- Authentication is ensured mainly by X509 certificates. Other authentication mechanisms are also used. In some cases it is possible to use an identity provider to obtain an X509 certificate on-the-fly, thus allowing more decentralized management of the authentication process.
- Users sign proxies with their X509 certificate and use them to connect with services using https protocol or typical Grid protocols like GridFTP or SRM for data management or GRAM for job management.
- The Grid services may have finer-grained authorization mechanism, using groups and roles within the VO. This possibility is difficult to implement in practice because of the decentralized nature of deployment of Grid resources.

In Bulgaria IICT-BAS is responsible to issue certificates for BG scientists/students, operating the BG.ACAD Certification Authority see http://ca.acad.bg.The same Grid certificates are used for other e-Science projects, e.g., PRACE1IP, PRACE2IP, HP-SEE. In some cases they are used to authenticate email or web servers.

IV. Security management in Clouds

Access to Cloud infrastructure resources can be achieved with web, GUI or command line interfaces. Popular languages for development are *java, python, ruby*. Both Linux and Windows operating systems are supported as guest OS, as well as others. We should point out that the user effectively obtains administrator (root) access to the virtual machines launched over the cloud, which is not the case of Grid usage, where only local Unix user access can be obtained. Here we review the security models of the most popular Cloud service providers. Amazon cloud services [8] include:

- EC2 Amazon Elastic Compute Cloud is a web service that provides resizable compute capacity in the cloud.
- S3 - Amazon Simple Storage Service provides a simple web services interface that can be used to store and retrieve data.

Access to Amazon cloud services is secured through use of:

- Access keys used to make secure (signed) REST or Query protocol requests to any AWS service API

- X.509 certificates - make secure SOAP protocol requests to AWS service APIs.
- Key pairs can be used to launch and then securely access your EC2 instances.

Many providers mimic the Amazon cloud model, sometimes using open source software. Some providers of cloud services follow a different model, where the user does not obtain administrative access to particular machine, but instead a whole scalable application environment is provided to them. This is the case of Google, for example. We should point out that the shared use of Cloud is not straightforward because of the lack of notion similar to the Virtual Organization. The Cloud paradigm allows for a layered approach, where for example one provider may provide added-value services to the customers using the infrastructure of another provider. In such cases the security model of the top-level provider may differ from those of the providers of the lower layers.

There is also growing use of private clouds where an organization manages their own infrastructure as a Cloud and treats the various projects and teams inside the organizations as customers. There is a perception of higher security in such case because of the higher isolation from external treats and lack of dependancy on third parties like the Cloud providers, but we should be aware that the increase in targeted attacks to well known companies, for example via specially crafted e-mails containing malware, means that the requirements for strict protection of data and high level of isolation should not be relaxed in this case.

V. Security threats and attack vectors and their mitigation

One of the main security threats on the Grid stem from the fact that users proxy certificates are sent to remote nodes, where they can be stolen, e.g., by a malicious user of the same cluster. Typically such a proxy is valid for 12 hours and provides access to most of the resources of the VO, as outlined above. On the worker nodes one usually employes a so-called limited proxy, which allows access to storage resources, but not the ability to launch jobs, thus limiting the impact of a potential breach. An unlimited proxy can be used to launch new jobs, but can be found on smaller number of machines with tighter security, for example on Workload Management System (WMS) nodes.

Unfortunately, some virtual organizations have been granted the ability to create voms proxies with duration much larger than 24 hours, which means that the potential impact of a stolen proxy certificate will extend to several days. They are security mechanisms in place to react to such violations, for example using ARGUS nodes to ban malicious users or by revoking the user certificate, but they will not be started unless the problem has been discovered and reported. In the meantime the malicious user can attempt escalation of privileges on the nodes where he or she obtained access or tampter with the data or metadata of the virtual organization. Taking the important example of the gLite middleware that is used in the European Grid Infrastructure and considering the fact that many of the nodes that serve as front-end nodes for the users to the Grid or to HPC facilities are managed by a variant of openssh which allows login with grid proxy credentials (*gsi-openssh*) This means that a stolen unlimited proxy allows a hacker to obtain access to such User Interface machines and then the danger of contagion increases dramatically. Such situations are rather worrisome and effectively suggest that some kind of virtualization of such User Interface nodes where each user obtains access to their own virtual machine is much more preferrable. We believe that since not all users are active at the same time it should be possible to manage such a virtual UI infrastructure without additional investment in hardware.

Although the limited proxies are not useful for the kind of attack described above, they are perfectly useful for stealing and destroying data and metadata. We believe that although the best practices dictate an adequate backup strategy which could mitigate the danger of metadata deletion or corruption by an attacker, it is not clear if a determined attacker can not cause major disruption by deleting or changing contents of data, even if all data centers affected had backups. We believe that the Grid middleware should provide more fine-grained control with regards to single files, so that deletion or changing of files by persons other than their creators should be made more difficult.

Now considering the case when a Grid application uses Cloud services, one should take into account that if cloud certificates and/or access keys are sent to remote Grid nodes, there is a danger that if they are stolen somebody will be able to do everything that the owner can do on the Cloud. Obviously the provider of an EC2-type service runs the risk of malicious users launching nodes which can be used to serve illicit content, control botnets or similar. Presumably the Cloud infrastructure providers ensure tight control and isolation between user's virtualized networks. However, investigation of security incidents is difficult due to the use of virtual machines.

Thus it is important that Grid jobs should not have access to the full cloud credentials of the users. This means that an extra level of redirection should be introduced to limit access, for example only to the necessary part of storage. This can be implemented as a broker service, launched on the cloud and answering to requests from the Grid jobs. It should be possible for such a service to use the elastic nature of Cloud to provide adequate response to requests even in situations of high load. In the future we plan to develop an implementation of such a service and test it with pilot applicaitons.

We also consider as a threat the situation when the same person is having multiple roles on the Grid side. It is not uncommon for the same person to be responsible both as administrator of a Grid site, support contact for the NGI and manager of a virtual organization. In this case the requirement for this person to have only one valid Grid certificate leads to a situation which makes this certificate valuable for exploitation. The possibility for cross-site scripting attacks against management web interfaces that authenticate

with Grid certificates supports the case for more separation between different roles of the same person, which could be achieved either by relaxing the requirement for one certificate for the same person or by introducing intermediate robot certificates that can then authenticate with the various management interfaces adding some additional checking.

At the application level the current Grid middleware does not enforce signing of applications. On the other hand there is great flexibility since adding new "gateway" service nodes that can submit applications to the Grid clusters is not highly resource intensive. Thus to facilitate the introduction of more industrial applications we envision that modified service nodes that provide access only to pre-defined or signed applications, can be deployed. Unfortunately the ideas to control more tightly the network access patterns of applications by introducing intermediate co-called "network box" that would authorize requests for network connections did not lead to fruition and thus all applications follow obey mostly the same restrictions. Looking at the firewall options of EC2 it is easy to see that such restrictions can be imposed with more virtualization and probably are within reach at the biggest Grid sites, which also have better relations with industry. In general our experience from the use of virtualization in the regional Grid sites in South Eastern Europe shows that it's usage is mostly concentrated in the service nodes and not as widespread as within Cloud providers, perhaps due to licensing costs and difficulties in the transition. For example, some HPC resources that have infiniband or GPGPU cards are difficult to virtualize due to lack of good free alternatives supporting such devices. In the future we can expect that these difficulties will be overcome and the use of virtual worker nodes will improve the manageability and security of the overall infrastructure.

Unrelated applications should also be separated in terms of credentials and infrastructure used. Users must perform careful evaluation of the dangers of contagion should one part of the nodes participating in a given computation become compromised.

VI. Conclusions and directions for future work

We can conclude from our investigation that the possibility of combining services or infrastructure resources from the Cloud with Grid resources and organization provides additional flexibility and substantial benefit to the demanding users and applications. The security issues that arise should be addressed firstly by infrastructure operators and Grid and Cloud middleware developers to provide for the necessary isolation and control. From out point of view the introduction of "Grid-Cloud brokerage" services that can translate between Grid and Cloud credentials and ensure limitations on the kinds of requests that can be issued between the Grid and Cloud parts of the scientific application thus effecitively reducing the exposure of the users to the inherent security risks and providing certain guarantees about the worst possible damage that may happen in case of security breach.

Abstract - Implementation, usage, and maintenance of complex dynamic web forms can be very time consuming, especially when they have a large number of fields which change very often. In combination with fields that require programming for implementation, the complexity further increases. In this article we describe the problem and suggest the framework for easier implementation of such forms. Later, we describe current implementation, its benefits, and propose future work on this subject.

Keywords: web forms, user input, dynamic, framework, web application

I. INTRODUCTION

In the web content management systems (WCMS) there are often many different modules available to users which can be used for building web sites in different ways [1, 2, 3]. Some of the basic modules are: module for static content, module for articles which are time relevant (e.g. news articles), forum, and navigation. These modules offer a simple and easy to use interface for specific purposes, and they don't change very often, so they can always be implemented in the same way.

Other types of modules are simple or more advanced surveys or questionnaires which are built on a form with questions and answers. In modern web content management systems these modules are available to the content administrators so they can build a survey or questionnaire without programming (e.g. Google Docs – Forms [4]). Also, modern web content management system is built with a framework which provides interfaces for easier implementation of forms in various modules (e.g. Zend Framework – Forms [5]).

Beside these modules and other similar general modules, there is often a need for building a complex web application according to the client's specification. It is difficult to use previously mentioned modules when a form is only a small part of such application even when these modules are available in the system, because they are built for only one purpose with a simple interface for the end user, and even if these modules provide interface for such usage, often there is need for additional custom fields which cannot be implemented without programing (e.g. complex connection between data, getting data from other systems, etc.).

The client's wish to change the form after it is created or it is in use is another problem for developers. If the form is hardcoded this can be done only by the developer. Further, another problem could be that the previously filled forms need to remain untouched which would require additional time for the developer to implement such behavior because he or she has to manage two forms now.

In this paper we suggest a framework which can simplify the previously described tasks and greatly reduce implementation time and maintenance of dynamic web forms.

II. THE FRAMEWORK

A. Requirements

To simplify tasks mentioned in the introduction, we have designed a framework which can be used for easier implementation of such web forms in a web content management system. The framework has to be implemented in the WCMS environment where it will be used and then it becomes an integral part of the system available to all other modules as a framework.

Beside the requirements in the introduction, our framework has been designed to support creating statistics reports based on the data users have entered using different form versions.

Summarized minimal requirements:

- Easy to implement
- Easy to reuse
- Easy to modify
- Creating statistics reports on users' data across similar forms

Additional requirements:

- Multi-language support
- Question description
- Answer description
- Different question display style per question
- Flag if field is required

B. Data Model

The information about forms and the data users have entered as feedback are stored in a database with the following structure:

- Form type
- Form instance
- Question type
- Question instance
- Link between form and question instance
- Question answers for questions with predefined answers
- Users feedback
- Users feedback – Answers
- Additional tables

1) Form Type

Form type is defined by the developer and can be used to identify different types of forms. Different types of forms can be useful when the developer wants to control how each form is displayed and if he or she wants to create additional fields to the form based on form type.

2) Form Instance

Form instance holds basic information about each form such as form name, form type and default display style of question.

3) Question Type

Question type table contains information about which question types exist in the system and additionally can store information about each question type. Question type defines how the question will be presented to the user.

Question type and the data that is expected as an answer:

- *Space* – Spacer in the form.
- *Group* – Used for grouping following question in a group.
- *Note* – A note to the user with no answer expected
- *Text* – One line of text
- *Multiline text* – Multiple line of text
- *HTML* – Rich text editor
- *Choice* – One choice of predefined answers/choices
- *Multiple-choice* – Multiple choice with predefined answers/choices
- *File* – Upload a file

4) Question instance

Question instance holds information about each question such as question type, question text, description, display style, and, optionally, requirement flag if answering the question is required.

5) Link between form and question instance

Link between form and question instance is defined in a separate table so that sharing questions between different forms is supported, which can be useful for creating statistics reports. This link also stores information about position of the question in the form.

6) Question answers for questions with predefined answers

This table contains information about answers for questions of types *choice* and *multiple-choice*. Information consists of a link to the question, answer text, description, and answer/choice position in the question.

7) Users feedback

Users feedback contains basic information about the feedback each user provided when filling the form such, as user's id, information which form user filled, date and time when user created or modified the form.

8) Users feedback – Answers

This table contains answers which users gave in their feedback. The information about answers in different question types can be held within one table or it can be divided across multiple tables.

C. Integration

For integration with the system we need to build an interface for creating and editing the forms, displaying the form, parsing the feedback from the user and loading user's feedback from the database.

Function descriptions are provided below and their interactions are shown in *Figure 1*, *Figure 2* and *Figure 3*.

1) Function addeditFormDisplay()

Function *addeditFormDisplay()* has *form type id* and *form id* as arguments. It generates HTML code for editing basic information about the form. If *form id* is empty, a new form is created.

2) Function addeditFormSave()

Function *addeditFormSave()* has *form type id*, *form id*, and *form data* as arguments. It parses the user data and creates or modifies the form. The function returns true on success.

3) Function addeditQuestionDisplay()

Function *addeditQuestionDisplay()* has *form id*, *question type id* and *question id* as arguments. It generates HTML code for editing a question. If *question id* is empty, a new question is created

4) Function addeditQuestionSave()

Function *addeditQuestionSave()* has *form id*, *question type id*, *question id*, and *question data* as arguments. It parses the user data and creates or modifies the question in the form. The function returns true on success.

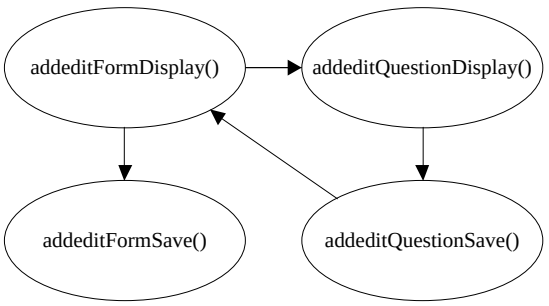

Figure 1 Creating and editing a form

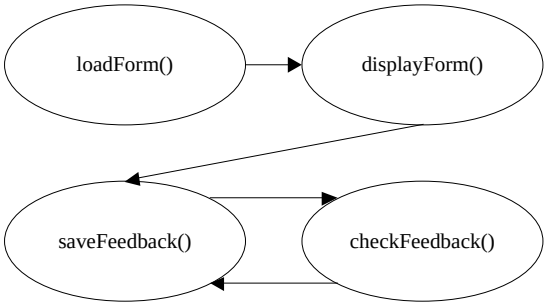

Figure 2 Filling the form

5) Function loadForm()

Function *loadForm()* has *form id* as an argument. Based on a given argument, function returns question and available answers for choice and multiple choice questions. The function is useful in other functions where there is a need for form data.

6) Function loadFormAndFeedback()

Function *loadFormAndFeedback()* has *form feedback id* as an argument and returns the data for displaying the form together with associated user's feedback. It is useful in other functions where there is a need for user's feedback.

7) Function displayForm()

Function *displayForm()* has *form data*, *feedback data*, and Boolean *view* value as arguments. Function generates HTML code for displaying the form. If *view* is true, the generated form will be in the view mode and if it is false, the form will be in the edit mode in which the user will be able to fill the form.

8) Function checkFeedback()

Function *checkFeedback()* has data that user submitted as feedback as an argument together with *form id* and Boolean value if required fields should be checked. The function parses and checks the data for errors. If no error is detected, it returns *true*, otherwise *false* is returned.

9) Function saveFeedback()

Function *saveFeedback()* has data that user submitted as feedback as an argument together with with *form id* and Boolean value if required fields should be checked. This function calls function *checkFeedback()* and if that function returns *true* it saves user's feedback to the database. Optionally, checking for required fields could be disabled if we are saving incomplete form.

D. Extending the Simple Forms

Extending the forms could be useful in case when there is a need for more advanced form where some of the data is acquired from other parts of the system or even another system. Other situations where extend basic functionality of the forms is required are advanced verification and checking of the user feedback, and adding points to the question and calculating the summary score.

Extending the functions from the previous chapter the developer can easily decide for the specific form type which additional fields he or she wants, which checks need to be done, and how to display the form. With this approach, we keep both advantages of different form

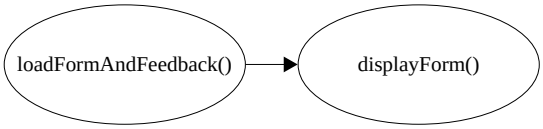

Figure 3 Displaying user's feedback

implementation; the first one is the flexibility and easy modification of questions and the second one is programmable support for complex fields.

III. CURRENT IMPLEMENTATION

Currently, this framework is implemented in Quilt CMS and it is mainly used in a web application for submitting, evaluating, and awarding e-courses which is done by Estonian e-Learning Development Centre (http://www.e-ope.ee/en/quality) [6]. There are 7 different forms in this single web application. Some of these forms are implemented as simple forms without extending, and some are implemented by extending the simple forms.

IV. FUTURE WORK

Described framework should be further simplified for using in the applications by creating custom field which content administrator can reuse in any of the form. In the current framework developer has to create custom fields per form type and these fields can only be at the top or bottom of the form.

V. CONCLUSION

We have shown that framework described in this paper can significantly decrease time needed for implementation of many forms in web applications. Also, we have shown that the need for development can be substantially decreased or even eliminated when some of the simple form field needs to be changed.

These features are beneficial for both developers and content administrators. Content administrator can easily create and edit forms, and developers don't have to repetitively waste their time on trivial tasks.

Interfaces of nested Web application framework as reusable software component

S. Prstačić *, M. Žagar ** and K. Kroflin*

svebor.prstacic@fer.hr

Abstract - The framework is designed to provide a simple and powerful way of Web application component development. Components of the framework can nest, and the framework is designed to be easy to reuse as a component, thus providing its components to be used by the host application. We explain the interfaces required to make this possible – what they provide, what issues they solve, and how their requirement was discovered. We also identify shortcomings of this approach, and issues that will be addressed by future work.

I. INTRODUCTION

Software industry is always trying to improve effectiveness of the development processes. One of the omnipresent impediments that persistently create issues is software component reuse. Software is often built from tightly coupled components that have no standardized interfaces, thus making them hard to reuse or replace.

Although software components have been much discussed and researched, even as early as 1968 [1], most issues still exist today. Many different definitions and ways to create components have been made, but there has always been the issue of reusing components outside of their definition area, outside the framework in which they have been defined and created as components. This is, by nature and complexity of software, unavoidable [1],[2].

For example a component, that is a part of a Web application that provides commenting functionality to some other component, or multiple components of that same application cannot be easily reused inside another application. The reason for this is that it is tightly coupled to both the application and the framework that the application provides, or is built with that application's framework for component development. As a consequence, all such components have to be modified before integration into another application or framework is possible.

We are researching possible ways which would reduce these limitations. We proposed [3] a framework that can be used as a component inside Web applications. In addition to that, the framework provides a Model View Controller (MVC) component development pattern [3]. The idea is to reduce effort required to enable reuse of components developed using said framework. Instead of modifying components or developing adapters for each component that we want to reuse, we have to take care of just one – the framework. So, by integrating the framework into an arbitrary application, we actually integrate all the components developed for that framework.

II. INTERFACES' REQUIREMENTS

Main requirement for successful software component reuse is communication. Every component must be able to effectively request and send all the data that it requires. The same is valid for the framework in question.

Data that the framework requires is defined by the nature of Web application and the nature of components that are used in them. For example, almost every Web application component should be able to decide if it should execute what the user requested. This could be decided from the type of the user, user permissions on some object, user role or some prior action that would have been recorded in that user's session.

In normal circumstances the *Hollywood principle* applies (don't call us we'll call you) [8], and components receive such data from the application when they are needed. The framework works in similar way. It has to be invoked as a component by the host application. But it also works as a controller for its own components. As a consequence, the framework has to receive all the context data a component of the host application would be given, so that its own components can be given that context. The problem is that the host application defines such common execution context data defined using one format, and the framework and components built in it use their own. And this is a common component reuse scenario, when an adapter has to be programmed so that two components that haven't been designed explicitly to interface one with another can communicate [9]. In this case, the two components are the host application and the framework.

Another goal, for which this framework's interfaces were designed, was to enable a simple and easily repeatable integration process with clearly outlined steps for various Web applications. After successful integration the framework will have access to the host application's execution context data that its own components need for execution.

III. FRAMEWORK INTERFACES

To understand the interfaces of the framework, it is important to understand how they support framework execution and integration, and for what data they are used. Let's consider a simplified Web application execution flow with the framework integrated as visualized by Figure 1. When a request is received, it is parsed and the application determines what components to execute, it gives them context in which to execute and in the end, renders the response and sends it to the client. The framework is designed in such way that host application's components can easily extend their functionality by requesting execution of a framework component. For that reason, we called framework components extensions.

In order for everything to work as shown by **Error! Reference source not found.**, we need to successfully achieve a few things:

- Transparent usability of extensions (as shown in **Error! Reference source not found.**) by the host application's components.
- Each extension has to be usable in a simple and uniform way and the host application needs to provide current execution context to the framework component. For example, permissions of the parent object have to be inherited and the current user must be known.
- The extension must know if it will be rendered as a part of a form or independently
- The extension must know what data will it hook onto – for example, provide some functionality for a parent component's article
- Extensions must know how to generate their actions' URLs in a way not to interfere with the host application.

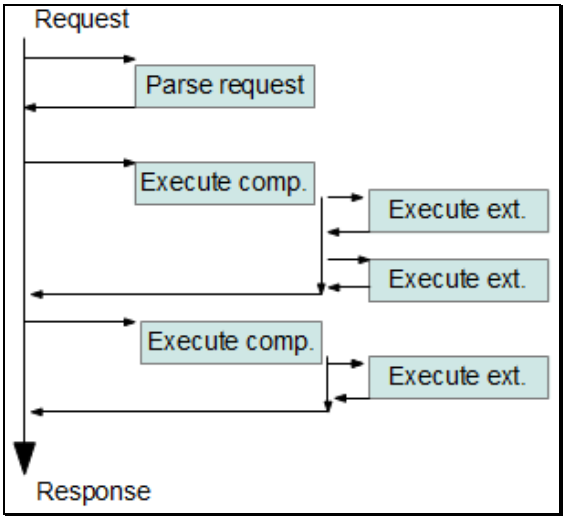

Figure 1. Execution flow

A. *Interfaces for extension execution*

Extensions' execution starts when a component makes a request to the framework. The interface through which a component can request this is fairly simple, and only expects a few data parameters. Mandatory parameters are: the type of data the parent component is showing, for which it wants to provide some extension; the unique identifier of that data, for example if the data type was color, identifier could be "red".

Optional parameters include information whether the extension execution is required within a form; the preferred mode of extension execution; and a handler class that is to be called upon by the framework if some event occurs for the data that an extension has been hooked onto.

The form nesting information is optional because the framework will assume that the extension will not be used inside a form and in most cases this will be true. Also, a default mode is executed if none is requested. However, if a more complex cooperation between a parent component and an extension is intended, these two parameters are unavoidable. If a parent component, say a blog application, wants to seamlessly integrate an extension that provides photo galleries, and provide gallery creation along with new blog creation so that both get saved when a user clicks save, the extension will have to be rendered inside the parent form in gallery editing mode.

There also exists a special case. When no unique identifier for the data can be given, because that data doesn't yet exist, the parent component has to create a stub (shown in Figure 2.). This stub will get replaced when the data is eventually created. There is an interface for this, provided by the framework. Once a component creates a stub, it can attach an extension to it and has to remember and use it until its own data is created. When this happens, the component must request stub replacement from the framework by providing the data to which it really wants to hook an extension, and the stub.

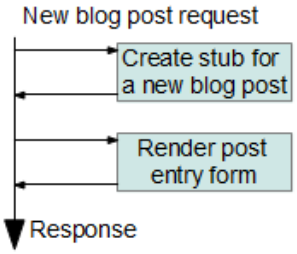

Figure 2. New blog article entry started, a stub entry gets created

Such behavior can be explained by example. Let's consider the previous one with a blog application and a photo gallery: the gallery extension has to be executed for a component that cannot yet specify the unique data because the user hasn't yet created a blog post. So, the blog application notifies the framework that a new post will be created, and the framework creates a stub. When the blog application creates the new post, it has to notify the framework and specify the stub it wants to replace with the data that now exists. Execution flow and interaction of the blog application and the gallery extension is visualized on Figure 3.

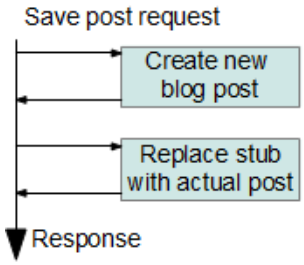

Figure 3. New blog article saved, stub reference replaced

B. *Interfaces for common Web application data*

During execution, every Web application component may require some common session or context data. An example of such data is information about the current user. This usually includes, but is not omitted to: username, id of the user, email, public display name etc. Extensions are no different, but since it is expected that they work uniformly across multiple applications that have this data stored, named and defined in different ways, the framework provides an interface for them to access it. For this to work, a few components have to be implemented as a part of the host application. Their purpose is to translate the host application's data into something the extensions uniformly understand.

Translation of host application's data is done by implementation of abstract classes which are part of integration configuration of the framework. Currently, there are three classes that provide these interfaces: PermissionsMapper, UserDataMapper and SessionDataMapper. On extension and implementation of these abstract classes, the names of implemented classes have to be registered with the framework, which is as simple as writing the class name into the configuration file.

1) *PermissionMapper*

The idea for classes that extend this abstract class is to provide translation of permissions and access control that the host application uses to a form which the framework extensions understand.

There are five access level rights that the framework defines: view, write, author, admin and god. Meaning of these levels is defined like:

- View: the user can view content
- Write: user can comment, like, grade or tag content
- Author: user can create new content
- Admin: user can define functionality of components, for example enable or disable posting comments, uploading galleries etc.
- God: user can add or remove components

Permission rights are stacking, which means, author permissions imply write and view permissions and so on.

If the host application defines three levels of user access, these have to be mapped to the described five the framework expects. As a consequence, some of the levels of the host application will have to be mapped to multiple framework levels, or, if the host application defines more than five, they will have to be narrowed down to five.

For example, if the host application defines access rights for unregistered, registered and admin users, mapping could be done as follows: map unregistered to view; registered to write; and admin to author, admin and god permissions. This is visualized in Figure 4.

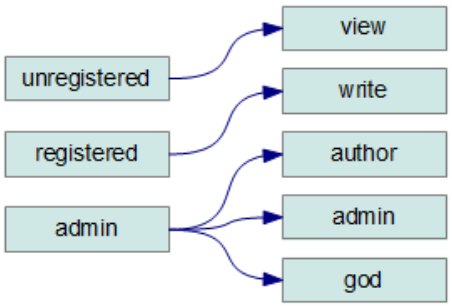

Figure 4. Host application to framework permission mapping

2) *UserDataMapper*

Common requirement for Web application components is recording which user did what, or signing a user with her public name or nickname when showing content she created – the author of a blog post, uploader of a photo gallery etc. Whether the idea is to create logs or simply give credit for created data, some basic and pervasive user data about the current user has to be available to the component that is being executed.

Again, extensions and the framework cannot provide their own users, but have to provide functionality for users of the host application. This, again, means we will have to translate the meaning of the data that is understood by the host application, to a format the framework extensions understand.

The UserDataMapper class is used to solve this by mapping the host application's data. Again, it is an abstract class with a number of abstract methods that have to be implemented, and the implementing class has to be registered with the framework. Data the class is expected to translate is:

- Timestamp of the last user's login;
- User's name;
- User's last name; user's initials;
- User's public, or display name;
- The username;
- The id of the user – in whatever way it is defined by the host application;
- Email of the user;
- User's profile URL
- And the URL to the user's profile picture or avatar.

3) SessionDataMapper

The SessionDataMapper abstract class has two purposes. Enable the framework components to write to a session variable that is unlikely to be used by the host application, and access to host application's session data that could be of value to extensions.

The variable that extensions can use to write to session, has the name defined in the configuration of the framework and is a MD5 hash sum of the actual name that the programmer defines in the configuration. Currently, extensions are not limited in any way and could write to session directly, but by design, should request a reference to a writable session variable by using the *getWriteableSession* method of the SessionDataMapper class. This is the only implemented method in the class, the rest are abstract and have to be implemented to provide intended functionalities of the class. The way to do this is to extend the class, and register the extended class in the framework configuration as the provider for session mapping.

Abstract methods of the SessionDataMapper provide a way to access various common session data of content management systems (CMS), or simpler Web applications. Complete list of data that is accessible to the framework and its extensions is:

- The ID of the current page
- ID of the current site
- Debugging mode is on or off
- ID of the currently used design
- Current page title
- Current site title
- W3C code of the current language the host application is using to display controls and content
- W3C code page that the host application is using [4]
- The IP address of the server
- The name of the server (address like www.fer.hr)
- Base URL of the host application on the specified address

C. *Interfaces of the framework as a component*

The framework, when integrated with an arbitrary application, will be used as a component – an instance of a singleton class ExtFramework. It will be handled and invoked by the host application to execute requested extensions and return results. There are only a few simple tasks the host application can, and is required to do, in order for the framework and its extensions to work properly. First, the framework has to be initialized, and the execution of extensions can consequently be requested as needed.

The ExtFramework object's public interface is very simple. Since it is a singleton class, the host application can request a reference to the object instance. With that, only three more actions can be performed:

1) Execute an extension

Execution of the extension occurs when a component wants to extend its capabilities with some of those offered by an extension. There are two ways to initiate extension execution: a method of the ExtFramework, or a Smarty [7], [3] plugin that is usable for host applications that use Smarty – a template engine for PHP.

When a component initiates the execution, the framework does the work of instantiating the extension and executing the required action. It then retrieves the rendered HTML that the extension rendered to the invoking component. If a Smarty plugin was used to execute the extension, the rendered extension will automatically be put into the template from which execution was invoked, and if a method was used, it is up to the host application and the invoking component to decide what to do with extension output.

2) Set execution mode

For some cases when the host application uses Smarty and a Smarty plugin of the framework, to request extension execution, caching can create problems. In those cases, the host application can sometimes render an outdated state of the extension.

To circumvent this problem, the framework can be configured to execute all the extensions at once, when all the extension invocations have been done. Data returned by the extension invocation Smarty plugin and method will, in that case, always be the same. For each extension instance data they return is a unique *stub* - a string that will later be replaced by the actual extension output. Difference in the execution flow when stubs are used is shown on Figure 5. , as opposed to Figure 1.

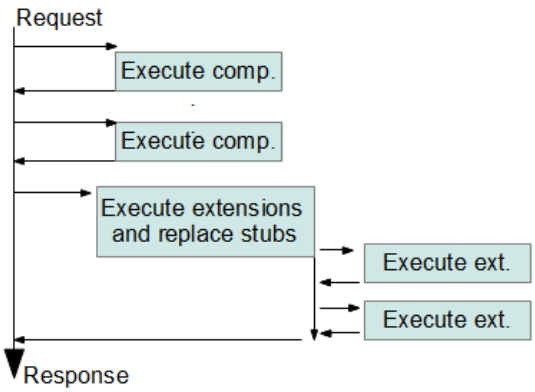

Figure 5. Execution flow when executing all extensions at once

3) Execute extensions and replace stubs

If the previously explained execution mode is set to execute every extension immediately upon invocation, the framework will do nothing when the *execExtensionsAndReplaceStubs* method is invoked.

But, if the execution mode is set to execute everything at once, this method will expect a string that represents the rendered HTML output of the host application, into which stubs have been written. For each extension the framework will initiate execution with the parameters it

remembered on invocation, and then search for a stub that corresponds to that extension and replace it with actual HTML the extension renders.

IV. FUTURE WORK

Testing of current methods of integration and communication of the framework with host applications and components has to be done with a wider array of applications. For now, it has only been done with Quilt CMS. The goal of this testing is to revise the integration interfaces and fix any possible shortcomings that we encounter.

We also plan to research how to enable better interaction between extensions and host application components concerning data that belongs to the host application, to which extensions hook onto, and data that belongs to extensions. We expect to identify new interfaces that would make this interaction possible and simple to achieve.

V. CONLUSION

We have shown that successful communication between the host application and the framework as a component is possible in a rather simple way. Interfaces that have been defined make this communication possible, and significantly improve component reusability for Web applications. Instead of having to integrate many components to use them, we can integrate one and use many.

Maxwell's Equations for Nanotechnology

Milan Perkovac
I. Technical School TESLA, Klaiceva 7, Zagreb
milan@drives.hr

Abstract - Classical physics, which includes Maxwell's equations, a hundred years ago couldn't explain the stability of atoms, the periodic table of elements, the chemical bond, the discrete excitation energies of atoms and their energetic state, the ionization of atoms, the spectra, including its fine structure and transition rules, experimental evidence about x-ray spectra and the behavior of atoms in electric and magnetic fields, the properties of the matter in solid state. That was the reason why classical physics fails when applied to the atomic area, i.e. to the area of nanometers or below. Now the situation has changed. It's because within the framework of classical physics, with the help of Maxwell's equations, we can derive Schrödinger's equation, which is the foundation of quantum physics. With this new knowledge all of the above can now be explained within the framework of classical physics. This article describes the procedure for obtaining the equation, which replaces the Schrödinger's equation using classical physics.

I. INTRODUCTION

The whole twentieth century in physics is mostly passed in the search for answers to fundamental questions of matter, primarily on the relationship between waves and particles. Discussions about this are still going on. All the studies are based on unique natural laws that apply universally in the universe and the atom. But this general approach to the macroscopic and microscopic scale seemed questionable in the case of Maxwell's equations. In fact, Maxwell's equations have reached excellent results in the macroscopic scale. Their application in the microscopic scale at first glance seemed disappointed. Namely, Maxwell's equations previously couldn't explain the stability of atoms, the periodic table of elements, the chemical bond, the discrete excitation energies of atoms and their energetic state, the ionization of atoms, the spectra, including its fine structure and transition rules, experimental evidence about x-ray spectra and the behavior of atoms in electric and magnetic fields, the properties of the matter in solid state. That was the reason why classical physics fails when applied to the atomic area, i.e. to the area of nanometers or below. This is why the entire physics divided into two branches: (traditional) classical and (new) quantum physics.

Despite the uncertain physical meaning of the wave function ψ at the famous Schrödinger's equation, $\nabla^2\psi+8\pi^2m(E-U)\psi/h^2=0$, the equation has played an important role in the development of quantum physics. The wave function $\psi(x,y,z)=\psi(\mathbf{r})$ is the solution of the Schrödinger equation, i.e. it is a mathematical expression involving the coordinates (x, y, z) of a particle in space ($\mathbf{r} = x\hat{\mathbf{i}} + y\hat{\mathbf{j}} + z\hat{\mathbf{k}}$, where $\hat{\mathbf{i}}$, $\hat{\mathbf{j}}$ and $\hat{\mathbf{k}}$ are unit vectors; all vectors below are bold letters). If we solved the Schrödinger equation for a particle in a given system then, depending on the boundary condition, the solution is a set of allowed wave functions of the particle, each corresponding to an allowed energy level. The physical meaning of the wave function ψ is that the square of its absolute value, $|\psi|^2$, at a given point is proportional to the probability of finding the particle in a small element of volume, dxdydz, at that point. For an electron in an atom, this gives the idea of atomic and molecular orbital. All of this was obtained without the use of Maxwell's equations. After the explanation of radiation [1, 2], Maxwell's equations can give a lot more contributions to quantum physics, than has been the case so far. It's because from Maxwell's equations we can derive Schrödinger's equation, which is the foundation of quantum physics.

The meaning of physical quantities in Maxwell's equations is completely clear. Therefore, the meanings of the wave functions of these equations, which are derived from Maxwell's equations, are completely clear.

This article describes how Schrödinger's equation is obtained using classical physics, with special emphasis on Maxwell's equations. With this equation all the previous disadvantages of Maxwell's equations can now be explained in the framework of classical physics.

II. DERIVATION OF WAVE EQUATION

Maxwell's equations are the four differential equations describing the space and time, i.e. ($\mathbf{r}$, t), dependence of the electromagnetic field [3, 4, 5, 6]:

♦ Gauss's law for electric flux (electric flux begins and ends on charge or at infinity);

$$\nabla \cdot \boldsymbol{\mathcal{D}}(\mathbf{r},t) = \rho(\mathbf{r},t)\,, \qquad (1a)$$

♦ Gauss's law for magnetism (magnetic field lines don't begin or end);

$$\nabla \cdot \boldsymbol{\mathcal{B}}(\mathbf{r},t) = 0\,, \qquad (1b)$$

♦ Faraday's law of electromagnetic induction; a changing $\boldsymbol{\mathcal{B}}$ produce $\boldsymbol{\mathcal{E}}$;

$$\nabla \times \boldsymbol{\mathcal{E}}(\mathbf{r},t) = -\frac{\partial \boldsymbol{\mathcal{B}}(\mathbf{r},t)}{\partial t}\,, \qquad (1c)$$

♦ Ampère's circuital law (with Maxwell's correction); $\boldsymbol{\mathcal{H}}$ is produced by current $\boldsymbol{\mathcal{J}}$ and by changing $\boldsymbol{\mathcal{D}}$;

$$\nabla \times \boldsymbol{\mathcal{H}}(\mathbf{r},t) = \boldsymbol{\mathcal{J}}(\mathbf{r},t) + \frac{\partial \boldsymbol{\mathcal{D}}(\mathbf{r},t)}{\partial t}\,, \qquad (1d)$$

where $\boldsymbol{\mathcal{D}}$ is the electric displacement, $\boldsymbol{\mathcal{E}}$ is the electric field strength, $\boldsymbol{\mathcal{B}}$ is the magnetic flux density, $\boldsymbol{\mathcal{H}}$ is the magnetic field strength, ρ is the volume charge density, and $\boldsymbol{\mathcal{J}}$ is the electric current density. The differential operator $\nabla = \hat{\mathbf{i}}\,\partial/\partial x + \hat{\mathbf{j}}\,\partial/\partial y + \hat{\mathbf{k}}\,\partial/\partial z$ is called "del" operator.

There are a total of 16 variables in (1a)-(1d) (the 15 components of the five vectors $\boldsymbol{\mathcal{E}}$, $\boldsymbol{\mathcal{D}}$, $\boldsymbol{\mathcal{B}}$, $\boldsymbol{\mathcal{H}}$, $\boldsymbol{\mathcal{J}}$, and the scalar ρ). If the source densities ρ and $\boldsymbol{\mathcal{J}}$ are given (four known variables) still remain 12 unknown variables. There are, however, eight equations; one from (1a), one from (1b), and three for components in (1c) and (1d) each. Obviously, to make system determinate we need additional relations.

For a completely linear medium there are constitutive relations describing the properties of the media in which the fields exist: $\boldsymbol{\mathcal{D}} = \varepsilon\boldsymbol{\mathcal{E}}$, $\boldsymbol{\mathcal{B}} = \mu\boldsymbol{\mathcal{H}}$, $\boldsymbol{\mathcal{J}} = g\boldsymbol{\mathcal{E}}$, where ε is dielectric constant, μ is the magnetic constant of proportionality, and g is the conductivity of the media. Hence [without writing $(\mathbf{r},t)$ which is implied] the Maxwell equations become:

♦ Gauss's law for electric flux; $\nabla \cdot \boldsymbol{\mathcal{E}} = \frac{\rho}{\varepsilon}\,,$ (2a)

♦ Gauss's law for magnetism; $\nabla \cdot \boldsymbol{\mathcal{B}} = 0\,,$ (2b)

♦ Faraday's law; $\nabla \times \boldsymbol{\mathcal{E}} = -\frac{\partial \boldsymbol{\mathcal{B}}}{\partial t}\,,$ (2c)

♦ Ampère's law; $\nabla \times \boldsymbol{\mathcal{B}} = \mu\boldsymbol{\mathcal{J}} + \mu\varepsilon\frac{\partial \boldsymbol{\mathcal{E}}}{\partial t}\,.$ (2d)

a) Let's take curl of Faraday's law, i.e. of (2c):

$$\nabla \times (\nabla \times \boldsymbol{\mathcal{E}}) = -\frac{\partial(\nabla \times \boldsymbol{\mathcal{B}})}{\partial t}\,. \qquad (3)$$

On the other hand, for each vector $\boldsymbol{\mathcal{E}}$ is true:

$$\nabla \times (\nabla \times \boldsymbol{\mathcal{E}}) = \nabla(\nabla \cdot \boldsymbol{\mathcal{E}}) - \nabla^2 \boldsymbol{\mathcal{E}}\,, \qquad (4)$$

and the substitution in (3) Ampere's law (2d) gives:

$$\nabla(\nabla \cdot \boldsymbol{\mathcal{E}}) - \nabla^2 \boldsymbol{\mathcal{E}} = -\frac{\partial}{\partial t}\left(\mu\boldsymbol{\mathcal{J}} + \mu\varepsilon\frac{\partial \boldsymbol{\mathcal{E}}}{\partial t}\right), \qquad (5)$$

where $\nabla^2 = \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} + \frac{\partial^2}{\partial z^2}$ is operator called the Laplacian. Now in (5) add Gauss's law for electric flux (2a), and $\boldsymbol{\mathcal{J}} = g\boldsymbol{\mathcal{E}}$:

$$\nabla^2 \boldsymbol{\mathcal{E}} - \mu g\frac{\partial \boldsymbol{\mathcal{E}}}{\partial t} - \mu\varepsilon\frac{\partial^2 \boldsymbol{\mathcal{E}}}{\partial t^2} - \nabla\left(\frac{\rho}{\varepsilon}\right) = 0\,. \qquad (6)$$

b) Let's take curl of Ampère's law, i.e. of (2d):

$$\nabla \times (\nabla \times \boldsymbol{\mathcal{B}}) = \nabla \times (\mu\boldsymbol{\mathcal{J}} + \mu\varepsilon\frac{\partial \boldsymbol{\mathcal{E}}}{\partial t})\,. \qquad (7)$$

On the other hand, for each vector $\boldsymbol{\mathcal{B}}$ is true:

$$\nabla \times (\nabla \times \boldsymbol{\mathcal{B}}) = \nabla(\nabla \cdot \boldsymbol{\mathcal{B}}) - \nabla^2 \boldsymbol{\mathcal{B}}\,, \qquad (8)$$

Using $\boldsymbol{\mathcal{J}} = g\boldsymbol{\mathcal{E}}$ gives:

$$\nabla(\nabla \cdot \boldsymbol{\mathcal{B}}) - \nabla^2 \boldsymbol{\mathcal{B}} = \mu g(\nabla \times \boldsymbol{\mathcal{E}}) + \mu\varepsilon\frac{\partial(\nabla \times \boldsymbol{\mathcal{E}})}{\partial t}\,. \qquad (9)$$

Now in (9) add Faraday's law (2c):

$$\nabla(\nabla \cdot \boldsymbol{\mathcal{B}}) - \nabla^2 \boldsymbol{\mathcal{B}} = -\mu g\frac{\partial \boldsymbol{\mathcal{B}}}{\partial t} - \mu\varepsilon\frac{\partial^2 \boldsymbol{\mathcal{B}}}{\partial t^2}\,. \qquad (10)$$

Using (2b), i.e. $\nabla \cdot \boldsymbol{\mathcal{B}} = 0$, and $\boldsymbol{\mathcal{B}} = \mu\boldsymbol{\mathcal{H}}$, and after sharing with μ, we get from (10):

$$\nabla^2 \boldsymbol{\mathcal{H}} - \mu g\frac{\partial \boldsymbol{\mathcal{H}}}{\partial t} - \mu\varepsilon\frac{\partial^2 \boldsymbol{\mathcal{H}}}{\partial t^2} = 0\,. \qquad (11)$$

Equations (6) and (11) are required wave equations. These two vector equations constitute six component equations with seven unknowns ($\mathcal{E}_x$, $\mathcal{E}_y$, $\mathcal{E}_z$, $\mathcal{H}_x$, $\mathcal{H}_y$, $\mathcal{H}_z$, ρ). The system becomes determined if viewed without charge, i.e. $\rho = 0$. So we get:

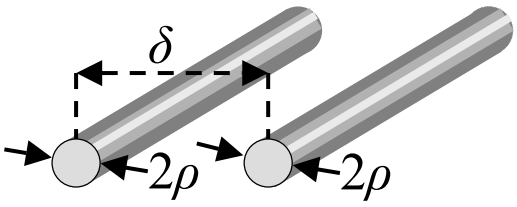

Figure 1. Lecher line (*section*); twin-lead transmission line consisting of pair of wires of diameter 2ρ, separated by δ.

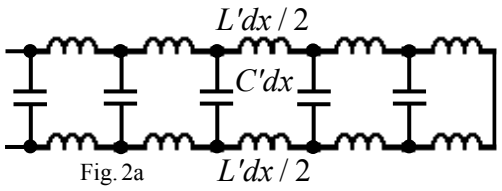

Fig. 2a

Fig. 2b

Figure 2. Lecher line is presented with an infinitely small capacitors $C'dx$ and inductors $L'dx$ (Fig. 2a), which are concentrated at its end; C at the open end of the line, and L on its short-circuited end (Fig. 2b).

$$\nabla^2 \boldsymbol{\mathcal{E}} - \mu g \frac{\partial \boldsymbol{\mathcal{E}}}{\partial t} - \mu\varepsilon \frac{\partial^2 \boldsymbol{\mathcal{E}}}{\partial t^2} = 0\,, \qquad (12)$$

$$\nabla^2 \boldsymbol{\mathcal{H}} - \mu g \frac{\partial \boldsymbol{\mathcal{H}}}{\partial t} - \mu\varepsilon \frac{\partial^2 \boldsymbol{\mathcal{H}}}{\partial t^2} = 0\,. \qquad (13)$$

In empty space, i.e. in vacuum, what is also the inside of atoms, we have $g = 0$, so the equations (12) and (13) becomes:

$$\nabla^2 \boldsymbol{\mathcal{E}} - \mu\varepsilon \frac{\partial^2 \boldsymbol{\mathcal{E}}}{\partial t^2} = 0\,, \qquad (14)$$

$$\nabla^2 \boldsymbol{\mathcal{H}} - \mu\varepsilon \frac{\partial^2 \boldsymbol{\mathcal{H}}}{\partial t^2} = 0\,. \qquad (15)$$

Wave equations of the electromagnetic wave on Lecher's lines, Fig. 1 (using Maxwell's equations and Kirchhoff's laws, [7]), have the same form as equations (14) and (15) of the electromagnetic wave in vacuum [8],

$$\frac{\partial^2 u}{\partial x^2} - L'C' \frac{\partial^2 u}{\partial t^2} = 0\,, \qquad (16)$$

$$\frac{\partial^2 i}{\partial x^2} - L'C' \frac{\partial^2 i}{\partial t^2} = 0\,, \qquad (17)$$

where L' is inductance of Lecher's line per unit length, and C' is its capacitance per unit length [9]:

$$L' = \mu \frac{\ln(\delta/\rho)+1/4}{\pi}\,, \qquad (18)$$

$$C' = \varepsilon \frac{\pi}{\ln\left\{\delta/(2\rho)+\sqrt{[\delta/(2\rho)]^2-1}\right\}}\,, \qquad (19)$$

where ρ is the radius of each conductor and δ is the distance between the conductors.

Transmission line can be a model for the observation of electromagnetic waves, given that they have the same differential equation. It takes only a mutual adjustment of parameters. Then the voltage u of transmission lines represents the wave function $\mathcal{E}$, while the current i of transmission lines represents the wave function $\mathcal{H}$.

III. Adjustment the Parameters of Wave and Lecher's Line

Lecher line can be regarded as a limiting case of an LC network with infinitely small capacitors and inductors, Fig.2a, [10]. If all the capacitors of the network are put on the open end, and inductances on the short-circuited end, Fig 2b, the natural angular frequency of such oscillatory circuit will be, [11]:

$$\omega = 1/\sqrt{LC}\,. \qquad (20)$$

The product of L' and C' is:

$$L'C' = \mu\varepsilon \frac{\ln(\delta/\rho)+1/4}{\ln[(\delta/\rho)/2+\sqrt{(\delta/\rho)^2/4-1}]}\,. \qquad (21)$$

The coefficient $L'C'$ in (16) and (17) determines the phase velocity of the wave on the line (Fig. 3), in

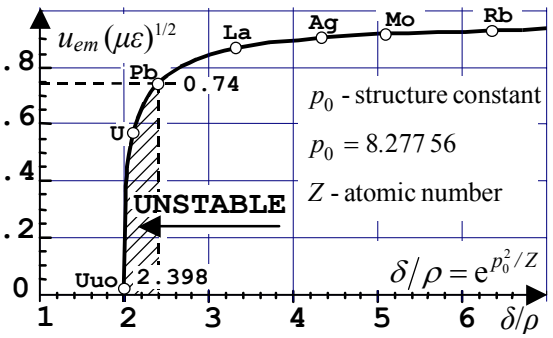

Figure 3. Phase velocity of electromagnetic wave on Lecher's line as a function of ratio δ/ρ. Areas of stability of atoms is determined in accordance with [12] (Z=82, lead, δ/ρ=2.398).

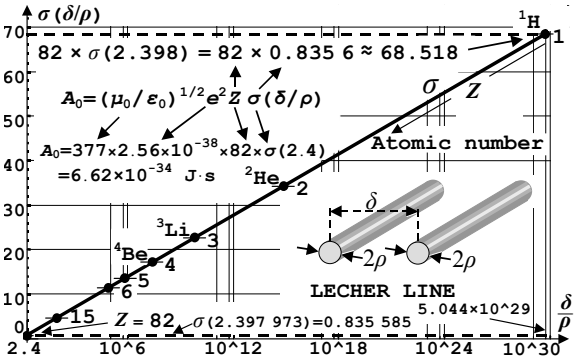

Figure 4. Structural coefficient of twin-lead transmission line, $\sigma(\delta/\rho)=\sqrt{[\ln(\delta/\rho)+1/4]\ \ln[(\delta/\rho)/2+\sqrt{(\delta/\rho)^2/4-1}\,]}$ (*Lecher line*) in function of δ/ρ (*log-lin scale*), Ref. 12.

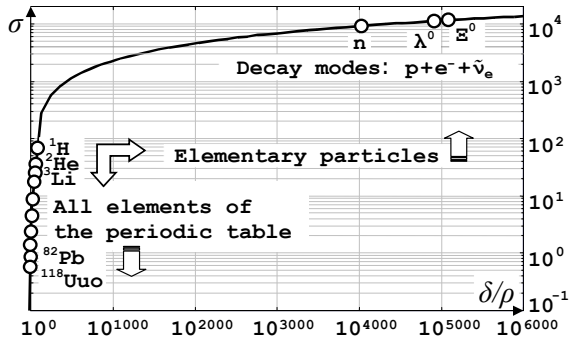

Figure 5. Structural coefficient of twin-lead transmission line, $\sigma(\delta/\rho)=\sqrt{[\ln(\delta/\rho)+1/4]\ \ln[(\delta/\rho)/2+\sqrt{(\delta/\rho)^2/4-1}\,]}$ (*Lecher line*) in function of δ/ρ (*log-log scale*), Ref. 12, (*Elements and Particles*).

accordance with the equation, [13]:

$$u_{em}=1/\sqrt{L'C'}\,, \tag{22}$$

i.e.,

$$u_{em}=\frac{1}{\sqrt{\mu\varepsilon}}\sqrt{\frac{\ln[(\delta/\rho)/2+\sqrt{(\delta/\rho)^2/4-1}]}{\ln(\delta/\rho)+1/4}}\,. \tag{23}$$

Using (18) and (19), the characteristic (wave) impedance of *LC* circuit, as well as the characteristic impedance of the Lecher's line read:

$$\begin{aligned} Z_{LC}&=\sqrt{L/C}=\sqrt{L'/C'}\\ &=\frac{\sqrt{[\ln(\delta/\rho)+1/4]\ln[(\delta/\rho)/2+\sqrt{(\delta/\rho)^2/4-1}]}}{\pi}\sqrt{\mu/\varepsilon}\\ &=\frac{\sigma(\delta/\rho)}{\pi}\sqrt{\mu/\varepsilon}\,, \end{aligned} \tag{24}$$

where σ from a mathematical point of view is a function of δ/ρ,

$$\sigma=\sqrt{[\ln(\delta/\rho)+1/4]\ln[(\delta/\rho)/2+\sqrt{(\delta/\rho)^2/4-1}\,]}\,. \tag{25}$$

From the physical point of view σ is a coefficient of the structure of transmission lines, so we will call it *structural coefficient* dependent on the parameters δ and ρ, more specifically on δ/ρ, (see Fig. 4 and Fig. 5).

Natural frequency of electromagnetic *LC* oscillator is determined by (20), i.e.,

$$\nu=1/2\pi\sqrt{LC}\,. \tag{26}$$

This means that the oscillatory period of a *LC* oscillator is equal to

$$T=1/\nu=2\pi\sqrt{LC}\,. \tag{27}$$

Electromagnetic energy of an *LC* circuit, E_{em}, theoretically can be presented as the electrical energy stored in a capacitor that has a capacitance equal to *C* and a maximum charge equal to $\hat{Q}_C$ (*or magnetic energy stored in a coil that has inductance equal to L and maximum current equal to* $\hat{I}_L$), so:

$$\begin{aligned} E_{em}&=\frac{1}{2}L\hat{I}_L^2=\frac{1}{2}\frac{\hat{Q}_C^2}{C}=\frac{1}{2}\frac{\pi}{\pi}\frac{\hat{Q}_C^2}{\sqrt{C}\sqrt{C}}\frac{\sqrt{L}}{\sqrt{L}}\\ &=\pi\sqrt{\frac{L}{C}}\hat{Q}_C^2\frac{1}{2\pi\sqrt{LC}}=\pi Z_{LC}\hat{Q}_C^2\nu=A\nu\,, \end{aligned} \tag{28}$$

where

$$A=\pi Z_{LC}\hat{Q}_C^2 \tag{29}$$

is an *action of electromagnetic oscillators*, defined as the product of energy, E_{em}, and period, *T*, of the *LC* oscillator:

$$A=E_{em}T=E_{em}/\nu\,. \tag{30}$$

All above is generally true at the macroscopic and the microscopic level.

IV. THEORY ON MICROSCOPIC SCALE

Now we will adjust the previous equations for the microscopic scale. From Newton's second law, $F=ma$, we substitute $a=v^2/r_a$ and Coulomb's law for *F*, and also from relativistic mass we obtain:

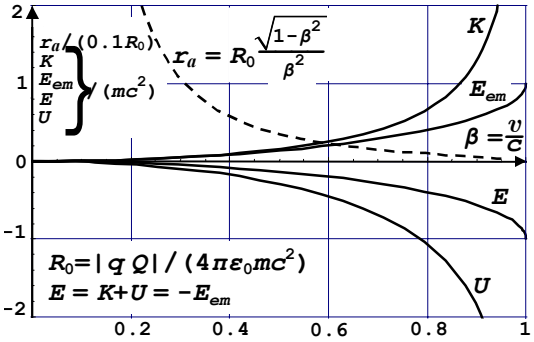

Figure 6. Radius of the atom r_a, kinetic energy K, electromagnetic energy E_{em}, total mechanical energy E, and potential energy U of the electron in an atom as a function of $\beta = v/c$, ($0 \le \beta \le 1$).

$$\frac{m\,v^2}{r_a\sqrt{1-\beta^2}} = \frac{|qQ|}{4\pi\varepsilon r_a^2}, \tag{31}$$

or

$$r_a = \frac{|qQ|}{4\pi\varepsilon mc^2}\frac{\sqrt{1-\beta^2}}{\beta^2}, \tag{32}$$

where r_a is the radius of the atom, q is the charge of the electron ($q = -e$, $e = 1.602\,177\,33\times10^{-19}$ C), Q is the core charge, $m = 9.109\ldots\times10^{-31}$ kg is the electron rest mass, $c = 299\,792\,458$ m/s is the speed of light in vacuum, $\beta = v/c$, where v is the electron velocity.

The kinetic energy of electrons in the atom is

$$K = \frac{mc^2}{\sqrt{1-\beta^2}} - mc^2, \tag{33}$$

and, using (32), noting that an electron is of opposite charge of the nucleus, the potential energy of electrons is

$$U = \frac{qQ}{4\pi\varepsilon r_a} = -\frac{mc^2}{\sqrt{1-\beta^2}}\beta^2. \tag{34}$$

Thus, the electromagnetic energy, E_{em}, (see Fig. 6) is equal to the total mechanical energy E with negative sign,

$$E_{em} = -E = -\left(K+U\right) = mc^2\left(1-\sqrt{1-\beta^2}\right). \tag{35}$$

When the electromagnetic wave leaves the atom it carries out the energy E_{em}, and vice versa, when it enters the atom, it brings in the same energy. This means that due to the reduction of energy E_{em}, the atom should be compensated with equally large energy eV:

$$E_{em} = -E = eV. \tag{36}$$

From the expressions (35) and (36) we obtain

$$\sqrt{1-\beta^2} = 1 - eV/mc^2, \tag{37}$$

i.e.,

$$\beta^2 = \left(2eV/mc^2\right)\left(1-eV/2mc^2\right), \tag{38}$$

or

$$\beta = \sqrt{2eV/mc^2}\sqrt{1-eV/2mc^2}. \tag{39}$$

Using (32), (37), and (38), we obtain

$$r_a = \frac{|qQ|}{8\pi\varepsilon eV}\,\frac{1-eV/mc^2}{1-eV/2mc^2}, \tag{40}$$

while from (40) we obtain eV using (28) and (36):

$$eV = \frac{|qQ|}{8\pi\varepsilon r_a}\,\frac{1-eV/mc^2}{1-eV/2mc^2} = \frac{1}{2}\frac{\hat{Q}_C^2}{C}. \tag{41}$$

From a single equation, (41), we need to determine two unknown sizes, i.e., parameter C and variable $\hat{Q}_C$. Therefore, we seek solutions with the help of Diophantine equations, [14]:

$$C = 4\pi\varepsilon r_a, \tag{42}$$

$$\hat{Q}_C^2 = |qQ|\,\frac{1-eV/mc^2}{1-eV/2mc^2}, \tag{43}$$

Using (24), (26), (41) and (42) we get the following, which is similar to the expression (28):

$$eV = \frac{|qQ|}{8\pi\varepsilon r_a}\,\frac{1-eV/mc^2}{1-eV/2mc^2} = \frac{|qQ|}{2C}\,\frac{1-eV/mc^2}{1-eV/2mc^2} = \pi Z_{LC}\,|qQ|\,\frac{1-eV/mc^2}{1-eV/2mc^2}\,\nu = A\,\nu. \tag{44}$$

From (29) and (43) follows

$$A = \pi Z_{LC}\,|qQ|\,\frac{1-eV/mc^2}{1-eV/2mc^2}. \tag{45}$$

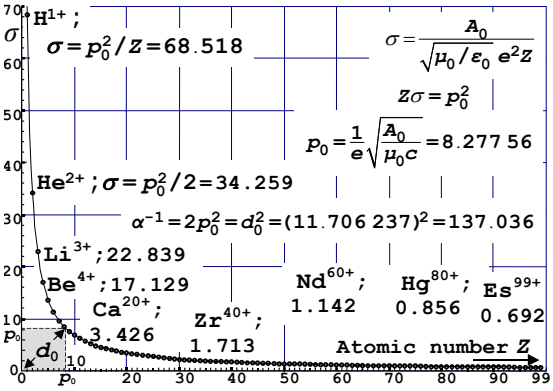

Figure 7. Structural coefficient $\sigma = p_0^2 / Z$ as a function of atomic number Z (*equilateral hyperbole of atoms*).

If $eV = 0$ then $A = A_0$. This means that (45) can be written as

$$A = A_0 \frac{1 - eV / mc^2}{1 - eV / 2mc^2}, \qquad (46)$$

where

$$A_0 = \pi Z_{LC} \mid qQ \mid . \qquad (47)$$

A_0 does not depend on the energies eV, which enter or leave the atoms. This ultimately means that A_0 is the universal constant of any atom (see Fig. 4 and Fig. 7), [15]:

$$A_0 = \sqrt{\mu_0 / \varepsilon_0}\, e^2 p_0^2 = 6.626\,075 \times 10^{-34}\ \mathrm{J \cdot s} \qquad (48)$$

where $p_0 = 8.277\,56$, $\mu_0 = 4\pi \times 10^{-7}\ \mathrm{H/m}$, $\varepsilon_0 = 8.854\,187\,817 \times 10^{-12}\ \mathrm{F/m}$.

From (44) follows $eV = A\nu$, and using (46) we get:

$$\nu = \frac{eV}{A_0} \frac{1 - eV / 2mc^2}{1 - eV / mc^2}. \qquad (49)$$

V. Relationship Of Maxwell's And Schrödinger's Equations

From (36) and (49) we get the general relativistic expression for the energy of electromagnetic waves emitted or absorbed by the atom,

$$E_{em} = A_0\nu + mc^2 - \sqrt{(A_0\nu)^2 + (mc^2)^2}\ . \qquad (50)$$

If the frequency is low, then

$$E_{em} \mid_{\nu \to 0} = A_0\nu\ . \qquad (51)$$

This, in the case of $A_0 = h$, proves the validity of empirically derived Planck-Einstein's relation $E_{em} = h\nu$, but also shows that Planck-Einstein's relation is limited only to relatively low frequencies ν. If this frequency is high, then

$$E_{em} \mid_{\nu \to \infty} = mc^2\ . \qquad (52)$$

From (28) and (50) follows the action of electromagnetic oscillators:

$$A = A_0 + \frac{mc^2}{\nu} - \sqrt{A_0^2 + \left(\frac{mc^2}{\nu}\right)^2}\ . \qquad (53)$$

We see that the action of electromagnetic oscillators, A, is not constant for all frequencies ν.

Momentum of electromagnetic wave, p_{em}, in accordance with [16], is equal to the ratio of its energy (E_{em}) and phase velocity

$$u_{em} = \lambda\nu\ , \qquad (54)$$

i.e.,

$$p_{em} = \frac{E_{em}}{u_{em}} = \frac{E_{em}}{\lambda\ \nu}, \qquad (55)$$

where λ is the wavelength of the electromagnetic wave. On the other hand, in accordance with the law of conservation of momentum, the momentum of electrons is equal to the momentum of the electromagnetic wave,

$$E_{em}/(\lambda\ v) = m\ v\ /\sqrt{1-\beta^2}\ = mc\beta\ /\sqrt{1-\beta^2}\ . \qquad (56)$$

From the expression (56), and using (28), (37), (39), (41), and (46), we obtain

$$\lambda = \frac{A_0}{\sqrt{2meV}} \frac{(1 - eV / mc^2)^2}{\sqrt{(1 - eV / 2mc^2)^3}}. \qquad (57)$$

If the voltage is low, then $eV \approx \tfrac{1}{2}\ m\ v^2$, and

$$\lambda \mid_{eV/mc^2 \to 0}\ = \frac{A_0}{m\ v}. \qquad (58)$$

If the voltage approaches $(mc^2 / e) \approx 511$ kV, then

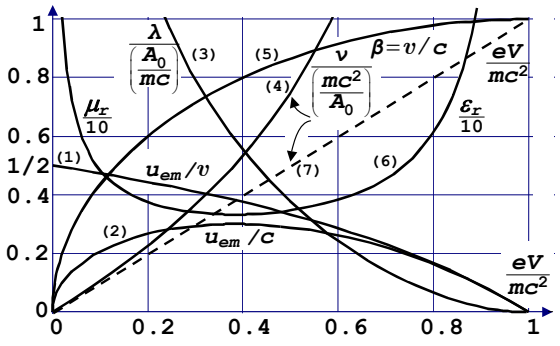

Figure 8. Phase velocity u_{em}, (1) and (2), wavelength λ, (3), frequency ν, (4), of standing-electromagnetic wave; speed of the particles $\beta = v/c$, (5); $\mu_r = \varepsilon_r$, (6); frequency of matter waves (*quantum mechanics*), (7); all as a function of eV/mc^2.

$$\lambda\,|_{\,eV/mc^2 \to 1} \to 0 \ \text{m}. \tag{59}$$

Phase velocity, according to (49), (54) and (57), (see Fig. 8) is

$$u_{em} = \lambda\nu = \sqrt{\frac{eV}{2m}}\,\frac{1-eV/mc^2}{\sqrt{1-eV/2mc^2}}. \tag{60}$$

If the voltage is low, then

$$\begin{aligned} u_{em}\,|_{\,eV/mc^2 \to 0} &= \sqrt{eV/2m} \\ &= \sqrt{\tfrac{1}{2}mv^2/(2m)} = v/2. \end{aligned} \tag{61}$$

On the other hand, Maxwell's equations also require that the following relationship be satisfied for the phase velocity:

$$u_{em} = 1/\sqrt{\mu\varepsilon}, \tag{62}$$

while the wave impedance $\sqrt{\mu/\varepsilon}$, because of energy reasons, should remain unchanged, i.e.,

$$\sqrt{\mu/\varepsilon} = \sqrt{\mu_0/\varepsilon_0}. \tag{63}$$

From (60) and (62) we get

$$1/\sqrt{\mu\varepsilon} = \sqrt{\frac{eV}{2m}}\,\frac{1-eV/mc^2}{\sqrt{1-eV/2mc^2}}. \tag{64}$$

System of equations (63) and (64) have solutions μ and ε as follows:

$$\mu = \sqrt{\frac{\mu_0}{\varepsilon_0}}\sqrt{\frac{2m}{eV}}\,\frac{\sqrt{1-eV/2mc^2}}{1-eV/mc^2} = \mu_r\mu_0, \tag{65}$$

$$\varepsilon = \sqrt{\frac{\varepsilon_0}{\mu_0}}\sqrt{\frac{2m}{eV}}\,\frac{\sqrt{1-eV/2mc^2}}{1-eV/mc^2} = \varepsilon_r\varepsilon_0, \tag{66}$$

i.e.,

$$\mu_r = \varepsilon_r = \frac{1}{\sqrt{\mu_0\varepsilon_0}}\sqrt{\frac{2m}{eV}}\,\frac{\sqrt{1-eV/2mc^2}}{1-eV/mc^2}. \tag{67}$$

Current values of linearly polarized standing wave, [17], in the atom read:

$$\mathcal{E}_x(z,t) = \mathcal{E}_0 \sin\left(\frac{2\pi}{\lambda}z\right)\cos(\omega t), \tag{68}$$

$$\mathcal{H}_y(z,t) = -\frac{\mathcal{E}_0}{\sqrt{\mu/\varepsilon}}\cos\left(\frac{2\pi}{\lambda}z\right)\sin(\omega t), \tag{69}$$

where $\mathcal{E}_0$ is the maximum value, i.e., the amplitude of electric field strength, $\mathcal{E}_x(z,t)$, the *x*-component of the electric field dependent on the *z*-axis of the rectangular coordinate system and the time *t*, and $\mathcal{H}_y(z,t)$ is the *y*-component of the magnetic field dependent on the *z*-axis of the rectangular coordinate system and the time *t*. If we use the second derivation of the equations (68) and (69) with respect to *z*, we get equations:

$$\frac{\partial^2\mathcal{E}_x(z,t)}{\partial z^2} + \left(\frac{2\pi}{\lambda}\right)^2\mathcal{E}_x(z,t) = 0, \tag{70}$$

$$\frac{\partial^2\mathcal{H}_y(z,t)}{\partial z^2} + \left(\frac{2\pi}{\lambda}\right)^2\mathcal{H}_y(z,t) = 0. \tag{71}$$

After substitution of wavelengths, (57), in the expressions (70) and (71), we get:

$$\frac{\partial^2\mathcal{E}_x(z,t)}{\partial z^2} + \frac{8\pi^2 meV}{A_0^2}\,\frac{(1-eV/2mc^2)^3}{(1-eV/mc^2)^4}\,\mathcal{E}_x(z,t) = 0, \tag{72}$$

$$\frac{\partial^2\mathcal{H}_y(z,t)}{\partial z^2} + \frac{8\pi^2 meV}{A_0^2}\,\frac{(1-eV/2mc^2)^3}{(1-eV/mc^2)^4}\,\mathcal{H}_y(z,t) = 0. \tag{73}$$

Since $eV = -E$, we can write,

$$\frac{\partial^2 \mathcal{E}_x(z,t)}{\partial z^2} - \frac{8\pi^2 mE}{A_0^2} \frac{(1+E/2mc^2)^3}{(1+E/mc^2)^4} \mathcal{E}_x(z,t) = 0, \tag{74}$$

$$\frac{\partial^2 \mathcal{H}_y(z,t)}{\partial z^2} - \frac{8\pi^2 mE}{A_0^2} \frac{(1+E/2mc^2)^3}{(1+E/mc^2)^4} \mathcal{H}_y(z,t)) = 0, \tag{75}$$

while in the case of low-energy ($eV = ½\, m\, v^2 = K = E - U$),

$$\frac{\partial^2 \mathcal{E}_x(z,t)}{\partial z^2} + \frac{8\pi^2 m}{A_0^2}(E-U)\, \mathcal{E}_x(z,t) = 0, \tag{76}$$

$$\frac{\partial^2 \mathcal{H}_y(z,t)}{\partial z^2} + \frac{8\pi^2 m}{A_0^2}(E-U)\, \mathcal{H}_y(z,t) = 0, \tag{77}$$

which in this form resembles the Schrödinger's equation.

In the same way as we got (70) and (71), using the second derivation with respect to time t, with $\omega = 2\pi\nu$, we get from (68) and (69):

$$\frac{\partial^2 \mathcal{E}_x(z,t)}{\partial t^2} + \omega^2 \mathcal{E}_x(z,t) = 0\,, \tag{78}$$

$$\frac{\partial^2 \mathcal{H}_y(z,t)}{\partial t^2} + \omega^2 \mathcal{H}_y(z,t) = 0\,, \tag{79}$$

or, using (49) and $eV = -E$,

$$\frac{\partial^2 \mathcal{E}_x(z,t)}{\partial t^2} + \frac{4\pi^2 E^2}{A_0^2}\left(\frac{1+E/2mc^2}{1+E/mc^2}\right)^2 \mathcal{E}_x(z,t) = 0\,, \tag{80}$$

$$\frac{\partial^2 \mathcal{H}_y(z,t)}{\partial t^2} + \frac{4\pi^2 E^2}{A_0^2}\left(\frac{1+E/2mc^2}{1+E/mc^2}\right)^2 \mathcal{H}_y(z,t) = 0\,. \tag{81}$$

Unlike wave function Ψ in the Schrödinger's equation, $\partial^2\Psi/\partial x^2 + 8\pi^2 m(E-U)\Psi/h^2 = 0$, [18], physical meaning of wave functions, $\mathcal{E}_x$ and $\mathcal{H}_y$, in this article is entirely clear. As discussed above, $\mathcal{E}_x(z,t)$ is the x-component of the electric field dependent on the z-axis of the rectangular coordinate system and the time t, and $\mathcal{H}_y(z,t)$ is the y-component of the magnetic field dependent on the z-axis of the rectangular coordinate system and the time t. Meaning of all the other physical quantities in this article is also completely clear.

The solutions of differential equations (76) and (77) are the same as the known solutions of the Schrödinger's equation only the meaning of the wave function is different.

VI. CONCLUSION

The article shows how Maxwell's equations adapted to the use in the nanometer range. The resulting equations are similar at the end of Schrödinger's equation, which was expected. Given the great success of the application of Schrödinger's equation, it is also a confirmation of the success of Maxwell's equations. The advantage of Maxwell's equations is that they are part of a comprehensive theory, while Schrödinger's equation is only one isolated part adapted to the atomic scale. Hence the resulting difficulty in interpreting the meaning of the wave function in the Schrödinger's equation. Such difficulties in Maxwell's theory, of course, do not exist. Therefore it seems appropriate to use Maxwell's equations in the nanometer range, in which up to now exclusively used Schrödinger's equations.

Abstract - Cloud computing has revolutionized how availability and access to computing and storage resources is realized; it has made it possible to provision a large computational infrastructure in a matter of minutes, all through a web browser. What it has not yet solved is accessibility of a tool execution environment where tools and data can easily be added and used in non-trivial scenarios. In this paper, we demonstrate how CloudMan (http://usecloudman.org) can be used to provide complete and complex tool execution environments for making cloud resources functional for a desired domain.

I. INTRODUCTION

Conducting controlled, consistent, verifiable and repeatable experiments is of utmost importance for the development of computer science [1] - although this paradigm is applicable for every research regardless of the field of study. Additionally, many branches of modern research are computation- and data-intensive forms of discovery, encompassing the generation, analysis and interpretation of vast amounts of data against catalogs of existing knowledge in complex multi-stage workflows that are enabled by a combination of analysis platforms and computational infrastructures. Massive amount of computing power, derived from a large number of computers, is often required to perform these large-scale experiments [2]. Scientific computing in most cases requires availability of such distributed computing and networking platforms which, in traditional high-performance computing solutions, account either for locally installed clusters and supercomputers, or distributed grids, that are often difficult to setup, maintain and operate. On the other hand, cloud computing provides a completely new model of utilizing the computing infrastructure, where computing and storage resources can be provisioned in a dynamic, scalable, on demand and pay per use basis, and released when no longer needed [2].

Cloud computing refers both to applications delivered as services over the Internet and the hardware and systems software in the data centers that provide those services [3]. In this manner, the cloud can be divided into three major service types that are available to end users, scientific institutions, and enterprises: Infrastructure as a Service (IaaS), Platform as a Service (PaaS) and Software as a Service (SaaS) [2]. IaaS refers to provisioning IT infrastructure resources over the network based on virtual or physical resources that meet the CPU, power, storage, and operating system requirements [2]. Amazon Web Services (aws.amazon.com) is an example of a major IaaS vendor, while other providers include GoGrid and Flexiscale [4]. PaaS encompasses the provisioning of a platform layer with resources such as software development frameworks for applications that will run on the cloud. Applications utilizing PaaS layer interact with the cloud on the higher level of abstraction while the low-level components are hidden behind the platform layer. Examples of PaaS providers include Google App Engine and Microsoft Azure. SaaS represents the top end of the cloud computing stack by providing functional applications and services but also yielding least user customization [2][4]. Examples of SaaS include Google Documents, online email clients, or photo sharing sites.

Although gradually adopted by select groups, the potential offered by cloud platforms is only partially exploited because much of its functionality is still cumbersome to use for the end users. The reality of using cloud resources is that the necessary tools, libraries, and applications for every day best practices in research and operational business routines are by themselves relatively complicated to install and customize. Even if those are made available via predefined platforms or custom solutions, their scope is often limited and usage predefined. They typically also involve a high level of on-going maintenance to keep the software and data up-to-date. Such maintenance currently requires significant expertise in software development and system administration. These requirements stand in the way of cloud adoption, particularly among small development and research groups with insufficient capacity to tackle such IT challenges.

Currently many powerful solutions exist for materializing the cloud concepts, but somewhat lack easy-to-use principles that would allow end users to take full advantage of them. Thus, developing cloud methodologies is no longer the main challenge in the uptake of the cloud. Instead the problem lies in making existing methodologies usable for end users so that they can take full advantage of the existing resources. Some of the challenges standing in the way of the widespread acceptance of clouds are being addressed by a number of research projects, contributing to minimize the technical complexities of using the cloud by leveraging and developing cloud platforms to reach higher levels of innovation and automation [5]. These research projects include (amongst others): mOSAIC [6], 4CaaST [7], Contrail [8], CumuloNimbo [9], StratusLab [10], StarCluster [11], RedHat OpenShift Flex [12], Manjrasoft Aneka [13], and Cirrocumulus [14].

To bridge this critically important gap between computational resources and end users we have previously developed CloudMan [1][15][17]. CloudMan makes it remarkably easy to exploit the potential of cloud resources without burdening users with tedious details: it delivers a framework and a platform for providing accessible solutions built on the flexibility of IaaS while delivering it in a PaaS format. The software and services offered by CloudMan have already attracted and established a growing community of users and developers, which confirms the emerging trend of acceptance and integration of accessible solutions based on the cloud computing model into the everyday workflow of end users.

In this paper we demonstrate the application of CloudMan as a tool execution framework for the cloud, and give insight to the ease and rapidity of deploying configured and ready to use systems. In Section II we present the overview of the CloudMan architecture including supported file systems, the data persistence model, and deployment concepts. Lastly, we describe three categories of applications that can be deployed into the CloudMan platform, thus alluding at the potential flexibility of the described platform.

II. TOOL DEPLOYMENT AND EXECUTION FRAMEWORK FOR THE CLOUD

The cloud infrastructure and the overlaying layer for operating it are in a mature phase (e.g. AWS, OpenStack, Eucalyptus, OpenNebula). Although the infrastructure provides most of the required functionality to gain access to a functional infrastructure, it is quite complicated and time consuming for the inexperienced and non-technically educated users to properly exploit infrastructure's full potential. CloudMan has successfully resolved many issues regarding accessibility to cloud resources.

CloudMan provides an interface between IaaS and SaaS, acting as a platform that encapsulates several important functionalities. Some of the most prominent features that are supported include automated (and thus reproducible) configuration for machine image, dynamic persistent storage for tools and data, automated scaling of the underlying infrastructure, and sharing of complete deployments. All this is exposed through a web browser making it very accessible to end users.

The underlying architecture allows each CloudMan deployment to be customized by individual users and thus meet their specific needs. Once customized, the customizations can be persisted even after the cloud instance is terminated (i.e. cloud image can be saved and re-opened again without losing any information). Furthermore, the customized instances can easily be shared with different users within the same cloud provider. This implies sharing of the deployment (including the applications and the data) so that the entire deployment runs under a different user account and is thus independent of other user's resources. Lastly, CloudMan provides support for elastic resource scaling, which can be manual or automatic. The elastic scaling reduces the cost as the certain resources (storage, CPUs, etc) can be removed or added dynamically during the instance runtime, based on the current workload.

CloudMan platform also defines functional but customizable application execution environments (e.g., SMP, MPI, map-reduce). These parallel execution environments are automatically set-up at the instance launch time and made available to users and applications. These environments cover a wide range of uses without requiring users to perform any configuration, which contributes toward making the underlying infrastructure accessible and instantly usable. Simultaneously, because each CloudMan instance of the can be customized, these environments can be adjusted to meet specific application needs. This enabled CloudMan to act as a platform - a platform that allows users to incrementally build on top of an already rich set of preconfigured and functional features. This is in direct contrast with having to recreate all of the lower-level features or mastering an entirely new methodology for working with the cloud infrastructures. This model makes it possible to support the entire life cycle of a tool and an analysis without requiring any special provisions from the developer or the end user.

A. CloudMan arhitecture

CloudMan architecture represents a step toward defining a universal environment for deploying a range of applications on cloud infrastructures. The motivation for this approach is twofold: (1) provide a template for those wishing to migrate their own application to an aggregated infrastructure environment and (2) enable the underlying infrastructure to be interchanged while minimizing changes required to realize the bridge between IaaS and SaaS.

The presented architecture focuses on encapsulating an existing application into a deployable unit that can be instantiated by an individual user. With this approach the applications are abstracted and infrastructure independent. At the same time, a readily deployable application unit allows users to easily and quickly gain access to the desired application. The user is thus not encumbered by having to install and maintain their own infrastructure or installation, nor limited by restrictions imposed by availability of a public deployment of an application. If the application deployment unit exists for multiple infrastructure providers, the user is also free to choose where to run the application. As a result of the self-contained application unit deployment process, the user can independently utilize IaaS infrastructure while enjoying SaaS usability. This approach creates a separation of concerns at a high level and allows everyone involved to focus on their domain instead of being bogged down by management and maintenance routines and requirements.

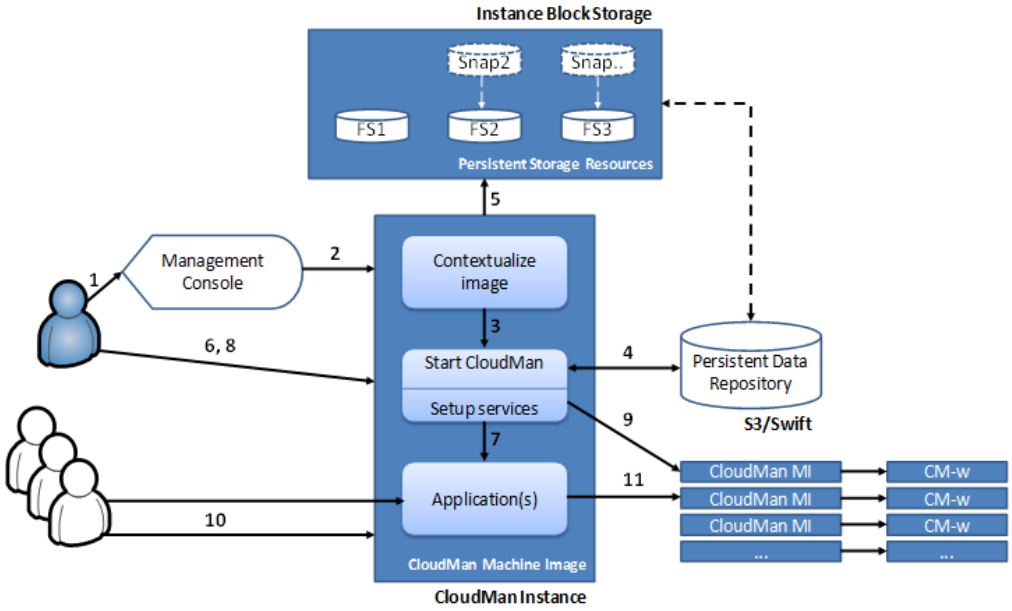

Figure 1. Composition of components composing the arhitecture to enable CloudMan exexution in virtualized environment: (1) The administrator user accesses the infrastructure console manager and requests an instance; (2) an instance is instantiated (this may be an instance with CloudMan already enabled or CloudMan can easily be added to the instance); (3) CloudMan controller starts; (4) the controller contextualizes itself by obtaining needed context from the persistent data repository; (5) any external storage resources are then attached and configured automatically by eCloudMan into appropriate file systems; (6) the administrator user has the option of providing configuration information about their new cluster through eCloudMan's web interface, e.g., cluster size limits; (7) optionally, eCloudMan configures and starts specific application(s); (9) the user can monitor and update deployment parameters via CloudMan, CloudMan automatically scales the cluster, acquiring and releasing additional worker instances as needed but also staying within the predefined constraints; (10) the platform and the application can be used directly or via the eCloudMan API; (11) applications run transparently on the backend resources.

CloudMan is implemented as a standalone web application that acts as a manager for the instantiated deployment. To enable composition of multiple instances into a compute cluster, at the implementation level, CloudMan is represented by two services, a master and a worker. The distinction between services is determined at instance boot time, based on the given instance's role. All of the instance contextualization, master-worker communication, and status reporting is performed through a messaging system implemented using the Advanced Message Queuing Protocol standard and using a RabbitMQ server deployed on the master instance [16].

Conceptually, CloudMan architecture is based on separation and subsequent coordination of otherwise independent infrastructure components: the *machine image*, a *persistent data repository*, and *persistent storage resources* (e.g. data snapshots). The composition and interaction of those three independent components, that comprise the CloudMan architecture, are described in Figure 1. The *machine image* is characterized by simplicity; it consists only of the basic services required to initiate the application unit deployment process. In particular, besides selecting the underlying operating system, only the core set of services is installed on the image itself. Alongside these services, a contextualization script is included in the basic machine image. Contextualization is the process of coordinating the machine instance preparation and deployment at runtime. The contextualization script included in CloudMan's machine image serves only as an access point to the instance while the contextualization details are extracted and stored from the persistent data repository. The *persistent data repository* lives independent of the machine image and is used to provide instance contextualization details, such as, the boot time scripts that define which services should be started. Lastly, *persistent storage resources*, or snapshots, are used as the storage medium for applications, any required tools, libraries, or datasets the application depends on, and the user data.

Once instantiated, these components are aggregated by CloudMan into a cohesive and operational unit with all the features described above becoming functional. As part of the setup, CloudMan automatically configures the master instance as a head node of a Sun Grid Engine (SGE) compute cluster but it does not start any additional worker instances or assign persistent storage to the cluster. In the context of cloud computing, compute instances are usually transient, meaning that any changes made to an instance while the instance is alive are lost at instance termination. In order to persist any data uploaded to the cloud or any analysis results, the data needs to be stored on an external data volume. In the case of CloudMan on EC2, Amazon's Elastic Block Storage (EBS) volumes are used as the persistent storage resources.

At termination time, any read-only persistent storage resources are deleted because they will be recreated from the preexisting snapshots. The persistent storage resources containing user data however are preserved in the user's account. Similarly, all of the cluster configuration settings are preserved in the persistent data repository and will be used upon next cluster instantiation to assemble the complete deployment.

Over the past two years of development, the described architecture has proven very effective and resilient to different cloud providers. Overall, the architecture provides the following benefits:

- Minimum setup time and cost: no need for an external broker

- Automated configuration
- Transparent data persistence
- Self-contained deployment: customizable instances; versioning of tools, data, and configurations

B. Running applications using CloudMan

CloudMan currently supports creation of compute clusters on Amazon's EC2 cloud computing infrastructure as well as OpenStanc and OpenNebula based clouds. The process of instantiating a cluster does not require any computational experience, and requires no compute infrastructure or software beyond the web browser used to control the cluster. Thus, CloudMan is ideal for independent researchers and small labs that have a specific or periodic need for computational resources but lack informatics expertise and commitment to manage and maintain a computational cluster. The process of instantiating a CloudMan compute cluster consists of three steps: (1) obtain an account on the supported cloud (AWS or OpenStack or OpenNebula private clouds), (2) use biocloudcentral.org portal to start a master instance, and (3) use the CloudMan web console on the master instance to manage the cluster size and data persistence. This approach takes very short time to setup a compute cluster and allows a user to have any number of independent clusters, thus supporting easy separation of projects or groups. Once set up, additional users may use the cluster. Depending on the type of application used, user may be able to use the cluster via the web interface or by logging into the instance via command line tools.

For the case of AWS, CloudMan comes preconfigured with more than 100 bioinformatics tools. In addition, at cluster start time, it can be configured to deploy Galaxy application with numerous other tools and 700GB of reference genome data. If a specific tool is not available, it is possible for a user to customize their instance and add the desired tool (see below). Once added, the instance changes may be persisted and shared with other users, as outlined in section B above.

Another interesting example of utilizing CloudMan platform is deployment of the WRF-ARW – weather research and forecasting model. This model requires large storage and computational resources and is favorable to see how it can exploit unique and powerful features of Cloud. In the past, several deployments of the WRF-ARW model has been made on Grid infrastructure [18][19]. All of these attempts of deployments were on a fixed and pre-defined architecture (computing nodes, storage, operating system, etc.).

Regardless of whether is a preinstalled tool or a user-installed one, SGE job manager is configured and used on the cluster for job management. This makes it possible for users to simply copy their job scripts to the cloud cluster and run them there - but with the scalability offered through cloud computing. When a given cluster is no longer needed, the CloudMan web interface can be used to terminate all of the services and worker instances. If persistent data storage was associated with the cluster, the data is preserved while the cluster is offline, and made available in the same state once the cluster is instantiated again. It takes only a few minutes to scale up or down a cluster and consume the required amount of resources.

When installing the set of tools supported by CloudMan platform by default, a script is used to automatically install all the tools. This script is available at https://bitbucket.org/afgane/mi-deployment/ and may be used when customizing individual instances to include the desired tools. Once customized, the user has an option to persist the changes via CloudMan's web interface, thus making those changes readily available for future cluster invocations and/or sharing with other users.

In order to install a custom application, a user instantiates a cloud cluster, modifies the contents of the persistent storage resources (e.g. EBS volumes) by installing the desired tools (performed just like on any other machine), creates a snapshot of the modified data volume (done automatically through CloudMan's web interface), and points their cluster setup to use the newly created data volume snapshot (also done automatically through a web UI). As a result, the functionality and the architecture of CloudMan can easily be adjusted to the computing needs of individual researchers and different domains. This makes it possible for end users to add their own tools to a CloudMan cluster instance while also reusing all of the other provided features.

Note that the implications of such customization mean that one could install a custom tool and provide some sample data. Then persist those changes and share the cluster with the community. Then, users can simply instantiate this shared instance and start using the tool and the data made available without actually having to install or configure anything. Along with the tool, the users were also able to acquire the infrastructure (form the cloud), thus making a given tool instantly accessible to the end users.

C. Application types and the CloudMan platform

Based on the defined architecture of CloudMan, one can define three applications types. Application types are divided depending on where, how and when the applications are installed. These types are:

Type I: a self-contained application that can be installed manually by the user as it would be installed on any user machine or cluster. This application and its dependencies should be installed on the user's persistent data volume and thus it will be retained across invocations of this cluster. The WRF-ARW model is an example for this type.

Type II: an application that wants to be shared with others or may have 3rd party dependencies but none of those include system-level changes. This type of application should be installed on the persistent data repository derived from a snapshot and use CloudMan's features to persist those changes on the otherwise read-only file system. An example for this type of application is SGE.

Type III: an application that requires system-wide install because its dependencies must be a part of the operating system. For this case, a new machine image

needs to be created. Once the new machine image is created, future invocations of this cluster should use that particular machine image. GalaxyTool is an example of this type.

III. CONLUSION

To keep up with the growth of research data being produced and the accompanying computational demand required to process those data, there is a need for increased access to computational resources. Cloud computing offers access to such resources but still makes it difficult to create complex deployments of useful standalone infrastructures. This is especially cumbersome for individuals and small labs that lack informatics support to fully harness this general-purpose infrastructure.

This paper showcases how CloudMan can be used to lower the barrier of entry into cloud computing while readily leveraging many of the features of the cloud. Namely, CloudMan handles all of the intricacies of cloud computing resource acquisition, configuration, and scaling to deliver a personal compute cluster in a matter of minutes. All of the interaction with CloudMan and the associated cloud cluster management is performed through a web based user interface and requires no computational expertise. Alternatively, if advanced access to the system is desired, one can easily gain access while continuing to operate in a traditional cluster environment.

Overall, the CloudMan platform can be preconfigured with numerous applications that are ready to be used. The installation procedure for those tools is fully automated thus supporting reproducibility. In addition, three different cloud application types were categorized according to the way of their deployment as potential candidates for customizing a given instance of CloudMan.

ACKNOWLEDGMENT

The authors acknowledge the support of scientific research project “Methods of scientific visualization” (098-098 2562-2567), founded by the Ministry of Science, Education and Sports of the Republic of Croatia. Additionally, the authors would also like to thank the Galaxy Team who was responsible for deployment of the Galaxy application with CloudMan.

m.kozlovszky@sztaki.hu

Abstract - The recently used deep sequencing techniques represent a new data processing challenge: mapping short fragment reads to open-access eukaryotic genomes at the scale of several hundred thousand. This problem is solvable by BLAST, BWA and similar sequence alignment tools. BLAST is one of the most frequently used tool in bioinformatics and BWA is a relative new fast light-weighted tool that aligns effectively short sequences. Local installations of these algorithms are typically not able to handle large problem size therefore the sequence alignment process runs slowly, while web based implementations cannot accept high number of queries. HP-SEE infrastructure allows accessing massively parallel supercomputing infrastructure. With gUSE/WS-PGRADE we have created successfully an online Bioinformatics eScience Gateway, which is capable to serve the short fragment sequence alignment demand of the regional bioinformatics communities within the SEE region. Using workflows we have ported algorithms (BLAST and BWA) to the massively parallel HP-SEE infrastructure. In this paper we describe the created Bioinformatics eScience Gateway, and show as case study how we have implemented the ported BLAST workflow using parameter study. With our online service, researchers can do high throughput sequence alignments against the eukaryotic genomes to search for regulatory mechanisms controlled by short fragments on HP-SEE's supercomputing infrastructure.

Keywords

Application porting, sequence alignment workflow, HP-SEE, gUSE

I. INTRODUCTION

Nowadays, bioinformatics provides key in-silico research procedures to match biological sequences against large sequence databases. DNA and protein sequences are built up from IUPAC codes (normal alphabetic characters), which can compared (aligned) with other sequences. The recently used deep sequencing techniques present a new data processing challenge: mapping short fragment reads to open-access eukaryotic genomes at the scale of several hundred thousand. Since in most of the cases searching on large data set means data-, and compute-intensive challenge, solutions to decrease the computational time are highly needed. eScience Gateways have been used worldwide to solve computational problems in bioinformatics like the MOSGrid portal [1,2] or ProGenGrid [3].

This paper shows how we have built up with the grid User Support Environment (gUSE)[4] the portal like HP-SEE Bioinformatics eScience Gateway and as a case study how one of the sequence alignment tools has been ported to HP-SEE's supercomputing infrastructure.

A. Motivation

Our work was carried out mainly from the collaboration between the Grid Application Support Centre of MTA SZTAKI and the Obuda University. The Grid Application Support Centre (GASuC) [5] at MTA SZTAKI has already a quite long track record with successfully ported applications to Distributed Computing Infrastructures (DCIs). GASuC is supporting large EU projects, where the Centre is providing knowledge transfer and development tools for DCI porting tasks. Our solution is heavily needed for some national research labs in Hungary to do short sequence alignments for tiRNA searches against large human datasets and with our service also researchers from the SEE (South East European) region can do sequence analysis with high throughput short fragment sequence alignments against the eukaryotic genomes to search for regulatory mechanisms controlled by short fragments.

II. THE HP-SEE PROJECT AND ITS INFRASTRUCTURE

The High-Performance Computing Infrastructure for South East Europe (HP-SEE) [6] project links existing and upcoming HPC facilities in South East Europe in a common infrastructure, and it provides support for the active regional research communities (shown in Fig. 1.). The HP-SEE project started in 2010 with duration of 24 months and involves 14 countries mainly from the SEE region. It receives EC support through FP7 under the "Research Infrastructures" action.

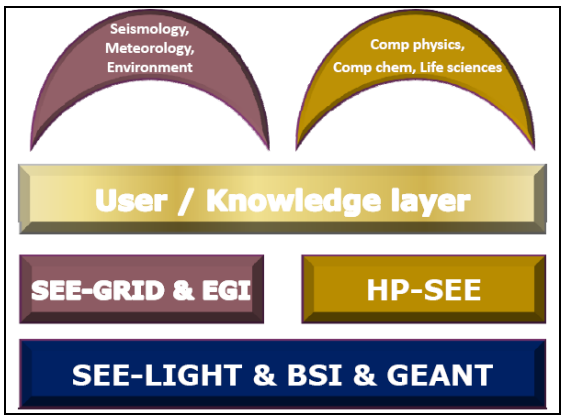

Figure 1. Converged Communication & Service Infrastructure Model for South-East Europe [7]

The initiative opens up the South East European HPC infrastructure to a wide range of new user communities, including those of less-resourced countries, fostering collaboration and providing advanced capabilities to researchers. Three main targeted research communities have been identified: computational physics, computational chemistry and life sciences. MTA SZTAKI and Obuda University are working together in the Life Science VO of the HP-SEE project.

III. HP-SEE'S BIOINFORMATICS ESCIENCE GATEWAY

The Bioinformatics eScience Gateway based on gUSE and operates within the Life Science VO of the HP-SEE infrastructure. It provides unified GUI of different bioinformatics applications (such as BLAST, BWA, or gene mapper applications) and enables end-user access indirectly to some open European bioinformatics databases. gUSE is basically a virtualization environment providing large set of high-level DCI services by which interoperation among classical service and desktop grids, clouds and clusters, unique web services and user communities can be achieved in a scalable way. gUSE has a graphical user interface, which is called WS-PGRADE. All part of gUSE is implemented as a set of Web services. WS-PGRADE uses the client APIs of gUSE services to turn user requests into sequences of gUSE specific Web service calls. Our bioinformaticians need application specific portlets to make the usage of the portal more customized for their work. In order to support the development of such application specific UI we have used the Application Specific Module (ASM) API [8] of the gUSE by which such customization can easily and quickly be done. Some other remaining features were included from WS-PGRADE. Our GUI is built up from JSR168 compliant portlets and can be accessed via normal Web browsers (shown in Fig. 2.).

Figure 2. Login screen of the HP-SEE Bioinformatics eScience Gateway

A. *Bioinformatics eScience gateway resources*

In our Bioinformatics eScience Gateway the gUSE back-end is connected to various DCIs (shown in Fig. 3.). Because the developed workflows are independent from the DCI middleware, the resource allocation depends mainly on the scale of the problem size and the available infrastructure.

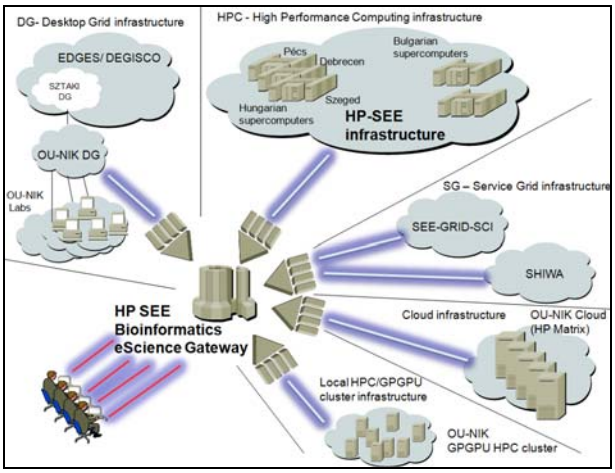

Figure 3. Computational and storage resources of the Bioinformatics eScience Gateway

IV. IMPLEMENTATION OF THE GENERIC BLAST WORKFLOW

Normal applications need to be firstly ported for use with gUSE/WS-PGRADE. Our used porting methodology includes two main steps: workflow development and user specific web interface development based on gUSE's ASM (shown in Fig. 4.). gUSE is using a DAG (directed acyclic graph) based workflow concept. In a generic workflow, nodes represent jobs, which are basically batch programs to be executed on one of the DCI's computing element. Ports represent input/output files the jobs receiving or producing. Arcs between ports represent file transfer operations. gUSE supports Parameter Study [9] type high level parallelization. In the workflow special Generator ports can be used to generate the input files for all parallel jobs automatically while Collector jobs can run after all parallel execution to collect all parallel outputs. During the BLAST porting, we have exploited all the PS capabilities of gUSE.

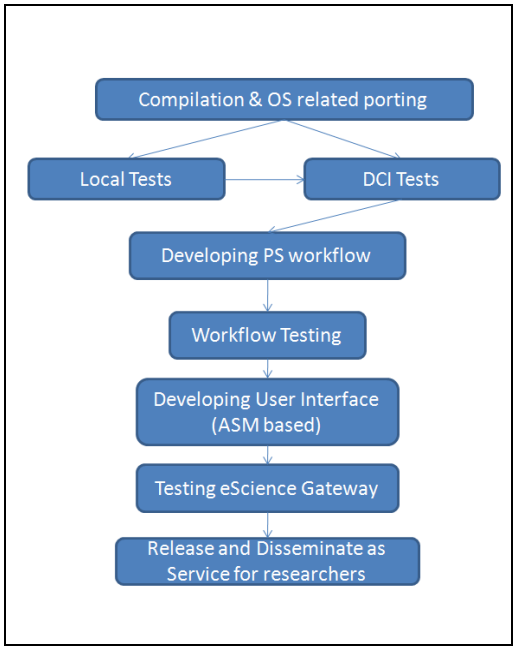

Figure 4. Porting steps of the application

Parallel job submission into the DCI environment needs to have parameter assignment of the generated parameters. gUSE's PS workflow components were used to create a DCI-aware parallel BLAST application and realize a complex DCI workflow as a proof of concept. Later on the web-based DCI user interface was created using the Application Specific Module (ASM) of gUSE. On this web GUI, end-users can configure the input parameter like the "e" value or the number of MPI tasks and they can submit the alignment into the DCI environment with arbitrary large parameter fields.

During the development of the workflow structure, we have aimed to construct a workflow that will be able to handle the main properties of the parallel BLAST application. To exploit the mechanism of Parameter Study used by gUSE the workflow has developed as a Parameter Study workflow with usage of autogenerator port (second small box around left top box in Fig 5.) and collector job (right bottom box in Fig. 5). The preprocessor job generates a set of input files from some pre-adjusted parameter. Then the second job (middle box in Fig. 5) will be executed as many times as the input files specify.

The last job of the workflow is a Collector which is used to collect several files and then process them as a single input. Collectors force delayed job execution until the last file of the input file set to be collected has arrived to the Collector job. The workflow engine computes the expected number of input files at run time. When all the expected inputs arrived to the Collector it starts to process all the incoming inputs files as a single input set. Finally output files will be generated, and will be stored on a Storage Element of the DCI shown as little box around the Collector in Fig 5.

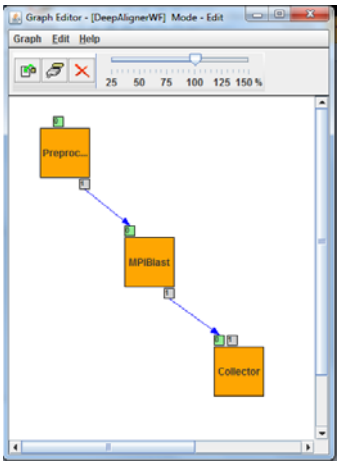

Figure 5. Internal architecture of the generic blast workflow

Due to the strict HPC security constraints, end users should posses valid certificate to utilize the HP-SEE Bioinformatics eScience Gateway. Users can utilize seamlessly the developed workflows on ARC based infrastructure (like the NIIF's Hungarian supercomputing infrastructure) or on gLite/EMI based infrastructure (Service Grids like SEE-GRID-SCI [10], or SHIWA[11]). After login, the users should create their own workflow based application instances, which are derived from pre-developed and well-tested workflows.

V. CONLUSION

In this paper we have described the HP-SEE Bioinformatics eScience Gateway, which operated by Obuda University. The web based portal gives HPC support and increased parallel processing power trough the HP-SEE supercomputing infrastructure to align short biological sequences. For the researchers the eScience Gateway provides high throughput sequence alignment service with parallel BLAST and BWA algorithms, however because the solution is easily extendable we are planning to include other ported alignment algorithms as well. Our project work addressed all issues how to port existing environments (such as bioperl, blast, bwa) to the HP-SEE infrastructure, howto build up effective workflows with gUSE -a stand-alone DCI focused application development environment- and howto create the GUI interface for the researchers using ASM in a seamless way. On the client side the web browser provides for eScience gateway users and workflow developers a native application programming interface to launch time-consuming tasks transparently on the available HPC resources. To demonstrate and test our solution we have used successfully the created workflow based HPC application to do short sequence alignments for tiRNA searches against large human datasets on HP-SEE infrastructure. According to our performance tests using 96 CPUs in HP-SEE's supercomputing infrastructure, thus even with moderate large datasets end users were able to achieve significant speedup in parallel alignment with DCI-enabled version comparing to single multi-core computers. The developed workflow based Bioinformatics eScience gateway is generic enough to host seamlessly later on more processing algorithms

helping to solve large scale alignment problems for HP-SEE's Life Science community.

VI. ACKNOWLEDGMENTS

The authors would like to thank three projects supported by the European Commission's 7th Framework Programme for their financial support. This work was supported by the EGI –InSPIRE (Integrated Sustainable Pan-European Infrastructure for Researchers in Europe, under contract number: RI-261323), by the SHIWA (SHaring Interoperable Workflows for large-scale scientific simulations on Available DCIs, under contract number 261585) and by the HP-SEE (High-Performance Computing Infrastructure for South East Europe's Research Communities, under contract no. RI-261499) projects.

Remote Monitoring of Vital Functions - Proof-of-concept System

A. Rashkovska, I. Tomašić, K. Bregar and R. Trobec
Jožef Stefan Institute, Department of Communication Systems, Ljubljana, Slovenia
Aleksandra.Rashkovska@ijs.si, Ivan.Tomasic@ijs.si, Klemen.Bregar@gmail.com, Roman.Trobec@ijs.si

Abstract - Modern information communication technologies (ICT) acting as a support to the medical activities is one of the possibilities to increase the efficacy of the health care system and to decrease its costs. We developed a proof-of-concept system, which uses modern, moderately-priced and user-friendly technology solutions, e.g. wireless body sensors for data acquisition, advanced algorithms for local analysis of data, widely available personal terminals for visualization of measurements, and the existing communication infrastructure for data transfer, either to medical experts or to a personal database. We pay a special attention to the fusion of different body sensors in order to keep their number at minimum. On the other hand, we want to improve reliability of the system with the introduction of a simple video sensor in order to prevent the rising of false alarms. We show that such a system can achieve a reliability needed for commercial implementation in applications offering services that can contribute significantly to an improved quality and efficiency of the medical care.

I. INTRODUCTION

The introduction of modern information communication technologies (ICT), as support to medical activities, is one of the possibilities to increase the efficacy of the health care system and to decrease its costs. This basic premise is included in all strategic plans of the EU and the rest of the world. Numerous studies have confirmed the benefit of the development of Telemedicine/Telecare systems [1, 2]. We are proposing a proof-of-concept system, which uses modern, moderately-priced and user-friendly technology solutions.

The health of hospitalized patients is regularly assessed by periodic measurements of indicators of vital functions, like respiratory rate (RR), heart rate (HR), blood pressure (BP) and body temperature (TT). With close monitoring of these patient parameters and according to dynamic changes, necessary medical assistance can be provided. The indicators of vital functions in the non-intensive wards are normally measured by nurses several times a day and then manually entered in the patient's charts. In case of clinical deterioration, additional treatment measures are needed, the effects of which are also assessed with the monitoring of indicators of vital functions. If the patient's condition deteriorates and continuous monitoring is needed, the patient is transferred to the intensive care unit. However, the intensive care unit has a limited number of beds. If the patient's condition deteriorates between the periodical measurements performed by nurses, the consequences for the patient could be fatal.

In addition to the issue of intermittent monitoring of vital functions in non-intensive wards, there are other weaknesses in the current health care system. The interpretation of the patient's condition and the consequent measures taken depend on the personnel, who could be, in certain conditions, overwhelmed with work or busy with other patients. The measured indicators can also be inaccurate, sometimes being biased by the presence or inexperience of the medical personnel and therefore unreliable. The subsequent interpretation of the documented measurements can be difficult because they are based on insufficient or unreliable data.

The proposed system for remote monitoring of vital functions establishes a virtual state of semi-intensive care unit, which significantly improves the quality of hospital care. Patients are fitted with body sensors for vital functions. The sensors communicate with the personal terminals (size of a mobile phone) via wired or wireless connections. The measurements are stored in the personal terminal for monitoring and later processing with automated procedures based on the comparison with threshold values, predetermined rules and automatic learning. The data are sent to a computer server, which maintains a database and is responsible for the presentation, alerts and necessary actions.

II. SYSTEM ARCHITECTURE

The scheme of the proposed system for remote monitoring of vital functions is shown in Fig. 1.

The design of the system takes into account the existing technical standards, allowing easy connection of various body sensors and their immediate replacement if an improved version becomes available. The system allows the connection of new sensors, which could help improve the monitoring of the patient's condition, for example, sensors for remote monitoring of respiratory acoustic phenomena (cough, obstruction), or video sensors for the analysis of live video (with the consent of the patient). Some of the measurements are feasible with our custom sensors [3]; for others, like blood pressure measurements, new unobtrusive and non-invasive body sensors are to be developed; remaining measurements are realized by inexpensive commercially available sensors.

For the transmission of measurements we use standard technologies (Ethernet, Bluetooth, Wi-Fi, etc.) and the Internet, which offers an inexpensive implementation, as well as wide availability. The information is available on

The authors acknowledge the financial support from the state budget by the Slovenian Research Agency under Grant P2-0095.

site and controlled/monitored by the staff on call, which enables immediate detection of deterioration in the patient's state and prompt actions.

Based on the graphic presentation of a critical vital parameter and its recent changes, it is possible to evaluate the effectiveness of a treatment and to foresee a possible deterioration. An alarm will alert the possibility of deterioration before the vital parameter reaches the critical value. Based on the simultaneous evaluation of multiple variables, the program will provide the threat level and its trend (MEWS) [4]. The analysis of vital functions in a longer time period allows for the implementation of the cognitive methods, for example, analysis of a cardiogram over longer time period contributes to the personalized patient's threat level [5, 6].

III. IMPLEMENTATION CONCEPTS

The implementation of the proposed system significantly increases the research potential of medical institutions. The system provides documented measurements and events obtained in an objective manner during different stages of the well-being of patients or other users (elderly, athletes, etc.). The system could be upgraded with new medical research methods. Following are related research activities and findings that contribute in the system implementation.

A. Development and implementation of a system for sound diagnosis of pneumonia

In clinical medicine, the gold standard for diagnosis of pneumonia is the X-ray imaging; nevertheless, in a clinical examination, pneumonia is diagnosed only in a small proportion of ill children. Computer analysis of the sounds in adult patients with pneumonia has been proved to confirm the diagnosis [7]; however, the method uses sixteen microphones, which is not suitable for clinical use. The proposed system enables development of convenient and computerized systems, designed by a smaller number of microphones, which spare the patients from the X-ray radiation.

B. Development of multifunctional body sensors

Body sensors should be non-disruptive to users; therefore, we consider small and multifunctional wireless sensors. We have already prototyped a differential wireless bio-electrode (WBE) for measuring ECG [8]. Other features can be also added to this electrode: EEG, vascular pressure, skin resistance and respiratory rate measurements. Such an electrode will represent an important worldwide technological breakthrough. An example of the prototype multisensory electrode is shown

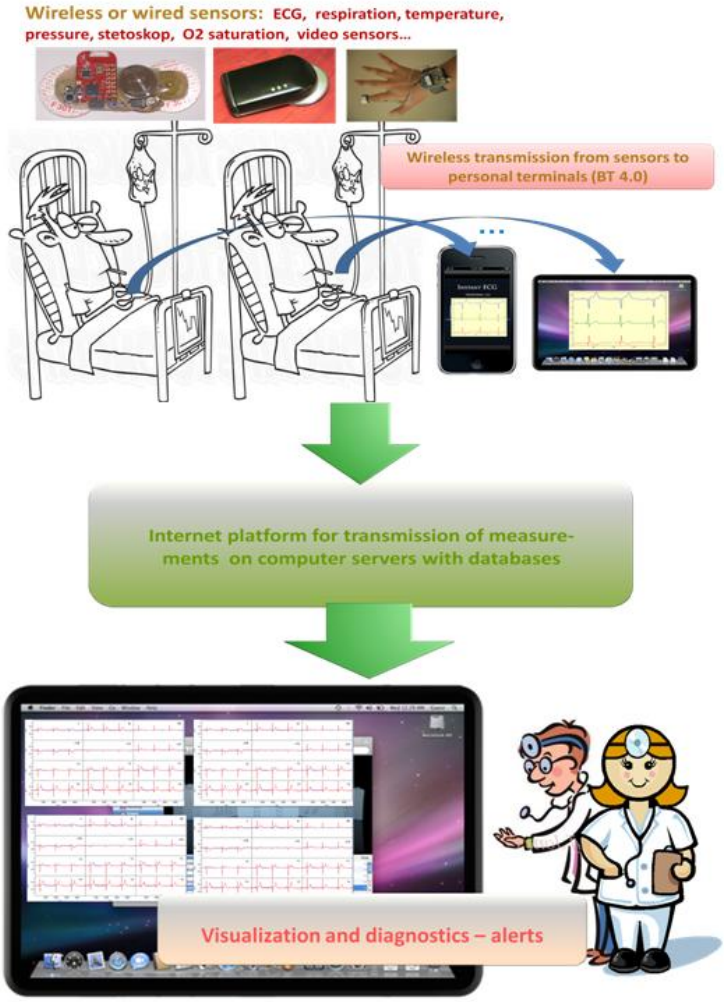

Figure 1. Conceptual scheme of the system for remote monitoring of vital functions

in Fig. 2a. On the measured raw ECG signal (Fig. 2b), a respiration signal as an envelope of the R-peaks is clearly visible.

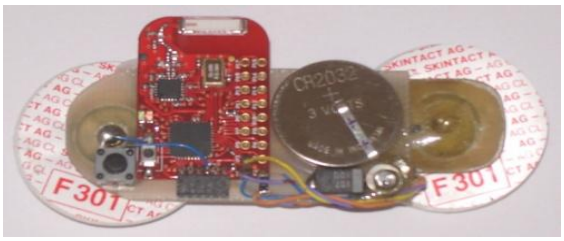
Furthermore, a new prototyped muscle contraction (MC) sensor [9] is considered for integration into the system. The sensor is relatively small and light. It is based on a novel principle for measuring muscle tension during muscle contractions and provides important data about patient's muscular activities. Additionally, we consider the option to use the MC sensor for detection of the tactile pulse. The sensor could be also adopted for measurement of changes in the blood pressure. An example of the prototype MC sensor and a preliminary measurement of the tactile pulse are shown in Fig. 3a and Fig. 3b, respectively.

C. *Long-term monitoring of ECG records*

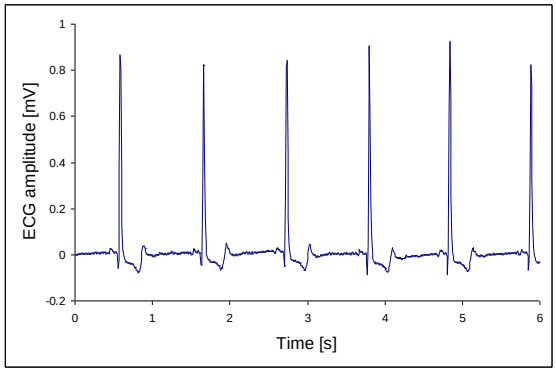
One of the advantages of the proposed system is the ability for continuous monitoring of ECG. In a recently published study on children with RSV bronchitis, the presence of abnormal heart rhythm was also found [6]. Long-term monitoring of ECG is an important source of data for confirming the correlation of the two diseases, which is not known so far.

D. *Synthesised 12-channel ECG*

The 12-lead electrocardiogram (ECG) is the gold standard in cardiology and lies at the center of the decision pathway for the evaluation and management of patients. However, the conventional 12-lead ECG is obtained from ten electrodes connected with wires to a data collecting device. Its application therefore imposes obtrusion and has negative effects on patient comfort. Moreover, due to the fact that the standard positions of the precordial electrodes are often difficult to locate accurately, particularly in women and children, the application of the conventional 12-lead ECG device can be impractical.

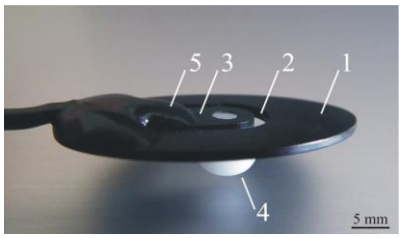


(a)

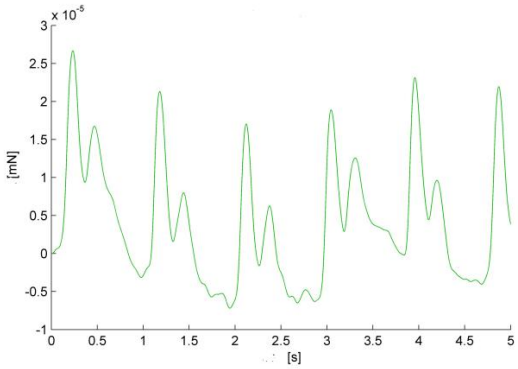


(b)

Figure 2. (a) A prototype of the WBE with two self-adhesive disposable electrodes, a lithium coin battery and a ceramic chip antenna. (b) An example of an ECG recorded wirelessly – raw signal.



(a)



(b)

Figure 3. (a) A prototype of the muscle contraction (MC) sensor. (b) An example of measured tactile pulse.

The WBE provides an alternative that resolves the standard 12-lead ECG devices imperfections. It enables minimal use of wires on the body and consequently maximal wearing comfort. The WBE enables the measurement and transmission of only local potential differences, i.e. bipolar measurements, from two closely placed skin electrodes. The measurements from few WBEs thus form a lead system that can potentially be used for reconstruction of the 12-lead ECG.

The fact that almost all electrocardiographic knowledge is accumulated in the 12-lead ECG imposes a need for the synthesis of the 12-lead ECG from the lead system of WBEs. In previous work [3] we have shown how to perform personalized synthesis for each patient. The positions of three wireless electrodes may be chosen by respecting signal/noise ratio [10] or by efficient personalized algorithm [3] developed for that purpose.

The algorithm for determining personalized positions of the WBEs, together with the algorithm for the synthesis, produces the 12-lead ECG that contains the same diagnostic information as the one obtained by a conventional device. The synthesized 12-lead ECG, compared to the 12-lead ECG obtained by a conventional device, is presented on Fig. 4. The synthesized 12-lead ECG is shown in red and the measured 12-lead ECG is shown in blue. The figure represents a case with no significant difference between the two ECGs.

The synthesis of the 12-lead ECG can be done on personal terminals, immediately after receiving the measurements from the WBEs, or later on the computer server.

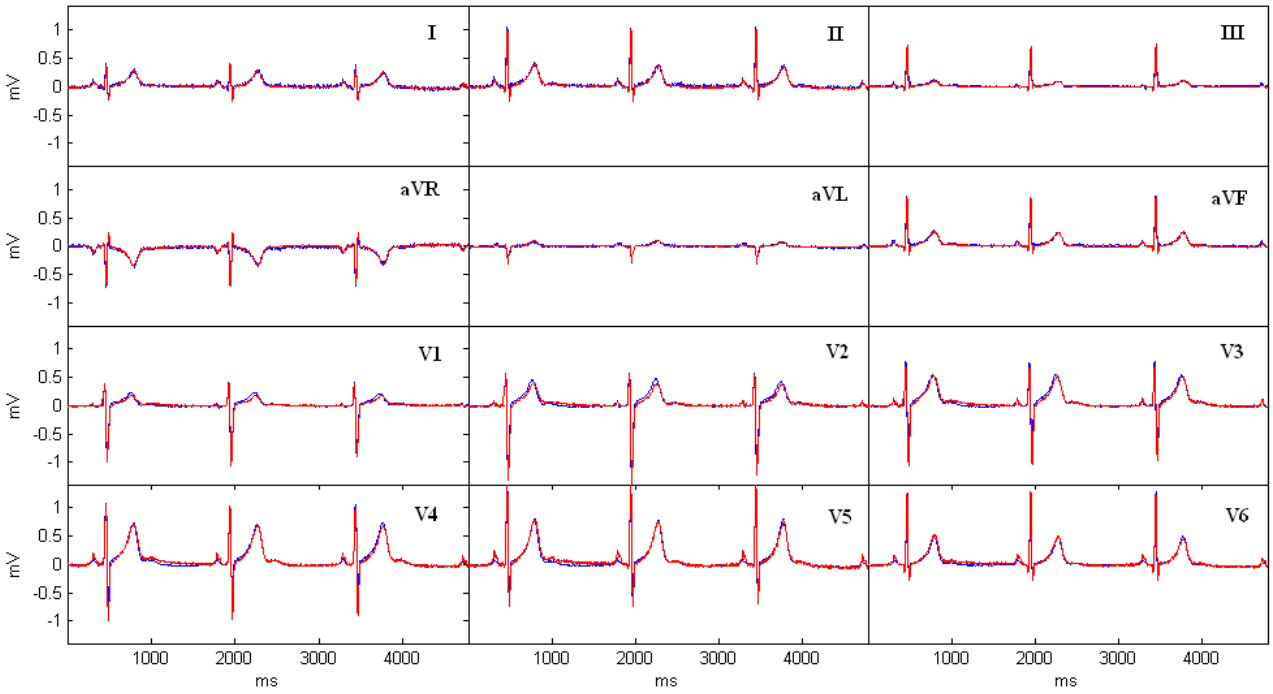


Figure 4. 12-lead ECG obtained by a conventional device (blue) compared to synthesized 12-lead ECG (red)

E. ECG-Derived Respiration

The ECG-Derived Respiration (EDR) techniques, that are relevant to our work, are based on the observation that the positions of ECG electrodes on the chest surface move relative to the heart. Additionally, the transthoracic impedance varies, as the lungs fill and empty. A single-lead wireless approach, based on the EDR algorithm that measures the beat-to-beat amplitude variation of the QRS complex was published in [11] for infant hearts with no detailed clinical evaluation. There are several later studies of the EDR algorithms based on the amplitude variations of ECG waves [12] that are associated with the respiratory-induced variation in the thoracic impedance and in the relative position of ECG electrodes and heart. In study [13] a quantitative comparison of EDR monitoring techniques based on direct measurement of the modulation components versus techniques based on calculation of the mean electrical axis variation was carried out. Authors concluded that single lead respiration rate estimates are more robust than the methods based on the mean electrical axis.

We confirm with the analysis of clinical mutichannel ECG measurements, which include also reference thermistor based respiration signals, that the proposed approach is a viable option for the monitoring of the respiration frequency and for the rough classification of the breathing types. The obtained results are evaluated on a wireless prototype of respiration body sensor from Fig. 2. We indicate the best positions for the respiration body sensor and prove that a single sensor of body surface potentials difference on proximal skin electrodes can be used for combined measurements of respiratory and cardiac activities.

F. Visual sensors

One of the most critical problems that influence a sustainable use of monitoring systems is issuing false alarms. The personnel that assists and manages a monitoring system cannot tolerate false alarms above some minimal limit. We pay special attention to overcome this problem with multilevel alarms based on data from more than a single sensor. To improve the quality of patients' status interpretation, we introduce visual sensors consisting of simple and low cost video detectors [14]. Visual sensors will not allow interference with personal intimacy. The video detectors cover just a near area of the patient's bed and, after a simple local video processing, detect and store patients' motion, movement and position. Based on these additional data, an improved reliability of raised alarms can be obtained.

G. Development of platforms for transmission, representation and collection of data

The transmission of data from the sensors, and later its representation, are planned on two levels: to the patient itself and to the medical personal.

First, we have wireless transmission of the measured data from the sensors to personal terminals, like Smartphones or other portable smart devices. Custom made applications provide the opportunity for suitable representation of the transmitted data and the possibility for the patient to monitor its vital functions. We have already developed an application that provides a comfortable option for telemonitoring of the heart activity. We use the prototyped wireless bipolar body electrode [8] to record ECG wirelessly, coupled with the advantages of existing portable smart devices to display the real-time data from the electrode [15]. Local processing of the measured data and alarm triggering can be done already on the portable device. For example, the reconstruction of

the standard 12-lead ECG from three wireless bipolar body electrodes can be additionally preformed already on the Smartphone and the reconstructed signal appropriately displayed.

Second, a SOAP (Simple Object Access Protocol) client on the portable platform transfers relevant data (for example, ECG data when an alarm has been triggered) to a computer server. The transferred data on the server is appropriately visualized to the medical personal for diagnostic purposes, and also is collected in a database for further analysis.

The wireless technology considered for transmission of measured data from the sensors to personal terminals is the newest version of Bluetooth technology – low energy Bluetooth 4.0. It enables direct communication between WBEs, and newest Smart phones and devices with incorporated Bluetooth Smart technology.

Bluetooth low energy protocol is low-cost wireless solution designed to meet special requirements for long-term operation in devices with limited energy capacity (e.g. coin-cell battery). Its ultra-low peak, average and idle mode power consumption and enhanced working range enables the WBEs to operate on a single coin-cell battery for several days while transmitting live stream of raw ECG data. Based on our preliminary measurements, we conclude that the low power Bluetooth 4.0 enables 4 days of external power supply independency for a WBE with a small coin battery. The maximal bit-rate of the data payload is 1 Mb/s, which is sufficient also for high resolution short-term measurements.

IV. CONLUSION

We have designed a pilot system for continuous monitoring of patients at risk and thus contribute to the significantly elevated quality of health care and patient safety. Widespread, accessible, and tested ICT solutions from the field of measuring sensor systems, mobile communications and network services, are incorporated into the system. Medical expertise are also included through the software for analysis of measurements, as well as the triggering of alerts and alarms for urgent action. The responses of medical personnel to clinical deterioration in patients will be faster; therefore the patients will experience fewer complications in case of sudden deterioration of their health. The work of medical personnel will be less stressful and more efficient.

The applicability of the proposed system is not limited only to hospitals and health care centers, where the added benefit of the system will enable "doctor-to-doctor" and "patient-to-doctor" communication. The system can be also installed in nursing and patients' homes, e.g. for early postoperative care. The patient-friendly approach will contribute to easier diagnostics and reduction of healthcare costs.

The proposed system for remote monitoring of vital functions acts as a test ground for medical staff and a basis for the future Telemedicine/Telecare services. Improved and clinically evaluated system will be an interesting product for the international markets, and opportunity for R&D companies.

ACKNOWLEDGMENT

The authors are grateful to academician prof. dr. Franc Strle MD, Marko Pokorn MD, and Tomaž Jurca MD, all from the University Medical Centre Ljubljana, and prof. dr. Uroš Stanič, BRIS, for their cooperation and ideas that are partially incorporated in this paper.

Abstract - The basic concepts and specific requirements for design of a distributed clinical information system for pediatric surgery are presented in this paper. The system is based on the Service Oriented Architecture, which ensures its interoperability. Web service adapters are proposed as a means to provide integration of the system with other existing e-health systems. The specific health information (investigations, treatments, diagnoses, etc.) for the patients of a pediatric surgery department is organized and stored in electronic health records. The main part of this information, concerning the undertaken surgical interventions and the treatment's results, is submitted as free text. The system described in the paper is designed to provide support for the physicians and PhD students in the department conducting scientific research in the area by allowing extended, different criteria searches and analysis of stored information for pediatric surgery cases.

I. INTRODUCTION

A Clinical Information System (CIS) is a computer based system that is designed for collecting, storing, manipulating and making available clinical information important to delivery of patient care [1]. CIS constitutes separate information system in clinics and hospital departments and can provide some of the following functions [2]:

- Collection and storage of patients' status and treatment data, organizing them in Electronic Patient Records (EPR) or Electronic Health Records (EHR); management and synchronization of health data exchange with other existing e-health systems such as Hospital Information Systems (HIS), if necessary;

- Management and organization of the activities of the clinic or hospital department which can be cardiology, internal medicine, pediatric surgery, etc;

- Support of training and scientific research in the area, extraction and analysis of stored information, preparation of reports.

The use of a CIS for storing, organizing and manipulating the information flow in a clinics or hospital department allows easy access to patient data. The information is structured and well organized, which makes it easier to maintain and quicker to search through, compared with such manipulations on paper records.

Electronic health record (EHR) is a concept, which defines the way to organize electronic health information about a patient. It is a digital record that is theoretically capable of being shared across different e-healthcare systems. EHR may include a wide range of data, which can vary according the specific area of its application.

The required functionality of a particular clinical information system and its specific area of application have to be considered, when a design of the system is proposed. The designing process also depends on the current status of e-health at national level in the country, where the system will be used. Basic concepts, which are applied to satisfy the data, functional and national requirements of building a clinical information system for pediatric surgery, are presented in the paper. The Service Oriented Architecture (SOA) is chosen to ensure the interoperability of designed system. Web service adapters are proposed as a means to provide its integration with other existing e-health systems. The specific health information (investigations, treatments, diagnoses, etc.) for the patients of the department is organized and stored in electronic health records. The system described in the paper is designed to provide support for the authorized physicians and PhD students conducting scientific research in the area by allowing extended, different criteria searches and analysis of stored information for pediatric surgery cases.

II. RELATED WORK

A large number of researches in the area of E-Health are dedicated to design and development of e-healthcare systems and networks. The challenges of designing suitable architecture for such an information system with key issues flexibility, adaptability, robustness, integration of existing systems and standards, semantic compatibility, security and process orientation are discussed in [3].

Many of the proposed solutions for e-healthcare systems [4, 5, 6, 7 and 8] are based on the Service Oriented Architecture. SOA offers the potential to achieve efficiency in application development, integration of third-party applications and greater agility by minimizing the need for extensive application replacement when seeking standardization or incorporating new technology [9]. This approach is preferred for systems, which provide diverse functionalities in e-healthcare and

can also be applied in telemedicine [4, 5] or as decision-support systems and networks [6, 7].

The distributed e-healthcare system, proposed in [8] uses the service oriented architecture as a basis for designing, implementing, deploying, invoking and managing healthcare services. The e-healthcare system provides support for physicians, nurses, pharmacists and other healthcare professionals, as well as for patients and medical devices used to monitor patients.

In a university research project [4], SOA is used in conjunction with grid computing technology for developing a sensor and actuator framework that allows a remote monitoring of the health status of a patient. The idea for personalized health management system based on SOA and Web Services is also implemented in Healthcare@Home [5]. It is a research project, which uses mobile devices and/or dedicated home-based network servers to 'push' or 'pull' patients data to a data analysis engine and evaluates diabetes risk assessment for a particular individual.

A distributed architecture for clinical decision support called SANDS (Service-oriented Architecture for National Health Information Networks Decision Support), which is based on the principles of a service-oriented architecture is proposed in [7]. The architecture allows disparate clinical information systems and clinical decision support systems to be seamlessly integrated over a network according to a set of interfaces and protocols. SOA is the preferred architecture style for designing Health Research Data Network, proposed in [6].

Care2x [10] is another open-source Web-based university research project that implements hospital information system. It has modules for different functions and departments in a hospital and includes a central data server and a health exchange protocol. PHP and JavaScript are chosen here for scripting languages in contrast with many other solutions, which use Java, the database system is mySQL.

There are also many commercial solutions in the area. Some enterprises in Bulgaria provide e-healthcare Web portals, systems and handsets, but none of them offers all of the specific functionality needed for a pediatric surgery department. Such an e-healthcare information system is developed by Gama Consult [11]. The main purpose of the system is to collect and store patients' status and treatment data in order to generate reports to the National Health Insurance Fund. Its design is not prepared to store huge amount of free text data and to support extended, different criteria searches and analysis of the stored information.

III. REQUIREMENTS OF BUILDING A DISTRIBUTED CLINICAL INFORMATION SYSTEM FOR PEDIATRIC SURGERY

Every medical specialty has its own characteristics and specifics. Surgical specialties focus on manually operative and instrumental techniques to treat disease. So the main part of health information for a patient in a surgery department must consider the undertaken surgical treatment. The need of collection, storage and manipulation of patient's information define some requirements for the design of a clinical information system for a surgery department.

A. Data requirements

The information for a patient in pediatric surgery department can be summarized in two categories: general information and specific medical information. General information is collected and stored for all the patients in a hospital. It includes demographic data and general medical data such as blood type, allergies, health status for the patient. The information, specific for a patient in a surgery department concerns the undertaken surgical intervention and treatment results among with attendant investigations – laboratory tests and medical images.

- Demographic data

When a patient enters a hospital in Bulgaria, his demographic data – name, address, age, etc., are usually stored in the information system, which services the hospital. If there is a separate information system (CIS) in the department, where the patient is treated, his demographic data should be also available there. In order to avoid inputting the data again in the CIS, they can be accessed and retrieved from the hospital information system.

- Laboratory tests and medical images

The results from laboratory tests and medical imaging instruments have to be transmitted digitally from the appropriate device to the CIS to be designed to avoid the need to manually file, retrieve, or transport them. The standards should be followed and the universal formats should be used for storage and transfer of the results and images. The CIS should also provide suitable services for information exchange with the appropriate devices.

- Specific medical information

The part of specific medical information for a patient in a surgery department, concerning the undertaken surgical intervention and treatment results, is mainly descriptive, not pliable for any standardization and is submitted as free text. These characteristics define some requirements when Database Management System (DBMS) is chosen and database of designed CIS is created.

- Security

Security and privacy are particularly important issues for healthcare. Personal health information is confidential, so access to such information must be restricted to authenticated and authorized users. Secure transmission of such information must be completed with secure storage of the data.

B. Functional requirements

Proposed CIS will be designed to satisfy the following basic functional requirements:

- collect and store general and specific medical information for patients in pediatric surgery department;
- maintain EHRs for organizing the patient's data;
- provide extended, different criteria searches, extraction and analysis of stored information for pediatric surgery cases.

