy).

Development of these systems was done in six stages and three twinning projects. Execution of Phare 2005. project started in September 2007. and was completed by July 2009.

Phare 2006. project had a goal to ensure full compatibility and functioning of the information systems with customs systems of the EU in the areas of customs tariffs, customs transit control and export of goods subjected to excises.

One of the main results of the above mentioned projects was the creation of “Customs tariff” application, which is shown in Fig 1.

Fig. 1: Customs tariff application in Republic of Croatia



The customs has also created a procedure named Rules of usage for electronic data exchange system and service delivery of the e-business of Ministry of finance, customs (e-Customs), that governs the basic principles for data exchange and delivery of services of Ministry of finance, customs and all users of the electronic date exchange system, based on laws and regulations related to customs, excise, taxation and official statistics. Since 1st November 2011., NCTS, the first electronic system of business operations on the national level has started operating [8]. It enables uninterrupted transit of goods under customs supervision, and it is iat the same time the first interoperable trans-European customs system. Development and implementation of a fully functional NCTS system was one of the main conditions EU Commission has assigned to all EU member states, so Republic of Croatia has opted for its own NTA (National Transit Application) that supports all NCTS functionalities. With implementation of the NCTS system, entered data is the only legally accepted evidence, in comparison to old system where paper declaration was treated as a legal warrant.

V. BORDER (MARINE) POLICE ICT SYSTEMS

ICT systems used by the border (marine) police are specific by nature. They have to adhere to the highest information security standards, and use a number of legal, organizational, logical and technical measures and standards in order to protect information confidentiality, integrity and availability. They are executed through five recognized areas of information security: background checks, physical security, data security, information system security and business cooperation security). Implementation of these measures ensures alignment with NATO and EU security politics [9].

NBMIS (eng. National Border Management Information System) is a new tool for efficient border control that at the same time ensures flawless traffic of people and goods. It was built by using EU CARDS program (project 2002. NBMIS). The project that is enhancing this system has started in 2010 and was completed at the beginning of 2012. The goal of the project was to upgrade and expand functionalities of the NBMIS application and develop a mobile platform. New equipment was installed in 25 international border crossings (11 road crossings, 5 sea crossings, 4 airport crossings, 4 railway crossings and 1 river crossing). The system operates by using the principle of reading bar code on travel documents and enables police officers to check the passengers in a quick and efficient manner.

ANPR (eng. Automatic Number Plate Recognition) is an additional subsystem that during the border crossing checks whether the vehicle was stolen and whether it is properly registered. The system takes a photo of the vehicle and checks all data related to the vehicle. If some irregularities are identified, the system will alert the police officer.

Another important system that will have to be implemented is SIS (eng. Schengen Information System). SIS is a database of European countries that stores information about people and goods. The purpose of this system is to safeguard national security, control borders and support the rule of law. Second generation of the SIS (SIS II) will contain warnings about people and objects and it will be used by the border police, customs control and state bodies issuing visas [10]. SIS II consists of the central system (Central SIS II), national systems (National SIS II) in all member states that will exchange data with Central SIS II and communication infrastructure between central and national system that will ensure encrypted data exchange. Every member state has to provide a national S.I.Re.N.E. office (Supplementary Information Requested at the National Entries), according to preset conditions. The role of these offices is consulting, notification exchange and implementation of checks and safeguards in order to avoid multiplication of warrants and priority setting.

Also, a manual was issued in form of set of guidelines, general and special procedures that have to be followed by authorized instances in order to exchange information about entry or residence denials, arrests and extraditions, missing persons, legal procedures, discrete and specific checks and objects that have to be temporarily confiscated because they might be used as evidence [11].

VI. MINISTRY OF MARITIME AFFAIRS, TRANSPORT AND INFRASTRUCTURE ICT SYSTEMS

Ministry of maritime affairs, transport and infrastructure is managing several information systems, whose purpose if the oversight and management of the maritime traffic, its safety, collection and distribution of the meteorological information. One such system is the VTS (Vessel Traffic Service), established in order to enhance traffic safety and efficiency and protect sea environment. This system has to provide information to all who participate in sea traffic in the area of VTS surveillance. This role can be divided in three different categories:

- provisioning of the information to ships in the area of VTS (information services)
- provisioning of the assistance in navigation through VTS area (navigational assistance services), and
- organization of the sea traffic in the area of VTS supervision (traffic organization services)

VTS consists of a set of Croatian and international regulations that ensure safe traffic on rivers, lakes and seas, practically executed by VTMIS (Vessel Traffic Management and Information Service). This service has been put in the spotlight of the system by a law passed in 2008. Also, establishment of the VTMIS service was the obligation of the Republic of Croatia, as a part of accession process to the EU.

VTMIS is a complex technical and information system whose purpose is to track, manage and organize overall sea traffic. It consists of Coastal Automated Identification of Ships System, VTS Radar System, maritime radio-communication system and other systems that enable insight in sea conditions and interaction with all involved stakeholders.

Project documentation shows that VTMIS has to contain one or both of the following elements:

- electronic data exchange and service provisioning towards the immediate environment, region or remote subjects (horizontal data exchange),
- electronic data exchange with other sea traffic subjects – officials (vertical data exchange).

VTMIS system is financed within PHARE 2006 program of the EU in amount of 75 % of the total project cost. Republic of Croatia has started VTMIS activities since 2004. In 2005. and 2006. the first phase was successfully completed when AIS system was put in service. This system is used to automatically identify ships. Full coverage was achieved in 2006. by creation of five AIS base stations. In second phase, additional 13 base stations were made functional and the system has achieved total area coverage. Data collected by VTS operators is forwarded to the police and customs, but only the Ministry is operating the system.

AIS (Automatic Identification System) is based on SOLAS convention [12]. It operates on maritime VHF band and transmits static and dynamic route data. Static data is entered manually, and it includes MMSI ship identification number, IMO number, name and call sign of the ship, its length and width, type, and antenna location. Dynamic data is entered automatically, and it requires integration with ship's navigation equipment installed on the bridge. This data includes ship's position, course, speed, several sets of technical data and navigation status. The purpose of AIS system is ship identification, tracking assistance, simplified data exchange and collision avoidance. AIS system is primarily aimed towards enhancement of the VTS service.

VII. PORT AGENT ICT SYSTEMS

Port agents are shipping company's representatives and they perform all formalities related to ship being in the port. Port (shipping) agent is in fact a shipping company's representative in seaports where the company does not have its branch or office. Agent conducts all business in the port on behalf of the shipping company. Port agents use information systems which are usually based on server/client technology. ICT equipment of the system can be integrated in the port information system, so data and information are distributed using standardized documents.

Agent information system consists of several modules or databases:

- Docking database, contains data about ship's docking, from its announcement, to accounting and archiving,
- Cargo database, includes separate tracking of announced and really performed offloading cargo operations, including related data: operations, cargo type, units, quantity, code and description
- Database of advances, contains data about requested and paid advances with related data: date, obligated party, requested amount, paid amount, type of payment, bank, document number, date of payment, notification
- Database of ships, contains data related to the ship, its code, flag, owner, port of origin and the following data: Call Sign, Gross Tonage, Net Tonage, Deadweight, Length Over All, Summer Draft, Max. Draft, Air Draft, Vessel Type, Built, Capacity: Grain, Bale, TEU, IMO No., notification.
- Code database, contains data about the flag according to ISO standard, port according to UN's port code list, information about cargo, currency, type of docking, business unit and packing type
- Event database, contains all data related to important events on the ship and in its surroundings that are neccessary to create document called Statement of Facts: date and hour of the beginning of the event, code and description, responsibles, warehouses and notifications
- Database of costs, follows up all costs and accounting of the ship and contains also agent costs that will be transferred to the Disbursemenet Account.
- Business partner database, a database of all business partners that work together with the agent.

Agent business information system usually has a graphical user interface (GUI) for data entry and applications used to print various documents that agent process produces, like cargo and freight manifest, invoicing, credit notes, statistic reports and other.

VIII. PORT AUTHORITY ICT SYSTEMS

Port authorities in Republic of Croatia use several ICT systems, where some of them (like VTS and VTMIS) are very similar to those used by the relevant Ministry. These systems are usually controlled from Port control centers, that become centers in charge of traffic oversight improvement and preventive environment protection. Except VTS and VTMIS, systems used to control sea traffic and ship communication can contain electronic charts (ECDIS) over which data from radar systems and automatic ship identification systems is integrated [13]. These systems can be further upgraded by using communication radio VHF system, meteorological data acquired from stationary sensors and meteorological buoys, video surveillance of the sea and port area using CCTV. All these systems are based on TCP/IP protocol using different communication links (telephone lines, ISDN, optical cables, broadband, microwave and satellite links).

The main difference between port VTS and VTMIS systems and those managed by the state systems is that they oversee exclusively the seaport area, while state managed systems are concentrated on sea ways and state see territory.

Efficient functioning of the seaport system is achieved by development of information management tools that allow seaport system management adequate support when executing management functions. These systems are called PMIS – Port Management Information Systems. Such systems are in fact composed of several information systems: data processing and office applications, information systems of external business units and information systems related to the environment of the ports. Management information systems enable communication between different functions within port clusters, by using the common database. Management reports is a separate functionality inside PMIS used by the management to extract information about business events and transactions and to enable control of the past transactions and plan the future ones. Using different data sources, it is possible to analyze the balance sheets, cash flow, income and costs, key performance indicators, trends, analysis of the reports through several time periods, structure of the long term and short term assets and debts etc.

IX. INTEGRAL BUSINESS INFORMATION SYSTEMS IN SEAPORT CLUSTERS

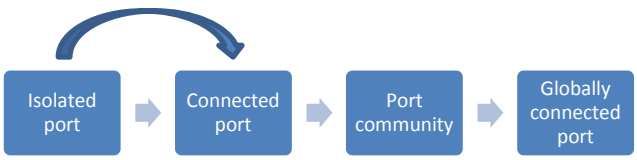
Integral business information systems in seaport clusters (Port Community Systems – PCS) are focusing all information, data and messages that are part of business information systems of various stakeholders in the port cluster. While individual business information systems that relate to individual stakeholders process and store only data and messages that are relevant for them, PCS can exchange data that is useful for a wider number of users. PCS can be defined as a system delivering information to supply chain members operating in the port. PCS are used to deliver, control, distribute and safeguard data. Its electronic platform connects various information systems used by different organizations that together make port community. PCS are holistic, geographically bound information centers in global supply hubs that serve interests of the heterogeneous collective that consists of various business entities. Main goal of PCS is to gather all stakeholders at a virtual table and establish virtual coordination by providing exact information about arrival and departure operations and cargo loading/unloading.

It is possible to identify four different phases of introduction of ICT and business information systems in seaport communities:

1. Isolated port. Stakeholders operating within seaport clusters are isolated, ICT systems are used only for internal processes of individual stakeholders.
2. Connected port. Introduction of ICT and business information systems spreads outside boundaries of internal cohesion and opens up to wider community and users of port services. This is achieved by usage of common Electronic Data Interexchange (EDI) system used to exchange documents and information.
3. Port community. ICT and business information systems are connected with land transport and shipping companies. New technologies like RFID (Radio Frequency Identification) are being used. Subjects of the seaport community are connected by Web applications.
4. Globally connected port. This is the highest level of integration and implementation of ICT technologies in the seaport community. On this level, all paper documents are replaced by electronic documents, logistic management is modernized, full integration with external subjects is achieved and all cooperation between ports is accomplished by using ICT technologies. This phase of implementation usually uses RFID and optical recognition (OCR) technologies, service oriented architecture and solutions based on XML (Extensible Markup Language).

Four different phases or development and integration of ICT technologies in seaport communities and achieved level in Croatian ports are shown in Fig. 2. [14].

Fig. 2: Phases of port community integration



Croatian seaports are currently between first and second phases of development and integration of ICT technologies in seaport community. There are two main reasons for this state of affairs: partially, the situation is caused by lowered investments in sea ports during 1980s, when ports in neighboring countries were heavily investing in port infrastructure and technology development. In 1990s, because of war events, large portion of cargo was lost to

other ports. After the war, ports have started investing in renewal of their infrastructure by using World Bank loans.

Implementation of PCS in Croatian ports is a complex and demanding task that requires active cooperation of all stakeholders in seaport clusters. The process of PCS implementation has to be based on adequate standards that will ensure efficiency, simple data and document exchange and information security. This process also includes implementation of relevant Data Classification and Information Lifecycle Management processes and measures for Disaster Recovery (DR) and Business Continuity Management (BCM).

X. CONCLUSION

Seaport clusters bring together various stakeholders - container terminals, customs, police, port authorities, shipping companies and agents - each of them having a complex set of different information systems serving their own purposes. All this makes the interaction between those systems very complex and elevates overall levels of the integral risk. Different stakeholders in Croatian seaport clusters had to implement various business information systems in order to be compliant to requirements imposed by the European laws and legislations. Majority of those were funded by applicable EU programs and World Bank loans. Due to lowered investments and recovery of traffic that was lost in the past two decades, Croatian ports are now in transition between isolated and connected ports, as the first two stages in the creation of integrated port community and eventually, a globally connected seaport system. Further efforts should be undertaken to align Croatian seaport business information systems with modern requirements and therefore increase efficiency, productivity, decrease costs and facilitate the underlying logistics chain.

Development of e-clusters

Milan Davidović
VSITE – College for information technologies, Zagreb, Croatia
milan.davidovic@vsite.hr

Abstract – In this paper key presumptions and prerequisites of e-cluster organization and sustain development in TIMES technology sectors (TIMES - Telecommunication, Information technology, Multimedia, Entertainment, Security) are analyzed and how can integrate small and medium enterprises (SMEs) in the e-cluster. E-clustering is macroeconomic policy and strategy with crucial impact on horizontal and vertical integration of SMEs in TIMES sectors and regional development. Possibilities of vertical e-clusters and building new value added e-chains as opposed horizontal e-clusters and their entering in large supply chain are compared. Innovation and knowledge are presented as drivers of horizontal and vertical e-cluster development.

Key words: e-cluster, e-clustering, knowledge management, innovation management, intellectual capital

I. INTRODUCTION

Organizational and technological grow are key of business success and sustainability of clusters, especially in TIMES sectors. Building and further development of e-cluster is a project of continuous organizational and technological growth of TIMES clusters.

E-clusters are information and communication technology (ICT) based organization structures derived from TIMES clusters (see Chapter II) with respect to macroeconomic policy and university-cluster alignment (see Chapter III). Organizational development of e-cluster is cyclical process that consisting four stages (foundation, growing, stagnation and declining) and growth, recovering and crisis cycles. Innovations and knowledge are drivers sustain growth of e-clusters and their members (see Chapter IV). Cluster member orientation and relationships in cluster determine horizontal and vertical integration TIMES companies and their partners, and organization of cooperation process and e-supply chains (see Chapter V).

ICT support fast and effective linking TIMES companies and their partners in e-clusters and e-supply chains, but only cluster member's positive expectations and absolute trust make interrelationships in e-cluster and e-supply chains sustain and synergetic. E-cluster is more than e-logistics of TIMES cluster; this is an example how create and work in world of digital economy.

II. FROM TIMES CLUSTER TO E-CLUSTER

A. *TIMES cluster*

TIMES clusters integrate independent organizations that strive for economic sustainability, so initiate and push the networking of TIMES companies, universities, research institutions, customers, and other stakeholders in a region [1][2][9]. Typical representatives of TIMES clusters are IT and communication clusters, film, TV production and other clusters in digital content industry. Their main togetherness is

- composed digital content and products,
- digitalized processes of creating (production), storage, transmission and using of digital content and products,
- knowledge, creativeness, innovativeness and
- Intellectual property (IP) rights.

Process of cooperation in TIMES cluster is a value added chain which involves creative activities, protecting of intellectual property rights (IPR) activities, digitalized production and services, and e-distribution (see Fig. 1).

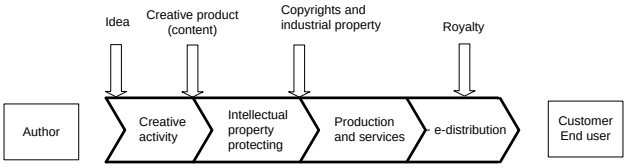

Fig. 1 Organization of creative activities and intellectual property protecting in cluster

Source: Adapted by [8]

Creative activity is transformation a new idea in digital content of creative products what intellectual property is (copyright work or industrial property). These properties need protect before their distribution (alone or as content of digital product). Created intellectual properties and IP rights are new economic values and inputs of digitalized production and services.

TIMES clusters organize value-added chains with different topologies (see Chapter V) that continuous improve and innovate it, so create add value for cluster members and customers at the same time (see Fig. 2). Innovations are new, improved or upgraded products, services and processes that have new commercial or/and social value. It is transformation knowledge and ideas in

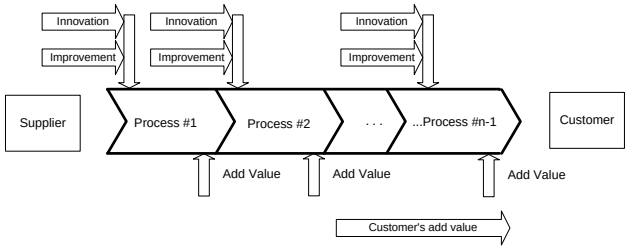

Fig. 2 Cluster's value-added chain

Source: Adapted by [8]

new added value. E-clusters have innovation management system which supports of innovation process from the idea fixing up, research and development, prototyping, pilot construction to implementation of innovation.

Presumptions and expectations cluster members and their benefits and trust, human resource abilities and other cluster potentials are base of cooperation (see Fig. 3).

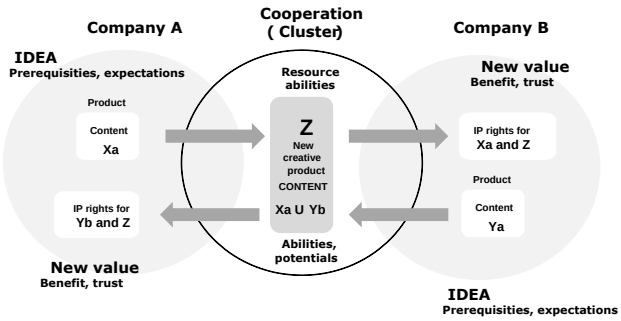

Fig. 3 Cooperation in the TIMES cluster

Source: Adapted by [8]

Digital content is intellectual property. TIMES cluster agreement and contracts between members, owners and users of their intellectual properties, should regulate acquiring and using IP rights and IP management in the cluster. IPM need incorporate in cooperation, innovation, and knowledge management processes (see Fig. 4).

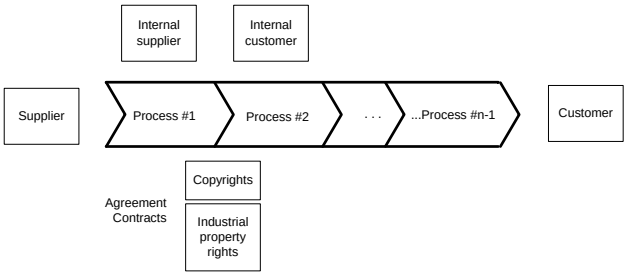

Fig. 4 Usage of intellectual property rights in cluster

Source: Adapted by [8]

Intellectual property management extends the process of cooperation in the TIMES cluster. This process begins before the creative activity (IP rights contracting) and lives long time after (e.g. licensing, royalty accounting). The intellectual property value chain exists in TIMES clusters and amplifies benefits of cooperation (see Fig. 5).

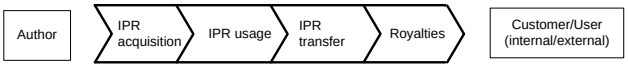

Fig. 5 Intellectual property value chain

Source: Adapted by [8]

Intellectual property rights are intangible property which stay in the TIMES cluster when authors gone or goes with authors if didn't contract elsewhere.

Intellectual capital is hide property which create added value. Hide property of the cluster are also:

- Cluster organizational knowledge,
- Relationship with suppliers and customers,
- Brand loyalty, and
- Market position.

B. Key presumptions and prerequisites of development TIMES cluster and e-clusters

TIMES clusters are human resource and innovation based clusters. Only creative individuals can produce digital contents and products, so human capital is key presumption for organizing TIMES clusters. **Human capital** is creative people with knowledge and abilities required for digital products and content creation, and sustainable growth of TIMES cluster based on creativity, productivity, profitability and competitiveness.

Creative people need organized infrastructure and processes for new values creating, as well as communication with other creators of digital products and contents. **Infrastructure or structure capital** is key prerequisite for organizing of human capital in TIMES companies and clusters, because it includes:

- Organizational culture and others declarative and procedural cluster organizational knowledge,
- Knowledge basis and knowledge management system,
- Intellectual property (e.g. trademarks, domains, patents, licenses and other intellectual property rights),
- Intellectual property management,
- Information basis and basis of documents, content management system, document management system and e-business systems.

Structure capital is everything what remain in TIMES cluster and cluster members) when people gone.

Human and structure capital are intellectual capital. TIMES cluster grows if his intellectual and creative capitals increase. Intellectual capital is knowledge and abilities that should convert in new economic value.

The cluster has **creative capital** if creativeness treats as capital property. Creativeness is realized when intellectual capital (own and/or strange) is used, new (individual) value added and new original product, process or service created.

Cluster organizational capital is ability of cluster that intellectual capital transforms into process of creating the new economic or/and social value.

Declarative knowledge are cluster politics and strategies, product specifications, organization models, document and knowledge basis. Procedural knowledge constitutes cluster organizational culture, business, production and logistics processes, procedures, applications, e-business cases and guidelines [3].

C. E-clusters

E-cluster is TIMES cluster with integrated processes of cooperation, innovation and knowledge management. It is a e-business network that horizontally or vertically integrates companies in TIMES sector and builds procurement and distribution e-channels and e-supply chains, provides product and processes innovation and applies knowledge, intellectual properties and other local strengths for growth of productivity and attainment global competitive advantage [2][3].

The geographic area covered by e-clusters can vary. They are usually regional clusters, but also may be national and even international (industrial clusters, clusters of excellence, union of clusters e.g.).

III. E-CLUSTERING

A. Main cluster development factors

Development of clusters determines several internal and external factors. Severe impact on founding and development of clusters has political, economic, social, technological, environmental and legislative factors. Political, economic, social, technologies, legislative and environment (PESTLE) analysis can indicate trends, possible long-term orientation and sustainability of TIMES clusters in the region. Key external factors are

- Macroeconomic policy (e-clustering) and
- Growth of TIMES technologies.

Key internal factors are

- Concept and e-cluster strategy,
- Connections (trust-based relationships between cluster members and their partners) and
- Cluster's intellectual capital.

B. Impact of macroeconomic policy on e-clusters

Macroeconomic policy has crucial impact on development and growth of clusters, because determines their main resources and competitiveness (availability of skilled human resources, labor and transaction costs, local market protection, investment in education, science and research). **E-clustering** is long-term macroeconomic policy that initiates and pushes founding and development of e-clusters in regions.

E-cluster composition is based on costs, resources or innovations, and their combination [4]. **Cost-based e-clusters** reduce transaction costs in TIMES sectors, **resource-based e-clusters** integrate human resources and services, and **innovation-based e-clusters** share know-how and other knowledge created in research and development of digital products and contents.

C. E-clustering as new strategy of TIMES cluster

E-clusters accelerate the distribution of knowledge, reduce transaction costs, produce increasing economies scale, and stimulate competition and cooperation. [2][9] So **e-clustering** is new TIMES cluster management strategy oriented to innovation and intellectual capital trough cooperation, growth and employment. E-cluster is a vision and strategic aim of established TIMES cluster.

D. University and cluster alignment

Growth of the cluster intellectual capital is key prerequisite of successful development of e-cluster. Universities are source of research and technology, knowledge, and creative workforce. Their impact on TIMES cluster growth is dominant, especially on cluster focused on innovative products and complex projects.

Foundation of innovation-based clusters is limited in region with low research intensity. When cluster concentration is high in the region, clusters are focused on building research and development units.

Establishing and development of innovation-based and human resource-based e-clusters is e-clustering strategy in regions with high research intensity and dominant universities. When clusters and universities are aligned, the focus is on efficiency and transfer of TIMES technologies and knowledge from university to e-clusters. Universities participate in innovation process in e-clusters from idea, research and development up to pilot construction and implementing the new digital products, digitalized processes or TIMES technologies.

Universities is industry-oriented and active regional engaged if new TIMES technologies and knowledge transfer to TIMES or e-clusters and other regional economy. Measures of success are licensing income, percentage of research and development funded by industry, start-ups per million EUR or USD, and full-time employees in the technology transfer. [11]

IV. ORGANIZATIONAL DEVELOPMENT OF E-CLUSTER

A. Organizational growth of cluster

Key cluster performance and organization growth indicators are employees, size (number of members and partners), added value, revenue and profit, average wage and intellectual capital or number of customers. Lifecycle of cluster's organization has four stages:

- Foundation,
- Growing,
- Maturity (stagnation), and
- Declining or crisis (see Fig. 6).

Foundation is the first stage of growth. At this embryonic stage, relationships and cooperation process need establish (see Pert B). Embryonic or emerging e-cluster is a group of TIMES SMEs and other actors in a region that want perform common in market. They start to cooperate and realize common opportunities through their linkages.

The cluster is established if have a room for further growth. Established or developing cluster continuously grows up to point of culmination when begin stagnate.

Cluster at stage of stagnation is maturity if its growth stable. It is at declining stage when growth declines.

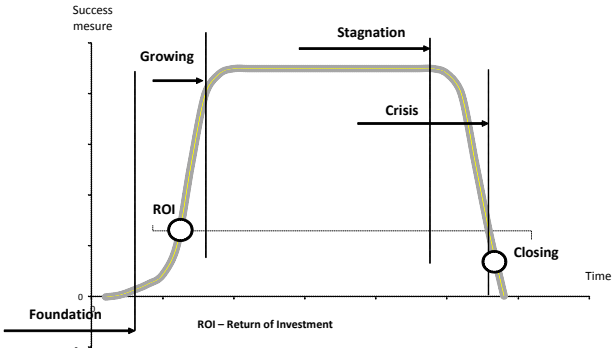

Fig. 6 The growth of e-cluster organization
Source: Author

Organizational development stages are detail described in Part C.

B. Foundation of e- cluster

In region with agglomeration of TIMES SMEs and other actors may be organize TIMES clusters with long-term perspective. Foundation of cluster is the end of complex process which involves

- Trust of potential founders creating,
- Linkages between actors building,
- Vision and strategic directions defining and then
- Undertake action with stakeholders.

Group of TIMES companies and other actors in one region can establish Marshallian, hub-and-spoke, satellite platform or state anchored TIMES cluster according to relationships to each other. Reasons of TIMES company for entering a TIMES cluster are costs or resource and innovation sharing. From this perspective TIMES cluster is cost, resource or innovation based.

The TIMES cluster organizational development planning should base on business environment indicators e.g. students in pre-vocational and vocational programs, lifelong learning, research and development personnel, household broadband access, part-time employment, human resources in science and technology, vacancy, skilled emigrants, and population aged from 15-34. [6] Building of e-cluster encloses next projects:

- Digitalization and integration process of cooperation,
- Innovation management system integration,
- Implementation of knowledge management system,
- Implementation of IP management system.

C. Organizational development stages and cycles

Unsuccessful embryonic e-clusters need close (see Fig. 7). Established e-clusters maintain growth and so stay in the growth cycle until the point of culmination. The culmination may be discarding with:

- Projects of new cluster's growth,
- The cluster development projects (organization, information systems, competitiveness, human resources, cluster management) and
- Projects for elimination of culmination.

Projects of new cluster's growth concerns new digital product and e-service implementation, innovations, new market accessing, investments, technology, new distribution e-channel and new e-supply chain.

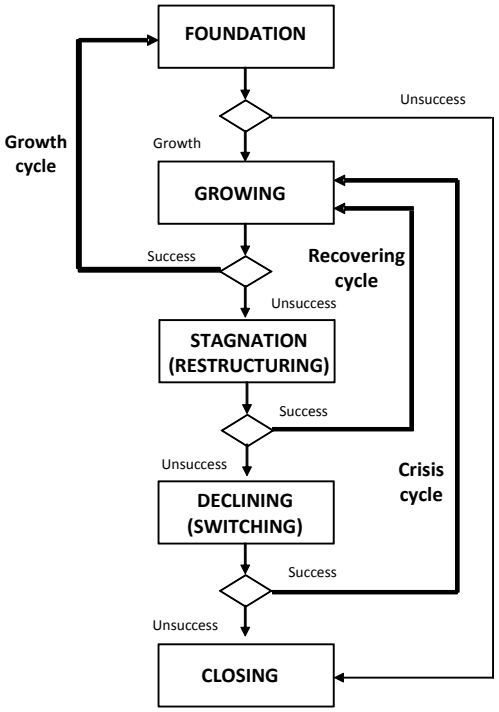

Fig. 7 Lifecycle of cluster's organization
Source: Author

Successful restructured maturity e-clusters exit out of the stagnation phase and return at the growing stage again. The e-cluster remains in the recovering cycle while growth stagnates. Restructuring can enclose products or projects portfolios restructuring, cooperation process innovation and redesign, e-channels and e-supply chain restructuring or redesign, and reorganization.

The e-cluster is at declining stage after unsuccessful restructuring and entering in the crisis cycle. The cluster is going out of the crisis with successful switching strategy that radically reducing costs of cooperation and only profitable products and projects leave. If switching strategy is unsuccessful then e-cluster need close.

D. Innovation and knowledge as development drivers

Innovation and knowledge are development drivers of e-cluster (see Fig. 8). Knowledge management supports acquisition, diffusion and applies cluster organizational knowledge (know-what, know-why, know-how, know-who, know-where and know-when) and so improves the e-cluster performance in e-market, and induce innovations of processes, digital products and e-services. [2]

Innovations increase cluster productivity and profitability, and improve products, services, cooperation processes and e-supply chains. They originate spiral growth of cluster knowledge in research and development phase. Innovation strategy activates creative capital for

the purpose of the cluster's strategic position improvement. It enables design and redesign products and e-services, and new TIMES technology and e-business systems implementation.

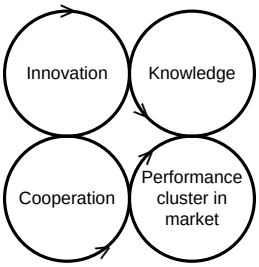

Fig. 8 E-cluster organizational development drivers
Source: Adapted by [1]

Creativeness and organizational capital are key e-cluster's development drivers in digital content industry.

V. ORGANIZATION OF COOPERATION IN E-CLUSTERS

A. Marshallian horizontal e-clusters

In Marshallian clusters there are no dominant members (leaders). Group of TIMES SMEs can establish successful Marshallian cluster if workforce in region is stable, focused on this industry and members want finance development of the cluster. This bottom-up development of TIMES cluster is sustain if cluster has:

- Low costs,
- Attractive resources (human resources, market, intellectual property, IP rights) and/or
- Competitive innovation and creative potential.

Governments initiate the founding of Marshallian TIMES clusters if TIMES sectors are target of macroeconomic policy and regional development.

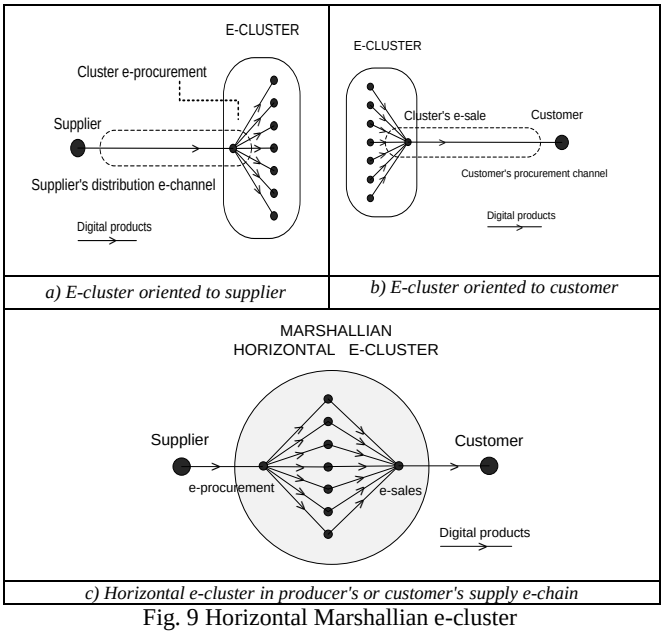

Fig. 9 Horizontal Marshallian e-cluster

Source: Adapted by [1] and [2]

Development of Marshallian e-cluster depends on the cluster members' orientation. The change of member's orientation is opening a new cluster's development cycle.

Members of horizontal Marshallian cluster perform common in the market, have similar characteristics, their products and services are complementary, or use same inputs. They are oriented to own business and few suppliers or the known customer.

Horizontal e-clusters oriented to supplier build e-procurement e-channels or enter in supplier's distribution e-channels (see Fig. 9a). E-clusters oriented to known customer build e-sales channels or enter in customer's supply e-chain (see Fig. 9b). Horizontal e-clusters develop procurement and sales e-channels and enter in suppliers' or/and customers' supply e-chains (see Fig. 9c). Transaction costs of cluster members are lower [5].

Among horizontal e-cluster members there is no digital product flows.

B. Cooperation in Marshallian vertical e-clusters

Vertical Marshallian e-clusters share innovation, knowledge and intellectual properties among members. Human and structure capital stays at cluster members. In e-cluster is only common structure capital.

Members of embryonic e-cluster build e-chains and integrate them in embedded e-clusters (see Fig. 11a, b). Transformation of horizontal in the vertical e-cluster starts when the first e-chain built. Topology of cooperation process is tree in e-clusters oriented to products, and direct graph (network schedule) in e-clusters oriented to projects (see Fig. 11c, d).

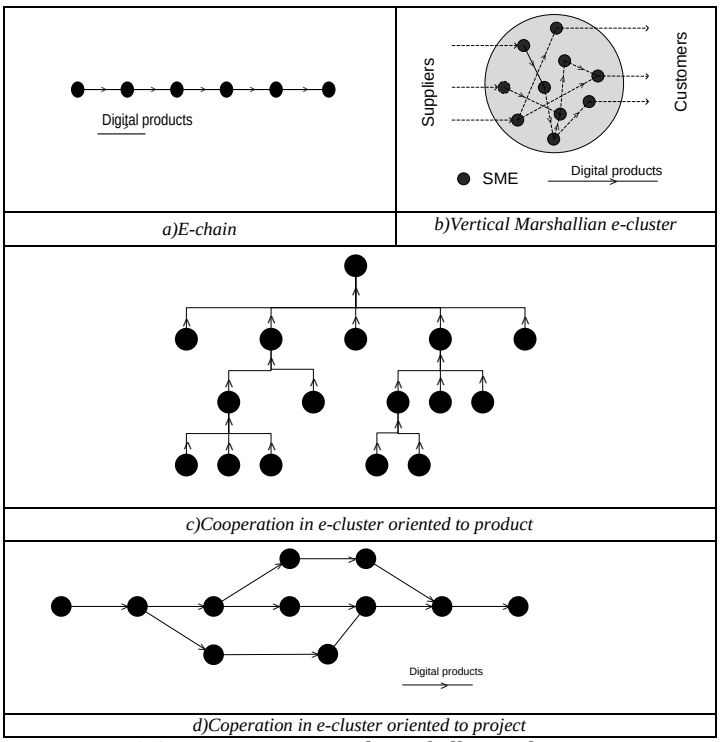

Fig. 10 Cooperation in vertical Marshallian e-cluster

Source: Adapted by [1][2]

Marshallian e-clusters may be support by e-logistic locate in public or private cloud. This solution is cost-effective, because cluster pay only used e-services.

C. Cooperation in other e-clusters

The hub-and-spoke TIMES clusters are organized by one or few large companies. Hubs are leaders and dominant member of cluster. They establish cluster in regions with low transaction cost, attractive resources and/or higher innovation and creative potentials. Cooperation between hubs and spokes are very intensive, but among spokes are little or no exist (see Fig. 11a). Finance capital of hubs will go elsewhere for better investment [7]. When hubs leave region, in region remain only human capital. Structure capital departs with hubs.

Cooperation between hub and their cluster members is supported by hub's e-business system. If cluster member participates in digital product or service development then enters in hub's knowledge management system. Hub can retain all copyrights and industrial property rights.

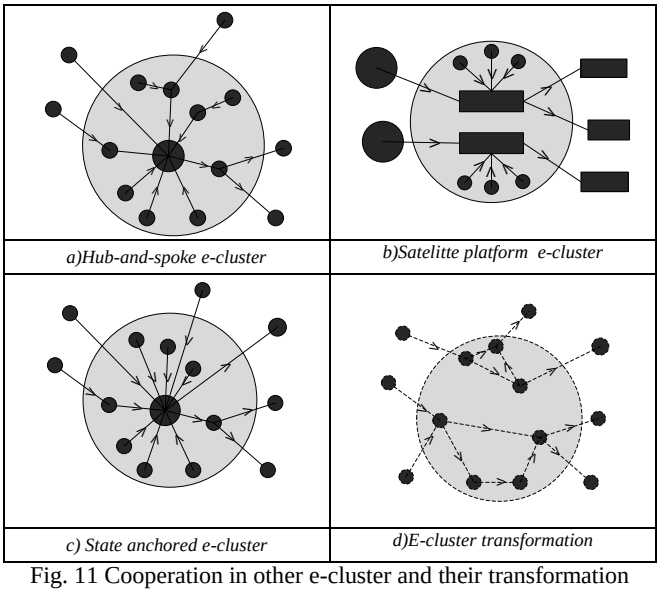

Fig. 11 Cooperation in other e-cluster and their transformation

Source: Author based on Markusen [2][10][12]

Large multinational companies establish satellite platform TIMES clusters in regions (see Fig. 11b) through government incentives such as free or inexpensive land, direct subsidies, or tax holidays. The government develops infrastructure and stimulates the large companies' coming and staying in the region [7]. These clusters will dissipate when government incentives dry up or favors development in other regions and industrial sectors. Infrastructure, workforce and small companies without own structure capital stay in the region.

Government institutions (university, research institute, military base, or capital) organize state-anchored clusters. The anchor institution cooperates with supplying companies. Cooperation among supplying firms is very little. Finance capital gone when better opportunity finds, but human capital remains (see Fig. 11c).

Basic topology of cooperation process in hub-and-spoke, satellite platform and state anchored e-clusters are star (see Fig. 11a-c). When hubs, founders of satellite platform and state anchor gone then cluster can transform in one or more Marshallian clusters (see Fig. 11d).

VI. CONCLUSION

E-clusters are cost, resource and innovation based TIMES cluster with integrated processes of digitalized cooperation, and innovation, knowledge and intellectual property management. Key factors of foundation and development of e-cluster are macroeconomic policy, development of TIMES technologies and cluster's intellectual capital (human and structural).

Knowledge and innovations are drivers of e-cluster growing, so e-clusters should cooperate with universities and research institutes and build research and development units. E-clusters can be supported by e-business and other management system located in private or public cloud.

E-consultations in Croatian central government

Klasinc, Anton-Jan*
* Vertex projekt d.o.o.
ajklasinc@gmail.com jan.klasinc@mail.inet.hr vertexprojekt@inet.hr

Abstract - So far citizen consultations and participation in policy-making has been mostly the feature of local governments and local administrations. This paper aims to explore the usage of public participation in policy making via e-consultations with interested public in central government, namely in two Croatian ministries - Ministry of Science, Education and Sport (MoSES) and MInistry of Culture. This topic is mainly related to the problems of accountability and transparency, but also citizen cynicism and digital divide. Moving beyond this general approach, there is an underlying issue of defining and measuring accountability and establishing the role of e-consultations in the strengthening of accountability principle and framework within governmental organisations. The main problems analysed are the creation of curricula in elementary and secondary school in MoSES and policy-making concerning mainly the distribution of subsidies (establishment of public cultural needs), theaters, and electronic media in the Ministry of Culture. The paper explores the type of comment left on the web sites of those ministries, their quality and general tone, by the means of content analysis, but also the type of organisation and/or inndividual leaving the comment in order to assess the motivation and impact of the coment. On the other hand, it explores and analyses the structures enabling accountability and transparency in those ministries in order to establish the role and potential of e-consultations in strengthening them and possible improvements of e-consultation methodology and practice.

I. INTRODUCTION

This paper attempts to analyse e-consultations in Croatian central government on the basis of conducted e-consultations in two ministries: Ministry of Culture and Ministry of Science, Education and Sports. Although the analysis of e-consultations has been conducted on the local level (e.g. The paper on e-consultations in the city of Pula), such analysis has never been conducted on central government level, although the framework for "consultations with the interested public" (savjetovanje sa zainteresiranom javnošću) has been defined by a Code of Regulations – a legal document – that has prescribed the necessary and minimum parameters for such consultations, and e-consultations as well. The reasons may be multiple, first, it is unlikely that Croatian central government operates on the same level in all ministries, and therefore we have chosen the aforementioned ministries as examples of novel practices, since the ministry involved with science and education is the most likely to promote the new technologies, and one involved with culture is most likely to be sensitive to citizen engagement issues. Therefore, those two ministries could be percieved as current examples of best practice in Croatia. However, this is not necessarily the case and more studies are needed to establish this fact. Also, the volume of conducted e-consultations by the Ministry of Science has forced us to narrow our research to just two of them, when it comes to analyisis of the actual comments left by citizens – the consultations on Health Curriculum in schools and the Act on Higher Education in the MoSES and the consultations on Theater Act and the Electronic Media Act in the Ministry of Culture.

The control variables were the number of consultations conducted, the number of consultations that have resulted in policy change, the number of comments, the quality of interested public (physical person, legal person, institution or whether they are directly involved in the proposed regulation by their activity or not). The comments were analysed with respect to their constructiveness towards the proposed topic, and were therefore divided into two groups – constructive and destructive/cynical commentaries, and each of those groups has been subdivided into further two categories.

On the other hand, we have analysed the involvement of broader public and media and resulting policy changes, as well as structures enabling accountability in those ministries and their relation to policy changes and policy making.

The total number of e-consultations carried out in both ministries is rather different. In MoSES, there was a total of 43 e-consultations of which 2 are currently open, and in the Ministry of Culture there was a total of 22 e-consultations, most of which were in 2013 (13).

Table 1 Nunber of consultations in MoC and MoSES from 2008 to 2014

Year	Number of consultations - MoC	Number of consultations - MoSES	Total
2008	1	-	1
2009	2	-	2
2010	1	2	3
2011	2	2	4
2012	2	9	11
2013	13	28	41
2014	1	2	3
Total	22	43	65

The e-consultation in MoC that attracted the largest interest of the public concerned the Draft of the ammendments of the Act on Culture Councils (OJ 48/04 and 44/09)[1] and in the case of MoSES it was the Consultation on Health Education Curriculum [2]. The growth in the number of e-consultations can be seen even in 2012, but only in 2012, whereas it has reached a dramatic peak in 2013 and is continuing on this level in 2014. The reason behind this was probably not the Code (Kodeks) for the consultations with the interested public, which the government [3] (of the former prime minister Jadranka Kosor) passed on November 21. 2009, but the resolution of the new government elected in 2011 to respect the Code and put it into practice. This has seen numerous obstacles. One of them is the deeply rooted party mentality in Croatia that is not really open to citizens and their suggestions, and the other is probably ideological, which means that we are dealing with a "war of culture" or opposing mentalities rather than dialogue of equals, albeit with different ideas and opinions. As the third problem, there appear to be numeorus vested interests of different groups, (e.g. NGOs, Catholic Church and organisations connected to it, etc.) that are constantly trying to have upper hand in the society no matter what the results of elections are or regardless of any government policies.

This situation makes the problem of e-consultations with respect to the culture of transparency and accountability of government officials rather complex. The normal policy cycle of the cycle of public policy making [4], consisting of 1) agenda making, 2) analysis 3) policy making, 4) implementation, 5) monitoring is undermined by different social groups fighting for different agendas that are really just the camouflage for the power play and spoils system of dividing the proceeds of government "businesses" among themselves. Therefore it appears that some of the main goal of e-democracy or electronic consultation and public participation in policy making is not met, namely the increasing of e-engagement of citizens from all walks of life. In theory, the reasons for better engagement of citizens in the process of policy making are:

- better policies
- building of trust and acceptance of policies
- sharing of responsibilites for policy making [5]

Within this context, the ICTs should enable better disemination of technology enabled information, consultation and participation in order to improve the process of policy making by the means enabling:

- reaching and engagement of wider public
- provision of relevant information in an aceesible and user friendly format
- enabling thorough consultations and support to deliberation online
- facilitating the analysis of inputs in order to help policy makers and improve policies.[5]

II. METHODOLOGY

The qualitative analysis is based on the comments left on the web pages in consultations conducted in Croatia in the Ministry of Culture (MC) and Ministry of Science, Education and Sport (MoSES) which have resulted in policy change and/or significant media coverage. The control quantitative variables are the total number of consultations conducted in those ministries in 2013. and the total number of consultations from the beginning of the introduction of this practice (2008), the total number of consultations that have resulted in policy change, the number of comments left in each consultation that resulted in policy change. Also we have analysed the quality control variables: the type of interested public (private citizen or physical person, legal person, institution or whether they are directly involved in the proposed regulation by their activity or not). On the basis of this analysis it is possible to determine which variables crucially affect policy change due to the consultations with interested public. The main criticism of the central government public consultations is that they are conducted just formally, in order to fulfil a legal obligation, and not in order to really consult the public in order to change the policies and strengthe accountability. It is sometimes possible to find arguments for this conclusion, such as too short terms for consultations and poor informing of the public about the consultations, which goes against the better practice and still fulfils the legal obligations to provide consultations.

In the quality of the comments we will try to find proof whether it is the comments themselves that resulted in the policy change or some other factor and to establish whether it is due to faulty accountability structures in the govenrment. A large number of cynical and unconstructive comments would indicate that the comments were not crucial for the change, and that instead some other factor contributed to it, such as media coverage or public outcry, or some other form of political action, such as demonstrations on the streets, involvement of the opposition political parties, etc., which would then imply that the accountability structures of the government are not working. Also, the accountability structures themselves will be analysed according to an already established methodology by the Galway Accountability project (2009). In the quantitative control variables we shall seek to establish whether the number of consultations that resulted in some degree of policy change is statistically significant enough so that the e-consultations can be justly referred to as a means to policy change and not just an empty formality. For this we shall analyse also the total number of comments left, the number of comments taken into further consideration and the number of comments that were partially accepted. The number of consultations in time series will help us to setablish whether the situation is progressing or deteriorrating, and in which way it is progressing or deterriorating – in the sense of enabling more or less constructive and more or less significant impact of the public in policy making or just increasing or decreasing the quantity of consultations that do not result in any

significant impact or policy change. Finally, we will conduct the qualitative analysis of the type of interested public in order to determine whether it was the vested interests that motivate the public to participate actively in the consultations, or the genuine desire or the interested public to improve the quality of legislation and the accountability of central government structures.

III. E-CONSULTATIONS IN THE MOSES

Two main e-consultations in MoSES that are analysed are the Consultation on Health Education Curriculum, which was provoked by the large interest of the public and was a rerun of the already conducted consultations, where the whole issue was provoked by the organised citizen group "In the name of the family" connected to the Catholic church and which has resulted in the first citizen initiated referendum; and the other is the consultation on javna rasprava o the Draft of the Code of Regulations on appointment and work methodology of expert councils for the assessment of textbooks and additional educational tools for elementary and secondary school (Nacrt prijedloga Pravilnika o sastavu, imenovanju i načinu rada stručnih povjerenstava za prosudbu udžbenika i pripadajućih dopunskih nastavnih sredstava za osnovnu i srednju školu). The first one has attracted large interest of the public and even resulted in a citizen referendum, for which it was necessary to collect 700000 signatures of citizens all over Croatia, and the other one concerned also the whole public (or at least those with children going to elementary and secondary school) and small vested interest groups of publishers of elementary and secondary school textbooks and educational tools.

In the analysis, the comments were divided into two groups: negative/cynical (without reference to the issue addressed, without supporting arguments) and constructive/positive (directly referred to the document, with supporting arguments and informed opinion, applicable solutions and offering alternative solutions and approaches).

Table2. Comments in e-consultations in MoSES, 2013

Title	Constructive	Cynical	Total comments
Health curric.	cca 10%	cca 90%	1962
Expert Councils	-	-	0
Stud. food cost	7	1	8

In the first case, a large percentage of comments were destructive and cynical, although some pointed out the need to have public consultations that are better suited for this issue, and that the consultations were already carried out on this topic, which made the consultations illegal. The number of comments was rather high and difficult to analyse, and only the abbreviations with the essence of the meaning were conveyed in the final analysis document. In the second case, the number of comments was exactly zero (0) reflecting probably the vested interests of publishers. The consultation did not reach wider audience nor did it affect considerably the policy outcome, although it is actually important which textbooks will be used in schools, but the topic is not politicised as such. The period for consultations was only 2 weeks, which is considered a minimum period in the Code. However, some issues regarding publishing of textbooks were widely debated in the newspapers, implying that the issue was not really resolved by deliberation or e-consultations. The third is a typical consultation with 7 comments. The total number of providers was high, probably due to high interest attracted by the issue of Health curriculum – 3034, and the number of comments taken into consideration was equally high – 3035. However, the number of accepted comments was only 287 with partially accepted 108 comments, which means that only about 10% of comments created policy changes. This confirms that the increase of public interest and comments not made purely out of vested interests do not yield more constructive comments, nor does it provide for proportionally more impact of the public in policy making. However, in absolute sense, it may provide for more impact, but also due to other factors, such as media campaign and political action (political parties, demonstrations, protests, referenda, etc.) The ratio of physical (125) to legal (35) persons in the "Textbook standard" consultation shows that the public has genuine interest in the issues important for accountability.

IV. E-CONSULTATIONS IN THE MINISTRY OF CULTURE

The Ministry of culture has attracted wide attention of the public with two of its e-consultations with the interested public. The first one was the consultation about the ammendments of the Act on Culture Councils, which has attracted a lot of attention from groups with vested interests, as the Councils are the bodies within the MoC that distribute subsidies. The Act that was to be ammended was not very transparent, and it appeared that the main goal was to enable the minister to have complete control over the decisions of the Councils. Therefore, a lot of constructive, but also destructive comments appeared and the image of the minister of culture in public media, and especially newspapers was considerably eroded. However, that did not really matter much to the minister, that continued its practice as usual.

The other consultation concerned the ammendments to the Theater Act that was in fact designed to enable the minister to have better control over the appointment of the Principal of Croatian National Theater and other theaters that are also partly or totally funded by local governments. This, however, was not immediately attacked by groups with vested interests, probably due to the fact that it was a "clash of titans" between the local government mayor of Croatian capital, Zagreb, and the minister of culture, in which the majority of public interested in culture and its groups with vested interests supported either one or the other, but not so much on principle, but more due to vested interests and different points of view (traditional/conservative or liberal/left-wing). Therefore, the only comment received in this particular case was the comment of the principal and owner of a small childrens' theater "Mala scena", despite the fact that the conflict between the minister and the mayor was the topic of daily newspaper headlines for months leading up to the consultations. In addition to this, the comment was mostly constructive, although it did not reach wider audience nor did it affect policy making in this particular case. The

comment pointed out the lack of overall strategy and previous cases of ad hoc decision making that led to disastrous results and mistakes that had to be corrected due to the fact that legal acts were changed only to accomodate ephemere whims of political figures and enable power play.

Table3. Comments in e-consultations in MoC 2013/14

Title of the consultation	Constructive comments	Cynical comments (or useless)
Culture Councils	11	2
Theater Act (2014)	1	-
Pula film festival	1	-
Pr. status of librarians	16	2
Non-profit media grant	4	6
Electronic media	17	3
Theater Act I (2013)	31	6
Croatia House	3	1

In an overall statistics for 2013, it is stated that there was a total of 108 providers of comments, and that 172 were taken in consideration (the total number of comments is unknown), and that 34 of these were accepted with 1 partially accepted which is about 20%. This statistics confirms that in the Ministry of Culture there is generally more openness to suggestions of the interested public, which also goes in line with the fact that the comments are more constructive than in the MoSES and reflect vested interests of the interest groups (such as publishers, theater owners, actors, librarians, etc.); however a large portion of consultations received less then 2 comments (0 or 1). In the case of more comments, ratio of physical to legal persons was sometimes about 3:1 or even more, except for media and el. media (almost all legal persons). Another problem that was pointed out by many comments is the lack of thorough preparation and information phase in such consultation and the short period for consultation, which was even shorter than the minimum of 2 weeks that was prescribed by the Code for consultations with the interested public (2009). Such practice is not unusual in Croatia, nor is it a surprise, but it is unusual that it is condoned by a declaratively liberal minister and the fact that the Code is not obeyed is justified that Codes are not binding legal acts, so they don't have to be respected by the public administration, although they serve "as a benchmark".

V. STATISTICAL DATA ON E-CONSULTATIONS

The Government of the Republic of Croatia adopted the Report on the implementation of the consultations with the interested public in 2013 in the procedures of adopting acts, regulations and other legal norms, on its session No 143, held on 27/02/2013. In 2013 there was a total of 374 e-consultations. This is an increase of almost 160% more consultation than in 2012, when there were only 144 and 675% more than in 2011, when there were only 48 consultations. In the consultation procedures there was a total of 8.299 legal and physical persons that provided a comment to the draft of an act, or another regulation or legal act to the responsible government body. The number of the providers of comments increased by 73% with respect to 2012, and 4697% with respect to 2011. The individual number of comments was 9270, of which 2391 were taken into further consideration, 579 were partially accepted, and the reasons for not accepting the comments were explained in 149 reports about the results of consultations that are prepared pursuant to the obligations of the Government Code of regulations. Of 348 consultations, 272 lasted less than 30 days, which is less than is provided by the Act on Right to Access to Information, due to emergency procedures of legal act adoption.

It can be seen that on the basis of those numbers, the 2013 was the first year that significantly implemented the code for the consultations with the interested public, although it had existed 4 years before. This increase means that the impact of the public has increased, but not necessarily when weighted against the increase of the quantity of consultations, meaning that there were possibly more consultations, but fewer comments leading to some policy change. In fact, if the increase in consultations was almost 160% more than in 2012 and the number of providers of comments increased only by 73%, it would mean that the number of providers per consultations has decreased by more than 50%. However, for the previous year, also the number of providers per consultations has increased, as there was an increase of 4697% in providers and increase of 675% in consultations (when there were only 48), so that the number of providers increased 7 times, with respect to 2011. Also, on the qualitative side, it could be seen that in consultations, especially those leading to some policy change, there was an increase in the number of public that did not have vested interest in the consultations, but some kind of genuine interest to increase the quality of legal acts, whereas before 2012 almost exclusively persons with vested interest provided comments. On the other hand, it means that the time series for such analysis are too short to yield statistically significant results, and could perhaps be used only for the ministries with some tradition in consultations (MoSES and MC). [10]

VI. E-CONSULTATIONS AND ACCOUNTABILITY

When discussing accountability there is a problem of definition of accountability and methods of achieving accountability in organisations. One such method is given in the 2009 Accountability project (Galway) [6]:

In 2009, Phase I of the Accountability Project (Galway) articulated a set of essential elements of accountability. It is against these elements that an organisation's accountability would be established. They are as follows: (1) Organisation commitment to accountability and adoption of internal policies consistent with external criteria. (2) Mechanisms to put (privacy) policies into effect, including tools, training and education. (3) Systems for internal, ongoing oversight and assurance reviews and external verification. (4) Transparency and mechanisms for individual participation. (5) Means for remediation and external enforcement.

As for these elements it is difficult to determine whetеher such elements exist or are in place in the MoC or MoSES. However, it may be established that the commitment to the Code for consultations is an element of the commitment to accountability, as it enables two way communication with citizens and that it may also affect actual policies and policy making. However, the systems for internal ongoing oversight and assurance reviews are certainly lacking, and the policy makers are certainly not evaluated on the basis of comments collected by e-consultations. There are no systems for external oversight and verification, nor for remediation or external enforcement. Therefore, the public is forced to protest by referenda or public outcries in media or other methods that may make government officials and policy makers more accountable. In order to upgrade e-consultations as a tool for enforcing accountability, their visibility and flexibility should be greatly improved, as well as its reach toward general public. Also the creation of policy institutes of some scope, authority and influence may serve as an external evaluation and oversight structure for government policy makers.

VII. CONCLUSION

In conclusion, it may be said that the policy making by e-consultations in Croatia suffers from the lack of broader perspective and strategy and is mostly reduced to power play and clash of different mentalities and points of view, without much referrence to concrete arguments and issues that are debated and deliberated on. The number of destructive comments in the issues that reach the attention of wider public shows that the culture of deliberation is missing and that the main goal of referenda and public engagement and involvement in policy making is not just to change or improve policies, but to attack the government as a whole or to impose a different general point of view (e.g. conservative or liberal), and to try to stop policy changes that are perceived as threatening to that mentality, general point of view or vested interests of certain social and professional groups.On the other hand, the number of constructive comments on issues that are relevant for policy making or interesting to certain smaller interest groups or even general population (such as school curricula and textbooks) don't attract wider attention, and are mostly ignored by policy makers. The only way that such policies can attract wider attention is when they contradict general points of view and mentality of larger portion of people or powerful institutions, such as Catholic church, in which case the consultations and other instruments for citizen engagement are used for waging "culture wars" or trying to gain political upper hand or score some points in the political arena, without paying much attention to the policies that are actually involved or deliberated on by such consultations.

Therefore, we must conclude that the culture of deliberation and dialogue is defective in Croatia, and that it also affects the accountability structures in the government, as they don't feel responsible for concrete policies and their outcomes and benefits for general population, but mostly for ideological issues and points of view that are important for scoring political points with the voters. The accountability structures in ministries also follow those lines, and the need to maintain e-consultations is also mostly dictated by ideological reasons and the stimulus coming from the EU and its culture of dialogue, accountability and transparency, rather then from some inherent desire to create better and more citizen oriented policies.

Another problem with e-consultations in Croatia may be that the policies should be better formulated and conveyed to the citizens in a more appropriate form, reaching wider population, more inclusively, so that citizens are informed about the issues that affect their lives even when they don't affect their religious beliefs and general outlook or world view. In addition to this the tools for public participation and consultation should offer more possibility for dialogue and two way communication with government in real time, such as electronic fora, and alike, and the results of such consultations should be widely disseminated and made public.

Abstract - Electronic market is a new economic space created by the development of the Internet and it has more than a billion of potential customers. In addition to all of the elements that define a classic market, e-market generates entirely new ways of doing business, such as the shared economy.
Shared economy is a sustainable economic system built around the sharing of private assets. This rather new system mostly relies on information technology (P2P) to empower individuals and other profit and non-profit organizations with ways of sharing excess capacity in goods, knowledge and services. Considering the fact that reliance and safety are crucial factors when it comes to sharing private assets, the value of those assets is increased just by sharing information about them. Airbnb.com, as an outstanding example of the new e-business model, enables individuals to rent their unoccupied living space and other short-term accommodation to guests. Besides being a rental mediator, Airbnb is also a social network used by its users to exchange experiences and interests related to traveling.
The research was conducted by an online survey that was posted on the Airbnb Facebook wall. The objective of this research is to determine the structure of Airbnb users and certain advantages and disadvantages of this type of e-business. The data acquired by this research was processed by the methods of descriptive statistics.

Keywords: digital economy, Internet, information technology, e-business, accommodation.

I. INTRODUCTION

Socio-economic phenomenon of tourism is based on the needs of people for a temporary change of residence. Today's modern concept of tourism causes significant changes in the tourism business and tourism development. Modern and sophisticated technology has resulted in improvement of communication, and the crucial role is played by the Internet. By abandoning the outdated forms of communication, the Internet has become an inevitable medium and communication channel and thus has brought distant places closer, facilitated travel organization, and improved the creation and marketing of tourist attractions. The development of the World Wide Web has affirmed the notion that the Internet can be used as a medium in performing various tasks and as an active and attractive business environment. Information and communication technology - ICT is developing rapidly and its change in use in everyday affairs, private, public and other market activities is expected. It eventually became the largest possible market of everything - goods, capital, labor and information content. More precisely, it is a new global economic space and virtual reflection of economic globalization. By the beginning of the 21st century the Internet was profiled as the segmented economic space within which four main economic sectors are now clearly distinguishable [1]:

- sector of producers of Internet infrastructure elements
- sector of providers of Internet services and applications
- sector of Internet entrepreneurs
- sector of intermediaries in the Internet business.

A plenty of people and organisations with innovative ideas of better or even completely new ways of doing business, ofering services and sales of tangible and intangible assets find their place in the sector of Internet entrepreneurs. There are such businesses which are not feasible in a traditional tangible business premises, but in the virtual space of the Internet we can notice a trend of specialization to conduct them. In this sector the most visible and the most interesting are the business benefits of e-business. The youngest sector is the one of intermediaries in electronic business, which brings together companies that organize and implement the provision of new types of intermediary services aimed at the better linking of supply and demand in the Internet market. These companies add value to the basic offer and therefore are called *value-added services*. The users of such companies do not perceive them as a "necessary evil" but as an added value that facilitates the achievement of business goals.

A direct consequence of the development of modern technology and ICT is the emergence of entirely new products and services on the Internet. It really is a global computer and communication "network of networks", which with its capabilities, features and amenities have enabled truly great acceleration of

virtualizing the market of private, public and other business services and activities, both in the social domain and the domain of economic relations [2]. Nowadays, in order to respond to the movement of modern world trends many enterprises transfer their operations from the traditional to the virtual space. This undoubtedly requires a modernization of business processes, so business is becoming faster, more efficient and profitable. The modernization of business processes makes the company extremely competitive in the global market exchange and in everyday competition.

The rapid development of information technology over the past fifty years has determined the information revolution. Today it is at the stage of maturity and has become the focus of business activities. The focus is increasingly shifting from technology to information and to the contents created by information technology. The growth of content and services related to information technology is inevitable as it opens new opportunities and encourages the creation of entirely new contents and services.

Digital Economy - DE is the modern way of doing business with the help of ICT, especially the Internet. Digital networking and communications infrastructure provide a global platform where people and organizations can cooperate, communicate, search for and obtain information as much as exchange digital products and services. Digital economy has led to the transition from the industrial economy to the economy characterized by information, intangible assets and invisible values and a new form of organization. The digital economy is characterized by the globalization, networking, mobility, integration, digital products and services and e-business. Every company faces with three kinds of pressure: the pressure of the market, technology and the pressure of society. The pressure of the market includes intense competition, global economy, changing workforce and powerful clients. The pressure of technology is characterized by technological innovation, accumulation and obsolescence of information technology. The pressure of society includes legislation, i.e. regulations and laws. Application of ICT enables companies to cope with everyday pressures. However, implementation of ICT does not ensure success, but it is necessary for the application of ICT to pursue the objectives, strategy and business processes of the company.

Today tourism is largely reliant on technology. ICT has become the support to many functions of tourism and has opened the door to innovation. Many tasks in the tourism sector, such as direct contact with clients, entertaining and services for clients, communication with customers and partners is being done through ICT. Since the early sixties, information technology and tourism have significantly influenced the mutual development. The first significant application of information systems, databases and computer networks occurred by introducing tourism booking systems, today indispensable in the tourism business. Tourism represents a significant application in the field of electronic business based on the B2C relations (business-to-consumer).

In the process of creating tourist attractions and its adjusting to the demand, various tourism products and services have been developed for the purpose of segmented business and creating specific forms of tourism. Most of the products and services result from an act of free innovation, while others appear as a by-product or a surrogate of indirect intentions.

The impact of the Internet on the tourism sector is reflected in the following. Suppliers, intermediaries and consumers (tourists) are the participants in the domain of the tourism. Suppliers (hotels, airlines, cars and vessels rental companies) provide the tourism and travel products. Tour operators and travel agencies, as intermediaries, create travel packages, and provide services of administration and sales to customers. Tourists as customers are playing role of the end users. The emergence of the Internet has led to major changes in tourism:

- prompted disappearance of intermediaries
- emergence of new mediators on the Internet with changing roles of traditional ones
- enabling direct access to end-users or consumers
- providing currently transmitting reliable information
- enabling display of financial position in real time
- decrease in organizational and distribution costs
- increase in convenience and flexibility.

The Internet has increased the possibility of suppliers' and customers' influence on prices, as well as on increase of the rivalry among existing competitors. It has also offered new direct sales channels in the travel industry. In this environment, the new company must be innovative to survive. At the same time, the tourism sector is forced to adapt to new technology.

Tourism today is a global activity which encompasses many areas of human activity including information technology, in addition to economics, ecology, sports and culture. Unlike other areas, tourism has always been open to new technologies. It wanted to meet the demanding needs of individual end users who, with the help of information and communication technologies, are not looking for the raw information only. Individual users want to become travel agents of their own in order to plan and organize their trips independently by using various forms of travel services. At the same time, the Internet has become an important medium of communication with the growing number of users in the world, and certainly the means of achieving the goals of end users who use the Internet not only for booking or buying plane tickets, but also for collecting relevant information for their possible travel arrangements. With the exception of the tourism offer that attracts tourists with its information, there are other types of information which, besides informing, encourage and guide the thinking of tourists, thus directly influencing their decision on taking trips. Useful information is often found on various social portals, blogs and networks, where individuals share their experiences and interests. Such forms of communication and information are increasingly serving the tourist industry, which places them on their websites and uses them as an additional way of attracting tourists.

The Internet is rapidly taking the characteristics of social media, which are:

- openness of communication

• reliance on community
• ease of connectivity
• active participation
• development of the spirit and atmosphere of cooperation.

In the first decade of the 21st century the Internet was transformed into a first-class social media, which in no way diminishes its business value and role. From a business standpoint online virtual space becomes even more interesting with the growth of its variety and diversity, and the interest of its users in what is happening in this space is increasing.

II. AIRBNB ONLINE SERVICE

Going on a trip that does not involve costly agency arrangements and hotel accommodation has become a frequent mission of tourists. The number of online services that enables it is increasing. Through them, one can book a desired type of accommodation in the desired destination and with the price range that is most acceptable to the traveller, in either modest or luxurious accommodation.

For this reason over the last few years, a multitude of Internet services have emerged based on the principle of shared economy or collaborative consumption or peer-to-peer (P2P) marketplaces, which are engaged in renting and sharing accommodation and various facilities and activities. An excellent example of such a service is Airbnb.com, a website that offers exclusive accommodation in a house, apartment, boat, room or something less conventional like a tree house or an igloo. Through Airbnb, accommodation can be found in almost every part of the world, and its advantage is that it is fast, clear, simple and secure. It is this latter reason why it is used by more and more tourists, but also by the renters.

The biggest problem of all these services, including Airbnb, is to establish trust with owners who open the doors of their homes. Airbnb was established in 2007 by the designers Brian Chesky, Joe Gebbia and Nate Blecharczyk. At that time, roommates Chesky and Gebbia could not afford the rent for their apartment in San Francisco, so they made their living room into a bed and breakfast, accommodating three guests on air mattresses and providing homemade breakfast. After renting their living room they earned enough to pay their own rent. They soon realized the potential in growing this market and joined with the programmer Nathan Blecharczyk to start Airbnb and changed the way people think about travel [4]. When they found the site, their goal was to create a base of private accommodation where guests can feel at home, but also to allow them to discover the local aspect of the destination, to connect with those who have already been there and to know what is not mentioned in guidebooks. Airbnb functions as a service used to host people who choose to travel cheaper around the world in an informal and friendly way. Airbnb offers comments and advices of tourists who have already stayed in a particular town, city or village and the users can find out if the accommodation is really as presented. Given that it works as a kind of social network, in a short time and firsthand one can find out where the nearest café or a shop is, as well as all the other practical tips. In order to protect their customers from unpleasant situations while still being able to plan additional facilities and activities, the approximate location of accommodation is marked on the map and the system reveals the exact street and house number only after the reservation is confirmed.

To avoid manipulation in the accommodation rating system, the reviews on Airbnb are purely qualitative. The unwritten rule is that after every staying in accommodation, travellers leave a comment, good or bad, so that future users of accommodation have better insight into the accommodation. But the site does not only assess the hosts and their apartments. As all users must create their own profile, the hosts can also assess their guests, which provide security to future hosts.

The Airbnb guests pay the full price increased for 6-12% which is the Airbnb guest fee, and Airbnb holds the money on its account until the customer appears. In this way, the host is insured in a case of cancellation by the guest, and the guest is insured in a case the accommodation is not as described on the website. In a case the guest does not show up his account will be charged and he is entitled to a refund only if the cancellation is made on time, but with a fee. Hosts are additionally insured by the deposit that Airbnb retains 48 hours after the guest's departure in a case something is broken. The day after the guest arrives and confirms that the accommodation is as described on the Airbnb site, the owner shall be paid the total amount reduced by 3% of the Airbnb charge. If guests are not satisfied with the accommodation and confirm it through the system, on the same day they must vacate the property and then they can get their money back or ask Airbnb to divert money into an alternative accommodation [6]. The advantage of Airbnb is extremely simple communication with the owners. Once the guest has selected some of the accommodation offered, via e-mail or social networks that are integrated into Airbnb site, he contacts the host and sends him his request. Since it is not obligatory to accept every guest, the host must first accept the request, and only then follow the booking and payment. Thus, the system of Airbnb's business is to a greater extent adjusted to hosts than to guests. Guests do not have much control in the process because the host can cancel their reservation at any time. On the other hand, Airbnb is investing a lot of effort in preventing the misuse of their services in terms of direct negotiation between guests and renters, because in that way the landlord could lower the price for the amount otherwise taken by Airbnb, and thus convince the customer to stay with him. Because of these actions, the system automatically disables the visibility of contact numbers or e-mail, until the booking has been confirmed.

In order to protect their users, Airbnb also started the offline verification during which the guest and host are identified by using identification documents such as passport, driver's license or ID card, and in adition to that a voice and video verification systems. Verification serves as a guarantee that their data on the profile are correct and accurate. Renting accommodation is possible only to those owners who have online verification of their profile. Airbnb also introduced a 50,000 dollars physical-

property guarantee for hosts to feel more secure about renting their accomodation [7].

In addition to online users, Airbnb pays a great deal of attention to the users of mobile phones. Over a quarter of its users visit Airbnb's site via their mobile apps. Today's 'mobile' generation of users finds the experience of knowing the environment more important compared to renting rooms. For example, instead of looking for a shop on the Internet, they will rather ask someone who lives there through the application and get an answer in a few seconds. Besides the world leading destinations, using Airbnb one can easily find accommodation in Croatia. By typing in Croatia in the desired destination, thousands of proposals are offered.

Until a few years ago this American startup was known only to the immediate community of Silicon Valley. After a year of business, its founders have almost given up on it. However, by 2014 Airbnb has reached a figure of over 11 million bookings. The site now offers over 600,000 units in 34,000 cities in 192 countries [3]. Besides being useful for tourists, Airbnb is one of the hottest technology startups in the U.S., and is valued at about 10 billion dollars [5]. Online site meant for finding accommodation around the world is employing over 600 people in 12 offices in the Americas, Europe, Asia and Australia. Expansion beyond the borders of the United States began in May 2011 when Airbnb bought German rival Acceleo. This lead to the opening of the first international Airbnb's office in Hamburg, and later of another one in London. Given the increasing number of its service users, in 2012 Airbnb has opened six more offices including Paris, Milan, Barcelona and Moscow. At the end of the 2012 the company announced that it would focus on Australia, the second largest market after the U.S., as well as Thailand and Indonesia. Therefore, Airbnb opened an office in Sydney, and the Australians now constitue one tenth of the Airbnb base. A few weeks after the announcement of aggressive expansion in Australia, they also announced expansion into the Asian market, and their goal is to reach 2 million accommodation units.

III. The questioning method

The aim of the research is to show the possible criteria for evaluating the structure of the content, manner of presentation of information and communication, internal and external motivation, and the simplicity and accessibility of the Airbnb database.

Testing was conducted through an online questionnaire which was originaly placed on the official Airbnb Facebook wall so that it could be accessible to the entire population of Airbnb users. Unfortunately, due to strict moderation policy the link was removed from their official Facebook wall very soon, which reflected negatively on the amount of collected data, ie. on the number and structure of respondents who filled out the survey. The online survey was opened during February 2014. and during that period a random sample of 118 respondents filled it out (77 females, i.e. 65.25% of the sample and 41 male respondents, i.e. 34.75% of the sample with the average age of 25 years). The online questionnaire consisted of 13 questions and all the questions in the survey were closed type with multiple choice answers.

IV. Results and discussion

Analyzing the survey results, we conclude that most of the respondents were from Croatia (54.23%) and Italy (18.21%), followed by a less significant number of those from France, Germany, Great Britain and other countries. Most respondents (38.1%) have a monthly income of less than 1,000 Euros, which was expected considering the age structure of respondents and the standard of living in the countries where most respondents come from. The average monthly income of the respondents amounted to 1529.66 Euros (SD. 1284.34). With the further analysis of the results, we see that 41.53% of the respondents travel 2-3 times a year, 21.12% of the respondents once a year. Ultimately, the respondents travel on average 2-3 times a year.

In the questionnaire there was a set of questions from which the TRI-index (*Technology Readiness Index*) was calculated for every respondent. Technology Readiness Index (TRI) is used to calculate the willingnes of respondents to adopt and use new technologies. This index is based on the examination of feelings that the respondent expresses for new technologies. Components, i.e. feelings covered by the TRI-index are: optimism, innovativeness, discomfort and insecurity. The above feelings are measured by Likert scale as a series of statements in which the respondents can assess how much they agree or disagree with a given statement on a scale of 1 to 5. The obtained result is the assessment of how much a particular individual or respondent is willing to accept new technologies. Readiness assessment includes the evaluation range of -20 to +20. If the above assessment scale is divided into five equal parts, it is possible to distinguish between the following categories of respondents:

1) people reluctant to use new technologies (from -20 to -13)
2) paranoids (from -12 to -5)
3) skeptics (from -4 to +4)
4) pioneers (from +5 to +12)
5) researchers (from +13 to +20).

Therefore, if the level of TRI-index is higher, the tendency of respondents to the acceptance and use of new technologies is greater.

Given the age of the respondents we get the expected structure of the respondents with respect to the TRI-index, i.e., we have 36.44% of sceptics, 61.86% pioneers, and 1.69% of researchers. 12.71% of the respondents have found out about the Airbnb service through newspapers and television, 36.44% via the Internet, 38.14% from friends or relatives, and 12.71% from other sources. 44% of respondents use this service to rent their own accommodation, 35.59% are planning to do so, while 20.33% of them are not attracted to the option of renting their own accommodation through the Airbnb service. Our respondents spend 3-5 days (51.7% of respondents) or one week (46.6%) on a trip in average.

Table 1. presents the average and the most common assessments of the Airbnb service elements arranged in groups according to the TRI-index of respondents.

Hosts English proficiency	**4,779**	**5**	**3,326**	**2**	**5,613**	**6**
Cancellation policies and fees	**4,356**	**3**	**4,326**	**3**	**4,373**	**3**
The amount of commissions for the hosts and users	**5,093**	**7**	**5,349**	**8**	**4,947**	**7**
The possibility of errors (lack of control) when setting prices for accommodation (for hosts)	**5,093**	**4**	**4,628**	**5**	**5,36**	**6**
The possibility of hosts last minute cancellation	**4,186**	**1**	**4,395**	**1**	**4,067**	**5**
The difference between verified photos and accommodation in reality	**5,061**	**8**	**5,605**	**4**	**4,760**	**8**

From the data given in table 1. we can see significant differences in the average assessment of individual service elements between the respondents groups of sceptics and pioneers, in the elements: ease of use (F-test[1] = 3.868, p = 0.05), search options (F-test = 2.443, p = 0.05), information about the host (F-test = 4.004, p = 0.05).

From the data given in table 2. we can see significant differences in the average scores of the individual components of the service between subject groups of sceptics and pioneers, and they include the components of the functionality of the service (search speed) (F-test = 1.978, p = 0.05), the possibility of changing accommodation on arrival due to dissatisfaction with accommodation (F-test = 2.255, p = 0.05), the Airbnb ways of doing business as a form of digital economy (F-test = 1.999, p = 0.05).

From the data given in table 3. we can see significant differences in the average assessments of particular shortcomings of service between the respondent groups of sceptics and pioneers, in various

[1] The ANOVA F-test is designed to test if two population variances are equal.

components: the amount of commissions for the hosts and users (F-test = 1.912, p = 0.05), the possibility of hosts last minute cancellation (F-test = 1.696, p = 0.05).

V. CONCLUSION

Airbnb is a fast-growing online service, i.e. an online travel agency for a broad community of clients that offers a worldwide connection of hosts and customers seeking accommodation. The service itself is funded by the commission charged from hosts for the contracted accommodation which amounts to 3% of the amount defined by the host and which is significantly less than the classic tourist agency commission (20-30%), and by the commission of 6% up to 12% charged from guests. Given that today's younger people are good users of information technology, which is evident from the calculated TRI-indexes of respondents, the popularity of the Airbnb service is growing rapidly. This service is best characterized by its ease of use, search options and a lot of good information about the host, the method and the security of payment. Top rated components of this service are the ability to change the reservation date, the functionality of the service and the use of information and communication technologies used for booking.

From previous results we notice that there are no major discrepancies in the average assessments of particular shortcomings, and we see that there are also significant differences in the priority of the greatest shortcomings of the service. We conclude that the biggest drawback is the possibility of the host's last-minute cancellation, followed by the necessity of checking the availability of accommodation with the host and cancellation policies and fees. The group of pioneers who are familiar with the new information technology is not highly dissatisfied with a lack of additional communication with the host and the host's possibility of cancellation at the last moment because they will, with the help of information technology, quickly and easily find alternative accommodation. Because of reduced commission this way of doing business where everything takes place in a virtual world is becoming increasingly common and popular among hosts and users looking for accommodation. This service is significantly growing from year to year and it is expected that more such services, i.e. online travel agencies or companies will become a good example of the digital economy and the companies that generate profits with minimal costs. This research can serve as guidelines about what future online travel agencies should improve or change to make themselves more acceptable to users.

Abstract - The digital economy brings with it a number of opportunities, but also new challenges and rules of the game in the global market. Positioning of the country on the global stage largely depends on its ability to adapt to new conditions. Digital economy brings a new set of benefits, which can make it possible to reduce the differences that exist between rich and poor nations. Developing countries have the opportunity to transform its economy and to contribute to the development of the digital economy. Although these economies are characterized by high added value, faced with numerous obstacles, many developing countries can not adequately respond to the demands of the digital economy. Inadequate access to the latest technology, sophisticated telecommunications infrastructure, low computer literacy as well as numerous cultural and socio-economic factors are just some of the challenges that developing countries have to face. On the other hand, with a clear policy and specific plans and objectives, it is possible to "skip" a few steps and effectively respond to the demands of the global market. This paper aims to analyze the challenges and opportunities that are facing developing countries in the process of creating the digital economy.

Key words: digital economy, ICT, digital divide

I. INTRODUCTION

Concepts 'digital economy', 'information economy', 'information society' and 'knowledge economy/society' are very connected and often interchangeably used. However, the concept of 'information society' substantially starting to be used as a unifying term . In favor of this, some authors suggest that the term 'information society' is presented as a strategic objective in order to overcome existing social stagnation. Central argument is that the information society can create and provide millions of new jobs; it guarantee economic competitiveness; brings environmental benefits; intensify democracy; revolutionize the way of life and work with the help of new communication technologies.

On the other hand, some authors define the information society as a society that is characterized by rapid growth in the use of information - a society in which the quality of life and economic development significantly depend on the information and its use/exploitation, increased use of computers, e-commerce and use of technology for community development. In addition, there is also the explanation that the information societies are the national economy in which more than half of the workforce are employed primarily on activities that are information-oriented and in which the net product of these activities is greater than half the gross national product .

II. CHARACTERISTICS OF THE DIGITAL ECONOMY

The digital economy is characterized by numerous phenomena in the global business environment, including, but not limited to globalization, digitalization, virtuelizaciju, and disintermediation [8]. The phenomenon of globalization has internationalized economy expanding market reach, scope and speed. Borders gave way to electronic constraints that enable millions of businesses through various, mainly online oriented initiatives to carry out (online) transactions in seamless manner. Digitization has eliminated the need for human contact, implying that goods and services are no longer required to be tangible, making activities directed towards the development of eBooks, digital music and the like. On the other hand, visualization has made the physical location and proximity irrelevant, in addition to providing opportunities to business transactions to be carried out in a virtual environment, including communication between multiple entities on both sides of the interaction and also communication between one or more subjects of interaction. Finally, disintermediation has enabled consumers to bypass intermediaries and directly reach to the producers.

Applications of the digital economy (like e-commerce) are mostly driven by information and knowledge sources, and their use is significantly facilitated by widespread access to computers and the Internet. The main resource for production and use in the digital economy is just knowledge, and therefore managing information and knowledge i the key element for organizations that want to improve their business. Centers of information management are focused on several issues, including the creation and maintenance information, search for documents and other data objects as well as reviewing and reuse of data. Further issues include setting information, data extraction, publishing and distribution, as well as providing access to information. As well as information management, effective knowledge management is very important for the development of the digital economy. From the point of knowledge

management, human ingenuity is the most important factor in the growing digital economy. Constant technological innovation make it that a success in the market is largely dependent on the skills of the workforce. In the digital economy, nothing is important as it is human ingenuity, and the future and the success of the digital economy of just relying on this new type of worker. Thus, knowledge management is becoming an important topic in public organizations, although private firms have been already taking into account the management of knowledge as a critical determinant of the competitiveness of the company. In the private sector, the importance of knowledge management has been recognized for more than a decade, and today this sector can boast to have a fairly developed knowledge management systems.

III. DIGITAL ECONOMY DRIVERS

Various factors have given encourage to the transformation from the industrial economy to the new digital economy. Building confidence and security in e-commerce transactions represents one of the most important issues. The development of the digital economy also depends on the elimination of obstacles (such as legal uncertainty regarding the execution of electronic contracts, protection of privacy and personal data, copyrights, etc.) that interfere with transactions in the electronic environment. An appropriate regulatory framework that is adjusted and corresponding to the electronic environment is very important because it can increase: the growth and development of SMEs; workforce with appropriate IT skills, sustainability and a significant number of highly-skilled workforce; growth and greater use of the Internet; significant coverage of the broadband Internet, and self-regulation, especially when it comes to using the Internet [8].

Digital economy can also be enhanced by the extensive development of broadband communications in the business sector, government buildings and residences. Further growth of improving will require enabling legislation and government incentives; effective knowledge workers, education and training, development of governmental and private sector programs that promote digital democracy and ensure that all sectors of society realize the benefits of broadband revolution, as well as the expansion of citizen participation in decision-making processes in government through e-governance. Advances in ICT has been created under the pressure for reform and the digitization of both internal activities as well as activities in relation with the customers and the related trading partners. As a result of these changes, businesses today need to accept the network society and install business processes which are based on information and communication technologies for both front and back offices. Measures that can improve e-business include: enabling legislative systems, the diffusion of electronic payments for the business sector, reducing communication costs, and the development of skills necessary for the use of e-commerce business models. Further, given that it is not simple for individual SMEs to require sufficient human resources, know-how, technology and content, SMEs can use of their characteristic mobility and flexibility to collaborate with others. They can also build mechanisms that will implement the overall business activities over the Internet.

IV. DIGITAL ECONOMY CHALLENGES

In the digital economy era, which is largely defined by applications of e-commerce, it is expected that there will be improvement of efficiency due to reduced transaction costs and time, increased competitiveness, and much more streamlined business processes. Some authors assume that the greater efficiency will be manifested in lower prices, much more frequent modifications price, and a lower price dispersion for identical products. Lower costs of research may also lead to Internet consumers become more sensitive to price changes. Also, the development of the Internet and e-commerce influence on changing the way in which payment is made for goods and services, which as a result may have some implications in the establishment and functioning of monetary policy. The characteristics of the digital economy can change the extent to which e-commerce facilitates much more efficient inventory management, which leads to lower inventory as a ratio of sales. In addition, increased competition in the prices of products on the market may allow the economy to sustain many more jobs without increasing inflation over time, and may also create greater pressure on companies to restrain income growth and change processes that generate inflation.

There are several challenges that the business sector is also met in the environment of the digital economy. These challenges include the small number of trained workers in jobs that use ICT, the dependence of most of the business transactions that require a low level of knowledge intensity, broad and growing social and economic disparities, as well as the challenges of a complete migration services online to make them accessible to everyone. Some authors emphasize the following challenges of the digital economy: problems of lack of information/ computer literacy, slow understanding of importance of broadband, low proportions of people in the "e-workplaces", social and economic inequalities. On the other hand, it is possible to identify the challenges such as productivity in the economy, protection of intellectual property rights, invasion of privacy of the individual, the disappearance of certain types of work.

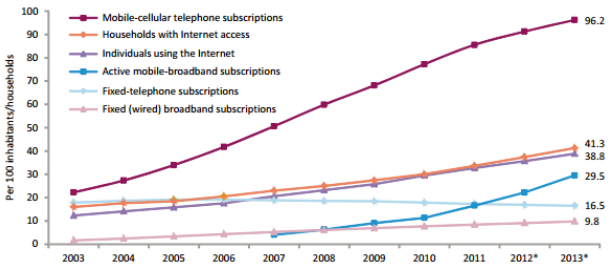

Figure 1: Global ICT developments, 2003-2013 (Note: *estimate) [14]

Some general trends indicate that the digital economy continues its rapid expansion. It is present in every country, in every sector, in most companies, and used over two billion people. By some estimates, already in 2016. year will be 3 billion Internet users. That same year, the digital economy will reach a value of about 4200 billion dollars within the G20. The digital economy in the 2010th took part with an average of 4.1% of GDP in group of the twenty most developed countries, representing about 2300 billion dollars. In some countries such as the United Kingdom, the digital economy contributes to GDP with 8.3%, which in other words presents a great web-dependence. The rapid growth of the digital economy will mostly depend on two factors, namely new users and faster Internet access. Thus the digital economy in the near future will be a very important factor for economic growth and job creation.[4]

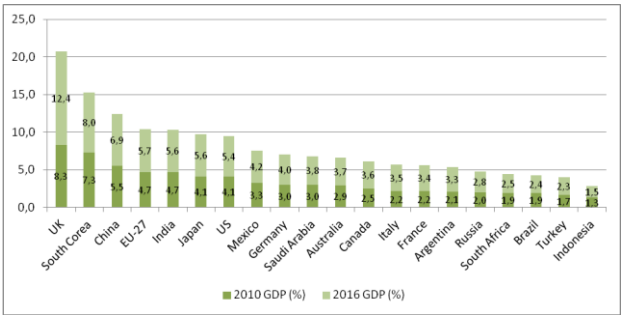

Figure 1. Internet economy as a percentage of 2010 and 2016 GDP [4]

As already stated, the digital economy is becoming a key element of growth and development. Almost all macroeconomic and statistical analysis show that the digital economy participated with 10 % in GDP growth of observed countries in the last fifteen years, and this influence is growing every day. [3]

The influence of the digital economy is evident in regard to a work force worldwide. The general trend is that certain traditional jobs disappear, while on the other hand new jobs are created with different qualifications. According to some estimation in developed countries like France, in the last 15 years the Internet has destroyed 500,000 jobs , while created 1.2 million new, which is a net difference of 700 000 new jobs. In other words , for every lost job elsewhere creates 2.6 new jobs.[3] The greatest significance of the digital economy is reflected in the modernization of traditional activities in the economy. The result is reflected in a major change in value between the sectors in the global economy, and thanks to that all industries have benefits. Creating an attractive business environment is following process of the digital economy and thus investment in the digital economy is the key to the prosperity of any country.

V. DIGITAL ECONOMY IN DEVELOPING COUNTRIES

An important question to be posed to the creators of economic policy is whether the new opportunities that are provided in the digital economy can improve the position of developing countries or they even further deepen the gap that exists between them and the developed countries. According to many authors, globalization and all its consequences make it possible to reduce the differences between rich and poor nations, where a key role is played by information and communication technologies. They provide to a developing countries a wide range of options to transform their economies into information economies with high added value that can compete with advanced economies on a global level. Simply put, developing countries can not "afford the luxury" to miss the opportunities that these technologies create. Some developing countries are increasingly turning to IT sector to accelerate its economic growth. However, this does not apply to all countries, because there is the other side of the coin: faced with numerous obstacles, many countries have not adequately responded to all the demands of the digital economy. Many problems are faced by developing countries, and which concern the implementation of modern information technologies, threatens to make those countries even more marginalized.

One of the main obstacles to the development of information technology in developing countries is the general use of computers by the population, i.e., the possibility of access to modern technologies. As one of the indicators, it can be seen the number of Internet users in these countries. While the world has become home to over 7 billion inhabitants, only one-third use the Internet. The data are worrisome from the standpoint of developing countries since in 2013. year only 30.7% of the population (on average) uses the Internet, which is unfavorable information in the age of the Internet revolution. However, important information that can be gained by analyzing the data is that the number of Internet users in these countries is growing at a higher rate than in developed countries. That's compared to 2005. year, the number of users in developing countries is increased by about 145%, while the indicator for developed countries is at the level of about 50%. So in the future we can expect a gradual "catching up" of developed countries on this indicator. [14]

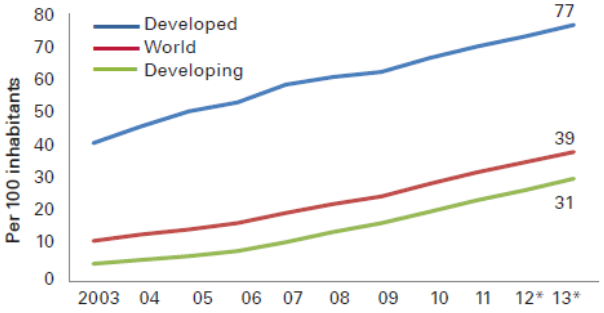

Figure 2: Internet users by development level 2003-2013 (Note: *estimate) [14]

Speaking of the digital economy it is the inevitable question of the use of broadband Internet. This information is important because this type of internet provides high speed data transfer, and thus it is the basis for the development of modern information technology in society. As for the number of Internet users, here is also evident a big gap in developing countries compared to developed countries. This indicator is for less developed countries by as much as 280% less compared to those that have been developed. In addition, the pace of growth of this indicator in these countries was insufficient for a period of 2007th to 2013th year.[14] It is for these reasons the slow growth of broadband has been cited as one of the main challenges of the information economy in developing countries. It is cheaper, faster and more secure access to the Internet, with the implementation of Wi -Fi basic prerequisite for the development of information economics, and thus a factor for the development of developing countries. As one of the recommendations for developing countries in terms of faster infrastructure development in the field of information and communication networks, it is stated the correct level of taxation in the field of ICT, in order to encourage domestic and especially to attract foreign investors. It also highlights the growing cooperation between the private and public sectors, as well as increased investment in research and development of both of these sectors. Telecommunications in developing countries are very weak in comparison with the current international standards.[1] In the 2013 the number of mobile phone subscribers was almost equal to the population of the planet. However, while in developed countries the number of mobile phones exceeds the number of inhabitants (that is 128%) in developing countries this figure is 89%. For example, mobile phone penetration rate in Montenegro is over 180% in many years: in 2008 it was 193%, 2009 - 197% and in 2010 - 197% while living standard i.e. GDP per capita is approximately 5.000 EUR. On the other hand, when compared to developed countries, mobile telephone penetration for example in Denmark is 153% and GDP per capita over 41.000 EUR, or in Netherlands where mobile phone penetration is 121% and GDP per capita over 35.000 EUR. This might be considered individual case instead of common rule for developing countries. However, the fact is that aforementioned level of information and communication technology use is much bigger than expected with regards to living standard of population.[9]

In addition to inadequate access to the latest technology, sophisticated telecommunications systems and infrastructure, also human factors in developing countries occurs as limiting. More specifically, one of the biggest challenges that this countries must face is the problem of low computer literacy as well as the low percentage of people who are dealing with an "e-businesses". Qualification of people to use information technology is often at a very low level. Most developing countries are characterized by low earning opportunities of this kind of education, especially when it comes to practical learning. Some of the measures that have been recommended to address these issues are: reducing cost of computer equipment and Internet access, free computer courses for the population; construction of computer classrooms in schools; constant training and upgrading of the teaching staff of the IT discipline; the introduction of specialized studies in the field of informatics science at universities; consumer protection, their safety and security while using the Internet and the like.[8]

Talking about these recommendations, it should particularly put focus on children and youth as a target group which most easily accept change, and already has a certain knowledge of using the computers. The importance of continuing education and learning is also increased, and in fact it is yet more proof that investing in knowledge is a basic precondition of using all the advantages of information and communication technologies.

The importance of computer literacy can be viewed also through the perspective of business enterprises. Modern enterprises around the world are increasingly turning to electronic commerce. The advantages that this type of business brings are various: starting from cost reductions on various grounds, via possibilities to respond faster to customer needs and attract the same all the way to global market presence.[10] To take full advantage of these benefits, i.e. that the company could start with the implementation of electronic commerce, the basic condition is that the company has a web site, i.e. that is being advertised on the Internet. Unfortunately, many companies in developing countries do not meet the basic criteria, mostly because of computer illiteracy, and therefore it is difficult for them to be competitive in the global market.

Besides the already mentioned problems of computer literacy, on the difficulties in the implementation of information technologies have the influence political and cultural factors. In fact, while in democratic societies, information and communication technologies are more than welcome as it will guarantee transparency, equal access to information and competitiveness, that is not the case in autocratic societies[7]. Different cultural and

sociological frameworks provide different significance to the information. In those environments that are "friendly oriented" when it comes to information, the education system has been created in the way to encourage curiosity and the search for information and answers to various questions. In other areas, people are accustomed to receiving information from the authority, someone who is in the hierarchy above them and therefore do not feel the need to search for them yourself . In these countries educational systems are often created not to encourage curiosity: there is only one right answer to the question, and what is the "right" answer is defined by the educational authorities. Regarding cultural factors, as one of the main problems emphasizes language barrier (about 55 % of web content is in English, 29 % of the content is in Russian, German, Japanese, Spanish, Chinese and French, and 15 % of the content is written on one of the 25 languages of Europe and Asia . Almost no content exists on any of the other 6000 languages in the world that are in use today[11]) .

In many countries, information technologies are hard to accept because they encourage "creative destruction", i.e. changing lifestyles that are traditionally used in these countries for many years. [5] This is especially present in countries with strong cultures, which hardly give up their traditions. Some countries even restrict access to the Internet due to concerns that it badly affects some religious or cultural beliefs. Another type of problem that comes from political authority in the country is the policy of maintaining the monopoly of national companies, which actually the state bureaucracy represents brake for the development. How will the country successfully position itself in the global market in the era of digital economy largely depends on the political process in the country. There are very often cases in which for the sake of achieving certain political interest groups, adversely affects the technological position of the country. Inefficient state monopoly enterprises in the ICT sector can with keeping high prices prevent large numbers of citizens to participate in courses that should characterize a information society.

As one of the key challenges of the digital economy in developing countries is referred to social and economic inequality. Generally speaking, the use of mobile phones and Internet access, namely the application of information technology should reduce the gap between rich and poor nations, because it provides equal opportunities to all. However, one should take into account that not all have the same starting position, or equal access to new technologies, which often affects even greater stratification between developed and developing nations. Also, the Internet in one country, people from the provinces, can provide capabilities that were previously reserved only for residents of the metropolis. But despite this, in some countries the gap between urban and rural areas is becoming increasingly higher. Developed cities are often surrounded by many villages that have almost no access to modern technologies. Due to the low population density in rural areas, they are often confronted with very high costs when it comes to investing in ICT infrastructure.

VI. CONCLUSION

Growth and development of the digital economy will certainly accelerate in the coming years through all areas of society because the number of people accessing the Internet multiplies as its commercial use is growing. Growth will be directed by four types of economic activities: using the Internet, a significant increase of computers, software, services and communications investments, e-commerce in the business sector, with improvements in productivity in the use of electronic networks to create, purchase, distribution, sale and supply of products and services, digital delivery of goods and services, such as software programs, music, etc., as well as retail sales of material goods and services that are produced, stored and delivered physically, such as computers, software, cars, books, flowers, etc.

It has been said that the digital economy brings a number of benefits to developing countries. Use of the Internet leads to greater transparency and strengthening democratic society. Also, it becomes essential to learning and career development. Information technologies increase productivity and affect the economic growth of the country. For this reason, developing countries need all its efforts to focus to overcome all the mentioned obstacles.

Clearly, the information-technology revolution as a new economic paradigm tends to reduce the differences in development between the rich and the poor, i.e. developed countries and developing countries. The application of new technologies, led by computers and the Internet has increased transparency and strengthened democratic society. However, as noted, there are many challenges facing the economies, societies, governments and individuals. All the challenges and obstacles can be overcome, but with the constant growth of productivity and competitiveness by investing in the knowledge that stands as a maxim in the new economic order. The pace of change is accelerating, and to avoid marginalization on the world stage over time it will require increasing investments in information and communication technologies and development of the information society as a whole to help developing countries achieve the objectives of the strategy of rapid, sustainable and inclusive development.

SECURE DATA STORAGE

Pančo Ristov[1], Ante Mrvica[2], Toni Mišković[3]
[1]The Faculty of Maritime Studies in Split
[2]Jadrolinija d.d. Rijeka
[3]Student of the Faculty of Maritime Studies in Split

Abstract - Secure storage of data and the current availability of data and information are the most important aspects of any ICT (Information and Communications Technology) system. Data storage systems are mandatory components of modern information systems. The term backup refers to creating a backup or copy of data with the aim of restoring the data in case the original data become corrupted and inaccessible. Reliable and secure automated data storage is nowadays of great importance for business based on the smooth progress of information in an enterprise. Companies have to implement appropriate systems for securing the data storage. Some shipping companies use systems for saving data and applications in the so-called cloud. Cloud computing enables efficient and reliable fleet management. This technology reduces the cost of managing data and information resources, regardless of the size of the fleet.

I. INTRODUCTION

The application of information technology in business processes of the companies generate large amounts of data to be stored, regardless of whether these include output data and information from information systems, ship agents and agencies or data downloaded from the Internet. It is known that data and information represent valuable corporate assets, therefore the loss of data and information may cause great damage, regardless of the company size. For this reason, managements have to consider and decide on the safe storage of their data and information.

Each domestic and foreign shipping company has a specific need to share data, information and patterns among their workers (seafarers), maritime agents, agencies and business associates. Also, individual departments within a company have a need to share some information among their members, while keeping these data unavailable to other employees (e.g. actual cost of the ship in operation, fixed and variable costs of the ship, insurance and insurance premiums, value of the vessel...). Furthermore, each employee such as a ship's master has a need to store data in a way that only one person or a certain number of authorized staff can see them (e.g. technical condition of the vessel, fuel and lubricants...). Therefore, it is necessary to secure locations. These locations include local drives, network drives and servers that are established within the company or at geographically diverse remote locations. Each company should decide on a single, comprehensive and reliable solution for secure data storage. Such a solution should have all or as many of the following characteristics as possible:

- The possibility of saving data in multiple media
- Ability to deploy recovery after failure
- Unique system of the management and monitoring of the data saving process
- Simple interface of management and control system of the data saving process
- Deduplication features and deduplication at the source and the destination (magnetic tape or disk)
- Options for archiving data from file systems, databases, electronic mail, etc.
- Simple upgrade of the management and supervision system of the data saving process
- Deployment of storage systems without burdening the LAN

All companies, especially small and medium-sized ones, have to define their backup policy for securing relevant data. A backup policy is a set of rules within an organization which defines the activities related to data storage. Prior to defining the backup policy the following facts should be taken into consideration:

- Backup frequency - daily, weekly, monthly?
- Point of recovery - depending on the speed of data changes and their importance
- Types of backups - it is possible to implement various types of data backups
- Devices for backup - magnetic tapes, DAS (Direct Attached Storage), NAS (Network Attached Storage), SAN (Storage Area Network) devices...?
- Secure storage at another location - backup data stored at another location. The question is how often and where to perform the backup?
- Backup in the cloud - whether a data backup in the cloud is required?
- Safety - whether the encryption during storage is preferred?
- Items to be stored - applications, business documents, emails, databases?

Backup creation has two different purposes. The primary purpose is to retrieve data in case of data loss, while the secondary purpose of backup is to restore the data from historical moments within the constraints set by the user for defining backup.

The implementation of the backup policy most often depends on the financial resources required for this

investment, on the legal regulations of the country and on the corporate policy.

II. STORAGE MEDIA

Regardless of the system used for secure data storage, the data have to be stored in certain media. A backup device is one of the most important factors when defining the backup policy. Workload during data storage will depend on the selected backup devices. In practice, the following media are in use:

- Magnetic tape is the most widely used media for storing large amounts of data, backup, archiving and sharing. Tape is the media that requires sequential access data. Data access time is longer compared to other media, while periods of continuous reading or writing can be very fast. Newer magnetic drives are faster than modern hard disks. The advantage of this medium is the reliability and availability because the stored content can seamlessly be used for 10, 20 years and over in comparison with other media. Another advantage of the magnetic tape is a better capacity/price ratio compared to other media.
- Hard disk as a storage medium is increasingly preferred for mass storage of data because the ratio between capacity and price has been significantly improved compared to magnetic tape. Computer technology offers high-capacity drives, low access times, availability and easy connection to the computer (portable hard drives). On the other hand, there are a number of downsides: the hard drive may be physically damaged, especially in transport, or burned out by unprofessional handling; moreover, the stability of data stored on hard disks is questionable in the long run (decades). As a data storing medium, the hard disk has been increasingly used in marine information systems such as propulsion information system. The implemented configurations of propulsion information systems use only one hard drive (industrial design). In order to increase the reliability and availability of the information propulsion system and thus increase the security and safety of the ship, it is necessary to implement redundant disks or configure RAID (Redundant Array of Independent Disks) array.
- NAS (Network Attached Storage) devices consist of multiple hard drives. Depending on the number of disks and the possibilities of a computer platform, NAS devices range from small household appliances to the enterprise solutions fitted with ten or more drives in various RAID redundant disk arrays, featuring high capacity and very high reliability. NAS drives are perhaps the best solution for medium and small businesses.
- Optical media include media such as blue-ray, CD (Compact Disc) or DVD (Digital Versatile Disc) discs. Blue-ray is the successor to the DVD. There are two variants of the Professional Disc for Data & Professional Disc for Broadcast. Writing data is based on the "phase change" technique with the possibility of multiple data logger. This technique allows the storage of massive amounts of data and is price competitive, compared with hard drives or tape drives. It is possible to use a CD-R/RW or DVD-R/RW media that are cheaper and more universal than blue-ray discs; however, it is not recommended to use these media as the results of technical and scientific studies indicate that this method of storing data is not sufficiently reliable. If a user is forced to use this media type, the DVD-RAM (Digital Versatile Disc-Random Access Memory) would be a better choice.
- Media with no moving parts include flash memory, USB sticks, SSD (Solid State Drive) drives, etc. Flash memory or flash EEPROM (Electrically - erasable Programmable Read-Only memory) does not require additional drivers to operate and is used where it is essential to store data on a medium that is physically as small as possible. SSD disks have no moving parts, which solves the problem of vibration and noise. In addition, they are characterized by low power consumption and, consequently, low heating rate. Two memory types, NAND flash and DRAM, are used for writing data. Magnetic radiation has no impact on SSD drives. Media with no moving parts are quite expensive compared to offered capacity (poor price/capacity ratio).
- Remote Backup is data storage on remote servers (storage in the clouds). The development of the internet technologies (broadband transmission) and computer technology has enabled the creation of data centers that provide secure availability of critical data, applications, office functions, etc. The services offered by data centers are becoming increasingly popular as a backup on remote servers protects from the worst scenarios such as floods, earthquakes, fires, war and other disasters that might destroy all local backups or those in close proximity. Besides the positive aspects of this method of storing data, there are drawbacks such as speed transmission on the Internet. It is known that the upload speed of the Internet is essentially slower than the speed of transfer to a variety of physical media, especially as upload speed is significantly lower than download, which makes backup extremely slow. Another negative feature of this data storage method is related to the trust in the people working in data centers. This problem can be solved by encrypting data before sending them to the data center.

III. DATA STORAGE TECHNOLOGIES

There are three basic types of data storage technologies: DAS (Direct Attached Storage), NAS (Network Attached Storage) and SAN (Storage Area Network) systems. DAS technology refers primarily to digital storage of data which is directly connected to a workstation or server where a computer network between computers does not exist. Data sharing is performed through computers. Figure 1 shows DAS architecture connecting the computer to a series of hard disk drives (it can be a single

disk) and the storage system. Interfaces such as SCSI, SATA, ATA or FC (Fibre Channel) are used to connect the computer and disks. The core concept of DAS architecture is the inexistence of a computer network for connecting storage devices and client computers. In other words, there is no direct access to storage devices, but the sharing of data is performed through computers. Storage devices are managed by the client operating system and the application accesses the data through the system calls.

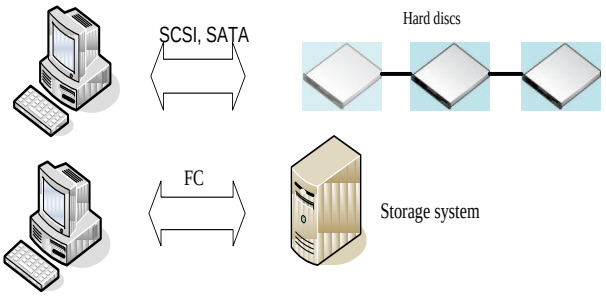

Figure 1. DAS systems

The downside of DAS architecture is that the storage capacity is limited by the number of discs. Adding or removal of one disc results in impaired access to all disks.

NAS technology involves storing data in a computer data storage (NAS device) that is connected to the LAN. Due to its network characteristics, NAS technology allows different client computers that are connected to the network with different operating systems to access the NAS device as shown in Figure 2.

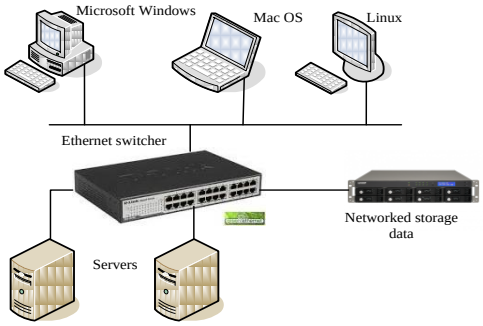

Figure 2. NAS systems

It can be noticed that the networked information storage is connected to the LAN on an equal footing with other computers so that other clients within the network can have access. Also, Figure 2 shows that the NAS device is directly connected to the switch, thus enabling all the computers within the network to share data. NAS architecture can be easily managed (internet or intranet) and the capacity can be increased to store a variety of data types (data, video, image data...). The NAS technology uses protocols such as NFS (Network File System), SMB / CIFS (Server Message Block / Common Internet File System), AFP (Apple Filing Protocol), FTP (File Transfer Protocol), HTTP (Hypertext Transfer Protocol), UPnP (Universal Plug and Play), SSH (Secure Shell), iSCSI (Internet Small Computer System Interface), AoE (ATA over Ethernet), FCoE (Fiber Channel over Ethernet), Rsync. In comparison with the other two technologies, the advantages of NAS technology include easier access to the administration, easier installation of services, data decentralization, easy set-up of RAID arrays and faster data access [1, 2]. Because of its advantages NAS technology prevails in medium and small business environments.

In the IT (Information Technology) market, there are open source software packages that provide services to NAS technology [2]:

- Openfiler is an operating system that provides a repository of data and is based on rPath Linux distribution. It is a free software package that is licensed under the GNU General Public License.
- NASLIite is a free Linux distribution (operating system) designed with the aim of converting computer-based x 86 environments into easily networked information storage. It is available for use on operating systems Windows, Linus, Mac OS K and other.
- Sun Open Storage is an open-source platform for data storage developed by Sun Microsystems organization.
- FreeNAS is a free NAS server which has support for protocols CIFS, FTP, NFS, AFP and others, and is released under the BSD (Berkeley Software Distribution Eng.) license.

SAN technology is similar to NAS technology. Data stores are separate from the LAN and implemented in their SANs networks. SANs commonly use SCSI and FC protocols. Storage of data implies a number of storage devices that are connected to each other sharing their data. A block schematic presentation of the SAN architecture is shown in Figure 3.

It can be noticed that SAN devices are connected to their own network and are separated from the LAN, using the server and thereby not affecting the traffic in the LAN network.

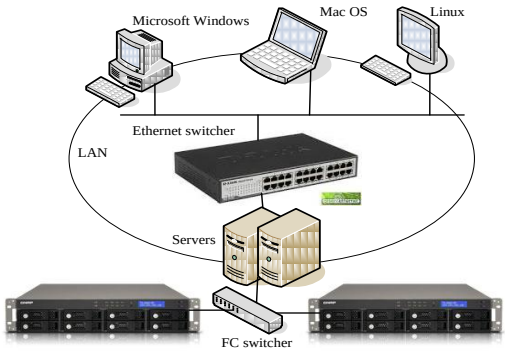

Figure 3. SAN systems

All displayed elements are connected as nodes. Each SAN system works in conjunction with one or more respective servers. With high reliability, they boast a very high configurability and adaptability. The most sophisticated systems can have up to 512 discs in a SAN system. One of the advantages of the SAN option is the quick and easy replacement of servers as SAN network "sees" resources for storage as SCSI devices. SAN architecture is a complex and expensive solution and is usually used only in large business sectors [2].

In practice, a combination of NAS and SAN technologies and SAN-NAS hybrid systems are often used. NAS system is suitable for heterogeneous environments, while SAN system is suitable for environments where large amounts of data are exchanged.

IV. THE TYPES OF DATA BACKUP

The company management shall decide on the type of data and information backup. Modern information technology offers several levels to be used depending on the size, organization, financial options, amount of data, reliability, availability, speed and availability of data, etc.

Level 1 is a way of storing data on a medium that is connected to the system which is always active and available. This level allows restoring the data in the event of a systemic failure of equipment or in the event of data corruption and mistakenly changed or deleted data. It is recommended to run in multiple layers so that individual files from multiple time points can be restored. This level does not protect data from fire, mechanical damage, theft, earthquake or flood and provides but a limited protection from electrical faults.

Level 2 or off-site backup is a way of storing data outside the company's computer center. This level of data storage protects against fire, mechanical damage, earthquakes, all kinds of power failures, floods, earthquakes, deliberate destruction of data, theft, etc. At this level the interaction and care of user (administrator) is necessary. This represents a bottleneck because administrators often do not have time to think about the defined procedures of data storage. The procedure of storing data defines: the storage time, storage media (tape, disk) and their removal to a safe location/position within the company (safe deposit box) or the outside premises of the company.

Level 3 or storing data in the cloud is an automatic back-up via the internet to secure data center servers and to a number of geographically remote locations. This method of secure data storage achieves 100% reliability because the backup procedures are programmed to be carried out automatically and without the direct influence of the administrator.

Some providers of data storage also define the state level 0 (systematic redundancy) which includes measures to be taken to maximize the security and availability of data. Practically this means that the hard drives are configured as RAID (Redundant Array of Independent Disks) arrays [4]. The concept of RAID is to draw most of the disc to the user, whether the user needs speed (RAID 0) security (RAID 1), or any combination (RAID 5, 5e, 6, 6e, 10).

V. STORAGE DATA IN THE CLOUDS

Cloud computing is an information technology that allows three models of service usage, including: software as a service – SaaS, platform as a service – PaaS, and infrastructure as a service – IaaS [4, 5]. Cloud computing represents a combination of many different existing technologies comprising the virtualization, data storage, connectivity and processing power to create a new environment. Storing data in the cloud is an easy and automated backup mechanism for real-time storage of data to a remote location. This mechanism provides a reliable solution for a centrally managed backup that facilitates easy storage of data and enables company managers and owners to protect their data as the most important corporate assets. Furthermore, this mechanism provides a very efficient compression, global data deduplication, significantly reducing the time frame for storage, energy storage capacity and loading on the network infrastructure. Data deduplication eliminates duplicate data at the corporate level, detached offices and mobile users. In addition, the mechanism verifies the integrity (Data Integrity Verification) with automatic recovery and the possibility of advanced rescue (Advance Recovery) that provides immediate availability and eliminates the need for manual data recovery activities.

Data storage system is an ideal way to effectively protect important data on a remote location against unexpected events such as theft, fires, earthquakes, floods… Data storage systems are software solutions that perform storage of data at several remote locations at certain time intervals. In a secure manner the software collects, compresses, encrypts and archives data on the servers of the service provider, which are located at several different remote locations.

Data storage systems in the clouds provide comprehensive support for a variety of user applications and databases. Moreover, the systems provide data archiving and archive of e-mail messages.

Before any piece of data is transferred, the data storage system in the clouds encrypts it with the most secure encryption mechanism. The data remain encrypted during storage and during all transfers. The system has a special module enabling that all data storage and recovery processes are registered, therefore allowing a clear overview of data operations. In addition, such a system features a multiple factor authentication of identity. In other words, the data storage system in the cloud is a set of regulations for digital storage and access to confidential data.

Data storage systems in the clouds are professionally maintained servers and disk systems, providing support 24 hours a day, seven days a week. Data are stored in three or more geographically remote data centers, thus providing unmatched availability and reliability. If there is a failure in the system, the data can be accessed in a secure manner until the re-establishment of the system's full availability.

Systems of data storage in the clouds will be increasingly present within the integrated information and communication systems because they are cost effective in financial and material terms. There is no need for a database administrator and there are no new or additional costs regarding the acquisition and maintenance of the software and hardware... The only cost is related to

paying for the service which eliminates the need for any subsequent significant investment.

Systems for storing data in the clouds provide the following basic functionalities:

- Protection of business assets - data are automatically compressed, encrypted, and transmitted immediately to the determined location or locations designated by the company management. The transfer to a safe location does not require human intervention, hence the risk of human error is reduced and the availability of information systems is increased.
- High-speed data recovery – the system ensures that all lost data can be returned to the current location or the location specified by the user. Any data can be recovered from any storage location and transferred to any specified location.
- The central point of management – the implementation of storage systems in the clouds eliminates the need for the local staff (database administrator) in charge of maintenance and the staff in charge of performing the backup process. The entire process of storing data is supervised from one location: defining the data to be stored, defining storage schedules, initiating retrieval, updating user data, access to data from any place any time. Furthermore, it is possible to monitor the status of servers and delegate users with certain rights from the central location.
- Data archiving – the system offers a simple module for data archiving. All files can be archived, including video recordings and e-mail messages. The system provides modules for searching and restoring individual email messages and attachments.
- Continuous and default schedule storage - in line with the corporate policy, the backup system performs safe storage of data in a well-defined arrangement of storage. Continuous storage allows for selecting the correct version for recovery, and each version indicates the version of the data from the period of storage.
- Secure data removal - when a piece of data reaches the end of the life cycle, the system has a module for removing the data in a secure manner, forbidding the access to unauthorized persons.
- Trace manipulation (handling) data – the system allows comprehensive monitoring of all activities and operations for internal or legally prescribed supervision. This module collects and stores all information in its original form, and provides access only to the legally authorized persons.
- Effective management of network traffic - through hardware and software support it is possible to have a flexible control of the network traffic. If necessary, it is possible to set limits of network traffic for given periods of time.

The advantages of storing data in the cloud include: fixed costs of space rental, expandability (scalability), saving to another location, speed of deployment, ease of administration, low energy consumption, reduction of electronic waste and decreased environmental impact.

The disadvantages of storing data in the cloud include data security, control, openness, scalability, backup duration, making contract with the service provider, etc.

The application of the mechanism of storing data in the cloud enables the companies to focus on their business processes and at the same time allows the technical departments (IT services) to reduce the risk of having difficulties due to the available memory capacity and the increased demand for storage space. The result is the increased efficiency and speed of carrying out the storing data process.

A. The application of cloud computing in the ship's organization

Recognizing the positive aspects of cloud computing, shipping companies such as Gardline have been increasingly implementing and using some or all of the services in cloud computing. A simplified block schematic representation of the use of cloud computing is given in Figure 4.

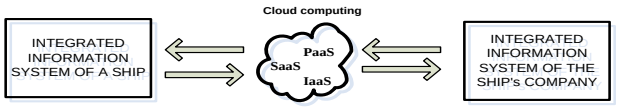

Figure 4. Use of cloud computing in a shipping company

By using cloud computing services the costs for IT management are reduced, regardless of the size of the shipping company or the growth rate. The implementation of cloud computing uses standard IT resources that are in the cloud. Secure and reliable internet connection is required for the end user.

IT companies closely associated with the maritime industry offer software applications for using services from the cloud or software applications for the management of the shipping companies and their fleets. For example, MASPAS AG company from Switzerland has produced technical software for fleet management, software as a service (Technical fleet management software as Software as a Service) [8, 9]. The name of the application is Maspas R5. It is a software application that covers the major functions in terms of the technical management of a fleet of ships including the management of assets, procurement and crew. The principle of operation of the application Maspas R5 is shown in Figure 5.

The staff in the company have access to the central database in real time via a secure internet connection no matter where they are located. Also, the crew members have access to the central database in the offline mode.

The database contains all details regarding the fleet and it is located on a central server in the cloud. Regular synchronization of data and information enables the crew and office staff to operate and use the same data and information. The flow of data between the company's offices, ships and suppliers takes place over Maspas R5.

The crew and staff of shipping companies have access to all data regarding the suppliers that are located in the central database.

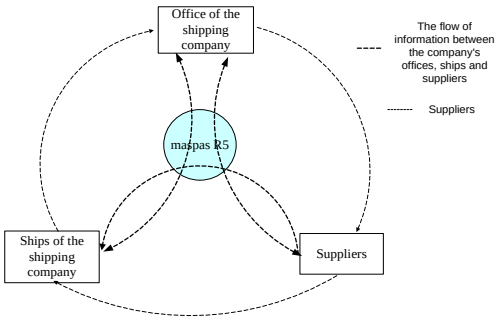

Figure 5. The operation principle of Maspas R5 [10]

Maspas R5 application contains the information system - Planned Maintenance System - PMS, which provides preventive and corrective maintenance. During ship's operation any equipment malfunction is reported via standardized interfaces (*Defect Report*). PMS includes a module for ordering and control of equipment and spare parts that are in the hold. In this way the whole process from the ordering to the receipt of the required equipment or spare parts can be monitored.

The benefits that Maspas R5 application provides include: lower operating costs (no need to purchase, manage and maintain IT resources, automatic updating of hardware and software and an improved quality of maintenance), transparency (overview in real time), improved efficiency of execution of marine processes (clear and precise instructions to the crew of the ship), fast implementation and updating of software with a small amount of data (always working with the latest version of the software), central data repository (automatic data synchronization ship-shore), accessibility to all relevant people and simple scalability (no limit growth) [8, 9].

Minimum requirements for using Maspas R5 [9]:

- Onboard the ship – ship-shore connection and server (industrial design) which is connected to the ship's computer network
- In the office of the shipping company - internet connection (> 500 kbit/s)

Satellite communication or internet connections via satellite are used to establish a communication channel when the ship is in the area outside the range of radio stations. It is known that Inmarst (International Maritime Satellite Organization) is still a leader in the field of maritime satellite communications. The latest Inmarsat's breakthrough is Broadband Global Xpress (Inmarst GX). Inmarsat GX is a global network that provides data transfer at speeds of up to 50Mbps in the incoming direction, while the outgoing speeds are up to 5Mbps. Inmarsat GX provides secure, reliable connections in real time between the ship and the shipping company [14, 16].