C. National requirements

Many countries suffer from a lack of healthcare IT standards creating interoperability barriers for healthcare IT adoption at local and national levels [12]. In Bulgaria, there is a lack of unified national standards for health data formats and EHRs [13]. There are no protocols defined for communication and health data exchange between existing e-health systems [14]. The hospital information systems, which are developed in Bulgaria last years, use local databases to store the whole health information for the patients in a particular hospital. There is no federation of the data, stored locally in different healthcare databases, and those of Ministry of Health (MH) and National Health Insurance Fund (NHIF). So the definitions for health data formats, EHRs and protocols for communication and health data exchange should be properly chosen in the designing process.

All the data, functional and national requirements can be summarized to govern the designing process and to achieve and ensure opportunity for the designed CIS to:

1) exchange patient information with other existing e-health systems such as HIS or NHIF ;

2) retrieve and store results from laboratory tests and medical imaging instruments by digitally transmiting information from the appropraite devices;

3) submit, store and manipulate large amount of free text data;

4) maintain EHRs for organizing the patient's data in secure manner and in accordance with the current status of e-healthcare in Bulgaria;

5) provide extended, different criteria searches, extraction and analysis of stored information for pediatric surgery cases.

IV. BASIC CONCEPTS IN DESIGN OF A DISTRIBUTED CLINICAL INFORMATION SYSTEM FOR PEDIATRIC SURGERY

A. SOA and system interoperability

The term service-oriented architecture refers to a style of designing reliable distributed systems that deliver functionality as services [15]. The Service Oriented Architecture reinforces basic software architecture principles such as abstraction, encapsulation, modularization and software reuse. It emphasizes implementation of components as modular services and provides interfaces that can be used by clients. The interfaces are separated from their implementations, so the underlying implementation of the individual service is free to change without affecting how the service is consumed.

Two major levels of integration can be achieved, using the SOA [16] – technical interoperability and syntactic interoperability [17]. According to the European Telecommunication Standards Institute (ETSI), technical interoperability is often centered on communication protocols and the infrastructure needed for those protocols to operate. It ensures the systems to be interconnected in a secure and reliable manner. From a technical point of view, SOA is a design paradigm aimed at creating or enabling applications to interoperate across different technical and operational platforms. This is achieved at a technology level by observing detailed international standards as XML and protocols, in particular those of Web services.

Syntactic interoperability or application integration is usually associated with data formats, which help systems and applications talk to each other in mutually understandable terms. This is achieved by connecting systems at the application level and resolving issues of data consistency.

These two levels of integration, if gained for an e-health system, based on SOA would help the system to interoperate and collaborate at a much higher level and to achieve semantic interoperability. It would enable applications as extraction and analysis of content-based knowledge, decisions support and patient intelligence.

B. Web Services and web service adapters

A Web service is a software system designed to support interoperable machine-to-machine interaction over a network [18]. It has an interface described in a machine-processable format. Other systems interact with the Web service in a manner defined by its description, obeying XML and other Web-related standards. These standards allow developers to implement distributed applications using different tools and different programming languages.

Web service adapters are applied for adopting web services to client needs. They are implemented to maintain the access of functionality in a different architecture. Web service adapters can be useful in two cases:

- when the service behavior of a system requires interactions with external Web services; or
- when a system exposes service behaviors as Web services.

Following some of data and functional requirements, the clinical information system to be designed has to interact and exchange information with existing information systems. Service oriented architecture is an appropriate approach to satisfy the need for interoperability of the system. Web service adapters can be designed to provide the opportunity of integration of the system with other existing e-health systems.

C. Electronic Health Records (EHR) and bottom-up approach

EHR is a repository of information regarding the health status of a subject of care in computer processable form, stored and transmitted securely, and accessible by multiple authorized users [19]. It has a standardized or commonly agreed logical information model which is independent of EHR systems.

From the viewpoint of standardization, the most important characteristic of the EHR is the ability to share EHR information between different authorized users. In technical terms, this requires interoperability of information in the EHR and interoperability of EHR systems which exchange and share this information. In

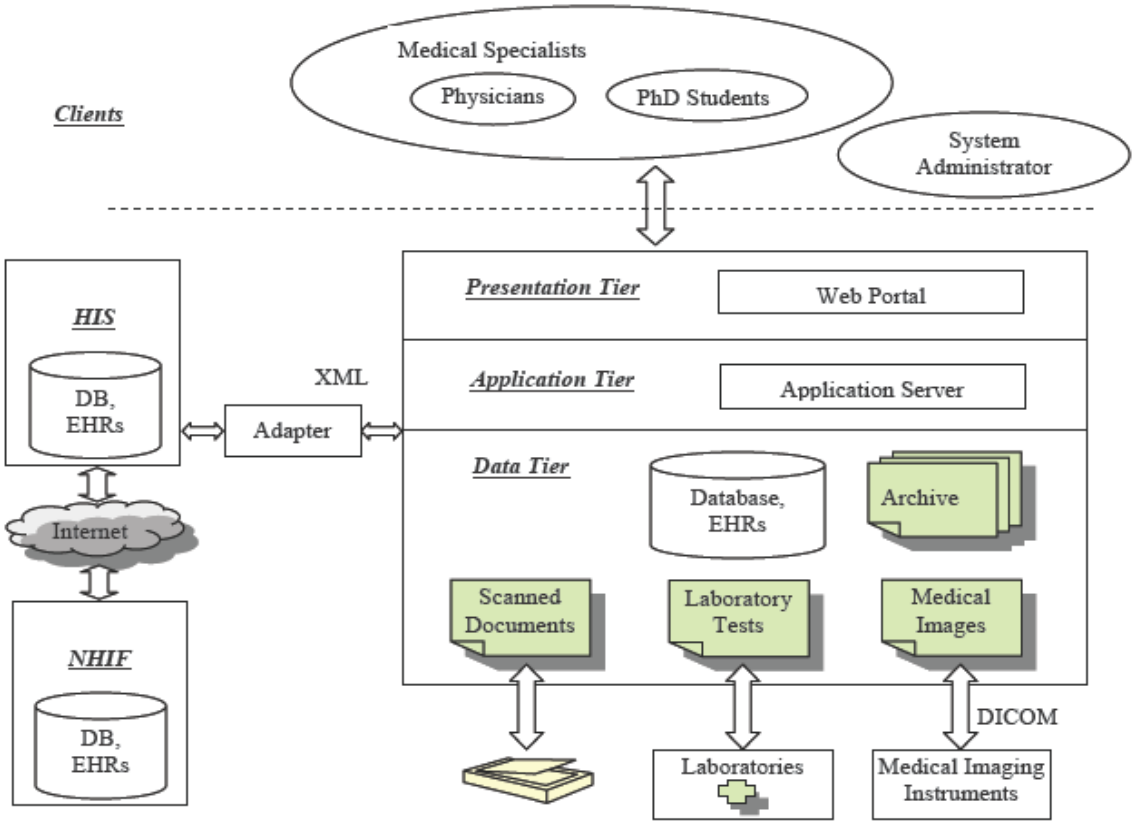

Figure 1. Multitired model of distributed Clinical Information System for Pediatric Surgery Department

order to achieve interoperability a set of standards and protocols are necessary in the area.

In most countries, where such standards are defined and available, a national approach to EHR adoption is the 'top-down' [12]. It is an approach for development of EHRs in clinical information systems, considering them as parts of hospital information system. The lack of unified national standards and protocols for EHRs makes it impossible to adopt this approach in Bulgaria. The 'bottom-up' approach [13] is applied instead; it suggests the development of local databases with EHRs, based on SOA. This approach allows easy integration of such a designed system with other e-health systems – existing or to be designed in the future. The coordination of information exchange between systems is ensured by the open XML format. An advantage of the approach is the opportunity to design the required clinical information system for pediatric surgery department without awaiting the indefinite time delay for development, acceptance and approval of national standards in the area.

V. DESIGN OF A DISTRIBUTED CIS FOR PEDIATRIC SURGERY DEPARTMENT

A. System architecture

The system is designed considering the people, who will use it, required functionality to be provided for them and data types and formats to be collected, stored, manipulated and exchanged with other systems.

Basic users of the system are the medical specialists – physicians and PhD students, who work in pediatric surgery department. They can: 1) enter data for the patients in department; 2) make inquiries for patients, treatments, surgical interventions, diagnoses etc.; 3) conduct extended, different criteria searches for pediatric surgery cases to make scientific research in the area.

Based on the requirements previously defined, a distributed architecture is proposed – fig. 1. The model has four tiers:

- Client tier – the clients of the system are resided here. The role of the tier is to allow the user access to the system. This tier can be implemented with Web browser or as desktop application to provide the necessary user interface by means of Web pages or Web services.
- Presentation tier – Web portal or the 'entry point' of the system. The user queries are submitted here and are accepted or rejected, according the rights for access. If accepted, the queries are transmitted to the next tier to be served. Presentation tier communicates with other tiers in two-way manner. When the results from a query are ready, the tier translates them to the client tier for output.
- Application tier (business logic, logic tier or data access tier) – presented with Application server. It controls the application's functionality by performing detailed processing. Two main directions in functionality of the tier can be distinguished: 1) query processing; and 2) control

of data access and transmission. The data are transmitted in XML format. The functions of the tier are realized on the basis of Web services, which ensure the interoperability of the system and allows its easy integration with other systems.

- Data tier – the information is stored and retrieved here. This information is organized as follows: 1) in a database; 2) as files in the file system and 3) in archive.

  The database is designed to store the main part of patient data and all the other information needed for the system to work properly – users of the system, rights, etc;

  The demographic data for the patients have to be retrieved from the information system [10], which services the hospital, the department belongs to. Web service adapter is proposed as a means to provide the access and data exchange between the designed system and the hospital information system. It can be used to access and retrieve data with NHIF too, if needed. The adapter also allows conversions, if there are any differences between corresponding structures and data formats of EHRs in both systems. The data are exchanged in XML format.

  Results from laboratory tests and medical imaging instruments are transmitted digitally from the appropriate devices to the CIS and stored as files. Standards are followed for handling, storing and transmitting the information. DICOM is adopted as a standard in medical imaging. Scanned documents can also be used as a source of information in order to make the transition easier from paper to electronic records keeping.

  The archive contains backup of information in the database and files.

  This tier keeps data independent from application servers or business logic. Separating data from logic and services improves scalability and performance of designed system.

B. Electronic Health Records

The definition for EHR, presented in table 1, is proposed to organize the information of a patient in pediatric surgery department. It is partitioned into 'core' and 'specific' information.

The core EHR sections hold basic information, which can be stored for a patient in any department in a hospital such as general data and description of patient's disease. The problem list, case history and diagnosis are followed by the clinical notes and medications, taken in the course of treatment and completed with epicrisis and final prescriptions – all submitted as free text.

The information, specific for a patient in a surgery department concerns the undertaken surgical intervention and attendant check up of patient status and results from laboratory tests and medical imaging instruments. The patient status consists of comprehensive, mainly free text description of his tissues, organs and systems. This information together with the results from laboratory tests, medical images and evaluation of anesthesiological risk is needed in a surgical treatment. The surgical intervention itself is described with a surgical protocol, where the surgical progress is given in details, the cultures, taken for analysis are recorded and complications are noted, if any.

A lot of information, included in core and specific EHR, is mainly descriptive, not pliable for any standardization and have to be submitted as free text. On the other hand this information is very important in order to conduct scientific research in the area of pediatric surgery, because it concerns some of the main criteria of searches as diagnosis, patient status and problem list and surgery description. So the opportunities for fast searches in large amount of free text data have to be considered and investigated as a future work at the stage of system implementation.

TABLE I. EHR FOR PEDIATRIC SURGERY DEPARTMENT

Core EHR	
Section	***Description***
Patient demographics	Information, retrieved mainly from the HIS
General medical data	Blood type, Rh, allergies, overall health status of the patinet
Problem list	The patient problem list, submitted as free text
Diagnosis	Code of disease and additional free text
Case (medical) histiory	Free text
Clinical notes and medications list	Free text
Epicrisis, prescriptions	Free text
Specific EHR	
Section	***Description***
Patient status	Comprehensive description of the status of patient's tissues, organs and systems. Submitted mainly as free text.
Anestesiological risk	Presented with class, marked with a digit, according ASA physical status classification system + "E" for emergency.
Laboratory tests – common and specific	Laboratory tests, specific for surgery department such as histology, haemostasis, tumor markers, etc. are included in the patient's record in addition to common laboratory tests. Stored as files.
Medical images	Transmitted digitally from the appropriate devices to the CIS and stored as files.
Surgical protocol: - surgical team; - anaesthesia; - surgery time; - surgery progress; - culture, taken for analisys; - complications	The members of surgical team are presentes with their physician's ID. The anaesthesia is submitted with itd code. The other part of the protocol (except surgery time) is submitted as free text.

VI. CONCLUSION

Design of a distributed clinical information system for pediatric surgery department is described in the paper. The data, functional and national requirements when building such a system are defined. The basic concepts, applied to satisfy the requirements are discussed. The system is based on the Service Oriented Architecture, which ensures its interoperability. Web service adapters are proposed as a means to provide integration of the system with other existing e-health systems. The specific health information for the patients of a pediatric surgery department is organized and stored in electronic health records. The system is designed to provide support for the physicians and PhD students in the department conducting scientific research in the area by allowing extended, different criteria searches and analysis of stored information for pediatric surgery cases. The main part of this information, concerning the undertaken surgical interventions and the treatment's results, is submitted as free text. So the opportunities for fast searches in large amount of data have to be considered and investigated as a future work at the stage of system implementation.

Abstract - The paper suggests a model for implementation of a body sensor network's gateway functions. The gateway is based on a mobile smartphone with a Linux kernel. Analysis on traffic management schemes based on different queue disciplines is presented in the paper. Since the gateway is modeled as a standard mobile device, the typical traffic flows for such devices are taken into account and their influence on the medical sensors data flow traversing through the gateway is considered. The paper presents the results from experimental analysis on performance parameters. Testbed experiments are conducted on a Nexus One smartphone platform and Linux traffic control tool.

I. Introduction

Body sensor networks are one of the key components of the new and emerging personal healthcare systems. They are formed by low-power wireless sensor nodes placed on or around the human body. These networks are opening the way for new healthcare and wellness applications by giving the individual person a more central role in its treatment and prevention process, and by giving healthcare professionals an access to data, collected under natural activities and environment.

Body sensor networks (BSN) often utilize a star topology with a clearly separated master/slave roles. The master node (also known as personal monitor, personal server, BSN aggregator and etc. [1], [2], [3]) is a device characterized with higher processing and communication capabilities that acts as a coordinator for the network. It performs multiple functions including sensing, fusing data from multiple sensors, serving user interface, and bridging BSN to higher-level infrastructures [3], [4], [Ullah09]. There are two approaches for realization of the coordinator node. The first one is to use a custom designed device [5], [6] that will be more reliable and optimized for the BSN applications in both hardware and software terms. The second and most preferred approach however is to use off-the-shelf mobile device such as PDAs, smartphones, tablets, etc. [1], [2], [4]. This not only brings the benefits of rapid prototyping, small form factor, and continuously increasing processing and communication capabilities, but also reduces the cost for development and acquirement by the end-users since it is very common that they already own such a device. The disadvantage of the solution is that the BSN application will have to share hardware and software resources with the other applications running on the device. In this paper a standard smartphone device will be assumed for the role of a BSN coordinator.

A. Motivation

Quality of service is a fundamental factor to achieve reliable and timely data delivery in healthcare applications. The primary QoS parameters are bandwidth, delay/latency, delay variation (jitter), packet loss and error rate. To meet the needs of healthcare applications without totally corrupting the performance of the other smartphone applications a flexible network management has to be applied. To control the latency and jitter parameters introduced by the BSN gateway an appropriate packet scheduling and queue management mechanisms should be used.

B. Background

Priority queuing (PQ) is the most effective scheduler when there is a prioritized traffic, because it is able to forward this traffic as soon as possible. However, PQ is not able to guarantee a minimum share to lower priority traffic. Link-sharing mechanism explicitly enforced at the output interface of the gateway can prevent starvation of lower priority traffic, while still satisfying the needs of higher-priority ones. Requirements for link-sharing, taken together with requirements for real-time services, lead to a requirement for hierarchical link-sharing [7]. It allows control on the bandwidth distribution between various entities that are organized in classes in a tree structure. Hierarchical link-sharing and packet scheduling are involved in the same process of choosing the packet to be sent next on the output link and can be implemented together.

One of the first implementation of this approach is Class-based queuing (CBQ) mechanism first presented in [7]. The architecture of CBQ combines a link-sharing scheduler with general scheduler (Fig.1). Incoming traffic is classified into appropriate queues based on a set of rules. The general scheduler than extracts packets from those queues ensuring each class receives its nominal bandwidth, taking into account the assigned priorities of the classes. The estimator together with link-sharing scheduler is used to control the distribution of excess bandwidth [7].

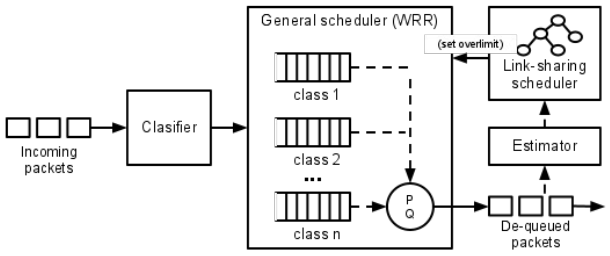

Figure 1. CBQ building blocks

Hierarchical Token Bucket (HTB) [8] is another implementation of the group of hierarchical link-sharing algorithms. HTB works similarly to CBQ, but unlike CBQ that uses calculated idle time periods to shape classes, HTB uses token bucket filter (TBF) algorithm. TBF is a simple queue discipline that only passes packets arriving at a rate not exceeding an administratively set limit, while still allowing short bursts. Each HTB class is associate with buffer constantly field with tokens. A packet is dequeued only when a token is available in the buffer. The size of the buffer defines the burst period. The advantage of TBF is that it does not depend on interface characteristics like bandwidth of the output interface [8].

The main elements of traffic control in Linux kernel are classification, scheduling and queuing. Linux traffic control combines queuing and scheduling into queuing disciplines. These queuing disciplines can be nested in each other. The traffic control in Linux works in the kernel space. To configure and control the Linux traffic control from user space a tool called *tc* is used.

The rest of the paper is organized as follows. Section II presents a model of BSN coordinator and traffic patterns. Section III describes the analysis on performance of traffic control schemes for BSN scenarios with test-bed experiments. Section IV shows some graphical representation of results from the analysis. Finally, section V gives some conclusive remarks and presents the future work directions.

II. BSN GATEWAY MODEL

A. System model

For the BSN gateway model, a standard smartphone device with Linux-based operating system is considered. The gateway is modeled as a set of queues and a traffic control logic (Fig.1). Ingress queues describe traffic sources and could be separated in three general groups. Body sensor network group describes packets coming from sensor network, Smartphone applications group describes traffic generated by applications running on the device, and System and tethering group describes system traffic generated from the operating system itself and from shared Internet connection.

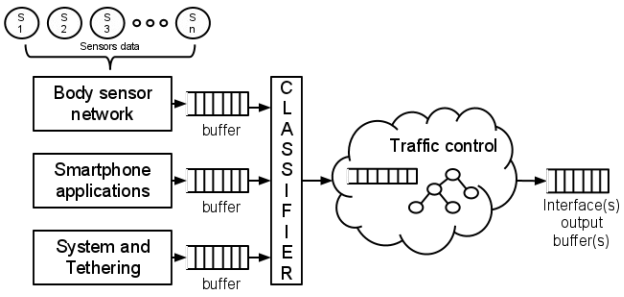

Figure 2. BSN gateway – queue model

B. Traffic model

BSN traffic is composed of multiple flows with periodic characteristics. An aggregation of these flows can be expressed by addition of the arrival functions [9]. Individual arrival function $A_i(t)$ together with the resulting aggregated arrival function $A_\Sigma(t)$ are expressed as:

$$A_i(t)=\frac{L_i}{T_i}.t \Rightarrow$$
$$A_\Sigma(t)=\sum_{i=1}^{n} A_i(t)=t.\left(\sum_{i=1}^{n}\frac{L_i}{T_i}\right), \quad (1)$$

where Li is the packet size and Ti is the interval between packets. Typical values of traffic generated by sensors of some of the most important physiological signals are summarized in Table 1. If we choose to select the minimal interval among all, than given the aggregated data rate from (2) the packet size will be given by:

TABLE I. BSN TRAFFIC PARAMETERS

Physiological signal	*Interval (sec)*	*Data size (bytes)*
ECG	0.001	16
Hearth rate & SpO2	1	4
Respiratory rate	300	10
Blood pressure	300	20
Blood glucose	3600	20
Body temperature	600	10

$$L_\Sigma = T_{min.}\sum_{i=1}^{n}\frac{L_i}{T_i}. \quad (2)$$

A study on smartphone applications traffic is presented in [10]. The extracted results indicates that more than 50% of the traffic is a web traffic. E-mail, media, and online maps corresponds to approximately 10% of the traffic each. Another considerable source of traffic not considered in the paper is the tethering or sharing Internet connection with other devices over wireless local area networks. The results for transferred packet sizes show an advantage of small data transfers (30% of transfers under 1K bytes) [10]. In [11] the same authors propose a usage of smartphones models. The authors proposed a mixture of exponential and Pareto distributions to model payload size [11]:

$$r.Exp(\lambda)+(1-r).Pareto(x_m,\alpha), \quad (3)$$

where parameter *r* gives the relative mixture between two distributions, λ is the exponential rate, α and x_m are Pareto shape and scale respectively.

Exponential distribution is used to model short user sessions, while Pareto distribution is proposed to covers long user sessions. According to [11] the screen timeout value is a best fit for the scale parameter x_m. The other three parameters are determined using EM algorithm. Since more than 50% of the traffic constitute Web traffic the inter departure time (IDT) will be best modeled using Weibull distribution [11], [12].

The tethering traffic constitutes the traffic routed from a shared Internet connection (Fig.2). Since this traffic is usually generated from one or more mobile devices locally connected to the BSN gateway, it is selected to be modeled as a multiply of the second group of traffic - smartphone applications. As the number of devices that use the shared connection increases, the aggregated traffic changes from Weibull distribution to exponential [12].

C. Evaluation scenarios

The processing and transmission delays are fairly constant while the access and buffering delays are highly time-variant due to variable occupancy levels of buffers. The total time delay T_{delay} can be broken into three parts [13]: delay at the source node, on the network - T_{tx}, and at the destination node T_{post}. Time delay at the source node includes the preprocessing time T_{pre}, and waiting time T_{wait}, which is the sum of the queue delay T_{queue} and the blocking delay T_{block} :

$$T_{delay} = T_{pre} + T_{wait} + T_{tx} + T_{post}$$
$$T_{wait} = T_{aueue} + T_{block} \quad . \qquad (4)$$

The queue delay T_{queue} is the time a message waits in the buffer at the source node while previous messages in the queue are being sent. The evaluation of the effect of different traffic control configurations on the queuing delay is one of the tasks in the presented analysis. Android kernel supports only a limited set of queue disciplines which determine the choice of scenarios to be evaluated.

The first scenario considers a FIFO queue management. This queue management discipline has no provisioning for QoS. All traffic flows are equally contenting for bandwidth and no prioritization and reservation is assumed. This discipline is expected to give worst case results for the queue delay of BSN traffic.

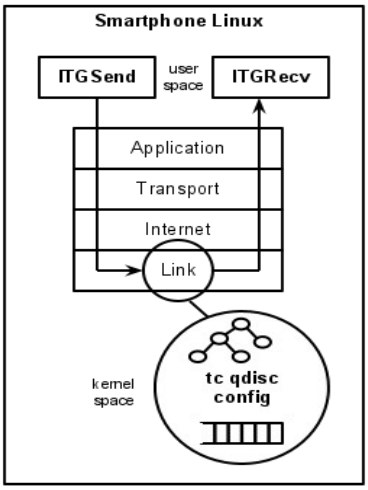

Figure 3. Testbed architecture

The second scenario considers a strict priority queue management discipline where BSN traffic is configured with highest priority, stream video and VoIP traffic is given the next priority level and all other traffic is configured with the lowest priority level. This scenario is expected to give the best possible results for the queue delay of BSN traffic, but at the price of a worse queue delay for stream video and VoIP traffic.

The third scenario under evaluation considers a hierarchical link-sharing mechanism, where each traffic type is isolated in a separate class with bandwidth reservation and prioritization configured appropriately.

III. Experimental analysis

In order to evaluate how different queue management and packet scheduling mechanisms could improve the delay and jitter values of the time critical traffic types on a BSN gateway a number of experiments have been carried out using the experimental testbed depicted at Fig.3. All of the experiments are conducted on a smartphone device HTC Nexus One (development version). The device is characterized with the following parameters: Processor Qualcomm QSD8250 Snapdragon ARMv7 @1GHz, RAM 512MB, Linux kernel version 2.6.35, Android version 2.3.6.

Traffic control in Linux is the name given to a set of queuing systems and mechanisms by which packets are received and transmitted on a gateway node. The *tc* tool, part of *iproute2* suite, is used to manipulate the traffic control settings in Linux kernel [14]. Its components include schedulers (qdisc), shapers (classes), filters, classifiers, policers, and handlers. In this paper we use tc to configure the evaluation scenarios described in the previous section. The queue disciplines used in the experiments are pfifo (packet-based FIFO queue), pfifo_fast (PQ, provides three strict priority pfifo queues), HTB (hierarchical link-sharing queue discipline).

The performance evaluation study has been performed using D-ITG (Distributed Internet Traffic Generator [15]. D-ITG is a platform capable to produce traffic at packet level accurately replicating appropriate stochastic processes for both IDT (Inter Departure Time) and packet size random variables with a set of supported statistical distributions. We have then proceeded to obtain empirical data from the different scenarios to be processed and the model described in the previous section. Output sequences are derived from packet numbers, transmission and delivery times, available by use of D-ITG. Since both sender and receiver component of D-ITG are running on the same device (Fig.3) the block delay T_{block} and transmission delay T_{tx} (4) are not considered in results.

Several traffic flows are used in the experiments confirming to the calculations in previous section. Only four of them are considered interested and their performance parameters are being monitored. BSN traffic, VoIP traffic, stream video traffic and Web traffic. The first three of them are considered because of their requirement for QoS. The fourth traffic is selected because it compromise significant percent of the smartphone traffic and is used as a marker of how different traffic control schemes influence rest of the traffics. Tethering

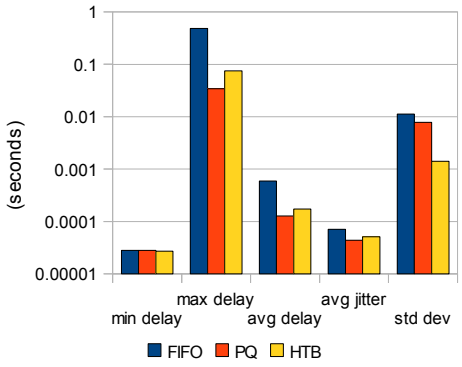

Figure 4. BSN traffic

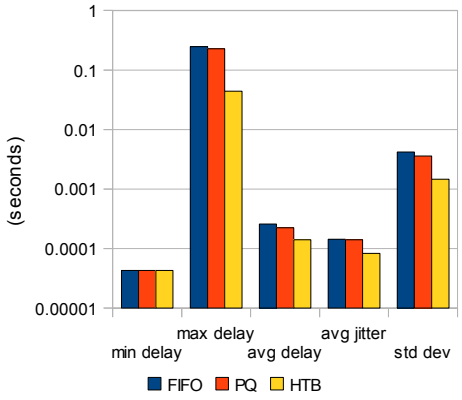

Figure 5. VoIP traffic

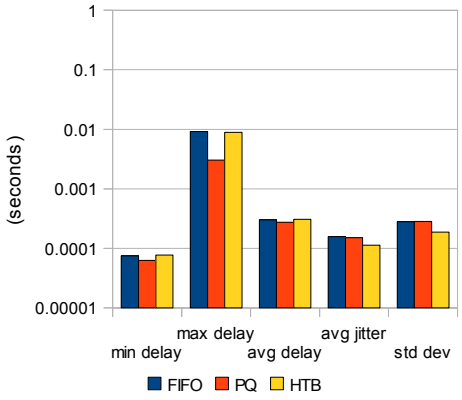

Figure 6. Video traffic

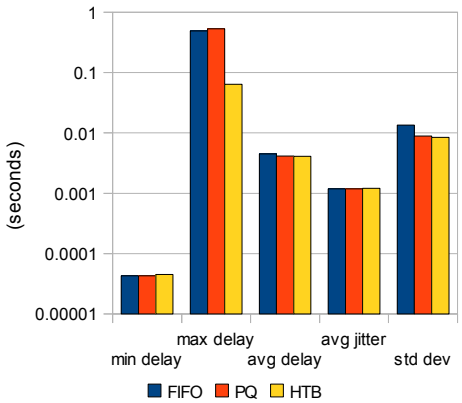

Figure 7. Web traffic

traffic is presented in the experiments as additional three of each of other smartphone traffic flows, assuming that the connection is shared among three clients.

IV. Results

In this section we present and discuss the experimental results of the evaluation. The influence of the three queue management disciplines (FIFO, PQ, and HTB) on the delay and jitter parameters of the four selected traffic flows is shown on next four figures. Fig.4 shows the experimental results for BSN traffic. As expected, we observe lowest maximum and average delays and jitter when priority queue is used. When HTB is used these values are a little bit higher, but still in the same magnitude as in the case of PQ. The same tendency is observed for the VoIP traffic as shown on Fig.5. For the video traffic however (Fig.6), the use of HTB results in values for maximum and average delay closer to that of FIFO queue discipline. Finally, Fig.7 shows how web traffic is influenced by the different queue management disciplines. Since Web traffic goes in the lowest priority queue, it is not surprisingly that PQ results in highest maximum delay values. However, the average delay and jitter are almost identical for all three disciplines.

The distribution of delay and jitter of the packets from BSN traffic flow for the scenario with HTB queue discipline are given on Fig.8 and Fig.9 respectively. The

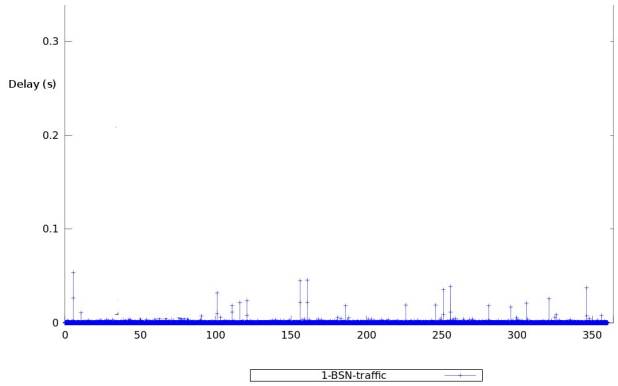

Figure 8. BSN packets delay distribution for HTB

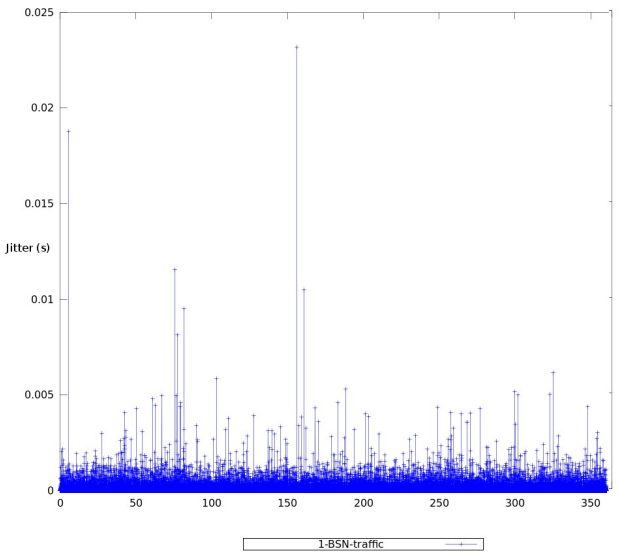

Figure 9. BSN packets jitter distribution for HTB

results show that most of the packets experience delays closer to average values, while only few packets experience higher delay and jitter. This peaks in the graphics cab be explained with burst traffic from other flows scheduled for transmission.

V. Conlusion

In this paper, we investigated the use of standard smartphone device for mobile healthcare applications. In addition to its typical usage the role of a gateway for a set of wireless medical sensors is assumed. Its functions and traffic patterns are then modeled in the paper. To address the special need for bandwidth, delay and packet loss of traffic from sensors nodes several traffic control mechanisms are being discussed. An experimental analysis is then conducted to evaluate how this mechanisms influence the performance of the other smartphone applications if this new application is going to be accepted by users. The obtained results indicate that applying a flexible traffic control could not only guarantee the needs of BSN applications, but could also improve the performance of other delay sensible applications such as VoIP and stream video.

Coarse grain simulation and visualisation of lipid and water molecules ensembles

J. I. Pavliļ and R. Trobec
Institute Joģef Stefan/Department of Communication Systems, Ljubljana, Slovenia
{janez.pavlic; roman.trobec}@ijs.si

Abstract ï We simulate and visualize the formation and behavior of lipid membrane and lipid vesicle in order to recreate the measured results obtained in previous experiments. Simulated lipid membranes, lipid membrane rings, and lipid vesicles are composed of 56, 264, and 2963 lipid molecules, respectively. All structures have dimensions in the range of a few nanometers and interact with the water environment. We use a coarse grain molecular dynamics (CG-MD) simulation method. The CG-MD simulations are run on multicore parallel computer to simulate up to 100 ns intervals. We confirm the formation of all three simulated structures and show that they remain stable through the whole simulated time intervals.

I. INTRODUCTION

The advent of contemporary computers enables *in silico* studies of biological nanostructures. One of the important application fields in medicine is the simulation of proteins and study of their physical properties, which can help to understand their behavior and improve or accelerate new drug designs [1, 2]. Lipid bilayers have been often used to model living cell membranes in the investigation of basic phenomena, such as interactions of membraneï protein, their mechanical and structural properties, conformational changes of membranes, etc. [3, 4, 5]. The bilayers can form vesicles that model living cells. The vesicles are composed of lipids arranged in a closed bubble-like shaped bilayer [6].

The lipid molecules are amphiphilic with a polar part and a nonpolar part. The polar part (head) is hydrophilic, i.e., it ñlikesò water, which is a polar solvent. The nonpolar part is hydrophobic, which means that it does not ñlikeò water. We use in our studies Distearoyl ï Sn ï glycerol ï PhosphoCholine (DSPC) zwitterionic lipids, which is shown in Fig. 1. The zwitterionic lipid headgroup is a dipole, so the lipid itself is electrically neutral.

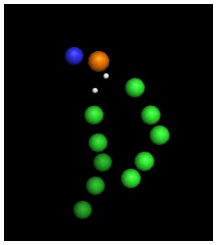

Fig 1: CG model of a single molecule of DSPC zwitterionic lipid.

The authors acknowledge the financial support from the state budget by the Slovenian Research Agency under grant P2-0095.

The rest of the paper is organized as follows: In Section II. we shortly discuss the background and the methodology of molecular dynamics (MD) simulations. Next section is devoted to simulation results. We present simulated formation of lipid bilayers, lipid membrane rings, and lipid vesicles, all in watery environments. The paper concludes with a short summary and outlooks for the future work.

II. METHODS AND SYSTEMS

A. Molecular dynamics simulations

The molecular dynamics (MD) simulation [7] is based on calculation of $O(N^2)$ particleï particle force interactions in a multi-particle system. The Newtonôs equation of motion has to be integrated for every particle of the system in order to obtain new positions and new velocities for each time step. The full atomic simulation is limited to short simulation intervals (few nanoseconds) and small number of particles because of significant computational requirements [8, 9]. In our study, we used the coarse grain (CG) MD simulation [10], which is appropriate for bigger simulation systems and able to perform longer simulation periods (up to a few microseconds). In the CG-MD simulation we apply the well known MARTINI force field (ff) [11]. The CG-MD simulations were performed by using open source software GROMACS [12]. All tests were run on a computing cluster at Institute Joģef Stefan (IJS), Slovenia, which consists of 37 Intel Xeon 5520, 2.26 GHz computing nodes, each with a single processor and four computing cores per processor. All nodes run under Ubuntu 11.04 Linux operating system and `mpich` MPI communication library. The cluster nodes are interconnected by Gigabit Ethernet links with up to 7 network interface cards per node.

We ran several simulations on computer nodes in parallel; trying out different parameter sets (e.g. radius, lipid placing, initial positions, simulation specific settings, etc). We show in the following typical cases of all three treated structures: membrane, ring membrane and vesicle.

B. Molecular System

The simulated molecular systems consist of DSPC lipids and water molecules. The lipid membrane is composed of 56 DSPC lipids and 31714 water molecules in a simulation box of size ~ 15.56^3 nm^3. The lipid membrane ring is composed of 264 DSPC lipids and 18493 water molecules in a simulation box of ~

13.05x13.15x13.70 nm^3. The lipid vesicle is composed of 2963 DSPC lipids and 82567 water molecules in a simulation box of size ~ 21.51x22.39x23.78 nm^3. All the molecules were modeled by the MARTINI ff model, which merges four heavy atoms (such as waters and carbons) into a single bigger particle. In such a way, the number of particles, constituting the molecular system, is greatly reduced, thus enabling us to simulate larger systems of interest for longer time periods.

Before we start an actual MD simulation an initial structure of particles, i.e., a lipid membrane, a ringï shaped membrane, or a vesicle, all without water molecules, is shaped with a dedicated particle-placing program. After having the starting structure, the energy minimization is carried out, which adapts initial positions of particles to the desired energy. The minimized lipid structure is already placed in the simulation box. The empty volume of the simulation box is filled with water molecules. The whole system (lipids and water molecules) is energy minimized, again. Such minimized simulation system is put under constant pressure run (NPT) at 1 bar with Berendsen barostat for 20 ns. Finally, the whole system is exposed to the final MD simulation run (MD run). All presented MD simulations perform the simulation of 100 ns time intervals. In all the MD runs, we use Parrinello-Rahman barostat at 1 bar and Nose-Hoover thermostat at 323 K, . The periodic boundary conditions are applied and the time step is set to 20 fs.

III. Results and Discussion

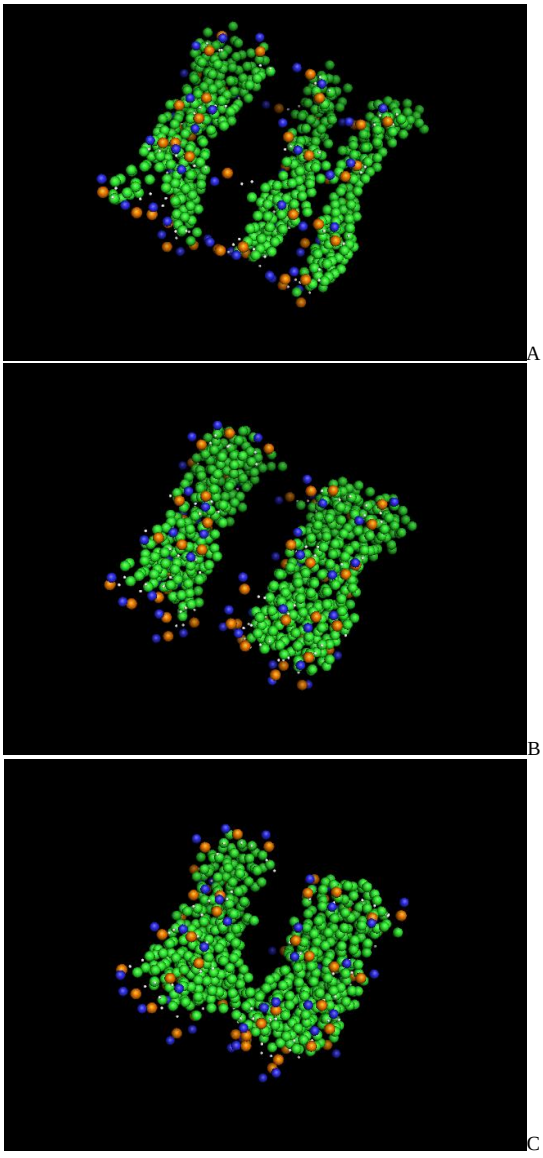
While running the MD simulations, all pieces of information about the atomic coordinates are being stored in a trajectory file. These coordinates can be used for animated visual representations. Variety of plots, with the respect to time or coordinates, can be obtained for simulated molecular ensembles (radius of gyration, energy, force, root mean square distance, density profile, etc.).

In an early stage of our research, we have started with a random distribution of lipid and water molecules and hoped that they will spontaneously form lipid bilayers or vesicles. However, we find out that such a process is very sensitive to initial molecular distributions and velocities, and to other simulation parameters, e.g., pressure, interaction models, etc. Up to now, we are not able to form a lipid membrane from a starting structure with randomly distributed lipids, probably because of relatively short simulated intervals. Instead, we generate, with a custom program, the desired placing of lipids (membrane, ring, vesicle). Such a procedure provides the desired shapes of starting structures, and allows us to spend much less simulation time for the formation of the final structures. The GROMACS software tools do not offer an option for the designing and manipulating initial custom shapes.

Our final goal is to simulate more complex cases, such as interactions between proteins and membranes. These interactions also depend on lipid composition and, probably, even on the shape of the membrane. That is why we need to build, for example, a ringï shaped membrane, which could mimic nanotubes protruding from a vesicle. Next, the ringï shaped membrane could be an approximation of a vesicle in its equatorial section. In this case, the simulation system could have a significantly smaller number of constituent molecules as in the case of complete vesicle simulation. Finally, the formation of different vesicles comes out as a natural one, since in the circulated blood there are many various kinds and sizes of spherical objects, such as leukocytes, platelets, cells, microvesicles, etc.

A. *Lipid membrane*

The simulation results of the lipid membrane are shown in Fig. 2. Water molecules are not shown for better visibility of lipids. After performing the energy minimization of the starting structure, composed of lipids and water molecules, we initially get three separated stripes of lipid bilayers as shown in Fig. 2A. After ~ 55 ns of the simulated time we get a stable lipid membrane patch as shown in Fig. 2E, which remains stable until the end of simulated interval of 100 ns.



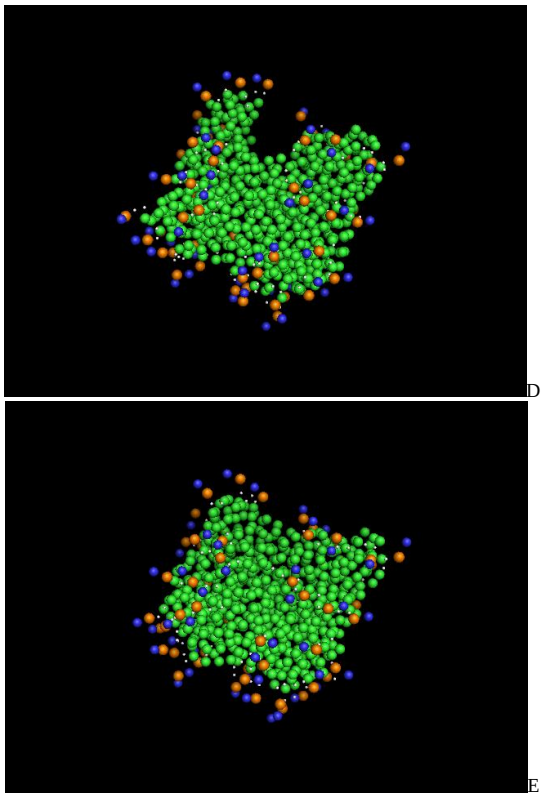


Fig 2: A) Starting structure of the lipid membrane composed of 56 DSPC lipids. After energy minimization three lipid bilayer stripes are formed (t=0). B) After ~ 2 ns of simulated time the right two stripes fuse together. C) and D) The left and the right bilayer patches start to fuse together after ~ 15 and 20 ns. E) Shows the final shape of lipid membrane after 100 ns of simulated time. Water molecules are not shown for better visibility of lipid structures.

B. Lipid ring membrane

The simulation results of lipid membrane ring structure are shown in Fig. 3. The radius of the ring structure is set to 5 nm. The length of cylindrically shaped structure is ~ 4.1 nm. The starting structure, composed of lipid and water molecules, does not change after energy minimization, as shown in Fig 3A. The ring shape remains stable also through the whole MD run. This is a clear indication, that the intermolecular forces among lipid molecules work in a proper way, which pushes the lipid molecules in proper way, not being too close or too far apart from each other. We do not see any disintegration of the membrane ring structure after 100 ns simulated time, as can be seen from Fig. 3D.

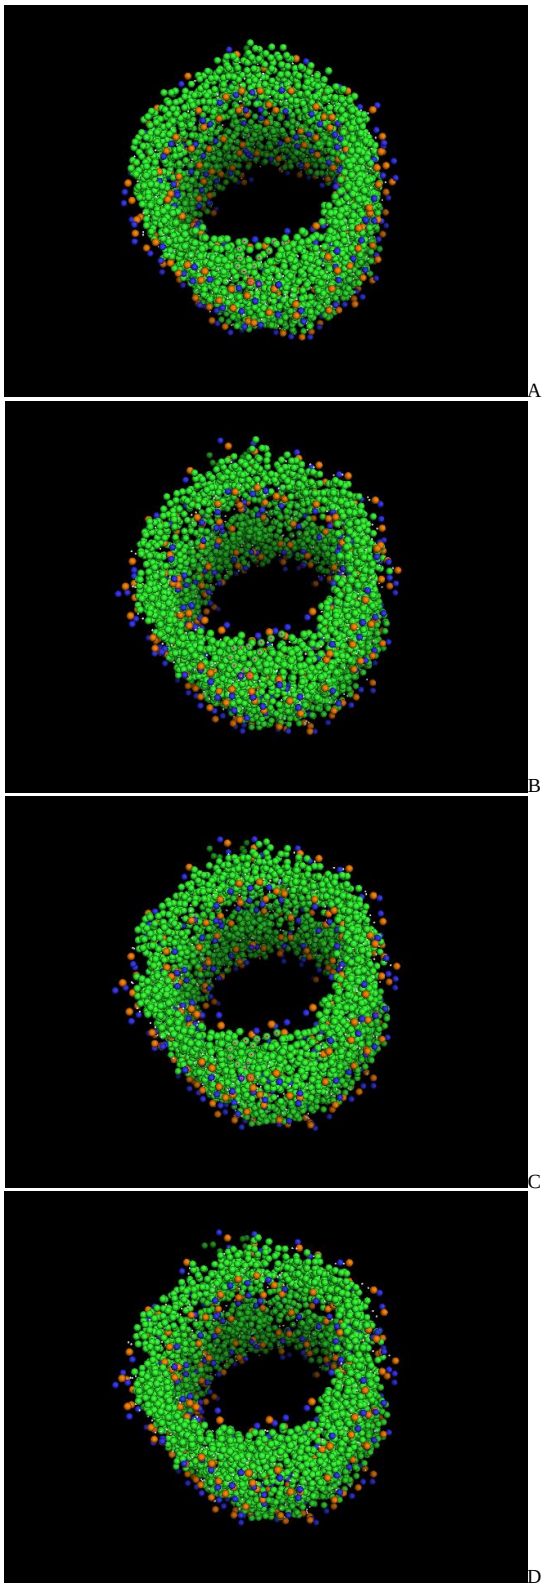

Fig 3: A) Starting structure of the lipid ring membrane composed of 264 DSPC lipids after energy minimization (t=0). B) and C) After ~ 26 and 80 ns the ring structure stays stable. D) Shows the final shape of the lipid membrane ring after 100 ns of simulated time. Water molecules are not shown for better visibility of lipid structures.

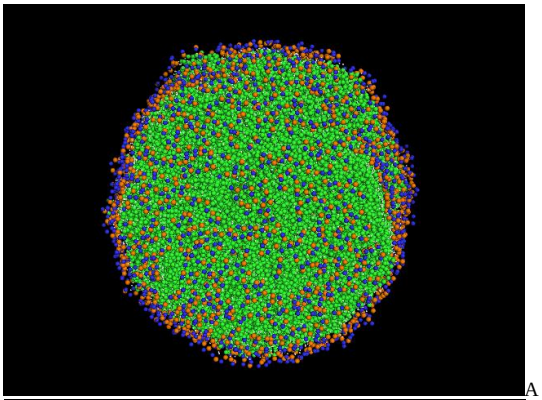
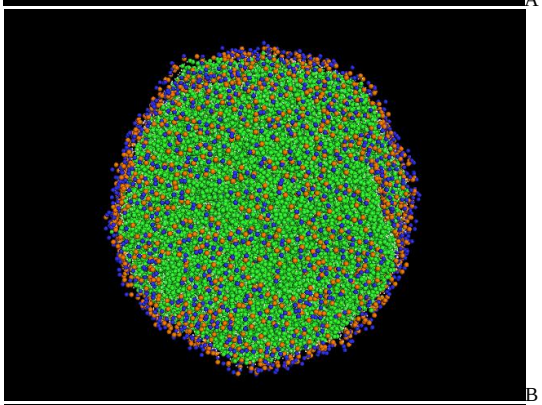
C. *Lipid vesicle*

The simulation results of a lipid vesicle are shown in Fig. 4. The radius of the lipid vesicle is set to 10 nm. The starting structure of the vesicle composed of lipids and waters does not change after energy minimization, as shown in Fig 4A. Through the whole MD run the vesicle shape stays more or less unchanged. The spherical membrane does not fall apart after 100 ns simulated time, as can be seen in Fig. 4C. Fig. 4D shows the density of lipid head molecules and the vesicle membrane thickness, which is 4.76 nm.



A



B

D

Fig 4: A) Starting structure of the lipid vesicle composed of 2963 DSPC lipids after energy minimization (t=0). B) After ~ 60 ns the vesicle structure is stable and does not change. C) Shows the final shape of the lipid vesicle after 100 ns. Water molecules are not shown for better visibility of lipid structures. D) Blue circles represent one-fourth of DSPC lipid vesicle. We see that the vesicle is not perfectly spherical. Shown are lipid head molecules (NC3 species) of DSPC lipid. Inner and outer monolayer can be seen at radius of 5 nm and 10 nm, respectively. The curves show the number density of NC3 lipid head molecules. The distance between two peaks represents the lipid bilayer thickness, which is approximately 4.76 nm.

D. *Summary and Future Work*

We confirmed, with the CG-MD simulation runs on multicore parallel computers, the stability of pre-formed structures, such as lipid bilayer membranes, ring membranes and vesicles from ensembles of a few tens to thousands of lipid molecules and tens of thousands of water molecules, simulated in a rectangular box for a time period of hundred nanoseconds. A typical computation time needed for such simulations on four hyper-threaded computing cluster cores is in the range of hours (6 to 10) to days (4 to 5). We can run multiple experiments in parallel, which could significantly speedup our simulations.

The future work will be concentrated in detailed analysis of simulated results, with a focus to evaluate and validate the results with already measured experimental values of density profile of constituent molecules and fluctuations of lipid bilayers, lipid headgroup sizes, etc. We finally plan to simulate the systems composed of proteins and lipid membranes in a water environment, to test the effects of chemical parameters on the protein binding.

IV. CONCLUSIONS

We have successfully simulated three different lipid structures, i.e., membrane, ring and vesicle all composed of DSPC lipids surrounded with water molecules in a rectangular simulation box. All our simulations were run with GROMACS software package using coarse grain molecular dynamics with MARTINI force field model. The above mentioned structures are our building blocks for future studies of mechanical and physical properties of lipid structures, interactions between proteins and lipid membranes, and effects of chemical parameters on their interactions.

dpecaric@ffzg.hr

Abstract - This paper analyses professional orientation and activities of scientists that were awarded with a doctoral degree in information science at the University of Zagreb. We will give an overview of master theses and doctoral dissertations according to periods and disciplines of information science. The overview of scientific engagement of information science doctors in scientific and educational institutions and their promotions during scientific career is only a formal indicator of their contribution to information science and educational system. Bibliometric analyses and methods are used in order to: a) research their scientific activities according to scientific areas and scientific productions (analyses are done on the data obtained from CROSBI); b) indentify and show basic areas of their interest by co-word analysis (the results were visualized by key word clusters). The results obtained by this research produce quantitative indicators about the scientific productivity of information science doctors, their position and role in scientific and educational institutions, and give an overview of their scientific interests. These results are a presupposition for the evaluation of current development of scientific community in information science, but are also the basis for the prediction of their future development.

I. INTRODUCTION

This paper studies professional orientation and scientific activities of information science doctors who completed their doctorate degree at the Faculty of Humanities and Social Sciences (FHSS) at the University of Zagreb. Studying former scientific activities of information science doctors can help to predict future progress and development for both the scientist and the entire field of information science.

Apart from the Faculty of Humanities and Social Sciences (FHSS), doctoral dissertation and master theses in Croatia can also be done at: the Faculty of Organization and Informatics in Varaždin and the University of Zadar. From 1966 to 2006, 727 master theses in information science were written in Croatia, while 170 doctoral dissertations were written from 1978 to 2009.

II. METHODOLOGY

The data about doctors of information science used in this research were obtained over the years in different researches, using different methods. Starting point was to obtained data about doctors that took their degree in information science at Croatian universities and to obtained bibliographic data from their doctoral dissertations (Đ. Pečarić, 2010). Then publications of information science doctors from CROSBI database (E. Bačić, et. al., 2009; L. Šćirek, et. al., 2009; and S. Bosanac, et. al., 2009) were obtained.

After the initial stage of collecting data about master of sciences (MS), the data about MS production, employment etc. were obtained by questionnaire (J. Bolkovac, et. al., 2010)

Bibliometric method co-word analyses were used to identify subject areas in information sciences and to compare these data to co-word analysis of scientific productivity of the members of information science department at the Faculty of Humanities and Social Sciences (FHSS).

III. BASIC DATA ABOUT MASTER THESIS AND DOCTORAL DISSERTATIONS AT FHSS

The Department of Information Sciences at the Faculty of Humanities and Social Sciences (FHSS) in Zagreb produced 98 masters of information science from 1994 to 2009[1] and 72 doctors of information science from 1991 to 2009[2].

Master theses done at FHSS have following distribution according to four different information science disciplines: 66 in librarianship, 18 in information science, 9 in museology, 5 in archivistics and documentation. Most master theses (84) were done in the period from 2000 to 2009. The remaining 14 master theses were done from 1994 to 1999.

Doctoral dissertations done at FHSS according to seven different information science disciplines have following distribution: 26 in information science, 24 in librarianship, 8 in archivistics and documentation, 6 in museology, 4 in communicology, 3 in information systems, 1 in lexicography. Most doctoral dissertations 74% (53) were done in the period from 2000 to 2009. The remaining 26% (19) of doctoral dissertations were done in the period from 1991 to 1999.

For 25% of information science doctors we could not find data about their master theses. One of the reasons for this is the reform of university postgraduate curriculum in

[1] J. Bolkovac, M. Piršljin, J. Turković (2010), p. 544.
[2] Đ. Pečarić (2011), 26.

which new PhD candidates do not have to complete (scientific) master degree in order to do their doctoral dissertation. According to CV of information science doctors, the largest number (63%) of information science doctors did their master thesis also in humanities and social sciences and 7% doctors did their master thesis in natural and technical sciences. Other scientific areas are represented to a lesser extent[3]. It is interesting to notice that 38% (21) of information science doctors who took their doctoral degree at FHSS, also took their master degree at FHSS.

IV. EMPLOYMENT OF MSS AND DOCTORS OF INFORMATION SCIENCES

The data about current employment of MSs and doctors of information science, as well as the employment of information science doctors at the moment of working on their doctoral dissertations were obtained from three different researches.

According to the data obtained by J. Bolkovac, J. Turković (2011), half of the MSs (50%) currently work in research and/or educational institutions, whereof 35% work at university departments. 23% of MSs work at libraries, archives, museums and documentation centers, and remaining 5% work at other types of institutions[4]. Distributions of scientific rank for 35% of MSs currently working at University departments are shown in Table 1.

TABLE I. SCIENTIFIC RANK OF MSS WORKING AT UNIVERSITY DEPARTMENTS

Scientific rank	No.	Percentage
Senior research fellow	1	4
Associate professor / associate research fellow	6	25
Assistant professor / assistant research fellow	7	29
Senior teaching assistant	3	13
Teaching assistant	6	25
Lecture	1	4

The same percentage as in MSs, 36% of information science doctors also worked at university departments at the moment of completing their doctoral dissertation. The remaining doctors of information science were employed: 14% in libraries, 7% in industry, and 5% in educational institutions and 3% in research institutions[5]. All 35% of PhD candidates working at university departments at the time they took their doctoral degree were junior research assistants or junior lecturers. Furthermore 16% of PhD candidates worked at FHSS at the Department of Information Sciences as junior research assistant at the time they completed doctoral studies.

As we mentioned before, at the moment of completing their doctoral dissertation, 35% of doctors worked at university departments. If we compare these data with present employment of information science doctors (J. Bolkovac, 2011), we can see that the size of scientific community i.e. the number of information science doctors that work in research and/or educational institutions increased over the years for 50%. So currently most (68%) of information science doctors work in research and/or educational institutions, whereof 57% work at university departments. This means that the largest number of information science doctors continue with scientific career after graduation and also participate in education and development of both young scientists and students. From 57% of doctors working at university departments, 22% work at The Department of Information Sciences at the Faculty of Humanities and Social Sciences in Zagreb.

The remaining (31) doctors of information science, 12% of information science doctors work at libraries, archives, museums and documentation centers, and remaining 5% work at other types of institutions[6]. Distribution of scientific rank for 57% of information science doctors working at University departments is shown in Table 2[7].

TABLE II. SCIENTIFIC RANK FOR DOCTORS OF INFORMATION SCIENCE WORKING AT UNIVERSITY DEPARTMENTS

Scientific rank	No.	Percentage
Full professor/Senior research fellow	8	14
Associate professor / associate research fellow	13	23
Assistant professor / assistant research fellow	16	28
Senior teaching assistant	14	25
Senior lecture	6	11

This distribution of scientific ranks is not surprising, since we know that 74% (54) of information science doctors did their doctoral dissertation recently, i.e. in the period from 2000 to 2009. It would be only natural to predict that the rank for the largest number of the information science doctors working at university departments will be: assistant professor/assistant research fellow or senior teaching assistant.

V. SCIENTIFIC ENGAGEMENT OF INFORMATION SCIENCE DOCTORS

A. Master of Sciences (MSs)

Examining scientific engagement of MSs we found that most of MSs 67.3% (66) continued publishing scientific work. Distribution of MSs scientific production is shown in Table 3.

According to the answers in questionnaires (J. Bolkovac, 2011), half of MSs 52.4% (22) continued with scientific work within the subject of their master theses,

[3] Data about employment for 27% of PhD candidates are not available. Other PhD candidates worked: 3% in archives, 3% in documentation centers and 3% in public administration. (Đ. Pečarić (2011), p. 52.)

[4] Data for 22% are not available.

[5] Đ. Pečarić (2011), p. 55.

[6] For 14% of doctors data are not available.

[7] J. Bolkovac, J. Turković, (2011).

13 MSs within their field but outside their master theses subject. 2 MSs dealt both within and outside the subject of their master theses. 1 MS continued both within and outside of the field, 1 MS outside the field and 4 MS selected the option other in this question.

TABLE III. SCIENTIFIC PRODUCTION OF MSS

No. of papers	MSs	%
0	2	5
1-10	13	33
11-20	9	23
21-50	12	31
51-100	1	3
more than 100	2	5

One third (33%) of MSs who participated in the questionnaire continued their education: 14 MSs hold PhD titles, 6 MSs are currently enrolled in a PhD program and 4 MSs are writing their doctoral theses outside of a PhD program. Some MSs (18% or13) did not answer this question. And 22% (16) MSs did not continue their education[8].

B. Doctors of information science

Until 2007 CROSBI database (E. Bačić, et. al., 2009, and L. Šćirek, et. al., 2009) registered 892 publications done by 52 doctors of information science that received their doctorate degree at FHSS. Since CROSBI database does not oblige scientists to enter all their publications, but only ones that were done as the result of scientific project financed by the Ministry of Science, Education and Sport of the Republic of Croatia, we assume that scientific production shown in this paper can be larger than recorded.

Examining the scientific engagement of information science doctors we found that the majority of information science doctors 77% (40) continued publishing scientific work. The percentage of doctors that continue scientific work can also be larger then recorded, not just because they are not included in the project financed by the Ministry of Science, Education and Sport of the Republic of Croatia, but also because some doctors work and live outside Croatia. Distribution of scientific production done by information science doctors is shown in Table 4.

The majority of these publications 59% are categorized as scientific publications, 18% as professional publications, 15% as other type of publications, and 8% are not categorized.

From registered 892 publications done by 52 doctors of information science, 72% of publications are from information science and 28% from other scientific disciplines. From 72% publications marked as information science, 15% of publications are "multidiscipline" work i.e. they are marked in CROSBI database in more than one discipline. Most of the disciplines in "multidiscipline" work are other social science disciplines like education, law, sociology, political science, etc. However, it can also be seen that the doctors of information science go beyond social science and produce papers from e.g. architecture, anthropology, archeology, biology, biotechnology, chemistry, history, physics, public health, dental health, etc.

TABLE IV. SCIENTIFIC PRODUCTION OF INFORMATION SCIENCE DOCTORS

No. of papers	No. of doctors	Percentage
1-9	12	23
10-19	9	17
20-29	6	12
30-29	6	12
40-49	4	8
50-59	2	4
Over 50	1	2
No data	12	23

Fig. 1 shows scientific production of information science doctors and age of their publications. The age of publication is presented in relationship to the dates of the publishing of the papers and their authors' graduation. For example, papers written 5 years after completing the doctoral study were marked as 5, while those written 5 years prior to the completion of doctoral study were marked as -5.

What we were interested to see is when, i.e. in what period, scientific production in doctor's scientific career is the largest. On Fig. 1 we can see, for the doctors who completed their studies from 2000 to 2007, that the time of the largest production for those young scientists, or researchers, was in the year of the completion of their doctoral dissertation. And for doctors who completed their studies from 1991 to 1999, or in other words, for scholars[9], the most productive period is around 10 years after the completion of study. Table 5 shows in more detail the overview of the scientific production of information science doctors. Distribution of scientific production is presented by the number of doctors who publish certain number of papers in particular year prior (years from -27 to -1) or after (years from 0 to 16) the completion of doctoral studies.

[8] J. Bolkovac, M. Piršljin, J. Turković, (2010) p. 546.

[9] Difference between researchers, scholars and predecessors is described in Đ. Pečarić, 2009.

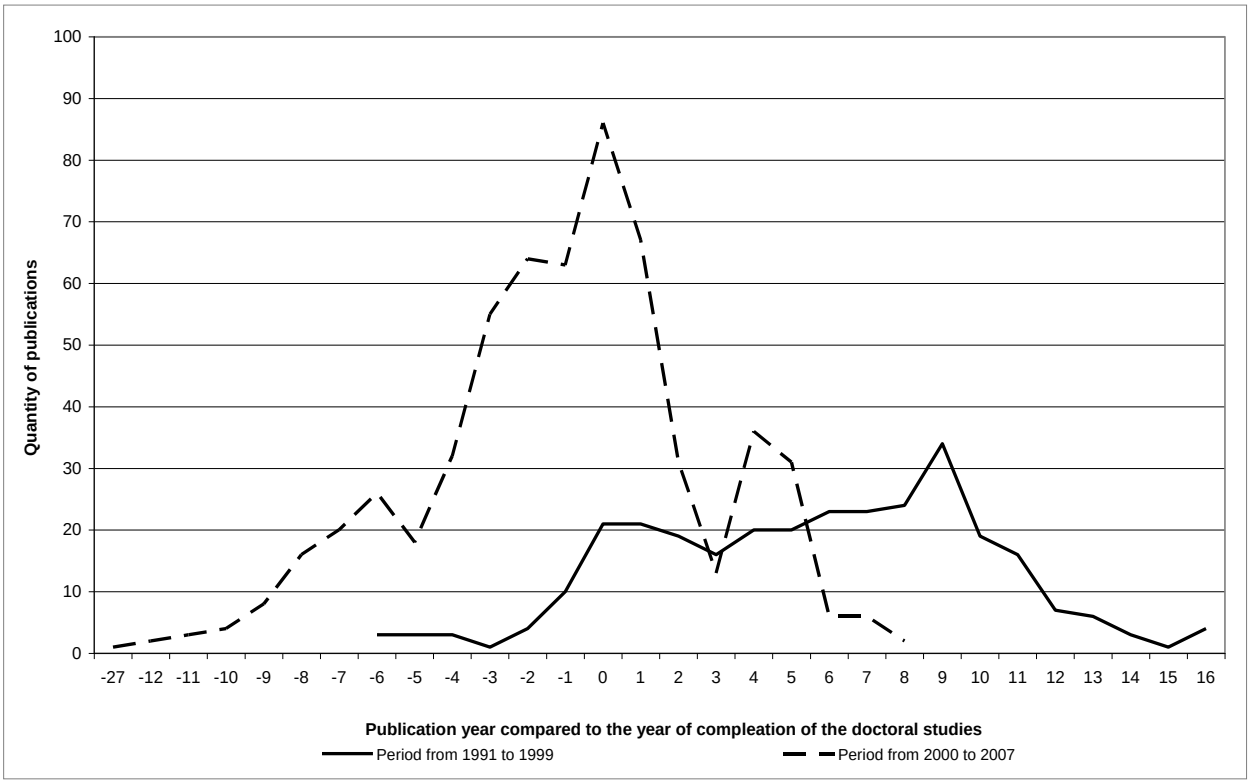

Figure 1. Overview of production of information science doctors at The Faculty of Humanities and Social Sciences according to time periods.

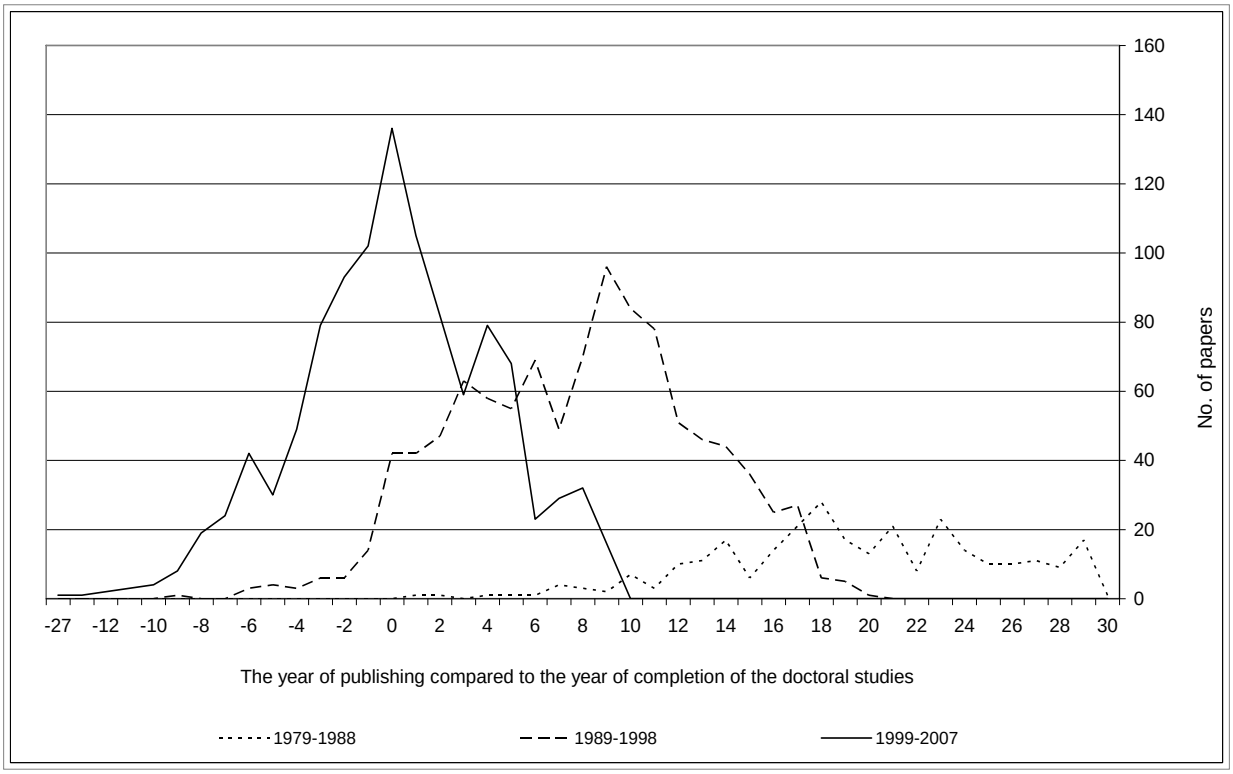

Figure 2. Doctorate candidates' production by period of completion doctorate studies (E. Bačić, et. al., 2009, p.731).

TABLE V. SCIENTIFIC PRODUCTION OF INFORMATION SCIENCE DOCTORS AT FHSS

Age	**No. of papers**												
	1	**2**	**3**	**4**	**5**	**6**	**7**	**8**	**9**	**10**	**11**	**12**	**15**
16				1									
15	1												
14	1	1											
13		1		1									
12	2				1								
11	1	2	3		1								
10	3	3		3									
9	2	1	1		1						2		
8	1	3	2			1	1						
7		2	5					1					
6	8	3	1	1		1							
5	4	3	2	1	1			1	2				
4	1	3	3	1	1	1			1				1
3	5	1	2	1	1	1							
2	6	5	3	2	2	1							
1	3	5	1	7	3	2	1		1				
0	8	7	7	2	2		1	1	2			1	
-1		2	2	2	2	2	1	1		1			
-2		3	2		2		2	3					
-3	7	3	2	1	1		1	1		1			
-4	3	4	3	1	1	1							
-5	6	3		1	1								
-6	7	4	3		1								
-7	3	1	5										
-8	2		1	1			1						
-9	3	1		1									
-10	2	1											
-11			1										
-12	2												
-27	1												

Comparing Fig. 1. with research of E. Bačić, et. al. (2007) which follows scientific production of all doctors of information science in Croatia (Fig. 2), we can notice that the most productive period for doctors that completed their studies from 1978 to 1988 is between 17 to 25 years. This group of scientists is named predecessors[10]. On Fig. 2 most productive period for other groups of scientists (researchers and scholars) remains the same as in Fig. 1.

Based on these data we can conclude that scientific production of information science doctors increases after the completion of doctoral studies, although certain oscillations exist.

VI. INTEREST OF INFORMATION SCIENCE DOCTORS

Basic areas of scientific interest of information science doctors are shown by co-word analysis of doctoral dissertations done at FHSS[11] (Đ. Pečarić, 2011) and publications done and registered at CROSBI database by members of information science department at FHSS[12] (S. Bosanac, et. al., 2007).

Fig. 3 shows knowledge map, or in other words, the "structure" of information sciences as it has been "produced" at the FHSS at the University of Zagreb by the doctoral dissertations analysis. Clusters were obtained from empirical data, i.e. based on the co-occurrence of pairs of words, extracted subject areas and their linkages. Several clusters can be recognized: *dominant cluster*, *information technology cluster*, and isolated clusters: *archives* and *museums*. In the dominant cluster we can recognize four thematic topics: libraries, e-learning, communication, information systems.

These clusters, or more precisely subject areas that are bound by those clusters, greatly correspond with organizational scheme of the Department of Information Sciences. The department consists of the following chairs: archivistics and documentation, librarianship, social-humanistic informatics, museology, knowledge organisation and lexicography. These subject areas greatly match the disciplines that can be studied at the Department of Information Sciences, FHSS: archival science study, library science study, museum study and information science study."[13]

As we see, already emphasized, the majority of doctors, 68%, who completed their degree at FHSS work in research and/or educational institutions, whereof 57% work at university departments. And furthermore, 22% work at the Department of Information Sciences at the Faculty of Humanities and Social Sciences in Zagreb. Since 1/3 of doctors work at the same department they took their degree, we think that Fig. 4 (Bosanac, et. al., 2007) is good example of trends of scientific interest of information science doctors, after completion of study. The possible objection to this conclusion is that it does not give complete analysis of production, in other words it does not give the overview of interest of the doctors who work in other institutions or in other countries.

Fig. 4 shows topics of interest of the members of the Department of Information Sciences at the FHSS[14] for the period from 1995 to 2009. The areas of interest of information science doctors are grouped in five clusters: *information literacy*, *education*, *museology*, *natural language processing*, *scientific communication*, and isolated cluster *web application*.

Cluster *information literacy* as a core cluster contains knowledge and library, which are public administration oriented concepts. Cluster *education* includes concepts related to networked society, which is a result of the impact of the Internet and information technology. Cluster *scientific communication* includes topics on scientific activities. Cluster *natural language processing* is related to natural language processing concepts and topics as the field of artificial intelligence. Cluster *museology*, includes topics related to users, museums and repositories. An isolated cluster which contains keywords computer-assisted language learning, web application and Croatian old dictionary portal can also be observed. This cluster is not related to any of the given clusters.[15]

[10] More about researchers, scholars and predecessors is written in Đ. Pečarić, 2009.

[11] In period from 1991 to 2009 at FHSS 72 doctoral dissertations in information science were done, from which 661 key words were investigated.

[12] "A total of 376 articles authored by 35 members of the Department of Information Sciences at the FHSS in Zagreb were harvested from the Croatian Scientific Bibliography (CROSBI) from 1995 to the present" (S. Bosanac, et. al., 2007, p.739)

[13] Đ. Pečarić (2011), p. 224.

[14] "A total of 689 unique keywords from 1136 tokens (keyword forms) were harvested out of 367 articles covering the 1995-2009 period" S. Bosanac, M. Matešić, N. Tolić (2009), p. 740.

[15] S. Bosanac, M. Matešić, N. Tolić (2009), p. 741.

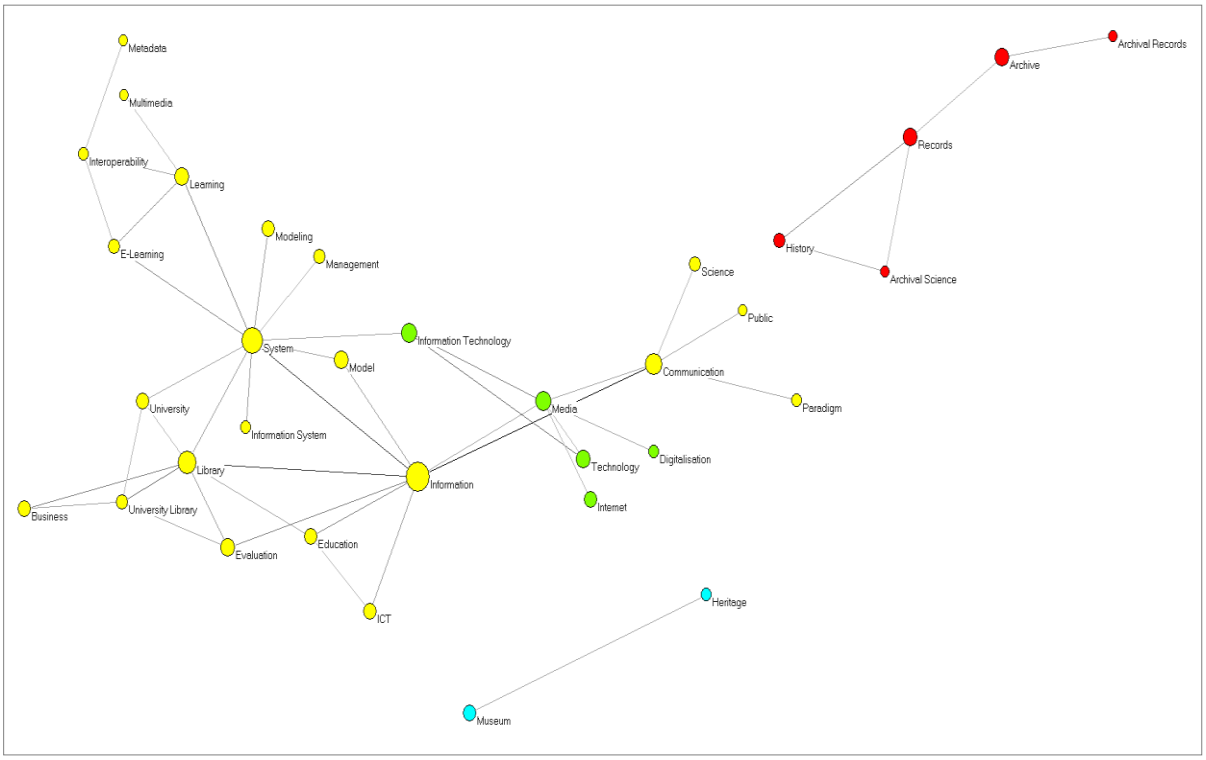

Figure 3. The Faculty of Humanities and Social Sciences: information science structure according co-word clusters (Đ. Pečarić, 2011, p.225)

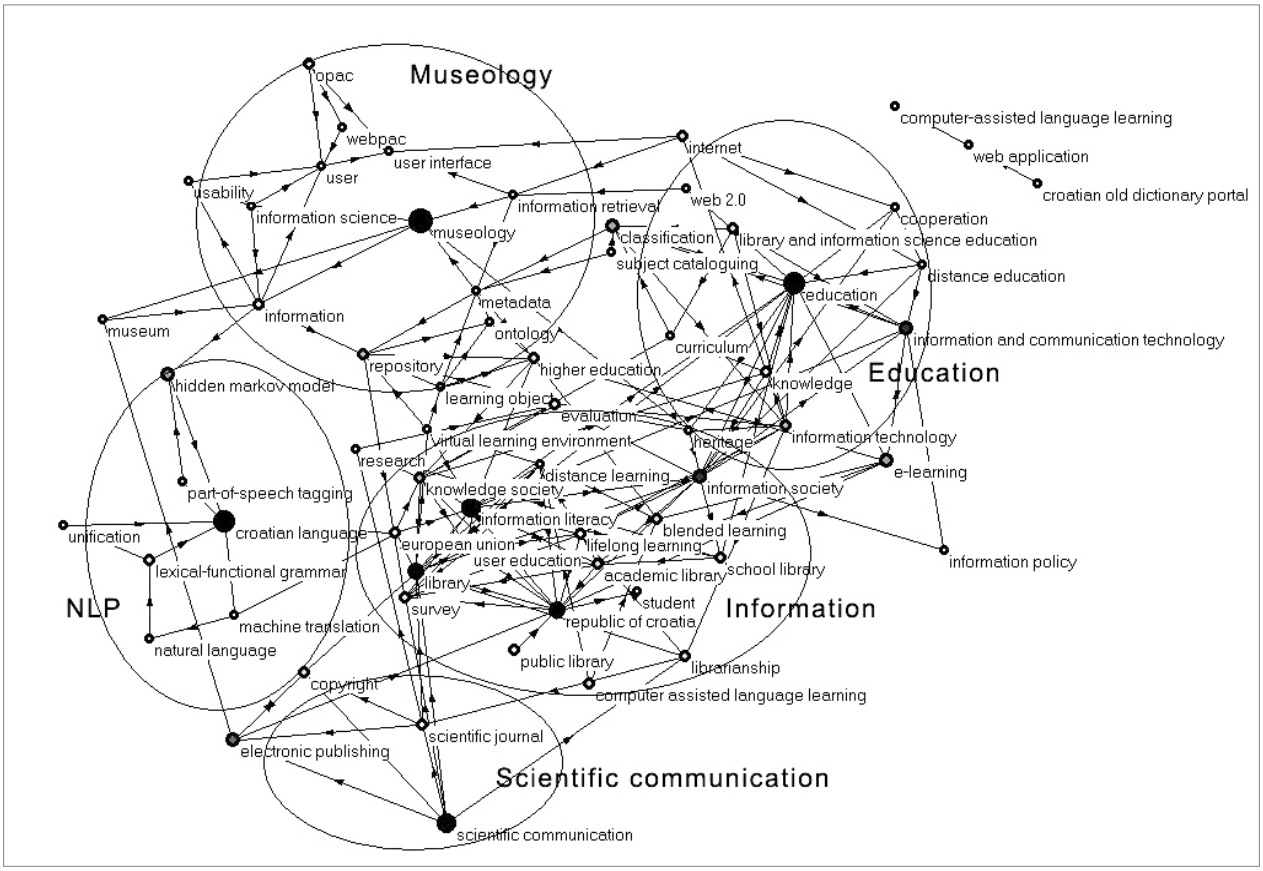

Figure 4. Co-Word Analysis of Keywords in Scientific Literature Produced at the Department of Information Sciences in Zagreb for the period from 1995 to 2009 (S. Bosanac, et. al., 2009, p.741)

Comparing Fig. 3 and Fig. 4 we can conclude that the data about research topics analyzed in doctoral dissertations at the FHSS overlap to a great extent with organizational schema and information studies offered at the FHSS: *information systems/technology, communication, libraries, archives, museums.* Observing the data about scientific production (367 papers) of the members of the Department of Information Sciences at the FHSS we can conclude that research interest expand to several new topics: *information literacy, education, natural language processing, scientific communication, web application*. However, basic topics still exist i.e. they are still recognizable, but not always as separate clusters.

VII. CONCLUSION

The aim of this paper is to analyze employment and scientific production of information science doctors that completed their doctorate degree at the Faculty of Humanities and Social Sciences at the University of Zagreb.

From overall number (98) of MSs, according to available data, 50% currently work in research and/or educational institutions, and 23% work at libraries, archives, museums and documentation centers. There are 35% of MSs who currently work at university departments.

From overall number (72) of information science doctors, according to the available data, 68% currently work in research and/or educational institutions, and 12% of information science doctors work at libraries, archives, museums and documentation centers; 57% of information science doctors currently work at university departments, whereof 1/3 work at the Department of Information Sciences at Faculty of Humanities and Social Sciences.

It is difficult to give precise estimation of the period of the largest productivity of information science doctors because the scope of this research covers two different educational systems. In the last decade Croatia reformed its educational system. Present educational system, contrary to the former educational system, is based on doctoral studies without prior completion of scientific master studies. Thus 25% of information science doctors completed this new educational system. It is our opinion that two different educational systems influence the time of the largest productivity of information science doctors. While the production of papers by the doctors from former educational system increases, the production by young doctors sharply decreases after the completion of doctoral studies. We assume that one of the reasons for the decrease in the production by young doctors is the insufficient time period for the observation of their productivity, as some of them completed their studies quite recently.

Scopes of scientific activity are observed by data comparison from two different researches. Comparing those researches we can conclude that the data about research topics analyzed in doctoral dissertations at the FHSS overlap to a great extent with organizational schema and information studies offered at the FHSS: *information systems/technology, communication, libraries, archives, museums.* Observing the data about scientific production (892 publications) of 52 information science doctors and (367 publications) of members of the Department of Information Sciences at the FHSS we can conclude that research interests are expanding to the fields outside information science. Also, inside information science research interests are expanding to the series of new topics: *information literacy, education, natural language processing, scientific communication, web application*. Basic topics still exist, they are still recognizable, but not always as separate clusters.

Auditory Display of Biomedical Signals through a Sonic Representation: ECG and EEG Sonification

V. Avbelj
Jožef Stefan Institute, Department of communication systems, Ljubljana, Slovenia
viktor.avbelj@ijs.si

Abstract - Visualization is a common way of data presentation in many fields where processing of visual information is further done by the human visual system. Signals from the heart (ECG) and from the brain (EEG) are normally presented as graphs and are also visually processed. Such signals can be transformed into sound (sonification) and then processed by the human auditory system. We made sonifications of ECG and EEG recordings to demonstrate the processing capabilities of the auditory system for these types of signals.

I. INTRODUCTION

An electrocardiogram (ECG) is a recording of electrical activity of the heart. In non-invasive measurements the electrodes are placed on the skin at several strategic locations. The result of the measurement is normally presented as a graph for visual inspection and analysis. With a standard 12-lead ECG, which is routinely used in medicine as diagnostic tool, the interpretation of its recordings are made automatically by the machine itself based on the knowledge accumulated in the last century. An ECG is used also for other purposes, namely for monitoring of patients during surgeries and in intensive care units, in implantable pacing and defibrillator devices, in long term ECG recorders for arrhythmia analysis etc. An electroencephalogram (EEG) is a recording of electrical activity of the brain. The electrodes are placed on the head at a number of places, even at up to several hundred of them. As with the ECG, the recording is presented as a graph of many traces for visual inspection and analysis.

Sonification is a procedure where a signal (or any other information), that is not a sound by its nature, is transformed into sound. As such, the analysis of the sound can be made by the human auditory system. ECG is the result of an electrical activation (depolarization, repolarization) of many hundred million heart cells working in highly synchronized manner. Could we hear this music [1]? On the other hand, EEG is the result of an orchestrated action of nearly 10^{11} neurons in the brain where an average frequency of neuron activity is 1.7 Hz [2].

The heart sounds are the result of mechanical movement of the heart, blood and tissues that can be heard by a stethoscope directly. Transformation of ECG and EEG signals into sound and listening (auditory display) gives a different insight into biological signals than graphical presentation [3].

II. SONIFICATION OF ECG AND EEG RECORDINGS

A. *Human sound processing capabilities*

The complexity of the auditory system is comparable to the complexity of the visual one. Although much is known about the sensory organ and the interconnections in the brain where the sound gets processed, it will be a challenge for future researchers to understand how this complex system analyzes and utilizes auditory information [4].

To demonstrate the capabilities of the human auditory system, we simultaneously played five songs performed by the same singer [3]. First the listener heard only one of the five songs and then he/she tried to track it in the mixture of all five songs being played together (Fig. 1).

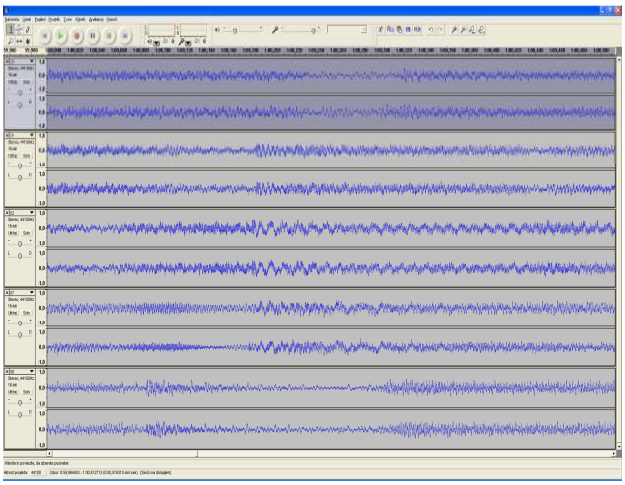

Figure 1. Short traces (0.5 s) of stereo recordings of five songs performed by the same singer. The task for the listener is to track the first song (darker) in the mixture of all five songs played together.

This task is not too hard for the human auditory system even though the signal to be tracked is deeply buried in the noise of other four songs. The question of sonification is how to use such sound processing capabilities for other tasks; namely for analyses of ECG and EEG recordings.

B. *Sonification of ECG*

It has been recently shown that the heartbeats of pregnant mother and unborn child are interconnected [5, 6]. They found a definite increase in synchronization epochs mostly at high maternal respiratory rates through the synchronization analysis of ECG recordings. Sonification of maternal and fetal ECG was made in the Fetal Heart Music Project of the Paracelsus Clinic [7]. The maternal heart rate was sonified as a cello and additionally as a piano. The fetal heart rate was sonified as a flute. The instantaneous heart rate was calculated for every consecutive heartbeat and given a musical note value, according to whether the rate is rising or falling. If the heart rate remained constant, the note was prolonged. A short example of the music produced is shown in Fig. 2.

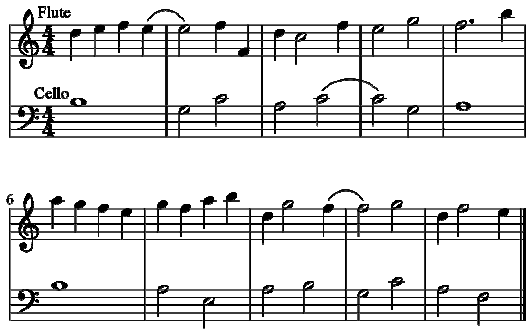

Figure 2. Ten measures of the composition, originating from the sonification of the maternal and the fetal ECG (After V. Avbelj [3], recording after M. Falkner [7]).

Another way of ECG sonification is achieved by fast playback of the original recording. We can examine 24-hour ECG recording in a few minutes. Yet another way of sonification is to pre-process an ECG, extracting characteristics such as the time interval between ECG waves or the amplitude of a particular wave (P, Q, R, S, T and U), or an ST-segment denivelation. Thus extracted features are then sonified.

C. *Sonification of EEG*

The frequencies of EEG signals measured on the head are well below human auditory perception. However, EEG signals are easily heard when speed up 20 times during reproduction. To show the performance of human auditory system, we sonified an EEG recording obtained during a routine EEG test (20 minutes). During the test, the patient opened and closed the eyes several times, respired deeply and rapidly (hyperventilation) and was exposed to flashing light with different frequencies (eyes closed).

An inspection of the EEG recording reveals only differences between times when the patient's eyes were opened and closed. When the eyes are closed, large alpha waves are present at frequency around 10 Hz (around 200 Hz during sound reproduction). We cannot see the periodic signal in EEG trace or in the spectrogram (Fig. 3) during flash light stimulation, but we can hear it, even though it is deeply buried in the noise.

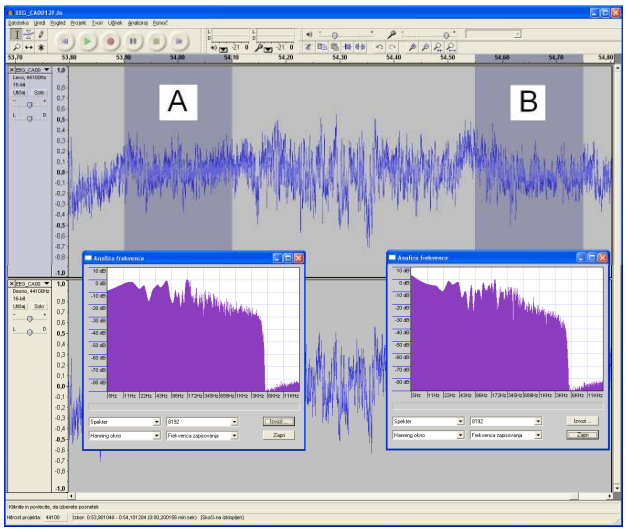

Figure 3. Twenty seconds of EEG signal from the electrode (O1) that was placed on the head above primary visual cortex during photo stimulation test. In the interval A (dark field), there was no photo stimulation, while in the interval B there was. Corresponding spectrograms are shown below the intervals A and B. Sonification is done by 20 times speed up (one second of audio signal is shown).

III. CONCLUSION

Processing capabilities of the human auditory system can be exploited for the analysis of biomedical signals. Fast overview of long ECG and EEG recordings is possible.

Video Driver Assistance System Using Optical Correlator

T. Harasthy[1], Ľ. Ovseník[2], and J. Turán[3]
[1,2,3] Technical University of Košice, Department of Electronics and Multimedia Communications, Košice, Slovakia
tomas.harasthy@tuke.sk[1], lubos.ovsenik@tuke.sk[2], and jan.turan@tuke.sk[3]

Abstract - Paper presents experiments and results of video driver assistance system using Optical Correlator (OC). In our system, the Cambridge Correlator was used. The traffic scene is captured by color camera and extracted frames are input for the Recognition System. The system consists of three main blocks, Preprocessing Optical Correlator and Traffic Sign Identification. First (preprocessing) block defines and chooses the Region of Interest (ROI) in captured frame. Preprocessed ROI (color filtered and resized) goes to Optical Correlator and then is compared with database of reference images (traffic signs). Those images are compared during correlation process in terms of two criteria, similarity and relative position. Output of correlation consists of highly localized intensities; know as correlation peaks (spots). The intensity of spots provides a measure of similarity and position of spots, how images are relatively aligned in the input scene. Several experiments have been done with this system. Results and conclusion are discussed.

I. INTRODUCTION

There are several possible options how to create new architecture of Traffic Sign Recognition System. Many video based object recognition systems to recognize traffic signs use shape detection and color segmentation [1,2,3]. Each of these systems has some specific requirements, but one of the most important is recognizing in real time. Video processing considers very high speed of processing.

There are many Traffic Sign Recognition Systems mostly based in Shape detection and Color segmentation such as Automatic Detection and Classification of Traffic Signs [4], Real Time Road Signs and Traffic Sign Recognition System [5]. Traffic Sign recognition is one of most important part of Drive Assistance System (DAS) [1,4,5]. DAS generally consists of more than one system. There are Park Assistance System, Active Park Assistance, Low Speed Safety and many other systems. In this paper is presented one of these subsystems, The Traffic Sign Recognition System. Goal of this paper is present Traffic Sign Recognition System, based on Optical Correlator, specifically Cambridge Correlator. This optical correlator use Optical Fourier Transform to make the Joint Power Spectrum and then optical correlation between input image and database of traffic signs. This system is tested on real traffic scenes captured from road of Slovakia. Traffic scenes were captured with ideal and low visibility.

In Chapter II the proposed system will be presented. There is shown block diagram of full designed Traffic Sign Recognition System (Fig. 1). In Chapter III the experiments and results will be presented. Experiments have been done with chosen traffic signs and results of recognition are recorded in Table I. Conclusions are covered in Chapter IV.

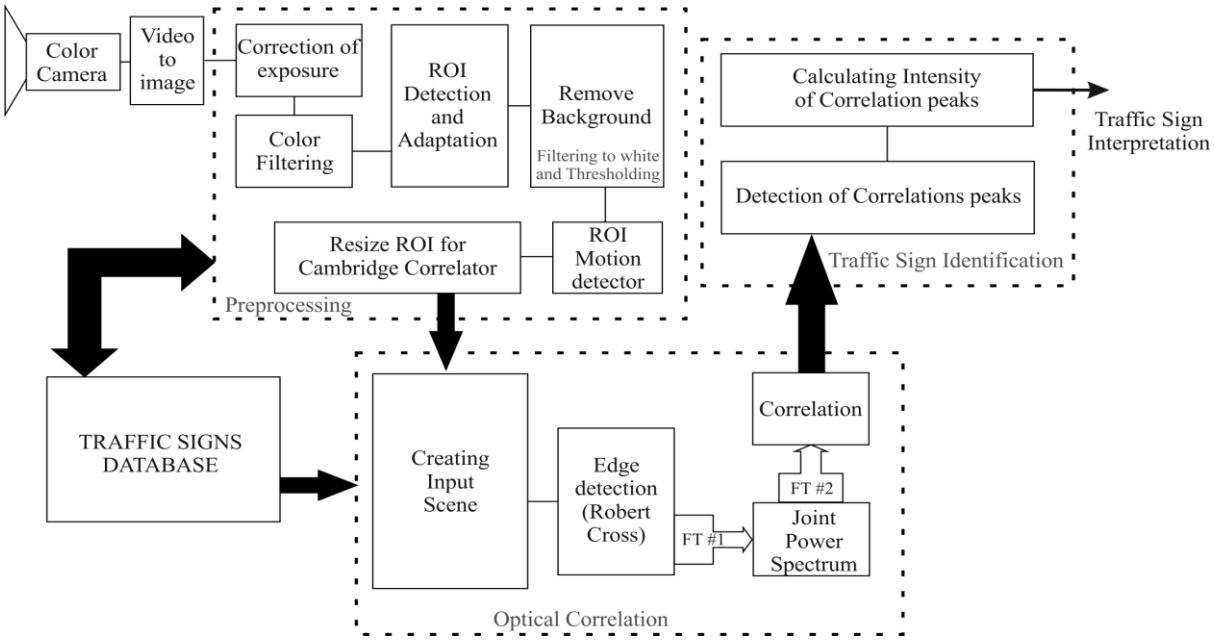

Figure 1. Block diagram of Traffic Sign Recognition System

II. System to Traffic Sign Recognition Using Optical Correlator

Nowadays Traffic Sign Recognition is very popular and more and more designers of cars use these systems in new cars. Traffic Sign Recognition helps keep car and crew safety. For this system fast process time is very important. In Fig. 1 is shown block diagram of proposed system to recognize Traffic Signs using Optical Correlator. Optical correlator is Cambridge correlator which uses Optical Fourier Transform to produce Joint Power Spectrum. This correlator is Joint Transform correlator (JTC).

System consists of three main blocks: Preprocessing, Optical Correlator and Traffic Signs Interpretation. Traffic scene is captured with the CMOS color camera. From traffic video stream the key frame is extracted and then used in next processing. As key frames from color video are referred only PCM coded reference frames from coded video sequence, which usually define also the starting point of any smooth transition in the scene. So key frames can be simply extracted from coded video and processed using PC. Next processing consists of converting key frame from RGB to HSV color space. First step of preprocessing is correction of exposure. In next step of preprocessing, the color filter is used. Color filters are designed to remove all irrelevant colors in input traffic scene (Fig. 2a,b)

Input image is in HSV color space. The color segmentation is processed. Every traffic sign has its dominant color. On the Slovak roads most often Yellow, Red and Blue color are used. This means we need to create three binary maps, one for each of these colors. By analyzing hue component (H), we can identify Blue, Yellow and Red regions in our processed image.

After color filtering, just relevant color is available. If the RED filter is used, bitmap looks such as Fig. 2b [3, 5].

Images after color filtering contains color clusters, which are irrelevant for detecting traffic signs. In next step, the irrelevant color clusters are deleted (Fig. 2c). After color filtering and irrelevant cluster removing, the potential Region of Interest (ROI) is extracted (Fig. 2d). Minimum and maximum size of ROI has to be defined to ignoring too big and too small objects. The potential ROI is defined at the input image. ROI crop input image to chosen traffic sign (Fig. 2d).

The ROI Motion Detector using moving vectors to discard moving features from traffic sign on moving object, i.e. vehicle. The background is removed from input image and then traffic sign without background is resized to correct size for input of Optical Correlation (Fig. 2e,f). Traffic Sign Identification Block assigns to obtained correlation peaks relevant Traffic Signs from database. Traffic signs are assigned based on the spatial coordinates obtained correlation peaks.

III. Experiments and Results

A. *Experiments*

In our experiments with designed system, we compared six types of traffic signs, “No passing zone”, “Bend to right”, “Double bend first to right”, “Truck no passing zone”, “Bend to left” and “Double bend first to left” showed in Fig. 3.

After preprocessing described above, information about color is irrelevant so after background remove we use edge detection to minimize energy of DC noise. Roberts Cross operators were used. Joint Power Spectrum obtain less information than JPS in begin of correlation process. Input scene of Cambridge Correlator is preprocessed using Robert Cross operator [1]. After this edge detection, just minimum of necessary information left. After Optical Fourier Transform of input scene we obtain JPS, which is then threshold (binary image).

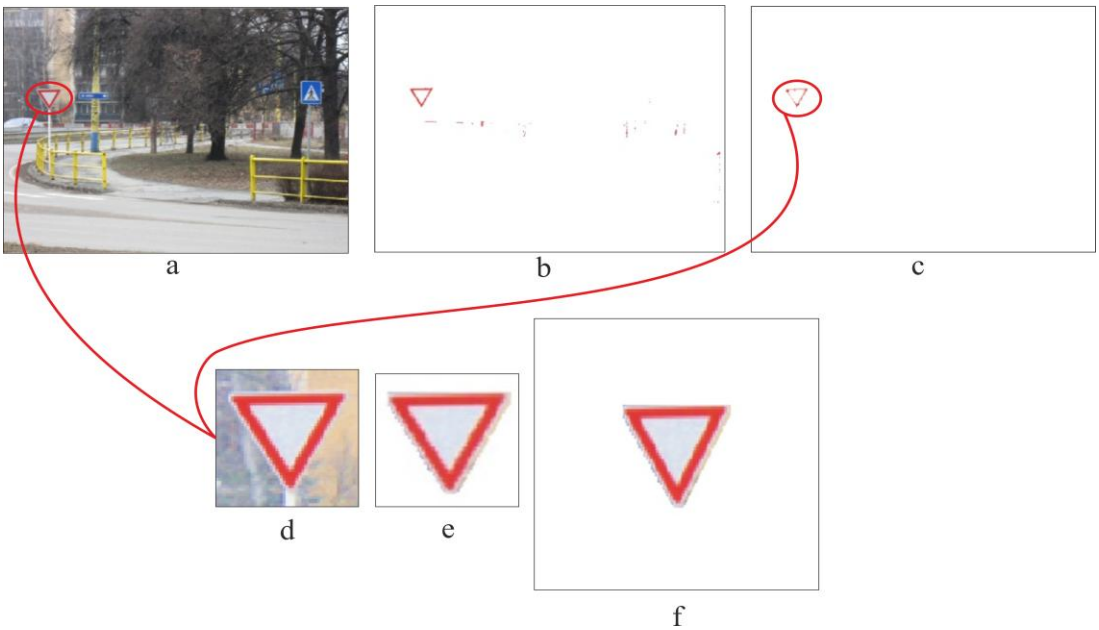

Figure 2. Block diagram of Traffic Sign Recognition System

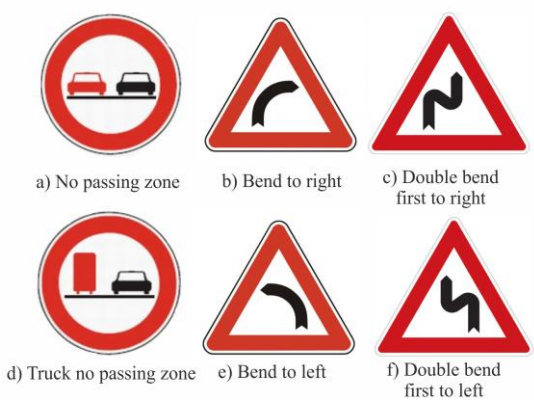

Figure 3. Traffic signs used in experiments

Preprocessed JPS is Optical Fourier Transformed again to obtain correlation peaks, shown in Fig. 4.

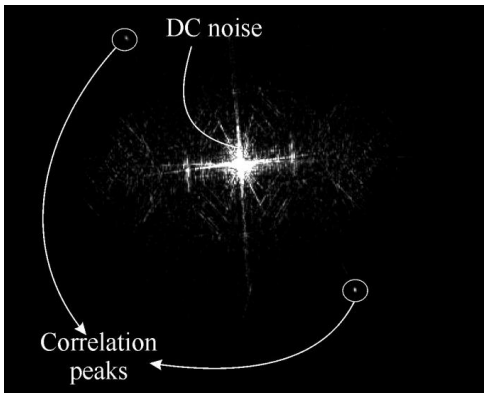

Figure 4. Optical Correlation with Joint Transform Correlator

Intensity of peaks obtained by correlation is represented in 8 bit depth grayscale, so every peak can take values from 0 to 255. Correlations peaks are situated relative how traffic signs are aligned in input scene. In these experiments we compare six types of traffic signs so six areas were monitored.

B. Results

Presented system was tested on real traffic scenes from road of Slovakia. Scenes were captured by color CMOS based camera and preprocessed with algorithm described in Chapter II.

Captured traffic signs entered to Optical Correlator and then were compared with reference signs shown in Fig. 3. Outputs of these correlations were correlations spots (Fig. 4) represented in 8 bit depth grayscale.

Traffic scenes were captured with ideal and low light conditions, mostly with fog.

Weak light conditions influence on detection and recognition part of system. On traffic scene captured with lower visibility were correctly recognized less traffic signs as it shown in TABLE I. In TABLE I are results of recognizing of all detected Traffic Signs. To testing of this system were used traffic scenes captured with ideal visibility and with low visibility.

TABLE I. RESULTS OF TRAFFIC SIGN RECOGNITION

Traffic Sign	Average Recognition Success [%]		
	Ideal visibility	Low visibility	Entire Recognition Success
No passing zone	93	85	89
Bend to right	94	86	90
Double bend first to right	91	86	88
Truck no passing zone	93	84	88
Bend to left	92	83	87
Double bend first to left	90	83	86

IV. CONCLUSIONS

In this paper the Traffic Signs Recognition system with Optical Correlator was presented. The Cambridge Correlator was used. Traffic scene was captured with color camera and then the key frame was extracted and preprocessed. In preprocessing part the red bitmap was extracted and ROI defined. In experiments, six types of Traffic Signs were tested. The preprocessing was concentrated to red, color. Correlation between Traffic Signs was determined using intensity value of correlation spots. In future we want to focus on preprocessing of input information and use preprocessed video as input for Optical Correlator. Another target is using this system to recognition all types of Traffic Signs. Also we want focus to implementation in hardware (FPGA) the image preprocessing algorithms, i.e. ROI extraction.

Integration of Skype client and performance analysts on television platform

D. Živkov, M. Davidović, M. Vidović, N. Žmukić and A. Anđelković
RT-RK LCC, Institute for Computer Based Systems, Novi Sad, Serbia
Dusan.Zivkov@rt-rk.com

Abstract - Focus of this paper is to analyze complexity of implementation Skype client on modern digital television platform. Considering popularity of Skype platform this is one of the features most user would prefer to have available on their TV sets. Main goal of this paper is to determine what impact Skype has on resources, which are very limited in television, and to designate if one average television platform meets the requirements. Additionally, this paper is demonstrating one way to implement Skype client in existing television software stack as independent module. Implemented features are covering chat, user management and voice calls. Complete concept has been successfully implemented, tested and measured on real platform used in commercial television set.

I. INTRODUCTION

Television is part of our home for very long period. Today it is hard to imagine modern home that doesn't possess at least one television set. For a long time television role in our life remained same, and main purpose was to deliver broadcasted video content to user. In last couple of years television made major change with transition from analogue to digital broadcasting. With digitalization new opportunities opened and TV started to expand its functionalities. New standards for digital television provided new features that enabled new services and applications to be available to users [1]. Beside new available content concept of television usage is changing, user is no more passive consumer of content and he is able to interact with TV. This is called Interactive TV and it is combination of broadcast video, broadcast radio, computing power and the Internet [2].

As result of this additional functionalities software component on television has become more complex and resource consuming. As result of this, hardware requirements has grown and forced manufactured to build televisions with advanced components. Nowadays major number of televisions is running with some operating system as software base. Linux is one of the most used solutions in this area. Such complex software environment on television provides flexible development of applications (music and video files playback, picture viewing, internet radio, browsing Internet) that were before only available on PC. With much more content and functionalities available on TV, it pretends to take over task that were previously reserved for PC in home.

This work was supported in part by the Ministry of Education and Science of the Republic of Serbia under the project No. III-44009, from year 2011.

Telecommunication technology has always been one of the most important aspects in modern society. Mobile telephony and PSTN (public-switched telephone network) are common telephony service provide for regular user, but, as Internet is becoming available to wider group of user, free Internet telephony services, known as VoIP (Voice over Internet Protocol) are becoming more popular. One of largest providers of this service is Skype. Main features that distinguish Skype form other services are: low cost calls to mobile and land lines worldwide, free voice and video calls between Skype users, SMS sending, chat etc. As Sripanidkulchai in [3] points out that lower costs of service is not only interesting thing about VoIP, also easier integration in other system is very important characteristic. According to studies performed in Taiwan low costs are important factor why active user are staying with Skype, while social influence is main reason for non-Skype users to start using this service [4]. Implementing Skype client on TV makes it more available to user and with that promoting idea of free communication. Performance test done by Lisha demonstrate that Skype voice service is good as other VoIP services (MSN) but main advantage is that it uses P2P-based communication which makes it easy to maintain and adapt to different network structures (NAT and firewall) [5].

Skype was not only selected because of its great popularity and wide range of functionalities, another important that stand in favor of Skype is excellent developer program that is available [6]. Although Skype client communication with his central Skype services is not public, as part of developer program, very well documented API are available that enable third party developer to use many Skype features. Support for many processor platforms (MIPS, ARM, x86) creates opportunity of development on large number of embedded devices. As part of developer program there is also certification program that poses as set of guidelines and rules that need to be address so Skype would make possible for your application/device to be used publicly. More about Skype programming environment will be explained in next section.

There have been numerous reports on videophone system development for home applications. Liao, Wang, Li, Zhu and Zhang in [7] explore a possibility to use multipath network interface proposing a scheme which preserves the packet arrival. Kastelan et al. proposes a separate box connected to a standard TV with VoIP communication in [8]. Pap et al. in [9] are investigating

possibility of using an audio beam forming with target to provide hands-free VoIP communication with remote speaker in embedded platforms for consumer electronic devices such as digital TV sets.

Target of this paper is to explore what are the consequents of Skype client software component on device with limited amount of resources like most CE (Consumer Electronic) devices, with digital TV set as case study platform. In the following section system environment and tools are described in detail. Section III focuses on organization of software and modules that needed to be implemented to archive desired functionality. In Section IV we present impact on system resources when different Skype functionalist such as chat, audio and video call, etc..

II. SYSTEM COMPONENTES

A. *SkypeKit*

SkypeKit represents set of tools that creates interface for applications to integrate Skype into the new environment (with emphases on embedded system). Skype Kit consists of these components:

- SkypeKit Runtime application
- Skype wrapper library for C++ (also Java and Python are available)
- Audio host component
- Video host component

SkypeKit runtime is pre-build application provided by Skype on request for specific platform and it's task is to perform communication with outside factors (Skype servers, other users), process that data and offers it to interested application using Skype API. There are 3 sets of API:

- UI(User Interface) related – handles chat, user search, authorization, user list
- Audio interface – split in two parts : PCM (Pulse-code modulation) and RTP (Real-time Transport Protocol) audio interface (in this implementation we used PCM audio)
- Video interface – based on RTP, but video component was not implement

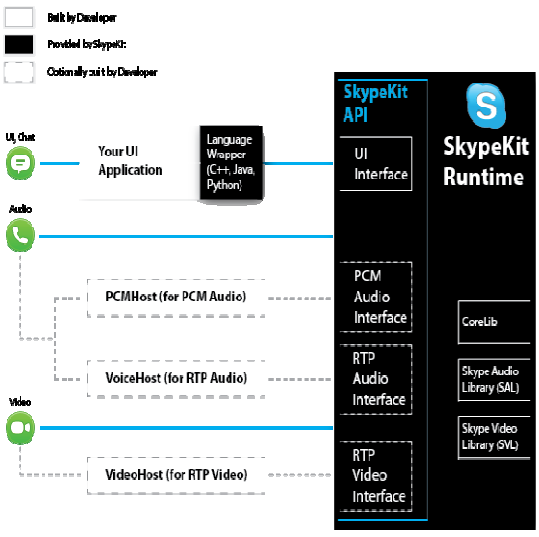

Figure 1. Structure of SkypeKit components [6]

On Figure 2. scheme is provided how the SkypeKit is structured and how components interact with each other. Similar model of multiple application integration was already proposed by Lin and presented model was used as a guideline for our implementation [10]. One more important thing in SkypeKit is keypars file. These are Base64-encoded X.509 certificates that enable your version of SkypeKit Runtime to communicate with Skype. There are two types of keypars: Development and Distribution. Development keys are used during development and expire after 60 days, distribution keypars doesn't expiry and it is meant to be used in final product when it passes Skype certification.

B. *TV platform*

Targeted platform was Broadcom 3556 SoC (System-on-a-Chip) Digital Television solution. This is next generation television platform and currently several commercial brands are using this platform to develop their devices. Beside support for major video formats (H.264, MPEG-2, Divx) and several TV broadcasting formats (DVB-T, DVB-C, DVB-S, Analogue) manly this platform is interesting because of networking capabilities. Used model uses dual-threaded little-endian MIPS working on 400 MHz and have 312 MB of RAM available.

Since original platform doesn't have ability to capture audio and video additional hardware need to be used. We used USB camera with integrated microphone array FreeTalk 7180 which is based on chipset Quanta QIC1802

C. *Television software*

Structure of typical TV software environment is depicted in Fig 2. It consists of operating system with a set of device drivers for particular hardware platform. On top of operating system there is a TV middleware with application environment for enriched user experience.

In this particular case a Linux operating system based on kernel version 2.6.18 is used. Original version of kernel shipped with platform doesn't have ALSA (Advanced Linux Sound Architecture) driver include in build since platform used proprietary drivers for sound playback. Because sound capture needs to go though ALSA drivers they need to be added to kernel.

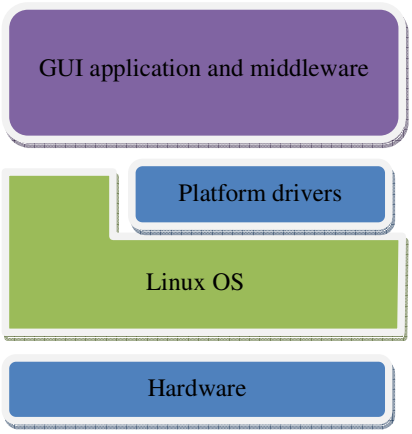

Figure 2. TV software organization

On top of Linux operating system set of propriety platform drivers is sitting. These drivers provide interfaces for management of hardware resources (tuner, audio and video decoders, storage devices, network etc.)

Top layer of software stack presents middleware with GUI (Graphical User Interface) application. Main processing and controlling logics is encapsulated in television middleware modules and this is where most work and modifications needed for implementation are located. GUI application purpose is to interact with user and present information to him. Some of main components are station list, EPG (Electronic program guides) dialog, media browser, settings.

III. IMPLEMENTATION

Implementation needed for this paper can be presented in these phases:

- Requesting SkypeKit runtime from our platform processor (little-endian MIPS).
- Compile SkypeKit C++ wrapper with platform tool-chain and test basic examples.
- Develop program module for communication with SkypeKit runtime over wrapper library.
- Develop module for audio data playback and capture
- Develop UI modules

Compiling SkypeKit wrapper library and testing it with runtime is straight forward work and very well documented process by Skype.

Critical work is concentrated in design and development of module responsible for communication with SkypeKit runtime. This module provides central point in application related to Skype logic. Idea in design was to create separate module to be completely independent from software organization of TV application. With this approach we are providing easier transition and integration if application environment changes. On Figure 3. is presented interactions between application modules.

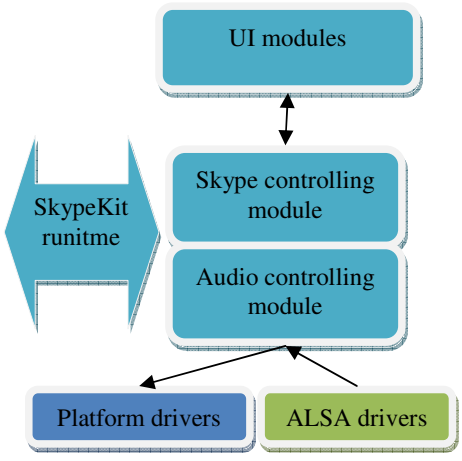

Figure 3. Software moduls comunication model

Methods of communication with module are separated in two groups:

- Get and Set functions – for setting and preferences, sending messages, requesting data etc.
- Listener-observer – this model us used for dispatching asynchronous events to all interested modules (incoming calls, messages, status changes)

Audio controlling module represents component whose responsibility is to control of audio data packet exchange between ALSA audio capture driver and SkypeKit runtime audio input buffers and between SkypeKit audio output buffers and platform audio decoder buffers. This module is active only during call. For receiving audio from Skype PCM API were used. Also audio captured from microphone array is from driver acquired in PCM format and in same format forwarded to SkypeKit runtime.

UI modules are covering largest amount of programming code and have purpose to interact with user and present data to him. These modules represent different dialogs displaying Skype data or state of Skype client. Functionalities that are covered with UI modules are user login, friend list, chatting, user authorization, friend search, call. Some of used dialog are on Figure 4. and Figure 5.

Figure 4. Search dialog

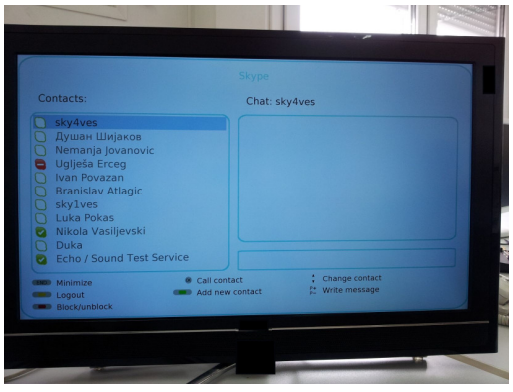

Figure 5. Friend list and chat dialog on TV

Every module requires reference to Skype controlling module and invoked needed function to perform desired tasks. Also modules are registering to messages that are of interested for them to be able to refresh on-screen information and keep user up-to-date.

IV. PREFORMANCE ANALYSIS

In this section we will present what impact did integration of Skype had on resources of device. Based on these results we can draw conclusion can our device successfully execute Skype. We measured processor and memory occupation.

Presented result in TABLE I. TABLE II. , TABLE III. were measured using *top* Linux command. Percentage of processor allocation for individual process is describing this per core, since we have two cores sum of them can excide 100%, and point of this data is to demonstrate how many resources is Skype runtime allocating in comparison with main TV application. Column *Total* is describing resources allocated on complete system (operating system, background process, application, Skype runtime ...) and from it we see that memory allocation is stable and that mainly consumed resources is process.

TABLE I. RESORUCE ALLOCATION WHEN SKYPE CHAT IS ACTIVE

Memory		***Processor***	
Application process 14.6 %	Total 27 %	Application process 10 %	Total 5.5%
Skype runtine 0%		Skype runtime 0%	

TABLE II. RESORUCE ALLOCATION DURING SKYPE CHAT

Memory		***Processor***	
Application process 14.8 %	Total 29%	Application process 40 %	Total 30%
Skype runtine 4.1%		Skype runtime 10 %	

TABLE III. RESORUCE ALLOCATION DURING SKYPE CALL

Memory		***Processor***	
Application process 15.4 %	Total 30%	Application process 90 %	Total 85%
Skype runtine 4.5%		Skype runtime 50%	

TABLE IV. RESORUCE ALLOCATION DURING SKYPE USER SEARCH

Memory		***Processor***	
Application process 13.2 %	Total 29 %	Application process 51.4 %	Total 42%
Skype runtine 3.8 %		Skype runtime 28.7%	

V. CONLUSION

Based on provided results we can conclude that this platform had provided enough resources to perform basic functionalities of Skype, also presented results can be used as referent point for estimate capabilities of other MIPS-base platform to support Skype. Important thing to notice here is that in presented implementation video call hasn't been implemented. Video call is most demanding feature of Skype and with this feature system would be driven to limitations of his abilities. Although video processing is considered very expensive (from resource point of view) one of the benefits with used platform is existence of dedicated hardware decoders that would perform video processing and take big load of main processor. Future development will be focused on two points: video call implementation and changing UI environment from proprietary framework to web-based MHP (Multimedia Home Platform) environment.

A Visualization and User Interface Framework for Heterogeneous Distributed Environments

Marko Mahnič, Danijel Skočaj
University of Ljubljana, Faculty of Computer and Information Science

***Abstract*—Systems that require complex computations are frequently implemented in a distributed manner. Such systems are often split into components where each component is employed to perform a specific type of processing. The components of a system may be implemented in different programming languages because some languages are more suited for expressing and solving certain kinds of problems. The user of the system must have a way to monitor the state of individual components and also to modify their execution parameters through a user interface while the system is running. The distributed execution and programming language diversity represent a problem for the development of graphic user interfaces.**

In this paper we describe a framework in which a server provides two types of services to the components of a distributed system. First it manages visualization objects provided by individual components and combines and displays those objects in various views. Second, it displays and executes graphic user interface objects defined at runtime by the components and communicates with the components when changes occur in the user interface or in the internal state of the components.

The framework was successfully used in a distributed robotic environment.

I. Introduction

Complex integrated systems often have to perform different complex tasks in parallel. For example, an intelligent cognitive robotic system has to be able to execute various tasks, which may heavily differ in complexity, requirements, and implementation of the corresponding solutions. Because of the complexity such a system is often implemented as a set of components that run in different threads across different processes running on different computers. Each component might be developed in a different programming language, either because the problem it solves is best expressed in that language or because of a developer's preference.

The operation of the system has to be monitored and controlled while the system is running. Often a graphic user interface (GUI) provides both the means to visualize the results and the inner state of the system and a set of actions that the user can execute to modify the behavior of a running system. It is very important for such a system to offer a user-friendly user interface that enables efficient interaction with the system. It is of equal importance to enable visualization of additional information about the execution of the system, at different levels of detail, which also enables efficient debugging and thorough analysis of such an integrated system. Due to the distributive and non-homogeneous nature of such a system, a centralized control and monitoring of the execution is a very challenging task.

In the research community the importance of development of efficient visualization tools and user interfaces is often under emphasized. Since the main focus of interest in research is targeted on the research work and problem solving, less attention is usually payed on the development of user interfaces (UI). This is even more true when the research involves multi-threaded or distributed systems in which a component and its UI run in distinct processes on separate computers. Quite often the component provides some kind of UI while it is being developed on its own but when the component runs with other components the UI is disabled because of incompatibility with the rest of the system. While such components could be controlled and monitored when developed and used in isolation, such an approach is completely inappropriate when the component is used as a part of a wider integrated system. It does not allow for display of information that the user would require, nor does it allow for efficient debugging of such a system.

In this paper we present our solution to this problem. We have developed a framework[1], that enables efficient visualization and UI management in heterogeneous distributed environments. The framework provides a server whose primary task is the management and rendering of objects that represent the information about the results or inner state of a running system at different levels of detail. The display objects are provided by different components and are combined by the server into views which are rendered in an arbitrary number of frames. The server displays UI elements such as tool buttons and dialog windows provided by the components and notifies the components when actions are performed on those elements, thus enabling the control of the components.

The paper is organized as follows. In the following section we define the problem and then present our solution in Section III as well as implementation details in Section IV. In Section V we describe the implementation of the proposed framework in a distributed robotic system. We conclude the paper with the final discussion and concluding remarks in Section VI.

II. Problem definition

As soon as the processing is distributed across multiple threads, the complexity of the user-interaction subsystem

[1]The source code is available at https://github.com/mmahnic/cogx-display-server.

raises. Even more so when the application is split into multiple processes running on multiple computers (*nodes*) possibly under different operating systems and using different programming languages for the development of components that constitute the system. In a highly configurable and scalable system the components can be configured to run all in a single process or each in a process dedicated to it. Running a component isolated in a process is desired when the component is being developed and tested. In a production environment, especially when the components share a lot of data it may be more efficient to execute many of them in a single process using multiple threads.

In a GUI application based on a standard framework like Qt, GTK or Java Swing, there is usually a dedicated thread that processes UI events. The developer has to be careful not to do too much processing in the event handling procedures, otherwise the UI code doesn't run often enough and the interface becomes unresponsive. Instead, working threads are created that process the data and pass the results back to the event processing thread for display or further processing. The resources for visualization are shared between multiple threads and the developer must pay a lot of attention to proper inter-thread protection mechanisms.

Standard frameworks like Qt or GTK allow only one event thread so loading two or more components that implement their own UI would create additional event threads and crash the application. For this reason the UI is usually implemented in a separate component, which is often part of the main application. This means that each component has to be developed in two parts: one part that does the actual work on a remote node and one that provides the UI for the component. The UI part can be either a source-level module for the main application or a *plugin* that can be loaded into the main application at runtime.

The two parts of the component may be developed in different languages. Because of this it is usually impossible to establish the communication between the parts using communication protocols provided by the framework like Java Remote Method Invocation (RMI). Instead, special protocols have to be developed or a more generic communication infrastructure has to be used.

By analyzing these problems we arrive at the following technical requirements that the visualization and user interface framework should fulfill:

- It should make the visualization of different information coming from different parts of a distributed system centralized and clear.
- It should reduce the amount of communication needed to transfer the visualization data to the server.
- It should reduce the problems of UI inter-thread communication.
- It should be scalable in the sense that new components and new servers can easily be added.
- It should allow simple extension of existing components to support such kind of visualization and UI.
- It should support the development of components in different programming languages.

We are not aware of any system that would fully meet these requirements and that would use a dedicated server for the management and execution of user interfaces defined by remote components at runtime. The technologies that are the closest to this idea are the X-Window System and Web Browsers. In X-Window System a client application can be configured to export it's display to a different machine. This requires that a component is implemented as a GUI application which is most often not desired. Web browsers display user interfaces that are generated by remote servers. Until recently only simple interfaces could be created but with the emergence of HTML 5 and WebGL [1] this will improve. For security reasons a Web browser page can only receive data from a single server so it can't communicate with each component separately. Instead an additional intermediate server is required to integrate data provided by multiple components.

In the development of robotic systems the Robot Operating System (ROS) [2] is becoming widespread. It supports two types of visualization. The first type is the off-line visualization of the messages of various types that were sent between individual components and were stored in a log file. The second is the on-line 3D interactive visualization of the systems state. The client interfaces exist in C++ and Python.

Other applications that are more task specific, such as Peekabot [3], are also used for 3D visualization, however they are not as general as the framework presented in this paper and they do not address all the requirements listed above. Having these requirements in mind, we have designed the system that is described in the following section.

III. A Distributed System

As shown in Figure 1 the system has a central display server that communicates with multiple local and remote client processes. In every client process a set

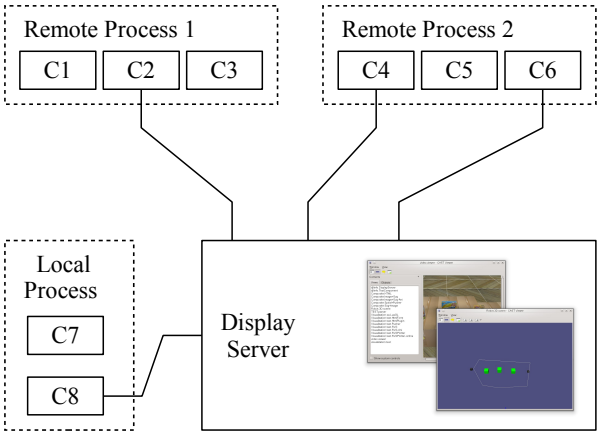

Fig. 1. Components running in multiple local and remote processes send objects to the display server and receive events from the UI elements.

of components is running each in its own thread. The mapping between processes and components is arbitrary although the components that process similar data are often instantiated in the same process.

The components generate and process data. The data may represent the end result of the processing or serve as input for other components. One could imagine that several types of data could be considered. Because of the variety of data and its interpretation, the display server doesn't try to visualize raw data. Instead, the client components transform the raw data into display objects (raster images, SVG images, 3D models, HTML documents) and send them to the server. The server keeps the objects until they are replaced or deleted and combines them into user-defined views. The display server creates windows on demand and offers a quick way to switch between different views in every window.

The components that support user interaction prepare the UI elements and send them to the display server which stores them and displays them when necessary. Simple UI elements are associated with views and are displayed in a dynamic toolbar of a window whenever an associated view is displayed in the window. Dialog forms are usually more complex so they are displayed in special dialog windows. Each dialog form is displayed on a separate page of a tabbed control.

HTML documents can also be used for user interaction if they contain specially prepared elements. In this case the display server injects additional code into the document that generates events for the client component when an active element is clicked or sends the values of the fields of a form to the component when the form is submitted.

IV. Implementation Details

A. The Overall Structure

The display server is internally split into three loosely coupled components: the public Ice interface, the model and the GUI. The significant components of a client and a server are shown in Figure 2.

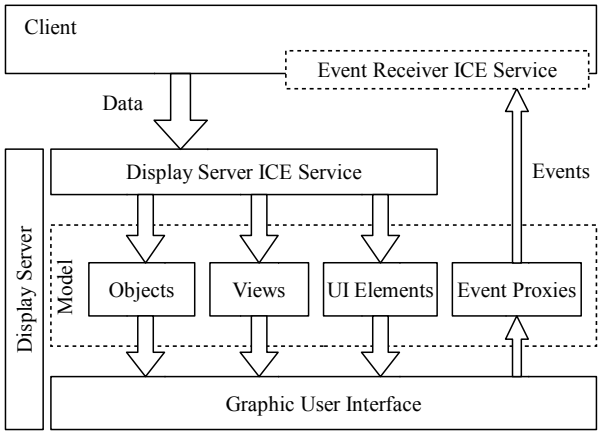

Fig. 2. The architecture of the framework

The public interface provides a proxy through which the clients can send requests for adding and modifying display objects, views and UI elements that are managed by the server. Each connection from a client runs in a new thread, but the threads are protected from each other by the use of locking mechanisms.

The objects are stored in various containers in the model of the display server. The model implements only the storage for the objects and is not aware of the types of objects it stores. This makes the model independent of the framework chosen for the implementation of the GUI.

The GUI is implemented with the Qt framework [4]. The framework was chosen because it is one of the most widespread open source C++ frameworks supported on multiple platforms. It offers excellent support for visualization of data in 2 and 3 dimensions and it embeds WebKit [5], one of the most advanced web browser engines. The communication between the Qt UI elements (widgets) is based on signals that are emitted when various events occur. The signals integrate easily with other non-UI elements and they were used to implement the event proxies in our framework.

The development environment of the Qt framework provides also and excellent form designer. The designed forms are stored as XML documents that can be compiled into native code of an application or loaded into a running application and instantiated without compiling. On top of all a scripting engine is integrated into the framework with which it is possible to create and execute code on the fly.

B. The Communication Interfaces

The distributed system is built on top of the Zero C's Internet Communications Engine (Ice) [6], [7] which provides the infrastructure for communication between the components of the system. The communication is based on remote method invocation (RMI). The communication interfaces (structures, classes and service interfaces) are defined in Specification Language for Ice (Slice). Slice compilers generate communication interfaces for many programming languages and the generated code is easily integrated into the components.

The display server Ice service provides only one-way communication so the clients can only send the data to the server. The clients that want to handle events emitted by the UI elements they create, have to instantiate an Event Receiver Ice service and register it with the server. Once the connection is established the server starts notifying the client about the UI events.

C. Views

A view is an entity that holds a list of visualization objects to be displayed in a window of the graphic user interface. It is associated with one of the rendering context types: 2D scenes, 3D scenes and HTML documents.

A view is hidden until the user selects it for display in a window. At that point a rendering context is created for the view. When the objects of a view are rendered, each object is asked to provide a renderer for the view's

rendering context. If an object can't provide a renderer, it is skipped.

When a view is being displayed, individual objects and/or their parts can be hidden by the user. The information about the visibility is stored with the view since an object can be displayed in multiple views and keeping visibility information with the object would hide that object in all views. A view is also associated with a list of simple UI elements defined by the clients. The UI elements are added to a dynamic toolbar when the view is shown in a window and removed when the view is hidden. Currently only tool buttons are supported.

D. The User Interface Elements

When a component has complex settings that require more than simple tool buttons, forms can be used. The framework takes advantage of the Qt XML format that is used to describe the user interfaces and of the scripting engine.

The component that needs a form-based interaction with the user sends two documents to the display server. The first is the XML document with the design of the form and the second is the JavaScript code that represents the logic of the form. The display server instantiates the form and waits for the user to interact with it.

The communication between the component and the form is implemented in the following manner. Whenever a value has to be passed from the form to the component the function provided by the display server that accepts an ID and an object is called from JavaScript. This function transforms the object into JavaScript Object Notation (JSON) [8] and sends it to the client as an event with the ID and the data. The component can set the values of the form if it sends JavaScript code to the display server. The code is executed in the scripting engine that belongs to the form and executes its logic.

E. Visualization Objects

The display server supports the following basic types of objects: raw and encoded raster images, SVG images, HTML documents and Lua OpenGL scripts. All objects except raster images can be composed of multiple parts which can be manipulated individually by the client. This greatly reduces the amount of data that has to be transferred from a client to the display server.

1) 2D Objects: Raster images are transfered from a client to the server as arrays of bytes. Images may be in any format supported by the Qt library. When the server receives a raster image it converts it to an uncompressed RGB image which is suitable for fast rendering.

SVG images were added to the system as a way to overlay annotations on raster images. For this reason the display server renders only self-contained SVG documents that don't reference any external resources like raster images. To add annotations to an image the client creates an SVG document with the annotations and defines a view that includes both the raster image and the SVG document.

2) HTML Objects: HTML objects are composed of multiple chunks that belong either to the head or to the body of the document. The chunks are merged into a full HTML document every time any of the chunks is updated, but only if the document is being displayed in a window and the auto-refresh option is enabled in the GUI.

HTML chunks can contain active elements such as forms or (active) HTML tags that notify a display client on `onClick` events. When such chunks are rendered into the full document additional JavaScript and HTML code is added to the document. This code generates events for the display client when an active element is clicked or a form is submitted.

3) 3D Objects: To keep the Ice interface simple we use the Lua programming language [9] with the LuaGL extension [10] to represent objects in our visualization of 3D scenes. Lua is a scripting language that is used in a wide range of industrial applications and in particular it is a leading language in game development. It is simple, fast and easily embeddable into applications. It's written in strict ANSI C so it is quite easy to write extensions in C/C++. The LuaGL extension maps OpenGL C functions and constants to Lua. With this it is possible to define 3D objects and entire scenes by calling OpenGL functions from Lua scripts.

3D objects are composed of multiple parts and every part is a Lua script. The scripts are created by the clients and sent to the display server. A LuaGL object is rendered into a 3D context by executing the scripts of all its parts.

In a complex 3D scene it is sometimes difficult to find a view that shows it in a way that gives the most information to the user. For this purpose a display client can define positions and orientations of the camera from which the objects it creates are best visible. These camera positions show up in the display server GUI as tool buttons and the user can easily switch between different views of the scene.

V. Implementation in a Robotic Environment

A. Description of the Environment

The cognitive robot that we have developed as a part of the CogX project [11] is a mobile platform that uses various sensors such as range lasers, odometers, video cameras and microphones. The cameras are mounted on a pan-tilt unit (PTU) and a robotic arm is mounted on the robot base. The robot is used in different scenarios employing a different set of sensors and performing different operations in each task. Because of the diversity and complexity of the tasks the system was designed to work as a set of components distributed over a network of computers (*nodes*).

The system is based on the CoSy Architecture Schema Toolkit (CAST) [12] that provides the environment in which the components can communicate with each other. The communication is based on a set of working memories (WM) that also serve as the containers of entries that represent the robot's state and knowledge. The system doesn't have a central server. Instead a set of CAST

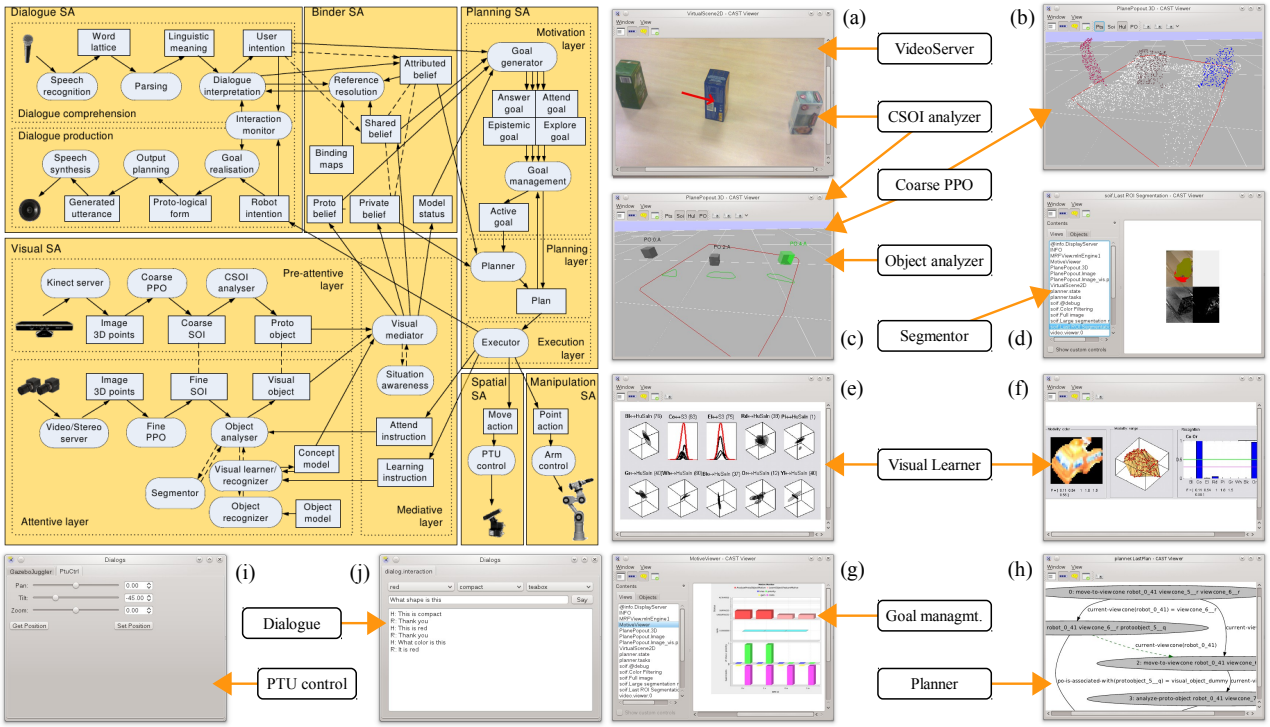

Fig. 3. The components of a cognitive robotic system. The large area on the top left represents the components, the connections between them and the data they produce. On the right and on the bottom are the windows of the display server showing different views, objects and dialogs created by the components.

servers is started on every node, one for each supported programming language: C++, Java and Python. To load the components into the servers a CAST client is used that reads a configuration file with the descriptions of the components and sends to every CAST server information about which components to load and what configuration parameters to pass to them.

B. *Visualization of the System's State*

The components of a cognitive robotic system that learns in interaction with a tutor about the properties of objects [13] are displayed in the top left part of Figure 3. The components generate various visualization views which are also displayed in the figure. Before the display server was introduced every component managed its own interface. Components that had a GUI interface created a number windows on multiple computers. Components used a logging system or even terminal output to display meaningful information about their state. This way the information about the system's state was spread across multiple graphic or terminal windows on different computers. Furthermore the components were not able to cooperate in the generation of complex views.

The centralized visualization server we have developed significantly alleviated the problems mentioned above and solved the visualization problems in a systematic way. In the following we describe the visualization interface that we introduced into the system and show a few example views that are displayed during the execution of the system. A very brief description of some of the processes is also given to better illustrate the type and diversity of the data that is being displayed. A detailed description of the system and individual components is omitted, since it is beyond the scope of this paper.

In Fig. 3-a we see an example of cooperation of two components. The Video Server generates images that are displayed in a 2D view and are annotated with an SVG line provided by CSOI analyzer that shows the direction of the next camera move. In Figures 3(b-c) the same view is displayed but with different objects enabled with the tool buttons of the dynamic toolbar. The view is built with the cooperation of three components. The Coarse PPO displays the 3D point cloud (Fig. 3-b), the detected principal plane (red line) and the spaces of interest (SOIs) which are potentially the objects that the robot learns about. The components CSOI Analyzer and Object Analyzer process the SOIs and create new entities that represent stable SOIs and recognized objects. The objects from all three components are displayed in a 3D view shown in Fig. 3-c.

The Visual Learner is the component that has the knowledge about object properties. Its input are segmented images which are provided by the Segmentor component. Segmentor extracts an area which represents the object from a video image using the information stored in a SOI. The result of the segmentation is displayed in a 2D view shown in Fig. 3-d. On the left side of the window in Fig. 3-d a list box with a list of available views is shown. Typically a running system creates more than 40 different views and the list box enables the user

to quickly switch between the views.

The models that the Visual Learner is using for the recognition and represent the knowledge are shown in Fig. 3-e. After a successful recognition an image with the recognition results is created which is shown in Fig. 3-f. The Visual Learner is written in Matlab and doesn't communicate directly with the display server. Instead it writes the figures and the HTML documents to the disk where they are picked up by the File Monitor component (not shown) which sends them to the display server every time they are changed. With the use of the File Monitor any application that can write a file can be integrated with the framework with only minor modifications.

Fig. 3-g shows a 2D view with an SVG document that displays the settings of the motivation subsystem and the status of the goals that the robot may achieve. A surfaced goal is passed to the Planner that creates a plan with a set of actions that lead to the achievement of the goal. An example of a graph for a plan is shown in Fig. 3-h. The displayed plan is an SVG document generated by Graphviz [14] which is called by the File Monitor every time the Planner writes a file with a textual description of the graph.

Two dialog forms are shown in Figures 3(i-j). In Fig. 3-i a form created by the PTU control enables the user to manipulate the pan-tilt unit manually. In Fig. 3-j a form created by a component from the Dialog SA provides a way to interact with the robot by typing and is used when speech recognition is not reliable.

Additionally the server manages various HTML documents that are generated by different components. One kind of document is a table of WM entries of a certain type that is created by a WM Viewer and is composed of WM entries serialized into HTML chunks that represent table rows. One document is created for each type of WM entry that the user wants to monitor. The Component Status document holds information about the states of the components that provide the chunks for the document. The Visual Learner component uses an HTML document with buttons and loads a different database when a button is pressed. Each component can generate an arbitrary number of additional HTML documents. This way the user can monitor the state of individual components as well as of the entire system all the time, at any level of detail.

VI. Conclusion

In this paper we addressed the problem of visualization and user interface in heterogeneous distributed environments. It is important for such a system to offer a user-friendly user interface that enables efficient presentation of results and interaction with the system, as well as visualization of additional information about the execution of the system, at different levels of detail, which also enables efficient debugging and thorough analysis of such an integrated system. In this work we analyzed the requirements of a visualization and user interface framework, presented the designed solution that fulfills these requirements and described the implementation details. The framework provides a server whose primary task is the management and rendering of objects that represent the information, which is supposed to be visualized to the user. The display objects are provided by different components and are combined by the server into views which are rendered in an arbitrary number of frames. The server also displays UI elements such as tool buttons and dialog windows that enable the user to control the components.

We showed how the proposed framework was used in the case of an integrated cognitive system. It proved to be very useful for the development and use of this system. The centralized visualization server enables more efficient and focused monitoring of the execution of the system, which significantly helped to solve problems on the system level, as well as to debug the individual components while working in the integrated system. In this way, the visualization and user interface server facilitated integration work and helped to increase the robustness of the system, as well as significantly improved the user experience for the final user of the system.

Since the design and implementation of the proposed framework are very general, the presented solution can be applied to a variety of problems that are modeled with heterogeneous distributed systems. It is relatively easy to integrate it with any application that is able to communicate through the Ice system. And if that isn't possible the File Monitor component can be used for visualization of data produced by the application using file-based communication.

VII. Acknowledgment

Abstract - Image segmentation can be computationally demanding, and therefore require powerful hardware in order to meet performance requirements. Recent rapid increase in the performance of graphic processing unit (GPU) hardware, coupled with simplified programming methods, have made GPU an efficient coprocessor for executing variety of highly parallel applications. This paper presents an implementation of k-means image segmentation on the GPU platform with Compute Unified Device Architecture (CUDA). Parallel k-means segmentation is realized in hybrid manner i.e. proposed approach distributes computation load between Central Processing Unit (CPU) and GPU. The emphasis is placed on adaptation of the core algorithm to efficiently process datasets characteristic for image segmentation while exploiting benefits of underlying GPU hardware architecture. Numerical experiments have demonstrated considerably faster segmentation execution with proposed approach comparing to classical CPU-based approach.

I. INTRODUCTION

Image processing systems can have very challenging performance requirements, either for processing massive amount of data in reasonable time or for performing in near real-time. Image segmentation is an important part of many image processing and computer vision applications. The aim of the segmentation process is to assign a label to every pixel in an image such that pixels with the same label share certain visual characteristics. Therefore, it can be used to partition an image into separate regions, which ideally correspond to different real-world objects. Consequently, image segmentation is a critical step towards content analysis and image understanding [11]. In general, image segmentation approaches can be divided into two main categories: region-based and boundary-based techniques [12]. By their nature, the image segmentation operations are also computationally demanding and therefore require a powerful hardware in order to meet desired processing speed.

Clustering is a process of grouping data points into disjointed clusters so that the data in each cluster are similar, yet different from the other clusters. K-means clustering is one of the simplest unsupervised learning algorithms for data clustering [7]. This algorithm can be applied to the image segmentation, where each cluster should represent an object in the picture. Clustered data points representing pixel position on the image are consisted from several components called features. Each feature can represent property like color, intensity, position or filter output. Cluster is formed depending on the similarity between feature points. K-means segmentation has the advantage of fast convergence and simple implementation, but it is not well suited for the application on complex images [7].

For many years, applications could simply rely on system performance improvements from advances in semiconductor manufacturing and single-thread architecture. Because of the power and the thermal limitations, industry switched to the more energy efficient design of multicore architectures [9].

Recently, graphics processing units (GPUs) have emerged as coprocessing units for central processing units (CPUs) to accelerate various numerical and signal processing applications [8]. GPUs may consist of hundreds of highly decoupled processing cores capable of achieving immense parallel computing performance. It must be emphasized that a critical implication of this architecture change to applications is that they must be parallelized to take advantage of multicore architectures. The best sequential algorithm may not be the best algorithm on multicore processors [9].

So far, many improvements in the performance of k-means algorithm have been proposed, but the majority is based on Single Instruction Single Data (SISD) processors (CPUs) which partly ignore parallel characteristic of the algorithm. To obtain competitive system performance, the CPU and the GPU need to be considered together for performing particular task. Investigating the optimal partition of computation tasks between the CPU and the GPU, however, could be very involved, and it requires serious evaluation on many issues [8]. In recent publications few different implementations of k-means clustering for GPU have been proposed [1] [2] [3]. Those papers mainly address k-means as general purpose clustering algorithm.

In this paper we analyze implementation strategies for the efficient GPU algorithm optimized for characteristics of the image segmentation. This is characterized by a

relatively low number of clusters (number of segments is not expected to be very high), a low dimensional feature space (usually only color and position) and a variable input size dependent on the image resolution. Implementation considering performance impact of those characteristics is proposed hereafter. We propose a hybrid approach to increase image segmentation processing throughput on general purpose hardware. With addition to the CPU as central processing element, the GPU (Graphic Processing Unit) is used as a co-processor for executing tasks which can be effectively parallelized. Our approach gave considerable performance improvement over classical sequential implementation based on the CPU.

The rest of this paper is organized as follows. We present a basic concept behind GPGPU programming in Section II. Section III discusses k-means algorithm and its parallelization approaches, Section IV discusses the image segmentation program flow and optimizations specific for the GPU. Experimental results are discussed in Section V and finally Section VI concludes the paper and points out some possible future venues to explore.

II. CUDA PROGRAMING MODEL FOR GPGPU

CUDA is the latest software and hardware architecture for managing computations on GPU, abstracting it as parallel data processing device [3]. The example of overall hardware architecture is illustrated by Fig. 1.

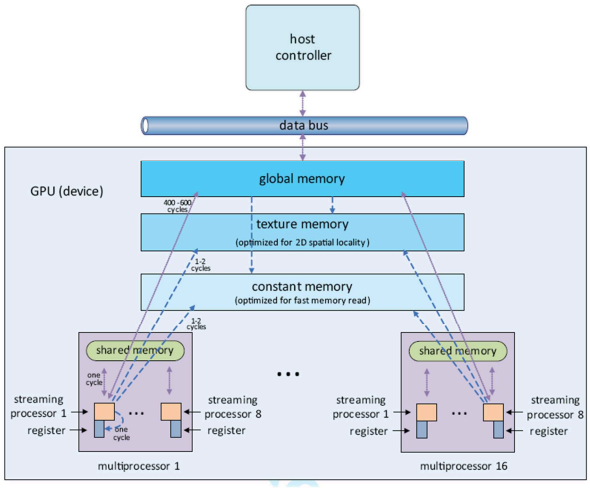

Figure 1. CUDA GPU architecture example

The GPU is viewed as a set of multiprocessors executing high number of threads in parallel. A typical CUDA application consists of two parts (phases). First part is executed on the host CPU responsible for transferring input data and results between GPU and CPU. Additionally, it is responsible for set-up of device code execution (kernel) by specifying quantity and logical organization of threads to be spawned on the GPU. Second part is completely executed on GPU and it is known as "kernel". Kernels are implemented in CUDA programming language, which is basically C programming language extended with few additional key words. Kernel code segment is executed by multiple threads that run on GPU hardware in parallel. CUDA threads are organized in groups of threads called blocks (Fig. 2). Number of blocks and threads each block contain is specified in host code prior to kernel execution. Furthermore, the blocks are grouped into a grid. Execution order of blocks inside the grid is undefined. Mechanisms for communication between threads are shared memory and limited synchronization mechanisms. However, as extensive synchronization can cause performance problems its usage is discouraged.

Threads have access to different types of memory, as illustrated on Fig. 2. In addition, each thread has very fast registers assigned to it. On the block level all threads have access to shared memory assigned to a particular block. If memory access pattern can avoid cache conflicts, shared memory can be accessed with low latency, just as registers. Constant memory is very limited, read-only portion of device memory. Access to constant memory is cached and it can be accessed from any thread running on the device. All threads running on device also have access to un-cached global memory, which has highest capacity, but higher latency then other types.

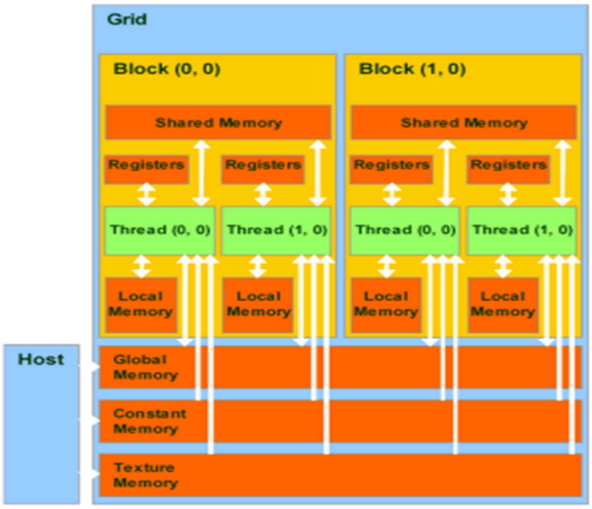

Figure 2. CUDA memory model

Memory access patterns should be carefully designed to avoid bottlenecks, otherwise performance of the GPU can be degraded significantly. Shared memory access by multiple threads in parallel can lead to memory bank conflicts serializing execution of affected threads [3]. Also, simultaneous access from multiple threads to global memory addresses should be arranged so that multiple memory requests can be coalesced into single continuous memory access. The number of threads active on the device is limited by the capacity of shared memory and registers. Device code should be optimized to run as many threads in parallel as possible and to mask relatively high latency access to main memory by having enough threads to execute while others are waiting on memory operation.

III. K-MEANS ALGORITHM

A. Problem definition

Clustering can be described as grouping of data points based on similarity in the feature space [7]. A set X of n data points is given in d dimensional feature space $x_i \in \mathbb{R}^d$, $i = 1 \ldots n$, as well as number of clusters $k \in \mathbb{N} < n$. A cluster $C_j \in X$, $j=1,\ldots,k$ with centroid $c_j \in \mathbb{R}^d$ is consisted from all points $x_i \in X$ assigned to a cluster based on similarity criterion. In the k-means algorithm each cluster is represented by its centroid (mean). Minimum distance between an evaluated point and the centroids is used as a criterion for assignment of point to the related cluster. Optimum set of centroids can be found by minimizing function [3][10]:

$$\Theta = \sum_{i=1}^{n} \min_{c_j \in C} \mathcal{D}(x_i, c_i)^2 \quad (1)$$

where $\mathcal{D}$ is defined as a distance between data point and cluster centroid, in practice this is usually Euclidean distance. Solving (1) is NP-hard problem even for two clusters. However, k-means algorithm provides non-optimal but feasible solution of the problem.

1) Initial clusters are created by choosing k random values from set X of data points. Values represent initial centroids of clusters, such initialization of cluster is known as seeding stage.
2) Next stage is known as labeling where each point x_i is assigned to cluster C_j with criterion of minimal distance $\mathcal{D}$ satisfied. Euclidian distance is commonly used as metric for $\mathcal{D}$.
3) Following the assignment of every point to the nearest cluster, centroids are recalculated in update stage. Each centroid c_j is recalculated as a mean of all assigned points $x_i \in C_j$ via equation

$$c_j = \frac{1}{|C_j|} \sum_{x_i \in C_j} x_i \quad (2)$$

Both labeling and update stage are repeted until all points are firmly assigned and cluster centroid positions are no longer being changed. However, final result is influenced by initial position of centroids. Depending on initial values, the algorithm converges to local minimum.

B. Computation complexity

Seeding stage of the algorithm, as being trivial, is omitted from the computational complexity analysis. In labeling stage, distance between each pixel x_i and each centroid c_i is evaluated. Distance calculations complexity depends on number of dimensions d, by which each point is defined. In our case, each point on image is represented by three RBG color components. Therefore to calculate Euclidean distance between the pixel and the centroid, one subtraction, one multiplication and one addition per each dimension (color component) are required, consisting altogether from nine operations. Additionally, calculated distances between the pixel and the centroids have to be compared before assigning the pixel to the closest centroid.

K-means algorithm labeling stage results in

$$O_{labeling} = 3nkd + 2nk = nk(3d + 1) = 10nk \quad (3)$$

operations per iteration, for k number of centroids and n pixel image.

Centroid mean for each cluster C_j is calculated at every iteration of centroid update stage. For each cluster total n vectors consisting from three components are added together. Each centroid is scaled by $|C_j|$ in total $3k$ operations. Centroid update stage takes

$$O_{update} = nd + kd = d(n + k) = 3n + 3k \quad (4)$$

operations per iteration. Number of iterations depends on the convergence criterion. Total number of operation per iteration is represented with

$$O_{iteration} = O_{labeling} + O_{update} =$$
$$nk(3d + 2) + d(n + k) = 10nk + 3d + 3k \quad (5)$$

Labeling is highly parallelizable and the most costly stage of k-means algorithm, therefore its parallelization should have the highest impact on overall performance of the image segmentation process [2].

C. Parallel k-means algorithm for GPU

Previous analysis shows that the execution time of labeling phase in sequential CPU case is bounded with $O(nk)$. In case of parallel GPU based execution, labeling can be executed in parallel on p independent processing elements (in concrete case GPU cores). According to that, labeling execution time is bounded by $O(nk/p)$ [2]. Label for each point in the dataset can be calculated independent from other points, which allows simple per point workload distribution among high number of CUDA threads. This means that depending on image resolution, one or more points for labeling can be assigned to each CUDA thread. From analysis it is clear that labeling stage of k-means algorithm is suitable for parallel GPU based execution and such approach is expected to result with performance gain.

Computational bound of sequentially executed update phase is $O(n + k)$ and this is significantly less complex compared to sequential labeling bound $O(nk)$. But if we compare the execution cost of sequential update phase with the cost of GPU executed labeling phase, we will get the ration between the two [2]:

$$O\left(\frac{nk/p}{n+k}\right) \cong O(k/p) \ \ (for\ n \gg k). \quad (6)$$

In case of image segmentation, a number of clusters k is usually of same order of magnitude or one order lower then number of processing elements p. Having that in mind, from (6) is clear that CPU executed update phase will take significant ratio of the overall execution time,

and this is confirmed with experimental results visualized by Fig 4.

The updating is executed in two sub-phases: first labels are assigned to clusters (bounded with $O(n)$), and then new cluster means are recalculated (bounded with $O(k)$). Our practical experiment with assignment implementation has shown that the prospect of accelerating assignments with GPU based execution is unfeasible, mainly because execution of code with divergent branches and intensive access to scattered memory locations is not suitable for execution on GPU architecture [4]. On the other hand, recalculation of the cluster means can be successfully parallelized for GPU execution, but transfer cost for low number of clusters (characteristic for image segmentation) is simple to high compared with gained benefits (see Fig 6). Additionally, it is expected that for purpose of image segmentation, number of clusters k will be up to order of magnitude lower than number of GPU cores p. Meaning, if the cluster mean is recalculated by a single CUDA thread, it will not be possible to fully exploit hardware resources of GPU, as only k from p cores will be utilized for recalculating k clusters means.

Therefore, in our approach only labeling phase of k-means is executed on GPU, while initialization and update phases are executed sequentially on CPU. Pseudo code of the GPU accelerated k-means image segmentation algorithm is listed below.

Algorithm 1 K-means clustering for GPU

```
initialize c_j ← random x_i ∈ X
initialize CUDA kernel
  block_per_grid ← image_width
  thread_per_block ← image_height
end init
repeat
  invoke CUDA kernel                                  GPU kernel code
    index i of x_i = thread.id* image_width+block.id
      l_i ← arg min 𝒟 (c_i,x_i)
  return control to host
  clear cluster means
  for all x_i ∈ X do
    c_i ← c_i + x_i
    m_i ← m_i + 1
  end for
  for all c_j ∈ C_j do
    cj ← 1/m_j c_j
  end for
 if converge then
    stop
until convergence
```

IV. GPU ACCELERATED K-MEANS SEGMENTATION

A. *Segmentation program flow*

Our hybrid image segmentation algorithm is executed by both CPU host and GPU as coprocessor (see Fig 3). CPU is responsible for overall control of execution control and number of tasks as fetching image, performing preprocessing, executing initialization and update phase of k-means algorithm. Flow starts after CPU fetches image from the source (e.g. camera or file system) and encodes it into RBG format. Execution continues with seeding of preconfigured number of initial clusters and provisioning of CUDA kernel. Labeling phase of k-means is implemented as CUDA kernel and executed by GPU and subsequent updating phase is executed by CPU, both phases are iteratively repeated.

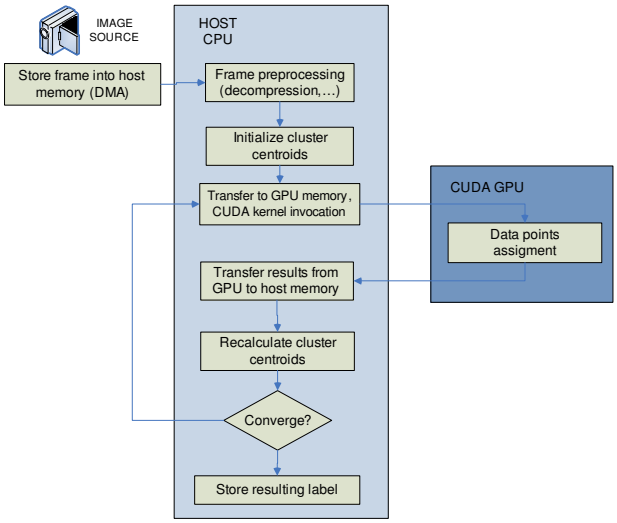

Figure 3. Hybrid image segmentation block diagram

The labels of pixels are calculated by CUDA threads launched the kernel function. Number of threads and corresponding structure of thread blocks should match the number of pixels for low resolution images. If an image has higher number of pixels than maximum threads on GPU, multiple pixels will be assigned to thread. Mapping between thread and pixels depends on its positions in the image. Each thread can access variables thread.id and block.id, which actually define thread's position in thread block and block's position in grid. Those variables are used as addressing mechanism for calculating memory address of pixel assigned to the thread. After kernel execution has been finished, control is returned to CPU. Cluster means are recalculated using labels returned by kernel function.

Algorithm execution is stopped after either the fixed number of iterations is exceeded or the convergence criterion of k-means algorithm is fulfilled. The result is expected in form of label image defining regions of segmented objects.

B. *CUDA specific optimization*

Architectural style of GPU does impose certain limits and programming strategies in order to efficiently exploit available computational capabilities. Therefore code executed on GPU, i.e. kernel function should be implemented considering specifics of underlying hardware. Our implementation has few CUDA specific optimizations applied.

One important aspect is usage of cached constant memory for storage of centroid values. Since all threads require centroid values for labeling, fast access to such variables is of key importance for fast performance of GPU implementation. Centroid values storage in cached constant memory has improved GPU code execution time for order of magnitude compared to solution without caching (global memory access).

Another important aspect is utilization of the coalesced memory access. CUDA memory controllers can group multiple memory accesses to sequential memory locations into single memory access, significantly reducing memory transfer time. Our implementation has pixel and label data structures organized to benefit from coalesced memory access. Also, memory shared between CPU and GPU for data transfer purpose, is excluded from operation's system paging in order to avoid performance overheads caused by indirect addressing or dislocation of the segment (e.g. on storage device).

There are indications that additional performance gains could be achieved by overlapping memory transfer from CPU to GPU with execution of kernel code on GPU. This is possible if kernels are invoked asynchronously over CUDA streams. Unfortunately, we could not conform this with experimental results as GPUs used in experiments are not supporting such feature.

V. EXPERIMENTAL RESULTS

Our algorithm is tested and verified on two different CUDA GPUs. Newer generation NVIDIA GeForce 250 GTS card has 1024 MB of RAM, 128 cores (streaming processors) and 8KB cache per core. Results are compared against older GPU, NVIDIA GeForce 8600M, with 256 MB of RAM and only 16 cores (streaming processors). Sequential version of the same algorithm is used as the reference for comparison. It is executed on Intel i3 3.06 GHz host CPU. Sequential code is compiled on VS 2008 compiler with maximum optimization settings, enabled SIMD extensions and "speed over size" option enabled. Color 24-bit RBG images obtained from Berkeley database [13] are used as input samples.

Fig. 4 visualizes the performance achieved by our image segmentation method deployed on different hardware configurations. Image frames with resolution of 512x512 pixels are used as input for the segmentation. In order to simulate a video stream, frames are sequentially feed into segmentator. Processing throughput is measured in number of processed image frames per second. Empirical measurements are obtained for different number of clusters as algorithm's parameter.

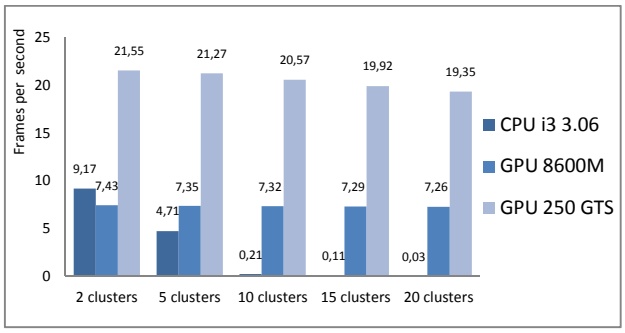

Figure 4. Segmentation throughput in frames per second measured for different cluster sizes with fixed convergence criterion of 20 iterations (512x512 image)

Measurements from Fig. 4 indicate that processing time of algorithms running on GPU is not scaling up as computational complexity of labeling is increased with higher number of clusters. This indicates that execution time of the algorithm is not bounded by computational complexity of the algorithm, rather by global memory bandwidth of the GPU. Cluster centroid structures are stored in cached constant memory and therefore small increase in number of clusters cannot have significant influence on overall memory performance.

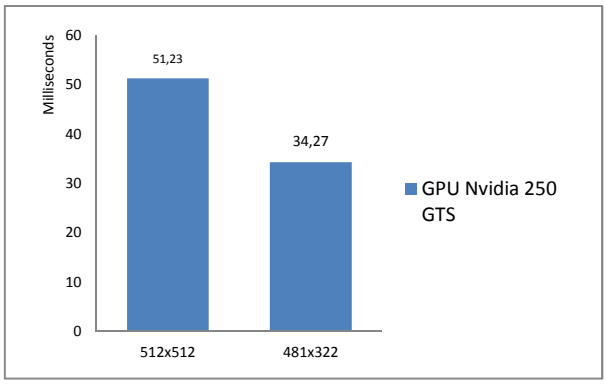

Figure 5. Segmentation duration in milliseconds for two different image resolutions

The influence of different image resolutions on overall processing time is shown by Fig. 5. As expected, higher image resolution has significant influence on the overall processing time as both computational complexity and memory transfer cost are affected. Labels and pixel data structures are stored in GPU's global memory. Memory access towards pixel and label values is successfully coalesced. Still, based on available measurements and CUDA profiler logs we can conclude that memory bandwidth of global memory is the bounding factor of our method.

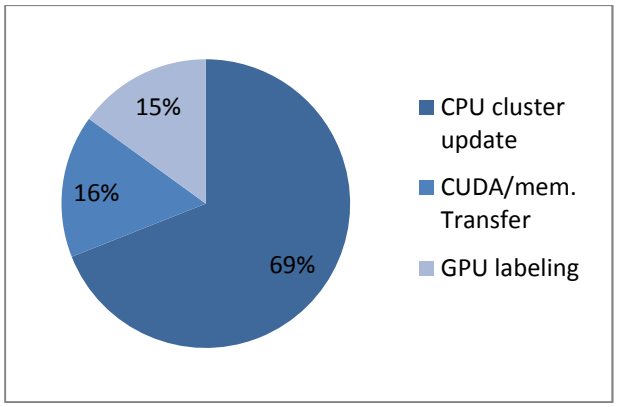

Figure 6. Ratio of the most significant operations in overall execution time for 15 clusters segmentation of 512x512 image

The ratio between CUDA kernel provisioning and memory transfers, GPU labeling and CPU cluster update in overall segmentation time is visualized on Fig 6. CUDA kernel provisioning and memory transfer between CPU and GPU significant ratio of 16% in overall execution time. Cluster update execution takes about 69% of overall time. Computationally most complex part of the algorithm, labeling stage executed on GPU takes only about 15% of overall execution time.

a) Input image

b) Segmented image

Figure 6. K-means image segmentation: a) input color image (381x240 resolution, 24-bit RGB encoding); b) segmented components for 5 clusters and 20 iteration set-up. Segmentation had duration time of 31.1 milliseconds.

VI. CONCLUSION AND FUTURE WORK

We have presented the approach for accelerating k-means image segmentation by using massively parallel graphic processing architecture. GPU is successfully used as coprocessor for accelerating highly parallelizable labeling stage. Experiment results involving segmentation of image sequence to up to 20 regions, have shown 2.3x – 600x improvement in execution time compared to the sequential version of the algorithm executed on CPU. Influence of different algorithm stages on the overall execution time has been analyzed and analysis verified by experimental results. Memory bandwidth is recognized as bounding factor for both GPU and CPU code segments.

After offloading labeling to GPU, CPU executed cluster updating stage is identified as far most dominant part of the algorithm. As we can conclude that GPU based execution would be unfeasible, our future work will explore optimization possibilities for k-means update execution on multi core CPUs. We belive that such approach could result with further significant gains. Also, more effective implementation of memory transfer between CPU and GPU will be further investigated.

PAPERS

CLOUD COMPUTING IN TELECOMMUNICATIONS

Opportunities for telecom operators in cloud computing business

Naida Katica i Ajla Tahirović
Ericsson, Sarajevo, Bosna i Hercegovina
naida.katica@ericsson.com
ajla.tahirovic©ericsson.com

Abstract - Evolution of the internet has resulted with the evolution of the new kind of business model called cloud computing. Advantages of cloud computing are widely recognized as a viable way to reduce operational costs. It gives companies and individuals access to different kind of services without the need for the investment in traditional way, they pay only for the infrastructure and applications they use, for the time they use them. In this work, we will try to discuss what telecom operators, as leaders in providing telecommunication services, can do to be competitive with other companies on the market as cloud service providers. As they already have the infrastructure, it gives them head start in this field, which they should use. Also, we will try to explain what is the role of Ericsson, as a vendor, in helping telecom operators to launch cloud services.
Key words: cloud computing, cloud provider, telecom operator, Ericsson

I. CLOUD OVERVIEW

Cloud computing is at the same time an emerging technology and a new business model. Beyond the traditional benefits for improving internal efficiency, cloud computing technologies facilitate the shift from a product based to a service based model. It provides significant benefits in time to delivery, flexibility in deployment and reduced operational costs.

There are many definitions for cloud computing, but the following one from the National Institute of Standards has gained broad support from the industry:

"Cloud computing is a model for enabling convenient, on-demand network access to a shared pool of configurable computing resources (e.g., networks, servers, storage, applications, and services) that can be rapidly provisioned and released with minimal management effort or service provider interaction. "

There are five essential characteristics of cloud computing:

1. On-demand self service –users are able to provision, monitor and manage computing resources as needed without the help of human administrators
2. Broad network access – computing services are delivered over standard networks and heterogeneous devices
3. Rapid elasticity – IT resources are able to scale out and in quickly and on as needed basis
4. Resource pooling – IT resources are shared across multiple applications and tenants in a non-dedicated manner
5. Measured service – IT resource utilization is tracked for each application and tenant, typically for public cloud billing or private cloud chargeback

Cloud Computing is commonly divided into three layers:

1. Software as a Service (SaaS),
2. Platform as a Service (PaaS)
3. Infrastructure as a Service (IaaS)

On the bottom layer is IaaS, which includes computing and data storage. The next layer up is PaaS, which enables developers (including enterprises) to write web applications quickly without the complexity of buying and maintaining the software and infrastructure underneath it. Sitting on top of the cloud computing stack is SaaS, where applications such as email, Customer Relationship Management (CRM), Enterprise Resource Planning (ERP), Unified Communications (UC) and device management are sold on a pay-as-you use basis.

The cloud model is composed of four deployment models:

1. Private Cloud – for exclusive use by a single organization and typically controlled, managed and hosted in private data centers. The hosting and operation of private clouds may also be outsourced to a third party service provider, but a private cloud remains for the exclusive use of one organization.
2. Public Cloud – for use by multiple organizations (tenants) on a shared basis and hosted and managed by a third party service provider.
3. Community Cloud – for use by a group of related organizations who wish to make use of a common cloud computing environment. For example, a community might consist of the different branches of the military, all the universities in a given region, or all the suppliers to a large manufacturer.
4. Hybrid Cloud – when a single organization adopts both private and public clouds for a single application in order to take advantage of the benefits of both.

Figure 1. Cloud computing characteristics and models

II. POSITION OF TELECOM OPERATOR AS A CLOUD PROVIDER

Telecom operators have long been in the business of offering highly reliable network connectivity to their customers. Many of them have also been strong players in the internet service provider (ISP) business. But now they must extend their strengths to other areas. Cloud computing has become a major topic within the telecommunications industry as operators begin to position themselves as a service and application providers. There is no reason why operators can't act like some existing cloud service provider.

Telecom operators are spending lot of money to maintain and enhance their network, while others cloud providers are monetizing the networks, at the expense of telecoms. After all, Amazon, Google and other similar cloud providers are delivering their services over the internet, which is provided and maintained mostly by telecom operators. Network investment can be dangerous if not accompanied by investment in services, as internet companies might be the one capturing the value. Operators have to avoid the possibility of becoming just a bit pipe for other cloud service providers.

Telecommunication operators are uniquely positioned to take advantage of cloud business opportunity. They have comprehensive network capabilities (broadband and mobile), long experience with integrating information technologies (IT) and other services into their network and delivering those services to the customers. They can provide managed connectivity between cloud users and third-party providers, offering flexibility in network resources both in real-time and on-demand. Cloud services depend on network performance and would suffer without good connectivity within and between them. Operators can offer connectivity services according to pre-determined agreements and choose to employ network-based techniques, including caching, optimization and data acceleration, to enhance the user experience of cloud applications.

Telecom operators can also partner and resell third-party service offerings, bundled with their own services, or they can invest in the infrastructure and deliver both third-party and their own offerings on that infrastructure more efficiently. By having in-house data centers, not only can operators offer own and third-party cloud-based applications, but more significantly, they can also provide IaaS in the form of on-demand hardware and computing platforms.

Operators already have existing billing and mediation platforms which enable them to charge customers based on usage. Also they made significant investments in their business support systems (BSS) and operations support systems (OSS) that are required to scale cloud services. Most important, telecom operators have a lot of intelligence about their subscribers: their preferences, the services they use, how and when they use them. They can embed these attributes with third-party cloud offerings, enhancing their value by making them more relevant and meaningful to users. For the business enterprises they can offer cloud services under a simple pricing structure that includes connectivity and devices, self-service provisioning, on-demand infrastructure hardware, as well as front- and back-office applications. They can also provide value-added services, including analytics and reporting, predictive capacity planning, and managed services. Target segments can be based on enterprise size, for horizontal applications, such as unified communications (UC) and enterprise resource planning (ERP), or it can be vertical market-based for industry-specific applications such as meter data management for utilities companies.

III. TELECOM AS CLOUD USER

Telecom service providers operate in a very complex operational environment, consisting of technologies which run their networks and support the delivery of their services. Just as telecom operators are promoting cloud as a new change opportunity for business enterprises, they can also benefit from its adoption.

With operators seeking to transform themselves from their legacy environments, adoption of cloud services can lead to efficiency gains, operational flexibility, and cost savings. Cloud-based services are also highly suitable for product prototyping and trialing ahead of large-scale market launches.

Telecom operators can simply transfer selected business functions to cloud, just as any large enterprise would. In the case of building cloud infrastructure, operators can become their own customers by migrating their existing services and support functions onto the shared infrastructure. The other way they can go is to simultaneously commercialize those cloud-based applications, becoming both user and provider at the same time.

Some operators already have internal systems, such as consolidate internal database for all services they provide, which are cloud based. In this way operator achieves significant savings in different ways and one of them are licenses. By building their own private cloud they can increase their flexibility, improve efficiency and support greener telecommunications by saving power, cooling and space, as well as money. In this way they can be an example for other business users in cloud consuming.

IV. CLOUD BENEFITS FOR DIFFERENT USERS

Among the first companies to adopt cloud computing are small and medium enterprises **(**SMEs**)**. Cloud computing allows these companies to use IT infrastructure without the need of purchasing hardware, software and maintaining large support teams. They can focus on their core business. Pay per use model divide expenditure into smaller periodic payments to the cloud provider and allows SMEs access to software that would otherwise be too expensive to purchase. Also they don't have to worry about software updates, licenses, backup or other maintenance of the system. The solution is fully scalable and if the company or business grows there is no need to expend the internal IT resources (hardware, software or human resources). This model is especially interesting for start-up companies, because these usually don't want to make big upfront investments.

Governments are also adopting cloud computing concept for various reasons. In today's economic environment, many public institutions are trying to find a way to reduce costs. Cloud computing can provide significant savings, especially when governments build shared cloud environments, which can be used by many public institutions.

Companies in the education sector (schools, universities, and others) are also using cloud computing to solve some of the challenges faced by these organizations. One of them is personal computers (PCs). Organizations, especially primary schools, spend a lot of money in hardware and software fixes, because their students do not treat PCs carefully. By using a desktop cloud environment, each student can have a fully managed virtual PC and access it through a thin client, which is less prone to hardware failures than a standard computer. Another possibility is the creation and maintenance of class labs. The use of cloud computing allows dynamically provisioning and de-provisioning resources which are necessary.

For private users cloud computing presents a new and easier form of accessing data (applications, documents, music, video files, pictures) from anyplace, using simple web browser on different devices. By hosting everything on a "cloud", users no longer have to carry their data on memory cards or hard drives. The primary advantage of such technology is that it frees individuals from their desktop and makes it possible for them to access their information anywhere and anytime as long as they have internet access, through a cable connection, over WI-FI or 3G mobile internet. Users don't have to know or care where the servers are located or where the programs they are utilizing are running.

V. CLOUD CHALLENGES

While the opportunities associated with cloud computing appear to be very attractive, there are challenges that need to be considered.

The main challenges are the availability and security. Companies and consumers often do not want to store their data in the cloud due to a lack of trust and the risk of exposing their data in an un-trusted environment. If a problem occurs and cloud infrastructure becomes unavailable to them it can cause a large business losses. Further the service may contain confidential information on a cloud, which then must be appropriate insured. Providers of cloud must therefore establish a relationship with customers based on confidence and ensure the privacy and data protection. If it comes to security violation and losing customer data that can destroy the provider. Provider must be ready to invest in providing the best digital security including securing data redundancy, support and backup.

Transitioning existing software and data to the cloud may be too expensive and technically challenging to undertake. This is particularly true in situations that involve legacy or non-standard software systems and data stores.

In order to avoid the risks, proper planning and enhanced service management policies are an absolute necessity. Without good plans and proactive service management, significant business and technical problems will occur.

VI. ERICSSON AND THE CLOUD

Ericsson has a vision of the world with 50 billion connected devices by the end of 2020. Three main forces are rapidly shaping the fundamental digital infrastructure in our world and leading to what we call the Networked Society, where everything that benefits from a connection will have one. Those three forces are: mobility, broadband and cloud.

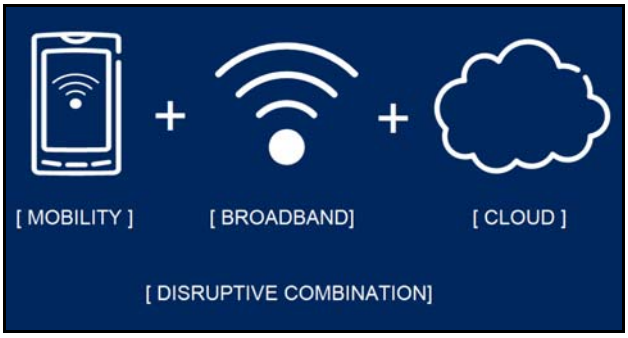

Figure 2. The new ICT industry

To realize its vision of the Networked Society, Ericsson is working with telecom operators, solution partners, and industry verticals across the cloud computing value chain

to create world-leading, innovative technology and sustainable business solutions.

As a strategic partner, Ericsson advises operators on strategies to leverage the benefits of the cloud as well as to expand their business opportunities through the cloud. Ericsson also works with operators to implement their cloud strategies by leveraging their network and operational assets and establishing cloud capabilities. In addition, Ericsson offers solutions-as-a-service, allowing operators to provide cloud-based offerings to their users.

So, it is possible to say that Ericsson's cloud value proposition is build on three pillars:

- Cloud services (revenue opportunity)

Ericsson provides cloud services/apps to grow operator business. Examples for this are Ericsson Device Connection Platform, Novatium – PC as a Service, and Mobile Cloud Accelerator.

- Building clouds (cost efficiencies)

Ericsson can help operators to build clouds, consolidating data centers and building private clouds. It has already been done for customers in Turkey, Spain and Italy resulting in OPEX and CAPEX reductions and savings on software licenses for the operators.

- Connecting clouds

Ericsson's most important contribution is connecting clouds. It means connecting both enterprise clouds and public clouds, via both fixed and mobile access, with quality of service, speed, reliability, security and a variety of business models.

In the context of providing cloud services for telecom operators, we will emphasis Ericsson Device Connection Platform, Akamai-Ericsson Mobile Cloud Accelerator, Novatium – PC as a Service.

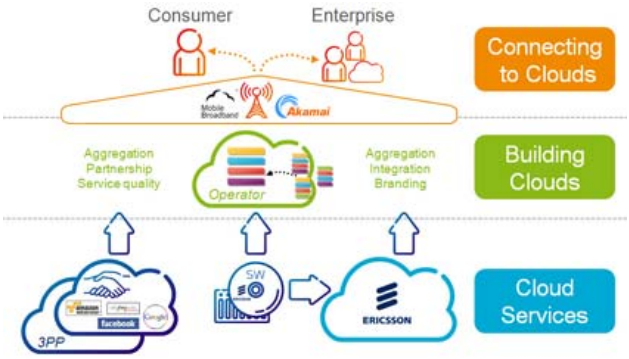

Figure 3. Ericsson's role in the cloud

A. M2M Platform: The Ericsson device connection platform

The service will be offered to telecom operators around the world, which in turn will set up M2M services tailored towards their enterprise customers. The platform is brought to market in a Software as a Service business model, offering operators benefits such as a low initial investment in technology and a fast time to market.

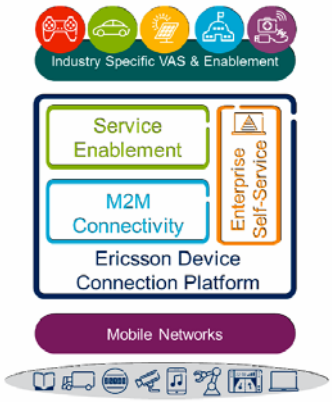

Figure 4. Ericsson Device Connection Platform as part of the total capability and eco-system

Ericsson's Device Connection Platform primarily makes it possible to create tailored connectivity and price plans for M2M services. Ericsson provides a complete service that the operator can adjust to serve its enterprise customers' needs, including a self-service interface, flexible billing, charging and connectivity plans for all devices connected to the network. Since M2M applications can communicate using any existing IP protocol they can be accessed and share data via internet. In addition, the operator's customer will be able to manage their subscriptions and devices in real time.

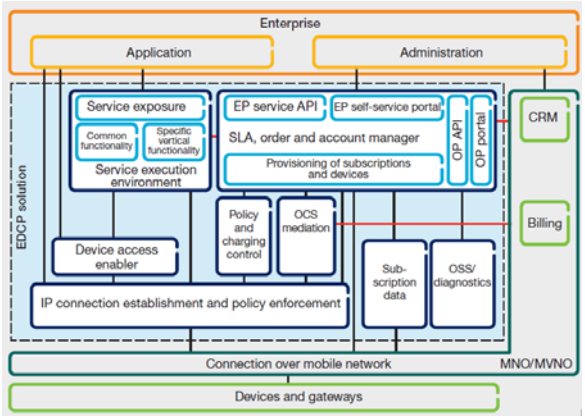

Figure 5. Ericsson Device Connection Platform architecture

B. *Ericsson mobile cloud accelerator*

The Ericsson and Akamai solution combines two parts:

1) Acceleration of content over Internet and

2) QoS prioritization over mobile networks, into a worlds-first true end-to-end Mobile Cloud Accelerator.

MCA is a unique Ericsson and Akamai proprietary solution that will be deployed in mobile networks, and offered as a service towards operators and content providers. It gives significant performance delivery improvements for all kind of web content such as e-commerce sites, portal pages or business critical applications all the way from web server to mobile end user devices. The solution will also work in multi-vendor networks including both RAN and packet core. The mobile prioritization part of the solution builds on and reuses the already existing QoS solution of the mobile operator. In addition to the existing opportunity to monetize the subscriber base it creates a new opportunity for mobile operators to monetize the network for over-the-top content. In addition the total solution also reduces TCO by reducing e.g. transit transport costs.

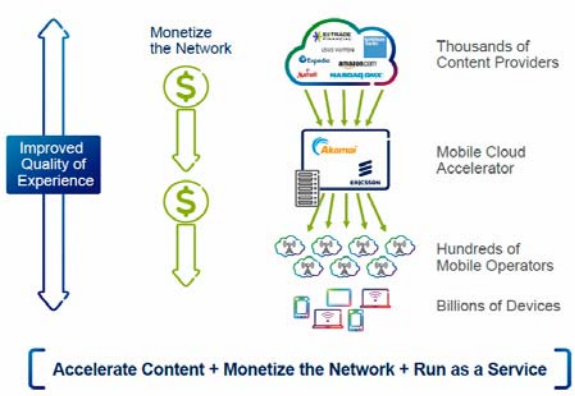

Figure 6. MCA overview

Key benefits:

- Addresses explosive growth in mobile data traffic, devices and cloud based applications
- Enables mobile operators to play bigger part in the mobile Internet value chain
- Jointly developed, end-to-end solutions to provide high-quality delivery of content and applications through mobile networks

C. *Novatium- PC as a service*

PC as a Service is a first-of-its-kind concept and a natural evolution of telecom and computing. PC as a Service offers telecom operators new ways to expand their broadband business. This helps drive mobile broadband penetration in emerging as well as developed markets as it motivates investments in rural as well as urban infrastructure.

Key Benefits:

- PC as a Service brings together the power of mobile broadband and cloud computing to reach out to the next billion users
- Transforms personal computing to the level of simplicity of a household appliance
- Dramatically reduces battery consumption and allows PC to start in 5 seconds
- To be available to telecom operators across Asia, Africa, Americas and Europe.

VII. CONCLUSION

The cloud opportunity, combined with telecom networks, is providing a synergistic platform for operators to add new revenues and make a new productive business models.

As providers of cloud services, telecom operators can manage connectivity, deliver cloud capabilities, and leverage network assets to enhance cloud offerings. Given their core competency, managing cloud connectivity appears to be the most natural value-adding activity. In delivering cloud capabilities, operators can deliver on-demand applications and computing capacity. By leveraging their network assets, operators add value by exploiting user attributes such as profiles and activities, making cloud services relevant and meaningful to users.

Telecom operators also benefit from cloud computing as users by transferring selected business functions to the cloud just as any large enterprise would. For operators building cloud infrastructure, they can become their own customers for cost efficiency and speed to market.

Operator must ensure cloud computing is an integral part of their strategies – either as providers, users or both. Their networks must have the capacity and intelligence while their business processes and support systems must be optimized for cloud services. An understanding of the evolving cloud ecosystem, partnerships and business models will be vital, as they enter the emerging cloud market.

Ericsson is actively researching different aspects of cloud computing and will help telecom operators to realize and use these opportunities.

Abstract - Cloud computing as defined by NIST is a model for enabling ubiquitous, convenient, on-demand network access to a shared pool of configurable computing resources (e.g., networks, servers, storage, applications, and services) that can be rapidly provisioned and released with minimal management effort or service provider interaction.

Focus of this paper will be on identifying the capabilities and requirements that need to be standardized in a cloud environment for successful deployment of the Cloud computing service.

IP Multimedia Subsystem (IMS) is a standardized architecture that ensures interoperability and simplifies integration of cloud services while supporting regulatory, QoS and capacity requirements.

I. INTRODUCTION

Although the concept of a Cloud to abstract detail has existed in telecommunications for many years and IP Multimedia Subsystem (IMS) is perceived as target architecture in modernization of existing telecom networks for last several years, there has not been much research regarding the co-existence of the two: IMS system and Cloud computing technology. In this paper we will focus on how could Cloud computing be integrated into IMS architecture and how could Cloud computing benefit from the IMS in means of increasing the system efficiency through providing desired Quality of Service and management mechanisms.

In spite of the fact that the fundamental communication services remain within the operator domain, the growth in new services and applications increasingly happens over the top (the customer perceives that the service is delivered by someone other than the operator). Traditionally, over the top services is a term that refers to all services delivered according to the internet model, i.e. services decoupled from the access running over IP and coming from outside the operator domain. However, in this paper we consider another scenario in which the operator takes a role in delivering the service e.g. by providing a better than best effort bit pipe to the service provided by someone else. This is the target architecture for network operators and will be explained in the following paragraphs. This includes network features, management aspects and ability to provide customized Cloud services, supporting an end-to-end approach from service to user.

II. CLOUD COMPUTING

Cloud computing is a term that was introduced to cover a multitude of existing practices adopted within the IT industry. Basically Cloud is about transferring ICT resources from an on-premise/equipment environment to an on-demand network service, but there are still many definitions in this area. In this paper we will use the Cloud computing definitions set up by The National Institute of Standards and Technologies (NIST) [1], which in short states that Cloud computing is a model for enabling convenient, on-demand network access to a shared pool of configurable computing resources that can be rapidly provisioned and released with minimal management effort or service provider interaction.

The "functional height" of the cloud services, also called Service Models, range from basic Infrastructure as a Service (IaaS) where processing, storage, networks, and other fundamental computing resources are provided, through Platform as a Service (PaaS) where a more complete application creation and execution environment are provided, to Software as a Service (SaaS) where the capability provided is full applications.

Cloud is also sometimes used to refer to all services delivered according to the internet model, i.e. services decoupled from the access running over IP. In this paper SaaS will be referred to services that are an alternative to classic software (or media) products.

To qualify as a "Cloud service" a number of characteristics of the service are defined:

- On-demand self-service interface from user to service provider
- Broad network access - accessed through standard mechanisms that promote use by heterogeneous thin or thick client platforms
- Resource pooling. - resources are pooled using a multi-tenant model
- Rapid elasticity – service capacity can rapidly scale out and in
- Measured Service - Resource usage can be monitored, controlled, and reported providing transparency for both the provider and user

Beside internet companies who have been early to launch Cloud services, operators have also started to launch Cloud services towards enterprises as a way to

grow their business. Beside existing customer relations and local presence, the operator's main competitive advantage towards internet based Cloud service providers is that they have control over both data center and access network, and thus are able to provide a complete Service Level Agreement end-to-end.

A. *Consumer Cloud users*

Today, many of the Cloud services targeted at consumers are offered by over-the-top (OTT) players, which exploit ubiquitous connectivity to provide easy-to-adopt, on-demand services. More often than not, these companies are not providers of communications or connectivity services; hence a market for bundling basic connectivity (fixed or mobile) and communications (voice, messaging, data and video) with cloud-based applications is opened – and largely untapped – for telecom operators.

Moreover, telecom operators often have an advantage over OTT web service companies when it comes to offering connectivity with hosted infrastructure. In the consumer market, this can be as simple as online storage services that enable users to store and share their digital assets in the cloud. Leveraging their network capabilities, operators also have an opportunity to offer prioritized or guaranteed services – instead of best-effort – on selected OTT cloud applications, leading to new revenue potential. By combining cloud services with connectivity and communications-as-a-service (CaaS), telecom operators are creating compelling offerings that enable the monetization of OTT applications to complement their core business.

B. *Managing cloud connectivity*

Cloud services, as distributed resources, depend on network performance and would suffer without good connectivity within and between them. Managing cloud connectivity appears to be the most natural value-adding activity for telecom operators given their expertise in connecting and managing networks. Operators are in a unique position to provide managed connectivity between cloud users and third-party providers, offering flexibility in network resources both in real-time and on-demand.

In this role, they are essentially intermediating brokers, enabling users to switch cloud vendors without worrying about network-related details. In addition, operators can offer connectivity services according to pre-determined agreements and choose to employ network-based techniques, including caching, optimization and data acceleration, to enhance the user experience of cloud applications. There are also possibilities for operators to offer device management, on top of end-to- end network management.

III. IP MULTIMEDIA SUBSYSTEM

The IP Multimedia Subsystem [2] is defined from 3GPP Release 5 specifications on as overlay architecture on top of the 3GPP Packet Switched (PS) Core Network for the provision of real time multi-media services.

Due to the fact that the IMS overlay architecture is widely abstracted from their interfaces, the IMS can be used for any mobile access network technology as well as for fixed line access technology as currently promoted by the European Telecommunications Standards Institute's (ETSI) Telecoms & Internet converged Services & Protocols for Advanced Networks (TISPAN) [3] within the Next Generation Network reference architecture definition.

IMS (IP Multimedia Subsystem) is a standardized architecture for control and delivery of multimedia services using the IP protocol for transport and the SIP protocol for service signaling. Figure 1 depicts different kind of access to IMS network through standardized interfaces.

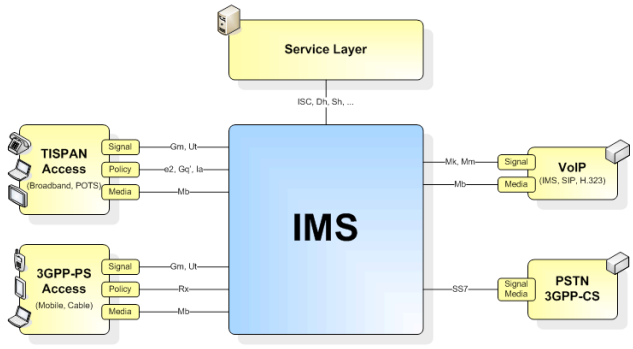

Figure 1 Access and interfaces to IMS network

IMS defines a layered architecture, which separates functionalities into three layers - an application layer, a control layer and a connectivity layer [6]. The application layer comprises: applications, content servers with the purpose to execute value added services to the end user.

The control layer comprises network control servers, which are in charge of call or session setup, modification and release. The control servers may also handle functions like security, charging and inter-working towards external networks on a control plane level.

The connectivity layer comprises routers, switches, media gateways and other user plane elements. The routers and switches provide transport capabilities for both control plane and user plane traffic. The media gateways provide different kinds of inter-working on a user plane level, including inter-working between different transmission technologies and inter-working between different media formats.

The core component of IMS architecture is Call Session Control Function (CSCF). CSCF is an essential node in IMS for processing signaling, using SIP as the signaling protocol [6], [10]. It provides support for Internet protocols on a scalable and high-performance platform. CSCF handles session establishment, modification and release of IP multimedia sessions using the SIP/SDP protocol suite. CSCF simplified architecture with interfaces is shown in Figure 2.

The CSCF has the following different roles in the network:

- Proxy Call Session Control Function (P-CSCF)
- Interrogating Call Session Control Function (I-CSCF)
- Serving Call Session Control Function (S-CSCF)
- Emergency CSCF (E-CSCF)
- Break-out Gateway Control Function (BGCF)
- Break-In Control Function (BCF)

P-CSCF is the first point of contact for the User Equipment (UE), either directly (mobile networks) or via an Access Session Boarder Gateway (A-SBG) (fixed networks). The P-CSCF forwards the SIP messages received from the UE to an I-CSCF or S-CSCF (and vice versa).

I-CSCF is the contact point inside an operator's network for all SIP requests destined to a user of that network operator. It locates the S-CSCF that was assigned to the user at registration through interaction with HSS (Home Subscriber Server).

S-CSCF performs the registration and session control services for the endpoint. This includes routing of originating requests to the terminating network and routing of terminating requests to the P-CSCF. The S-CSCF supports establishment, modification and release of IP multimedia sessions using the SIP/SDP protocol suite.

E-CSCF performs the handling of emergency calls while BGCF and BCF provide breakout routing and give the possibility for users connected to other networks to execute originating IMS services.

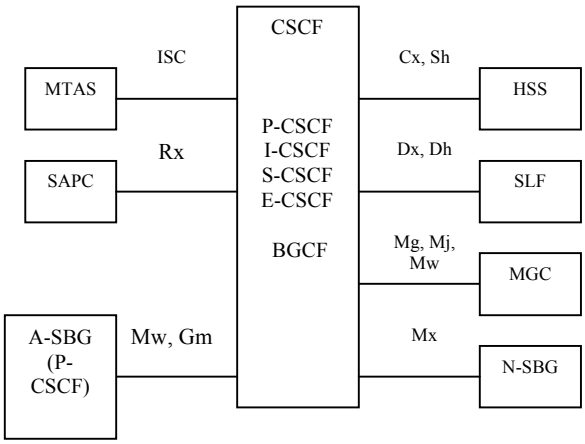

Figure 2 Simplified CSCF architecture and interfaces

IV. POLICY CONTROL AND CHARGING STANDARDS

The standard specifications for policy control and charging in broadband networks are issued by organizations such as the 3GPP, the European Telecommunications Standards Institute (ETSI) and CableLabs. The three bodies discuss harmonization of their respective standards in this field for wireless, wireline and cable networks. CableLabs has reached an agreement with 3GPP, which means that its PacketCable standard is aligned with the 3GPP policy control and charging (PCC) standard [4], [5].

The cooperation between ETSI and 3GPP has not yet resulted in a shared view on policy control and charging. The challenges arise from the different approaches used for policy control in the wireline and wireless domains, as illustrated by Figure 3.

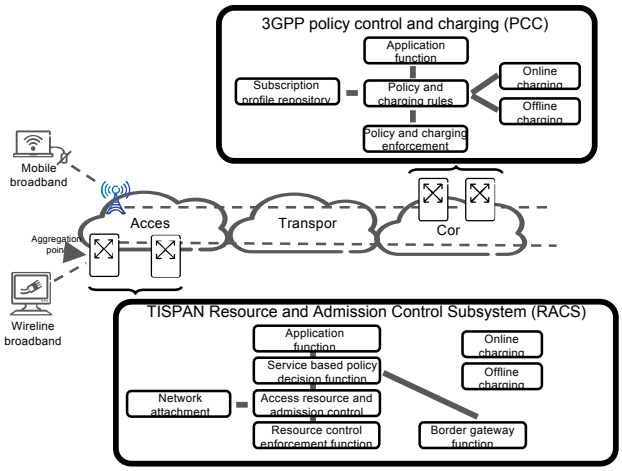

Figure 3 Policy control and charging standards

The Telecoms and Internet Converged Services and Protocols for Advanced Networks (TISPAN) Resource and Admission Control Subsystem (RACS) standard from ETSI [5] specifies how the required functionality should be implemented in the access network. The rationale is that lack of capacity in the wireline domain is mainly a potential problem on the aggregated level.

In the IMS architecture Session Border Gateway (SBG) is found at crossings between IP networks, where it funnels sessions – signaling together with associated media streams – of real time IP voice, video and other data across the borders between the IP networks in order to ensure Security, Quality of Service, Service Level Agreements, Legal Intercept, NAT/FW traversal, media enforcement / policing and other critical functions for IP streams.

In the wireless domain, the critical resources are found in the radio network. Hence, there is a need to control resource allocation from an end-to-end perspective. When the 3GPP PCC standard was specified, key functionality was already available in the core network for charging purposes (according to earlier releases of the 3GPP standard). A centralized solution, building on this functionality and signaling between the network elements concerned, was therefore preferred.

In TISPAN architecture Policy control functionality is split in two different functions. A-RACF is placed in the Access Network and it is responsible for Resource Management. Service based Policy Decision Function (S-PDF) is situated in the Core Network. TISPAN S-PDF uses the Gq' interface towards the AF (e.g. P-CSCF), and not the Rx, it includes handling of NAT and also has no bearer control and only very simple network policy handling. A-RACF main role is to provide policy control for the IP edge as well as admission control.

The current dominating implementation for TISPAN session border control is to use session border gateway

products that implement P-CSCF, SPDF and BGF in one product. In the enforcement side RAC functionality is what in 3GPP configuration, is more or less integrated in the different node elements such as RNC, SGSN and GGSN. A NASS, network attachment subsystem, provides authentication, authorization and handles dynamic provision of IP addresses. A NASS asks for policies and resources to the A-RACF.

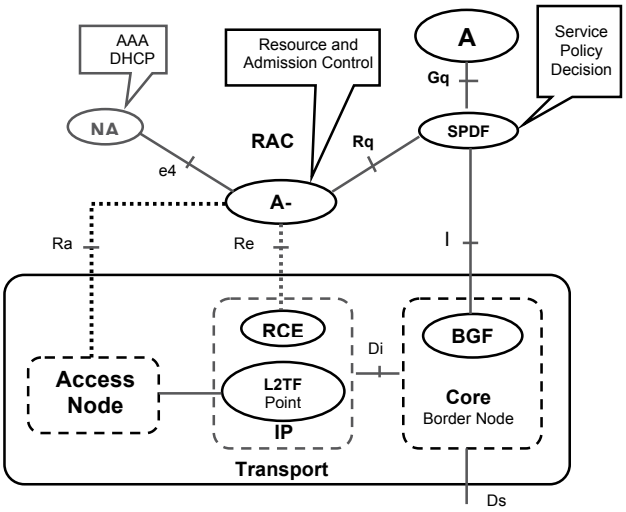

Figure 1. TISPAN architecture

The PCRF supports the functionality according to the Policy and Charging Control (PCC) architecture in 3GPP R7 for Mobile access. The Ericsson Service Aware Policy Controller (SAPC) acts as PCRF (Policy and Charging Rule Function) [5], [12].

PCRF supports services and applications requiring guaranteed quality of service (QoS) in a mobile network. To provide that support, the PCRF ensures that the proper policies are provisioned in the GGSN in that regard, as well as the proper charging rules to charge for those services.

PCRF is intended for IMS peer-to-peer services based on dynamic negotiation of the service/media components between peers. PCRF generates dynamic QoS and charging rules, based on session description and operator policies, which are enforced in the GGSN.

The functionality provided by SAPC in the IMS architecture is the following:

Gating control: it makes possible to control the flow of IP packets associated with a service, through the GGSN. GGSN, based on the Gating status received from SAPC, creates a simple state machine related to the flow of IP packets. The state machine can be thought as a gate that, when closed, does not allow the flow of packets on the bearer path, and when open, allows the flow of packets between the identified endpoints. It is used to correlate in time the events occurring in the IMS signaling plane with what is allowed to pass through the GGSN in the user plane and allows functions such as early media and hold/resume functions.

- Charging correlation: It makes possible for the charging system to correlate charging information generated by the GGSN and the IMS.
- By means of an IMS-generated unique charging identifier (ICID), that is, passed to the GGSN as part of SAPC authorization decision.
- Media authorization: its purpose is to ensure that the medium that the UE attempts to negotiate for an IMS session falls within the boundaries defined by the operator for the network.
- Bearer Event notification: SAPC enables the GGSN to report events related to bearer status to the P-CSCF. This is a feature that makes it possible for the P-CSCF to react to events in the user plane such as loss of radio contact (modifications from 0 kb/s for conversation and streaming class) and deactivation of PDP context.

V. QUALITY OF SERVICE

The number of broadband capable devices is rising rapidly and the volume of traffic generated by bandwidth intensive services such as file-sharing, downloads or streaming applications is increasing. According to many analytics reports, audiovisual traffic will heavily dominate all other traffic types, with figures of up to 90% of the traffic volumes. Result of that is that behavior is that competition for network resources is also increasing.

Over the top services usually include applications that do not behave well network wise, like widgets with frequent and non coordinated signaling updates or even simply a non RAN-optimize TCP/IP stacks on windows machines connected to radio networks. Also, in the current OTT model, the consumers are expected to foot the access bill for consuming OTT services themselves. A more "double-sided" model would allow operators to take part in the value chains of the OTT services by offering internet actors to either subsidize the consumer's access bills or acquire additional QoS capabilities to enhance the consumer experience of the service.

There are multiple ways in which operators become a more explicit part of the value chain within the OTT eco system, even in a situation where all services are actually provided by the OTT players. The operator can add value through the connectivity itself ("Smart Pipe") or could go longer, leveraging e.g. IMS (allowing OTT providers to make use of IMS through e.g. WebIMS), or User Data Management (e.g. let OTT providers access data), hosting services (including Cloud services) or using their charging/billing capabilities (e.g. carrier billing).

Advanced "Smart Pipe" capabilities in the network allow operators to expand from just being a best effort (dumb) bit pipe into a situation where they add value to end users as well as the OTT players, allowing them to expand their sources of revenue and increase end user satisfaction (which leads to lower churn and lower cost).

Operators may take a role in ensuring a good quality of the delivery, which is of benefit to end users and OTT players. This can be done through QoS mechanisms,

mechanisms for delivery optimization (compression etc), caching (to reduce latency) etc.

Operators can leverage their end user relationships in various ways, for instance by providing carrier billing services (where they e.g. act as a charging intermediary), they can be an enabler for single sign on solutions, they can provide/sell information to OTT players (location, access characteristics etc.), they may create service bundles (Gold subscribers of operator A gets premium OTT service B included). They may even leverage their "in-the-middle" position by doing things like content/ad insertion.
Exactly what operators can do will depend on business intentions as well as on local conditions, for example what is allowed by regulation (e.g. "Net Neutrality"), perspectives on consumer integrity etc.

A lot of the necessary mechanisms for these capabilities exist in the network already (and are used). There are however areas, where there is room for improvement like for example packet filters being nowadays static in nature which might need to become dynamic to adapt to OTT traffic

It must be noted that, as many of these capabilities depend on bi-lateral agreements between operators and OTT providers there are scalability limitations (making it hard for OTT to interface many operators and vice versa). Another important note is that, to be successful, the implemented mechanisms must be designed to be attractive to the OTT players (easy to integrate).

VI. CONLUSION

The Cloud opportunity combined with current IMS based telecom networks is providing a synergistic platform for operators to realize new revenues. Those investing in the capability to provide Cloud services are opening the doors to holding an elevated position in the Networked Society.

As providers of Cloud services, telecom operators can manage connectivity, deliver Cloud capabilities, and leverage network assets to enhance Cloud offerings. Given their core competency, managing Cloud connectivity appears to be the most natural value-adding activity. In delivering Cloud capabilities, operators can deliver on-demand applications and computing capacity either through partnerships or on their own infrastructure. By leveraging their network assets, operators add value by exploiting user attributes such as profiles and activities, making Cloud services relevant and meaningful to users and providing the linkage between the upstream and downstream components of two-sided business models.

Operator must ensure Cloud computing as an integral part of their strategies – either as providers, users or both. Their networks must have the capacity and intelligence while their business processes and support systems must be optimized for Cloud services.

Procedures and mechanisms like ones described in this paper (policy control, QoS etc.) that are implemented in IMS architecture provide strong tools for managing traffic and optimizing operations across fixed and mobile access network. Such tools optimize the utilization of network resources, facilitate service differentiation and provide the competitive edge through the bundling of IMS services and Cloud based services in new, attractive ways.

Most important, in comparison to pure over the top service, with policy control and QoS mechanisms operators can protect their brand by ensuring that subscribers get the service they pay for and expect.

** Siemens, Zagreb, Croatia
sergej.pocuca@nsn.com, bruno.marsic@siemens.com, anto.grgic@nsn.com

Abstract - A reason that many operators are introducing a cloud computing and SaaS in their offerings is to stay competitive and not to lose their business. One of the great advantages of cloud is scalability, faster time to market and less risk to launch a new service, which brings operators in position where they don't need any more to invest in a huge installed base and spent on CAPEX (Capital expenditures) in order to be profitable. The paper gives overview of telecommunication operator position in cloud computing market and how end users can benefit out them.

I. INTRODUCTION

Cloud computing is real and gaining momentum and the operators play a central role in the cloud computing boom with opportunities in efficiency through back-office transformation and increased revenue through new applications for Consumers, Enterprises /Small Medium enterprises (SMEs) [1] , Machine-to-Machine, selling and buying capacity and functionality on-demand as well as in re-establishing the role in Telco networks for privacy, security, customer experience and insights and quality of service differentiation.

Many operators around the globe have plans to launch Public Cloud Services in order to generate new revenue streams from their customers [2] and deploy an internal Private Cloud for internal cost savings.

One stop shopping as enhanced customer experience is most important driver leveraging operators and Cloud assets for new and innovative services. Operator's own and cloud based assets and services are combined for most efficient operator resource management and optimized investment in hardware and software. The combination of enhanced customer experience and increased operational efficiency is the key foundation of a new Telco eco system generating new revenues and what's more important; the role of the operators becomes more important through the network services in delivering the quality of experience and security for cloud services.

Telecommunication vendors are set to lead the transformation and efficiency by providing the cloud solutions to operators by leading the adoption of cloud technology and business models in Telco products and providing them as a Service, innovating for new consumer and enterprise services for operators, offer broad, for example M2M, portfolio to help operators enter to industry verticals and providing the best end-to-end Telco solutions.

Basic principles of cloud computing segments like Platform as a Service (PaaS), Infrastructure as a Service (IaaS), Software as a Service (SaaS) and technical and business dimension of cloud offerings are introduced in the chapter II. In addition, this paper discusses pros and cons of cloud and SaaS for operators and other verticals such as energy, health [3], telematics and retail. Operators' opportunities in Cloud computing and what are possible scenarios for Business to Consumer (B2C) offering (centered on VAS in a cloud and a solution to expose telecommunication assets to internet and web application community) and for Business to Business (B2B) offering (centered on machine to machine solutions) are discussed as well in chapters 3 and 4. In the chapter 5 as a an overview the paper is showing how CSPs in a small, high-ARPU market like Croatia want to behave, what are their benefits compared to big OTT players like Google, Amazon etc. and what they are currently offering in the field. In addition, this paper gives proposal how telecom vendors could help CSPs to become successful in a cloud business.

II. BASIC PRINCIPLES OF CLOUD COMPUTING

Cloud computing is a style of computing where scalable and elastic IT-related capabilities are provided as a service to customers, using Internet technologies [4][5].

Cloud Computing refers to both the applications delivered as services over the Internet and the hardware and systems software in the datacenters that provide those services. The services themselves have long been referred to as Software as a Service (SaaS), so we use that term. The datacenter hardware and software is what we will call a Cloud.

A reason that many operators are introducing a cloud computing and SaaS in their offerings is to stay competitive and not to lose their business. One of the great advantages of cloud is scalability, faster time to market and less risk to launch a new service, which brings operators in position where they don't need any more to invest in a huge installed base and spent on CAPEX in order to be profitable.

Briefly speaking, Cloud computing is a paradigm shift in the way enterprises approach procurement of IT resources, services and applications, and a new business model that promotes a new way of managing infrastructure and service delivery. It advocates changes in the traditional process of resource delivery and business

model, typically in the way of a public cloud service, which implies that services can now be accessed by customer with an internet connection:

- IT resources (Physical resources) are shared on demand basis (i.e. resources are allocated dynamically to the client) which differs from over-provisioning scalability in the past
- IT resources in the cloud are virtualized, which means clients see logical runtime units, but not the physical ones. This also reliefs the client of having to deal with resource limitations.
- Cloud services are provisioned over the internet. With the help of web-based tools or portals users can access the resources as if it were installed locally on their own computer.
- Cloud services (public) are sold with for example pay-per-use or per user pricing model i.e. the client pays only for and when using the resources, and not investing to own them, it's a rental model
- It's not necessary to maintain detailed IT knowledge anymore but only to focus on a case realization

In addition, some large and geographically diverse organizations may opt to invest in their own data centers to create cloud computing capabilities for use within the enterprise only (private clouds). This allows them to optimize their IT investments, as well as reduce operational costs involved in running the IT infrastructure from a (few) single facility.

Internet (the cloud) serves as an ubiquitous information high-way connecting users to their services, systems to cloud services, and cloud services to each other. Cloud computing represents a growing market with significant business potential, where cloud services spending will exceed $36B in 2012 growing at 4x the industry rate [6]

The typical cloud offers include:

- Infrastructure as a Service (IaaS),
- Platform as a Service (PaaS) providing computing and data storage resources,
- Software as a Service (SaaS), such as office tools or Customer Relationship Management (CRM).

A. Infrastructure as a Service (IaaS)

IaaS is the capability provided to the consumer to provision processing, storage, networks and other fundamental computing resources where the consumer is able to deploy and run arbitrary software, including operating system (OS) and applications. The consumer doesn't manage or control underlying cloud infrastructure but has control over OS, storage, deployed applications, and possibly limited control of select networking components (e.g. host firewalls).

The value of IaaS is still related to costs and shifting Capital Expenditures (CAPEX) to Operational Expenditures (OPEX), but increasingly, IT values IaaS for flexibility, speed to market and the ability to add new capabilities. The market in general is maturing and enterprises are more often evaluating cloud technology and services on the soft benefits of worker productivity and time to market rather than purely trying to reduce CAPEX.

B. Platform as a Service (PaaS)

The capability provided to consumer is to deploy onto the cloud infrastructure consumer-created or acquired applications created using programming languages and tools supported by the provider. The consumer does not manage or control the underlying cloud infrastructure including network, servers, OS or storage, but has control over the deployed applications and possibly application hosting environment configurations.

C. Software as Service(SaaS)

The capability provided to consumers is to use the provider's applications running on a cloud infrastructure. The applications are accessible from various devices through a client interface (e.g. browser). The consumer doesn't manage or control the underlying cloud infrastructure including network, servers, OS, storage or even individual application capabilities, with exception of limited user-specific application configuration settings.

The online delivery of software has been a long standing dream for some vendors and Chief Information Officers (CIO). The concept is simple and attractive: rather than buying a software license for an application such as enterprise resource planning (ERP) or customer relationship management (CRM) and installing this software on individual machines, a business signs up to use the application hosted by the company that develops and sells the software, giving the buyer more flexibility to switch vendors and perhaps fewer headaches in maintaining the software.

For many years, traditional software vendors (selling software and maintenance) have been able to overlook a rising number of competitors that offer software as a service, as the latter have struggled to develop truly competitive services. It is now time for traditional companies to pay attention, because they risk losing their privileged position to attackers that offer applications in this new way.

The online software delivery must meet the reliability and quality standards demanded by business users. The migration will not happen overnight, but several factors are impacting the growth. New software design and delivery models allow many more instances of an application to run at once in a common environment. Bandwidth costs continue to drop, making connectivity cheaper and allows online applications to perform gracefully. On the other side, the customers are frustrated by the traditional cycle of buying software license, paying for a maintenance contract and having to go through time-consuming and expensive upgrades. Many customers believe they would have more control over the relationship if they simply paid monthly fees that could be switched to another vendor if the first failed to perform.

The advantages of SaaS to both end users and service providers are well understood. Service providers enjoy greatly simplified software installation and maintenance and centralized control over versioning; end users can access the service "anytime, anywhere", share data and collaborate more easily, and keep their data stored safely in the infrastructure.

D. Business and technical dimension of cloud offerings

There are 2 key essential business models:

- **Software license sales**: Customer purchases a software license e.g. with upfront payment for transaction capacity, fixed fee, variable fee and subscriptions. Hardware based licensing metrics cannot easily be measured in virtualized/ cloud environments. Virtual machines, virtual CPU's or alike may be used instead.
- **As a Service**: Customer buys right to use software, but does not own the asset. Customer payment is based on consumption, e.g. transaction and invoices sent to customer once a month. For example there could be start-up fees and possible additional KPI linked fees.

Technically, infrastructure can reside either:

- Off-customer premises – **Public cloud**: Infrastructure can be outsourced to 3rd party or purchased on usage, though a hosted private infrastructure or on-demand scaling infrastructure. In simple terms, public cloud services are characterized as being available to clients from a third party service provider via the Internet. The term "public" does not always mean free, even though it can be free or fairly inexpensive to use. A public cloud does not mean that a user's data is publically visible; public cloud vendors typically provide an access control mechanism for their users. Public clouds provide an elastic, cost effective means to deploy solutions.
- On-customer premises - **Private cloud:** Network is protected by firewalls and accessible from internal network. Customer may own the infra, and carries capital costs. Many operators seek efficiency by outsourcing operations (OPEX). A private cloud offers many of the benefits of a public cloud computing environment, such as being elastic and service based. The difference between a private cloud and a public cloud is that in a private cloud-based service, data and processes are managed within the organization without the restrictions of network bandwidth, security exposures and legal requirements that using public cloud services might entail. In addition, private cloud services offer the provider and the user greater control of the cloud infrastructure, improving security and resiliency because user access and the networks used are restricted and designated.
- **Hybrid** - a combination of the both, a public and private cloud that interoperates in this model, users typically outsource non-business-critical information and processing to the public cloud, while keeping business-critical services and data in their control.

E. Pros and cons of cloud and SaaS for operators

For most users, the cloud and SaaS model offers alternatives, not nirvana. Benefits include:

- pay for what you use (theoretically),
- costs derive from an operational budget,
- more basic functionality that users really need, not "bells and whistles" that they might need,
- no operational management worries,
- no infrastructure overhead and management,
- lower total cost of ownership (TCO),
- faster implementations.

But there are also drawbacks:

- no asset value,
- less central management of IT,
- more basic functionality (sometimes real, sometimes perceived).

The main business drivers of cloud computing for operators (described in Figure 1[4]) are:

- **CAPEX converted to OPEX** - means that there are no up-front investments (or just limited investments) and costs follow business volume,
- **improved asset utilization** – means improved hardware utilization, improved SW license utilization, reduced operating costs and reduced provisioning costs,
- **improved business flexibility** – it's an ability to buy services in small increments, based on a Pay-as-you-go model and with a short service roll-in and roll-out times,
- **uniform IT environment** – means uniform infrastructures and applications, with same environment available globally and device-agnostic access to cloud,
- **simplicity for end-users** – because IT complexity is moved from PC to cloud, applications are in cloud and a maintenance is in cloud.

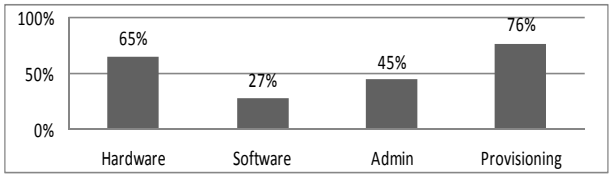

Figure 1. Cost-savings of private clouds (Source: IBM, Capturing the Potential of Cloud, September 2009, May 2010)

One of the main questions of cloud based deployments is **data safety** [7][8][9]. The SaaS model relies heavily on the cloud provider for security management through web

portal access safeguards such as identity management, IP address access filtering and application level configuration. When files are transferred from one site to another, industry standard encryption algorithms will be tightly managed to protect data security and to meet compliance regulations. Customers should choose a cloud provider that adheres to strict standards such as ISO 27001 [10] and meets their own local requirements.

It is important to know which issues are critical for the SaaS model and how it differs from traditional hardware and software delivery cases [3].

IDC, a global provider of market intelligence, did a survey during IDC Enterprise Panel in 2008 where 244 IT executives/CIOs and their line-of-business colleagues answered about their companies' use of, and views about, IT Cloud Services to find out what are the barriers for the adaption of Cloud Computing. And the top 3 challenges they were worried about was: security, performance and availability. From an overall perspective according to a the survey, Mobile Computing represents the highest security risk (46%) and Cloud Computing (21%) and Social Networking (18%) at much lower risk.

Aspects of **regulatory issues** should be also considered. Data protection rules are of key importance if operator provides SaaS as a service. If operator only provides the SaaS related HW and SW to the customer (but does not run the service), then typically there should not be major data protection issues during the delivery term. In order to be able to address the data protection issues in any individual case, it is important to know:

- where is the customer located and what is the data that is processed in the solutions
- what parties (including country) are involved and in what role
- what type of data is processed and how does the data transfer from one party to another.

F. Benefits from consumer, enterprise and operator point of view

A lot of enterprises have already started with cloud usage and SaaS services (it's not longer a hype) but also a lot of enterprise have no plans so far (means that market window is still open) (Figure 2).

Benefits for consumers are:

- low costs or free service often expected,
- ease of use,
- multiple devices in use,
- "on-demand" type of usage,
- Social networking and collaboration needs.

Benefits for Small & Medium Enterprises (SME) are:

- no up-front investment, especially important for startups,
- business flexibility,
- ease of use,
- buy in expertise.

Benefits for large enterprises are:

- low TCO (because just low CAPEX is not enough),
- uniform IT environment
- ease of use,
- business flexibility.

Benefits for operators as cloud users are:

- heavy cost pressure pushes use of cloud computing [11]
- low TCO as the main driver
- business flexibility to offer new end-user services

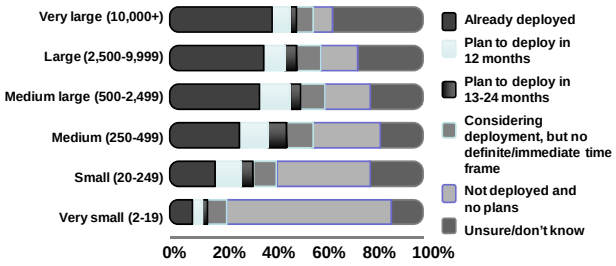

Figure 2. SaaS deployment status and plans (Source: Yankee, 2010 FastView Survey: Cloud Computing Grows Up: July 2010)

III. OPERATORS OPPORTUNITIES WITH CLOUD COMPUTING AND SCENARIOS FOR B2C OFFERING

The main opportunities for operators [12][13][14] thru cloud services are:

- new revenues from unique cloud services for end users and any kind of enterprises,
- operators as central and unique service provider for differentiating cloud services with an broad ecosystem of cloud service partners,
- flexibility thru new business models and increased efficiency through telecom cloud solutions reducing CAPEX and OPEX

Based on a research of TM Forum conducted 2010 by interviewing 20 Tier 1 communications service providers' senior executives around the world, it became clear from the interviews that there are many different views of cloud services from almost every perspective. This is an indication of the diversity of markets around the world, but also by-product of market maturity, as service providers determine what their customers require and how to deliver it. A large majority indicated that they needed to move quickly, but at the same time recognized that this is a market that will develop in a number of years. Almost all said this was visible issue with their senior management, but not all felt that top management had realistic or even clear view of the market.

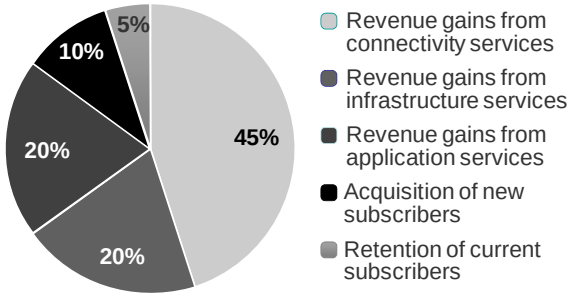

Figure 3. Primary benefits to communication service providers of the cloud initiative (Source: TM Forum Insights Research 2010))

While opinions how operators would benefit from their cloud initiatives were split, the most frequent answer was gains in revenues from connectivity services. This was particularly true of those service providers focused on partnerships to drive revenues. Operators expect the move of applications and computing services to the cloud to drive big increase in connectivity and transport services. They also believe that much of the increase will be in higher quality, managed communications services, and not just best effort Internet traffic.

The second most popular response was revenue gains from applications services and computing infrastructure services. A few of the services providers felt that by differentiating themselves with cloud services, they could gain new customers which do not subscribe to their core services currently.

Different consumer applications where for example operators expose Telco assets to bridge the developers and operators for enriched end-customer service innovations can drive to the totally new innovative services.

Consumer applications by enabling the operators expose Telco assets such as messaging, charging, billing and location information safely to application developers to enrich their end customer service portfolio as well as the configurable messaging service, where for example the small and medium enterprises can assure no customer service calls will be un-answered.

A. *VAS cloud solutions*

Operators can consider two VAS cloud solutions. One is exposure of telecommunication assets in a cloud to web developers and internet application community[15]. Following assets can be exposed and used by new and innovative internet applications:

- In-application charging for increasing revenues
- location
- identity
- messaging

Another example of VAS cloud based solution is VAS services in a private and public cloud using elastic resources of operator private or public (e.g. Amazon) cloud data centers. With this solution (shown in following figure) operators can easily scale HW and license capacities for their existing (MMSC, SMSC, VMS, etc.) and new VAS services (e.g. Rich Communication Suite (RCS) [16]).

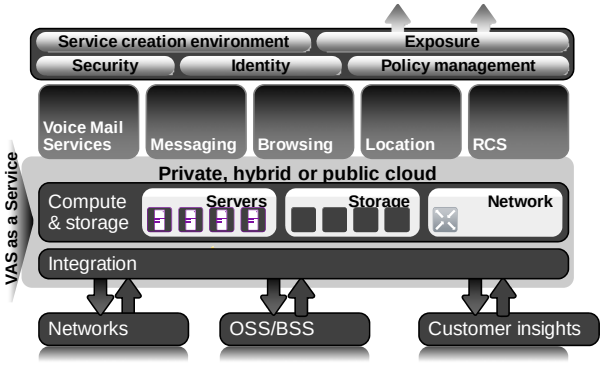

Figure 4. VAS as a Service (VaaS) solution

IV. SCENARIOS FOR B2B OFFERING

B2B ICT markets will grow attractively in the coming years, and operators are in a good position to shape them[17]. Operators in local Croatian market already started with different B2B offerings [18][19][20]. Following figure gives overview of some cloud based solutions provided by Croatian operators.

TABLE I. CLOUD BASED OFFERING BY CROATIAN OPERATORS

Hrvatski Telekom	• Virtual PC (computer + OS instances) • Targeted at home and office customers • Basic service fee 149kn/month • tCloud Management package (Basic + MS Office, Office Email) 198kn/month
Metronet	• Cloud market of business applications (CRM, HR, e-learning, Time mngm, etc) • Cloudmarket.hr • Pay per use model • Localized apps
Hrvatski Telekom	• tCloud Human Resource offered as SaaS (basic package 45 Kn/month/person) • tCloud ERP offered as SaaS (start package 199 KN/month • Adapted to local law
vip	• Working Time monitoring/management • Car Fleet management • Vip boat surveillance • Targeted at enterprise customers • 91 KN/month

In following subchapter we describe a solution that is still not present in the local market but it can help operators to extend portfolio.

A. *Machine to machine cloud solutions*

With a Machine-to-Machine (M2M) offering operators can leverage the platform as a service to enter new adjacent industries. Availability of M2M platform [21] is suitable to offer multi-tenancy and manage devices/objects for various industry verticals. It enables operators to integrate heterogeneous smart devices and to

utilize operators' telecommunication assets to create rich M2M business and consumer applications.

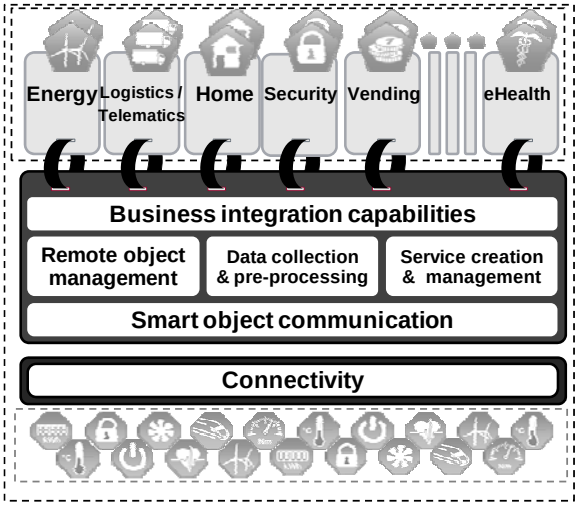

Figure 5. M2M Cloud Application Platform with vertical specific applications

V. WHAT OPERATORS IN A SMALL, HIGH-ARPU MARKET CAN DO

Main advantage of operators is a business bundling of connectivity with IT-services and new services/applications like e.g. M2M use cases to create end-to-end enterprise offering. Operators can offer new value-added services for consumer (through Telco assets exposure), multiple M2M verticals and new business models. In parallel operators can guarantee quality of experience differentiation for cloud services through their network connectivity and quality of service, secure the cloud services and privacy.

A. Comparison between telekom operators and big OTT (Over the Top) players

Telekom operators can take a major role in providing cloud services bundled with voice services as trusted partner towards enterprises and consumers, contains the aspect of operators strengths in strong authentication through SIM, trustful charging and billing, location, localized and global support and compliance to local laws. Their biggest advantage over big OTT players is their already established relationship with consumers and enterprises at local market thru providing communication services to them.

B. Telecom vendors solutions for operators

Telecommunication vendors can support operators to be a unique cloud service provider to generate new revenues and enable operational excellence by providing:

- innovative Telecom-grade platforms and framework to handle cloud services and leverage various cloud infrastructures (private, public, hybrid)
- Telco-Cloud applications as a Service with integrated Cloud Service Management for operational efficiency
- Combining mobile, networks and Telco's know-how with cloud computing and enabling those benefits for operators in terms of new revenues, the ability to benefit from partner ecosystem and to address new services based on customer experience
- Solution evolution from existing telecom offering towards cloud services deployment with low entry barriers, pay-as-use model and fast service roll-in/out times

VI. CONCLUSION

Three major opportunities arising from cloud for operators are new revenues, re-establishment of the major role of the operator for cloud services and increasing of internal efficiency. Local presence in market gives strong advantage of local operators over big OTT players where they can offer not only IT cloud services but also cloud services enabled by telecommunication assets and various M2M use cases on unique M2M cloud based platform bundled with connectivity.

REST-style Actionscript programming interface for message distribution using Amazon Simple Queue Service

K. Popovic, Z. Hocenski
Siemens d.d. / Communications, Media and Technology, Osijek, Croatia
Faculty of Electrical Engineering / Institute of Automation and Process Computing, Osijek, Croatia
kresimir.popovic@siemens.com

Abstract - Amazon Simple Queue Service (Amazon SQS) is a message-oriented middleware in the cloud using software as a service model. It aims to eliminate the traditional overhead associated with operating in-house messaging infrastructures by providing reduced costs, simplified access to messaging resources, scalability and reliability. In order to provide those benefits Amazon SQS leverages cloud resources such as storage, network, memory, processing capacity. Using virtually unlimited cloud computing resources, an Amazon SQS provides an internet scale messaging platform. This paper presents benefits and examples of Amazon SQS programming interface developed in Actionscript 3.0 object-oriented programming language. This interface was developed to enable Adobe Flex mobile developers to facilitate integration efforts within organizations and between them using mobile devices (tablets and smartphones).

I. INTRODUCTION

Mobile computing has drastically impacted the social and commercial aspects of our society [1]. Seeing the explosion of mobile applications in the consumer world, companies can't avoid dreaming about revolutionizing their businesses with the presence of mobile applications. The ability of extending business capabilities to mobile devices (tablets and smartphones) leads the priority list of most CIOs (Chief Information Officer) [2]. However, the path to enterprise mobility goes beyond building sporadic applications for a specific line of business systems. Companies embarking on the enterprise mobility journey need cohesive strategies for important mobile infrastructure aspects such as device management, identity, security, and monitoring, that are required to provide a true enterprise mobility experience. During the last few years, cloud infrastructures have pushed the frontiers of software development to areas never before imagined. In the context of enterprise mobility, the cloud model and services present a unique model to simplify the challenges of the traditional enterprise mobility model and to open new possibilities in the space. Conceptually, an enterprise cloud mobility platform removes the complexities of the mobile enterprise server from the corporate network by placing it in a cloud infrastructure where it can leverage various cloud services to enable its native capabilities. A cloud enterprise mobility infrastructure represents a higher simpler model from the infrastructure standpoint than its on-premise counterpart. In this model organizations are only responsible for deploying the portion of the applications that interact with the web services and message queues.

Message and data exchange are an essential aspect of any enterprise mobile application [3]. The ability to exchange messages or consume data from on-premise or cloud environments in a mobile device is, arguably, the most relevant element of an enterprise mobility platform. The key is to build components that do not have tight dependencies on each other, so that if one component were to die (fail), sleep (not respond) or remain busy (slow to respond) for some reason, the other components in the system are built so as to continue to work as if no failure is happening. In essence, loose coupling isolates the various layers and components so that each component interacts *asynchronously* with the others and treats them as a black box. Loosely coupled system can be build using *messaging queues*. If a queue is used to connect any two components together, it can provide concurrency, high availability and mitigate load spikes.

Today, technologies such as Amazon SQS [4], CloudMQ [5], Linxter [6], Microsoft Azure Message Queue [7] and others offer simple cloud-based messaging services to broker the communication between different endpoints. In this paper benefits and examples of Amazon SQS programming interface developed in Actionscript 3.0 object-oriented programming language (library name: **as3awsSDK.swc**) are presented [8]. Interface is developed as publicly available Community Contributed Software for thin clients [9].

The goal of this paper is to present developed Amazon SQS programming application interface for Actionscript 3.0 and its benefits for Flex developer community.

The paper is organized as follows: Section II lists recent available software development kits from prominent cloud providers and open-source community. Also benefits of Amazon Simple Queue Service (Amazon SQS) are considered, and mobile application portability issue solution is recommended. Section III presents architecture of Amazon SQS API for Actionscript 3.0 and one use case sample how it can be used in practice.

II. RELATED WORK

As of recent, software development kits available from prominent cloud providers and open-source community provide APIs (libraries) that hide much of the lower-level complexity, including authentication, request retries, and error handling. They take the complexity out of coding directly against a web service interface. TABLE I shows available software development kits from different cloud providers.

TABLE I. SOFTWARE DEVELOPMENT KITS

Software Development Kit	Cloud provider			
	Microsoft	*Linxter*	*CloudMQ*	*Amazon*
Home computer				
Java	✓	✓	✓	✓
.NET	✓	✓	✗	✓
PHP	✓	✗	✗	✓
Ruby	✗	✗	✗	✓
Mobile				
iOS	✗	✗	✗	✓
Android	✗	✓	✗	✓
BlackBerry	✗	✗	✗	✗

Each provider provides several publicly available libraries for different development environments. For proper use developer needs to have technical knowledge about the environment in which he/she develops. This can be time consuming and costly because e.g. for mobile development it is necessary to have iOS, BlackBerry and Android knowledge. Also, the same application needs to be developed three times. Solution to the portability issue is to use technology which enables developers to *write code once, and run anywhere*. This is possible since June, 2011 using Adobe Flex SDK (version 4.5 or later) framework [10]. Flex is a highly productive, open source framework for building and maintaining expressive web applications that deploy consistently on all major browsers, desktops and operating systems. This means that source code written in Actionscript 3.0 can be also compiled for all mobile devices. Knowing that, it was prudent to develop an Actionscript 3.0 library for one of cloud providers which offer message queue service. Purpose of this library is to enable Adobe Flex developers to facilitate integration efforts within organizations and between them using mobile devices. The benefit of doing it this way has impact on application maintenance costs. Amazon SQS owned by Amazon Inc. was chosen as message middleware because of proven maturity when compared to others and due to Amazon's vast cloud market share.

III. AMAZON SQS APPLICATION PROGRAMMING INTERFACE FOR ACTIONSCRIPT 3.0

Amazon SQS is used as message-passing mechanism between components. It acts as glue that holds together different functional components. This not only helps in making the different components loosely coupled, but also helps in building a more failure resilient system overall. If one component is receiving and processing requests faster than other components (an unbalanced producer consumer situation), buffering will help make the overall system more resilient to bursts of traffic (or load). Amazon SQS acts as a transient buffer between two or more components (controllers). If a message is sent directly to a component, the receiver will need to consume it at a rate dictated by the sender. For example, if the system was slow or if the launch time of the cluster was more than expected, the overall system would slow down, as it would just have to wait. With message queues, sender and receiver are decoupled and the queue service smoothens out any "spiky" message traffic. These service benefits can be used by mobile devices in an innovative, simple and transparent way.

A. Characteristics of a good API

What are characteristics of a good application programming interface (API)? Answer to this question has to be known to software developers **before** API implementation.

- Easy to learn (steeper learning curve) - an easy-to-learn API features, consistent naming conventions and patterns, economy of concepts, and predictability. It uses the same name for the same concept, and different names for different concepts. A minimal API is easy to memorize because there is little to remember. A consistent API is easy to memorize because you can reapply what you learned in one part of the API when using a different part. The semantics should be simple and clear, and follow the principle of least surprise.
- Hard to misuse - A well-designed API makes it easier to write correct code than incorrect code, and encourages good programming practices. It does not needlessly force the user to call methods in a strict order or to be aware of implicit side effects or semantic oddities.
- Easy to read and maintain code that uses it - readable code can be concise or verbose. Either way, it is always at the right level of abstraction—neither hiding important things nor forcing the software developer to specify irrelevant information.
- Easy to extend - Libraries grow over time. New classes appear. Existing classes get new methods, methods get new parameters, and enums get new enum values. APIs should be designed with this in mind. The larger the API, the more likely the clashes between the new concepts and the existing concepts. In addition, binary compatibility

concerns must be taken into consideration during the original design phase.

Guidance above was taken as main beacon toward good API during the design and development phase of Amazon SQS API for Actionscript 3.0. After development phase it was shown that developers should strive for minimalism and consistency, but only to the extent that they contribute to meeting the criteria listed above. Consistency coincides broadly with conceptual integrity, the principle that a complex system should have a coherent design, reflecting the vision of one architect.

Quote from F.P. Brooks [11]: *„I contend that conceptual integrity is the most important consideration in system design. It is better to have a system omit certain anomalous features and improvements, but to reflect one set of design ideas, than to have one that contains many good but independent and uncoordinated ideas.“*

B. *Architecture of developed Amazon SQS API for Actionscript 3.0 – as3awsSDK.swc*

Amazon SQS library for Actionscript 3.0 as3awsSDK.swc is consisted of three basic model types: event model, interface model and class model. Interface model employs a simple interface *com.amazonaws.services.sqs.AmazonSQS* (defined in Amazon SQS WSDL version 2011-10-01) that is easy to use and extend (see Figure 1).

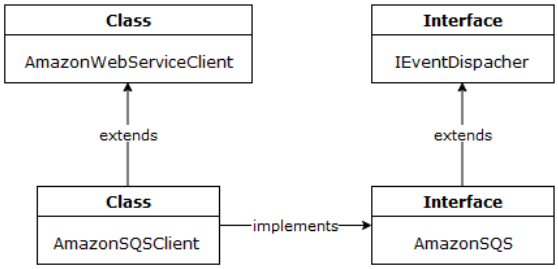

Figure 1. Basic architecture overview of Amazon SQS API for Actionscript 3.0

The following AmazonSQSClient requests defined by interface AmazonSQS are provided:

- createQueue - create queues for use with your Amazon AWS account.
- listQueues - list your existing queues.
- deleteQueue - delete one of your queues.
- sendMessage - add messages to a specified queue.
- sendMessageBatch - add multiple messages to a specified queue.
- receiveMessage - return one or more messages from a specified queue.
- changeMessageVisibility - change the visibility timeout of previously received message.
- changeMessageVisibilityBatch - change the visibility timeout of multiple previously received messages.
- deleteMessage - remove a previously received message from a specified queue.
- deleteMessageBatch - remove multiple previously received messages from a specified queue.
- setQueueAttributes - control queue settings like the amount of time that messages are locked after being read so they cannot be read again.
- getQueueAttributes - get information about a queue like the number of messages in it.
- getQueueUrl - get the queue URL.
- addPermission - add queue sharing for another AWS account for a specified queue.
- removePermission - remove an Amazon AWS account from queue sharing for a specified queue.
- releaseResources – this is a special function which removes all event listeners and releases any resources that might be held open on client side. Execution of this method minimizes memory consumption.

Class model contains two core classes:

- com.amazonaws.AmazonWebServiceClient – abstract class which performs data stream encoding using *createURLRequest* protected function. It is designed as a base class which can be reused by other Amazon AWS services, e.g. Amazon Cloudwatch monitoring service [12], DynamoDB noSQL database [13], etc.
- com.amazonaws.services.sqs.AmazonSQSClient – queue client which contains implemented and documented asynchronous queue service public functions. Each function is unique and there is no dependence between each other.

Event model uses interface flash.events.IEventDispatcher. The IEventDispatcher interface defines methods for adding or removing event listeners, checks whether specific types of event listeners are registered, and dispatches events. Event targets are an important part of the Flash® Player and Adobe AIR event model. The event target serves as the focal point for how events flow through the display list hierarchy. When an HTTP/HTTPS COMPLETE event occurs, an event object is dispatched into the event flow from the root of the display list. The event object makes a round-trip journey to the event target, which is conceptually divided into three phases: the capture phase includes the journey from the root to the last node before the event target's node; the target phase includes only the event target node; and the bubbling phase includes any subsequent nodes encountered on the return trip to the root of the display list.

HTTP(s) request responses in XML format are caught by an event model, parsed and deserialized to Actionscript 3.0 result object for easier user handling. During XML namespace parsing, response format and

mandatory parameters are checked if they are properly formatted, if not exception will be thrown.

Usage of these three models guarantees **consistency** in future Amazon SQS API library upgrades. This means that Amazon SQS API can be used as a template for creation of new services in the future.

C. *How to use Amazon SQS API for Actionscript 3.0*

For proper programmatic usage it is necessary to understand that API only works in asynchronous environment because it is based on Adobe Flash and Adobe AIR technology. Every request (sendMessage function, see Figure 2) has assigned two callback functions called when a specific event occurs.

```
/** Send UTF-8 message to Amazon SQS service */
public function sendMessage(): void {
  // set user credentials
  // set queue URL
  // set event handlers
  // execute sendMessage action
}
/** Asynchronous positive response. */
private function resultHandler(event:
CompleteActionEvent): void {
  // extract positive response data from 'event' object
}
/** Asynchronous negative response. */
private function faultHandler(event:
IOErrorActionEvent): void {
  // extract negative response data from 'event' object
}
```

Figure 2. Amazon SQS sendMessage sample for Actionscript 3.0

ResultHandler function is called when positive HTTP/ HTTPS response event occurs (result code 200 OK) and the faultHandler for negative event (result code >= 400). Other functions defined in interface *com.amazonaws.services.sqs.AmazonSQS* are used in the similar way. This means that developers will have a steep learning curve and become quite proficient in API usage with a minimum amount of effort/time.

D. *Taxi reservation service – usecase sample*

One of possible usage of mobile device and custom developed as3awsSDK.swc library is for connecting to Amazon SQS service to store taxi reservation messages (see Figure 3). It can be quite useful when taxi dispatcher phone lines are busy. The mobile application which does reservation is portable to all mobile devices because it must be compiled with Flex compiler for proper library usage.

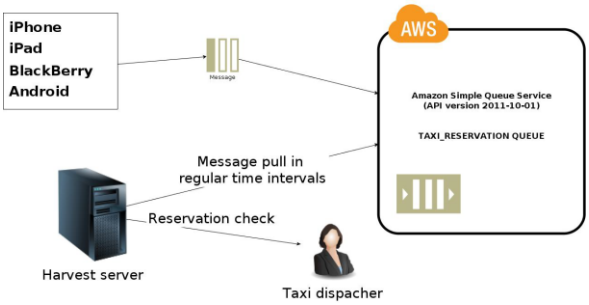

Figure 3. Taxi reservation service

Use case description:

- iPhone / Android / BlackBerry user opens Taxi reservation mobile application.
- User enters his first name, last name, pickup location, dropdown location, number of people and a phone number.
- Reservation request is send towards Amazon SQS queue TAXI_RESERVATION and stored there until service consumer (e.g. harvest server) pick it up.
- Harvest server checks every e.g. 30 seconds TAXI_RESERVATION queue status and harvests messages if there are any. When the message is consumed from queue it needs to be processed and stored into a database. After the message is consumed it needs to be deleted from the TAXI_RESERVATION queue.
- If a user reservation request can be served (taxi car is available) dispatcher will call the user and confirm reservation or send an SMS / e-mail.

The advantage of working with queues is that if the harvest server is offline reservation records can be consumed later after harvest server comes back online. With this degree of independence, taxi software components are protected from each other and can better recover from component failure. If the SOA (Service Oriented Architecture) is designed correctly, the failure of a single component should not take down other components in the system and thus loose coupling creates architectures that are more resilient. Moreover, this also lends itself better to creating a failover subsystem, moving from one instance of a component to another without affecting the other components in the SOA.

IV. CONLUSION

In this paper Amazon Simple Queue Service (Amazon SQS) programming application interface for Actionscript 3.0 (as3awsSDK.swc) has been presented and its benefits for Flex developer community. Most valuable advantage of programming application interface for Actionscript 3.0 (compiled with Flex SDK compiler 4.5 or greater) from technical point of view is portability. Code compiled with the Flex SDK compiler follows the slogan "*write code once, and run anywhere*". It enables developers to deploy

cloud message queue enabled mobile application on several different mobile OS result of which are reduced development costs and time. During the time of writing this paper library was downloaded by open source community 176 times.

TELECOMM BUSINESS MANAGEMENT

Result of using formal methods in modeling telecommunication business management

Darko Markulin, M.Sc.

Abstract – Specification of business management for telecommunication service provisioning is a very demanding procedure. All possible scenarios have to be estimated and for every scenario all needed network configurations and other actions have to be ensured. Additionally, business rules in every scenario have to be satisfied.
Best way for modelling telecommunication business management is using tools for graphical presentation. In this work UML is used like tool for graphical presentation of business process. UML is a standard language with wide using in different system modelling. UML activity diagram is very useful tool for modelling of business processes. But, modelling of very complex business processes without simulation of requested system management does not give enough clear picture which can result with many mistakes during development. Simulation gives developers of system management possibility to see requested changes deeper and clearer. This paper gives result of using formal methods for the purpose of business management simulation.

Key words – formal methods, simulation, business process modelling, business management, UML activity diagram

I. INTRODUCTION

Specification of business mangement is very important segment of telecommunication system support development. Specification is a document through which business requirements and business processes for service provisioning are defined. Process is mainly consisted of signals between systems which participate in business management, actions which are needed during the service provisioning, decisions which define flow through the process and parallel branches which bring parallel activities in the process. Flow of the process depends on many factors such as the input data from CRM (Customer Realation Management) system, answer after the automatic configuration of network element, data about network fesibility for service connection or result of manual action during the service provisioning. Further, during the service provisioning different scenarios are possible. In many cases business process is consisted of more simplest business process for provisioning of one service. In this complex process coordination of simplest ones is very important issue. According to these facts it is obvious that specification of business management for service provisioning is very demanding procedure. To meet demand for clear and accurate specification of business management business processes has to be modelled so all needed actions during every scenarios are covered on correct way.

The best way of system support modelling is posibbility of system behavior simulation [9]. In this work UML is used like tool for graphical presentation of business process. UML diagram activity is a diagram which is very suitable for business process modelling. Syntax of the diagram is adequate for modelling of telecommunication business management. But the UML activity diagram cannot be used for visual simulation of business management without using formal methods. Obtained formal model with his semantics allows visual simulation of business management. In this work example of simulation business management for real telecommunication service was presented.

II. SPECIFICATION OF POSSIBLE SCENARIOS IN SERVICE PROVISIONING

Business management for provisioning of VoIP service in telecommunication network is very complex. There are many scenarios and all of them have to be included for successful provisioning of this service. Widespread use of service additionally gives to the importance of modeling service provisioning. There is a need to add scenarios of migrations of customers to another Operator and migration from PSTN service to VoIP which is especially pronounced in the traditional Operators. Model of such business management for such service is very complex too.

Complexity could be decrease by way of modeling where business processes are modeled through the more levels. On the highest level some parts of actions (e.q. configuration of some network elements, feasibility check for the service, manual actions on the field) are put in one unit and process is composed from several units which gathers similar actions. On the next level units are decomposed on more activities and so on. But some situation could not be clear enough without simulation of business management execution. Especially at the lowest levels of decomposition which describe basic actions such as manual work at the field or message to another OSS or BSS system.

Basic sets of possible scenarios for provisioning of this service can be divided on:

A. Provisioning of the basic service including provisioning other triple play services

B. Processes for migration of subscriber who uses VoIP service (including other triple play services) to another Operator

Provisioning of the basic service can be divided according to the type of the process and type of the access technology. Process can be connection, disconnection, temporary disconnection, relocation, changes in the existing service. Access technology can be ADSL or FTTH. Every technology demands different actions according to the network elements configuration and activations on the field. Provisioning includes migration from PSTN services to VoIP.

Processes for migration of subscriber to another Operator are complex processes which demands actions on more different services. Usually actions are directed to disconnection of subscriber's services and creation of conditions for customer migration to another Operator. Similar situation is in case when subscriber comes from another Operator. If subscriber has more services before migration process is more complex.

III. RESULT OF USING FORMAL METHODS

Formal model which was used for modeling business management in case of VoIP service provisioning is described in [8] and [9]. Model uses UML 2 diagram activity and it has all elements which are needed to describe flow of business management for provisioning of VoIP services or, general, for provisioning of telecommunication services. Diagram Activity is additionally formalized by formal method Abstract State Machine. Tool which was used in modeling is UML 2 Activity charts [1], [5] and [6]. Tool, in addition to using UML 2 activity diagram, allows using C# programming language in action node. Result of this code can be condition for continuation of the flow after the action node execution. Thereby in this way advanced functionality is enabled in relation to using only basic elements of activity diagram.

Figure 1 depicts static view of systems environment which participates in service provisioning. Systems are shown like classes. As business management in workflow system is modeled, only class "Workflow system" is behavioral class. This means that just for this class behavior is modeled with activity diagram. Since the behavior of the other classes are not modeled communication between systems are shown by action node, not like signals. This contributes to the simplicity of the model.

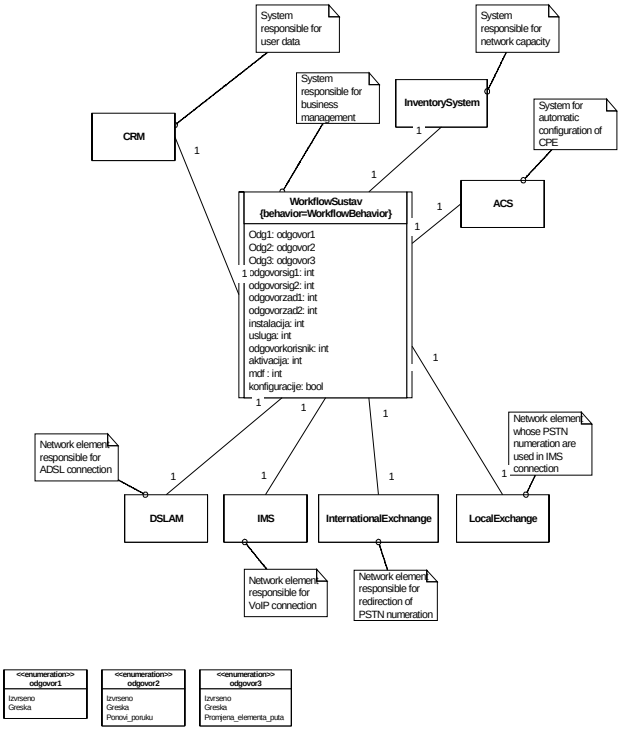

Figure 1: Class diagram which gives static view of systems environment

Process for VoIP connection is shown on figure 2. This is the highest level of modeling and process is divided on a several basic parts. These parts are feasibility check for service, network elements configuration (figure 3) and service activation on the field (figure 4). Service activation varies depending on type of activation. Activation can be installation from the Operator or selfinstallation.

Model can be verified by simulation according to the input data which present one of the possible scenarios in service provisioning. Possible scenarios in case of VoIP service connection (in accordance to triple play services) are:

A. VoIP connection with Operator's installation

B. VoIP connection with selfinstalation

C. VoIP and Internet access connection with Operator's installation

D. VoIP and Internet access connection with selfinstalation

E. VoIP and IPTV connection with Operator's installation

F. VoIP and IPTV connection with selfinstalation

G. VoIP, Internet access and IPTV connection with Operator's installation

H. VoIP, Internet access and IPTV connection with selfinstalation

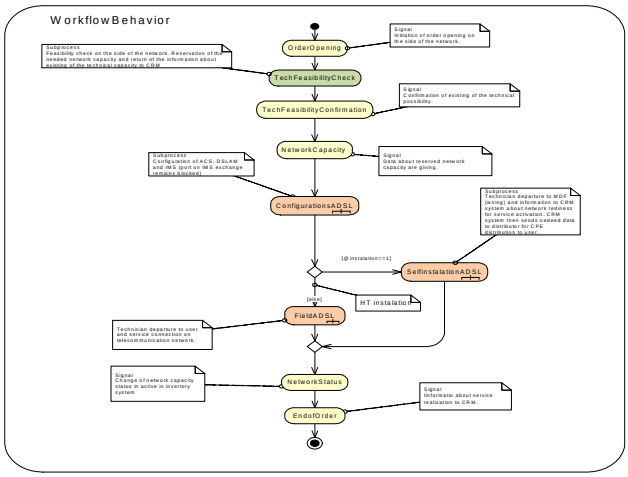

Figure 2: Business process for VoIP (and other triple play services) connection

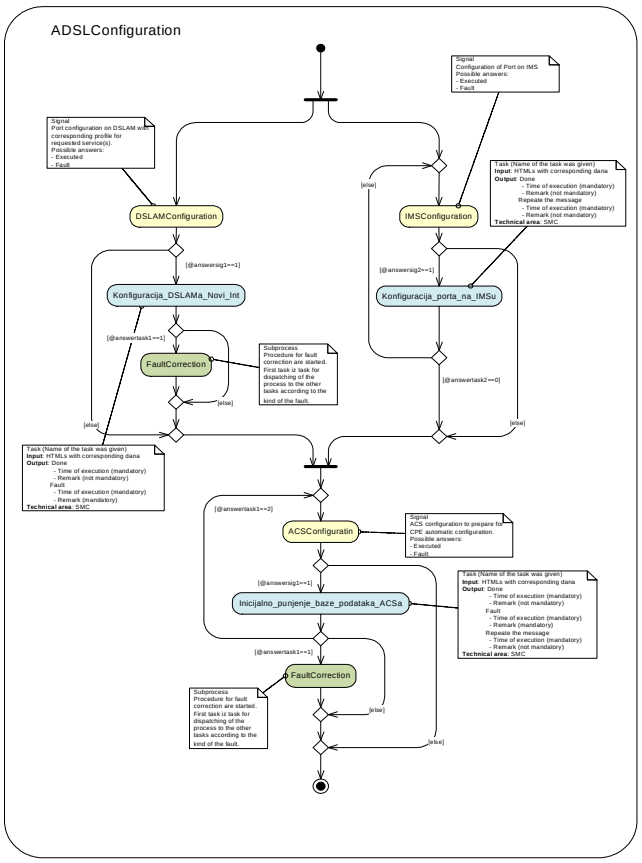

Figure 3: Subprocess for network elements activation before the field tasks

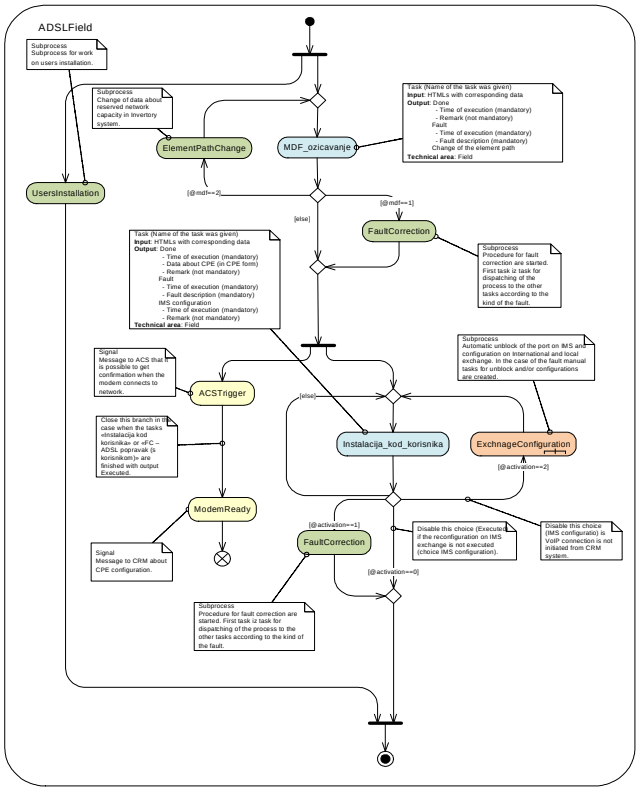

Figure 4: Activities on the field

Model can be verified by simulation according to the input data which present one of the possible scenarios in service provisioning. Possible scenarios in case of VoIP service connection (in accordance to triple play services) are:

I. VoIP connection with Operator's installation

J. VoIP connection with selfinstalation

K. VoIP and Internet access connection with Operator's installation

L. VoIP and Internet access connection with selfinstalation

M. VoIP and IPTV connection with Operator's installation

N. VoIP and IPTV connection with selfinstalation

O. VoIP, Internet access and IPTV connection with Operator's installation

P. VoIP, Internet access and IPTV connection with selfinstalation

Figure 5 shows GUI form with name "Forma za unos podataka". Form is used for input of the data needed for simulation of the some possible scenario. In this case it is scenario "VoIP connection with Operator's installation".

First two data define data from CRM (service and kind of installation) and on this basis it is possible to simulate process flow according to the requested service and kind of installation. Second two data (result of the field activation and result of MDF wiring) define ending of the actions which means, in this example, result of manual work for service activation in the network.

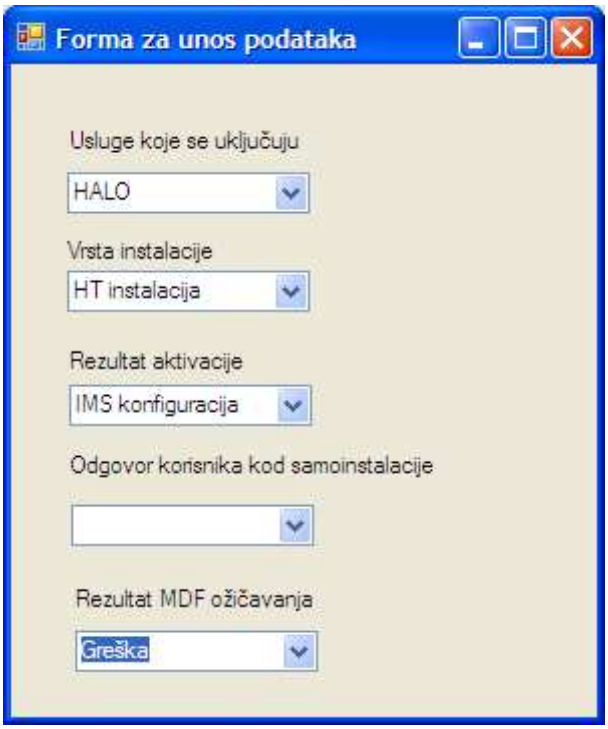

Figure 5: Input parameters for business management simulation

Figure 6 to 9 depicts simulation of business management for connection of VoIP service. Only simulation through the most interesting parts of the model is shown.

Results of the interaction with the other systems which communicate with workflow system are predefined by using C# code:

```
public void Konfiguracija_porta_na_IMSu()
    {
       odgovorzad2 = (int)odgovor2.Izvrseno;
    }
```

Results of the manual work are predefined by using C# code too.

It should be noted that using C# code in modelling business management has to be simply. Otherwise using model for modelling business management will not be practically.

For parts of the process where more detailed simulation is needed result of the action can be defined over GUI form as was shown on figure 5. Examples are manual task for MDF wiring and field activation. It is possible to simulate different scenarios for closing these actions.

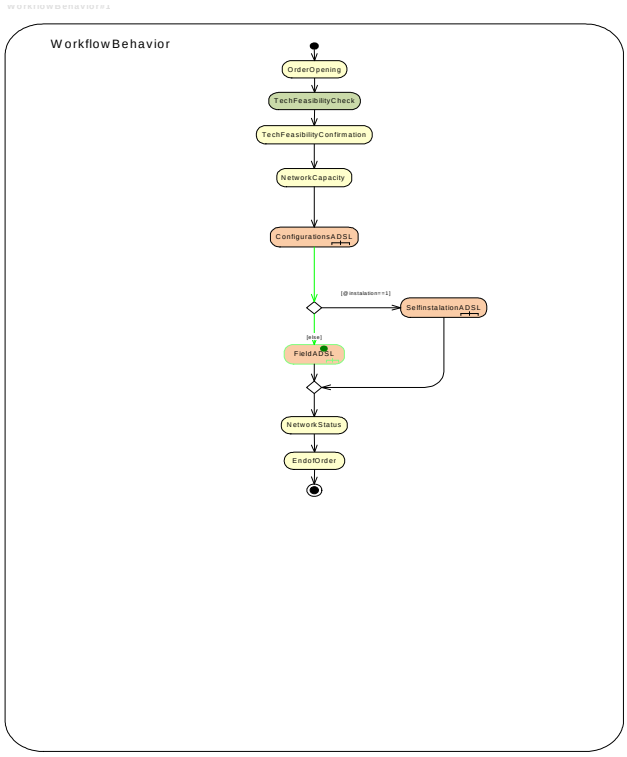

Figure 6: Simulation of network elements configuration before the field activation

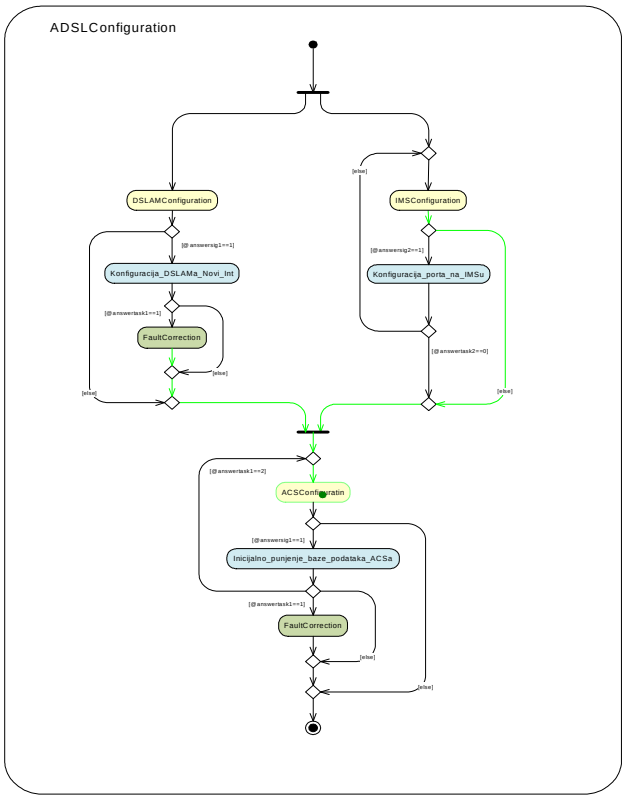

Figure 7: Call a subprocess for field activation

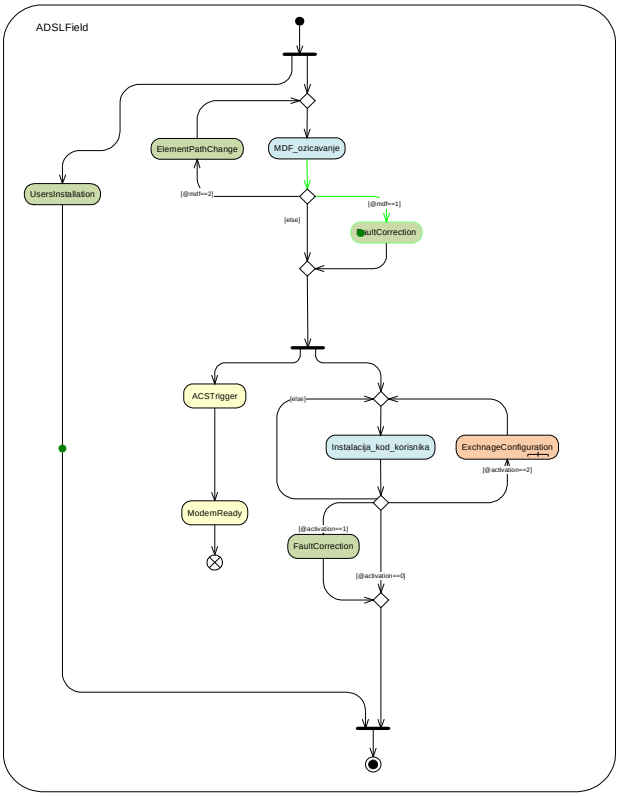

Figure 8: Result of MDF wiring

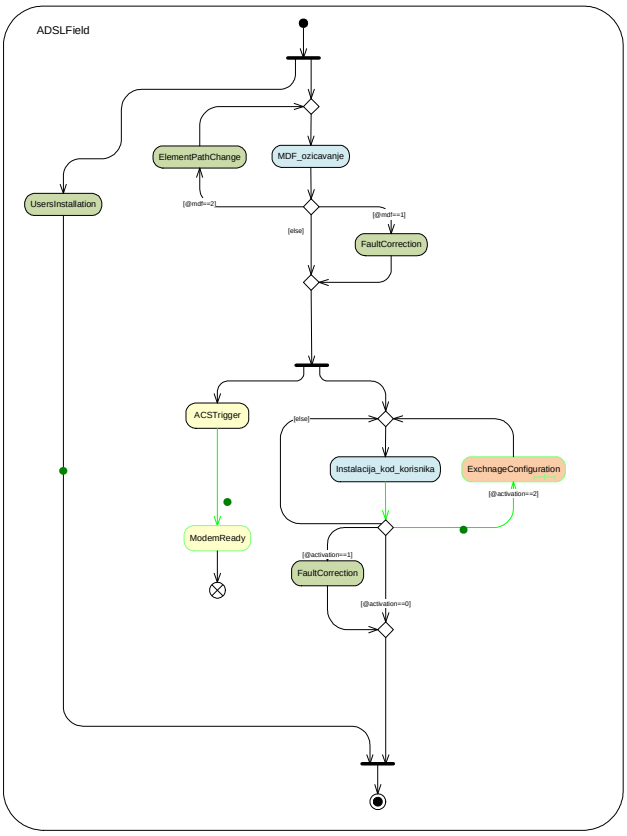

Figure 9: Result of activation at customer

Given results confirm that formal model can give clear picture of the requested business management. By defined scenarios and corresponding data it is possible to simulate flow of the activities for certain case which can occur during the service provisioning. It is very important because business management has to ensure support for more possible cases. Needed activities for one case have to be selected between several possible activities in the flow.

Simulation of the business process through the model defines actions which are needed to execute in one of the possible scenario which presents possible business process in the service provisioning. In the given example simulation defines actions kind and sequences needed for network elements configuration and activation on the field in case of chosen scenario. So it is possible by simulation of model behaviour to verify business requests for business management support.

IV. CONCLUSION

Business management for provisioning of telecommunication service is very complex. Reason for this is increasing number of services, complexity of services and competitive telecommunication market. To provide appropriate system support for such business management is complex and demanding procedure. Because of all these facts development of business processes without modeling is practically impossible. Moreover modeling of such complex business processes without possibility for simulation can lead to errors during the development or implementation of business management.

In this work one example of modeling business management for provisioning of VoIP service was presented. Formal model that allows simulation of modeled business management was applied. Given result showed that this formal model could be used in phase of specifying needed business process for provisioning of the telecommunication services.

Future work will include application of this formal model on real development of business management for one of the telecommunication service. This will be a way to examine the practical application of this formal model. From one side model has to be clear and accurate enough and from the other side development of the model has to be simple enough that its using in development of business management is practical.