VI. CONCLUSION

The system for secure data storage is an integral part of any integrated maritime information system and should be treated accordingly – i.e. seriously.

The companies should have a defined policy for secure data storage practice and observe and enforce the policy of secure data storage because data loss may represent a huge financial cost and may result in problems in the business process and in loss of reputation on the global maritime market.

Combining storage technologies can boost the performance of an integrated information system on board the ship and across the shipping company. It is expected that the increased application of information technology in marine systems will result in a wider use of NAS technology because of data storage requirements.

Cloud computing is a new information technology that will increasingly expand and find application in information systems, owing to the advanced technology and the speed of the connection to the internet (e.g. Inmarsat GX).

The implementation of storing data in the cloud requires lower initial costs and shorter time to achieve productivity compared to traditional ways of storing data. Storing data in the cloud will reduce costs, increase availability and reliability of computer resources and increase profits of maritime companies. The core concept of data storage in the cloud is that the customer pays only for the service of data storage in the cloud. Regardless of the advantages, users are still concerned about the security of their own data stored in the cloud. In the near future the security problems as well as ship-shore communication difficulties will be solved and the servers of cloud computing will enable the use of almost all IT services in the cloud.

IMPLEMENTATION OF GREEN ICT FOR SUSTAINABLE ECONOMIC DEVELOPMENT

Marijana Vidas-Bubanja, PhD[1]
Belgrade Business School and Faculty for Trade and Banking, Alpha University, Belgrade
Serbia
e-mail: marijana.bubanja@bbs.edu.rs

Abstract - In the past few years, a new aspect of ICT use has emerged and become a focal point of attention in order to realize development goals respecting in the same time ecological standards and norms. This "green" potential of ICT is oriented to use of ICT in transforming activities to be more energy-efficient and, as a result, to reduce greenhouse gas emissions. There is much hope that ICT can be a major part of the solution in tackling climate change and related environmental challenges.

I. INTRODUCTION

Modern, global world based on the richnes of information and ever more oriented on information society and e-economy put sustainable development in the focus of its existance. Sustainable development must incorporate social and environmental considerations, respecting human and natural resources along with economic factors.

World Commission on Environment and Development defined the sustainable development as „development that meets the needs of the present, without compromising the ability of future generations to meet their own needs" [1]. It implies considering the desired quality of life and the attainable speed of social development, as well as the need to balance different social values. In accordance with theoretic explanations such dvelopment relies on three pillars: the economy and improved standard of living; social equity through the reduction of poverty and enhanced quality of life; and the environment enabling the preservation of natural resources for the future generations. Policy-makers are an important factor in establishing synergies and complementarities among the three pillars.

In 2008, the world was confronted with multiple crises (fuel, food and financial). As a response at negative effects of economic development on environment, but also at the financial crisis, the international community seeks solutions for creating a sustainable economy and society. In this context the concepts of "green economy", "green growth", „and green society" became more present on the international level and in the developed countries. The 'green' economy can be considered synonymous to a 'sustainable' economy. However, the Green Economy concept often carries a more distinctive meaning, one that focuses specifically on the fundamental changes that are required to ensure that economic systems are made more sustainable. That is, green economy is seen as a framework for restoring economic growth meanwhile responding to the climate change and other subjects of environmental sustainability [2].

One of the key roles in this framework has information-communication technologies (ICT) through creation of digital economy. Miller and Wilsdon [3] sustain that digital economy modifies the relation of human being with environment, changing the business models. They propose the concept of „sustainable digital economy" as a solution for the environmental issues and consider the possibility to use the creativity and dynamism of digital economy for the good of economy, environment and society. Green digital economy is based on sustainable business practices as opposed to those which function based on non-renewable resources and inefficient methods. It seeks to promote financial, business and other economic transactions without depending on or damaging the environment.

II. GREEN ICT POTENTIALS

As a "general purpose technology" or an "enabling technology" ICT are widely used in different domains, and have a profound effect on the entire economy. ICT use in business is not only becoming more pervasive, it is also progressing towards more advanced and sophisticated applications.

The role of ICT in economic development is in particular recognized for innovation, for competitiveness and for sustainability. The three domains are strongly

[1] This paper is the result of the research realized under the project 179038 –„ Modelling of the development and integration of Serbia into world trends in the light of the economic, social and political commotions", Ministry of science and education of the Rep. of Serbia.

interrelated. For example, if a company increases its energy efficiency ("sustainability"), it reduces costs and becomes more competitive. However, there can also be conflicts of interests between these domains: investments in innovative green technology may increase the environmental sustainability, but not pay off for the company, at least in the short term [4].

All three domains of ICT impact – sustainability, competitiveness and innovation – are relevant at different levels: at the micro level of the individual company, the meso level of the industry and the macro level of the economy as a whole. Because of the meso and macro effects, industrial and innovation policy in advanced economies has for many years been paying close attention to ICT.

In the past few years, a new aspect of ICT use has emerged and become a focal point of attention: the "green" potential of ICT, in particular the use of ICT to become more energy-efficient and, as a result, reduce greenhouse gas emissions. There is much hope that ICT can be a major part of the solution in tackling climate change and related environmental challenges [4].

Over the past 5–10 years a consensus has emerged that ICTs can support the development of the green economy in three principal ways [5]:

1. by decreasing *direct effects* on the environment of the production, distribution, operation and disposal of ICTs through improved energy and materials efficiency, increased use of renewable energy sources, reduced use of toxic materials and improved recycling and end-of life disposal of ICTs;
2. by increasing the *enabling effects* of ICTs on the development of the green economy through improvements in the efficiency of production, distribution and consumption of goods and services throughout the economy and society; by reducing demand for energy and materials through the whole or partial substitution of virtual products and services for their physical equivalents; and through the dematerialization of human activities and interactions;
3. By supporting *systemic effects* that result in the transformation of behavior, attitudes and values of individuals as citizens and consumers; economic and social structures; and governance processes.

The ICT industry, in partnership with other sectors, has a key role to play in helping to make society's impact visible and to demonstrate the demand for new ways of reducing that impact.

III. GREENING ICT - REDUCING THE ENERGY AND CARBON FOOTPRINTS OF ICT SECTOR

The use and application of information and communication technologies in economic and social life is rapidly increasing throughout the world. For example, it is estimated that there are now some 6 billion mobile phone users and over 2.4 billion Internet users. ICT products and systems are resource-intensive in manufacturing and distribution, consuming ever-greater amounts of energy while in use, and creating escalating volumes of solid and toxic waste. ICT products may also have negative effects on human and social health as they are produced, used, and discarded [6 and 7].

Statistical data show the following [6 and 7]:

a) Energy consumption

- It is estimated that the 1.5 billion computers in the world consume about 90.000 MW of electric power, which is about 10% of global consumption.
- Energy consumption for servers worldwide has doubled over the period from 2000 to 2005. Recent estimates proclaimed that worldwide Internet usage, via the necessary computers and servers, needs the equivalent of fourteen power stations and produces the same amount of carbon dioxide as the entire airline industry.
- Estimates confirm that total electricity consumption by ICT range from 3 percent to 10 percent in the United States and Europe.

b) Carbon emissions

- Global carbon emissions for ICT as an industry are estimated at 2 percent to 2.5 percent of world totals, but would be much higher (14 percent) if indirect energy use were included. IT now causes the release of as much carbon dioxide into the atmosphere as nearly 320 million cars. According to some calculations, worldwide IT now generates CO^2 emissions of about 600 million metric tons a year. And if the sector continues growing at the current rate, emissions in Germany alone, for example, are expected to increase by another 60% by the year 2020.
- In Europe - the use of ICT equipment in the delivery of services represents about 1.75% of carbon emissions and further 0.25% of carbon emissions come from the production of ICT and consumer electronic equipment.

The ICT industry has a major challenge to adopt and implement additional standards for increased energy efficiency of networks and services. In fact, the ICT sector needs to focus on **s**ystemic improvements and further reduce the energy consumption of its own processes (including operations, manufacturing, service delivery and the supply chain). If the sector were to adopt a more systematic approach to monitoring and measuring energy consumption at every step in a process, it could generate verifiable and comparable data, allowing it to identify opportunities for improvements and reduce energy required to deliver ICT product and services [8].

Concerning the carbon emission, the environmental footprint of ICT is large and growing rapidly. The 'carbon footprint' of an organization is the volume of greenhouse gas emissions it generates. It is calculated by assessing energy usage, business travel, and all components of the organization's operations that consume power or generate waste and by-products. An organization is 'carbon neutral' when there is balance between the amount of carbon released and the amount of carbon sequestered (for example, by planting trees). The ICT industry is in a unique position to demonstrate leadership in reducing its footprint, through *structural change* and *innovation* as well as by leading the way in identifying and creating efficient solutions for other socio-economic sectors to follow.

Good example is announcement made by the Microsoft Corporation at Rio+20 Conference. Microsoft promised to become carbon neutral in just a single year—by the start of its fiscal year beginning July 1, 2013. Registered with the UN Global Compact, an Action Network of commitment-makers from business and industry, and under the SE4ALL initiative, Microsoft's promise was to achieve zero net carbon missions (CO_2e) for it's all data centers, software development labs, offices, and employee air travel. Microsoft, one of the most reputable computer technology companies in the world

with almost 100,000 employees in more than 100 countries, generated more than 1.6 million metric tons of CO_2 in 2011. Its pledge to become carbon neutral is significant given the size of its global operations, but it is also an important demonstration of private sector leadership in the global drive to a low-carbon economy [9].

The ICT sector should be called upon to engage collectively in a process of self-improvement by agreeing on common methodologies and metrology tools to generate data about its energy performance, set realistic targets and benchmark progress. Such efforts should give due consideration to the full life cycle and related environmental impact. The ICT sector should lead by example and will be encouraged to commit such innovative practices that can be replicated in other industries.

TABLE I. ICT – VOLUNTARY ICT SECTOR COMMITMENTS TO DECREAS GHG EMISSIONS, AND RISE ENERGY EFFICIENCY

Companies	Target reduction %	Baseline *	Target date	Comment
Bell Canada	15	Not given	2012	GHG emissions
British Tele-Comm.Plc	80	1996	2020	CO 2 emissions per unit of contribution to GDP
Cisco Systems	25	2007	2012	GHG emissions
Dell	Additional 15	Not given	2012	Operational carbon intensity
Deutsche Telecom AG	20	2006	2020	CO 2 emissions
France Telecom	20	2006	2020	CO 2 emissions
IBM	7	2005	2012	GHG emissions
Intel	20 30	2007 2004	2012 2010	Carbon footprint GHG emissions per production unit
Motorola	6	2000	2010	CO 2 emissions
Nokia	6	2006	2012	Energy consumption of offices and sites
Sun Microsystems Inc.	20	2007	2015	GHG emissions

IV. ICT FOR MONITORING AND CONTROLING PROCESSES IN THE WHOLE ECONOMY

In order to realize "green sustainable economy" it is **crucial to encourage structural changes** aimed at realizing the potential of ICT to enable energy efficiency across the economy. 'Structural change' means re-engineering the way an organization operates. This can be done for instance by replacing products with on-line services ('dematerialization'), by moving business to the internet (e.g. costumer's support), by adopting new ways of working (tele-working and flexi-work enhanced by video-conferencing and tele-presence tools) and by exploring the viability of using green suppliers and energy from renewable resources.

ICTs can be an opportunity for a sustainable and inclusive future by revolutionizing business models and behavior, by making management of energy distribution and transportation more efficient, by enabling new ways of working, learning, e-health and providing public services, and by helping countries adapt to climate change and reducing disaster risk. Green ICT can improve business processes that are not directly involved in ICT, and dramatically lower CO^2 emissions throughout the process chain helping in this way to significantly reduce the other 98 % of all CO^2 emissions not caused by ICT.

With ICTs now an intrinsic element of every economic sector, the need to integrate ICT-based solutions into the environmental actions of each industry sector has become essential.

Company-level - On the company level it is increasingly important to use ICT solutions to support business processes. These solutions can streamline processes and have enormous potential for reducing CO^2 emissions, because they improve the utilization of resources and allow them to be shared. ICT also permits in-depth monitoring of energy consumption and CO^2 emissions throughout the value chain, so processes and organizational structures can be enhanced accordingly.

Fore modern companies "Green IT" is what analysts, manufacturers and providers call all IT solutions that save energy at business organizations. These include hardware, software and services [6].

Where hardware is concerned, energy-efficient desktop PCs, thin-client architectures and data-center hardware offer answers, and so do energy supply and cooling systems.

In the software and service area, there is significant potential in virtualization, in solutions for dynamic capacity management and data-center planning, and in storage-system off shoring.

And with the increasing convergence of IT and telecommunications, it possible to take the Green concept a step further. Green ICT extends to other, less commonly considered aspects of the entire life cycle. This includes eco-friendly procurement, employee behavior, running data centers on sustainable generated energy, environmentally sound disposal of used electrical equipment, and as much recycling as possible.

The most obvious benefits of Green ICT for companies are reduced environmental impact and cost savings. Besides cost reduction a comprehensive Green ICT strategy offers many other benefits – appealing to all stakeholder groups: employee satisfaction increases, the company's standing with capital markets and with society as a whole improves, and the business can attract new customer groups.

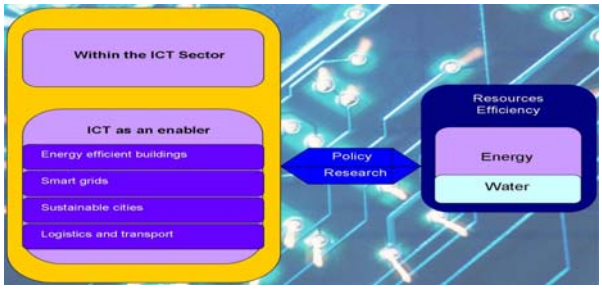
A survey carried out by Forrester in 2009 to identify the three most important reasons for Green IT activities revealed that the principal motivation was to cut spending on energy (69%). The second was to cut down on IT costs (40%) and the third to improve image. The fourth

reason cited was legal compliance (15%). It is remarkable that cost considerations play an above-average role in the United States, while image and legal compliance are more important in Europe [11].

Industry level - The potential savings are particularly great in industries with extensive, complex supply chains. Examples are involving automotive components, and the development and manufacture of cars. ICT can also have a major impact on supporting processes, i.e. via resource utilization in offices. In EU special focus on the industry level is given to buildings and construction, and to transport and logistics [8].

Buildings account for approximately 40% of energy end-use in the EU, of which more than 50% is electrical power. The sector has significant untapped potential for cost-effective energy savings which, if realized, would mean an 11% reduction in total energy consumption in the EU by 2020. There is scope for ICT to contribute to energy and environmental performance, through the application of building and energy management systems, smart metering technologies, solid-state lighting and lighting control systems, intelligent sensors and optimization software.

Transport systems represent about 26% of energy end-use in the EU. Many opportunities exist for improvements in energy efficiency and rationalization, notably through logistics. The focus is on the deployment of ICT to promote modal shift, notably on transport corridors for freight, and through the provision of multi-modal journey planners for passengers to enable significant reductions in congestion.



Picture 1. Resource Efficiency through ICT

Country level - Studies in various countries, generally suggest broad potential for ICT to cut energy use and carbon emissions. One U.S. study projects that changes enabled by broadband networks could save the equivalent of 11 percent of U.S. oil imports through transportation substitution and "dematerialization." A recent study supported by the U.S. Department of Energy demonstrated significant results from "Smart Grid" technologies to monitor and adjust home energy consumption, reducing average household consumption by 10 percent. Proactive management of home energy use by consumers in this way could reduce peak loads on utility grids up to 15 percent annually. The UK RAC Foundation has estimated that "through the use of ICT, there is potential within 10 years for a 15 percent reduction in commuter travel, 18 percent reduction in heavy freight, and a 10 percent reduction in shopping journeys by car" [7].

Partnerships between the ICT sector and other industry sectors are encouraged to identify where and how ICTs can play a role in improving efficiency and reducing emissions in those sectors and thus accelerate the delivery of tools to assess and to optimize energy performance on a comparable basis.

V. ICT IN ENERGY PRODUCTION AND DISTRIBUTION

There are two aspects of the links between energy and ICT [12]. On the one hand, ICT plays a daily part in the production and use of electricity, from the operation of power plants to electricity transport. ICT is used to model, simulate and optimize these processes in order to improve energy efficiency and reduce costs. On the other hand, ICT itself uses a lot of electricity, and work has begun on reducing the consequent economic and ecological costs.

The Information and Communication Technologies are an enabling factor in developing innovation in the whole energy sector. The main initiatives implemented by countries to reach energy efficiency targets are: increased efficiency in generation plants and reduction of network losses (technical and non technical losses). Also challenges deriving from the integration in the network of: large scale renewable sources, electric vehicles, systems for multidirectional flows management, new equipments and power electronics and real time information devices can be faced only with a strong, reliable and fast ICT infrastructure.

The energy transformation sector, dominated by electricity generation, uses around one-third of all primary energy. Given the potential for improvement in electricity generation (estimated at 30-40%) and the considerable losses in transport (2%) and distribution (8%), it is critical to improve transformation efficiency, address losses and identify any potential problems before they compromise supply. ICTs have a major role to play not only in reducing losses and increasing efficiency but also in managing and controlling the whole processes in energy production to ensure stability and reinforce security as well as in supporting the establishment of a well functioning electricity retail market [13].

Smart metering is an activity which introduces ICT potentials in energy sector. Smart metering, introduces ICTs into traditional energy-metering, can be deployed in many ways, taking advantage of ICTs to a greater or a lesser extent. Information can flow between the meter and the energy provider and between the meter and the consumer. The so-called "one-way" implementation, that only serves the energy supplier, is often favored over the 'two-way' implementation which serves both supplier and consumer.

According to the French regulator CRE, with the implementation of smart metering, they estimate an increase in supplier switch capability by factor of 10, decrease residential consumption by 5% and decrease CO2 emissions by 5% [13].

Smart metering is just a first step on the path to smart electricity grids. Smart Distribution network solutions embrace the changing structure of generation, market and use of electricity, and improve the efficiency, reliability, flexibility, accessibility and cost-effectiveness of the end to-end system. Ultimately, smart grids should facilitate, not just a better management of energy consumption, but the integration of alternative and renewable energy sources on a far greater scale than is possible today, with positive impacts for energy security and for the environment. The

liberalization of market for energy, the multiplication of local energy networks, the integration of renewable energy sources (RES), the spread of co- and micro-generation (micro-grids, virtual power plants), and new user demands require the use of the most advanced technologies for monitoring and control as well as for electronic trading of electricity enabled by the smart grids implementation [8].

The grid becomes "smart" because it will not only transport electricity but also information that will become an active part of the electricity supply system. This shall be considered as a paradigm shift in the way the electricity distribution grids are today and how they will become in the future: user and customer centric, service oriented, accommodating all needs and providing adequate solutions, supporting the migration towards and shaping of the low-carbon economy and society.

The energy efficiency targets can only be achieved with the contribution from many different sources, coming from all the energy system stakeholders, mainly customers, utilities, manufacturers, industries, governmental actors and regulators. In fact, the road towards a society without energy waste can be made easier thanks to the availability and the management of large amount of information on energy consumption for all the actors.

VI. GREEN ICT IN EU

Energy security and climate change are becoming more and more prominent on political agendas worldwide and across all sectors of the economy, so that it ranks highest among the EU's priorities. The resolve of the European Council to transform Europe into a low-carbon, high energy efficiency economy means that the continued growth of the European economy, essential to achieve full employment and inclusion, needs to be decoupled from energy consumption. The current trends are unsustainable. Indeed, if nothing were to change, final energy consumption in the EU is predicted to increase up to 25% by 2012, with a substantial rise in greenhouse gas emissions [14].

At the 2007 Spring European Council, the Heads of State and Government highlighted the development of a sustainable integrated European climate and energy policy as a top priority and adopted an energy and climate package to guide the EU towards a competitive and secure energy economy while promoting energy savings and climate-friendly energy sources. That is, Europe has set itself ambitious targets for 2020: saving 20% of primary energy consumption, reducing greenhouse gas emissions by 20% and raising the share of renewable energy to 20%. Fulfillment of these targets faces Europe following main challenges — tackling climate change, guaranteeing secure, sustainable and competitive energy, and making the European economy a model for sustainable development in the 21st century.

Information and Communication Technologies have an important role to play in reducing the energy intensity and increasing the energy efficiency of the European economy, in other words, in reducing emissions and contributing to sustainable growth. In order to achieve the ambitious targets set and meet the challenges ahead, Europe needs to ensure that ICT-enabled solutions are available and fully deployed.

The European Union policy answer to above mentioned challenges can be described as some strong combination of the Knowledge Economy and a Green New Deal. It means putting together economic recovery, by the creation of new ICT markets that address the environmental crisis, with the need to move up the value scale, to a knowledge economy. Essentially the vision is of a *Green Knowledge Society* – a Europe in which citizens and enterprises are empowered through ICT in an inclusive, innovative, secure and sustainable knowledge society [15].

In order to create the *Green* Knowledge Society the following policy issues should be included in an ICT policy agenda for Europe to 2015 [14]:

- A stimulation programme for application of ICTs in energy saving roles across all relevant industry sectors;
- Ensuring ICT is used in more sustainable behavior patterns by citizens and business;
- EU production of a next generation of green ICTs with new technologies and usage patterns – as an opportunity for Europe.

VII. GREEN ICT IN SERBIA

Serbian economy consumes 2.5 times more energy per unit of GDP than the world average and four times more than the average in the EU and can be considered as energy inefficient country. Negative statistics data further confirm need for economic structural change and transition to more energy efficient and environmental responsible economy [16]:

1. Serbian households spend 2.5 times more energy per square meter of living space from some EU countries;
2. Public lighting consume 50 percent more energy than the EU countries;
3. Serbia is dependent on energy imports - even 33.6 percent of the whole import;
4. Emissions of greenhouse gases from the energy sector in Serbia amounts to 76 % of total emissions.

Investing in the use of modern technology and IT solutions is one of the ways to increase energy efficiency and competitiveness of Serbian industry and economy as the whole. Some calculations confirm that the use of advanced ICTs in Serbian enterprises would provide savings of up to 40 percent of the energy. Current data confirm that for the most companies in Serbia energy spending usually accounts up to 30 percent of the operating costs.

Implementation of the advanced IC technologies for the increase of energy efficiency and renewable use, would directly contribute to better position and greater competitiveness of domestic companies, communities and the entire country.

Improving energy efficiency is also one of the key initiatives of the energy policy of the Republic of Serbia. New Law on efficient energy use in Republic of Serbia was adopted by the Serbian Parliament on 15 March 2013. This law establishes a system of organized energy management (energy management) for large energy consumers and the public sector (responsible for about 70 % of primary energy consumption). This Act also introduces minimum energy efficiency requirements for new and revitalized plant in the manufacturing, transmission and distribution, introduce

charges to metered energy consumption and labeling of products that affect energy consumption, and introduce eco-design requirements. The final aim is to open the market for energy services and to implement energy audits in order to identify potential energy efficiency improvements [16].

This Act is also in line with the international obligations of Serbia to save at least 9 % of gross final energy consumption to 2018, and to reduce carbon dioxide emissions by about 9 % to 2030 [17].

VIII. CONCLUSION

Nowdays world is facing multiple crisis and challenges that are mutually interlinked. We have unique opportunity to rethink current perception of growth consumption, inclusion, and how we utilize our limited resources. The transition to a resource-efficient economy and society requires new levels of innovation, breaking out of locked-in systems and technologies. It will be led by forward-looking countries, companies, researchers, inventors and investors.

Such innovations and solutions can be realized only by increasingly closer cooperation among all stakeholders with the aim of unlocking the potential of ICTs to improve energy efficiency, thereby promoting the competitiveness of industry, creating a wealth of opportunities, jobs and services, and building an everyone-wins momentum for industry, users, and society at large.

The private sector can and should have a key role, but it needs the right framework conditions and well-functioning markets. Good regulation and its effective implementation are there to provide a level playing-field and the right incentives and rewards.

Only in such well defined framework the role of ICTs can be fully explored and exploited in the following respects: a) as an enabler of energy efficiency across the economy including fostering the change in citizen's behavior, b) in improving efficiency in the use of natural resources while reducing pollution and dangerous waste.

To put ICTs at the core of the energy efficiency effort and to enable them to reach their full potential, it is necessary to foster research into novel ICT-based solutions and strengthen their take-up — so that the energy intensity of the economy can be further reduced by adding intelligence to components, equipment and services. On the other side, efforts should be made so that ICT leads by example and reduces the energy it uses**.**

The transformation to a Green Economy asks not just business (including producers and retailers), but also consumers, to change behavior. Consumers have the right to be informed about products and they are increasingly asking for more information. However, recent surveys show some worrying trends: half of EU citizens do not trust environmental claims, while 1/3 of them encountered misleading environmental claims. Consumers need to be better informed on how they can contribute to reduce their footprint on the planet and its resources [13].

Increasing social awareness through policies and communications to explain the urgency of the issue and urge conservation is also needed.

The above efforts require that quantifiable benchmarks and metrics be developed to gauge their effectiveness and ensure progress towards established goals.

Final conclusion is that ICT products, systems, and networks are the essential driver of productivity improvements and innovation for the 21st century. They will be the enabler of sustainability solutions in all networks: energy production and use, mobility, water and sewage, open spaces, education, and public health and safety. ICT innovation is also the catalyst for changes in personal, work, and community life that will be a fundamental requirement for sustainable economic development.

***Abstract*—This paper studies the properties of the Croatian texts via complex networks. We present network properties of normal and shuffled Croatian texts for different shuffling principles: on the sentence level and on the text level. In both experiments we preserved the vocabulary size, word and sentence frequency distributions. Additionally, in the first shuffling approach we preserved the sentence structure of the text and the number of words per sentence. Obtained results showed that degree rank distributions exhibit no substantial deviation in shuffled networks, and strength rank distributions are preserved due to the same word frequencies. Therefore, standard approach to study the structure of linguistic co-occurrence networks showed no clear difference among the topologies of normal and shuffled texts. Finally, we showed that the in- and out- selectivity values from shuffled texts are constantly below selectivity values calculated from normal texts. Our results corroborate that the node selectivity measure can capture structural differences between original and shuffled Croatian texts.**

I. Introduction

The complex networks sub-discipline tasked with the analysis of language has been recently associated with the term of linguistic's network analysis. The linguistic network can be based on various language constraints: structure, semantics, syntax dependencies, etc.

In the linguistic co-occurrence complex networks properties are derived from the word order in texts. The open question is how the word order itself is reflected in topological properties of the linguistic network. One approach to address this question is to compare networks constructed from normal texts with the networks from randomized or shuffled texts. Since the majority of linguistic network studies have been performed for English, it is important to test whether the same properties hold for Croatian language as well. So far, there have been only sporadic efforts to model the phenomena of the Croatian language through complex networks [7] [11].

In this paper we address the problem of Croatian text complexity by constructing the linguistic co-occurrence networks form: a) normal texts, b) sentence-level shuffled texts, and c) text-level shuffled texts. This work extends our previous research [11] with additional sentence-level shuffling procedure and by introducing a node selectivity as a new complex network measure. Our experiment tests whether selectivity can differentiate between normal and meaningless texts.

Section 2 presents an overview of related work on complex network analysis of randomized texts. In Section 3 we define measures for the network structure analysis. In Section 4 we present shuffling procedures and the construction of co-occurrence networks. The network measures are in Section 5. In the final Section, we elaborate the obtained results and make conclusions regarding future work.

II. Related work

Some of the early work related to the analysis of random texts dates to 1992, when Li [5] showed that the distribution of word frequencies for randomly generated texts is very similar to Zipf's law observed in natural languages such as in English. Thus, the feature of being a scale-free network does not depend on the syntactic structure of the language. Watts and Strogatz [10] showed that the network formed by the same amount of nodes and links but only establishing links by choosing pairs of nodes at random has a similar small network distance measures as in the original one. Caldeira *et al.* [2] analyzed the role played by the word frequency and sentence length distributions to the undirected co-occurrence network structure based on shuffling. Each sentence is added to the network as a complete subgraph. Shuffling procedures were conducted either on the texts or on the links. Liu and Hu [6] discussed whether syntax plays a role in the complexity measures of a linguistic network. They built up two random linguistic networks based on syntax dependencies and compared the complexity of non-syntactic and syntactic language networks. Krishna *et al.* [4] studied the effect of linguistic constraints on the large scale organization of language. They described the properties of linguistic co-occurrence networks with the randomized words. These properties were compared to those obtained for a network built over the original text. It is observed that the networks from randomized texts also exhibit small-world and scale-free characteristics. Masucci and Rodgers showed [8] [9] that the power law distribution holds when they shuffled the words in the text. Thus, they showed that degree distribution is not the best measure of the self-organizing nature of weighted linguistic networks. Due to the equivalence between frequency and strength of a node, shuffled texts obtain the same degree distribution, but lose all the syntactic structure. They have analyzed the differences between the statistical properties of a real and a shuffled weighted network and showed that the scale-free degree distribution and the scale-free weight distribution are induced by the scale-free strength distribution. They proposed a measure, the node selectivity, that can distinguish a real network from a shuffled network. Selectivity is defined as the average weight distribution on the links of the single node.

Preliminary results of our research on Croatian co-occurrence networks presented in [7] point out that the increase of the co-occurrence window size is followed by a decrease in diameter, average path shortening and, expectedly, the condensing of the average clustering coefficient. The stopwords removal causes the same effect. When comparing Croatian literature networks to networks from other languages such as English and Italian [1] some expected universalities such as small-world properties are shown, but there are still some differences. The Croatian language exhibits a higher path length than English and Italian language which can be caused by the mostly free word order nature of Croatian.

Initial attempt [11] to analyse network properties of normal and shuffled Croatian texts show that the text shuffling causes the decrease of the network diameter, due to the establishment of previously non-existing links. Furthermore, the results indicate a slight difference in the average clustering coefficient which is higher for the networks based on the shuffled text. Also, obtained results showed that node degree distributions are preserved in text-level shuffled networks, due to the same word frequencies (e.g. Zipf's law).

III. The network structure analysis

In the network, N is the number of nodes and K is the number of links. In weighted networks every link connecting two nodes has an associated weight $w \in R_0^+$. The co-occurrence window m_n of size n is defined as n subsequent words from a text. The number of network components is denoted by ω.

For every two connected nodes i and j the number of links lying on the shortest path between them is denoted as d_{ij}, therefore the average distance of a node i from all other nodes is:

$$d_i = \frac{\sum_j d_{ij}}{N}. \tag{1}$$

And the average path length between every two nodes i, j is:

$$L = \sum_{i,j} \frac{d_{ij}}{N(N-1)}. \tag{2}$$

The maximum distance results in the network diameter:

$$D = max_i d_i. \tag{3}$$

For weighted networks the clustering coefficient of a node i is defined as the geometric average of the subgraph link weights:

$$c_i = \frac{1}{k_i(k_i-1)} \sum_{ij} (\hat{w}_{ij}\hat{w}_{ik}\hat{w}_{jk})^{1/3}, \tag{4}$$

where k_i is the degree of the node i, and the link weights $\hat{w}_{ij}$ are normalized by the maximum weight in the network $\hat{w}_{ij} = w_{ij}/\max(w)$. The value of c_i is assigned to 0 if $k_i < 2$.

The average clustering of a network is defined as the average value of the clustering coefficients of all nodes in a network:

$$C = \frac{1}{N} \sum_i c_i. \tag{5}$$

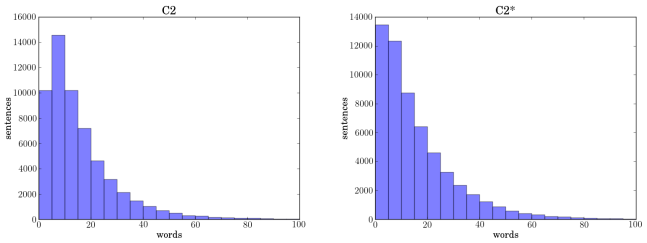

Fig. 1. Histograms of sentence length frequencies for C2 and C2*

If $\omega > 1$, C is computed for the largest network component.

The out-degree and in-degree $k_i^{out/in}$ of node i is defined as the number of its out and in nearest neighbors.

The out-strength and the in-strength $s_i^{out/in}$ of the node i is defined as the number of its outgoing and incoming links, that is:

$$s_i^{out/in} = \sum_j w_{ij/ji}. \tag{6}$$

We then define for the node i the out and in selectivity as

$$e_i^{out/in} = \frac{s_i^{out/in}}{k_i^{out/in}}. \tag{7}$$

IV. Methodology

A. Data

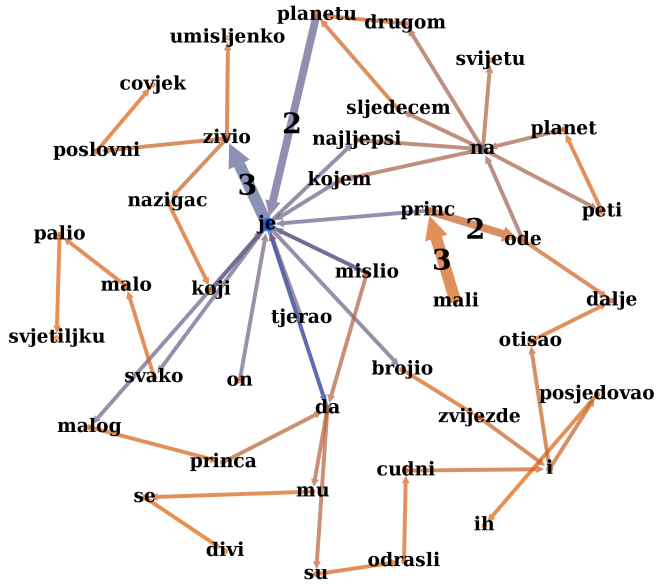
For the construction and analysis of co-occurrence networks, we used the corpora of 10 books written in or translated into the Croatian language. We divided the corpora into two parts: the first - C1 includes one book, and the second - C2 includes all books. The C1 contains: 191941 words (27453 unique) in 17045 sentences; and C2: 888293 words (91420 unique) in 57179 sentences.

B. The shuffling procedure

Commonly, the shuffling procedure randomizes the words in the text, transforming the text into the meaningless form. We shuffled the C1 and C2 corpora in two ways: a) shuffling on the sentence level, and b) shuffling on the text level. In both ways we preserved the vocabulary size, the word and sentence frequency distributions.

In the sentence-level shuffling we preserved the sentence length (the number of words per sentence) and sentence order. Versions of C1 and C2 shuffled on the sentence level are noted as C1' and C2'. In the text-level shuffling, the original text is randomized by shuffling the words and punctuation marks over the whole text. This approach preserves the number of sentences but changes the number of words per sentence. Versions of C1 and C2 shuffled on the text level are noted as C1* and C2*. Fig. 1 shows the histograms of sentence length frequencies for C2 and C2* corpora.

Our shuffling procedures destroy the sentence and text organization in a way that the standard word-order and syntax of the text is eradicated. As expected, the typical word collocations and phrases of Croatian language are completely lost,



mali princ je mislio da su odrasli cudni i otisao dalje. na drugom planetu je zivio umisljenko. mislio je da je najljepsi na svijetu. tjerao je malog princa da mu se divi. mali princ ode dalje. na sljedecem planetu je zivio poslovni covjek. on je brojio zvijezde i posjedovao ih. mali princ ode na peti planet na kojem je zivio nazigac koji je svako malo palio svjetiljku.

Fig. 3. Example network constructed from sentence-level shuffled text

as well as the forms of the morphological structures and local structures of words' neighborhood.

C. The construction of co-occurrence networks

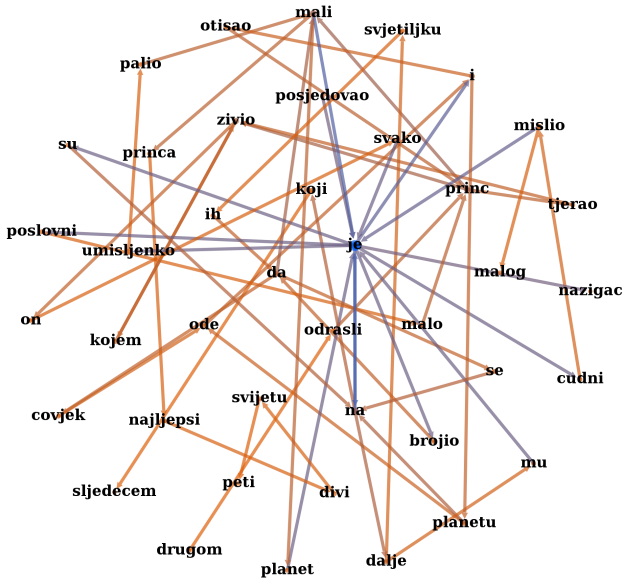
Text can be represented as a complex network of linked words: each individual word is a node and interactions amongst words are links. We constructed six different co-occurrence networks (C1, C1', C1*, C2, C2', C2*) all weighted and directed. Words are nodes linked if they are co-occurring as neighbors to each other in a sentence. The weight of the link is proportional to the overall co-occurrence frequencies of the corresponding word pairs within a corpus.

Network construction and analysis was implemented with the Python programming language using the NetworkX software package developed for the creation, manipulation, and study of the structure, dynamics, and functions of complex networks [3].

Figures 2, 3 and 4 show simple examples of networks constructed from original and shuffled text samples. Networks are directed and weighted; the numbers on the networks' edges represent weights larger than 1. At the bottom of each figure is the text from which the visualized network was constructed. The original sample text (Fig. 2) was shuffled on sentence (Fig. 3) and text (Fig. 4) level in the same way as the corpora C1 and C2.

V. Results

The measures of the networks constructed from C2 corpus, sentence-level shuffled C2', and text-level shuffled C2* are presented in Table 1. The results show that the shuffled networks have decreased values of the average path length L



dalje svjetiljku ih da se na. posjedovao je nazigac. planetu ode i otisao princ tjerao zivio kojem zivio on svako je je su na je na dalje mu je umisljenko palio mali planet je brojio da mali je i planetu na. je cudni mislio je poslovni malo princ mali princa najljepsi divi svijetu peti. zvijezde. mislio malog. da covjek ode. na koji sljedecem. drugom odrasli princ zivio

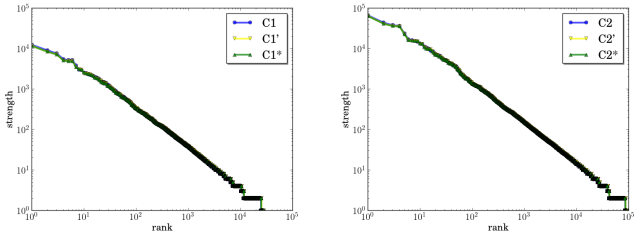

Fig. 6. Strength rank distributions for the C1, C1', C1*, C2, C2', C2*

tences containing just one word are disregarded, because our approach limits the word linkage to the sentence delimiters. This causes sentences with exactly one word to be isolated from the network, which reduces the number of nodes N in C1* and C2*.

One of the standard approaches to examine properties of co-occurrence networks is node degree distribution for unweighted and node strength distribution for weighted. Shuffling preserves the degree distribution due to the word frequencies [9] [11]. In this work we use rank distribution to compare different texts. Rank and frequency distributions are related through Zipf's law: the word frequency is inversely proportional to it's rank.

Initially, we computed the degree and strength rank distributions only for C2 and corresponding shuffled versions. As expected, the degree rank distributions, as well as the strength rank distributions are preserved during the shuffling procedure. In order to explore whether the same holds for substantially smaller corpus we checked degree and strength rank distributions for C1 as well. Fig. 5 and Fig. 6 present degree and strength rank distributions for the C1, C1', C1*, C2, C2' and C2*. Degree rank distributions exhibit no substantial deviation in shuffled networks, and strength distribution is preserved due to the same word frequencies. At this point all network measures and distributions showed no substantial differences between the structure of the original and meaningless texts.

The global network measures: average shortest path length, diameter, clustering coefficient and degree and strength distribution may not be well-suited to discriminate between original and meaningless texts. Therefore, it is necessary to include local (node level) network measures. Motivated by the reported results form [9], which introduced the local measure of node selectivity, we applied the same principle on our data. In weighted and directed co-occurrence networks nodes have ingoing and outgoing links, therefore it is necessary to consider the in- and out- selectivity.

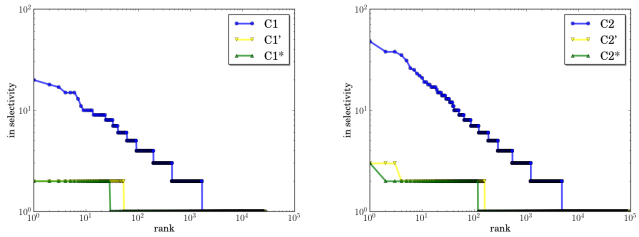

Fig. 7. In-selectivity rank distributions for the C1, C1', C1*, C2, C2', C2*

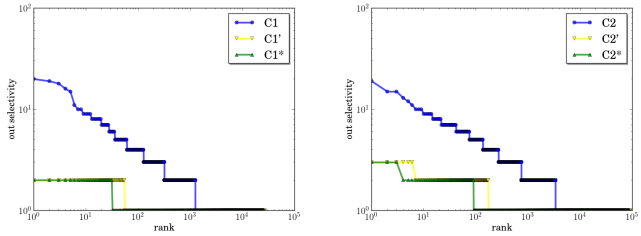

Fig. 8. Out-selectivity rank distributions for the C1, C1', C1*, C2, C2', C2*

Fig. 7 and Fig. 8 present obtained in- and out- selectivity ranks for C1 and C2, and their shuffled counterparts. Regardless of the links direction (in or out), selectivity values of networks from the shuffled texts are constantly below selectivity values calculated from the normal texts. This can be explained by the well known properties found in text - collocations. Collocations are typical word pairs, triples,...etc. which are recognized as standard phrases or names (e.g. New York). Shuffling procedures rearranged the word order, which disassembled collocations. This effect is reflected in the selectivity, since the high weights of common phrases and collocations are lost, which flattens and abates the selectivity ranks.

VI. CONCLUSION

We studied the structure of the linguistic networks constructed from normal and shuffled texts in Croatian. As expected, the text shuffling causes the decrease of the average path length L and the network diameter D, and the increase of the average clustering coefficient C.

We showed that the degree rank distributions exhibit no substantial deviation in shuffled networks, and the strength rank distributions are preserved due to the same word frequencies. The standard approach to study the structure of linguistic co-occurrence networks showed no substantial differences among the topologies of the original and shuffled texts. Therefore we utilized the node selectivity measure proposed by Masucci and Rodgers in [9].

Our results showed that the in- and out- selectivity values from shuffled texts are constantly below selectivity values calculated from normal texts. It seems that selectivity captures typical word phrases and collocations in Croatian which are lost during the shuffling procedure. The same holds for English where Masucci and Rodgers found that selectivity somehow captures the specialized local structures in nodes' neighborhood and forms of the morphological structures in text. Based on this findings, the measure of selectivity can be useful to discriminate between different text types, which will be the part of our future work.

We have shown that the Croatian language networks have similar properties as language networks from English and other languages. Firstly, Croatian text shuffling has no influence on the degree and strength distributions, which has already been shown for English [8], [9], English and Portuguese [2] and English, French, Spanish and Chinese [4]. Furthermore, distance measures (average shortest path length and diameter) show that networks based on normal texts have a greater L and D value than the corresponding network based on shuffled text. The same relations for average clustering coefficient, average shortest path length and diameter are shown in [4] for all studied languages (English, French, Spanish and Chinese). Similar results are shown for English and Portuguese in [2], although the authors used different shuffling procedures.

Our results imply that the node selectivity is a measure suitable for fine-grained differentiation between an original and meaningless text. Furthermore, selectivity can potentially be considered as a measure for discrimination between different text types, capturing the aspect of quality of texts. This should be thoroughly examined in the future work, which will cover: a) differentiation between text types from linguistic network structure, b) finding which set of measures reflects the quality of the texts, c) the analysis of the Croatian linguistic networks using syntax dependencies instead of pure co-occurrence.

Comparison of the language networks from literature and blogs

Sabina Šišović, Sanda Martinčić-Ipšić, Ana Meštrović
Department of Informatics University of Rijeka, Rijeka, Croatia
ssisovic@uniri.hr, smarti@uniri.hr, amestrovic@inf.uniri.hr

Abstract - In this paper we present the comparison of the linguistic networks from literature and blog texts. The linguistic networks are constructed from texts as directed and weighted co-occurrence networks of words. Words are nodes and links are established between two nodes if they are directly co-occurring within the sentence. The comparison of the networks structure is performed at global level (network) in terms of: average node degree, average shortest path length, diameter, clustering coefficient, density and number of components. Furthermore, we perform analysis on the local level (node) by comparing the rank plots of in and out degree, strength and selectivity. The selectivity-based results point out that there are differences between the structure of the networks constructed from literature and blogs.

I. INTRODUCTION

The representation and analysis of written texts in terms of graphs and complex networks offers an alternative approach for studying the language with different applications in the domain of natural language processing (NLP). Various types of linguistic networks have already been studied: syntax networks [1,2], semantic networks [3], phonological networks [4], syllable networks [5,6], word co-occurrence networks [7-19]. In [3,20,21] a systematic methodological overview of linguistic complex networks principles is presented. Recently, linguistic co-occurrence networks have been intensively studied in order to analyse the structure of the language [7-19].

As the networks incorporate associations between words and concepts, their structure, quantified by global and local network measures [22], such as clustering coefficient, shortest path, diameter, density, node degree, can provide information on some properties of the text. The motivation of our research was to find which network measures are sensitive on different texts categories.

In our previous research [8, 9] we showed the advantages of using a directed and weighted co-occurrence network as the model to capture the structure of a text. In this work we study global and local network measures for the networks constructed from different categories of texts. In particular, at the local level, we applied the node selectivity measure in order to examine if it is sensitive on different styles of texts. Node selectivity is defined as the average weight distribution on the links of the single node [10]. Therefore, in our approach we constructed directed and weighted co-occurrence networks from different texts: 4 books and 4 blogs. We compare global and local network measures for book-blog network pairs.

In the second section we present the overview of related work. In the third section we present key measures of complex networks. In the fourth section the data and network construction techniques are presented. In the fifth section we present the results. In the last section we elaborate on the obtained data and provide concluding remarks.

II. RELATED WORK

Ferrer i Cancho and Solé in [11] first showed that the co-occurrence networks have a small average path length, a high clustering coefficient, and a two-regime power law degree distribution; the network exhibits small-world and scale-free properties. Drogotsev and Mendes [12] used co-occurrence networks to study language as a self-organising network of interacting words. Masucci and Rodgers in [13] investigated the co-occurrence network topology of Orwell's '1984' focusing on the local properties: nearest neighbours and the clustering coefficient. Furthermore, in [10] they introduced the node selectivity measure that can distinguish the difference between normal and randomised text. Liu and Cong [14] constructed co-occurrence networks from text in different languages and used complex network parameters for the classification (hierarchical clustering) of 14 languages, where Croatian was amongst 12 Slavic.

Different applications of linguistic network analysis in NLP includes: evaluation of language complexity [15], automatic summarisation [16] and evaluation of machine translation [17], authorship attribution [18] and text quality analysis [19].

Costa et al. [15] studied the relationship between the topology of network and complexity of the text. They studied texts with different levels of simplification in co-occurrence networks and found that topological regularity correlated negatively with textual complexity. Furthermore, they showed that strength, shortest path, diversity and hierarchical measures can make a distinction between normal text and simplified text. In [16] the authors describe a method that uses complex networks concepts for the summarisation task. In [17] several metrics from complex networks are exploited in order to evaluate the quality of translations. The best distinctions were obtained with the out-degree, in-degree, minimum

path and cluster coefficient. In [18] authors investigate the correlation between the properties of networks and author characteristics. It is shown that the networks produced for each author are sensitive to specific features, which indicates that complex networks can capture author characteristics and, therefore, could be used for the authorship identification. In [19] authors investigate the possibility of automated evaluation of text quality using topological measurements extracted from the corresponding complex networks. All the measures are correlated with grades assigned by human experts. It is shown that out-degree, clustering coefficient and deviation from linear dynamics in the network growth are correlated with the text quality.

However, there are no comprehensive studies focused on finding network measures that are sensitive to different text categories. Our work is the first attempt to analyse which network measures can differentiate between literature and blog networks.

III. THE NETWORK STRUCTURE ANALYSIS

This section contains explanations of network-based measures [22, 10] that are used in our approach for the comparison of two categories of language networks.

Every network has an *N* number of nodes and *K* number of links. Considering the fact that our networks are weighted every link connecting two nodes has an associated weight.The degree of a node *i* is the number of links with which the node is connected, k_i. In the case of the directed network, there are two kinds of the degree: the in-degree, k_i^{in} corresponding to the number of incoming links and the out-degree, k_i^{out} equal to the number of outgoing links. The average degree of the network is:

$$< k >= \frac{2K}{N}. \tag{1}$$

For every two connected nodes *i* and *j*, the number of connections lying on the path between them is represented as d_{ij}, and so d_i is the average distance of a node *i* from all other nodes, and it's obtained by:

$$d_i = \frac{\sum_j d_{ij}}{N}. \tag{2}$$

For the next two measures, if a network contains more than one component, we consider the largest component. The average shortest path length between every two nodes in network is:

$$L = \frac{1}{N(N-1)} \sum_{i \neq j} d_{ij}, \tag{3}$$

and the maximum distance results in the network diameter, D:

$$D = max_i d_i. \tag{4}$$

The clustering coefficient is a measure which defines the presence of connections between the nearest neighbours of a node. And so, ci (clustering coefficient) of a node is a fraction between the number of edges Ei that exist between that ki and the total possible number:

$$c_i = \frac{2E_i}{k(k-1)}. \tag{5}$$

The average clustering of a network is defined as the average value of the clustering coefficients of all nodes in a network:

$$C = \frac{1}{N} \sum_i c_i. \tag{6}$$

Density of network is a measure of network cohesion defined as the number of observed relationships divided by the number of possible relationships:

$$d = \frac{K}{N(N-1)}. \tag{7}$$

Strength of the node i is the number of its outgoing and incoming links (sum of its weights). For the directed networks the in-strength and the out-strength are defined:

$$s_i^{out/in} = \sum_j w_{ij/ji}. \tag{8}$$

The node selectivity measure can capture the effective distribution of numbers in the weighted adjacency matrix, and it is obtained as a ratio of (out/in-) node strength and its (out/in-) degree:

$$e_i^{out/in} = \frac{s_i^{out/in}}{k_i^{out/in}}. \tag{9}$$

All presented measures are standard network measures usually used for network structure analysis, except the node selectivity measure which is introduced in [10] as the measure that can differentiate between networks based on normal and randomized texts. According to these results, we expected that node selectivity may be potentially important for the text categories differentiation and include it in the set of standard network measures.

In order to illustrate the relationships between node degree, node strength (which are the standard local network measures) and node selectivity, we constructed a small network of seven nodes presented in Figure 1.

Additionally, Table 1 contains values of in-degree, out-degree, in-strength, out-strength and in-selectivity and out-selectivity for all seven nodes in the network presented in Figure 1.

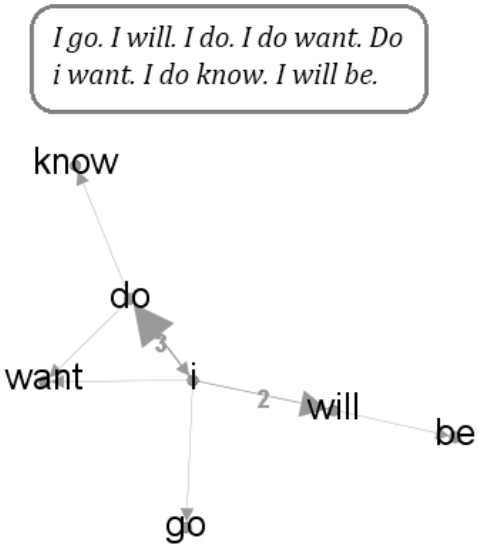

Figure 1 Weighted and directed co-occurrence network of seven nodes, created from the short text below

TABLE 1 - VALUES OF IN/OUT - DEGREE, STRENGTH AND SELECTIVITY

NODE	k^{in}	k^{out}	w^{in}	w^{out}	s^{in}	s^{out}
i	1	4	1	7	1	1,75
do	1	2	3	2	3	1
will	1	1	2	1	2	1
want	2	0	2	0	1	0
know	1	0	1	0	1	0
go	1	0	1	0	1	0
be	1	0	1	0	1	0

IV. NETWORK CONSTRUCTION

A. Data

Our corpus contains 4 books written or translated into the Croatian language, and 4 blog texts written in Croatian language. The books are: *Picture of Dorian Gray*, *Bones,The Return of Philip Latinowicz* and *Mama Leone*. The blogs are: *Index.hr*, *Slobodna Dalmacija*, *Narodne novine and Gospodarski list* (daily newspaper portal, or business portal). The feature which prompted us to do the comparison is the linguistic distinction between book and blog. Books are written in formal language, standard expressions and phrases are used, whilst blogs are mostly written in a casual mode, with the use of slang, the shortenings of the words or mistakes in syntax. Books come in different sizes and so we compared them with the approximately same sized blog (with the same number of different words), which means we had 4 book-blog pairs for comparison. The sizes of books and blogs in number of total words are shown in the first row of Table 2, while the numbers of different words are presented in the second row (as the number of nodes).

B. The construction of co-occurrence networks

We used Python and the NetworkX software package developed for the creation, manipulation, and study of the structure, dynamics, and functions of complex networks [23].

The first step in creating networks was text "cleaning": normalising symbols for Croatian diacritics (č, ć, ž, đ, and š), removing special symbols and removing punctuation which does not mark the end of a sentence. We created 8 networks, weighted and directed. Nodes are words that are linked if they are direct neighbours in a sentence. The next step was creating the networks as weighted edgelists, which contain all the pairs of connected words and their weights (the number of connections between two same words).

V. RESULTS

In this section we present the results of our measuring described in section 2, such as average degree $<k>$, average path distance L, diameter D, and the average clustering coefficient C, density d, node strength s_i and node selectivity e_i.

In Table 2 we present the estimated global network measures. There are certain differences between measures for book-blog network pairs, but there is no uniform rule that may be used to differentiate these two styles of writing.

TABLE 2 - THE COMPARISON OF NETWORK MEASURES FOR BOOK-BLOG NETWORK PAIRS

Measure	**Text**							
	Bones	***Gospodarski list***	***Mama Leone***	***Narodne novine***	***Picture of Dorian Gray***	***Index.hr***	***Return of Phillip Latinowicz***	***Slobodna Dalmacija***
Number of different words	191 986	199 417	85 347	146 731	75 099	118 548	28 137	44 367
Number of nodes (*N*)	27396	27727	13067	13036	15631	15065	9531	9553
Number of edges (*K*)	102052	105171	49383	55661	46201	28972	21760	25155
Average degree (<*k*>)	7,45	7,58	7,56	8,54	3,88	3,85	4,57	5,27
Avg. shortest path (*L*)	3,21	3,28	3,11	3,17	3,45	3,45	3,59	3,56
Diameter (*D*)	10	21	10	12	14	22	16	13
Average clustering coefficient (*C*)	0,25	0,22	0,29	0,22	0,18	0,016	0,15	0,17
Density (*d*)	0,0002	-	0,00056	0,00066	0,0004	0,0002	0,00048	0,00055
No. of connected components	15	7	1	2	1	45	5	3

Furthermore, we compare networks on the node-level using degree, strength and selectivity measures. For the purpose of comparison we used rank plots. The in/out-degree rank function represents the relationship function between the rank and the in/out-degree of the degree sequence of all nodes sorted in decreasing order.

Similarly, the in/out-strength rank plot and the in/out-selectivity rank plot are defined.

Figure 2 represents the results of the comparisons of the in-degree rank plot and the out-degree rank plot for one book-blog network pair.

The plots do not show significant difference for the in-degree nor for the out-degree rank plots between book-blog network pair. We also experimented with additional three book-blog pairs and we obtained similar results (not reported here due to limited space).

The results of the comparisons of the in/out-strength rank plot for the same book-blog network pair are shown in Figure 3. Again, there is no difference except some small deviation that can be noticed in the plot, but we cannot conclude that in/out-strength distinguish books from blogs.

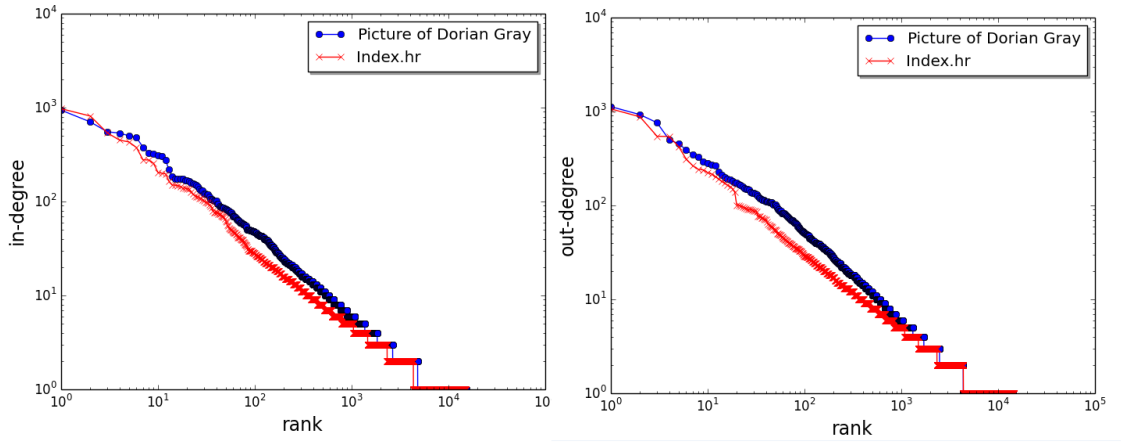

Figure 2 in-degree and out-degree rank plots

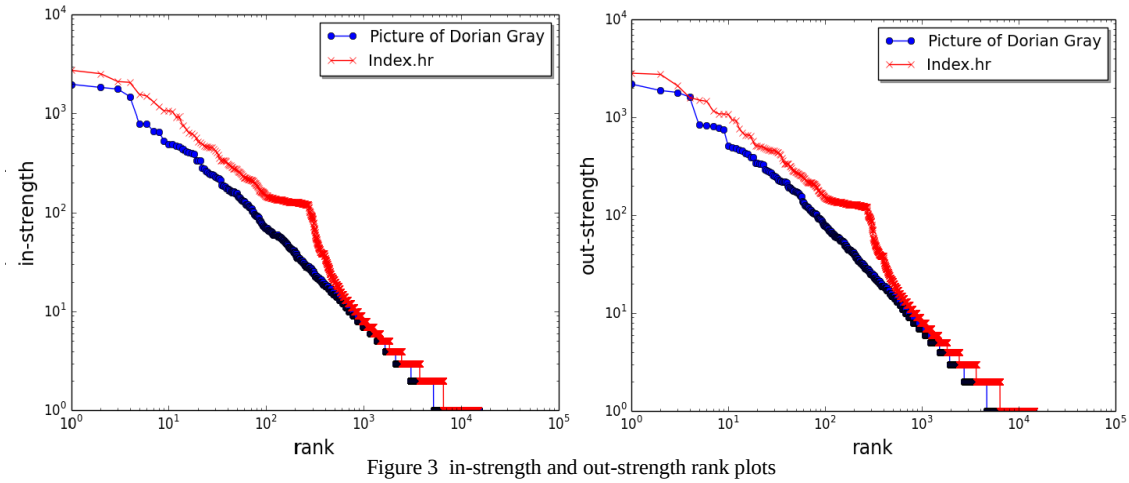

Figure 3 in-strength and out-strength rank plots

The selectivity rank plots are shown in Figure 4 (in-selectivity) and in Figure 5 (out-selectivity). The results show that there are differences in selectivity rank plots between networks constructed from books and networks constructed from blogs for all 4 book-blog network pairs.