Abstract – In condition of complex and competitive telecommunication market time reaction of Telecommunication Operator in case of implementation new telecommunication service is very important. Another situation when fast reaction of Telecommunication Operator is very important is satisfaction of Regulator's requests. These requests are mainly demanding and with the short deadline. Business processes in these situations are playing one of the key roles. Most of these processes are complex and it is very important to model these processes on optimal and easy applicable way.
In this paper kind of business process modelling suitable for complex business processes are introduced. Model is consisted of more modules which contain activities for realising of certain configuration in telecommunication network. Modules have to be designed on optimal way so that implementation of new processes and change of the existing ones is easy. Syntax of UML activity diagram is used for modelling. Diagram is suitable for modelling of system support and human behaviour. It gives visual picture of business support which is acceptable for all participants in business process and system support design.

Key words - business processes, scenarios, module, complex telecommunication market, business process modelling, UML activity diagram

I. INTRODUCTION

Telecommunication market is becoming more and more complex. Increasing number of new services, increasing number of customers who requests more services at once, migration from one kind of service to another (e.g migration from PSTN service to VoIP), migration of customers from one Operator to another, different requests of Agency for Telecommunication etc. are some of reasons why telecommunication market is complex and dynamic. In accordance with this fact businss processes are complex too. Dynamic of new processes introduction and changes in existing processes is very large. It is very important that processes can support all possible sitautions during the service provisioning, customer migration or service migration. On the other side competitive telecommunication market requires fast introduction of new services on market which means, among the others, fast development of needed system support. Another situations which requires fast reaction and development of system support are Regulator's request which are frequent, demanding and with the short deadline.

To satisfy these two basic requirement for introduction and changes in business processes design and development of business support has to be enough precise and flexible. Business support has to be enough robust that changes in process does not demand much changes in existing system support. Design of system support has to be such that implementation is as far possible easier and faster. It is especially important in cases where many of business processes are complex.

One of the possible kind of business process design was given in this paper. Business process was modelled with the aim to allow easier and faster implementation of complex business processes through the system support for telecommunication service provisioning. Business process implemented in workflow system has to be independent in relation to system support platform and focused on actions which are needed for service provisioning in telecommunication network.

UML activity diagram was taken like tool for modelling business processes. Diagram is suitable for modelling of business processes and obtained model is suitable for understanding of requested system support for all side included in development. UML is tool which uses graphical presentation of modelled system and this kind of presentation is suitable for specification of business rules, actions and messages between systems [6].

II. MODEL OF COMPLEX BUSINESS PROCESS

Business processes in telecommunication have to ensure all possible scenarios in service provisioning and every scenario has impact on some of network elements, CPE, kind of service installation, manual work of technician on network or customer side [6]. Basic elements of business process model were defined in [5].

These elements are:

A. Start and end nodes

Denote start and finish of the business process and corresponding subprocesses.

B. Manual tasks

These are activities which represent tasks for job. Job belongs to some of the participants of the business process.

C. Outgoing and incoming signals

Signals perform interaction between systems which participate in business process.

D. Subprocesses

Contain similar actions in the business process or actions which are repeated more times in one business process or in more processes.

E. Decision nodes

Denote decision which branch in process will be chosen. It depends about the option chosen in manual task, data from CRM system, network elements or answer from the other system.

F. Split node

Denotes place where two or more parallel branches started in the process.

G. Join node

Denotes place where two or more parallel branches are joined in the process.

H. Time control

Time control which finishes waiting for an answer which the system is asking after an outgoing signal.

I. Process interruption

This is moment when CRM system cancels a process. It could be happened at any moment during the process and it will not be modelled here.

In [5] these elements were described in detailed. Syntax of UML diagram activity corresponds to these denominated elements [5], [6].

Critical moment in such design of telecommunication process is decision how to use parts of the process within the possible scenarios which are part of service provisioning. Part of the process which presents similar activities in telecommunication network could be module and process is consisted of these modules. For example, module could be activities for network configuration before manual actions in the network or manual actions in the access network. Process construction from the modules should be easy. Every scenario is represented by single process. Every change in service provisioning should be easy made by change in the single module.

Model of the process is made by basic elements which are modules. Module is presented by subprocess and module itself is mainly made from one or more subprocesses. On the lower level subprocesses has another elements like signals or manual tasks. In a case of complex process consisted of activities which are related to more services every module is a set of activities related to only one service. It is important to respect before mentioned rule that module is a set of similar activities in telecommunication network. Thereby model gain in flexibility and simplicity of implementation. Service provisioning is consisted of more scenarios which are constructed from modules like base units.

III. EXAMPLE OF MODELLING COMPLEX BUSINESS PROCESS

Like example of modeling complex business processes, processes related to VoIP connection was taken. VoIP connection is a relatively simple process which is consisted of several basic modules. These modules are technical feasibility for service, network configuration and actions on the field and during the service activation. Modules were chosen like one unit. In the process depicted on figure 1 end of the one module is condition for start of the following one. Here all business logic is located in modules. Structure of the modules will be described later in the text. It should be noted that process defines all what is needed to do to connect service. It includes needed actions and correct order of these actions. Architecture of the systems for business support is not considered because focus is on business process and way of implementation must follow these rules.

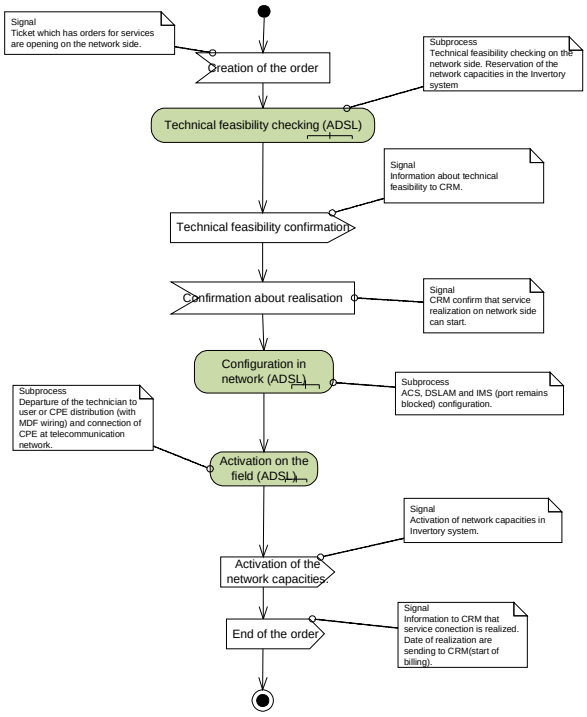

Figure 1: Process for VoIP connection over ADSL

Of course relatively simple process for VoIP connection is not only possible situation during the service provisioning. There is connection of the other services together with VoIP, relocation of the ADSL alone or with the other customer connections, disconnection of the service, disconnection of the service because customer crossing to other Operator with or without number portability, temporary disconnection and so on. Some of these scenarios could be covered with the existing process for VoIP connection, but for the most ones there is need for new processes. From the above it is obvious that business process modeling for telecommunication service provisioning is very complex and demanding. Figure 2 depicts one of the possible scenarios. Process is much more complex than single process for VoIP connection. Here we have actions on two different location and three possible situations. Customer can request service disconnection now, on defined date and when service will be connected on the new location. Because of that in this process level decision nodes are needed. It is needed to stress again modules are basic units and process is constructed from them. Figure 3 depicts another scenario where ADSL connection has to be disconnected because customer is crossing to another Operator. Process is simpler and rule is: first prepare the network for crossing of the customer to another Operator and then disconnect the service.

Since the service provisioning for telecommunication service has many scenarios it is needed to provide fast and effective creation of business processes. Using modules it is possible to create processes combining these modules. Every module has its defined role. Change in one module could have impact on more processes. Therefore it is necessary to define modules on optimal way that change in module does not cause additional changes in basic processes.

Next level of modeling is modeling of modules. Figure 4 depicts module “Configurations in network (ADSL)”. Module contains flow with actions which are directed to configuration of network elements for ADSL connection. Which actions and subprocesses will execute in module depends on input data, result of previous actions, result of automatic configuration of network elements and result of communication with the other systems in system support. Figure 5 depicts subprocess “Switch configuration (LE, IN)” whose execution starts in presented module. Like module, subprocess can contains actions and another subprocesses.

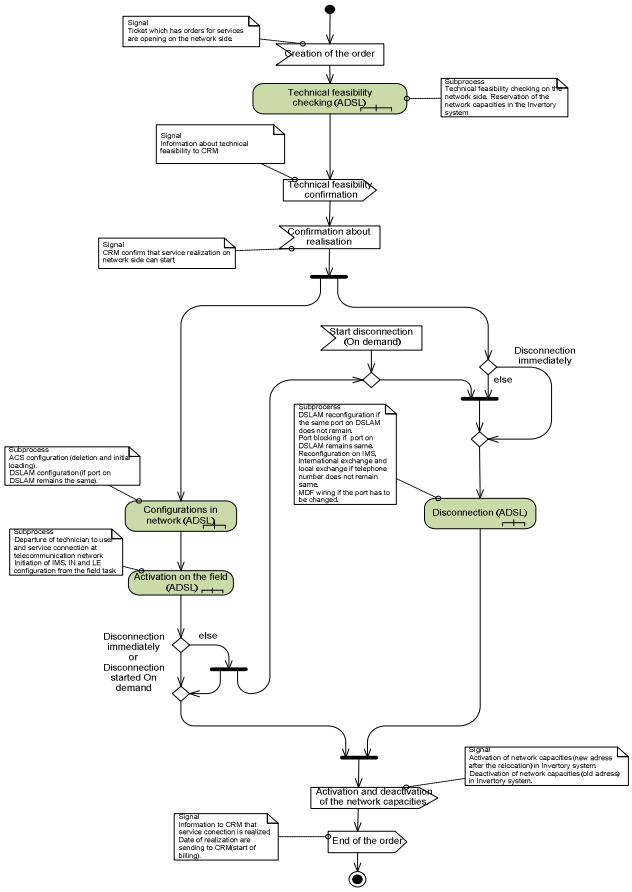

Figure 2: Relocation of the VoIP service together with ADSL connection

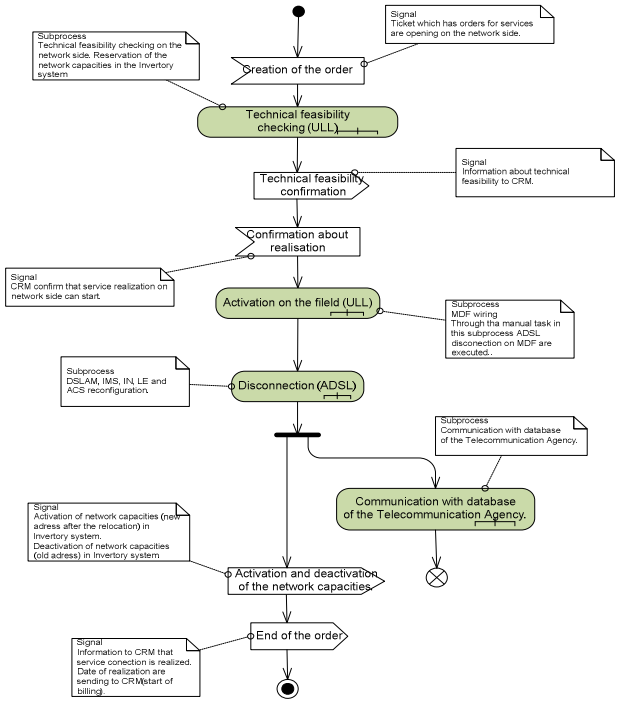

Figure 3: Disconnection of the service because customer is crossing to another Operator

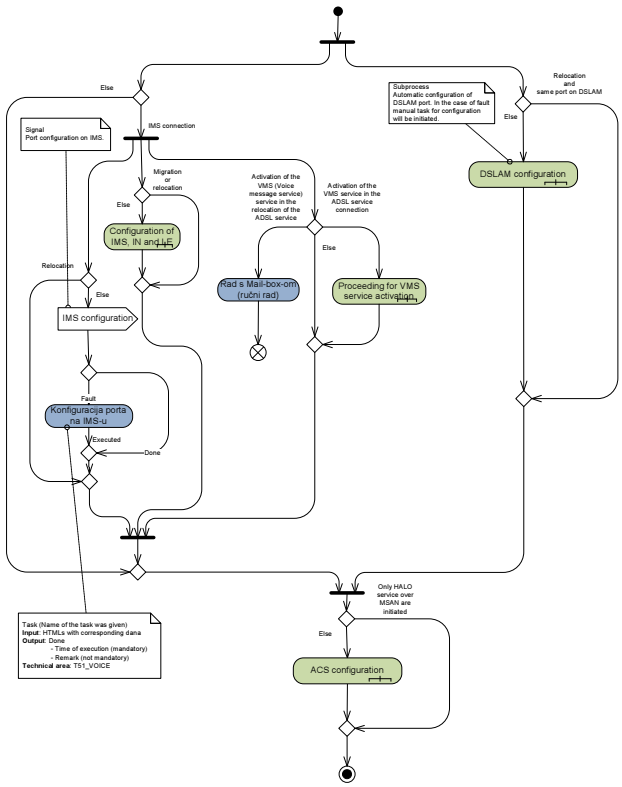

Figure 4: Module “Configurations in network (ADSL)”

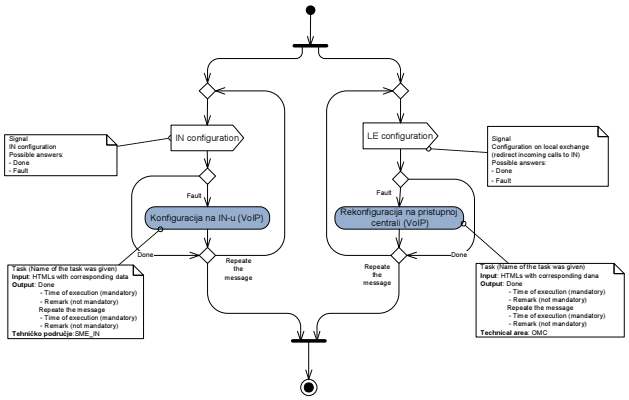

Figure 5: Module “Switch configuration (LE, IN)”

As well as in the case of modules subprocesses in modules have to be designed so the change in subprocess does not cause unnecessary changes in modules or basic processes. Figure 6 depicts subprocess “Configuration on DSLAM”. Subprocess gathers actions related to actions on DSLAM in ADSL connection, change, relocation, suspension or disconnection process. Change in subprocess could have impact on one or more basic process but does not require changes in them. Basic process, for example ADSL connection, is shown simple over modules. Modules contain more details, decision nodes, actions and subprocesses and could be used by one or more basic processes. Subprocesses are deeper in process and could be used in one or more modules. It is very important that one change in existing service provisioning causes one change in module or subprocess and does not causes changes in basic processes. That principle enables flexible and easy change in business processes.

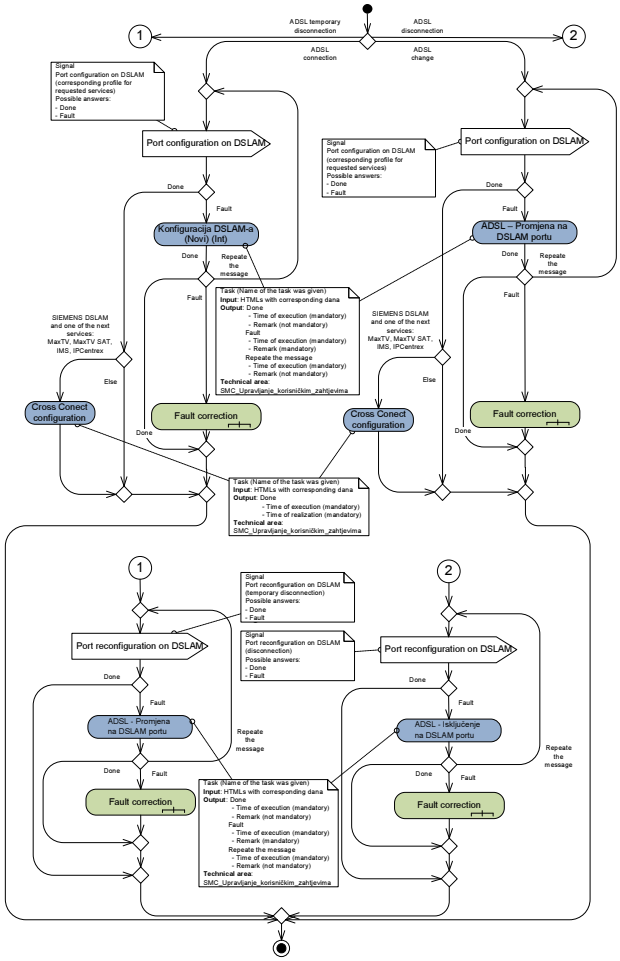

Figure 6: Module “Configuration on DSLAM”

Such kind of modeling business processes for implementation in workflow system is used in HT. Two basic reasons why it was done are to get clear picture of business processes which are needed for service provisioning and to get clearer and simpler model of complex business process. Complex processes are consisted of more simple process related to one of the services and it is need to synchronize actions execution needed for proper provisioning of these services. Such modeling gives good results especially in specification of the points in the complex process where part of the simple process should be synchronized. It is easier to follow required changes in business system support and to avoid mistakes in development of business process for service provisioning.

IV. CONCLUSION

In this paper proposal for one of the possible complex telecommunication business processes modeling was given. Modeling is based on scenarios and modules. Scenario is

one of the possible business processes which can be appear during the service existence and module is a basic unit for business process constructing together with the basic business rules. Model itself comprises actions, business rules and subprocess related to similar activities in telecommunication network. It is important to design modules on optimal way. Module could be use in more processes and change in module does not cause additional change in basic processes.

Proposed way of modeling business process allows flexible and clear design of process provisioning for telecommunications service. Business processes are focused on actions which are need for service activation and they are independent of system support platform.

Evaluation of a development framework for a mobile gaming platform with financial transfers

R. Hable*, E. Platzer*
* Evolaris Next Level GmbH, Graz, Austria
richard.hable@evolaris.net

Abstract - Mobile gaming is a research field of growing interest due to increasing usage numbers and revenue rates. The increases are mostly caused by improvements of mobile devices and networks that enable better performance and usability of mobile games. In this paper a new framework for the development in a mobile gaming platform environment is presented. The gaming platform includes financial transfers that require specific precautions in the development process as well as in the maintenance of the platform. The development framework is evaluated in a comparative research design against other available frameworks that also meet most of these specific requirements. Evaluation criteria applied in the comparative setting are efficiency and effectiveness in form of development effort and expenses. As a result we present the differences between frameworks as well as disadvantages and advantages of our framework regarding economic as well as technical target values.

I. INTRODUCTION

We present and evaluate a framework intended to support mobile gaming on mobile phones.

The requirements for products based on this framework include supporting a large range of devices by all major mobile phone producers and operating systems. The games have to be competitive on both simple low-end mobile phones and powerful high-end smart phones. In addition to the gaming component, it is also necessary to support financial transfers based on game success. Thus, user account handling, transaction security, and prevention of fraudulent manipulation have to be an integral part of the system.

It is obvious from the requirements that tightly integrated server and client components are required to allow game development and operation with reasonable investment of resources. Existing frameworks do not meet these demands. Therefore, a new framework has been designed based on the comprehensive requirements and the current state of technology.

Major challenges during framework design were finding reasonable compromises between development effort and gaming user experience, and facilitating both responsiveness and security of game play with limited connectivity on the mobile Internet.

In the following chapters we first describe the current state of practice concerning development of client-server platforms for mobile devices. Then we present the main design decisions and structures of our framework. Finally, we show the results of a comparison with other frameworks and concepts based on the method of comparative analysis. The paper concludes with some remarks on both a general and a specific level.

II. STATE OF PRACTICE

A. General Situation

Contrary to server software and desktop client software, development for mobile devices is characterized by fragmentation into several largely varying operating systems and frameworks with non-neglectable market share [1]. Additionally, the distribution of market share and even the operating systems used by single manufacturers are changing rapidly [2].

B. Development Strategies for Mobile Devices

In order to provide competitive products for a large market share, normally several different versions have to be created with little, if any, code reuse. However, several frameworks are available which try to unify development on different device classes while still providing the specific look-and-feel and taking advantage of their unique hardware capabilities [3].

Another approach is to create server-centric software and thus to minimize client-specific code as much as possible, e.g. in [4]. The main task of the client software then is to interpret commands sent from the server. Most interactions with the user are based on business logic implemented by server software, which can be the same for all mobile clients.

One may even choose to create web applications instead of native applications and thus avoid installing application-specific software on the mobile devices altogether [5]. These applications rely on the common capabilities of web browsers pre-installed on modern smart phones. This, however, can lead to poor user experience caused by weak performance and the inability to use the native APIs of the mobile devices [6]. Nevertheless, platform-specific extensions can be used to approximate native look-and-feel to some extent.

C. Development of Mobile Games

The main task of many mobile applications is to provide information to the user either edited locally or gathered from the Internet. These requirements can

usually be fulfilled both in native and in web applications. Mobile gaming often requires taking advantage of the full hardware and operating system capabilities of the device in order to be competitive. Thus, native programming with largely different development environments [7] can be absolutely necessary.

However, even high-performance, stand-alone games can profit from server support, e.g. in order to allow central multi-player user management and sharing of game scores [8].

In the case of mobile games which include financial transfers security aspects become additional design criteria. In principle the more operations are server-based, the more control can be enforced over user actions and thus fraud can be detected more easily.

D. The Role of Frameworks

When creating non-trivial applications for mobile devices, in addition to principal software design decisions it is important to carefully select tools, libraries and frameworks to be used for the implementation. Since a large number of both commercial and open-source frameworks is available, one would rarely exclusively use the tools recommended by the manufactures of mobile devices.

Both server- and client-side frameworks can be used to significantly reduce development effort and expenses. On the client side, they usually offer the opportunity to unify development [3] and thus allow code sharing across mobile device classes. On the server side, they allow implementing support services for the mobile applications based on existing software, e.g. with efficient low-level communication support [9].

III. FRAMEWORK DESIGN

A. A New Development Framework

The comprehensive requirements for the gaming platform necessitate coordinated selection and application of methods and tools. In particular, the necessity to support secure financial transfers requires complete control over both user actions and server transactions.

Back office support for accounting and payment can be implemented in a quite straight-forward way as server software using established technology like the Java Platform, Enterprise Edition (Java EE) [10] for security and scalability. Nevertheless, integration and deployment have to be carefully aligned with real-time game play.

Development of actual games and the required server support has to deal with a lot of uncertainties and also restrictions concerning the supported devices and game features. Therefore, this is the part where the important design decisions and concrete implementations of the new framework come into play.

B. Deployment Architecture

The framework has to integrate itself into the client and server landscape installed for the gaming platform. Due to a large number of potential customers using the platform at the same time and high reliability demands, the platform has to be deployed on several, partly redundant physical servers. Most of these aspects can be ignored during game development, since game play is independent from the division of tasks between the supporting servers. However, the games have to be flexible enough to connect and reconnect to different server instances according to dynamically adapted game server assignments.

The following main software artifacts are involved in the operation of the gaming platform:

- Game Client: an application running on mobile phones communicating with a dedicated game server.
- Game Server: server software supporting and controlling game play. It communicates both with an assigned number of game client instances and the back office.
- Back Office: server software supporting accounting and payment. It provides the game server with user account information and receives information about game results.

Game clients are available for different operating systems, all of them using the same communication protocol. Unified interfaces between clients and servers allow sharing code between different devices and game types. This also significantly reduces testing effort and the risk of undiscovered security holes.

The server software is tightly connected with file repositories and database management systems for game delivery and logging purposes. Reliable full-fledged logging is especially important, since financial transfers are involved, which must be reproducible particularly in case of legal disputes.

C. A Rather Thin Client

The most crucial decision in framework design has been to define the division of tasks between game client and game server. User experience considerations for conventional mobile games normally lead to native clients for optimal performance. Network communication with its limited speed and frequent delays is avoided whenever possible.

In our framework, however, we must maintain a tight connection between game clients and their assigned game servers. The game server always has to know about the current state of game play in order to be able to respond appropriately to situations like unexpected game termination. The user should not lose credit gained during game play due to technical problems. On the other hand, it must not be possible to cheat by interrupting game play intentionally before losing a game.

It was, therefore, necessary to find a solution which combines continuous client-server communication with high performance and responsiveness in order to gain both an attractive gaming experience and the necessary security and monitoring of game play. This was achieved in two ways: using an efficient communication protocol between the client and the server, and supporting complex

independent client actions for performance-critical tasks like animated graphics. Additionally, in order to avoid having to transfer large amounts of data from the server to the client, all graphics and sounds used within a game are preinstalled.

Thus, the framework strives for a client-server model combining centralized application logic and security of thin clients with performance and user experience of rich clients.

D. Communication Protocol

As a consequence of the centralized application logic, communication between game client and game server is a performance critical part of the gaming platform. The framework also has to cope with widely varying hardware capabilities of the mobile devices concerning connection speed and reliability.

Based on earlier experiences with binary TCP and UDP protocols, it was decided to develop a custom binary TCP-based game message protocol (GMP) usable for all communication between game clients and servers independently of mobile device classes. This protocol supports transferring structured game data objects (GDOs), which are based on basic data types like integer values and character strings. Values are encoded as sequences of varying length, depending on the required range and precision, in order to minimize the number of transferred bytes and thus required transmission time.

GDOs are transferred within independent packets in both directions. The protocol takes care of automatic reconnection in case of connection problems and automatic recognition of transmission losses. Thus, it frees the game designer and the game client developer from handling most exceptional cases possible during communication on the Internet.

In order to prevent manipulation of transferred data all communication has to be encrypted. Therefore the TCP network connection is secured with Transport Layer Security (TLS) by default.

E. Commands and Messages

Client-server communication is controlled by the server sending event messages. These messages contain command GDOs which tell the game client to perform actions like drawing graphical objects on the screen or playing sound appropriate to the game flow.

Some of these commands can take a significant amount of time to perform, e.g. when showing an animation. However, the client does not have to wait for received commands to be completed before accepting new commands. Instead, it stores all commands within separate queues according to queue numbers assigned by the server. Commands within different queues are executed in parallel. In order to allow synchronized execution of commands, special compound messages are supported, which block execution within a queue until all included commands are finished.

The client may respond to server commands with information about user actions like pressing a button on the mobile phone. The server will then adapt game flow accordingly.

F. Game Resources

All graphics and sounds required for a game are stored in the game client. Game designers have to provide these resources for a large number of different devices. Different image formats, resolutions and color depths are used to show graphics adapted to the capabilities of these devices. Similarly, different audio formats and different bit rates are required to support sounds on all devices.

In addition to device-specific versions of resources, it is also possible to define different themes for each game. This way, different variants of the same game can be created without having to change code in the game software.

In order to easily keep track of available resources and to create device-specific game client versions, all resources of a game are specified within a device resource definition file. This is an XML file containing elements which assign unique numeric identifiers to resources referenced via file paths. These identifiers are sent to the game clients within server commands during game play for efficient retrieval of embedded resources.

G. Code Generators

In order to reduce development effort for changes and extensions, generators are provided which create server and client code usable by the target systems.

1) GDO Classes

The structure of GDO objects is defined in a custom interface definition language (IDL). An IDL file contains names and components of all data objects transferable between client and server. The GDO generator program analyzes this file and creates one class definition for each GDO. The programming language Java is used for server code and Java-based game clients. Objective-C is used for iOS clients, JavaScript for web application targets.

2) Device Resource Classes

In order to easily access resource objects within game clients the device resource generator program analyzes device resource definition files and creates classes retrieving resources embedded in the game client. The game client implementers can use this class to load resources like graphics and sound into memory in a format suitable for the operating system APIs.

IV. METHODOLOGY

A. General Approach

The framework is evaluated against other systems using the method of comparative analysis. Different criteria like development effort and user experience are examined which may even be in conflict with each other, allowing only an estimation of the quality of the achieved compromise rather than an absolute grading.

B. Comparison Targets

Our framework is based on several design decisions which are not always self-evident. Therefore, we do not restrict ourselves to evaluating it only against frameworks providing similar concepts and functionality. Instead, we also look at separate aspects of the framework, which could have been handled quite differently.

1) Technology

Before even considering different frameworks, technical implementations have to make basic choices about the technology used. We include technological decisions in our comparison because they are just as important as the actual features provided by different frameworks.

Sometimes such decisions are obvious: enterprise applications which should not be restricted to a single operating system will almost always use Java Enterprise Technology [10]. Server frameworks will then be restricted to products which can be used with Java application servers. Since this was the case with our framework, we do not compare it to systems based on different server technology. Instead, a comparison between the framework approach depending closely on J2EE configuration mechanisms and a similar framework with additional provisioning support [11] is made.

The requirements for our framework also include support for a large number of different mobile phone types. Therefore, we do not consider solutions based on technology which can only be used with a single class of devices. Based on this need to support mobile phones with largely varying capabilities in a uniform server environment, we compare the method chosen for network communication with other possible approaches.

2) Framework Scope

Our framework is specifically intended to support different types of mobile games with centralized server support and high security demands. Therefore, we only consider in our comparison other frameworks and methods which could be used to achieve similar goals. Stand-alone gaming frameworks or frameworks tailored for only one specific type of game are not included.

We therefore compare native client development as used in our framework with possible cross-platform development methods.

TABLE I. DEPLOYMENT ARCHITECTURES

Strategy	Consequences		
	Supported Game Clients	***Real-Time Capability***	***Development Complexity***
J2EE-based game server assignmenta	mobile phones	no	low
Adaptable according to client types	PDAs, mobile game consoles, mobile phones, PCs, arcade machines	not on mobile phones	high

a. Framework

V. RESULTS AND DISCUSSION

A. Deployment Architecture

For any mobile game using centralized services e.g. to share game results, it is a logical step to distinguish between game clients and game servers. However, frameworks and possible strategies vastly differ concerning the task distribution and the server landscape used to support a potentially large number of players for different games on different platforms.

See Table I for a comparison of the main deployment options.

1) Multi-Platform Support

Reference [12] describes server support for an even wider variety of platforms than our framework: In addition to mobile phones, also potentially less connected PDAs and mobile game consoles, but also high-performance PCs, game consoles, and even arcade machines are supported. Nevertheless, the server architecture is characterized by (multi-platform) game servers and additional back-end servers for CRM and billing similar to our framework. A prototype first-person shooting game was implemented; however, only PC and arcade machine users were able to perform real-time actions, probably due to the limited network connectivity of the smaller devices.

2) Provisioning and Services

Our framework is mainly concerned with run-time game support, leaving administrative tasks to explicitly programmed and configured software on the J2EE application server level. Other platforms as described in [11] try to relieve game providers from managing the system infrastructure. Services are installed which support game provisioning, collect game metrics, and support game content distribution with a sophisticated peer-to-peer architecture for network communication.

Since in our framework all game resources are embedded within the game clients, special content distribution support is not necessary. Data transfer rates between game clients and game servers are therefore similar for all clients. Servers can be assigned fixed numbers of players per game based on empirical measurements without the need for dynamic load balancing.

B. Communication

With efficient client-server communication being crucial for user experience, frameworks attach great importance to highly efficient network communication when trying to allow real-time gaming even with mobile phones. Table II gives an overview of the different strategies which are described in the following subchapters.

1) Leveraging the Mobile Network

A mobile gaming platform based on the 3GPP IP Multimedia Subsystem (IMS) [13] takes advantage of the specific features of the third-generation (3G) mobile data network. Different Quality of Service (QoS) levels allow optimizing network utilization according to the needs of specific gaming tasks. The pre-defined IMS message

TABLE II. NETWORK COMMUNICATION

Strategy	Consequences		
	Encoding Efficiency	***CPU Load***	***Network Latencies***
Binary IP-based[a]	good	low	medium
Protocol buffers	good	low	medium
IMS Standards	medium	high	variable
Text-based (compressed)	medium (very good)	low (high)	medium (medium)

a. Framework

types can be used to support interactivities between players. The platform uses both the Media Gateway Control Protocol (Megaco) for session control and an XML-based protocol for game related information. Standardized IMS services are also used for game distribution and provide a frame for administrative tasks.

Compared to our framework, this platform offers more possibilities for fine-tuning e.g. concerning different QoS levels. Adhering to the IMS standards and protocols, however, significantly limits freedom of design of the overall architecture of the framework. Also, the principal problems of networking efficiency could not be overcome in the described prototype implementation: a game (volleyball) with high requirements concerning network delays was not playable via the GPRS network. Other measurements [14] show that the same is valid for the UMTS network.

2) Optimizing the Protocol

Responsiveness and throughput also depend strongly on the protocol and data format used.

When using stream-based communication such as in IP connections some kind of request-response pattern has to be implemented. In case of our framework data packets are exchanged between game servers and game clients. A simple non-standard binary encoding is used in order to minimize the amount of data that has to be transferred. According to [15] using an efficient binary format compared to uncompressed textual standard formats significantly improves performance on the smartphone. With the binary Protocol Buffers [16] format data size could be reduced by between 40 and 60 % compared to the textual XML and JSon formats. Reference [15], however, also shows that highly compressed textual formats are even more efficient than the binary protocol concerning data size.

Therefore, it seems that using a compressed textual standard format would be a good alternative to the binary encoding used in our framework. This would allow using standard libraries for encoding and decoding of messages instead of having to manually implement serialization and deserialization for the server software and the different client systems. However, it is not clear if using standard JSON or XML parsers plus effective compression libraries would be efficient enough on all supported low-end mobile phones.

3) Coping with Network Latencies

Even the most efficient protocol cannot eliminate the principal delays which occur during communication between game servers and game clients via mobile Internet connections. Reference [17] shows that even delays below 100 ms are noticeable by players of first-person shooter games. This shows that architectures with server-side game control are simply not suitable for some types of games.

Game designers also have to be aware that different mobile devices and reception qualities can lead to different amounts of delays. The odds of winning or losing a game must never depend on the speed of delivery of information to the user.

C. Client Development Frameworks

Although our framework supports game clients for a large number of mobile devices and operating systems, it does not use any existing cross-platform framework to reduce development efforts. We will compare this development approach with alternatives described in the following subchapters. See Table III for an overview of the consequences.

1) Pure Web Applications

Due to the requirement of efficient performance on low-end devices and competitive performance on high-end devices, offering a game client as pure web application was not considered satisfactory. However, it would be possible to aim for hybrid solutions as recommended in [6] and described in the following chapters.

2) Embedded Web Applications

Web applications can be embedded within native applications using tools like PhoneGap as described in [6]. JavaScript libraries like JQuery Mobile and Sencha Touch can then be used to achieve near-native look-and-feel and to access to some operating system APIs. This leads to a unified programming language (JavaScript) and unified screen design with HTML and CSS style sheets.

However, advanced JavaScript libraries are only available for high-end devices, and the framework has to provide good user experience for low-end devices too. Web applications would also lead to lower graphical performance and less efficient client-server communication on all devices due to the exclusive use of

TABLE III. CLIENT DEVELOPMENT

Strategy	Consequences		
	User Experience	***Flexibility***	***Development Effort***
Native Clients[a]	very good	very high	high
Pure web applications	poor	low	low
Embedded web applications	medium	medium	low
Cross-platform framework	good	high	medium

a. Framework

Web technologies.

3) Cross-Platform Frameworks

Commercial products like Rhodes Rhomobile and Appcelerator Titanium create native code for smart phones based on a unified development environment [18]. In principle, this allows creating applications with performance and user experience similar to native applications.

These products, however, are not available for simple phones. Therefore, they would only help to unify development on some smartphones targets. The additional requirement to use a different development environment and possibly a different programming language seems to make this an endeavor with doubtable benefits.

Instead of that the framework unifies development to a certain amount with common portable Java libraries.

VI. CONCLUSION

A plethora of different tools and frameworks is readily available for developers of both client and server software. This includes software specifically designed to support mobile gaming. Therefore, one might ask if developing yet another framework makes sense both concerning financial resource investment and successful accomplishment of project goals.

However, any major software development project requires an agreed-upon overall structure and consistent use of tooling in order to avoid creating a system resembling the tower of Babel. Overall design decisions have to be made, and generally usable support code connecting existing components for the project at hand has to be created. A framework targeted to specific project requirements is just a step further in the same direction.

The design of our framework has shown that even broad requirements like different game types on different devices can be supported largely with unified concepts. Thus, development of a gaming platform can certainly profit from this custom-made framework. Also, the comparison with other systems and alternative approaches has shown that our framework is competitive with regard to development effort and achieved product quality.

The framework has been specifically designed to allow adding new target platforms and new game types with little development cost. It is not necessary to extend existing game clients in order to allow for new game concepts. Similarly, it is not necessary to change existing games when new target platforms are added.

Nevertheless, the principal structure of the framework with its generic game clients and tight client-server integration imposes some limits on the possible types of games and achievable user experience. Network communication limits, for example, preclude real-time action games, and the necessity to support largely different target platforms prohibits game designers from taking advantage of all advanced hardware capabilities of high-end devices. Both problems will, however, become less severe in the future due to improvements in network connectivity and hardware capabilities even of low-end devices.

In summary we consider the framework a success. The design decisions proved themselves reasonable in comparison with other systems and concepts. Still there is room for improvement concerning new game types, future mobile phone platforms, and general functionality.

Abstract – As specific systems in substations develop and improve, there appears a greater need for remote control and communication. The company's own optical infrastructure is primarily used for the purposes of business and process network. Because of their geographical setting, certain substations cannot be connected by optical cables. Instead, rented connections are being used, and, more and more often, wireless connections that help reduce renting costs and increase safety. In substations, business network (e-mail, internet, intranet...) is used occasionally, and process network (systems of remote guidance, measuring, managing...) is used constantly whereby it is necessary to separate the data flow of these two networks. The usual way to separate these two networks within the optical infrastructure is by means of VRF-Lite technology, which should also be implemented for the wireless connections of substations. This makes the wireless technology even more complex. Increased data safety, the availability of the wireless network, and return on investment in wireless equipment justify the use of this technology for the purpose of connecting substations in a unique IP network of HEP. The analyzed case describes and tests the wireless network connecting the substation Brodsko Brdo 35/10 kV over substation Slavonski Brod 110/35 kV onto IP network, which meets the requirements of both the business and the process network.

I. INTRODUCTION

Connecting specific locations in a unique IP network becomes more demanding every day. Own optical infrastructure is not available at all locations where communication is necessary, therefore connecting is solved by connections renting, and more recently with the use of wireless technology, where there are conditions for that. The basic requirement for wireless connectivity of locations is optical visibility without obstacles and specific maximum distance determined in respect to the wireless devices used. This paper describes the wireless technology and the separation of process and business network during connection of the substation Brodsko Brdo 35/10 kV and the substation Slavonski Brod 1 110/35 kV.

II. BUSINESS AND PROCESS INFORMATICS IP NETWORK

HEP telecommunication network provides all types of communication in performing everyday functions, and also in the process of substation management. HEP's basic telecommunication transport network is based on optical conductors that are embedded in a protective roping of high-voltage transmission lines, and on underground optical fiber and copper cables, with the use of the latest technology (DWDM, CWDM, SDH, IP, ...).

The access network consists of CWDM backbone with the capacity of n x 1 Gbit/s and uses Gigabit Ethernet switching/routing technology. All HEP's locations and objects, on which the optical infrastructure is available, can be connected with CWDM technology. There are redundant paths on the most of the nodes that further enhance the availability parameters. CWDM is technology of multiplexing the signals on optical fiber by using the GBIC (Gigabit Interface Converter), multiplexers and add/drop multiplexers. Multiservice IP network is used primarily for business network, but there is a growing number of requests for connecting remote system management of process network system for substations.

HEP's multiservice IP network was built under all international standards, using the latest technology, therefore it enables the following:

- separation of remote system management traffic into a separate segment,

independently of other traffic (separate VPN);
- provides a high availability of a system (99,9% – 99,99%);
- allows the use of QoS (Quality of Service) parameters to ensure the required transmission speed, delays, etc.

The basic requirements that are set for increasing the security of process network are inability to access the computers, servers and associated services, and the security of data within the process network. Since the already built business network is used as the network infrastructure, it is necessary to somehow separate the IP traffic of process and business network on a logic layer. Therefore, a VPN network for data transfer is created in the process network. One of technologies that meet these requirements is the VRF-Lite technology because separate routing protocols can be carried out on the same active network device, both for business and for the process network of remote system management.

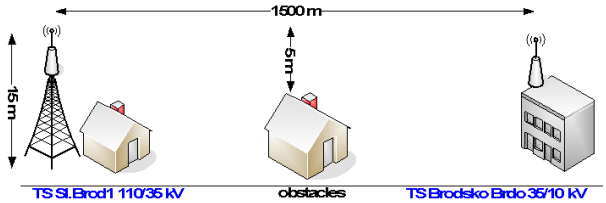
VPN (Virtual Private Networks) provide a secure way for customers to share bandwidth over an IP backbone network. A VPN is a collection of sites sharing a common routing table. A customer site is connected to the network by one or more interfaces, and the service provider associates each interface with a VPN routing table. A VPN routing table is called a VPN routing/forwarding (VRF) table. VRF-lite is a feature that enables a service provider to support two or more VPNs, where IP addresses can be overlapped among the VPNs. VRF-lite uses input interfaces to distinguish routes for different VPNs and forms virtual packet-forwarding tables by associating one or more Layer 3 interfaces with each VRF. Interfaces in a VRF can be either physical, such as Ethernet ports, or logical, such as VLAN SVIs, but a Layer 3 interface cannot belong to more than one VRF at any time.

III. WIRELESS NETWORK

Optical infrastructure is the basis for connecting all the objects in a unique IP network, used either for the needs of business or the process network. Construction of the optical pathways towards some locations requires longer time period, and the needs for connecting systems are growing. Locations that are not on the main routes of optic or the connection on the optics is anticipated in a longer time period, connect over the rented connections and recently, more frequently through the wireless connections wherever possible. Some locations are only a few kilometers distant from the nearest location with the optical infrastructure, but they are not in the plan for connecting on the optical infrastructure. For such places, communication for the purpose of business and process networks can be solved by wireless connection. Example of such location, which is connected through the wireless connection, is TS Brodsko Brdo 35/10kV. Optical visibility and distance of 1500 meters from TS Slavonski Brod 1 110kV enable a quality connection on multiservice IP network through the wireless connection. TS Sl. Brod1 110/35kV and TS Brodsko Brdo 35/10 kV are connected through wireless point-to-point connection, as presented on picture 1.

For the realization of this wireless network, following devices were used:
- AIR-BR1310G-E-K9-R, access point designed for installation in outdoor conditions
- AIR-ANT1949 Antenna (2.4 GHz) for installation in outdoor conditions
- AIR-CAB100ULL-R ultra low loss coaxial antenna cable

As shown in Picture 1, antennas should be installed so that they are 4-5 meters above the highest obstacle (as recommended by the manufacturer's specification)
Antenna at the TS Sl.Brod1 TS 110/35 kV was placed on a top of the antenna column (~ 15 m), and at the location of the TS Brodsko Brdo 35/10 kV antenna was mounted on a wall of the substation (~ 8 m in height), which is all to ensure the needed optical visibility. Power supply was solved by using power injectors, which have the task to deliver the required voltage through the UTP cable, which is used to connect wireless devices to the rest of the existing IP network. According to manufacturer's specifications, in the conditions shown in Picture 1 and with the equipment used, the average communication speed is 5.5 Mbit/s. Table I. shows transfer speeds taken as a statistic result from the wireless device. It can be seen that the most data was transferred at a rate of 1 Mbit/s, although higher speeds were also represented but to a lesser extent.



Picture 1. – Point-to-point wireless connection

Measuring of speed and of transmitted packets was done in the time period of 30 days. Other parameters of wireless communication from manufacturer's calculations are given in Table II.

TABLE I. STATISTICS OF DATA SPEED TRANSMISSION

	Bytes Recieved
Rate 1.0 Mbps Statistics	3601605866
Rate 2.0 Mbps Statistics	144236
Rate 5.5 Mbps Statistics	2001132
Rate 6.0 Mbps Statistics	2447157
Rate 9.0 Mbps Statistics	3939854
Rate 11.0 Mbps Statistics	9004351
Rate 12.0 Mbps Statistics	14241768
Rate 18.0 Mbps Statistics	39369381
Rate 24.0 Mbps Statistics	98192341
Rate 36.0 Mbps Statistics	177680613
Rate 48.0 Mbps Statistics	165125650
Rate 54.0 Mbps Statistics	24157885
Total Host Bytes Received	4137910234

TABLE II. PARAMETERS OF WIRELESS CONNECTING

Max Distance (w/ min 5dB Link Margin)	2,32 km
Earth Bulge at above distance	1,5 m
Fresnel Zone clearance for above distance	5,1 m
Required antenna height above obstructions	6,6 m

Table II. confirms the parameters that are used at locations and they are in accordance with recommendations of the wireless connection equipment manufacturer.

Wireless point-to-point network uses its own VLAN 140 and its own subnetwork 10.226.250.72/28 allowing 4 IP adresses for devices that are conected through the wireless link. Connecting this subnet onto the rest of the network is done by OSPF (Open Shortest Path First) protocol, as well as the entire IP network. Wireless bridge device on the location TS Sl.Brod 1 110kV is defined as the root bridge. For mutual identification of wireless devices pre-shared key with WPA (Wi-Fi Protected Access) authentication and TKIP (Temporal Key Integrity Protocol) encription is used. Defined SSID (Service Set IDentifier) does not announce itself as a broadcast and thus it is not visible under the standard scaning for wireless network. To connect additional devices to this existing wireless network it is necessary to know this information, but since the network is only meant for connection of two locations, connection and authentication of clients who would use this wireless connection is disabled. Access to used wireless devices is provided through connection with console cable and with telnet, using username and two-level password, so called access and enable password. The main wireless device settings are given in the following examples.

Example 1. General settings of wireless bridge:

```
dot11 ssid NAME
  vlan 140
  authentication open
  authentication key-management wpa
  infrastructure-ssid
  wpa-psk ascii 7 PRE-SHARED KEY
```

Example 2. Settings of wireless interface:

```
interface Dot11Radio0
 no ip address
 no ip route-cache
 encryption vlan ID mode ciphers tkip
 ssid NAME
 speed basic-1.0 2.0 5.5 6.0 9.0 11.0 12.0 18.0 24.0 36.0
48.0 54.0
 power local cck 20
 power local ofdm 20
 station-role root bridge
 cca 75
 concatenation
 infrastructure-client
```

A. *Separation of the process and business network on the wireless link*

Separation of the business and process network is done using VRF-Lite technology that enables individual traffic and separate routing tables within the same device. Business and process network are separated from each other with special VLANs, which are defined at the end-user interfaces. A specific user interface is added to a specific VLAN. The specificity of using the VRF-Lite technology lies in the fact that specific routing tables are defined for each network using separate OSPF routing protocols. Since the wireless technology has only one interface it is necessary to create new virtual interfaces in order to separate different networks. For this purpose, virtual interfaces are created:

```
interface Dot11Radio0.140
 encapsulation dot1Q 140 native
 no ip route-cache
 bridge-group 1
!
interface Dot11Radio0.3017
 encapsulation dot1Q 3017
 no ip route-cache
 bridge-group 2
```

In this case VLAN 140 is used for the business informatics network and VLAN 3017 for the process informatics network. Also, on the other side, where the wireless device is connected onto the rest of the network through the cable, virtual interfaces are defined:

```
interface FastEthernet0.140
 encapsulation dot1Q 140 native
 no ip route-cache
 bridge-group 1
!
interface FastEthernet0.3017
 encapsulation dot1Q 3017
 no ip route-cache
 bridge-group 2
```

For each network, separate OSPF routing protocol is defined on the next Layer 3 network device.

IV. THE PROS AND CONS OF WIRELESS CONECTIVITY

The main reason for using wireless technology in connecting locations to unique IP network is to be independent from external network service providers. Problem solving communication is easier with the devices where possibility of immediate intervention exits as opposed to situation where external network service provider has to be involved in problem solving process. Another reason is to reduce the costs of communications network renting since the calculation leads to information that investment in wireless technology pays off already after 1-2 years, depending on the speeds that are rented from the external network service providers. The data transfer rate of wireless connection is typically greater than the speed of rented connections.

When using own wireless network higher availability is recorded in comparison to rented connections because the external network service provider often announces interruptions in certain sections of rented connections. Although the scheduled interruptions occur during the night, for the process informatics system such interruptions can mean a serious problem. With rented connections, the frequency of unexpected problems on the network is also very common, and problem solving depends on external network service providers, while with own infrastructure problem solving can be started immediately.

The basic security of wireless network is solved by configuring point-to-point network that does not allow connection of additional clients to this wireless network. The main parameter of the wireless network (SSID) is not announced, the authentication of end-devices is performed by using the WPA Protocol with pre-shared key and TKIP encryption. When using rented connection, packets go through devices of external network service provider, therefore safety and integrity of data may be impaired.

V. CONCLUSION

Optical infrastructure is often unavailable to certain locations outside of the main optical paths, but the connectivity is needed because of the increasing number of systems that require constant communication with the rest of the network. Such locations are substations, which are on a greater or lesser distances from the objects that are equipped with optical infrastructure. One way to connect these isolated locations is the use of connections rented by the external network service providers or by the use of the wireless communication. The use of wireless communication reduces the costs of renting the communication paths. Although initial costs are higher, over a certain period of time investment proves to be cost effective. Data transfer speeds satisfy the required bandwidth and with the development of the technology it is possible to multiply the speed increase in comparison to the speed of the rented connections. The process network security problem is solved in the same way as with the optical infrastructure, using VRF-Lite technology. In that way, there is no deviation from the process network secure policy. Wireless network security meets the basic criteria, although there is room for improvement, which would raise the safety to a higher level.

e-mail: boris.jukic@ericsson.com

Posljednjih nekoliko godina dolazi do velikih promjena u telekom sektoru. Od visoko profitabilne industrije koja je godinama bilježila rast poslovanja, telekom industrija u posljednje vrijeme prolazi kroz turbulentno razdoblje. Telekom operatori, suočeni s padom prihoda i sve većim pritiskom na održanje korisničke baze u području fiksne telefonije, traže nove izvore prihoda uz zadržavanje vlastitih korisnika i privlačenje novih korisnika. Uz već postojeće napredne tehnologije za fiksni i mobilni prijenos podataka, IP televizija je prepoznata kao jedan od glavnih pokretača razvoja poslovnih modela telekom operatora.

Osnovna ideja ovog rada je sagledati utjecaj IP televizije na evoluciju poslovnih modela telekom operatora u Hrvatskoj, a temeljni doprinos rada je sadržan u rezultatima provedenog empirijskog istraživanja.

Rezultati empirijskog istraživanja, koje je obuhvatilo 436 ispitanika iz cijele Hrvatske, daju uvid u preferencije i očekivanja hrvatskih korisnika na IPTV uslugu, te daju smjernice za daljnji razvoj IPTV poslovnih modela telekom operatora u Hrvatskoj.

Poznavanje navika i očekivanja krajnjih korisnika je nužan preduvjet za prilagodbu korisničkih paketa. Integracijom IPTV usluge s klasičnim komunikacijskim uslugama, telekom operatori su u mogućnosti ponuditi krajnjim korisnicima nove inovativne usluge prilagođene njihovim željama i potrebama koje se mogu konzumirati bilo kad, bilo gdje i na bilo kojem uređaju.

I. UVOD

Doživljaj gledanja televizije godinama je bio istovjetan. Nekoliko različitih tehnoloških skokova koji su se dogodili u posljednjih 80-tak godina, kao što su uvođenje televizije u boji, izum daljinskog upravljača, pojava videorekordera te televizora ravnih ekrana, nisu bitno promijenili doživljaj gledanja televizije. Do prije nekoliko godina televizor je služio prvenstveno za gledanje TV programa, te filmova putem različitih kućnih uređaja za reprodukciju. Osobno računalo se koristilo za potrebe posla, edukacije, traženja informacija putem interneta i dr. Iz perspektive konzumiranja video sadržaja računalo se uglavnom koristilo za gledanje sadržaja generiranog od strane krajnjih korisnika (engl. *user generated content*) te u određenoj mjeri za gledanje filmova, dok je gledanje TV programa putem računala bilo zanemarivo. Pojavom Internet protokol televizije (IPTV) došlo je do velikog skoka u evoluciji televizije. Po prvi puta je internetsko (PC) iskustvo konzumiranja video sadržaja, koje uključuje personalizaciju i interaktivnost, preneseno u dnevni boravak. U kombinaciji s ležernošću koju nudi gledanje video sadržaja na velikom ekranu televizora, gledateljima je omogućen potpuno novi doživljaj gledanja televizije.

Telekom operatori su prepoznali IPTV uslugu kao glavni pokretač koji će generirati rast poslovanja njihovih kompanija narednih 10-tak godina. U kombinaciji s mobilnom televizijom tradicionalna televizija će u bliskoj budućnosti evoluirati u konvergentnu televiziju koja će istovremeno biti interaktivna i personalizirana.

IPTV usluga u Hrvatskoj je već ostvarila značajan uspjeh u svjetskim razmjerima. Primjerice, IPTV usluga na svjetskoj razini zauzima 5% tržišta distribucije televizijskog sadržaja i 2% svjetskih kućanstava. Hrvatska s penetracijom IPTV usluge od 25% trenutno zauzima 4. mjesto u svijetu, dok primjerice vodeći Hong Kong ima penetraciju od 37% [1].

Upravo zbog toga jedan od glavnih čimbenika za uspjeh i daljnje širenje IPTV usluge u Hrvatskoj je kvalitetna ponuda prilagođena hrvatskim potrošačima. S obzirom da svako tržište, pa tako i hrvatsko, nosi svoje specifičnosti, dobro poznavanje navika i očekivanja potrošača je ključ za uspjeh. Tu se prvenstveno misli na što kvalitetnije kreirane korisničke pakete, gdje je pravilna ravnoteža između cijene, mogućnosti kreiranja paketa po vlastitoj želji, dodatne usluge i naravno kvaliteta presudna za uspjeh IPTV usluge, a pogotovo u usporedbi s drugim načinima distribucije televizijskog sadržaja (zemaljska televizija, kabelski operatori, satelitska televizija, itd.).

Cilj ovog znanstvenog rada je istražiti utjecaj IPTV usluge na razvoj poslovnih modela telekom operatora u Hrvatskoj. Kroz empirijsko istraživanje cilj je sagledati očekivanja hrvatskih korisnika na IPTV uslugu u budućnosti, identificirati glavne motive za korištenje IPTV-a te koje od dodanih usluga su hrvatskim korisnicima najatraktivnije.

II. INSTRUMENT ISTRAŽIVANJA

Osnovni instrument istraživanja je anketni upitnik [2] koji se sastoji od 11 pitanja, a koji je kreiran u skladu s problemima istraživanja.

Anketni upitnik se sastoji od tri skupine pitanja:

- Opći podaci o ispitaniku
- Ciljana pitanja o trenutnim preferencijama te motivima za korištenje IPTV usluge

- Ciljana pitanja o očekivanjima hrvatskih korisnika na IPTV uslugu u budućnosti

Za potrebe ovog istraživanja korištena je metoda slučajnog uzorka te se vodilo računa da uzorak bude reprezentativan. Ovim anketnim upitnikom prvenstveno je ciljana skupina radno sposobnog stanovništva u Republici Hrvatskoj. S obzirom na ciljanu skupinu poželjno je da uzorak bude čim veći, kako bi uzorak bio reprezentativan. Korišten je neizravan i izravan pristup pri provođenju anketnog upitnika i to koristeći WEB anketu te direktnim anketiranjem koristeći anketni upitnik u tiskanom obliku.

III. UZORAK I NAČIN PRIKUPLJANJA

Anketu je sveukupno popunilo 436 sudionika (tablica I.). Radi provjere reprezentativnosti uzorka izračunat ćemo interval pouzdanosti (engl. *confidence interval – CI*) uz 95% razinu pouzdanosti u varijanti „najlošije" proporcije od 0,5 (proporcija za koju je interval pouzdanosti najveći) [3].

TABLICA I: VELIČINA UZORKA

Uzorak prikupljen koristeći on-line WEB anketu	373
Uzorak prikupljen koristeći anketu u tiskanom obliku	63
Ukupni uzorak	**436**

Interval pouzdanosti izračunavamo po formuli,

$$CI = Z_{0,025}\sqrt{((p(1-p))/n)}, \quad (1)$$

gdje je koeficijent pouzdanosti $Z_{0,025}$ za 95% razinu pouzdanosti očitan iz tablice površine ispod normalne distribucije iznosi 1,96, p je proporcija od 0,5 dok je n veličina uzorka 436. Prema tome, interval pouzdanosti iznosi 0,0469. Dakle, u ukupnoj populaciji s 95% sigurnošću možemo reći da je proporcija u rasponu od 0,5±0,0469 te sukladno tome možemo ustvrditi da uzorak od 436 ispitanika predstavlja reprezentativan uzorak u ispitivanoj populaciji.

Segmentacija uzorka je rađena po spolu, te po dobnoj skupini. Za potrebe istraživanja uzorak je segmentiran u 5 dobnih skupina. S obzirom da je prema statistici svjetske zdravstvene organizacije [4] prosječni očekivani životni vijek u Hrvatskoj 76 godina (72 godine za muškarce, te 79 godina za žene), napravljena je segmentacija na 5 jednakih dobnih skupina u rasponu od 15 godina. Dobne skupine su: 15 ili manje godina, 16 – 30 godina, 31 – 45 godina, 46 – 60 godina, te 61 i više godina. Kako istraživanje cilja radno sposobno stanovništvo, relevantni su rezultati za četiri „gornje" dobne skupine odnosno za populaciju stariju od 15 godina.

IV. REZULTATI ISTRAŽIVANJA

U tablici II. Možemo vidjeti distribuciju uzorka prema spolu i dobnoj skupini. Kako istraživanje cilja radno sposobno stanovništvo Hrvatske, jedan odgovor iz dobne skupine 15 ili manje godina možemo zanemariti.

Odluke vezane uz odabir i korištenje IPTV usluge u prvom redu donose osobe iz kategorije radno sposobnog stanovništva te je i bilo za očekivati da osobe mlađe od 15 godina neće biti zainteresirane za sudjelovanje u anketi, što su rezultati ankete i pokazali.

TABLICA II: DISTRIBUCIJA UZORKA PREMA DOBNOJ SKUPINI I SPOLU

	Spol				
Dobna skupina	**M**	**%**	**Ž**	**%**	**Ukupno**
15 i manje	0	0%	1	0,2%	1
16 - 30	111	25,6%	68	15,6%	179
31 - 45	125	28,7%	62	14,2%	187
46 - 60	20	4,6%	30	6,9%	50
61 i više	7	1,6%	12	2,8%	19
	Ukupni uzorak				**436**

A. *Motivi za korištenje IPTV usluge*

Motivi za korištenje IPV usluge analizirani su kroz dva pitanja u anketnom upitniku, gdje se jedno pitanje fokusira na motive za uvođenje/promjenu IPTV usluge, dok je drugo pitanje usmjereno na analizu važnosti postojećih mogućnosti odnosno funkcionalnosti u sklopu IPTV usluge.

Prvo pitanje glasi: *„Koji su po Vama glavni motivi za uvođenje/promjenu IPTV usluge?"*, a ponuđeni su slijedeći odgovori:

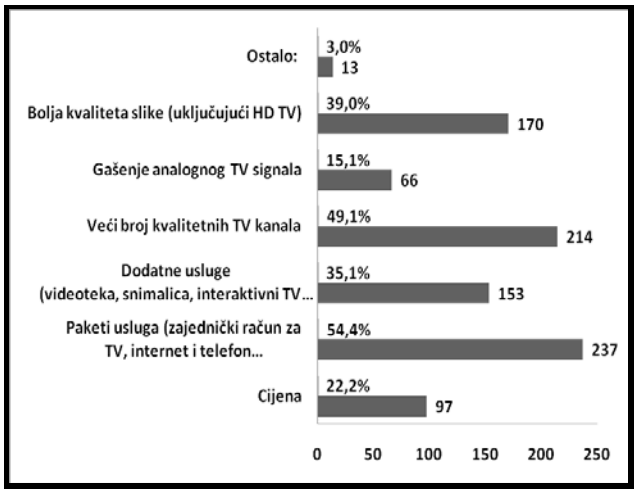
- Cijena
- Paketi usluga (zajednički račun za TV, internet i telefon (2u1, 3u1, Duo, Trio))
- Dodatne usluge (videoteka, snimalica, interaktivni TV vodič, usluga vremenskog pomaka, itd.)
- Veći broj kvalitetnih TV kanala
- Gašenje analognog TV signala
- Bolja kvaliteta slike (uključujući HD TV)
- Ostalo:.

Između ponuđenih odgovora moguće je bilo odabrati više odgovora, ali do maksimalno tri ponuđena odgovora, s obzirom da u velikoj većini slučajeva motiv za uvođenje IPTV usluge nije jednoznačan, već više različitih faktora doprinosi odluci o uzimanju ili promjeni IPTV korisničkog paketa.

Na slici 1. možemo vidjeti koji su glavni motivi za uvođenje odnosno promjenu IPTV usluge.

Najveći broj ispitanika (54,4%) vidi pakete usluga kao glavni motiv za uvođenje ili promjenu IPTV usluge.

Na drugom mjestu s 49,1% je veći broj kvalitetnih TV kanala, dok je na trećem mjestu s 39% bolja kvaliteta slike. Dodatne usluge s 35,1% također su visoko pozicionirane na listi motivacijskih faktora za uvođenje i promjenu IPTV usluge.



Slika 1: Glavni motivi za uvođenje ili promjenu IPTV usluge

Drugo pitanje je usmjereno na analizu važnosti postojećih mogućnosti odnosno funkcionalnosti u sklopu IPTV usluge. IPTV usluga, u usporedbi s „tradicionalnom“ distribucijom TV signala koristeći radiodifuziju, nudi puno više od samog prijama TV programa. Osnovna razlika su dodatne interaktivne usluge kao videoteka, snimalica i dr.. Sve trenutno dostupne funkcionalnosti u sklopu IPTV usluge nemaju jednaku „vrijednost“ za korisnike. Sagledavanje trenutnih preferencija hrvatskih korisnika važno je i radi boljeg razumijevanja budućih očekivanja korisnika na IPTV uslugu.

U istraživanju je napravljena analiza deset „uobičajenih“ mogućnosti/funkcionalnosti u sklopu IPTV usluga koje su trenutno dostupne na hrvatskom tržištu. Provjera važnosti pojedine mogućnosti/funkcionalnosti IPTV usluge, napravljena je koristeći petostupanjsku Likterovu[1] ljestvicu, odnosno skalu procjene. Važnost u skali procjene je kodirana od 1 (za nevažno) do 5 (za jako važno).

U tablici IV. vidimo usporedbu srednje vrijednosti, standardne devijacije te koeficijenta varijacije svih varijabli koje su ispitivane.

Uspoređujući rezultate iz tablice IV. interesantno je za primijetiti da koeficijent varijance skoro pa linearno raste s padom srednje vrijednosti ispitivane varijable. Odnosno, rezultati za varijablu s većom srednjom vrijednosti su ujedno i homogeniji. To nam ukazuje na činjenicu da su ispitanici prvenstveno ocjenjivali funkcionalnosti koje su im važnije, u rasponu od srednje važno do jako važno, te je ujedno koeficijent varijacije za te varijable manji. Manje važne funkcionalnosti, su različito ocjenjivane. Dio ispitanika ih je ocijenio u rasponu od nevažno do manje važno, dok se dio ispitanika odlučio za „neutralnu“ ocjenu, srednje važno. Iz tog razloga proizlazi činjenica da je koeficijent varijacije puno veći za varijable s nižom srednjom vrijednosti.

[1] Prema autoru Rensisu Likteru (1903 – 1981)

TABLICA IV: SREDNJA VRIJEDNOST, STANDARDNA DEVIJACIJA I KOEFICIJENT VARIJACIJE SVIH ISPITIVANIH VARIJABLI

Varijabla	Srednja vrijednost	Standardna devijacija	Koeficijent varijacije
Kvaliteta slike (uključujući HD kanale)	**4,289**	**0,899**	**20,96%**
Veliki broj/izbor TV kanala	4,000	1,001	25,03%
Videoteka (s velikim brojem/izborom filmova)	2,963	1,273	42,97%
Snimalica (snimanje TV programa bez dodatnih uređaja u kući)	3,085	1,256	40,70%
Paketi usluga (zajednički račun za TV, internet i telefon (2u1, 3u1, Duo, Trio))	3,677	1,220	33,18%
Prikaz broja pozivatelja na TV-u	2,484	1,214	48,87%
Internet preko TV-a	2,839	1,251	44,06%
Roditeljska zaštita (ograničenje pristupa djeci neprimjerenom sadržaju)	3,239	1,407	43,45%
Interaktivni TV vodič (EPG)	3,438	1,209	35,15%
Usluga vremenskog pomaka (pauziranje programa, vraćanje na početak, itd.)	3,479	1,189	34,17%

Rezultati pokazuju da još uvijek dobar dio korisnika od IPTV usluge očekuje veću kvalitetu „bazične“ usluge, odnosno veću kvalitetu prijama TV kanala (bolju sliku). To ukazuje na činjenicu, da je prijam i kvaliteta TV kanala „van“ IPTV usluge na nezadovoljavajućem nivou te korisnici uzimanjem IPTV pretplate prvenstveno očekuju poboljšanje kvalitete TV signala. Osim kvalitete slike, visoko na ljestvici važnosti je i veći broj te izbor TV kanala. U Hrvatskoj je, do unazad nekoliko godina, većina korisnika za prijam TV signala koristila analognu zemaljsku TV antenu. Dio tih korisnika je osim analogne TV antene u paraleli koristio i satelitsku antenu (bilo analognu ili digitalnu). Tek manji dio korisnika je koristio kabelsku televiziju za prijam TV signala. Korisnici kabelske televizije već duže vrijeme mogu uživati u kvalitetnijem TV signalu, iako kvaliteta analogne kabelske televizije nije na razini digitalnog prijama TV signala, još uvijek je ta kvaliteta daleko veća od kvalitete koja se, u prosjeku, mogla dobiti koristeći analognu TV antenu.

Hrvatska spada među zemlje s najvećom penetracijom IPTV usluge na svijetu (na 4. mjestu) [1], dok je penetracija kabelske televizije niska. Niska penetracija kabelske televizije je ujedno zaslužna i za veliki uspjeh IPTV usluge u Hrvatskoj. To ujedno pojašnjava razloge visoke važnosti kvalitete slike i velikog izbora TV kanala kod hrvatskih korisnika što je postalo dostupno većem broju korisnika tek dolaskom IPTV usluge.

Iako su IP televizija i kabelska TV tehnološki potpuno različite, iz perspektive krajnjeg korisnika to su vrlo slične usluge. Primarna namjena i jedne i druge tehnologije je distribucija televizijskog signala do krajnjih korisnika odnosno pretplatnika. Ono što čini razliku između pojedinih načina distribucije televizijskih kanala je doživljaj krajnjeg korisnika, bilo da je riječ o kvaliteti prijama, dodatnim uslugama i dr.

B. IPTV usluga u budućnosti

Očekivanja hrvatskih korisnika na IPTV uslugu u budućnosti je analizirano kroz pitanje koje glasi: „*U sklopu IPTV ponude u budućnosti, rado biste vidjeli?*“. U samom pitanju ponuđeno je više različitih funkcionalnosti, mogućnosti odnosno koncepata koje trenutno nisu dostupni u sklopu IPTV ponude u Hrvatskoj, te se od ispitanika tražilo da identificiraju funkcionalnost ili koncept koji bi željeli vidjeti u sklopu IPTV ponude u budućnosti. Svaki ispitanik ima mogućnost odabrati više različitih funkcionalnosti ovisno o vlastitim preferencijama.

Na izbor su ponuđene slijedeće funkcionalnosti odnosno koncepti:

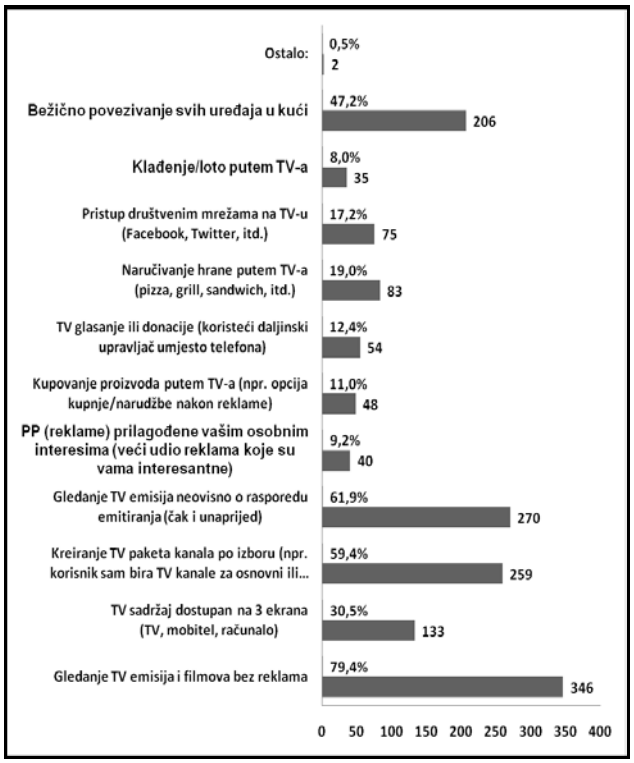
- Gledanje TV emisija i filmova bez reklama
- TV sadržaj dostupan na 3 ekrana (TV, mobitel, računalo)
- Kreiranje TV paketa kanala po izboru (npr. korisnik sam bira TV kanale za osnovni ili proširen paket)
- Gledanje TV emisija neovisno o rasporedu emitiranja (čak i unaprijed)
- PP (reklame) prilagođene vašim osobnim interesima (veći udio reklama koje su vama interesantne)
- Kupovanje proizvoda putem TV-a (npr. opcija kupnje/narudžbe nakon reklame)
- TV glasanje ili donacije (koristeći daljinski upravljač umjesto telefona)
- Naručivanje hrane putem TV-a (pizza, grill, sandwich, itd.)
- Pristup društvenim mrežama na TV-u (Facebook, Twitter, itd.)
- Klađenje/loto putem TV-a
- Bežično povezivanje svih uređaja u kući
- Ostalo:

Treba naglasiti da je sve navedene funkcionalnosti ili koncepte tehnički moguće već danas realizirati, pitanje je samo investicije u tehničko rješenje, te kreiranja adekvatnog poslovnog modela.

Kako bi se određena dodatna usluga ponudila pretplatnicima potrebno je zadovoljiti više različitih kriterija:

- implementirati tehničko rješenje potrebno za realizaciju te usluge,
- provjeriti postoje li određena ograničenja za realizaciju same usluge,
- provjeriti postoje li kakve pravne zapreke za realizaciju takve usluge,
- dogovoriti s vlasnicima sadržaja prava na distribuciju sadržaja i sl.

Međutim, da bi uopće krenuli u sve ove aktivnosti, telekom operatori prvo moraju analizirati koje su to usluge koje će biti prihvaćene od strane hrvatskih korisnika. Kako svaka država nosi svoje specifičnosti, uspjeh usluge u jednoj državi ne garantira uspjeh u drugoj državi. Stoga, bolje razumijevanje preferencija i očekivanja hrvatskih korisnika na IPTV uslugu u budućnosti je preduvjet za osiguranje uspjeha plasmana određenog korisničkog paketa ili nove napredne usluge/funkcionalnosti.



Slika 2: Funkcionalnosti ili koncepti koje bi hrvatski korisnici željeli vidjeti u sklopu IPTV ponude u budućnosti

Na slici 2. vidimo koje od ponuđenih funkcionalnosti ili koncepata bi hrvatski korisnici najradije vidjeli u sklopu IPTV ponude u budućnosti. Kako je svaki ispitanik mogao odabrati više različitih funkcionalnosti odnosno koncepata, tako i suma svih odgovora uvelike prelazi veličinu uzorka.

Čak 79,4% svih ispitanika željelo bi imati mogućnost gledanja TV emisija i filmova bez reklama. Na drugom mjestu funkcionalnosti ili koncepata, rado viđenih u sklopu IPTV ponude u budućnosti, je gledanje TV emisija neovisno o rasporedu emitiranja (čak i unaprijed) sa 61,9%. Treće mjesto zauzima kreiranje TV paketa kanala po izboru za što se izjasnilo 59,4% ispitanika. U koncept koji preferira veći broj ispitanika spada još i bežično

povezivanje svih uređaja u kući što bi rado imalo na raspolaganju 47,2% svih ispitanika.

Interesantno je napraviti analizu, postoji li razlika u očekivanjima hrvatskih korisnika na IPTV uslugu u budućnosti ovisno o dobnoj skupini?

TABLICA V: USPOREDBA RANGIRANJA RAZLIČITIH FUNKCIONALNOSTI/KONCEPATA OVISNO O DOBNOJ SKUPINI

	Dobna skupina			
Funkcionalnost/koncept	**16-30**	**31-45**	**46-60**	**61 i više**
Gledanje TV emisija i filmova bez reklama	82,7%	74,9%	80,0%	94,7%
TV sadržaj dostupan na 3 ekrana (TV, mobitel, računalo)	35,2%	27,3%	26,0%	31,6%
Kreiranje TV paketa kanala po izboru (npr. korisnik sam bira TV kanale za osnovni ili prošireni paket)	60,3%	63,6%	42,0%	57,9%
Gledanje TV emisija neovisno o rasporedu emitiranja (čak i unaprijed)	65,9%	66,3%	46,0%	26,3%
PP (reklame) prilagođene vašim osobnim interesima (veći udio reklama koje su vama interesantne)	9,5%	9,1%	6,0%	10,5%
Kupovanje proizvoda putem TV-a (npr. opcija kupnje/narudžbe nakon reklame)	10,6%	12,3%	6,0%	15,8%
TV glasanje ili donacije (koristeći daljinski upravljač umjesto telefona)	8,9%	15,5%	16,0%	5,3%
Naručivanje hrane putem TV-a (pizza, grill, sandwich, itd.)	22,9%	18,2%	12,0%	10,5%
Pristup društvenim mrežama na TV-u (Facebook, Twitter, itd.)	19,0%	18,7%	12,0%	0,0%
Kladenje/loto putem TV-a	11,2%	7,0%	2,0%	5,3%
Bežično povezivanje svih uređaja u kući	49,2%	47,1%	48,0%	31,6%

U tablici V. možemo vidjeti usporedbu kako je određena funkcionalnost ili koncept rangiran ovisno o dobnoj skupini. Podcrtano je označeno kojoj dobnoj skupini je koja funkcionalnost/koncept najatraktivnija.

Primjećujemo da je „gledanje TV emisija i filmova bez reklama“ najatraktivnija funkcionalnost svim dobnim skupinama u usporedbi s ostalima funkcionalnostima ili konceptima, međutim, tu se izdvaja najstarija dobna skupina, 61 i više godina, gdje čak 94,7% ispitanika te dobi bi rado imalo navedenu funkcionalnost dostupnu unutar IPTV ponude u budućnosti. Osim toga, navedena dobna skupina se također ističe i u preferiranju PP (reklama) prilagođenim njihovim osobnim interesima (10,5%), te mogućnosti kupovanja proizvoda putem TV-a (15,8). Očito je da stariju populaciju najviše smetaju reklamni blokovi koji „prekidaju“ TV emisije i filmove.

Najmlađa dobna skupina koja je analizirana, od 16 do 30 godina, prednjači u preferiranju nekoliko različitih funkcionalnosti/koncepata. Ako analiziramo koje su to funkcionalnosti/koncepti koje mlađa populacija (16-30 godina) više preferira u usporedbi s ostalim dobnim skupinama, vidimo da su to stvari koje velika većina već sad konzumira koristeći druge tehnologije (internet, mobilna telefonija, i dr.), te bi ih rado vidjela i u sklopu IPTV ponude.

Tako npr. mlađa populacija bi najradije vidjela mogućnost pristupa Facebooku ili Twitteru koristeći TV uređaj (19%), dok starijoj populaciji ta funkcionalnost uopće nije interesantna (0%).

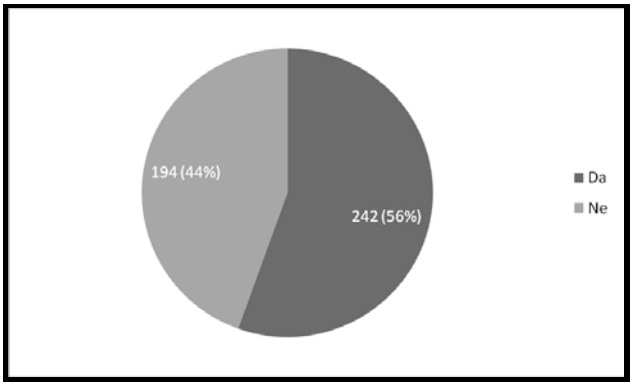
Činjenica da starija populacija najviše preferira mogućnost gledanja TV emisija i filmova bez reklama, a mlađa populacija se ističe u preferiranju mogućnosti pristupa Facebooku ili Twitteru je očekivana. Međutim, činjenica da starija populacija u usporedbi s ostalim dobnim skupinama najviše preferira ciljano oglašavanje i mogućnost kupovine preko TV-a, može biti donekle iznenađujuće, s obzirom da bi mogli prije očekivati da će te funkcionalnosti biti atraktivnije mlađim korisnicima. Ovo još jednom dokazuje da je radi boljeg upoznavanja preferencija i očekivanja hrvatskih korisnika potrebno napraviti kvalitetnu analizu.

Ovakav podatak može biti od iznimne koristi marketinškim kućama pri osmišljavanju kampanja, a također daje uvid telekom operatorima koja populacija je najpoželjniji segment za ciljano oglašavanje.

Nakon što je napravljena analiza koje su to funkcionalnosti/koncepti koje bi hrvatski korisnici htjeli vidjeti u sklopu IPTV ponude u budućnosti, interesantno je pogledati jesu li hrvatski korisnici spremni platiti neke od dodatnih usluga koje su identificirali kao poželjne.

Jedno od pitanja iz anketnog upitnika analizira spremnost hrvatskih korisnika na plaćanje dodatnih naprednih usluga.

Na slici 3. možemo vidjeti koji je postotak ispitanika u ukupnom uzorku spreman platiti dodatne napredne usluge.



Slika 3: Jeste li spremni dodatno platiti neke od gore navedenih usluga?

Rezultati pokazuju da je ipak većina ispitanika (njih 56%) spremno dodatno platiti neke od navedenih naprednih usluga.

Analizom rezultata prethodnih pitanja dolazi se do saznanja o očekivanjima hrvatskih korisnika na IPTV uslugu u budućnosti te spremnosti na plaćanje tih istih usluga, te koje su razlike između različitih segmenata populacije (dobne skupine i spol).

Rezultati ovog istraživanja uvelike mogu pomoći telekom operatorima prilikom kreiranja novih korisničkih paketa.

V. ZAKLJUČAK

S ciljem boljeg razumijevanja smjera evolucije IPTV usluge u Hrvatskoj, provedeno je istraživanje o preferencijama i očekivanjima hrvatskih potrošača u pogledu IPTV usluge.

Kao rezultat istraživanja napravljena je analiza glavnih motiva za korištenje IPTV-a, identificirane su dodatne usluge koje su hrvatskim korisnicima najatraktivnije, te je napravljen uvid u očekivanja hrvatskih korisnika na IPTV uslugu u budućnosti.

Na kraju, može se zaključiti da će rezultati ovog istraživanja doprinijeti razvoju ovog području, te će pružiti kvalitetan uvid u sklonosti i očekivanja hrvatskih korisnika u pogledu IPTV usluge, što će pomoći telekom operatorima u Hrvatskoj pri osmišljavanju novih poslovnih modela.

NETWORK MANAGEMENT

An Optimum Scheme for WiMAX Bandwidth Management Using Dynamic Channel Allocation

Abstract - WiMAX is a promising technology that provides broadband wireless access and supports high data rate, wide service coverage, and strong QoS. The uplink bandwidth management in WiMAX networks is one of the important issues that requires effectively allocating the bandwidth among contending users according to their services. In this paper, an efficient bandwidth management scheme, named WiMAX Dynamic Channel Allocation Scheme (WDCAS), is proposed. The scheme uses the cognitive radio for dynamic channel allocation in order to improve the bandwidth utilization while satisfying the QoS requirements. A queuing model based on the maximum entropy principle for performance analysis is introduced, and closed-form expressions for the state probability and the blocking probability are obtained. The simulation results show that the proposed scheme has a better performance than existing schemes, in terms of bandwidth utilization and network throughput.

Keywords: Bandwidth management scheme, Dynamic channel allocation, Maximum entropy, Queuing theory, WiMAX.

I. INTRODUCTION

The Worldwide Interoperability for Microwave Access (WiMAX) is a technology for broadband wireless access. It provides high data rate, wide service coverage and strong quality of service (QoS) [1-4]. WiMAX is based on the IEEE 802.16 standard for Broadband Wireless Access, and it has two main types: Fixed WiMAX, based on the IEEE 802.16-2004 standard [5], and Mobile WiMAX, based on the IEEE 802.16e-2005 standard [6]. Fixed WiMAX is designed for providing fixed broadband services and is usually used as an alternative to cable and DSL. Mobile WiMAX is an improvement of the IEEE 802.16-2004 standard and is designed for providing mobile and fixed broadband services [7,8].

In order to provide QoS, Mobile WiMAX has defined five scheduling service classes for data transport over a connection [6,9]: Unsolicited Grant Service (UGS), Real-Time Polling Service (rtPS), Extended Real-time Polling Service (ertPS), Non-Real Time Polling Service (nrtPS), and Best Effort (BE). Each service class has QoS requirements and is designed for specific applications. The UGS supports real-time streams of periodic fixed-size packets with constant bit rate, such as Voice over IP without silence suppression. The rtPS supports real-time streams of periodic variable-size packets, such as MPEG video. The ertPS supports real-time streams of periodic variable-size packets with minimum data rate and delay, such as Voice over IP services with silence suppression. The nrtPS supports non-real-time streams of variable-size packets that are tolerant to delay, such as FTP. The BE service supports traffic that does not require delay or throughput guarantees, such as HTTP.

WiMAX provides several mechanisms for users to request bandwidth on the uplink. However, the details of how to perform bandwidth allocation are left unspecified. The bandwidth allocation mechanism should guarantee efficient bandwidth utilization and QoS requirements. In this paper, a new bandwidth management scheme using dynamic channel allocation [10-13] is proposed to improve the bandwidth utilization and meet the QoS requirements of different service classes. The proposed scheme uses the cognitive radio [14-17] for dynamic channel allocation among the users. Cognitive radio allows secondary (unlicensed) users to communicate over the channel (spectrum band) allocated to primary (licensed) users when they are not fully utilizing it. In our scheme, the BE service class acts as a secondary user which means it can use channels that are unused by the other service classes (i.e.; the primary users). A queuing model based on the maximum entropy principle [18,19] is introduced for evaluating the performance of the proposed scheme. The scheme is modeled as interacting multiclass queues from different classes that are contending for the channel access, and closed-form expressions for the state probability and the blocking probability are obtained.

Recently, several bandwidth management schemes in WiMAX networks have been proposed. Closely related to our work are the two bandwidth management schemes presented in [24]: the WiMAX Complete Partitioning Scheme (WCPS) and the WiMAX Partial Sharing Scheme (WPSS). In WCPS, fixed partitions of the total bandwidth are allocated for all service classes. In WPSS, the bandwidth allocated for a higher-priority class (rtPS/ertPS) can be used by a lower-priority class (nrtPS/BE). However, the higher-priority class can preempt the bandwidth that is being used by the lower-priority class. The main difference between the work in [24] and our work is that we use the concept of cognitive radio, in which the BE service class acts as a secondary user and it can share the bandwidth with all other classes not only with one service class.

The remainder of this paper is organized as follows. Section II provides a detailed description and a mathematical model of the WDCAS proposed scheme. Performance evaluation and simulation results are presented in Section III. The paper is concluded in Section IV.

II. WDCAS PROPOSED SCHEME

A. Overview

The WDCAS bandwidth management scheme basically uses the partial sharing concept introduced in [24] with modifications, in order to improve the bandwidth utilization and increase the total throughput of the network. The scheme still uses the concept of sharing between different classes, but it treats the lowest priority service class, BE, as a secondary user in cognitive radio networks. The BE service class does not get a predefined share of the resources; instead it uses the channels left after each higher-priority class reserves channels for its needs. By exploiting the BE class resources, more channels will be assigned to each higher-priority class and hence increasing the total throughput without affecting the QoS requirements.

In WDCAS, each of the four higher-priority classes (i.e.; UGS, rtPS, ertPS, and nrtPS) is given a fixed number of channels at the beginning of each transmission period. Each of these classes deals with upcoming jobs and uses the available resources. After all the jobs are ready to be served, the BE class takes whatever resources left. Since the BE service is designed to support traffic with no delay guarantee, the BE jobs can wait till the next transmission period.

B. System Description

Assuming a total number of N channels are available at the beginning of a transmission period, the service classes of WiMAX connected users will have the following channel allocation:

UGS is allocated n_1 channels. Apparently, n_1 will be the largest allocation among the three other classes left. These allocated channels are not shared with the other service classes. If c_1 jobs are generated in this class, and due to the low probability of generation of the UGS jobs, it is most probable that c_1 is smaller than n_1, and the QoS for this class is improved.

For rtPS, the number of allocated channels is n_2, where $n_2 < n_1$. Since rtPS is a real-time service, it may require more channels at certain transmission period. Therefore, the concept of partial sharing is used, allowing rtPS to demand a share of the channels allocated to nrtPS. To prevent the delay in the transmission of packets associated to it, the share taken from nrtPS is constrained to a limited number of channels. Moreover, the probability of generation of the rtPS jobs is relatively small, so when c_2 jobs are generated, it is most probable that c_2 is smaller than n_2.

ertPS is allocated n_3 channels ($n_3 < n_2$) and will not be able to share other classes resources, since the BE class is no longer allocated in the resources share. n_3 is still able to serve c_3 upcoming jobs in low and medium traffic scenarios, and it does not affect the total throughput of the system.

nrtPS is allocated n_4 channels that are left after the required channels are allocated to the three higher-priority classes (i.e.; $n_4 = N - (n_1 + n_2 + n_3)$). As in WPSS, nrtPS shares its resources with rtPS; however, this does not affect the total throughput since nrtPS is a low priority class and not delay-sensitive. So whenever n_4 is not covering c_4 jobs, the residual jobs will be delayed to the next transmission period without affecting the QoS.

For the BE service class, no channels are allocated, and it is treated as a secondary user in cognitive radio networks. After all higher-priority classes reserve resources needed for their upcoming jobs, the BE jobs are served using the available channels. Though, uncertain number of channels is available, the BE jobs are limited to n_5 channels in each transmission period, in order to control the flow of the BE traffic in a way that does not affect the total throughput.

C. Mathematical Model

For the four upper classes, the packets generated are Poisson processes and have the following probability of generation:

$$P\ (c_i\ ;\lambda_i) = \frac{\lambda_i\ .\ e^{-\lambda_i}}{c_i!} \tag{1}$$

where:

$P\ (c_i\ ;\lambda_i)$: The probability of generation of c_i jobs in the i-class, $i = 1, 2, 3, 4$

c_i : The number of jobs in the i-class, and

λ_i : The mean arrival rate for the i-class packets.

The probability that c_i jobs will pass to the network and not be queued (processed), is given by:

$$P_{pass}(c_i) = \sum_{c_j}\sum_{c_k}\sum_{c_l} P\ (S) \qquad j,k,l\ \neq i \tag{2}$$

where:

$P(S)$ is the stationary state probability.

It can be shown that the stationary state probability P(S) is given by [25]:

$$P(S) = e^{-(1-\alpha)} \prod_{i=1}^{5} \left\{ \prod_{k=1}^{C} e^{-\beta_{ik}\, s_{ik}\,(S)} . e^{-\gamma_{ik}\, f_{ik}\,(S)} \right\} e^{-\rho_i\, n_i\,(S)} \tag{3}$$

where:

$S = (c_1, c_2, c_3, c_4)$ is the available states,

c_i is the number of jobs served by class i,

c is the total number of jobs in one transmission period,

α, β_{ik}, ρ_i, and γ_{ik} are the lagrangian variables needed for the optimization problem.

The detailed derivation of the mathematical model will be submitted to a Journal for publication.

The blocking probability is given by:

$$P_{b_i} = prob\,\{c_i > n_i\} \quad (4)$$

where:

n_i is the available number of channels assigned for the i- class.

For the BE class, some additions should be done

$$P\,(C_5\,;\lambda_5) = \frac{\lambda_5\,.\,e^{-\lambda_5}}{c_5!} \quad (5)$$

$$P_{pass}\,(c_5) = prob\,\{c_5 < (N - (c_1 + c_2 + c_3 + c_4))\}$$

$$= \sum_{C_1,C_2,C_3,C_4} P(S) \quad (6)$$

under the condition $c_5 < (N - (c_1 + c_2 + c_3 + c_4))$

The blocking probability is:

$$P_{b5}\,(c_5) = prob\,\{c_5 > (N - (c_1 + c_2 + c_3 + c_4))\}$$

$$= 1 - P_{pass}\,(c_5) \quad (7)$$

The average blocking probability is:

$$P_{b5,av} = \sum_{c_5=0}^{n_5} \frac{\lambda_5\,.\,e^{-\lambda_5}}{c_5!}\,.\,P_{b5}\,(c_5)$$

Using equation (7), the average blocking probability becomes:

$$P_{b5,av} = \sum_{c_5=0}^{n_5} \frac{\lambda_5\,.\,e^{-\lambda_5}}{c_5!}\,.\,[1 - P_{pass}\,(c_5)] \quad (8)$$

The average number of packets for the five service classes at any time is:

$$p_{g_t} = \sum_{i=1}^{5} \lambda_i \quad (9)$$

The average number of transmitted packets at a unit time is:

$$p_{t_t} = \sum_{i=1}^{5} \lambda_i [1 - P_{b_i}(c_i)] \quad (10)$$

The utilization is defined as:

$$U = \frac{p_{t_t}}{p_{g_t}} * 100\% \quad (11)$$

For the best utilization, we have to maximize the following constrain:

$$U = MAX\left[\frac{\sum_{i=1}^{5} \lambda_i [1 - P_{b_i}(c_i)]}{\sum_{i=1}^{5} \lambda_i}\right] \quad (12)$$

III. PERFORMANCE EVALUATION

In this section, the performance of the WDCAS proposed scheme is evaluated and compared with the two bandwidth management schemes WCPS and WPSS. In the simulation environment, a constant upload data rate of 1Mbps is assumed, and it supports 100 channels. Poisson distribution was used for data generation and a packet size of 1024 bytes was assumed.

The overall utilization for the three schemes is shown in Fig. 1. It is shown that WDCAS has accomplished a great performance improvement even in high traffic scenarios, and reaches saturation at arrival rate of 14 packets per seconds. For low traffic, WDCAS makes good utilization of the available bandwidth, so improvement in utilization and QoS is achieved.

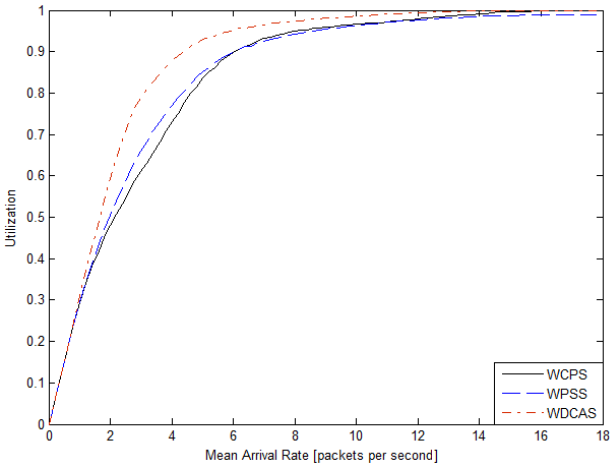

Fig. 1 Overall Utilization

Fig. 2 shows that WDCAS lowers the blocking probability, compared to WPSS and WCPS. Note that WDCAS has a very low blocking probability, taking advantage of using the cognitive radio concept in managing different traffic scenarios.

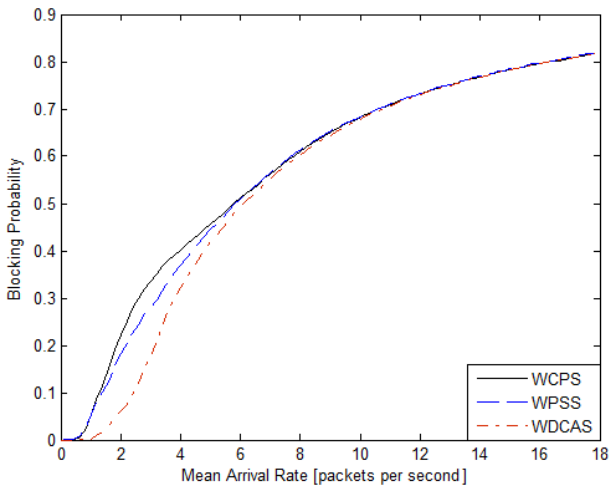

Fig. 2 Blocking Probability

IV. CONCLUSION

In this paper, a new bandwidth management scheme is introduced to improve bandwidth utilization in WiMAX systems. The scheme uses partial sharing and a new concept in the communication field, known as cognitive radio network. Moreover, an analytical model for analyzing the performance of the scheme is presented. The proposed scheme is evaluated and compared with existing schemes for similar traffic scenarios. The results show that the scheme improves the bandwidth utilization and increases the total throughput. Furthermore, the results show that the scheme reduces the blocking probability and reaches the saturation at higher arrival rates.

Abstract - Network throughput and bandwidth overprovisioning do not provide equal quality of service for all applications. Time characteristics of the network must also be taken in mind when deploying applications which are sensitive to delay and jitter, e.g. VoIP. By means of changing the path of traffic significant improvement of the time-variable can be achieved.

In this paper we propose a methodology for optimal link selection based on modeling network characteristics using a Multivariate normal distribution model – cube model. This approach enables real-time identification of reliable links and provides input for a modified composite optimal path selection algorithm. Aside from this our model can be used for determining future network improvements to increase the quality of service.

Keywords. Routing, QoS, Measurement, Network, VoIP, Path, Cube model, Analysis, Design.

I. INTRODUCTION

Sub-optimal traffic distribution in heterogeneous computer networks is the issue we are facing when delivering bandwidth intensive services with QoS guarantees. Usually the decision on which paths to use to forward traffic is left on the interior routing protocol [1], [3] and the process of adding IP telephony functionality to an existing network environment is often cumbersome [2], [4]. Our objective is to optimize the flow of delay sensitive traffic by creating a VoIP backbone overlay in the network in a computationally efficient and effective manner. Two parameters which mostly impact the quality of VoIP traffic are delay and jitter (delay variance) [5], [6]. In our approach, we aim to identify network links which provide minimum delay and jitter by utilizing network probes as a method of active network measurement in production environments. While gathering results continuously, a multi-dimensional data structure is built wherein maxima can be found which represent optimal links for VoIP traffic and these are marked as VoIP backbone components. Further, these VoIP backbone components can be joined by known graph algorithms. Having a VoIP backbone clearly identified in the topology, design considerations apply which can strongly improve the quality of service for VoIP traffic by placing crucial components of the IP telephony architecture (e.g. call managers, gatekeepers, Unity servers, PSTN gateways, border elements, etc.) on the VoIP backbone [7], [8].

II. CONCEPT

We assume a transit IP network (e.g. service provider backbone) which consists of large number of routers and is using an interior gateway routing protocol (e.g. OSPF). Generally, VoIP flows will traverse the best path as chosen by the routing protocol together with ordinary data flows; however this path doesn't have to provide the best time-variables like delay and jitter which are necessary for VoIP traffic (Fig. 1), as in most cases these parameters are not taken into consideration by the routing protocol.

Using standard routing voice-related devices can be placed arbitrarily as there is no specific VoIP backbone [9]. In our approach standard routing will be divided into two independent routing instances, one will be used for data flows (existing one) and the second one will be used inside the determined optimal VoIP backbone based on our proposed network modeling. As the VoIP backbone has to be a continuous network [10], it will consist not only of the best links chosen by our algorithm but of an additional minimal amount of links which will make the backbone continuous (Fig. 2). List of these additional links can be considered for a potential future upgrade.

Knowing the new VoIP backbone we are able to decide where to place and connect specific voice-related devices in the real network environment.

To be able to decide which links will form the VoIP backbone, we need to use some key elements like the proposed cube model, active variable discovery and multivariate normal distribution. These techniques are described in the below subchapters.

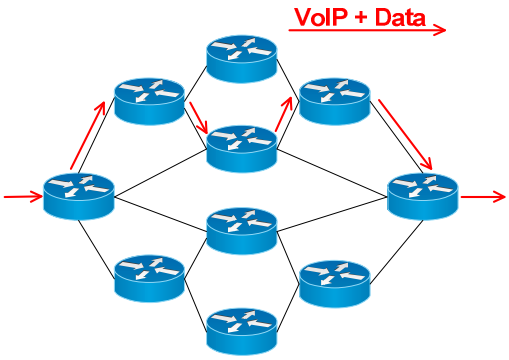

Figure 1. VoIP and data flows traverse the same best path

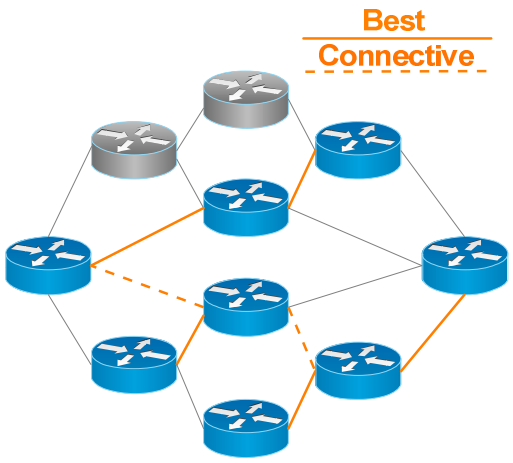

Figure 2. VoIP backbone

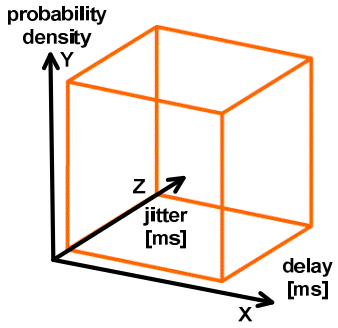

Figure 3. Model of the cube

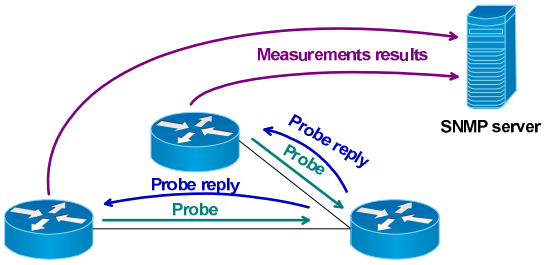

Figure 4. Measurement scenario

A. *Cube model*

First key element is a model of the cube. As it is 3D model, we are able to use each of the 3 axes for a separate attribute (Fig. 3):

- Axis X – variable jitter
- Axis Y – probability density
- Axis Z – variable delay

Measured values will be plotted in the cube model. Each link will have its own cube model with a multivariate normal distribution. Axes X and Z will represent the base of this distribution while axis Y will represent the probability density of delay-jitter pairs. Later on all these multivariate normal distributions will be merged into one cube and processed to determine the best links.

B. *Variable discovery*

Key component to time-variables' measurement is a periodic active measurement probe (SAA). This probe is small datagram sent over specific link towards a known destination. Sender of this probe knows the exact time when the probe was sent out as well as waiting period between consecutive probes. Once the probe reaches its destination, the probe is sent back towards to the original sender. As each probe contains unique identifier, original sender is able to calculate time-variables once the probe is received. Using the probes a network node is able to measure delay and jitter for a specific link in the network.

Final phase of the variable discovery is dedicated to the data collection. To facilitate measurement data exports, SNMP is used. In our approach, threshold of each probe will be set to 0. This means that once the probe will be received back, the router will always send an SNMP trap to a central SNMP server with the measurement results (Fig. 4). Once the SNMP server collects a representative amount of the measurement results, these results can be released for further processing (cube model, minimal tree in the graph).

C. *Multivariate normal distribution*

Our objective is to identify specific areas of the plotted surface inside the cube model, which are characterized as peaks of a multivariate normal distribution that represent edges with discovered values of delay and jitter, as depicted in the Fig. 5. We model the multivariate normal distribution peaks by determining parameters of the probability density function of the d-dimensional multivariate normal distribution (see Formula 1)

$$y = f(x,\mu,\sigma) = \frac{1}{\sqrt{|\sigma|(2\pi)^d}} e^{-\frac{1}{2}(x-\mu)\sigma^{-1}(x-\mu)'} \quad \textbf{(1)}$$

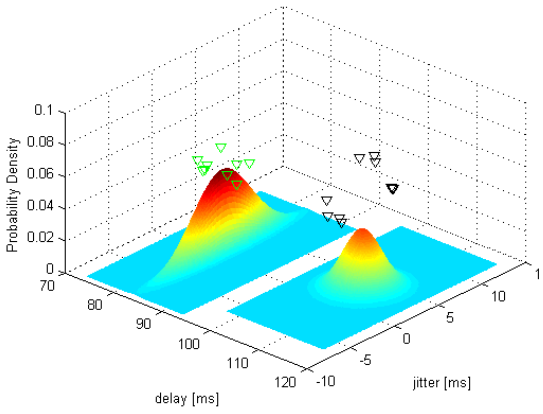

Figure 5. Cube model with 2 links

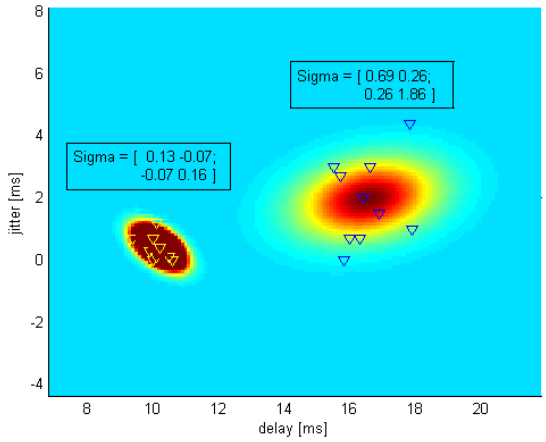

Figure 6. Examining the trustworthiness of a link in the cube model

where the parameter μ is a 1-by-d vector of mean values of vectors of gathered variables (delays and jitters) and σ is determined as a covariance matrix of the vectors of gathered variables, as can be seen in Formula 2 below.

$$\mathrm{cov}(x_1, x_2) = E[(x_1 - \mu_1) * (x_2 - \mu_2)] \quad \textbf{(2)}$$

In Formula 2, E[x] is the expected value of x. Representation of the network links as edges with directly measured parameters in the cube model has several advantages.

First, the trustworthiness of a link can be directly determined by the σ parameter as depicted in Fig. 6. The σ parameter corresponds to the steepness of the distribution. Those edges with steeper modeled distributions experience low variation in delay and jitter as opposed to those with gradually distributed probability function.

III. ALGORITHM

The whole modeling process can be divided into following steps:

1. Data gathering phase.
2. Update of multivariate normal distributions for each link.
3. Merging all distributions into one model.
4. Seeking voice-capable links.
5. Turning list of links into continuous graph.

Steps 1 to 3 are clear and are explained in the chapter dedicated to the concept of our work. Last two steps cover more operations which are described in the following chapters.

A. *Seeking voice-capable links*

The main idea of seeking voice-capable links is to take the cube with multivariate normal distributions of all links and do a three phase filtering. First phase will filter out all unstable links. Stable links are important for VoIP backbone as it's easier to face with stable links even if they don't provide best time-variables. We are able to apply some mechanisms to reduce the effect of worse time-variable in case we can predict these variables. From the point of the cube model and multivariate normal distribution stable links are represented with small base, narrow distribution and high peaks. Small base means that measured values don't differ in significant way and high peak represents the probability density. To be able to find these stable links we have introduced new variable η_1 – threshold of probability density for voice-capable links (Formula 3 and 4). Based on this threshold, new layer (parallel to area of axes X-Z) is added to the final cube model. Every link whose peak exceeds this layer (threshold) has matched the first of three conditions to become voice-capable link.

$$\eta_{\max} = f(x', \mu', \sigma') \geq f(x, \mu, \sigma) \quad \textbf{(3)}$$

$$\eta_1 = 0.8 * \eta_{\max} \quad \textbf{(4)}$$

$$\eta_2 = 0.56 * \eta_{\max} \quad \textbf{(5)}$$

Last two conditions are related to time-variables. Matching just the first conditions isn't enough because this condition will guarantee only the stability of the link – it doesn't matter how high the delay or jitter is, once the values aren't varying excessively, the link is stable. To be able to filter out links with worse time-variables we have introduced another 2 variables (thresholds).

First variable φ_1 is jitter threshold (Formula 7). We don't keep exact jitter, this value represents the fraction of the worst measured result (Formula 6). Based on this threshold another layer (parallel to area of axes X-Z) is added to the final cube model. Every link whose multivariate normal distribution belongs to the area bordered with the new layer and the area of axes X-Z has matched the second condition to become voice-capable link.

$$\varphi_{\max} \in \Phi, \forall \varphi' \in \Phi; \varphi' \leq \varphi_{\max} \quad \textbf{(6)}$$

$$\varphi_1 = 0.8 * \varphi_{\max} \quad \textbf{(7)}$$

$$\varphi_2 = 0.5 * \varphi_{\max} \quad \textbf{(8)}$$

Second variable called χ_1 represents the delay. As for φ_1, we don't keep exact delay value (Formula 10), this value represents the fraction of the worst measured result (Formula 9). Based on this threshold another layer (parallel to area of axes X-Y) is added to the final cube model. Every link who's Gaussian distribution belongs to the area bordered with the new layer and the area of axes X-Y has matched the last, third condition to become voice-capable link.

$$\chi_{\max} \in \mathrm{X}, \forall \chi' \in \mathrm{X}; \chi' \leq \chi_{\max} \quad \textbf{(9)}$$

$$\chi_1 = 0.8 * \chi_{\max} \quad \textbf{(10)}$$

$$\chi_2 = 0.5 * \chi_{\max} \quad \textbf{(11)}$$

To sum it up all three thresholds η_1, φ_1 and χ_1 and appropriate layers created sub-cube model in the main cube model and all links with their peaks in this sub-cube model are voice-capable links (Fig. 7).

With thresholds calculated it is now possible to separate measured data in the cube model into regions. Each region Ω is defined by upper and lower planes and

links are considered to be part of a region when the link's probability function maximum is located between the regions planes (Formulas 12, 13, 14).

$$\Omega_1 = \begin{bmatrix} \varphi_1 & \chi_1 & \eta_{\max} \\ 0 & 0 & \eta_1 \end{bmatrix} \quad (12)$$

$$\Omega_2 = \begin{bmatrix} \varphi_2 & \chi_2 & \eta_1 \\ \varphi_1 & \chi_1 & \eta_2 \end{bmatrix} \quad (13)$$

$$\Omega_3 = \begin{bmatrix} \varphi_{\max} & \chi_{\max} & \eta_2 \\ \varphi_2 & \chi_2 & 0 \end{bmatrix} \quad (14)$$

A continuous sequence of links will be called a VoIP backbone component. To calculate a single VoIP backbone, all unique VoIP backbone components must be connected by a minimal series of other links (edges). To be able to make the connection of all VoIP backbone components into one single component with the best of remaining links, these links needs to be classified. As this connection process will be based on the theory of graphs, we need to assign each link one composite metric – weight of the edge.

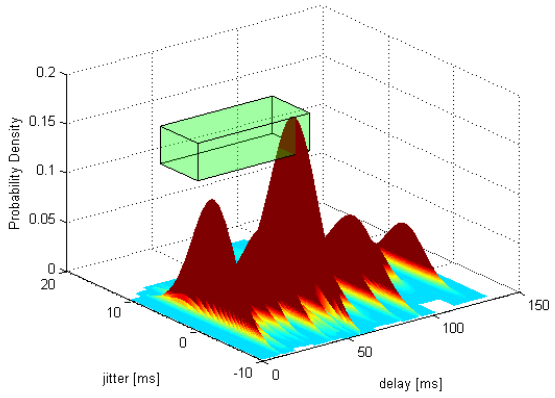

Figure 7. Sub-cube model determing VoIP backbone links (1 region)

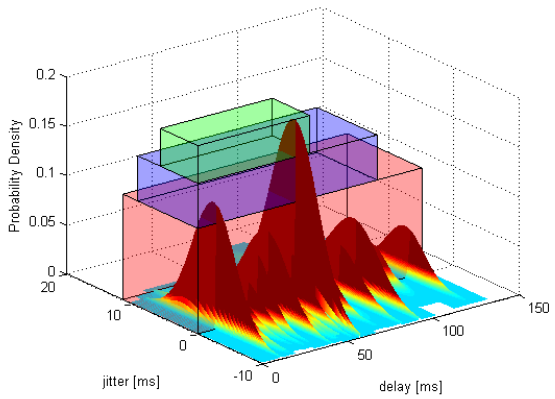

Figure 8. Link classification for VoIP backbone (3 regions)

Table 1. Data structure for main graph

Link ID	Start Node	End Node	Metric	Tree

Table 2. Data structure for paths

ω_1	θ_1	ω_2	θ_2	Cost	Use

We have decided to define another set of thresholds – η_2, φ_2 and χ_2 which will be worse than the original set of threshold (Formula 5, 8 and 11). These thresholds will divide the cube model into 3 regions (Fig. 8). Green region contains voice-capable links (region Ω_1). For future processing, these links have metric of 1. Purple region (Ω_2) contains link which aren't suitable VoIP backbone but can be used for voice flows. All these links have metric of 2. Last region (Ω_3), pink region represents the rest of the links which aren't suitable for VoIP traffic and should be used only as a temporary solution. These links have metric of 5.

Based on these details, the whole network topology can be represented by a single table. This table will be used during the last phase of our proposed algorithm where the final single VoIP backbone will be created. This table will keep following details (Table 1):

- Link ID – unique identifier of the link, e.g. 1, 2.
- Start Node – identifier of the first of two routers which this link connects, e.g. A, B, C.
- End Node - identifier of the second of two routers which this link connects, e.g. A, B, C.
- Metric – metric based on the link's situation in the cube model with 3 regions, valid values are 1, 2 and 5.

B. *Fetching the minimal tree*

The process of fetching the minimal tree is based on graph theory. Graph is an ordered pair G = (V, E) comprising a set V of vertices or nodes together with a set E of edges or lines, which are 2-element subsets of V – our requirements best fits the undirected weighted graph. This graph is represented with the dataset stored in table with structure as in Table 1. Similar approach can be found in [13]. Together with this, it's necessary to define group of border routers *BORDR* (vertices) which needs to be included in the final backbone (tree). Next steps are as follows:

1. Select all voice-capable links (edges with *Metric = 1*) from the table and store them in variable *VC_LINKS*.
2. Create subgraphs from *VC_LINKS*. In case start vertex of one edge is end of another edge, these edges can be merged into vertex. Repeat this operation for every single edge from *VC_LINKS*. All created subgraphs will be stored in *SUBGR*.
3. Check if vertices in *BORDR* are present in *SUBGR*. In case vertex from *BORDR* is not present in *SUBGR*, create new subgraph in *SUBGR*. New subgraph will contain only 1 vertex from *BORDR*. Repeat for every vertex in *BORDR*.

4. Use Dijkstra's algorithm to find the best (cheapest) path between every pair of vertices in the main graph [11, 12]. Store information for each vertex in separate table.
5. Find the best path between every pair of subgraphs in *SUBGR*. As the graph is undirected, path between subgraph 1 and 2 is the same as path between subgraph 2 and 1. Take first pair of subgraphs (*S1, S2*) and first vertex (*VS1, VS2*) from each subgraph. Check the cost from VS1 to VS2 using tables calculated in step 4. Put all these values (*S1 as* ω_1*, VS1 as* θ_1*, S2 as* ω_2*, VS2 as* θ_2*, Cost, Use=0*) into table for paths with structure as in Table 2. Table for paths will have *(n.(n-1))/2* rows, where *n* stands for the number of subgraphs in *SUBGR*. Repeat for every combination of vertices of selected two subgraphs. If path cost is lower while using another pair of vertices, replace details about cost and vertices in the path table for specific pair of subgraphs. Repeat for each pair of subgraphs.
6. Complete table of path is representation of another full-mesh graph. To get the minimum spanning tree for this connected weighted graph use the Kruskal's algorithm [14]. Mark the edges of the minimum spanning tree in the table of paths with *Use=1*.
7. Find every path with *Use=1*. Find all vertices from θ_1 to θ_2 for that specific row in path table and mark this vertices with *Tree=1* in the table of the main graph.
8. Find every vertex with metric of 1 in the table of the main graph and mark it with *Tree=1*.
9. Links in the table of the main graph marked with Tree = 1 creates VoIP backbone. Part of these links with *Metric=1* is the main backbone. The other links are capable for upgrade.

IV. Preliminary Testing

To test our concept we gathered samples from active measurements performed in a real network environment. These measurements conducted over a period of 24 hours represent the average values of delay and jitter (averaged per hour) on 20 high-speed WAN links (Fig. 9). The gathered data was fed to our proposed cube model in Matlab and results were evaluated both statistically and graphically. The measured data are plotted in Figure 9, were first 10 links are plotted in the top part and the remaining 10 links in the bottom part of the figure.

Based on the results only one link (#5) is fully VoIP capable, another two links (#2 and #7) have a metric of 2 while all the other links have metric of 5. Link #5 creates one subgraph GK, others subgraphs are border routers A, C, J. Following the algorithm variable *SUBGR* contains {GK, A, C, J}. Steps 4, 5 and 6 (Dijkstra's and Kruskal's algorithm) produce results shown in Table 3. Following the last 3 steps of the algorithm we are able to create VoIP backbone with connection to all border routers. Final network topology (Fig.11) contains voice capable (solid), usable (dashed) and temporary (dotted) lines.

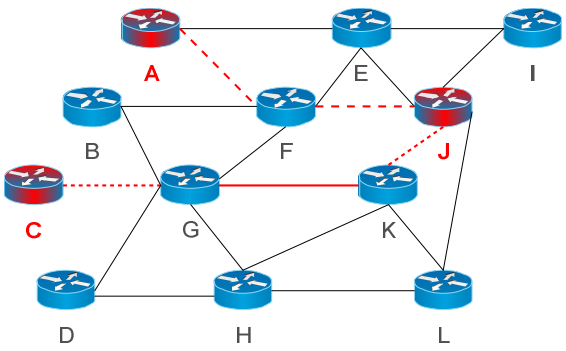

Figure 11. VoIP backbone connected to border routers

V. CONCLUSION

In this paper we proposed a cube model which helps to determine optimal VoIP backbone links. The identification of such links is based on the performance parameters crucial to VoIP traffic – delay and jitter, but also on the reliability of the network. By means of active network measurements we establish a data set for the cube model, which then calculates the link probability distributions and quality regions of the cube model. This data is further used in our modification of Dijkstra's and Kruskal's algorithm to establish a VoIP backbone. We define the VoIP backbone as an ideal sub-network to serve VoIP traffic demands and applications.

Our preliminary results present an example state of VoIP readiness in a WAN environment as well as design considerations which can be drawn from our calculations. We believe that this paper provides a useful methodology for VoIP implementation in both design and production stages of wide area network deployment.

Abstract - The management of the available bandwidth in a WiMAX system is one of the active research areas since it deals not only with the available bandwidth but also with the QoS requirements of different traffic classes. In this paper, a new bandwidth management scheme, named WiMAX Dual Cognitive Radio Scheme (WDCRS), is proposed. A cognitive radio approach is applied in order to obtain high bandwidth utilization and high throughput, and lower the blocking probability. An analytical model for performance analysis of the proposed scheme is developed. The results show that the proposed scheme achieves higher bandwidth utilization and lower the blocking probability compared to existing schemes.

Keywords: Cognitive radio, Bandwidth management scheme, Quality of service, IEEE 802.16, WiMAX.

I. INTRODUCTION

WiMAX (Worldwide Interoperability for Microwave Access) is wireless technology, based on the IEEE 802.16 standard, for nomadic and mobile data access [1-5]. The IEEE 802.16-2004 standard [6] deals with fixed wireless broadband access, while the IEEE 802.16e standard [7] deals with both fixed and mobile wireless broadband access. WiMAX offers cost-effective and quickly deployable alternative to cable and DSL networks. It provides high bandwidth and various levels of quality of services (QoS) for different classes of traffic [8,9].

The IEEE 802.16e standard considers five classes of service [7,10]: Unsolicited Grant Service (UGS), Real-Time Polling Service (rtPS), Extended Real-time Polling Service (ertPS), Non-Real Time Polling Service (nrtPS), and Best Effort (BE). The UGS supports real-time traffic that periodically generates packets of fixed length, such as Voice over IP without silence suppression. The rtPS supports real-time traffic that periodically generates packets of variable length, such as MPEG video. The ertPS supports real-time traffic that periodically generates packets of variable length, such as Voice over IP services with silence suppression. The nrtPS supports non-real-time traffic that generates packets of variable length and tolerant to delay, such as FTP. The BE service supports traffic that does not require throughput or delay guarantees, such as HTTP.

In a WiMAX network, users share the uplink bandwidth to transmit their data. Therefore, managing the uplink access is necessary for efficient use of bandwidth resources. In this paper, a new bandwidth management scheme is proposed to obtain high bandwidth utilization and to increase the total throughput. In the proposed scheme, the concept of cognitive radio [11-15] is applied to different service classes of a WiMAX uplink in order to improve the bandwidth utilization without affecting the QoS of other classes.

Cognitive radio lets secondary or unlicensed users to use the channel or spectrum allocated to primary or licensed users when they are not fully using it. In our scheme, the nrtPS and BE service classes act as secondary users which means they can use channels that are unused by the other service classes (i.e.; the primary users).

Recently, a number of bandwidth management schemes for WiMAX have been presented [16-19]. Closely related to our work is that of [20] and [21]. In [20], two bandwidth management schemes were proposed, namely, the WiMAX Complete Partitioning Scheme (WCPS) and the WiMAX Partial Sharing Scheme (WPSS). WCPS allocates fixed partitions of the total bandwidth to all service classes, while WPSS allows a lower-priority class (nrtPS/BE) to use the bandwidth allocated for a higher-priority class (rtPS/ertPS). However, the higher-priority class can prevent the lower-priority class from using that bandwidth. In [21], a bandwidth management scheme, called WiMAX Dynamic Channel Allocation Scheme (WDCAS), was proposed. The scheme uses the partial sharing concept introduced in [20] and the cognitive radio for dynamic channel allocation [22-25]. In this scheme, the BE service class acts as a secondary user which means it can use channels that are unused by the other service classes. Unlike [20] and [21], this work does not use the partial sharing concept and it treats both the nrtPS and BE service classes as secondary users in cognitive radio networks.

The rest of the paper is organized as follows. Section II provides a detailed description and a mathematical model of the WDCRS proposed scheme. Performance evaluation and simulation results are presented in Section III. We concluded our work in Section IV.

II. WDCRS PROPOSED SCHEME

A. System Description

In WDCRS, the two lower-priority classes, nrtPS and BE, are not allocated any channels in advance and are

treated as cognitive radio users, with priority to the nrtPS class to access the network first and search for available channels. By exploiting the nrtPS and BE class resources, more channels will be assigned to each higher-priority class and hence increasing the total throughput without affecting the QoS requirements. Each of the three higher-priority classes (i.e.; UGS, rtPS, and ertPS) is given a fixed number of channels at the beginning of each transmission period. Each of these classes deals with upcoming jobs and uses the available resources. After all the jobs are ready to be served, the nrtPS and BE classes take whatever resources left. Since the nrtPS and BE service are designed to support traffic that does not require any delay guarantee, the nrtPS and BE jobs can wait till the next transmission period.

Assuming a total number of N channels are available at the beginning of a transmission period, the channels will be allocated to the service classes as follows:

The UGS class is allocated n_1 channels. n_1 will be the largest allocation among the other classes (i.e.; rtPS and ertPS). The rtPS class is allocated n_2 channels, where $n_2 < n_1$. The ertPS class is allocated n_3 channels that are left after allocating channels to the UGS and rtPS classes (i.e.; $n_3 = N - (n_1 + n_2)$). The nrtPS and BE classes are treated as cognitive radio users with priority to the nrtPS class to access the network first and search for available channels. Both classes can reserve limited number of channels, n_4 and n_5, respectively, so that the total throughput is not affected.

B. Mathematical Model

In WDCRS, the total bandwidth is divided among the service classes. The choice of division is to be an optimization problem to get the maximum utilization of the bandwidth. The three higher-priority classes (UGS, rtPS, and ertPS) can be studied separately, since each class has a fixed channel allocation pattern. For the two lower-priority classes (nrtPS and BE), they are treated as two separate cognitive radio users, and the analysis is based on the fact that nrtPS scans the resources first, followed by the BE class.

For the three higher-priority classes, the packets generated are Poisson processes and have the following probability of generation:

$$P\ (c_i\ ;\lambda_i) = \frac{\lambda_i\ .\ e^{-\lambda_i}}{c_i!} \tag{1}$$

where, $P(c_i\ ;\lambda_i)$ is the probability of generation of c_i jobs in the ith class ($i = 1, 2, 3$), c_i is the number of jobs in the ith class, and λ_i is the mean arrival rate for the ith class packets.

The blocking probability, which occurs when the total number of jobs exceeds the available number of channels, can be defined as:

$$P_{b_i} = Prob\ \{c_i > n_i\} \tag{2}$$

where P_{b_i} is the blocking probability of ith class jobs, and n_i is the available number of channels assigned for ith class ($i = 1, 2, 3$).

The average blocking probability is given by:

$$P_{b_i,av} = \sum_{c_i = n_i+1}^{\infty} \frac{\lambda_i\ .\ e^{-\lambda_i}}{c_i!} \tag{3}$$

For nrtPS, the probability of packet generation is given by:

$$P\ (c_4\ ;\lambda_4) = \frac{\lambda_4\ .\ e^{-\lambda_4}}{c_4!} \tag{4}$$

where $P\ (c_4\ ;\lambda_4)$ is the probability of generation of c_4 jobs in the nrtPS class, c_4 is the number of jobs in the nrtPS class, and λ_4 is the mean arrival rate for the nrtPS class packets.

Since no channels are assigned to this class, the blocking probability is defined when the total number of jobs in this class exceeds the available bandwidth left, or:

$$P_{b_4}(c_4) = Prob\ \{c_4 > (N - (c_1 + c_2 + c_3))\} \tag{5}$$

The average blocking probability is:

$$P_{b_4,av} = \sum_{c_4=0}^{n_4} \frac{\lambda_4\ .\ e^{-\lambda_4}}{c_4!}.\left[1 - P_{pass}(c_4)\right] \tag{6}$$

where n_4 is the maximum number of channels allowed for the nrtPS class, and $P_{pass}(c_4)$ is the probability that c_4 jobs will pass to the network, or:

$$P_{pass}(c_4) = Prob\ \{c_4 < (N - (c_1 + c_2 + c_3))\} \tag{7}$$

For BE, the probability of packet generation is given by:

$$P\ (c_5\ ;\lambda_5) = \frac{\lambda_5\ .\ e^{-\lambda_5}}{c_5!} \tag{8}$$

where $P\ (c_5\ ;\lambda_5)$ is the probability of generation of c_5 jobs in the BE class, c_5 is the number of jobs in the BE class, and λ_5 is the mean arrival rate for the BE class packets.

The average blocking probability is:

$$P_{b_5,av} = \sum_{c_5=0}^{n_5} \frac{\lambda_5\ .\ e^{-\lambda_5}}{c_5!}.\left[1 - P_{pass}(c_5)\right] \tag{9}$$

where n_5 is the maximum number of channels allowed for the BE class, and $P_{pass}(c_5)$ is the probability that c_5 jobs will pass to the network, or:

$$P_{pass}(c_5) = prob\ \{c_5 < (N - (c_1 + c_2 + c_3 + c_4))\} \tag{10}$$

The average number of generated packets for the five service classes at any time is:

$$N_g = \sum_{i=1}^{5} \lambda_i \tag{11}$$

The average number of transmitted packets at a unit time is:

$$N_t = \sum_{i=1}^{5} \lambda_i [1 - P_{b_i}(c_i)] \quad (12)$$

The utilization is defined as:

$$U = \frac{N_t}{N_g} * 100\% \quad (13)$$

For the best utilization, we have to maximize the following constrain:

$$U = MAX \left[\frac{\sum_{i=1}^{5} \lambda_i [1 - P_{b_i}(c_i)]}{\sum_{i=1}^{5} \lambda_i} \right] \quad (14)$$

III. PERFORMANCE EVALUATION

In this section, the performance of the WDCRS proposed scheme is evaluated and compared with the bandwidth management schemes WCPS, WPSS, and WDCAS. In the simulation environment, a constant upload data rate of 1Mbps is assumed, and it supports 100 channels. Poisson distribution was used for data generation and a packet size of 1024 bytes was assumed.

The overall utilization of the four schemes is shown in Fig. 1. As shown, WDCRS provides the highest utilization of the bandwidth available, and reaches saturation at arrival rate of 14 packets per seconds. For low traffic, WDCAS makes good utilization of the available bandwidth, so improvement in utilization and QoS is achieved.

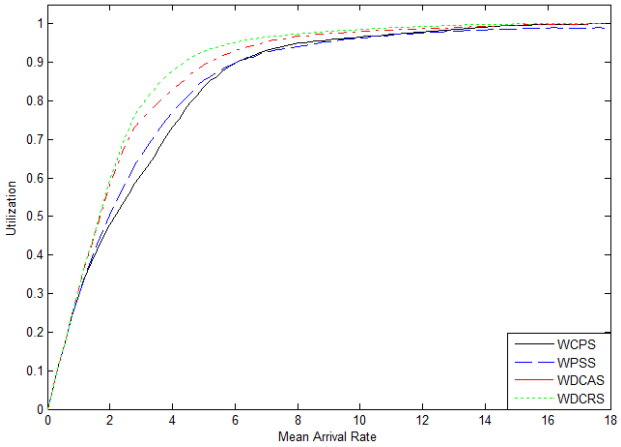

Fig. 1 Overall Utilization

Fig. 2 shows that WDCRS has the lowest blocking probability among all schemes. Note that WDCRS has very low blocking probability, taking advantage of using the cognitive radio concept in managing different traffic scenarios.

IV. CONCLUSION

This paper presents a new bandwidth management scheme to obtain high channel utilization and to increase the total throughput in WiMAX systems. The scheme applies the concept of cognitive radio to the lower-priority service classes in order to improve the bandwidth utilization without affecting the QoS of the higher-priority classes. An analytical model for performance analysis is developed and the effect of applying the cognitive radio concept on each service class is studied. The proposed scheme is evaluated and compared with existing schemes for similar traffic scenarios. The results show that the scheme can achieve higher bandwidth utilization and lower the blocking probability in WiMAX networks.

Abstract - The channelisation codes used in Universal Mobile Telecommunications System (UMTS) belong to the family of OVSF codes. They are organised according to a code tree structure. OVSF codes are primarily used to preserve orthogonality between different channels. The 3G system has to provide applications with higher and multirate and different quality of service (QoS) requirements. UMTS networks employ wide-band code division multiple access (WCDMA) to support multirate applications utilizing OVSF codes. The transmission rate can be easily changed by changing the spreading factor of orthogonal spreading code. The objective of code assignment is to enhance statistical multiplexing and spectral efficiency of WCDMA systems supporting variable user data rates. This paper compares the performance of OVSF code assignment schemes, in terms of code blocking probability. We analyze the problem of assigning OVSF codes at download link in 3G mobile communications systems employing WCDMA.

I. INTRODUCTION

OVSF codes in a Node-B (3G base station) are valuable and limited; therefore, 3G operators must utilize them efficiently. Several OVSF code allocation schemes have been studied, but few assessments of OVSF code allocation performance have been conducted, especially in terms of call blocking probability and bandwidth utilization – measures that respectively represent subscriber quality of service (QoS) and operator profitability. Selection of codes has a large impact on the performance of the system. The longer the code, the higher the processing gain, but the lower the channel bit rate. Another important property of the codes is the correlation. If the codes are not completely orthogonal, the correlation factor is unequal to zero. In this situation different users interfere with each other. In order to provide the necessary resources to the user there are different resource management schemes such as code allocation scheme and bandwidth allocation scheme. The code allocation scheme determines the specific set of codes to be used simultaneously and the bandwidth allocation scheme determines when and to whom to assign codes. Both of these schemes are not clearly specified in OVSF-CDMA systems as WCDMA and are implementation dependent [1]. In this paper, we propose three strategies which can be adopted by code placement. Those are random, left-most and crowded-first schemes. The paper is organized as follows: section II discusses spreading and dispreading process while section III introduces the code assignment in the cell and deals with its various definitions. Section IV shows results while the final section of the paper provides conclusion.

II. SPREADING AND DESPREADING PROCESS

In a CDMA scheme, every user sends and receives information using the whole frequency band continuously in time. However, each user is separated from one another by means of orthogonal codes. Each user's signal is multiplied by an assigned code. This multiplication adds some redundancy to the signal and produces a signal with higher bandwidth requirements. The signal is then transmitted over a channel. During the transmission, at the receiver side, a correlator despreads the received signal with the user's assigned code. Then the despreaded signal is passed through a narrow band filter. The signals that are added after the spreading process such as background noise and interference cannot pass through the filter. Thus, the original signal is recovered. UMTS utilizes a specific type of CDMA technology, namely Wideband Code Division Multiple Access (W-CDMA). The term W-CDMA is used to describe a wideband Direct Sequence-Code Division Multiple Access (DS-CDMA) method. In W-CDMA, the user data is spread over the whole bandwidth using a chip sequence. For example, one 5 MHz UMTS frequency band operates at the chip rate of 3.84 Mchips/s. Spreading is the term used to refer to the process of multiplying the original baseband information signal with the high chip rate binary code. The chip rate is the rate at which the CDMA code is being produced. The transmitted sequence has a higher rate than the original sequence. In W-CDMA, a piece of user information (before encoding) is called bit and a symbol from the encoded sequence is called chip [Figure 1].

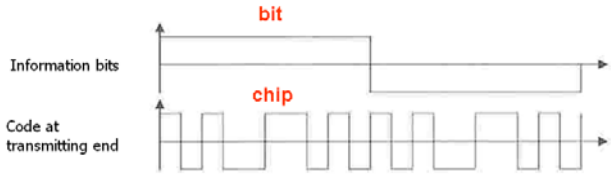

Figure 1 Bit and chip

The spreading factor (SF) is the ratio of the chip rate (CHR) to the information (transmission) rate (R):

$SF = \frac{CHR}{R}$. For instance, for SF=256 chips/bit and CHR=3.84 M chips/s provide the following transmission rate: $R = \frac{3.84 \quad Mchips/s}{256 \quad chips/s} = 15\,kbits/s.$ The codes can have different lengths, but the chip rate is constant for all users. Consequently, shorter codes enable a higher data-rate.

Assume that the original data takes the form of a ±1 sequence of numbers, produced at the data rate R. The spreading code is also a series of ±1 numbers, produced as example at 8 times of the data rate. By multiplying the data sequence and the code sequence together, chip period by chip period, a new spread signal is created. Since the original signal now requires 8xR bandwidth to transmit, it is said that the spreading factor of 8 is used.

At the receiver side, the same chip sequence is used to despread the signal. The received signal is multiplied by the chip sequence, chip by chip, once again. The correlator at the receiver integrates the product from multiplication. The original signal is thus recovered. Another user's signal is spread by a different code. If another user's signal is despread by the own code, the integration of the resulting signal will result in a value around 0. In other words, other signals will appear as noise.