In general, all in/out-selectivity values are lower for books than for blogs. We disregarded nodes with zero values of degree because it causes the division by zero (in total 4% of nodes).

VI. CONCLUSION

In this work we analysed which complex network measures can distinguish between different texts categories: literature and blogs.

Our results indicate that global network measures are not precise enough to capture the structural differences between networks constructed from different text categories. Even the compared in/out- degree rank plots and in/out- strength rank plots on the local level do not clearly show the differences. However, in-selectivity and out-selectivity rank plots indicate that there are structural

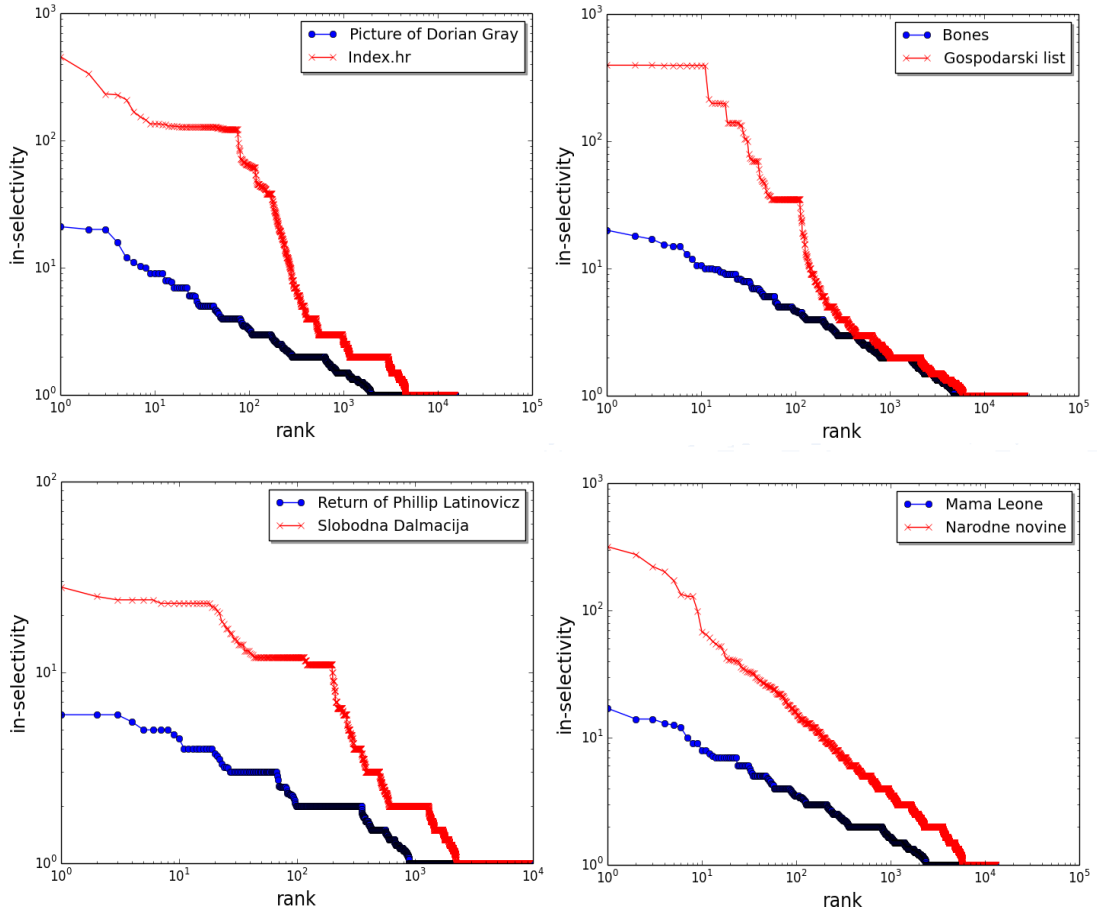

Figure 4 in-selectivity rank plots for 4 book-blog network pairs

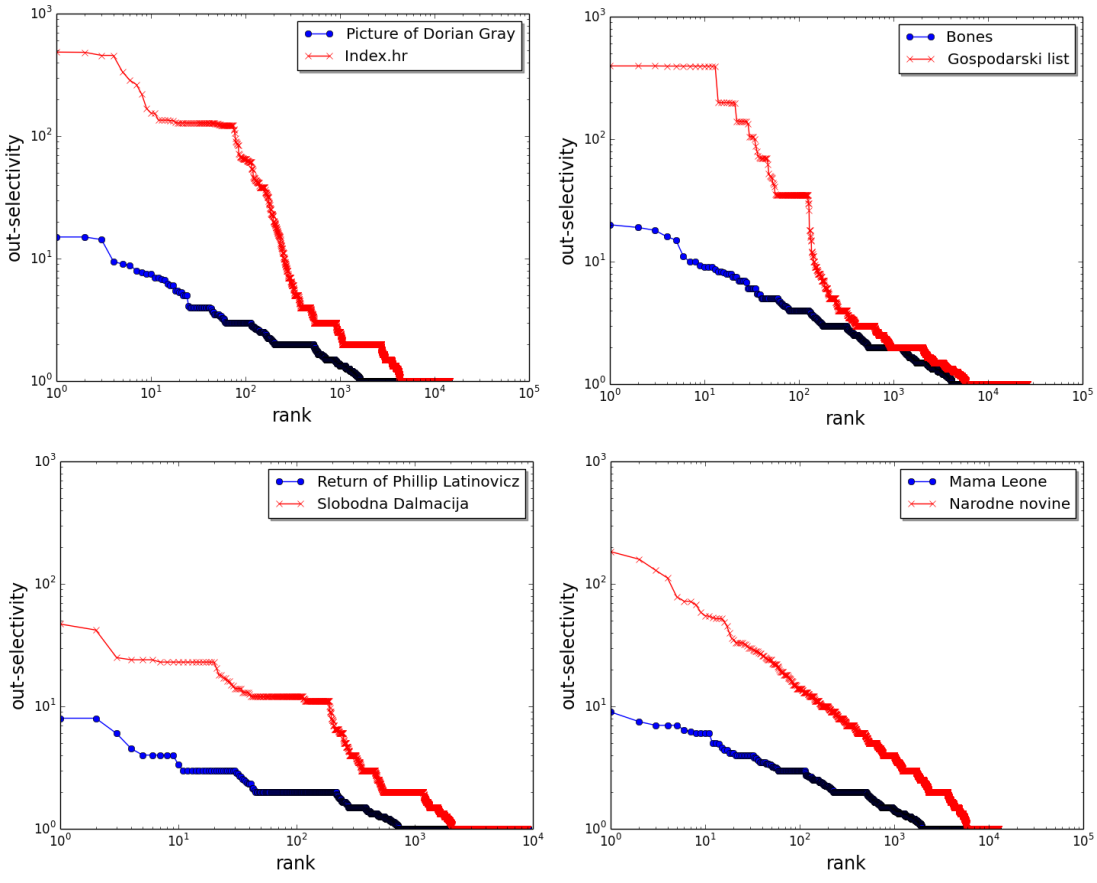

Figure 5 out-selectivity rank plots for 4 book-blog network pairs

and networks constructed from blogs. The values of in- and out- node selectivity measure are higher for networks generated from blogs than for networks generated from books. The node selectivity based measures are the only measures from the set of tested measures that can capture the structural differences between two classes of networks.

The presented approach should be extended with examination of other network measures that depend on the strength, degree and link direction in combination with other measures such as clustering coefficient. For future work we will test the broader set of measures on various categories of texts. We plan to include forum comments, texts from Wikipedia, poems and other genres of literature in our corpus. Obtained results encourage us to investigate the complex network properties for text classification, text evaluation or even text quality assessment.

Abstract – Evolutionary strategies is a heuristic, guided-search based evolutionary algorithm, widely used as optimization technique for computationally intensive problems. Python is a high-level programming language known for code readability, reusability and the ease of use, making it preferable choice for quick and robust software development, although it is lacking in performance and concurrency area. Emerging technologies such as Anaconda Accelerate Python compiler attempt to combine Python's ease of use with both declarative and explicit parallelization and high performance in computationally intensive problems. In this paper an example of master – slave parallel Evolutionary strategy ES(μ,λ) implementation in Python is given, and its performance on CPU and GPU are analyzed.

Keywords – Parallel computing; Python-Anaconda; GPU; Multithreading; Heuristic algorithms; Test functions for optimization;

I. INTRODUCTION

Heuristic algorithms, especially Evolutionary algorithms are widely used as optimization techniques for computationally difficult problems. Due to the nature of such problems, numerous attempts of acceleration of heuristic algorithms have been made. Heuristic algorithms are not embarrassingly parallel, so there is not one simple and obvious approach to their acceleration. Additionaly, good performance and the code's ease of use, readability and usability seldom go with one another, e.g. good performance can be achieved in C++ but the cost is prolonged development time, longer and hard-to-maintain source code. High-level, just-in-time compiled and interpreted languages can alleviate some of the development and maintenance troubles, but underperform in computing intensive situations. Evolutionary strategies (ES) is one of the most widely used heuristic algorithms and thus theoretical models for parallelization have been developed. In this paper, Master-Slave ES model is implemented using special Python compiler that supports declarative parallelizaton of Python code. Performance analysis is based on parallelized code executed both on CPU as multiple slave threads, and on GPU using CUDA integration as multiple GPGPU kernels. For comparison, sequential algorithm's performance is measured as well. Algorithm's performance is measured using standard benchmark functions for heuristic algorithms.

A. Parallelism of cpu

Central Processing Units (CPUs) are devices made to be primary general purpose processing unit in computers. As a result of ever growing demands, CPU architectures evolved and became faster in terms of FLOPS (Floating Point Operations Per Second). Numerous attempts of paralellization have been made, such as clusters and distributed computers, but not on single chip up until Intel HyperThreading concept, and multi core concepts emerged. Modern CPUs consist of certain number of cores ranging from 2 up to 32 or more for todays' most advanced CPUs.

B. Parallelism of gpu

Graphics Processing Units (GPUs) are devices primarily made for processing/rendering and displaying 2D and 3D graphic objects. In an attempt to meet high requirements set primarily by computer games and their graphics engines, GPU architecture radically changed, and it became what is known today as “modern GPU”[2]. New GPU architectures made it possible and feasible to do computations other than processing graphics on GPUs. Modern GPUs are massively parallel structures. Heart of modern GPUs is a set of Multithreaded Streaming Processors. Each of them is made of a certain number of smaller Scalar Processors and shared memory. Architecture is organized so that each stream processor has access to the global video memory. Each scalar processor executes the same code, while the data used as input or output is determined by respective scalar processor's unique identification. This arhitecture is named SIMD (Single Instruction [on] Multiple Data)[3][4].

C. Evolutionary strategies

Evolutionary strategies (ES) represent one of the most commonly used types of evolutionary algorithms, alongside with Genetic Algorithm (GA). It is used for optimization, or, finding adequatly good (best if possible) solution in the designated problem space. Multiple different types of ES have been developed, but the ES(1+1), ES(μ,λ) and ES(μ+λ) are the ones most widely used. Because the ES(1+1) is inherently sequential, only one of the population ES's - ES(μ,λ) is considered [1]. Its search model is considered to be guided because it does not consider all possible solutions (either randomly or in a predefined order). It rather relies on the fact that by creating offsprings of pairs of solutions contained within current population and by randomly mutating the offspring by offsetting it's coordinates by random, normally-distributed value with variable standard deviation, the population's overall fitness will keep increasing until most of the solutions converge to the determined optimum. Initial population can either be fixed, randomly generated or determined by some other algorithm. Unlike the GA, ES

solutions that make the population are tuples of real values and thus the ES eliminates the need for mapping between the algorithm's and problem's domains. However, the quality of the found optimae is generally considered to be lower than it is the case with the GA - operators of crossover used for creating the offspring and mutation have lower impact when used on real numbers than when they are used on tuples of binary values. Therefore, the self-adaptation of the variable standard deviation is the key for obtaining overall adequate results.

II. RELATED WORK

Two major concepts in parallel evolutionary strategies are master – slave model and island model [5].

Master-slave model stores whole population within master and executes mutations and recombinations there while it delegates slaves to execute fitness function evaluation[6]. This approach to parallelization is used when function evaluation is the most expensive operation of the algorithm, as it is the case with multidimensional functions that contain sums or products dependent on the dimension, or that rely heavily on floating point arithmetics [6] .

Island model partitions the population among the slave nodes (threads or seperate nodes in a cluster), and each of them runs algorithm separately on its own population[7]. In island model, master node or master thread is used as a synchronizer between the slaves. More advanced models include the redistribution of the best solutions among the slaves as for to prevent premature convergence.

Numerous attempts have been made to compare performance of GPU and CPU in various scientific computations. Performance comparisons between computations made on CPUs and GPUs are mainly biased or published by GPU or CPU manufacturers or their business partners[4]. In this instance, Evolutionary Strategies (μ,λ) parallellization in Python has been chosen to demonstrate that the difference in performance is not always clear or applicable in problems with different dimensionality. Break-Even analysis is performed as a means to indicate the dimensionality of the problem at which the performance of the CPU and GPU implementations start to diverge. Also, difference in the ease of development using Python with specialized compiler is documented so that it can be factored in when considering the tradeoffs between the different platforms and technologies.

III. MASTER-SLAVE EVOLUTIONARY STRATEGY AND BENCHMARKS

A. *Evolutionary strategy (μ,λ)*

There are various types of evolutionary strategies, roughly they can be divided in population algorithms and algorithm with single individual. As those with single individual are not suitable for parallelization, as there is no parallelizable parts, only population algorithms can be considered for parallelization. Most suitable evolutionary algortihms for parallelization are ES(μ,λ) and ES(μ+λ). Evolutionary strategy ES(μ,λ) is chosen as it converges slower than ES(μ+λ), and for that reason is more suitable when measuring performance of algorithms. In fact, implementation differences are minor as one algorithm can easily be can converted into another.

Generalized procedure of ES(μ,λ) is given below [1]:

1. Population P of μ random solutions according to gaussian distrubtion is instantiated
2. Perform mutation for each solution of population P
3. Perform recombination for 2(λ - μ) selected solutions from P
4. Create new population P' from solutions obtained from steps 3 and 4
5. Evaluate every solution form population P'
6. Sort population P' according to results of evaluation obtained from step 5
7. μ best solutions from P' become P
8. Adapt Ps – parameter of „success“
9. Repeat steps 2-8 if condition of stopping not met
10. Stop

Pseudocode of Mutation operator is defined as:

```
for each solution s in P
    new=s+gauss(0,sigma)
    add new to P'
end for
```

Annotation „gauss“ presents gauss distribution whose parameters are 0 – as mean of distribution, and „sigma“ – as standard deviation.

Pseudocode of Recombination operator is defined as:

```
select 2(λ - μ) solutions form P by uniform
distribution
for each s1,s2 in selected
    new = (s1+s2)/2
    add new to P'
end for
```

In step 8 of generalized procedure of ES(μ,λ) parameter of success or Ps is mentioned. Parameter of succes in algorithm is intended to prevent early convergence of algorithm, or to prevent algorithm from returning false optimum. Parameter of success is used to adjust parameter sigma used as standard deviation parameter for gaussian distribution. Pseudocode of adapting Ps is defined as:

```
if iteration mod 20 == 0
    Ps = nS/iteration
    if Ps>0.2
        sigma = sigma x 1.4
    end if
    if Ps<0.2
        sigma = sigma/1.4
    end if
end if
```

In pseudocode given above nS represents number of successful iterations, where successful iteration is iteration in which mean value of the fitness of the population is better than the one from the previous iteration.

Stopping conditions for Evolutionary strategies may vary between different implementations and problems. Most commonly used, and are also used in this implementation, are fixed number of iterations, and improvement in max value of population, or improvement in mean value of the fitness of the population over n iterations. All of listed criteria are not to be used alone, because in case of fixed number of iterations, algorithm may do half of iterations for no reason if it already had converged to (sub)optimum. Or in case of other two stopping criteria algorithm may never stop.

B. *Master-slave model*

Evaluation of problem solutions is taking most time when executing evolutionary strategies. For that reason evaluation of solutions is parallelized according to master-slave model. Master-slave model of evolutionary strategy is implemented in Python programming language using Anaconda Accelerate module and its features. In this specific case master represents main loop, and delegates slaves to work parallel on evaluation of problem solutions. There is no explicit delegation of slaves, and all work is done implicitly using Anaconda Accelerate features which reduces complexity of the code and makes debugging and maintenance easier but limits the programmer to the predesignated means of utilizing the GPGPU or multithreading capabilites - for obvious reasons it cannot be as flexible as the native API.

Prerequisite for parallelization using Anaconda Accelerate is to vectorize code which is to be parallelized. Criteria functions are vectorized, or customized to work with vectors. This customization is done with „vectorize“ feature of Anaconda Accelerate module.

A simple example of Sphere function is given below.

```
def value(x,y):
    z =[]
    for i in range(0,len(x)):
        z.append(x[i]**2+y[i]**2)
    return z
```

Then vectorization is of function given above can be implemented as follows:

```
from numbapro import vectorize

@vectorize(["float32(float32, float32)"],
target="cpu")
def value(x,y):
    return x**2+y**2
```

As it can be seen vectorization is done by putting „@vectorize“ annotation before definition of function, and iti is necessary to specifiy number and types of input and output arrays. Annotation „target“ can have three different parameters, where parameter „cpu“ defines that function is to be run on single thread, „parallel“ defines that function is to be run on multiple threads, depending on how many are available, and finally “gpu” definest that function is to be run on CUDA platform if available. Vectorized function is than divided to slave components automatically by the compiler.

Master calls the vectorized function just like any other function:

```
import numpy as np
…
y = np.zeros(self.Lambda, dtype=np.float32)
y = value(x1,x2)
```

Parameters x1 and x2 in example above are arrays of problem solutions obtained before by mutation and recombination. Prerequisite for using Anaconda Accelerate, and its vectorize feature is using numpy module arrays.

C. *Benchmarks*

Master-slave evolutionary strategy has been implemented to find the global minimum of Rastrigin and Styblinsky-Tang functions in their five variables versions.
Rastrigin function is defined as:

$$f(x) = 10n + \sum_{i=1}^{n} (x_i - 10\cos 2\pi x_i)$$

Rastrigin function is very difficult because it has numerous local minuma and poorly implemented algorithm can easily return local minimum and converge to it. Rastrigin function has global minimum in f(x) = 0 for x = 0.

Styblinski-Tang function is defined as:

$$f(x) = \frac{\sum_{i=1}^{n} x_i^4 - 16x_i^2 + 5x_i}{2}$$

Styblinski – Tang function has 4 minima, one of which is global minimum. All of minima have relatively close values, and function gradient between them is not high so the algorithm can easily converge to one of local minima. Styblinski – Tang is somewhat heavy to evaluate due to having a sum dependent on the dimension of the problem and floating point division in it. One of advantages of Styblinski – Tang function over Rastrigin function as means of testing and benchmarking optimization algorithms is that it has a global minimum in f(-2.903534,…n… -2.903534) = -39.16599n where n is number of problem variables, thus the chances of hitting the minimum by initializing one of the initial solutions directly to or nearby the coordinates (0,…,0) is greatly reduce. That guarantees a certain level of randomness while testing the algorithm's behavior.

IV. PERFORMANCE MEASUREMENT AND ANALYSIS

All performance measurements were done on a machine running Windows 7 on an Intel Core i7 3770 processor with core frequency of 3,4 GHz, with 8GB of DDR3 RAM at 1600 MHz, nVidia GTX 660 GPU with 960 CUDA processors at 980MHz and 2048 MB of GDDR5 graphics memory. Algorithms were implemented in Python v2.7.6 and compiled using Anaconda v1.8.0 MKL and Anaconda v1.8.0 Accelerate features for speedup.

A. *Master slave model results*

Implemented evolutionary strategies algorithm was ran at max 3000 iterations as it was experimentally determined that algorithm converges to one value no sooner than iteration 1500, and no later than iteration 2500. Algorithm was ran with start value of standard deviation sigma set at 1.2. Parameters μ and λ were arranged so that λ is 1.5 times larger than μ. Three types of measurements for each function were conducted. Measurements were conducted on population ranging from (40,60) to (2500,3750). First the measurement was performed on single threaded CPU, than on the multithreaded CPU and lastly on the GPU Python implementation. Every measurement for each population was run 30 times, and mean value was taken in account, so that the standard deviation of measurement tends to zero.

	40	100	500	1000	2500
CPU - Single thread	3.166077	6.268949	37.081168	93.918496	139.024702
CPU - Multi thread	4.333635	9.087163	28.767020	77.778232	109.539457
GPU	7.053621	9.568107	53.250709	99.440529	122.237030

Figure 1 Time representation of Evolutionary strategy run on three platforms when evaluating Rastrigin function

As it can be seen from Figure 1. for small populations sequential implementation elapsed time is considerably smaller due to large overhead for preparation of parallelization. Obviously, for larger population there is more job to be done in parallel, so the benefits from parallellization come to the fore. Multithreaded implementation has better results than GPU implementation due to not enough large data set for GPU to excell. In terms of results every measurement returned results considered as adequate and all results were as high as $1x10^{-6}$ which is a small deviation from the actual minimum.

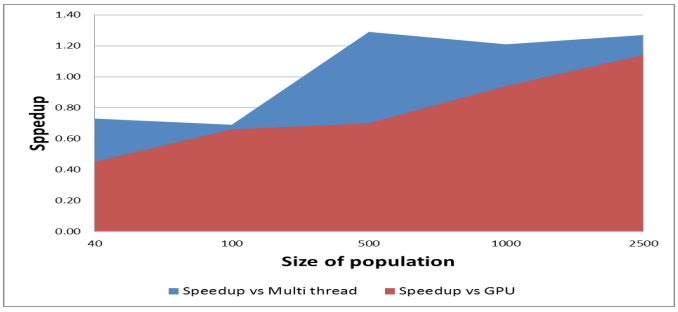

Figure 2 Speedup gained/lost using Multithreading and GPU when evaluating Rastrigin function

All the aforesaid is clearer presented in Figure 2. where it can easily be seen that for smaller populations parallelized implementations slow down the algorithm. It can easily be seen that with increase of population speedup increases as well. In case of Speedup gained by using GPU, speedup can be easily aproximated with linear function

$$y = \frac{0{,}69}{2460}x + 1{,}128$$

	40	100	500	1000	2500
CPU - Single thread	3.24472	4.67253	66.89806	139.96874	361.22384
CPU - Multi thread	4.01428	5.78346	41.85732	112.98866	317.72601
GPU	4.84771	6.79417	78.97776	139.84049	301.45514

Figure 3 Time representation of Evolutionary strategy run on three platforms when evaluating Styblinski - Tang function

As it can be seen from Figure 3. sequential implementation is considerably faster than parallel implementations for smaller populations. Also, the execution times for Styblinski – Tang function are significantly higher than those from Rastrigin function due to Styblinski – Tang being more complicated to evaluate, and also evolutionary strategies algorithm converges slower for Styblinski – Tang, relative to Rastrigin function. Also, for largest population is faster relative to same multithreaded implementation, probably due to Styblinski – Tang being harder to evaluate, and having an arithmetic operation division in it.

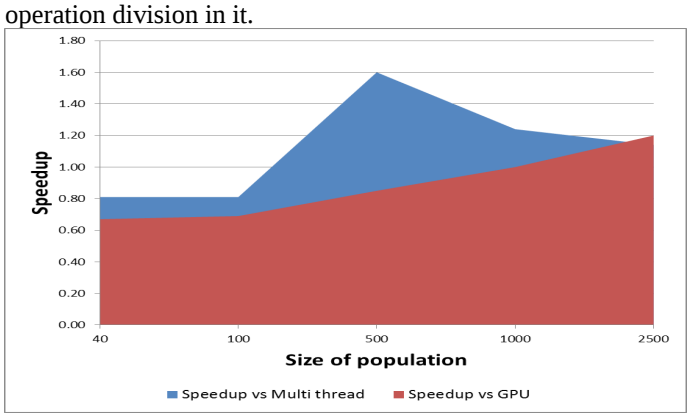

Figure 4 Speedup gained/lost using Multithreading and GPU when evaluating Styblinski - Tang function

Figure 4. gives better preview of all afore mentioned, there is no speedup for smaller populations, but with increase of population amount of speedup gradually increases. Speedup against GPU can be easily aproximated with linear function just as is the case with previous Rastrigin function.

In terms of results of evaluation, smaller population implementations do not always return correct value, or value that is very close to optimum. While larger population implementations, μ higher than 500, always return optimum value. It happens due to large problem space, and Styblinski – Tang complexity.

V. CONCLUSION AND FUTURE WORK

In this paper two kind of performance measurements on GPU, CPU using single thread, and on CPU using multithreading were presented. Results indicate that for smaller problems there is no speedup at all, and for larger problems the

speedup achieved by using parallelized implementations is not as large as it may seem at a first glance.

Presented results in no way indicate that the parallelized implementations should be discarded, or that its performance is not better than sequential one in evolutionary strategies. Performance measurements on Styblinski – Tang function show that there is some progress when problem space becomes larger, evaluation of criteria itself becomes harder, and population becomes even larger. Sequential and parellelized implementations of evolutionary strategies can coexist for different types of problems, depending on their size. Python language's ease of use and inherent reusability can help with maintenance of the code. With the increase of problem dimensionality speedup of parallelized implementation should excell even more relative to sequential implementation.

Sequential implementations of evolutionary strategies should be used for solving small or medium sized problems, while parallelized implementations are to be used for solving of enormous sized problems, where they can gain speedup over sequential implementations.

Travelling salesman problem (TSP), vehicle routing problem (VSP), and similar NP compelete problems higher dimensionality should be consider as candidates to be solved with parallelized implementations of evolutionary strategies algorithm.

Python, when used with adequate technologies, libraries and compilers proved to be a prospective platform for parallelization and high performance computing - parallelization is achieved with low costs and can achieve considerable performance boosts.

kostenetskiy@gmail.com

Abstract - The modern manycore coprocessors and GPUs demonstrate very high performance on certain problems. Recent research has shown that these coprocessors can be used to accelerate database operations. But, to the best of our knowledge, there is only a little prior work on using coprocessors in multiprocessor database systems. This paper focuses on evaluation of database multiprocessor architectures with manycore coprocessors and GPUs. We implemented the emulator of parallel DBMS that uses computing cluster with NVIDIA GPUs or Intel Xeon Phi coprocessors for relational query processing. It allows to simulate simple SELECT and JOIN queries. A number of experiments have been done using this emulator. These experiments have shown that coprocessors are less efficient than CPUs for processing modeled SELECT queries, but more efficient than CPUs for processing INNER JOIN queries.

I. INTRODUCTION

The modern coprocessors like Intel Xeon Phi and NVIDIA Tesla demonstrate very high performance on certain problems. Database community shows a growing interest in applying this power to database systems [1].Recent research has shown that these coprocessors can be used to accelerate database operations. For example, paper [2] covers relational join algorithms. Architecture-sensitive search tree is presented in [3], [4]. Papers [5], [6] focus on sorting algorithms. Paper [7] describes speculative processing of database operations. To the best of our knowledge, there is only a little prior work on using coprocessors to accelerate database operations in multiprocessor database systems. Modern scientific and engineering problems can imply storing and processing terabytes of data what requires use of high performance database multiprocessors. It is important to determine the appropriateness of using different types of coprocessors when constructing such systems. This paper focuses on evaluation of database multiprocessor architectures with manycore coprocessors and GPUs.

II. IMPLEMENATION

To evaluate performance of different coprocessors in database multiprocessor systems we implemented the emulator of parallel DBMS. Emulator uses computing cluster with NVIDIA GPUs or Intel Xeon Phi coprocessors for relational query processing. It allows to simulate simple SELECT and JOIN queries. At this stage, for JOIN, only nested loops algorithm is implemented. Implementation was done with OpenMP, MPI and NVIDIA CUDA technologies. To achieve high level of parallelism, we use the principle of partitioned parallelism [8]. Each relation is partitioned into fragments, which are distributed over different worker processes (parallel agents). Worker processes exchange data using MPI technology.

III. EXPERIMENTS

Experiments with CPUs and Intel Xeon Phi were done on Tornado Supercomputer in South Ural State University, Chelyabinsk, Russia [9]. Experiments with GPUs were done on computing cluster in Lobachevsky State University, Nizhniy Novgorod, Russia. Experiments have used two CPUs or one coprocessor on each computing node. Characteristics of hardware are summarized in table I. To simulate SELECT and JOIN queries processing, we ran our emulator on computing clusters. The following simple queries were simulated:

1. SELECT * FROM Relation WHERE Attribute = Value;
2. SELECT * FROM Inner INNER JOIN Outer ON (Inner.Attribute1 = OuterAttribute2);

In this paper we consider a select on relation with cardinality of 370M that has size 5.5 GB. Join is done on following two relations: inner relation with cardinality of 33500 and size of 0.5 MB and outer relation that has size of 500MB and cardinality of 33.5M. Each relation consists of two integer (int64_t) attributes. Experiments include two steps. The first step is to evaluate query processing performance on a single computing node and determine settings that give maximum performance. In the first step we have run emulator on single computing node and varied its settings. For CPU version of algorithms, we have varied number of MPI processes. For GPU version, we have varied number of CUDA threads. For Manycore

TABLE I. TYPES OF COMPUTING NODES

	Type 1	Type 2
Processor	Intel Xeon X5680 3.33 GHz	Intel Xeon L5630 2.13 GHz
Number of processors/cores	2/12	2/8
RAM	24GB	24GB
Coprocessor	Intel Xeon Phi SE10X	NVIDIA Tesla X2070
Coprocessor memory	8GB	6GB

version, we have varied number of OpenMP threads. Results of the first step are summarized in table II. The second step is to evaluate query processing performance on a computing cluster, using settings from previous step In the second step we have run emulator on computing cluster and varied it's the number of nodes from 1 to 8. On each computing node, emulator has been run with settings from previous step. Results of second step are summarized in figure 1 and figure 2. As can be seen from figures, coprocessors are less efficient than CPUs for processing simulated SELECT query. Small speedup is explained by overhead costs for transferring data over the network and over PCI Express bus. In the case of INNER JOIN query, all versions of algorithms have similar speedup. However, coprocessors can process these queries faster, than CPUs. Thus, one can conclude that coprocessors can be effectively used for processing JOIN queries in multiprocessor database systems.

IV. CONLUSION

This work focuses on evaluating performance of manycore coprocessors and GPUs in multiprocessor database systems. We have implemented the emulator of parallel DBMS. This emulator uses computing cluster with NVIDIA GPUs or Intel Xeon Phi coprocessors for relational query processing. All algorithms have been implemented for CPUs, NVIDIA GPUs and Intel Xeon Phi coprocessors. A number of experiments have been done using this emulator. These experiments have shown that coprocessors are less efficient than CPUs for processing modeled SELECT queries, but more efficient than CPUs for processing INNER JOIN queries. Results of experiments will be used for extending DMM (Database Multiprocessor Model) [8]. Future work directions include:

1. Performance evaluation of heterogeneous computing systems in database applications.
2. Implementation and evaluation of more complicated JOIN algorithms, such as Hash Join for different types of coprocessors.
3. Design and implementation of algorithms that can use CPUs and coprocessor simultaneously for processing database queries.

ACKNOWLEDGMENT

This work was supported in part by the Russian Foundation for Basic Research, project no. 14-07-00420 and the Russian Federation president grant no. MK-3711.2013.9.

TABLE II. BEST EMULATOR SETTINGS FOR A SINGLE COMPUTING NODE

Simulacija dotoka autoregresivnim modelom prvog reda

S. Bošnjak, E. Sutlović
Sveučilište u Splitu, Fakultet elektrotehnike, strojarstva i brodogradnje, Split, R. Hrvatska
Stipo.Bosnjak@fesb.hr, Elis.Sutlovic@fesb.hr

Sažetak - U elektroenergetskim sustavima sa znatnim udjelom hidroenergije planiranje rada hidroelektrana je od izuzetnog značaja. Nepoznavanje i stohastički karakter budućih dotoka je glavni problem. Cilj planiranja je naći „optimalan“ način korištenja raspoložive količine vode nastojeći zadovoljiti brojna ograničenja. U optimizacijskom proračunu prirodni dotoci na određenoj lokaciji mogu se predstaviti deterministički, u kojem se dotoci tretiraju kao poznate veličine ili stohastički, u kojem se već u modelu ulaznih podataka u proračun nastoje ugraditi stohastičke karakteristike. Cilj rada je vrednovanje prikladnog stohastičkog modela za generiranje dotoka na nekom mjestu. Testirana su dva stohastička modela koji dotoke u različitim vremenskim periodima tretiraju kao međusobno ovisne slučajne varijable opisane autoregresivnim Markovljevim modelom prvog reda. Jedan model se koristi ako se dosadašnji dotoci na tom mjestu podvrgavaju normalnoj, a drugi ako se dosadašnji dotoci na tom mjestu podvrgavaju log-normalnoj razdiobi. Nakon izrade programa i simuliranja niza dotoka po oba modela, generiranim dotocima ispitivana su razna statistička obilježja: srednja vrijednost, standardna devijacija, faktori korelacije dotoka u uzastopnim vremenskim periodima itd. Generirani dotoci zadržali su sva ispitivana obilježja kao stvarni dotoci mjereni na tom mjestu u nizu godina. Oba ispitivana modela podataka su ocjenjeni kao pogodni za potrebe srednjoročnih i dugoročnih simuliranja i optimiranja rada hidroelektrana.

I. UVOD

U elektroenergetskim sustavima sa znatnim udjelom hidroenergije planiranje rada hidroelektrana, naročito hidroelektrana sa velikim akumulacijskim bazenima je od izuzetnog značaja. Kada vodu čuvati, a kada je i koliko ispustiti iz akumulacijskog bazena, utječe na moguću proizvodnju nizvodnih hidroelektrana, a posredno na potrebnu proizvodnju iz ostalih elektrana, na troškove pogona elektroenergetskog sustava, na profit itd. Cilj planiranja je naći „optimalan“ način korištenja raspoložive količine vode nastojeći zadovoljiti brojna ograničenja [1].

Proces planiranja obično se dijeli na kratkoročno (do sedam dana), srednjoročno (nekoliko mjeseci do godinu dana) i dugoročno (godina dana i duže). Dok se kod kratkoročnog planiranja redovito polazi od pretpostavke da su nam budući dotoci u riječne profile i akumulacijske bazene poznati, kod srednjoročnog i dugoročnog planiranja nepoznavanje i stohastički karakter budućih dotoka je glavni problem. Pristup problemu neizvjesnosti budućih dotoka određuje i karakter cjelokupnog optimizacijskog postupka, utječe na izbor optimizacijske metode, definiranje funkcije cilja i ograničenja itd.

Za rješavanje problema planiranja rada akumulacijskih bazena razvijeni su brojni optimizacijski proračuni koji koriste različite kriterije pri definiranju funkcije cilja (npr. maksimalna proizvodnja hidroelektrana, minimalni troškovi proizvodnje u EES-u, maksimalni profit proizvođača električne energije itd.) i različite matematičke optimizacijske metode (gradijentna metoda, linearno programiranje, dinamičko programiranje, itd.). U svim tim analizama cjelokupni period promatranja se dijeli u manje, jedinične vremenske periode odnosno diskretne vremenske korake unutar kojih se različite varijable i ulazni parametri ne mijenjaju. Obično se za osnovni vremenski period kod srednjoročnog i dugoročnog planiranja rada akumulacijskih bazena uzima jedan tjedan ili jedan mjesec [2] - [8].

U optimizacijskom proračunu prirodni dotoci na određenoj lokaciji mogu se predstaviti na više načina. Najjednostavniji način je deterministički model dotoka u kojem se svi dotoci (na svim lokacijama i u svim vremenskim periodima) tretiraju kao poznate veličine. Prednost determinističkog pristupa je što jednostavan model ulaznih podataka dozvoljava korištenje jednostavnijih i pouzdanijih optimizacijskih metoda koje sigurno vode ka „optimalnom“ rješenju. Jednostavnije optimizacijske metode mogu uzeti u obzir niz dodatanih ograničenja i utjecajnih parametara što kod složenijih optimizacijskih metoda može dodatno komplicirati proračun. Međutim, deterministički model ulaznih podataka zahtijeva čitav niz proračuna sa različitim mogućim scenarijima. Svaka kombinacija ulaznih podataka dat će različite rezultate stoga je nužna dodatna analiza i obrada odgovarajuće velikog broja izlaznih rezultata, čto često nije jednostavno. Kvaliteta dobivenih rezultata ovisi o broju analiziranih scenarija.

Za razliku od determinističkog pristupa, stohastički pristup pri simulaciji ili optimizaciji nastoji već u modelu ulaznih podataka i varijabli u proračun ugraditi stohastičke karakteristike. U stohastičkom modelu izlaz je po prirodi slučajan. Deterministički model je samo specijalan (pojednostavljen) slučaj stohastičkog modela. Za stohastičko modeliranje često se koristi tzv. nezavisni model koji dotoke (na svim lokacijama i u svim vremenskim periodima) tretira kao nezavisne slučajne varijable opisane statističkim parametrima ili pak zavisni

model podataka koji protoke tretira kao međusobno ovisne slučajne varijable opisane Markovljevim lancima

Cilj ovog rada je vrednovanje prikladnog zavisnog stohastičkog modela za generiranje dotoka na nekom mjestu predstavljenog autoregresivnim Markovljevim modelom prvog reda. Ispitivani model uzima u obzir stohastički karakter dotoka vodeći računa i o sezonskim varijacijama tijekom godine.

Izrađen je program za simulaciju budućih dotoka te je analizirano da li simulirani „budući“ dotoci zadržavaju karakteristike do sada zabilježenih dotoka na tom mjernom mjestu.

II. MODELIRANJE DOTOKA

Ako se zabilježeni dotoci u riječna korita ili akumulacijske bazene u razumno dugačkom periodu promatranja mogu opisati stacionarnim stohastičkim procesom (procesom čiji se parametri ne mijenjaju tijekom vremena), tada se može kreirati stohastički model dotoka prilagođen mjerenim podacima. Taj stohastički model može potom generirati proizvoljno dugačak niz pogodan za različite proračune, simulacije, optimiranja itd. Prvi korak u kreiranju prikladnog stohastičkog modela je ekstrakcija osnovnih statističkih karakteristika dotoka u različitim vremenskim periodima.

A. Model dotoka

Model dotoka kojeg ćemo ispitivati izmjerene dotoke (srednje dnevne, srednje mjesečne, ...) definira kao jednodimenzionalni vremenski niz opažanja bilježen u pravilnim vremenskim intervalima $t_0+n\tau$, n= 1, 2, ..., N. Za razliku od nezavisnih slučajnih uzoraka, kod vremenskog niza red opažanja je važan. To znači da opažanja nisu nezavisna. Slučajna varijabla čija se vrijednost mijenja u vremenu prema zakonu vjerojatnosti je stohastički proces. Određen vremenski niz se interpretira kao realizacija slučajnog procesa.

Značajno pojednostavljenje pri modeliranju čine slučajevi kada se budući razvoj procesa može predvidjeti samo pomoću trenutnog stanja, bez pozivanja na prošlost. To je Markovljevo svojstvo. Specijalni slučaj Markovljevog procesa je onaj kod kojeg stanja mogu biti poprimiti samo diskretne vrijednosti. Takav se proces zove Markovljev lanac. Radi pojednostavljenja modela, kontinuirani stohastički procesi se često aproksimiraju Markovljevim lancem.

Autoregresivni proces je niz slučajnih varijabli uzastopno definiranih određenim pravilom. Kod autoregresivnog modela izlazna varijabla je linearno ovisna o vlastitoj prethodnoj vrijednosti. Oznaka AR(*p*) označava autoegresivni proces reda p. AR(*p*) model se općenito definira kao

$$X_t = c + \sum_{i=1}^{p} \varphi_i X_{t-i} + \varepsilon_t \,, \tag{1}$$

gdje su φ_1, ..., φ_n parametri modela, c je konstanta a ε_t je niz nezavisnih normalnih slučajnih varijabli s očekivanjem nula i varijancom σ^2 (bijeli šum). Autoregresivni proces prvog reda AR(1) ovisan o jednom parametru se definira kao

$$X_t = c + \varphi X_{t-1} + \varepsilon_t \,. \tag{2}$$

Uobičajena i razumna pretpostavka je da se godišnji dotoci mogu tretirati kao Markovljev proces prvog reda. Izbor modela ovisi o raspoloživim podacima, karakteristikama dotoka i namjeni modela. Pretpostavit ćemo da imamo relevantne podatke o izmjerenim dotocima na nekom mjestu, sa poznatim statističkim parametrima. Fokusirati ćemo se na dva modela koji reproduciraju dotoke u kraćim vremenskim periodima (mjesecima ili tjednima) prikladna za potrebe srednjoročnog i dugoročnog planiranja rada hidroelektrana.

Ako se mjesečni dotoci na nekom mjestu podvrgavaju normalnoj distribuciji sa poznatim parametrima budući se dotoci mogu simulirati koristeći autoregresivni Markovljev model sa prvog reda [6 ,7]

$$\begin{aligned} i_{j,m} = \mu_m + r_m(\sigma_m / \sigma_{m-1})\left(i_{j,m-1} - \mu_{m-1}\right) + \\ + z_m \sigma_m \sqrt{1 - r_m^2} \,. \end{aligned} \tag{3}$$

Dotoci na nekom mjestu $i_{j,m}$ u godini j (j=1, 2, ,n) i mjesecu m (m=1, 2, ...,12) mogu se izračunati ako se poznaje prethodni dotok $i_{j,m-1}$, parametri normalne razdiobe (μ_m i σ_m) za svaki mjesec te koeficijenti korelacije r_m između dva uzastopna mjeseca. Ovi se parametri mogu izračunati na temelju višegodišnjeg mjerenja dotoka koristeći izraze

$$\mu_m = \frac{1}{n} \sum_{j=1}^{n} i_{j,m} \,, \tag{4}$$

$$\sigma_m = \sqrt{\frac{1}{n-1} \sum_{j=1}^{n} \left(i_{j,m} - \mu_m\right)^2} \,, \tag{5}$$

$$r_m = \frac{\sum_{j=1}^{n} (i_{j,m} - \mu_m)(i_{j,m-1} - \mu_{m-1})}{\sigma_m \sigma_{m-1}} \,. \tag{6}$$

Varijabla z_m u (1) je standardna normalna slučajna varijabla sa očekivanjem 0 i varijancom jednakoj 1. Uvjetna vjerojatnost dotoka u mjesecu m uz zadani dotok u prethodnom mjesecu

$$\mu_{m|m-1} = \mu_m + r_m(\sigma_m / \sigma_{m-1})\left(i_{j,m-1} - \mu_{m-1}\right) \tag{7}$$

je deterministička komponenta u izrazu (1) dok je uvjetna standardna devijacija

$$\sigma_{m|m-1} = \sigma_m \sqrt{1 - r_m^2} \tag{8}$$

pomnožena sa z_m slučajna komponenta koja predstavlja slučajno odstupanje dotoka neovisno o dotoku u prethodnom mjesecu. Za r_m=0 jednadžba (1) bi postala nezavisni model mjesečnih dotoka.

Ako se dotoci podvrgavaju log-normalnoj razdiobi, izraz (1) se može primjeniti na logaritme dotoka koji se podvrgavaju normalnoj razdiobi.

$$\ln(i_{j,m}) = \mu'_m + r_m'(\sigma'_m / \sigma'_{m-1})\left(\ln(i_{j,m-1}) - \mu'_{m-1}\right) + \\ + z_m \sigma_m' \sqrt{1 - r'^2_m}\ , \tag{9}$$

gdje su μ_m', σ_m' te μ_{m-1}', σ_{m-1}' srednja vrijednost i standardna devijacija logaritama protoka $\ln(i_{j,m})$ and $\ln(i_{j,m-1})$. Srednja vrijednost i standardna devijacija log-normalne razdiobe za sve jedinične periode može se izraziti pomoću srednje vrijednost i standardne devijacije normalne razdiobe [10]

$$\mu'_i = \ln \frac{\mu_i^2}{\sqrt{\sigma_i^2 + \mu_i^2}}\ , \tag{10}$$

$$\sigma'^2_i = \ln\left(1 + \frac{\sigma_i^2}{\mu_i^2}\right). \tag{11}$$

Koeficijent korelacije r_m' između $\ln(i_{j,m})$ and $\ln(i_{j,m-1})$ također se može izraziti preko koeficijenta korelacije r_m no precizniji rezultati se dobiju ako direktno mjerimo korelacije logaritama protoka [7].

Varijabla z_m u (7) je također standardna normalna slučajna varijabla sa očekivanjem 0 i varijancom jednakoj 1.

Ako normaln varijabla $\ln(i_{j,m})$ slijedi autoregresivni Markov model (7), tada odgovarajući dotok $i_{j,m}$ slijedi model

$$i_{j,m} = (i_{j,m-1})^{r_m' \frac{\sigma'_m}{\sigma'_{m-1}}} \cdot \exp\left[\mu'_m - r_m' \frac{\sigma'_m}{\sigma'_{m-1}} \mu'_{m-1}\right] \cdot \\ \cdot \exp\left[z_m \sigma_m' \sqrt{1 - r'^2_m}\right] \tag{12}$$

Autoregresivni modeli dotok (3) i (12) mogu se primjeniti i na tjedne dotoke, ako postavimo da je m index tjedna (m=1, 2, ..., 52), te da su poznate srednje vrijednosti, standardne devijacija i faktori korelacije između uzastopnih mjeseci.

B. Generiranje dotoka

Za simulaciju budućih dotoka napravljena su dva programa, jedan koji dotoke generira prema jednadžbi (3), a drugi koji dotoke generira prema jednadžbi (12). Rezultati rada programa su svaki put različiti jer se pri svakom pokretanju programa generira drugi skup slučajnih brojeva z_m za svaki vremenski period m. Programi se mogu koristiti za generiranje tjednih i mjesečnih protoka za niz godina jer se broj vremenskih perioda m (12 ili 52) i broj godina definiraju na početku.

III. PRIMJER

Za testiranje rada programa mogu se uzeti bilo kakvi početnii podaci, no mi smo ipak uzeli stvarne podatke o dotocima u jedan veliki akumulacijski bazen mjerenz dugi niz godina. Cilj testiranja je ispitati da li dotoci koji se generiraju pomoću programa za niz godina zadržavaju početne karakteristike.

A. Generiranje i analiza dotoka koji se podvrgavaju normalnoj razdiobi

U tablici 1 u prva tri retka su prikazani zadani ulazni podaci μ_m, σ_m i r_m za svih 12 mjeseci te prosječna vrijdnost ovih veličina tijekom godine. Sve vrijednosti dotoka prikazane u tablici, te srednje vrijednosti i varijance date su m^3/s. Npr. srednji godišnji protok iznosi 36,98 m^3/s. Jedino je faktor korelacije r veličina bez dimenzije.

Nakon toga su, u slijedećih 30 redaka prikazani dotoci generirani u programu za 30 godina u nizu. Također su u predzadnjoj kolone prikazane prosječne vrijednosti dotoka generirani za svaku godinu te razlika („pogreška“) između prosječnog godišnjeg protoka dobivenog simulacijom i zadanog prosječnog godišnjeg dotoka u postotcima.

U slijedeća tri retka prikazani su izračunati μ_m, σ_m i r_m za svih 12 mjeseci koji su dobiveni simulacijom, prosječni μ_m, σ_m i r_m dobiveni simulacijom te razlika prosječnih simuliranih i prosječnih zadanih vrijednosti ove tri veličine. U posljednja 3 retka prikazana je razlika za μ_m, σ_m i r_m u postotcima između zadanih i simuliranih vrijednosi dotoka za sve mjesece.

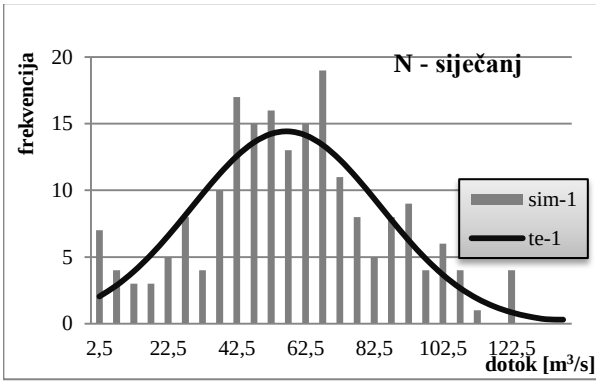
Analizirajući rezultate dane u tablici 1, ali i niza sličnih tablica koje se dobiju pri svakom novom pokretanju programa, možemo uočiti slijedeće:

- Razlika srednjih godišnjih protoka generiranih u programu i zadanog srednjeg godišnjeg protoka u nizu godina je obično unutar ±40%. Kod stvarnih podataka u zadnjih 30 godina razlike prema prosjeku su varirale od – 31% 2004. godine do +40% 2011. godine.
- Razlika simuliranog srednjeg godišnjeg protoka za svih 30 godina i izmjerenog srednjeg godišnjeg protoka je uvijek puno manja (unutar ±5%). U ovom primjeru +3,45 %.
- Srednje vrijednosti generiranih dotoka po mjesecima μ_m su također blizu polaznih vrijednosti. Razlike su obično unutar ±15%. Slično se ponašaju varijance generiranih dotoka po mjesecima σ_m.
- Nešto veće razlika između početnih i simuliranih vrijednosti se javljaju kod faktora korelacije r_m, odnosno velika razlika se javlja kod faktora r_m jer je zadani faktor korelacije izuzetno nizak, dok su razlike za ostale mjesece obično unutar ±25%.

Dotoci simulirani u programu moraju zadržati karakteristike raspodjele prema kojoj se raspodjela vrši. Rezultati simulacije dani u tablici 1 obuhvatili su samo 30 godina što je malo za točnije utvrđivanje pripadne raspodjele. Stoga smo napravili novi pokus sa istim početnim parametrima, ali smo generirali protoke za 200 godina. Time smo dobili 200 protoka za svaki mjesec koje smo grupirali u razrede i grafički prikazali. Na slici 2 stupčastim grafom je prikazana raspodjela simuliranih protoka u 1. Mjesecu, a glatkom krivuljom toeretska normalna razdioba za zadane parametre μ_1, σ_1. Standardnim χ^2 testom sa pragom od 0,05 ispitivana je hipoteza o „prilagođenosti“ simulirane i teoretske razdiobe za sve mjesece. U većini slučajeva hipoteza se mogla prihvatiti. Za slučaj na slici vrijednost χ^2 testa je 0,034343.

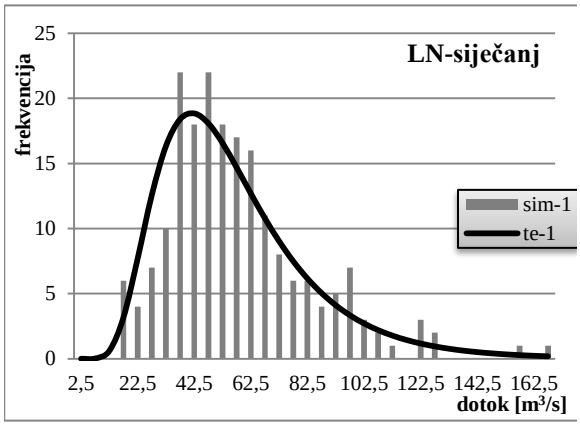


Slika 1. Toretska normalna raspodjela i raspodijela generiranih dotoka u prvom mjesecu za niz od 200 godina

B Generiranje i analiza dotoka koji se podvrgavaju log-normalnoj razdiobi

Kao što smo analizirali dotoke generirane prema normalnoj razdiobi, napravili smo analizu dotoka generiranih prema log-normalnoj razdiobi. Razlike statističkih parametar dotoka μ_m', σ_m' i r_m' dobivene simulacijom u odnosu na početne vrijednosti su u sličnim graničnim vrijednosti kao kod normalne razdiobe.

Također su simulirani dotoci zadržali željeni oblik log-normalne razdiobe što je provjeravano grafički i preko χ^2 testa. Na slici 2 stupčastim grafom je prikazana raspodjela simuliranih protoka u 1. mjesecu na uzorku od 200 dotoka, a glatkom krivuljom toeretska log-normalna razdioba za zadane parametre μ_1' i σ_1'. Vrijednost χ^2 testa u ovom prikazanom primjeru je 0,034343.



Slika 2. Toreska log-normalna raspodjela i raspodijela generiranih dotoka u prvom mjesecu za niz od 200 godina

IV. ZAKLJUČAK

Stohastički model podatka je onaj koji prepoznaje slučajnu prirodu ulaznih komponenti. U radu su testirana dva stohastička modela za simulaciju budućih dotoka na nekom mjestu koji dotoke u različitim vremenskim periodima tretiraju kao međusobno ovisne slučajne varijable opisane autoregresivnim Markovljevim lancima. Jedan model se koristi ako se dosadašnji dotoci na tom mjestu podvrgavaju normalnoj, a drugi ako se dosadašnji dotoci na tom mjestu podvrgavaju log-normalnoj razdiobi.

Nakon simuliranja niza dotoka po oba modela, generiranim dotocima ispitivana su razna statistička obilježja: srednja vrijednost, standardna devijacija, faktori korelacije dotoka u uzastopnim vremenskim periodima itd. Generirani dotoci zadržali su sva ispitivana obilježja kao dotoci mjereni na tom mjestu u nizu godina. Oba ispitivana modela podataka za simulaciju dotoka su relativno jednostavna linearna regresijska modela, robusna, primjenjiva za potrebe srednjoročnih i dugoročnih simuliranja i optimizacijskih proračuna rada hidroelektrana. Primjenu testiranih modela može otežat potreba za poznavanjem što točnijih karakteristika dotoka na nekom mjestu koje se mogu dobiti samo dugogodišnjim mjerenjem.

Sažetak – U okviru korelacijske analize ustanovljava se postojanje veze između slučajnih varijabli, njen oblik, jačina i smjer. Cilj rada je na osnovu relevantnih hidroloških podataka mjerenih u nizu godina na jednom mjernom mjestu napraviti korelacijsku analizu prirodnih dotoka grupiranih u manje vremenske periode. U radu su izračunate simetrične matrice Pearsonovih koeficijenata korelacije za srednje mjesečne dotoke i srednje tjedne dotoke. Analizirane su prosječne vrijednosti koeficijenata korelacije srednjih mjesečnih i srednjih tjednih dotoka za uzastopne periode, ali i za veće vremenske korake. Na kraju su računate korelacije među prirodnim logaritmima srednjih mjesečnih i srednjih tjednih protoka potrebne pri modeliranju dotoka koji se podvrgavaju log-normalnoj razdiobi. Uočene su razlike u prosječnoj jakosti veza obzirom na tip korelacijske veze i period promatranja. Dobiveni rezultati su značajni za razvoj modela podataka prirodnih dotoka za potrebe optimizacijskih proračuna.

I. UVOD

Optimalno planiranje i korištenje voda na nekom hidroenergetskom slivu temelji se na sustavnom višegodišnjem prikupljanju hidroloških podataka te njihovoj analizi i obradi. Međusobne veze u pojavi određenih dotoka značajno utječu na modeliranje dotoka u proračunima i složenost proračuna. U okviru korelacijske analize ustanovljava se postojanje veze, njen oblik, jačinu i smjer ne ulazeći u to što je uzrok a što posljedica.

Cilj rada je na osnovu relevantnih hidroloških podataka mjerenih u nizu godina napraviti korelacijsku analizu prirodnih dotoka. Treba istražiti i statistički definirati korelacijske veze među dotocima grupiranih u manje vremenske periode. Prema jakosti veze ocijeniti da li je opravdano zanemariti neke korelacijske veze u određenom tipu proračuna.

Izračunate su simetrične matrice Pearsonovih koeficijenata korelacije za srednje mjesečne dotoke i srednje tjedne dotoke. Analizirane su prosječne vrijednosti koeficijenata korelacije srednjih mjesečnih i srednjih tjednih dotoka za uzastopne periode, ali i za veće vremenske korake. Na kraju su računate korelacije među prirodnim logaritmima srednjih mjesečnih i srednjih tjednih protoka potrebne pri modeliranju dotoka koji se podvrgavaju log-normalnoj razdiobi. Uočene su razlike u prosječnoj jakosti veza obzirom na tip korelacijske veze i period promatranja.

II. KORELACIJSKA ANALIZA

Pojave u prirodi mogu biti povezane različitim vezama. Neka neki događaj ima dva obilježja x i y, gdje je x mjerena vrijednost jednog, a y mjerena vrijednost drugog obilježja. Nakon n mjerenja dobit ćemo skup od n parova (x_i,y_i), i=1,2, ..., n. Budući da je riječ o uređenim parovima, nakon n mjerenja rezultat ćemo moći predstaviti sa n točaka u koordinatnom sustavu. Skup tih točaka se zove dijagram rasprostiranja. Oblik dijagrama rasprostiranja otkriva zavisnost između obilježja x i y:

- kod funkcionalne veze točke (x_i,y_i) leže na jednoj krivulji, a ako je ta krivulja pravac govorimo o linearnoj funkcionalnoj vezi;
- kad obilježja x i y nisu vezana funkcionalnom vezom, ali dijagram ipak pokazuje tendenciju izduživanja u jednom smjeru govorimo o stohastičkoj vezi među slučajnim varijablama x i y;
- ako točke (x_i,y_i) ne pokazuju tendenciju gomilanja u nekom smjeru, obilježja x i y su nepovezana.

Kod stroge funkcionalne veze (ili determinističkog odnosa) za svaku vrijednost x se točno zna vrijednost varijable y. Kada su slučajne varijable x i y stohastički povezane, za jednu vrijednost od x dolazi više vrijednosti od y koje su raspoređene po nekom zakonu vjerojatnosti. Stoga se pri stohastičkoj vezi za određeni x može samo odrediti interval kojem se ta vrijednost nalazi i to uz izvjesnu vjerojatnost.

Jakost stohastičke veze mjeri se koeficijentom korelacije ρ. Koeficijent linearne korelacije osnovnog skupa (populacije), ili Pearsonov koeficijent definiramo kao

$$\rho = \frac{ko\,\mathrm{var}\,ijanca(x,y)}{\mathrm{var}\,ijanca(x)\cdot \mathrm{var}\,ijanca(y)} = \frac{\sigma_{xy}}{\sigma_x^2\sigma_y^2} \qquad (1)$$

Vrijednost koeficijenta korelacije je $-1 \geq \rho \geq +1$. Za $\rho=\pm 1$ govorimo o funkcionalnoj vez dviju varijablii, a za $\rho=0$ varijable su nezavisne. U ostalim slučajevima imamo stohastičku vezu među varijablama. Općenito labavijoj vezi odgovara manji $|\rho|$, a čvršćoj veći $|\rho|$.