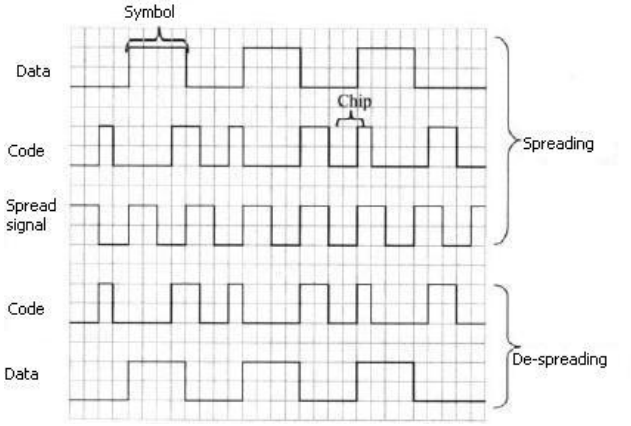

Figure 2 Spreading and De-spreading process

The data rate of the resulting signal will be the data rate of the spreading signal [Figure 2]. In UMTS, there are two modes of operation: UTRA-FDD and UTRA-TDD. The spreading factor in UTRA-FDD varies from 4 to 512 and in UTRA-TDD the spreading factor varies from 1 to 16.With the advancement in the cellular technology and convergence of wireless technologies, there is a need to combine two messages with different data rates in an orthogonal manner.

III. Code Assignment in a Cell

Code assignment schemes can be of the nonrearrangeable and rearrangeable type. Specifically, rearrangeable code assignment schemes allow OVSF codes to be rearranged so that they have better performance at the expense of higher computational complexity. In this paper, we focus on the environment where one single OVSF code is available for each call (i.e., the multi- OVSF-code cases is not considered). OVSF codes can be represented as a code tree. Many single-code rearrangeable code assignment schemes have been proposed in literature. Among them, the priority issue between realtime traffic and best-effort traffic has been considered. Several single-code non rearrangeable code assignment schemes have been proposed. In [2], the number of OVSF codes for each service class is found by maximizing the average throughput. The paper compares the performance of random, leftmost, and crowded-first schemes. Multicode rearrangeable code assignment schemes proposed in [3] and [4] show uniform mobile terminals having exactly the same capability in supporting multicode transmission and in [5] different multicode capable terminals. All these multicode schemes are designed only for multirate real-time traffic. The paper addresses code placement and not replacement issues in a WCDMA system where OVSF code trees are used to downlink transmission from base stations to mobile terminals. The general objective is to make the OVSF code tree as compact as possible so as to support more new calls by incurring less blocking probability. Different objects can be addresses too as less reassignment costs [6]. Three strategies which can be adopted by both code placement and code replacement are proposed: random, leftmost, and crowded-first. The random strategy is used here for comparison purposes. The leftmost strategy attempts to place codes starting from the leftmost available position, while the crowded-first strategy tries to allocate a code in a subtree that has the most occupied codes. Our simulation results have demonstrated that both the leftmost and the crowded-first strategies perform pretty well compared to the naive random strategy. The possible OVSF codes can be represented by a code tree. When a new call arrives requesting for a code of rate kR, where k is a power of two, we have to allocate a free code of rate kR for it. The code placement problem is to address the allocation policy when such multiple free codes exist in the code tree [Figure 3].

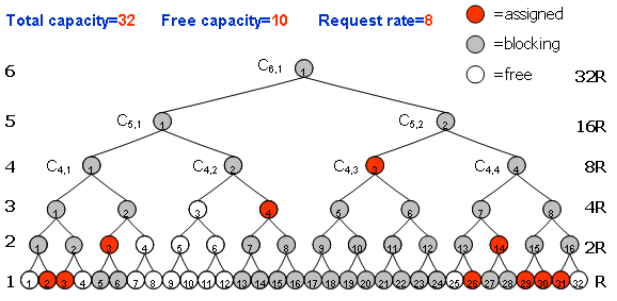

Figure 3 Code tree and method of marking

When no such free code exists, but the remaining capacity of the code tree is sufficient (i.e., summation of data rates of all free codes is ≥ kR), two possibilities occur. The first one is to reject the call, which is called code blocking. The second is to relocate some codes in the code tree to "squeeze" free space for a new call. This is called the code replacement problem. We define OVSF code blocking as the condition where a new call cannot be supported although the system has excess capacity to support the rate requirement of the call. If system does not have enough capacity, we call that call blocking. In this

example we use another method of marking where each OVSF code is denoted as $C_{layer,\,k}$.

Assuming that no code reassignment will be conducted, we propose three strategies below:

Random. If there is one or more than one code in the code tree with a rate kR, randomly pick any one and assign it to the call. Otherwise, the call is rejected.

Leftmost. If there is one or more than one code in the code tree with a rate kR, pick the leftmost one in the code tree and assign it to the call. Otherwise, the call is rejected. The intuition is to always vacate a larger capacity in the right-hand side of the code tree so as to accommodate higher-rate calls in the future [Figure 4].

Crowded-first. If there is one or more than one code in the code tree with a rate kR, pick the one whose ancestor code has the least free capacity [Figure 5]. More specifically, suppose codes x and x0 are both of rate kR. We will compare the free capacities in their ancestors, say y and y0, respectively. The one with less free capacity (i.e., more crowded) will be picked to accommodate the new call. When there are ties, we will go one level up by comparing y and y0's ancestors. This is repeated until the subtree with the least free capacity is found. One special case is that y may represent the same subtree as y0. If so, we will follow the leftmost rule to pick the code on the lefthand side.

The only paper that elaborates on the issue of code selection and attempts to conduct a comparison of three different schemes, namely the random, ordered or leftmost, and crowded-first schemes, is represented in [7]. The random and ordered schemes are very fast but less efficient in alleviating the problem of scattered codes, while the crowded-first scheme results in significant improvements in the code blocking probability. However, the main drawback of this scheme is longer decision time, because it may require recursive search from the level of the code rate up to the root level during the decision process. The main idea behind this scheme is the attempt to always keep the allocations of codes as compact as possible. This is achieved by always selecting the code, whose immediate upper layer subbranch will have the least free capacity after the allocation. In the case of ties the search continues one more layer up, until the tie is resolved [8].

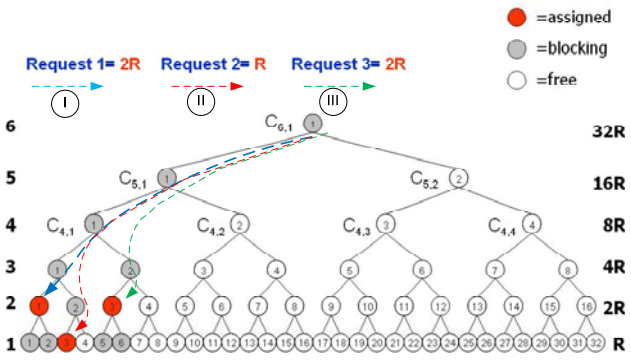

Figure 4 Leftmost code assignment

The random scheme selects with equal probability one of these codes, while an ordered scheme selects either C21 (leftmost), or C26 (rightmost). On the other hand, the crowded-first scheme additionally attempts to keep the code tree allocation as compact as possible, by incurring further computational cost during the decision process at no significant benefit in terms of capacity [9]. The additional cost is expected to be higher

(a) for larger trees, because there will be more layers and codes to search, and

(b) for light loads because there will be many candidates to choose from.

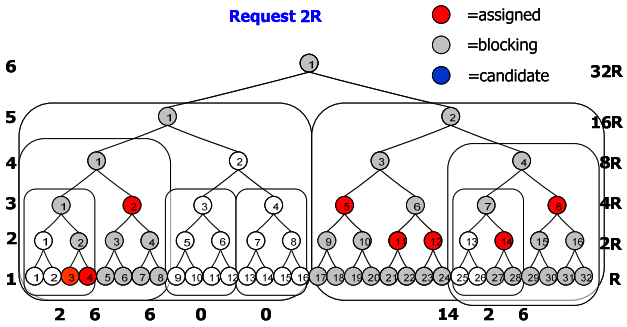

Figure 5 Crowded-first assignment

IV. Simulation Results

We have used a simulator to evaluate the performance of the proposed strategies. We show the code blocking probability at different traffic loads when SF is 32, 64, 128 and 256. The call arrival process is modeled by a Poisson distribution, while the call duration is exponentially distributed with mean $1/\lambda k$. The possible rates for a new call are R, 2R, 4R, and 8R (transmission rate of 2kR arrive at rate λk, k=0, 1, 2, 3), each with a different probability of appearance. In our simulations we use a uniform rate distribution (R:2R:4R:8R=25:25:25:25).

To ensure stable results, each point on the figures has been produced by a simulation run with at least 20000 incoming calls. Figure 3 shows the total blocking probability. We see that crowded-first schemes performs the best. This is because the crowded-first strategies, by reducing code blocking, increase the acceptance of higher rate calls that in turn reduces the acceptance of lower rate calls. The result is that, in total, the blocking probability remains the same but the call acceptance becomes fairer, by allowing higher rate calls to be serviced. Furthermore, the total serviced rate is significantly higher.

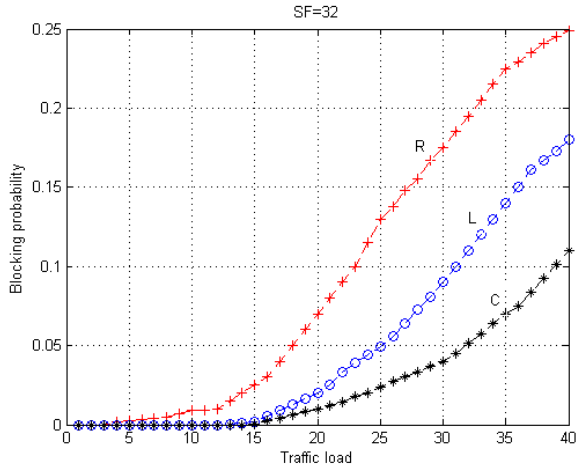

Figure 6 SF=32, R-random, L-left most, C-crowded first

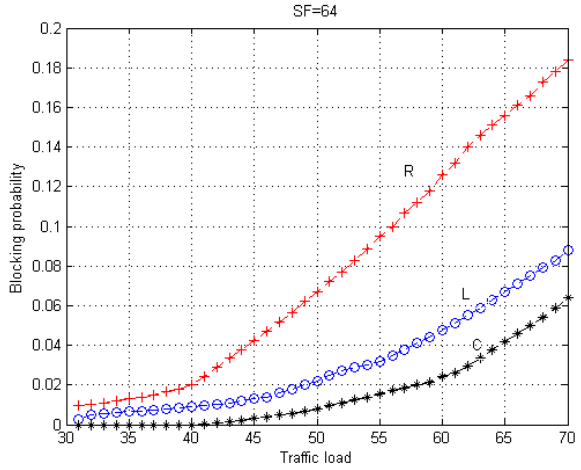

Figure 7 SF=64, R-random, L-left most, C-crowded first

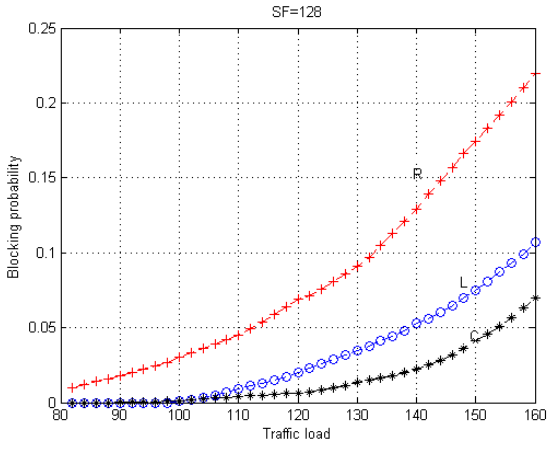

Figure 8 SF=128, R-random, L-left most, C-crowded first

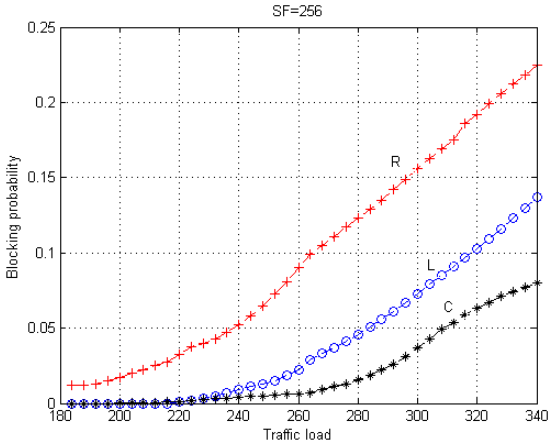

Figure 9 SF=256, R-random, L-left most, C-crowded first

At light load, the blocking probability is quite insensitive to the code placement strategy. After the system is around 70 percent fully loaded (Figure 6), the code placement strategy will have a significant impact on blocking probability. For example, on Figure 6 when SF=32, and the code tree is about 80 percent fully loaded (at around load = 32), the blocking probabilities are 18 percent, 10 percent, and 4,5 percent for R, L and C, respectively. Figures 7, 8, 9 show the same simulation when maximum SF=64, 128 and 256. The trend is similar, but code placement strategy starts to have an impact when the system is about 67, 62 and 57 percent fully loaded. This indicates an interesting phenomenon that code placement is more important when SF is smaller. We note that we did not consider dynamic strategy because no code blocking will happen when code replacement strategies are implemented. However, processing time for replacement strategies will increased.

V. CONCLUSION

We have shown that the code placement strategies do have significant impact on the utilization of code trees and, thus, the call blocking probability. The main idea is to keep the code tree less fragmented so as to accept more calls. A simulation model has been proposed to evaluate the utilization of a WCDMA OVSF code tree. Among the strategies we propose, the crowded-first strategy seems to be most promising. The result is expected to more efficiently utilize the scarce wireless bandwidth in WCDMA systems. In the future it will be more interesting to test impact of code replacement and impact of call pattern. In this paper we test uniform requests call but more realistic case is with non-uniform traffic requests.

***Abstract* - This paper presents an approach to the development of custom agents and their integration with network management systems. For the development of agents is given one approach, and according to this approach an implementation of the agent using Open Dynamic Management Kit (OpenDMK) libraries in the Java programming language is performed. Within the agents are implemented all standard Simple Network Management Protocol (SNMP) functionality - reading values, setting values and traps sending. Finally, the integration is performed with several network management systems such as Zenoss and Cacti. Tests have confirmed the success of this integration, thus verifying the proposed approach.**

***Keywords* – SNMP, agent, management system, NMS, OpenDMK, Java.**

I. INTRODUCTION

Currently we are witnessing the increasing expansion of the computer network, and network services. At the same time, customer demands on service level, and the implementation of the Service Level Agreement (SLA) are forcing network providers to implement the monitoring and management of almost all elements of network infrastructure. Accordingly, there is a need for the implementation of specific network management agents, which will provide measurement and monitoring of performance, in order to guarantee SLAs.

This paper consists of six sections: in the next section we will briefly describe architecture of network management model based-on Simple Network Management Protocol (SNMP); in section 3 we present process of design an SNMP agent; in section 4 we describe process of implementation SNMP agent using Open Dynamic Management Kit (OpenDMK) framework; in section 6 we present basic procedures that are made during the integration of agent with network management systems; in the last we give conclusion of this paper.

II. ARCHITECTURE OF NETWORK MANAGEMENT MODEL BASED-ON SNMP

There are three principal components of network management architecture: a managing entity, the managed devices, and a network management protocol [1]. Fig.1 represents these components. Specified, division of network components is generic, and broadly applies to a number of network management standards. Development of the network management standards began in the late 1980s. Currently, there are two standards: Common Management Information Services Element/Common Management Information Protocol (CMISE/CMIP) proposed by OSI organization, and SNMP proposed by IETF [2, 3]. Due to the simplicity of its architecture, SNMP found widespread use and acceptance. At present, almost every network device supports SNMP.

The managing entity is an application, and it is the locus of activity for network management; it controls the collection, processing, analysis, and display of network management information. The managing entity serves as the interface for the human network administrator into the network management system.

A managed device is a piece of network equipment together with its software that resides on a managed network. Within a managed device, may be several managed objects that represent resources. Each object is, essentially, a data variable that represents one aspect of the managed system. These data variables are pieces of information associated with managed object and collected into Management Information Base (MIB). Related MIB objects are gathered into MIB modules. A data definition language, known as Structure of Management Information (SMI) is used to define data types, object model, and rules for writing and revising management information [4]. SMI is data-oriented language based on Abstract Syntax

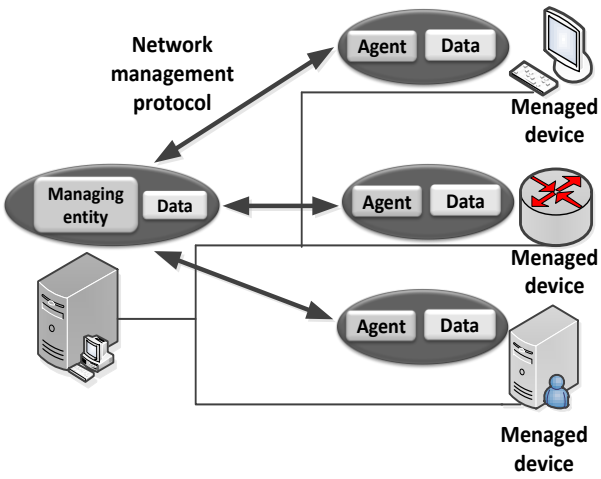

Figure 1. Components of network management architecture

Notation One (ASN.1). Agent software maintains the MIB, and managing entity performs the monitoring functions by retrieving the value of MIB objects.

The managing entity and agents are linked by network management protocol. The protocol allows the managing entity to query the status of managed devices and indirectly take actions at these devices via its agents. Agents can use the network management protocol to inform the managing entity of exceptional events. Let us emphasize that network management protocol does not itself mange the network. Simple Network Management Protocol version 2c (SNMPv2c) defines seven protocol data units (PDUs): GetRequest, SetRequest, GetNextRequest, GetBulkRequest, InformRequest, Response and trap. All the first five PDUs enable the managing entity to retrieve or set the values of objects in the agent. The agent in the form of GetResponse message acknowledges these actions. Spontaneously, an agent may generate trap message to inform managing entity of an event.

III. DESIGN OF SNMP AGENT

A. *Project OpenDMK*

The proposed SNMP agent is designed using OpenDMK Java libraries. The Project OpenDMK source code is based on the Java Dynamic Management Kit version 5.1 (Java DMK), with the exception of some legacy or deprecated APIs which were removed. OpenDMK provides the necessary tools for integration of Java technology with SNMP Internet network management standard. OpenDMK compatibility with SNMP-based management model enables the development of an agent using the Java programming language, which can be accessed via SNMP protocol [5]. Our SNMP agent developed using this toolkit is completely independent of the SNMP management application installed in the manger station, which allows integration of the developed agent with different management systems. The developed agent is a process that is executed on a managed device that realizes the communication with the managing entity for the purpose of realization management operations. This communication will be later verified by integration of the SNMP agent with two monitoring entities (applications) - Zenoss and Cacti.

In order to achieve full implementation of SNMP-based network management system the managed part of the network – the managed device, must organize all the management information for managed objects that are attached to the device in the MIB base [6]. The agent then provides access to management information found in the MIB for the manager application. By sending the appropriate SNMP commands to SNMP agent, the manager receives the requested information.

In relation to the above, our next goal is the design of a SNMP MIB.

B. *MIB design*

SNMP management information bases are written in SMI language which is based on ASN.1. Using the OpenDMK framework MIBs can be represented as Mbeans, where the Java code for Mbeans can be generated with mibgen tool [7]. MIBs that we have designed are translated into the corresponding Java code using this tool.

The mibgen tool creates all the skeleton getters and setters that will be invoked upon receipt of the SNMP requests from the manager station and which will then make the appropriate management actions (change or retrieve SNMP variable values in the MIB). The generated MBeans are exposed to the SNMP manager using the SNMP protocol adaptor. The same SNMP protocol adaptor provides the mechanisms for sending unsolicited event reports through SNMP Trap messages to the management application which is identified by the management station IP address and TCP port for receiving notifications (port 162). Note that we use a SNMP protocol adaptor to implement a compatible SNMPv2c agent.

To illustrate the process of creating a SNMP agent based on OpenDMK framework, we have created a MIB (Voip_terminal MIB) containing a MIB module called "voip-terminal" using Structure of Management Information version 2 (SMIv2) language. We have placed a collection of related objects of this module in the following object identifier (OID):

iso.org.dod.internet.private.enterprises.tnm.example

which numerical representation is:

1.3.6.1.4.1.2011.4

For successful design of MIB module, it is necessary to go through the following steps:

- Import classes that will be used to design the module.
- Define the module identity.
- Define the module OID.
- Define the textual conventions.
- Define the objects within the module.
- Define the notifications within the module.

For purposes of defining MIB module identity, we use SMI MODULE-IDENTITY construct, and to define a collection of related managed objects within the module we use the SMI construct OBJECT-TYPE. NOTIFICATION-TYPE construct is used to specify information related to the SNMPv2c Trap messages generated by SNMPv2c agent. The figures Fig.2, Fig.3, Fig.4, Fig.5, Fig.6, illustrate an example of a MIB module design.

```

```

Figure 6. Example of notification definiton in MIB module

After designing the MIB, we want to manage in our SNMP agent, we need to generate its MBean representation and other Java classes using the mibgen tool. This will be done by using the following command:

./mibgen Voip_terminal

Detailed structure of the module is shown in Fig.7.

IV. SNMP AGENT IMPLEMENTATION

For implementation of the SNMP agent in the Java programming language for the MIB module described in the previous section, it is necessary to go through the following steps:

- Translation of previously prepared MIB in the corresponding Java classes and interfaces.
- Implementing methods for the generated classes that will be invoked when receiving SNMP Get and Set messages.
- Implementing methods for the generated classes that will be invoked when sending a SNMP Trap message.
- Implementing a class for the registration of the SNMP agent and connecting with SNMP protocol adaptor.

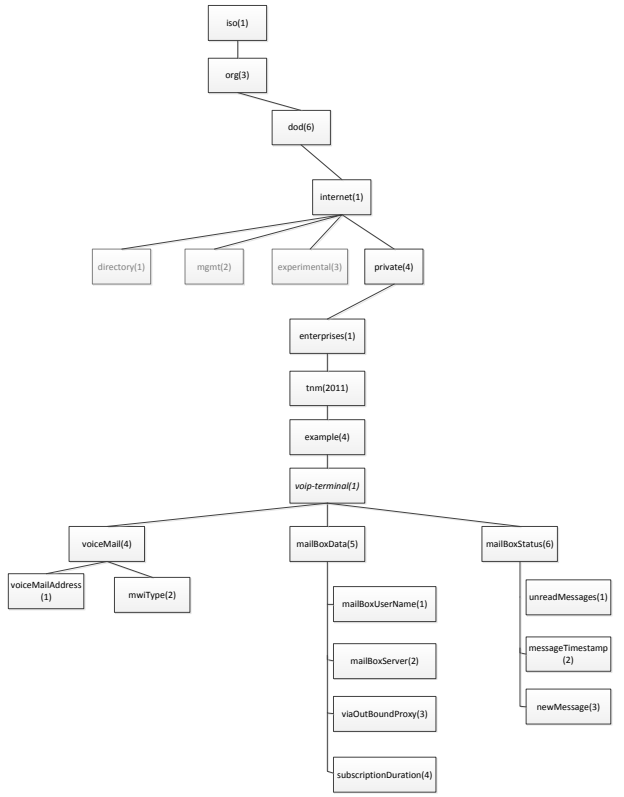

Figure 7. Example of managed object definitons in MIB module

As previously described after using the mibgen tool a set of Java classes will be generated. For the MIB we have created the following classes will be generated:

EnumMwiType.java

EnumUnreadMessages.java

EnumViaOutBoundProxy.java

MailBoxData.java

MailBoxDataMBean.java

MailBoxDataMeta.java

MailBoxStatus.java

MailBoxStatusMBean.java

MailBoxStatusMeta.java

VoiceMail.java

VoiceMailMBean.java

VoiceMailMeta.java

Voip_Terminal.java

The mibgen tool has generated standard MBeans for our MIB, so that SNMP variable attributes are implemented with individual getter and setter methods. To enable sending of notifications we need to create the appropriate Java method. We called it sendTrap(). In accordance with Fig.1 the object responsible for sending notification messages is defined with the OID 1.3.6.1.4.1.2011.4.1.6.3. We designed Trap messages to carry two pieces of data (unreadMessage and messageTimestamp), that is two

pairs of SNMP PDU variable bindings inside the SNMPv2c Trap message PDU payload. For this purpose we will create the sendTrap() method in the MailBoxStatus generated class. The structure of the sendTrap() method is:

```
private void sendTrap(String snmpVarName, String
snmpVarName1, String snmpVarName2,
EnumUnreadMessages snmpVarValue1, Long snmpVarValue2)
{
        SnmpVarBindList varBindList = new
SnmpVarBindList("Notification for newUnread Messages and
their timestamp!");
        Voip_TerminalOidTable oidTable = new
Voip_TerminalOidTable();
        SnmpOidRecord oid;
        SnmpOidRecord oid11;
        SnmpOidRecord oid22;
   try {
        oid = oidTable.resolveVarName(snmpVarName);
//getting the OID value of the first and second managed object
        oid11 = oidTable.resolveVarName(snmpVarName1);
        oid22 = oidTable.resolveVarName(snmpVarName2);
        SnmpOid oid1 = new SnmpOid(oid.getOid());
        SnmpOid oid111 = new SnmpOid(oid11.getOid());
        SnmpOid oid122 = new SnmpOid(oid22.getOid());
//creating a variablebinding for each managed object which
value will be sent in the Trap
SnmpVarBind varBind1 = new SnmpVarBind(oid111, new
SnmpInt(snmpVarValue1));
SnmpVarBind varBind2 = new SnmpVarBind(oid122, new
SnmpInt(snmpVarValue2));
   //Adding the two variableBindings in a varBindList
        varBindList.addVarBind(varBind1);
        varBindList.addVarBind(varBind2);

VoipSnmpAgent.getSnmpAdaptor().snmpV2Trap(InetAddress.
getByName("127.0.0.1"),"public", oid1, varBindList);

          } catch (Exception e) {
        }
   }
```

The specific method call would be:

```
sendTrap("newMessage","unreadMessages","messageTimestam
p" ,getUnreadMessages(), getMessageTimestamp());
```

VoipSnmpAgent is the class that is creating a SNMP protocol adaptor and instantiating the Voip_Terminal and registering both with the MBeanServer. It also starts the snmpAdaptor and sends a SNMP Trap to the Trap receiver as a part of initialization.

To simulate a live status of the operation, we invent two methods that change the status periodically: getUnreadMessages() and getMessageTimestamp() :

```
private static boolean dbMss=false;
public EnumUnreadMessages getUnreadMessages() throws
SnmpStatusException {
     if (dbMss == false) {
        dbMss = true;
        return new EnumUnreadMessages(1);
     } else {
        dbMss = false;
        return new EnumUnreadMessages(2);
     }
   }
public Long getMessageTimestamp() throws
SnmpStatusException {
        if (MessageTimestamp<2000) {
        MessageTimestamp=MessageTimestamp+100;
        return MessageTimestamp;
   } else {
        MessageTimestamp=new Long(0);
        return MessageTimestamp;
   }
}
```

V. INTEGRATION OF AGENT WITH NETWORK MANAGAMENT SYSTEM

In order to test the implemented SNMP agent we performed integration with two network management systems: Zenoss and Cacti. Zenoss is a powerful open source IT monitoring product, while Cacti is an open source, web-based graphing tool designed as a frontend to RRDtool's data storage and graphing functionality.

Since Cacti is only graphing tool, it does not support receiving SNMP trap messages, however it is possible to monitor managed entities using SNMP polling. In order to integrate custom agent with Cacti, it is necessary to define Extensible Markup Language (XML) file that represents a description of MIB table structure. Fig.8 represents XML file that describes MIB table structure for implemented agent.

Because Cacti management system has no support for the acceptance of SNMP Trap it does not provide the ability to fully test the functionality of our implemented agent. Therefore, the SNMP agent has been integrated with another management system, Zenoss. Zenoss provides complete testing of the installed agent, through retrieving/setting the values of managed objects in the MIB and the acceptance of Trap messages. To perform the integration of our agent and management system Zenoss, it is necessary that the MIB, we have designed, is added

Figure 8. XML file

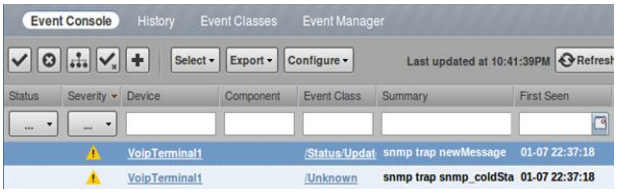

Figure 9. SNMP trap messages

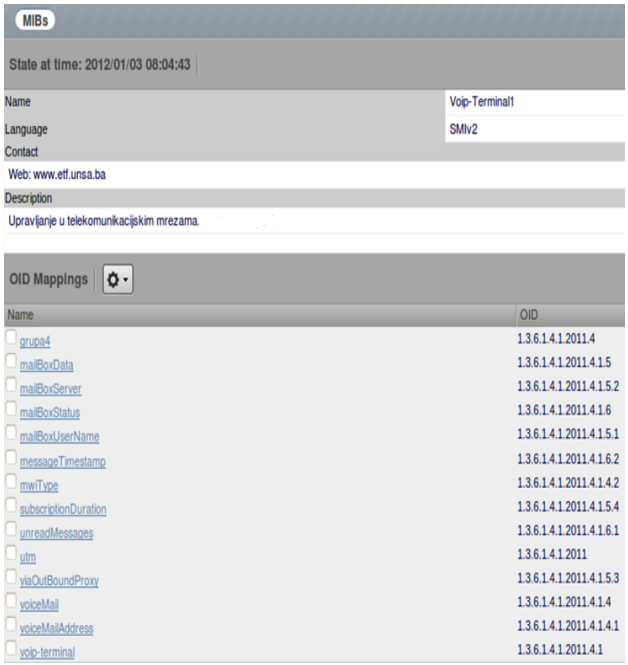

Figure 10. Imported custom MIB into Zenoss

into the base of non-standard MIB's used by Zenoss, and define the device we want to monitor.

For access to management information in the MIB we need to create user defined commands – equivalent to SNMP SET and GET commands.

VI. CONLUSION

The aim of this paper - to explore the possibility of custom agents development and their integration within standard network management systems - has been achieved in the following way. According to the given approach an implementation of one simple SNMP agent using OpenDMK libraries is performed. As is shown in previous chapter, the integration is performed with several network management systems (e.g. Cacti, Zenoss) and tests have confirmed the success of integration. We see future work in researching the possibility of Service Oriented Architecture (SOA) based agents development and their integration within current network management systems.

Implementacija sustava za dinamičku prilagodbu karakteristika DSL linija u okruženju telekomunikacijskog operatora

Dren Butković, Nenad Dragun
HT – Hrvatski telekom d.d. / Sektor za upravljanje mrežom i korisničkim uslugama
Kupska 2, 10000 Zagreb, Republika Hrvatska
dren.butkovic@t.ht.hr, nenad.dragun@t.ht.hr

Sažetak - Telekomunikacijski operatori svakodnevno se susreću s izazovima povećanja broja korisnika, povećanja propusnosti mreže i smanjenja troškova održavanja u pružanju širokopojasnih usluga temeljenih na xDSL tehnologijama koje koriste bakrenu paricu kao medij za prijenos podataka. Bakrena parica u svojem nastanku nije bila zamišljena za prijenos velike količine podataka, podložna je vanjskim utjecajima (preslušavanje u kabelu, meteorološke nepogode, radio interferencije i slično) pa je potrebno uložiti dodatne napore kako bi se optimalno iskoristila kao medij.

Ovaj članak opisuje izvedbu DSM (Dynamic Spectrum Management) sustava u mreži velikog telekomunikacijskog operatora. U radu opisani sustav prepoznaje degradacije usluge u mreži, prilagođava DSL linijske parametre te poboljšava kvalitetu linije i smanjuje njenu osjetljivost na vanjske utjecaje.

I. UVOD

Bakrena parica još uvijek predstavlja najzastupljeniji medij za pristup brzom Internetu i ostvarivanje širokopojasne komunikacije u Hrvatskoj. Ne samo da bakrena parica nije zamijenjena drugim prijenosnim medijima npr. optičkim vlaknom nego se pred operatere postavljaju zahtjevi pružanja sve većih brzina i kompleksnijih usluga uz konstantno povećanje broja korisnika. Brzine prijenosa koje se ostvaruju na bakrenoj parici nerijetko prelaze 10 Mbit/sek a postojeća pristupna mreža nije imuna na razne vanjske utjecaje kao što su: preslušavanja u kabelu, meteorološke nepogode, radio interferencije i slično.

Sustav za dinamičku prilagodbu xDSL[9] linija (DSM) [10] razvijan i implementiran u mreži operatera s ciljem prepoznavanja korisničkih linija s lošijim performansama i servisnim karakteristikama te automatske prilagodbe korisničke linije čime se direktno utječe na kvalitetu usluge.

DSM sustav je zamišljen kao proces koji kontinuirano prati definirani skup parametara za koje je testiranjima dokazano da imaju direktan utjecaj na kvalitetu prijenosa podataka. Linije koje su prepoznate kao nekvalitetne ulaze u proces optimizacije pri čemu se vodi računa o samoj vrsti usluge koja se pruža korisniku. Proces optimizacije u konačnici primjenjuje novi odgovarajući profil na DSLAM-u [14].

Sustav ima ugrađen mehanizam kontrole rada linije s novo primijenjenim profilom. Osim želje za povećanjem kvalitete linije DSM sustav vodi brigu o tome da se sve promjene na korisničkim linijama odvijaju u vrijeme kada će utjecaj na uslugu biti najmanji.

DSM sustav se sastoji od nekoliko aplikacija i procesa:

Aplikacija APP (Automatska Promjena Profila) - upravlja procesom odabira DSL linija koje ulaze u proces optimizacije, inicira promjene profila te provjerava status linije nakon promjene profila.

Proces APP se u svojem radu naslanja na slijedeće OSS/NMS (Operations support systems/ Network Management System) sustave [16]/[15]:

POL (Periodičko Očitanje Linija) - baza periodičkih očitanja linijskih i servisnih parametara korisničkih portova s DSLAM-ova.

BBProvisioner – univerzalno sučelje za konfiguraciju DSLAM-ova. Sustav pristupa element managerima (EM) [11] putem NBI sučelja [12].

Osim navedenih sustava APP proces ima sučelje prema tehničkoj bazi opreme i servisa.

U poglavlju II opisana je arhitektura i implementacija DSM sustava. U III poglavlju opisan je algoritam rada APP procesa. U IV poglavlju opisani su DSLAM profili korišteni u optimizaciji xDSL linija a u IV poglavlju opisan je mehanizam promjene profila.

U V poglavlju predstavljeni su rezultati rada sustava a u sljedećim poglavljima opisana su moguća poboljšanja i reference.

II. ARHITEKTURA I IMPLEMENTACIJA DSM SUSTAVA

Centralni dio DSM sustava je aplikacija APP (Automatska Promjena Profila) koja u svojem radu komunicira s nekoliko OSS/NMS sustava i aplikacija. Na slici 1 prikazana je arhitektura DSM sustava.

Opis komponenti DSM sustava te komponenti s kojima DSM sustav komunicira:

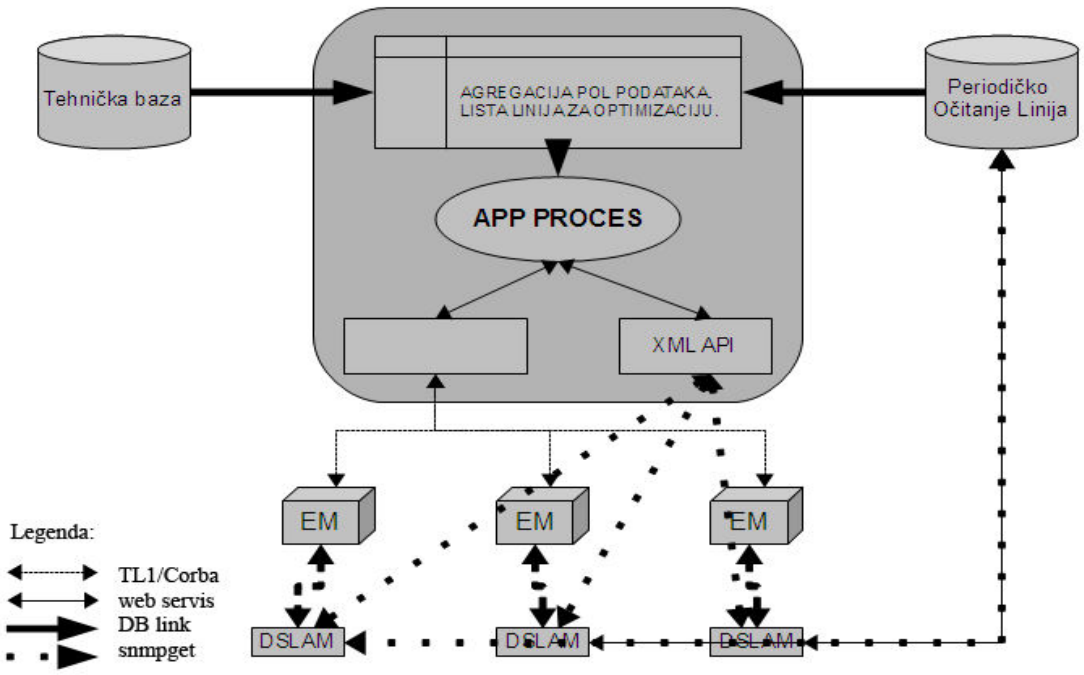
APP (Automatska Promjena Profila) – aplikacija u kojoj je implementirana logika detekcije DSL linija koje ne zadovoljavaju definirane parametre kvalitete. Podaci o kvaliteti linije dnevno se agregiraju iz POL sustava a tehnička baza opreme i servisa koristi se u procesu primjene graničnih vrijednosti. APP također upravlja procesom odabira profila koji se primjenjuju na pojedinom korisničkom portu a sama promjena profila odvija se preko sustava BBProvisioner. Nakon uspješne promjene profila APP aplikacija provjerava rada DSL linije nakon primjene novog profila. Aplikacija komunicira s više OSS/NMS sustava koji su niže navedeni. Za razvoj aplikacije APP korišteni su OpenSource alati (Python v2.5 [2], PostgreSQL v8.1 [3], Apache [4], Linux CentOS v5.3[5]).

POL (Periodičko Očitanje Linija) - baza periodičkih očitanja linijskih i servisnih parametara korisničkih portova s DSLAM-ova. Sustav očitava parametre putem snmp protokola u intervalima od 15 i 60 minuta. Podaci iz POL baze nužni su za određivanje kvalitete DSL linije

BBProvisioner – univerzalno sučelje za konfiguraciju DSLAM-ova. Sustav pristupa element managerima (EM) putem NBI sučelja. APP ostvaruje komunikaciju s BBProvisioner aplikacijom kako bi dobio informaciju o trenutnom profilu na korisničkom portu i/ili inicirao promjenu profila. Sustav trenutno ima mogućnost komunikacije s tri različite DSL platforme.

XMP API – sučelje za provjeru statusa korisničkog porta na DSLAM-u. DSM sustav prije promjene korisničkog profila provjerava da li je na DSL liniji ostvarena sinkronizacija između DLSAM porta i korisničkom mopdema.

DIS (Documentation and Inventory System) – tehnička baza opreme i servisa. DSM sustav primjenjuje različite kriterije kvalitete linije ovisno o uslugama koje korisnik ostvaruje preko DSL linije. Tehnička baza je centralno mjesto spremanja informacija o korisničkim uslugama.



Slika 1. Arhitektura DSM sustava

III. ALGORITAM APP PROCESA

Zadatak APP sustava je prepoznati korisničke DSL linije lošije kvalitete tj. linije s narušenim linijskim i/ili servisnim parametrima te promjenom parametara na liniji povećati stabilnost linije, povećati otpornost linije na vanjske utjecaje a time povećati kvalitetu usluge.

Algoritam APP sustava je zamišljen kao kontinuirani proces koji se sastoji od nekoliko koraka koji se izvršavaju slijedećim redoslijedom:

- dnevna agregacija POL podataka, generiranje dnevne liste portova s narušenim performansama
- period praćenja korisničkih linija u duljem vremenskom periodu i generiranje liste portova koje ulaze u proces optimizacije
- odabir novog profila koji će se primijeniti na korisničkoj liniji
- provjera statusa korisničke linije prije promjene profila
- promjena profila na korisničkom portu
- provjera statusa korisničke linije nakon promjene profila
- period praćenja stanja linije nakon primjene novog profila te odlučivanje o zadržavanju postojećeg profila ili vraćanje starog profila

Početni korak u radu algoritma je prepoznati linije narušene kvalitete a sustav se za potrebe detekcije takvih linija koristi podacima koje prikuplja sustav naziva POL (Periodičko Očitanje Linija). POL sustav kontinuirano očitava linijske i servisne parametre sa svih xDSL linija.

Slijedeći parametri su definirani kao ključni pokazatelji stabilnosti DSL linije te direktno ukazuju na kvalitetu pružene usluge.

- SNR_DS (signal noise ratio downstream) [8] – omjer signal/šum u silazu
- SNR_US (signal noise ratio upstream) [8] – omjer signal/šum u uzlazu
- ES (error second) [6] – broj intervala od jedne sekunde s bilo kojom zabilježenom pogreškom u prijenosu
- SES (severely errored second) [7] – broj intervala od jedne sekunde unutar kojeg se više puta dogodio out-of-frame (OOF) i ozbiljno je narušena kvaliteta prijenosa
- INITS [13] – broj pokušaja inicijalizacije DSL sinkronizacije

Kriterij odabira linija s narušenom kvalitetom usluge nije isti za sve korisničke linije već ovisi o tipu usluge koje je podijeljena u dvije osnovne skupine:

1 – samo Internet usluga
2 – Internet + IPTV i/ili VoIP usluga

Tablica niže prikazuje kriterije kvalitete DSL linije.

Tablica I. kriteriji kvalitete DSL linije

Parametar	„samo Internet“	„Internet+ IPTV/VoIP“
SNR_DS	< 4dB za > 10% očitanja	< 6dB za > 10% očitanja
SNR_US	< 4dB za > 10% očitanja	< 6dB za > 10% očitanja
ES	> 40 za > 10% očitanja	> 10 za > 10% očitanja
SES	> 4 za > 10% očitanja	> 0 za > 10% očitanja
INITS	> 0 za > 10% očitanja	> 0 za > 5% očitanja

APP sustav jednom dnevno agregira POL podatke za protekla tri dana a zatim primjenjuje kriterije o kvaliteti linije prikazane u tablici broj 1. Ukoliko linija zadovolji bilo koji od pet navedenih uvjeta biti će uvrštena u dnevnu listu portova narušene kvalitete.

Praćenjem rada DSM sustava u duljem vremenskom periodu primijećeno je da vremenske nepogode direktno utječu na pad kvalitete usluge. Algoritam APP-a definiran je tako da će djelovati samo na linije koje dulji vremenski period imaju narušene parametre kvalitete. Kako bi se iz procesa isključili portovi s povremenim, kratkotrajnim lošim parametrima kvalitete u proces optimizacije ulaze samo portovi koji se pojavljuju u više dnevnih lista nastalih agregiranjem POL podataka.

Ulazna lista portova za obradu APP procesa nastaje presjekom tri dnevne liste u zadnjih 9 dana. Proces ima još jedan uvjet na ulaznu listu portova a to je da se promjene parametara smiju primijeniti na najviše 10% portova istog mrežnog elementa tj. DSLAM-a. Ovaj uvjet je uveden iz razloga što sinkronizacija DSL linije ima utjecaja na susjedne linije u kabelu.

Kako bi proces promjene profila što manje utjecao na pružanje usluge, promjene profila se odvijaju isključivo u noćnim satima u intervalu od 1 sat poslije ponoći do 6 sati ujutro.

Proces istovremeno vrši promjene na više platformi i više mrežnih elemenata. Broj procesa je moguće po potrebi prilagođavati, zavisno od broja portova nad kojima se radi promjena profila, specifičnostima pojedinih platformi i slično.

Proces APP prije promjene profila provjerava trenutni profil na portu te status DSL linije. Novi profil će se primijeniti samo ako je korisnički modem sinkroniziran jer je jedino u tom slučaju moguće provjeriti da li se korisnički modem nakon promjene profila opet

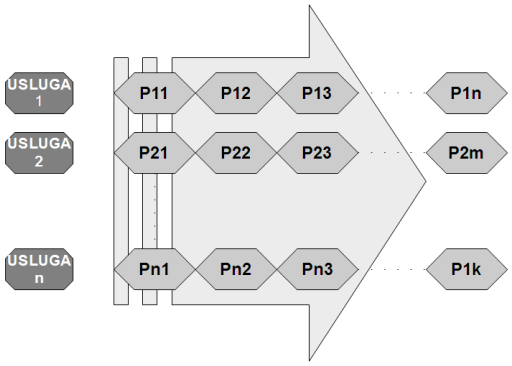
sinkronizirao. Ukoliko modem nije sinkroniziran, novi profil se neće primijeniti a korisnička linija će u nekoj od idućih iteracija APP procesa, kada bude sinkronizirana, doći na red za promjenu profila. Trenutni profil na DSL portu ulazni je podatak za odabir novog profila koji APP sustav primjenjuje s ciljem poboljšanja kvalitete linije.
Nakon promjene profila korisnički DSL modem ponovno se sinkronizira s portom na DSLAM-u. Proces ima ugrađen mehanizam provjere sinkronizacije nakon promjene profila te u slučaju da se nakon 10 minuta od promjene profila modem nije sinkronizirao profil se vraća na profil prije posljednje promjene.

Linije za koje DSM sustav nije postigao zadovoljavajuće poboljšanje performansi označavaju se kao „nepopravljive“ te se putem sustava za upravljanje resursima i procesima zadaci prosljeđuju tehničarima na terenu koji će izvidom na terenu ustanoviti problem te otkloniti smetnju.

IV. OPIS KORIŠTENIH PROFILA

S obzirom da je na strani telekomunikacijskog operatora DSLAM (Digital Subscriber Line Access Multiplexer), odnosno port na DSLAMu vezan uz korisničku liniju, točka na kojoj se najviše može kontrolirano utjecati na karakteristike linije, APP sustav težište svog djelovanja stavlja na ovaj element.

Na korisničkom DSLAM portu moguće je djelovati na različite parametre linije ovisno o proizvođaču opreme, međutim postoje i standardne grupe parametara koji su zastupljeni kod svih proizvođača. Tako je na primjer osim parametara koji su vidljivi i krajnjem korisniku kao što su brzina u silazu i uzlazu i kanala za pojedine usluge (PVC – Permanent Virtual Circuit), uobičajeno konfigurirati i izlaznu snagu po liniji, broj istovremeno spojenih uređaja po liniji, razne zaštite od napada izvana (npr Anti IP spoofing), ADSL standard po kojem radi linija i mnoge druge ovisno o mreži operatora i usluzi korisnika.
Željene karakteristike linije dobivaju se kao posljedica ispitivanja i mjerenja karakteristika linija s točno podešenim vrijednostima određenih parametara. Uobičajeno je nakon takvih ispitivanja vrijednosti različitih parametara grupirati i takvu grupnu konfiguraciju parametara primjenjivati na sve portove u mreži za koje se želi dobiti ista ili slična karakteristika linije. Takva grupna konfiguracija više parametara linije koja se željeno postavlja na korisnički port na DSLAM-u naziva se korisničkim ADSL profilom. Ovisno o mogućnostima platforme moguće ga je kao takvog spremati na samoj platformi ili se o grupiranju parametara brinu prateći OSS sustavi.
Za potrebe DSM sustava unutar T-COM Hrvatska napravljeni su tzv. lanci profila za svaku pojedinu uslugu po brzinama. Unutar istog lanca će se tako nalaziti profili koji korisniku omogućavaju korištenje tražene usluge a redoslijed im je složen po sličnosti inicijalnom profilu koji se postavlja na korisnički port prilikom aktiviranja usluge. DSM sustav u svom radu za pojedini port prolazi kroz pripadajući lanac tako da prvo na korisnički DSL port postavi profil najsličniji početnom, zatim ako je potrebno sljedeći najsličniji itd.



Slika 2. Lanci profila za DSM sustav

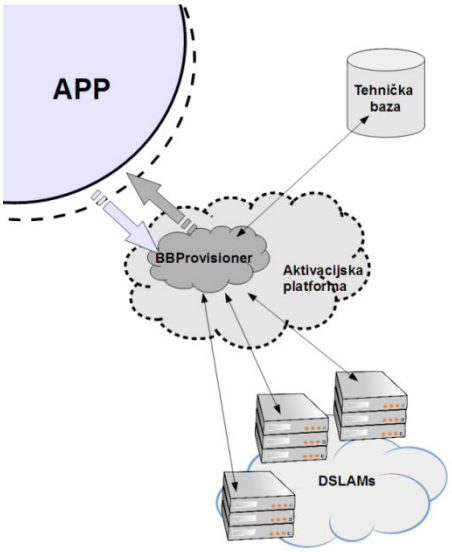
Profili koji su bliži početnom, prvenstveno koriste različite mehanizme zaštite prijenosa podataka, a kako se odmiče po lancu ide se i prema degradaciji brzine prijenosa podataka. Kao mehanizmi zaštite prijenosa podataka koriste se zaštite od utjecaja impulsnog šuma kao što su INP [18] (Input Noise Protection) koji mjeri nalete šuma u intervalima od 0,25 milisekundi i kašnjenje (delay) koje nastaje kao posljedica korištenja mehanizma umetanja kontrolnih bitova u pakete podataka i njihovog micanja na odredištu. Praćenjem omjera ova dva parametra može se određivati potrebna dužina podatkovnih paketa i na taj način utjecati na kvalitetu DSL linije. Dodatno se kao zaštita koristi i isključivanje SRA [17] (Seamless Rate Adaptation) mehanizma kojeg nudi ADSL2 standard.

V. MEHANIZMI PROMJENE PROFILA

APP sustav u svom radu komunicira s nekoliko mrežnih platformi, izvedenih od strane različitih proizvođača.
Da bi ostvario promjene sustav šalje zahtjeve prema jednom od modula OSS aktivacijske platforme. Prije slanja zahtjeva s promjenama sustav očitava i vrijednosti parametara o kojima će ovisiti daljnji tijek aktivnosti prema pravilima algoritma aplikacije.
Komunikacija OSS aktivacijske platforme s odredišnim mrežnim platformama izvedena je koristeći njihova otvorena programibilna sučelja (API – Application Programming Interface). Putem ovih programibilnih sučelja sustav preko element managera pojedine platforme postavlja ili čita parametre linije u skladu s ranije spomenutim pravilima.

Modul OSS aktivacijske platforme na koji APP šalje svoje zahtjeve za promjenama ili očitanjima konfiguracija naziva se BBProvisioner. Ova komponenta u procesu promjene konfiguracije na mrežnom elementu koristi

tehničku bazu pomoću koje je moguće uspostaviti vezu između usluge i mrežnih elemenata koji su korišteni za njenu realizaciju. Čitajući ove podatke komponenta zna prema kojem element manageru treba proslijediti zahtjev.



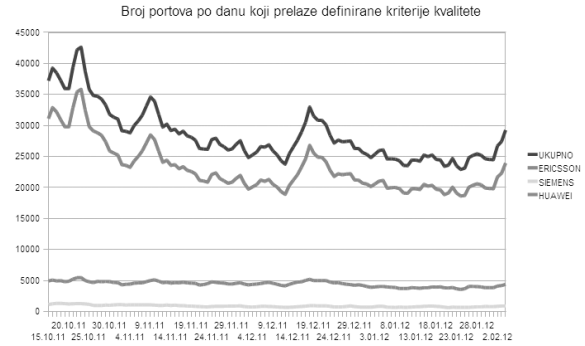
Slika 3. Prikaz mehanizma promjene profila

Dodatno, komponenta ovisno o platformi, a u skladu s definiranim sljedovima profila na element manageru postavlja odgovarajuće parametre za svaku pojedinu DSL liniju čije definicije se pohranjuju na aktivacijskoj platformi.
U trenutnoj izvedbi BBProvisioner za komunikaciju s element managerima se koristi TL1 i CORBA sučelja, ali sama komponenta praktički nema ograničenja na tehnologiju.
BBProvisioner modul aktivacijske platforme izveden je korištenjem Java Servlet tehnologije putem koje zaprima HTTP zahtjeve i dalje ih prosljeđuje na core komponente koje znaju komunicirati s odredišnim platformama.
Komponenta kao servlet container koristi Apache Tomcat.

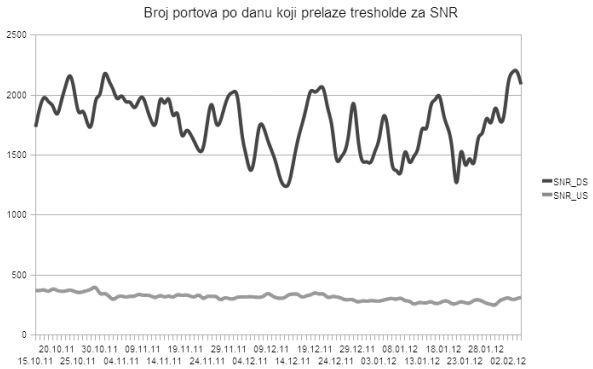
VI. REZULTATI RADA SUSTAVA

Rezultati rada DSM sustava temelje se na 5 mjeseci rada u produkcijskoj mreži telekomunikacijskog operatera. Iz analize se može zaključiti da je DSM sustav vidno smanjio broj ES/portu u danu. Osim toga, ukupan broj portova koji prelaze granične uvjete kvalitete DSL linije su također smanjeni. Vidljivo je također da je došlo do trenda smanjenje broja SES/portu no isto tako je vidljivo da povremene vremenske nepogode mogu kratkotrajno narušiti performanse DSL linije.

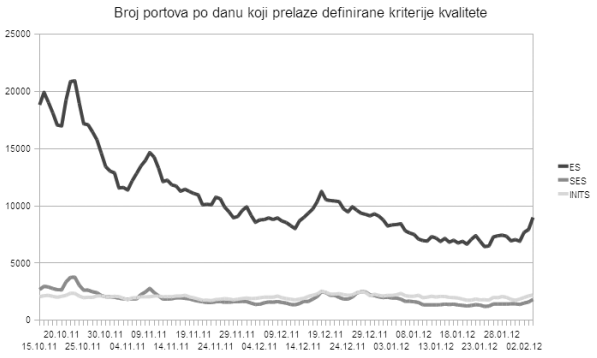
Na slijedećim grafovima prikazan je utjecaj DSM sustava na mrežu operatera.



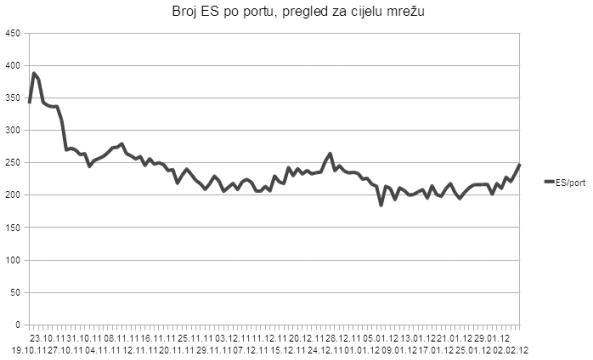
Slika 4. Prikaz broja DSL linija po platformi koje ne zadovoljavaju kriterije kvalitete.



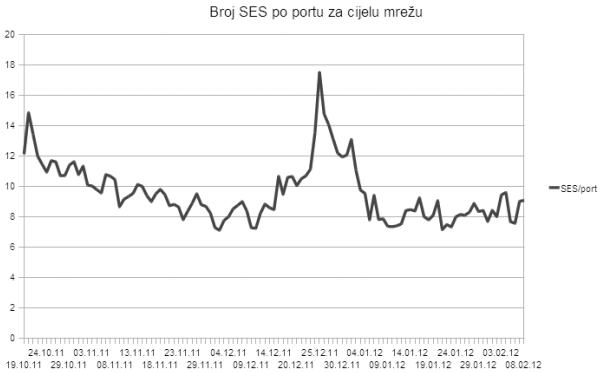
Slika 5. Prikaz broja DSL linija koje ne zadovoljavaju kriterij za SNR



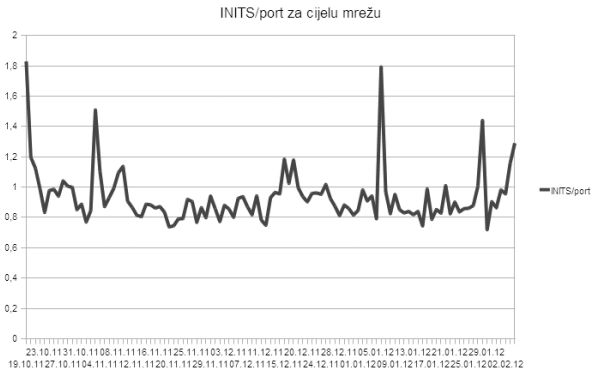
Slika 6. Prikaz broja DSL linija koje ne zadovoljavaju kriterij za ES, SES ili INITS



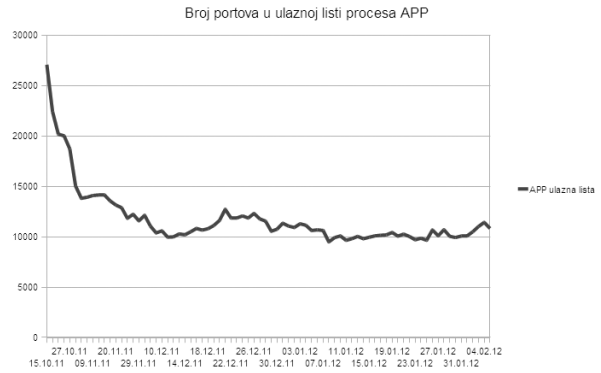
Slika 7. broj ES, normalizirano po portu za cijelu mrežu operatora



Slika 8. broj SES, normalizirano po portu za cijelu mrežu operatora



Slika 9. broj INITS, normalizirano po portu za cijelu mrežu operatora



Slika 10. Prikaz broja DSL linija koje ulaze u proces optimizacije profila

VII. MOGUĆA UNAPRJEĐENJA

DSM sustav trenutno kvalificira korisničku DSL liniju analizirajući samo pet parametara koje dohvaća iz POL sustava. Sustav se može poboljšati tako da analizu kvalitete linije radi na osnovu većeg broja parametara. Također, sustav ne mora biti ograničen samo na analizu podataka iz POL sustava nego ulazni podaci mogu biti razne tehničke baze, podaci iz baze kontaktnog centra i slično. Također, DSM sustav trenutno profile mijenja slijedno po unaprijed definiranom redoslijedu. Slijedeće inačice sustava mogu odabir optimalnog profila određivati uspoređivanjem linijskih i servisnih parametara linije prije i nakon promjene svakog od profila.

VIII. Zaključak

DSM sustav se pokazao kao koristan sustav koji preventivno djeluje na povećanje kvalitete korisničkih DSL linija. Sustav automatizirano prepoznaje problematične linije i utječe na poboljšanje performansi čime se direktno povećava kvaliteta usluge.

Najveće značajke sustava su:

- Automatsko prepoznavanje linija narušene kvalitete
- Preventivno podizanje kvalitete DSL linija
- Smanjenje broja poziva u kontaktni centar
- Veći broj otklona smetnji bez potrebe za radom tehničara na terenu

Sustav svojim radom povećava efikasnost održavanja mreže čine se smanjuju troškovi održavanja.

OPTICAL NETWORKS

Optimal techno-economic selection of the optical access network topologies

Željko Božinović, Haris Dizdarević, Sead Dizdarević
BH Telecom d.d. Sarajevo,
Obala Kulina Bana 8, 7100 Sarajevo, BiH
E-mail: zeljko.bozinovic@bhtelecom.ba, haris.dizdarević@bhtelecom.ba, sead.dizdarevic@bhtelecom.ba

Abstract - Optimal techno-economic selection of optical access network topologies involves finding the key techno-economic criteria that will be used for the topology selection. We have developed an analytical method for calculating optimal techno-economic selection of topologies. The proposed method determines the required number of optical fibers of certain characteristic segments of the access network, taking into account the density of users per 1 km^2, guaranteed bandwidth for each user, and the possible topology of optical access networks. The results show that the increase in density of users, with a constant guaranteed bandwidth, isn't the determining factor for the optimal choice of topology. On the other hand, the same results show that increasing the guaranteed bandwidth, with a constant density of users, represent critical elimination factor for optimal techno-economic selection of topologies. Under the same conditions, results show that the initially favorable topology, in terms of techno-economic feasibility, after a few iterations in bandwidth increase may become unfavorable compared to competing considered topologies.

I. INTRODUCTION

Authors involved in research related to finding the optimal choice of technologies and corresponding topologies for FTTx access networks usually start from the fact that the new network being built on the fiber optical cables basis or to perform the reconstruction of the existing copper network using method of shortening the copper wires. It often argues that the optical networks CAPEX, compared to solutions based on the shortening of copper pairs is still too high, because the share of construction costs which is dominant in relation to other costs [4] (Figure 1). Therefore it is proposed a gradual transition to FTTH solutions using xDSL technology.

The existing telecommunications infrastructure (cable ducts, pipes and sheathing of existing copper cables), which has previously invested huge capital, is often ignored or placed in another plan. Taking advantage of existing telecommunications infrastructure can significantly reduce construction costs and create favorable preconditions for investment in optical access networks as a better long term solution (Figure 2.). Figure 2 shows that the cost of cabling and fiber optic cables also have a significant share of CAPEX, and it would be desirable to minimize that part of the future investment.

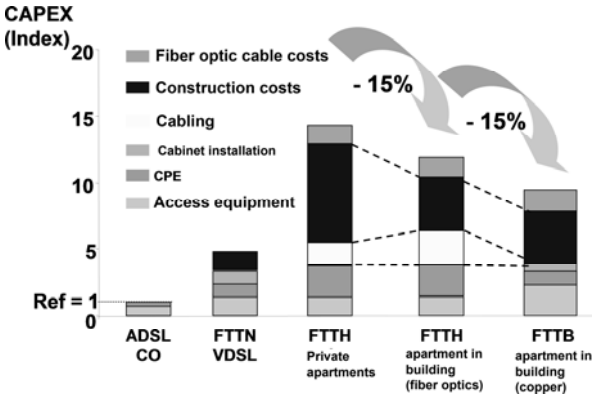

Figure 1. CAPEX comparison for FTTx solutions.

On the other hand, a lower number of required optical fibers imply a greater probability that the existing telecommunications infrastructure will be able to meet all present and future needs for expanding the capacity of the access network, caused by the increasing number of users or the guaranteed bandwidth to the user.

In this study we started with the thesis that there is a great probability that the increase in the number of users and the guaranteed bandwidth, initially favorable

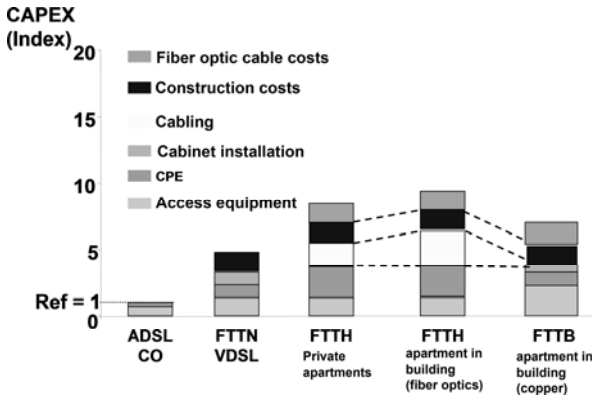

Figure 2. Comparison of reduced CAPEX for FTTx solutions.

technology, in terms of number and length of fiber optic strands, can turn into a very unfavorable and vice versa.

The first task of our research was to find those technical solutions of the FTTx access networks that

maximum use the existing telecommunications infrastructure, in terms of permanent increase in the number of users, and guaranteed bandwidth for end users, in order to reduce construction costs, cabling and fiber optic cables.

The second task of the research was mathematical model, formed for the comparative analysis, which has to be technologically independent and relatively easy to use and understand.

In order to fulfill these tasks, we planned to check the behavior of available access technologies and associated topologies in terms of required number of optical fibers and their total length, in terms of increasing the number of users and guaranteed bandwidth.

Since the results for different technologies must be mutually comparable, telecommunications infrastructure and its topology has to be equal for all technologies.

For the purpose of analysis, we decided to use the users density as one of the influential parameters, rather than the number of users. We also decided that the density is uniform and that applies to an area of 1km^2. In this way it's possible to apply analytical calculation method and relatively simple mathematical model to demonstrate the increase in the number of optical fibers in accordance with the increasing density of users and the guaranteed bandwidth to the user. A detailed description of the mathematical model is presented in chapter two.

By applying the mathematical model we developed as well as analysis of the obtained results we have confirmed the starting hypothesis, but only in terms of increasing the guaranteed bandwidth, while in terms of increasing the users density it isn't confirmed. Some of the considered technologies and the corresponding topologies, by increasing the guaranteed bandwidth, have ceased to be the most suitable for the application and become unfavorable or very unfavorable. On the other hand, the initial schedule of technology under favorable condition doesn't change with increasing of users density. Comparing the areas with high and low status of benefits we have defined technologies and associated topologies which arises as the best candidates for further evaluation based on additional criteria, which was not the subject of this research, but the proposal for future research in this area. Other results and conclusions will be presented in detail in chapters III and IV.

II. DEVELOPING A MATHEMATICAL MODEL

A. *Initial assumptions*

Initial assumptions in defining the mathematical model are:

- Observed users are located within the squared area;
- Users in observed area are uniformly distributed that won't affect the universality of model, although they neglected their real grouping in the buildings as well as the number of building stories.
- Mathematical model treats a segment from central office (CO), through a central distribution cabinets (CDO) and distribution cabinets (DO) to the end user.

B. *Mathematical model*

If we look a part of an squared area of 1 km^2, where there are situated users with density g, the elementary area where there is only one user is given by expression:

$$P_e(g) = \frac{1}{g} \quad [m^2] \tag{1}$$

In this case area with N users is given by the following expression:

$$P_N(g) = N \cdot P_e(g) \quad [m^2] \tag{2}$$

Side of the square described with expression (2) is a following function:

$$a_N(g) = \sqrt{N \cdot P_e(g)} = \sqrt{\frac{N}{g}} \quad [m] \tag{3}$$

Assuming that the optical fibers distribution point to

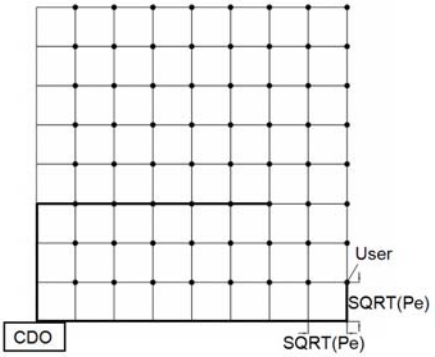

Figure 3. Distribution of the users on the imaginary surface of the observed square.

the users is on the edge of the square with surface area of $P_N(g)$, where is $N = 1, 2, 3, \ldots$, assuming that each user is located on the edge of the square with surface area P_e (Figure 3), which doesn't lose the generality of the obtained solution, we obtain that the total length of optical fibers from the distribution point to each user (one fiber per user), represented by the following expression:

$$L_N(g) = \sqrt{P_e(g)} \sum_{i=1}^{\sqrt{N}} \sum_{j=1}^{\sqrt{N}} (j+i) \quad [m] \tag{4}$$

The expression (4) applies when the $\sqrt{N}$ is whole number and otherwise we are using the following expression:

$$L_N(g) = 2 \cdot \sqrt{P_e(g)} \sum_{i=1}^{\sqrt{\frac{N}{2}}} \sum_{j=1}^{\sqrt{\frac{N}{2}}} (j+i) \quad [m] \tag{5}$$

where $L_N(g)$ function gives a total length of optical fiber from optical fibers distribution point to N end users, as a function of the density of users

For cases of optical fibers distribution, into CDO or DO, active or passive network elements (*splitters*), in accordance with $1{:}2^i$, where i = 1, 2, 3, ..., n, expressions (4) and (5) are translated in the following form:

$$L_N(g) = \sqrt{P_e(g)} \sum_{i=1}^{M} \sum_{j=1}^{M} (j+i) \quad [m] \tag{6}$$

and

$$L_N(g) = 2 \cdot \sqrt{P_e(g)} \sum_{i=1}^{M} \sum_{j=1}^{M} (j+i) \quad [m] \tag{7}$$

where the variable $M = \sqrt{N}$ *and* $M = ROUNDUP\sqrt{N}$ (function ROUNDUP (x) is the rounding of the variable *x* to the first integer greater value), respectively, causing a minor mistake which is negligible.

If a technical solution of the access network predicts, except CDO, the existence of a number of DOs, which is closer to end users and their groups, then the expressions (4), (5), (6) and (7) refers to the access network part from DO to the end users. In this case, the optical fibers total length from DO to the end users, for a single CDO which is powered by the N users, we get by using the following expression:

$$L_{N(1:D)}(g) = \sum_{i=1}^{n} L_{N\,i}(g) = \begin{bmatrix} za\ N_i = N_{DO} \\ gdje\ je \\ i = 1,2,3...n \end{bmatrix} = N_{DO} \cdot L_N(g) \quad [m] \tag{8}$$

where *n* represents the number of DO within the area covered by a single CDO, and $L_{N\,i}(g)$ refers a total length of optical fibers from the i-th DO to end users.

$L_{N(1:D)}(g)$ represents the total length of optical fibers from all DOs to the end users within the area covered by the CDO.

We have assumed that each DO is situated on the further lower corner of square, compared to the CDO, and that these squares represent the total surface area of P_e, covered by single DO.

Based on such adopted assumption, the additional optical fibers length from the CDO to the all DOs, for the idealized topologies, which depends on guaranteed bandwidth to the end user and the user density, where $\sqrt{\frac{N_{\max}}{N_{DO}}}$ is an integer and $N_{\max} \neq N_{DO}$ and $N_{DO} \neq 1$, and splitter type $1{:}2^n$, $n = 0, 1, 2, ...$, represent a function given by the following expression:

$$L_{di}(B_G, g) = \left(2 \cdot \sqrt{\frac{N_{\max} \cdot P_e(g)}{N_{DO}}} \cdot \sum_{i=0}^{\sqrt{\frac{N_{DO}}{2}}-1} \sum_{j=1}^{\sqrt{\frac{N_{DO}}{2}}} (j+i) \right) \left(N_{DO} + \operatorname{sgn}(K(B_G)) \cdot \sum_{i=0}^{K(B_G)-1} 2^i \cdot N_{DO} \right) =$$
$$= \left(2 \cdot \sqrt{N_{\max} \cdot N_{DO} \cdot P_e(g)} \cdot \sum_{i=0}^{\sqrt{\frac{N_{DO}}{2}}-1} \sum_{j=1}^{\sqrt{\frac{N_{DO}}{2}}} (j+i) \right) \left(1 + \operatorname{sgn}(K(B_G)) \cdot \sum_{i=0}^{K(B_G)-1} 2^i \right) \quad [m] \tag{9}$$

When $\sqrt{\frac{N_{\max}}{N_{DO}}}$ isn't an integer, under the same conditions, then we used the following expression:

$$L_{di}(B_G, g) = \left[\sqrt{\frac{N_{\max} \cdot P_e(g)}{2 \cdot N_{DO}}} \cdot \left(-\frac{N_{DO}}{2} + \sum_{i=0}^{\sqrt{N_{DO}}-1} \sum_{j=1}^{\sqrt{N_{DO}}} (j+i) \right) \right] \left(N_{DO} + \operatorname{sgn}(K(B_G)) \cdot \sum_{i=0}^{K(B_G)-1} 2^i \cdot N_{DO} \right) =$$
$$= \left[\sqrt{\frac{N_{\max} \cdot N_{DO} \cdot P_e(g)}{2}} \cdot \left(-\frac{N_{DO}}{2} + \sum_{i=0}^{\sqrt{N_{DO}}-1} \sum_{j=1}^{\sqrt{N_{DO}}} (j+i) \right) \right] \left(1 + \operatorname{sgn}(K(B_G)) \cdot \sum_{i=0}^{K(B_G)-1} 2^i \right) \quad [m] \tag{10}$$

where N_{DO} represents the number of DO, and N_D is a number of splittings in each DO, or number of users that is powered by this DO. $K(B_G)$ is a function which represents the ratio of users guaranteed bandwidth B_G and the maximum guaranteed bandwidth, which in the considered topology requires no additional optical fibers between the CDO and DO, and depends on the number of distribution cabinets N_{DO}. The function $K(B_G)$ is given by the following expression:

$$K(B_G) = \begin{cases} 0 & , za\ \dfrac{B_G}{\left(\dfrac{B_{\max}}{N_{D\max}}\right) \cdot N_{DO}} \leq 1 \\ \ln\left(\dfrac{B_G}{\left(\dfrac{B_{\max}}{N_{D\max}}\right) \cdot N_{DO}} \right) & , za\ \dfrac{B_G}{\left(\dfrac{B_{\max}}{N_{D\max}}\right) \cdot N_{DO}} > 1 \end{cases} \tag{11}$$

where B_{max} is the maximum bandwidth of one OLT module, and $N_{D\ max}$ is a maximum possible number of dividing the signal from one OLT module. On the other hand $B_G = B_{G\min} \cdot 2^i \quad [Mb/s]$, and $i = 0, 1, 2, 3, ..., n$, where *n* is the largest number such that the $\frac{N_{\max}}{2^n}$ is odd number or equal to one.

In expressions (9) and (10) square roots $\sqrt{\frac{N_{\max} \cdot P_e(g)}{N_{DO}}}$ and $\sqrt{\frac{N_{\max} \cdot P_e(g)}{2 \cdot N_{DO}}}$, respectively, determine the length of the side of the square whose area equals the surface occupied by a single DO, on the total area covered by a single CDO. The second bracket in expressions (9) and (10) determines the number of optical fibers depend on increasing of the guaranteed bandwidth B_G.

The total length of optical fiber from the CDO to the end user, depending on the guaranteed bandwidth on the

end users side and the users density, for the idealized topology, is given by the formula:

$$L_{UKi}(B_G, g) = L_{N(1:D)}(g) + L_{di\,(1:D)}(B_G, g) \quad [m] \quad (12)$$

Mathematical model for nonidealized (real) topologies (topologies with real users distribution) is derived from the mathematical model for the idealized topology, which is described in terms from (1) to (12). It doesn't mean that the idealized topologies can be used in real topologies, but they are less possible in practice.

Part of the mathematical model described in expressions from (1) to (8) is universal and applies to nonidealized topologies, except in terms of the real users distribution, because it assumes a uniform users distribution. The reason is that in this segment (from the point of the last splitting of the signal to the end user), all users have their own fiber, which isn't shared with other users, and this segment is independent of the increase of user guaranteed bandwidth.

The modified expression for nonidealized topologies is given by relation:

$$L_{dn\,(1:D)\,i\,(i+1)}(B_G, g) = L_{di\,(1:D)\,i\,(i+1)}(B_G, g) \cdot \frac{D \cdot N_{(1:D)\,i\,(i+1)}}{N_{D\max}} \quad [m] \quad (13)$$

where $L_{dn\,(1:D)\,i\,(i+1)}(B_G, g)$ is a function that gives a total additional length of optical fibers between the *i*-th and *i+1* splitting level, depending on the guaranteed bandwidth B_G and user density g, for the nonidealized topology. $N_{(1:D)\,i\,(i+1)}$ is the splitters number *1:D* in nonidealized topology, on the *i+1* level of splitting. *D* is the maximum possible number of users behind the observed DO.

In equation (13) factor $\frac{N_{D\max}}{D}$ determines how much is the maximum possible number of splitters with splitting ratio of 1: D in idealized topology, between the first and second splitting levels. By dividing $L_{di\,(1:D)\,i\,(i+1)}(B_G, g)$ with this ratio and multiplying by the number $N_{(1:D)\,i\,(i+1)}$, we get the total increase in length of optical fibers between the *i*-th and *i+1* splitting level for all splitters with splitting ratio of *1:D*.

The total length of optical fibers in no idealized topology, depending on the guaranteed bandwidth for end users and the users' density, we get by using the following formula:

$$L_{UKn}(B_G, g) = L_{N(1:D)} + \sum_{i=1}^{2} \sum_{\substack{k=2 \\ k\in\{2,3,4,6,8,12,16,24,32,48,64,128,\ldots,D_{\max}\}}}^{D_{\max}} L_{dn\,(1:k)\,i\,(i+1)}(B_G, g) \quad [m] \quad (14)$$

where $L_{N\ (1:D)}$ is given by the expression (8), and $L_{dn\,(1:k)\,ij}(B_G, g)$ is given by the expression (13). In equation (14), in the first sum, *i* represents splitting ratio. The second sum determines the presence of the splitter with splitting ratio *(1:k)*, where $k \in \{2, 3, 4, 6, 8, 12, 16, 24, 32, 48, 64, \ldots, D_{\max}\}$.

The total length of optical fibers from the CO to the CDO, which depends on the distance from the CO to the CDO and guaranteed bandwidth, is given by the following expression:

$$L_{CO-CDO}(B_G, l) = \sum_{i=1}^{N_{OLT}} \frac{B_{G\,i}}{\left(\frac{B_{\max}}{N_{\max}}\right)} \cdot l_i = \left[\begin{array}{l} ako\ je \\ B_{G\,i} = B_G \\ za\ \forall\ i\ gdje\ je \\ i = 1, 2, \ldots, N_{OLT} \\ tada\ slijedi\ da\ je \end{array}\right] = \frac{B_G}{\left(\frac{B_{\max}}{N_{\max}}\right)} \sum_{i=1}^{N_{OLT}} l_i \quad [m] \quad (15)$$

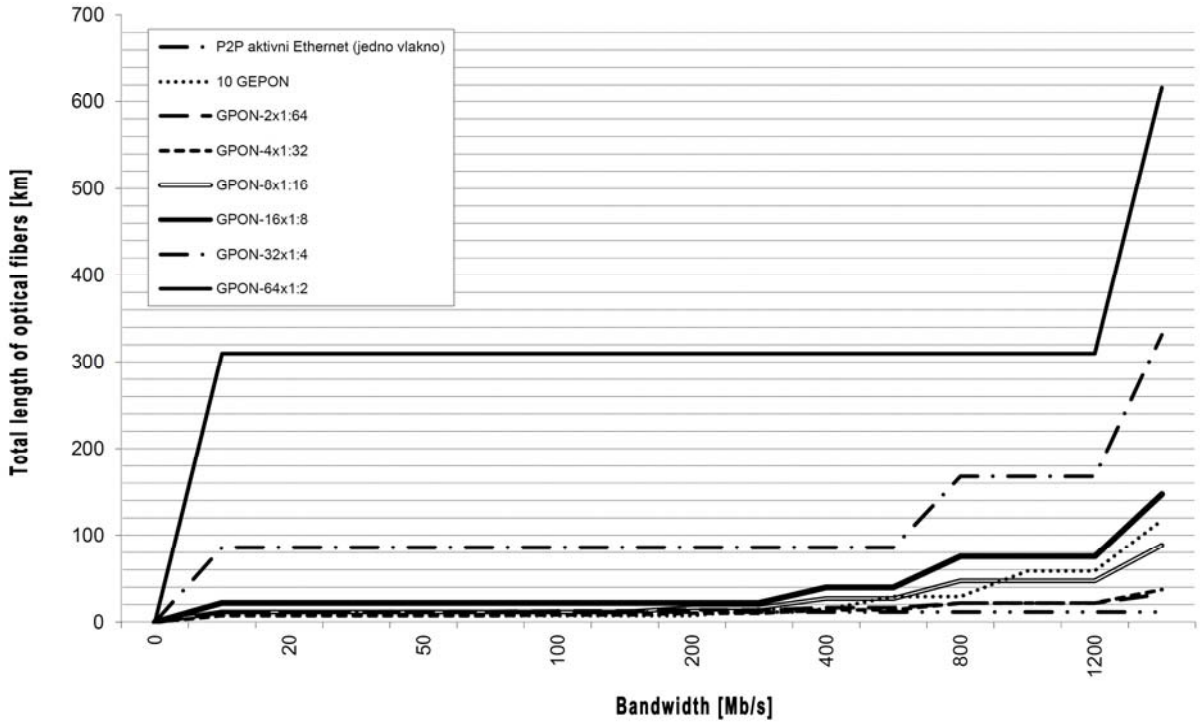
where *l* represents the distance between the CO and CDO, N_{max} is a maximum number of users per single OLT module, and N_{OLT} represents the number of OLT modules required to serve users on area of 1 km^2.

III. RESULTS AND DISCUSSION

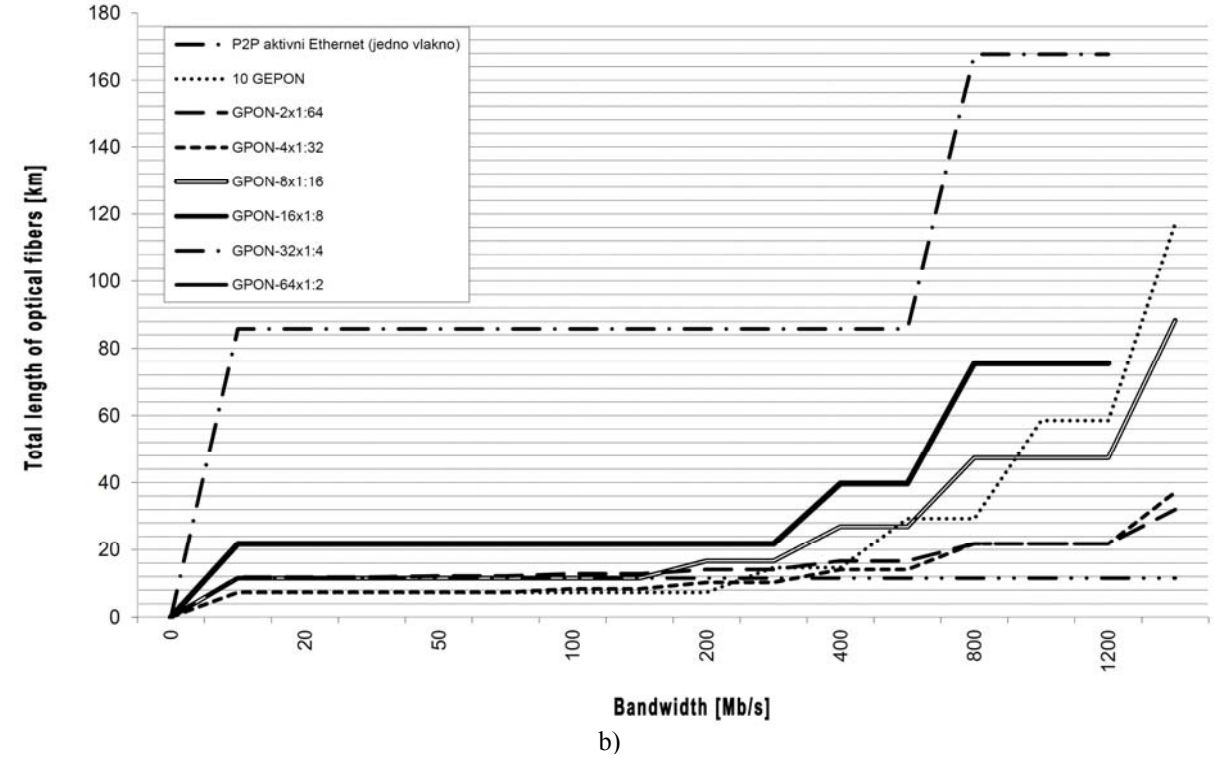
Comparative analysis of the dependence of the number and length of optical fibers by the increasing of users' density with guaranteed fixed bandwidth at the user side showed that the initial advantages or disadvantages of some technologies don't change. This result could be expected due to increased density of users only multiplies the number and length of optical fibers, in the same way in all technologies and corresponding topologies.

On the other hand, comparative analysis of the dependence of the number and length of optical fibers with an increase of guaranteed bandwidth on the user side and a fixed density of users shows that up to 50 Mb/s, GPON with initial topology 4x1:32 and 10GEPON, requiring a minimum length of optical fibers (Figure 4.a and 4.b). However, GPON technology in the base topology 4x1:32 has an advantage, because 10GEPON achieved these lengths without of contribution of optical fibers, in the segment of DO to the end user. GPON technology in the base topology 4x1:32 achieves the best balance between the required lengths of optical fibers for bandwidth up to 300 Mb/s.

We note that the figures 4.a) and 4.b) are identical but the Figure 4.b) shows a narrow range of optical fibers length for easy identification of typical graphics elements. Due to this reason, in Figure 4.b) we don't see GPON 64x1:2 topology. A typical transitions for all technologies and associated topologies are the same for all users density, and for this reason we show only the graphics in Figures 4.a) and 4.b).



a)



b)

For the bandwidth up to 40 Mb/s, second result, regarding the optimality, take the topologies of P2P active Ethernet and GPON topology 2x1:64 and 8x1:16. After increasing the bandwidth, required length of optical fibers for GPON topology of 2x1:64 increases. GPON topology 8x1:16 follows the topology of the P2P active Ethernet up to 150 Mb/s bandwidth, after which grows required length of optical fibers in this topology, and because of the rapid rise, quickly becomes weaker than GPON topology of 2x1:64. After this bandwidth, initial GPON topology 8x1:16 alternates with 10GEPON topology permanently. For a bandwidth exceeding 400 Mb/s, topology of P2P active Ethernet becomes optimal, as might be expected, because the change of bandwidth doesn't affect on this topology only (in terms of passive part of the network), but it initially requires a greater length of optical fibers and thus the greater initial investment, especially in the version with two fibers per customer. It is also characterized by a great length of the optical fibers in part from the CO to the CDO as it degrades further in terms of benefits for implementation and optimal utilization of existing telecommunications infrastructure.

We considered the idealized topologies of selected technologies, in which all the splitters are equal. It will be a very rare case in reality than the case of topology with different types of splitters. Practical topologies have a combination of properties of idealized topologies, but due to the large number of possible combinations we didn't specifically discuss them. We can only say that these topologies can simultaneously have both good and bad qualities of the considered idealized topologies, and in concrete situation can be better or worse than them. We have to model each of these topologies with offered mathematical model and compared their characteristics with the characteristics of the idealized topologies, and on that basis make a conclusion about the optimality of their application in concrete situations.

Finally, let's say that this analysis considers only the passive part of the network, and after such a comparative analysis, that was conducted on the basis of mathematical modeling, it's necessary to consider other components (active equipment) and under the same conditions consider their techno-economic behavior at the change of guaranteed bandwidth to the user, and user density in the considered area. This will be the subject of our further research in this field.

IV. CONCLUSION

In terms of the required length of optical fibers, starting GPON topology 4x1:32, represents an optimal solution, when we talk about the passive part of the network, both for the initial investment and future needs, because in a large range of guaranteed bandwidth provides the best results. In terms of demand for PEHD pipes, micro pipes and the optical fibers number in some segments, this topology also shows the optimal results, both in terms of initial investment, but also in terms of the need for future investment in the passive part of the network, increasing the guaranteed bandwidth.

The study provided the best candidates for further research, which will include other crucial factors in choosing a final solution in concrete situation in practice.

In this study we confirmed the initial hypothesis, and also we fulfill both the set up tasks, and we opened a series of new questions and tasks for future research in this field.

Abstract - The application of all-optical switching fabrics will be an important breakthrough in avoiding capacity bottleneck caused by electronic-switching in optical networks. All-optical domain of achieved network is characterised by absence of optical-electrical-optical conversions. In this paper, the-state-of-the-art of optical switching fabrics used in optical cross-connect is reviewed. Moreover, availability analysis of those switching fabrics have been examined. Methods for increasing availability of MEMS switches and entire optical network have been shown.

I. INTRODUCTION

Contemporary telecommunication networks demand huge amount of capacity due to the exponential growth of IP traffic. In order to face this problem, considerable research is devoted to design and implementation of optical network layer. One of the main aspirations regarding optical network design is avoidance of capacity bottleneck caused by electronic switching[1]. As single optical fiber can offer transmission capacity of 5 THz, it is important to have adequate equipment that will be able to exploit large bandwidth. Although optical Dense Wavelength Division Multiplexing (DWDM) is providing impressive transmission capacity, extension of optics from transmission to switching is needed. In this context, all-optical switching fabrics play a central role and will be a significant breakthrough in providing huge bandwidth capacities.

Fundamental issue in all-optical switching is supporting efficient and cost-effective transport services for wide range of bandwidth granularities. Multi-granular optical cross-connects (MG-OXCs)[2-4] are supporting optical circuit switching (OCS), optical burst switching (OBS) and even optical packet switching (OPS). Architecture on Demand (AoD)[5] concept of MG-OXC consists of large number of not fully wired optical components, which can dynamically adapt in real time in order to provide the required functionality to satisfy the switching and processing requirements of network traffic. In AoD two optical switching fabrics are used: slow MEMS (*Micro-Electro-Mechanical Systems*) optical switches and fast switches based on SOA (Semiconductor-Optical-Amplifier) or PLZT (*Plumbum Lanthanum Zirconate Titanate*). Those two switching types can support OCS, OBS and OPS. In this paper MEMS switching technologies are reviewed.

The remainder of this paper is organized as follows: Section II and III describe and classifies the optical switching technologies used in optical cross-connects. Section IV explains how the component failure rates were selected. Section V shows the analytical availability calculation for MEMS switches and introduces possible approaches for the usage of internal redundancy. Section VI concludes the paper.

II. OPTICAL SWITCHING TECHNOLOGIES

The basic premise of optical switching is that by replacing existing electronic network switches with optical ones, the need for OEO (optical-electrical-optical) conversions is removed. Advantages of avoiding OEO conversions are significant[6]. First, optical switching technologies should be cheaper, as there is no need for lots of expensive high-speed electronics. Secondly, complexity removal of electronics switching elements should make switching element smaller and more practical to implement. Unfortunately, most solutions for all-optical switching are still under study. As different technologies feature different performance, and optical switching technologies support wide range of applications, it seems reasonable that there will not be one wining solution. Switching technologies differ in their performances (scalability, switching speed, insertion loss, crosstalk, etc.) In this paper MEMS switching technologies will be reviewed.

III. MEMS OPTICAL SWITCHES

MEMS[7-9] are characterized as slow optical switches. They switch data in ms range and can be used for optical channel switching. There are two main approaches to implement MEMS optical switches: 2D and 3D MEMS switches. These technologies differ in terms how they are controlled and on principle they direct light beams. 3D MEMS are preferred when the switch scaling is bigger, because they use less mirrors than the 2D MEMS for same number of input and output fibers.

Both switches have low insertion loss. The main sources of insertion loss are:

- Variation in optical path lengths
- Variation in position and angle of optical beam sent to the output port
- Loss of optical power at the mirror boundary

- Roughness and warping of mirror surfaces

A. 2D MEMS

In this architecture, mirrors are arranged in a cross-bar configuration as shown on Figure 1. Each mirror has only two states: *cross* and *bar*[10]. *Bar* represents state in which light is passed uninterrupted, while in *cross* state light is reflected to one of the output fibers. The binary nature of the mirrors positions simplifies the control mechanism. Control mechanism consists of simple TTL (Transistor-Transistor-Logic) gates and appropriate amplifiers to provide adequate voltage levels to actuate mirrors.

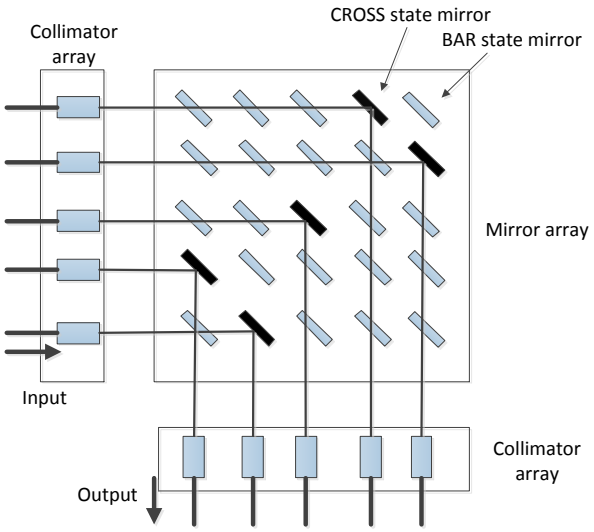

Figure 1. Structure of 2D MEMS optical switch

For an *M*×*M*-port switch, a total of M^2 mirrors are required to implement a strictly non-blocking switching fabric. For each input port, an output port to be coupled is determined by selecting the mirror is in *cross* state. For example a 32×32-port switch will require 1024 mirrors. To overcome this exponential increase of mirrors, it is possible to implement alternative approach in which are smaller 2D MEMS combined in multistage switching network architecture. However, this cascades require a lot of complex interconnections between smaller switching modules. Also, the beam propagation distances among ports-to-ports switching are not constant, so the insertion loss is not uniform for all ports. The 2D MEMS find applications in areas of communication networks which require smaller ports sizes. For applications which require bigger ports sizes (over 32) 3D MEMS are used.

At 2D MEMS optical switches, optical path lengths vary according to the selected pair of input and output ports. Variation of optical paths increases as the number of ports increase. To eliminate variation in position and angle of optical beam collimators and mirrors must be precisely aligned.

B. 3D MEMS

3D MEMS switches have mirrors that can rotate around two axes and achieve multiple positions for each of them. In this way it is possible to precisely redirect light to multiple angles, as it is shown on Figure 2. The number of possible angles is at least as the number of input fibers. In this way the maximum number of mirror is 2M, if M is the number of inputs and outputs. Second advantage is that differences in free-space propagation distances among ports are much less dependent on the scaling of the port-count. Number of ports for 3D MEMS can increase to thousand without big loss differences.

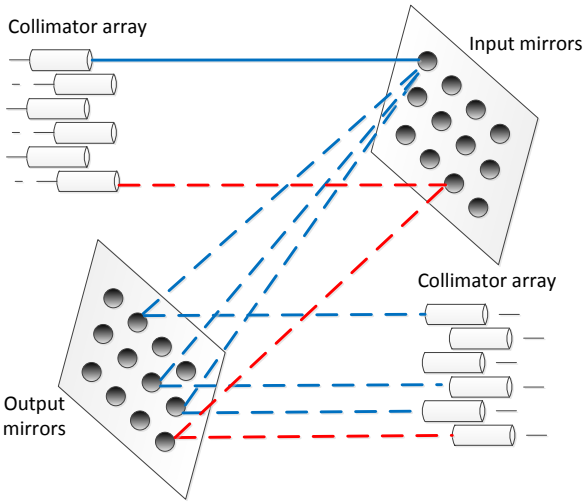

Figure 2. Structure of 3D MEMS optical switch

The light path passes through three sections of the optical switch: the input collimator (device which precisely line up input fibers for better switching performances and low loss), the switching matrix (which contains two mirror arrays) and the output collimator. The switch matrix enables switching time of approximately 20 ms and low optical loss (around 2.0 dB). Each mirror array has big number of individually controllable mirrors (even up to thousand). The input signal passes to the switch matrix where the mirrors are aligned in a way to direct light to the output port.

Optical switches need external components that control appropriate switching behavior. For mirror control cord cards are used. Each cord card controls a set of input and output fibers. For example, one cord card can control 8 input and 8 output mirrors. In case of 96 input and output ports, MEMS must be connected to 12 cord cards. Also, there can exist some spare cord cards for system operation and testing. Optical switch is also controlled by configuration processor, which establishes and maintains connections. Because of the vital role, the processor regularly has its redundant one. If first fails, the secondary processor takes over. On each port optical power can be measured, so it is possible to detect any signal degradation.

IV. COMPONENT FAILURE RATES

The failure rates for optical switches and their components rely on data from several sources. We assume component failure rates are constant. Failure rates are presented in FIT.

TABLE I.
COMPONENT FAILURE RATES

Component	Symbol	Failure rate [FIT]
MEMS mirror	MIR	21
Entire MEMS	MEMS	10 FIT / port
Fiber	FIB	310 FIT/km
EDFA	EDFA	2850

EDFA

The failure rate of node-internal EDFA was taken from [11] and [12].

MEMS mirror

The failure rate was obtained from [13]. Static availability has been experimentally verified for more than two years over 4,000 switch elements.

MEMS optical switch

MEMS failure rate was obtained from [14].

Fiber per km

Fiber failure rate was taken from [15]. It is assumed that a link failure rate per kilometer includes fiber and inline amplifier failures.

V. MEMS AVAILABILITY

The critical part of 2D MEMS optical switch is moving MEMS mirror. Additional assumption is that control electronics is redundant and high available. Possible arrangement could be done by adding additional back loop from MEMS exit to MEMS entry in order to bridge possible failure of a mirror on the "right and up" part of MEMS matrix where primary or spare path are passing through. Path represents connection between input and output fiber. If the 2D MEMS is used to switch redundant component there are two possible paths enabling correct operation. The redundant arrangement is illustrated on a simple example of4×4 2D MEMS, as depicted on Figure 3.

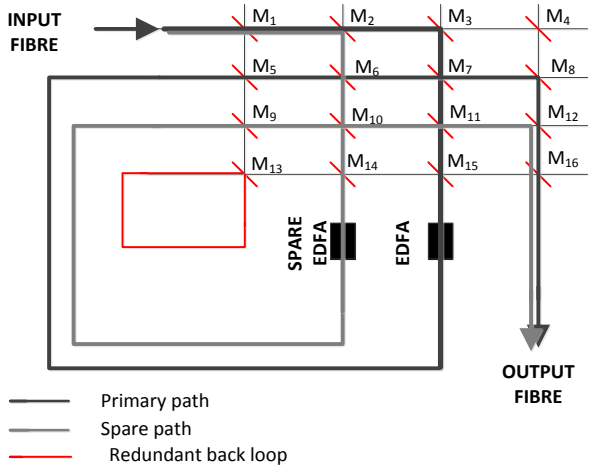

Figure 3. Redundant back loop in the lower left corner of MEMS matrix

In the example an application of Architecture on Demand (AoD) with only one component - Erbium doped fibre amplifiers (EDFA) is assumed. One EDFA is placed on a primary path and spare EDFA is a part of the spare path. Note, another arrangement of components in AoD do not change availability analysis. An assumption is that a failure of any mirror on a path causes the failure of entire path. Mirrors M_1 and M_{16}, as input and output mirrors respectively, are critical switching elements because they have no redundancy. Black line represents primary path between input and output fibres, including eleven mirrors and one EDFA. The spare path is represented by grey line with nine mirrors and the spare EDFA. Redundant back loop connects one output port and one input port in lower left corner, next to the mirror M_{13}. For example, if the mirror M_3 fails, the primary path does not work and it can be switched over to the spare path. In the case the mirror M_2 fails neither primary or spare path cannot be accessed through input port 1. In this case redundant back loop can be helpful connecting additional two ports. Optical signal is redirected down to M_1, through back loop to the mirror M_{15} (for primary path) and to the mirror M_{14} (for spare path). By using the redundant loop there are two additional spare paths which can overcome some failed mirrors.

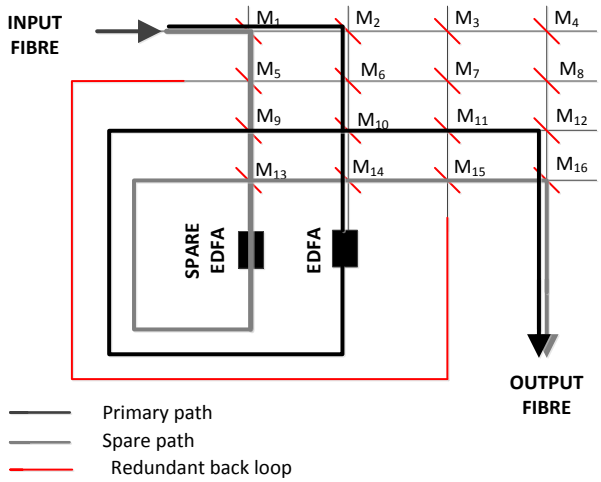

Figure 4. Redundant back loop in upper right corner of MEMS matrix

On Figure 4., redundant back loop is "on the right" of primary and spare path. Primary and spare path passes through fewer mirrors than on Figure 3, but availability isn't increased because redundant loop uses more mirrors then primary and spare path.

Availability comparison of MEMS with and without redundant back loop is given on Figure 5. Availability performance was calculated by transformation of union of non-disjoint paths through mirrors to the union of disjoint path elements, assuming the union in both cases is the same. The transformation was done by Abraham's algorithm [16]. If redundancies of mirrors are not used (there are only two paths), better solution is to put all paths in lower left corner because in this case the paths use less mirrors, and there are less chances of a path failure. If redundancy in 2D is used (with 2 additional spare paths), then is a better solution to put the redundancy in lower left corner because additional spare paths and primary path have less mirrors in common.

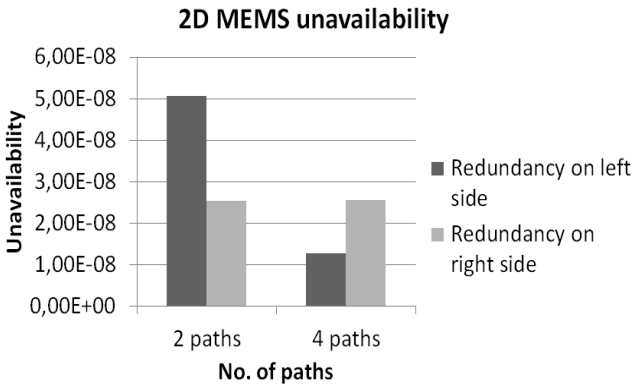

Figure 5. Availability comparison with or without redundant back loop

The *N*×*N* MEMS and eight fibers connecting node A and node B are shown on Figure 6. Each fiber is 20 km long. Logical channel (LCH) represents two-way connection from node A to node B. There are two logical channels (green and red one). Logical connection (LC) is up if at least one logical channel is working correctly, which can be presented through Boolean expression:

$$LC = LCH_1 \vee LCH_2 \qquad (1),$$

where LC, LCH_1 and LCH_2 are true (working path) or false (broken path).

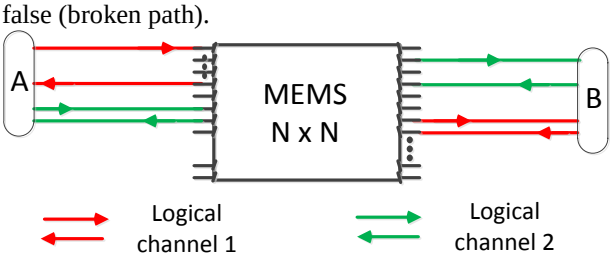

Figure 6. Two logical channels with one MEMS

On Figure 7 is depicted structure consisted of two smaller MEMS (*N/2*×*N/2*) each supporting one logical channel. The availability comparison of these two structures is calculated.

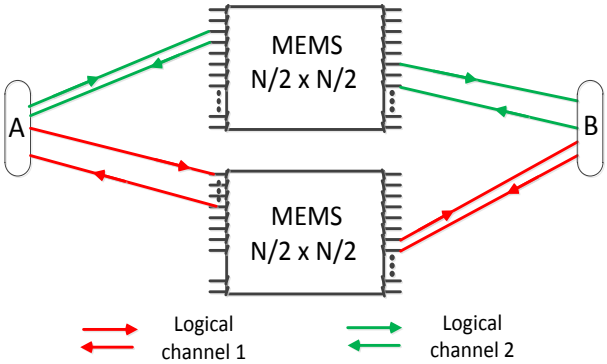

Figure 7. Two logical channels with two MEMS

The availability model of structure with one MEMS is depicted on Figure 8(a) and on Figure 8(b) is shown the availability model of structure with two smaller MEMS.

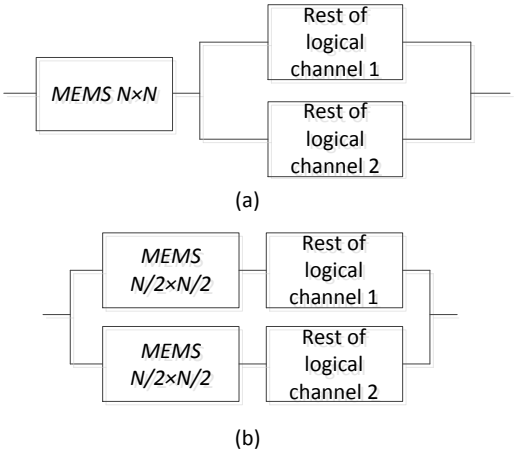

Figure 8. Availability models of case study structure

Unavailability of structure with larger MEMS is $3{,}84*10^{-5,}$ which corresponds to downtime of approximately 20 minutes per year. The unavailability of the structure with two smaller MEMS is $2{,}82*10^{-8}$. It corresponds to downtime of 0,014 minutes per year. Usage of two smaller MEMS instead of one bigger MEMS adds redundancy, which increases availability thousand times (Figure 9), while cost increase is much lower.

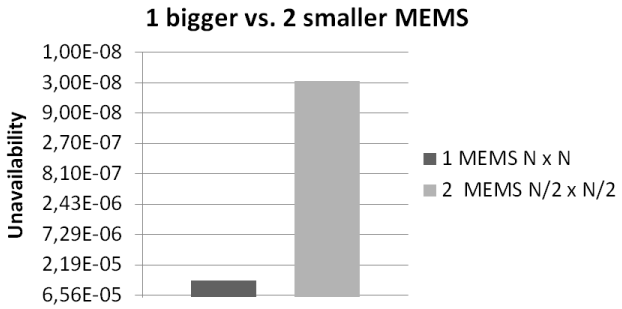

Figure 9. Availability comparison of MEMS structures

VI. CONCLUSION

In this paper, the all-optical MEMS switching fabrics used in optical cross-connects were reviewed. MEMS switches are mature technology for building large optical cross-connects. They offer ability to integrate electrical, mechanical and optical elements on a single chip, which can support switching capabilities with low loss, low cost and crosstalk. MEMS switch data in ms regime, thus supporting optical channel switching. Through this paper availability analysis and possible approaches for availability increase of MEMS optical switches and optical network have been reviewed. It has been shown that 2D MEMS optical backplane can use internal mirror redundancy. One back loop connection can replace some multiple mirror failures. Back loop connection which connects one input port and output port in lower left corner of the MEMS increase availability for 5 times. In the case of 2D MEMS of bigger scale, availability benefit is higher. Usage of two smaller MEMS instead of one bigger can increase availability, as well.

Iločka 27, 10000 Zagreb, Hrvatska
E-mail: sasa.horvat@timcom.hr, ivan.baresic@timcom.hr, zvonimir.trlin@timcom.hr

Sažetak - Najveća prepreka kod prelaska s bakrene na svjetlovodnu infrastrukturu jest trošak investicija u pasivnu optičku i aktivnu opremu. Otvoreni pristup aktivnoj FTTH (engl. *Fibre to the home*) opremi temelji se na povjerenju i poštenju između operatora, koji zajednički koriste pasivnu pristupnu i aktivnu opremu, te je idealan za operatere grupirane u konzorcij (npr. konzorcij alternativnih operatora). Ovaj rad dat će prijedlog rješenja kako ostvariti otvoreni pristup aktivnoj opremi i iskoristiti njegove prednosti za održivost tržišta operatora.

I. UVOD

S obzirom na brzo rastuće zahtjeve za kapacitetom suvremenih podatkovnih mreža, a potaknuti aplikacijama poput IPTV-a (engl. *Internet Protocol television*) i VoD-a (engl. *Video on Demand*), kao i radom na daljinu (engl. *teleworking*), optičko vlakno je jedina tehnologija s kojom se ti zahtjevi mogu zadovoljiti. Jednom kada je dostupna veća propusnost podataka, aplikacije i suluge će ju brzo moći iskoristiti.

Iz današnje perspektive, propusnost optičkog vlakna za prijenos podataka je gotovo neograničena. Stoga se polaganje optike u kućanstvima smatra ulaganjem u budućnost. No, to zahtijeva vrlo visoku početnu investiciju koju nije moguće vratiti u uobičajenom amortizacijskom razdoblju.

Stoga tržišni subjekti traže poslovne modele koji omogućuju ulaganja u infrastrukturu, visoko iskorištenje mreže i veće prihode. Iskustvo s marketiranjem ADSL (engl. *Asymmetric digital subsriber line*) i mobilne telefonije ukazuje na to da operatori mrežne infrastrukture mogu biti puno uspješniji na tržištu usluga ukoliko otvore svoje mreže. Prema tome, većina subjekata na telekomunikacijskom tržištu slaže se da je otvaranje pristupne mreže (otvoreni pristup mrežama, engl. *Open Access Networks*) *win-win* situacija i za operatore i za pružatelje usluga (engl. *service providers*).

Polaganjem svjetlovodnih mreža, njen vlasnik osigurava dugoročno jamstvo svojih ulaganja. Kao jedini nedostatak svjetlovodnih mreža ističe se upravo visoko početno investiranje, no pojavljivanjem različitih proizvođača, cijena optičkih vlakana i kabela pada te instalacije svjetlovodnih mreža postaju isplativije no ikad.

Svjedoci smo kako se unazad nekoliko godina provodi inicijativa u sektoru mobilnih komunikacija o dijeljenju pasivne infrastrukture (lokacijske kućice, antenski stupovi i nosači) među operatorima. Da li je došlo vrijeme da se razmišlja o dijeljenju i aktivne opreme, kao drugi korak u racionalizaciji troškova?

II. SVJETLOVODNE MREŽE I TROŠKOVI INVESTIRANJA

Optička vlakna pronašla su veliku primjenjivost u različitim industrijama, ali nigdje tako veliku kao u telekomunikacijama. Iako je od početka po mnogima smatrana skupom tehnologijom, u potrazi za praktičnom primjenom danas su potpuno izmijenila infrastrukturu telekomunikacijskih mreža. To je postignuto zbog dvije vrlo jednostavne prednosti nad bakrenim instalacijama:

- sposobnost za prijenos podataka većim brzinama i na velikim udaljenostima
- sposobnost prijenosa s manje grešaka i gubitaka (osjetljivost prema elektromagnetskim smetnjama, smetnje sa signalom emisija, razlike potencijala i greške uzemljenja)

Iako su optička vlakna na samom dnu telekomunikacijskog lanca dodanih usluga, ona su najbitnija tehnologija koja danas pokreće industriju.

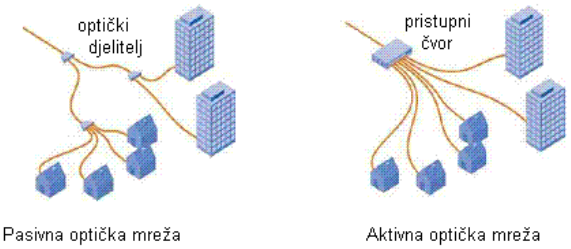
TABLICA I. USPOREDBA ZNAČAJKI BAKRENIH I OPTIČKIH INSTALACIJA

Značajka	**Bakrene instalacije**	**Optičke instalacije**
Udaljenost	100 metara	100 kilometara
Propusnost podataka	niska (max 100 Mbit/s)	100 Gbit/s
Cijena	cijena bakra raste	optičko vlakno sve jeftinije
Interferencije	problemi s osjetljivošću	nema interferencija
Uzemljenje	mogući problemi kod uzemljenja	nema potreba za uzemljenjem

Zbog fizičkih ograničenja bakrenih kabela, VDSL2 tehnologija (engl. *Very High Speed Digital Subscriber Line 2*) dosegla je granice svojih tehničkih potencijala na postojećim pristupnim linijama. S druge strane, bežična rješenja, kao što su WiMAX (engl. *Worldwide Interoperability for Microwave Access*), LTE (engl. *Long Term Evolution*) ili 4G (engl. *Fourth generation of cellular wireless standards)* u sektoru mobilne telefonije brzo dostižu svoje granice, zbog većeg ograničenja prijenosnih kapaciteta u usporedbi s bakrenim kabelom. Kao rezultat, iz današnje perspektive, samo optička vlakna su sposobna pružiti neograničene brzine i budućnost razvoja mreža.

A. *Usporedba arhitektura pasivnih i aktivnih pristupnih svjetlovodnih mreža*

Prilikom implementacije svjetlovodnih mreža, koriste se dvije topologije: PON/P2MP (engl. *Passive optical network/Point to MultiPoint*) i AON/P2P (engl. *Active Optical Network/ Point to Point*) topologija.



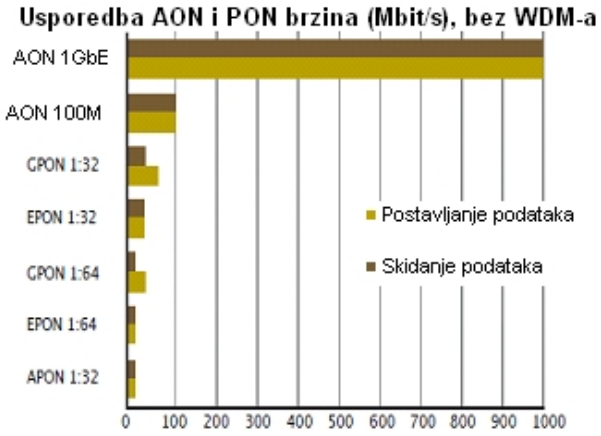
Slika 1. PON i AON topologije mreža

Pasivna svjetlovodna mreža (PON) ne koristi aktivnu opremu koja bi razdvojila optički signal na veći broj korisnika, već za to služe optički djelitelji (engl. *splitter*). Time se na jednostavan način optički signal (ukupna propusnost podataka) distribuira do 64 korisnika.

Kod aktivne svjetlovodne mreže (AON), svaki korisnik je spojen vlastitim optičkim vlaknom na aktivnu opremu pristupnog/distribucijskog čvora, te ne dijeli propusnost podataka s drugim korisnicima.

TABLICA II. USPOREDBA ZNAČAJKI AON I PON RJEŠENJA

Značajka	AON topologija	PON topologija
Propusnost podataka	nema ograničenja	ograničena brojem korisnika
Prosperitet	nema ograničenja	ograničen maksimalno WDM-PON-om
Potrošnja energije	visoka potrošnja	niža nego kod AON topologije
Potrošnja svjetlovodnih niti	Jedna/dvije niti do svakog korisnika	prvi dio kabla je zajednički
Testiranje s centralne lokacije	jednostavno zbog direktne veze s korisnikom	kompliciranо, potrebno je spojiti se na opremu u uličnom kabinetu
Ispravljanje problema (engl. *troubleshooting*)	jednostavno pronalaženje problema	kompliciranо pronalaženje pogrešaka
U slučaju pogreške u pristupnoj mreži	zahvaćen samo jedan korisnik	zahvaćena do 64 korisnika
Potreba za prostorom kod centralne lokacije	velika potreba za prostorom zbog velikog broja optičkih kabela	manja potreba za prostorom
Polaganje optičkih putova od centralne lokacije	kompliciranо ukoliko se ne vodi računa o redu	pošto se ne koristi mnogo opreme, jednostavnije polaganje
Geografska pokrivenost	pogodno za manja područja	pogodno za velike udaljena razgranata područja



Slika 2. Usporedba brzina kod PON i AON mreža

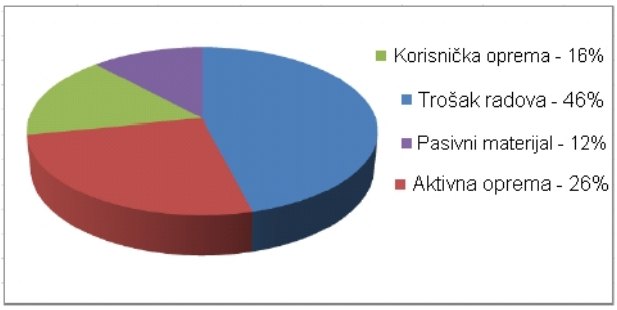
Također, postoje i varijante topologija, pa je tako moguće izvesti aktivno grananje signala prema korisnicima (Ethernet P2P) ili uz AON koristiti zasebno vlakno za odašiljanje TV signala (iskoristiti PON opremu).

Što se tiče ekonomske usporedivosti, dojam koji se nameće jest da investiranje u PON mreže znači i niže troškove, što nije uvijek potpuno točno. Gledajući početne troškove investicija, spajanje samo rezidencijalnih korisnika u kratkoročnom periodu (oko 3 godine), PON mreže jesu komercijalno isplativije, no ukoliko računici pridodamo i poslovne korisnike, povećanje broja rezidencijalnih korisnika i brzine, PON mreže postaju sve manje isplativije te je u konačnici jedino dugoročno rješenje AON mreža.

B. *Udjeli u troškovima investiranja, načini i prijedlozi smanjenja troškova*

Bakrena parica stigla je gotovo do svog limita, dok su potrebe za sve većim brzinama korisnika neminovne. Kako su troškovi investiranja u FTTx infrastrukturu toliko visoki da ih čak i donedavni monopolisti nisu u stanju financirati te osigurati povrat investicija u uobičajenom roku, sve se više traže različiti načini sufinanciranja.

Prema FTTH Bussines Guide-u [9], trošak investicija materijala pasivne optiče mreže iznosi oko 12%, a korisničke aktivne opreme oko 16%. Nadalje, trošak aktivne opreme operatora iznosi oko 26%, dok je najveći trošak na radovima postavljanja optičke infrastrukture, oko 46%. Kako se već naveliko krenulo s prijedlozima smanjenja upravo tog dijela (razlike u topologijama, materijalima i tehnikama postavljanja), vrijeme je da se okrene i smanjenju troškova aktivne opreme operatora, a otvoreni pristup mreži je jedan od njih.

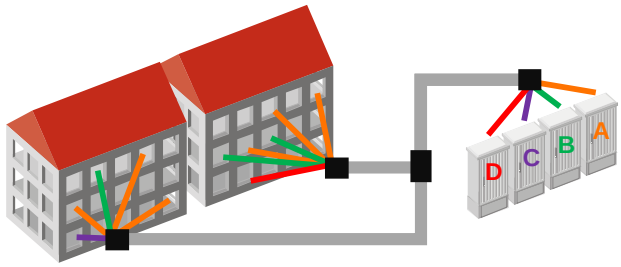


Slika 3. CAPEX podjela troškova

Treba naglasiti i da politika Europske unije prisiljava bivše monopol operatore da otvore pristup svojoj infrastrukturi te se tu također nalazi jedan od razloga za traženje alternativnog načina financiranja. Sami bivši monopolisti ne žele ili nemaju pripremljen poslovni model kada se od njih traži investiranje u infrastrukturu i otvaranje iste alternativnim operatorima. Zahtjevi regulatornih agencija (tako i HAKOM-a, prema [8]) svakako idu u smjeru ravnopravne tržišne utrke i očuvanja konkurencije na tržištu. Mogućnosti da se i alternativni telekom operatori uključe u investicije u ovom trentuku nisu realne, naročito radi skupog i ograničenog kreditiranja. Također, mobilni operatori smatraju da se širokopojasni pristup korisnicima i velike brzine mogu omogućiti i bežičnim putem (4G mreže), a ne isključivo izgradnjom optičke infrastrukture. Uz trajanje snažne gospodarske krize, sve su ovo razlozi koji usporavaju ili stopiraju investicije u novu optičku infrastrukturu, koja bi osigurala uvođenje novih tehnologija i aplikacija, gospodarski rast te konkurentije gospodarstvo.

Kao moguće alternative za nastavak financiranja i izgradnje spominje se nekoliko varijanti, a kao jedna od najzanimljivijih jest poslovni model s horizontalnom podjelom uloga operatora na infrastrukturnog operatora (vlasnik/upravitelj/operator pasivne infrastrukture), mrežnog operatora (vlasnik/upravitelj elektroničke komunikacijske opreme, pružatelj otvorenog pristupa) i pružatelja usluga (servisnog operatora).

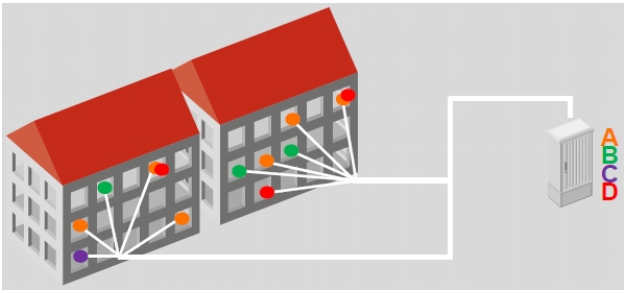
Kao primjer možemo navesti da država ili lokalna samouprava financira izgradnju infrastrukture, bude vlasnik iste (infrastrukturni operator) te ju iznajmljuje na tržištu prema jednakim uvjetima za sve zainteresirane operatore.



Slika 4. Dijeljenje pasivne infrastrukture na fizičkom nivou

Infrastrukturni operator može imati u vlasništvu uz pasivnu mrežnu opremu, također i aktivnu opremu čime je ujedno i mrežni operator, ovisno o primjenjenom poslovnom modelu.

Dodatno, infrastrukturni operator bi vodio brigu o infrastrukturi (održavanje, nadogradnja) dok bi različiti servisni operatori mogli samo nuditi usluge krajnjim korisnicima.



Slika 5. Dijeljenje pasivne i aktivne infrastrukture uz primjenu jednakih uvjeta za sve operatore

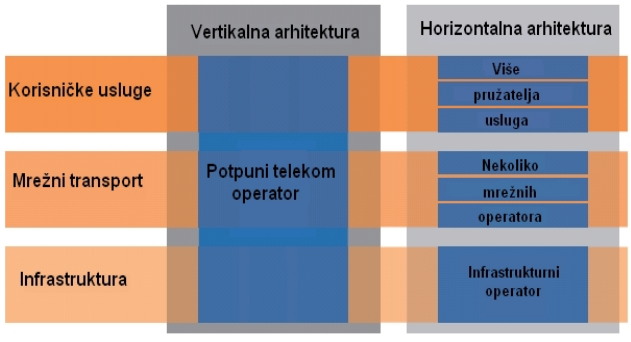
Ova varijanta bila bi posebno zanimljiva na ruralnim područjima gdje sadašnji telekom operatori nemaju veliki interes zbog manje gustoće naseljenosti, ali nikako se ne isključuje i u velikim gradovima. Time se troškovi investiranja sasvim sigurno smanjuju te ovakav tip realizacije usluga ima svoju financijsku prednost.

III. PRIJEDLOG RJEŠENJA DIJELJENJA AKTIVNE OPREME

A. Pojam otvorenog pristupa i horizontalne mrežne arhitekture

Termin ″otvoreni pristup″ u telekomunikacijskim mrežama označava horizontalnu mrežnu arhitekturu ili poslovni model koji razdvaja pasivnu od aktivne infrastrukture. Također se postavlja razlika između upravljanja mrežom i pružanja usluga krajnjim korisnicima.

Standardna mrežna arhitektura u današnjim telekomunikacijskim mrežama temeljena je na vertikalnoj mrežnoj arhitekturi, što znači da telekom operatori najčešće posjeduju pasivnu infrastrukturu, aktivnu pristupnu i transportnu opremu te pružaju vlastiti portfolio usluga.



Slika 6. Modeli operatora i regulacija

Nova horizontalna mrežna arhitektura vodi do restrukturiranja tradicionalnog telekomunikacijskog poslovnog modela s tri komercionalno nezavisna poslovna subjekta:

- Infrastrukturni operator, koji omogućava pristup pasivnoj infrastrukturi

- Mrežni operator, koji osigurava aktivnu opremu, upravlja mrežom i prenosi usluge od krajnjeg korisnika
- Pružatelj usluga, koji tržištu nudi svoje usluge: telefoniju, pristup Internetu, TV usluga itd.

Dijeleći poslovni model horizontalno otvara se mogućnost pružateljima usluga da ponude svoje usluge krajnjim korisnicima, čime se stvara konkurencija te nova svjetlovodna pristupna mreža postaje atraktivnija krajnjim korisnicima.

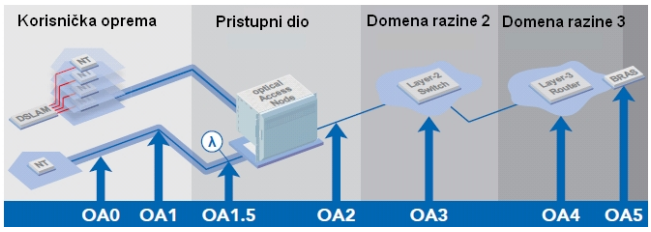
Otvoreni pristup temelji se na zajedničkom korištenju pasivne ali i aktivne opreme. Za mrežnog operatora to znači, u usporedbi s klasičnim vertikalnim poslovnim modelom, da je iskorištenost mreže značajno povećana, a financiranje olakšano i sigurnije. U budućnosti je moguće da jedna kompanija ima nekoliko uloga na otvorenom tržištu, te je stoga potrebno spriječiti diskriminaciju na pristup između poslovnih područja (preferencijalni status).

Svrha horizontalne strukture je stvoriti novo poslovno okruženje koje je atraktivno za sve uključene strane, te je kao takvo dobra podloga za rast i uvođenje novih kreativnih usluge. Svi tržišni subjekti se mogu fokusirati na područje svog interesa.

B. Tehnička implementacija rješenja otvorenog pristupa

Primjena IP Ethernet tehnologije u pristupnim i transmisijskim mrežama omogućuje kovergenciju prema horizontalnom mrežnom modelu. Rezultati su brže primjene novih usluga, uštede u vođenju troškova i na marketingu, kao i za optimizacija ukupnih troškova. Ovaj razvoj je baza za nove horizontalne poslovne modele, poput otvorenog pristupa.

Različiti mrežni čvorovi primjereni su kao sučelja za pristupne točke operatora, prema slici 7.



Slika 7. Pristupne točke za otvoreni pristup

Pristupne točke OA0 – OA5 imaju svoje prednosti i nedostatke:

- OA0 – postojeće prazne kanale infrastrukture operatori mogu iskoristiti za dodatnu svjetlovodnu mrežu.
  - Prednosti: omogućuje operatoru slobodan izbor mrežne topologije i medija
  - Nedostaci: visoki inicijalni troškovi zbog vlastite infrastrukture i aktivne tehnologije na terenu, potrebno mnogo planiranja
- OA1 – operatori imaju pristup nekorištenim korisničkim optičkim priključcima (engl. *dark fibre*).
  - Prednosti: princip poput izdvojenog pristupa lokalnoj petlji, svaki operator ima slobodan izbor aktivnih komponenti.
  - Nedostaci: zahtjeva puno prostora na optičkom distributoru, jer svaki operator mora postaviti vlastitu opremu, visoki investicijski troškovi.
- OA1.5 – operatori imaju pristup vlastitoj valnoj duljini.
  - Prednosti: teoretski manje kompleksno nego *dark fibre*, zahtjeva manje prostora.
  - Nedostaci: trenutno ne postoji oprema koja je financijski prihvatljiva, ovisnost o jednom proizvođaču opreme zbog nedostatka standardizacije.
- OA2 – operatori imaju pristup aktivnoj pristupnoj opremi mrežnog operatora (pristupni čvor razine 2 (engl. *Layer 2*)).
  - Prednosti: financijski prihvatljivo zbog zajedničkog korištenja pristupne tehnologije.
  - Nedostaci: raznovrsnost usluga bi mogla biti ograničena pristupnom opremom, pristupne regulacije moraju biti uspostavljene (Ugovor o razini usluge)
- OA3 – operatori imaju pristup agregacijskom čvoru mrežnog operatera (Razina 2).
  - Prednosti: financijski prihvatljivo zbog pristupa i transmisijske tehnologije koja se zajednički koristi.
  - Nedostaci: raznovrsnost usluga bi mogla biti ograničena pristupnom opremom, pristupne regulacije moraju biti uspostavljene (Ugovor o razini usluge).
- OA4 – operatori imaju pristup domeni Razine 3 (engl. *Layer 3)* mrežnog operatera.
  - Prednosti: financijski prihvatljivo jer se mrežne komponente koriste zajednički, omogućen *provisioning* korisnika
  - Nedostaci: ograničenost raznovrsnosti usluga, uvođenje IPTV signala možda nije moguće, kvaliteta usluge (engl. *QoS*, *Quality of service*) i Ugovor o razini usluge (SLA) moraju biti međusobno dogovoreni
- OA5 – operatori imaju pristup BRAS-u (engl. *Broadband Remote Access Server)* mrežnog operatera (danas korišten za *bit stream* pristup).
  - Prednosti: financijski prihvatljivo jer se koristi cijela mreža mrežnog operatora.
  - Nedostaci: nije pogodno za IPTV usluge, korištene usluge definira mrežni operator.

Svaka zemlja ima drugačiji pristup biranju najprimjerenije pristupne točke za otvoreni pristup mreži. U praksi bi se mogle koristiti različite pristupne točke, ali interkonekcije u mreži se mnogo jednostavnije rade ako su dogovorena tehnička i komercijalna pravila, kako se suradnje između mrežnih operatora i pružatelja usluga ne bi morale uvijek iznova pregovarati.

Zajedničko korištenje opreme stavlja posebne zahtjeve na sustav u pristupnom dijelu koji nisu postojali prije otvorenog pristupa, tj. oprema mora podržavati nove funkcionalnosti:

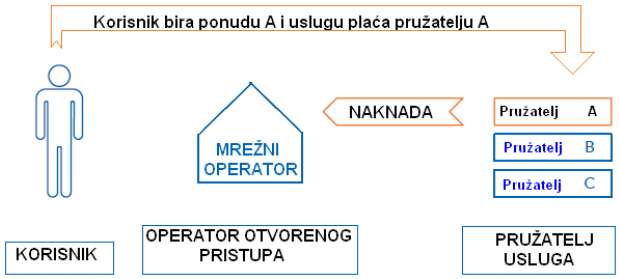
- Funkcionalnosti razine 2 (*Layer 2*)
  - Prijenos jednostruko ili dvostruko označenih (engl. *single-/double- tagged*) VLAN (engl. *Virtual local area network*) usluga
  - Korištenje cijelog VLAN adresnog područja
  - Paralelna operacija n:1 i 1:1 usluga
- Funkciolnalnosti kvalitete usluge (QoS)
  - Klase usluga za glasovne, podatkovne i TV usluge
  - Mapiranje pružateljevih specifičnih klasa usluga
- Funkcionalnosti prometa
  - Ograničenje propusnosti podataka u upstreamu i downstreamu
  - Širokopojasno upravljanje i nadzor klasa usluga – posebno za IPTV usluge
  - Označavanje u suradnji s kvalitetom usluge za prevenciju blokiranja
- Sigurnosni zahtjevi
  - Razdvajanje podataka između korisnika
  - Dodatno razdvajanje podataka između pružatelja usluga
- *Multicast* mogućnosti:
  - Podrška za nekoliko različitih pružatelja usluga
  - Visoki zahtjevi na broj *multicast* tokova
  - Paralelne operacije *unicast* i *multicast* tokova

Ovi visoki zahtjevi bi uvijek trebali biti vodilja pri odabiru aktivne opreme u pristupnoj mreži kako bi se omogućio nesmetan rad u okruženju otvorenog pristupa.

C. *Komercijalni pogled na mreže otvorenog pristupa*

Kako bi se procijenio poslovni model u okruženju otvorenog pristupa, važno je ispitati mogućnosti načina plaćanja. On ima trajni utjecaj na uspjeh ekspanzije svjetlovodne mreže. Bazirano na tehničkim aspektima koji su ranije spomenuti (OA2 i OA3 ili OA4 i OA5), modeli plaćanja su drugačiji.

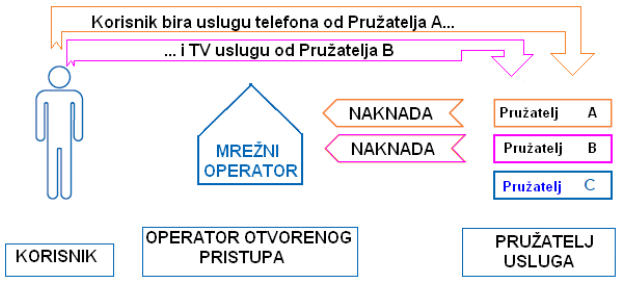
Sa pristupom prema slici 8 (slično praksi s DSL (engl. *Digital subscriber line*) vezama), krajnji korisnici će moći izabrati paket usluga od pružatelja usluga.