Nepristranu procjenu koeficijenta korelacije ρ, označimo sa r. Tada je koeficijent linearne korelacije uzorka [9]

$$r = \frac{\sum_{i=1}^{n}(x_i-\bar{x})(y_i-\bar{y})}{\sqrt{\sum_{i=1}^{n}(x_i-\bar{x})^2\sum_{i=1}^{n}(y_i-\bar{y})^2}} = \frac{s_{xy}}{s_x^2 s_y^2}. \qquad (2)$$

Nepristrana procjena kovarijanca varijabli x i y je

$$s_{xy} = \frac{1}{n-1}\sum_{i=1}^{n}(x_i-\bar{x})(y_i-\bar{y}) . \quad (3)$$

Nepristrana procjena varijance varijable x je

$$s_x^2 = \frac{1}{n-1}\sum_{i=1}^{n}(x_i-\bar{x})^2 . \quad (4)$$

Nepristrana procjena varijance varijable y je

$$s_y^2 = \frac{1}{n-1}\sum_{i=1}^{n}(y_i-\bar{y})^2 . \quad (5)$$

U primjeni se stupanj jakosti korelacije r obično definira na slijedeći način

| r |	**Jakost korelacije**
0	nema korelacije
0 - 0,5	slaba korelacija
0,5 - 0,8	srednje jaka korelacija
0,8 - 1	jaka korelacija
1	potpuna korelacija

Kada imamo više varijabli i zanima nas veza među svim kombinacijama varijabli možemo kreirati matricu korelacija. Redovi i kolone matrice predstavljaju promatrane varijable, a članovi matrice su koeficijent korelacije. Dobivena matrica je simetrična ($r_{ij}=r_{ji}$), pa je dovoljno promatrati gornji ili donji trokut matrice. Svi dijagonalni članovi su jedinice jer je svaka varijabla sama sa sobom u potpunoj korelaciji.

Ako su varijable članovi nekog vremenskog niza, stupanj k označava razmak između osnovnih perioda, a r(k) koeficijent korelacije stupnja k. Za k=1 imamo koeficijent korelacije susjednih vremenskih perioda itd.

Međutim, Pearsonov koeficijent korelacije r može se računati na gornji način kod linearne povezanosti varijabli koje imaju simetričnu raspodjelu. Prirodni dotoci u pravilu nemaju simetričnu distribuciju jer dotoci ne mogu biti negativni. Distribucija prirodnih dotoka u pravilu ima pozitivni koeficijent asimetrije, donja granica protoka je obično blizu nule, a gornja je gotovo neograničena. Distribucija prirodnih dotoka obično više naliči log-normalnoj nego normalnoj distribuciji.

U takvim slučajevima općenito je preporučena metoda transformacije slučajnih varijabli u varijable koja se podvrgava normalnoj (simetričnoj) distribuciji i korištenje koeficijenata korelacije među simetričnim distribucijama definirane na prethodni način [2].

Ako se npr. slučajna varijabla Q, koja predstavlja protok na nekom mjestu, podvrgava dvoparametarskoj logaritamsko-normalnoj distribucijom, tada se ln(Q) podvrgava normalnoj distribuciji. Očekivanje, varijanca, koeficijent asimetrije itd. log-normalne razdiobe mogu se jednostavno izračunati iz očekivanja, varijanca i koeficijenta asimetrije normalne razdiobe koristeći dobro poznate izraze [8].

Kod kasnijeg modeliranja protoka Q koji se podvrgavaju log-normalnoj razdiobi, veza stupnja k među protocima u periodu u i v označena sa $\rho_{LN}(k,u,v)$ može se odrediti iz veze stupnja k među transformiranim varijablama ln(Q) koje se podvrgavaju normalnoj razdiobi označena sa $\rho_N(k,u,v)$ i njihovih varijanci $\sigma^2_N(u)$ i $\sigma^2_N(v)$ [2] koristeći izraz

$$\rho_{LN}(k,u,v) = \frac{\exp\left[\rho_N(k,u,v)\cdot\sigma_N(u)\cdot\sigma_N(v)\right]-1}{\sqrt{\exp(\sigma_N^2(u)-1)}\cdot\sqrt{\exp(\sigma_N^2(v)-1)}} \quad (6)$$

Mnogo efikasnija metoda estimacije stvarne zavisnosti među protocima koji se podvrgavaju log-normalnoj razdiobi je transformacija zabilježenih protoka u ekvivalente ln(Q) koji se podvrgavaju normalnoj razdiobi te korištenje zabilježenih korelacija između transformiranih varijabli kao estimacija za $\rho_N(k,u,v)$.

III. PRORAČUN MATRICA KORELACIJE

Korelacijsku analizu dotoka proveli smo nad mjerenim podacima dotoka u rijeku Krku. Imali smo dva niza mjerenja zabilježenih na istom mjernom mjestu. To mjerno mjesto se nalazi uzvodno od svih vodnih zahvata na slivu pa predstavljaju prirodne dotoke. Prvi niz su zabilježene vrijednosti srednjih mjesečnih dotoka u periodu od 59 godina (1950 – 2013 s prekidom 1991-1995). Drugi niz je kontinuirani niz srednjih dnevnih dotoka zabilježen u posljednjih 17 godina (1997-2013).

Na uzorku srednjih mjesečnih dotoka u periodu od 59 godina izračunata je matrica 12*12 Pearsonovih koeficijenata linearne korelacije (tablica1). Matrica je simetrična pa je naglašen samo gornji trokut. Prema očekivanju koeficijenti korelacije između susjednih mjeseci (k=1) su značajno veći nego koeficijenti korelacije sa k>1. Na slici 1 i slici 2 prikazani su dijagrami rasprostiranja i to u prvom slučaju kad dijagram pokazuje tendenciju izduživanja (r=0,728) i kada točke ne pokazuju tendenciju gomilanja (r=0,029). U drugom stupcu tablici 2 sažeto su prikazani prosječni iznosi koeficijenta korelacije srednjih mjesečnih dotoka u periodu od 59 godina iz tablice 1 za vremenski korak 1 do 4.

TABLICA 1. MATRICA KOEFICIJENATA KORELACIJE SREDNJIH MJESEČNIH DOTOKA U PERIODU OD 59 GODINA

	1	2	3	4	5	6	7	8	9	10	11	12
1	1	0,497	0,376	0,284	0,126	0,197	0,144	0,058	0,020	0,011	0,142	0,023

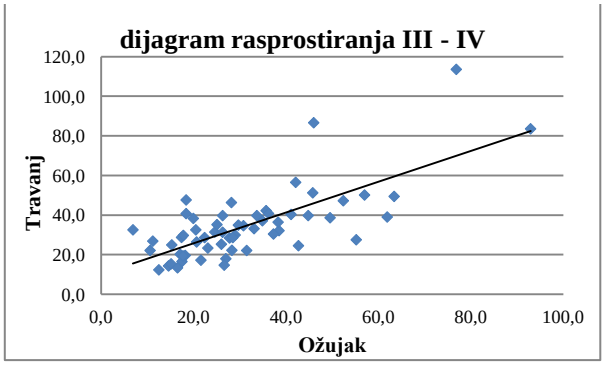
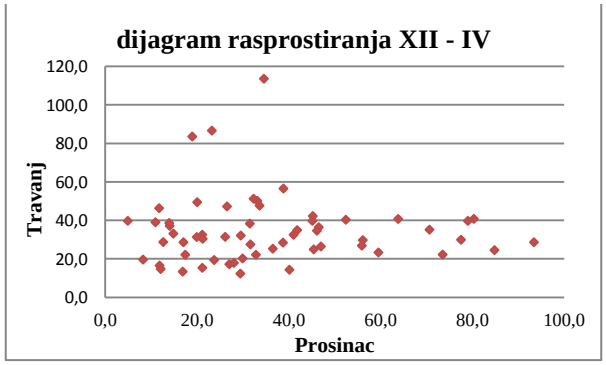
8	0,058	0,256	0,121	0,001	0,262	0,432	0,600	1	0,464	0,204	0,283	0,073
9	0,020	0,178	0,012	0,068	0,020	0,232	0,154	0,464	1	0,090	0,078	0,089
10	0,011	0,012	0,077	0,168	0,040	0,190	0,244	0,204	0,090	1	0,449	0,114
11	0,142	0,147	0,019	0,025	0,124	0,103	0,152	0,283	0,078	0,449	1	0,495
12	0,023	0,114	0,136	0,029	0,051	0,201	0,107	0,073	0,089	0,114	0,495	1



Slika 1. Dijagram rasprostiranja između protoka u ožujku i travnju na uzorku od 59 godina



Slika 2. Dijagram rasprostiranja između protoka u prosincu i travnju na uzorku od 59 godina

Drugi niz podataka o srednjim dnevnim protocima grupirali smo u manje vremenske jedinice, mjesece i tjedne te dobili niz srednjih mjesečnih protoka za svih 12 mjeseci i niz srednjih tjednih protoka za sva 52 tjedna u nizu od 17 godina. Potom smo još jednom izračunali koeficijente korelacije srednjih mjesečnih dotoka, ali ovaj put na uzorku od posljednjih 17 godina. Također smo dobili matricu 12*12 Pearsonovih koeficijenata linearne korelacije. U trećem stupcu tablice 2 prikazani su prosječni iznosi koeficijenta korelacije srednjih mjesečnih dotoka u periodu od 17 godina za vremenski korak 1 do 4. Nešto veći iznosi prosječnih koeficijenata korelacije u drugom nizu podataka su vjerojatno posljedica kratkog perioda mjerenja 2. niza te što je u drugi niz kontinuiran. Cilj ove analize nije točan iznos koeficijenata korelacije na određenom mjernom mjestu, za što je potreban što duži niz mjerenja, već usporedba srednjih mjesečnih i srednjih tjednih koeficijenata korelacije, a to je najbolje raditi na istom uzorku.

Obzirom da je za očekivat kako se srednji mjesečni dotoci ne podvrgavaju simetričnoj normalnoj već nekoj asimetričnoj razdiobi tipa log-normalne, izvršena je transformacija prirodnih srednjih mjesečnih dotoka Q na uzorku od 17 godina u logaritme tih dotoka te ponovno izračunata matrica koeficijenata linearne korelacije među varijablama koje se sada sigurno podvrgavaju normalnoj simetričnoj razdiobi. Sažeti prikaz prosječnih koeficijenata korelacije između dva mjeseca u ovom slučaju je prikazan u drugoj koloni tablice 3.

Pearsonovi koeficijenata linearne korelacije srednjih tjednih dotoka računati su u nizu od posljednjih 17 godina. Rezultat analize je simetrična matrica veličine 52*52. Sažeti prikaz prosječnih koeficijenata korelacije između dva tjedna na uzorku od 17 godina je prikazan u četvrtoj koloni tablice 2.

Na kraju smo, slično kao kod srednjih mjesečnih dotoka, izvršili transformacija srednjih tjednih dotoka Q na uzorku od 17 godina u logaritme tih dotoka te ponovno izračunali matricu veličine 52*52 koeficijenata linearne korelacije logaritama protoka. U trećoj koloni tablice 3 dan je sažeti prikaz prosječnih koeficijenata korelacije u ovom slučaju.

TABLICA 2. PROSIJEČNA VRIJEDNOST KOEFICIJENTA KORAELACIJE PROTOKA Q ZA RAZLIČITE VREMENSKE KORAKE

Korak	Prosječni koef. korelacije između dva mj. na uzorku od 59 godina	Prosječni koef. korelacije između dva mj. na uzorku od 17 godina	Prosječni koef. korelacije između dva tj. na uzorku od 17 godina
1	0,508	0,599	0,743
2	0,273	0,400	0,572
3	0,208	0,302	0,491
4	0,095	0,213	0,440

TABLICA 3. PROSIJEČNA VRIJEDNOST KOEFICIJENTA KORAELACIJE LOGARITAMA PROTOKA LN(Q) ZA RAZLIČITE VREMENSKE KORAKE

Korak	Prosječni koeficijent korelacije između dva mjeseca na uzorku od 17 godina	Prosječni koeficijent korelacije između dva tjedna na uzorku od 17 godina
1	0,656	0,838
2	0,402	0,678
3	0,292	0,589
4	0,236	0,516

Za srednje mjesečne protoke napravili smo proračun koeficijenata korelacije prema (6), na osnovu koeficijenata korelacije izračunatih za logaritme protoka. Rezultati su prikazani u tablici 4. Iznosi koeficijenata stvarne korelacije među protocima r_{LN} su neznatno niži neko r_N iz kojih se računaju. Proračune koeficijenata korelacije r_{LN} za srednje mjesečne protoke nismo računali.

TABLICA 4. PROSIJEČNA VRIJEDNOST KOEFICIJENTA KORALACIJE STVARNIH PROTOKA r_{LN} RAČUNATA IZ KORELACIJE LOGARITAMA PROTOKA r_N ZA RAZLIČITE VREMENSKE KORAKE

Korak	Prosječni koef. korelacije između dva mjeseca na uzorku od 17 godina
1	0,619
2	0,367
3	0,265
4	0,209

Uspoređujući rezultate u tablicama 2 i 3 vidimo da su korelacijske veze između tjedana uvijek jače nego korelacijske veze između mjeseci, što je bilo očekivano. Dotoci su općenito jače korelirani za kraće vremenske intervale.

Analizirajući iznose koeficijenata korelacijskih veza možemo uočiti da se koeficijenti korelacije između uzastopnih mjeseci kreću oko 0,6, što predstavlja srednje jaku korelacijsku vezu. Iznosi koeficijenata korelacije za k>1 su uvijek manji od 0,5, što označava slabe korelacijske veze. Prema tome, kod modeliranja srednji mjesečnih dotoka, precizniji model treba uzeti u obzir veličinu dotoka u prethodnom periodu, a ostale može zanemariti. Jednostavniji i manje precizan model može zanemariti utjecaj svih prethodnih dotoka.

Koeficijenti korelacije srednjih tjednih dotoka za k=1 od približno 0,8 govore o srednje jakoj i jakoj korelacijskoj vezi susjednih tjedana. Čak i koeficijenti korelacije srednjih tjednih dotoka za k=2 nisu beznačajni. Dakle, kod modeliranja srednji mjesečnih dotoka, manje precizan model treba uzeti u obzir veličinu dotoka u prethodnom periodu, a ostale može zanemariti. Precizniji model može uzetu u obzir i korelacijske veze sa korakom k>1, ili na neki drugi način uzeti u obzir utjecaje ostalih korelacijskih veza. Jedan od načina je npr. računanje parcijalnog koeficijenta korelacije između dviju varijabli uz „uklanjanje“ utjecaja drugih nezavisnih varijabli.

Za kraj uočimo da se svi naši računati koeficijenti korelacije približno pokoravaju uobičajenoj formuli koja se koristi pri modeliranju koeficijenata korelacije višeg reda [2].

$$r(k) = [r(1)]^k = r^k . \quad (7)$$

IV. ZAKLJUČAK

Cilj rada je napraviti korelacijsku analizu prirodnih dotoka na osnovu relevantnih hidroloških podataka mjerenih u nizu godina. Prema jakosti veze ocijeniti da li je opravdano zanemariti neke korelacijske veze. Izračunate su simetrične matrice Pearsonovih koeficijenata korelacije za srednje mjesečne dotoke i srednje tjedne dotoke. Analizirane su prosječne vrijednosti koeficijenata korelacije srednjih mjesečnih i srednjih tjednih dotoka za uzastopne periode, ali i za veće vremenske korake.

Korelacijske veze između tjedana uvijek su jače nego korelacijske veze između mjeseci, što je bilo očekivano. Uzastopne mjesece karakterizira srednje jaka korelacijska veza, a ostale korelacijske veze među mjesecima su slabe i zanemarive. Uzastopne tjedne karakterizira srednje jaka i jaka korelacijska veza. Korelacijske veze koraka 2 između tjedana također nisu zanemarive. O ovim činjenicama treba voditi računa prilikom modeliranja mjesečnih i tjednih protoka za različite proračune

Sažetak - Za srednjoročno i dugoročno planiranje rada hidroelektrana obično se ciljani period promatranja od nekoliko mjeseci do godine dana dijeli u manje vremenske intervale, dugačke jedan tjedan ili jedan mjesec. U radu su analizirani višegodišnji rezultati mjerenja prirodnih dotoka na jednom mjernom mjestu grupirani u mjesečne i tjedne intervale. Ispitano je da li teorijske funkcije vjerojatnosti kontinuiranih razdioba, koje se uobičajeno koriste u hidrologiji za modeliranje dotoka, dobro aproksimiraju empirijske podatke prirodnih dotoka koje smo imali na raspolaganju. Ispitivanje kompatibilnosti serija srednjih mjesečnih i serija srednjih tjednih empirijskih podataka s teorijskim funkcijama raspodjele vjerojatnosti je provedena sa χ^2 (hi-kvadrat) testom. Prema veličini χ^2 testa rangirali smo distribucije u svakom periodu promatranja. Cilj rada je naći tip distribucije koja se dobro prilagođava mjerenim podacima u velikom broju promatranih osnovnih vremenskih perioda, a također je relativno jednostavna za korištenje - po mogućnosti dvoparametarska distribucija i da se parametri distribucije određuju jednostavnim analitičkim postupkom. Na osnovu tog tipa distribucije koji najbolje opisuje učestalost pojavljivanja protoka po mjesecima ili tjednima kasnije želimo graditi „univerzalni" model dotoka u nekom osnovnom vremenskom periodu.

I. UVOD

Optimalno korištenje vodnih potencijala temelji se na dugogodišnjim hidrološkim i meteorološkim mjerenjima te statističkim obradama izmjerenih podataka. Pouzdani podaci prikupljeni na odgovarajući način podloga su prvo za planiranje razvoja i izgradnje hidroenergetskih sustava, a potom za planiranje optimalnog korištenja raspoloživih količina vode na nekom slivu. Statistička analiza prikupljenih podataka i određivanje prikladnih funkcija vjerojatnosti je znanstveni pristup problemu neizvjesnosti prirodnih dotoka [1]-[6].

Srednjoročno i dugoročno planiranje rada hidroelektrana izučava moguće scenarije u budućem ciljanom periodu od nekoliko mjeseci do godine dana, ponekad i duže. Neizvjesnost i stohastički karakter budućih dotoka je glavni uzrok složenosti ovakvih analiza. Ukupni ciljani period planiranja se obično dijeli u manje, osnovne ili jedinične vremenske intervale, dugačke jedan tjedan ili jedan mjesec. Pretpostavka je da se u osnovnim vremenskim intervalima ne mijenjaju vrijednosti varijabli u proračunu. Isto tako možemo pretpostaviti da će budući dotoci, koji su uvijek dio ulaznih podataka raznih analiza i optimizacijskih proračuna, zadržati statistička obilježja kakva su imali do sada.

Korištenje prethodno zabilježenih vrijednosti neke slučajne varijable, npr. prirodnog dotoka, za simuliranje mogućih vrijednosti koju ta varijabla može poprimiti u budućnosti je prilično nepraktično. Nepoznata je matematička forma koja bi opisala taj događaj. Jednostavnije je tim empirijskim podacima prilagoditi neku teorijsku distribuciju, a potom koristiti matematičku formu teorijske distribucije za predstavljanje empirijske raspodjele učestalosti, generiranje mogućih vrijednosti, modeliranje u optimizacijskim proračunima itd.

Poznat je veliki broj funkcija vjerojatnosti koje se mogu koristiti u različitim područjima za statistički opis podataka i više statističkih metoda koje pomažu pri odabiru prikladne funkcije učestalosti. Obično treba prilagoditi nekoliko teorijskih distribucija, koje po svojim karakteristikama odgovaraju prirodi problema kojim se bavimo, usporediti rezultate i izabrati najbolju. Nakon toga potrebno je odrediti kako dobro se odabrana teorijska distribucija prilagođava mjerenim podacima koristeći prikladne testove. Prema rezultatima testa, odnosno stupnju prilagodbe, bira se model koji najbolje opisuje stvarne podatke.

U radu smo analizirati višegodišnje rezultate mjerenja dotoka na jednom mjernom mjestu i tražili prikladnu teorijsku funkcija vjerojatnosti za opis izmjerene učestalosti pojavljivanja tih dotoka u jediničnim vremenskim intervalima. Svi prikupljeni podaci su mjereni u jednoj mjernoj stanici na isti način kako bi se smanjila moguća greška pri mjerenju. Nakon sortiranja i grupiranja izmjerenih podataka ispitano je da li teorijske funkcije vjerojatnosti kontinuiranih razdioba koje se uobičajeno koriste u hidrologiji za modeliranje dotoka (normalna, log-normalna, gama, log-gama, Pearson tip 3, log-Pearson tip 3, Weibull, Gumbel Max, …) dobro aproksimiraju empirijske podatke dotoka koje smo imali na raspolaganju. Ispitivanje kompatibilnosti serija srednjih mjesečnih i serija srednjih tjednih empirijskih podataka s teorijskim vjerojatnosti raspodjele funkcija je provedena sa χ^2 (hi-kvadrat) testom. Prema veličini χ^2 testa rangirali smo distribucije u svakom periodu promatranja.

Cilj rada je naći tip distribucije koja se dobro prilagođava mjerenim podacima u velikom broju promatranih osnovnih vremenskih perioda, a također je

relativno jednostavna za korištenje. Jednostavna za korištenje znači da je po mogućnosti dvoparametarska distribucija i da se parametri distribucije određuju jednostavnim analitičkim postupkom. Na osnovu tog tipa distribucije koji najbolje opisuje učestalost pojavljivanja protoka po mjesecima ili tjednima kasnije želimo graditi „univerzalni“ model dotoka u nekom osnovnom vremenskom periodu.

Ispitivanja smo proveli koristeći vlastita programska rješenja i jedan dostupan računalni program sa s gotovim algoritmima obrade.

II. STATISTIČKA ANALIZA PRIRODNIH DOTOKA

A. Osnovna statistička obrada nizova podataka

Kada distribucija slučajne varijable nije poznata, ali je raspoloživ niz od N nezavisnih mjerenja (x_1, ..., x_N), numeričke karakteristike nepoznate distribucije slučajne varijable x mogu se procijeniti na osnovu empiričkih mjerenja na uzorku veličine N koristeći slijedeće izraze [1].

Nepristrana procjena očekivanja μ varijable x je aritmetička sredina slučajnog uzorka

$$\bar{x} = \frac{1}{N}\sum_{i=1}^{N} x_i \,. \tag{1}$$

Nepristrana procjena varijance σ^2 varijable x jest veličina definirana izrazom

$$\hat{\sigma}_x^2 = s_x^2 = \frac{1}{N-1}\sum_{i=1}^{N}(x_i - \bar{x})^2 \,. \tag{2}$$

Nepristrana procjena koeficijent asimetrije α_3 varijable x jest veličina definirana izrazom

$$\hat{\alpha}_3 = Cs_x = \frac{N}{(N-1)(N-2)}\sum_{i=1}^{N}\frac{(x_i - \bar{x})^3}{{s_x}^3} \,. \tag{3}$$

Prirodni dotoci su uvijek pozitivne veličine s asimetričnim oblikom distribucije čiji je koeficijent asimetrije u pravilu pozitivan. Donja granica protoka je obično blizu nule, a gornja je gotovo neograničena.

B. Teorijske razdibe kontinuirane slučajne varijable

Za modeliranje učestalosti srednjih tjednih i srednjih mjesečnih dotoka razmatrano je nekoliko jednostavnih kontinuiranih distribucija koje imaju slijedeće karakteristike:

- Definirane su na području vrijednosti varijable x (0,+∞) kao i empirički podaci. Izuzetak je normalna razdioba koje je, kao najčešća kontinuirana razdioba, prikazana radi usporedbe s drugim razdiobama;
- Oblik funkcije vjerojatnosti razmatrane teorijske razdiobe i pridruženi statistički parametri (koeficijent simetričnosti itd.) približno su jednaki karakteristikama histograma zabilježenih vrijednosti dotoka;
- razdiobe se uobičajeno koriste u hidrologiji, a parametri razdiobe se daju lako estimirati bez posebnih statističkih programa za estimiranje.

Teorijske funkcije vjerojatnosti i izrazi za estimiranje parametara razmatranih raspodjela dani su u nastavku.

Normalna (ili Gussova) razdioba slučajne varijable x definirana je u rasponu (-∞, +∞), simetrična je (α_3=0) te ima karakterističan zvonoliki oblik opisan funkcijom vjerojatnosti [7]

$$f(x) = \frac{1}{\sigma\sqrt{2\pi}} e^{-\frac{1}{2}\left(\frac{x-\mu}{\sigma}\right)^2} \,. \tag{4}$$

Normalna razdioba je jednoznačno određena očekivanjem μ i varijancom σ^2 pa se uvodi i kraća oznaka za tu razdiobu $N\{\mu, \sigma^2\}$.

Da bismo empiričkoj distribuciji prilagodili normalnu razdiobu, aproksimirat ćemo očekivanje μ aritmetičkom sredinom $\bar{x}$ empiričkih podataka (1), a varijancu σ^2 opet varijancom empiričkih podataka s_x^2 (2).

Logaritamsko-normalna (ili Galtonova) razdioba varijable x je razdioba kod koje je lnx distribuirano po zakonu normalne razdiobe, a područje vrijednosti varijable x je (0, +∞). Dakle, ako y = lnx pripada normalnoj raspodjeli $N\{\mu_y, \sigma_y^2\}$, funkcija vjerojatnosti varijable x glasi [7]

$$f(x) = \frac{1}{x\sigma_y\sqrt{2\pi}} e^{-\frac{1}{2}\left(\frac{\ln x-\mu_y}{\sigma_y}\right)^2} \,. \tag{5}$$

Očekivanje, varijanca i koeficijent asimetrije varijable x glase:

$$\mu_x = e^{\mu_y + \sigma_y^2/2} \,, \tag{6}$$

$$\sigma_x^2 = e^{2\mu_y+\sigma_y^2}(e^{\sigma_y^2} - 1) \,, \tag{7}$$

$$\alpha_{3x} = (e^{\sigma_y^2} + 2)\sqrt{e^{\sigma_y^2} - 1} \,. \tag{8}$$

Logaritamsko-normalna razdioba je potpuno određena sa očekivanjem μ_x i varijancom σ_x^2 varijable x, što kraće pišemo $N_L\{\mu_x, \sigma_x^2\}$. Očekivanje μ_y i varijancu σ_y^2 varijable y možemo izraziti očekivanjem i varijancom varijable x:

$$\mu_y = \ln \frac{\mu_x^2}{\sqrt{\sigma_x^2 + \mu_x^2}}, \quad (9)$$

$$\sigma_y^2 = \ln\left(1 + \frac{\sigma_x^2}{\mu_x^2}\right). \quad (10)$$

Prilikom prilagođavanja log-normalne razdiobe empiričkim podacima, aritmetičku sredinu $\overline{X}$ i varijancu s_x^2 empiričkih podataka uvrstit ćemo na mjesto μ_x i σ_x^2 u gornje izraze i dobiti aproksimativne vrijednosti za μ_y i σ_y^2.

Gama razdioba je familija dvo-parametarskih funkcija raspodjele za kontinuiranu slučajnu varijablu. Za varijablu x kažemo da je distribuirana po zakonu gama razdiobe ako je područje njenih vrijednosti interval (0, +∞), a funkcija vjerojatnosti

$$f(x) = \frac{1}{\Theta^k \Gamma(k)} x^{k-1} e^{-x/\Theta}. \quad (11)$$

U gornjem izrazu k je parametar oblika, a Θ parametar mjerila (k, Θ > 0), pa gama razdiobu kraće označavamo kao Γ(k, Θ). Različite vrijednosti parametra k omogućavaju gama funkciji da poprimi različite oblike pa zato kažemo da je gama razdioba familija dvo-parametarskih funkcija raspodjele.

Za gama razdiobu se očekivanje, varijanca i koeficijent asimetrije mogu definirati kao:

$$\mu = k\Theta, \quad (12)$$

$$\sigma^2 = k\Theta^2, \quad (13)$$

$$\alpha_3 = 2\sqrt{k}. \quad (14)$$

Vidimo da je gama razdioba uvijek pozitivno asimetrična ($\alpha_3 > 0$), ali kada k teži u beskonačno gama funkcija teži u simetrični oblik ($\alpha_3 \to 0$).

Gama raspodjela ima nekoliko generalizacija. Ako se uvede i treći parametar, tzv. parametar položaja x_0 tako da se $(x - x_0)$ podvrgava gama razdiobi, distribucija varijable x je troparametarska gama distribucija ili **Pearson 3** distribucija čija je funkcija raspodjele za $x \geq x_0$ i k, Θ > 0 definirana slijedećim izrazom

$$f(x) = \frac{1}{\Theta^k \Gamma(k)} (x - x_0)^{k-1} \exp(-\frac{x - x_0}{\Theta}). \quad (15)$$

Parametri gama distribucije **(**11**)** mogu se estimirati kosisteći slijedeće izraze [1], [8]

$$\hat{k} = \frac{(\bar{x})^2}{s_x^2}. \quad (16)$$

$$\hat{\Theta} = \frac{s_x^2}{\bar{x}}, \quad (17)$$

dok se parametri Pearson 3 distribucije (15) mogu estimirati koristeći izraze [1]

$$\hat{k} = \frac{4}{(Cs_x)^2}, \quad (18)$$

$$\hat{\Theta} = \frac{s_x Cs_x}{2}, \quad (19)$$

$$\hat{x}_0 = \bar{x} - 2\left(\frac{s_x}{Cs_x}\right), \quad (20)$$

pri čemu su estimirane vrijednosti aritmetičke sredine $\bar{x}$, varijance s_x^2 i koeficijenta asimetričnosti Cs_x dane sa (1), (2) i (3).

Ako pak logaritmi slučajne promjenjive X slijede Pearson 3 razdiobu, tada varijabla X slijedi **log-Pearson 3 (**ili kraće LP3) razdiobu čija je funkcija vjerojatnosti dana izrazom

$$f(x) = \frac{1}{x\Theta^k \Gamma(k)} (\ln(x) - y_0)^{k-1} \exp(-\frac{\ln(x) - y_0}{\Theta}) \quad ,(21)$$

a definirana je za $y_0 \leq \ln(x) < \infty$ i k > 0. Srednja vrijednost i varijanca za LP3 distribuciju se definiraju sa [1]

$$\mu_x = \left(\frac{1}{1-\Theta}\right)^k \exp\left(\frac{y_0}{\Theta}\right), \quad (22)$$

$$\sigma_x^2 = \left[\left(\frac{1}{1-2\Theta}\right)^k - \left(\frac{1}{1-\Theta}\right)^{2k}\right] \exp\left(-2\frac{y_0}{\Theta}\right). \quad (23)$$

Kada logaritmi slučajne promjenjive X slijede dvo-parametarsku gama razdiobu, varijabla X slijedi **log-gama** razdiobu čija je funkcija vjerojatnosti može napisati kao (19) uz izostavljanje člana y_0.

LP3 distribuciju možemo prilagoditi empiričkim podacima tako da za prirodne logaritme zabilježenih protoka odredimo estimirane vrijednosti aritmetičke

sredine $\bar{x}$, varijance s_x^2 i koeficijenta asimetričnosti Cs_x dane sa (1), (2) i (3), a nakon toga pomoću izraza (18), (19) i (20) odredimo parametre P3 distribucije od ln (x). Log-gama distribuciju prilagođavamo empiričkim podacima na analogan način uz korištenje izraza (19) i (20) za određivanje parametara gama distribucije od ln(x).

Gumbel_Max razdioba (ili „Maksimum Extreme Value Type 1“ razdioba) je nesimetrična dvoparametarska razdioba čija je funkcija vjerojatnosti definirana sa

$$f(x) = \frac{1}{\beta}\exp(-\frac{x-\mu}{\beta})\exp(-\exp(-\frac{x-\mu}{\beta})) \qquad (24)$$

gdje je β parameter mjerila (β> 0), a μ parametar mjesta (pomaka). Ovu razdiobu karakterizira:

Očekivanje	μ+0.5772β
varijanca	$\frac{\pi^2}{6}\beta^2$
koeficijent asimetrije	≈1,14

Parametri razdiobe mogu se estimirati koristeći slijedeće izraze [8]:

$$\hat{\beta} = \frac{s\sqrt{6}}{\pi}, \qquad (25)$$

$$\hat{\mu} = \bar{x} - 0{,}5772\hat{\beta} = \bar{x} - 0{,}45006s, \qquad (26)$$

gdje su $\bar{x}$ i s aritmetička sredina (1) i standardna devijacija uzorka (2).

Weibull razdioba je kontinuirana distribucija definairana na području varijable x (0, +∞) čija je funkcija vjerojatnosti definirana sa

$$f(x) = \frac{\alpha}{\beta}\left(\frac{x}{\beta}\right)^{\alpha-1}\exp\left(-\left(\frac{x}{\beta}\right)^{\alpha}\right), \qquad (27)$$

gdje je α parametar oblika (α> 0), a β parametar mjerila (β > 0). Moguće je uvesti i treći parametar, parametar pomaka γ ako umjest x uvrstimo (x- γ) pa tada dobivamo troparametarsku weibull razdiobu.

Estimiranje parametara Weibull razdiobe zahtjeva provedbu iterativnog proračuna na računalu. Mi smo koristilo komercijalne programske pakete za proračun parametara α i β , a potom računali teorijske vrijednosti raspodjele prema (27) i dobrotu prilagodbe .

C. Testiranje dobrote prilagodbe funkcije raspodjele

Analizu dobrote prilagođavanja teorijskih raspodjela empiričkim podacima proveli smo uobičajenim HI – kvadrat (χ^2) testom. Obzirom da smo imali uzorak većeg opsega ovaj test je ocijenjen kao najpodesniji [8[,[13].

Za uzorak od N elemenata (x_1, ..., x_N) koji se grupiraju u k razreda neka f_{ei} označava broj elemenata i-tog razreda. Izraz

$$\chi_0^2 = \sum_{i=1}^{k}\frac{(f_{ei} - f_{ti})^2}{f_{ti}} \qquad (28)$$

predstavlja mjeru odstupanja empirijskih frekvencija f_{ei} od teorijskih f_{ti}.

Hipotezu da empirički podaci slijede neku teorijsku raspodjelu prihvaćali smo uz prag značajnosti od 0,05. Pri tome smo vodili računa o broju parametara koji definiraju neku teorijsku razdiobu. Prema rezultatima testa, odnosno stupnju prilagodbe, rangirali smo testirane razdiobe.

III. NUMERIČKI PRIMJER

Empiričkim podacima prirodnih dotoka u rijeku Krku pokušali smo prilagoditi različite teoretske distribucije opisane u prethodnom poglavlju i tražili razdiobu koja se najbolje prilagođava. Na raspolaganju smo imali niz srednjih mjesečnih dotoka zabilježenih na jednom mjernom mjestu u periodu od 59 godina (1950 – 2013 s prekidom 1991-1995). Također smo imali kontinuirani i niz srednjih dnevnih dotoka mjerene na istom mjernom mjestu u neprekidnom nizu u posljednjih 17 godina (1997-2013). Mjereni dotoci su „sirovi“ podaci, odnosno nikakve uzvodne aktivnosti nemaju utjecaja na mjerene dotoke. Svi dotoci su mjereni na jednak način, kako bi se smanjila mogućnost greške.

Zabilježene vrijednosti srednjih dnevnih dotoka grupirani su u manje vremenske jedinice, mjesece i tjedne. Zabilježene vrijednosti srednjih mjesečnih dotoka mogli smo grupirati samo po mjesecima. Prema (1) – (3) izračunate su nepristrane procjene očekivanja, standardne devijacije (i varijance) te koeficijenta asimetrije za pojedine vremenske intervale. Osnovne statističke parametre računali smo za svih 12 mjeseci i desetak tjedana.

Distribucija srednjih mjesečnih dotoka je asimetrična. Na uzorku od posljednjih 17 godina koeficijenti asimetričnosti za pojedine mjesece variraju između 0,5 i 2, prosječno 1,42. Na većem uzorku od 59 godina prosječni koeficijent asimetrije je 1,56. Niz srednjih tjednih dotoka, u analiziranim tjednima na uzorku od posljednjih 17 godina, karakterizira nešto veća asimetričnost, oko 1,8. Distribucije srednjih dnevnih dotoka, bez obzira da li su grupirani po tjednima mjesecima ili godinama, su izrazito asimetrične. U našem primjeru vrijednosti koeficijenata asimetrije su uvijek veće od 1, prosječno oko 3.

Empirički podaci srednjih mjesečnih dotoka na uzorku od 59 godina mogu se, različito po mjesecima, opisati sa nekoliko testiranih razdioba. Za mjesece sa koeficijentom asimetrije oko prosječnog ili većim od prosječnog 1,56 bolje se daju prilagoditi logaritamske razdiobe (LN, LP3, log-gama), dok su u mjesecima sa

koeficijentom asimetrije manjim od prosječnog dobrima pokazuju i neke druge razdiobe (Weibull, Pearson 3, …). U pravilu je LN razdioba u svim mjesecima bila dobra. Nešto malo lošija se u našem primjeru pokazala LP3 razdioba. Obzirom da χ^2 test ovisi o broju razreda u koje su podaci grupirani, varirali smo širinu razreda. Promjena širine razreda ponekad bi promijenila rank distribucija, ali LN i LP3 su se u pravilu prilagođavale empirijski podacima dovoljno dobro za prihvaćanje hipoteze da podaci slijede danu distribuciju.

U tablici I dati su izračunati parametri razdioba koje smo prilagođavali empiričkim podacima za mjesec ožujak. Prema izračunatim parametrima izračunate su teorijske frekvencije pojedinih razdiba, prikazane tablicom II. Na slici 1 histogramom su prikazani empirički podaci za mjesec ožujak, a krivuljama različite teorijske distribucije sa parametrima dobivenim u postupku prilagođavanja.

TABLICA I. PARAMETRI RAZDIBA ZA MJESEC OŽUJAK

RAZDIOBE	**PARAMETRI**
Normalna	μ=31,334, σ=16,661
Log-normalna	μ_y=3,404, σ_y=0,469
Gama	k=4, Θ=8,400
log-gama	k=47, Θ=0,0723
Pearson 3	k=2, Θ=11,792, x_0=7,792
LP3	k=1031, Θ=-0,015925, y_0=19,733
Gumbel Max	μ=12,991, β=23,8
Weibull	α =2,092, β=36,404

Slika 1. Histogram srednjih mjesečnih dotoka za mjesec ožujak i prilagodba različitih teorijskih funkcija distribucije

Izmjereni dotoci u mjesecu ožujku imaju $\overline{X}$ =31,33, s_x=16,66 i Cs_x=1,42. Slične dijagrame dobili smo i za ostale mjesece, a mjesec ožujak smo prikazali obzirom da je procijenjeni koeficijent asimetrije Cs_x najbliži prosječnom. Dobrotu prilagođavanja pojedinih teorijskih razdioba empiričkim podacima u mjesecu ožujku sažeto smo prikazali u tablici III. Vrijednost χ^2 za pojedine razdiobe je računata prema (28) grupirane u k razreda uz stupanj slobode s. U zadnjem stupacu data je vjerojatnost testa. Vidimo da se sve razdiobe, s izuzetkom Pearson 3, dobro prilagođavaju empiričkim podacima u ovom primjeru. Također se vidi da se LN i LG izuzetno dobro prilagođavaju empiričkim podacima.

Teorijskim funkcijama distribucije pokušali smo opisati i izmjerene srednje tjedne dotoke međutim uzorak od 19 godina, odnosno skup od 19 srednjih tjednih dotoka, je prekratak period za relevantnu analizu. Izabrana širina razreda ima značajan utjecaj na oblik distribucije i rezultat χ^2 testa. Ipak, za analizirane tjedne ponovno su se LN i LP3 razdiobe dobro prilagođavale empiričkim podacima u većem broju slučajeva, što ne čudi obzirom na slične koeficijente asimetrije srednjih tjednih i srednjih mjesečnih dotoka.

Također smo, radi usporedbe, analizirali empiričke podatke srednjih dnevnih dotoka (u nekom tjednu i mjesecu). Obzirom da su distribucije srednjih dnevnih dotoka izrazito asimetrične, uvijek su se mjereni podaci bolje prilagođavali logaritamskim razdiobama (LN, LP3, log-gama) nego ostalima koje smo razmatrali. Neke od razmatranih razdioba samo u nekim vremenskim intervalima bi uspješno opisale empiričke podatke (gama, Pearson 3, Weibull, Gumbel max), dok se normalna razdioba nije dala prilagoditi empiričkim podacima u niti jednom slučaju. Dakle, ponovno su LN i LP3 bile dominantne. Slično kao na slici 1, na slici 2 su histogramom prikazani empirički podaci za 1. tjedan u godini, a krivuljama različite teoretske distribucije sa parametrima dobivenim u postupku prilagođavanja. Izmjereni dotoci u 1. tjednu imaju $\overline{X}$ =38,41, s_x=37,22 i Cs_x =1,91. Dobrotu prilagođavanja pojedinih teorijskih razdioba empiričkim podacima sažeto smo prikazali u tablici IV. Sada je samo LN razdioba prešla prag od 0,05.

TABLICA III. DOBROTA PRILAGOĐAVANJA TEORIJSKIH RASPODJELA EMPIRIČKIM PODACIMA ZA MJESEC OŽUJAK

	N	LN	G	LG	P3	LP3	gMax	Wbull

Slika 2. Histogram srednjih dnevnih dotoka u 1. tjednu i prilagodba različitih teorijskih funkcija distribucije

IV. ZAKLJUČAK

Pronalaženje odgovarajuće teorijske funkcije vjerojatnosti koja dobro opisuje neki stohastički događaj je od izuzetne važnosti pri modeliranju tih podataka za različite potrebe. U radu smo analizirati višegodišnje rezultate mjerenja dotoka na jednom mjernom mjestu i tražili prikladnu teorijsku funkcija vjerojatnosti za opis izmjerene učestalosti pojavljivanja tih dotoka u jediničnim vremenskim intervalima. Cilj rada je naći tip distribucije koja se dobro prilagođava mjerenim podacima u velikom broju slučajeva. Distribucija mora biti prikladna za korištenje, sa parametrima koji se estimiraju jednostavnim analitičkim postupkom.

Vrijednosti koeficijenta asimetrije izmjerenih podataka definiraju tip distribucije prikladne za opis izmjerenih vrijednosti. Distribuciju srednjih mjesečnih dotoka i srednjih tjednih dotoka karakterizira srednja ili velika asimetričnost (koeficijent asimetrije između 0,5 i 2) dok je kod distribucije srednjih dnevnih dotoka asimetričnost izrazito velika (prosječni koeficijent asimetrije oko 3). Što je osnovni vremenski period kraći koeficijent asimetrije je veći.

Srednji mjesečni i srednji tjedni dotoci, u većini analiziranih slučajeva su se dobro prilagođavali log-normalnoj i log-Pearson 3 razdiobi. Promjena širine razreda ponekad bi promijenila rank distribucija određen χ^2 testom, ali LN i LP3 su se u pravilu prilagođavale empirijski podacima dovoljno dobro za prihvaćanje hipoteze da podaci slijede danu distribuciju.

Cloud dilemma

A.B. Robert Petrunić, bacc.ing.comp. Algebra university college for applied computer engineering, robert@petrunic.com C. Vjeran Bušelić, Senior Lecturer, MApMa, Polytechnic of Zagreb, vbuselic@tvz.hr

Cloud is changing the way IT thinks and works, it's changing the way administrators do their job, the way businesses offer their services, how consultants create new offerings and solutions, and how management divide capital and operational expenses.

Most of the administrators are reluctant to use cloud services because of the fear that the Cloud will make them obsolete. The rest of them, including the management have a dilemma whether to use it or not, and most important whether they are allowed to do it, based on local and global laws and regulatory compliances.

This paper will deal with dilemmas administrators, consultants and management may encounter during the transition to the cloud solution, from the technical, through business, to the regulatory and legal perspective. It will give an overview on Croatian laws and rules created by Croatian regulatory bodies, which will help to solve this dilemma and make the transition to the cloud solution easier and smoother for most of the businesses that are having abovementioned dilemma.

I. INTRODUCTION

Cloud is the way of service delivery that makes the service more accessible and chipper to the end user, and it changes the usage of computing resources by using the innovation known as utility computing [1]. Utility computing is an approach that packages computing, storage and network resources as a new metered service ready to be delivered to the end user.

During the last decade, more and more companies are trying to cut IT (information technology) expenses by changing the business model from CAPEX (capital expenses) to OPEX (operational expenses). By "leasing" the computing resources they are able to achieve desired state. Cloud is offering the same thing with better TCO (total cost of ownership) and ROI (return on investment) by offering "pay-per use" or "pay as you go" services, where one has to pay only for used resources, with "easy to grow" options that allows a company to cover greater demand on resources when needed with minimal impact on services and finances. There is also an additional benefit, because cloud is offering shorter "time to market", especially for startups and small to medium companies, with easy to configure services. This is only one part of potential cloud users, because the other companies, the ones that do not care about the price of the service, can, and will use the cloud as long as the service is offering a benefit (financial or any other).

One of the characteristics of the cloud is the easy way to increase the resources needed for the running services and to decrease the resources when the demand has lowered. Together with already mentioned "pay-as-you-go" system it changes the IT perception on computing, storage and network resources, and it's opening the door to replace classical oversized datacenter (CAPEX) into a fixed and manageable system (OPEX).

An example of capacity to demand ratio in classical (static) datacenter and cloud based datacenter is shown on figure 1 and figure 2.[1]

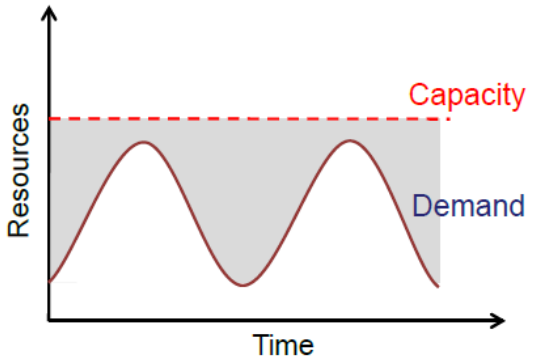

Figure 1: Capacity and demand ratio in cloud based (dynamic) data center

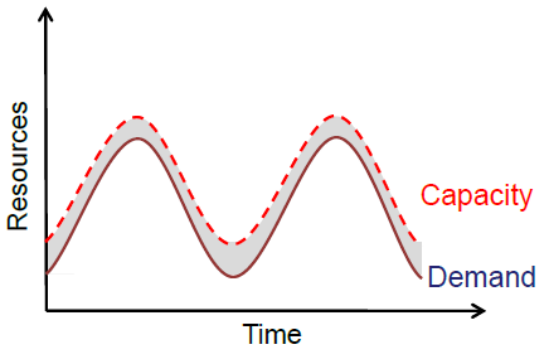

Figure 2: Capacity and demand ratio in cloud based (dynamic) data center

[1] Franković, Vračić: Algebra University College for applied computer engineering, 2014. Retrieved 9th of February 2014.

From the IT management perspective, cloud is categorized as: public, private, hybrid and community cloud.

Public cloud is accessible to anyone, and this is the service offered by a provider to a general public.

Private cloud is, as the word suggests, a cloud created and used by a "private" entity.

Hybrid cloud is a type of cloud used by medium sized companies and it allows for merger of private cloud with public one. This merger can be triggered on a whole or only for parts of the private cloud and it can be dynamic.

Community cloud is a special cloud type made by group of companies offering their services for closed group of consumers.

Because cloud offerings have different "flavors" there is another classification used to subdivide and describe the services offered by a cloud provider, and those are: SaaS (software as a service), PaaS (platform as a service) and IaaS (infrastructure as a service).

SaaS is the type of service where the end user is offered fully functional service that can be used with no or minimal configuration from the user side.

PaaS is the type of service where the end user is offered everything except the application. The service provider is offering fully functional OS (operating system) and additional services needed by most of the applications like database, and those parts will be patched and guaranteed to be functional by service provider. The user has to install, configure and patch its own application by using the provided platform services.

IaaS is the type of service where the end user is offered computing, storage and network resources, and service provider guarantees that those resources will be available, while OS, platform modules and applications are user responsibility. User will have to patch all the components used.

More formal definition for cloud types and services is given by NIST [2]

II. CLOUD BENEFITS

Some of the cloud benefits are:
Geopolitical independence, redundant locations, standardization, risk management, manageability and measurability, high availability and scalability, "pay-as-you-go" model, less or ne CAPEX, faster deployment time, shared resources, increased mobility, easy to manage and higher productivity.

Geopolitical independence is cloud characteristic that can play a crucial role in a decision process whether to use cloud or not. Since cloud providers are usually geopolitically independent, they can offer their services even do countries using those services are politically unstable and on the brink of war, or in a situation where natural disaster or some other type of devastation is inevitable or imminent. Being geopolitically independent makes the cloud providers the best solution for startups and medium to large companies, because they can offer some kind of security and continuity.

Redundant locations is at the same time an addition and the part of already explained geopolitical independence. By having redundant locations, cloud providers can offer continuity in any case of political or natural disaster.

High availability is the feature used in abovementioned benefits that offers availability of the system when some parts of this system are malfunctioned or nonfunctional for any other reason.

Scalability on the other hand is a feature that allows the cloud provider and cloud user to grow their resources as needed horizontally (by adding more instances of the application, service or OS) and vertically (by adding more resources - CPU and memory to an existing systems).

Standardization helps cloud provider to lower their expenses because standardization will make a system more reliable, easier to manage and by doing that the system will give better ROI.

Risk management is the next step in lowering the cost of the system and creating it more secure and robust. During the risk management process most of the threats to the service will be treated and corrective measures will be taken. This process will in the long run save money, make system more resilient and customer more satisfied.

Manageability and measurability are the most important parts of the cloud provider services, because this is the only way to make the services useful and chargeable. By having manageable system, cloud provider can manage the system and offer the service to the customer, and by having this service measurable service provider can measure and charge used resources, thus offering cloud services.

From the economic perspective, "pay-as-you-go" and less or no CAPEX are attractive to almost any manager searching to cut expenses and save the money.

From the administrator and IW (information worker) point of view, faster deployment is offering more time and less work to be done, shared resources are allowing for cheaper testing and working environments, and increased mobility makes IW more productive and agile.

III. CLOUD CHALLENGES

There are some factors one has to take in the account when discussing the cloud, and those factors are related to possible problems, disadvantages and challenges of the cloud based products and solutions. Some of those factors are: regulatory compliance, local and global laws, data location, data separation, loss of manageability, forensics and/or incomplete data deletion, vendor lock-in, lack of education, client part of the communication channel, public and private sector dependency, new technologies and business models and more and more complex attacks.[3] [4]

Data location maters in various situations. For instance, most of the countries have laws preventing sensitive data from being stored on a computer systems located outside the country boundaries. Some countries

have policy to spy on the data (US for instance) and by using US based cloud provider with datacenter located in US, data itself will be treated by US laws, not by the laws of the country the user is from. [5]

Data separation is one other sensitive data related problem because it may happen that company A is sharing the resources with company B, and if data separation (multi-tenancy) is not configured and enforced correctly company A might be able to see the data belonging to company B and vice versa.

Manageability loss depends on the cloud service type used (SaaS, PaaS, IaaS), and it's emphasized in the SaaS and PaaS type of service. IaaS type of service is as manageable as any other OS in the internal network if the machine is accessible over the network.

Forensics and/or incomplete data deletion is one of the security question one will have to ask when an incident occurs, and one have to analyze it. The problem with forensic investigation in the cloud environment is that data is scattered across various storage devices, possible across datacenters too. This will most certainly make the forensic investigation difficult if not impossible. The other part of the problem is incomplete data deletion that might have an impact on data privacy and isolation. If the data is not entirely deleted on the source drive, somebody might recover it and gain access to sensitive data. This can also be done if data separation is not correctly implemented.

Vendor lock-in is something one have to deal with in the cloud transition planning phase. The thing is that if one choose a particular cloud provider, and this provider is using particular technology that no other provider is offering, one will have a problem changing providers, thus ending up in a vendor lock-in or being tied to a single vendor. This is again highly dependent on type of service used and it's less problematic with IaaS then with SaaS and PaaS, because IaaS VMs can be easily converted between vendors (VMware to Microsoft and vice versa for instance).[2]

Lack of education is one of the possible problems that's not so obvious at the first glimpse. In order to accept and properly use the cloud services one have to be familiar with the technology and capable of supporting and using it.

Client part of communication channel is not directly related to the cloud provider, but since it's used to access cloud provider services it has to be properly secured. Most of the security breaches are done on the client part of the communication channel, thus in order to have secure and reliable cloud service, client has to be secured and properly used.

Public and private sector dependency is security and accessibility related. Regarding the security, both sectors want to have all three CIA (confidentiality, integrity/authenticity and availability) triangle requirements met. When the accessibility is in question, what will happen should the Internet in Croatia is down for an hour? A day? A week? A month? With cloud in perspective, everything is dependent on Internet connection, so the infrastructure has to be reliable and accessible in order to be able to use the cloud services

Regulatory compliance, local and global laws are one of the biggest issue for most of the government and government related companies and banks. In Croatia, HNB (Hrvatska Narodna Banka – Croatian National Bank) define rules and guidelines that all the banks have to obey.

IV. REGULATORY COMPLIANCE AND LAWS IN CROATIA

If we look at the regulatory compliance and the banks in Croatia, there are some rules defining how the banks can store the data, and where this data can be stored. The regulatory body (HNB) has defined exact rules that has to be followed in two documents: Guidelines for IS management in order to lower the operational risk [6] and Guidelines for adequately managing outsourcing related risks. [7]

The most important part related to cloud services is defined in those two documents with the following rules (translation – just the parts needed for this theses):

… Provider can be resident or nonresident.... direct supervision by HNB should never be (by any means) obstructed or denied … thus, the bank should determine whether the provider local laws are compatible with this guideline … [3]

By reading this clipping, one can understand one of the biggest problem related to cloud computing, and this is the territory, or to be more precise no territorial boundaries in the cloud can lead to problem with the laws of the country where the data is at the particular point in time. For instance if Croatian bank is using the cloud provider with datacenter in US, data will be treated by local US laws, and HNB will not be able to access the data in an unobstructed way. The other problem is that cloud providers are utilizing their own cloud power, so they have datacenters on different continents and the data is being moved from one datacenter to another (in some cases) without user knowledge. So, one day data can be in US, the other in Europe and after that in Asia, and the laws applicable to data being in the cloud are changing without user knowledge. Of course, some cloud providers gives you the ability to choose where the data will be stored, but by reading the "small letters" one can see that they have the right to move the data wherever they want to in order to preserve the ongoing operation of the cloud and possible backup scenarios. From this perspective it is difficult for the bank to find the right public cloud provider, thus leaving them with the option to use private cloud instead.

Regarding the applicable laws in Croatia there are: law on private data protection [8], information security law [9], data secrecy law [10] and law on electronic signature [11].

[2] Starwind software. Retrieved 9th of February 2014. http://www.starwindsoftware.com/converter

[3] Croatian National Bank (October, 2005.) "Guidelines for adequately managing outsourcing related risks". Retrieved 9th of February 2014. http://www.hnb.hr/supervizija/eksternalizacija/h-smjernice-za-adekvatno%20upravljanje-rizikom-eksternalizacije.pdf

Private data protection law has similar parts as abovementioned HNB guidelines regarding personal data collections: (translation – just the parts needed for this theses):

Article 13: Private data collections can be taken out of Croatian territory only if the country hosting the data has appropriate regulations regarding private data protection…[4]

Office of the National Security Council is the roof body responsible to support the abovementioned laws, by creating regulations regarding data secrecy, manipulation etc. In the document called "Regulation on information security measures" [12] there is article 6:1 discussing that classified data can be exchanged only with countries and international organizations if they have signed the document on mutual protection of classified data with Republic of Croatia. There are also rules regarding the physical requirements that have to be met in case the document is classified as Top secret, secret or confidential.

One more regulatory body in Croatia that have his own rules regarding data that leaves the country boundaries is Ministry of Finance. They have rules regarding gambling and technical requirements that has to be met. The Minister of Finance shall prescribe standards on the technical requirements of betting through interactive sales channels online gaming [13], and the registration and identification of players, the terms of software (software) and equipment, certification systems and games, handling transactions of receipts and payments, security principles, conditions of supervision, responsible for preparing the principle, and more. The organizer who wants to organize games betting has to coordinate system for the preparation of the technical standards set by the Minister of Finance. Given the above, we conclude that a taxpayer who has no registered office, permanent establishment, domicile or habitual residence in the country is not obliged to register for PDV purposes in the Republic of Croatia, was to perform a host or computing cloud computing taxpayer undertaking abroad. Also note that the issue of invoices and payment of PDV that the taxpayer is obliged to apply the rules of the Member State of residence or permanent establishment from which the service is performed

V. CLOUD SECURITY

Security in a cloud is on a higher level than in the normal small to medium sized business environment, because higher standards are being met in the process of creating and managing the cloud environment. In spite of that it has some security issues. Top 9 threats to the cloud environment are as follows: [14] data breaches, data loss, account hijacking, insecure APIs, DoS (denial of service), malicious insiders, abuse of cloud services, insufficient due diligence and shared technology issues. Those security concerns are not exclusively cloud based – they are all applicable to normal computing environment, but in the cloud each and every of those implications could be multiplied and much more intense in nature.

Data breaches are taken to a higher level in the cloud environment. If a person breaks into an application running on the shared database system she could have an access to other tenant's data. The other problem lies in the virtualized nature of cloud, and one compromised VM (virtual machine) could lead to all machines on the same hypervisor being compromised should hypervisor have unknown or unpatched vulnerability.

Data loss is administrators nightmare, because by losing data, customer is denied the sole purpose of the IS (information system) and the business will have to deal with the consequences. Data loss can be on the cloud provider side (hardware or software failure, and no backup in place), it can be malicious in nature (hackers, competitors, dissatisfied employees), and customer based (if customer loses encryption keys – cloud provider backup is unusable, the other incident could be accidental data deletion).

Account (or service) hijacking is being more and more implemented in targeted phishing attacks, and it can be triggered by various fraud schemes and software vulnerabilities exploitations. By having account or service hijacked an attacker can use it for its own purposes and to their own willing. Hijacked services become part of the botnets, being run and managed by the attacker allowing her to use the computing, storage and network resources to her own will. This can have implications in various levels regarding law and regulatory compliance, just to mention some of them.

Insecure APIs can lead to service degradation or hijacking, because APIs are used for provisioning, monitoring and management. By having an access to APIs, an attacker can have access to client data and services, and in some cases to all other tenants on the cloud system.

DoS can also have multiple implications in cloud environment. DoS can be used to deny an access to the targeted system or to use a system to attack other systems. Usually botnets are used to create DDoS (distributed denial of service) attack against a target, and in some cases even the largest providers are unable to stop, mitigate or deflect such an attack.

Malicious insiders definition by CERT: (computer emergency response team) is as follows: [5] *"Malicious insider threat to an organization is a current or former employee, contractor, or other business partner who has or had authorized access to an organization's network, system, or data and intentionally exceeded or misused that access in a manner that negatively affected the confidentiality, integrity, or availability of the organization's information or information systems."* Insiders or privileged users have access to secure systems and are capable of creating more damage than outsiders by having the privileges and physical access.

Abuse of cloud services is again interesting field for most of the attackers because it can give them financial or

[1] [4] Croatian parliament (12th of Jun 2003) "Private data protection law". Retrieved 9th of February 2014. http://narodne-novine.nn.hr/clanci/sluzbeni/305952.html

[5] CERT. Retrieved 09th of February 2014. http://www.cert.org/insider-threat/index.cfm

other gains. For instance, cracking the encryption keys can be much easier by having virtually unlimited resources in the cloud, and this is just one of the possible implications. Calculating bit coins is another example, because it will give an abuser direct financial gain.

Insufficient due diligence is entirely on the cloud provider domain, because users of the service cannot directly influence the cloud providers irresponsibility. Since the cloud services are growing each and every day, more and more irresponsible providers are emerging.

Shared technology issues are in the very nature of the cloud. Cloud services are based on virtualization technologies that share CPU, memory and network resources between virtual machines. Those virtual machines can belong to different customers (tenants) and should anyone be able to access the shared resources from another tenant he will be able to access sensitive information and possibly the part of, or the entire cloud environment.

VI. CONCLUSION

By looking at all the benefits, challenges and security related issues the cloud based services have to offer, deal with and are vulnerable to, one has to ask a question whether to use it or not. The answer depends on the company risk management procedures, knowledge about the cloud services and security awareness. It is obvious that some companies will benefit from using public cloud, and yet some will find hybrid or private cloud to be more flexible and appropriate solution.

Abstract – In order to mitigate overheated interior of a vehicle parked in the hot summer sun and thereby to make the entering into the vehicle more comfortable, microcontroller managed module for automatic ventilation of vehicle interior is made. The module is implemented using a microcontroller as a central logical unit and a series of sensors which provide sufficient data to ensure functional, but also efficient, reliable and safe ventilation. The ventilation process is performed by opening vehicle windows slightly, which enables air to circulate. Microcontroller controls the position of the windows autonomously and independently of the driver's presence, following predefined algorithm that uses sensors data obtained from the vehicle's surroundings. Besides temperature, the most important factors to ensure quality implementation of ventilation are detected movements around the vehicle, the presence of precipitation and other. This paper shows the components, their purpose and capabilities, advantages and disadvantages, as well as potential implementations and upgrades. The test results give insight into utilization options of this module and its usefulness.

Key words – automatic ventilation of vehicle interior, microcontroller, sensors, temperature, controlling position of vehicle windows.

I. INTRODUCTION

Closed area without air circulation and directly exposed to sunlight heats up much faster and reaches significantly higher temperatures than the open space where air circulates freely – so-called "greenhouse effect". That is exactly what happens in a vehicle parked in the hot summer sun, which later represents a problem when entering such overheated vehicle.

The basic idea of this project is to prevent or at least mitigate overheating of the vehicle interior in order to facilitate entering into the vehicle.

The problem can be solved by leaving the vehicle windows partially opened so air can circulate, which reduces the heating of the vehicle interior. However, as the ventilation process takes place in a parked vehicle, without human presence, and the vehicle is exposed to external influences, such as precipitation or potential burglary, it is unreliable and unsafe. Consequently, it is necessary to automate the ventilation process.

According to [12], the complete automatic ventilation process is managed by microcontroller default algorithm, considering input signals read using various sensors. The temperature sensor measures the temperature inside the vehicle. If it exceeds predefined level of "comfortable temperature", microcontroller automatically lowers the power windows to enable air circulation which alleviates aforementioned "greenhouse effect".

The automatic ventilation process must be reliable and not affect the safety of the vehicle. For this reason, additional sensors are used, whose task is to annul dangers appeared with this ventilation method. Before all, these are precipitation sensor that makes the ventilation process reliable, and motion sensors that make it safe. There are also other sensors whose implementation gives additional quality, but these are the most important of them. Together with temperature sensor, they meet the minimum requirements to perform automatic function of ventilation, without endangering the vehicle.

Following chapters show components and technologies used, operation modes, advantages and disadvantages, capabilities and potential upgrades of the module, as well as ability of integration with existing automatic systems within the vehicle. Results of testing the module in real conditions are presented and analyzed.

II. COMPONENTS AND MODULE ARCHITECTURE

According to [12], the module's task is to control the ventilation process autonomously in order to facilitate vehicle utilization, i.e. providing conditions to make the entering into the vehicle parked in the sun more comfortable. In order to meet all the criteria of quality ventilation, the module has to collect enough data from the vehicle's immediate environment and, based on that data, it has to decide whether it is necessary to lower the windows and thus start the ventilation process. Accordingly, the module can be divided to three logical units: peripheral unit - collects data, control unit - manages module operations, and switching unit – adjusts signals. Figure 1 shows logic diagram of module.

The switching unit exclusively receives commands, which makes it the output unit. The control unit, or microcontroller, receives, processes and sends signals which makes it the central logical unit, while peripheral

Polytechnic of Zagreb, Zagreb, Croatia
University of Applied Sciences Velika Gorica, V. Gorica, Croatia

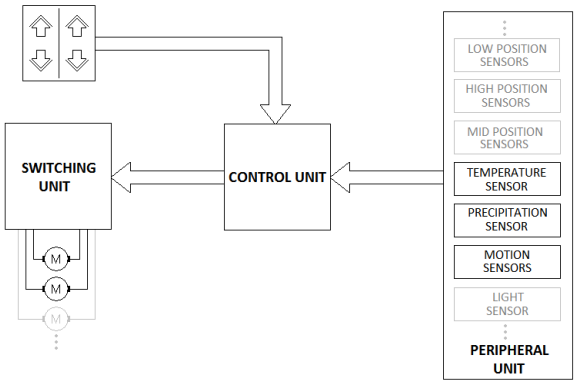

Figure 1. Logic diagram

unit exclusively collects data and sends it to control unit, which makes it the input unit.

A. Peripheral unit

Since the peripheral unit is also the input unit, it is presented first, for better insight into module operations and modes.

By having to collect many different types of data, the peripheral unit is complex enough as it is. The necessity of placing different sensors in separate locations, in order to achieve data collection, makes it even more complex.

- The temperature sensor is the most important sensor of this module because measuring of the vehicle interior temperature enables this method of automatic ventilation. The sensor is located inside the vehicle, protected from direct sunlight in order to measure the actual temperature of the vehicle interior, not the ostensible temperature (which is slightly higher due to the direct expose to the sun rays). The sensor consists of temperature sensitive resistor - NTC (Negative Temperature Coefficient) as a main part of sensor's electronic circuit with other necessary electronic components. In accordance with temperature change, sensor gives different output value. The control unit processes it and thus receives information about the actual temperature inside the vehicle.
- Precipitation sensor [9] is very important because it makes the automatic ventilation reliable. If precipitation occurs during the ventilation process, sensor detects the new circumstances and sends a signal to the control unit which orders to close the windows immediately. The sensor is situated on the windshield inside the vehicle, above the rear-view mirror in order to detect the falling drops of water on the glass. LED (Light Emitting Diode) or IR (Infra-Red) diode is used as a transmitter that emits light at a certain angle onto the windshield. The light of the expected intensity reflects to the photodiode which is used as a receiver. If droplets appear onto the windshield, the light reflects differently which causes a change in the receiving electronic circuit connected to the microcontroller. That is recognized as the presence of precipitation and windows close. Figure 2 shows precipitation sensor.
- Motion sensors are very important for the vehicle's safety while the ventilation process takes place. If there are movements detected within the vehicle's surroundings, it is classified as a potential danger and the system closes the windows. Commercial motion sensors on the principle of infrared technology - "Velleman PIR416" [10] are used for purpose of this module. The infrared motion sensor works on a similar principle as the precipitation sensor; by detecting the infrared radiation reflected from a moving object within the sensor's range. Infrared sensors have the disadvantage of not receiving signal effectively through the glass, so they should be mounted outside the vehicle, which is aesthetically undesirable. For this reason, microwave motion sensor(s) can be used, such is [11], which will surely detect all motions within the vehicle's surroundings, from inside the vehicle.

The basic function of automatic ventilation inside the vehicle is achieved using temperature sensor. Ventilation inside the vehicle is achieved by method of slightly lowering windows for a few centimeters, which makes it functional, discreet enough, but relatively reliable and safe. By adding the precipitation and motion sensors, the ventilation process becomes reliable and safe, but it opens up the possibility of even better ventilation. That is, now when there is a control system and protection from external impact, the windows can be further lowered to increase air circulation, and more air circulation means more quality ventilation. These critical input units are the most important for stable ventilation process. Other input units which contribute to efficiency and vehicle safety are:

- The light sensor; used for economic reasons. Given that the interior can be heated more than the environment only when the vehicle is exposed to direct sunlight, which does not exist at night, whole ventilation process at night does not make sense, and it is automatically suspended until morning. It results in a more efficient and economical usage of the module. Sensor is placed inside the vehicle, protected from direct

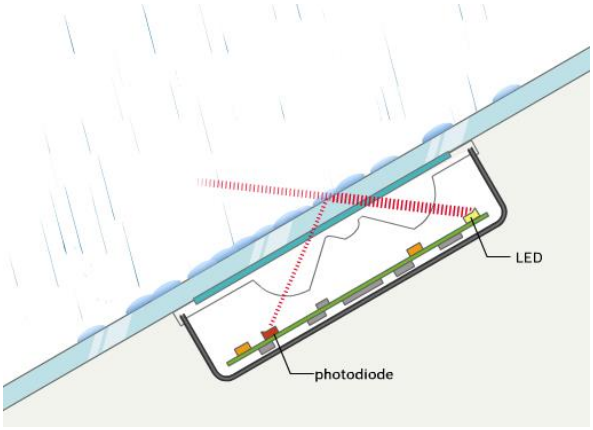

Figure 2. Precipitation sensor

sunlight in order to reduce sudden changes in light intensity readings caused by disruptive factors such as clouds. The sensor itself is actually a photo resistor that has a characteristic of resistance change depending on the intensity of light in the area where it is located. Photo resistor used here has an extremely fast response to changes in light intensity. Resistance changes are large even for the least change of the brightness. Therefore, it is necessary to use additional electronic components that slow down and reduce these rapid and large changes to obtain stable and reliable signal which can then be sent to the control unit for processing. [12]

- Position sensors; contribute to the quality work of module. These are the lower and upper end as well as mid position sensors. They are located in the vehicle doors, that is, the end positions of windows movement range. They signal an entirely opened or entirely closed position of the window. The mid position sensor signals when window reaches position where should be placed in the automatic ventilation mode. Position sensors provide a reliable windows setting in the desired position. This benefits to all aspects of the module quality; provides the reliability and security because the windows will always reach an end position whenever it is necessary, improves efficiency because windows will stop immediately when they reach a target position, preventing unnecessary overload of the electric motors and needles consumption of limited electrical energy, as well as potential danger of blowing electric motors or module is prevented and the vehicle is protected from potential conflagration. Moreover, a very important input information is obtained - direct feedback that informs the microcontroller on the execution of the given commands. All this greatly improves the quality of the ventilation process. Position sensor functionality is achieved using conventional buttons and switches. When reaching the mid or end position, the window carrier press the button/switch that closes the electronic circuit which confirms successfully executed operation to microcontroller. According to [12], various components and methods were considered for this purpose, such are photo and infra-red diodes or instead of using additional components this function is programmable via microcontroller in the form of time circuit. However, classic buttons and switches are the simplest, most reliable and most resistant components that are to be applied for this purpose.

B. Control unit

Control, or central logical unit, is the "brain" of the module. By default algorithm and collected input signals, module independently controls power windows in automatic mode - the automatic ventilation inside the vehicle. In manual mode, when a person is present in the vehicle, module just relays human commands onto the windows.

For this purpose is used AVR ATmega32 microcontroller. Since the microcontroller is available as one component, this is seemingly a very simple logical unit. However, it is a highly complex integrated circuit that contains thousands of electronic components inside [8]. All in all, this microcontroller is too powerful for this module. However, as it has an affordable price, and considering the additional module upgrades and extensions, it would be imprudent to limit its potential immediately at start by implementing a microcontroller with fewer features.

The control unit could be implemented even without microcontroller by using some other logic electronic components, however, the module would not be programmable, nor upgradeable or be adaptable to individual vehicles and customer requirements.

C. Switching unit

Switching unit is also used as the output unit and is responsible for the stable transmission of the output control signals from the microcontroller and to adjust them for window's electric motors. It consists of several components that are responsible for the conversion of weak control signals from the microcontroller to the strong electric signals that directly drive the electric motors. These are various transistor amplifiers and relays which, in addition to amplifying the weak control signals from the microcontroller, also galvanically isolate logic module's electronic circuit from a strong motor's electric circuit. There are various options of transfer and adjustment of control signals from the microcontroller to the electric motors. In this case, a driver L293NE is used. It turns logic signal from the microcontroller into much stronger electric signal that can directly power the electric motor. Considering that in real circumstances current reaches 1 A, it turns out that this driver component overheats and does not deliver enough power for electric motor to move windows quality enough. Therefore, besides the aforementioned galvanic circuit separation, relays are used to prevent overheating of the driver component, achieving a sufficient power for quality work of electric motors and prevent the flow of large currents within the module, which is not advisable because of the strong magnetic fields that are generated by large currents and their negative effects on sensitive electronic components.

D. Other units

Peripheral unit, control unit and switching unit compose a logical unit that is oriented to the specific module's role - automatic ventilation inside the vehicle. In addition to them, the module includes other components that perform a particular role; voltage converter and stabilizer, integrated connector and a set of components that allow the microcontroller to be programmed directly within the module.

III. ALGORITHM AND MICROCONTROLLER PROGRAMMING

It is mentioned that a microcontroller decides what to do and operates independently. The microcontroller basically just follows the algorithm behavior, predefined program of what to do in a certain situation. Simplified flowchart shows the microcontroller's algorithm of behavior (Figure 3).

Method of operation can easily be noticed by the flowchart. At the beginning, initialization of microcontroller and auxiliary variables is performed. After completion of the initialization, program starts checking parameters and thus sets the state of the output. First, it determines whether the vehicle is parked or in use. This is determined by checking whether the key is in the ignition lock, which is not a one hundred percent confirmation, but it is considered satisfactory. Depending on the result, manual or automatic mode is switched on. In manual mode, while a person uses the vehicle, microcontroller only transmits input state to output and thereby has only a minor role in the protection of electric motors from overload. When the automatic mode is on, other preconditions are checked in order of priority; whether it is night, is there precipitation and are there suspicious objects near the vehicle. If the answer to any of these queries is confirmative, it means the ventilation process is not necessary or it could endanger the vehicle and will not even start until the appropriate conditions. If all conditions are satisfied, only then microcontroller checks if the vehicle interior is overheated and, if it is, opens the windows for ventilation. If, at any time during the ventilation process, disturbing factors appear, the windows close, thus suspending the ventilation process until the required conditions are met again. Left and right window can be opened and closed separately in automatic mode. This also provides the efficiency. For example, if in the middle of the ventilation suspicious movements are detected on the right side of the vehicle, only the right window will close which still allows partial ventilation through left window only, which is better than none.

IV. FINAL IMPLEMENTATION

The module is designed and developed for the installation into a one older car without automatic air conditioner and with already existing basic electric mechanism for lowering and raising the windows. The

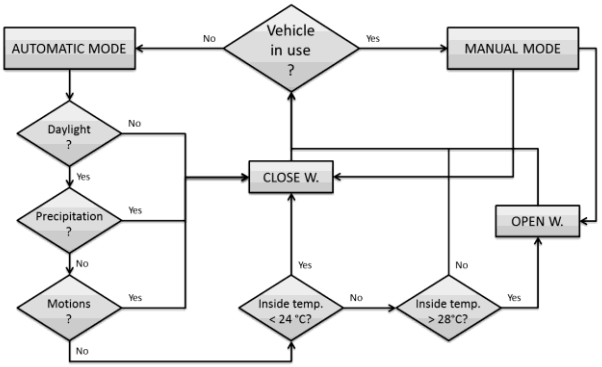

Figure 3. Flowchart diagram

car has two power windows which can be managed. That is why this module prototype manages only two sets of input and output signals for connecting two independent windows. Figure 4 shows the electric scheme of a module prototype. Control unit, switching unit, other units and some of the peripheral units (temperature and light sensors) can be perceived. Since the rest of the sensors cannot be integrated into the module's main electronic circuit, connectors for their signals are located inside the module. However, what is not mentioned so far are a lot of buttons, switches and LEDs that can be seen alongside input and output connectors. With buttons, switches and LEDs, this prototype module becomes the simulator as well – inside the module are simulators of all input and output signals that make this prototype even more convenient for the further development and testing. Although this is just a module prototype, it satisfies all requirements for working in real conditions and can be implemented in any vehicle.

Considering different characteristics of individual microcontroller pins and the various possible upgrades, important criterion was to place and connect components in a logical and calculated order, with respect to all present and possible hardware or software upgrades so it is important to be careful while designing and connecting all electronic circuits, inputs, outputs and electronic components in general. Integration of certain electronic components protects module against different sort of nuisances that exist or could appear in real circumstances. Electronic circuit was developed parallel with the program code to achieve even better congruence between individual components and operations. Besides all the attention that was given in the hardware development, a lot of attention was committed to the software segments that improve quality work of module and protect system against contingent situations. Aesthetic appearance of the assembly was also taken into consideration. Result is a complete product that is ready for real use. Of course, the software can still significantly improve in order to obtain a more "intelligent" and efficient module, but it is efficient enough, functional, reliable and safe to use.

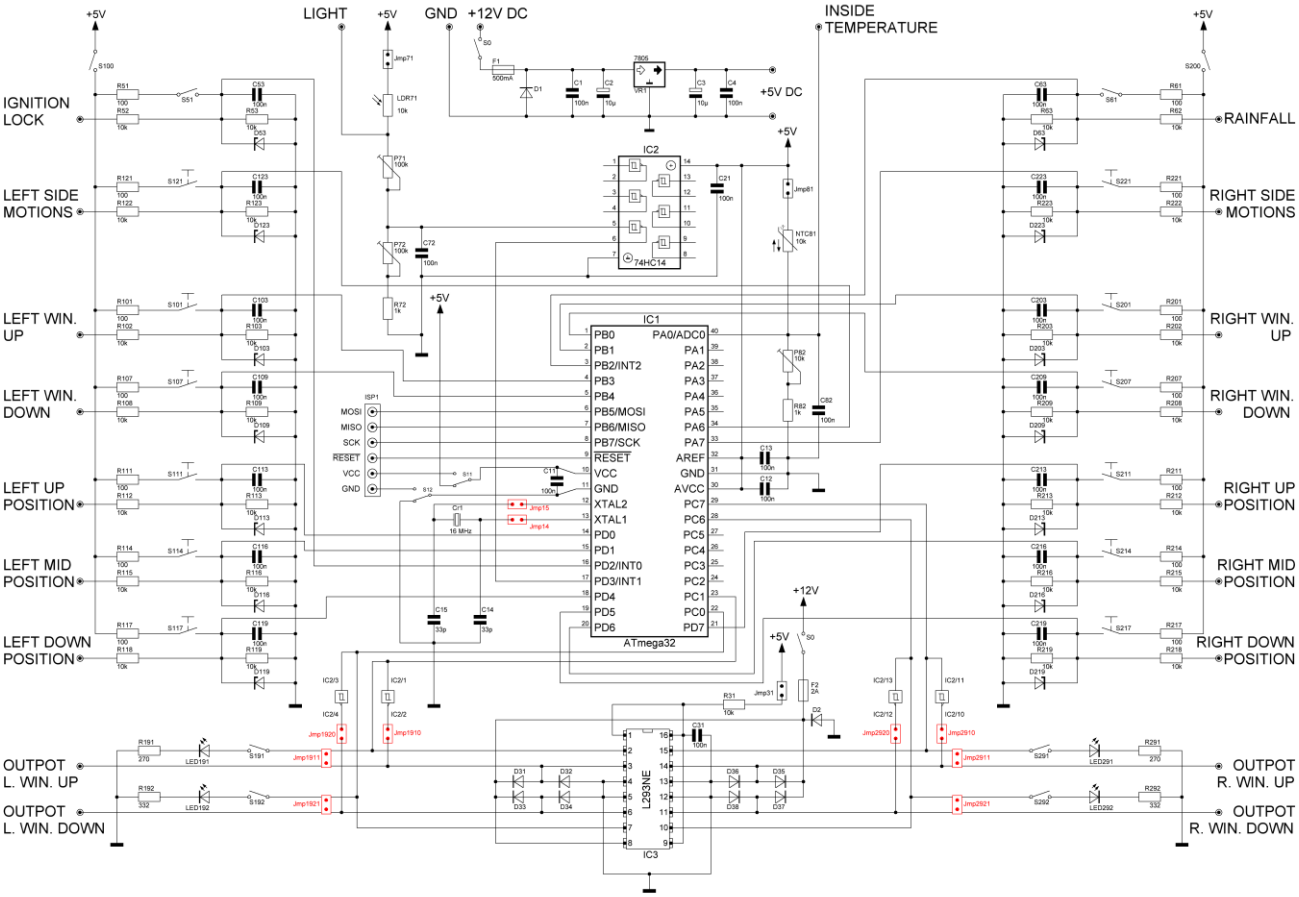

Figure 4. Electric scheme

The module is assembled using DIP (Dual In-line Package) electronic components, primarily due to the ease of making, testing and changing the hardware, which is quite important since it is a prototype that will spend most of the time in simulation instead of operating into the real world. Figure 5 shows the final implementation of printed circuit board.

Necessity of placing sensors around vehicle interior is already presented, but it is good to emphasize it again because it directly disables implementation of this module as one physical unit, which triggers other aggravating effects for easy installation and minimum costs.

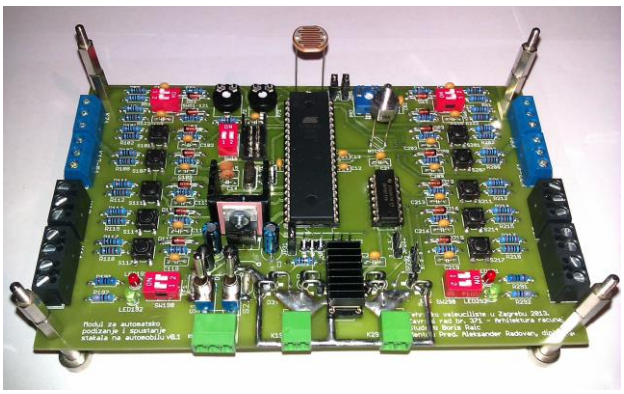

Figure 5. Final implementation

V. TEST RESULTS AND DISCUSSION

Module has been tested under real operating conditions in few vehicles on outside temperatures in range of 21 °C to 27 °C. Mid position sensors were set on few different levels. Also, temperatures inside vehicles while fully opened/closed windows were measured for better comparison. Measured temperatures are presented by Figure 6. The samples were collected during longer period of time. Comparing measured inside temperatures it is concluded that slightly opened windows (up to 5 cm) do not get satisfying results. To achieve quality ventilation it was necessary to lower windows at least 10 to 15 centimeters. Of course, more opened windows, and finally completely opened windows gives the best results, but 15 to 25 centimeters is optimal regarding inside temperature drop, energy consummation and safety concerns.

Presented results should be taken into consideration as informative since measurements were not taken in exactly the same weather conditions for each individual vehicle so there are visible disrupting effects. It can be remarked that many different factors, besides obvious direct sunlight, outside temperature and windows position directly affect ventilation process; weather conditions have significant influence on the ventilation process – e. g., wind noticeably accelerates and enhances ventilation. Further, size of the vehicle, even vehicle body color and vehicle orientation relative to the sun makes noticeable difference.

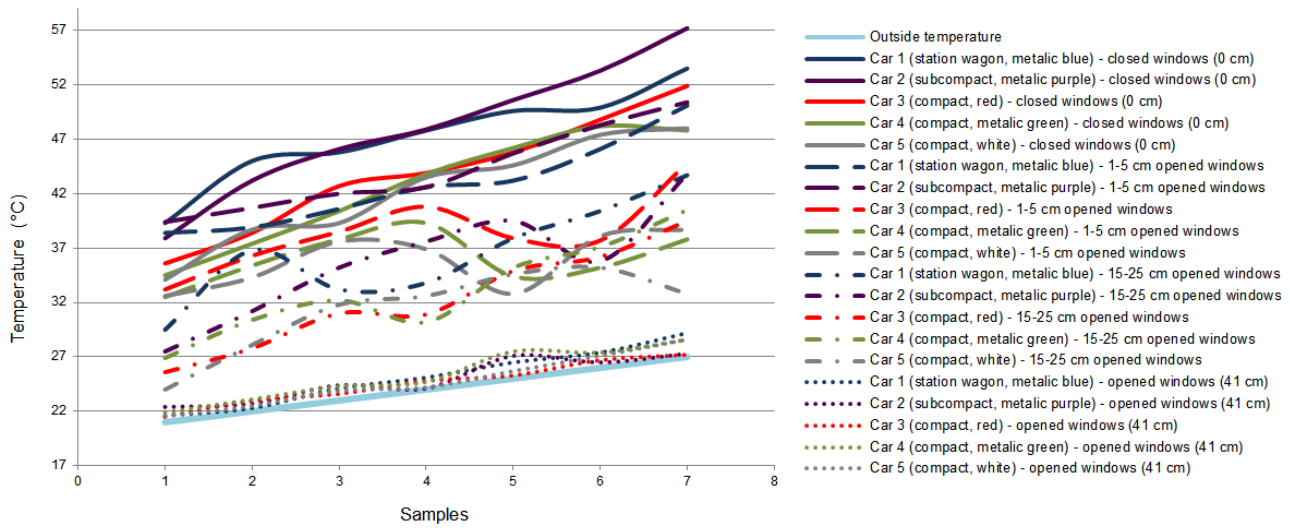

Figure 6. Measured temperatures

Except module proved to be safe, reliable and efficient, satisfactory results of the ventilation function were achieved. Without the module and with closed windows (or slightly lowered windows), temperature inside of the vehicle parked in the sun on light spring temperatures of 25 °C can reach over 50 °C. In summer, inside temperature rises even more drastically. While lowering windows for at least 10 to 15 centimeters to enable quality ventilation process, inside temperature becomes much bearable. Considering the fact that this ventilation process is a passive method of cooling overheated interior, it accomplishes very good results.

VI. CONCLUSION

It can be summarized that this module, although only a prototype, is completely functional device that performs its function safely, reliably and efficiently. Possibility of application is not limited only to the vehicle ventilation. The module is extremely expandable in both ways: it is upgradeable for new tasks as well as compatible for integration into some existing systems. Nearly every component can be used for several other functions, which can be achieved only by software upgrade. Upgrading hardware opens even greater possibility to upgrade the software and there are countless capabilities. Despite all the positive sides of this module, the question remains whether it can find its application in the market. Since the module is impracticable as a physical unit (because of peripheral unit), it is necessary to adapt it to any individual vehicle. Thus its individual installation is not cost-effective. It could find its purpose and economic efficiency if it would be serially mounted in same type of vehicle.

ABSTRACT - This paper presents methods for collecting and processing data using the acquisition card NI USB-6009 and MATLAB's Data Acquisition Toolbox. It also enables analysis of control system elements and responses of closed loop systems. Results obtained by series of experiments are used as examples for further use in Automatic Control Laboratory Exercises. A detailed explanation of procedures can be used as a base for the preparation of further laboratory exercises. The paper covers topics of initial installation and various use of the acquisition card.

I. INTRODUCTION

This paper will show the necessary steps how to link acquisition card NI USB-6009 and Matlab. After these procedures various experiments and measurements will be presented how to use this device. There are some problems that occur for this type of acquisition card that can be minimized by certain methods and procedures that will be explained in the paper. Today's technology allows the collection and processing of data from many physical processes using acquisition cards and computers. That makes it easier to process data for analysis of control systems. The initial idea of this paper is to improve and simplify laboratory exercises. It will be further described and done in this paper. The paper will also describe how to use Data Acquisition Toolbox, which is located within Simulink, which is part of the Matlab.

II. DATA ACQUISITION

Data acquisition is the procedure of collecting information from the process. With analog instruments it is difficult to collect data. There is also a lot of problems such as noise, drift, instability and high energy consumption. In digital systems it is easier to control noise and they provide easy transfer and storage of data. Digital signal processing is virtually unlimited. It all makes digital systems better for data acquisition.
Measurement and acquisition system consists of three parts:

1. acquisition
2. analysis
3. data presentation.

Part that relates to the data acquisition is a card that connects to a PC. Here it is realized by:

1. connection
2. A/D conversion
3. signal processing.

The analysis part is performed by calculations such as filtering, spectral analysis, data formatting and statistics. Data formatting is necessary because different devices and instruments may require information in a different format. Third part of the system is a presentation, which provides displaying, saving and printing of results, data transfering between different applications and communications between systems and networks.

III: A/D CONVERSION

The tasks in this paper were processed with analog data and for that there are given basics of analog-digital conversion. A conversion process consists of three steps.

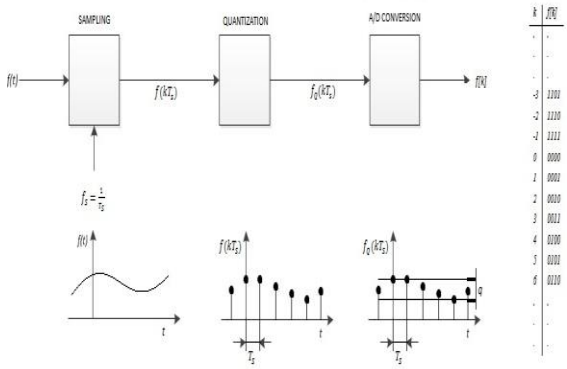

Fig. 1 The basic model of the conversion of the analog signal f (t) into a digital format that is shown a series of f [k]

The first step is carried out by the time discretization. With quantization level signal becomes a discrete value. In the final step there is performed coding of quantization level samples $f_Q(kT_S)$ or analog digital conversion. Each sample is associated with a corresponding binary number *f[k]*. A/D simbol stands for unit for analog to digital signal conversion (coder). That unit makes digital signal in the third step of the conversion. In practice an electronic circuit performs operations from Fig 1. Some of the signals between the two steps don't exist in practice. That is why usually ADC (*Analog Digital Converter*) stands for analog to digital converter as a unit that makes operations from each of three steps of the conversion. Analog signal must be reconstructed after the digital signal processing.

That conversion takes place in two steps. In the first step impulses of samples were reconstructed based on digital data *f[k]*. There is performed digital to analog conversion. This produces quantized level pulses $f_Q(kT_S)$. In the second step the analog form of the signal is beening reconstructed$f_r(t)$. It can be expected deviation of reconstructed analog signal$f_r(t)$. This deviation is due to quantization errors. Corresponding analog signal is reconstructed by filtering samples.

IV. ACQUSITION CARD NI USB-6009

Acquisition card *National Instruments USB-6009* allows data acquisition for mobile measurements, practice and lab measurements etc. It connects to the computer via the USB interface and that is a big advantage. The card is good for some complex measurements that can be seen at lab exercises.

A. SPECIFICATIONS

Acquisition card *NI USB-6009* has 8 analog inputs, 2 analog outputs, 12 digital inputs/outputs and 32-bit counter. Maximum sample speed by each analog input is 48 kS/s. Sample speed on analog outputs is 150 S/s and it can't be changed. Analog inputs have 14-bit resolution and analog outputs have 12-bit resolution. USB interface allows better transferability and easier connecting with the PC. The external appearance of the card is shown in Fig. 2.

Fig. 2 Acquisition card NI USB-6009

Maximum voltage that can be connected to analog inputs is from -20 V to 20 V (card specifications says -10 V to 10 V, but in practice -20 to 20 V can be connected). Analog outputs voltage is from 0 to 5 V and it can't be changed. The card connects with PC via USB interface. At digital inputs it can be connected voltage from 0 to 5 V and at digital outputs it gives 5 V. The card also has a counter that gives voltage from 0 to 5 V and maximum frequency of 5 MHz.

The card also has a green control LED that switches on when the card is connected to a PC via USB interface. If LED is not switched on card is not connected properly or it is malfunctioned. If it flashes that means that the card is in function.

Conductors merge with inputs and outputs with screw fittings connections that are at sides of the card.

Analog inputs and outputs were used in measurements.

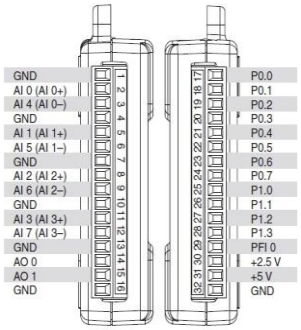

Fig. 3 Colloaction of screw fittings connections

B. CARD INSTALATION

At the beginning of using the card it is necessary to install a driver that is obtained on a CD with the card. Program *Measurement & Automation Explorer* needs to be installed. *Measurement & Automation Explorer* is used to test the card, reset it and adjust its characteristics.

V. FUNCTIONAL TESTING OF NI USB-6009

A. USE OF PROGRAMMING PACKAGE MATLAB

Work with acquisition card *NI USB-6009* is possible with 32-bit programm package *Matlab* and its library *Simulink*. Inside of *Simulink* there is a toolbox called *Data Acquisition Toolbox* which reads the card and makes possible to use its inputs and outputs in schemes inside of *Simulink*. That makes measurement easier because it enables to work with data inside of program.

Data Acquisition Toolbox takes place inside of *Simulink* library. *Simulink* library takes place inside of *Matlab*.

B. THE INITIAL MEASUREMENT

The first task was to observe the signal delay when processing data inside the card. Sinusoidal frequency 1 Hz was selected for the test signal. It was obtained from the function generator and it was brought to analog input and observed with 2-channel digital oscilloscope on analog input and output of the card. The model is made inside *Simulink* with usage of *Data Acquisition Toolbox* and it is very simple. Input and output parameters are set within the model. The window in which the parameters are set opens by double-clicking on the

input block. It is possible to select the input that will be used, sampling frequency, input voltage range, mode and whether there is used one or more cards. Modes are asynchronous and synchronous. The difference is that the asynchronous mode is FIFO (First In, First Out), or the card sends data out in the order that it receives and synchronous mode is such that all data are processed within the card and then it is sent to the output. The difference between these two modes is observed in larger models and affects the duration of the simulation. Asynchronous mode is faster. Output parameters that can be set are: output that we want to use and how many cards we want to use. Output voltage range is from 0 to 5 V and it can't be changed.

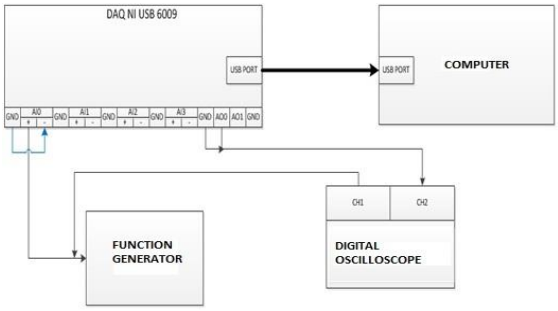

Fig. 4 Linking Up

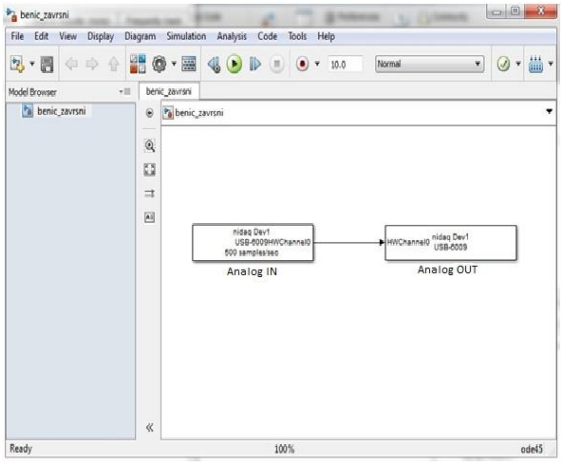

Fig. 5 Simulink model

The measurement signal on the analog input was sampled with the frequency of 500 S/s. Sample frequency is one of the factors that affects on data processing speed and the duration of the simulation. Sampling frequency at analog output is 150 S/s and it can't be changed as mentioned before.

Measured result is that sinusoidal frequency at the output of the card has delay of approximately 136 ms. Reason for that is data processing inside of the card that requires A/D conversion on the input of the card and D/A conversion at the output. Another reason is time that is necessary for acquisition and data processing that is given by a *Simulink* model. The result of this measurement is shown in fig 6.

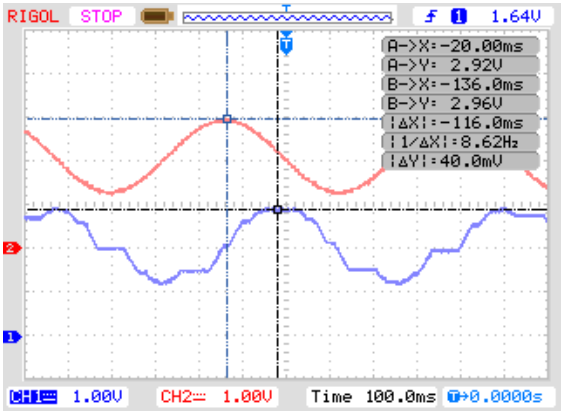

Fig. 6 Initail measurement of card delay

C. TEST RESULTS FROM THE INITIAL MEASUREMENT

Given results were obtained with repeated measurements. The test signal obtained from function generator was now rectangular with the frequency of 1 Hz and 10 Hz. Digital oscilloscope *Velleman PCSU1000* which is connected to the computer was used. Given results show that card has delay in range of 120-140 ms which confirms result that was given in initial measurement.

VI. RECORDING AND PROCESSING TIME RESPONSES OF SECOND ORDER ELEMENTS

A. ESTIMATION OF THE TRANSFER FUNCTION OF PT_2 ELEMENT

Double RC circuit is second order element. It is described by differential equation of the second order. It has two time constants and two energy storges. Energy storges are its two capacitors.

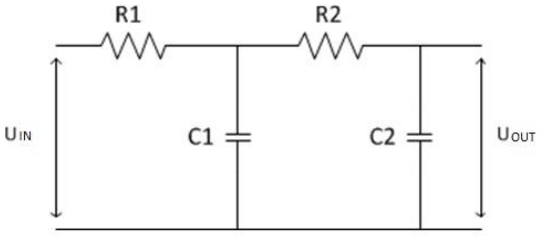

Fig. 7 Double RC circuit

The purpose of this experiment is to examine the possibilities of card. Tool *SIT* (*System Identification Toolbox*) is used in this experiment. *SIT* is used in a way that it compares the given time response with some known response inside *SIT* and it determines in which percentage they match with each other. *SIT* automatically determines system parameters (gain, time constants, dead time and transfer function).

The experiment measurement was made in a way that the double RC circuit was connected with card.

Input voltage of the double RC circuit is program designed step which is connected to the analog output of card. Output voltage of the double RC circuit is brought to the analog input of the card and it is observed on program oscilloscope.

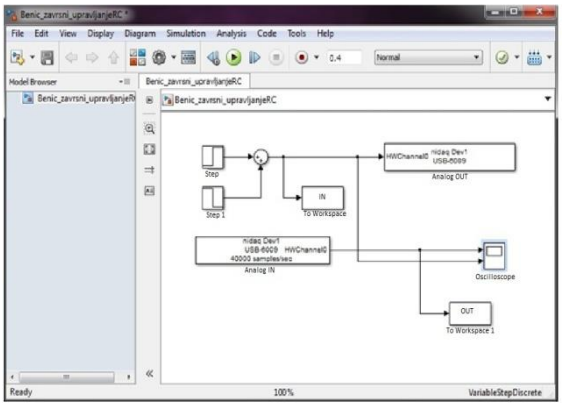

Fig. 8 Simulink model

Sampling frequency at the analog input is 40000 S/s and at the analog output it is 150 S/s. Input voltage of the double RC circuit are two program designed steps which starts in different moments. At Fig. 8 it is evident that given response matches with assumed in 98.68%.

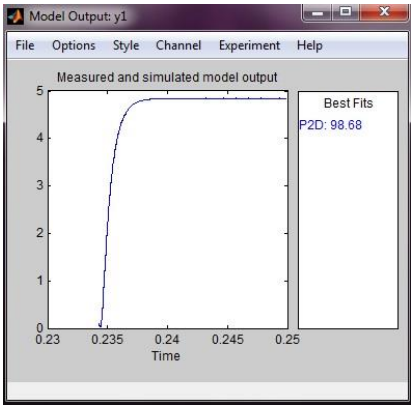

Fig. 9 The resulting accuracy of double RC circuit

Obtained accuracy is satisfying. Obtained time constants are almost equal to the time constants obtained by habitual classic procedure.
That all means that the card is good for measurements like in this experiment and that it can be used for laboratory exercises of this type.

B. ESTIMATION OF THE TRANSFER FUNCTION OF PT_2S ELEMENT

Serial RLC circuit is the element of second order. It has two energy stores and two time constants. It is described by differential equation of second order. Its energy stores are capacitor and coil.

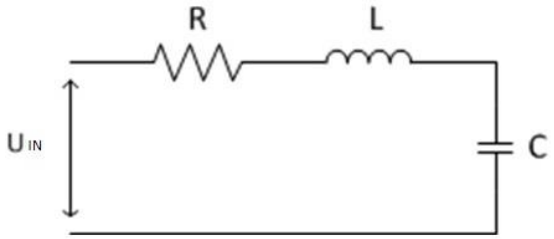

Fig. 10 Serial RLC circuit

The purpose of this experiment also is to examine the possibilities of card. The experiment measurement is made in the same way as last one. *SIT* (*System Identification Toolbox*) is also used. The expected response of the system is damped oscillatory response. The difference compared to the previous experiment is that the frequency of sampling analog input is set on 10000 S/s. Obtained system response is shown on Fig. 11.

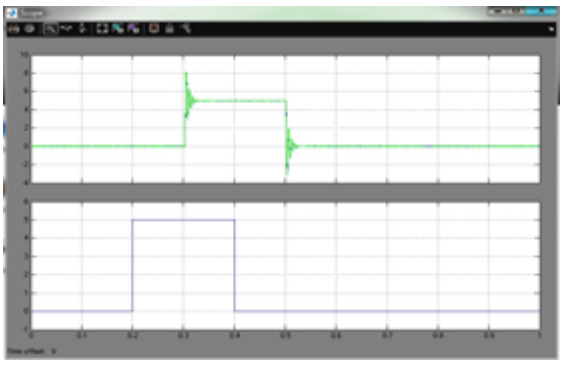

Fig. 11 Response of serial RLC circuit

System response is like it was expected. SIT is used in a further process of identifying the parameters of system as in the previous measurement.

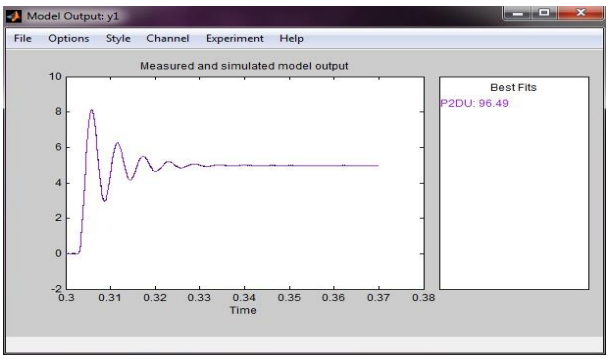

Fig. 12 The resulting accuracy of serial RLC circuit

Obtained accuracy is 96.49%. That is also good result like in previous measurement.
Conclusion of this test is that card is suitable for this type of measurement in laboratory exercises.

VII. CONCLUSION

After various tests of *NI USB-6009* work potentials with use of *Matlab* conclusion is that the card is good for laboratory excersises. Plenty of measurements performed on laboratory exercises in subject *Automatic control* can be simplified by using the card and *Matlab*. It is useful that the students familiarize themselves with the data acquisition and virtual instrumentation because that is present and the future and it is is likely for them to encounter some kind of data acquisition in their profession after they graduate.

While the card was tested some conclusions about possibele improvements were made. Folowing pro and cons:

Disadvantages:

1. Card with use of *Data Acquisition Toolbox* works only on 32-bit *Matlab*
2. The voltage at the analog outputs of the card is limited to the range of 0-5 V, and can not be changed.
3. Samle frequency at analog outputs is 150 S/s and can not be changed.
4. Maximum sample frequency at the analog inputs (48 kS/s) can be achieved using only one analog input. Maximum sampling frequency is reduced if used multiple inputs simultaneously.
5. It often happens that *Matlab* simulation stops working and that *Matlab* blocks if the card is not previously reseted inside *Measurement & Automation Explorer*.
6. The card has a signal latency which is not fixed.
7. Card does not work in real-time mode.
8. Simulation time and real time of process are not the same. Eg. for simulation time 10 s process usually will not last 10 s. The time required for the implementation of the simulation depends on many factors, including the complexity of the model and the step size inside Solver.
9. Card has a problem with noise and drift while receiving and processing analog data.

Benefits:

1. Connecting to a computer via the USB interface.
2. Easy to work in a graphical environment (*Data acquisition toolbox*).
3. Small dimensions.
4. No additional power supply of the card is needed.
5. Using the card reduces the necessary equipment to perform labaratory exercises.
6. The card "remembers" the last voltage state in which it found itself.
7. Simulation time inside of *Simulink* can be set on unlimited in a way that instead of numerical value for end of the simulation enters *inf*
8. Using the *Rate transition* block.

Fig. 13 Rate Transition Block

The *Rate transition* block is inside of S*imulink* library (**Simulink → Signal attributes → Rate transition**) and it is used for changing sample frequency to its divisor. (Eg. 1000 S/s u 100 S/s). The purpose of this is that signal at analog input can be sampled on a given frequency, and within the simulation can be viewed only parts of the signal (Eg. if at input is 1000 S/s it is possible for some part of the simulation later to put 100 S/s and watch every tenth sample of the input signal). It makes possible that in simulation every block needs not to have same sample frequency and it is possible to work with fixed discretization step.

Possible improvements:

1. Work with 64-bit *Matlab*.
2. Possibility of changing range of output voltage at analog outputs.
3. Possibility of changing sample frequency at analog.
4. Troubleshooting blocking simulation.

Udaljeno praćenje ljudske aktivnosti prikupljanjem podataka s ugrađenih senzora pametnog mobitela

J. Begovac i L. Celić
Sveučilište u Zagrebu Fakultet elektrotehnike i računarstva, Zagreb, Hrvatska
juraj.begovac@fer.hr
luka.celic@fer.hr

Sažetak - Korištenje pametnih mobitela koji sadrže veliki broj senzora, kao što su žiroskop, magnetometar, akcelerometar i sl. raširenо je u populaciji, pa se sve više razmišlja o njihovom korištenju za udaljeno praćenje kroničnih bolesnika i uključivanju u programabilno zdravstvo (m-zdravstvo). Cilj ovoga rada je ispitati vjerodostojnost udaljenog praćenja osoba prikupljanjem podataka izmjerenih troosnim akcelerometrom koji je ugrađen u pametni mobitel. Istraživanje je provedeno na ispitanicima koji redovito i rutinski koriste pametni mobitel. Kao kontrolni parametar o trenutnoj fizičkoj aktivnosti ispitanika, ispitanik je ručno unosio podatak o planiranoj aktivnosti. Fizičke aktivnosti koje su se pratile tijekom istraživanja su hodanje, hodanje uz stepenice, hodanje niz stepenice, brzo hodanje i trčanje, te sjedenje, kao neaktivno stanje. Obrada prikupljenih podataka je obavljena pomoću programskog paketa Matlab. Za signal svake aktivnosti izračuna se brza Fourierova transformacija te se usporedbom spektara signala pojedinih aktivnosti traže razlike radi vrednovanja mogućnosti automatske klasifikacije aktivnosti. Temeljem spektra signala ubrzanja, moguće je dobro klasificirati sjedenje, trčanje i općenito hodanje, ali je teža klasifikacija pojedinih oblika hodanja (normalno, uz stepenice, niz stepenice, brzo hodanje).

I. UVOD

Zahvaljujući inženjerskim rješenjima danas je moguće pratiti zdravstveno stanje osoba oboljelih od kronične bolesti i/ili tijekom rehabilitacije i izvan zdravstvene ustanove [1,2,3]. Ovisno o situaciji (bolesti, ozljedi itd.), osobe kroz dnevni život, terapiju i rehabilitaciju vodi stručni tim uz pomoć informacijsko-komunikacijske tehnologije. Prijedlozima i savjetima tim pomaže praćenoj osobi što djelotvornije provoditi predviđene dnevne aktivnosti i mjere potrebne za oporavak. U mjere prevencije pogoršanja bolesti, uz edukaciju i promociju zdravog načina življenja, uključuje se fizička aktivnost putem vježbanja, rehabilitacija u izvan-zdravstvenim ustanovama te udaljeno praćenje osobe oboljele od kronične bolesti u vlastitom domu [4].

Mobilna tehnologija pruža velike mogućnosti u daljnjem unaprjeđenju zdravstvene njege kroz mobilne zdravstvene aplikacije, ugrađene senzore u mobilne uređaje i povezivanje mobilnih uređaja s medicinskim uređajima [5]. U današnje vrijeme raširenо je korištenje pametnih mobitela (*smartphone*) [6]. Pametni mobiteli sadrže veliki broj senzora, kao što su žiroskop, magnetometar, akcelerometar i sl., pogodnih za praćenje fizičke aktivnosti oboljelih osoba i primjenljivih u njihovoj rehabilitaciji [7]. Cilj ovoga rada je ispitati vjerodostojnost udaljenog praćenja osoba prikupljanjem podataka izmjerenih troosnim akcelerometrom koji je ugrađen u pametni mobitel.

Za istraživanje provedeno ovim radom je korišten sustav koji čine aplikacija za operacijski sustav (OS) Android razvijena za potrebe ovog rada te računalo na kojem su obrađeni prikupljeni podaci (Slika 1.). Funkcionalnost Android aplikacije je prikupljanje podataka s akcelerometra ugrađenog u pametni mobitel i prikupljanje podataka o aktivnosti ispitanika (korisnikov *feedback*).

Slika 1. Sustav za ispitivanje vjerodostojnosti udaljenog praćenja osobe pomoću pametnog mobitela

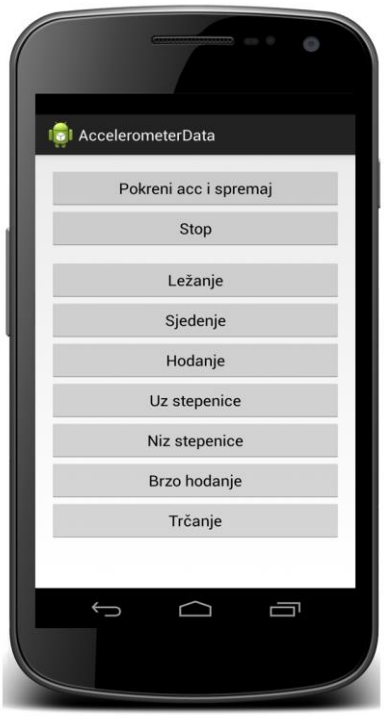
II. MJERENJE I OBRADA PODATAKA

A. *Aplikacija za operacijski sustav Android*

U ovom radu je kao ispitni uređaj korišten Samsung Galaxy Nexus I9250, koji ima ugrađen troosni akcelerometar BMA220 [8].

Razvijena je aplikacija naziva „AccelerometarData“ za operacijski sustav Android (Slika 2.). Primarna funkcionalnost aplikacije je prikupljanje izmjerenih podataka sa senzora pametnog mobitela o fizičkoj aktivnosti korisnika aplikacije (ispitanika). Međutim, kako bi se dobila kontrolna informacija o fizičkoj aktivnosti korisnika, aplikacija ima funkcionalnost prikupljanja informacije korisnika o fizičkoj aktivnosti koju trenutno izvršava (korisnikov *feedback* o njegovoj fizičkoj aktivnosti). Sljedeća funkcionalnost aplikacije je spremanje navedenih podataka i informacija u tekstualnu datoteku u memoriju pametnog mobitela.

Korisničko sučelje aplikacije se sastoji od jednog zaslona koji sadrži tipke. Tipke su podijeljene u dvije sekcije. U prvoj sekciji se nalaze dvije tipke koje imaju funkcionalnost pokretanja i zaustavljanja Android servisa koji radi u pozadini. Funkcionalnost navedenog servisa je prikupljanje mjernih podataka s akcelerometra.
Drugu sekciju čine tipke čija je funkcionalnost prikupljanje korisnikovog unosa o vlastitoj aktivnosti.



Slika 2. Aplikacija za praćenje fizičke aktivnosti

B. *Snimanje signala*

Za potrebe istraživanja izabrane su uobičajene dnevne aktivnosti, a snimanje signala akcelerometra tijekom pojedine fizičke aktivnosti odvijalo se na Fakultetu elektrotehnike i računarstva. Signali su snimani na odabranoj grupi studenata. Snimale su se sljedeće fizičke (ne)aktivnosti: sjedenje, hodanje, hodanje uz stepenice, hodanje niz stepenice, brzo hodanje i trčanje.

U istraživanju je korišten pametni telefon koji je bio smješten u džepu uskih hlača (traperica) ispitanika za vrijeme obavljanja svake navedene fizičke aktivnosti.

Moguće frekvencije očitavanja podataka s akcelerometra (*sampling rate*) ovise o primijenjenom mobilnom uređaju. Za potrebe ovog istraživanja odabrana je frekvencija očitavanja SENSOR_DELAY_GAME, tj. frekvencija vrijednosti 50Hz [7].

C. *Obrada podataka i klasifikacija aktivnosti*

Nakon što su podaci snimljeni i spremljeni u tekstualnu (.txt) datoteku u memoriju pametnog mobitela, moguće ih je dohvatiti na računalu povezivanjem mobitela s računalom.

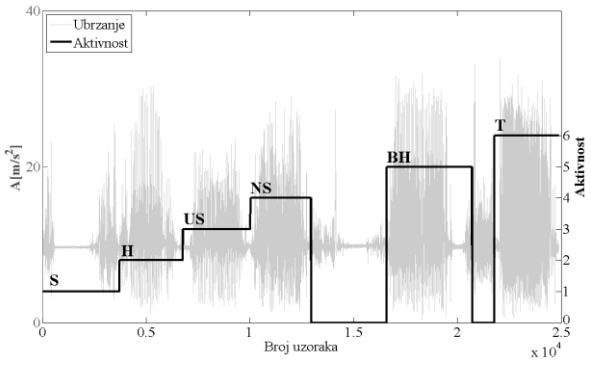
Nakon dohvata podataka na računalu, obavlja se obrada podataka u programskom paketu Matlab. Za potrebe rada su razvijene Matlab skripte (.m skripte) koje sadrže programski kod za obradu podataka.

Budući da akcelerometar mjeri komponente ubrzanja u tri smjera (x, y i z) u ortogonalnom sustavu, u prvom koraku se podaci učitani iz tekstualne datoteke spremaju u četiri vektora (*ax*, *ay*, *az* i *activity*). Prva tri navedena vektora predstavljaju vrijednosti komponenata ubrzanja izmjerene akcelerometrom pametnog mobitela. Dodatni vektor (*activity*) predstavlja zapisani podatak korisnika o aktivnosti koju je obavljao.

Zatim se pomoću (1) izračuna iznos (*magnitude*) linearnog ubrzanja [9].

$$A = (ax^2+ay^2+az^2)^{1/2} \qquad (1)$$

Paralelni prikaz iznosa ubrzanja (A) i unesene informacije o aktivnosti koju korisnik obavlja nalazi se na slici (Slika 3.).



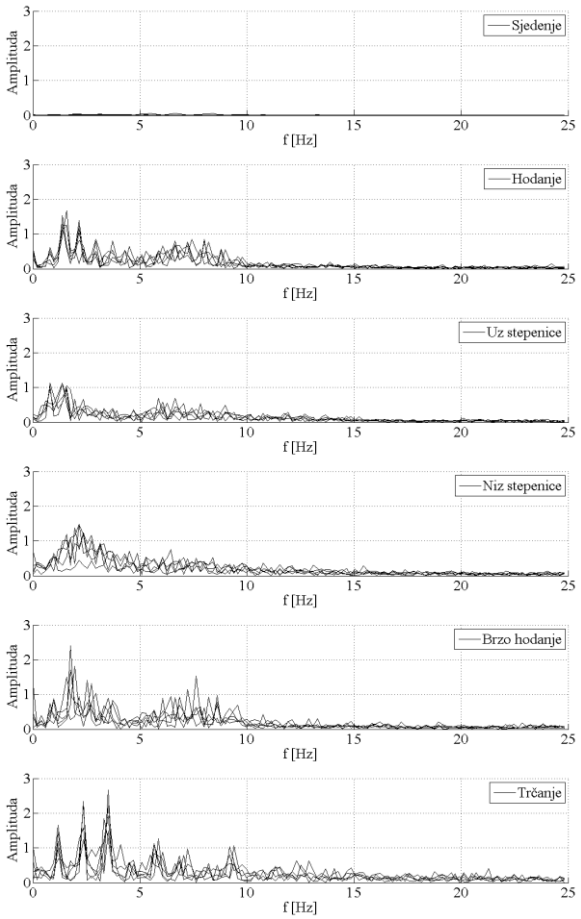
Slika 3. Paralelni prikaz ubrzanja i korisničkog unosa tipa aktivnosti
(S – sjedenje, H – hodanje,
US – hodanje uz stepenice,
NS – hodanje niz stepenice,
BH – brzo hodanje, T – trčanje)

Nakon usporedne analize signala ubrzanja i korisničkog unosa tipa aktivnosti, izdvajaju se uzorci signala ubrzanja za svaku aktivnost i pohranjuju u zasebne datoteke. Za

svaku aktivnost, nad 256 uzoraka izračunava se brza Fourierova transformacija (*Fast Fourier Transform*, FFT) te se usporedbom izračunatih spektara pojedinih aktivnosti traže razlike radi vrednovanja mogućnosti automatske klasifikacije aktivnosti.

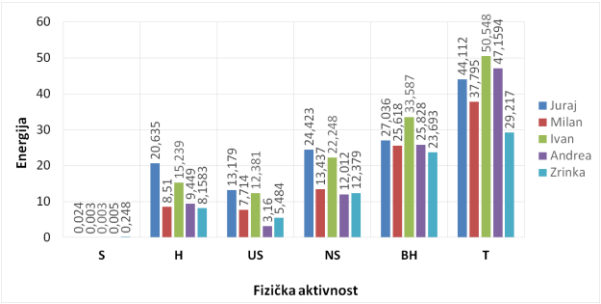
Prikaz spektara svih aktivnosti jednog ispitanika se nalazi na slici (Slika 4.). Slika spektra se dobiva tako što se nad pet različitih dijelova signala od 256 uzoraka izračunava FFT za svaku aktivnost. Na temelju izračunatih spektara, može se zaključiti:

- za vrijeme sjedenja amplitude signala na svim frekvencijama su približno jednake nuli,
- u amplitudnom spektru signala trčanja (u usporedbi sa signalom hodanja) izraženije su amplitude na višim frekvencijama,
- temeljem spektra signala ubrzanja, moguće je dobro klasificirati sjedenje, trčanje i općenito hodanje, bez obzira o kojem obliku hodanja se radi (normalno, uz stepenice, niz stepenice, brzo hodanje),
- temeljem spektra signala ubrzanja teža je klasifikacija pojedinih oblika hodanja.



Slika 4. Spektri aktivnosti jednog ispitanika

Dodatno se može primijetiti da je ukupna energija prilikom trčanja značajno veća od energije za bilo koji oblik hodanja. Ostale amplitude variraju od ispitanika do ispitanika (Slika 5.).



Slika 5. Izmjerena energija pojedinih aktivnosti za različite ispitanike
(S – sjedenje, H – hodanje,
US – hodanje uz stepenice,
NS – hodanje niz stepenice,
BH – brzo hodanje, T - trčanje)

III. ZAKLJUČAK

Na temelju istraživanja može se zaključiti da je analizom spektra signala ubrzanja moguće dobro klasificirati (ne)aktivnosti sjedenje, trčanje i općenito hodanje. Međutim, teže je klasificirati slične aktivnosti kao na primjer klasifikacija između pojedinih oblika hodanja (normalno, uz stepenice, niz stepenice, brzo hodanje). Uključivanjem dodatnih senzora (npr. žiroskopa) koji su ugrađeni u pametni mobitel odluke o klasifikaciji aktivnosti bile bi izraženije, a kombiniranjem signala s različitih senzora dobila bi se bolja klasifikacija aktivnosti.

U daljnjem istraživanju praćenja ljudske aktivnosti prikupljanjem podataka s ugrađenih senzora pametnog mobitela planirano je praćenje višesatne aktivnosti ispitanika. Planirano je provođenje obrade signala i klasifikacija aktivnosti na pametnom mobitelu umjesto na računalu. Također, planirano je ispitivanje automatiziranog praćenja aktivnosti ispitanika smještanjem pametnog mobitela na različita mjesta uobičajena za nošenje pametnog mobitela (npr. džep od jakne, torbica ili džep od komotnije odjeće poput trenirke).