Slika 8. Model plaćanja uz pristup OA2 i OA3

Sa komercijalnog stajališta krajnji korisnik plaća usluge direktno pružatelju usluga, koji potom plaća naknadu (po korisniku mjesečno) pružatelju otvorenog mrežnog pristupa/mrežnom operatoru. Ova naknada može se definirati bez obzira na pružene usluge, ili da ovisi o potrebnoj propusnosti ili parametrima kvalitete veze.

U slučaju da operator otvorenog pristupa/mrežni operator ostavlja mogućnost krajnjem korisniku da bira kojeg pružatelja usluga će izabrati za pojedinu zasebnu uslugu (telefonija, Internet pristup, televizija, *online banking*, telemedicina, video-on-demand, nadzor i sigurnost, pohrana podataka,...), krajnji će korisnik plaćati mrežnom operatoru naknadu za pristup mreži (poput pretplate za telefoniju), prema slici 9. Također, plaćat će naknadu za svaku individualnu uslugu zasebno pružatelju usluga (ovisno o korištenju, mjesečno,...).



Slika 9. Model plaćanja uz pristup OA4 i OA5

Osim spomenutih modela, u budućnosti su mogući i hibridni modeli, ovisno o faktorima poput dosadašnjih praktičnih iskustava, konkurenciji na tržištu, regulaciji i standardizaciji.

D. *Nove usluge i aplikacije u otvorenoj pristupnoj mreži*

Usporedno s intenzivnim korištenjem brzog Internet pristupa, TV i video usluge su ključni čimbenici u porastu širokopojasnog pristupa u telekomunikacijskim mrežama. Mnogi telekom operatori vode borbu da omoguće televizijske usluge zbog nekoliko razloga. Uz pravne i komercijalne izazove, propusnost u pristupnoj mreži je dosad bila usko grlo. No upravo te usluge su način kreiranja odanosti korisnika. IPTV jest usluga koja postaje standardna ponuda svih pružatelja usluga.

Nije teško predvidjeti da će biti sve više širokopojasnih usluga kojih danas još nismo ni svjesni ili ih percipiramo kao nevažne. Dobar primjer su SMS poruke u mobilnoj telefoniji. SMS poruke su postigle takav uspjeh, a da niti jedan stručnjak to nije predviđao. Nadalje, zbog povećanja prosječne dobi ljudi u društvu, usluge kao što su eHealth će postati sve više značajne, a

tehničke karakteristike kao što su prijenos u stvarnom vremenu praćenja vitalnih tjelesnih funkcija ili videa visoke rezolucije biti će ključne. Pametno mjerenje (engl. *Smart metering*) je jedna od aplikacija koja trenutno ima relativno niske zahtjeve prema propusnosti. Ako zamislimo da će se u budućnosti sve više kućanskih aparata moći nadzirati, a svaki imati svoju IP adresu, možemo očekivati višestruke potrebe za propusnošću. Ovi aspekti se moraju uzeti u obzir kod planiranja pristupne mreže.

Kod poslovnih korisnika postoji također rastući trend prema većoj propusnosti, kroz ustupanja poslovnih procesa i pohrane podataka vanjskim kooperantima. Trenutno, *cloud computing* je hit tema. Za poslovne korisnike, *cloud computing* je u najširem smislu vanjsko ustupanje IT usluga kao što su pohrana podataka, pohrane web sadržaja (engl. *webhosting*), ERM/CRM sustava (engl. *Enterprise risk Management/Customer Relationship Management*) koji su dostupni putem brze veze specijaliziranog pružatelja usluga s kojim je sklopljen ugovor o razini usluge (engl. *SLA*, *Service Level Agreement*).

U ovim slučajevima je optika (ili barem VDSL2 tehnologija) neminovna jer korisnik treba imati dojam da radi s podacima koji se nalaze na njegovom tvrdom disku.

E. Prednosti i nedostaci otvorenog pristupa za operatore i korisnike

Prednosti otvorenog pristupa:

- Za vlasnike infrastrukture:
  Vlasnici svjetlovodne mreže predaju upravljanje mrežom operatoru, te time nestaje rizik od postavljanja aktivne mreže. Kako se predviđa da u budućnosti neće postojati druga kompanija koja bi ulagala u paralelnu infrastrukturu do određene lokacije, ulazak na tržište kao vlasnik svjetlovodne mreže izgleda kao vrlo sigurna investicija.
- Za pružatelje otvorenog pristupa/mrežnog operatora:
  Investiranje u pasivnu mrežnu infrastrukturu ostavlja se lokalnoj zajednici ili drugim zainteresiranim stranama. Iznajmljujući pristup mreži trećim stranama (ISP-u (engl. *Internet service Provider*) ili većim mrežnim operatorima), mreža je atraktivnija krajnjim korisnicima.
- Za pružatelje usluga:
  Mogu se udaljiti od konkurencije nudeći usluge koje su prije bile nemoguće zbog nedostatka propusnosti. Isto se odnosi na adresiranje cijelih segmenata tržišta (poslovni korisnici).
- Za krajnje korisnike:
  Imaju brzi pristup Internetu koji mu pruža širok raspon usluga i izbor između različitih pružatelja usluga, uz simetrično korištenje širokopojasne usluge.

Nedostaci otvorenog pristupa (u principu isti kao i kod svakog drugog modela):

- Inicijalna ulaganja za vlasnika infrastrukture i pružatelja otvorenog pristupa/mrežnog operatora su visoka (iako ne toliko visoka kao da su objedinjena).
- Period povrata investicija je puno duži nego inače u ICT (engl. *Information and communication technology*) industriji (više od 10 godina).
- Tržnišna cijena za ICT usluge preko nove mreže je limitirana jer se nivo cijena usluga spustio kroz nekoliko godina (vrijedi za sve svjetlovodne mreže).

Iz svega navednoga jedna stvar je jasna: unatoč svim izazovima otvaranja pristupne mreže činjenica jest da će krajnji korisnici profitirati iz povećanja konkurencije i usluga.

IV. ZAKLJUČAK

Budući da su se telekomunikacijske mreže tržištu otvorile u 1990-ima, kao rezultat toga izniknuli su mnogi mali i veliki pružatelji usluga, što je dovelo do liberalizacije tržišta te napretka u inovaciji usluga. Kao dokaz je IPTV usluga koju razni operatori, bez svoje infrastrukture, nude krajnjim korisnicima stvarajući nadmetanje u kvaliteti usluge.

Pristupna telekomunikacijska mreža treba biti pažljivo isplanirana jer zauzima veliki udio u troškovima, osobito ulaganje u aktivnu mrežnu tehnologiju. Naglasak pri odabiru optičkog transmisijskog sustava treba biti stavljen na to da li je sustav spreman za budućnost, te posjeduje li standardizirana i otvorena sučelja. Preduvjet je to da se već u startu smanje troškovi ulaganja i poveća dobit od najma opreme za infrastrukturnog operatora, za lakšu održivost i razvoj alternativnih pružatelja usluga i njihov pristup korisnicima, a koji financijski nisu u mogućnosti ulagati u infrastrukturu, te konkurentnost i razvoj usluga za krajnje korisnike. Dijeljenjem infrastrukture između svih zainteresiranih subjekata, uz jasno definirane uvjete korištenja i obveze, otvara se mogućnost da svi operatori krenu pružati usluge na određenom području s jednakih startnih pozicija, a na korisniku ostaje izbor da odabere operatora koji pruža najpovoljniji omjer cijene i kvalitete određene usluge.

REGULATIONS AND STANDARDIZATION

Pravno uređenje nadzora i tehničko snimanje telekomunikacija u državama Evropske unije i Bosni i Hercegovini

Feriz Gabela
Dioničko društvo BH Telecom Sarajevo
Ulica Obala Kulina broj 8, Sarajevo, Bosna i Hercegovina
Telefon: 387 – 33 768 296; 387 – 061 507 – 530 E-mail: feriz.gabela@bhtelecom.ba

Ovaj rad daje pregled pravnog uređivanja presretanja telekomunikacijskih usluga u Evropskoj uniji i Bosni i Hercegovini. U ovom radu opisane su obaveze svih pravnih i fizickih osoba koje pružaju telekomunikacijske usluge, da osiguraju telekomunikacione mreže i obavljaju telekomunikacione djelatnosti, da o vlastitom trošku osiguravaju održavanje funkcije zakonitog presretanja telekomunikacionih usluga i/ili djelatnosti koje obavljaju, kao i da čuvaju i osiguravaju telekomunikacione podatke. Posebne obaveze tih subjekata su da osiguraju kapacitete koji će omogučiti ovlaštenim agencijama da vrše zakonito presretanje telekomunikacija, te u vlastitom trošku čuvaju tajnovitost svih podataka i saznanja koja imaju o sredstvima, procedurama i podacima u vezi sa primjenom mjera zakonitog presretanja i čuvanjem i osiguranjem telekomunikacijskih podataka, ukljucujuci i ogranicenja fizickog i logičkog pristupa ovlaštenom osoblju. Zakonito presretanje telekomunikacija koje provode nadležne institucije i agencije u Bosni i Hercegovini treba da budu u službi njenih građana. U radu je navedeno da je potrebno izvršiti usklađivanje odredbi Zakona o komunikacijama, Zakona o krivičnom postupku, Zakona o obavještajno-sigurnosnoj agenciji Bosne i Hercegovine i zakona koji reguliraju rad agencija koje provode zakon u Bosni i Hercegovini u smislu primjene posebnih istražnih radnji i mjera tajnog prikupljanja podataka.

Ključne riječi: Centri za snimanje i monitoring, funkcija zakonitog presretanja, davalac usluge, informacije u vezi sa presretanjem, javna telekomunikacijska infrastruktura, mrežni operater, operater telekomunikacija, ovlaštene agencije, subjekt presretanja.

I. UVOD

Kako sve više zavisimo od informacionih i komunikacionih tehnologija, elektronske komunikacije postaju jedna od najranjivijih tačaka zaštite privatnosti svakog pojedinca. Odstupanja od načela nepovredivosti tajnosti elektronskih komunikacija dozvoljena su samo na određeno vrijeme i na osnovu odluke suda, ako su neophodna radi vođenja krivičnog postupka ili zaštite sigurnosti, na način predviđen zakonom. U doba tehnološkog prosperiteta i umrežavanjem svijeta pomoću moderne tehnike, velike su mogućnosti praćenja svih učesnika u komunikacijama, snimanjem ili prisluškivanjem. Telefoniramo li, šaljemo li nekome e-mail ili fax, ovlaštene agencije (sigurnosno-obavještajna agencija i policija), imaju mogućnost pristupa tim informacijama. Davateljima telefonskih i internetskih usluga je zakonski propisano da ovlaštenim agencijama moraju osigurati pristup korisničkim podacima.

Operativno-istražne potrebe ovlaštenih agencija, koje spovode zakonom ovlašćen nadzor telekomunikacijskih usluga, odnose se na: identifikaciju korisnika, lične podatke o korisnicima, podatke o ostvarenim i pokušanim komunikacijama kao što su

vrijeme, mjesto, trajanje, drugi učesnici, presretanje podataka o komunikacijama i sadržaj govornih, negovornih i signalizacionih poruka. Efikasan nadzor telekomunikacijskih usluga može se izvesti odgovarajućom infrastrukturom i operativnom podrškom operatora telekomunikacija, mrežnih operatera, davaoca usluga i davetelja pristupa. Pošto operatori telekomunikacija, mrežni operateri, davaoci usluga i davetelji pristupa nemaju nikakav komercijalni ili poslovni interes da za te potrebe dodatno investiraju u opremu, njihovu obavezu da osiguraju tehničke uslove i državnim organima omoguće nadzor utvrđuju se zakonom.

Privatnost i zaštita ličnih podataka u zakonima država Evropske unije temelji se, kao uostalom i u Bosni i Hercegovini, na konvenciji Savjeta Evrope o zaštiti lica u odnosu na automatsku obradu podataka. U skladu sa Konvencijom, EZ je donijela okvirnu Direktivu 95/46/EC o zaštiti podataka o ličnosti. Uvažavajući specifičnosti sektora elektronskih komunikacija, Evropski parlament i Savjet Evrope 2002. godine donose Direktivu 2002/58, koja utvrđuje okvire zaštite privatnosti, podataka o ličnosti i integriteta javnih mreža elektronskih komunikacija [1]. Nakon više terorističkih napada u državama Evropske unije (Madrid, London i dr.), pod pritiskom sigurnosnih agencija država EU, ova direktiva je 2006. godine dopunjena Direktivom 2006/24, koja uređuje okvir za zadržavanje podataka u saobraćaju za potrebe borbe protiv tzv. ozbiljnog kriminala [2].

Direktiva je naišla na veliki otpor javnosti i telekomunikacijske industrije, uz glavne primjedbe da je mjera zadržavanja neproporcionalna prijetnji, neefikasna u domenu Interneta, da nameće veliko finansijsko opterećenje operatora telekomunikacija, mrežnih operatera, davaoca usluga i davetelja pristupa, smanjujući njihovu konkurentnost, i da na mala vrata uvodi princip prezumpcije krivice za sve korisnike telekomunikacijskih usluga.

II. MEĐUNARODNA PRAKSA ZAKONITOG PRESRETANJA U ELEKTRONSKIM KOMUNIKACIJAMA

Presretanje svih oblika elektronskih komunikacija znatno je porastao nakon 11.09.2001. godine, kada se potvrdilo da su teroristi koristili Internet i druge napredne informacijske i komunikacijske tehnologije za planiranje napada na ciljeve u SAD. Već 2001. godine Američki Kongres je donio Patriotski zakon. U Njemačkoj je 2002. godine donesena Uredba o presretanju telekomunikacija, a u Velikoj Britaniji vlada je donijela Uredbu prema kojoj su svi pružaoci telekomunikacijskih usluge obavezni tehnički omogućiti stalno presretanje telekomunikacija.

Godine 2001. održana je Konvencija Vijeća Evrope o Internet kriminalu koja države potpisnice obavezuje na usvajanje zakonodavnih mjera kojima su sva pravna i fizicka lica koja pružaju Internet uslugu, dužni omogućiti presretanje telekomunikacija i dostavljanje informacija o tome na zahtjev države potpisnice, te im omogućuje zajedničku saradnju u borbi protiv Internet kriminala. U cilju presretanja elektronskih komunikacija pružaoci usluga su dužni instalirati opremu kojom će se sva komunikacija, prije slanja, usmjeriti na uređaj za snimanje.

Evropski pravni okvir za elektronske komunikacije, mreže i usluge predstavlja osnov za sve nacionalne zakone država članica EU. Pravni okvir pored osnovne direktive uključuje i direktivu 2002/58, kojom se utvrđuje okvir zaštite privatnosti, podataka o ličnosti i integriteta javnih mreža elektronskih komunikacija [3]. Evropska komisija je 2001. godine utvrdila politiku koja naglašava sigurnost telekomunikacijskih usluga za razvoj informacionog društva.

Evropska unija je 2004. godine formirala Evropske agencije za sigurnost mreža i informacionih sistema (ENISA), a početkom 2007. usvojila Strategiju za sigurno informaciono društvo u Evropi u kojoj naglašava potrebu za zajedničkim

nastupom svih zainteresiranih strana, kako bi odgovorila na nove sigurnosne izazove i najavila jačanje sigurnosti i integriteta telekomunikacionih mreža.

Suočeni sa velikim problemima u praksi, Evropska komisija je 25.03.2008. godine donijela odluku o formiranju eksperata, kao stalnog konsultativnog tijela Komisije i država članica za pitanja zadržavanja podataka o telekomunikacionom saobraćaju. Evropska komisija je 2009. godine usvojila i akcioni plan za zaštitu informaciono komunikacione infrastrukture. Evropski parlament i Evropski Savjet usvojili su značajne izmjene i dopune Direktive 2002/58 koje se tiču povrede tajnosti podataka o ličnosti, upotrebom Internet kolačića. Države članice EU su dobile rok do maja 2011. da usaglase svoja nacionalna zakonodavstva sa ovim izmjenama [4].

III. PRESRETANJE TELEKOMUNIKACIJSKIH USLUGA U BOSNI I HERCEGOVINI

A. Pravni okvir presretanja telekomunikacijskih usluga u BiH

Kada je u pitanju Bosna i Hercegovina, odstupanja od nepovredivosti tajnosti telekomunikacijskih usluga dozvoljena su na određeno vrijeme i na osnovu odluke suda, ako su neophodni radi vođenja krivičnog postupka ili zaštite sigurnosti Bosne i Hercegovine, na način predviđen zakonom. Pravo na nepovredivost tajnosti telekomunikacijskih usluga nije apsolutno pravo, naročito ako se zna da ga kriminalci koriste kao sredstvo za ostvarivanje svojih ciljeva, ili sa namjerom da izbjegnu otkrivanje. Efikasan nadzor telekomunikacijskih usluga je značajan za ovlaštene agencije, zadužene za otkrivanje i gonjenje počinilaca, ali pod uslovom da se nadzor primjenjuje po propisima koja su pravno obavezujuća, javno objavljena i uz zaštitu od zloupotrebe.

U Bosni i Hercegovini pravo na presretanje telekomunikacijskih usluga regulirano je odredbama član 4. Zakona o komunikacijama Bosne i Hercegovine ("Sl. glasnik BiH", br. 31/03 i br. 75/06) [5] i Odlukom o posebnim obavezama pravnih i fizičkih lica koja pružaju telekomunikacione usluge, administriraju telekomunikacijske mreže i vrše telekomunikacijske djelatnosti, u pogledu obezbjeđenja i održavanja kapaciteta koji omogućuju ovlaštenim agencijama da vrše zakonito presretanje telekomunikacija, kao i kapaciteta za čuvanje i obezbjeđivanje telekomunikacijskih podataka, koja je usvojena od strane Vijeća ministara Bosne i Hercegovine 14. novembra 2006. godine [6]. Prava na privatnost u domaćem zakonodavstvu regulirana su i Zakonom o centralnoj evidenciji i razmjeni podataka ("Sl. glasnik BiH", br. 32/01), Zakonom o zaštiti tajnih podataka ("Sl. glasnik BiH", br. 54/05.), Zakonom o zaštiti potrošača ("Sl. glasnik BiH" br.25/06) i Zakonom o obavještajno – sigurnosnoj agenciji Bosne i Hercegovine ("Sl. glasnik BiH", br. 12/04; 20/04; 56/04 i 12/09).

Odlukom o posebnim obavezama pravnih i fizičkih lica koja pružaju telekomunikacione usluge, administriraju telekomunikacijske mreže i vrše telekomunikacijske djelatnosti, u pogledu obezbjeđenja i održavanja kapaciteta koji omogućuju ovlaštenim agencijama da vrše zakonito presretanje telekomunikacija, kao i kapaciteta za čuvanje i obezbjeđivanje telekomunikacijskih podataka, uređeno je zakonito presretanje u Bosni i Hercegovini u skladu sa rezolucijom Savjeta Evropske unije o zakonitom presretanju telekomunikacija od 17. januara 1995. (OJ 96/C 329/01) i standardima i preporukama Evropskog instituta za telekomunikacijske norme (ETSI).

Operateri telekomunikacija, mrežni operateri, davaoci usluga i davaoci pristupa, tj. sva pravna i fizicka lica koja pružaju telekomunikacijske usluge, administriraju telekomunikacijske mreže i vrše telekomunikacijske djelatnosti, u pogledu osiguranja i održavanja kapaciteta imaju obavezu da omoguće ovlaštenim agencijama da vrše zakonito presretanje telekomunikacija, kao i kapaciteta za

cuvanje i obezbjeđivanje telekomunikacijskih podataka.

Zakonito presretanje je presretanje i dostavljanje ciljanih telekomunikacija u toku njihovog prenosa tako da, osim za pošiljaoca ili ciljanog primaoca telekomunikacije, dio ili cijeli sadržaj telekomunikacije i s njom povezanih telekomunikacijskih podataka postane dostupan ovlaštenoj agenciji, kako je to određeno za posebne istražne ili obavještajne radnje, a u skladu sa odredbama zakona u Bosni i Hercegovini.

Procedura za pokretanje zakonitog presretanje u telekomunikacijama je slijedeća: državni tužilac predaje prijedlog za pokretanje istražnom sudcu, koji nakon provjere osnovanosti donosi pisani obrazloženi nalog. Nalog izvršavaju ovlaštene agencije u saradnji s Interfejs centrom za zakonito presretanje telekomunikacija.

B. Telekomunikacijski podaci

Telekomunikacijski podaci, u svrhu čuvanja telekomunikacijskih podataka su:

- signalizirajuci podaci sadržani u ili vezani za telekomunikaciju za potrebe bilo kojeg telekomunikacijskog sistema kojim se ona prenosi;
- informacije o pružanju telekomunikacijske usluge ili sistema bilo kojem licu ili o njihovom korištenju od strane bilo kojeg lica, isključujući sadržaj bilo koje telekomunikacije izuzev podataka o prometu sadržanih u njoj; i
- svaka druga informacija koju ima operator telekomunikacija o licu kojem obezbjeđuje ili je obezbjeđivao usluge, kao što su podaci o pretplatniku.

C. Inrefejs centar za zakonito presretanje

Interfejs centar za zakonito presretanje ima direktan elektronski pristup sistemu za upravljanje presretanjem kod operatora telekomunikacija, mrežnih operatora, davaoca usluga i davaoca pristupa u Bosni i Hercegovini, kao i sisteme kojima se obezbijeđuje dostavljanje sadržaja telekomunikacije i informacija u vezi sa presretanjem centrima za snimanje i monitoring policijskih organa i OSA-e. Tehnicku administraciju interfejs centra za zakonito presretanje, ukljucujuci pokretanje operacija zakonitog presretanja i dostavljanje produkta presretanja centrima za snimanje i monitoring policijskih tijela i OSA-e, vrše tehnicki stručnjaci određeni od strane ovlaštenih agencija o kojima se dogovore članovi Zajednickog upravnog odbora. Tehnicka administracija interfejs centra za zakonito presretanje je odvojena za policijske organe i za OSA-u, kako bi se onemogućilo da policijski organi imaju pristup podacima OSA-e, odnosno da OSA ima pristup podacima policijskih organa.

D. Obaveze operatera telekomunikacija, mrežnih operatera, davatelja usluga i davatelja pristupa

Operatori telekomunikacija, mrežni operateri, davaoci usluga i davetelji pristupa osigurali su tehnicke i organizacijske preduslove, iz vlastitih resursa i o vlastitom trošku, da bi omogucili da se zakonito presretanje telekomunikacijskih usluga i aktivnosti provodi od strane interfejs centra za zakonito presretanje i to:

- ugradnju opreme za zakonito presretanje i interfejsa za fiksnu mrežu, mobilnu mrežu i Internet mrežu u skladu sa ETSI ili drugim standardima;
- ugradnju neophodne telekomunikacijske opreme i infrastrukture, te tehnickih rješenja u domenu upravljanja telekomunikacijskim mrežama, kojima se omogućuje upravljanje dostavljanjem ciljanih telekomunikacija od strane interfejs centra za zakonito presretanje;
- dostava sadržaja, kao i podataka u vezi s presretanjem, svih ciljanih telekomunikacija sa cijelog prostora koji pokriva operator interfejs centru za zakonito presretanje uz upotrebu minimalnog broja konekcija dovoljnog kapaciteta;
- procedure i stručni kadar kojima se osigurava dostava presretanih

telekomunikacija interfejs centru za zakonito presretanje u skladu sa garantovanim LJoS standardima;
- trajno održavanje i ispravan rad primijenjene funkcije zakonitog presretanja.

Operatori telekomunikacija, mrežni operatori, davaoci usluga i davaoci pristupa:
- obavezni su čuvati tajnovitost svih podataka i saznanja koja imaju o sredstvima, procedurama i podacima u vezi sa primjenom mjera zakonitog presretanja i čuvanjem i obezbjeđivanjem telekomunikacijskih podataka, ukljucujuci i ogranicenja fizickog i logickog pristupa ovlaštenom osoblju.
- smiju koristiti podatke u vezi sa presretanjem i signale, ali ne i sadržaj telekomunikacija dobijen primjenom funkcije zakonitog presretanja, i to samo za potrebe održavanja funkcije zakonitog presretanja i samo na nacin koji odobri Zajednicki upravni odbor.

E. Funkcionalni zahtjevi za primjenu funkcije zakonitog presretanja

Funkcija zakonitog presretanja sastoji se od presretanja telekomunikacija u toku njihovog prenosa, isporuke sadržaja i informacija na ciljanoj telekomunikacijskoj adresi ili adresama i mora osigurati isporuku: neprekinut sadržaj telekomunikacija i informacije u vezi sa presretanjem. Informacije u vezi sa presretanjem: moraju se bilježiti pri pokušaju uspostave komunikacije, pri uspostavi komunikacije, pri prekidu komunikacije, pri neuspjelom pokušaju uspostave komunikacije, pri promjeni telekomunikacijske usluge ili obilježja usluge i pri promjeni lokacije u toku mobilne telekomunikacije.

Operatori telekomunikacija, mrežni operatori, davaoci usluga i davaoci pristupa moraju osigurati isporuku informacija u vezi sa presretanjem i sadžaj ciljane telekomunikacije na način koji omogučava tacno i jednoznacno povezivanje informacija u vezi sa presretanjem sa njegovim sadržajem, omogučiti zakonito presretanje u stvarnom vremenu (sve informacije u vezi sa presretanjem moraju biti na raspolaganju odmah po završetku komunikacije i neprekinuto za cijelo vrijeme trajanja komunikacije, moraju osigurati da subjekt presretanja ili ostala neovlaštena lica ne osjete bilo kakvu promjenu koja bi mogla biti uzrokovana primjenom zakonitog presretanja, odnosno funkcionisanje ciljane telekomunikacijske usluge mora biti nepromijenjeno za subjekta presretanja, moraju osigurati da pouzdanost funkcije zakonitog presretanja bude veca ili jednaka pouzdanosti ciljane telekomunikacijske usluge pružene subjektu presretanja, te da kvalitet usluge koja se odnosi na prosljeđivanje presretane telekomunikacije Interfejs centru za zakonito presretanje, bude u skladu s tehnickim standardima operatora telekomunikacija, mrežnog operatopa, davaoca usluga i davaoca pristupa i obavezni su o vlastitom trošku čuvati telekomunikacijske podatke.

Operatori telekomunikacija, mrežni operatori, davaoci usluga i davaoci pristupa moraju:
- čuvati, tokom perioda od najmanje 12 meseci informacije o pružanju telekomunikacijske usluge ili sistema bilo kojem licu ili o njihovom korištenju od bilo kog lica:
- osigurati da se u periodu od najmanje 12 mjeseci čuvaju i sve druge informacije koje posjeduju o licu kojem pružaju ili su pružali usluge;
- posjedovati kapacitete za dostavu obračunskih podataka i podataka o preplatnicima u elektronskoj formi;
- imati kapacitete za obezbjeđivanje svih dostupnih podataka o trenutnoj ili poznatoj geografskoj, fizickoj ili logičkoj lokaciji određenog sredstva telekomunikacija;
- imati kapacitete za obezbjeđivanje podataka o telekomunikacijskim sredstvima koja su se pojavila na određenoj geografskoj, fizičkoj ili logičkoj lokaciji u posljednjih 48 sati.

IV. ZAKLJUČAK

Presretanja telekomunikacijskih usluga, odnosno zaštita privatnosti korisnika i sigurnost informacionih i komunikacionih tehnologija predstavljaju društveno i sigurnosno pitanje za svaku državu. Stalno uvođenje novih komunikacijskih tehnologija i usluga dodatno otežava već veoma složen problem. Rješavanje pitanja privatnosti i sigurnosti u elektronskim komunikacijama zahtjeva sveobuhvatan pristup, uključivanje širokog kruga zainteresovanih i usaglašavanje različitih interesa.

Bosna i Hercegovina na svom putu da postane članica Evropske unije, ispunjava standarde zaštite privatnosti i sigurnost informacionih i komunikacionih tehnologija, predviđenim direktivama EU i ETSI standardima. Tako su u Zakon o komunikacijama ugrađeni dijelovi Direktive 2002/58/EZ o obradi ličnih podataka i zaštiti privatnosti u elektronskom komunikacijskom sektoru, koji se odnose na sigurnost telekomunikacijske mreže, čuvanje i uvjete korištenja podataka u komunikacijama. Takođe u Prijedlog Zakona o krivičnom postupku BiH mora u dokazne radne ugraditi i "presretanje, prikupljanje i snimanje računarskih podataka". Lica prema kojima se dokazna radnja nadzora i tehničkog snimanje telefonskih razgovora i drugih komunikacija na daljinu može primijeniti su i lica "koja kriju počinitelja kaznenog djela ili na drugi način pomažu da ne bude otkriven".

Ovaj rad daje pregled pravnog uređivanja korištenja elektronskih potpisa u državama Evropske unije, kao i pravnu regulativu primjene elektronskih potpisa u Bosni i Hercegovini. Direktiva 1999/93/EC o okviru Zajednice za elektronske potpise je uspostavila pravni okvir za elektronske potpise i usluge potvrđivanja na nivou Evrope. Direktiva 2000/31/EC Evropskog parlamenta i Vijeća od 8. juna 2000. godine o određenim pravnim aspektima usluga informacionog društva, naročito elektronskog poslovanja, („Direktiva o elektronskom poslovanju"), usvojena 2000. godine, uspostavila je okvir za elektronsko poslovanje na unutrašnjem tržištu. Iako je Zakon o elektronskom potpisu Bosne i Hercegovine na snazi od 2006. godine i donešeni ostali propisi na nivou države Bosne i Hercegovine koji uređuju primjenu elektronskih potpisa, usklađeni sa Direktivom 1999/93/EC Evropskog parlamenta i Vijeća od 13. decembra 1999., o pravnom okviru Zajednice po pitanju elektronskih potpisa, i Direktivom 2000/31/EC Evropskog parlamenta i Vijeća od 8. juna 2000., po pitanju elektronskog poslovanja, na unutrašnjem tržištu („Direktiva o elektronskom poslovanju"), mnoga neriješena institucionalna i politička pitanja onemogućavaju proces primjene Zakona o elektronskom potpisu. Trenutno Bosna i Hercegovina kasni u implementaciji elektronskog potpisa, što znači, da su usporene i sve primjene e-potpisa u eTrgovini, eBankarstvu, eUpravi, ePoslovanju.....

Ključne riječi: elektronski potpisi, siguran elektronski potpis, podaci za formiranje potpisa, sredstva za formiranje potpisa, potvrda, kvalificirana potvrda, ovjerilac, vremenski pečat.

I. UVOD

Razvoj informacijskih i komunikacijskih tehnologija, u svim oblastima djelovanja građana, privrednih društava i državnih organa, u pravnom i poslovnom prometu, je utjecao na razvoj ekonomskih i drugih odnosa. Imajući u vidu prednosti primjene informacijskih i komunikacijskih tehnologija na svim poljima djelovanja, potrebno je stvoriti pravni okvir za njihovu primjenu, jer svako zaostajanje u primjeni ovih tehnologija je istovremeno kočnica razvoju tržišnih odnosa i ozbiljna smetnja konkurentnosti i razvoju privrede i javne uprave.

Uspostava pravnog okvira kojim se uređuje formiranje i upotreba elektronskog potpisa, i priznavanje potvrda stranih ovjerilaca, omogućava primjenu informacijskih i komunikacijskih tehnologija u pravnom i poslovnom prometu i omogućava elektronsko poslovanje.

Elektronsko poslovanje je razmjena standardizovanih elektronskih poruka između fizičkih i pravnih osoba u pregovaranju, ugovaranju, kupovini, prodaji, plaćanju, komuniciranju sa javnom upravom i sudovima i u svim drugim poslovnim transakcijama, a za koje je zakonom dozvoljena njegova primjena. Da bi se elektronsko poslovanje moglo odvijati moramo imati odgovarajuću elektronsku infrastrukturu i pravnu regulativu koja bi rješavala zloupotrebe i nesporazume.

II. RAZVOJ ELEKTRONSKOG POSLOVANJA U BOSNI I HERCEGOVINI

Vijeće ministara Bosne i Hercegovine je pokrenulo strategiju razvoja informacionog društva, odnosno elektronskog poslovanja u BiH kao ključni strateški zadatak [1]. Zakonsko uređenje elektronskog poslovanja služi kao preduvjet za razvoj i prevazilaženja zaostajanja Bosne i Hercegovine na putu da postane članica Evropske unije. Bosna i Hercegovina mora uskladiti svoje propise o elektronskom poslovanju sa propisima Evropske unije, jer države članice Evropske unije posebnu pažnju posvećuju pravnom uređivanju elektronskog poslovanja.

Najvažnije direktive iz ove oblasti koje je donijela Evropska unija su: Direktiva o elektronskim potpisima – 1999/93/EC, Direktiva o elektronskoj trgovini – 2000/31/EC, Direktiva o zaštiti potrošača kod prodaje na daljinu – 1997/7/EC, Direktiva o elektronskom novcu – 2000/46/EC, Direktiva o zaštiti podataka o osobama 95/46/EC i Direktiva o zaštiti podataka o osobam u elektronskim komunikacijama 2002/58/EC [2].

Najnažniji propisi koji zahtjevaju upotrebu informacionih i komunikacionih tehnologija u Bosni i Hercegovini su:

- Zakon o komunikacijama („Sl. glasnik BiH“, broj 33/02);
- Zakon o slobodi pristupa informacijama Bosne i Hercegovine stupio na snagu 01.01.2006. godine a objavljen u (Službenim novinama F BiH“, broj 72/05);
- Zakon o zaštiti osobnih podataka („Službeni glasnik BiH“, broj 49/06);
- Zakon o autorskom pravu i srodnim pravima („Službeni glasnik BiH“, broj 63/10);
- Zakon o elektronskom potpisu („Službeni glasnik BiH“, broj 91/06);
- Zakon o elektronskom pravnom i poslovnom prometu („Službeni glasnik BiH“, broj 88/07);
- Zakon o upravnom postupku („Službeni glasnik BiH”, broj 29/02, 12/04, 88/07, 93/09);
- Odluka o osnovama upotrebe elektronskog potpisa i pružanja usluga ovjeravanja („Službeni glasnik BiH“, broj 21/09);
- Odluka o elektronskom poslovanju i e-vladi (“Službeni glasnik BiH“, broj 07/10);
- Odluka o uredskom poslovanju ministarstava, službi, institucija i drugih organa Vijeća ministara BiH (“Službeni glasnik BiH”, broj 21/01, 29/03);
- Uputstvo o izradi i održavanju službenih Internet stranica institucija Bosne i Hercegovine („Službeni glasnik BiH“, broj 21/09).

Za razliku od entiteta, uspostavljanje pravnog okvira na državnom nivou za zakonsko uređenje elektronskog poslovanja ide veoma sporo.

III. PRAVNO REGULIRANJE ELEKTRONSKIH POTPISA

A. *Razvoj reguliranja elektronskog potpisa*

Pojedine američke savezne države (California, Utah, i dr.), prve su zakonski regulirale elektronska dokumenta.

Njemačka je prva država u Evropi koja je zakonski regulirala elektronske potpise. Zakon o digitalnim potpisima donešen 1997. godine, sadrži odredbe o telekomunikacijskim uslugama i zaštiti podataka. Zakon je predviđao upotrebu digitalnih potpisa zasnovanih na kriptografiji javnog ključa s posebno specificiranim tehničkim zahtjevima. Italijanski Zakon o digitalnim dokumentima donešen 1997. godine, osigurao je pravno priznanje digitalnim dokumentima, potpisima, ugovorima i plaćanjima. Francuski i britanski zakoni donešeni 2000. godine, ne govore više o "digitalnim potpisima", već uvode u upotrebu elektronski potpis [3].

B. EU direktive

Direktiva o elektronskim potpisima – 1999/93/EC, koja je formalno stupila na snagu 19. januara 2000. godine, predstavlja

pravno utemeljenje elektronskog poslovanja i na osnovu nje su donijeti zakoni o elektronskim potpisima u svim državama Evropske unije kao i u većini ostalih država Evrope [2]. Direktiva o elektronskim potpisima priznaje pravnu snagu neovisno o korištenoj informacijskoj i komunikacijskoj tehnologiji. Direktivom se uređuju pravni učinci elektronskih potpisa i potvrda, osnivanje i rad ovjerilaca koji izdaju kvalificirane potvrde, te njihova odgovornost, a normativno je regulirano i pitanje priznavanja stranih potvrda.

Direktiva obavezuje države članice Evropske unije da elektronskim ispravama s naprednim elektronskim potpisom osiguraju jednake pravne učinke, kao svojeručno potpisanoj ispravi u papirnom obliku i propisuje da se elektronskom potpisu ne smije oduzeti pravna snaga i prihvatljivost u dokaznim postupcima samo zbog njegovog elektronskog oblika ili zato što nije utemeljen na kvalificiranoj potvrdi. Funkcija izdavanja kvalificiranih potvrda slična je onoj koju ima ovjera svojeručnog potpisa na papiru.

Predviđeno je da ovjerilac usluge izdavanja kvalificiranih potvrda odgovara: za tačnost podataka sadržanih u potvrdi, da je u vrijeme izdavanja potvrde potpisnik posjedovao podatke za izradu potpisa koji odgovaraju podacima za provjeru potpisa navedenim u potvrdi, da podaci za izradu potpisa odgovaraju podacima za provjeru potpisa. U pogledu uvjeta za osnivanje i rad ovjerilaca usluge izdavanja kvalificiranih potvrda, Direktiva EU o elektronskim potpisima traži da države članice omoguće svakom zainteresiranom subjektu pružanje te usluge bez ograničenja njihovog broja, ali im je ostavljena mogućnost da propišu uvjete za osnivanje [2].

Najznačajnija polja primjene elektronskog potpisa su:

- elektronsko poslovanje (e-Business)
- elektronska trgovina (e-Commerce)
- elektronsko bankarstvo (e-Banking)
- elektronska uprava (e-Government)
- elektronsko zdravstvo (e-Healthcare)
- platni sistemi na bazi čip kartica (EMV), itd.

IV. PRAVNA REGULATIVA ZA PRIMJENU ELEKTRONSKOG POTPISA U BOSNI I HERCEGOVINI

Zakonsko uređenje elektronskog poslovanja u Bosni i Hercegovini započelo je Zakonom o elektronskom potpisu koji je objavljen 14. 11. 2006. godine, a stupio na snagu 14.05.2007. godine, i Zakonom o elektronskom pravnom i poslovnom prometu (donešen 29.10.2007. godine), koji uređuje pravni okvir za određene aspekte elektronskog pravnog i poslovnog prometa koji obuhvata preduzimanje i pružanje usluga informacionog društva, obaveze davaoca usluga u vezi s informiranjem, zaključivanje ugovora i odgovornost davaoca usluga [4].

A. Zakon o elektronskom potpisu u Bosni i Hercegovini

Cilj reguliranja elektronskih potpisa u Bosni i Hercegovini je podstaknuti i omogućiti razvoj elektronskog poslovanja, otkloniti normativne i administratvne smetnje za elektronsko poslovanje, izjednačiti elektronski potpis sa vlastoručnim potpisom, uspostaviti jasna pravila za upotrebu elektronskog potpisa i rad davalaca usluga, uskladiti zakonodavstvo Bosne i Hercegovine sa zakonodavstvom Evropske unije, te osigurati međunarodno priznavanje elektronskog potpisa.

Donošenjem Zakona o elektronskom potpisu uspostavlja se zakonski okvir koji omogućava elektronsko poslovanje i upotrebu informacijskih i komunikacijskih tehnologija u pravnom prometu, upravnim, sudskim i drugim postupcima.

Zakon o elektronskom potpisu implementira najznačajnije zahtjeve i pravna rješenja postavljena Direktivom 1999/93 EC:

- za početak rada i pružanje usluga u vezi s elektronskim potpisom i ovjeravanjem ovjeriocu nije potrebna posebna dozvola,
- dobrovoljno akreditiranje,
- potvrda da tehnička sredstva i postupci ovjerioca zadovoljavaju sigurnosne zahtjeve,

- zahtjevi koje mora ispunjavati ovjerilac koji izdaje kvalificirane potvrde,
- zahtjevi za kvalificirane potvrde,
- zahtjevi za tehnička sredstva i postupka za formiranje sigurnog elektronskog potpisa,
- priznavanje stranih potvrda,
- odgovornost ovjerilaca,
- zaštita podataka.
-

Elektronski potpis je skup podataka u elektronskom obliku koji su pridruženi ili logički povezani sa drugim podacima u elektronskom obliku i koji služe za identifikaciju potpisnika, i u potpunosti zamjenjuje svojeručni potpis u svim procedurama, osim u nekoliko, zakonom predviđenih slučajeva [4].

Siguran elektronski potpis je elektronski potpis koji je dodijeljen isključivo potpisniku, koji omogućava identificiranje potpisnika, koji je formiran upotrebom sredstava koja su u potpunosti pod kontrolom potpisnika, koji je povezan s podacima na koje se odnosi, zasnovan na kvalificiranoj potvrdi i formiran upotrebom tehničkih sredstava i postupaka koji su u skladu sa sigurnosnim zahtjevima Zakona o elektronskom potpisu i na osnovu njega donesenih podzakonskih propisa.

Zakon o elektronskom potpisu se ne odnosi na pravne poslove iz oblasti porodičnog i nasljednog prava koji zahtijevaju pisanu formu i drugih izjava volje ili pravnih poslova za čije se važenje zahtijeva sudska ili notarska provjera autentičnosti ili notarska isprava i na pravne poslove koji zahtjevaju službenu ovjeru, sudsku ili notarsku provjeru radi unosa u zemljišne knjige i registar (ugovor o uređivanju imovinskih odnosa između bračnih drugova, ugovor o imovini osoba kojima je oduzeta poslovna sposobnost, ugovor o ustupanju i raspodjeli imovine za života i ugovor o doživotnom izdržavanju.).

Zakonom o elektronskom potpisu je elektronska forma i pismena forma ”izjednačena“:

- podacima u elektronskom obliku se ne može odreći valjanost ili dokazna snaga samo zato što su u elektronskom obliku;
- elektronskom potpisu se ne smije odreći valjanost ili prihvatljivost kao dokaza samo zbog elektronskog oblika, ili zbog toga što nije zasnovan na kvalifikovanoj elektronskoj potvrdi, ili zbog toga što nije oblikovan sredstvima za izradu kvalifikovanog elektronskog potpisa;
- pouzdanost elektronskog poslovanja garantira se kvalificiranim elektronskim potpisom, kojim se osigurava integritet valjanosti podataka u elektronskom obliku, kao i identifikacija potpisnika [4].

Kvalifikovani elektronski potpis i potvrde

Ključ za implementaciju e-poslovanja i e-uprave je postojanje tehnoloških, institucionalnih i pravnih uslova za formiranje kvalifikovanog elektronskog potpisa. Za njegovu primjenu neophodno je posjedovati sredstva za formiranje elektronskog potpisa i kvalifikovanu elektronsku potvrdu potpisnika. Tek tada kvalifikovani elektronski potpis pouzdano garantuje identitet potpisnika, integritet elektronskih dokumenata i onemogućava naknadno poricanje odgovornosti za njihov sadržaj, u protivnom on predstavlja „samo“ elektronski potpis.

Kvalifikovana potvrda je elektronska potvrda koja ispunjava uslove iz Direktive 1999/93/EC.

Ovjerilac koji izdaje kvalificirane potvrde dužan je demonstrirati pouzdanost koja se zahtijeva za pružanje usluga u vezi s elektronskim potpisom i ovjeravanjem, voditi brz i siguran registar potvrda i osigurati pružanje neodgodive i sigurne usluge opoziva i odgovoran je za pričinjenu štetu “ukoliko ne dokaže da je šteta nastala bez njegove krivice” [4].

Davaoci usluga se dobrovoljno akredituju kod Ureda za akreditaciju ministarstva, i prihvataju dobrovoljno nadzor ovog organa, u cilju veće sigurnosti i povjerenja.

Priznavanje potvrda koje su izdali strani ovjerioci

Potvrde koje su izdali ovjerioci sa sjedištem u državi članici Evropske unije ili državi koja je članica Evropskog ekonomskog prostora i čiju validnost Bosna i Hercegovina može provjeriti tretiraju se isto kao i domaće potvrde. Kvalificirane potvrde ovih ovjerilaca imaju isto pravno djelovanje kao domaće kvalificirane potvrde.

Potvrde koje su izdali ovjerioci sa sjedištem u trećim državama i čiju validnost Bosna i Hercegovina može provjeriti bit će priznate u Bosni i Hercegovini. Kvalificirane potvrde ovih ovjerilaca pravno će se tretirati kao i domaće kvalificirane potvrde ako:

- ovjerilac demonstrira pouzdanost koja se zahtijeva za pružanje usluga u vezi s elektronskim potpisom i ovjeravanjem, vodi siguran registar potvrda i ako je akreditiran u skladu sa sistemom dobrovoljne akreditacije, u Bosni i Hercegovini, ili u državi članici Evropske unije;
- domaći ovjerilac ili ovjerilac sa sjedištem u državi članici Evropske unije ili državi koja je članica Evropskog ekonomskog prostora, ako ovjerilac demonstrira pouzdanost koja se zahtijeva za pružanje usluga u vezi s elektronskim potpisom i ovjeravanjem, vodi siguran registar potvrda, garantira za njegove potvrde u skladu s propisima o odgovornosti;
- se potvrda priznaje kao kvalificirana, ili se ovjerilac smatra ovjeriocem koji izdaje kvalificirane potvrde, na osnovu dvostranog ili višestranog međunarodnog ugovora između BiH i drugih država ili međunarodnih organizacija;
- se potvrda priznaje kao kvalificirana, ili se ovjerilac smatra ovjeriocem koji izdaje kvalificirane potvrde, na osnovu dvostranog ili višestranog međunarodnog ugovora između Evropske unije i trećih država ili međunarodnih organizacija.

U cilju zaštite potrošača, koji nemaju odgovarajuća tehnološka znanja, davaocima usluga se propisuju različite obaveze, među kojima se posebno ističe obaveza da se korisnik usluga upozna sa pravnim i tehničkim mogućnostima, te sa posljedicama elektronskog poslovanja.

Radi zaštite ličnih podataka, precizno se propisuje prikupljanje i posredovanje ličnih podataka potrebnih za rad davalaca usluga. Lica koja čuvaju dokumente koji su elektronski potpisani, upotrebom podataka i sredstava za izradu elektronskog potpisa, obavezna su čuvati podatke i sredstva za provjeru elektronskog potpisa sve dok čuvaju i dokumenta.

Zakon je otvoren i upotrebljiv za nove tehnologije i daje mogućnost različitih tehnoloških rješenja sa različitim nivoima pouzdanosti što ima za posljedicu različit pravni tretman pojedinih solucija, omogućava da svoje usluge ponude različiti davaoci usluga te time i korisniku da sam izabere nivo sigurnosti elektronskog potpisa.

Vijeću ministara Bosne i Hercegovine data je nadležnost za donošenje podzakonskih propisa za provođenje Zakona o elektronskom potpisu. U cilju razvoja elektronskog poslovanja u BiH, od podzakonskih propisa Vijeće ministara BiH donijelo je 2008. godine Odluku o osnovama upotrebe elektronskog potpisa i pružanja usluga ovjeravanja [5]. Odluka regulira pružanje usluga u vezi s elektronskim potpisom i ovjeravanjem, kao i rad nadzornog tijela. Usvojenim rješenjima u izradi elektronskog potpisa osigurana je primjena tehnoloških standarda u skladu sa standardima u državama članicama Evropske unije - ETSI standardi.

U BiH nije formirano certifikacijsko tijelo za certifikaciju elektronskih potpisa i nadzor u skladu sa odredbama Zakona o elektronskom potpisu, te zbog toga ni korištenje kvalificiranih elektronskih potpisa nije moguće u BiH. Pored toga, implementiranje Zakona o elektronskom potpisu zavisi i od formiranja Agencije za informaciono društvo, koja je Prijedlogom zakona o Agenciji za informaciono društvo predviđena kao ovjerilac.

B. Pravna regulativa za primjenu elektronskog potpisa u Republici Srpskoj

U Republici Srpskoj 2008. i 2009. godine usvojena su tri zakona i pet podzakonskih propisa koji reguliraju primjenu elektronskog potpisa na teritoriji Republike Srpske, i to:

- Zakon o elektronskom potpisu, koji uređuje pravo fizičkih i pravnih lica na upotrebu elektronskog potpisa u upravnim, sudskim i drugim postupcima, poslovnim i drugim radnjama, te prava, obaveze i odgovornosti fizičkih i pravnih lica u vezi sa davanjem usluga certifikacije elektronskog potpisa na teritoriji RS, ako posebnim zakonom nije drugačije određeno ("Sl. glasnik RS", broj 59/08);
- Zakon o elektronskom dokumentu ("Sl. glasnik RS", broj 110/08);
- Zakon o elektronskom poslovanju ("Sl. glasnik RS", broj 59/09);
- Uredbu o nosiocu poslova elektronske certifikacije u Republičkim organima uprave (“Sl. glasnik RS“ br. 114/08, 73/09);
- Pravilnik o evidenciji certifikovanih tijela ("Sl. glasnik RS", broj 88/09);
- Pravilnik o elektronskoj razmjeni poslovnih poruka ("Sl. glasnik RS", broj 30/06);

- Pravilnik o sadržaju i načinu vođenja registra certifikacionih organa za izdavanje kvalificiranih elektronskih certifikata (“Sl. glasnik RS“ broj 88/09);
- Pravilnik o mjerama zaštite elektronskog potpisa, i kvalificiranog elektronskog potpisa, najnižem iznosu obaveznog osiguranja i primjeni organizacionih i tehničkih mjera zaštite certifikata – (”Sl. glasnik RS” broj 88/09);
- Pravilnik o tehničkim pravilima za osiguranje povezanosti evidencija („Sl. glasnik RS“ broj 88/09).

U R Srpskoj 2007. godine, osnivana je Agencija za informaciono društvo R Srpske [6].

C. Buduća pravna regulativa za primjenu elektronskog potpisa u Bosni i Hercegovini

Kako pravno reguliranje elektronskog poslovanja treba da bude na državnom nivou, Vijeće ministara BiH u partnerstvu sa UNDP BiH izradilo je nacrte pravne regilative za primjenu elektronskog potpisa u BiH, koju sačinjavaju:

- usvojeni Zakon o elektronskom potpisu BiH i Zakon o određenim pravnim aspektima elektronskog pravnog i poslovnog prometa BiH;
- Nacrt Uredbe o mjerama zaštite elektronskog potpisa;
- Nacrt Uredbe o uslovima za povezivanje evidencija izdanih i opozvanih certifikata;
- Nacrt Uredbe o registru davatelja usluga certificiranja i elektronskih potpisa koji izdaju kvalificirane certifikate; i
- Nacrt Uredbe o evidenciji davatelja usluga certificiranja elektronskih potpisa [7].

V. ZAKLJUČAK

Sistem elektronskog potpisa i elektronske isprave zahtjevna je i važna tehnologija bez koje će bilo kakav oblik administracije u budućnosti biti nezamisliv. Elektronski potpis je kljuc povjerenja i sigurnosti u savremenom poslovanju. Omogućio je brže zaključivanje ugovora i jednostavnije poslovanje, ljudima i privrednim društvima štedi vrijeme i novac. Elektronski potpisi imaju svijetlu budućnost jer je postao gotovo ne zamjenjiv u međunarodnoj komunikaciji tokova i sve više prodire u sve sfere društva pružajući mogućnost ljudima da lakše obavljaju pojedine radnje.

Donošenjem Zakona o elektronskom potpisu, Bosna i Hercegovina je tek započela izgradnju tog dijela pravnog sistema, a nužno je još zakonski regulirati elektronsko poslovanje. Naš je zakon izrađen po uzoru na Direktivu EU o elektronskim potpisima pa su na taj način osigurani minimalni preduvjeti za priključenje savremenim tokovima međunarodne razmjene, te je istovremeno zakonodavstvo jednim dijelom usklađeno sa zahtjevima Evropske unije.

U Bosni i Hercegovini je nedovoljna pravna regulativa za upotrebu tehnologije elektronskog potpisa, te je zadatak u slijedećem periodu požuriti sa usvajanjem niza zakona i podzakonskih propisa, ukoliko BiH želi pratiti projekcije Evropske komisije. Elektronska zakonska regulativa bi trebala obuhvati sve elemente našeg budućeg e-razvoja u svim djelatnostima: državnoj upravi i državnoj samoupravi, trgovini, zdravstvu, obrazovanju, bankarstvu, turizmu, sportu, kulturi itd. Međutim, budućnost elektronskih potpisa neće ovisiti samo o zakonodavnom uređenju, već i o raširenosti popratne tehnologije, pa je važno poticati njihovu dostupnost svim sferama društva.

Sažetak - Rad daje pregled i usporednu analizu regulatornih aspekata usluga IPTV-a u svijetu i Europi te ističe važna pitanja regulacije usluga IPTV-a specifičnih za Republiku Hrvatsku. Prvo je dan pregled usluga IPTV-a i razmotren utjecaj konvergencije na tržište medijskih usluga. Nadalje, predstavljena je detaljna analiza postojećih praksi za licenciranje operatora IPTV-a kako bi se identificirali potencijalni problemi koji se mogu pojaviti tijekom razvoja tržišta usluga IPTV-a u Republici Hrvatskoj. Na osnovi ove analize donosimo inicijalne smjernice za definiranje regulatornih obveza operatora koji pružaju usluge IPTV-a u Republici Hrvatskoj.

I. UVOD

Službena definicija internetske televizije (engl. *Internet Protocol Television*, IPTV) koju je potvrdila tematska skupina za IPTV ITU-T-a (engl. International Telecommunication Union Focus Group on IPTV, ITU-T FG IPTV) glasi: „Usluge IPTV-a su višemedijske usluge koje isporučuju korisnicima razne digitalne sadržaje, primjerice televizijski program, video, audio, tekst, slike, ili podatke, preko mreža temeljenih na protokolu IP (engl. *Internet Protocol*), a uz podršku za zahtijevanu kakvoću usluge (engl. *Quality of Service*, QoS) ili kakvoću doživljaja (engl. *Quality of Experience*, QoE), te definirani nivo sigurnosti, interaktivnosti i pouzdanosti“ [1]. Usluge IPTV-a se nude preko zatvorenih mreža za distribuciju sadržaja gdje mrežni operator kontrolira tehničke parametre puta prijenosa s jednog kraja na drugi. IPTV pokriva kako prijenos TV programa uživo tako i prijenos videa na zahtjev. Usluge IPTV-a su u pravilu sastavni dio kombinirane usluge „tri u jedan“ (engl. *triple-play*) koju pružaju telekom operatori širom svijeta, a objedinjuje govornu uslugu, pristup Internetu i usluge IPTV-a. U posljednje vrijeme se na tržištu pojavljuju i usluge *quad-play* koje uz „tri u jedan“ nude i podršku za osobnu pokretljivost korisnika i pristup sadržaju s fiksnih i pokretnih terminala.

Osim usluga IPTV-a, danas su na tržištu dostupne usluge kao što je Internet TV ili Internet video, koje se razlikuju od usluga IPTV-a jer se pružaju preko javnog Interneta, za razliku od IPTV-a koji podrazumijeva zatvorenu mrežu u vlasništvu operatora. Stoga su Internet TV i Internet video nekontrolirane usluge od strane mrežnog operatora u smislu tehničkih parametara prijenosa te nude strujanje (engl. *streaming*) video sadržaja preko javnog Interneta. Neki ponuđači usluga Internet videa, kao što su Youtube i Metacafe, omogućuju isporuku i pristup video sadržaju koji je generiran od strane korisnika te dijeljenje vlastitog video sadržaja s drugim korisnicima. S obzirom na nemogućnost garancije razine kakvoće usluge ove usluge ne podliježu pravoj kontroli produkcijske kakvoće. Operatori usluga Internet TV-a (npr. Joost, Babelgum, Zattoo) temelje arhitekturu svog rješenja na mrežama ravnopravnih sudionika (engl. *Peer-to-Peer*, P2P) i obično ne naplaćuju pristup sadržaju, a financiraju se od reklama. Međutim, njihove usluge su sadržajno vrlo slične uslugama koje nude operatori IPTV-a po nekoliko ključnih pitanja. Prvo, kao i IPTV, Internet TV omogućuje pristup profesionalno proizvedenom i autorskim pravima zaštićenom video sadržaju. Drugo, operatori Internet TV-a kao i operatori IPTV-a teže koristiti standard MPEG-4 za kodiranje video sadržaja visoke razlučivosti. Treće, operatori Internet TV-a često nude i uslugu video na zahtjev (engl. *Video on Demand*, VoD) koja omogućuje korisnicima kontrolu prikaza video sadržaja u stvarnom vremenu, kao što je omogućeno i korisnicima IPTV-a. Prije nego što se počne govoriti o IPTV regulaciji potrebno je pogledati kratku analizu vezanu uz pitanje usporedbe IPTV-a, Internet TV-a i Internet videa radi lakšeg definiranja glavnih razlika između tih usluga. Tablica I. pokazuje da iako su Internet video i Internet TV besplatne usluge koje se financiraju isključivo reklamama, usluge IPTV-a nisu besplatne. Usluge IPTV-a pružaju samo profesionalni sadržaj koji je zaštićen autorskim pravima, dok usluge Internet videa i Internet TV-a uključuju i amaterski sadržaj generiran od strane korisnika ili operatora koji ne podliježe autorskim pravima.

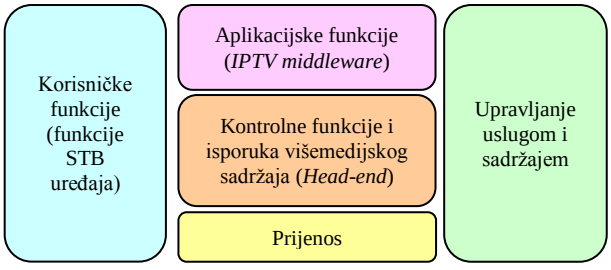
TABLICA I.
USPOREDBA USLUGA IPTV-A, INTERNET TV-A I INTERNET VIDEA

	IPTV	INTERNET TV	INTERNET VIDEO
Operatori	MaxTV (HT) U-verse (AT&T) Orange TV (France Telecom) Imagenio (Telefonica) Now TV (PCCW)	Joost Zattoo Babelgum	Youtube Metacafe
Korisnici	Samo pretplatnici; zatvorena mreža	Besplatno, financiranje od reklama	Besplatno, financiranje od reklama
Usluge	Emitiranje TV programa uživo, video na zahtjev, interaktivne	Video na zahtjev i/ili emitiranje TV programa uživo u	Samo video spotovi, kratki filmovi

	usluge	okruženju koje omogućuje istodobno izvršavanje više zadataka	
Mreža	IP platforma, kontrolirana mreža	Javni Internet; peer-to-peer	Javni Internet
Video produkcija	Samo profesionalni video sadržaj	Samo profesionalni video sadržaj	Samo amaterski sadržaj; sadržaj generiran od strane korisnika
Video kakvoća	Kontrolirana kakvoća usluge (QoS); MPEG2 to MPEG 4, MSVCI	Kontrolirana kakvoća usluge (QoS); Kvalitetni MPEG 4	Nekontrolirana kakvoća usluge; Niska razina, ali se poboljšava
Oprema	STB sa TV-om ili PC-om	PC	PC
Razlučivost	Cijeli TV ekran	Skoro cijeli TV ekran	QCIF/CIF
Autorska prava	Sadržaj je zaštićen DRM-om	Sadržaj je zaštićen DRM-om	Sadržaj nije zaštićen
Komercijalno uvođenje usluge	Pruža se u ograničenim geografskim područjima u različitim zemljama	Većina sadržaja je ograničena na korisnike u SAD-u jer operatori nisu dobili međunarodne licence za emitiranje	Potpuno dostupna

II. KONVERGENCIJA MEDIJSKIH USLUGA

Za pružanje usluga IPTV-a ključne su sljedeće četiri komponente: izvor sadržaja (davatelj sadržaja), jezgrena mreža, pristupna mreža i krajnji korisnik. Izvor sadržaja je davatelj video sadržaja koji posjeduje ili ima dozvolu za prodaju televizijskog programa koji se emitira uživo, sadržaja na zahtjev (engl. *content on demand*, CoD) ili nekog drugog sadržaja na Internetu. Televizijski program koji se emitira uživo obično se prima preko satelita ili preko svjetlovodnih mreža, dok se sadržaj na zahtjev pohranjuje kod mrežnog operatora. Osnovne usluge IPTV-a prema Open IPTV Forumu su: višemedijska usluga za prijenos TV programa uživo, video na zahtjev (engl. *Video on Demand*, VoD), plaćanje po odgledanom sadržaju (engl. *Pay Per View*, PPV), usluga osobnog video snimača (engl. *Personal Video Recorder*, PVR), elektronski programski vodič (engl. *Electronic Program Guide*, EPG), podsjetnik, pristup web-u, interaktivne aplikacije, roditeljska zaštita (engl. *Parental control*) i usluga poručivanja.



Slika 1. Općenita arhitektura usluge IPTV-a prema ETSI-u

Općenita arhitektura usluge IPTV je prikazana slikom 1 [2]. Aplikacijske funkcije omogućuju korisnicima odabir željene usluge i autorizaciju korisničkih zahtjeva te kontrolu i upravljanje uslugom za operatora. U praksi ih implementira sustav poznat pod nazivom IPTV *middleware*. Kontrolne funkcije omogućuju kontrolu usluge i prijenosa višemedijskog sadržaja te pripremu sadržaja za paketski prijenos i samu isporuku krajnjem korisniku. U praksi pripremu sadržaja i isporuku vrši mrežno čvorište (engl. *head-end*). Prijenosne funkcije se odnose na paketski prijenos u jezgrenoj IP mreži operatora i omogućuju rezervaciju potrebnih mrežnih resursa za kvalitetnu isporuku sadržaja. Korisničke funkcije objedinjavaju funkcije krajnjeg korisničkog uređaja (*set-top-box*) i prijenosa pristupnom mrežom.

Tehnološke prednosti stvaraju nove proizvode i segmente unutar industrije, vode povećanju korištenja i trošenja na medijske proizvode, dok u isto vrijeme uništavaju postojeća tržišta, segmente i poslovne modele. Na primjer, video kasete i kasnije digitalni mediji (engl. *Digital Versitle Disc*, DVD) su značajno utjecali na prihode filmske industrije prije desetak godina, dok se obogaćivanjem doživljaja gledatelja pojavila HD i 3D tehnologija koja daje prednost drugim medijima kao što je Blu-ray koji opet stvaraju nove prihode za filmsku industriju. Internet se razvija od distribucijske platforme za generiranje običnog video sadržaja od strane korisnika (engl. *User-generated Video Content*, UGC) do platforme koja nudi puno više mogućnosti za isporuku preko više uređaja. Ove mogućnosti uključuje usluge s iznimno visokom kompresijom i kakvoćom sadržaja (engl. *Over-The-Top*, OTT) i video usluge kao što su Netflix, Amazon i LOVEFiLM, koje nude video preko Interneta. Mnogi nakladnici audio i video sadržaja pokrenuli su *catch-up* usluge. Operatori plaćene televizije su pokrenuli OTT video usluge kao što je TV Anywhere in the US. Dok vrlo brzi širokopojasni Internet ne bude dostupan na većim područjima, korisnici neće moći pristupati, bilo kad i bilo gdje, video sadržaju visoke kakvoće, glazbi ili bilo kojem digitalnom mediju. Upravljanje širokopojasnim pristupom uzrokovalo je razvoj usluga IPTV-a, kao što je FiOS [3] usluga u Sjedinjenim Američkim Državama ili usluga SingTel's Mio [4] u Singapuru, te povećanje broja IPTV instalacija širom svijeta. Krajem 2010. godine bilo je preko 700 usluga IPTV-a širom svijeta. Razvoj pokretnog širokopojasnog pristupa (kao što je 3G/HSPA i LTE) omogućuje vrlo brzu dvosmjernu komunikaciju putem pokretnih mreža preko šireg geografskog područja. Korisnički uređaji koji su tradicionalno imali samo jednu svrhu, kao što su TV prijamnici, pokretni telefoni, osobna računala, uređaji za reprodukciju zvuka i igraće konzole, sada postaju višefunkcijski uređaji i razvijaju se naprijed pružajući slične razine kvalitete video sadržaja.

Popularnost korištenja usluga na zahtjev i vremenski pomaknutog sadržaja (engl. *Time-Shifted Content*) i želja za pohranjivanjem video sadržaja na privatne ili javne medije za pristup istom sadržaju u svakom trenutku i na svakom mjestu se povećavaju radi njihove široke dostupnosti na masovnom tržištu i mogućnosti obrade sadržaja uz nisku cijenu pohranjivanja sadržaja. To znači

da će sadržaj sve više biti pohranjen na mrežnim poslužiteljima u formatima višestruke razlučivosti kako bi se mogao isporučiti na svaki korisnički uređaj preko bilo koje mreže. Ovakav način isporuke sadržaja povećava raznolikost isporuke, omogućuje individualizaciju i ne veže gledatelje za unaprijed određeni raspored programa. Konvergencija medija i distribucija video sadržaja na različite uređaje nije povezana samo s razvojem tehnologije već i s novim uslugama za korisnike, novim načinom poslovanja, novim tipovima medijskih proizvoda i novim načinima interakcije s krajnjim korisnicima. Korisnici sve više očekuju uživati u audiovizualnom sadržaju na zahtjev od bilo gdje i u bilo koje vrijeme. Ovaj pomak je najviše vidljiv među mlađim korisnicima usluga, koji se još nazivaju „digitalnim urođenicima“ (engl. *digital natives*). S vremenom će takva nova generacija korisnika postati sljedeće masovno tržište digitalnog sadržaja. Svaka od tri osnovne dimenzije koje čine audiovizualni sektor – sadržaj, distribucijski sustavi i uređaji koji prikazuju sadržaj – moraju biti predmetom promjene koju je izazvao tehnološki razvoj. Posebno je važno da regulatorni okvir drži korak s tehnološkim razvojem. Novi, u osnovi različiti tržišni i poslovni uvjeti koji se razvijaju podrazumijevaju i razvijanje novih regulatornih okvira. Suprotno tradicionalnoj politici emitiranja sadržaja, koji zahtijeva ravnopravno dodijeljen nedostatan radiofrekvencijski spektar, potrebno je prepoznati mogućnosti brzo rastućeg višeplatformskog audiovizualnog pristupa te pristup audiovizalnom sadržaju koji se odvija u različitim komplementarnim i alternativnim mrežama. U višeplatfomskom okuženju trebala bi se primijeniti ista pravila i standardi na sve tehnologije i distribucijske platforme. Politika medijske regulacije bi trebala biti tehnološki neutralna i neovisna o platformi preko koje se sadržaj prenosi. Međutim, većina današnjih studijskih istraživanja medija potvrđuje da su ponašanja gledatelja u velikoj mjeri ista onima u proteklih desetak godina te da je masovna audiovizualna konzumacija medija još uvijek linearna. No provedene studije u načelu ne uzimaju u obzir važne tehnološke promjene jer krajnji korisnici sada imaju pristup širem opsegu digitalnog sadržaja (uključujući TV, video, glazbu i knjige) te koriste nove načine za međusobno komuniciranje (npr. kroz društevno umrežavanje, dijeljenje informacija i komuniciranje preko bilo kojeg drugog uređaja).

Korisnici imaju puno više izbora danas nego ikad prije u odabiranju načina na koji gledaju TV i video sadržaj, tako da ne iznenađuje činjenica da se korisnička očekivanja i navike razvijaju. Nedavna Ericssonova studija o korištenju medija na više različitih uređaja [5] je pokazala da korisnici troše preko trećinu svoga slobodnog vremena gledajući video sadržaj, dok manje od pola (43%) tog vremena provedu gledajući standardnu linearnu televiziju. To znači da već sada preko 50% sadržaja se gleda preko sve većeg broja uređaja, od osobnih računala, prijenosnih računala, pokretnih telefona do tableta i igraćih konzola. Kada je riječ o IPTV-u, Kina je ta koja dominira tim područjem. Kina se sada pomaknula na drugo mjesto na listi prvih 10 IPTV zemalja prema broju pretplatnika. Sada time stječe nove pretplatnike brže od Francuske, te se približava poziciji vodećeg IPTV tržišta na svijetu. Isto tako jasno je da ima i puno više mjesta za rast. Raznovrsni paketi usluga će biti važni čimbenici u održavanju niske cijene IPTV-a za potencijalne korisnike, te dodatne usluge poput sadržaja na zahtjev. To je osobito slučaj s obzirom na sve veću dostupnost nove generacije usluga osobnih video snimača (engl. *Personal Video Recorder*, PVR) povezanih širokopojasnom internetskom vezom. Kada se kombiniraju s digitalnom zemaljskom televizijom ili satelitskom televizijom, oni nude mnoge od usluga IPTV-a na zahtjev, a u kombinaciji s mogućnošću odašiljanja kanala visoke razlučivosti slike.

III. LICENCIRANJE OPERATORA IPTV-A

Regulatorni okvir EU-a iz 2002. godine je uveo opći autorizacijski sustav [6] za rad elektroničke komunikacijske mreže (uključujući mreže za emitiranje) ne zahtijevajući ništa više do obavještavanja regulatornog tijela za elektroničke komunikacije o početku pružanja usluga. Hrvatski regulatorni okvir je u potpunosti usklađen s Direktivom o autorizaciji elektroničkih komunikacijskih mreža i usluga [6], te je za obavljanje usluga IPTV-a potrebno nacionalnom regulatornom tijelu (HAKOM) podnijeti Prethodnu obavijest o obavljanju elektroničkih komunikacijskih mreže i usluga, a sukladno Pravilniku o načinu i uvjetima obavljanja elektroničkih komunikacijskih mreža i usluga (Narodne novine, broj 154/11) [7]. Operator usluga IPTV-a bi trebao ishoditi dodatna ovlaštenja ili dozvole od regulatornog tijela za emitiranje sadržaja ovisno o tipovima ponuđenih usluga u devet zemalja članica EU-a[1] prema dokumentu ITU-a s radionice o IPTV-u održane u Seoulu od 12. do 13. listopada 2006. godine [8]:

- Video na zahtjev - budući da je video na zahtjev usluga informacijskog društva pod Direktivom elektroničke trgovine, u načelu nije potrebno posebno ovlaštenje ni dozvola za pružanje ove usluge. Takav je slučaj u sedam zemalja[2]. U Belgiji (nizozemsko govorno područje) i Nizozemskoj treba se obavijestiti regulatorno tijelo za emitiranje sadržaja, dok u Belgiji (francusko govorno područje) ovlašteno tijelo mora odobriti punu dozvolu za rad. Takav pristup regulaciji nije u skladu s Direktivom o autorizaciji elektroničkih komunikacijskih mreža i usluga [6].
- Distribucija TV kanala koji već imaju dozvolu za emitiranje sadržaja (bilo da su dozvolu dobile po principu zemlje porijekla prema Direktivi za televiziju bez granica iz 1997. godine (engl. *Television Without Frontiers Directive*, TWF) u istoj ili u nekoj drugoj zemlji članici) [8]. Ova aktivnost ne zahtijeva obavijest ili dozvolu od

[1] Belgija, Danska, Francuska, Njemačka, Italija, Nizozemska, Španjolska, Švedska i Ujedinjeno Kraljevstvo

[2] Danska, Francuska, Italija, Nizozemska, Španjolska, Švedska i Ujedinjeno Kraljevstvo

regulatornog tijela za emitiranje sadržaja u šest zemalja[3]. U Belgiji (francusko govorno područje), Francuskoj i Španjolskoj (autonomnoj regiji Katalonija) mora se obavijestiti regulatorno tijelo o pružanju usluga IPTV-a. To bi se moglo smatrati protivnim Direktivi o televiziji bez granica iz 1997. godine koja navodi da zemlje članice ne mogu ograničiti ponovni prijenos emitiranog televizijskog sadržaja koji potječe iz drugih zemalja članica.

- Kada operator usluga IPTV-a premašuje jednostavnu distribuciju TV kanala koji već imaju dozvole i obavlja uredničku kontrolu nad sadržajem programa, onda je potrebna dozvola od strane regulatornog tijela za emitiranje sadržaja u svih devet zemalja. Međutim, iz nacionalnih zakona nije potpuno jasno što se smatra uredničkom kontrolom te kako se ona definira. Na primjer, može li se odabir kanala ponuđenih u različitim pretplatničkim paketima ili vremensko planiranje programa smatrati uredničkom kontrolom ili samo u slučajevima u kojima operatori IPTV usluga emitiraju vlastiti sadržaj, na primjer kanal za tele-kupovinu?
- Nadalje, u dvije zemlje sa strukturom federalne vlasti (Belgija i Njemačka) je odgovornost za emitiranje u regionalnoj nadležnosti te se ovlaštenja, odnosno dozvole za emitiranje izdaju na regionalnoj razini (iako je u Njemačkoj moguće da jedno regionalno ovlašteno tijelo za medije izdaje nacionalnu dozvolu za emitiranje). Isto se primjenjuje na autonomnu regiju Kataloniju u Španjolskoj.

Glavni operatori IPTV usluga su obično telekom operatori, ali i kabelski i satelitski operatori isto tako sve više počinju ulaziti na to tržište. Postoje dva tipa telekom operatora koji nude usluge IPTV-a: operatori sa značajnom tržišnom moći proizašli iz razdoblja monopola (engl. *incumbents*) i alternativni operatori. Prva kategorija uključuje operatore kao što su: Hrvatski Telekom (Hrvatska), France Telecom (Francuska), PCCW (Hong Kong), Telefónica (Španjolska) te AT&T i Verizon (SAD). Bivši monopolistički operatori nude usluge preko vlastitih ADSL (engl. *Asymetric Digital Subscriber Line*) ili svjetlovodnih pristupnih mreža. U alternativne operatore spadaju: OT-Optima Telekom (Hrvatska), Amis Telekom (Hrvatska), Iskon Interent (Hrvatska), Iliad (Francuska), Fastweb (Italija) i Hanaro (Južna Koreja). Ovi novi tržišni igrači su često uspješni u ponudi IPTV-a uz osnovnu ADSL pretplatu. IPTV usluga obično nudi od 40 do 300 TV kanala kao i VoD, HD i PVR usluge. Npr. u Hong Kongu IPTV usluga „Now" operatora PCCW je imala 560.000 pretplatnika u lipnju 2007. godine i obuhvaćala gotovo 40% od ukupnog broja televizijskih pretplatnika.

[3] Belgija (francusko govorno područje), Italija, Nizozemska, Švedska, Ujedinjeno Kraljevstvo i Danska

U 2010. godini oko polovica od 30 milijuna set-top-box uređaja (STB) korištenih u svijetu je bilo hibridno (usluga IPTV-a kombinirana s nekim oblikom digitalnog kabela, zemaljskog ili satelitskog pristupa). Nadalje, neki operatori pretplatničke televizije (TV kuće) koji su već prisutni na tržištu kombiniraju IPTV tehnologiju i usluge s njihovim postojećim paketima kanala kako bi ponudili poboljšanu funkcionalnost kao što je sadržaj na zahtjev. Npr. Premiere u Njemačkoj nuditi kombiniranu satelitsku i uslugu IPTV-a u partnerstvu s Deutsche Telekomom omogućujući pristup DT-ovoj IPTV ponudi i vlastitoj satelitskoj pretplatničkoj usluzi. Također, u Japanu je satelitski operator Sky PerfecTV razvio IPTV ponudu. U Ujedinjenom Kraljevstvu, operator British Telecom (BT) je lansirao kombiniranu IPTV/DTT uslugu (BT Vision) koja pruža tradicionalne kanale utemeljene na odašiljanju preko zemaljske digitalne televizije (engl. *Digital Terrestrial Television*, DTT) uz dodatni sadržaj preko IP mreže. Važno je naglasiti da je IPTV značajna usluga za oko 45 operatora usluge širokopojasnog pristupa Internetu širom svijeta.

Regulatori imaju različite pristupe licenciranju IPTV operatora. U mjeri u kojoj IPTV operator nudi televizijski program uživo, npr. može podlijegati istim uvjetima licenciranja koji su nametnuti televizijskim kućama. Europljani slijede tehnološki neutralan pristup koji smatra bilo koju televizijsku uslugu pruženu preko bilo koje platforme (kabelske, satelitskog Interneta, ADSL-a ili mobilne mreže) uslugom radiotelevizijskog emitiranja. Npr. u Francuskoj IPTV operator mora podnijeti izjavu Vijeću za audiovizualne medije (CSA), dok mali operatori s godišnjim proračunom manjim od 150.000 € ne moraju ispunjavati ovu obvezu [9]. Na sličan način Kanada zahtijeva da bilo koja televizijska usluga, uključujući VoD, koja se pruža preko kontrolirane IPTV mreže, ima dozvolu za distribuciju radiotelevizijskog programa. Međutim, u Europi se VoD ne smatra televizijskom uslugom zbog njezine interaktivnosti. Iz Tablice II. je vidljivo da pojedine zemlje EU-a imaju različite pristupe regulacije usluga IPTV-a.

TABLICA II.

IPTV REGULATORNI OKVIR - EU

	KOMERCIJALNO PRUŽANJE USLUGA IPTV-A	IPTV REGULATORNI OKVIR
Austrija	AonDigital TV (Telecom Austria)	IPTV se ne smatra emitiranjem TV programa
Belgija	Belgacom TV	Smatra se uslugom emitiranja TV signala
Danska	TDC TV (Telecom Denmark)	Nema regulatorni okvir za IPTV
Finska	TDC Song	IPTV ne spada pod broadcasting regulatorni okvir, nisu potrebne posebne dozvole za rad
Francuska	Ma ligne TV (France Telecom)	Smatra se oblikom broadcastinga
Njemačka	T-Online Vision (Deutsche Telekom)	Smatra se broadcasting uslugom i spada pod broadcasting regulatorni okvir

Irska	Smart Vision (Smart Telecom)	Nema regulatorni okvir za IPTV. Pruža se na temelju opće dozvole.
Italija	Fastweb (koristi mrežu od Telecom Italia)	Potrebna prijava Ministarstvu za elektroničke komunikacije
Španjolska	Imagenio (Telefónica)	Pružanje TV usluga i digitalnih audio usluga predmet su broadcasting regulacije te je potrebno ishoditi dozvolu za distribuciju istih.
Švedska	Bredbandsbolaget (Telenor)	Nije potrebna posebna dozvola za pružanje usluga IPTV-a
Velika Britanija	Homechoice (koristi mrežu BT-a)	Nema regulatornog okvira za IPTV. Homechoice posjeduje dozvolu za emitirnje sadržaja preko kabelske televizije i satelita

U zemljama kao što su Južna Koreja, Pakistan i Singapur, nadležna su tijela za regulaciju emitiranja televizijskog programa definirala nove dozvole za usluge IPTV-a. Prema južnokorejskom Zakonu o emitiranju internetskog multimedijskog sadržaja (engl. Internet Multimedia Broadcasting Business Act) [10] IPTV operatori moraju ishoditi dozvolu za emitiranje internetskog multimedijskog sadržaja od Ministarstva informacija i komunikacija. U Pakistanu IPTV operatori moraju ne samo ishoditi dozvolu za uslugu distribucije IPTV kanala od Regulatornog tijela za elektroničke medije kako bi pružali uslugu, već moraju isto tako imati i dozvolu za fiksnu lokalnu petlju za ista područja emitiranja. Tijekom 2007. godine je singapursko Regulatorno tijelo za razvoj medija (engl. Multan Development Authority, MDA) [11] razvilo okvir za tehnološki neutralno licenciranje kako bi olakšalo uvođenje novih medijskih usluga kao što je IPTV. Svim operatorima medijskih usluga koji nude IPTV usluge (ili bilo kakav oblik pretplatničkih televizijskih usluga) je sada potrebna dozvola od MDA. MDA definira IPTV kao prijenos televizijskog programa, bilo u obliku potpuno isplaniranih kanala ili VoD-a, do domaćinstava putem širokopojasne IP veze. Korištenje IPTV mreže operatori usluge mogu isto tako ponuditi bogatu interaktivnost i usluge kao što su televizijska trgovina, VoIP, video konferencije i igranje različitih zabavnih igara.

Nadalje, singapurski novi regulatorni okvir je primijenio ograničenja vlasništva prema Zakonu o emitiranju televizijskog programa na dozvole koje se izdaju operatorima na nacionalnoj razini s više od 100.000 pretplatnika, ali ne i na dozvole koje se izdaju operatorima određenog dijela tržišta s manje od 100.000 pretplatnika. Nedostatak ovog dvostupnog razlikovanja je u tome da kako operatori povećavaju pretplatničku bazu, mogu biti prisiljeni osloboditi se stranog vlasništva jer Zakon o emitiranju televizijskog programa zabranjuje stranom subjektu da drži više od 49% udjela u vlasništvu. MDA predlaže sličan dvostupni vlasnički pristup za operatore mobilne televizije.

Hong Kong nije uspostavio posebnu kategoriju dozvola za IPTV operatore. Umjesto toga regulira IPTV operatore na isti način kao i operatore pretplatničke televizije te zahtijeva od njih da ishode dozvolu za domaći pretplatnički televizijski program. Međutim, takve dozvole se jedino mogu ishoditi ako operator već posjeduje dozvolu za fiksnu mrežu, kao što je slučaj i u Pakistanu. Indijski regulator TRAI je preporučio da IPTV telekomunikacijski operatori budu regulirani pod uvjetima njihove telekomunikacijske dozvole, a da kabelski operatori budu regulirani pod uvjetima Zakona o regulaciji kabelske televizijske mreže iz 1995. godine [12]. TRAI je ukazao da IPTV usluge koje pružaju telekomunikacijski operatori nisu iste kao kabelska usluga. Ova procjena je bila utemeljena na tehničkim aspektima usluga i načina na koji je sadržaj isporučen korisniku (već odabrani kabelski kanali se isporučuju korisniku dok u slučaju IPTV kanala korisnik sam bira kanale koji će mu biti isporučeni). Zemlje u našem okruženju kao što su: Slovenija, Bosna i Hercegovina, Mađarska, Srbija i Crna gora, nemaju propisane regulatorne obveze za pružanje usluga IPTV-a, ali njihova regulatorna tijela prikupljaju podatke o broju korisnika usluga IPTV-a.

IV. REGULATORNA TIJELA NADLEŽNA ZA USLUGE IPTV-A

Neka nacionalna regulatorna tijela (engl. National Regulatory Authority, NRA) temelje svoje regulatorne klasifikacije usluga IPTV-a ovisno o razini interaktivnosti koje te usluge omogućuju. Na temelju toga, mnoge zemlje prave razliku između emitiranih i VoD elemenata IPTV-a. Npr. zemlje Europske unije (EU) i Novi Zeland prave razliku između prijenosa koji je linearan (emitiran prema rasporedu) ili nelinearan (sadržaj koji korisnik bira i gleda na zahtjev kada to želi). Linearno emitiranje općenito podliježe regulaciji emitiranja sadržaja. Nelinearni sadržaj može biti izuzet iz ovih propisa, kao što je slučaj u Novom Zelandu, ili podlijegati samo nekima od njih, kao što je to slučaj u EU-u.

Do 2009. godine je više od 150 zemalja osnovalo nezavisna regulatorna tijela za reguliranje tržišta elektroničkih komunikacija. Među njima je i nekoliko konvergiranih regulatora, kao što su oni u Australiji [13], Maleziji, Južnoj Africi, Singapuru, Sjedinjenih Američkim Državama i pojedinim zemljama članicama EU-a[4]. Konvergirani regulatori su ona državna tijela čija djelatnost obuhvaća regulaciju elektroničke komunikacijske mrežne infrastrukture i audiovizualnog sadržaja koji se prenosi preko te infrastrukture. IPTV je proizvod konvergencije medijskih usluga. U Hrvatskoj je osnovano tijelo koje bavi reguliranjem tržišta elektroničkih komunikacijskih i poštanskih usluga (HAKOM), dok se regulacijom audio i audiovizualnih medijskih usluga te usluga elektroničkih publikacija putem elektroničkih komunikacijskih mreža bavi Agencija za elektroničke medije (AEM). Gotovo je 30

[4] Finska, Italija i Ujedinjeno Kraljevstvo

konvergiranih regulatornih agencija počelo s radom zadnjih sedam godina. Razlog za ovaj ubrzavajući trend je u činjenici da je konvergirani regulator bolje osposobljen za reagiranje na okruženje gdje se gube razlike između usluga i mrežne platforme. Konvergirani regulator osniva jedinstveno vladino tijelo koje će nadzirati sva pitanja koja uključuju komunikacijski sektor. Usprkos ovom trendu, većina zemalja članica Organizacije za ekonomsku suradnju i razvoj (engl. *Organisation for Economic Co-operation and Development*, OECD) još uvijek imaju odvojene regulatore za radiotelevizijsko emitiranje (engl. *broadcasting*) i za elektroničke komunikacije. Nadalje, regulacijom sadržaja se obično bavi odvojeno ministarstvo ili vladino tijelo (kao što je to slučaj u Indiji i Saudijskoj Arabiji) ili tijelo koje je zaduženo za regulaciju radiotelevizijskog emitiranja (Bocvana, Čile i Kolumbija). U Indiji postoje dva tijela odgovorna za regulaciju sadržaja. Ministarstvo informacija i radiotelevizijskog emitiranja (engl. Ministry of Information & Broadcasting) [14], nadzire sadržaj vezan uz radiotelevizijsko emitiranje i film, dok Ministarstvo komunikacija i informacijskih tehnologija (engl. Ministry of Communications & Information Technology) [15] regulira sadržaj vezan uz Internet. Mnoge zemlje zadržavaju brojna vladina tijela odgovorna za funkcije licenciranja radiotelevizijskog emitiranja, licenciranja elektroničkih komunikacija, dodjeljivanje radiofrekvencijskog spektra i regulaciju sadržaja.

Regulatori su često uključeni u rasprave o nadležnostima vezane uz to gdje njihova ovlast počinje, a gdje završava ovlast druge agencije (regulatornog tijela). Zajednički rezultat birokratske unutarnje borbe je da telekom operatori ne mogu dobiti ovlaštenja za pružanje usluga IPTV-a dok njihovi rivali, kabelski operatori, slobodno mogu početi nuditi usluge.

V. ZAKLJUČAK

Regulacija audiovizualnih medijskih usluga treba djelovati neovisno o distribucijskoj platformi. Ključni elementi koji bi se trebali uzeti u obzir u definiranju usluga IPTV-a su:

- jasna definicija audiovizualne usluge i operatora (davatelja) audiovizualne medijske usluge zajedno s njihovim odgovornostima i obvezama,
- mehanizmi za nepristrano upravljanje natjecanjem unutar audiovizualnog tržišta (alati koji osiguravaju učinkovitost skupljanja programskog sadržaja prema distribucijskom tržištu),
- reforme autorskih prava koje bi trebale otvoriti prepreke prema višeplatformskoj politici te digitalnoj distribuciji u bilo koje vrijeme i bilo gdje.

IPTV će biti jedna od niza usluga koje će biti važan čimbenik na tržištima elektroničkih komunikacija. Primjena IPTV-a mijenja tradicionalno viđenje i predstavlja izazov za postojeće zakone i propise. IPTV nudi ogromne prilike da se korisnicima ponude nove platforme za višemedijski sadržaj, poticanje konkurencije te povećanje primjene širokopojasnog pristupa. Prema Pravilniku o načinu i uvjetima obavljanja djelatnosti elektroničkih komunikacijskih usluga [7] u Hrvatskoj IPTV nije zasebna usluga već je, kao i usluga kabelske distribucije sastavni dio usluge prijenosa slike, govora i zvuka putem elektroničkih komunikacijskih mreža (što isključuje usluge radiodifuzije). Ako se uzme u obzir da je broj korisnika IPTV-a u Hrvatskoj tri puta veći od broja korisnika kabelske televizije, dolazi se do zaključka da IPTV postaje jedna od najbrže rastućih usluga u području elektroničkih komunikacija u Hrvatskoj [16]. Stoga bi je trebalo promatrati kao zasebnu uslugu i primjenjivati određena regulatorna pravila, kako na sadržaj, tako i na platforme preko kojih se pružaju usluge IPTV-a.

An approach to estimate correlation between QoS and perceptual video quality in packet-switched networks

Abstract - Traditional QoS parameters estimated at network level are not suitable for describing quality of service perceived by the end user, but user experience can be described by QoE (Quality of Experience). QoS at user level is perceptual and subjective parameter, but there are recommendations which formalize procedures for testing perceptual quality. There are subjective and objective video quality assessment methods which are used for estimating video quality.

This paper proposes a model for estimating the impact of QoS parameters on the perceptual quality of video signals. The proposed model assumes use of layered QoS model. QoS parameters of MPEG-4 video transmission in various network configurations were analyzed and by comparing estimated QoS parameters to perceived video quality a conclusion was made how some of the QoS parameters impact perceptual quality of video signals.

EvalVid integrated into NS-2 simulator was used for estimating QoS parameters. SSIM index was used as objective video quality metric, which has been calculated using MSU VQMT tool.

I. INTRODUCTION

The ability to measure QoS in video communication is becoming increasingly important due to the growing interest in delivering video content over unreliable channels, such as wireless networks and the Internet. A network that can provide QoS for video and audio streams is the key to success of new multimedia applications, particularly video applications. At the network level, QoS is evaluated by monitoring network performance parameters such as delay, jitter and packet loss.

User satisfaction has become one of the most important goals of service providers. QoS parameters such as delay, bandwidth, jitter and packet losses tell us much about the network that provides data transfer services, but do not provide information about the quality of end-user experiences. From the standpoint of users, the overall service quality is that what counts. Quality of service at the user level is perceptual and subjective parameter, and there is no exact gradation of QoS at this level because it is a subjective experience of the user.

There are two categories of video quality assessment methods: subjective and objective. Subjective methods require human subjects who evaluate, compare or adjust quality of tested image. Subjective testing for visual quality assessment has been formalized in ITU-R Rec. BT.500-11 (2002) and ITU-T Rec. P.910 (1999), which suggest standard viewing conditions, criteria for the selection of observers and test material, assessment procedures, and data analysis methods [1]. Most famous qualitative subjective metric is MOS (Mean Opinion Score). MOS provides a measure of the perceived quality of the end user, and is evaluated by using subjective tests with human subjects, and thereby gaining a quantitative indicator of system performance of multimedia transfer. In the case of video transmission assessment, individuals evaluate the perceived quality of video test signals after they are sent over a real or simulated network by rating on a score from 1 (poor) to 5 (excellent). MOS score is the mean individual score. However, the process of obtaining a MOS score is expensive, time-consuming, and cannot be automatically implemented into a practical video processing system [2].

Objective assessment techniques represent an alternative to subjective techniques by avoiding human intervention in assessing the quality of video transmission, and enable automatic estimation of video transmission quality. Objective assessment refers to methods that assess video quality by taking measurements from the electrical video signal [3]. An example of objective measurement in the evaluation of video transmission is the PSNR (Peak Signal-to-Noise Ratio). PSNR measures the error between the reconstructed and original images. The lack of these so-called "pixel-by-pixel" based methods for assessing the video quality is that they do not take into account the characteristics of the human visual system, the impact of video content and viewing conditions, and for these reasons their predictions often do not coincide with the actual perceptual quality. Metrics that take into account the characteristics of the human visual system provide better correlation with MOS.

If it would be possible to calculate the MOS based on network QoS parameters, the necessity of performing the previously described testing procedures could be avoided,

and thus time and financial savings could be achieved. In addition, knowing the exact impact of individual QoS parameters on the perceptual quality and determining the factors that degrade the video quality would enable optimization of the QoE using a network that minimizes the impact of the identified factors.

II. EVALUATING IMPACT OF QOS ON PERCEPTUAL VIDEO QUALITY

A. Proposed model

When talking about networked multimedia systems, the traditional QoS concept must be further extended because many services besides network and transport services contribute to end-to-end quality behavior. This paper will assume that a networked multimedia system and QoS models comply with a layered architecture, as proposed in [4].

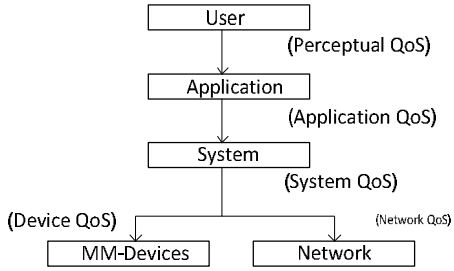

Figure 1: Example of layered QoS architecture [4]

For MPEG video stream, application QoS parameters could be sample size of I/P/B frames, sample rate, number of frames per GOP, etc. Examples of system QoS parameters are packet size and packet rate. Process of deriving QoS parameters from one layer to another is called translation. The idea of this paper is to measure packet loss rate and packet jitter, and translate these QoS parameters to QoS of application level, e.g. frame loss rate and frame jitter.

This paper proposes a model of evaluating the impact of QoS parameters on perceptual video quality by measuring system QoS, translating them into application QoS, and analyzing the resulting video quality in different network conditions.

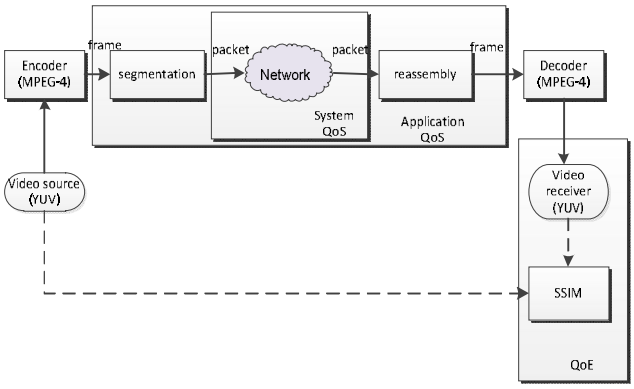

Figure 2: Proposed model of evaluating impact of QoS on perceptual video quality

The video source is a source of raw video signal. The raw video signal is a series of images, called frames, where each image consists of a number of picture elements, so-called pixels.

The encoder performs compression of the raw video signals. In this paper, MPEG-4 encoder is used. Output from the encoder are frames, which can be I, P or B type. Frame size is a unit of application QoS layer. Frame size usually exceeds the size of the network MTU (Maximum Transmission Unit), so segmentation into packets must be done.

The network can be a real or simulated. Limitations of the network may cause "damage" of video stream, in particular due to delay and packet losses. The network must be configurable in order to simulate various cases of network conditions. The model will enable estimation of packet loss, packet delay and jitter.

Received packets must be reassembled into frames. Frame loss, frame delay and frame jitter are calculated using estimated packet loss, packet delay and packet jitter.

The decoder performs decoding of the received MPEG-4 signals.

Video receiver will display reconstructed video signal. Every lost frame is replaced by the last correctly decoded frame. This stage enables evaluation of signal quality in a way the user experience the video. In this paper, SSIM method will be used for assessing quality. The Structural SIMilarity (SSIM) index is a method for measuring the similarity between two images. The SSIM metric is calculated on various windows of an image. The measure between two windows x and y of common size $N \times N$ is:

$$SSIM = \frac{(2\bar{x}\bar{y} + C_1)(2\sigma_{xy} + C_2)}{\left[(\bar{x})^2 + (\bar{y})^2 + C_1\right](\sigma_x^2 + \sigma_y^2 + C_2)} \quad (1)$$

$\bar{x}, \bar{y}, \sigma_x^{\,2}, \sigma_y^{\,2}, \sigma_{xy}$ are the means of x, y, the variance of x, y, and the covariance between x and y, respectively, computed using a sliding window approach. C_1 and C_2 are constants [5]. SSIM metric has shown higher correlation to MOS then pixel-based metrics [6]. Another advantage of SSIM metrics is its availability. A MatLab implementation of SSIM metrics is free available online. There are also implementation for other programming languages such as C + + and Java, and they can be used free of charge.

B. Test environment

In order to analyze impact of QoS on perceptual video quality, a MPEG-4 coded video signal was sent over a network in different network conditions. Network was simulated using network simulator NS-2 [7]. An open source tool – Evalvid was integrated into NS-2 in order to evaluate QoS parameters [8]. MSU VQMT (MSU Video

Quality Measurement Tool) was used to calculate SSIM index for received videos.
MSU VQMT is a tool used for objective video quality assessment which supports about 20 video quality metrics and various video codec. There is a free version available on [9].

Table 1: Frame statistic for test signal "foreman qcif.yuv"

FRAME TYPE	NUMBER OF FRAMES	MIN. FRAME SIZE	MAX. FRAME SIZE	MEAN FRAME SIZE	PACKETS PER FRAME (MTU=1000B)
I	45	1725B	4049B	3437,03B	2-5
P	89	669B	1713B	803.82B	1-2
B	266	35B	982B	363,32B	1
TOTAL	**400**	**35B**	**4049B**	**825.8B**	

A QCIF video signal (foreman qcif.yuv) is used as a test video signal. The frame rate is 30fps. MPEG-4 encoding of the raw video generates a video signal of 400 frames with following GOP pattern: IBBPBBPBBI.

Testing was done for a point-to-point network without background traffic, but also for a more realistic scenario, i.e. point-to-multipoint network with additional traffic sources. The bottleneck bandwidth is in both cases configurable. Following cases are simulated for each network:
1) All routers use Drop Tail queue management mechanism
2) Edge routers use Drop Tail mechanism, while core routers use RED (Random Early Detection) queue management mechanism.
3) Categorization of traffic is done by assigning traffic priorities. Packets transferring I frames data are assigned the highest priority because it is assumed that I frame losses have the greatest impact on the quality of the video signal. Packets transferring P frames are assigned medium priority, and packets transferring B frames are assigned lowest priority

A Java GUI application was developed for testing purpose. The developed Java application enables user to intuitively configure network parameters, automatically start simulations, and store the evaluated QoS parameters into MySQL database.

For each of the scenarios and for each combination of network parameters a received video signal was created. Using MSU VQMT tool SSIM index was calculated for each received video and compared to evaluated QoS parameters.

C. Point-to-point network configuration

Following scenarios were tested:
• pp - Drop Tail / FIFO mechanism: buffer size = 12
• ppRED - RED queue management mechanism
• ppDiff - Categorization of packets by assigning priority

Figure 3 and Figure 4 show that higher packet loss does not necessarily mean a poorer quality of video signals. Test "ppDiff" had the largest packet loss, but also gave the highest SSIM. Only few packets that carry I frame data were lost in the test "ppDiff", but there was a large number of lost B frames. I frames are independently coded frames and B frames are obtained based on the I and P frames within the GOP, so B frames without the corresponding I and P frames become unusable even if they are received intact and on time. RED mechanism gave similar results to Drop Tail mechanism. Jerkiness is evident in "ppDiff" received videos, due to the large number of lost B packets. Blocking effect and very disturbing image distortion are evident in "pp" and "ppRED" received videos for bottleneck bandwidths below 0.2 Mbps.

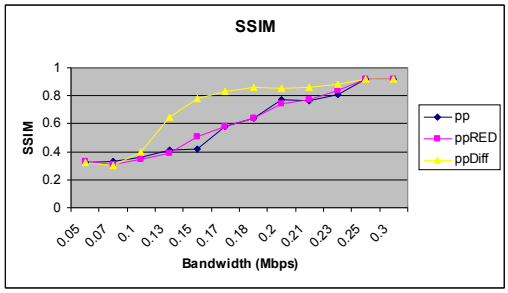

Figure 3: SSIM index for various network configurations (pp, ppRED, ppDiff)

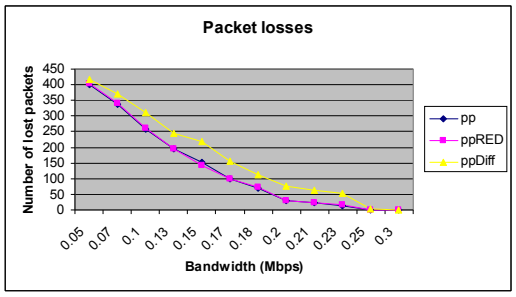

Figure 4: Packet losses for various network configurations (pp, ppRED, ppDiff)

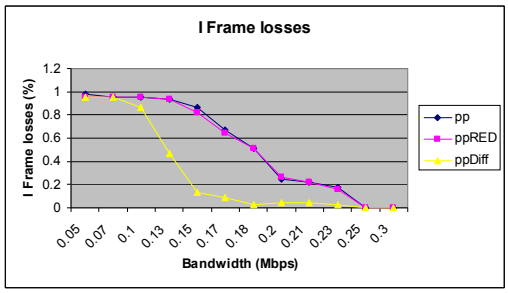

Figure 5: I frame losses (pp, ppRED, ppDiff)

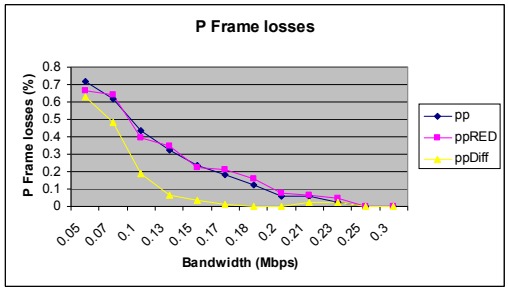

Figure 6: P frame losses (pp, ppRED, ppDiff)

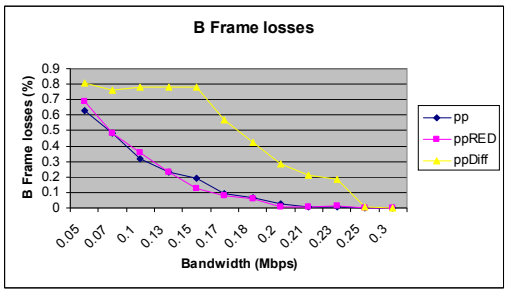

Figure 7: B frame losses (pp, ppRED, ppDiff)

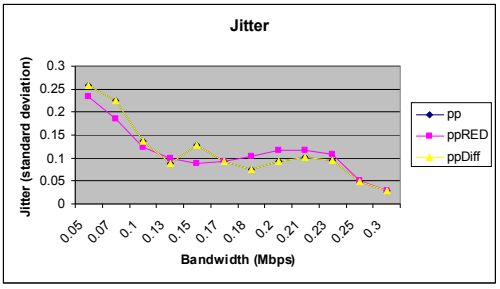

Figure 8: Frame jitter (pp, ppRED, ppDiff)

D. Point-to-multipoint network configuration

Three traffic sources are connected to router 3: FTP traffic source, CBR traffic source and video source. All nodes are connected by 1.5 Mbps links and a latency of 10ms, but the link between router 3 and router 4 is configurable. Testing was done by changing the bandwidth between router 3 and router 4. Simulation is done for following bottleneck bandwidths: 0.2 Mbps, 0.5 Mbps, 0.8 Mbps, 1 Mbps, 1.2 Mbps, 1.5 Mbps, 2 Mbps, 3 Mbps, 5 Mbps, 10 Mbps, 20 Mbps and 30 Mbps.

Following scenarios were simulated:
- mp - Drop Tail / FIFO mechanism: buffer size = 12
- mpRED - RED queue management mechanism,
- mpDiff - Categorization of packets by assigning priorities. Other sources of traffic in the network receive a medium priority, i.e., as P packets.

Video traffic is transmitted to video receivers as multicast traffic.

Figure 10 and Figure 11 show that test "mpDiff" had the highest packet loss, but also gave the best results in case of larger network load, i.e. the bottleneck bandwidth up to 1.2 Mbps. The loss of packages at higher bandwidths was reduced to a minimum for all three tests so that the signal quality was almost equal for all of them. Jerkiness is evident in "mpQoS" received videos, due to the large number of lost B frames.

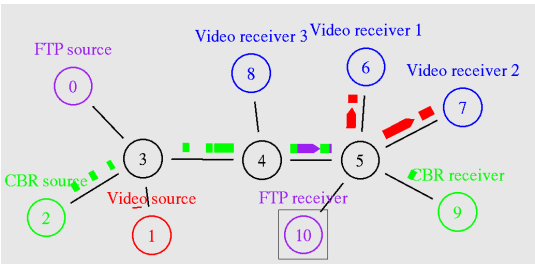

Figure 9: Point-to-multipoint scenario network configuration

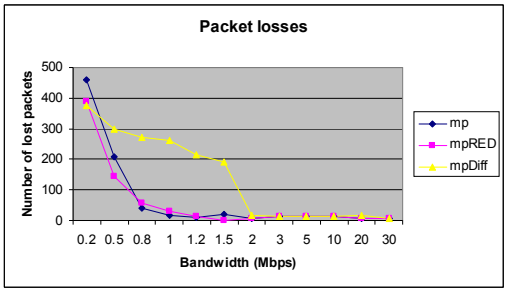

Figure 10: Packet losses for various network configurations (mp, mpRED, mpDiff)

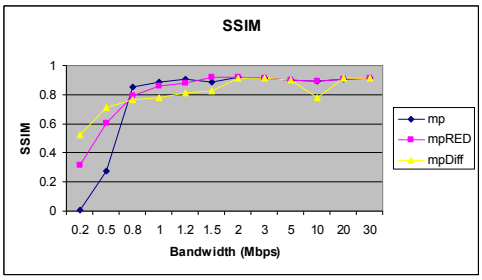

Figure 11: SSIM index for various network configurations (mp, mpRED, mpDiff)

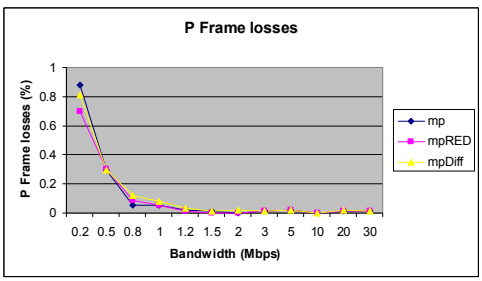

Figure 13: P frame losses (mp, mpRED, mpDiff)

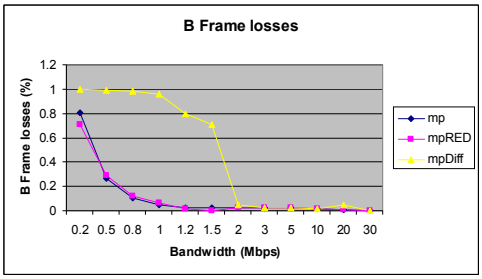

Figure 14: B frame losses (mp, mpRED, mpDiff)

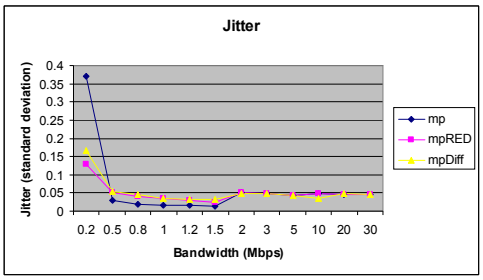

Figure 15: Frame jitter (mp, mpRED, mpDiff)

E. Network configuration with four core routers and three edge routers

There are 7 routers in the network: 4 core routers and 3 edge routers. Router 3, 8 and 9 represent the edge routers (see Figure 16). Router 4, 5, 6 and 7 are the core routers. Three traffic sources are connected to router 3: FTP traffic source, CBR traffic source and video source. All traffic sources and receivers are connected to edge routers by 10Mbps links with a delay of 5ms. Core routers are interconnected by 2Mbps links with a delay of 5ms.

Following scenarios were tested:

- mpCore - All routers in the network are using Drop Tail/FIFO queue management mechanism (buffer size = 12)
- mpCoreRED - Core routers use RED queue management mechanism and edge routers use Drop Tail mechanism (buffer size = 12)
- mpCoreDiff - Categorization of packets by assigning priorities (buffer size = 12) is used

Video traffic is transmitted to video receivers as multicast traffic. Video receivers send requests to join the multicast group 0.2s after the beginning of the simulation. To exclude the possibility that the "mpCoreDiff" test achieves quality improvement at the expense of background traffic, FTP and CBR sources are assigned the highest priority, i.e. the same priority as I frames.

In terms of SSIM, the "mpDiff" test gave the best results, and "mpCore" test the worst. SSIM graph (Figure 17) shows periodic peaks for tests "mpCore" and "mpDifff", especially for "mpDiff".

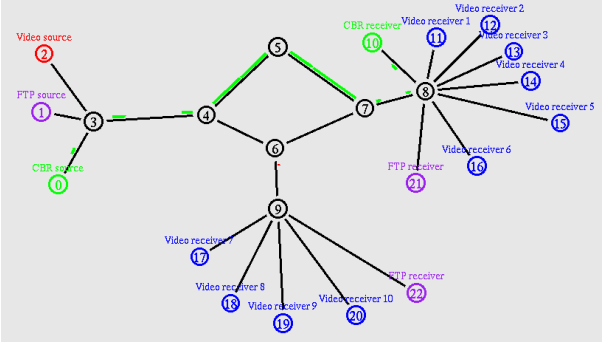

Figure 16: Network configuration with four core routers and three edge routers

Table 2: Number of lost frames by type

FRAME TYPE	NUMBER OF FRAMES SENT	NUMBER OF FRAMES LOST		
		mpCore	mpCoreRED	mpCoreDiff
I	45	44	29	16
P	89	27	19	82
B	266	132	64	260
TOTAL	400	203	112	358

Table 3: SSIM index (mean, min, max)

	mpCore	mpCoreRED	mpCoreDiff
Mean SSIM	0.32637	0.53011	0.55024
Min. SSIM	0.11323	0.19886	0.22946
Max SSIM	0.93599	0.93617	0.95468

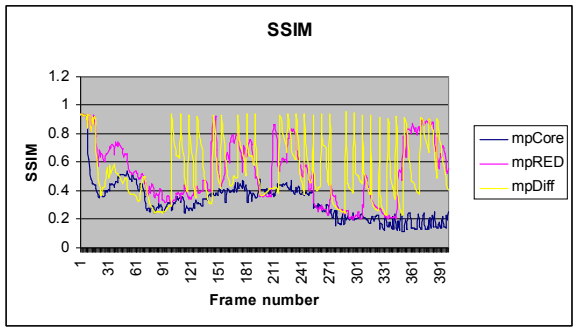

Figure 17: Comparison of SSIM index for mp, mpRED and mpDiff

Distance between peaks in SSIM graph for "mpCoreDiff" is 9 frames which can be explained by analyzing video trace file and taking into account the GOP pattern of the observed video signal, and the fact that every lost frame is replaced by the last correctly decoded frame. Namely, only few I frames were lost in "mpCoreDiff" test, and that caused a high SSIM index. However, "mpCoreDiff" had a large loss of B and P frames. Many B and P frames that come after the I frames are lost, so the quality decreases, as each succeeding frame is more different from the previous I frame which was used for encoding. There are peaks on the graph for every received I frame. Distance between peaks is minimal 9 frames, because the distance between I frames in GOP patterns is 9 frames. Looking at the graph that compares the behavior of SSIM for all three tests, we see that the lowest values of SSIM index for "mpCoreDiff" test have similar values as SSIM index of "mpCore". However, "mpCore" has no possibility to restore the video quality, because a large number of lost I frames disables the decoding of a large number of P and B frames, even if those frames are received correctly and in time. RED mechanism had fewer losses for all types of frames due to more efficient queue management than Drop Tail mechanism, thus achieving better SSIM index.

III. CONLUSION

Evaluating QoS parameters like packet loss is not sufficient to make conclusions about the perceptual quality of video. Minimizing packet loss does not always lead to better video quality. In order to make predictions

about the perceptual video quality, knowledge about video codec and GOP pattern is needed. In order to evaluate the impact of QoS on perceptual video quality, frame loss must be calculated based on packet loss. There is a strong correlation between video quality and number of lost I frames.

***Sažetak* – Radio frekventni spektar sve brže postaje najvredniji prirodni resurs na planeti. Povećan interes za razvoj bežičnih komunikacijskih tehnologija zahtijeva pronalaženje načina za dinamičniji i efikasniji pristup spektru. Tehnologija koja se nameće kao rješenje za takav izazov je kognitivni radio (CR - Cognitive Radio) koji predstavlja pravu revoluciju u bežičnoj komunikaciji sa značajnim uticajem na razvoj buduće tehnologije pružanja usluga korisnicima. CR sistem koristi informacije o zauzetosti spektra kako bi prilagodio svoje emisione parametre kao što su frekvencija, predajna snaga i dr. On je dizajniran da osigura efikasno korištenje i veću fleksibilnost u korištenju dijelova spektra koji su neiskorišteni od strane trenutnog (primarnog) korisnika bez štetne smetnje. Ova tehnologija stvara izazove ne samo učesnicima na telekomunikacijskom tržištu već predstavlja jedan od ključnih elemenata u budućem sistemu upravljanja radiofrekvencijskim spektrom. Za primjenu CR tehnologije neophodna je koegzistencija između različitih službi u istom frekvencijskom opsegu gdje se podrazumijeva i njihovo istovremeno korištenje bez obzira na njihov regulatorni status (primarni, sekundarni).**

I. UVOD

Temeljem osnovnog ekonomskog zakona ponude i potražnje, stalni rast zahtjeva za korištenjem ograničenog resursa radiofrekvencijskog spektra, dovodi do porasta njegove vrijednosti. Kako se spektar kontinurano i sa sve većom dinamikom dodijeljuje korisnicima to se više dolazi do zagušenja određenih opsega. Zbog toga nove aplikacije sve teže nalaze svoje mjesto u spektru. Ključna stvar koja se u takvom okruženju nameće je povećanje efikasnosti korištenja pomoću različitih tehnologija i metoda. Ovakav trend predstavlja veliki izazov za regulatora koji treba naći prostor za razvoj novih usluga uz zaštitu postojećih korisnika i javnog interesa. Potrebno je naći mjeru između tržišno orijentirane regulacije i one koja štiti javni interes. Zbog sve veće vrijednosti spektra, regulacija se provodi sve češće prema tržišnim principima.

II. OPĆE KARAKTERISTIKE KOGNITIVNIH SISTEMA

Radiofrekvencijski spektar predstavlja okruženje u kome se vrše stalne analize i istraživanja kako bi se došlo do metoda koje će poboljšati iskorištenost frekvencijskih opsega i time otvoriti mogućnost za dalji razvoj ove vrste komunikacija, razmatrajući različite modalitete od pojednostavljivanja administrativnih procedura do tehničkih i tehnoloških unapređenja sistema kojim bi se osiguralo efikasnije korištenje raspoloživih resursa. S tim ciljem javljaju se nove tehnologije koje su u mnogome adaptivnije od postojećih sistema. One sadrže odgovarajuće komponente koje ih čine „pametnim“ i omogućavaju im korištenje spektra na mnogo elastičniji, efikasniji način koji je prilagodljiv uvjetima u praksi. Novi radio sistemi zahtijevaju inteligentne mogućnosti za podršku distribuiranom kvalitetu servisa kada dijele spektar sa sličnim radio sistemima koji nemaju mogućnost koegzistencije. Jedna od takvih novorazvijenih tehnologija je kognitivni radio (CR - Cognitive Radio).

Osnovne karakteristike CR-a su [2]:

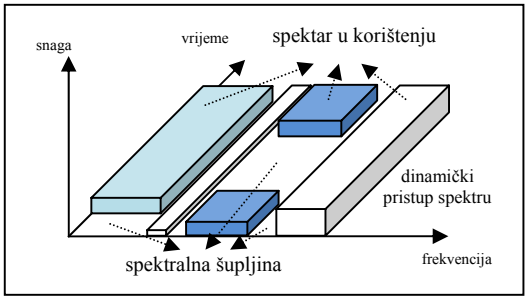
1. fleksibilnost,
2. agilnost,
3. RF senzitivnost,
4. umrežavanje.

Fleksibilnost je sposobnost promjene valnog oblika i konfiguracije uređaja. Primjer je stanica na tornju koji se koristi za ćelijsko pokrivanje u određenom opsegu za pružanje govornih usluga, ali izmjenom valnog oblika može primiti telemetrijske podatke od automata za prodaju, u periodu slabog korištenja bazne stanice, ili druge jednako korisne informacije. Što znači, isti opseg se koristi za dvije vrlo različite uloge sa različitim prenosnim karakteristikama kao što je brzina prijenosa podataka, kašnjenje, prioritet i sl.

Agilnost je sposobnost promjene opsega u kojem će uređaj raditi. Ćelijski telefoni imaju agilnost, jer mogu raditi na dva ili više opsega (npr. 900 i 1800 MHz). Kombiniranje agilnosti i fleksibilnosti daje "adaptivni" radio, jer radio može koristiti različite valne oblike u različitim opsezima.

RF senzitivnost je sposobnost promatranja stanja sistema, koja uključuje radio karakteristike i što je još važnije, okolinu. To je sljedeća logična komponenta u omogućavanju dinamike CR-a. Senzitivnost omogućuje radio uređaju samosvjesnost i na taj način može da procjenjuje svoj utjecaj na okolinu.

Umrežavanje je sposobnost komuniciranja između više čvorova i na taj način se olakšava rad kombinirajući očitavanje i kontrolu kapaciteta tih čvorova.



Slika 1. Spektralna šupljina

Ova tehnologija koristi za svoj rad tzv. šupljine u spektru (*spectrum hole*) prikazane na Slici 1., odnosno dijelove spektra dodijeljene primarno korisniku koji ga u datom momentu na određenoj geografskoj lokaciji ne koristi. Ovakav pristup spektru se naziva i prilagođeni pristup spektru (*OSA – Opportunistic Spectrum Access*). On ima i dodatnu kompleksnost slušanja drugih predajnika kako bi napustio „spektralnu šupljinu“ kada primarni korisnik pristupa spektru [5].

III. DIJELJENJE SPEKTRA

Veliki broj usluga uvjetuje nagli rast potrebe za korištenjem spektra tako da imamo opsege koji su iskorišteni u velikom procentu. Najviše opterećeni opsezi su oni u kojima se nalaze usluge koje zahtijevaju veliku širinu opsega za svoj rad, kao npr. širokopojasne veze točka - točka i točka - više točaka i sl. U cilju prevazilaženja prevelike zauzetosti, vrši se uspostavljanje sistema upravljanja spektrom koristeći nove metode i modele kao što su: refarming, koegzistencija službi i usluga, fleksibilno korištenje i harmonizacija. Za kognitivne radio sisteme najznačajniji je model fleksibilnosti što u stvari predstavlja sposobnost da se podrži modifikacija ili da se prilagodi novouspostavljenom sistemu.

Do sad se uvijek govorilo o zauzetom i slobodnom opsegu radio frekvencija. Zbog sve veće iskorištenosti ovog prirodnog ograničenog resursa potrebno je prihvatiti novu filozofiju koju pruža kognitivni radio. Dakle, ovdje se radi samo o zauzetom opsegu i to o stepenu njegove zauzetosti: potpuna, djelimična i slaba zauzetost opsega (crni, sivi i bijeli opseg).

Kanali u kojima je kontinuirano prisutan signal velike snage su potpuno zauzeti (crni), oni kanali kod kojih je snaga uređaja primarnih korisnika niža ili su periodično aktivni su djelimično zauzeti (sivi), a najpogodniji za primjenu kognitivnih radio sistema su kanali slabe zauzetosti (bijeli). To su kanali u kojima ne postoje drugi interferirajući signali. Prvobitni koncept razvoja kognitivnih sistema bilo je korištenje samo tzv. bijelih kanala, međutim u zadnje vrijeme se razmatraju i korištenja sivih kanala [3].

IV. KOGNITIVNI PRISTUP SPEKTRU

Temeljno polazište u upravljanju radio frekvencijskim spektrom je da nacionalni regulator u svakoj zemlji treba odlučiti tko ima pravo pristupa radio spektru. Regulator omogućava pristup bilo izdavanjem dozvola ili izuzimanjem pojedinih uređaja iz procesa licencenciranja. Stoga, kognitivni pristup u komercijalnom dijelu spektra bi se općenito mogao tumačiti kao protuzakonit, dok regulator ne propiše, kroz niz parametara, uvjete pod kojima se ta vrsta tehnologije može koristiti.

Regulator može usvojiti različite modele kognitivnog pristupa spektru uključujući [3]:

- Omogućavanje postojećim nosiocima dozvola da mogu dozvoliti kognitivni pristup u svom dijelu opsega, ako oni to žele;
- Licenciranje kognitivnih sistema u određenim opsezima;
- Izuzimanje kognitivne opreme iz procesa licenciranja sa odgovarajućim ograničenjima o tome kada, gdje i u kojem režimu da rade;
- Zabrana korištenja (kosi se sa načelima efikasnog korištenja spektra).

Odabir načina pristupa će izvršiti svaki regulator pojedinačno i on u određenoj mjeri ovisi o samoj politici upravljanja radio spektrom kao i u nekim slučajevima od zakonskih prava postojećih vlasnika. Obzirom da se radi o veoma osjetljivom području potrebno je pažljivo proučiti sve aspekte i eventualne efekte koje može prouzrokaovati ovakva regulacija, pa tek onda poduzeti odgovarajuće prikladne mjere. Postoje različita mišljenja u vezi s vlasništvom nad spektrom. Jedni su mišljenja, da obzirom da je spektar vlasništvo države, regulator ima pravo omogućiti korištenje dodatnim korisnicima opsega koji su već licencirani za određenog operatora. Drugi su mišljenja da se mora uzeti u obzir, da kupovinom odgovarajuće regionalne ili nacionalne dozvole operator ima potpuna prava na iskorištavanje tog spektra, uključujući i ograničavanje pristupa kognitivnim korisnicima ako to primarni korisnik želi.

Regulator koji implemantira sistem upravljanja radio spektrom s tzv. "punim imovinskim pravima nad spektrom" će omogućiti nosiocu dozvole da iznajmljuje svoje "viškove" spektra sistemima s kognitivnim načinom pristupa. Onaj tko preferira model tzv. "državnog prava" će omogućiti pristup spektru kroz licencirani ili nelicencirani režim rada.

Konačna odluka za regulatora, koji je odlučio dopustiti kognitivni pristup, treba definirati izdaje li dozvole za pristup ili ne. Većina zagovornika kognitivnog pristupa su mišljenja da dozvolu nije potrebno izdavati, već da korisnici mogu kupiti uređaj i odmah pristupiti korištenju spektra. Alternativa ovome bi mogla biti u izdavanju dozvole za organizaciju, nekom od dostupnih modela dodjele, koja bi imala prava na korištenje kognitivnog pristupa u određenom opsegu.

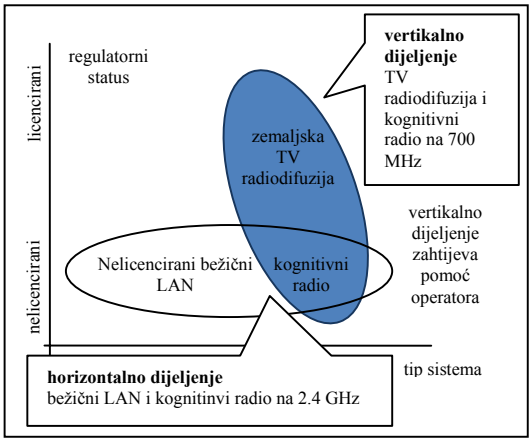
Licencirani pristup spektru pruža mogućnosti prije svega izgradnje infrastrukture, kao što su mobilne mreže, a nelicencirani model pristupa više potiče ideju razvoja kognitivnih uređaja kratkog dometa. U idealnom slučaju, regulator treba odabrati pristup koji maksimizira vrijednost za zemlju. U ovoj ranoj fazi razvoja kognitivnog pristupa, to je još poprilično nejasno koji je model najprikladniji.

Ako regulator odluči dopustiti kognitivni pristup u određenom opsegu, npr. TV opseg, mora prije svega definirati pravila ulaska. Obično će ta pravila sadržavati parametre koji osiguravaju vrlo nisku vjerojatnošću smetnje trenutnim korisnicima datog RF opsega, i u isto vrijeme postavljanje što manje ograničenja kognitivnim sistemima. Regulator se također treba fokusirati na mogućnost pojave smetnji između kognitivnih uređaja kako njihovo korištenje bude raslo. Izbjegavanje smetnji je općenito vrlo težak tehnički problem. Na primjer, kognitivni uređaji su bazirani na tehnologiji očitavanja odnosno mjerenja postojećeg signala, kako bi se utvrdilo je li određeni kanal trenutno u upotrebi. Regulator mora utvrditi i propisati nivo signala koji uređaj mora biti u stanju osjetiti kako bi se osigurala vrlo niska vjerojatnoća smetnje. Kao što je iskustvo pokazalo, takvo određivanje nivoa signala je vrlo kompleksno i uključuje mnoge probleme procesuiranja signala pri određivanju snage uređaja, širine opsega, kontrole, itd.

Ovakav pristup korištenja spektra tj. njegova dinamička dodjela u kognitivnim radio sistemima postavlja pred regulatore veoma zahtjevan zadatak. Potrebno je formirati odgovarajući regulatorni okvir koji bi bez dodatnih administrativnih barijera potpomogao rad i razvoj ove nove tehnologije.

Da bi se koristila CR tehnologija odnosno shvatila problematika vezana za uvođenje ovih sistema mora se napraviti razlika između dva osnovna oblika koegzistencije između različitih službi i usluga u istom opsegu [1]:

- *Vertikalna podjela*: resursi se dijele po primjeni s različitim regulatornim statusom (primarna ili sekundarna namjena jednom servisu ili različitim servisima). Npr. pravljenje programa za specijalne događaje (PMSE – Programme Making and Special Events) aplikacije koje imaju manji prioritet mogu koristiti CR tehnologiju kako bi izbjegli interferenciju s drugim aplikacijama koje su već aktivne u opsegu kao što je radiodifuzija;
- *Horizontalna podjela*: Dijeljenje službi po aplikacijama s istim regulatornim statusom (obje aplikacije primarna ili sekundarna). U ovom slučaju oba servisa mogu koristiti CR tehnologiju, npr. ćelijski sistemi.



Slika 2. Vertikalni i horizontalni način dijeljenja službi/usluga

Oblik dijeljenja vertikalni ili horizontalni (Slika 2.) opisuje odnos između dvije službe od kojih svaka može biti primarna ili sekundarna. To formalno proizvodi osam potencijalnih kombinacija od kojih su samo neke značajne:

- dvije primarne službe ili dvije aplikacije primarnih službi mogu dijeliti resurse na osnovu vertikalne ili horizontalne podjele;
- dvije sekundarne službe ili dvije potencijalne aplikacije sekundarnih službi mogu dijeliti resurse na osnovu vertikalne ili horizontalne podjele. Vertikalna podjela između dvije sekundarne službe je na osnovu njihove veze sa primarnom službom;
- primarna služba i sekundarna služba mogu dijeliti resurse na osnovu vertikalne podjele.

V. REGULATORNE IMPLIKACIJE RAZLIČITIH METODA KOGNITIVNOG PRISTUPA

Danas najčešće korištene tehnike za utvrđivanje zauzetosti pojedinih opsega su: očitavanje (*sensing*) spektra, pomoću radiofarova (*beacons*) i pomoću geolokacijske baze podataka (*Geolocation Databases*). Ove tehnike se mogu koristiti individualno ili u kombinaciji, u cilju postizanja niskog nivoa smetnji u okolini [3].

U ovom dijelu nećemo razmatrati njihove tehničke parametre niti njihovu efikasnost, već samo dati osvrt na to kakav utjecaj ove tehnike imaju na regulaciju.

Što se tiče tehnike očitavanja, ranije je već kazano da regulator treba odrediti odgovarajuće pragove osjetljivosti uređaja. Alternativa tehnici očitavanja predstavlja geolokacijska baza podataka koja sadrži podatke o frekvencijama koje su dostupne za datu lokaciju. Kognitivni uređaj pomoću pristupa ovoj bazi može na određenoj geografskoj lokaciji "spoznati" frekvenciju koja je dostupna za njegov rad.

S ovom tehnikom otvaraju se brojna regulatorna pitanja kao što su:

- Koja je potrebna točnost uređaja u pogledu određivanja lokacije?
- Tko će održavati bazu podataka referentnom?
- Hoće li biti jedna usluga za sve opsege ili ne?
- Koliko često treba prilagođavati uređaj bazama podataka i tko će biti odgovoran za to?
- Što je s dinamičnim korištenjem spektra frekvencija koje su samo povremeno u upotrebi?

Korištenje baza podataka daje jednu zanimljivu prednost za regulatora, a to je sposobnost kontroliranja uređaja koji rade u nelicencnom režimu na način koji nikad prije nije bio moguć. Tako, na primjer, regulator koji želi ukloniti sve kognitivne uređaje iz opsega na određenoj geografskoj lokaciji može postaviti u bazu podataka za sve frekvencije oznaku "zauzet". Kognitivni uređaji u tom slučaju ne bi mogli vršiti prenos podataka na tim lokacijama. Pored toga, regulator može razdvojiti različite vrste kognitivnih uređaja i provoditi različita pravila za uređaje s različitim kognitivnim sposobnostima [4].

Tehnika prijema signala s radiofara podrazumijeva postojanje odgovarajuće komunikacijske infrastrukture (*radiofar*) pomoću koje kognitvni sistem dobiva informaciju o slobodnim kanalima koji su raspoloživi na datom području odnosno u blizini sistema. Kognitivni radio podešava prijemnik kako bi primio infomaciju te na osnovu te informacije pronalazi prefeririani kanal za rad. Ukoliko uređaj nije u stanju primiti signal s radiofara odnosno ako se nalazi van dometa emisije radiofara, ne smije vršiti emitiranje signala, jer može prouzrokovati interferenciju. Ova tehnika je najmanje popularna te se razvoju regulative za ovakve sisteme najmanje posvećuje pažnja. U vezi sa regulacijom ove tehnike za detekciju slobodnog prostora u spektru vežu se sljedeća pitanja:

- Tko će odašiljati signal s radiofara?

- Kako održati referentnost odaslane infomacije u sredini koja se jako brzo mijenja?
- Koji dio spektra koristiti za radiofarove?
- Je li prihvatljivo za kognitivne sisteme da su van službe ako nemaju vezu sa radiofarom?
- Kako ograničiti signal s radiofara samo na određenu zonu pokrivanja?

Ova i mnoga druga pitanja koja se nameću regulatoru će morati biti riješavana prije puštanja u rad ove vrste uređaja. Svjedoci smo da kognitvni radio predstavlja temu o kojoj se sve više raspravlja na svjetskim skupovima regulatora. Uvrštena je i u rad Svjetske radio konferencije 2012 (*World Radio Conference 2012 Geneve*) koja se održava u Ženevi, kao posebna tematska cjelina.

VI. ZAKLJUČAK

Kako bi se na što je bolji način izvšio uvid o stanju iskorištenosti spektra, vrši se stalni montoring frekvencijskih opsega odnosno prati se nivo zauzetosti pojednih opsega u vremenu i na određenoj lokaciji. Mjerenjima koje su proveli regulatori širom svijeta je utvrđeno da se dodijeljeni radio spektar koristi veoma neefikasno. U pojedinim, već dodijeljenim, opsezima spektar se koristi manje od 5% u odnosu na moguće kapacitete.

Podaci o popunjenosti spektra veoma su važni za formiranje politike uređenja frekvencijskog spektra regulatornih tijela koja su odgovorna za donošenje odgovarajućih propisa koji definiraju dodjelu spektra i pravila pristupa ovom vrijednom prirodnom resursu. Obzirom na ovu činjenicu potrebno je veoma detaljno analizirati trenutno stanje u RF spektru i na osnovu toga vršiti odgovarajuće regulatorne aktivnosti u pogledu fleksibilnijeg načina korištenja spektra i implementacije kognitivnih sistema u odgovarajućim opsezima. Potrebno je napraviti studije kompatibilnsti i koegzistencije više različitih sistema i usluga unutar datog opsega. Obzirom da na telekom tržištu postoji interes za razvoj i uvođenje novih usluga i sistema, saradnjom regulatora, prometnih instituta te telekom industrije urađeno je već više takvih studija.