ZAHVALA

Zahvaljujemo se našem mentoru i profesoru Ratku Magjareviću na tome što nas je poticao u izradi ovoga rada te se zahvaljujemo na njegovim savjetima. Također, zahvaljujemo se Kristijanu Jurkoviću koji nam je pomogao sa savjetima pri izradi aplikacije za operacijski sustav Android.

Visualization of Streaming Trajectories

D. Osmanović, E. Mešković
University of Tuzla, Faculty of Electrical Engineering, Franjevačka 2,
75000 Tuzla, Bosnia and Herzegovina
dario.osmanovic90@gmail.com, emir.meskovic@untz.ba

Abstract - One of the basic requirements when managing moving objects in data stream management systems (DSMS) is visualization of continuous queries results on the map. In most cases, the result of a continuous query is data stream whose elements contains information about locations of moving objects so that we are talking about visualization of streaming trajectories. Such visualization involves redrawing the location of moving objects for each new arriving element of data stream that represents the result of a continuous query. In this paper we present an application that allows you to pose continuous queries and visualize their results in OCEANUS DSMS prototype for managing spatio-temporal data streams. The application is based on the Java programming language, swingx-ws library for interacting with web services and OpenStreetMap web service that provides free maps of the world. The application allows users familiar with CSQL to pose queries directly using this query language, while beginners can pose a query through creating the conditions by selecting one or more operations from a set of basic operations on moving objects. In addition to presenting current positions of each moving object which satisfies the condition of continuous query it is also enabled to view the entire trajectory of a moving object.

I. INTRODUCTION

Moving object databases support objects whose position and/or extent changes continuously and enable posing queries not just about history of movements, but also about current and future movements. Such databases are overloaded with frequent updates of moving objects' positions which is the reason for objects' movements to be considered as continuous, time varying and possibly unbounded data streams. Several research projects provided prototype systems for managing such large and possibly unbounded data streams and continuous queries, while other attempt to extend these prototypes with support for spatio-temporal data types and operations in order to efficiently manage moving objects. OCEANUS [1] is one of those prototypes that presents an effort to extend TelegraphCQ DSMS (TCQ) with spatial support providing a platform for spatio-temporal streaming applications.

Besides defining appropriate spatio-temporal data types and algebra that would satisfy all requirements for moving objects management, one of the basic requirements is also a possibility to visualize results of spatio-temporal continuous queries on the map. Such visualization is possible if the result of a continuous query consists of elements containing information about locations of moving objects. In that case we have a data stream that represents trajectory of moving object and requirement to redraw a moving object's position with each new arriving element, since each spatio-temporal continuous query returns incremental results refreshed with the most recently received positional information generated at data source.

Applications for visualization of such streaming trajectories have to offer appropriate method for processing incremental results of continuous queries, as well as map background for their appropriate presentation. Since there are a number of web services with open source visualization libraries offering capability to build an application with appropriate functionality, it is reasonable to select one of them as a basis for developing a prototype for visual presentation of streaming trajectories. Our OCEANUS Visualizer prototype is based on OpenStreetMap web service that provides free maps of the world and swingx-ws library for interacting Java programs with web services. Prototype also enables posing continuous queries directly using CSQL query language or indirectly by choosing query parameters.

II. RELATED WORK

Modeling, analyzing, monitoring and visualizing trajectories of moving objects has been a focus of research in recent years. This research was mostly done separately in the context of conventional spatio-temporal databases in which data is assumed to be less dynamic and in the context of continuous, time varying and possibly unbounded spatio-temporal data streams carrying information about moving object's positions at any time instant.

Visualization of a generic model for moving point objects in spatio-temporal database management system (DBMS) is presented in [2]. It is based on ESRI Tracking Analyst extension on ArcGIS for handling spatio-temporal data in a way that enables displaying point and tracking data, showing the aging of data, symbolizing actions based on attribute or spatial queries and highlighting.

Conceptual model for visual exploration of trajectory data with multivariate attributes by using timemap.js web visualization library is proposed in [3]. Developed prototype has the capability to display overview of each trajectory and the details of each trajectory with different zoom levels through map view and timeline.

An online spatial data analysis and visualization system, TerraFly GeoCloud, which facilitates end users to visualize and analyze spatial data, and to share the

analysis results is presented in [4]. It is built on the TerraFly Geo spatial database and can efficiently support many different visualization functions and spatial data analysis models. It also enables the MapQL technology to customize map visualization using SQL-like statements.

Work presented in [5] introduces design and implementation of a geospatial data stream query engine in SECONDO, together with web interface for dynamic visualization of streaming results. It uses AJAX technology to support asynchronous rendering of streaming contents on a map interface. The GUI can accept SQL queries from the web form and pass the queries to the parser. The streaming results returned are then dynamically visualized.

Method for visualization of trajectory data proposed in [6] utilize XSLT and XPath technologies to convert the original trajectory data to GML format for storage and transmission and then convert GML to KML for visualization of trajectory data in browser. Trajectory data are then visualized rapidly in Google Maps and Google Earth.

Design and implementation of a powerful map application for managing, querying and visualizing evolving locations of moving objects is presented in [7]. This application offers capabilities for specifying typical continuous queries (such as range, distance and nearest neighbor search) and visual display of objects' trajectories and online collection of movement statistics. Interface was implemented with Java SDK 1.4.2, making use of ESRI's MapObjects-Java 2.0 libraries for rendering and manipulating geographic features on map.

Our approach for developing special-purpose application for handling and visualizing streaming trajectories is closed to one presented in [7] since this application is developed on the top of TCQ on which OCEANUS is based on. But we also overcome limitations of this approach originating from PostgreSQL built-in spatial data types and operators in a way that visualization includes spatio-temporal extension in OCEANUS which relies on full standardized spatial support for data types and operations found in PostGIS.

III. OCEANUS VISUALIZER ARCHITECTURAL OVERVIEW

OCEANUS Visualizer represents mapping application that enables querying and visualizing streaming trajectories through a user-friendly graphical interface and OpenStreetMap background. It is possible to pose various spatio-temporal continuous queries using embedded set of operations in OCEANUS DSMS, each one producing incremental results. To ensure such comprehensive functionality, we have designed and implemented OCEANUS Visualizer as a desktop application consisting of three layers illustrated in Fig. 1.

At the first (bottom) layer we have an OCEANUS prototype of spatio-temporal data stream processing engine that extends TCQ with a spatial support for efficient evaluation of continuous queries over moving objects. This support is ensured with PostGIS extension, Proj4 and GEOS libraries, and MovingObject library

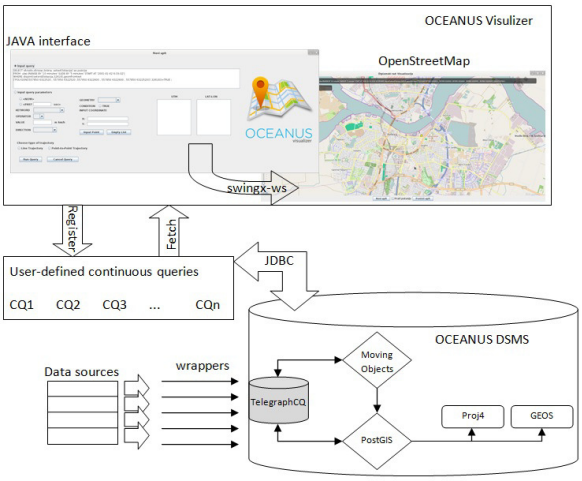

Figure 1. OCEANUS Visualizer architecture

containing data types an functions for moving objects. Special wrappers that read data from external sources representing moving objects and forward them into system with desired rate for further processing have also been designed.

At the second (intermediate) layer we have a Java interface for posing spatio-temporal continuous queries and retrieving their incremental results. Connection with data stream processing engine at the bottom layer is established through standard JDBC (Java Database Connectivity) interface for PostgreSQL 7.3, since TCQ is based on it. Continuous queries for reporting locations of moving objects can be specified using spatial operators inherited from PostGIS (such as *distance*, *disjoint* or *within*) and functions from MovingObject library (such as *passes*, *mdirection*, *trajectory*, etc.). This means, it is also possible to define conditions that combine dynamic spatio-temporal streams with static spatial entities. At running time, user can immediately suspend continuous query execution and start the new one.

At the third (top) layer we have a map offered by OpenStreetMap web service that persistently reads result of a continuous query containing locations of moving objects, and redraws it with each new arriving element in resulting stream. Communication with Java interface at the intermediate layer is accomplished with swingx-ws library for interaction with web services. Static spatial entities involved in condition of continuous query are also presented on map taking into account typical cartographic functionality such as zoom.

Since the visualization of continuous queries is done at the third layer, we will describe its implementation briefly. The map viewer is a common component needed in applications for generating and using geographic data and we use the open source JXMapViewer that enables embedding mapping abilities into Swing-based Java application. It is just a special JPanel whose API enables converting coordinates to pixels, caching tiles, and stitching them together on screen. We use JXMapKit as a wrapper for the JXMapViewer because it includes the most commonly used features as zooming and mini-view and also has many customization options. First thing need

to be done is setting a map center by calling *setAdressLocation()* method with GeoPosition object as a parameter representing coordinate at the globe as a latitude and longitude. WayPoint class is used for implementing moving objects on the map which are customized by implementing the WaypointRenderer interface. These objects are drawn by using WaypointPainter, the JXMapViewer's special painter that can properly draw points on the map, and by calling *paintWaypoint()* method. For drawing static spatial objects, trajectory of a moving object and text of a posed query we use painters (objects of a Painter class) which can customize drawing of a JXMapViewer by setting them with *setOverlayPainter()* method.

IV. TRAJECTORY VISUALIZATION IN OCEANUS VISUALIZER

Modular design of OCEANUS Visualizer application presented previously offers a comprehensive framework for managing, querying and visualizing streaming trajectories of moving objects. User-friendly graphical interface for posing various spatio-temporal continuous queries and advanced capabilities for visual display of moving object's trajectories make it suitable for wide range of users, from beginners to advanced ones. Hence, Java graphical interface is divided into two sections enabling two different methods for definition of a spatio-temporal continuous queries.

A. JAVA grafical user interface

In first section, users can type query directly in text area using CSQL query language. This section is intended for advanced users since there is no limitations in using PostGIS spatial operators and functions or functions for operations over moving objects embedded in OCEANUS prototype. Application parse posed continuous query just in a way to test weather selection list is suitable for a visualization on map (i.e. does one contains information about location of a moving object). Except this case, entire query parsing is addressed to a data stream processing engine at the bottom layer, and if query results with an exception, application discard it without any visualization and informs user with appropriate message.

In second section of JAVA interface users can pose spatio-temporal query in a way to define a condition over streaming trajectory by choosing certain operation from a offered subset of PostGIS functions and operations on moving objects. According to selection made by user, application offers him to choose just certain options in order to properly define a condition of query. List of all required options and parameters for each available operation is given in Table I and section for parameter query is illustrated in Fig. 2. For each continuous query

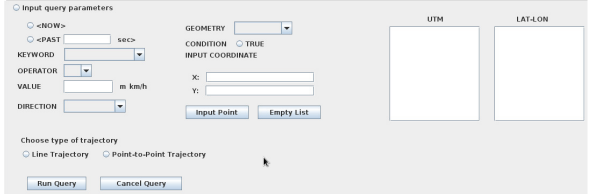

Figure 2. Section of JAVA interface for defining input query parameters

TABLE I. OPERATIONS AND REQUIRED OPTIONS AND PARAMETERS

Operation	Operator and value	Static spatial object	Direction options
within		Yes	
disjoint		Yes	
distance	Yes	Yes	
passes		Yes	
trajectory length	Yes		
{*min* | *max*} *distance*	Yes	Yes	
{*min* | *max*} *speed*	Yes		
direction			Yes

user have to determine time based sliding window and in this interface section *now* or *past* window can be chosen. For *past* window chosen, one must enter a time period in seconds. When user selects an operation that involves interaction with static spatial object, one must be defined with its coordinates. User first chooses a type of spatial object (*point*, *linestring*, *polygon*) and then defines one by one points it consists of by entering their coordinates. By not choosing an option "true", users determine to select and visualize locations of moving objects that don't fulfill the specified condition.

According to subset of operations listed in Table I, spatio-temporal queries that can be defined by choosing query parameters could be classified into three classes:

- positional queries – continuous queries that examine spatial interaction of moving objects with specific static spatial object. This class includes operations *within*, *disjoint* and *passes*.
- distance queries – continuous queries that founds current locations of moving objects within or outside a given distance from a reference object (*distance*), or current location of moving objects in particular relation with distance from a reference object in the past (*minimal distance* and *maximal distance*).
- scalar queries – continuous queries that examine values of particular features of moving objects such as their trajectory length during some period, minimal or maximal speed reached or direction of their movements (south, north-east, west, etc.).

OpenStreetMap uses the WGS84 spatial reference system used by the Global Positioning System (GPS) (geographic coordinates between -180° and 180°

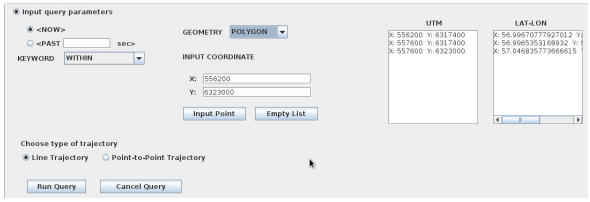

Figure 3. Defining condition of query Q1

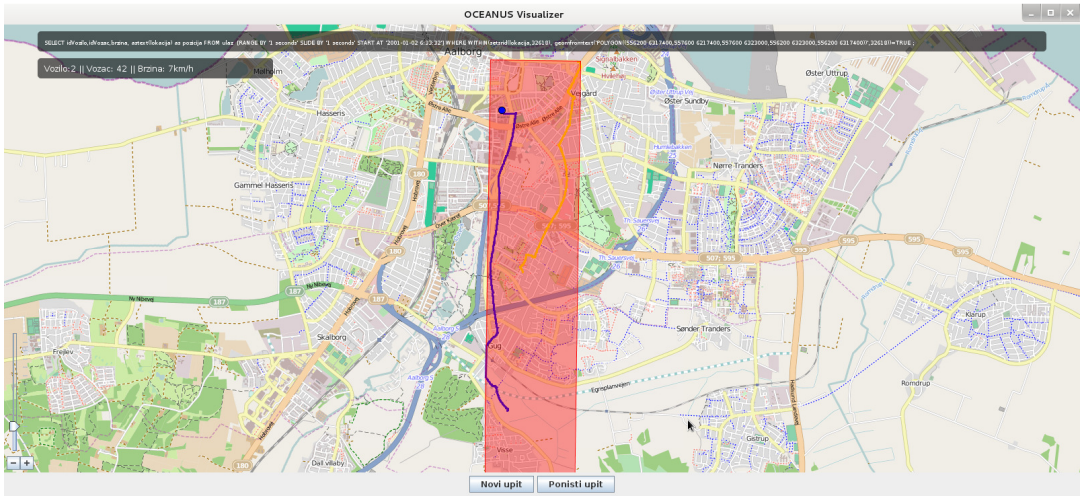

Figure 4. Visualization of query Q1

longitude and -90° and 90° latitude) and application also offers possibility to convert coordinates from Universal Transverse Mercator (UTM) projected coordinate system to WGS84. Hence, users can define spatial objects involved in query execution by using any of these two spatial reference systems.

B. Query examples and visualization

Following the rules for defining query condition explained in previous subsection, users can pose various spatio-temporal queries in second section of Java interface. Query examples in this subsection are based on the following schema[1] of a data stream receiving data from moving objects:

```
carStream <
   id:        integer,
   carType:   varchar(8),
   driver:    smallint,
   pos:       intime(point),
   speed:     real,
   tcqtime:   timestamp timestampcolumn
>
```

For example, if user wants to pose the following query:

Q1: *Continuously report current locations (or trajectories) of all vehicles within particular region of interests.*

he will need to: choose a window *now*, choose an operation *within*, choose polygon type of geometry and define it with its coordinates, as it is illustrated in Fig. 3. This will result with the following CSQL query generated by the application:

```
SELECT id, val(pos), speed
FROM carStream <Now>
WHERE within(val(pos),geomfromtext
('POLYGON((557850 6322520, 557950 6322520,
557950 6322600, 557850 6322600, 557850
6322520))'));
```

[1] Schema is derived from INFATI data set [8], used for generating *archived* streams

After defining a query, Java interface forwards it to the OCEANUS prototype at the bottom layer for a registration as a continuous query and displays an OpenStreet map for a visualization. Map continuously listens for the results of the query and when first element of data stream that satisfies query condition arrives it starts displaying results. There are two ways for visualizing results, either as a continuously "moving" marker on the map or as a continuously "growing" trajectory of the moving object with marker representing last location at the top. Second way of visualization of a query Q1 is illustrated in Fig. 4. Notice that static spatial object defined for evaluating a condition of continuous query is also displayed on map.

In query Q1 we have used PostGIS function *within* in combination with window *now*. In next example, we will illustrate usage of operation on moving objects in combination with window *past* since it considers recent history of movement. For query such as:

Q2: *Continuously report current locations (or trajectories) of all vehicles that were heading north-east 40 seconds ago.*

user just needs to select an operation *direction* and appropriate value for it (north-east), as it is illustrated in Fig. 5. Notice that for this type of operation user can not define any other parameter values except the one for direction. In this way, users don't have to be familiar with operation signatures (interface) because application takes care about appropriate usage of each operation. Choice made by user given in Fig. 5 will result with the following CSQL query generated by the application:

Figure 5. Defining condition of query Q2

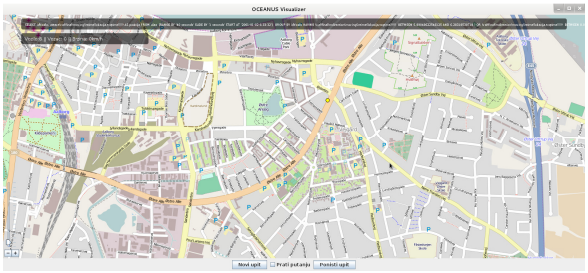

Figure 6. Visualization of query Q2

```
SELECT id, val(final(moving(pos)))
FROM carStream <Past 40 seconds>
GROUP BY id
HAVING
val(initial(mdirection(moving(pos))))
BETWEEN (3.14159265)/8 AND
(3.14159265*3)/8;
```

Visualization of query Q2 is illustrated in Fig. 6 presenting moving objects as continuously "moving" markers on the map.

V. CONCLUSIONS AND FUTURE WORK

In this paper we have presented OCEANUS Visualizer, an application for querying and visualizing streaming trajectories of moving objects. It is developed on the top of OCEANUS prototype engine for processing spatio-temporal data streams and is based on Java programming language and OpenStreetMap web service. Communication between application modules is accomplished through standard JDBC interface and singx-ws library for interaction with web services. Possibility to define continuous query directly using CSQL language enables posing wide range of spatio-temporal queries that include PostGIS operators and functions and operations on moving objects as well. Through query examples presented in the last section, we have illustrated advantages of defining continuous query condition by a simple mouse clicks and definitions of parameter values. With this approach, application is found appropriate for beginners and advanced users as well.

Focus of our future work will be improvement of existing and adding new functionalities. We will examine a possibility of adding new operations for defining conditions of continuous query that would enable users not familiar with CSQL to take advantage of operations on moving objects such as *atinstant*, *present*, *at*, *intersect*, *inside*, etc. Since specifying static spatial objects for query condition is not an easy task (user must know the exact coordinates of an object), our future work will also focus on specifying these objects interactively with the map. An open issue is also to find a possibility to express results of continuous queries that don't represent streaming trajectories, i.e. data streams whose elements except location of moving objects contain other information as well.

SPAM trends and techniques used on Exchange Online system used for racunarstvo.hr domain

Igor Pavleković[1] and Vjekoslav Gašparević [1]
[1]University College Algebra, Ilica 242, Zagreb, Croatia
[1] igor.pavlekovic@racunarstvo.hr

Abstract - This paper will give an overview of the technologies and techniques employed in SPAM protection on University College Algebra (UCA). UCA uses Exchange Online system included in Office 365 service that is free of charge for every educational institution covering majority of countries around the world. In today's world of electronic communication, e-mail is still primary system for exchanging messages and data. Globally, average mail user daily sends and receive around 115 e-mail messages and from that number around 19% or 13 of received e-mail messages are considered as SPAM. Exchange Online system is based on the Microsoft Exchange 2013 server and it is located in the multi-tenancy datacentres around the world, serving corporate, governmental and educational users. That system has built in anti-SPAM protection and reporting services that will be used for conducting results in this paper. Those results will be than compared with other publicly available researches to achieve comparison reports that is presented in this paper.

Keywords **– SPAM; Exchange Online; Office 365**

I. INTRODUCTION

SPAM [1] is defined as irrelevant or unsolicited messages sent over the Internet with the purpose of advertising, phishing, spreading malware etc.

Majority of world's SPAM messages are sent by using infected computers with worms or viruses, which are centrally controlled. Those kind of networks are called bot-nets or zombie-networks. History shows that when those kind of networks are turned off, volume of SPAM messages drops dramatically by 60% or more [2].

One of the primary task of messaging administration includes fighting SPAM messages. This job is not an easy one, because e-mail systems need to resolve messages that are SPAM and treat them by company rules and on other hand to resolve messages that aren't SPAM not blocking their normal delivery. Today's anti-spam systems use different techniques to achieve this goal. Some of them includes investigating originating e-mail's Internet Protocol (IP) address, sender's server and body and the content of the e-mail message itself.

A. Investigation of sender's IP adress

When e-mail message enters e-mail server, the server will do few checks on the sender server IP address. The first and most basic check is checking on IP allow and IP block list. Those lists are generated by messaging administrator by manually entering IP addresses of allowed of denied sender server IP addresses.

Next checks include checking on Real-time Black Lists (RBL) and Real-time White Lists (RWL). RBLs and RWLs are provided by third party providers to what anti-SPAM systems are subscribed to. They check, in real time whether an IP address is on that real-time list or not. One of the well-known and used provider of RBLs and RWLs is Spamhaus Project [3].

One more common check is Sender ID defined in RFC 4406 [4]. This check presumes that sender's domain has valid Sender Policy Framework (SPF) record in Domain Naming System (DNS) system stating IP addresses of the servers allowed to send e-mail for that domain. If the sender's server IP address is not stated on the list, recipient's server can discard that e-mail message or treat it as a SPAM message. This technique tries to stop phishing e-mail messages.

B. Analisys of the senders' servers characteristics

This usually includes more different tests that are done on the senders' servers. When the receiving server receives a message from the senders' server, it will do several checks to assess it.

Most common check is called open-relay test. It means that receiving server will do open-relay test to see if the senders' server will deliver open relay message or not [5].

Other checks include checking if the sending IP address has its corresponding DNS pointer (PTR) record and if that record matches the hostname stated in the HELO/EHLO part of the Simple Mail Transfer Protocol (SMTP) communication.

Based on servers' characteristics, e-mail messages can receive higher Spam Confidence Level (SCL) value, messages can be rejected, or even IP addresses of the servers can be put on the temporary block list – so called gray listing.

C. Analisys of the content

Last tests that are done on the e-mail message inspect content of it. This includes searching of the keywords, different Hyper Text Markup Language (HTML) elements

in the message, language of the messages, attachment names and extensions and similar tests.

Usually, there are definitions used by the anti-spam software provided by 3rd party vendors.

Depending on the content, message receives SCL value and based on the anti-spam policy, messages can be altered, rerouted, quarantined, rejected or even deleted.

II. ANTI-SPAM IN EXCHANGE ONLINE

Microsoft Exchange Online (EXO) uses Exchange Online Protection (EOP) service as its anti-malware and anti-spam solution. Even dough EOP is available as a standalone service, UCA uses it as a part of its MS Office 365 subscription with EXO services that are provided to all students, faculty and staff on racunarstvo.hr domain.

EOP uses all three anti-spam techniques described in Introduction, as well as anti-malware inspection of every e-mail message that enters or exits EXO.

As it is visible in Fig. 1. every e-mail message that comes to the EOP system in Microsoft datacenter is firstly filtered by connection policy. If the message fails to pass policy rules it will be rejected or deleted. After that

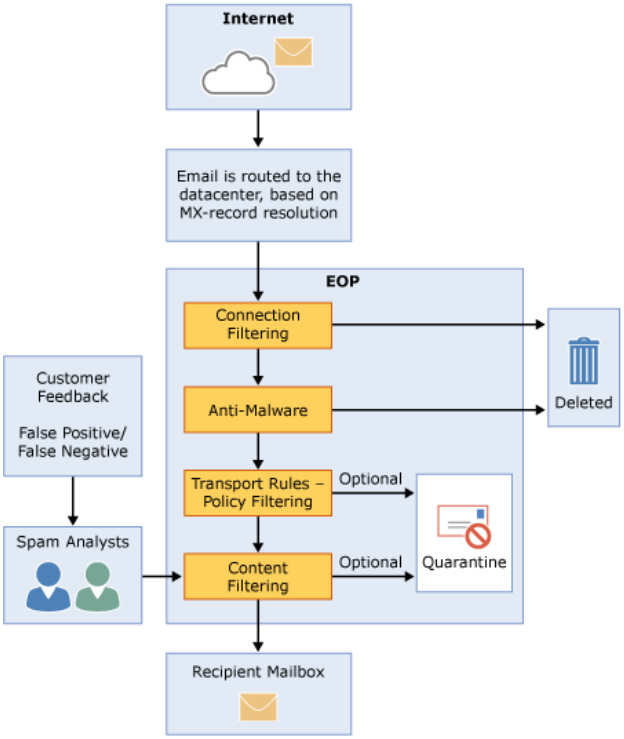

Figure 1. Diagram of inbound message flow through EOP system [6]

message passes through anti-malware filtering and policy. Also if the message fails to pass that settings, it will be deleted automatically. Third filter checks for policies that define content of the message in terms of subject text, body text, attachments or other relevant part of the message. This kind of filtering is called transport-rules filtering. Last filter that checks content of the message in terms of overall content, HTML elements and anti-spam definitions provided by EOP itself.

Interesting thing is how Microsoft builds anti-spam definitions. Majority of the other anti-spam vendors need to collect respectable amount of SPAM messages so they will be able to comply anti-spam definitions. They do that by opening so called honey-pots, ie. E-mail addresses that are subscribed to vast number of newsletters, porn sites and similar web sites and by that way they collect large number or SPAM messages. On the contrary, Microsoft uses their free e-mail service Outlook.com that enables them to rely on their customers classification of messages as if they are junk or not. Based on that, Microsoft will comply that information with the anit-spam definitions that are used in EOP and even in Microsoft Office Outlook product used as Personal Information Management (PIM) application.

III. EOP IMPLEMENTATION IN UNIVERSITY COLLEGE ALGEBRA

To avoid deletion of any e-mail message that could be detected as false-positive and eventually not delivering that message to the recipient's mailbox, UCA doesn't use any custom policy at all. This means that EOP configuration is default, without any custom policies. E-mail message will pass the system and the only place that the message can be deleted or rejected is by means of Connection Filtering component. Otherwise, e-mail message will go through the filtering rules and based on the SCL values set by Content Filter, message will be passed to the recipients Inbox folder where the user itself can choose to create rule to transfer message to the Junk folder or let MS Office Outlook handle message automatically.

By using this approach, every e-mail user is responsible for maintaining hygiene of their mailbox by using default setup or defining their own custom rules for managing messages with higher SCL values. As a best practice, messages with SCL values between 5 and 7 are most likely to be spam and those with values between 8 and 9 are definitely spam messages.

EOP services enables its customer receiving statistical data and reports for the period of last 60 days with detailed reporting for the last 7 days.

For this paper, statistical data was collected in two periods:

- first reporting period (FRP) – from Dec-12-13 to Feb-10-14
- second reporting period (SRP) – from Feb-11-14 to Apr-24-14

Data from FRP is as follows:

- total number of e-mail messages sent and received is 27,414 messages or in average 456.9 messages per day
- total number of received spam messages is 5,268 or in average 87.8 messages per day
- percentage of spam messages in total volume of received messages is 24.30%

Data from SRP is as follows:

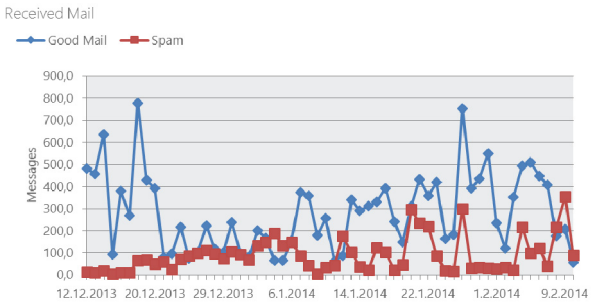

Figure 2. Report on daily distribution of received good and spam messages for FRP

- total number of e-mail messages sent and received is 53,517 or in average 891.95 messages per day
- total number of received spam messages is 22,998 or in average 383.3 messages per day
- percentage of spam messages in total volume of received messages is 42,97%

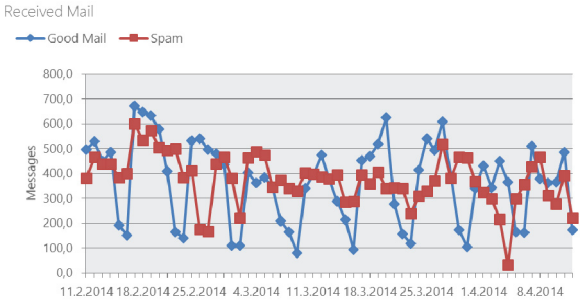

Figure 3. Report on daily distribution of received good and spam messages for SRP

When taken into consideration that "many Internet networks report the figure of spam messages greater than 90% and some as high as 96%" [7] it is obvious that UCA has much lower volume of SPAM messages than average computer network.

A. *First reporting period analisys*

In Figure 2, for FRP it is visible that number of SPAM messages vary from day to day. It can be concluded that only in two days, daily volume of SPAM messages was higher than non-SPAM messages. It was on January 4 and January 5 when it was weekend in Croatia. In addition, two dates are spiked with number of total number of received mail. First of them is December 18, 2013, but number of SPAM messages is not spiked, so it means that users received larger amount of messages, possibly as messages for the upcoming holydays. Second spike occurred on January 28, 2014 when there was intense communication between teachers and supporting staff for preparing upcoming semester in UCA.

In further analysis of the received SPAM messages for the same reporting period, it is visible that:

- 91.66 % of all spam messages is filtered based on IP receive blocking mechanism like RBL
- 0.01% of all spam messages are filtered based on SMTP communication analysis
- 8.31% of all spam messages are marked as spam messages by assigning them SCL value of 8 or 9

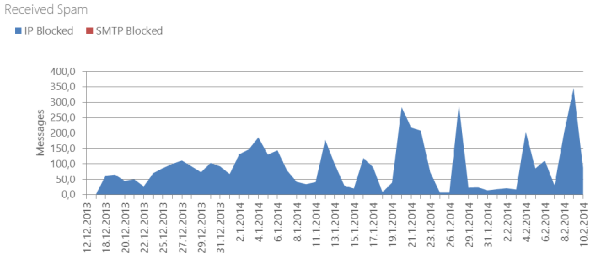

Figure 4. Report on dailiy distribution of spam messages filtered by Connection Filtering system for FRP

B. *Second reporting period analisys*

Figure 3. for SRP shows different e-mail distribution that it was in FRP. In this period is can be differentiated when there is weekend as volume of good e-mail messages drops. There are also many more periods in which number of SPAM messages is higher than good e-mail messages. Also, it is visible, that number of SPAM messages is relatively steady during whole reporting period, with only one drastic drop on Apr-4-14.

Detailed analysis shows following:

- 96,4% of all spam messages is filtered based on IP receive blocking mechanism like RBL
- 3,60% of all spam messages are marked as spam messages by assigning them SCL value of 8 or 9

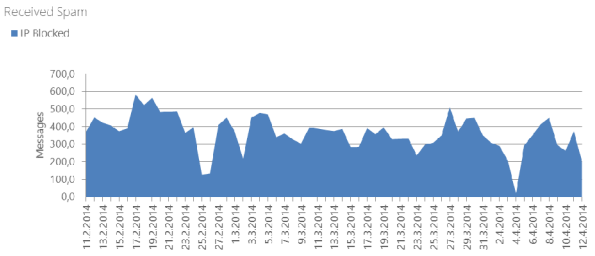

Figure 5. Report on dailiy distribution of spam messages filtered by Connection Filtering system for SRP

IV. CONCLUSION

By comparing global statistics and data about spam messages in global e-mail systems, volume of spam messages in UCA e-mail system is at least 65% lower than in global systems. In addition, after crunching

numbers from available reports, it is visible that only every fifth message that enters system is spam message in FRP, but in SRP every 2nd message is marked as spam. In average 94.05% of the rest spam messages will be filtered and deleted or rejected, and only 5.95% of spam messages will be delivered to the users' mailboxes. This means that in received 1000 e-mail messages to the system, only 59 of them will end up in users' mailboxes.

When taking into consideration that UCA has around 450 mailboxes and average daily number of received messages is 674 for the both reported period, this means that mailboxes will daily receive 14 spam messages, or this means that around 3% of all recipients on domain racunarstvo.hr will have one spam message delivered to their mailbox daily.

In addition, it is imperative to stress out that those messages delivered to the users' mailbox will have SCL value 8 or 9 and the users' PIM application, like Microsoft Outlook will treat that message as a spam and will move them to the Junk folder automatically. Of course, user itself can change this behavior by turning off that functionality so users will control all inbound messages that are not filtered by EOP, by users themselves.

By analyzing report on Figure 3. it is visible that number of SPAM messages vary from day to day. This depends on the global SPAM activity and supporting bot-nets that are active on the internet and that are used for sending SPAM messages. Based on that information, one can conclude, that during FRP period Jan-29-2014 until Feb-3-2014 some global bot-network was taken offline and that is the reason for much lower SPAM activity during that period.

However, it is importing to stress that during two reporting periods mentioned here, average volume of e-mail messages, either legitimate or spam varies. It is visible that during SRP daily e-mail volume almost doubled than in FRP. It can be concluded that during FRP there was less e-mail activity as UCA had winter holidays and there were no classes. Never the less, it is visible that number of spam messages quadrupled in SRP meaning that global spam activity increased, but EOP itself has blocked 5% more messages based on IP receiving mechanism, and number of messages that got to the users' Inbox was decreased by 5%. This means that IP blocking mechanism got better. Microsoft didn't announce any change in the configuration of EOP that could justify that change.

An Approach using Simulation Techniques to estimate Quality of Service Parameters in Communication Networks

Hrvoje Kozačinski*, Petar Knežević *
* Faculty of Electrical Engineering and Computing/Department of Fundamentals of Electrical Engineering and Measurements, Zagreb, Croatia
hrvoje.kozacinski@fer.hr

Quality of Service in communication networks is a request for minimal required performance needed for transferring IP packets in a network. The performance can be ensured with a set of mechanisms that guarantee required performance through shaping and policing of packet traffic. Their goal is to prevent congestion, packet delays and packet loss. The goal of this paper is to introduce some of the commonly used Quality of Service mechanisms and analyze their impact on network traffic in order to improve its performance, mainly packet delay and buffer congestion. The mechanisms are analyzed trough a simple packet transfer simulator that offers different combinations of mechanisms to be used in the simulation, allowing different packet transfer scenario setups. After a simulation is complete, the simulator offers results along with relevant packet transfer graphs. The impact of Quality of Service mechanisms is analyzed and interpreted trough those results. It is shown that combining Quality of Service mechanisms in packet transfer generally gives better results. Also, different combinations of mechanisms give different results, allowing more flexibility in improving packet transfer in a desired way, but also making it more predictable and controllable.

I. INTRODUCTION

Basic elements of a computer network include hardware, software and protocols. The interrelationship of these elements constitutes the infrastructure of the network. A network infrastructure is the topology in which the nodes of a network are connected to each other. Connections involve routers, switches, bridges and hubs connected by cables or wireless technologies.

Because of the way the communication networks are built, with many possible transfer routes and with possibility that some routes can be congested or slower than others, IP packets travelling through the network can arrive too late, with errors, in wrong order or be discarded during transfer. This causes transfer errors and degradation of transfer performance.

Quality of Service (QoS) is a set of requirements that guarantee certain performance in packet transfer. A good implementation of QoS usually minimizes packet delay and reduces the number of discarded packets. To ensure such performance, QoS has a set of mechanisms that help regulate the transfer, so that the desired performance requirements are met [1].

There are different approaches to solving inadequate transfer performance, mainly by introducing different QoS mechanisms to communication networks [2, 3, 4]. Also, different approaches and recommendations are given through a number of RFCs, regarding guaranteed QoS [5], defining a information model for QoS network managing policies [6], QoS Mechanism Selection [7] and others [8, 9]. All of these approaches help reduce packet delay and packet loss. The problem this paper analyzes through a simple network simulator is how exactly QoS mechanisms impact a communication network performance in attempt to improve packet transfer, primarily by reducing packet delays and packet loss associated with the buffer mechanism.

II. QUALITY OF SERVICE MECHANISMS

Some of the main QoS mechanisms that are used in communication networks will be explained in this paragraph, along with their desired effects and shortcomings.

Retransmission: resends packets lost in transmission, thus preventing loss of information. It helps with acquiring complete information, but with a cost - increased transfer time and packet delay.

Buffer: container used to temporarily store packets that cannot be processed immediately upon arrival, preventing retransmission to cause bigger time delay and unneeded bandwidth usage. However, increasing the buffer size also extends packet delay, unless other mechanisms are applied [10].

Buffer collecting strategies: various ways of collecting packets from the buffer, involving various criteria like order of arrival, packet priority, etc. Different approaches try to improve on different aspects of QoS. For instance, round robin buffer collecting strategy is used to even buffer delay times of packets in the buffer.

Packet priority: classifies packets by their importance - important packets get higher priority and will be processed first. This helps reducing packet loss and delays of packets with higher priority, but by increasing packet delay of lower priority packets [11].

Policing mechanisms: mechanisms used to discard packets from the buffer to prevent its congestion, allowing newer packets to enter the buffer in favour of discarded packets. The most common policing mechanisms are RED (Random Early Detection; also Discard or Drop)[12] and WRED (Weighted RED, uses packet priority in deciding which packets to discard). If the priority mechanism is used, WRED can discard less significant packets to prevent congestion and allow future higher priority packets to be received [3, 13].

Shaping mechanisms: mechanisms used to shape the sending flow of packets to prevent buffer congestion, packet drop and retransmission, avoiding unnecessary bandwidth usage, possible congestion and packet delays. The most common are the Token Bucket and Leaky Bucket algorithms [14, 15].

III. THE SIMULATOR OF QUALITY OF SERVICE MECHANISMS

In order to better study the impact of different QoS mechanisms on a communication network, a network simulator was developed. Its function is to simulate a simple TCP packet transfer between two network nodes, in a dumbbell topology, with different QoS mechanisms involved and track buffer capacity, packet loss and packet time delay. The mechanisms implemented in the simulator are: retransmission, buffer, buffer collecting strategies (first packet in the buffer or round robin), packet priority with 3 priorities (0-2, 0 being the highest) and the Token Bucket algorithm.

The simulator in its essence is a multithreaded Java application, in which the sender thread generates packets and sends them to the buffer, while the receiver thread collects packets from the buffer. There is also a third thread that collects relevant transfer data. Packet generation is a simple, best effort solution, packet length is fixed and packet priority is generated randomly.

The simulator is controlled through the main screen. The user can set up the desired simulation parameters (buffer size, number of packets generated, sender and receiver speed - slowdown in milliseconds) and choose the desired QoS mechanisms, with the exception of retransmission, as it cannot be disabled.

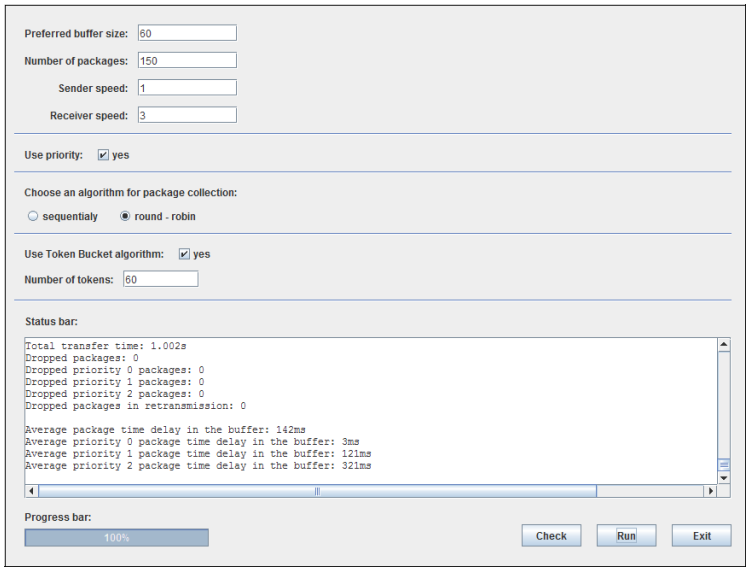

Figure 1. Main simulator screen after a completed simulation

TABLE I. SIMULATION SCENARIOS AND MECHANISMS USED

Scenarios	Priority	Buffer collecting	Token bucket
Scenario 1	No	First available	No
Scenario 2	Yes	First available	Yes
Scenario 3	No	Round robin	No
Scenario 4	Yes	Round robin	Yes

After the simulation is completed, three graphs are generated: two packet transfer delay graphs (with and without marked priorities) that show the time delay of each packet in the buffer and a buffer capacity graph that shows how the buffer capacity changed during the transfer. The simulator also generates log files and displays relevant transfer data: total transfer time, number of discarded packets (total and divided by priorities), number of packets discarded in retransmission and average packet time delay inside the buffer (total and divided by priorities). An example of a finished simulation is shown in Figure 1.

There have been a lot of different studies of QoS mechanisms where a simulation approach was used, but they were mostly used in specific areas like Composite Web Services [16], VoIP [17], Video Traffic [18], Mobile Ad Hoc Networks [19], UMTS Terrestrial Radio Access Networks [20] or evaluating complex systems [21]. Also, there are discrete event simulators targeted at networking research. One example is the ns-2 simulator [22]. The simulator of this paper is constructed to implement only the needed components and its deliberate simplification allows better emphasis and clearer study on how the buffer handles incoming packets with different QoS mechanisms involved and how do those mechanisms impact packet delay and congestion in the buffer.

There is also a matter of packet generation. While using Poisson distribution for packet generation [23] provides a more realistic simulation, it was not necessary for the analysis of observed QoS mechanisms and their impact on buffer capacity and packet time delay.

The impact on packet transfer will be observed and measured in four transfer scenarios. In every scenario, the basic transfer parameters will remain constant:

- Buffer size: 60
- Packets to send: 140
- Sender speed: 1
- Receiver speed: 3
- Tokens: 60 (maximum number of tokens for the Token Bucket algorithm)

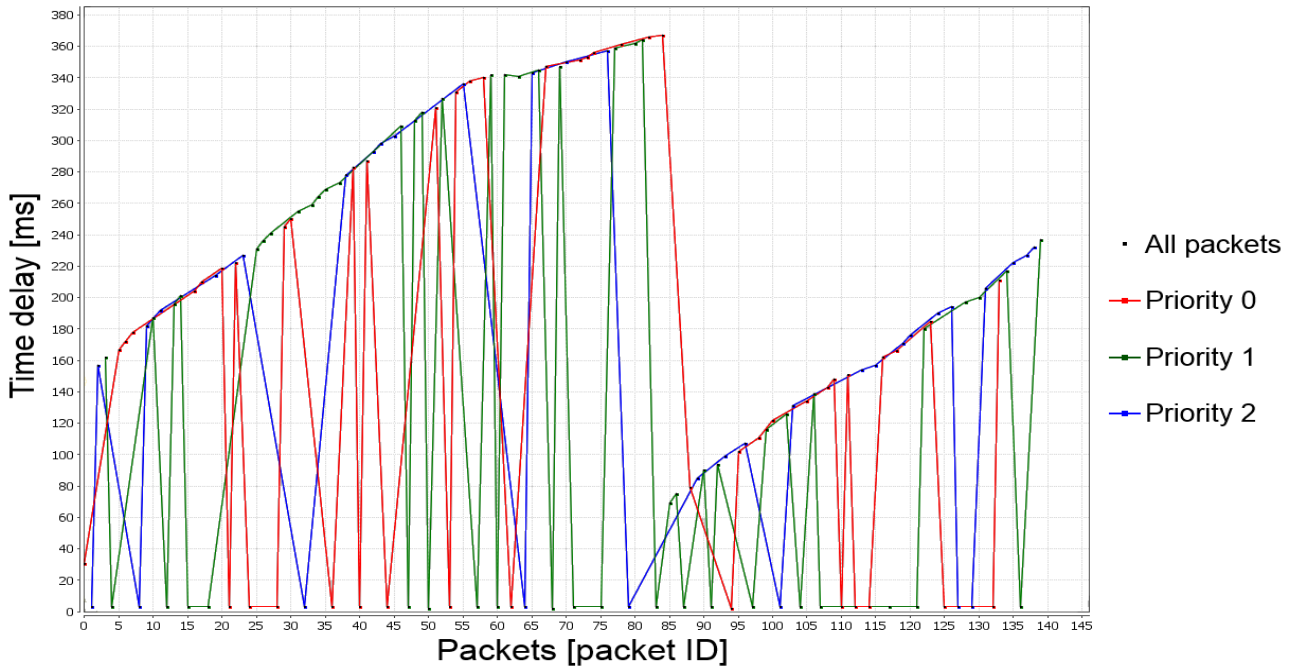

Figure 2. Packet delay during transfer graph, scenario 1 (no mechanisms, basic collecting)

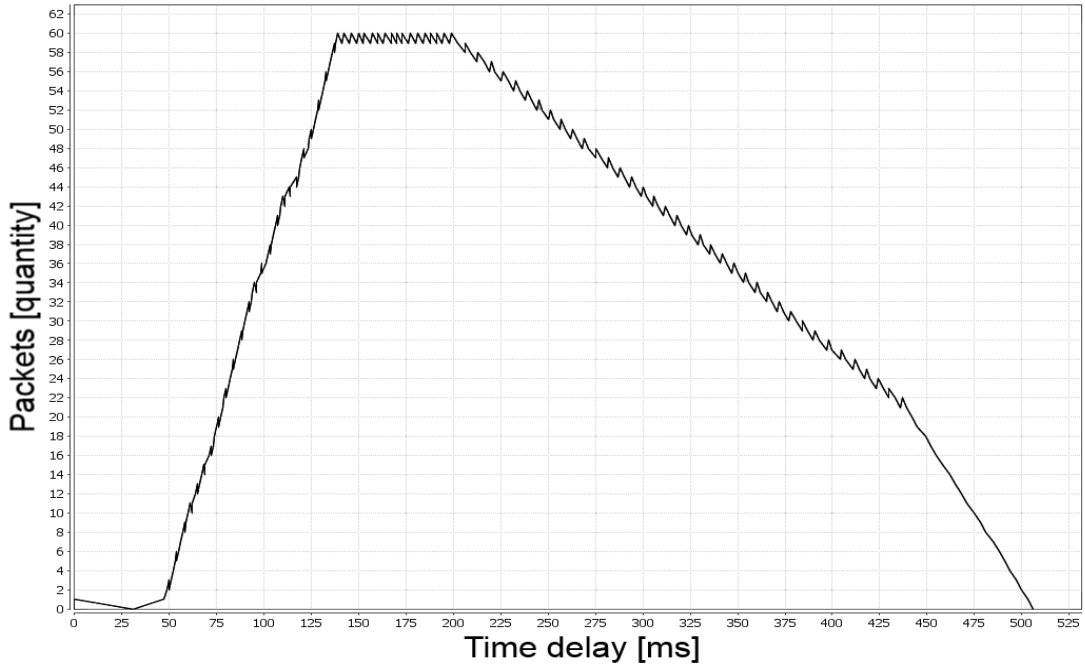

Figure 3. Buffer capacity during transfer graph, scenario 1 (no mechanisms, basic collecting)

Each scenario was run 25 times and average values are presented. This was necessary to reduce measuring errors, because the simulation was run on a personal computer which contained other running processes.

IV. SIMULATION SCENARIOS

The simulation is divided in four different scenarios, depending on the combination of QoS mechanisms used, as seen in Table 1. All scenarios use retransmission and the buffer mechanism with one of the buffer collecting strategies. Optional mechanisms are packet priority, buffer collecting strategy and the token bucket algorithm. Each scenario will be explained in more detail, along with its results, through one typical simulation of each scenario.

A. Scenario 1 - no mechanisms, basic collecting

The first scenario uses only the unavoidable mechanisms (retransmission and buffer) along with the buffer collecting strategy that collects the first available packet in the buffer.

Delays of packets can be seen on Figure 2. The graph marks different packet priorities with different colours, but because the priority mechanism isn't activated, packet priority has no effect on delay times. There are three

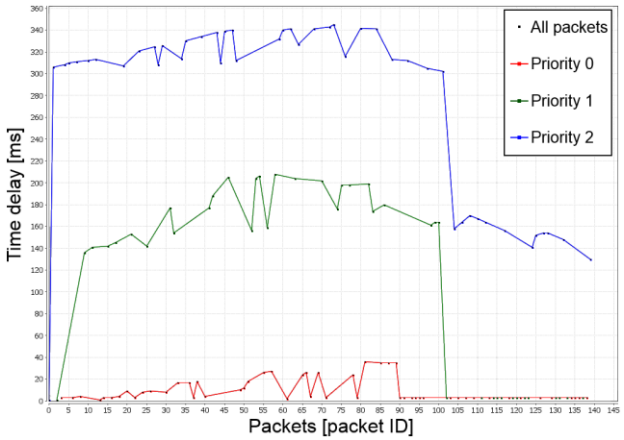

Figure 4. Packet delay during transfer graph, scenario 2 - all mechanisms, basic collecting

distinct lines on the graph, one horizontal line and two lines with linear growth. The horizontal line is caused by the buffer collecting strategy, which collects the first packet in the buffer it comes across, resulting in low time delays. The first linear growth is caused by the delay packets have while waiting in the buffer. The second linear growth is the result of retransmission that started after approximately 85 packets were sent and the buffer was congested. The retransmission time delay appears smaller, but it is in fact larger. This graph shows only time delays of packets while waiting in the buffer. Packets that went into retransmission were sent, rejected, retransmitted again and then waited in the buffer, so their total time delay is larger than that of the packets that immediately went into the buffer.

Another relevant graph is the buffer capacity graph, shown in Figure 3. The buffer capacity was exponentially filled to the point of congestion, at approximately 135 ms. After that, surplus packets were discarded and sent into retransmission. At that point, the receiver collected packets, but the sender filled the empty buffer spot quickly, as is shown on the graph with the horizontal line spanning to 200 ms in transfer. After that the drop in sending rate because of the slow retransmission rate that helped lower the buffer capacity, until all packets were collected from the buffer.

The total transfer time was 507 ms, total of 38 packets were dropped in transfer (12 priority 0, 12 priority 1 and 14 priority 2). Average packet time delay is 161 ms (164 ms priority 0, 154 ms priority 1 and 168 ms priority 2). The results clearly show that without a priority mechanism all packets are treated equally. This is the basic scenario on which all others will try and improve.

B. Scenario 2 - all mechanisms, basic collecting

This scenario adds the priority mechanism to scenario 1, to observe and measure its effects on packet transfer, seen on Figure 4. Packets are clearly distinguished by their priority: priority 0 has the lowest time delay, followed by priority 1 and priority 2 with the biggest time delay.

This scenario also introduces the Token Bucket algorithm. The idea behind the algorithm is to control the rate at which packets are sent. The algorithm periodically fills a container (bucket) with tokens, up to a set capacity. A packet can only be sent if there are sufficient tokens in the bucket to "pay" for sending. At first, with enough tokens at the beginning of transfer, packets can be sent in a large burst, until the container has no more tokens. After that, the periodical appearance of tokens controls the send rate. This helps buffer congestion, reduces the need for retransmission and because of that also reduces packet drop rates and delay times [14].

The total transfer time was 446 ms and no packets were dropped in transfer. Average packet time delay is 127 ms (9 ms priority 0, 115 ms priority 1 and 272 ms priority 2). In this case, combining both mechanisms really paid off, especially when observing the priority 0 delay times. The time delay drop at the end of the graph is the result of the Token Bucket algorithm that reduced the send rate once it ran out of tokens. The shaping mechanism helped with packet drops, but this is an idealized example, where the algorithms tokens are refilled at the same rate the receiver can receive a packet. In a real life situation, the algorithm would require a careful parameter calibration to get as close to the idealized example as possible. Higher sending rate would cause packet drops and lower rate would cause bigger packet time delay.

The buffer capacity graph (Figure 5) looks similar to the graph in scenario 1, only the horizontal line where the sender and the receiver compete while the buffer is at full

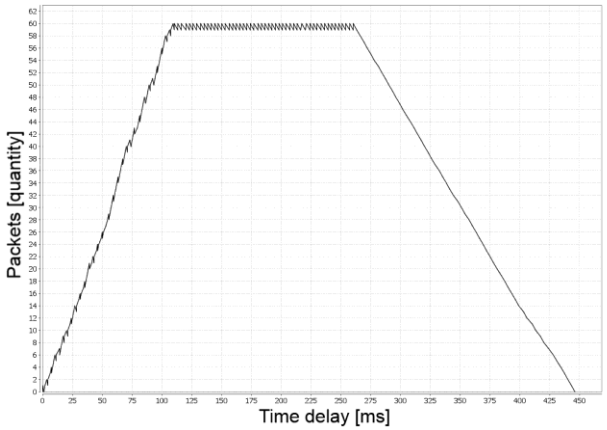

Figure 5. Buffer capacity during transfer graph, scenario 2 - all mechanisms, basic collecting

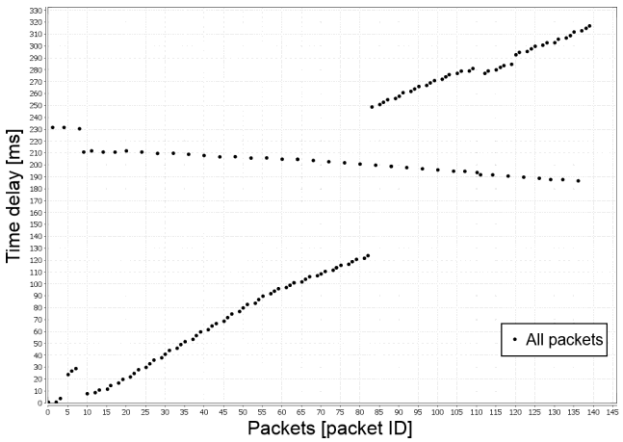

Figure 6. Packet delay during transfer graph, scenario 3 - no mechanisms, round robin

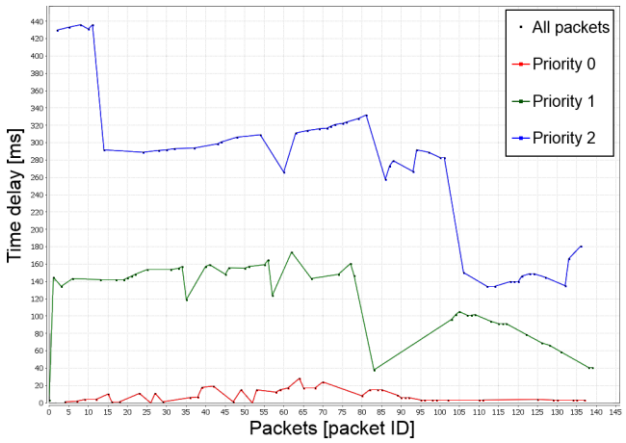

Figure 7. Packet delay during transfer graph, scenario 4 - all mechanisms, round robin

capacity lasts longer and ends with a smooth linear drop.

C. *Scenario 3 - no mechanisms, round robin*

In this and the following scenario, the buffer collecting strategy is changed. Packets will be collected using the round robin strategy. This scenario has no additional mechanisms. The effect this collecting strategy has on packet transfer can be seen in Figure 6.

The idea of the round robin collecting strategy is to improve the basic collecting strategy. Because of the way packets are collected, this strategy evens time delays across all packets that enter the buffer. In the graph this is shown as a horizontal line in the middle. Two linear growths appear because the sender is filling the buffer faster than the receiver can collect packets and because of inevitable retransmission once the buffer is congested.

The total transfer time was 486 ms, total of 41 packets were dropped in transfer (19 priority 0, 12 priority 1 and 10 priority 2). Average packet time delay is 166 ms (182 ms priority 0, 157 ms priority 1 and 158 ms priority 2).

The buffer capacity graph is similar to the same graph in scenario 1.

D. *Scenario 4 - all mechanisms, round robin*

In this scenario both the priority mechanism and the shaping mechanism are combined with the round robin buffer collection strategy. The effect this has on packet transfer is visible on Figure 7.

The total transfer time was 450 ms and no packets were dropped in transfer. Average packet time delay is 133 ms (8 ms priority 0, 120 ms priority 1 and 270 ms priority 2). In this case, combining both mechanisms also paid off, like in scenario 2, especially when observing the priority 0 delay times. The time delay drop at the end of the graph is the result of the Token Bucket algorithm that reduced the send rate once it ran out of tokens.

The buffer capacity graph is similar to the one in scenario 2.

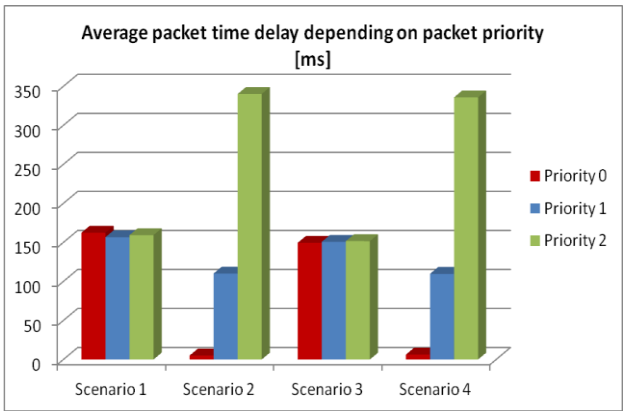

Figure 8. Average packet time delay depending on packet priority

V. SIMULATION RESULTS

After all the scenarios were run 25 times, average values of observed parameters were calculated. The most interesting parameters to analyze are average packet time delays depending on packet priority, given in Figure 8, and the average transfer times, given in Figure 9.

If average transfer times are observed, the conclusion is that scenario 3 (no priority, round robin, no Token Bucket) has the lowest transfer time of 469.72 ms. The highest transfer time can be seen in scenario 4 (round robin, priority, Token Bucket) with 575.8 ms, followed closely by scenario 2 (575.24 ms). The conclusion that can be drawn from this figure is that if lowest possible transfer time is desired in a communication network, in this case, only a buffer and the round robin collecting strategy will suffice.

On the other hand, if average packet time delay depending on packet priority is observed for each scenario, there are two distinct patterns. The even columns of scenarios 1 and 3 are the result of the scenarios not having the priority mechanism, and are not relevant for this observation. Other two scenarios have more interesting results. The lowest time delay for priority 0 can be seen in scenario 2 (5.04 ms), with scenario 4 close by (6.32 ms). They also have the lowest time delay of priority 1 packets (110.16 ms and 109.72 ms respectively). However, their delay times of priority 2 packets is substantially (more than two times) higher than in scenarios 1 and 3.