Regulator kao kreator pravila i politike korištenja radiofrekvencijskog spektra ima veoma složen zadatak regulacije ovakvog načina pristupa spektru. Ključna stvar je pomiriti zahtjeve telekom industrije i korisnika uz zaštitu javnog interesa. Potrebno je izvšiti konzultacije o ovoj temi sa većim brojem potencijalnih učesnika ovog procesa kako bi se na pravi način odabrala rješenja koja će doprinijeti daljnjem razvoju telekomunikcijskog tržišta. Pored regulatora u procesu donošenja regulative za ovaj specifičan način pristupa spektru, značajnu ulogu treba da preuzmu i proizvođači opreme, instituti za certificiranje, kreatori sadržaja, mrežni operatori, korisnici, itd. Sinergijom svih spomenutih se može kreirati regulatorni okvir koji će usmjeravati daljnji tok razvoja kognitivnih sistema dajući odgovarajuću potporu ali i određene restrikcije u službi zaštite postojećeg sistema upravljanja radiofrekvencijskim spektrom.

Regulacija ovog načina pristupa spektra u Bosni i Hercegovini će se razvijati u skladu sa zahtjevima tržišta i ići pravcem harmonizacije korištenja s ostalim CEPT članicama. Za sada je to u formi izvještaja određenih radnih skupina koje se bave ovom problematikom. U narednim godinama se može očekivati brz razvoj ovog vida komunikacija i prateće regulative, imajući u vidu da se daljnji razvoj mobilnih (LTE) sistema pristupa veže za razvoj kognitivne tehnologije.

Neka predviđanja pokazuju da će ekspanzija ovog vida komunikacija nastati u periodu nakon donošenja odgovarajuće regulative, a to je period u narednih pet godina.

Access Regulatory Remedies in Point-to-Multipoint Fiber Access Networks

Tomislav Majnarić
Lator d.o.o., Zagreb, Croatia
tomislav.majnaric@lator.hr

Abstract – This article analyzes access regulatory remedies in fiber access networks, built by operators with significant market power. A focus is put on point-to-multipoint fiber networks. Considering that such topology generally prevents economically viable wide-spread unbundling of fiber loops, comparable to traditional copper loops, other access remedies at local network level have to be imposed by regulators. These remedies include physical access to fibers in terminating sections of access networks and bitstream access at local nodes. The article gives detail overview of technical aspects of these regulatory remedies. The comparison to traditional copper access networks is also given, as well as importance of imposition of adequate fiber migration paths for alternative operators.

I. INTRODUCTION

Traditional fixed access networks, based on copper pairs, have been upgraded to new access network architectures, which are partly or fully based on fibers. Dependent of a final point in access network that fiber reaches with respect to customers, fiber access network are designated with "FTTx" abbreviation, where "x" can be "H" for *Home*, "P" for *Premises*, "B" for *Building*, "C" for *Curb*, "N" for *Node* or "Cab" for *Cabinet*. Except for FTTH and FTTP, the remaining FTTx architectures still contain copper pairs in final parts of access network that are close to customers.

Derived from the term *Next Generation Networks* (NGN), *Next Generation Access Networks* (NGA), as the term for the access part of NGN, has also been widely used for FTTx networks, especially within the official EU documents [1],[2]. The latter referenced document additionally provides service definition of NGA, specifying NGAs as *networks which are capable of delivering broadband access services with enhanced characteristics, when compared to those provided over already existing networks*.

Comparing to traditional broadband networks, NGA networks support enhanced services, with much higher connection quality and throughputs in both directions. Also, according to the studies [3],[4], deployment of NGA networks results with enhanced economic growth, in terms of faster increase of Gross Domestic Production (GDP) and employment rate indicators.

In 2010 the European Commission has presented *Digital Agenda* strategy, aiming to, among other, significantly increase the availability of NGA networks till year 2020. With respect to broadband speeds, the targets are 100% and 50% coverage of EU household with fast broadband connections (at least 30 Mbit/s) and ultra-fast broadband connections (at least 100 Mbit/s), respectively, in 2020 [5].

In European Union (EU), the electronic communications market has been under strict *ex-ante* regulatory regime since 1990s, aiming to mitigate inherited monopoly of incumbent telephony operators, open the market for other operators and promote service and infrastructure competition, resulting in better availability of electronic communications services for end customers. So called *bottlenecks* in physical communications infrastructure are of great concern for regulation, corresponding to parts of network that cannot be replicated in economically feasible way (e.g. copper loops access infrastructure). Similarly, fiber access infrastructures also present the regulatory bottlenecks, as they cannot be profitably replicated in the majority of EU [6]. Considering this, as well as Digital Agenda targets, European Commission has published dedicated regulatory Recommendation that should foster wide-spread market implementation of NGA connections and services [2].

The deployment of NGA networks has especially advanced in East-Asian countries (e.g. South Korea and Japan), where penetration of households covered with fiber access networks reached more than 35% by mid-2011. In the same time, in EU, the average penetration of fiber covered households was significantly less - 1,9%, with the penetration exceeding 10% in only three EU countries – Lithuania, Sweden and Slovenia. The average EU take-up rate, indicating the share of active fiber connections in total number of fiber covered households, was 17,5% [7].

The Croatian Government has also brought national strategy for NGA networks development, formalized through National Broadband Strategy till year 2015 [8]. The NGA relevant target in the Strategy is 35% national coverage with fast broadband connections (at least 30 Mbit/s) by 2015. By the end of 2011, according to various local industrial sources, it is estimated that maximum of 8% of Croatian household were covered with fiber access networks, with take-up rate of active fiber connections being less than 10%. However, it is expected that majority of these inactive fibers will be commercially offered in the market during 2012, following the implementation of proper NGA regulatory regime imposed to incumbent by Croatian National Regulatory Agency (NRA) – HAKOM.

In this article general technical aspects of FTTH networks are analyzed, together with access regulatory remedies that can be imposed to FTTH network operators. Point-to-multipoint FTTH networks, where limited number

of access remedies are practically available, are analyzed in detail, stressing the importance of proper access regulatory regime for market competitiveness in case of such topology.

The article is organized in five chapters. After this introduction, the second chapter provides an overview of most common FTTH architectures with relevant standards. In the third chapter, architectural characteristics of FTTH networks are related with possible access remedies. The fourth chapter analyzes available remedies and their practical feasibility in case of point-to-multipoint FTTH networks. Finally, the article gives conclusion in the last chapter.

II. FTTH NETWORKS ARCHITECTURE

This chapter gives architectural overview of FTTH networks. Firstly, infrastructural details with respect to the layout of access fibers are discussed. After that, an overview of related network technologies that can be applied on the FTTH networks is given. Terminology used in this chapter has mainly been taken from EU NGA Recommendation [2] and Croatian Ordinance Act relevant to fiber access networks [9].

A. Fiber layout

Similarly to traditional copper access networks, the access fibers spread out from single access network node, which is traditionally designated as Local Node (LN), Local Exchange (LE) or Central Office (CO). With respect to terminology in fiber networks, this node is also called Metro Point of Presence (MPoP). Depending on particular geodemographical conditions, each access node usually covers up to few thousands households, where larger figures are applicable to urban areas. Furthermore, in case of a fiber in the access, due to a higher maximum customer distance from access node, several traditional copper access nodes can be replaced with single fiber MPoP. The MPoP node is equipped to house both passive network parts (e.g. optical distribution frames) and active network parts (e.g. access switches, backbone routers).

The fiber access network is organized in two segments, divided by intermediary Distribution Point (DP) node (Figure 1). The first part of access network, closer to customers, is referred as distribution or drop segment. It aggregates multiple fiber sections from households towards single DP node. There can be several DP nodes belonging to a single MPoP node. The other access network section, closer to MPoP node, is referred as feeder or main segment. It connects DP nodes with MPoP, usually consisting of a single fibers section among these two nodes (although sometimes, due to the redundancy reasons, a number of DPs and single MPoP are linked in ring topology). If flexibility of fiber connections within access networks is required, DP node is equipped with optical distribution frames. Contrary to this, if no flexibility is required, DP node can be a simple aggregation point for fiber cables, placed e.g. within duct hole or at building entrance.

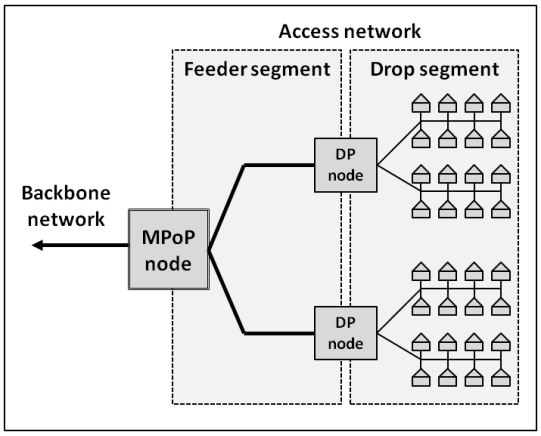

Figure 1 – Fiber access network architecture

The fibers in access network are usually laid in underground duct network. In rural areas fibers are also guided over pole infrastructure, which is generally dependent on urbanistic rules throughout local municipalities.

At least one fiber per household covered is always laid in drop segments of access network. In feeder segments the number of fibers is equal to a sum of all drop segments' fibers or it is less than this sum. The former case corresponds to point-to-point (P2P) access network topology (meaning that each covered household has at least one dedicated fiber that reaches MPoP node), while in the latter case the access network is organized in point-to-multipoint (P2MP) topology, requiring that several households, i.e. end customers, share a single fiber within feeder segment.

B. FTTH technologies

There are several fiber access technologies that have become the most influential in the telecom market [10]. ITU-T G.984 group of standards for Gigabit Passive Optical Networks (GPON), as well as its counterpart IEEE 802.3ah standard for Ethernet Passive Optical Networks (EPON), are both suited for P2MP access network topology. In P2MP fiber networks a single fiber within feeder segment is, by mean of passive optical splitters, physically portioned in several fibers that reach end users through drop segment. Splitters are usually placed within DP nodes. On the other side, P2P topologies utilize the suitable Ethernet protocol from IEEE 802.3 standard group, depending on the required transmission capacity and maximum distance to customer in access network.

According to the latest market report from mid-2011 [7], nearly 2/3 of FTTH deployments in Europe were based on P2P access topology and Ethernet standard, while the remaining FTTH deployments utilized P2MP topology with related PON technology.

III. REGULATION AND ACCESS TO FTTH NETWORKS

Generally, the regulation of telecommunications market has been focused on encouraging of efficient investments and promoting of competition among market players, i.e. telecom operators and service providers. The

power of regulation in many countries has been given to separate national authorities, operationally independent of Governments (commonly referred in EU as National Regulatory Authorities – NRAs). In EU, the regulation policy and rules are defined through *EU Regulatory Framework*, corresponding to a set of formal directives and recommendations to be followed by EU member states and their NRAs. Considering the dominance of traditional copper access networks and incumbent telephony operators in Europe, the significant regulatory effort has been made on providing access to this copper infrastructure for alternative operators. This has resulted, among other, with a number of access remedies (or obligations), imposed usually to incumbent operators, enabling access to incumbents' networks on various infrastructural and service levels [11].

This chapter provides an overview of typical access regulatory remedies that can be imposed to FTTH network operators that are dominant at the market (commonly referred in EU as situation of Significant Market Power – SMP). The relevant technical details concerning these remedies are also analyzed.

A. Reference network architecture

Regulatory remedies covering the access to SMP operator's FTTH networks are related to several reference points within access and backbone network, where interconnection between SMP operator and alternative operators can be established. Here, backbone network corresponds to a part of operator's transport network that links all MPoPs and core part of the network, forming hierarchically organized transport network composed of lower level Regional Nodes (RN) and higher level Core Nodes (CN). Figure 2 gives an overview of reference architecture of SMP operator's FTTH network with interconnection points. The architecture shown is based on the structure of bitstream services, as specified by Body of European Regulators for Electronic Communications (BEREC) [12], extended with network architecture relevant to NGA networks [2],[11].

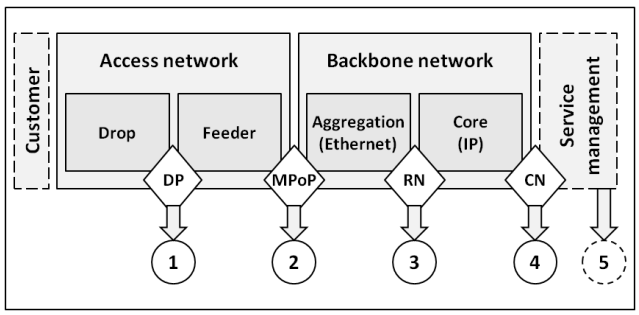

Figure 2 – Reference FTTH network architecture with interconnection points

Depending on a position of interconnection point with respect to network hierarchy level, alternative operator, as an access seeker, is able to cover particular amount of end customers, while simultaneously modelling its own retail service portfolio as allowed by technical capabilities at particular interconnection point chosen. For instance, while positioning of interconnection point hierarchically higher within SMP operator's network enables extended customer coverage, in the same time it offers less flexibility on adjusting of customer services offered, making them highly dependent on SMP operator's network architecture and technology.

Furthermore, in ideal market situation it is expected that alternative operators enter the market on higher hierarchical interconnection levels, optimizing their initial investments, and later advance to lower levels, increasing their investments in own network equipment and infrastructure, while simultaneously decreasing their dependence on SMP operator's network. Such gradual approach on investments is usually referred as *investment ladder* and, especially within EU, presents important postulate of regulation rules [11].

The consequent subchapters describe in detail each reference interconnection point given in Figure 2, together with relevant technical and service capabilities.

B. Access at DP node (1)

Regardless of P2MP or P2P topology deployed, access at DP node enables access to individual fibers in drop segment that directly reach each customer. In regulatory terms, this corresponds to physical access to unbundled fiber sub-loops. This kind of access is in the scope of relevant no.4 market that is generally susceptible to *ex-ante* regulation within EU regulatory framework [2],[13].

While access at this level both enables full physical access to each customer's fiber and is independent of technology applied in SMP operator's FTTH network, it can be economically infeasible for alternative operators. This is practically a case if DP node covers relatively low number of customers, which makes investments in necessary infrastructure for unbundling at DP node unprofitable, especially if DP node is housed within outdoor cabinet. A typical example of low-profile DP node is one that is placed in the vicinity of customer premises, e.g. at the entrance of multi-tenant building.

C. Access at MPoP node (2)

In P2P topologies, all customer fibers reach MPoP node. Therefore it is possible to establish physical access to individual customer fibers at MPoP node. Regulatory, this corresponds to a case of fiber local loop unbundling (LLU), also in the scope of EU *ex-ante* relevant market no.4. Also, such kind of access is comparable to traditional unbundling of copper local loops in DSL networks. Fiber unbundling at MPoP nodes generally presents economically more suitable case comparing to sub-loop unbundling at DP nodes, as MPoP nodes covers much larger areas comparing to DP nodes. Furthermore, in case of copper unbundling in DSL networks, alternative operators have already built necessary unbundling infrastructure at MPoP nodes (which are co-located with copper LE nodes).

Contrary to P2P, in case of P2MP access network topology, fiber unbundling at MPoP node is technically not possible, as single fibers in feeder segments are shared by a

number of end customers (reduction of customer fibers from drop segment is performed at DP node, by mean of optical splitters). By this, alternative operators' access at MPoP level is tied to PON technology applied over P2MP fibers and can be achieved only by bitstream service. In EU regulatory terms, the bitstream access is part of relevant market no.5 [13]. Considering PON technology, bitstream access is performed at the backbone port of Optical Line Termination (OLT) node, utilizing Layer 2 network protocol (e.g. Ethernet).

It should be also noted that access to fibers at DP and MPoP nodes can be combined with access to duct space in both drop and feeder segments of access network. In that case it is expected from alternative operators to lay necessary fibers in ducts within access network. Furthermore, EU regulatory framework even states that existence of competitively efficient access to duct space can preclude a need for access to fibers in FTTH networks [2]. However, this is rarely true, as SMP operators' control over duct infrastructure and insufficient space within ducts usually give to SMP operators a competitive advantage over other operators.

D. Access at RN (3)

Access to individual customer at Regional Node level can be achieved only by bitstream access (relevant market no.5), similarly to traditional bitstream access in DSL networks. As majority of incumbent (SMP) operators have already upgraded their aggregation networks with Ethernet protocol, the interconnection point at this level usually corresponds to an interface on Ethernet aggregation switches. The access at this level is also referred as Ethernet level bitstream [12].

E. Access at CN (4)

Core Nodes are placed higher in network hierarchy and, considering national coverage, there are usually only several Core Nodes. Therefore, considering a small number of interconnection points and relatively high customer coverage that can be achieved with single core interconnection point, this bitstream access option requires low investments from alternative operators. However, it gives to alternative operators limited flexibility for differentiation of their retail services comparing to SMP operator's ones.

Core network usually operates on IP protocol, so interconnection is achieved on IP router's interface, therefore designating this bitstream option as IP level bitstream [12]. The fiber IP bitstream access is technically equivalent to DSL network's IP bitstream.

F. Simple resale (5)

By *simple resale* is considered a business model in which alternative operators only resale SMP operator's retail services. Alternative operators even do not own a network infrastructure. The services resold are technically identical to SMP operator's ones. Simple resale model is sometimes treated as type of bitstream service, but is generally not regulated by EU NRAs.

IV. ACCESS REGULATION IN P2MP FTTH NETWORKS

P2P FTTH access networks generally offer more flexibility with respect to the implementation of network technology (Ethernet) and options for alternative operators' physical access to deployed fibers. This also increases a number of available access remedies that can be imposed to SMP operators, therefore facilitating regulatory process.

When comparing investments costs of P2P and P2MP networks per household covered, the cost of P2P network is on average 10% higher than P2MP one, where both passive network infrastructure (e.g. fibers, duct space) and active network equipment at MPoP node are considered [6].

P2P networks have been twice more frequently built in Europe during past few years, comparing to P2MP networks (with respect to number of households covered). Furthermore, P2P topologies have been more common to greenfield projects, i.e. to fiber networks not built by incumbents with traditional copper networks [7].

However, in many cases local market conditions and incumbents' strategies have resulted with P2MP networks being built. These typically included following cases:

- insufficient space in existing ducts in access network (e.g. occupied by copper pairs), which is usually combined with inadequate topology of ducts, that lacks proper intermediary points for fiber DP nodes (duct holes, street cabinets); finally limiting amount of fibers that can be laid (less than one per household covered),
- optimization of investment costs, as P2MP networks are less expensive than P2P networks, including active network equipment,
- incumbents' reluctance to allow access to its fiber network to other operators, opting to build P2MP network which in practice limit physical access by alternative operators, binding them to use bitstream options with less flexibility of retail services.

The remaining part of this chapter analyzes in detail available access regulatory remedies that can enhance competition in case SMP operator's FTTH network is built in P2MP topology. The remedies include physical fiber access at location of splitters and bitstream access at OLT node level. Bitstream accesses at Ethernet and IP levels are as well available remedies in FTTH networks, but are not discussed here, as these bitstream options are technically equivalent to ones in case of DSL networks. This also relates to limited flexibility of alternative operators to model their FTTH retail services at Ethernet and IP bitstream levels, in comparison to SMP operator's retail services.

A. Access at splitters

Splitters within P2MP network are placed at DP nodes, presenting a physical point where number of customer

fibers from drop segment are reduced by ratio *n:1* (splitting ratio, the most common values of *n* practically used are 32 or 64). Depending on the access network architecture, DP node can be placed closer to customers or closer to MPoP node, therefore altering the number of customers covered by DP node. Also there are practical cases when splitting is performed in multiple stages (or cascades), and DP node relevant for this access remedy is considered to be the one that houses the last cascade of splitters, located closest to the customers.

Considering this access remedy, alternative operators are able to establish access to terminating sections of fibers at DP node by interconnection of their own feeder fibers in Optical Distribution Frame (ODF). Also alternative operators have to install own ODFs and splitters (usually leasing a part of SMP operator's space at DP node), and OLT and backbone switch (SW) at MPoP or similar local node (Figure 3 – network parts belonging to alternative operator are marked with *(2)*). Alternative operators even have a possibility to deploy P2P network (if there is sufficient duct or fiber capacity in the feeder available).

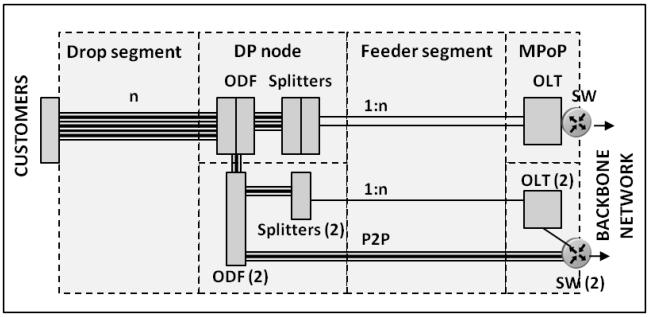

Figure 3 – Access to P2MP FTTH network at DP (splitters) node

The main advantage of the splitters access option is possibility for alternative operators to establish physical access to drop segment fibers, which part of the FTTH network presents the major economic bottleneck for competitive FTTH deployments [2]. On the other side, alternative operators have to make considerable investments in the feeder and backbone parts of the network, which promotes infrastructural competition among operators in the part of the networks where it is generally economically viable.

However, following constraints in practice can prevent full implementation of this access option:

- splitter nodes are placed in the vicinity of end customers (e.g. within multi-tenant buildings), which, due to a low number of customers covered by single splitter node, eliminates economic viability of access (taking into account both the costs of necessary equipment at splitter nodes and the length of feeder fibers),
- splitting is performed in multiple stages (cascades), where the last splitter cascade is placed in the vicinity of end customers, also resulting with economically infeasible access,
- insufficient space or inadequate housing conditions for alternative operators' equipment at DP nodes, requiring significant investments in node infrastructure (either by SMP operator or access operators), which can decrease the overall profitability of this access option for alternative operators.

Conclusively, in order for splitter access to be both economically and technically viable option in the market, P2MP access networks have to be carefully planned in advance, with respect to relative position and customer coverage of DP nodes. A sufficient space at DP nodes has to be ensured for equipment housing (both for SMP and access operators). This is especially important if DP nodes are housed in outdoor cabinets. As it is practically more difficult to introduce any subsequent modifications in already built fiber networks, NRAs should find an optimal way of imposing of these planning rules prior to the construction of new P2MP networks.

B. Bitstream access at OLT level

When physical access at DP (splitters) node is not feasible for any reason, including poor economic prospects of this option for alternative operators, it is important for NRAs to impose access option at the next available level in the network, which is bitstream access at OLT level at MPoP node (Figure 4).

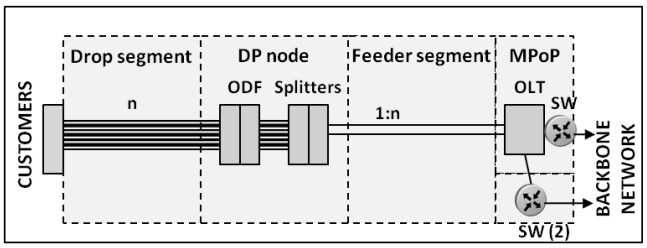

Figure 4 – Access to P2MP FTTH network – OLT level bitstream

Although bitstream services generally offer to alternative operators less flexibility when designing own retail services, this primarily relates to bitstream services on higher network levels (Ethernet and IP level), where alternative operators do not have control over access network parameters. However, in case of OLT level bitstream, interconnection to SMP operator's network is realized at local level MPoP node, where it is technically possible to set corresponding parameters of individual customer access fibers (e.g. maximum throughput, number of virtual channels for multiple services like voice or video, etc.). This is practically performed by changing of parameters of OLT node for individual customer within particular PON splitting group.

OLT level bitstream also presents a suitable access substitute for physical fiber unbundling at MPoP nodes, that is not supported in P2MP network topology. With respect to alternative operators that have already been unbundling copper loops for DSL services in local nodes, this type of bitstream access presents the most suitable migration path towards fiber networks and corresponding services, especially if physical access at splitters node is not available or is economically unattractive. This is also important with respect to preserving of previous

investments of alternative operators in copper unbundling (e.g. in room space at local node, equipment racks, backbone switches, backbone links), as generally MPoP nodes are co-located with copper LEs.

In P2MP networks, in case bitstream access at OLT level would not be available (together with access at splitters node), operators using physical copper unbundling would have to use bitstream services at higher levels (Ethernet and IP), when migrating to fiber networks. Considering main postulates of regulation and specifically fostering of infrastructure competition, such step would imply weakening of these postulates and practical descent on the investment ladder.

Therefore, imposition of regulated access at OLT level by NRAs presents very important remedy for smooth migration path towards NGA network for alternative operators, particularly in case of poor prospects of physical access at splitter level.

V. CONCLUSION

The article analyzed the technical capabilities of regulated access options in FTTH networks, with focus on P2MP topology. Comparing to traditional physical and bitstream access options in DSL networks, introduction of FTTH networks has resulted with additional access option that is concentrated on technical possibility of physical fiber access at DP node. Particularly in P2MP topologies of FTTH networks, due to an access fiber organization and PON technology considerations, a number of available access options is limited. This primarily relates to unavailability of physical fiber access at local node level, therefore implicating a need for introduction of P2MP specific bitstream access at PON OLTs at local nodes. In case physical access at splitters (DP) node level is not available or is not economically viable, OLT level bitstream presents a sutiable substitute for fiber unbundling at local node. This is especially true when existing operators that have deployed copper unbundling facilities in local nodes are planning to migrate their customers to FTTH networks. Such smooth migration path, with OLT level bitstream, retains alternative operators' position on investment ladder and excludes regression to Ethernet and IP level bitstreams.

SIGNALING AND PROTOCOLS

Improvement of Method for Telephony Network Signal Sending over Internet

A. Lebl, Ž. Markov and D. Mitić
IRITEL A.D., 11080 Zemun, Batajnički put 23, Serbia
e-mail: mita@iritel.com

Abstract - This paper describes one drawback in the Internet recommendation RFC2833 biscas. The recommendation deals with the method of telephone signalling sending over Internet network and the problem existed in the case of line R2 signalling sending when E1 transmission system is used in classic telephone network. The authors of the recommendation accepted our suggestion and changed the text of the recommendation in accordance with our proposal. The changes are introduced in the new recommendation RFC5244.

I. INTRODUCTION

One important problem in mixed classic and Internet telephony, which appears in the networks of lower technological level, is how to send the signals of classic telephony across Internet. This process was originally defined in the Request For Comment (RFC) recommendation RFC2833 [1]. As it was necessary to introduce many new situations in telephony signals sending over Internet, the authors decided to split it into three recommendations. Today we have following recommendations:

a) RFC4733, which deals with DTMF, telephony tones and telephony signals sending over Internet [2];

b) RFC4734, which deals with events for fax, modem and text telephony signals sending over Internet [3];

c) RFC5244, which defines events for channel-oriented telephony signal sending over Internet [4].

The recommendation [4] is defined the last and we took part in defining its final text when it was in the draft form [5]. Considering suggestions described in this paper, the authors made the next draft [6]. These changes were also accepted in all following drafts, and are also accepted in the final text of recommendation [4].

II. METHODS OF TELEPHONY SIGNAL SENDING OVER INTERNET

Fig. 1. presents the block scheme of one telephone connection over Internet network (IN). The gateways (GW1 and GW2) are situated at the point of contact of classic telephone network (CTN) and IN. GW1 and GW2 are intended in one direction to adapt telephone signals for sending over IN and in other direction to put it back in the shape used in CTN.

Telephony signalling may be sent over Internet in three ways. The first way is to send coded samples of (analog) signals. The second way is to determine the parameters of signals (its level, frequency and duration) without detecting the meaning of the signal. And, finally, the third way is to determine the exact meaning of the transmitted signal and to present it by the event code.

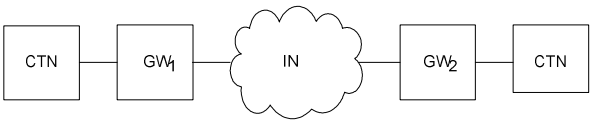

Figure 1. Telephony connection over Internet

The first method is the simplest and fastest one, but the greatest channel bit flow is required. The second method is slower, less channel capacity is needed, but it is possible to transmit the parameters of the weakened signal. The third method is the slowest one, but the parameters of the weakened signal are not sent over Internet. For our consideration the third method is the most important one.

The structure of the Internet packet, used for telephony signalling sending over Internet, is presented in Fig. 2. After all necessary headers (Ethernet, IP, UDP, RTP) and before frame check sequence field (FCS), the RTP payload contains the information about the telephony signal. The structure of this RTP payload depends on way of signal sending, i.e. which of three mentioned methods is used.

Fig. 3. presents the structure of RTP payload in the case of using the third method of telephony signal coding. The meaning of the telephony signal is presented by the 8-bit field "event code". The other fields in the frame are the level of the signal (6 bits) and the duration of the signal (16 bits). The examples of signals, presented by event code, are DTMF signals (codes 1 to 15), R2 register signals (codes 176 to 205), and, for this paper the most important, R2 line signals (codes 144 to 159).

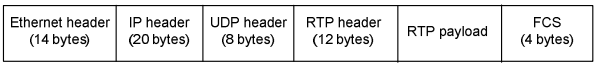

Figure 2. The structure of Internet packet

Figure 3. The structure of RTP payload for event code sending

III. STUCTURE OF E1 TRANSMISSION SYSTEM

For the understanding of problem, considered in this paper, it is important to remind us of the structure of European E1 transmission system.

The structure of the European E1 system is presented in Fig. 4. The blue signed values present the exact values of the bits on those positions, intended for the frame and multiframe synchronization.

The frame of E1 system is based on the group of 32 channels (CH0, CH1, ..., CH31). The group of 16 frames (FR1, FR2, ..., FR16) constitutes one multiframe. Frame synchronization is carried by the content of channel 0, and multiframe synchronization using the first half of the channel 16 in the FR1 (data 0000). The signalling for speech channels is transmitted in 16th channel of frames FR2 to FR16 (signalling for two speech channels in each of these channels).

The code combination 0000 in the 16th channel is only intended for multiframe synchronization. It appears in CH16 of FR1 and must not appear in the remaining16th channels of E1 system [7].

IV. THE R2 LINE SIGNALIZATION

R2 signalization is intended for the exchange of signalling information between telephone exchanges. It includes its line and register part. For this paper it is important to repeat some facts dealing with the line signalling.

The R2 line signalling is used to exchange information about link status between two exchanges. The R2 line signals are, for example, channel seizure signal, clear-forward signal, and so on. Two important R2 line signalling schemes are used: analog line signalling and digital line signalling.

In the analog version of R2 line signalling only one bit (A-bit in Fig. 4.) is used for transmission of signalling information [8]. The channel can be in the idle state ("tone-on" condition), and the channel seizure is defined as "tone-off" condition.

In the digital version of R2 line signalling, two bits are used to exchange signalling information (A-bit and B-bit in Fig. 4.) [9]. Possible meanings in this case are the same as for analog line signalling.

	CH0	CH1	CH2		CH16		CH31
FR1	8 0 0 1 1 0 1 1	8 7 ··· 1	8 7 ··· 1	···	0 0 0 0 1 a 1 1	···	8 7 ··· 1

FR16	8 1 a 0 1 1 1 1	8 7 ··· 1	8 7 ··· 1	···	A B C D A B C D	···	8 7 ··· 1

Figure 4. The structure of European E1 system

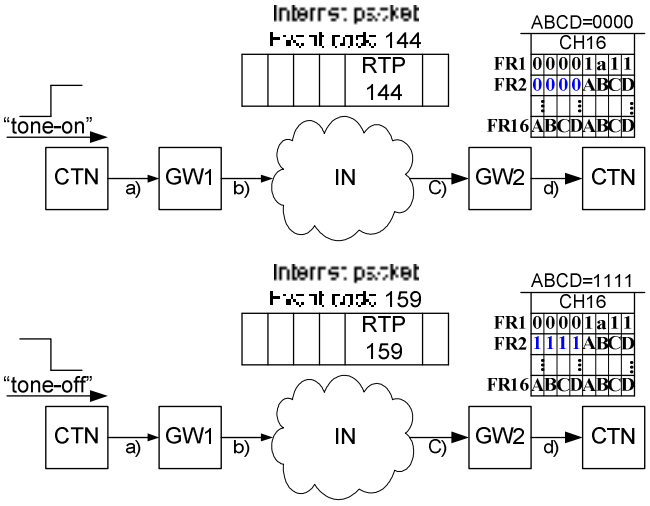

Figure 5. Transmission of line R2 signals across Internet

V. DRAWBACK OF THE RECOMMENDATION RFC2833

According to [5], the event codes 144 to 159 were intended for the transmission of line R2 signals ("tone-on" and "tone-off" signal) across Internet. The transmission of these signals is presented in Fig. 5.

When GW1 at the ingress of IN detects the presence of "tone-on" state in the CTN, it forms the Internet packet with the event code 144 in the RTP payload part of the Internet packet. This packet is transmitted across IN and at the egress, GW2 puts the code combination 0000 into, in presented example, the first half of CH16 in FR2. According to [7], this code combination must not appear at this place. In fact, the presence of code combination 0000 in CH16 of frames other than FR1 would lead to the problem of multiframe synchronization establishment, if the code combination 0000 from the first half of CH16 in FR1 is not the first detected one. If the synchronization of multiframe is, eventually, established correctly, the recommended method of multiframe synchronization check would not lead to the loss of multiframe, because only the content of the first half of CH16 in FR1 is checked in this situation. But, if the check procedure is realized according to [10], chapter 5.2, as, for example, one of synchronization possibilities in [11], the multiframe synchronization could be lost, if code combinations 0000 were detected in two or more consecutive 16th channels of one multiframe.

In the similar way, the "tone-off" signal is presented by the Internet packet with the event code 159. In GW2, the code combination 1111 is put in the first half of CH16 in FR2.

VI. IMPROVEMENT OF THE RECOMMENDATION RFC2833

In order to revise the drawback of the recommendation, we suggested to the authors of the recommendation to use following event codes for the transmission of R2 line signalling:

1. In the case of analog line R2 signalling, where only A bit is used for line signalling, the code 149 for the "tone-on" state (meaning ABCD=0101) and the code 157 for the "tone-off" state (meaning ABCD=1101).

2. In the case of digital line R2 signalling, where A bit and B bit are used for line signalling, the codes would be 145 (ABCD=0001), 149 (ABCD=0101), 153 (ABCD=1001) and 157 (ABCD=1101).

The authors of the recommendation agreed that it is necessary to change the text of recommendation. The changes were first put in the text of draft [6], and, finally, in the text of the new recommendation [4]. The only difference between our suggestion and the final solution was that the authors introduced special codes for the event codes. For "tone-on" and "tone-off" state in analog line signalling they introduced codes 206 and 207. For four states in digital line signalling they used codes 208 to 211.

VII. CONLUSION

In this paper the drawback of the draft recommendation RFC2833biscas is described. After that, our suggestion for the change of the draft, and, also, the final solution in the new recommendation, which is very similar to our suggestion, are presented. If this change had not been made, the transmission of R2 line signalling across Internet in the case of using E1 transmission system would not have been possible.

According to our experience with this suggestion, it can be concluded that well explained suggestions on the text of Internet recommendations are relatively easily accepted. Comparing to the ITU-T recommendations, changes are made more easily. The authors are free to say this according to the experience of one of them, who, before this suggestion, also made contribution to Internet and to ITU-T recommendations [12].

Everybody can suggest the change in the Internet recommendation, without the support of any trade, national or international institution. Also, this suggestion is available to the whole community and everybody can make changes in the suggestion. The discussion about the proposal is usually very fast, by e-mails, and the number of drafts before the recommendation is adopted can be great. After the end of discussion, the final text of the draft is considered in Internet Engineering Steering Group (IESG), which provides the first technical review of Internet standards. Following the positive opinion of IESG, the draft is verified in the Internet Engineering Task Force (IETF), the body that coordinates the technological development of the Internet, and the draft becomes the Standard Track (the recommendation). But, after the final text of the recommendation is made, it can still be changed. The old version of the recommendation then becomes obsolete and the new version, with the new number, is actualized.

Process of RFC recommendations creation is faster than in the case of ITU-T recommendations, but the duration of the RFC recommendation is shorter. Also, it can be said that the new trends in technique are very quickly followed by the new RFC recommendations.

ACKNOWLEDGMENT

This work is partially supported by the Ministry of Science and Technological Development of the Republic of Serbia within the Project TR32007.

Abstract - In this paper, non-service related signalling in mobile networks, also known as HLR lookup is discussed. Although initially HLR lookups were intended for SMS, MMS and voice routing purposes, there are other services that could create additional revenue streams for both mobile network operators and enterprises. This paper will also discuss technical, commercial and security challenges of HLR lookup service with a detailed description of an international ATM anti-fraud use case.

Keywords: mobile networks, HLR, MSC, IMSI, ATM

I. INTRODUCTION

Non service related signalling in GSM mobile networks is sensitive and often considered as a misuse of signalling in mobile networks. Altough mobile operators consider only challenging impacts that such signalling causes, there are many use cases that could introduce new services and revenue streams for all involved parties such as mobile number database cleaning, ATM anti-fraud checks, Least Cost Routing, resolving Number Portability issues, etc.

Usually there are four groups of interest:

- End user who has a mobile phone with a unique mobile number and IMSI.
- Mobile operator that holds the core and access network infrastructure as well as the connection to the HLR lookup providers.
- HLR lookup providers who are connected to the mobile network operators and provide HLR lookups to various enterprises translating obtained HLR data to a user-friendly format.
- Enterprises that implement various services (internal and external) based on HLR lookups.

All these parties share a common value chain and it is in their mutual interest to introduce services that are currently neglected.

A. Technical background

HLR (Home Location Register) lookup is a synonym for standardized SS7 MAP (Signalling System #7 Mobile Application Part) messages communication, *SRI_for_SM* and *SRI_for_Call* (Send Routing Information for Short Message/Call) [1], which are the mandatory „first part“ of signalling while sending SMS or initiating a call in mobile networks as described in figure 1.

To perform an HLR lookup, *SRI_SM_REQ* request with MSISDN (Mobile Station Integrated Services Digital Network Number) parameter is needed to be sent to users home MNO's (Mobile Network Operator) HLR which will respond with *SRI_SM_RESP* MAP message that includes users IMSI (International Mobile Subscriber Identity) number and its current serving MSC (Mobile Switching Centar) address. Example trace of described MAP procedure in figure 2 (request) and figure 3 (response). Due to the protection of privacy, user sensitive data is withheld in the figures.

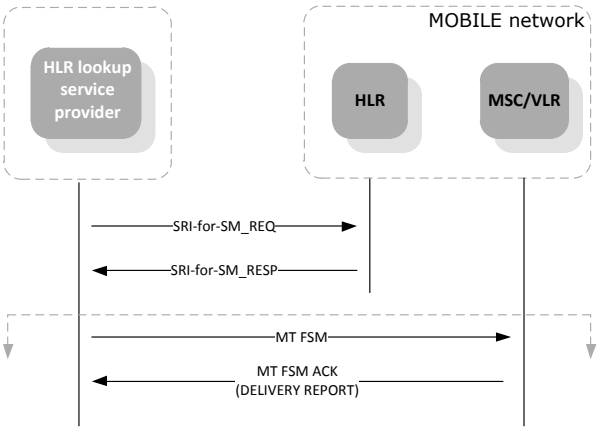

Figure 1.
Standard SMS sending MAP messages flow

As a parameter, *SRI_for_SM* request must have an MSISDN to be queried and the address of the serving HLR.
Within the *SRI_for_SM* response message, the needed information will be collected for further processing, such as IMSI and serving MSC.

There are five main parameters that can be extracted from submitted and collected signalling data:

```
-------------------------------------
MAP
-------------------------------------
Begin = begin (Begin)

     *******

parameter = local
         OP Code = 45 (SendRoutingInfoForSM)
         argument
         MAP-SM-DataTypes.RoutingInfoForSM-Arg
         msisdn = [redacted]

     *******

1------- Extension Bit = 1 (no extension)
         Address signals = [redacted]
         sm-RP-PRI = TRUE
         serviceCentreAddress = [redacted]

     *******

1------- Extension Bit = 1 (no extension)
         Address signals = [redacted]
```

Figure 2.
SRI_for_SM MAP request example

```
-------------------------------------
MAP
-------------------------------------
End = end (End)

     *******

parameter = local
         OP Code = 45 (SendRoutingInfoForSM)
         resultinfo
         MAP-SM-DataTypes.RoutingInfoForSM-Res
         imsi = [redacted]

         locationInfoWithLMSI
         msc-Number = [redacted]

     *******

1------- Extension Bit = 1 (no extension)
     Address signals = [redacted]
```

Figure 3.
SRI_for_SM MAP request example

1) SRI_for_SM request

From the MSISDN parameter it is possible to conclude the exact original network operator that holds this numbering range.

2) SRI_for_SM response

From IMSI number [2] it is possible to extract MCC (Mobile Country Code) and MNC (Mobile Network Code) that uniquely identify the current mobile operator that the end customer uses.

From the serving MSC/VLR (Visited Location Register) address, it is possible to conclude if the end customer is roaming, and if it is, in which country and which roaming network.

For example, if the MSISDN number to be queried is in the E.146 format [3] – 4479[redacted], when HLR lookup is completed, the results as follows:

MSISDN = 4479[redacted]
IMSI = 23415[redacted]
VLR = 6019[redacted]

Respective HLR analysis has to be performed as displayed in table 1.

TABLE I. HLR ANALYSIS EXAMPLE

MSISDN	**Original network provider**		
	CC	NDC	SN
	44	79	[redacted]
	United Kingdom	Vodafone Ltd	Subscriber No.
IMSI	**Home Network provider**		
	MCC	MNC	MSIN
	234	15	[redacted]
	United Kingdom	Vodafone Ltd	Mobile Sub. Identification No.
MSC / VLR address	**Current Network provider**		
	CC	NDC	SN
	60	19	[redacted]
	Malaysia	Celcom	Subscriber No.

Results of respective HLR analyses are interpreted as follows:

- According to the end customers' MSISDN one can conclude that its original network provider is from UK (United Kingdom) defined by its CC (Country Code) [3],[4], and that its operator, defined by NDC (National Destination Code) is Vodafone UK Ltd.
- According to the customers IMSI one can conclude that its current Network provider is from UK defined by its MCC [3] and that it is Vodafone UK Ltd. By the IMSI analysis one can conclude if the user has ported the number to another MNO (in which case IMSI will show a different MNC than the original one).
- According to the MSC/VLR address received from the HLR, one can conclude that this user is currently roaming due to the CC which shows that the roaming country is Malaysia and, according to the NDC, the users current MNO provider is Celcom.

In most cases SN (Subscriber Number) and MSIN (Mobile Subscriber Identification Number) can be discarded.

According to the HLR analysis, the final results are presented to the customer but with privacy concern as discussed by GSMA [5] SG (Security Group) where MSC/VLR and IMSI parts must be withheld from third parties [6].

II. IMPACT ON MOBILE OPERATORS

There are multiple impacts on the MNO's structure presented in figure 4. Each of those have positive and negative sides and should be treated case-by-case to find feasibility.

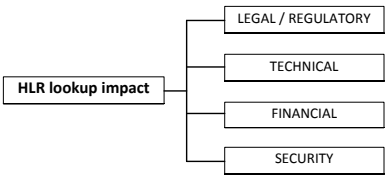

Figure 4.
HLR lookup service impact on mobile operators

A. *Legal / Regulatory impact*

According to national telecommunications or legal regulations in some countries (for example [7], [8]) there is a telecommunications operator responsible for keeping customer data private and not to disclose it to the third parties. This is the case where the third party provider doesn't have written consent of each customer. It is not clear if data such as IMSI is private or not if MSISDN is public. There are other cases that have no regulation at all (for example [9]).

As a positive legal impact, HLR lookup could be used to reduce growing frauds in financial sector such as ATM skimming fraud [10] which will be discussed in chapter IV.

B. *Technical impact*

Due to additional *SRI_for_SM* MAP messages (non-service related) there is more proccessing power needed by MNO's equipement than initially planned (HLR esspecially) that can cause overloads or the need for additional licences and hardware installations as well as some additional work-hours to be introduced within the MNO.

As a positive side, HLR lookups will ease the handling of outdated number databases by call/contact centres, financial institutions, etc. Resolving number portability issues for messaging hubs, VoIP (Voice over Internet Protocol) providers, virtual operators, etc.

C. *Financial impact*

There is additional signalling cost for *SRI_for_SM* MAP responses that operators are charged for from their signalling providers. There is an additional cost for workforce that handles the HLR lookup product line (altough this is not as significant).

As a positive, MNO's have additional revenue stream that can be very significant in comparison with overall costs caused by HLR lookup product line.

D. *Security issues*

There are several security issues reported that HLR lookup results are required to perform. Mainly those are eavesdropping and fraudulent SMS. All of them are eliminated if there is no complete/exact IMSI or MSC/VLR address provided or if parts of IMSI and MSC/VLR address that are not relevant to agreed use cases (such as subscriber number, etc ...) are masked.

HLR lookups can be partialy blocked by operators that implement SMS Home Routing procedure with some disadvantages of this procedure such as assurance of SMS delivery, additional cost for Home network operator, etc. described more detailed in [11].

III. ATM ANTI-FRAUD USE CASE

As an example of positive HLR lookup usage, ATM anti-fraud use case is presented and discussed. This use case is not only limited to ATMs but is also applicable to POS devices, credit cards, electronic banking and mobile payment.

A. *Problem*

Many of ATM card frauds are based on “card cloning” and cashing out in international destinations without the card owner approval or knowledge.

Let’s assume that an ATM card from client in Country A has been cloned/skimmed and replicated in Country B. The criminal in Country B goes to a local ATM and tries to initiate a cash-out with a fake ATM card, causing unwanted cost to the card owner, the bank and insurance companies. This case is described more in detail in [12], [13].

According to [14], in 2010. overall ATM skimming losses in European Union reached approximately €270.000.000 which has had great impact on all involved parties.

B. *Proposed solution*

Upon each ATM transaction, the bank or processing house has the possibility to check if a mobile phone of registered ATM card owner is in same country/region where ATM cash withdrawal is initiated as described in figure 5. According to the received result one can initiate appropriate action, such as:

- Allow withdrawal,
- Deny withdrawal and
  - Call the client to recheck the request directly,
  - Send one-shot password to repeat the transaction,
  - Initiate USSD session towards client to validate transaction.
  - etc.

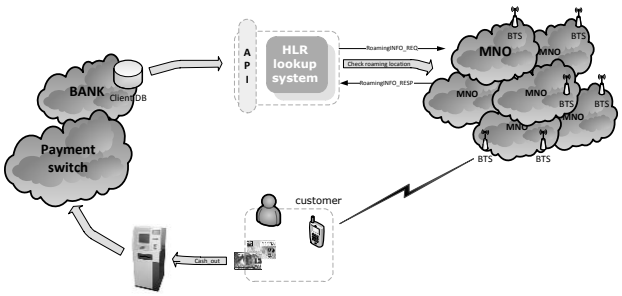

Figure 5.
HLR lookup check example

Potential drawbacks of the proposed solution are:

- ATM or Credit Card issuer must have written approval of the customer to initiate HLR lookups towards its MSISDN in some situations or upon each ATM/POS transaction.
- End user may not have a mobile phone nearby when travelling and initiating ATM/POS transactions.

If those cases are applicable, the credit card holder can fall back to the traditional, more complex and expensive, methods of validation ATM/POS transactions, such as phone calls or similar.

IV. CONCLUSION

This paper addresses the growing usage of HLR lookups in both unwanted but also preferred way. ATM anti-fraud use case clearly shows that the proposed solution is one way to fight growing fraudulent activities in the financial sector. Altough mobile operators consider HLR lookups as an unwanted or fraudulent non-service related signalling, there are many cases of new and secure revenue streams for all involved parties including the end customer who benefits with more secure and comfortable way of doing transactions, financial institutions that can decrease financial losses of ATM fraud, HLR lookup providers, signalling providers and mobile operators with new and sustainable revenue stream.

Implementacija IPv6 na OSPF usmjernički protokol

Dubravko Žigman, Igor Jesih, Nikolina Kasunić
Tehničko veleučilište u Zagrebu
Vrbik 8, Zagreb, Hrvatska
dzigman@tvz.hr, ijesih@gmail.com, nikolina@netakademija.com

Sažetak – Tijekom 2011. godine organizacijama koje upravljaju i raspodjeljuju IPv4 adresnim prostorom (Regional Internet Registry) dodijeljena je zadnja skupina slobodnih javnih adresa. Kako bi se omogućio daljnji rast "Interneta" nužno je ubrzati prijelaz na novu verziju – Internet protokol verzije 6 (IPv6), čija implementacija teče mnogo sporije od predviđenog. Novi protokol promijenjenog je dizajna, a neka od unaprijeđenja koja donosi su jednostavnije upravljanje mrežama, veliki adresni prostor te direktno povezivanje računala bez translatacija adresa.

I. UVOD

Snažni razvoj informatičke i komunikacijske industrije postavlja sve veće zahtjeve naspram mrežne infrastrukture. Sukladno tome, količina slobodnih javnih Internet adresa naglo se smanjivala te je krajem 2011. godine dosegla svoj minimum. Taj nadolazeći nedostatak slobodnih adresa prepoznat je prije više od 15 godina te kako bi se uklonio IETF je počeo razvijati novu verziju protokola. Funkcija protokola je da u budućnosti zamijeni tada aktualni Internet protokol verzije 4. Nakon dugog perioda koji je prošao od početka njegovog razvoja, došlo je vrijeme za globalnu implementaciju novog protokola – Internet protokola verzije 6. Kako bi se mogao koristiti operativni sustavi usmjernika i usmjernički algoritmi morali su proći mnoge preinake. Jedan od njih je i OSPF usmjernički protokol koji mnogim promjenama i dopunama prelazi u novu verziju 3.

II. INTERNET PROTOKOL VERZIJE 6

Internet protokol verzije 6 razvijen je s ciljem nadoknađivanja nedostataka već zastarjelog prethodnika, Internet protokola verzije 4, čija je glavna slabost nedostatak adresnog prostora. Kako bi se osigurala mogućnost daljnjeg rasta mreže, IPv6 adrese se počinju sve više koristiti. Operativni sustavi su spremni za njihovu primjenu, kao i veliki broj mrežne opreme kojoj je u nekim slučajevima potrebno samo nadograditi upravljački program. Iako znatno drugačiji, IPv6 se može promatrati kao nadogradnja prethodnog protokola te će ga tako i većina protokola transportnog i aplikacijskog sloja moći koristiti bez ikakvih modifikacija.

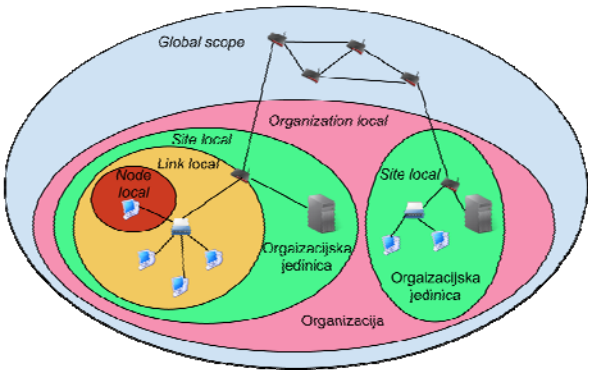
Osim većeg adresnog prostora, novi protokol više pažnje posvećuje sigurnosti. Sigurnosni mehanizam IPsec od sada je ugrađen u sam protokol putem dodatnih zaglavlja paketa koja pružaju enkripciju i autentifikaciju.

Velika promjena u odnosu na dosadašnji način funkcioniranja lokalnih mreža je izostavljanje NAT-a. Obzirom da adresni prostor pruža dovoljno veliki raspon adresa kako bi svaki uređaj imao jedinstvenu adresu, više nema potrebe za pretvorbama privatnih u javne adrese. Time se omogućava staro načelo rada TCP/IP protokola u kojem je zamišljeno da krajnji uređaji koji komuniciraju imaju jedinstvene adrese.

A. *Adrese*

IPv6 adrese sastoje se od 128 bita i time omogućavaju 2^{128} različitih kombinacija odnosno $3{,}4*10^{38}$ različitih adresa, što je dovoljno da svaki uređaj na svijetu posjeduje i više od jedne jedinstvene adrese. Adrese se zapisuju kao osam grupa po četiri heksadecimalna znaka, a organizirane su tako da minimalno prvih 64 bita označava mrežu dok ostatak identificira uređaj. Internet protokol verzije 6 odbacuje mogućnost slanja paketa svim uređajima na mreži te omogućava samo slijedeće načine grupiranja:

- unicast adresa – jedinstvena adresa uređaja na mreži.
- multicast adresa – označava grupu sučelja koja pripadaju različitim uređajima, a paketi namijenjeni multicast adresi dostavljaju se na sva sučelja unutar grupe. Sve multicast IPv6 adrese započinju s heksadecimalnom vrijednošću ff, što čini 1/256 adresnog prostora.
- anycast adresa – kao i multicast adresa označava grupu sučelja, s time da se paketi poslani prema takvoj grupi dostavljaju samo jednom pripadniku grupe.



Slika 1. Organizacija IPv6 adresa

IPv6 se uvelike bazira na multicast adresama koje ujedno i zamjenjuju broadcast adrese. Te adrese podijeljene su po grupama kako bi i usmjernički uređaji znali o kojem se tipu radi i u ovisnosti o tome obrađivali pakete te povećavali učinkovitost mrežne infrastrukture. Adrese su podijeljene prema segmentu kojeg pokrivaju. Grupiranje adresa je slijedeće [1]:

- *Node local scope* adrese – odnosi se samo na jedan uređaj.
- *Link local scope* adrese – odnosi se na sve uređaje spojene na istu mrežu.
- *Site local scope* adrese – odnosi se na sve uređaje unutar jedne poslovne jedinice.
- *Organization local scope* adrese – odnosi se na sve uređaje unutar organizacije.
- *Global scope* adrese – odnose se na cjelokupni Internet.

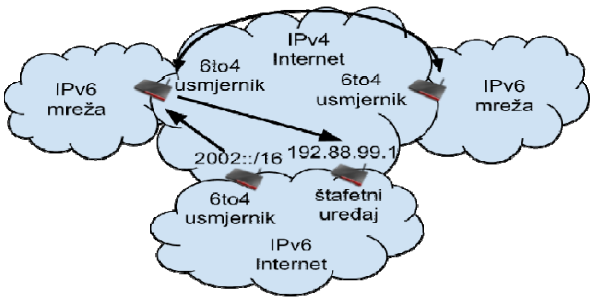
B. Prijelaz s verzije 4 na verziju 6

Kako bi se omogućio prijelaz, najprije je potrebno omogućiti pružateljima internet usluga korištenje protokola verzije 6 te zatim postepeno raditi na prijelazu krajnjih korisnika. Prijelaz je moguće izvršiti na više načina. Prvi je određivanje fiksnog dana prestanka korištenja IPv4 protokola. Iako ovaj način ima smisla, u praksi je neizvediv obzirom da dio infrastrukture i dalje ne podržava IPv6. Sljedeći pristup je uporaba uređaja koji podržavaju oba standarda. To je znatno prihvatljiviji pristup iako i on ima svojih nedostataka. Uređaji koji šalju pakete ne mogu znati je li na cijelom putu podržan IPv6, čime bi se nailaskom na IPv4 usmjernike podaci izgubili. Kako bi se doskočilo ovom problemu koriste se oba protokola, s time da se paketi prilikom napuštanja IPv6 domene, inkapsuliraju u IPv4 pakete te im se na povratku u IPv6 domenu, uklanja IPv4 zaglavlje [2]. Nakon prijelaza na verziju 6 treba ostaviti mogućnost korištenja "starog" protokola kako korisnici koji ga budu i dalje koristili ne bi bili uskraćeni za mogućnost korištenja Interneta.

C. Metoda prijenosa 6to4

Ova metoda omogućava prijenos IPv6 paketa preko IPv4 mreža bez konfiguracije određenih tunela. Koriste se javne IPv4 adrese pomoću kojih se stvaraju jedinstvene IPv6 adrese uređaja. Paketima se pridružuje generirana adresa te se takav IPv6 paket inkapsulira u IPv4 paket s tipom protokola 41.

Sve 6to4 adrese započinju s 2002::/16. Na to se nadodaje IPv4 adresa uređaja zapisana u heksadecimalnom formatu koja tvori /48 adresu. Kako su autokonfigurirane IPv6 adrese uvijek /64, do nadopune prefiksa ostaje još 16 bitova. U tom se slučaju nadodaje proizvoljna vrijednost ili jednostavno ::1. Ostatak od 64 bita je identifikator sučelja, odnosno EUI-64 adresa.



Slika 2. Metoda prijenosa 6to4

Kako bi ova metoda funkcionirala, potrebno je da usmjernik koji povezuje lokalnu mrežu na javnu podržava 6to4 adrese. Važno je i da usmjernik bude konfiguriran na način da njegov server za translataciju adresa propušta pakete s tipom protokola 41.

Prilikom komunikacije dva IPv6 otoka konfigurirana s 6to4 adresama preko IPv4 infrastrukture, pošiljatelj IPv6 pakete inkapsulira u IPv4 i kao takve šalje na javnu adresu odredišnog IPv6 otoka konfiguriranog s 6to4 adresom. Odredišni usmjernik skida IPv4 omot te mu ostaje IPv6 paket koji šalje do odredišnog klijenta.

Ukoliko se paket šalje na klijenta s globalno jedinstvenom IPv6 adresom, paket se na krajnjem usmjerniku konfiguriranim s 6to4 adresom, inkapsulira u IPv4 paket i šalje na rezerviranu adresu 192.88.99.1. Ta adresa predstavlja ulaz paketa s 6to4 adresama na "IPv6 Internet". Tu se uklanja IPv4 zaglavlje i paket se dalje usmjerava kao pravi IPv6 paket. Prilikom odgovora, odnosno povratka paketa na IPv4 Internet, koristi se princip komunikacije kao kod dva usmjernika konfigurirana s 6to4 adresama.

D. Metoda prijenosa Teredo

Ova vrsta tuneliranja prenosi IPv6 paket preko IPv4 mreže, ali razlikuje se od prethodno opisane metode u tome što ne zahtjeva da IPv4 adresa bude javna. Metodom prijenosa Teredo omogućeno je korištenje i iza uređaja za translataciju adresa u lokalnim mrežama koji nisu posebno konfigurirani.

Radi na principu inkapsuliranja IPv6 paketa u UDP pakete, koji mogu biti usmjeravani kroz uređaj za translataciju adresa i dalje na Internet.

Teredo tuneliranje uključuje sljedeće uređaje:

- Teredo klijent – IPv4/IPv6 uređaji koji imaju adaptere i komuniciraju s drugim klijentima ili IPv6 mrežama preko Teredo štafetnih uređaja. Oni se u pravilu nalaze iza uređaja za translataciju adresa.
- Teredo server – server povezan na IPv4 i na IPv6 mrežu. Služi za konfiguraciju Teredo klijenata i inicijalizaciju prijenosa paketa u slučaju kada se klijenti nalaze iza ograničenog uređaja za translataciju adresa.
- Teredo štafetni uređaj – server povezan na IPv4 i na IPv6 mrežu. Povezuje Teredo klijente s IPv6 mrežama.

Prilikom generiranja IPv6 adresa za Teredo klijente, šalje se zahtjev za adresom prema Teredo serveru koji vraća potrebne parametre. Adresa se generira na slijedeći način:

1. Teredo prefiks 2001 (32 bita)
2. IPv4 adresa Teredo servera u heksadecimalnom zapisu (32 bita)
3. Zastavice – sadrži oznaku vrste uređaja za translataciju adresa (16 bita)
4. Broj vanjskog UDP porta koji je pridružen od uređaja za translataciju adresa, a nad kojim je izvršena operacija ekskluzivno ili s heksadecimalnom vrijednošću FFFF (16 bita)
5. Vanjska IPv4 adresa uređaja za translataciju adresa nad kojom je izvršena operacija ekskluzivno ili s heksadecimalnom vrijednošću FFFF (16 bita)

Nakon što klijent iz dobivenih podataka generira IPv6 adresu, može započeti komunikaciju s ostalim Teredo klijentima i IPv6 mrežama. Ovisno o vrsti uređaja za translataciju adresa, povezivanje potpomaže Teredo server, a kada je veza uspostavljena klijenti mogu samostalno komunicirati. Time se smanjuje opterećenje servera i ubrzava komunikacija.

III. OSPF VERZIJE 3

Većina OSPF procesa ostaje nepromijenjena u odnosu na OSPF za IPv4. Među najznačajnijim novostima koje donosi IPv6, a imaju utjecaj na OSPF protokol je drugačija organizacija mreža bez ranije poznatih podmreža. Tako sada dva uređaja koja se nalaze na istoj vezi, unatoč tome što nemaju istu podmrežu, mogu međusobno komunicirati. Uzimajući u obzir tu činjenicu, OSPF za IPv6 radi po vezama, a ne po podmrežama kako je to bilo na IPv4 mrežama. Navedene promjene utjecale su na OSPF pakete kao i na hello pakete te pakete stanja veze. Tako usmjernički i mrežni paket stanja veze više ne sadrže mrežnu adresu, već samo nose informacije o topologiji.

Svi usmjernici se u OSPF IPv6 procesu identificiraju samo putem ID oznake usmjernika, obzirom da je ID oznaka usmjernika, područja i paketa stanja veze ostala duljine 32 bita te joj nije moguće pridružiti IPv6 adresu .

Kako bi mreža mogla funkcionirati, sučeljima usmjernika je potrebno dodijeliti IP adrese. Kod IPv6 mreža, sučeljima se dodjeljuju link-lokalne adrese u svrhu otkrivanja susjeda ili auto-konfiguracije.

Dodijeljene link-lokalne adrese na svim sučeljima usmjernika, osim virtualnih, koriste se kao izvorišne adrese svih paketa koje usmjernik šalje. Usmjernici uče link-lokalne adrese svih susjednih usmjernika te ih koriste kao adresu slijedećeg skoka prilikom prosljeđivanja paketa.

Promjene u zaglavlju OSPF paketa [3]:

- OSPF verzija je promijenjena, trenutno verzija 3
- Polje opcija je povećano na 24 bita i premješteno iz zaglavlja u sam paket
- Hello paket više ne sadrži adresu, već identifikacijsku oznaku sučelja koju je usmjernik dodijelio kao jedinstvenu identifikacijsku oznaku na toj vezi
- U zaglavlju paketa se sada nalazi i oznaka instance OSPF protokola, čime je omogućeno da se više instanci OSPF-a vrti na istoj vezi.

Osnovne promjene u LSA paketu:

- Tip paketa stanja veze proširen je na 16 bita u polje gdje su se ranije nalazile opcije
- Adrese se prikazuju kao mrežni prefiksi i dužina prefiksa, a ne kao adresa i mrežna maska
- Usmjernički i mrežni paketi stanja veze više ne sadrže adrese te su postali neovisni o mrežnom protokolu

Uz promjene u samom paketu stanja veze, dodani su novi te preimenovani neki od već postojećih paketa. Tako se primjerice ASBR sumarni paket stanja veze u verziji 3 naziva Inter-area usmjernički paket stanja veze, a sumarni mrežni paket stanja veze je inter-area prefiks paket.

Od novih paketa, dodani su Link lokalni paket i Intra-area prefiks paket. Link lokalni paket pruža link lokalnu adresu (prefikse) svim usmjernicima spojenim na vezu te sadrži listu svih IPv6 prefiksa na linku na kojem se i objavljuje. Intra-area prefix paket stanja veze upravlja informacijama unutar područja umjesto mrežnog paketa. Objavljuje ga imenovani usmjernik i sadrži IPv6 prefikse u području [4].

Prošireno je i područje slanja paketa stanja veze. Postoje tri opsega za slanje paketa:

- Link-lokalni opseg – paket se šalje samo na lokalnom linku
- Opseg područja – paket se šalje samo unutar područja u kojem je nastao
- Opseg autonomnog područja – paket se šalje kroz cijelu usmjerničku domenu

Uz sve navedeno došlo je i do promjene u izvođenju SPF algoritma. IP adrese se više ne koriste tijekom kalkulacije SPF stabla. Novo uvedeni Intra-area prefiks paket stanja veze upravlja mrežama koje se nalaze unutar područja umjesto mrežnog paketa koji je vršio tu ulogu u OSPFv2. Obzirom da se adresiranje vrši neovisno o paketima stanja veze koji se koriste u kalkulaciji SPF stabla, dodavanje ili modificiranje OSPF domena nema utjecaja na integritet SPF stabla, čime se izbjegava njegova rekalkulacija.

IV. PRIMJER KONFIGURACIJE OSPF PROTOKOLA VERZIJE 3

Kako bi se detaljnije naglasile razlike između OSPF protokola verzije 2 i verzije 3, biti će prikazana konfiguracija protokola verzije 3 između dva Cisco usmjernika spojena *point-to-point* vezom.

Najprije je potrebno naredbom *ipv6 unicast-routing* omogućiti prosljeđivanje IPv6 datagrama.

Konfiguracija OSPF procesa je slična je onoj verzije 2, s time da je potrebno eksplicitno unijeti identifikacijsku oznaku usmjernika, s obzirom da je ona ostala dužine 32 bita i nije ju moguće konfigurirati iz neke od IPv6 adresa. Također nema potrebe niti za konfiguracijom autentifikacije jer se koristi sigurnosno zaglavlje IPv6 paketa.

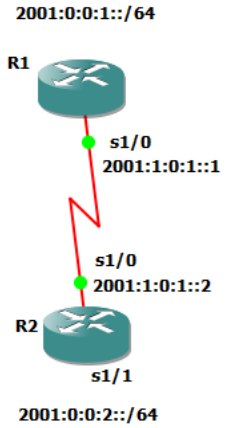
Konfiguracija sučelja s IPv6 adresom omogućava se naredbom *ipv6 enable* prilikom konfiguracije. Tom se naredbom sučelju pridružuje link lokalna adresa oblika *FE80::EUI-64*, koja bi i sama trebala biti globalno jedinstvena obzirom na uvjet za jedinstvenost MAC adrese iz koje se računa EUI-64 ostatak. Prema potrebi, sučelju je moguće definirati i globalno jedinstvenu adresu putem naredbe *ipv6 address adresa*. U zadnjem koraku potrebno je sučelje pridružiti OSPF procesu naredbom *ipv6 ospf x area y*.

Prikazana konfiguracija je dovoljna za korištenje unutar jednostavnije mreže potpomognute OSPF protokolom verzije 3.

Konfigurirana topologija prikazana je na slici 3. te su dobiveni slijedeći ispisi konfiguracije.

Naredbom *show ipv6 ospf interface s1/0* na usmjerniku R1 dobivene su informacije vezane za konfiguraciju sučelja i pridruženog ospf procesa:

- Prikazana je link lokalna adresa sučelja obzirom da se ona koristi kao referentna za OSPF proces - *FE80::C800:1FF:FEAC:0*
- Identifikacijska oznaka usmjernika – *1.1.1.1*
- Identifikacijska oznaka sučelja – *5*
- Vrijednosti vremenskih brojača
- Tip veze koja se koristi na sučelju



Slika 3. Primjer konfiguracije OSPFv3

Naredbom *show ipv6 route* dobiva se usmjernička tablica. Ovom naredbom na usmjerniku R1 dobiva se slijedeći ispis:

O 2001:0:0:2::/64 [110/128]

via FE80::C801:1FF:FEAC:0, Serial1/0

C 2001:1:0:1::/64 [0/0]

via Serial1/0, directly connected

L 2001:1:0:1::1/128 [0/0]

via Serial1/0, receive

C 2001:0:0:1::/64 [0/0]

via Serial1/1, directly connected

L 2001::1:c800:1FF:FEAC:0/128 [0/0]

via Serial1/1, receive

L FF00::/8 [0/0]

via Null0, receive

Ispis sadrži direktno spojene mreže na usmjernik s oznakom C i mrežu s oznakom O konfiguriranu na usmjerniku R2 koja je primljena putem OSPF procesa. Zapis s oznakom L označava adresu sučelja spojenog na usmjernik.

V. ZAKLJUČAK

Iako je Internet protokol verzije 6 budućnost Interneta, njegovo uvođenje teče izrazito sporo. U listopadu 2011. godine tek je 3% ukupnog broja internetskih domena imalo IPv6 zapise na domenskim serverima, dok je u globalnim BGP usmjerničkim tablicama tek 12% mreža imalo IPv6 podršku.

OSPF kao protokol za usmjeravanje unutar autonomnih sustava u verziji 3 u potpunosti je prilagođen uporabi na mrežama konfiguriranim Internet protokolom verzije 6. Jedini je uvjet posjedovanje usmjernika koji ga podržavaju, a s njima i lokalnih mreža s opremom novije generacije koja je u mogućnosti već danas prijeći na novi protokol. Unatoč tome, naša komunikacija preko Interneta će još neko vrijeme biti bazirana na tranzicijskim metodama prijenosa.

***Abstract*—The goal of this paper was to develop a Simple Access Object Protocol (SOAP) Parlay X Web service interface that supports standard GSM modems and can be used as development and testing environment for SMS based applications. The service interface was translated into Java classes from a selected set of Parlay X version 2.1 Web Service Description Language (WSDL) files providing mandatory SMS functionality. SendSms, ReceiveSms, NotificationManager and SmsNotification Web services were fully implemented. Other Parlay X services (e. g. MMS, ringtone services and other) can be built in a similar fashion and easily integrated into the system architecture. The service backend was implemented using Java wrapper classes that mimic the described Web services, their datatypes and membership functions. The SIM300 GSM modem was used to transmit and receive SMS, while a MySQL database schema was used as interface between the modem and the service interface. Handler classes (also implemented in Java) were used as modem behaviour controller, while the database connection was established using the Java Database Connectivity classes provided by Oracle. Detailed System architecture, implemented Web services functionality, database structure and Message Sequence Charts are given.**

Keywords — Parlay, Parlay X, SMS, SOAP, SMS gateway, SIM300, WSDL.

I. Introduction

With the emerge of Next generation networks (NGN), Service oriented architecture has become the dominant software architecture in telecommunicational software engineering. Web service frameworks usually provide an emulator which gives software developers a simulation platform to test the developed Web services. Those services usually depend on existing telecommunicational services (e.g. SMS and MMS services) defined by their respective standard. In order to test such services with real world data it is necessary to embed external communication functionality into the emulator.

As is shown in [1] the current trend on service provision in telecoms is based on open interfaces and protocols exposing core network functions. The use of standardized interfaces to interract with the network is a significant factor contributing transparency, modularity, reusability and clear distribution of administrative responsibilities to the service development process. In the paper [2] the Parlay X approach was adopted for exposing telecom capabilities as well as notifications of telecom-related information from the IMS (IP Multimedia Subsystem) network to the Web 2.0 domain. The telecom industry is gravitating towards a standard definition of a service delivery platform, which embraces telecom Web Services coupled with partner management, as an important element in service delivery [3].

The paper is organized as follows. A short overview of related work is presented in section 2. In section 3 the system architecture is described. Detailed information about the database schema is given in section 4. The implemented Parlay X SMS Web services are described in section 5. Conclusions and further research guidelines are discussed in the final section.

II. Related work

Mobile devices have limited resources and low bandwidth. Due to cellular data characteristics, interacting with Web Services from a mobile phone is problematic using plain HTTP. In order to increase the performance of mobile devices during the access of Web Services, telecommunication services are used. Therefore, the paper [4] describes Web services with SOAP binding for SMS protocol utilization.

In papers [5], [6], [7] the authors have made an integration of GSM modem and software solutions developed according to their needs, but in fact they did not observe a single standard for this type of integration, which made their solution inflexible, non-modular and difficult to administer.

This paper proposes a design to create a software system that provides mandatory SMS functionality with a standardized Parlay X SOAP Web service interface. The developed software implemented using the proposed approach can easily be integrated into existing Java based network simulators.

III. System architecture

The system architecture is shown in Fig. 1. It consists of three layers: the service layer, the interface layer and the core layer. The service layer is based on the multitier

service oriented architecture. SOAP Web services provide the Web interface to the external service consumers. The service interface translates Web service input data into database data and vice versa. The DataAccessObject (DAO) of the service layer is a object wrapper to the database. This way a classical delegate pattern is implemented via the shared database tables. The core layer handles the stored output data from the database and sends it to the receiving terminal units. When a new SMS is received it is stored via the core layer into the database and accessed by the relevant consumer via the respective Web service. The interface layer is used as middleware between the core and service layer and is used as asynchronous event notification from the core to the service layer. This way the notification service can be called from the core layer to notify subscribed clients.

IV. Database Structure

The Entity relationship diagram (ERD diagram) of the database is shown in Fig. 2. The tables can be divided into two groups: inbox tables and outbox tables. Each message the modem receives is stored into the Inbox table. Each received message is matched against ClientList correlators provided by the service clients. The respective client is notified via his endpoint and interface name in case that the message matches his correlator. That way a software link between the Inbox and ClientList table exists. When a client invokes the Web service method named sendSms, the SMS message, as earlier explained, is first stored into the Outbox table and a unique delivery id is generated and returned to the client. The modem processes the message queue using the FIFO priority approach. A unique modem delivery id is generated for each message that the modem sends to the network. The modem delivery id and outbox table delivery id form a unique pair that is used for delivery status updates. The Client can send a SMS using optional fields providing message status tracking. Whenever a message status is updated via the network, the corresponding delivery id is matched with the registered delivery ids in the OutboxNotificationList. If a match is found then the respective client is notified via the provided endpoint and interface name.

V. Web Services

The autogenerated Apache Tomcat list of hosted Web services and their respective methods is shown in Table I. Those whoare familiar with the Parlay X standard will recognize the Target namespace and the Endpoint address, as they are strictly predefined by the standard (As a side note, all Web service and method names are case sensitive). As we can see the ReceiveSms, SendSms and SmsNotificationManager Web services were implemented [8], [9].

To get better understanding of how each system component interacts during we will analyze Message Sequence Charts (MSC) for typical system scenarios.

The MSC of the getReceivedSms method from Table I is shown in Fig. 3. By invoking this method the user requests from the SMS Gateway all received short messages that

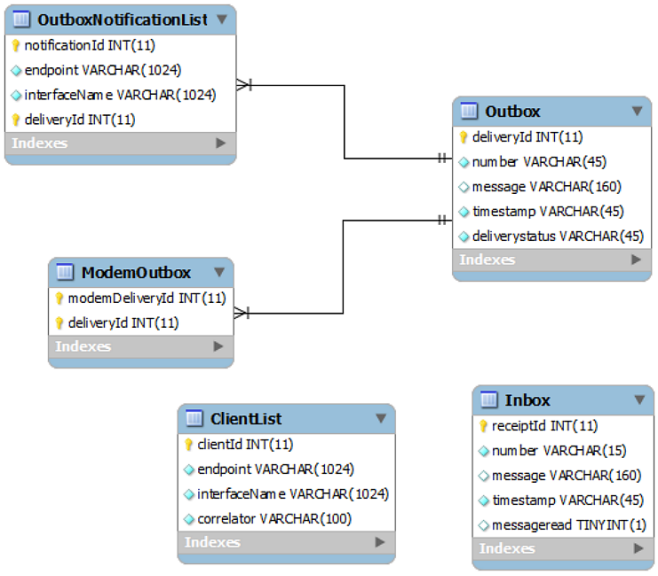

Fig. 2. Entity relationship diagram of the database schema

match the provided request correlator. This request is delegated into the database by calling the function DaoGetReceivedSms which returns the requested inbox message list.

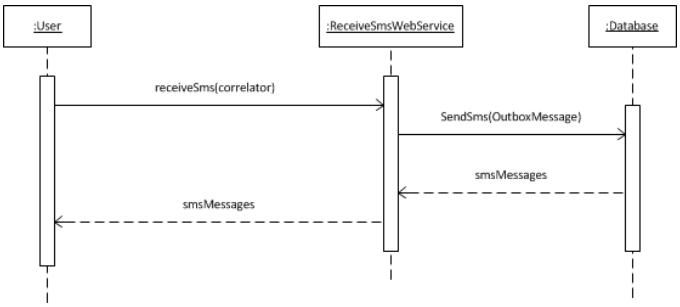

Fig. 3. MSC of the getReceivedSms method from the ReceiveSms web service

To be able to list received SMS we need to receive short messages. This scenario is shown in Fig. 4. The short messages arrive asynchrony from terminal devices and are stored into the modems' buffer. The Receiver class gets notified via a message tracking notification generated from the modem over serial port. When a new message arrives the Receiver class stores it into the database and deletes it from the modems' buffer.

The MSC of the sendSms method from Table I is shown in Fig. 5. By invoking this method the client requests from the SMS Gateway to send the short message provided in the request. This request is delegated into the database and the system creates a unique identifier for this message which is returned to the client. The Modem Core checks periodically if there is a short message for delivery in the database and delivers it to the client if such message exists. The network asynchrony returns status notifications of the delivery which the Modem Core updates in the database.

TABLE I
SMS GATEWAY AVAILABLE SOAP WEB SERVICES

ReceiveSms: • getReceivedSms	Endpoint address: http://146.185.20.25:8080/ParlayXSmsServices/services/ReceiveSms WSDL: {http://_interface.v2_1.receive.sms.parlayx.wsdl.csapi.org/}ReceiveSmsService Target namespace: http://_interface.v2_1.receive.sms.parlayx.wsdl.csapi.org/
SendSms: • sendSms • getSmsDeliveryStatus	Endpoint address: http://146.185.20.25:8080/ParlayXSmsServices/services/SendSms WSDL: {http://_interface.v2_1.send.sms.parlayx.wsdl.csapi.org/}SendSmsService Target namespace: http://_interface.v2_1.send.sms.parlayx.wsdl.csapi.org/
SmsNotificationManager: • startSmsNotification • stopSmsNotification	Endpoint address: http://146.185.20.25:8080/ParlayXSmsServices/services/SmsNotificationManager WSDL: {http://_interface.v2_2.notification_manager.sms.parlayx.wsdl.csapi.org/}SmsNotificationManagerService Target namespace: http://_interface.v2_2.notification_manager.sms.parlayx.wsdl.csapi.org/

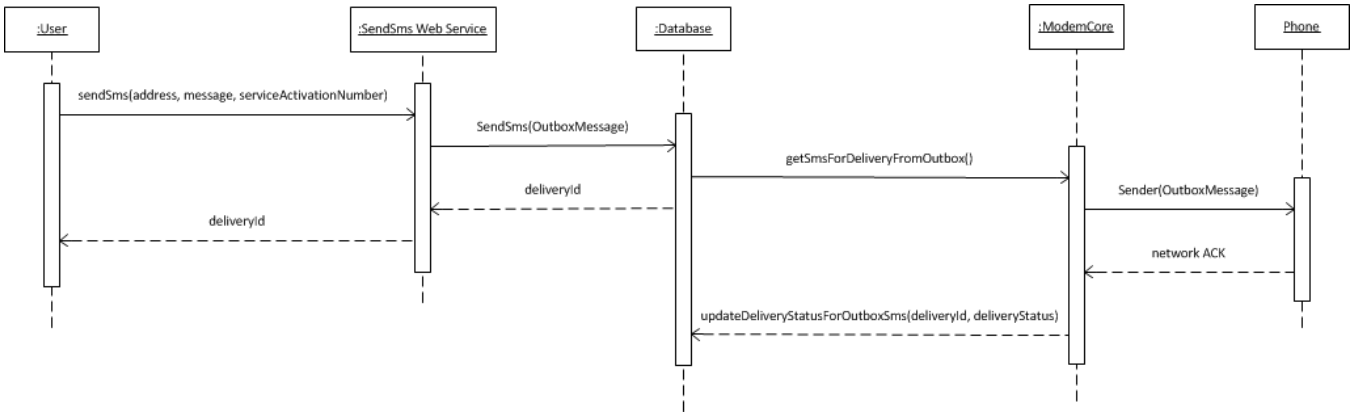

Fig. 5. MSC of the sendSms method from the SendSms Web service

The MSC of the getSmsDeliveryStatus method from Table I is shown in Fig. 6. The client passes the unique identifier he got when he sent a short message and the system returns the status of the message as defined in [8].

It is even possible to track the send short message by using the NotificationManager Web service. The MSC of the startSmsNotification and stopSmsNotificationMethods are shown in Fig. 7. and Fig. 8., respectively. The startSmsNotification method serves as subscription for message tracking, while stopSmsNotification cancels the active subscription.

The MSC of the sendSms method from the SendSms Web service with active short message tracking is shown in Fig. 9. The message flow is the same as in Fig. 5 with only difference that the client is receives status updates provided by the network. In order to be able to receive those notifications the client needs to implement the server side of the SmsNotification Web service given in [8], while the SMS gateway possess a client side implementation of this service.

VI. Conclusion

This paper presented a design approach to implement a SMS Gateway software. The proposed design is based on a stack multitier software architecture with SOAP Web service interface. The Web service interface was built from Parlay X version 2.1 Web service WSDL files. Detailed database ERD schema and implemented Web services MSC were given. The implemented software based on the proposed design can easily be integrated into a Network simulator. Other Parlay X functionalities, e. g. Call and MSM services, can easily be added which is result of the proposed layered architecture.

Further research will cover the following topics:

- **Full Parlay X version 2.1 standard implementation:** As earlier explained only mandatory SMS functionality was provided in this implementation. The first step in the future would be to extend the system to provide full SMS functionality as per standard. After that other Parlay X defined Web services, e. g. Call and MSM services, should be implemented.
- **Emulator integration:** The primary goal of this paper was to provide a hardware software solution suited for real world data Web service testing. To achieve this goal it is necessary to find an emulator into which the implemented solution could be embedded.
- **SMS router:** The system design could be reused with

slight modifications to create a SMS router consisting of multiple SMS Gateways.

- **Modem compatibility:** In order to cover a vast range of modem models it is required to do further research on minimal modem AT command set that is necessary to implement all system requirements.

NgP
Protokol za dogovor parametara

S. Brčina, L. Kovačević, M. Marić, M.Mikuc, T. Marini, V. Pokornić, V. Vasić i R. Vežnaver
Fakultet elektrotehnike i računarstva, Zagreb, Hrvatska

Nedostatak većine današnjih sigurnosnih protokola poput SSH, SSL, IPsec, PPP, TSL i sličnih je taj što se, pomoću unaprijed poznatih algoritama, dogovaraju oko razmjene ključeva za sigurnu komunikaciju, a da pri tome ne daju fleksibilnost odabira samih algoritama. S obzirom na to da danas postoji nekoliko različitih preporuka o tome koje algoritme koristiti (uz preporučenu duljinu ključa), nameće se ideja o protokolu koji bi služio za dogovaranje algoritma koji najviše odgovara i jednom i drugom sugovorniku u komunikaciji. U radu je opisan protokol NgP (Negotiation Protocol) koji omogućava međusobno dogovaranje mrežnih čvorova o kriptografskim algoritmima koje će koristiti prilikom daljnje međusobne komunikacije. Protokol je osmišljen i implementiran tako da omogućuje sigurnu razmjenu i dogovor parametara između dva ravnopravna čvora. Sigurnosni zahtjevi obuhvaćaju zaštitu integriteta i autentifikaciju. Protokol je prvotno specificiran, te potom verificiran pomoću programskih alata za simulaciju Petrijevih mreža. Implementacija je izvedena u programskom jeziku Python i validirana u sklopu mrežnog simulatora/emulatora IMUNES. Kao rezultat dobivena je aplikacija koja je u potpunosti kompatibilna s operacijskim sustavom FreeBSD i programskim alatom IMUNES.

I. UVOD

Zahtjevi za protokol koji služi dogovaranju kriptografskih algoritama su: jednostavnost, brzina, efikasnost, nadogradivost i sigurnost.

Protokol mora biti jednostavan zbog lakše integracije i implementacije u već postojeće aplikacije. S obzirom na to da je predviđena mogućnost dogovora prije svake nove veze između računala, protokol je rađen da bude brz i da što efikasnije troši dostupne mrežne resurse.

Sigurnost protokola se temelji na zaštiti integriteta poruka digitalnih potpisom, a lista kriptografskih algoritama nije specificirana unutar protokola već se ona definira unutar implementacije, što omogućuje laku nadogradnju protokola.

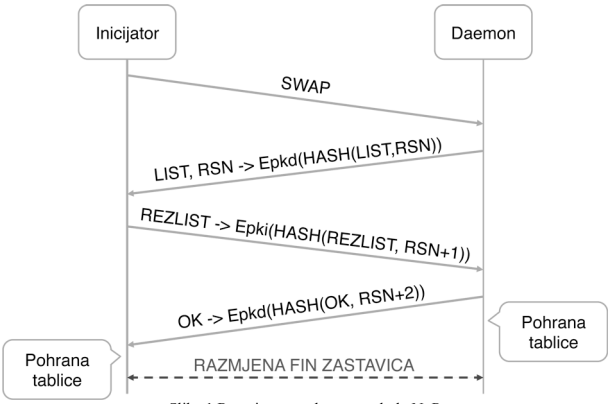
II. SPECIFIKACIJA

A. Entiteti

Poruke protokola se razmjenjuju između dva ravnopravna entiteta: *inicijator* i *daemon*. *Inicijator* započinje pregovaranje, a *daemona* se poziva na pregovaranje. Njihove uloge su „gotovo“ ravnopravne. Ishod dogovora je isti neovisno o tome koji čvor je inicijator, odnosno nikome se ne daje pravo većeg prioriteta. Međutim, postoje stanja u kojima su konflikti neizbježni te se takva stanja rješavaju davanjem prioriteta inicijatoru.

B. Poruke

Protokol NgP sastoji se od četiri poruke.



Slika 1 Razmjena poruka u protokolu NgP

1) SWAP

Poruku SWAP šalje inicijator. Ona postoji zbog sprečavanja napada ponavljanjem (*replay attack*) – daemonu se daje odgovornost da generira početni slučajni broj (RSN). Bez poruke SWAP napadač bi mogao snimiti promet inicijatora i daemona te u budućnosti koristiti spremljene poruke kako bi izazvao napad ponavljanjem koristeći se krivotvorenjem IP adrese (*IP spoofing*).

2) LIST

DULJINA	LIST, RSN	\0HASH\0	Ekpd(HASH,(LIST,RSN))

Slika 2 Izgled poruke LIST

Poruku LIST daemon šalje inicijatoru. U poruci LIST se prenosi lista poznatih kriptografskih algoritama s kojima je daemon spreman pregovarati. Lista se šalje skupa sa RSN brojem, te se lista i RSN zajedno *hashiraju* te se *hash* potpisuje privatnim ključem daemona. Lista i RSN te potpis su međusobno razmaknuti sa nizom bajtova „\0HASH\0“. Duljina cijele poruke se šalje u prva četiri bajta u poruci zbog tokovne orijentiranosti protokola TCP i sprječavanja *buffer overflow* napada.

3) REZLIST

DULJINA	REZLIST	\0HASH\0	Ekpd(HASH,(LIST,RSN+1))

Slika 3 Izgled poruke REZLIST

Poruku REZLIST inicijator šalje daemonu. Poruka REZLIST (rezultantna lista) prenosi listu dogovorenih

algoritama koju je inicijator stvorio na temelju algoritma dogovora. Za razliku od poruke LIST, poruka REZLIST ne prenosi RSN u otvorenom formatu nego samo unutar *hasha* jer je daemonu poznato koji broj mora biti u potpisu. Poruka se potpisuje privatnim ključem inicijatora. Koristi se isti niz znakova za razdvajanje informacija od njihovog potpisa i duljina od 4 bajta polja DULJINA kao i kod poruke LIST.

DULJINA	OK	\0HASH\0	Ekpd(HASH,(LIST,RSN+2))

Slika 4 Izgled poruke OK

4) OK

Poruku OK daemon šalje inicijatoru. To je poruka potvrde od strane daemona prema inicijatoru da je primio ispravnu rezultantnu listu. U trenutku primitka inicijator pohranjuje dogovorene algoritme s računalom na kojem se vrti daemon (daemon ih sprema nakon provjere ispravnosti potpisane REZLIST poruke i poslane poruke OK). Koristi se isti format poruke kao i kod poruke REZLIST, samo što je RSN uvećan za jedan. Poruka OK se potpisuje zbog mogućeg zlonamjernog prijevremenog pokušaja raskida komunikacije. Kada OK poruka ne bi bila potpisana napadač bi mogao izazvati pogrešku na REZLIST i poslati OK inicijatoru, što bi inicijator shvatio kao da je dogovor postignut iako daemon nije pohranio rezultantnu tablicu.

C. Analiza protokola

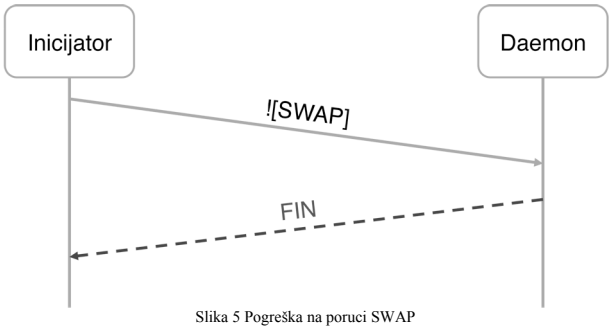
Mogu se razlikovati četiri scenarija u kojima napadač može kompromitirati podatke koji se prenose između inicijatora i daemona. Osnovni zahtjev na protokol je *konzistentnost dogovora*, te da bi taj zahtjev bio ispunjen svaki scenarij mora završavati s jednom od dvije mogućnosti:

- Inicijator i daemon nisu ništa dogovorili
- Dogovorili su se i dogovor je postignut prema algoritmu dogovora s točnim ulaznim podacima njihovih listi poznatih algoritama.

Ako je jedna od ovih dviju odrednica ispunjena tada inicijator i daemon završavaju u konzistentnim stanjima, u suprotnom završavaju u nekonzistentnim stanjima.

1) Napad na poruku SWAP

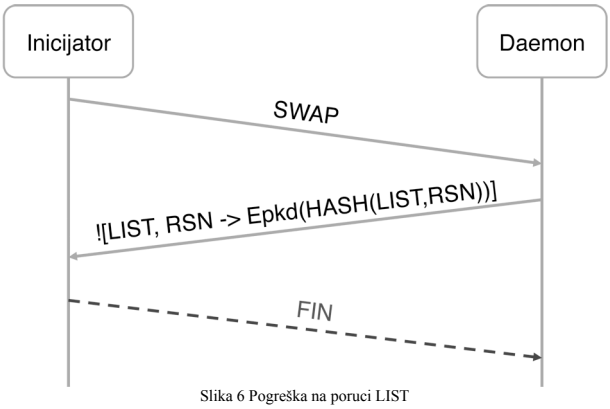
Slika 5 prikazuje prvi scenarij u kojemu se događa zlonamjerni napad. Ovo je primjer klasičnog napada *denial-of-service* (DoS) gdje napadač nastoji prekinuti pokušaj dogovora. Međutim, inicijator i daemon nisu ništa dogovorili, što olakšava implementaciju protokola.



Slika 5 Pogreška na poruci SWAP

2) Napad na poruku LIST

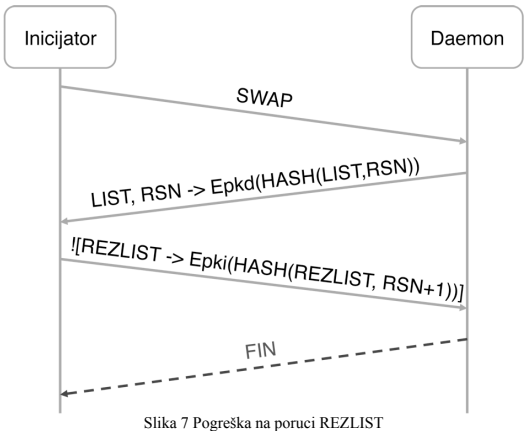
Drugi slučaj ometane razmjene poruka se događa zlonamjernim napadom na poruku LIST. Ovo je primjer napada *bidding down* kojim bi napadač pokušao promijeniti listu kriptografskih algoritama prioritizirajući slabije, te u budućnosti lakše utjecati na komunikaciju inicijatora i daemona. Napad je spriječen digitalnim potpisom, te oba entiteta završavaju u konzistentnim stanjima.



Slika 6 Pogreška na poruci LIST

3) Napad na poruku REZLIST

U trećem scenariju napadač pokušava promijeniti REZLIST poruku, što mu još više pogoduje napadu *bidding down* jer direktno utječe na dogovorenu listu. Kao i u prošlom scenariju, napad je spriječen mehanizmom digitalnog potpisa. Inicijator i daemon se nalaze u konzistentnim stanjima.



Slika 7 Pogreška na poruci REZLIST

4) Napad na poruku OK

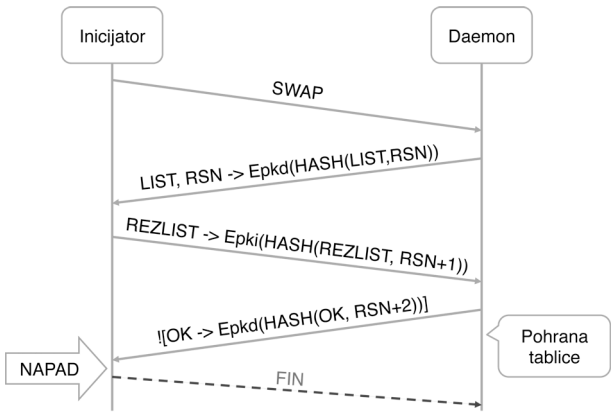
Zadnji scenarij razmjene poruka jest jedini slučaj u kojemu inicijator i daemon mogu završiti u nekonzistentnim stanjima. Ukoliko inicijator primi poruku OK s pogreškom, to može značiti sljedeće:

a) napadač je promijenio poruku OK, a daemon je zapamtio dogovor

b) napadač je napao poruku REZLIST i poslao promijenjenu poruku OK prije bilo kakvog odgovora od daemona

Inicijator ne može znati koji se slučaj dogodio, međutim može zaključiti da se napadač umiješao. Iz tog

razloga inicijator nanovo pokreće postupak dogovora jer postoji mogućnost da on i daemon nisu u konzistentnim stanjima.



Slika 8 Pogreška na poruci OK

D. *Algoritam dogovora*

Algoritam dogovora provodi inicijator. Dogovor se provodi na temelju tablice koju je primio od daemona i svoje koju ima pohranjenu. Svaka tablica se sastoji od tri liste:

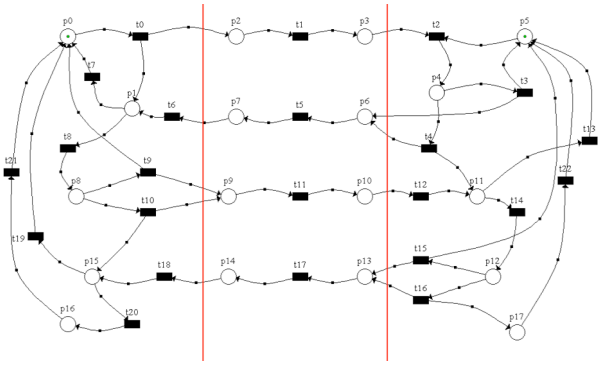
- lista poznatih kriptografskih algoritama raspršivanja (*hash* algoritmi)
- lista poznatih kriptografskih algoritama simetričnog ključa
- lista poznatih algoritama javnog ključa

Svakom algoritmu u svakoj listi je pridružen prioritet kojim se taj algoritam prioritizira na nekom entitetu. Entiteti imaju različite prioritete za svoje algoritme jer različito vjeruju u njihovu snagu. Algoritmi koje neki entitet ne pozna se ne mogu uzimati u obzir pri dogovoru, ali one koje poznaju oba entiteta se uzimaju u dogovor tako što se koristi princip *„slažemo se oko nečega onoliko koliko se najmanje slaže netko od nas“*. Drugim riječima uzima se najmanja preferencija dva entiteta kao mjera za slaganje oko nekog algoritma. Najveća složnost (maksimum od svih minimuma) za npr. kriptografski algoritam simetričnog ključa daje algoritam koji je dogovoren. Ukoliko je najveća složnost postignuta za više algoritama uzima se onaj s najvećim prioritetom koji nema prioritet jednak složnosti. I samo u krajnjem slučaju, ako se nađu algoritmi za koje nije moguće odlučiti po prije navedenim osnovama, odlučuje se u korist inicijatora.

III. VERIFIKACIJA

Verifikacija protokola NgP izvedena je u programskom alatu „DaNAMiCS“. Obojena Petrijeva mreža izrađena je isključivo sa gledišta aplikacijskog sloja. Razlog tome je jasno rješenje uz koje ne treba brinuti o upravljanju komunikacijom među dva čvora sugovornika jer se o tome brinu implementacije nižih slojeva. Jedini dio preuzet iz TCP/IP sloja je poruka FIN s kojom se izvodi završetak konekcije između 2 čvora. U mreži je to samo jedna poruka, kojom se označava kraj komunikacije, a za ostatak standardne procedure zatvaranja veze brine se niži sloj.

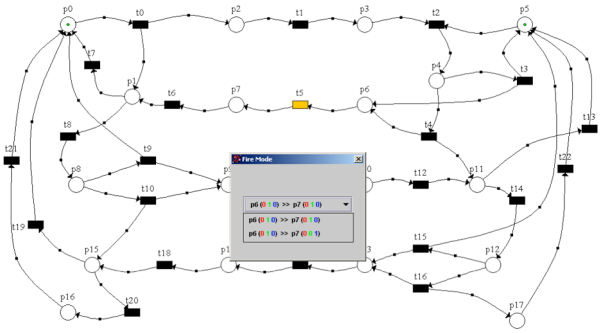
Na slici 9 prikazana je Petrijeva mreža podijeljena u tri dijela. Lijevi dio slike odgovara čvoru koji započinje komunikaciju - inicijatoru, a desni dio slike odgovara čvoru koji trenutno čeka inicijaciju veze - daemonu. Sredina slike pripada komunikacijskom kanalu kroz koji se razmjenjuju poruke. Na tom dijelu se pretpostavlja da može doći do eventualnog prisluškivanja prometa, presretanja, odnosno pokušaja napada na međusobnu komunikaciju. Ako jedan od čvorova primi krivu poruku, na nju odgovara porukom FIN, nakon čega se i klijent i poslužitelj vraćaju u početno stanje te su spremni započeti novu komunikaciju.



Slika 9 Inicijator – kanal – sugovornik

Analizom mreže pomoću alata DaNAMiCS dobivena su neka svojstva Petrijeve mreže. Tako je ustanovljeno da je mreža aktivna, 2-ograničena, reverzibilna, nije sigurna, nije perzistentna, te nije konzervacijska. Važno je istaknuti aktivnost mreže, što znači da nema stanja u kojem se može dogoditi blokiranje ili potpuni zastoj, te da je mreža reverzibilna, odnosno da se iz bilo kojeg stanja može vratiti u početno. Ta dva svojstva su dovoljna za pokušaj implementacije protokola po zadanom modelu Petrijeve mreže bez ozbiljnih poteškoća. Kao i kod slanja bilo kakve informacije kroz javnu mrežu, jedno od važnijih pitanja u računalnom svijetu je sigurnost koja može biti narušena od treće strane tj. zlonamjernog napadača. U svrhu što realnijeg prikaza rada protokola, koriste se simulirani napadi koji se mogu dogoditi u kanalu na porukama prilikom njihove razmjene između inicijatora i sugovornika.

Kao što je prikazano na slici 10, prilikom razmjene poruka između inicijatora i sugovornika u prijelazu „t5“ na kanalu između stanja „p6“ i „p7“ dolazi do simulacije napada. Stanje „p6“ predstavlja poruku sa listom algoritama koju sugovornik šalje na razmatranje



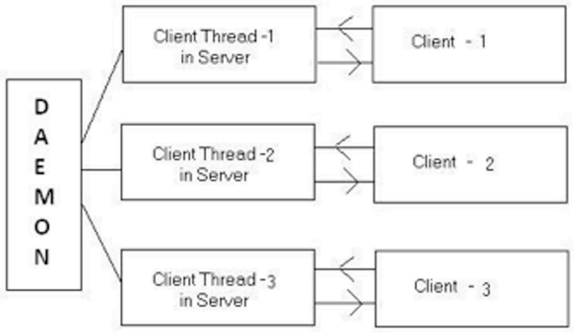
Slika 10 Primjer simulacije napada na sugovornikov odgovor namjenjen inicijatoru

inicijatoru, dok stanje „p7“ prikazuje je li došlo do napada ili ne (u primjeru prikazanom na slici dolazi do napada). Kada takva izmijenjena poruka od strane zlonamjernog napadača stigne na inicijatorovu stranu, sigurnosnim algoritmima se utvrđuje da je poruka izmijenjena i šalje se odgovor sugovorniku za prekid dalje komunikacije. U tom slučaju i inicijator i sugovornik odlaze u početna stanja kako bi bili spremni za ponovnu komunikaciju ili komunikaciju sa ostalim čvorovima.

IV. IMPLEMENTACIJA

Protokol NgP implementiran je u programskom jeziku Python radne inačice 2.6. Rješenje je dizajnirano kao 2 odvojena programa. Jedan od njih predstavlja inicijatora veze (*ngp_klijent*), odnosno klijenta, dok drugi predstavlja poslužitelja (*ngp_server*). Programi se trebaju pokrenuti zajedno na svakom željenom čvoru u mreži, tako da svaki čvor može izvoditi funkciju poslužitelja i klijenta po potrebi.

Sve kriptografske funkcije korištene su iz modula „PyCrypto“. Za komunikaciju preko mrežnog sučelja koristi se modul socket koji dolazi u standardnoj distribuciji Pythona. Nakon parsiranja ulaznih parametara program za klijenta otvara TCP konekciju prema poslužitelju i protokol se odvija prema specifikaciji. Ono što klijentovu implementaciju razlikuje od poslužiteljeve je dio koda koji opisuje algoritam razmjene kriptografskih algoritama. U specifikaciji klijent je onaj koji generira rezultat dogovora. Poslužitelj (*deamon*) izveden je kao višedretveni poslužitelj (slika 11) gdje svaka dretva poslužuje jednog inicijatora (klasa "Thread").



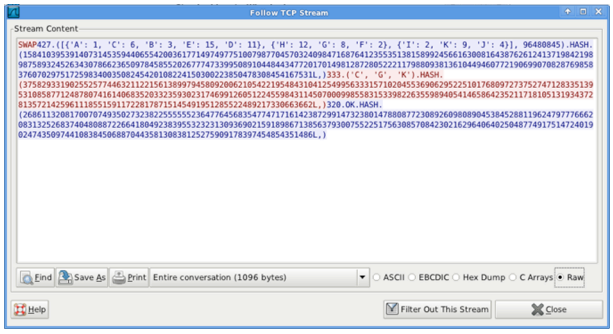
Slika 11 Višedretveni model poslužitelja

U datoteci *file_kprivate* nalaze se privatni i javni ključ klijenta, a u datoteci *file_kpublic* zapisani su svi poznati javni ključevi razmijenjeni nekim višim protokolom. Algoritmi se nalaze u *file_algs* datoteci zapisani kao lista hash algoritama (HA), algoritama simetričnog ključa (SA), algoritama javnog ključa (AA). Svaki član liste je rječnik s algoritmima i njihovim prioritetima.

Kako protokol sam po sebi koristi algoritme sigurnosti, odlučeno je da se koriste široko rasprostranjeni algoritam javnog ključa RSA i algoritam sažetka poruke SHA-1, te su oni preporučeni specifikacijom protokola. Sama implementacija nije zamišljena kao interoperabilna, jer ni protokol nije zamišljen kao gotovo proizvod već kao protokol koji prethodi nekom drugom protokolu koji želi prema dobro poznatom standardu dogovarati sigurnosne parametre za potrebe svojeg cilja. Implementacija dana ovim projektom služi isključivo za potrebe validacije protokola.

V. VALIDACIJA

Za validaciju implementacije korišten je programski alat „IMUNES“ (An Integrated Multiprotocol Network Emulator / Simulator) te analizator mrežnog prometa „Wireshark“. Klijent i server izvode se na dva virtualna računala, povezana u jednostavnu lokalnu mrežu. I klijent i server sadrže datoteku s podržanim protokolima. Javni ključevi su unaprijed razmijenjeni. Pokretanjem klijenta i servera započinje komunikacija. Na slici 12 nalazi se primjer komunikacije između klijenta i servera, snimljen programom „Wireshark“.



Slika 12 Primjer simulacije napada na sugovornikov odgovor namjenjen inicijatoru

Klijent i server se dogovaraju oko tri skupa parametara. Prioriteti parametara zadani su na sljedeći način:

TABLICA I. PRIMJER ZADANIH PRIORITETA PARAMETARA

	Prioritet klijenta	**Prioritet servera**
Prvi skup parametara:		
A	1	3
B	3	6
C	6	14
D	11	3
E	5	5
Drugi skup parametara:		
F	2	5
G	8	12
H	12	2
Treći skup parametara:		
I	2	3
J	4	8
K	9	6

Nakon uspješne razmjene parametara računala koja pokreću inicijatora i daemona će imati pohranjene zajedničko dogovorene sigurnosne algoritme. Dogovor je proveden prema algoritmu dogovora opisanom u specifikaciji. Tako je primjerice $min_c(6,14)=6$, što je najveći minimum svih parova algoritama prve skupine parametara, slično vrijedi i za ostale skupine, pa su dogovoreni parametri C, G i K. Ovdje su imena parametara predstavljena slovima radi jednostavnosti, no pretpostavka je da će se u stvarnoj primjeni dogovarati sigurnosni algoritmi poput SHA-1, MD5, DECT, 3DES, RSA i dr.

VI. ZAKLJUČAK

Protokol NgP omogućuje sigurnosnim protokolima viših slojeva jednostavnu, brzu i sigurni razmjenu parametara, čime se oni rasterećuju tog problema. Širom primjenom protokola NgP omogućila bi se standardizacija razmjene parametara između različitih operacijskih sustava neovisno o protokolima viših slojeva.

Daljnji razvoj protokola bi omogućio potpunu neovisnost o TCP-u, mogućnost razmjene javnih ključeva, te standardizaciju imena kriptografskih algoritama koji se razmjenjuju.

SMART TELECOMM PLATFORMS

Smart Automated Platform For Telecom Operators And Enterprise Users In Industry, Transport And Energy

Abstract - In an environment of economic crisis, new business models are required that can successfully respond to business challenges and stimulate economic growth. During these changes, technology takes on a strategic value. Bringing together the following trends and technologies: cloud computing, advanced analytics, client computing, green business, reshaping data centers, social computing, virtualization of resources, and mobile communications and applications - the Smart Automated Platform (SmAP) platform opens up new opportunities for economic development in industry, transport and energy sectors. This paper describes the technical and business opportunities of the SmAP advanced platform.

I. INTRODUCTION

Information and communications technologies play a key role in developing the economy and society, ensuring competitiveness, improving people's lives, improving management efficiency and transparency, greater efficiency of the business sector and safeguarding the environment. Therefore, the years that are before us will be marked by important new information and telecommunications technologies emerging from the concrete needs of citizens, businesses and government, namely the need for business growth while reducing costs.

The telecom industry, faced with such a demanding task, and growing competition among telecom operators, is turning to new solutions and services based on new technologies.

The Smart Automated Platform (SmAP) is based on solutions for communication between automated machines and contains a wide range of technologies and applications. Function-wise, the SmAP system includes a variety of geographically dispersed devices that communicate with the application solution for data acquisition, making use of communication networks of different technologies such as mobile networks (2g, 3g and 4g), fixed broadband access networks, satellite communications, wimax, wi-fi and other short-range wireless technology for electronic communication.

According to statistical data, an overview is presented of potential areas where the Smart Automated Platform can be used successfully.

For each application category the forecast includes numbers of devices and numbers of connections and traffic with splits by technology (2g, 3g, 4g, short range, man, fixed wan and satellite). We also forecast total revenue, mobile network operator addressable revenue, mno expected revenue and mobile traffic revenue.

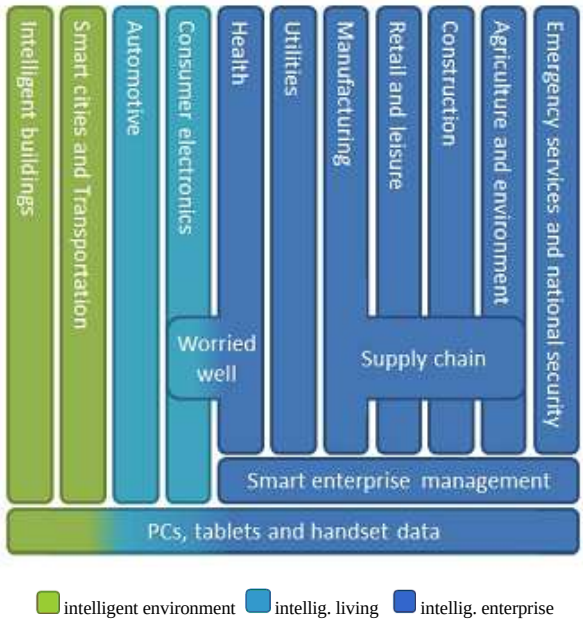

Figure 1. Tabular presentation of grouped technical areas where the greatest need for intelligent connectivity is emphasized

II. SMAP TECHNICAL SOLUTION

Telecom network operators can ensure different value other than the existing tariff concepts. One such solution is to apply differentiated connectivity packages tailored to meet the needs of different devices and different types of users. Today's networks are designed to deliver and enforce different connectivity packages and types. However, to fully cater for the demands created by new types of devices and applications, innovative support systems will be required.

The fundamental features of such systems include: support for IP connectivity over private networks, as well as over the Internet; efficient provisioning for a large

number of subscriptions; capabilities to create and enforce tailored subscriptions with respect to QoS and charging models; mobile network operator and enterprise management portals.

To meet the market need for m2m support systems, a „Software as a service" solution is provided - Smart Automated Platform (SmAP) - offering operators and m2m enterprises an initial low-cost solution for connecting devices and supporting applications and allowing them to grow as the market demand increases.

on the Internet. The platform includes a service execution environment, which provides support functionality to enterprise applications such as a subscribe/notify communication scheme and location services. The policy and charging control block handles the various settings for tailored subscriptions, such as data capping and charging levels. Enforcement of the parameters takes place in the GGSN and online charging systems (OCS). The latter components also pre-rate and sort charging information - Call Detail Records (cdr) for each enterprise and operator.

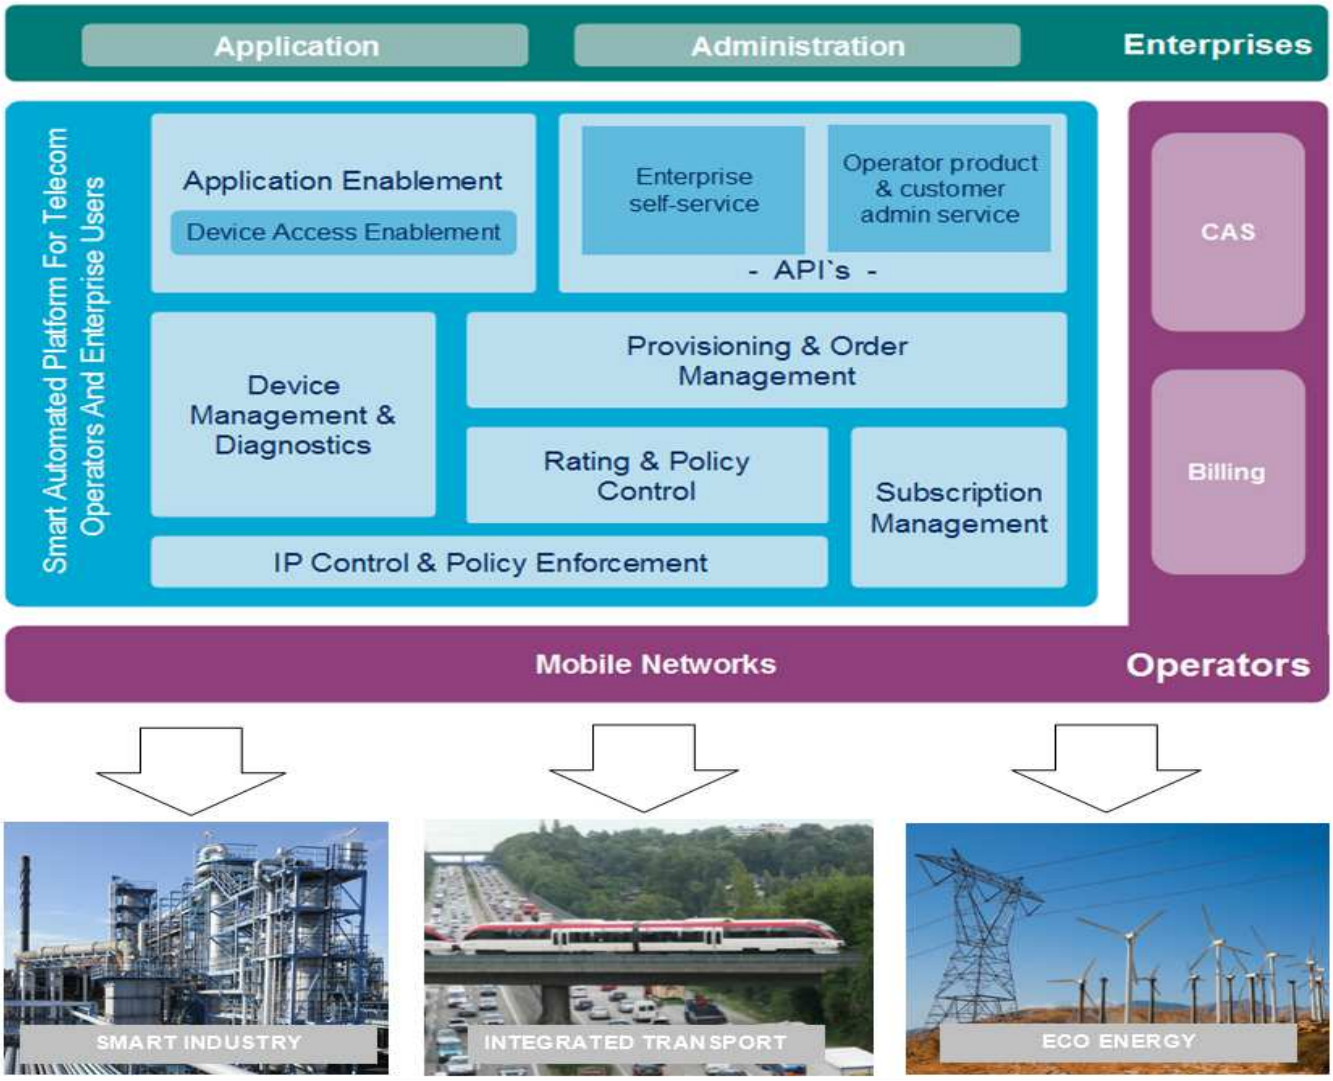

Figure 2. SmAP architecture scheme as a basis for development of transformed industries

SmAP solution interfaces (Figure 2.) with enterprises as well as mobile operators, providing functionality in three main areas: device connectivity; policy control and charging; management and provisioning of subscriptions and devices.

Devices are connected to enterprise applications through the SmAP and via the operator's mobile network. For transparent IP connectivity, the Gateway GPRS Support Node (GGSN) supports private IP networks, while the device access enabler grants access to devices

CDRs are then transferred to the operator's billing system according to a desired control cycle.

For operator and enterprise users, dedicated portals provide access to the platform for SLA, order and account management components. The operator can, for example, create enterprise specific subscriptions, set up portals and monitor SLA reports.

Through the self-service portal the enterprise can purchase services, order SIM cards, and monitor real-time / statistical data on devices. The self-service portal also

includes provisioning of subscriptions into the SmAP components as well as auto configuration of connectivity parameters into the devices. All devices supported by the SmAP are provisioned in the subscription database.

The oss / diagnostics component provides operational and maintenance functions, such as alarm handling, as well as statistics for SLA reporting. A subset of status information and alarms is provided to the operator's network operation center. Not all of connected devices will be equipped with sim cards. Figure 3. shows a probable scenario in which SmAP interacts with m2m devices via a gateway. The gateway, which can be connected to several different m2m devices, handles communication over the mobile network.

Smart Automated Platform deployment architecture "Software as a service" offered in a cloud style is a convenient and cost-effective way to connect devices and applications. The cloud model features pay-as-you-grow characteristics, rapid elasticity of system resources and ease of use.

In the m2m arena there will be many different devices. Some will send and receive small amounts of data infrequently, some will send small amounts often and others will send and receive large amounts of data often or rarely. What m2m devices have in common, however, is that they could all benefit from the convenience of re-using infrastructure nodes for m2m services, such as provisioning, connectivity, charging and policy.

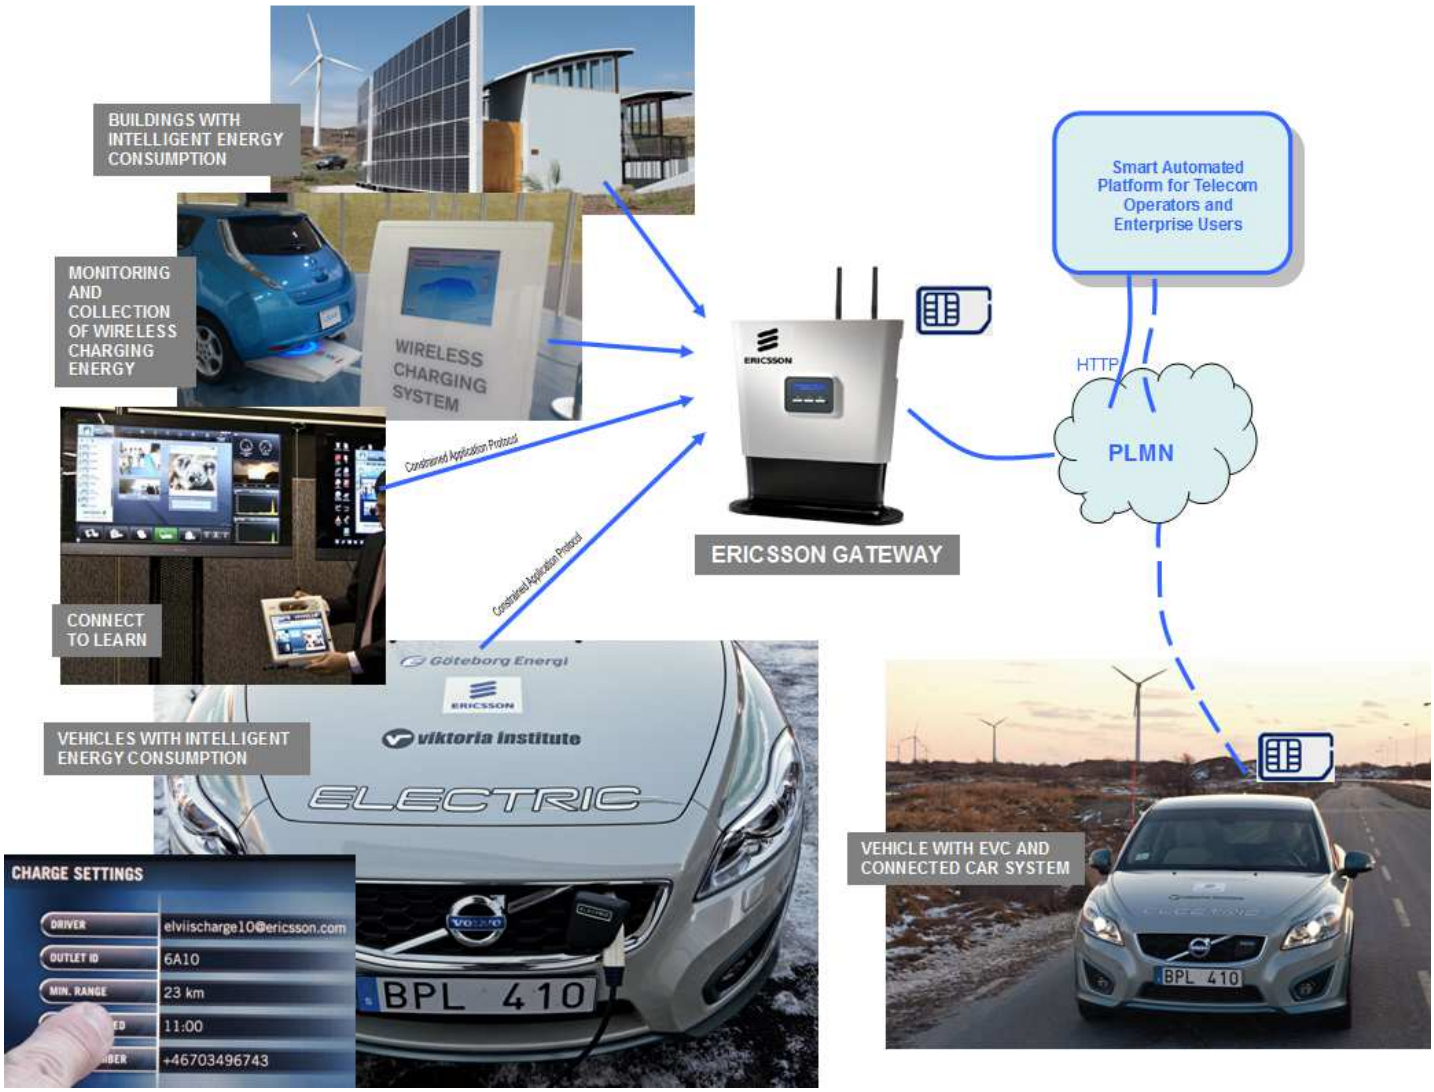

Figure 2. SmAP platform interacting with m2m, v2i devices via a gateway and directly via mobile connections

Communication protocols used may be of any type. This example shows http being used between SmAP and the gateway and the IETF-specified CoAP between the gateway and devices.

The SmAP will be deployed as a "Software as a service" to support this convenience and will interface to several nodes.Below are short examples of how SmAP will support multi-tenant services in areas such as provisioning; OSS; charging; and accessing devices from

the Internet. To handle the use of the subscription database (HLR - home location register), which is shared among customers, for its own or MNO-owned IMSI series, the SmAP will typically have its own HLR/AUC and interface to Serving GPRS Support Node (SGSN) via the interface. The different mobile network operator MNOs share the SmAP but use their own radio and core networks for sending messages to the platform.

When the m2m device is equipped with an SmAP SIM card, 3GPP messages such as Attach and Authentication messages, which will be routed via the IMSI number to the SmAP HLR and processed according to standard 3GPP methods.

When the m2m device issues a Packet Data Protocol (PDP) context activation message, that message will be routed to the SmAP GGSN via the MNO-controlled SGSN by a Domain Name System (DNS) lookup of the Access Point Name (APN) derived from the m2m device plus the SmAP IMSI number.

For MNO-owned IMSI series, the routing to SmAP HLR will additionally be based on Mobile Station Identification Number MSIN (plus the ordinary usage of MCC and MNC). Operators will need to configure their networks to route messages to SmAP HLR for specific ranges of IMSI.

The envisaged large amount of connected devices will differ greatly in functionality, ranging from smart meters to real-time video-surveillance cameras. A smart meter, for example, might report a kilobyte or two of data every other week or so, in which case accuracy is vital – as it determines costs reflected on the subscriber's bill – but bandwidth and latency are unimportant.

On the other hand, a video-surveillance camera constantly requires a lot of bandwidth (uploads of between 120kbps and 2MBps depending on the video quality, and even up to 10MBps for very high quality, such as is required for telepresence). Both smart meters and videosurveillance cameras are, for the most part, stationary, whereas other applications are mobile and require constant connectivity.

Vehicle-tracking devices, would for the most part be on the move and as such, a fleet management application would require constant connectivity.

These examples show that both devices and applications involved in m2m have very different connectivity requirements.

The conclusion is that one size does not fit all. SmAP provides the means to create tailored subscriptions and offers the possibility to fine-tune and tailor subscriptions for specific devices and applications.

Differentiated tariffs go hand in hand with tailored subscriptions, adding the requirement on such a platform to provide the functionality to rate a tailored subscription with a differentiated tariff.

The multitude of parameters that can be tuned when designing tailored subscriptions. The different subscription parameters are controlled and enforced by the different parts of the SmAP architecture.

The policy and charging control block uses the 3GPP-standardized interfaces Gx and Gy, based on the Diameter protocol, towards the GGSN that enforces these policies. The Gy interface is used to control usage (such as number of bytes, number SMSs, and voice minutes), ensuring that a device stays within the caps specified by the MNO and allows or denies access depending o time and location. The Gx interface and HLR profiles are responsible for policy control parameters such as mobility and bandwidth. The Device Access Enabler (DAE) controls SMS wake-up and finally the SLA, order and account manager controls the configuration of the device.

III. WHAT ARE THE OPPORTUNITIES FOR SMART AUTOMATED PLATFORM

At the end of the day, awareness implies a total paradigm-shift. It's a shift from knowing "what happened" to knowing "what is happening"—all the time—and then automatically controlling systems with that knowledge. When products become networked, the environment in which they are utilized shifts to a much more "aware," and responsive support environment.

Eventually, this environment helps product manufacturers and their customers optimize processes, save money, and become significantly more efficient.

Managed services providers believe that smart embedded device automation will create significant value up and down the equipment support chain, allowing customers and their equipment vendors to develop truly new and unique value. By enhancing support over the network, product suppliers will be able to provide new value-added services.

In an "intelligent" network environment, information becomes currency, and can be shared and utilized collaboratively.

The significance of new m2m platform technology is not really their gee-whiz factor, but precisely the opposite: the great convenience and service offered by their near-invisibility. In the long run, such "invisible" machine-to-machine technology will be much more important to business than the dramatic and intrusive services that require human attention to deliver full value.

Eliminating the need for human intervention for network and device support has the potential to save manufacturers significant sums of money through reduced technician calls and "truck rolls" (see diagram below).

Technical Field Support Personnel	Annual Field Support Calls (capacity 3/day)	Cumulative Support Call Expense (average expense 400/call)	Potential Support Call Reduction	Cumulative Annual Savings Via Reduction In Service Calls
40 Technicians	36.200 Calls/Year	eur 11,23 Million/Year	38%	eur 4,49 Million/Year
120 Technicians	110.500 Calls/Year	eur 33,71 Million/Year	40%	eur 14,12 Million/Year
480 Technicians	360.000 Calls/Year	eur 112,36 Million/Year	42%	eur 44,94 Million/Year

Diagram 1. Direct Economic Returns Via Embedded Diagnostics

For product SmAP, their partners and customers, embedded services automation opens the opportunity for new connected support and value adding opportunities to capitalize on and helps to grow the overall market.

IV. CONCLUSION

Smart m2m platforms are developing rapidly, continuously integrating new devices, which shows a big potential for Telecom operators and Enterprise users, and lately for private users of electronic devices. Networks are now handling equipment and systems of increasing breadth and diversity. Many business processes are becoming automated, such as asset tracking, supply chain management, and procurement. The next chapter in the smart m2m arena will be driven by platforms and solutions that realize the full value of the connected device, stripping out unnecessary costs in customer support, replacing uninformed human activity with embedded intelligence in devices and developing new applications value via cloud computing.

With the rise of true networked applications, smart intelligent devices will become visible to the network and platforms managing them. All of this illustrates that as more and more processes, systems, and devices become dependent on smarter networks and application delivery platforms, the ability to see failure before it happens and the ability to leverage third party "specialists" for application development will need to increase.

The adoption of smart m2m systems has been challenged with many unforeseen barriers. The Smart m2m Platform program holds the potential to change the entire structure of value delivery, alter long-standing business models, and prompt all participants to consider how to design new modes of service delivery and build new relationships with customers and with developers.

SmAP provides tools for actors, such as operators and enterprises, to handle provisioning in a self-service way. It also delivers methods to tailor subscriptions to meet the varied connectivity requirements of the massive number and variety of connected smart m2m devices. The device access enabler function in SmAP solves the issue with find and connect in a world of Network Address Translation (NATs) and firewalls, and at the same time shields m2m devices from unsolicited usage.

Solving connectivity challenges is the natural first step towards achieving the networked society vision. The next step will be to offer solutions for application support – in other words, to develop, install and execute smart m2m applications in a more cost-effective and convenient way.

With the continuous growth of market demand, a bright future awaits smart m2m platforms.

The „horizontalization" of the machine to machine (M2M) world and how to market it

A. Metnitzer
Nokia Siemens Network/Business Development, Vienna, Austria
andreas.metnitzer@nsn.com

Abstract - Today, many small, medium and big companies develop „vertical" M2M applications on their own. This leads to redundant functionalities in each application and doesn't give the opportunity to open functions to a bigger market. A „horizontalization" of such applications and disposal in a „marketplace" will open new possibilities and markets even for small companies. This paper will highlight the M2M application/device world today and its challenges, the principles of „horizontalization" and its benefits and what Nokia Siemens Network (NSN) is doing in this area.

I. INTRODUCTION

The M2M [1] market is growing significantly. According to Harbor Research the total global M2M market value forecast is 280 B € in 2013, with an average growth rate of 33%. The M2M market grows steadily resulting in CAGR (Compound Annual Growth Rate) of 20 to 40%, depending on the actual segment. Figure 1 illustrates the overall M2M service market forecast by Industry segment.

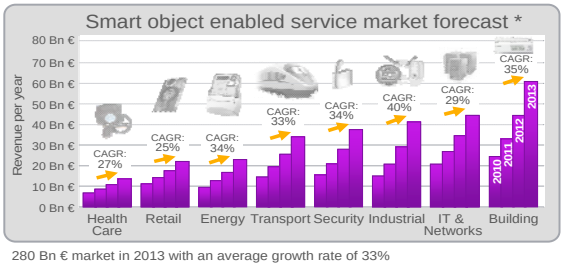

Figure 1. Overall M2M service market by industry segment

Figure 2 shows the overall approach to develop M2M applications/devices today.

The majority of developing companies in the M2M sector rely on a "vertical" approach with M2M development; means, from top (applications) over basic functionalities (integration, remote control, data collection,…) down to smart devices integration, all functionalities are taken care of by single vendors (end-to-end supply). Many of the basic functionalities are developed for each and every application again and the synergy effect is rather low.

This, however, bears a couple of disadvantages in itself:

1) Basic functionality re-development:
Basic functions like the business integration capabilities, data collection and storage, remote object management and the smart object communication have to be developed and integrated for each M2M application separately and the re-use effect is rather limited. This results in a longer, more expensive development of applications and or devices and the time to market is significantly higher.
Last, an M2M connection layer, which is not optimized for data transmission, might result in unnecessary data traffic, which might cause additional costs and/or result in network capacity problems.

2) M2M application – device connection:
Due to the fact that M2M applications are mainly developed with one type of device (which might come from a 3rd party), the risk occurs that failing to continue with the respective device(s) will result in a redevelopment/-integration of parts of the application. Relying on proprietary interfaces might result in loss of solutions.
Additionally, application 1 will only access data from the devices, which have been directly integrated to them; there is no possibility to feed data from devices, which are used by application 2 (and might be of interest for application 1, too).

3) Marketing possibilities:
With creating M2M applications/devices in a vertical mode, the possibilities of marketing them over a "Marketplace" seem to be limited: there is no possibility to rely on standardized platforms/interfaces, which makes selling of M2M solutions as easy as e.g. selling apps over Android.

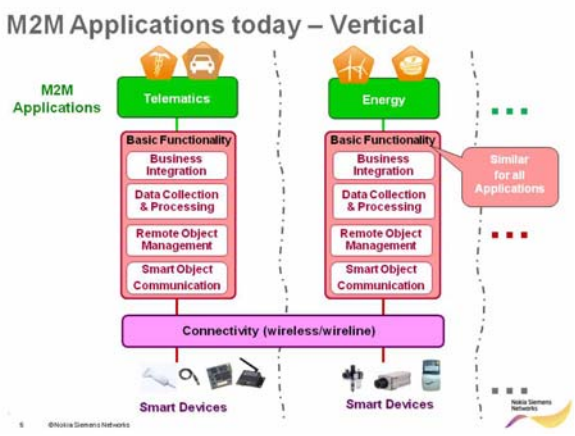

Figure 2. M2M application development today

II. M2M Application Development "Tomorrow"

The key components of M2M application/device development "tomorrow" is shown in Figure 3 [2].