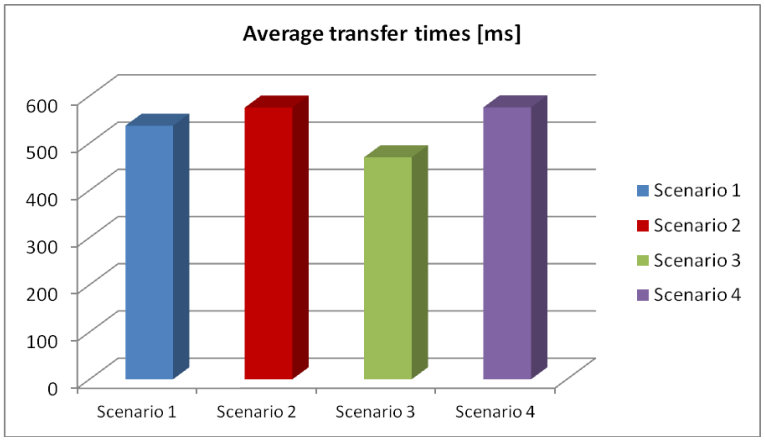

Figure 9. Average transfer times for all scenarios

For best priority 0 and 1 packet time delay, the priority mechanism should be used along with the Token Bucket algorithm, regardless of the buffer collecting strategy. Round robin strategy does give a bit higher priority 0 delay, but has better delays for other priorities, which can also be relevant, depending on the situation.

VI. CONCLUSION

This paper deals with IP packet delay, the impact it has on communication networks and how it can be reduced to improve Quality of Service, with the buffer as the main observation point. A simulator was developed to further study the impact each of the mechanisms has on buffer packet delays and buffer congestion, alone or combined with other mechanisms. The results show that a clear solution to QoS in communication networks does not exist. Instead, the solution greatly depends on the network itself and the individual needs for that particular network. The results have also shown that different combinations of QoS mechanisms improve network traffic in different ways. If there is a need for fast packet transfer, regardless of packet priority, the round robin buffer collection strategy can prove sufficient. If, on the other hand, packets have different priorities or some are more sensitive to delays than others, priority mechanism should be used combined with the Token Bucket shaping mechanism.

Other previously mentioned studies also show that network traffic improves with the introduction of QoS mechanisms. Again, their conclusions are drawn from simulations of specific, complex systems, with real life application, while simulation in this paper was deliberately simplified to emphasize how QoS mechanisms affect packet delay and buffer congestion.

Although an ultimate solution does not exist, a careful selection of mechanisms can provide a good solution, because using the QoS mechanisms makes packet transfer more clear, more predictable and more manageable, eliminating or lessening the undesirable effects in network transfer. This also allows declaring minimal performance guarantees necessary when establishing QoS in a communication network[1, 24, 25]. As a next step, the simulator will implement more advanced QoS mechanisms and will be improved to support larger traffic flows and allow flow customization to further study the impact of QoS mechanisms on different traffic flows.

Mobile data Wi-Fi offloading

[1]Martin Sraga,[1]Norman Momčilović, [1]Alberto Tekovic
[1]University College Algebra, Ilica 242,10 000 Zagreb, Croatia
norman.momcilovic@racunarstvo.hr

Abstract - The predicted exponential growth of mobile data traffic demands suitable solutions for coping with the high amount of data. Increasing number of Wi-Fi enabled smartphones and Wi-Fi access becoming more widely available is opening the possibility of offloading a large chunk of data traffic from 3G/ 4G mobile networks to Wi-Fi IEEE 802.11. However, the quality of experience must be preserved no matter which network layer is currently engaged. Therefore, the scope of this paper was to determine the usability of the free of charge Wi-Fi available networks and to compare it with the legacy 3G\4G networks.

I. INTRODUCTION

This paper refers to the survey conducted on December 2013 in the city of Zagreb capital of Croatia mainly focusing on the center of the capital.

The goal of the survey was to determine the current performance of available Wi-Fi and 3G\ 4G networks, used by the typical user in the busy hour.

It is expected that the mobile data traffic will reach the following milestones within the next five years [1].

- By 2018, over half of all devices connected to the mobile network will be "smart" devices.
- Over two-thirds of the world's mobile data traffic will be video by 2018.
- The average smartphone will generate 2.7 GB of traffic per month by 2018, a 5-fold increase over the 2013 average of 529 MB per month.
- By 2018, 4G will be 15 percent of connections, but 51 percent of total traffic.
- By 2018, more than half of all traffic from mobile-connected devices (almost 17 exabytes) will be offloaded to the fixed network by means of Wi-Fi devices and femtocells each month.

From the milestones cited above, it is clear that existing 3G and 4G network won't be able to handle the expected traffic load. Beside few other proposed offload techniques, Wi-Fi offload is currently one of the most promising strategies.

II. WI-FI & 3G TECHOLOGY

A. 3G\4G and Wi-Fi

Wi-Fi and 3G\ 4G are both types of wireless data networks, providing high-speed Internet service for laptops, desktop PCs, smartphones and tablets. Although Wi-Fi enjoys an advantage in terms of raw speed, a 3G connection offers greater mobility; devices get a service across a much wider area. Many mobile devices can access either kind of network automatically, depending on which has the stronger signal. But it should be noted that in order to access WLAN network, one has to manual connect to it. In a future scenario it will be possible to automatically connect to the WLAN with the authentication being resolved via the SIM card [2].

3GPP Release 8 introduces a client-server based protocol, Dual Stack Mobile IP (DSMIP), to enable seamless handover between 3G and Wi-Fi. DSMIP is a mobility protocol specified in IETF that provides IP address preservation for IPv4 and IPv6 sessions, allowing the user to roam independently in IPv4 and IPv6 accesses.

The solution does not require any support from WLAN accesses. If the cellular radio access network supports a Home Agent (HA), the only new requirement is that the UE (i.e., client) and the Home Agent (i.e., server) are dual-stack capable [3].

Although the described Wi-Fi offload solution doesn't require any support from WLAN accesses, that doesn't mean that there is no ongoing work on the IEEE side. The standardization bodies for the next generation Wi-Fi (802.11ac) has taken into account increased Internet usage, smartphones, portable and smart TV devices, offload from 3GPP networks, and the fact that video is still growing [4].

B. Range

As user moves farther from a wireless network's antenna, the signal strength fades, limiting ability to get a connection, and its maximum possible speed. Wi-Fi ranges vary from 45 meters for the oldest versions to 70 meters for 802.11n [1]. A single Wi-Fi access point is sufficient for a coffee shop, but larger organizations need multiple access points. 3G covers a much wider area; service providers already have multiple cell towers servicing cities, towns and major highways.

C. Transfer data

The download speed of a Wi-Fi connection varies depending on the type of Internet connection that the Wi-Fi access point is connected to. Download speeds can be as low as 1 megabit per second (Mbps) or as high as 5 to 8 mbps or more. With 3G Internet service, download speeds can vary between 1 Mbps at the cell border, up to 25 Mbps in case of dual carrier capable terminal and network and a good radio conditions. The average upload speed on a 3G connection is approximately 1.5 Mbps, depending on signal strength and network congestion. The 4G speeds are even greater. Typically, a Wi-Fi connection will have upload speeds ranging from approximately 300 to 600 kbps [5].

III. MEASUREMENT METHODOLOGY

In order to evaluate achievable performance on currently available 3G and Wi-Fi networks in the city

center, three main KPI's were measured: FTP download throughput (Mbps), FTP upload throughput (Mbps) and PING (ms).

Measurements were conducted by the usage of a regular commercial smartphone Samsung Galaxy S3 that was downloading the information via the VIP server.The radio network parameters were acquired using measurement application NEMO Handy. Speedtest application has been used to acquire KPI data. Measurement has been conducted in the city of Zagreb, on nine different micro locations. On every measurement spot, thirty minutes test has been performed. Fifteen minutes for 3G\ 4G, and fifteen minutes for Wi-Fi. The final result for each location was taken from the average of conducted ten test samples per technology.

Figure 1 Measurement locations

IV. RESULTS OF THE SURVEY

The accumulated data from the results of the survey can be found below represented graphically

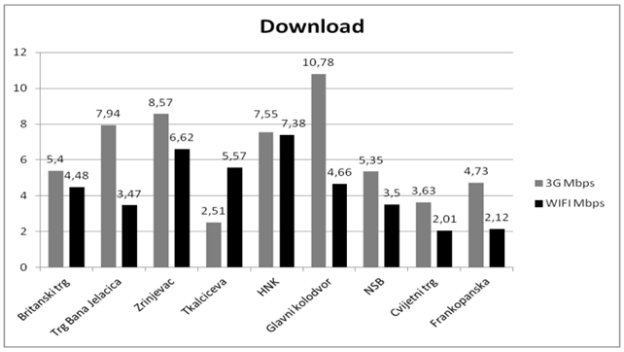

Figure 2 FTP download test

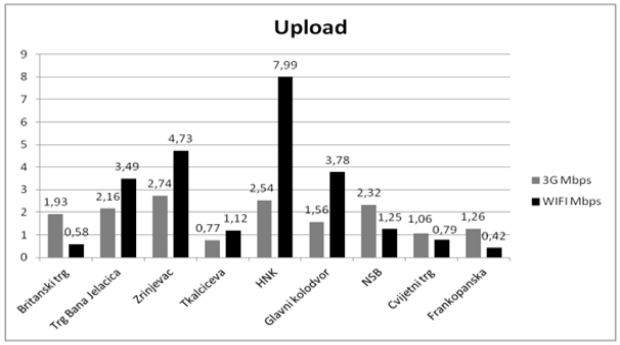

Figure 3 FTP upload test

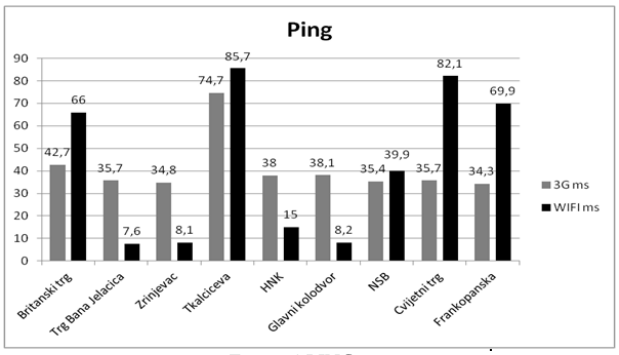

Figure 4 PING test

From the presented graphs it can be concluded that there is a good quality Wi-Fi network currently availability for the regular consumer as a free of charge alternative to 3G\ 4G network. In the city center there are enough open Wi-Fi locations to accommodate the basic needs: reading, sending emails and internet browsing. Average download throughput of 4-5 Mbps is currently enough to partake in those kinds of activities without experiencing any noticeable problems. 3G\ 4G technology provides a good quality of service through the whole city.

V. CONCLUSION

In the center of Zagreb city both network types have a good quality of service and they fulfill the average needs of a wireless internet user, but still 3G\4G networks performs slightly better keeping in mind that may be due to Wi-Fi measurements being performed outdoors while the access points are located indoors and for that reason may have slightly worse results. Taking into account that the two networks are still not "communicating" with each other, it is required to reconnect from one to the other, which from the user perspective can be found annoying. Therefore, it seems that the planned 3G\ 4G and WLAN integration will be really appreciated from the users, since it will enable automatically camping on the best network. That can be accomplished by using the 802.11f standard if all the providers deal with the handover in the same manner that implies not modifying the standard to their needs but following it.

ACKNOWLEDGMENT

We would like to thank Professor Alberto Teković for giving us the opportunity to make this paper and the device required to complete it.

Testing optical splitters

Ivan Žuti [1], Aleksandar Komparić [1]
[1] University College Algebra, Ilica 242, 10 000 Zagreb, Croatia
izuti@racunarstvo.hr

Abstract – This paper gives an overview of bidirectional optical splitter characteristics. It outlines the basics of passive optical network infrastructure, describes the most common attenuation mechanisms in optical fibers and the testing methodology for measuring optical splitter performance. The paper compares two types of Planar Light wave Circuit (PLC) splitters and provides measurement results for samples of both.

I. INTRODUCTION

Single mode optical fiber is now the transport medium of choice in metropolitan and long-haul passive optical networks (PONs). Fiber optic cables are becoming common even in the last mile – the segment of the network that extends from the central office to the subscriber. In order for the subscribers to share the total available bandwidth, a splitter is commonly used. The splitter is a bidirectional branching device that has one input port and multiple output ports, 1xN [2]. The input optical signal is divided among the output ports. Splitters are passive devices because they require no external energy source other than the incident light beam. Depending on network topology, there may be one splitter or several cascaded splitters. ITU-T recommendation G.983 allows split ratios of up to 32, while Recommendation G.984 allows split ratios of up to 64 splits. The splitter must accommodate the allowed optical budget, regardless of topology [1].

Splitters can be packaged in different shapes and sizes, depending on the basic technology used. The most common type is a planar waveguide (Fig. 1), typically used for high split ratios, and fused biconic taper, usually used for low split counts. As a result, the planar waveguide splitters are more commonly used.

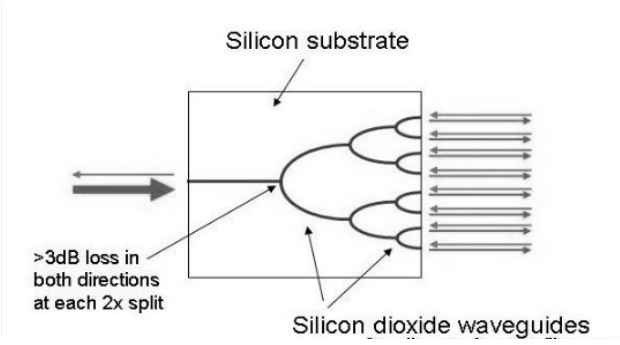

Figure 1 Planar light wave circuit diagram [7]

Planar Light wave Circuit (PLC) is based on semiconductor chip fabrication technology and is cost effective at large splitting ratios. However, since it is not fiber based it suffers from problems with fiber connectivity and can suffer from polarization effects due to its design. Because splitters account for the majority of signal loss in an optical network, they must be thoroughly tested to minimize that loss [2].

Fused Biconic Taper (FBT) is a type of splitter formed by two independent optical fibers. It works as a result of an energy transfer caused by the coupling proximity between optical fiber cores. Using two separate fibers will always result in a 2x2 coupler. To obtain a 1x2 coupler, one of the input fibers must be cut and terminated to avoid back-reflections from that end [6].

II. PASSIVE OPTICAL NETWORK ARCHITECTURE

Passive optical network (PON) is a telecommunications network that uses point-to-multipoint fiber to the premises in which unpowered optical splitters are used to enable a single optical fiber to serve multiple premises. A PON consists of an optical line terminal (OLT) at the service provider's central office and a number of optical network units (ONUs) near end users [2] as shown in Figure 2.

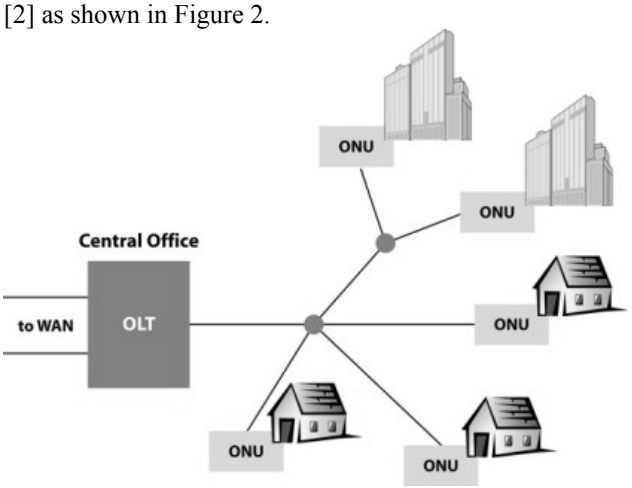

Figure 2 PON example [9]

PON reduces the amount of fiber and central office equipment required compared with point-to-point architectures. A passive optical network is a form of fiber-optic access network. In most cases, downstream signals are broadcast to all premises sharing multiple fibers. Encryption can prevent eavesdropping. Upstream signals are combined using a multiple access protocol, usually time division multiple access (TDMA) [2].

Optical network starts at the headend, where the public-switched telephone network and Internet services are interfaced with the optical distribution network via the optical line terminal. They, along with a TV signal, are converted into an optical signal and sent by the optical line terminal. That means that the same optical fiber simultaneously carries different information in different directions. This feeder fiber cable then connects to a splitter which splits the signal depending on the network design [1].

The signal can be split again as long as the network remains within the allowed optical budget. Each splitter compounds the signal loss and with it, the bandwidth that is available to the subscriber is lesser. The signal then arrives to the subscribers endpoint device, be it an optical network unit which can host a number of subscribers, or an optical network terminal which serves a single subscriber. That device then transforms the optical signal into electronics in order to present the delivered content on its respective devices [1].

Fiber optic cable installation is one of the most costly elements in network deployment, and depends on numerous factors, such as whether the fiber is installed in new premises or in an existing development over active routes. There are several cable installation methods used, the most common being direct burial, in which the cable is placed underground, duct installation, which is more expensive but allows for easy maintenance later, and aerial installation, in which the cable is typically installed on poles or towers [2].

III. FIBER OPTIC ATTENUATION

Attenuation in fiber optics, also known as transmission loss, is the reduction in intensity of the light beam (or signal) with respect to distance travelled through a transmission medium. Attenuation coefficients in fiber optics usually use units of dB/km through the medium due to the relatively high quality of transparency of modern optical transmission media. The medium is typically a fiber of silica glass that confines the incident light beam to the inside. Attenuation is an important factor limiting the transmission of a digital signal across large distances. Thus, much research has gone into both limiting the attenuation and maximizing the amplification of the optical signal. Empirical research has shown that attenuation in optical fiber is caused primarily by both scattering and absorption [5]. This leads to the inherent signal loss along the fiber. With it, there are several other causes for signal loss in an optical network.

Total fiber optic attenuation can be the result of several optical fiber loss mechanisms:

- Rayleigh scattering
- Absorption
- Macroscopic and microscopic bends
- Simulated nonlinear scattering
- Mechanical issues around fiber connections

Attenuation coefficients in fiber optics typically use units of dB/km because of the high quality materials used in modern fiber optic mediums.

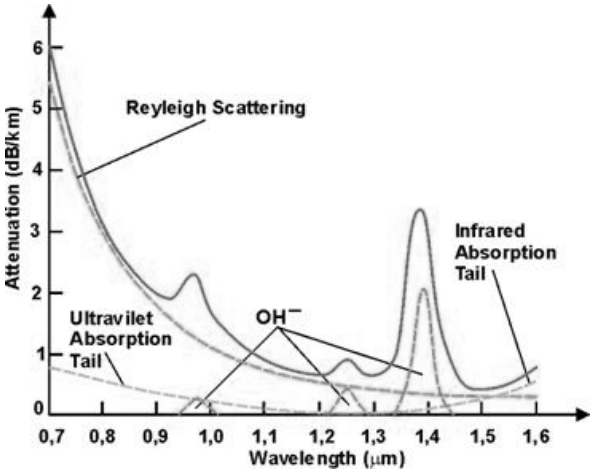

Figure 3 Spectral attenuation of a silica optical fiber [4]

Rayleigh scattering occurs when irregularities exist in the optic fiber, and they are smaller than wavelength. These irregularities can either be uneven internal surfaces or in homogeneities in the material [1]. Rayleigh scattering depends on the wavelength; the losses can be expressed as:

$$\alpha_r[\text{dB/km}] = 1.7(0.85/\lambda[\mu\text{m}])^4. \quad (1)$$

Rayleigh scattering defines the fundamental limit of reachable fiber attenuation, and it is the most significant attenuation mechanism within optical limits [4]. Absorption is a process of conversion of electro-magnetic energy into other forms of energy [4]. In optical fibers, the electro-magnetic energy of the light is converted into lattice vibrations. Each material used as a fiber optic medium has different absorption rates based on the wavelength of the signal. Most impactful impurity comes from water in form of hydroxyl ions (OH^-).

Macroscopic bends occur when the optical fibers are installed. If the band diameter is greater than 50 mm the losses are negligible.

Microscopic bend losses occur as a result of localised bends or bumps in the fiber core which then redirect or scatter the laser signal.

Simulated nonlinear scatterings are typically divided into Stimulated Brillouin backscattering and Stimulated Raman scattering. Stimulated Brillouin backscattering (SBS) occurs when the laser signal travelling through the optic produces vibrations in the medium due to the variations in the electric field of the beam itself. Threshold power for the SBS effect is:

$$P_B = 4.4 * 10^{-3} d^2 \lambda^2 \alpha_{dB} \upsilon. \quad (2)$$

Where d is fiber core diameter, α_{dB} is fiber attenuation, λ is beam wavelength and υ is optical beam bandwidth. Stimulated Raman scattering (SRS) occurs when in elastically scattered photons are forced to stay in the

medium, which causes high frequency photon generation that propagates in both directions in the medium. Threshold power for the SRS effect is:

$$P_R = 5.9 * 10^{-2} d^2 \upsilon \lambda \alpha_{dB}. \quad (3)$$

The threshold optical power of the SRS effect can be up to three orders of magnitude higher than the Brillouin threshold.

The connection points of two fibres are susceptible to varying degrees of mechanical issues. These include discontinuities, gaps, misalignments, cracks, faults etc. All of these affect the signal travelling through the optical fiber.

IV. TESTING OPTICAL SPLITTERS

Splitter loss usually accounts for the majority of the loss in the system. It depends mainly on its number of output ports. The downstream optical signal is divided equally into a cascade of branches, so each path gets the corresponding percentage of the original incident beam. The splitter also adds approximately the same amount of loss for the light travelling in the upstream direction [1].

One of the most important factors in ensuring proper transmission is controlling the power loss in the network against the link loss budget specifications. This is done firstly by establishing a total end-to-end loss budget with a sufficient margin. In addition, back reflections must be reduced to a minimum [1].

Optical return loss (ORL) is defined as the ratio of incident power (P_i) to reflected power (P_r) (4) and is measured at the input of a device under test. ORL is measured in dB and is a positive number.

$$ORL[dB] = 10\log_{10} P_i/P_r \quad (4)$$

The higher the ORL value, the better the system will perform. Optical loss is defined as the difference in power level between the transmitting source and the receiving power meter.

Insertion loss (IL) is the loss of optical energy resulting from the insertion of a component or device in the optical network.

Channel uniformity is defined as the difference between maximum and minimum measured insertion losses on a specific wavelength. Lower is better.

Because communication over the fiber is bidirectional, the ORL must be measured in both directions using an ORL test meter or a compatible optical loss test set (OLTS) at each end of the link. When using an OLTS it is important to remember that the test set requires a sequence of two measurements, which are taken in two steps [2]:

1) Two OLTSs are first referenced to each other using their individual light sources.

2) Each OLTS then sends a calibrated power value from its light source over the section under test to the other OLTS, which measures the received power and calculates the loss.

The splitter causes an inherent loss because the input power is divided between several outputs. Splitter loss depends on the split ratio and is approximately 3 dB for a 1x2 splitter. The loss increases by 3 dB each time the number of outputs is doubled. A 1x16 splitter has a splitter loss of at least 12 dB [1].

V. TEST RESULTS

Testing was performed using an OLTS. Both instruments were configured by selecting appropriate wavelengths (1310nm and 1550nm) and establishing other test parameters. Then, referencing on both instruments was performed. This was necessary to measure loss through the splitter only, and not through the test jumpers and accessories. One OLTS instrument was then connected with the input port of the splitter and the other instrument to the first output port of the splitter. This was repeated for all output ports Fig. 4.

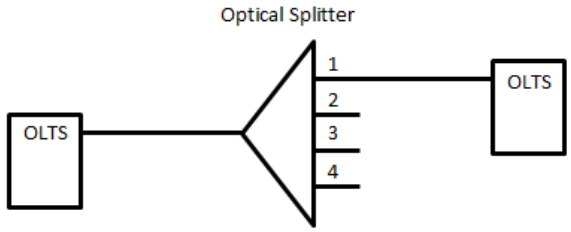

Figure 4 Measurement setup

First tested splitter was a PLC-R2 104 with a split ratio 1x4. Specification parameters for this splitter are: maximum 7.2 dB insertion loss, minimum 55 dB optical return loss and maximum 0.7 dB uniformity. Results are shown in Table I.

TABLE I. PLC SPLITTER1X4 INSPECTION REPORT

Item	IL(dB)		ORL (dB)	
Wavelength	1310	1550	1310	1550
Spec	MAX ≤ 7.2		MIN ≥ 55	
Port1	6.80	6.77	Pass	Pass
Port2	6.86	6.82	Pass	Pass
Port3	6.81	6.79	Pass	Pass
Port4	6.84	6.77	Pass	Pass
MAX.	6.86	6.82	N/A	
MIN.	6.80	6.77	N/A	
Average	6.83	6.79	N/A	

Typical insertion loss for a 1x4 splitter is between 6 and 8 dB. The highest measured loss for this splitter was 6.86 dB on the 1310nm wavelength and the lowest was 6.77 dB on the 1550nm wavelength. The average losses were 6.83 dB on 1310nm and 6.79 dB on the 1550nm wavelengths. Uniformity is 0.06 dB on the 1310nm and 0.05 dB on the 1550nm wavelengths.

Second tested splitter was a PLC-R2 116 with a split ratio 1x16. Specification parameters for this splitter are: maximum 13.5 dB insertion loss, minimum 55 dB optical return loss and maximum 1.4 dB uniformity. Results are show in Table II.

TABLE II. PLC SPLITTER1X16 INSPECTION REPORT

Item	IL(dB)		ORL (dB)	
Wavelength	1310	1550	1310	1550
Spec	MAX ≤ 13.5		MIN ≥ 55	
Port1	13.00	13.15	Pass	Pass

Typical insertion loss for a 1x16 splitter is between 12 and 14 dB. The highest measured loss for this splitter was 13.15 dB on the 1550nm wavelength, lowest was 12.72 dB on the 1310nm wavelength and the average losses were 12.96 dB on the 1310nm and 12.91 dB on the 1550nm wavelengths. Uniformity is 0.31 dB on the 1310nm and 0.43 dB on the 1550nm wavelengths. In comparison to the 1x4 splitter we can conclude that the 1x16 splitter amounts approximately twice more insertion loss is but we get four times as many output ports.

Taking into consideration that connectors usually create 0.2 dB of inherent power loss and splices usually create only 0.05 dB of inherent power loss we can conclude that splitters create the majority of optical power loss in PONs today.

VI. CONCLUSION

There are many advantages of using optical splitters in PONs. The loss of transmission is not sensitive to the wavelength of light, to meet the transmission needs of different wavelengths. Spectroscopic uniform signal can be uniformly allocated to the user. They are small and compact, and as such can be installed directly in an existing junction box. Only a single device shunt channel can achieve in excess of 32 channels. However there are some disadvantages. Not only are the power losses on splitters much greater than on other elements of the PON, but they split the maximum available bandwidth of a single fiber to multiple users so that each user receives a fraction of that bandwidth. Production process is complex, has a high technical threshold and also the signal needs to be coded, which results in more expensive end devices.

The tested splitters have passed the specification parameters and can be installed into segments of PONs that require a larger number of channels then there are available fibers. When choosing a particular split ratio it is necessary to provide enough output channels and also take into account reserve channels for possible future expansion, while staying within the optical loss budget the whole time. Another important factor to consider is the uniformity of splitter loss across every port of the splitter, and also across multiple splitters of the same type. This helps with planning and maintenance of the PON. As a result, the splitter with the most uniform loss across all of its ports and the lowest split ratio necessary is the best option to choose.

ACKNOWLEDGMENT

We would like to thank Professor Zvonimir Zelenika for providing us with very useful materials, and to Professor Alberto Teković for making us do this paper in the first place.

Abstract – A comparison between different DC motor positioning control algorithms is performed in this work. Transient responses while employing a PID controller, a cascade controller and a state-space controller are considered. LabVIEW programming environment with a suitable acquisition card and a miniature DC motor with an integrated encoder are used for experimental assessment. Calculations and control system simulations are made using Matlab. The PID controller is implemented via the predefined PID block in LabVIEW. In turn, the state-space controller is modelled by using Matlab while the accuracy of the results is confirmed experimentally using LabVIEW. The cascade controller is developed as a series of two Proportional-Integral (PI) controllers, one representing the positioning and the other the velocity loop. The obtained results allow establishing that positioning control via the state-space controller has the fastest response and the lowest settling times.

I. INTRODUCTION

A widely used actuator in positioning systems is a Direct Current (DC) motor. It finds application in many of today's mechatronics systems such as robots, precision positioning machines or industrial applications. Positioning control of mechatronic devices is also used in situations when there is a need for an accurate response in a predictable and repeatable manner. In a pick-and-place machine for production of Printed Circuit Boards (PCB), for example, components must be placed precisely on the board before the soldering process. Another example is a robot manipulator that uses several motors for 2D or 3D positioning of the robotic arms. Although stepper motors are sometimes employed for these purposes, DC motors can also be a viable solution. However, when DC motors are used, a feedback sensor is needed in order to establish positioning control [1, 2].

A DC motor with an embedded quadrature rotational incremental encoder as a feedback sensor is employed in this work. Three different control algorithms are compared in the terms of simulations in Matlab and experimental results obtained by using the LabVIEW programming environment.

II. DC MOTOR POSITIONING CONTROL ALGORITHMS

A. PID control

One of the most common controllers in industrial applications and control systems is the Proportional-Integral-Derivative (PID) controller. The transfer function of an ideal parallel PID structure can be expressed as (refer to the list of symbols at the end of the paper) [1]:

$$G_R(s) = \frac{U(s)}{E(s)} = K_P\left(1 + \frac{1}{T_I s} + T_D s\right) \tag{1}$$

The PID parameters are defined as:

- K_P proportional gain
- T_I integral time
- T_D derivative time

$E(s)$ can be calculated as the difference between the reference position $Y_0(s)$ and the actual position $Y(s)$:

$$E(s) = Y_0(s) - Y(s) \tag{2}$$

In the time domain, the PID controller can be expressed as:

$$u(t) = K_P \cdot \left(e(t) + \frac{1}{T_I}\int_0^t e(\tau)d\tau + T_D\frac{de(t)}{dt}\right) \tag{3}$$

Using the finite time values:

$$t \to kT_s \tag{4}$$

a discretized form of PID controller can be obtained [1]:

$$u(kT_s) = K_P \cdot \left(e(kT_s) + \frac{T_s}{T_I}\sum_{i=0}^{k} e(iT_s) + \frac{T_D}{T_s}[e(kT_s) - e(kT_s - T_s)]\right) \tag{5}$$

The PID controller is implemented in this work via the predefined PID block in LabVIEW. The tuning of the PID controller parameters is conducted in two steps. The Ziegler-Nichols method is used first to achieve a rough estimate of the gains; in a second step, an experimental method of fine-tuning of PID parameters is performed.

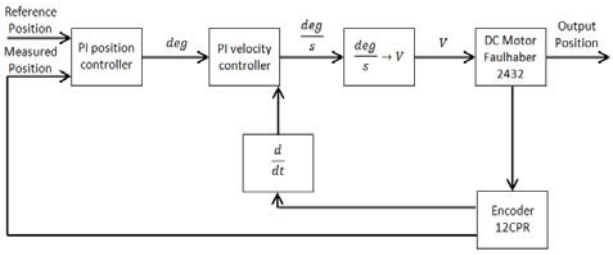

Figure 1. Cascade control scheme

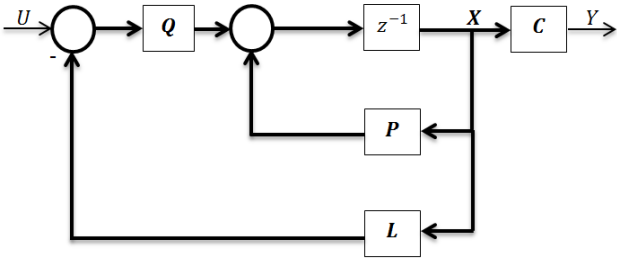

Figure 2. z-transformation of the state-space model

B. Cascade control

Cascade control is composed of two loops: the velocity and the position loop. In the simplest form, an analogue command (set point velocity) is compared with the signal from the feedback sensor (incremental rotational quadrature encoder) to generate voltage that induces rotational motion. The produced torque will speed up or slow down the actuator in order to reach the velocity set point. The most known velocity loop is the Proportional-Integral (PI) loop and it is constituted by two parameters: a proportional gain (K_P), which scales the velocity error, and an integral time constant (T_I), which defines the integration time. A velocity loop itself cannot ensure that the actuator stops in a certain position. Hence, one of the common configurations is to place a positioning loop in cascade (series) with the PI velocity controller (Fig. 1) [3].

Tuning of the regulators in cascade can often prove to be a challenging task since there are four parameters to tune [3]. The parameters are thus tuned in this work by using a custom developed Matlab model. The resulting parameters are then implemented in the LabVIEW environment where additional online fine tuning is performed in order to match better real system response.

C. State-space control

State-space control derives from the state-variable method of representing differential equations. When compared with transfer-function based control, state-space control is designed by working directly with the state-space-variable description of the system [2].

Advantages of state-space design are particularly relevant for Multiple-Input – Multiple-Output (MIMO) systems, although the system considered in this work is a Single-Input – Single-Output (SISO) system. A further advantage of this method is its robustness to dynamic perturbations in the system [2].

A process with one input $u(t)$ and one output $y(t)$ can hence be described in a state-space model as [4-6]:

$$\frac{d\mathbf{x}(t)}{dt} = \mathbf{A}\mathbf{x}(t) + \mathbf{B}u(t)$$
$$y(t) = \mathbf{C}\mathbf{x}(t) \tag{6}$$

where **A** is the system matrix which correlates the current state with its change, **B** is the control matrix and determines how the system input affects the state change and **C** is the output matrix which determines the relationship between the system state and its output. The considered process in a discrete form can thus be described as:

$$\mathbf{x}[k+1] = \mathbf{P}\boldsymbol{x}[k] + \mathbf{Q}u[k]$$
$$y[k] = \mathbf{C}\mathbf{x}[k] \tag{7}$$

The **P** and **Q** matrices can be defined by using the fundamental matrix $\boldsymbol{\Phi}(s)$ [4]:

$$\boldsymbol{\Phi}(s) = (s\mathbf{I} - \mathbf{A})^{-1}$$
$$\mathbf{P} = \mathcal{L}^{-1}\{\boldsymbol{\Phi}(s)\} \tag{8}$$
$$\mathbf{Q} = \mathcal{L}^{-1}\left\{\frac{\boldsymbol{\Phi}(s)}{s}\right\}\mathbf{B}$$

The process can also be described by applying the z-transformation of the equations of the state-space model [4]:

$$\mathbf{X}(z) = (z\mathbf{I} - \mathbf{P})^{-1}\mathbf{Q}U(z)$$
$$Y(z) = \mathbf{C}(z\mathbf{I} - \mathbf{P})^{-1}\mathbf{Q}U(z) \tag{9}$$
$$G(z) = \frac{Y(z)}{U(z)} = \mathbf{C}(z\mathbf{I} - \mathbf{P})^{-1}\mathbf{Q}$$

Now the state-space controller equation can be defined:

$$U(z) = -\mathbf{L}\mathbf{X}(z) \tag{10}$$

The basic principle of the synthesis of the state-space controller is to achieve the desired closed-loop dynamics with proper values of the **L** vector. These values can be obtained by using the following equations:

$$z\mathbf{X}(z) = (\mathbf{P} - \mathbf{Q}\mathbf{L})\mathbf{X}(z)$$
$$|z\mathbf{I} - \mathbf{P} + \mathbf{Q}\mathbf{L}| = 0 \tag{11}$$

where the roots of equation (11) are correlated with the poles of the desired closed-loop dynamics. The state-space controller gain vector **L** can then be calculated by using Ackermann's formula [4]. The block diagram of the resulting state-space model is shown in Fig. 2.

D. DC motor model in state-space

The behaviour of a DC motor can be modelled as [5]:

$$\frac{d\varphi}{dt} = \omega \tag{12}$$

$$J\frac{d\omega}{dt} + b \cdot \omega = \frac{K_m}{R_a}(u - K_e \cdot \omega)$$

For simplicity, the armature time constant is neglected.

In turn, in state-space a DC motor can be described as:

$$s\begin{bmatrix}\varphi\\ \omega\end{bmatrix} = \begin{bmatrix}0 & 1\\ 0 & -\frac{1}{T_m}\end{bmatrix} \cdot \begin{bmatrix}\varphi\\ \omega\end{bmatrix} + \begin{bmatrix}0\\ \frac{K_m}{J \cdot R_a}\end{bmatrix} \cdot u$$

$$Tm = \frac{J \cdot R_a}{b \cdot R_a + K_m \cdot K_e} \tag{13}$$

$$b = K_m \frac{I_{an}}{\omega}$$

The DC motor transfer function is:

$$G(s) = \frac{\Phi(s)}{\Omega(s)} = \frac{\frac{K_m}{J \cdot R_a}}{s^2 + s \cdot \frac{1}{T_m}} \tag{14}$$

while the respective discretized model in state-space is:

$$z\begin{bmatrix}\varphi\\ \omega\end{bmatrix} = \begin{bmatrix}1 & \alpha \cdot T_m\\ 0 & \beta\end{bmatrix} \cdot \begin{bmatrix}\varphi\\ \omega\end{bmatrix} + \frac{K \cdot T_m}{J \cdot R_a}\begin{bmatrix}\gamma \cdot T_m\\ \alpha\end{bmatrix} \cdot u$$

$$\beta = e^{-\frac{T_s}{T_m}}$$
$$\alpha = 1 - \beta \tag{15}$$
$$\gamma = \frac{T_s}{T_m} - \alpha$$

The requirements for aperiodic closed-loop dynamics imply then:

$$\xi = \frac{1}{\sqrt{2}}$$
$$\omega_n = \frac{1}{T_m\sqrt{2}} \tag{16}$$

while the recommended sample time is [5]:

$$T_s = \frac{0.2}{\omega_n} \tag{17}$$

Vector **L** can hence be approximately calculated as [5]:

$$\mathbf{L} = \frac{J \cdot R_a}{K_m \cdot T_m}\left[\frac{0.4983}{T_m} \quad 0.0672\right] \tag{18}$$

By inserting the characteristic values for the used DC motor (see Table I), vector **L** becomes:

$$\mathbf{L} = [1.1173 \quad 0.0011] \tag{19}$$

To estimate finally the variables used in the control algorithm, the Matlab software is used.

III. EXPERIMENTAL SET-UP

The assessment of the characteristics of the described positioning control algorithms is performed on an experimental set-up, whose block-scheme is shown in Fig. 3. The system is composed of a DC motor coupled with a gearbox and an encoder, the operational amplifier and the control system based on the National Instruments (NI) hardware and the LabVIEW software.

A. Actuator and encoder

The main component of the experimental set-up is the Faulhaber 2342 DC motor with an embedded planetary gearbox and an incremental rotational encoder [7]. The main characteristics of the actuator are given in Table I. As shown in Fig. 4, the shaft of the actuator is connected to the gearbox unit (1) with a reduction ratio 1:64. On the opposite side, an encoder (2) is installed.

The used encoder is an incremental encoder with 2 channels (A and B) with a 90 degree phase delay and 12 cycles per revolution (cpr). Two encoder channels enable not only position and speed but also the direction of movement to be determined. A very important parameter for encoder measurements is the encoding type, which directly affects encoder resolution. In this application, rising and falling edges on both channels are counted (Fig. 5). This type of encoding is usually referred as X4 encoding [8-10].

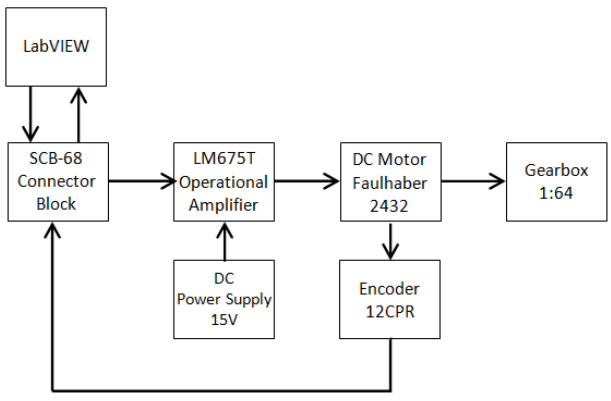

Figure 3. Experimental set-up scheme

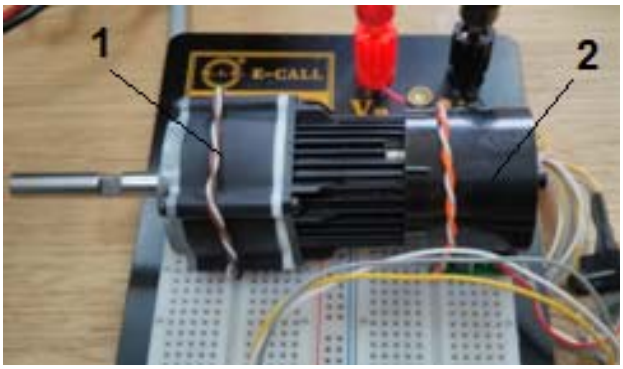

Figure 4. DC motor with gearbox and encoder

B. *National Instruments Hardware*

The electronics of the experimental set-up is based on the National Instruments PXI-1050 chassis, including a PXI-8196 embedded controller and a PXI-6221 Data Acquisition Card (DAQ) which is connected to a SCB-68 connector block [11]. The SCB-68 has 68 terminals with digital and analogue inputs and outputs. Counter inputs are used for connecting the encoder while the analogue output is used for driving the DC motor.

IV. LABVIEW CONTROL IMPLEMENTATION

The LabVIEW development environment is used for implementing the control algorithms and storing measurement data. This configuration meets the requirements for embedded system design such as real-time computing, wide choice of peripheral equipment and extensive support for accessing instrumentation hardware. Moreover, its library contains predefined mathematical blocks that process acquired data to enable appropriate outputs. In the considered case, the DAQmx *Start Task block* is used to trigger the used channels. The acquired data is then passed to the DAQmx *Read block* that, due to continuous position readings, is located within the time loop. Similarly, voltage output is driven using the DAQmx *Write block*. On the other hand, measurements are stored in a CSV file. This file is created by using a *Write-to-spread sheet file block* which enables to capture the data that can subsequently be used for further analysis in Matlab.

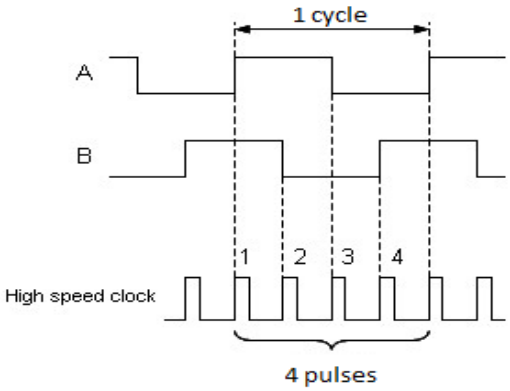

Figure 5. Reading and encoding signals from the encoder

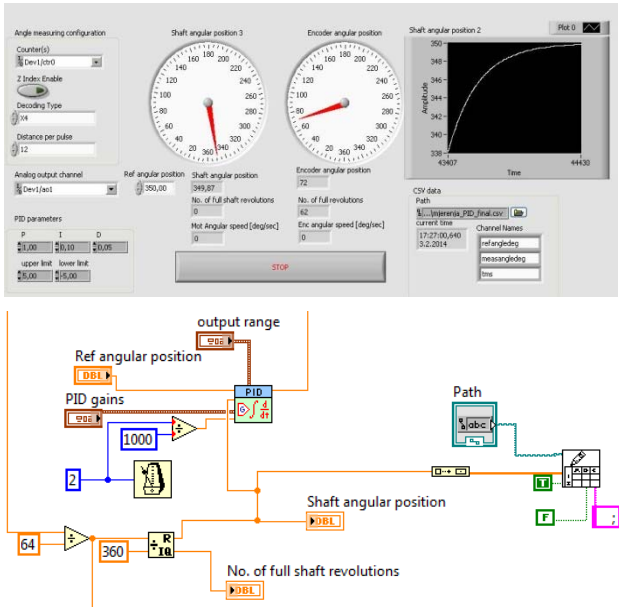

Figure 6. PID regulation VI: front panel (up), block diagram (down)

A. *PID control*

PID control is implemented in LabVIEW by using the predefined PID block from the *LabVIEW Control, Design and Simulation Module*. The respective front panel as well as the main elements of the block diagram are shown in Fig. 6.

Input and output channels have to be selected first.

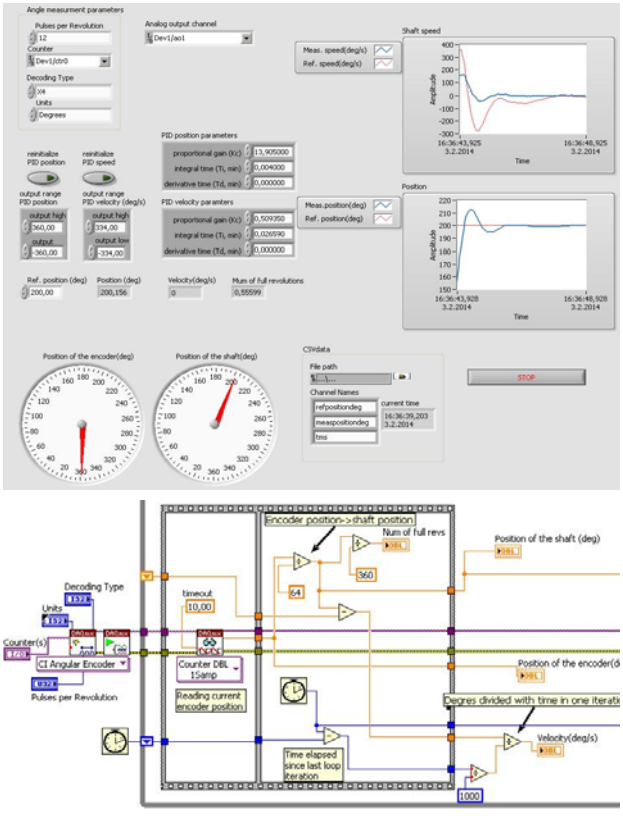

Figure 7. Cascade control VI: front panel (up), block diagram (down)

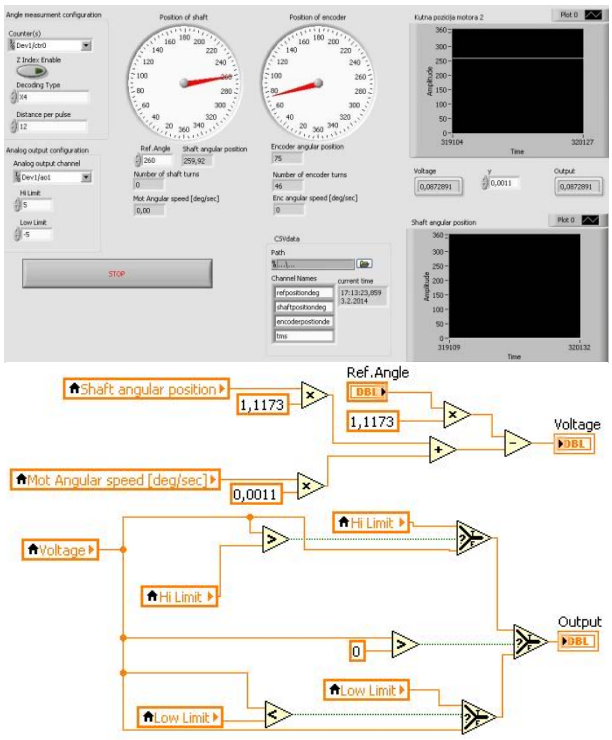

Figure 8. State-space control VI: front panel (up), block diagram (down)

Using the DAQmx counter as input, information about position is obtained from the channels of the encoder. This is compared to the defined reference position so as to determine the analogue input to the actuator.

B. Cascade control

The front panel and the block diagram of the cascade control scheme are shown in Fig. 7. The front panel allows the following input parameters to be defined: number of pulses per revolution, input and output channels, decoding type, position measurement units, parameters for the PI regulators as well as the file path. For a given reference position, the dynamic response of the system can be visualised via a waveform chart and/or a circular gauge. The number of full motor shaft revolutions is also shown. The inferred velocity is hence calculated as shown in the block diagram in Fig. 7. Experiments allowed establishing that a disadvantage of the used method is that, for sample times shorter than 50 ms, the velocity signal results in errors because the computational routines are slower than motor's response.

C. State-space control

The state-space regulator is implemented in LabVIEW using equations (12-19) – Fig. 8. The measured position and velocity are scaled by the gain vector **L** using equation (19). These values are then compared to the desired reference values. Since there are no additional time constants (no additional poles) added to the system, the state-space control algorithm has faster response times than the PID and the cascade controller. On the other hand, since state-space control has only proportional gain, a residual steady-state error is present. To minimize this error, the reference position is multiplied with a compensation gain.

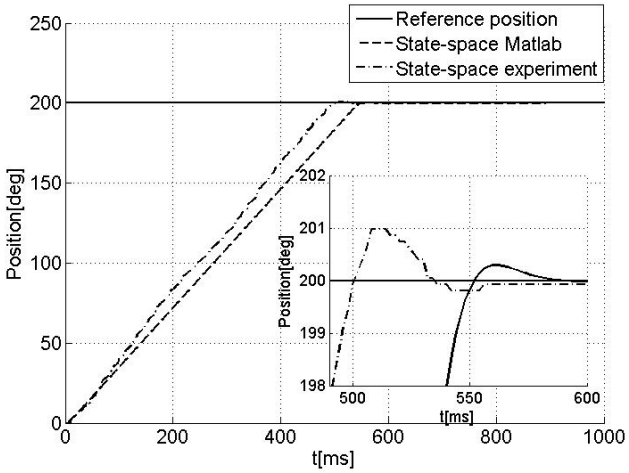

Figure 9. State-space transient response

V. EXPERIMENTAL RESULTS AND DISCUSSION

To test the performances of the described DC motor position control systems, a set of experiments using PID, cascade and state-space control typologies is performed. All tests are made with an input step command from 0° to 200°. DC motor input voltage is limited to ± 5V. The parameters of the PID and the cascade controllers are given in Tables II and III both for the simulations and the experiments. It is interesting to notice here that the simulations did not allow the correct integral time of the positioning loop of the cascade control to be determined. This value will thus be obtained in future investigations.

The comparison of simulated and experimentally obtained transient responses in the case of the state-space controller is shown in Fig. 9 and Table IV. From the magnified detailed view of the system dynamic response during settling, it can be seen that an aperiodic transient response occurs with a negligible difference in rise times between the simulated and actual results. In the case of the PID and the cascade controllers, due to simplified modelling assumption, some discrepancies of the simulated and experimental dynamic results occur. Future investigations will be done to obtain better matching of the simulated and experimental results.

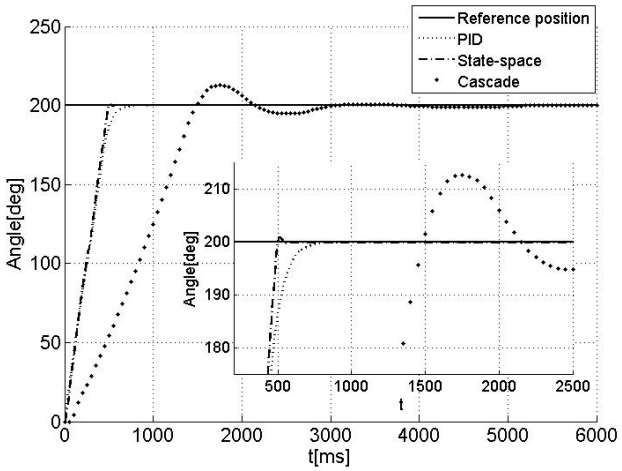

Figure 10 Combined experimental results

TABLE II PARAMETERS FOR THE PID CONTROL METHOD

	MATLAB	Experiment
Proportional gain K_p	0.576	0.6
Integral time T_I[ms]	0.313	0.3
Derivate time T_D [ms]	0.021	0.02

TABLE III PARAMETERS FOR THE CASCADE CONTROL METHOD

		MATLAB	Experiment
Positioning loop	Proportional gain K_p	13.56	13.905
	Integral time T_I [ms]	?	4
Velocity loop	Proportional gain K_p	0.508	0.508
	Integral time T_I [ms]	5	5

TABLE IV DYNAMIC RESULTS FOR THE STATE-SPACE CONTROL METHOD

	MATLAB	Experiment
Rise time τ_r [ms]	430	390
Percent overshot σ [%]	0.35	0.5
Settling time τ_s [ms]	580	550
Steady-state error [%]	0	0.04

TABLE V COMPARISON OF DYNAMICS FOR DIFFERENT CONTROL METHODS (EXPERIMENTS)

	PID	Cascade	S.S.
Rise time τ_r [ms]	425	1120	390
Percent overshot σ [%]	0	6.35	0.5
Settling time τ_s [ms]	800	3500	550
Steady-state error [%]	0	0.1	0.04

The comparison of transient responses obtained experimentally for all three used controllers is given in Fig. 10. Rise time, percent overshoot, settling time and steady-state error for each control algorithm are in turn given in Table V. It can be concluded that the fastest response is obtained by using the state-space control algorithm. The PID control algorithm results, however, in the smallest steady-state error.

VI. CONCLUSIONS AND OUTLOOK

An overview of different DC motor control approaches is given in this work. A conventional PID controller is employed first. The respective parameters are obtained using the Zieger-Nichols method and fine tuning. A cascade controller is developed next. Finally, the state-space controller with positioning and velocity loop is employed. A Matlab model of the used actuator is established in order to simulate different control approaches. Controllers are then implemented in the LabVIEW environment and experiments are conducted.

By comparing experimental results (Table V), it is concluded that positioning control via the state-space controller has the fastest response and the lowest settling times. Cascade control can be efficiently used, although the tuning of its parameters can often be cumbersome and computationally more intensive due to the presence of two PI blocks and the needed velocity calculation. This all limits the execution time which directly affects system's dynamic response. Improvements of cascade control could be achieved by using real-time hardware (e.g. the NI FPGA module) or if direct measurement of velocity would be possible. PID control results in negligible steady-state errors and acceptable rise and settling times.

LIST OF SYMBOLS

A	system matrix
B	control matrix
b	friction coefficient [mNm/rpm]
C	output matrix
$E(s)$, $e(t)$	difference between the reference and the process value
$G_R(s)$	PID transfer function
I_{an}	nominal armature current [mA]
J	motor inertia [kg·m^2]
k	finite time values factor (k=1, 2, 3, …)
K_e	back EMF constant [V/rpm]
K_m	torque constant [Nm/A]
K_P	proportional gain
L	state-space controller gain vector
P	system matrix in discrete domain
Q	control matrix in discrete domain
R_a	armature resistance [Ω]
s	Laplace variable
t	time variable
T_I, T_D	integral and derivative time constants
T_m	mechanical time constant
T_S	sample period
$U(s)$, $u(t)$	output from the controller
U_n	nominal voltage [V]
Y(s), y(t)	process value
Y_0(s)	reference position
z	discrete (z) domain variable
Δt	time change [ms]
$\Delta\varphi$	motor shaft angle change [°]
ξ	attenuation coefficient
σ	percent overshot [%]
τ_r	rise time [ms]
τ_s	settling time [ms]
φ	motor shaft position [°]
ω	velocity of the motor shaft [rpm]
Φ	fundamental matrix

Hrvatski Telekom kao predvodnik tehnoloških trendova

Kad se kaže: sve što može biti digitalizirano – bit će digitalizirano, možda to zvuči kao floskula ambicioznog profesora informatike za vrijeme štrajka, no s obzirom da je to rekao Nicholas Negroponte, jedan od najvećih vizionara današnjice, nad ovakvim se tvrdnjama valja zamisliti. Ipak, posrijedi je izjava koja datira iz devedesetih, i uistinu, premda proces još nije dovršen – sve što se može digitalizirati, uspješno se digitalizira.

Negroponteovu izjavu parafrazirao je predsjednik Uprave Deutsche Telekoma Timotheus Höttges na ovogodišnjem Mobile World Congressu u Barceloni rekavši: "Sve što može biti umreženo – bit će umreženo." Uistinu, umrežavanje ljudi i uređaja jedan je od glavnih tehnoloških trendova, koji se može uočiti svuda oko nas. Automobili su dovoljan primjer. Danas prosječni automobil sadrži 60 do 100 senzora, a u bliskoj budućnosti bit će ih više od 200. Razvijamo e-government, e-školstvo, e-zdravstvo, no u pozadini moramo imati i mreže koje to mogu podržati. Stoga u HT-u svakodnevno ulažemo u razvoj najnaprenije mreže kako bismo korisnicima u svakom trenutku omogućili pristup svemu što žele, te stvorili preduvjete za količine podatkovnog prometa koje nam tek dolaze. Jer, budućnost se mora graditi sada.

Među prvima u Europi i svijetu s IP migracijom

Hrvatski Telekom modernizira svoju fiksnu mrežu i to na multimedijsku platformu nove generacije temeljene na internet protokolu, te je u planu do kraja 2015. godine na novu tehnologiju prebaciti sve korisnike. Pored korištenja postojećih usluga, nova platforma korisnicima omogućuje konvergenciju visoko kvalitetnih multimedijskih usluga i inovativne načine korištenja bezgraničnih mogućnosti koje im pruža internet. Vrhunske multimedijske usluge i uobičajene telekom usluge bit će korisnicima dostupne praktički odmah i to bez ulaska tehničkog osoblja u dom, a korisnik će moći jednim klikom izabrati željenu brzinu interneta.

HT nudi najveću garantiranu brzinu u Hrvatskoj u sklopu svojih Ultra MAX paketa, i to 100 Mbps u downloadu i 20 Mbps u uploadu. Riječ je o paketima baziranim na FttH tehnologiji

Usluge na super brzom internetu

U fiksnom segmentu HT korisnicima nudi najveću garantiranu brzinu u Hrvatskoj u sklopu svojih Ultra MAX paketa, i to 100 Mbps u downloadu i 20 Mbps u uploadu baziranih na FttH tehnologiji. Maksimalna brzina od 100 Mbps downloada i 20 Mbps uploada upravo je ona za koju Hrvatski Telekom jamči da će je korisnik i dobiti, budući da FttH tehnologija omogućuje garantiranu brzinu do korisnika, za razliku od drugih ponuda na tržištu gdje se ponuđena maksimalna brzina dijeli među korisnicima na optičko-kabelskoj mreži. Budući da su zahtjevi korisnika za brzim internetom i umrežavanjem sve veći, u HT-u radimo i na mreži budućnosti TeraStream: novom mrežnom konceptu temeljenom na protokolu IPv6, koji smo predstavili prvi u svijetu i koji omogućuje korisniku brzinu od 1 Gbps.

Najveća pokrivenost 4G mrežom u Hrvatskoj

Dostupnost brzog interneta strateška je odrednica Hrvatskog Telekoma i u mobilnom segmentu. Svakodnevno povećavamo pokrivenost i brzim 3G i 4G mrežama i nudimo najveću dostupnost obje mreže u Hrvatskoj. Hrvatski Telekom je prvi u Hrvatskoj i među prvima u regiji i Europi u rad pustio 4G mrežu temeljenu na naprednoj LTE tehnologiji. Osim u urbanim i korisnicima u ruralnim područjima nudimo brzine prijenosa podataka do 75 Mbps u downloadu te do 25 Mbps u uploadu. Ponosni smo da naša ulaganja u razvoj i inovacije prepoznaje i šira javnost pa je tako Hrvatski Telekom prošle godine proglašen liderom na području inovativnosti u kategoriji velikih tvrtki prema rezultatima nacionalnog istraživanja o stanju inovativnosti hrvatskih tvrtki. Budućnost digitalnog društva kojeg stvaramo želimo zajedno s korisnicima živjeti već sada.