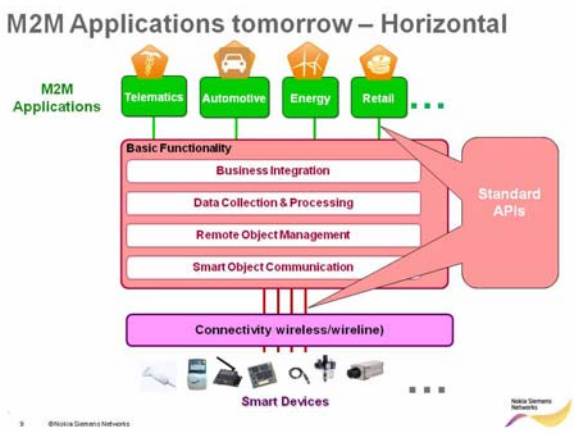

Figure 3. The Key Components of M2M application/device development "tomorrow"

In the near future, the development of new M2M applications and devices will change significantly: With the standardization of interfaces towards the application layer and the device layer, basic functionalities can and will be taken by bigger platforms (possibly in a "cloud") to separate applications from devices and benefit from synergies of basic functionalities [3]. It means, when developing M2M applications/devices, companies can "rely" on basic functions like business integration capabilities, data collection and storage, remote object management and the smart object communication to be taken care of by this kind of platforms.

This does in fact bring a number of benefits for the respective companies:

1) Reuse of basic functionality:
Basic functions like the business integration capabilities, data collection and storage, remote object management and the smart object communication are being located on the horizontal platform and both M2M applications and devices can "rely" on them, without need to integrate them into the application or the device as such. This makes the development of applications and devices much simpler and more reliable, as the functions mentioned are easier to be taken care of in a common platform. This results in cheaper, shorter development of applications and or devices and the time to market is significantly lower.
An M2M platform can deal with the connection layer in an optimized way, which can save on network capacity.

2) Standardized interfaces to applications and devices
As a result of standardized interfaces to M2M applications and devices [4][5], an application developer can choose from a variety of different devices for his solution. This results in a form of independence from vendors of devices, as one can be relatively easily replaced by another.
Additionally, one application can relatively easily get data from different type of devices, which might also serve another application (cross-usage).

3) Marketing possibilities
Having a big horizontal platform to host applications and devices, it can be used as a kind of marketplace to sell them.
Similar to e.g. Android, different application and device development companies can use the marketplace to sell via it. A potential developer toolkit might even make it easy to bring ideas to life, even without being into software development.

4) Testing against predefined solutions
In order not to be bound to develop and test devices and applications always in "pairs", a predefined set of sandbox functionalities will enable companies to test devices without caring about applications and vice-versa. This requires the accessibility of both applications and devices and also a detailed description of how to use and how to administrate the sandbox mode.

III. THE NOKIA SIEMENS NETWORK M2M PLATFORM

NSN created its own M2M platform "Cumulocity"(Figure 4), which contains all the necessary functions as described in Section II [6].

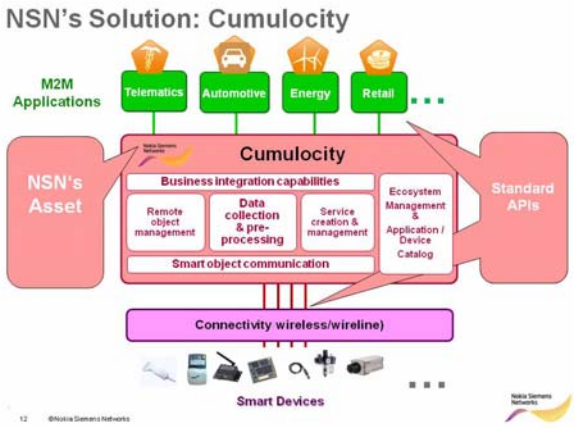

Figure 4. NSN's M2M platform "Cumulocity"

Cumulocity is a horizontal M2M application platform. Basing M2M applications on Cumulocity gives many out-of-the-box features, saving development-, engineering- and testing time.

The application platform part contains a comprehensive set of tools for managing meters and sensors, collecting and validating data and providing it to enterprises back-office applications. Using Complicity's Software Development Kit (SDK), it is easy for companies to integrate new M2M devices and develop new applications. It serves as a horizontal M2M product; companies can use it for applications and devices from different M2M domains like telematics, energy, utility, and vending. Additionally, Cumulocity helps companies by decoupling devices from applications, allowing them to develop devices for various applications or develop an application for various devices.

Cumulocity has been designed for cloud-based environments: it provides software as a service (SaaS). It is multi-tenant, allowing companies to use single application deployment to serve multiple enterprises. It is based on elastic cloud technology and Big Data principles, ensuring that application scales to the required transaction and data requirements.

For application developers, Cumulocity simplifies the implementation of M2M services by hiding the complexity to communicate with diverse device types, each having its own data model, protocol and transport mechanisms. The platform provides ready-made components for rapid development of applications. Cumulocity provides data storage for inventory, measurements, event, alarm, and audit log data. Its Complex Event Process (CEP) engine allows easy processing of real-time M2M traffic and rapid implementation of M2M business logic. Using the remote control functionality, devices can be reliably reconfigured and maintained. All this functionality is available via REST web service interfaces [7] and web user interface components based on the latest AJAX technology.

For device developers, Cumulocity makes it easy to cloud enable device: make device data and controls available for applications with minimal effort. Install Cumulocity's software agent and connect it to sensors and controls. Afterwards you can remotely control your device from the internet or develop additional server-side business logic for it.

Towards the application side, the platform offers access to the multi functions, which are implemented and necessary for proper functionality.

These are:

- Business Integration Capabilities – interfaces towards the end user's eco system
- Remote Object Management – remote control of the devices incl. firmware updates
- Data collection and processing – device user data collection and storage (even for years)
- Service Creation and Management – multi tenant able for different companies to create their own M2M applications
- Ecosystem Management and Device Catalogue – integration into an operator's eco system and providing a catalogue of proven devices to be used for new applications

Towards the device side, the offered functionalities are the same; means, device developers are also benefiting from the horizontal platform and its functionalities, similar to application developers.

Being located in a cloud, it can be operated without own HW / SW for an M2M developer.

The platform can be integrated into an existing environment such as billing, fraud management or customer care of a CSP.

M2M application- and device developing companies can benefit from all the bespoken items in Section II.

There are test-devices for application- and test applications for device-development available and the scalability of a cloud based solution offers low entry costs [8][9].

Another big advantage –especially for small development companies– is the possibility to use Cumulocity as "Marketplace" to position own developed devices and/or M2M applications for global sale.

Similar to what is known as e.g. Android Marketplace, companies can add, advertise and sell their products via a large international platform, which allows different kinds

of new business models for mere device-, mere application- or end2end solution selling.

Small companies with smart ideas get a channel in this way to reach new customers without investing heavily into sales force.

IV. CONCLUSION

The M2M business is just at its start. It will influence all our lives in future. The way M2M applications are being developed today will differ significantly from the one tomorrow. NSN has developed its own M2M platform “Cumulocity”, which allows both application- and device developing companies to benefit from a horizontal development approach.

Machine to machine (M2M) communication impacts on mobile network capacity and behaviour

S. Počuča, D. Giljević
Nokia Siemens Networks, Zagreb, Croatia
sergej.pocuca@nsn.com, darko.giljevic@nsn.com

Abstract –Today there is a challenge how to handle all network aspects of M2M [1] communication. In this paper it is discussed how to smartly and effectively handle M2M communication in future networks. There are 2 main topics which should be considered. One would be network needs which should be prepared for M2M communications. The second one is that M2M devices need to become much more optimized for mobile communications and M2M applications.

I. INTRODUCTION

Smart objects will scale far beyond smart phones and smart devices [2] because over 1 Billion mobile based M2M subscribers are expected by 2015 (Figure 1).

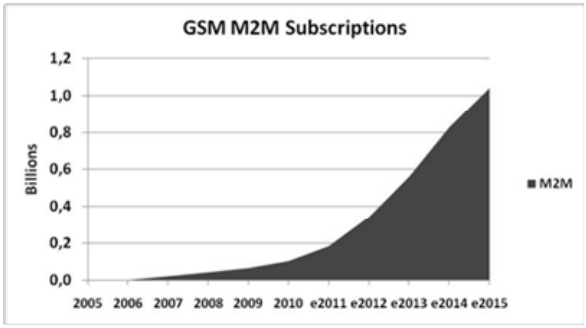

Figure 1. Traffic forecast for GSM M2M Subscription (Source: NSN GSM trafic forecast, June 2011)

The number of transactions (short data calls) will be more than 10 folded in next few years (Figure 2) but the increase in total data traffic is expected to be marginal (Figure 3).

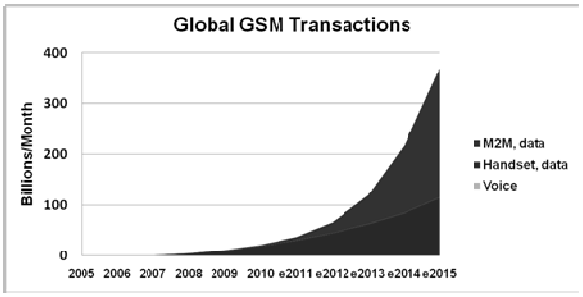

Figure 2. Global GSM transactions (Source: NSN GSM trafic forecast, June 2011)

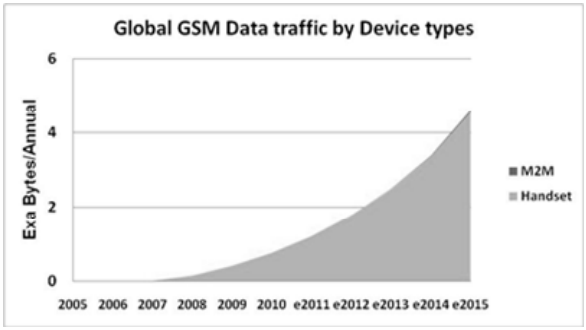

Figure 3. Global GSM Data traffic by device type (Source: NSN GSM trafic forecast, June 2011)

Some applications transmit only the minimal amounts of data and only intermittently. Intermittent data updates can create a major signaling overhead on the mobile network. This has already been a problem for smart phone users. The biggest challenge is how to manage M2M network usage coming with exponential raise of objects (Figure 4).

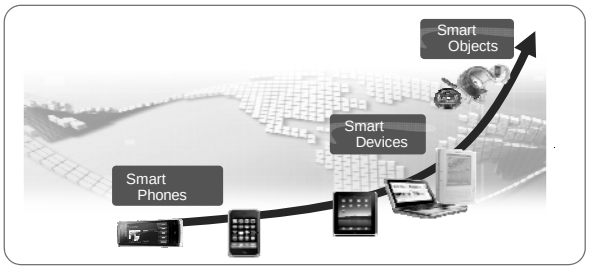

Figure 4. Raise of "smart" devices is exponetial

There are various M2M applications which will influence mobile traffic heavily [3], like:

- Smart meters (power, gas, water)
- Smart vehicles (road tolling, real time traffic info to vehicles)
- Vending machines
- Payment (unmanned gas stations, parking meters)
- Security alerting/reporting (in-car modems creating an emergency call in case of an accident)
- People tracking (kids, elderly)

These M2M applications have different requirements, e.g.

- some are stationary, some are mobile,
- some exchange small amount of data rarely, some have real-time requirements for data transfer,
- some communicate with one or more M2M servers, some with each other,
- some may have identifiers such as MSISDN, some may not.

It is important to understand the characteristics of M2M applications

- when selecting the right packet core features,
- when dimensioning the network,
- when developing protocol to communicate with end devices.

In section 2 challenges and impacts on mobile network and end users by introducing M2M object communications are described. Section 3 will give overview of traditional solutions to increase capacities of the mobile network but as well other theoretical solutions to optimize mobile networks for M2M communication in more appropriate way. In section 4, status and outlook is outlined to show what Telco vendors like Nokia Siemens Networks (NSN) have been done by developing software solution and features in radio network, what 3rd Generation Partnership Project (3GPP) has been standardized for future Packet Core networks in respect of M2M communication. Finally it is discussed how to develop and use new application protocol features in M2M application platform to communicate with end devices in more optimized way to save the network capacities when M2M traffic starts to grow heavily.

II. IMPACT OF HIGH M2M OBJECTS TRAFFIC TO A MOBILE NETWORK

A. *Impact to radio network*

Impacts of high M2M traffic to a radio network can be summarized as follows:

- huge increase in number of Packet Switched (PS) data calls – potential Control channel signaling channel (CCCH) congestion, and reduction of the network quality for other users sharing the same resources,
- transmission delays and lower throughput ,
- M2M traffic is typically one directional, Uplink (UL) dominating, but due to acknowledgements in Downlink (DL) the transactions load will be in both directions and impacting all users,
- huge increase in SMS messages delivered in short intervals causing Stand-alone Dedicated Control Channel (SDCCH) signaling channel congestion,
- increase in paging load dominated by stationary smart M2M objects,
- high number of non-urgent M2M transactions in uplink reduce the network service quality,
- urgent M2M transactions need higher Quality of Service (QoS),
- short M2M data calls (e.g. acknowledgements) reduce the network service quality in downlink.

B. *Impact to Packet Core*

Impacts to a Packet Core network can be summarized as follows:

- User Equipment (UE) density can be manifold compared to Human to Human (H2H) devices,
- data transfer tends to happen upwards the network, as opposite to H2H communication,
- PS core dimensioning is impacted, depending on following factors: Number of M2M devices added in the network, M2M UE accessibility requirements from the network side and how frequently the M2M UE needs to send or receive data,
- when an M2M device needs to be reachable by the network it usually means it needs to be attached to the PS core system. For a LTE device, this is a must and for a 2G/3G device a Circuit Switching (CS) Short Message Service (SMS) can alternatively be used to trigger the device active,
- when an M2M device can autonomously decide when to establish a connection, it can do attach, send/receive data and then detach or it can stay attached all the time. M2M devices that are attached to the network consume more bearer capacity, but they generate less signaling, particularly if they are stationary. M2M devices that do Attach/Detach upon need can share and thus save bearer capacity from the packet core, but they generate more signaling (transactions) in the packet core. Thus, optimization of the packet core resources for M2M communication means finding the right balance between bearer and transaction capacity. The balancing depends how often UE needs to exchange data with the network (Figure 5).

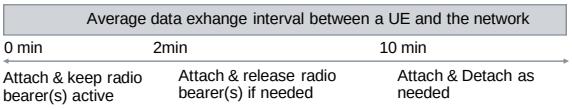

Figure 5. Average interval UE needs when exchanging data with a network

The mentioned figures are just rough estimates because other factors like mobility, latency and blocking tolerance requirements would also have impacts. It actually depends on the application requirements how the devices should communicate with the network. This means that the devices need to be much more flexible to use the network resources in a way tailored better for the application load. More accurate dimensioning is achieved

by a creating traffic mix for each M2M application what could be reused as a basis for dimensioning.

C. *Impact to end user experience*

Impacts to an end user experience can be summarized as follows:

- Network could be busy which can follow to "missed call alerts"
- Lower data throughput
- SMS message not sent

III. SOLUTIONS

Traditional solutions would be to invest into end to end capacity to:

- add signaling channels,
- add traffic channels,
- expand GPRS territory,
- split the cells,
- split the Base transceiver station (BTS) sites,
- add transport capacity,
- add PCU capacity,
- add Gb interface capacity.

Such capacity extensions are cost consuming and increase Total Cost of Ownership (TCO), and more optimal solutions can be proposed.

In order to save money to operators and to prepare the network for M2M communication, it's possible to implement changes in Radio network to optimize and reduce the load in the network.

In addition to preparation of network needs, the M2M devices need to become much more optimized for mobile communications and M2M applications.

IV. STATUS AND OUTLOOK

In this section it is described what NSN has implemented in the radio network and in Cumulocity M2M application platform[4][5][6], and what is to come including Packet core standard features proposed by 3GPP.

A. *Radio network based solution*

NSN proposal is based on introduction of following software solutions shown in Figure 6:

Precise Paging – It reduces paging load by sending paging first to the smart object's last known BTS site. It can reduce M2M signaling load by up to 70%,

Priority Class based QoS - QoS profiles for smart objects according to the need minimize the impact to other users and maximize the speed for urgent transactions. M2M objects with low QoS class can increase data throughput for other users by 50%. High QoS class can be used for urgent health and safety transactions,

Smart Resource Adaptation - Short data calls need only one traffic channel (radio timeslot). It can bring up to 5 times more M2M transaction in downlink with existing network,

The described features can bring to significant reduction in TCO for operators.

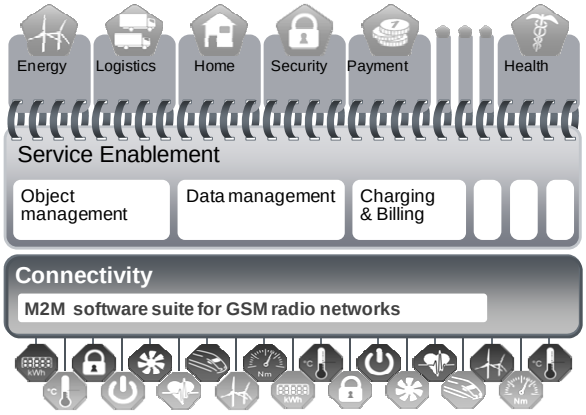

Figure 6. New functionalities in GSM radio network packed in one M2M software suite for M2M connectivity

B. *3GPP standard features for M2M devices*

In 3GPP Release 9 (R9) and earlier [7][8], for machine type communication nothing is defined and an M2M UE is just like any device. In 3GPP R10 [9] [10] an M2M UE can indicate low priority towards RAN/CN. In case of an overload, Mobility Management Entity (MME) and/or Serving Gateway (SGW) / Packet Gateway (PGW) do specific actions for low priority UEs, e.g.

- rejection of Mobility Management / Session Management requests,
- allocation of a long periodic tracking area update (TAU) timer in MME,
- sending a back-off timer from MME to UE which prevents signaling by UE until the back-off timer expires,
- adding low priority indication for charging in SGW/ PGW.

The overload control (shown in Figure 7.) can be applied on network element level, or be specific for certain Access Point Names (APN) only.

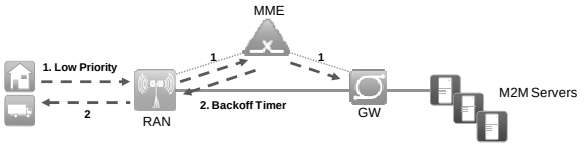

Figure 7. Overload control for M2M devices

In 3GPP R11, several new items are being discussed currently:

- Architectural changes: An Interworking Function (IWF) is added between Machine Type

Communication (MTC) server and 3GPP system. MTC is 3GPP name for M2M.

- Device triggering: Non Access Stratum (NAS) signaling or Mobile Terminating - Short Message System (MT-SMS) could be selected. Offline device triggering (non-Attached devices) is postponed to Release 12.
- Identifications: System shall support both Mobile Subscriber ISDN Number (MSISDN) and MSISDN-less UEs.
- PS-Only: System should be able to work even without Mobile Switching Center(MSC)/Visitor Location Register (VLR) functions.

The R11 MTC standardization topics (Figure 8.) are expected to finalize in 2012. NSN is actively participating to the standardization work.

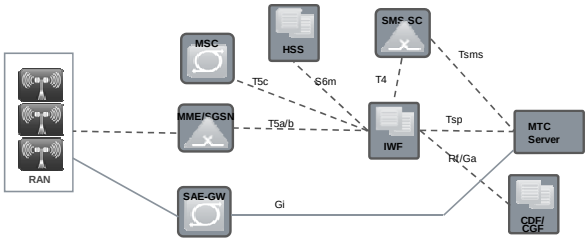

Figure 8. M2M architectural improvments in 3GPP R11

C. *Solution in application platform layer for communication with M2M objects*

In order to optimize the traffic in mobile network, the protocol between devices and application needs to be much more fault tolerant (if it runs on low priority, it has to robustly handle errors) thus NSN has designed the protocol for communication between devices and NSN M2M application platform - Cumulocity (Figure 9.) based on Hyper Text Transfer protocol (HTTP)/ Representational state transfer (REST) paradigm and agent implementation. The platform manages M2M objects in a way that a device is just an HTTP client towards Cumulocity. Today many devices don't have it implemented but NSN sees many benefits of using HTTP and its extensions for this communication, and the fact that European Telecommunications Standards Institute (ETSI) is going to standardize it for M2M, is a good direction[11] [12].

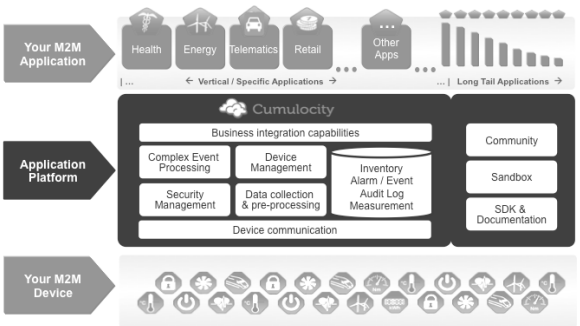

Figure 9. Overview of NSN M2M platform - Cumulocity

Benefits are:

- Device doesn't need to keep connection/ packet data protocol (PDP) context open to receive commands. It's possible to send them a flash SMS for wake up and they'll retrieve operations that they need to carry out,
- no Virtual Private Network (VPN) infrastructure is needed in order to be able to connect to the device,
- dynamic IP addressing is fully supported,
- it gives good security, where no hardening of device is needed,
- it's possible also to do auto-provisioning. (E.g., text credentials to the device and then it will upload its topology to the system,
- link between SIM card and tenant could come from connectivity platform of the operator (if present),
- Web based data compression between devices and Cumulocity can be used, e.g. Internet Engineering Task Force (IETF) Constrained Application Protocol (CoAP) [13] as protocol.

To interface with M2M devices and other M2M-related data sources from M2M Cumulocity platform, a driver software called agent is required. M2M devices come with a wide variety of protocols, parameters and network connectivity options. Protocols to devices range from low-level serial links to full-blown IT protocols such as web services. Today's M2M standards [14] rarely define exactly how to access particular readings of particular sensors or manipulate particular controls. Devices may be connected through mobile networks and gateways. To shield machine-to-machine applications from this diversity, Cumulocity uses so-called agents (Figure 10). An agent is a function that fulfils different responsibilities for a given vendor and type of devices among which there is a function that enables secure remote communication in various network architectures.

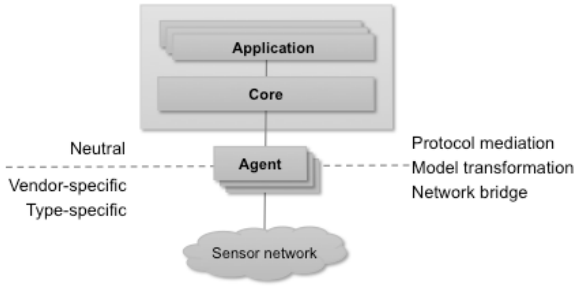

Figure 10. Device agent responsibilities

Managed agents are based on the Cumulocity run-time environment and are deployed and started by Cumulocity in the cloud. Such agents connect from the cloud to the devices in the sensor network using the device-specific protocol. This variant can be chosen whenever there is a secure and internet-enabled communication path to the devices – either directly supported by the device protocols or through a VPN infrastructure (Figure 11).

Non-managed agents run on hosts in the local sensor network. Such hosts could be mobile phones, gateways or other devices where the software is pre-installed and pre-configured. The agent software is based on whatever run-time environment the hosts support, hence it cannot be managed from the Cumulocity core (but it might be managed through other technologies like over-the-air programming).

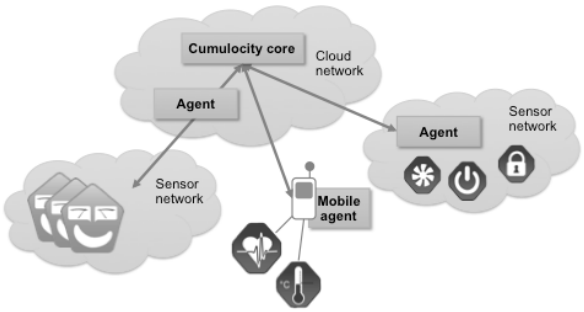

Figure 11. Supported agent architectures

Cumulocity uses a simple and secure reference protocol based on REST (i.e. HTTP) and JSON [15], which can be used from a wide variety of programming environments down to small embedded systems. To support near-real-time scenarios, the protocol is designed around a "push" model, i.e., data is sent as soon as it is available.

To provide a reliable M2M service, it's necessary to ensure that the M2M devices are available to the M2M applications. This responsibility is split up in the following way:

•Cumulocity keeps track of agent availability.

•The agents keep track of the devices that they manage.

For tracking agent availability, Cumulocity records the time stamp of the last communication with the agent. If the last communication occurred more than a configurable interval ago, the agent is considered unavailable. If there is no actual need for a request between agent and platform, an agent may send regular alive messages to fulfil this interval. This mechanism supports also cases where bandwidth is critical and connectivity is unreliable. E.g., in smart metering, it is sometimes enough to get connectivity only once in a day. Avoiding that the connection is always open and under traffic, the cost of connectivity would be decreased.

V. CONCLUSION

Smart objects will scale far beyond smart phones and smart devices and operators need to prepare their network for upcoming traffic which is more than 10 times higher by number of transactions and in parallel to attract the application developers for the M2M ecosystem with M2M application platforms while it is in an early stage.

To save on network capacities and reduce the risks of coming M2M communication, operators can introduce new functionalities in radio and packet core networks to support optimal behavior of telecom network for M2M communication.

Benefits of introducing the described functionalities are improved customer satisfaction (e.g. data throughput and network accessibility), improved network quality (e.g. higher paging success rate and lower multi timeslot blocking) and more efficient use of existing network hardware resources which all leads to reduced Total Cost of Ownership for operators. In the end the network prepared for M2M communications is more attractive for application developers, which can benefit also with existence of NSN M2M Cumulocity platform which takes care and handle the interaction and communication with objects/machines.

ACKNOWLEDGMENT

The work presented in this paper was supported by Nokia Siemens Networks and NSN M2M team. Especially we would like to thank a colleague, Andre Eickler for his constructive hints and professional review of this paper.

Bfriend: Context-Aware Ad-Hoc Social Networking for Mobile Users

Vanja Smailovic[1] and Vedran Podobnik[2]
[1] Ericsson Nikola Tesla, Zagreb, Croatia
[2] University of Zagreb, Faculty of Electrical Engineering and Computing, Department of Telecommunications, Zagreb, Croatia
vanja.smailovic@ericsson.com, vedran.podobnik@fer.hr

Abstract - Ad-hoc social networking provides a goal-oriented platform for vibrant communication and value-added interaction among users. Through managing user social relationships in a novel fashion based on establishment of temporary social relationships among users with mutual interest or need, ad-hoc social networks provide an innovative medium for upgrading existing, as well as developing new social relationships. This paper proposes the Bfriend, a location-aware ad-hoc social networking platform based on the Facebook social graph. The Bfriend platform is used by mobile users equipped with a smartphone - after users install and activate the Bfriend client application, they are able to receive push notifications when a certain rule is triggered (e.g., it is Friday evening, Ewan and Luke are drinking beer in a bar and one of their female Facebook friends passes nearby). The proof-of-concept application is available for users possessing Android-based smartphones.

I. INTRODUCTION

Ad-hoc social networks [1][2] provide an alternative, temporary and goal-oriented medium for communication and interaction among users. This kind of social networks represents an innovative platform for handling ego-user current social relationships, as well as provides an effective solution for developing new social relationships.

For example, imagine a person walking downtown. Let us assume that this person is not moving very fast (e.g. is on a bicycle or by foot) nor is moving in an unpredictable manner. This person is shopping, which deems her available to others for social interaction. Indeed, this person has some of their friends close by, which is where Bfriend kicks in. Bfriend is a context-aware ad-hoc social networking platform which gives its users the ability to receive notifications when one of their Facebook friends passes nearby. Both parties get notified as soon as they approach each other close enough to meet each other. This distance is 100 meters by default, assuming that people do find this distance satisfying for meeting somebody who is their friend. In practice, this could be proven useful in cities, where such distance is appropriate for the "same place, same time" principle (see section 3) [3].

This paper is organized as follows. In the Section 2, related work gives an overview of what has already been done in the area of location-aware ad-hoc social networking. After that, Section3 gives an answer to the question *"what does Bfriend do"*. Afterwards, Sections 4 and 5 give answers to questions *"how does Bfriend work"* and *"what does Bfriend have to offer to end-users"*. Finally, Section 6 concludes the paper and gives an overview of the planned future work.

II. RELATED WORK

To begin with, one should grasp at the main keywords used throughout his paper.

Definition of a *context* is given by Dey in [4][5][6] – "context is any information that can be used to characterize the situation of an entity. An entity is a person, place, or object that is considered relevant to the interaction between a user and an application, including the user and application themselves". Therefore, a context-aware system is "a system that uses context to provide relevant information and/or services to the user, where relevancy depends on the user's task". *Mobile users* are nowadays accompanied by their mobile devices, usually smartphones. In February 2012, the biggest *social network* Facebook has had 845 million active users, out of which more than half (425 million) are mobile [7][8][9]. Clearly, the ability to go mobile gives social networks an advantage when it comes to usability and popularity among users. In terms of context-awareness, this enables context information such as ego-user's location, friends' locations, friends of friends' locations, etc.

Facebook Places service is a good example of a well-known service related to the Bfriend system. Facebook is the largest social media website and has a huge amount of users, as already mentioned. In the summer of 2010 Facebook announced a new feature, namely a location based service, called Facebook Places. The idea is that a user can share his or her location by using their smartphone's GPS (*Global Positioning System*) data. This is useful if one tries to find friends using the same service for a night out in town, brag about attending a concert, having a dinner in a restaurant or such [10]. In May 2011, Places already had 1.8 million check-ins globally per day [11].

Other similar services are *Foursquare* [12], *Gowalla* [13], *Brightkite* [14], *Google Latitude* [15] and *Skout* [16], just to name a few. These services give the user an opportunity to keep in touch with friends using location-based data. While Facebook Places has not really invented anything new, the key to its success is the amount of users

already on Facebook before Places entered the business. An average user might not be interested in a location-based Facebook service if he or she has never heard about it or even more important – none of his or her friends use it. Google Latitude is a location-aware mobile application which uses well-known and widely-used Google accounts for accessing it. It enables users to see locations of their friends (other users of Latitude) and to publish their own location as well. Google expanded the service in late 2009, enabling historical view of previous locations plus some other features on which the user was willing to agree upon. Google Latitude got its own API (*Application Programming Interface*) in May 2010, which enables access to stored user information with explicit user's consent. The main difference between Google Latitude and Bfriend is that the latter gives users an option to control their availability status (i.e. presence) just like IM (*Instant Messaging*) services do. On the other hand, Latitude enables users to publish their current location, while Bfriend does not allow explicit insight into anyone's location, but rather notifies in case of spatial proximity. Moreover, Bfriend application works in the background and requires minimal user input to operate.

It is the context-awareness that those services have in common, making them stand out from other mobile or social services. The context-awareness within the Bfriend system includes:

- *Social context* – i) ego-user's friends; and ii) ego-user's presence information;
- *Geolocation context*;
- *Temporal context*.

III. BFRIEND MODEL – SAME PLACE, SAME TIME

Context information is necessary and crucial for new social interactions and connections. In Figure 1. the referent *Person A* is cycling down the street, going to meet his/her *Friend B* and *Friend C*, who are already at the bar. *Person A* does not know exactly where they are, so he/she decides to try out his/her luck. Soon after, if all three of them were *Online* on Bfriend, they would receive a notification saying that they are close to each other, giving them the ability to meet at the same bar. It is all about being in the same place, at the same time.

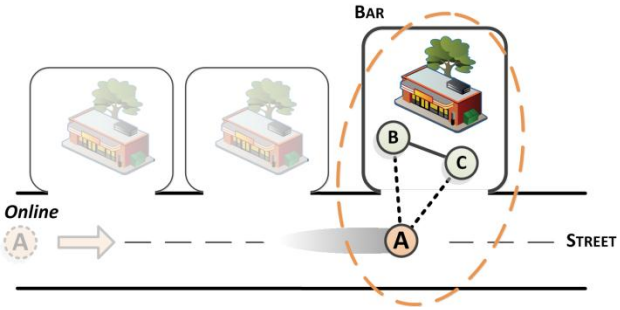

Figure 1. Social, geolocation and temporal information as a context

Bfriend model is based on a social graph, which can effectively be used to describe social connections. First, Bfriend uses the Facebook graph as a starting point. In Figure 2. referent *Person A* is a friend with *Person B* and *Person C* on Facebook. What happens next is that they end up being in the same place at the same time (i.e. context information includes gelocation and time). Besides *Person B* and *Person C*, *Person D* is also in company of ego-user *Person A*. *Person D* is a friend of the *Person C* which makes him/her a friend-of-a-friend for the referent *Person A*. *Person A* and *Person D* interact with each other and find out that their application Bfriend "sees" them as friend-of-a-friend to one another. The same could be said for *Person B* and *Person D*, as well. This allows them (pair *Person A* and *Person D*, as well as pair *Person B* and *Person D*) to connect and become friends on Facebook just by being in the same place, at the same time, while having mutual direct friends on Facebook.

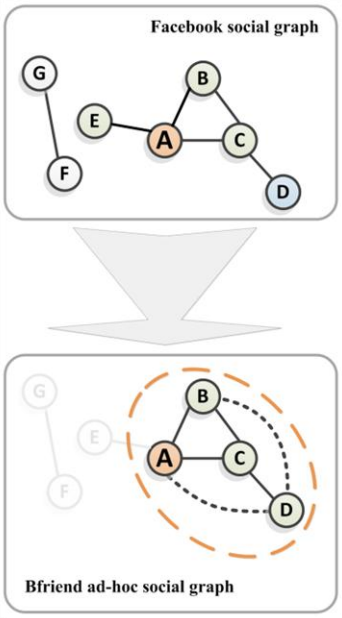

Figure 2. A social graph translation from Facebook to Bfriend

IV. BFRIEND SYSTEM ARCHITECTURE

Bfriend system is based on client-server architecture and consists of three types of servers and a thin client [17], as shown in Figure 3. A *central server* holds all the logics and computing algorithms for the Bfriend application. It is connected to a database in which the user data and social graph (connections between users) are stored. The central server connects to the *Facebook server* (using Facebook Graph API) for retrieving friend lists for Bfriend users. Prior to that, the user has to grant access to his private data on Facebook, hence the connection between the two. Push service is utilized through *Xtify*[1] *servers*, which enable notification delivery. Push servers are used solely to deliver content; the content itself is generated by the central server that sends the data towards push servers to complete the delivery. Push server needs to know where to send the content; therefore it has to have its own internal tracking of Bfriend users (their IP (*Internet Protocol*) addresses, to be precise).

A communication in the Bfriend system is quite complex, as shown in Figure 3. as well. First, there is the communication with Facebook Graph API which dedicates a unique Facebook ID for the user, after which

[1]Xtify (www.xtify.com) is a company that developed push-servers for smartphone-based content delivery.

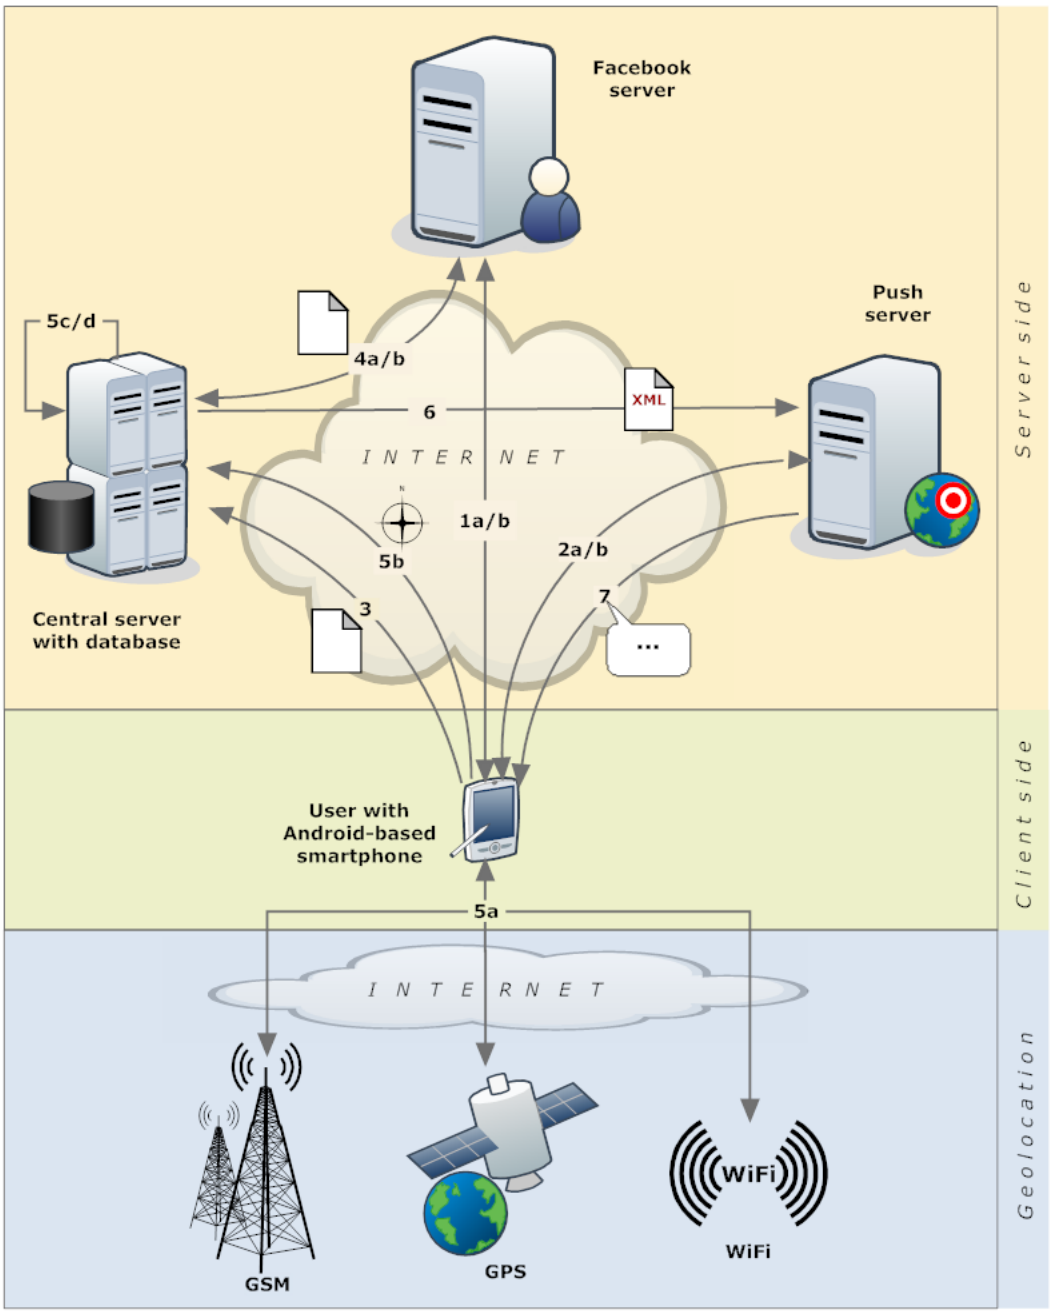

Figure 3. Bfriend system: an architecture and communication

the user has to allow access to his or her personal data on Facebook (*steps 1a, 1b*). Next is the communication with the push server for retrieving an Xtify ID (*steps 2a, 2b*). This is necessary in order to be identified by that server for notification delivery later on (*step 7*). The initialization process of the Bfriend applications begins with the *step 3*, in which the user's device sends initial data (i.e. Facebook ID an Xtify ID), so that the central server can bring those in correlation with the user. After the initialization step, the central server can proceed with algorithms – refreshing user's friends list (*step 5d*) by retrieving the data from Facebook (*steps 4a, 4b*) and periodically calculating the distances between Bfriend (i.e. Facebook) friends to be aware of any spatial proximity that triggers notifications between them (*step 5c*). In the meantime, for the central server to have the latest geolocation of each user – user's devices have to periodically check for their current location and send that data to the central server (*step 5b*). This is done by means of GSM (*Global System for Mobile Communications*), GPS or WiFi, all of which provide different degrees of precision for retrieving user's current location (*step 5a*) [18]. When two or more users are close to each other (e.g. within 100 meters), distance calculation algorithm (*step 5c*) triggers the server to generate an XML (*Extensible Markup Language*) document with a notification's content. Figure 4. presents a flowchart which describes the algorithm that calculates the distances between friends in the Bfriend social network periodically, every 60 seconds. The XML document generated in *step 5c* is sent to the push server (*step 6*) which delivers the content to the target user in a form of the notification (*step 7*).

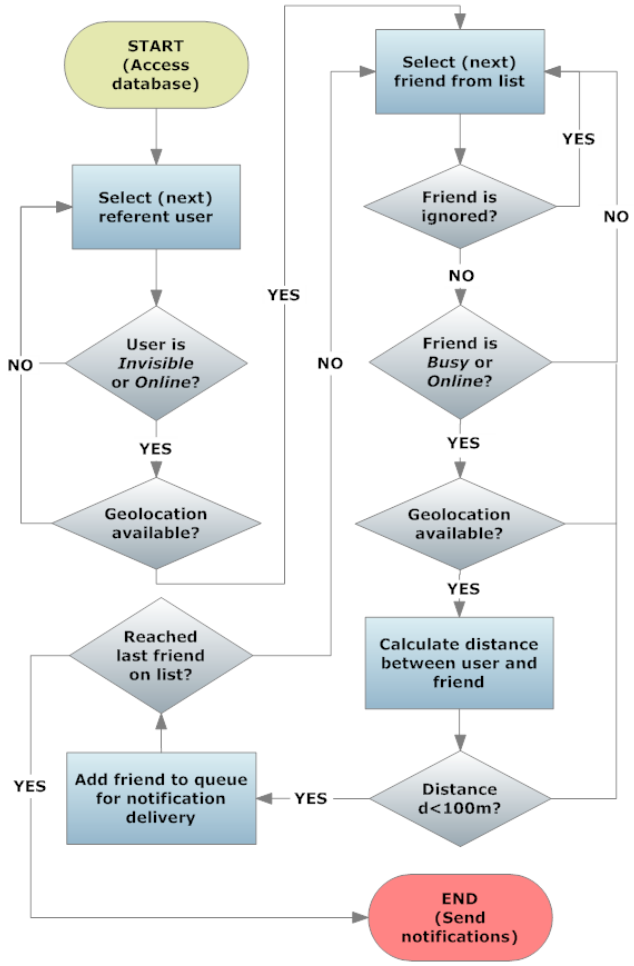

Figure 4. A flowchart of the distance-calculating algorithm

V. PROOF-OF-CONCEPT FOR BFRIEND PLATFORM

In order to use the Bfriend service, one should have an active Facebook account, a smartphone with an available Internet connection and Bfriend application installed. The application is available for Android OS (*Operating System*), using screen notifications for content delivery.

A. *Bfriend application for Android OS*

Figure 5. presents a screenshot of a Facebook login form when a user starts the Bfriend application for a first time.

Figure 5. Facebook login form in the Bfriend application

After logging in, the user is prompted to allow Bfriend to access his/her basic information on Facebook social network (Figure 6.).

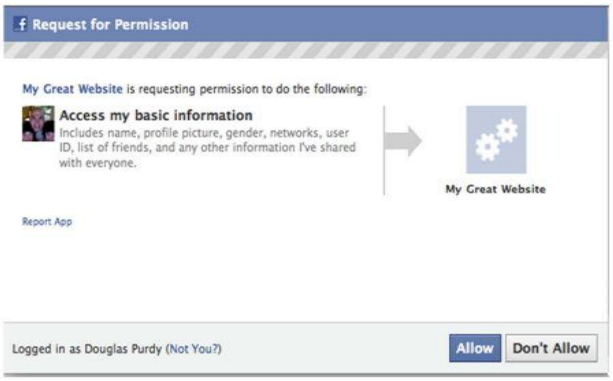

Figure 6. Bfriend request for accessing ego-user's info on Facebook

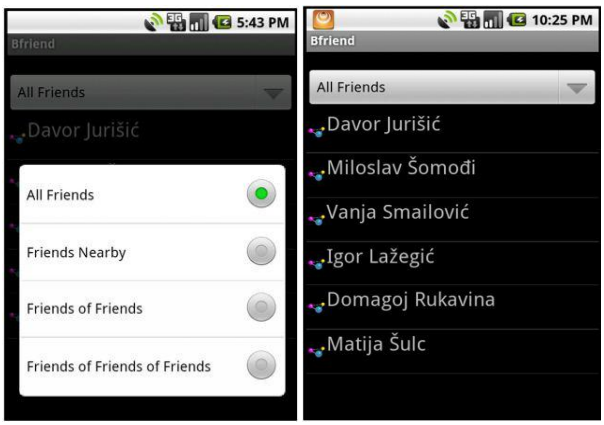
By allowing access, user gets the following options (Figure 7. a):

- view *All friends* list on Bfriend;
- view *Friends Nearby* list on Bfriend;
- view *Friends-of-friends* list on Bfriend;
- view *Friends-of-friends-of-friends* on Bfriend.

The *All Friends* option is not context-aware and thus shows all of the ego-user's friends, i.e. Bfriend and Facebook friends (Figure 7. b). *Friends Nearby* shows friends within a given distance (the default is 100 meters), which makes it context-aware. *Friends-of-friends* and *Friends-of-friends-of-friends* lists are similar context-aware lists of people that are two and three degrees away from the ego-user, respectively.



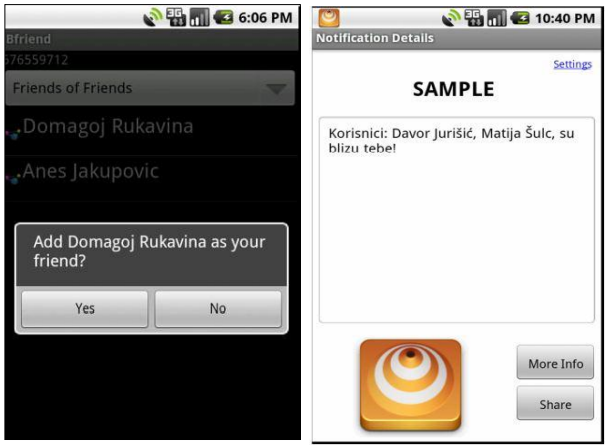
a) b)

Figure 7. a) Bfriend application home screen; b) The *All Friends* list

In case the ego-user wants to add some new friends from Friends-of-friends or Friends-of-friends-of-friends list in the Bfriend application, he or she can do so easily. After adding a friend in Bfriend application, user is prompted to do the same on his/her Facebook page as well, to keep his/her social connections up to date[2] (Figure

[2]At the time of writing this paper (Jan 2012), Facebook API did not allow this process to be automated, but instead demanded explicit user action.

8. a). Finally, in case the user has one or more friends nearby and has a presence value set to *Online* or *Invisible*, he or she will get notified as it can be seen in Figure 8. b). Only friends that are not on the *Ignore List* (i.e. they are not ignored when in the ad-hoc network) are stated in the notification.



a) b)

Figure 8. a) Adding a new friend through Bfriend; b) Example of a notification alerting about three friends nearby

B. User presence

There are four presence states supported by the Bfriend – *Available*, *Busy*, *Invisible* and *Offline*. These are important to acknowledge as they represent a significant and distinctive feature of the Bfriend system. TABLE I. describes presence states in more details.

TABLE I. USER PRESENCE

Presence	User visible to others in the network	Notifications can be delivered to the user
Online	Yes	Yes
Busy	Yes	No
Invisible	No	Yes
Offline	No	No

C. Prerequisites to usage scenarios

User scenarios described below have certain prerequisites. First, the ego-user should be logged into the Bfriend application from his Android-based smartphone. In order to achieve this, ego-user has to have an active Facebook account that enables Bfriend system to access described private data about the ego-user.

D. Common usage and basic functionality

"Let us say a student named Ewan is sitting in the classroom, listening to the introductory lesson of a certain subject. He was hoping that his friend Luke would be in the same group as him, but he is not there. During the break, as he is walking to the cafeteria, he receives a notification on his smartphone saying that his friend Luke is at the college too, close to his current location. They meet up and discuss changing subject groups in order to attend lessons together."

A typical scenario, such as this one, describes the basic functionality and the main feature of the Bfriend system – informing the ego-user of Facebook friends nearby. The distance which triggers notifications is not great; it is a value of tens of meters or so. Figure 9. shows a use case diagram showing steps of basic functionality.

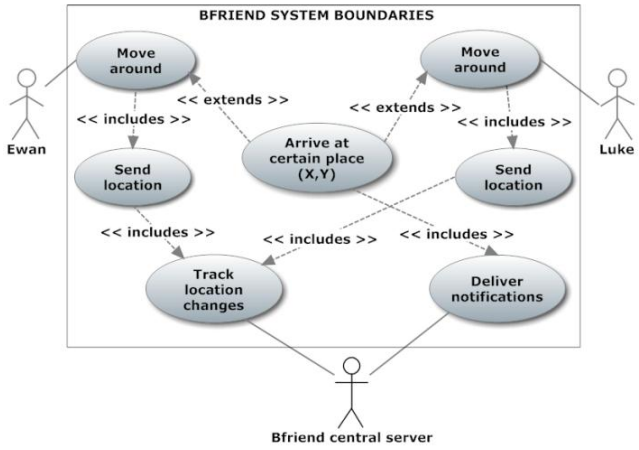


Figure 9. Use case diagram showing basic usage of a Bfriend system

Figure 10. presents a sequence diagram of the scenario describing Bfriend's basic usage. It reveals in what order processes from Figure 9. interact and execute.

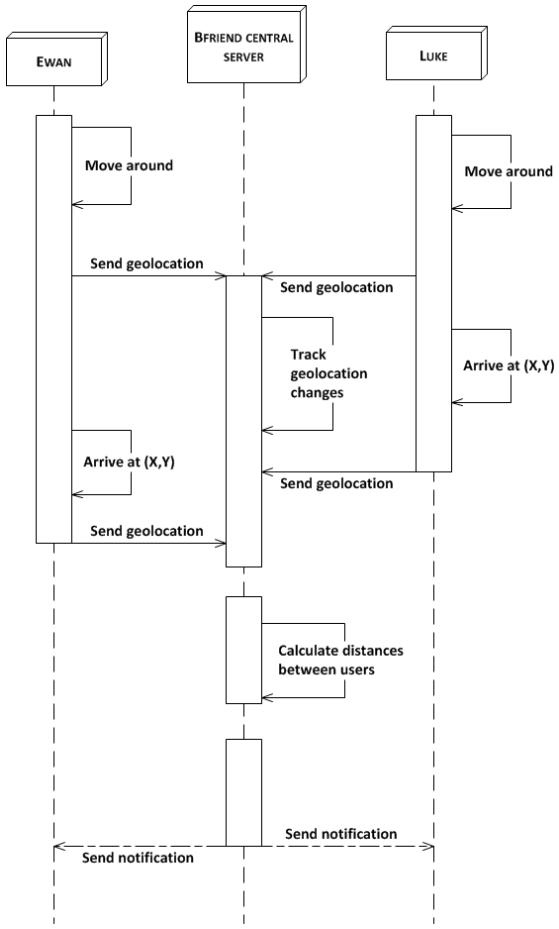

Figure 10. A sequence diagram showing Bfriend's basic usage

E. Advanced Features

"Ewan is walking towards the main square to meet his girlfriend. He sets his availability status to Invisible, as he does not want to be present in the ad-hoc network with his friends but, nevertheless, wants to be aware of other friends nearby. As he passes by the most famous pub in

the city, he receives a group notification saying that five of his friends are close by. On the other hand, his friends did not receive the notification about his proximity as he is invisible in the network. Despite being in a hurry, he decides to drop by just to say hello. On his way out, he quickly checks for friends of friends' names because he did not have much time to meet everybody properly. Maybe he will add them as his direct friends some day."

This example shows advanced functionalities and features Bfriend has to offer. Ewan is invisible throughout the entire scenario and, eventually, uses "friends-of-friends" feature to find out more about people he just met. Similar scenario would include meeting new people in a disco club during a night out (using friends-of-friends feature) or using some other availability statuses (e.g. *Busy*) while attending a business meeting.

F. In case of emergency

"Ewan is driving in his car when suddenly he hears on the radio that there has been a traffic accident nearby. At the same time, he receives a notification that his friend Luke is close to his current location. He figures – Luke could be in serious danger. He proceeds to the site to find out that his friend has been injured and is unconscious. The paramedics are already on their way, so Ewan waits there to help them identify Luke and to notice them of any medically relevant information they should be aware of – such as drugs Luke is taking, any diseases he has been treated for, as well as certain allergies he suffers from or possibly his blood group."

In this example, there has been an accident in which emergency services, such as 112, often need some additional information about injured people involved in the accident. Close friends or family are a great source of such information. For more effective means of communicating than using radio transmitted information regarding the accident, dedicated hardware and software could be used instead. Currently, eCall is an example of such project, assisting in traffic accidents by providing additional information prior to sending emergency teams or others to help [19].

VI. Conclusion

Advances in ICT (*Information and Communication Technology*) during the last decade have enabled telecom operators and other providers to go mobile with a wide range of services and social networking services are not an exception. Context-awareness, such as being able to pinpoint the user geographically or know whether he or she is at work, in school or just shopping downtown, is critical for dynamic, goal-oriented and temporal approach that ad-hoc social networks assume. Users are no longer satisfied just with "being connected", they need their PC's, laptops and smartphones to be aware of where, when or how they are connected. The Bfriend system makes use of those facts by making them the core user requirements of the service – users create, maintain and end their own, temporary ad-hoc social networks using spatial proximity with their friends as context information.

Future work will include adding more features to the Bfiend service, e.g. implementing a chat service available to users within the ad-hoc network, adding a personalization layer on top of the service (making the experience more personal to the user), raising context-awareness in terms of part of a day (i.e. day or night), giving users the ability to sign-out and sign-in with different Facebook accounts or even viewing map with locations of their friends nearby.

Abstract - **Massively Multiplayer Online Role-Playing Games (MMORPGs) comprise persistent virtual worlds in which thousands of players are interacting. Information regarding player behavior in MMORPGs is highly relevant for network planning, game design, server load balancing, etc. The main contribution of this paper is wJournal – a tool for detailed measuring of player behavior for the most popular MMORPG – *World of Warcraft* by *Activision Blizzard*. The behavioral model on which wJournal is based upon consists of six player action categories (*Questing, Trading, PvP combat, Dungeons, Raiding, and Uncategorized*). We demonstrate the use of wJournal by monitoring and analysis of 16 players over the course of four weeks' time.**

I. INTRODUCTION

Massively Multiplayer Online Role-Playing Games (MMORPGs), unlike other multiplayer games, support very large numbers of concurrent users, possibly tens of thousands, playing together in a common, persistent virtual world. Each user is represented by a virtual character through which the player interacts with the game. Through the course of the game, virtual characters become more powerful and progress in terms of levels (up to a maximum level), abilities, and possession of virtual items (e.g. swords and armor). As of February 2012, according to *mmodata.net* [1], a reference source for the (estimated) number of players for subscription based games, there are around 21 million MMORPG subscribers, out of which more than 10 million play the *World of Warcraft* (WoW), a MMORPG developed by *Activision Blizzard*.

A wide popularity of MMORPGs reflects onto network traffic as well. For example, according to measurements reported in 2007 in a live 3G mobile core network in Austria [2], the amount of TCP traffic generated by WoW constituted over 1% of total TCP traffic. While the volume of MMORPG traffic is, in general, still relatively low, it is growing fast. According to Cisco Visual Networking Index [3], the online gaming traffic volume (including casual online gaming, networked console gaming, and multiplayer virtual-world gaming) will grow with a compound annual growth rate of 43% in the period 2010–2015; topped only by Internet video (48%).

Network traffic monitoring and analysis have always played a key role in studying and improving the operation of telecommunication networks and the Internet. With respect to online gaming, a recent trend in traffic monitoring and analysis has been oriented towards understanding player behavior with respect to traffic modeling and user perceived quality. Information about player behavior can be utilized in many ways. From the perspective of network infrastructure equipment vendors and network operators, it is a key for development of traffic models used for network planning dimensioning, and testing [4][5]. From the game design perspective, information regarding player behavior and movement in the virtual world is crucial for virtual world partitioning, area of interest management algorithms, and setting minimum bandwidth and latency requirements. From the business perspective of a game provider, it helps estimate users (dis)interest in the game and predict player churn (i.e., the number of users who quit playing entirely). Player behavior also has an impact on computational resources and energy consumption [6]. Thus, tools for monitoring and analysis of player behavior are needed by all stakeholders in the online gaming business.

In this paper, we present our contribution, a tool we developed for monitoring and analysis of player behavior in WoW. The tool collects player behavior related data on selected game related characteristics, such as a number of sessions over a monitoring period, a number of different game characters within each session, types and timing of gaming activities, and the areas visited in the virtual world. For the categorization of gaming activities, we apply a previously developed model of player behavior [7]. As people keep journals to record their activities and happenings in real life, so does the tool for their virtual persona(s) in WoW – hence its name *wJournal* (as short for "*WoW journal*"). We illustrate the use of the *wJournal* by performing measurements to characterize user behavior in a group of 16 players, and compare it to previous results, and also to investigate the relationship between the player behavior, location, and movement patterns in the virtual world.

The remainder of the paper is structured as follows: Section II briefly summarizes related work on approaches and monitoring and data collection for studying player behavior, and Section III presents the player behavior model which serves as a basis for our tool. Section IV presents the design and implementation of *wJournal*, and Section V describes and discusses the measurement results. Finally, Section VI concludes the paper.

II. RELATED WORK

There are three complementary approaches for studying player behavior in MMORPGs, based on where and how the player behavior data is tracked and recorded:

- At the server: this approach is based on the game provider's internal server data logs, which, obviously, can only be obtained or accessed only in close cooperation with the game provider;
- At the client: this approach is based on either extending the default game client by developing an add-on (using an API provided by the game developer), or, creating a new or modified game client with desired functionality (possibly subject to technical, legal, and/or licensing restrictions). Using an add-on (also spelled as "addon"), or a modified client for behavior monitoring requires cooperation with players;
- In the network: this approach is based on capturing game traffic in the network and analyzing it, usually offline, to extract the behavioral information from those traces. Access to network infrastructure is needed in this approach, and depending on the measurement point, cooperation with the network operator may be needed (or not).

Each approach has its advantages and disadvantages with respect to the amount and descriptiveness of data, as well as its suitability for a particular purpose. For the purposes of this work, we briefly summarize the user behavior characteristics which have been studied in literature.

Server data approach. Feng, Brandt and Saha [8] have performed an analysis on several years of server log data provided by developers of popular MMO *Eve online*. They investigate the number of players logged into the game at any given time. They have also presented a long term analysis and demonstrated how adding new content to the game influences player behavior.

Client data approach. In addition to collecting data about the player using the client itself, several works use polling, meaning they use a script, running on a client, which uses regular game client mechanisms to "poll", i.e., obtain information on, other virtual characters (i.e., players' avatars) present in the virtual world. This approach is used by Pittman and GauthierDickey [9] who record and model the behavior of two MMORPGs: WoW and *Warhammer Online* by *Mythic Entertainment*. Authors also mention that another option for measuring player behavior would be to modify the game client, which could provide better results, but with possible legal consequences. Lee, Chen, Cheng and Lei [10] gather the data of player behavior in WoW over the course of three years, constantly refreshing the avatar presence. Data is used to predict avatar play time, since there was no way to correlate the avatar to the actual player. Zhuang et al. [11] measure session length, player availability, player downtime, and player location in the virtual world. Authors classify the virtual world zones into areas named *Questing*, *Traveling*, and *Cities*, and calculate the time a player stays in each area. In our previous work [7], we introduced a WoW add-on named *World of Warcraft Session Activity Logger* (WSA-Logger), a predecessor to *wJournal*. (Compared to WSA-Logger, *wJournal* has several improvements in terms of functionality and performance, which will be described later in this paper.)

Network approach. This approach is applied by Kihl, Aurelius, and Lagerstedt [12] who inspect network traffic in an access network in Sweden and extract the traffic from a number of households in which people played WoW. They present information regarding hourly and daily patterns of the number of active players, traffic load, and session length. A correlation between time of the day and traffic generated by WoW is used to predict server load.

III. PLAYER BEHAVIOR MODEL

In this section we briefly explain the behavioral model on which *wJournal* is based upon. The behavioral model, specified in our previous work [7], and examined in respect to psychological player motivation [13], specifies six action categories of user behavior, which translate to the states in the finite state machine used by the software. We base the internal logic in *wJournal* on states and transitions corresponding to their equivalents in the system of WoW: the states correspond to the action categories, and the transitions correspond to events (messages sent) which denote the start of a certain game activity.

In our player behavior model [7], we have defined the following action categories for MMORPGs: 1) *Questing*, 2) *Trading*, 3) *Dungeons*, 4) *Raiding*, 5) *Player versus Player (PvP) combat*, and 6) *Uncategorized*. We briefly describe the action categories next.

Questing is an action category involving solving task given by Non-Player Characters (NPCs) for a reward in terms of experience, virtual items, or in-game currency. It is usually performed by a player alone, as questing tasks are usually fairly simple (e.g., kill 10 wolfs).

Trading category includes actions which serve for exchange of virtual goods or money between two players, or, an NPC and a player. Such actions include sending in-game mail, trading virtual items, visiting banks, etc.

Dungeons is a primary small group activity in which a group of players, typically 4-5, fights against a large number of hostile NPCs inside confined areas of the virtual world. These areas are replicated for each group of players and are called instances.

Raiding is an action category which is very similar to *Dungeons*, but larger on all scales. It involves larger groups of players (i.e., 10 and more), NPC opponents are more challenging, and fights are more complex. Therefore, *Raiding* provides better rewards then *Questing* and *Dungeons*.

PvP combat involves actions of battling between players, both in instanced and in non-instanced areas. Its distinctive characteristics are high action pace, high player mobility, and low number of NPCs.

Uncategorized comprises the time within the session which cannot be uniquely assigned to one of the five categories mentioned previously.

IV. DESIGN AND IMPLEMENTATION OF WJOURNAL

wJournal has been designed as a WoW add-on. This design choice has been based on the fundamental requirement which stems from the player behavior model

– the ability to detect what the user is doing in the WoW virtual world (i.e., to which action category this activity refers to), when and for how long, and where (in which are of the virtual world). *wJournal* enables tracking of the number of sessions, the number of different characters within each tracked session, start time and end time of session segments which represent a single behavior category within a session, and the list of visited areas with associated time duration of the visit. Compared to our previous add-on (WSA-Logger), *wJournal* has improved performance in terms of reduced memory usage (70kB total) and CPU load (less than 1% on the default CPU performance meter). It also has a new functionality for tracking user movement patterns. Other minor improvements include bug fixes and some GUI details.

A. *Event tracking in wJournal*

Whenever a certain activity in the game is performed, the WoW API of the game client fires an event related to that activity. For example, when the user opens a mailbox inside the game, the MAIL_SHOW event is fired. The number of events has been growing with the game evolution, and as of March 2012, there are 736 distinct events within WoW. In order to track player behavior with respect to the player behavior model, certain in-game events are helpful for determining action categories, and some are not. For example, the event MAIL_CLOSE may be uniquely assigned to the *Trading* category, and the event BATTLEFIELDS_SHOW may be uniquely assigned to *PvP combat*. However, a large number of events happen constantly during gameplay; making it impossible to distinguish the action category based solely on that event. Event tracking by using WoW API is explained in more detail in our previous work [7].

For the purposes of this work, it suffices to say that *wJournal* tracks *Questing*, *Trading*, and *non-instanced PvP combat*, as a chain of events starting from the first event assigned to a given category, to the first event which does not belong in the same category. *Dungeons*, *Raiding*, and *instanced PvP combat* are all variations of instanced world space and are tracked differently. Namely, these categories are fully defined by two events labeling the entrance in and exit out of the instanced area.

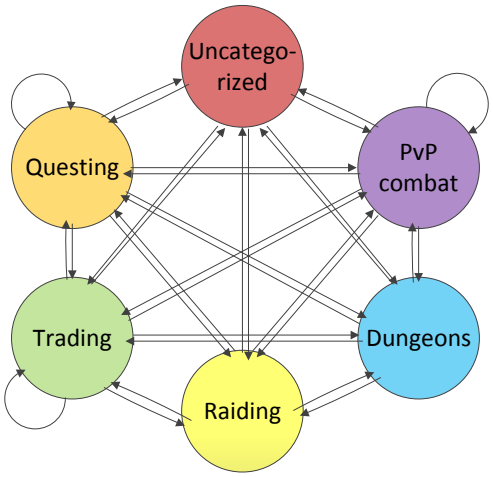

Figure 1. User behavior tracking finite state machine in wJournal

So, each time a player enters and spends time in an instanced area, the player is considered to be performing events belonging to the respective behavior category.

B. *Player behavior tracking in wJournal*

A player behavior within the game client, as tracked by the add-on, can be modeled as a finite state machine, as shown in Fig. 1. The set of states corresponds to "user state", as the user "being active" in one of the six action categories. The set of input events corresponds to user actions in the game world, and a set of output events corresponds to events fired by the API. The transition function takes the current state and an input event, and returns the output event and the next state. Since there are no such restrictions within WoW, any state can change into any other state, thus transitions are possible from each state to all other states. Also, for non-instanced states (*Questing*, *Trading*, and *non-instanced PvP combat*), there is a loop denoting that there can be a series of events which do not change the current state. For instanced states (*Raiding*, *Dungeons*, and *instanced PvP combat*), as mentioned before, the state is defined through the instance entry and instance exit events.

By implementing the model described above, we are able to track the players' behavior in all of their characters separately, show them the gathered statistics in form of bar-charts, and export all the data needed in a log file.

C. *wJournal implementation*

As mentioned earlier, *wJournal* has been implemented as a WoW add-on, by using Lua scripting language and Ace3 development framework (http://www.wowace.com/add-ons/ace3/). A WoW add-on, in general, is a collection of files which reside within the respective subdirectory in the WoW directory tree on the player's computer. An add-on directory contains a (mandatory) table of contents file, and a collection of individual components which implement the desired functionality, such as Lua scripts, XML files, fonts, graphics, sounds, etc. These files are loaded into the game scripting system when the client is started, and executed within the client to make desired modifications to the user interface. Due to security reasons, the scripting interface has limitations, in particular in terms of access to the file system and the operating system resources. It should also be noted that the scripting interface does not have access to the game world part of the client, so as to prevent misuse such as, e.g., automating behaviors or modifying gameplay. For more information on creating and programming WoW add-ons, an interested reader is referred to [14].

1) *wJournal add-on structure*

The wJournal directory contains the following files: 1) a table of contents (metadata) file, 2) an XML file used to determine the location of, and order in which Lua scripts (files with .lua extension) are loaded, and 3) Lua script files (the actual code which runs the add-on). The amount of data that needs to be tracked at any given time is substantial, so our add-on is broken down into multiple files for better code readability. In addition to the files

mentioned above, two additional files include *Zones* and *Events*. Their function is explained in the text below.

2) Zone tracking

Virtual world of WoW contains more than 100 distinct zones. A *zone* is an area in the virtual world defined by its size and name. A character's location at a given time can be determined by using a script. Keeping track of the zone in which the player is in drastically reduces the number of events that we need to keep track of. For example, if a player's character is transferred to an instanced zone like battlegrounds, there is no need to keep track of any other events while in it. Simply noting the zone entrance and exit is enough to determine which instanced behavior category a player is currently in.

3) Event tracking

The *Events.lua* file is used for storing a list of events used for determining the behavior category. This list is extendable, in the sense that new events (meaningful for our categories) added into the game (e.g., by game updates) may be added into this file to make *wJournal*'s decisions more precise.

4) Core logic

wJournal's program logic is stored in the *Core.lua* file. This file implements the finite state machine described above and records the data about the player behavior, with the goal of calculating and presenting the player behavior statistics. Obviously, calculating these in real time would have a negative impact on game client performance so that has to be avoided. The next problem that has to be solved is how to store collected data, and remain in line with security restrictions for add-on's Lua scripts. To avoid performance degradation and to work around file system access limitations, *wJournal* separates the behavior data presentation to the player from data storage for offline processing.

5) Player statistics shown within extended GUI

The display showing the behavior statistics to the player has been designed so as to be rather simple and non-intrusive and it can be easily put aside if needed.

Fig. 2 shows the display, using a bar chart for graphical representation of the basic player behavior statistics. In addition to bar length indicating the time spent in each action category, the chart also displays the percentage of the time spent in a certain category with respect to the total playing time.

6) Player statistics stored in a text file

For security reasons, Lua scripts in WoW add-ons are permitted write access only to an isolated folder, where settings for all add-ons are stored.

Figure 2. wJournal display of playing statistics

The problem is that using an add-on over an extended period of time, results in storing large amounts of data in files originally designed for settings.

This, obviously, has a cumulative negative impact on performance. Our past experience with *WSALogger*, which used this mechanism, taught us that a better solution was needed. For *wJournal*, another solution has been found by using the WoW's option for creating custom chat channels. Custom chat channels have several properties that enable this solution: 1) they can be used by any number of users, 2) add-ons are allowed to write in such channels without the users having to type themselves, and 3) add-ons can selectively toggle chat logging on and off, allowing to write only the text generated by the add-on into the game client's chat history, virtually making it our export file.

A chat history line is structured as follows:

```
MM/DD hh:mm:ss [channel name] <avatar
          name>: <text>
```

Where the MM/DD field represents month and day, and it is followed by the time of the day expressed in hours, minutes and seconds (hh:mm:ss). The "channel name" is used to identify the originator of the chat message, as the avatar's name is used to identify the player who wrote the message. The "text" field represents the message received. Since the game client provides timestamps, channel names, and avatar names automatically, we use the text field for writing the data of interest. An algorithm for writing into a chat log is as follows:

1. Wait for an event;
2. If an event is registered as belonging to a certain behavior category, forward it to the state machine as a new input event;
3. If the state machine transitions to a new state, send the new behavior category name and zone in which this event has occurred to a custom chat channel.

There is also a basic algorithm for data filtering before writing into the chat log, defined as follows:

1. Wait for a change in the chat window;
2. If the channel on which the message is received and the current player's avatar name have been previously registered in *wJournal*, enable chat logging. Otherwise, disable chat logging.

Based on the chat history, it is possible to chronologically reconstruct the sequence of player behaviors, i.e., the behavior start time, the behavior end time, and the zone in which the behavior has occurred. To make handling of data easier, a C# parser in has been developed, which creates output in Microsoft Excel (XLS) format. This file contains the following: Player ID, character name, behavior category name, starting time of a category, ending time of a category, and a session ID. This allows us to easily sort, enumerate, find peak values and create graphs from collected data. We also study the data to analyze the time duration spent by the player per action category, and the spatial positioning of characters.

V. MEASUREMENT RESULTS

We demonstrate the use of *wJournal* by the following experiment, run by student volunteers at the Faculty of

Electrical Engineering and Computing of the University of Zagreb, over a four weeks' time. The students "enlisted" a total of 16 WoW players to participate in the research. The participating players were requested to set up the *wJournal* add-on on their computers, and to continue their usual behavior inside the virtual world during the course of the experiment.

Data gathering started on May 5th, 2011, and it ended on June 10th, 2011. During this period, WoW patch 4.1.0 of the Cataclysm expansion was active. As the previous patch was introduced on October 12th, 2010 (meaning that no new content has been introduced which would "skew" the user behavior), players have behaved in their already settled ways, i.e., in usual patterns. During the experiment no personal data was collected, except player's age and gender. A total of 16 players participated in our research, with an average of 1.937 characters per player (as one player may use several characters in a same session).

The log analysis has been performed to establish the age and gender characteristics of the test group, their session characteristics, and the player movement.

A. *Age and gender analysis of the test group*

The average player age in our dataset is 24 years, with a 16-year-old being the youngest, and a 32-year-old the oldest subject. In general, younger subjects showed the tendency to play mainly with one character and focusing on single behavior categories, while older players showed a variety of interests. Distribution by gender is roughly equal (i.e., 9 male and 7 female players). With respect to activity categories, the collected data shows that "traditional" gender roles seem to extend into the virtual world as well, as female participants showed more interest in cooperative and healing roles, while male participants focused on playing competitive and more aggressive roles.

B. *Session length analysis*

We define a *session length* as the time spent in the game between logging in and logging out of a single character. One player can have multiple characters, but only one can be active at a time.

We also define a *session segment* as a part of the session in which only the activities in one action category take place. In our test group, an average session time is 62 minutes, with the longest session just under 14 hours. The shortest sessions lasted only a couple of seconds. Such sessions can represent an accidental character logons, as well as logons to simply check some equipment status, or chat. Therefore, information about shortest sessions is not reported separately, but it is calculated into average session lengths.

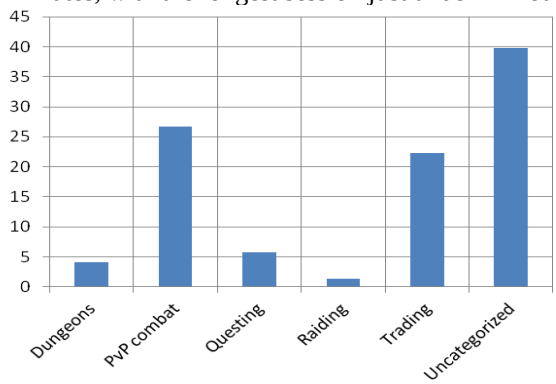

Figure 3. Occurrence percentages of behavior categories

C. *Behavior category duration analysis*

Fig. 3 shows the average occurrence (percentage) of the six behavior categories in our dataset, and Fig. 4 shows (the percentage of) the time spent in each category. Due to a relatively small number of participants in the experiment, who happened to be mostly interested in *PvP combat*, the behavior category spread is imbalanced. Actions recorded mainly belong to *PvP combat*, *Trading* and *Uncategorized* categories, while *Questing*, *Dungeons* and *Raiding* (in descending order) are less represented. A typical session with a maximum level character contains chatting, discussing tactics and trading while waiting to be matched against other players in *PvP combat*, which is played the most. When not playing *PvP*, players are mostly questing with their alternative characters, or leveling them through dungeons.

Only three (out of sixteen) test subjects have shown interest in raiding, which is played mainly in evening hours. By comparing Fig. 4, and Fig. 3, it may be noted that, even though *Uncategorized* session segments happen very often, their total time is not as high in percentage as expected. It is also noticeable that dungeons and raids have only a few occurrences, but their percentage in total time played is not insignificant because the corresponding session segments tend to be long (as shown in [7][13]). We can order the behavior categories from the most to the least frequent, as follows: *Uncategorized*, *Trading*, *PvP combat Questing*, *Dungeons*, *and Raiding*. The average length of each category, also in descending order: *Raiding*, *Questing*, *Dungeons, PvP combat, Uncategorized , Trading*.

D. *Player movement analysis*

Players are able to move through virtual zones in several ways: by land, by air, and through teleporting.

Travelling by land means a player can follow designated routes on foot. Thus, a player can only visit zones adjacent to his current zone.

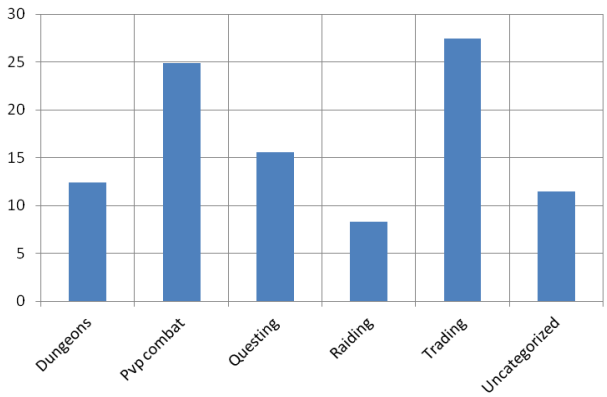

Figure 4. Percentages of time spent on each behavior category

This is characteristic for low level characters, since they have no faster options available until higher levels.

Travelling by air is acquired at mid levels. A player is able to purchase a flying mount which still limits him to travelling only to adjacent areas, but not as strict as roads do. Once the flying ability is acquired, there is no recognizable pattern in player movement when travelling by air.

Teleporting is a way of instantly transporting a player to a zone not necessarily adjacent to his current position.

Since there are virtually endless combinations of traveling patterns, no automated process is used for recognizing player movement. Instead, the parsed data is manually analyzed.

In our dataset, only 16% of characters are lower levels and are traveling by land or air. Most players are maximum level, where we find little to no movement at all. We have also confirmed that characters tend to gather in major cities. Idling and trading are the two behaviors found there. From capital cities they tend to enter queues for instanced actions. Approximately every 26 minutes players are teleported to a dungeon, or every 19 minutes to a battleground. Afterwards, they continue to idle or trade until the next queue is up. Most of the maximum level players follow this behavior pattern.

E. Relationship between actions performed and location in the virtual world

We have also analyzed which are the most frequent areas related to each action category. In general, players tend to visit only a few zones. Trading almost exclusively happens in capital cities or adjacent areas. Time spent in *Uncategorized* is mostly (over 75%) spent in capital cities as well. *PvP combat* is almost completely focused in instanced areas, and occurrences of *PvP combat* outside these areas are very rare. All instanced areas for *PvP combat* are frequently used. This differs from the *Dungeons* category, where the *Dungeons* intended for maximum level players are used 91% of the time. This means that a large amount of content is not used. This is even more pronounced in *Raiding* where only two instances have ever been visited.

VI. CONCLUSION

By using *wJournal*, we have gained an interesting insight into the player behavior in the test group. The following conclusions have been made:

- Players tend to gather at certain hotspots (hubs), making spatial distribution of server load uneven.
- Behaviors that players show most interest in, (e.g., PvP combat), mostly take place in instanced zones, causing constant "server hopping".
- Some of the instanced areas for dungeons and for raiding are very rarely used.

This information may be significant for designing virtual world partitioning algorithms and server load balancing, as well as on network capacity planning and dynamic resource reservation. Other uses, as explained at the beginning of the paper can also be envisioned.

For future work, we plan to create a tool for predicting server and CPU load based on user behavior patterns we have identified.

ACKNOWLEDGMENTS

This work was supported by the research project 036-0362027-1639 "Content Delivery and Mobility of Users and Services in New Generation Networks", by the Ministry of Science, Education, and Sports of the Republic of Croatia, and Ericsson Nikola Tesla, Zagreb, Croatia. Also, the research leading to these results has received funding from the European Community's Seventh Framework Programme under grant agreement no. 285939 (ACROSS).

KNOWLEDGE MANAGEMENT

Social Analytics for Mobile Operators

M.Poldrugač, M.Komadina
Nokia Siemens Networks, Zagreb, Croatia
monika.poldrugac@nsn.com, marin.komadina@nsn.com

Today's in highly competitive market place, push mobile operators to optimize their subscriber's life time value by implementing efficient marketing campaigns. Social analytics offer the means to act upon subscriber information with the right target, the right timing and the right offer. Mobile operators can target campaigns, increasing customer loyalty, preventing churn, maximizing ARPU based on Alpha Score and therefore optimizes the acquisition and retention investments.

I. INTRODUCTION

Until now, the business insight has been backward looking, mainly focusing on having all the data available in a consolidated data warehouse as well as analyzing what has happened in the past. However, businesses has an increasing need for forward looking approach to understand more and more what will happen in the future in order to make right decision early enough in order to stay ahead of competition. Social analytics provide that forward looking tools that will turn the vast amount of data into actionable information regarding future, unlocking the interconnected data structures of users – mapping lists of friends, their comments and messages, photos and all their social connections, contact information and associated media.

II. SOCIAL INTELIGENCE AND SOCIAL ANALITICS

Social intelligence is a new approach to subscriber profiling and segmentation by leveraging a combination of both personal/psychological and social/cultural factors necessary to better understand your customer behavior (**Figure1**).

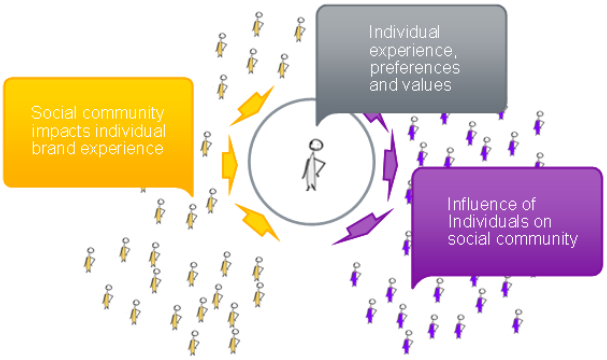

Figure 1: Customer Understanding [1]

Social Analytics uses 3 step approaches as follows:

1.) PREDICT

Early detection and identification of customers most likely to churn and/or take-up next level services to prioritize targeting.

2.) ACT

- Design of right offers to right customers to enhance customer value
- Micro-campaigns to enable fast and effective execution for maximum result

3.) AUTOMATE

- Automated marketing campaign execution
- Lowered cost, faster execution, detailed results and reporting

Social Analytics (SNA) is the process of measuring, analyzing and interpreting the results of interactions and associations between people, topics and ideas. It is the first and most important prediction phase (**Figure 2**) where personal factors, typically related to demographics (e.g. gender, age) and behavior (e.g. purchase history, usage preferences) are joint together with social factors related to social neighborhood, social role and connection behavior using specific mathematical prediction model.

Figure 2: Holistic View on the Customer [1]

Prediction model uses specific roles to model social network to be use and classifies the subscriber's base according with their connections and activities (**Figure 3**):

- Hubs – customers that have a lot of connections when comparing to others.
- Bridges – customers that connect two or more hubs.

- Outliers – customers having only few connections.
- Loners – subscribers having no connections

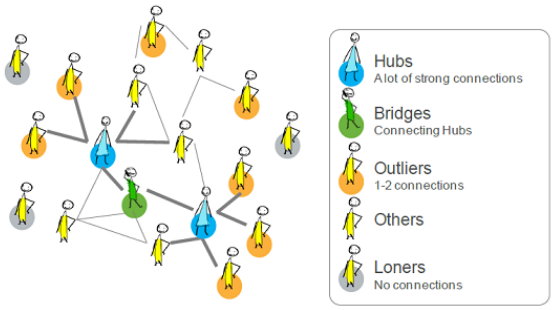

Figure 3: Social Network Roles [1]

Utilizing social input in predictive analytics greatly improves the accuracy of understanding the customer and predicting his or her future behavior. Therefore, Social Analytics builds a holistic customer view based on behavior, demographics and social analysis.

SNA surfaces social network activity, identifying the influencers and followers in social networks, and displays the results in user-friendly network diagrams which provides information about the relationship strength between individuals, can be used in conjunction with other analytical and campaign management applications to provide organizations with insight into how customers interact with each other (propensity and influence).

SNA is self-sufficient and evaluates the impact of certain input data types autonomously ("the more data the better"), no pre-defined rules or assumptions are needed. Self-learning allows for training of models and enables dynamic adaptation to changing environment and can accurately calculate the subscriber's propensity within a particular context; identify top contributors, track user social participation and calculating probability.

SNA uses methodology of Predictive Modeling, known as automated learning from significantly large historic data sets that allows for accurate predictions on future events and to create holistic view on the customers.

Three key requirements for SNA:

- **Automation requirement** - support for real time decision making
- **Data fusion requirement** - numerous data streams of seemingly incompatible data to be integrated
- **Scalability requirement** - huge volumes of transactional data to be processed.

SNA predictive modeling capabilities are:

- **Forecasts a specific behavior**, such as churn or product adoption, in the future using the current data
- **Forward-looking**, examining what will most probably happen
- Social Analytics Predictive Modeling uses **preconfigured data mining** approaches to generate data for the models
- Social Analytics is **self-sufficient** and evaluates the impact of certain input data types autonomously ("the more data the better"), no pre-defined rules or assumptions are needed
- **Self-learning** allows for training of models and enables **dynamic adaptation** to changing environment

To obtain SNA using Predictive Model, two main phases are needed: Training Phase (**Figure 4**) and Prediction Phase (**Figure 5**).

In the Training Phase (**Figure 4**), ground is on all available historical learning data. It uses preconfigured data mining approaches to generate data for the model.

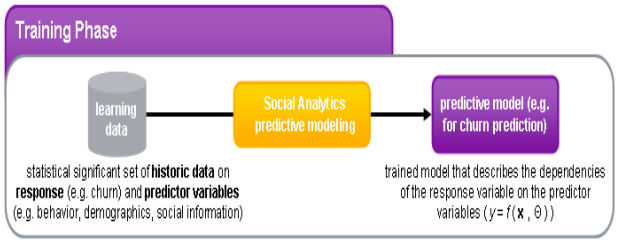

Figure 4: Predictive Model Training Phase [2]

In Prediction Phase (**Figure 5**), predicting data is combined with previously created predictive model to forecast specific behavior, create forward-looking (most probably) scenario.

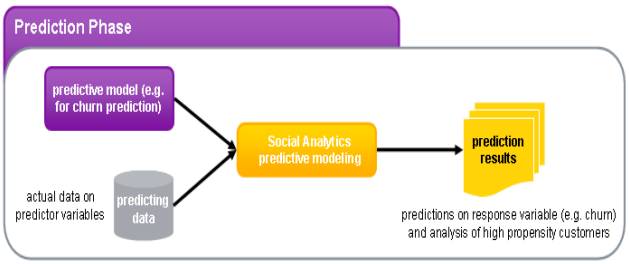

Figure 5: Predictive Model Prediction Phase [2]

During integration of SNA models, mobile operators must leverage on both structured and unstructured datasets. Social media analytics enable operators to gauge sentiment more accurately, as well as identifying influencers and individuals receptive to offers from them. Social Analytics is self-sufficient and evaluates the impact of certain input data types autonomously ("the more data the better"), no pre-defined rules or assumptions are needed. Self-learning allows for training of models and enables dynamic adaptation to changing environment. In order to produce accurate results it is recommended to have five months of subscriber data as basis for the analytical runs and to be used by adaptive continuous learning process.

III. ALPHA SCORE

SNA comprises of an integrated suite of analytic modules dedicated to support accurate subscriber profiling according with demographics, behavior and social context relevant factors.

Alpha Score (**Figure 6**) is measure for subscribers with high risk of churning and those that would pull others with them. This combination of context sensitive

propensity plus the effect that the individual has on its community (e.g. number of peers churning as well) is called Social Links Alpha Score.

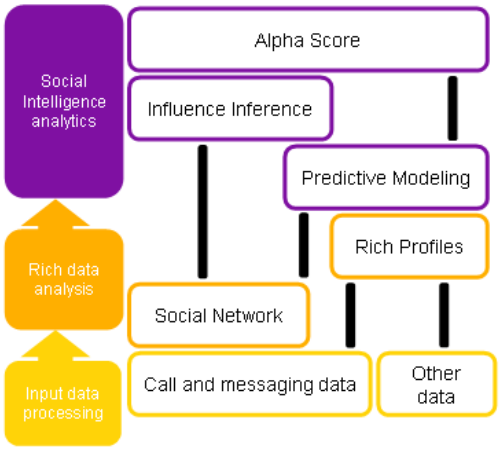

Figure 6: Alpha Score Concept [4]

Subscribers with the highest Churn Alpha Score (**Figure 7**) are called Alphas and they are listed on the **Alpha List** containing a categorized list of subscribers with respective churn propensity and churn alpha scores.

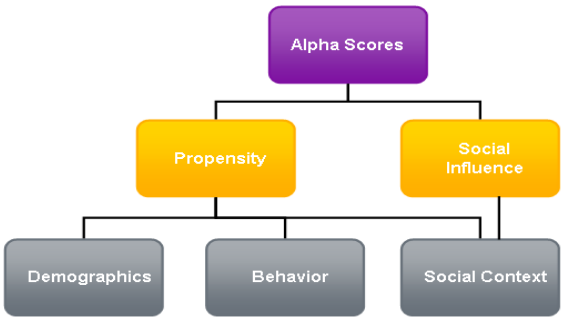

Figure 7: Alfa Score Model [4]

Mathematical model that stays behind Alpha Score calculation is proprietary code developed by different vendors. Alpha Scores take into account the individual propensity (e.g. churn probability) plus the effect that the individual has on its community (e.g. number of peers churning as well).

Calculation of Alpha Score is happening in circles and is recalculated each time one or all conditions inside Demographics, Behavior or Social Context are subject of change. Users with high Alpha Score are targets for:

- Product up sell & cross sell (predict new product adopters that have a high personal propensity towards the product or are connected to others similar subscribers to maximize viral effect)
- Product launch (find subscribers that are likely to take a new product, but who are also likely to spread the message , and iterative launch approach with self learning mechanism to increase accuracy)
- Campaign & offer optimization and personalization (profit optimization: what is the minimum subscriber specific, incentive for maximum top-up, target list generation over different campaign /offer types to maximizing the pull , strategic insight of product users for campaign personalization)

IV. SOCIAL ANALYTICS USE CASES

The social analytics solution is specifically designed to support the following main use cases:

- Churn prevention
  - Churn propensity - identifies "pressured customers" for use in churn-propensity scoring model
  - Retention activities – providing retention incentives or gifts to influencer customers to build loyalty and thereby reduce future churn
  - VIP benefits – offer special packages to influencers
  - Multi-SIM card identification
  - Rotational churn identification
- Viral campaign
  - VAS stimulation - Those identified as influencers can be targeted with VAS stimulation offers
  - Prepaid to postpaid - Offers to convert prepaid customers to postpaid tariffs
  - New product trials - Trials of new products (in a later stage of development) offered to customers who have a history of influencing others to use new products/services that they have tried
- Customer Acquisition Activities
  - Attracting new customers - Member-get-member activities directed toward influencers, boundary spanners or those with many links to customers on other operator networks
  - Family identification - Identification of family groups to offer cross family deals or to make offers of household level purchases, such as IPTV packages
  - Group identification - Identification of groups such as ethnic communities to offer targeted packages (for example, inexpensive international calls)
- Customer segmentation
  - Analysis of prepaid customers - SNA provides demographic and behavioral information on prepaid customers who do not typically provide mobile operators with information when they sign up
- New product or services launch activities
  - Get influential customers into stores - Give them demos and time with store staff so they are aware of important new products and know how to use them
  - Focus groups - Use influential customers to help shape product development
- Advertising

- Targeted advertising - Provide advertisers with details of influencers and other targeting information. Scoring can be used to set prices for different target audiences based on their influence level. Could also be used for mobile operators and their mobile marketing activities.

The SNA solution supports the marketing campaign management activities during the complete customer life cycle process, but also improves knowledge on customer providing answers for those and many other questions such:

- Who is using the phone (age, gender, etc.)?
- What is the influence to the community?
- What is the social value of this subscriber?
-

Approximately 10% of mobile operators are actively using SNA bringing benefits of churn reduction and product take-up. New customer acquisition increased in average by 25%, compared with 4% with classic methods.

Integrating downstream campaign management tools in combination with customer's experience (for example, dropped calls and delays in SMMS delivery) and predictive analytics enable more streamlined and industrialized use of the results from SNA modeling. Any decrease in the time between obtaining results from the modeling and getting the campaign out is beneficial, particularly in viral marketing, as social relationships shift over time. Reason to still use traditional CDR's (call detail records) is simple, relationships that people have on their social media sites are usually a less complete representation of their real-life relationships. The output of socially derived variables within predictive SNA can add insight when combined with other subscriber characteristics, behaviors and derived variables (for example, the number of calls made in eight weeks, the total talk time, the number of calls to customer support and the number of negative-sentiment tweets).

V. SOCIAL REVENUE

Social Revenue is a monetary metric that reveals the value of a subscriber (**Figure 13**).

It combines both the individual as well as social value of

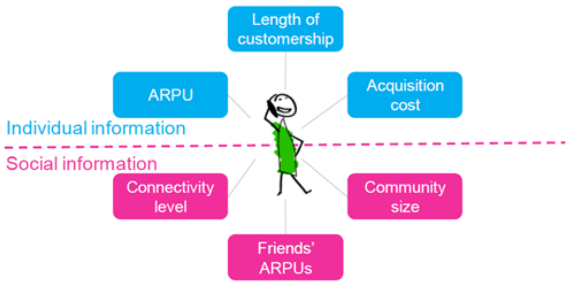

Figure 13: Social Revenue [2]

the subscriber. The individual subscriber value can be measured by:

- ARPU – how much revenue the individual subscriber is generating
- Length of relationship – how long is a subscriber
- Acquisition cost – how much has been spent in acquiring/keeping him

The social subscriber value can be measured by:

- Community size – how large is the social network
- Friend's ARPU – how much revenue are the friends generating
- Influence – how much influence does subscriber has on friends

Social revenue is in close relation with customer churn management, where improved churn prediction is closely connected with individual subscriber alpha scores.

VI. CAMPAIGN CASE STUDY

One most obvious case where social analytics sharpens focus on personalized top-up offers to produce 100 % gain in campaign revenue is viral campaign case.

A mobile operator wanted to improve campaign effectiveness for prepaid customer and to build customer relation. The operator analyzes customer behavior (**Figure 8**) to identify the customers with highest propensity to accept the offer and the right size of top-up and incentive for each customer.

Next step is to calculate Social Influence by Alpha Score

Customer	Campaign list	ARPU bands	Propensity	Top-up size	Incentive
012345678	2	2	67109	130	13
123456789	2	1	2341483	17	2
234567890	2	1	1581516	19	3
345678901	2	2	1048270	125	11
456789012	2	1	1437576	61	12
567890123	2	1	1332558	50	9
678901234	2	2	2069695	115	10
789012345	2	2	1914409	124	10
890123456	2	1	1487537	25	5
901234567	2	2	2494027	70	6

Figure 8: Social Analytics Case TOP-UP [2]

(**Figure 9**) where mobile operator analyses the customer base using CDR's and other customer related input data and divides and scores it based on specific social characteristics.

Upon identification of target customer group, message

SubID	Churn Alpha score	Social Revenue	SMS use
	0.9	25€	High
	0.9	20€	High
	0.9	20€	Low
	0.8	22€	Medium
	0.8	18€	Low
	0.8	23€	High

Figure 9: Social Analytics Case TOP-UP [2]

with offer is created by customer management system (CRM) and delivered on mobile device (**Figure 10**).

In a case where social data are not available only prophecy can be used. Simple four steps approach stays

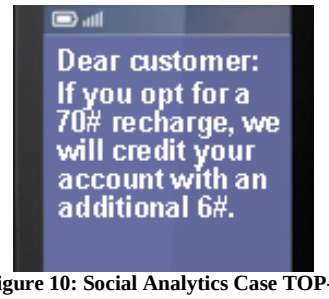

Figure 10: Social Analytics Case TOP-UP [2]

behind case:

- **Step 1:** Collect customer data, build customer insight, predict customer behavior and prepare campaign
- **Step 2:** On Charging&Billing system start off-line collection of customer behavior and reaction on test campaigns
- **Step 3:** Using Reporting & Analytics systems start predictive modeling of personalized offer/incentive values for top-up campaign
- **Step 4:** Start actual campaign and sent new offering proactively to customers who are most likely to react positively.

To achieve desired outcome, integration with enterprise data warehouse, top-up system and campaign management system is curtail as well as data privacy and security. Benefits achieved:

- Revenue acceleration – more than 100% improvement in net campaign gain from pre-paid recharge campaign for high ARPU (average revenue per user) customers in first month

- Increase loyalty along the whole customer life-cycle – personalization & offer optimization for 80% of the whole customer base by offerings matching exactly individual needs

Another use case example is case where a mobile operator wanted to reduce churn in their pre-paid market segment. Method used is to analyze customer behavior to identify the customers at the highest risk of churning (**Figure 11**).

Customer	Propensity	Offer_ask	Offer_bonus
1234567	0.64215115	talk 20 min	get 20 min
2345678	0.63283283	talk 20 min	get 15 min
3456789	0.59949953	talk 10 min	get 10 min
4567890	0.57355429	send 50 SMS	get 10 SMS

Figure 11: Social Analytics Case -Churn [2]

Personalized offers were then defined to retain them (**Figure 12**).

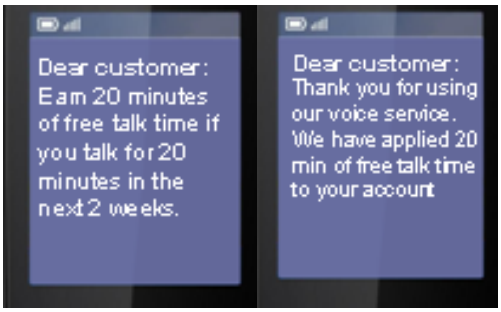

Figure 12: Social Analytics Case -Churn [2]

Campaign management applies the insight from analytics to target personalized offers to the segments at risk of churning. In most cases customers responded very positively on the mobile operator initiation and following directions given, accepting benefits given and improving satisfaction. By offering free talk time and bonus text messages, the mobile operator reduced churn by up to 21% in selected segments and 3,5% overall.

VII. CONCLUSION

Efforts to integrate social tools and strategies with traditional support efforts will revolve around customer sentiment. Integrating SNA within analytics packages helps to improve the chances of a sale and exploit the benefits of market. SNA will reflect main company marketing footprint upon implementation, followed by the replacement of business reporting with business analytics, advance predictive analytics instead of data mining & ad hock reporting and on-line analytics instead of batch based processing.
But, in this phase a frenzy of publicity typically generates over-enthusiasm and unrealistic expectations for SNA, resulting that there might be some successful applications of a technology, but there are typically more failures.

The Challenge of Customer Experience Management

Damir Tučkar

Hrvatski telekom d.d. , Zagreb, Hrvatska

damir.tuckar@t.ht.hr

Abstract - Building customer centric organization is a challenge for *Communication Service Providers (CSP)* today, in rapidly changing technology world and competitive market. Customer's expectations regarding telecommunication services, features, prices, availabilities, support and their experience in service usage often determine customer loyalty toward operator. Additional pressure to operators comes from customer's awareness of consumer's and national telecommunication regulators legislate. The *Customer Experience Management* (CEM) can make the difference between operators, creating unique and from customers unexpected, surprisingly affirmative and positive outcome in customer's requirements treatment, across all contacts channels. CRM[1] is the basic tool, but whole BSS/OSS environment have to be synchronized, meaning key internal business processes requires to be transformed as the customer sees or feel their consequences. Telco's are facing the challenge of 4C's: complexity, competition, cost, customer expectations and where CEM is the only respond!

I. INTRODUCTION

The new market reality for CSP is to transform their business around their customers, which requires radical shift about the way they are defining, developing, launching their products (services), billing and supporting the service usage. At the same time, customers are driven to buy CSP service or extend their loyalty to CSP or any of its service by adequate offers, flexibility of products and pricing plan, accurate activation. The pressures to CSP are the facts that consumers also changed with raising expectations [2]:

-prediction is that 5 billion people will behave themselves, by 2015, according to the concept, *Network Anywhere* (always on and connectivity anywhere),

-current (2011 in USA) data shows, consumers spend in average 4h and 13 m daily in WEB browsing, instant messaging, e-mailing or social networking,

-new *players on the market* and new *gadgets* like Blackberry, iPhone, iPad, tablets offered new applications, which created new consumer's demand reality, new CSPs revenue opportunities,

-Mobile CSP learned the lesson that customer's loyalty is based on device and application choices rather than network (brand), while fixed CSP experienced that customer's behavior changed, toward new customer need for fixed network communication infrastructure, switching majority of *services* usage from *"voice" over wires"* to "*data (content) over wires"*.

Focusing on end-to-end customer *life cycle* processes enables CSPs to improve the overall customer experience. The goal is to improve operations, lower costs, acquire new customers and generate new revenue streams, all while delivering the right customer experience keeping them happy and the CSP's business profitable.

There is not an exact, scientific definition of term customer experience (CE), since it is mainly about customer's emotions, which is hard to exactly *measure*, but can be described as:

A *Customer Experience* is an interaction between an organization and a customer. It is a blend of an organization's physical performance, the senses stimulated and emotions evoked, each intuitively measured against customer expectations across all moments of contact [3]. Another CE definition states: "The feelings and thoughts resulting from all impressions, tangible and intangible, from anyone or anything representing, directly or indirectly, an organization, brand or product." [4].

Most CSPs implemented different *methods* to measure the *index of customer's satisfaction* as one of tools for purpose of managing their customers *experience* and mutual CSPs comparing efforts. Key to delivering an enhanced customer experience is in *bridging the gap* between what a customers actually experiences and what the business thinks they are experiencing.

II. SERVICE PROVIDERS and 4C CHALLENGE

Since *telecom* market reality is based on facts that network is assumed and products are commoditized than CE is the only differentiator, where each

[1] CRM - **Customer Relationship Management**, IT tool, which CSP implement from vendors as "of the shelf" product or develop by themselves, as for ex. Hrvatski telekom d.d. [1]

customer have own perception on product offers (including development process and marketing), sales and provisioning experience, usability, operational quality and support for telecomm service when *something* occurs (quality of service delivered or bill issues). CSPs are facing so called "*4 C's challenge*" (complexity, competition, cost and customer expectations), pressure to rely more heavily on OSS/BSS[2], to simplify operations and manage costs [5].

A. COMPLEXITY

Past decades brought CSPs challenge of technology jumps, which requires knowledge (resources) to apply, maintain, and readiness to rapidly upgrade or replace it (Fig 1). CSPs have to manage traffic from third parties bandwidth and content providers, to increase variety of services in offer, to support intelligent devices in customer hands and homes. Customers will, when occurs, regardless of source of problem in this complex environment, blame CSP. As the result, CSP maintain a rapidly expanding inventory of network elements, applications in complex IT environment to support telecommunication service delivery and usage.

B. COMPETITION

Market landscape changed dramatically, comparing with *PTT times*, making CSP extremely vulnerable toward competitors and new players, like computer, software or internet vendors (ex. Apple, Microsoft, Google), who are competing, not on network level, but strictly on product level. CSPs who own the network infrastructure are using the capabilities of that *capital*, to deliver, ensuring quality, innovative products to customers, that *over-the-top* providers cannot.

C. COST

Network infrastructure is a large capital investment, currently mostly owned by former monopoly CSP. The volume and complexity of network, products and applications continues to explode causing the increase of CSPs failure risk in maintaining performance of the network, services and internal business processes. CSPs are not pressed only by *national regulatory* requirements and regulations, but other consumer protecting *rules* as well, while customers are aware of it. Excellent customer experience requires costly customer supporting processes, which are more costly if they are not performing smoothly as planned, when problems occurs and CSP is forced to additional efforts. The best example, for these unnecessary costs, is order failure costs (Fig 2), for complex high-value IP services, shows how spiraling costs of supporting customers can be and its financial impact on profitability. Consequently, CEM tools, correctly applied, should prevent them. BSS tools are facing transformation, necessary to prevent this, from CSP standpoint, unnecessary costs, and from customer's point of view unwanted experience. Modification is based on CSP interviews findings, conducted in 2011. (Yankee Group Research Inc.) and presented on Fig. 3 [6].

D. CUSTOMER Demand

With technology innovative solution implementation, customers are more and more demanding, while their personal experience becomes major differentiator between *good and bad* CSP. Customers want mobile data capabilities as what is delivered by DSL[3] or fiber; they want video services on demand and recorded for playback when they choose ("*network anywhere*"), even high-quality voice service, they expect for all telecommunication services (fixed net) immediate provisioning, later, in service usage period, variety of *unlimited* product support, for *free* or charging as low as possible!

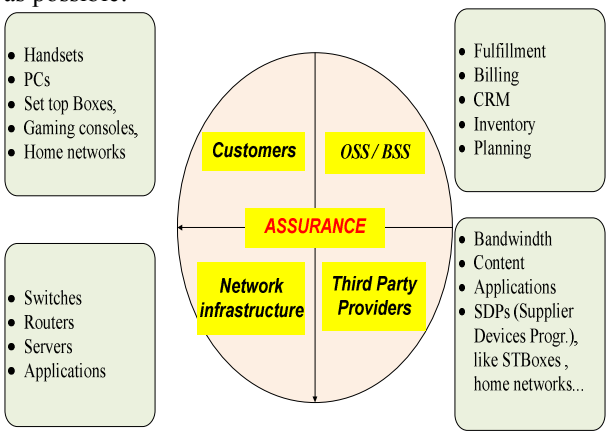

Fig1. Assurance interfaces

As the internet and especially the mobile internet transforms our daily lives, a revolution is underway, transforming the way customers interact and stay connected to work, communities, friends, content,

	Approximatly in US $/incident	Total cost for 1 million orders per year, with estimated 20-40% order fallout rate
Order fallouts requiering an engineer's time	60-75	75 x 160.000 = **12 million** (estimated 20-40 % of the time)
Truck rolls as result of incomplete provisioning	300	300 x 40.000 = **12 million**
Ongoing problems resulting in customers calls	12-50	12 x 400.000 = **4,8 million**

Fig2. **Calculating the cost of Order management Failure** [2].

[2] OSS – Operational System Support, The term OSS most frequently describes "network systems" dealing with the telecom network itself, supporting processes such as maintaining network inventory, configuring network components, provisioning services and managing faults
BSS-Business System Support, refers to "business systems" dealing with customers, supporting processes such as taking orders, processing bills, and collecting payments

[3] DSL – Digital Subscriber Line (meaning cooper line)

leisure activities and entertainment. Increasingly, service providers struggle to be recognized and **a**ppreciated for the central role they play. Recognition, influence and loyalty have slowly migrated from CSP to other parts of the value chain, namely device manufacturers, and content providers.

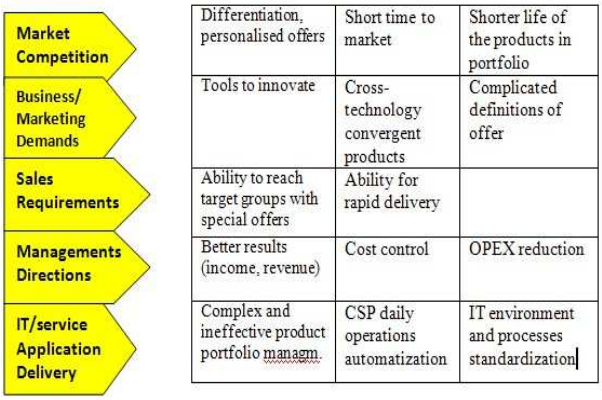

Fig3. **Drivers for BSS transformation** [6]

III. CUSTOMER SATISFACTION and CUSTOMER EXPERIENCE MANAGEMENT

Customer favors CSP, vendors of services, capable to provide good service, through the customer lifecycle, generating positive customer experience.

The importance of customer satisfaction based on his personal experience lies in *influence* on his personal circle of relatives, friends and people he usually met on daily basis (CSP's *customers or prospects*). Bad customer experience is spread on 10 time wider *circle* of people, causing *damage* to CSP, hard to repair.

Customers interact with CSP through different channels, points of contacts, in different moments (lifecycle) of their relationship with CSP. Beside *personal contact* in CSP shops, or its partner's shops, nowadays most frequently used channel is free phone number of *contact centre*. With internet accessibility, customer's computer literacy and widespread usage of all kind users' terminals for internet access, communication by WEB, e-mail, together with social networking influence becomes most important CSP interacting channel. One, however, does not have to underestimate the influence of other, traditional channels like postal letters, faxes and particularly *personal contacts* with CSP's or *outsourced company*, technicians (at home or streets).

Customers and CSP collects, mutually, *experience* of each other, throughout whole lifecycle, which wise CSP captures (Fig. 4), store and analyses later when needed. ***Prospects*** start to collect their *personal experience* and shape their attitude regarding certain CSP or its service, through: daily media influence, CSP's marketing campaigns, "word of mouths". After CSP service provisioning, relationship with customer is usually long termed, beside process of *billing* for service usage, usually with rare customer-CSP interactions.

From customer's point of view, *consumer* of telecommunication service, mobile or fixed network, there are 4 main reasons for interacting with CSP:

- Enhance or upgrade telecommunication service customer use, or buy new one,
- Maintaining customer personal data in CSP CRM, preferably, when possible, using "self maintaining" *procedures* on WEB. Customers can also check their current services usage or view their bills, in itemized bills manner (for each service, for each *communication usage,* full set of data), which enables customers to control their expenses.
- Customer persuasion of bill or bill item incorrectness. Usually, national regulator body describes the complaining process and procedures, customer and CSP have to follow
- Customer experienced and objects issues with telecommunication service quality or faults (again, customer point of view).

From CSP point of view, all interactions with customers, regardless of reasons, have its costs, which need to be controlled and kept within predicted budget for that purpose. Most frequently used methods in CSP daily operations, to achieve the "budget" goals and keep most customers *satisfied*, are:

-optimizing internal business processes, with implemented metrics,
- setting KPIs[4] for operations (internal processes) and employee performance,
- measuring customer satisfaction and comparing with competitors, as basic source for future measures to improvements in processes,

Another strong influence on subjectively gathered customer personal CSP related *experience* is customer (as a person) education for using technically complex telecommunication services and environment. Telecom consumer education and adequate support resources must be tuned to support consumers as their product portfolios grow in complexity.
Although OSS is critical to enable and ensure positive customer experience, customers who, despite network complexity, cares only about their own services and

[4] KPI – Key Performance Indicators; For ex. in fixed network voice service provisioning process, time, measured in days, set for providing the service at customer installation location, often determined by national regulator to USP (universal Service Provider)

usage, experience any kind of *issues* using CSP services, mostly due to:

- Lack of coordination, as a consequence of structural and organizational divide, between network-facing functions (OSS) and customer-facing functions (BSS),
- Fulfilment, delivering realities, compared to CSP promises in selling, *fault repair* or advising customers for service adequate (correct) usage processes.
- Unclear or not sufficiently explained service billing (and all bill items) to customers, in selling or service promotional period, how customer habits or telecommunication service usage behaviour influence expenses presented on the bill. If customers expectations regarding bills are not fulfilled, due to wrongly understood, or not correctly explained, from service promo-*messages* or sell representatives, his perception of *negative experience* is hard to change.

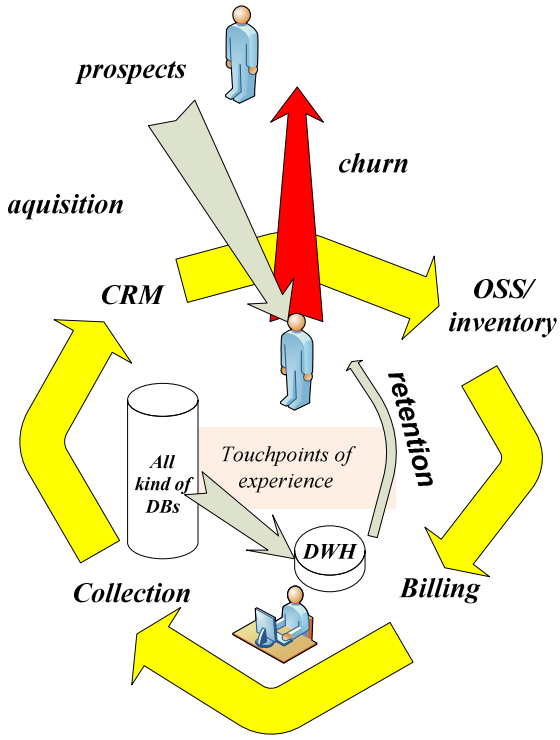

Fig4. **Capturing customer experience on mutual interactions in CSP IT environment**

Measuring customer satisfaction regularly, comparing results with own past measurements and competitors, applying feedback measures to areas where there is visible trend of negative results is simply "must have" for CSP. Satisfaction *measurement* process means interviewing CSP customers, a relevant and representative number of customers, with carefully chosen questions, same ones in consequently conducted inquiries for one CSP or applied for different CSP, obviously for results comparing reasons. Therefore, it's usually done by external inquiry companies, which are *neutra*l (objective standpoint) toward CSP and customer, in *research* process. This company usually get's list of relevant customers for interview, from CSP (for example divided according criteria like CSP services users, customer age, location of living, service using expenses etc) and provide CSP, as result of inquiry process, with report which presents how customers experienced CSP, observed as "black box", through CSP touch points. CSP itself constantly tries to improve internal business processes (within CSP as black box) in the way CSP consider it's the best for customers. Inquiry results always confirm that customer may forgive for the temporary lack of access or quality degradation of a service but won't forgive CSP for the lack of accurate action and information from the operator's side. Proactive service management and closing the loop between the OSS and BSS domain are the third key in improving customer experience.

IV. SERVICE PROVIDERS and CUSTOMER EXPERIENCE MANAGEMENT TOOLS

Each CSP nowadays use DWH[5] available data and methods for analyzing customer's behavior and captured in CRM or other data bases, mutual interaction data. This intelligence has been focused on delivering the operator's employees sophisticated tools to tailor their offerings, manage products, promotions, customer orders, complaints or assistance requests. For fixed network CSP it's essential to automate and integrate BSS with OSS processes, which is quite a tough task for IT, due to CSP IT complex heritage. Usually, CSP customers, subscribers of one or more telecommunication services, are segmented, at least at residential and business segments, but more often, this basic segmentation is additionally divided according the criteria each CSP establish to best suit its budgetary limitations toward wished treatment polices according to segments. Segmenting customers is delicate task, usually CSP use service average spending data for each customer, calculating the value of that customer, for CSP. According to the value, CSP put customer in one of N predefined segments. When interacting with CSP, customer is, at each channel of contact, recognized by adequate application and segment data recorded in CRM. This is followed to, automatically in systems, applied adequate policy and treatment procedure, for customer segment and interaction reason.

However, consumption of services and delivered bills should not be the only criteria for segmentation of customer; equally important is customer habit to pay his bills on time. Calculation of segment to which customer belong is dynamic parameter, ideally

[5] DWH – Data Warehousing IT tools and applied data analyze procedures

calculated each month. Segment calculation needs to consider *single customer view,* meaning usage of one or more CSP services, duration of customer subscriptions or history of relations with CSP, usage of one or more services and take into adequately account eventually applied dunning levels in recent history for customers services. Dunning procedure is expensive procedure for CSP, often sophisticated, requires dedicated resources, not rarely terminating with court epilogue. Beside national regulator body which determines basic dunning legal levels, respecting CSP and customers interests, each CSP defines additional levels (reminders and warnings for customers) using e-mails, SMS, voice messaging machines, agents calls etc. Shifting customers, from one to another neighboring value segment, is therefore influenced with revenue, dunning, and other relationships history. CSP than applies different policies for each segment for different reasons (route cause) of customer interaction. For example, different segments of residential customers are differently treated when calling free number (0800) of CSP supporting contact centre, meaning speed of accessing the agent or IVR[6] avoidance. Provisioning of any new service or problem assisting and malfunction repairing of subscribed one, for customer of higher CSP value can be faster performed and executed from more skilled technicians. On the same time, when employing loyalty programs or discount policies, as tools for creating positive *experience* for existing or attracting new customers, in battle to minimize churn, CSP must be cautious regarding possible costs and customers disappointments, if wrongly set policies have to be corrected.

Most subscribers have only a vague idea of their actual usage and costs. As data caps become more commonplace, customer confusion over the amount of data used puts them at risk of bill shock. Traditional approaches to keeping subscribers informed of usage, such as SMS alerts, are not interactive enough or accurate in metering applications. Customers have a need and *expectation* that they can control *costs* - consumption approaching their CSP data on WEB (with minimum delay on actual CDRs[7]), from home, on their device, which create positive experience.

One have also to stress the influence of national regulator and other laws and regulations, on each CSP, regarding fulfillment of "*law requirements"*[8] in implemented internal, customer interacting, business processes and supported IT applications.

V. CONCLUSION

In a services environment**,** the interactions with sales and service touch points are crucial to model *experience* memory regarding CSP, in customer's mind. Unlike manufacturers of physical products, service providers need to provide constant QoS (quality of the service) in customer (service usage) lifecycle. Therefore, customer experience is most important differentiator between CSPs, from perspective of each segment of their targeted customers, for whom management define applied policies in processes, according to CSP defined customer segments and budgetary issues. No. 1 goal is to achieve excellent customer experience, primarily by defining internal business processes as the customer sees them rather than what is convenient for the business. Maintaining a positive customer experience requires that CSPs deliver unique, high-quality products, implement customer focused processes and manage them with proper tools (BSS/OSS) and with educated and motivated employees and partners (if parts of business processes are outsourced). CSPs evolved from traditional suppliers of separate, network-dependent services (*telco* operators) into carriers delivering converged services on top of converged networks (IP[9]). Since *experience* of CSP and service customer use, is unique for each customer, based on customer *emotional attitudes*, managing the customer experience requires BSS/OSS capable of delivering products that ensure quality, from the handset to the core of the network, as well as rapidly responding to customer requirements and problems. Capturing all interaction with each customer, on all touch points, personalized approach to customers in each contact, regardless of contact channel, with visibility of whole customer's relationship history to empowered employees, is simply MUST have feature in processes adequately IT supported, in applied end-terminal application. And, what is most important, CSP must never, acting in saturated market, betray *promises* (in service *selling* or any supporting processes) given to customers.

Knowledge Granulation in a Telecom Operator Information Systems

Nenad Dragun
HT- Hrvatski Telekom d.d./Network and Service Platform Department,
Kupska 2, 10000 Zagreb, Croatia
nenad.dragun@t.ht.hr

Abstract - It stands as a widely accepted truth that knowledge is a power and the saying can easily be applied to business domains as well. Telecom business is well known for dealing with immense quantities of data which, if properly managed and organized, can represent a good source of knowledge. Common logic tells us that empowering telecom business by extracting knowledge from something that already is a constituent part of everyday activities should come very naturally. Process for achieving such goal can be identified as knowledge management and it comprises knowledge acquisition, sharing and transfer as well as its creation, organization and application.
All of the above mentioned can be accomplished through granular approach based on the knowledge granule as a founding element for all knowledge related actions. Such granule represents a concept i.e. something to be learned, can be related to other granules and can form structures for complex descriptions of concepts. This paper introduces granular approach as a foundation for building knowledge management systems in telecommunications domain.

I. INTRODUCTION

With evolution of information systems to the level on which they are more or less independently capable of making decisions about the flow of actions in the future, or to predict the outcome of certain action, it is becoming more important to better organize information which comprises the core of such systems.

Very important part of this kind of systems is storing and processing relevant information. When taking those two actions in consideration it is very common to speak about belief in facts the corresponding information is dealing with, of course with acceptable probability of truthfulness. Systems dealing with information satisfying the afore mentioned can easily be classified as knowledge related systems [1] with main goals of organizing, storing, and using the knowledge.

The final goal of knowledge organization is increase of its utilization and reusability, better possibilities of knowledge representation, but also easier derivation of new knowledge based on the existing one. The latter partially covers the process of knowledge acquisition also known as learning; therefore the knowledge organization can significantly affect and improve the process of learning.

Most frequently mentioned entity for knowledge organization is knowledge base with various implementations. Regardless of knowledge base implementation its logical architecture is always defined by its ontology. One of the ways to implement knowledge base ontology is using the granular approach. Granulation in this case means defining the knowledge levels which satisfy certain conditions and at the same time respecting the rule that lower level of knowledge contains more detailed information than next, higher level. It is common to say that the higher level of knowledge has abstracted details of its neighboring lower level of knowledge. Basic principles of such approach are given in the following chapters of the article.

II. GRANULAR KNOWLEDGE STRUCTURES

Knowledge itself is tightly related to the process of its acquisition better known as learning. Learning is being discussed in various domains such as psychology, logic and philosophy in general, but also in so called informatics domains [1]. However, regardless of the point of view the main object of the learning process can be identified as concept. The term concept describes something we want to learn and is marked by its intension and extension [2].

Going further in this direction it is also possible to identify knowledge granule as a certain level of concept abstraction. Basic granule is indivisible or there is no need to further divide it on the corresponding level of abstraction. It is formed by elements grouped by indistinguishability, similarity, proximity and functionality [3].

The level of abstraction is partly defined by the extension of information which can be practically represented in form of information table [2] or formal context [3]. Formally an information table is described as:

$$T = (U, A_t, V_a, R_a, I_a), \quad a \in A_t \tag{1}$$

Where U represents a finite nonempty set of objects, At represents a nonempty set of attributes, V_a represents a nonempty set of values for $a \in A_t$, R_a represents a set of binary relations between attributes and values, $I_a: U \rightarrow V_a$ is an information function for $a \in A_t$.

If we continue thinking in terms of information tables we can easily group objects into granules according to formulas or combination of formulas. This kind of formula, denoted as ϕ, is represented as:

$$(a, r, v) \quad (2)$$

where $r \in R_a$ represents a binary relation between an attribute ($a \in A_t$) and corresponding value ($v \in V_a$). This type of formula is called atomic formula.

With all this in mind we could conclude that concept granule is a basic unit of human thoughts and basic component of knowledge which can be formally described as:

$$\left(\phi, m(\phi)\right) \quad (3)$$

where $m(\phi)$ denotes a set of objects satisfying ϕ formula. Remembering the idea of describing concepts with their intension and extension one could say that ϕ formula represents concept intension, while $m(\phi)$ represents its extension.

As an example of information table we will present one as illustrated by TABLE I. This table was created as an excerpt of data from a telecom operator's technical databases containing information on characteristics of customers' services and lines. The table does not contain all technical details about customer's line nor does it contain details about customer's services. As an illustration, the only introduced data from technical perspective are access technology type, element manager profile and line resynchronization parameter. The meaning of the resynchronization parameter is line stability, or more precisely, the number of periods in which customer's equipment lost synchronization with network during one day.

From the customer's service perspective table contains only high level information such as customer identification number, service category, service type and desired bandwidth.

An example of concept granule for the information table shown in TABLE I is:

$$\left((Access\ technology, =, ADSL), m(Access\ technology, =, ADSL)\right) \quad (4)$$

The intension of this granule is atomic formula with a meaning that the customer's service is implemented using ADSL (Asymmetric Digital Subscriber Line) as an access technology [4]. The extension of the concept granule is a set of all customers having their services implemented using ADSL as an access technology.

Thinking in terms of granules sooner or later raises the need to describe relations between granules i.e. their organization. Therefore we can talk about partially ordered relation between two concept granules which can be described by relation between subsets of the corresponding extensions:

$$\left(\phi, m(\phi)\right) \preccurlyeq \left(\varphi, m(\varphi)\right) \Leftrightarrow m(\phi) \subseteq m(\varphi) \quad (5)$$

The above written relation describes relation between subconcept granule and superconcept granule therefore $\left(\phi, m(\phi)\right)$ granule is subconcept of the $\left(\varphi, m(\varphi)\right)$ granule if $m(\phi) \subseteq m(\varphi)$.

TABLE I. PART OF INFORMATION TABLE DESCRIBING TECHNICAL INFORMATION ABOUT TELCO CUSTOMERS

Customer ID	Service category	Service	Access technology	Bandwidth	Element manager profile	Number of resynchs in the past 24 hours
1289538	Broadband	Internet	ADSL	4Mbps/256kbps	Internet1k	1
1759381	Broadband	Internet+ IPTV	ADSL	4Mbps/256kbps	IntIPTV1m	7
1759399	Broadband	Internet	ADSL	20Mbps/768kbps	Internet3k	1
1346788	Broadband	Internet+ VOIP	ADSL	4Mbps/256kbps	IntIMS1k	3
1347538	Broadband	Internet+ POTS	ADSL	4Mbps/256kbps	IntHalo1m	3
1347734	Broadband	Internet+ POTS	ADSL	4Mbps/256kbps	IntHalo1m	2
1447535	Broadband	IPTV	ADSL	4Mbps/256kbps	IntHalo1m	1
1425531	Broadband	Internet+ POTS	ADSL	4Mbps/256kbps	IntHalo1m	0
1425531	Broadband	Internet	GPON	20Mbps/768kbps	Internet3m	0
1425531	Broadband	Internet+ IPTV	GPON	20Mbps/768kbps	IntIPTV3m	0
1285531	Broadband	Internet+ POTS	ADSL	10Mbps/512kbps	IntHalo2m	8
1347721	Broadband	Internet+ HDTV	GPON	20Mbps/768kbps	IntIPTVHD3	0

Generally speaking subconcept compared to its superconcept is always characterized by the greater number of attributes, but on the other hand lesser number of instances.

If we go back to the information table illustrated in TABLE I, relation between two granules could be denoted as:

$$\big((Service, =, Internet + POTS), m(Service, = , Internet + POTS) \preccurlyeq (Access\ technology, = , ADSL), m(Access\ technology, =, ADSL)\big) \quad (6)$$

The meaning of the above relation is that domain of the concept saying that a customer's service comprises of Internet access and voice service over POTS (Plain Old Telephone Service) is a subset of the domain belonging to the concept saying that customer's service is implemented using ADSL technology.

Practical meaning of this relation is a knowledge about the fact that all customers having Internet access and voice service realized using POTS technology have their Internet access implemented using ADSL.

Bearing all previously mentioned in mind we are ready to define granular knowledge structure as:

$$GKS = \big(\{(\phi_n, m(\phi_n))|n \in I^+\}, \{R_i|i \in I^+\}\big) \quad (7)$$

where $\{R_i|i \in I^+\}$ denotes a set of binary relations between a set of concept granules $\{(\phi_n, m(\varphi_n))|n \in I^+\}$, and I^+ denotes a set of integers. Each two concept granules on one binary relation form an ordered pair. Having said this and with condition of $i, j \in I^+$ an ordered pair can be denoted as $< (\phi_i, m(\phi_i)), (\phi_j, m(\phi_j))$ where $(\phi_i, m(\phi_i))$ and $(\phi_j, m(\phi_j))$ represent two concept granules.

If concept granules can be organized into levels in a way that all granules of the same level share common characteristics it can be stated that a granular knowledge structure represents hierarchy of concept granules.

Furthermore, introduction of aspects in granular knowledge structures world leads to an intuitive understanding of knowledge [3] [5].

III. BUILDING GRANULAR KNOWLEDGE STRUCTURES

As it was already stated in previous sections of the article granular knowledge structures enable us to create knowledge by placing concept granules in relations and establishing hierarchy among them, but also by introducing relations among granular knowledge structures themselves. The rest of this chapter will describe techniques and ways to create granular knowledge structures.

A. Use of attributes and values

The simplest way of knowledge creation is with help of attributes and values [6]. In an information table, let an attribute satisfy $a \in At$, having at the same time corresponding set of values denoted by $\{V_a|a \in At\}$ so the granules can be described as $\big((a, =, v), m(a, =, v)\big)$. If in addition to that there exists a granule $\big(\rho, m(\rho)\big)$ such that ρ is a disjunction of all $(a, =, v)$ then we can establish a partially ordered relation between $\big((a, =, v), m(a, =, v)\big)$ and $\big(\rho, m(\rho)\big)$ granules, and in that way form granular knowledge structures.

An example of such granular knowledge structure in case of our information table illustrated by TABLE I could be the following: for $At = \{Access\ technology\}$ we can form a granular knowledge structure made of the two following concept granules $\big((Access\ technology, = , ADSL), m(Access\ technology, =, ADSL)\big)$ and $\big((Access\ technology, = , GPON), m(Access\ technology, =, GPON)\big)$

This granular knowledge structure tells us that customers from the information table have their services implemented either via ADSL or GPON (Gigabit Passive Optical Network) access technology.

B. Use of generalization

If we consider two concept granules $\big(\phi, m(\phi)\big)$ and $\big(\varphi, m(\varphi)\big)$ that have a common attribute-value pair, then there is a possibility for creating a superconcept granule which describes this relation.

In case of our information table, we could consider the same two granules dealing with access technology knowledge, we considered in previous section and conclude that they share the "Service category" attribute having the same value "Broadband". This granule is denoted by the following atomic formula: $(Service\ category, =, Broadband)$.

Establishing this concept as a superconcept of the access technology concept, we create a granular knowledge structure with the meaning that according to our information table broadband services can be implemented either by using ADSL or GPON access technology.

C. Use of unions

Let us consider a concept granule denoted as $\big(\phi, m(\phi)\big)$ which is contained in two certain granular knowledge structures denoted as GKS_1 and GKS_2. In each

granular knowledge structures the concept can be composed of subconcept granules. Relations between concept and its subconcept granules can be described as:

$$m(\phi) = m(\phi_1) \cup m(\phi_2) \cup ... \cup m(\phi_n) \text{ for GKS}_1$$

$$m(\phi) = m(\phi_{n+1}) \cup m(\phi_{n+2}) \cup ... \cup m(\phi_{n+p}) \text{for GKS}_2$$

having $n, p \in I^+$. Union of these two subsets of granules forms a new granular knowledge structure. The relation between $(\phi, m(\phi))$ and new set of concept granules is denoted as :

$$m(\phi) = m(\phi_1) \cup m(\phi_2) \cup ... \cup m(\phi_k) \quad (8)$$

where $k \in I^+$.

Returning once again to our information table shown in TABLE I we could think of it as if it was created of two tables, one illustrating granular knowledge structures for GPON, and the other one for ADSL technology. In that case, the concept of service category as "Broadband" for GPON table would be comprised of subconcept service having "Internet", "Internet+IPTV" and "Internet+HDTV" as values. However, union of these subconcept granules and service subconcept granules of ADSL, having values of "Internet+POTS", "Internet+VOIP" and "IPTV", extends the concept of service of the broadband category. In this way we get a much better and more detailed description of the concept out of two existing granular knowledge structures.

D. Use of intersections

Let $(\phi, m(\phi))$ and $(\phi, m(\phi))$ be two concept granules from different granular knowledge structures, if and only if $\phi = \varphi$, an intersection can be used to find sub granular knowledge structure formed of the above mentioned two granules and their subgranules.

Figure 1 and Figure 2 illustrate an example of such two granules referring to information table shown in TABLE I in the same way as in the previous section i.e. two information tables for each of the access technologies.

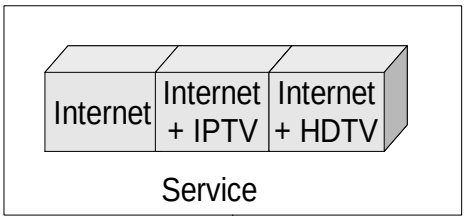

Figure 1. Granular knowledge structure for GPON technology

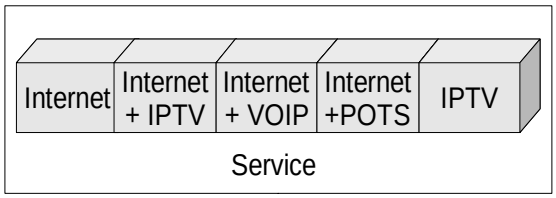

Figure 2. Granular knowledge structures for ADSL technology

Using the intersection we could create new granular knowledge structure with "Internet" and "Internet+IPTV" granules. The meaning of the new granular knowledge structure is the knowledge stating which services are popular among customers regardless of technology being used to implement their service.

E. Use of differences

Considering two concept granules $(\phi, m(\phi))$ and $(\varphi, m(\varphi))$ from different granular knowledge structures, if and only if $\phi = \varphi$, a new operation can be introduced in order to determine difference among them. The operation can be denoted as $(\phi, m(\phi)) - (\varphi, m(\varphi))$.

Referring to granular knowledge structures illustrated by Figure 1 and Figure 2 and by using difference operation one could create a new granular knowledge structure with "Internet+HDTV", "Internet+VOIP", and "Internet+POTS" granules.

Practical meaning of this granular knowledge structure is identifying services which are technology-dependent, so a telecom operator must consider available access technology before offering such services to the customer.

F. Use of selection and change of level or perspective

Existing granular knowledge structures can further be used for knowledge creation by choosing the level of granularity inside of themselves.

If $\{(\phi_i, m(\phi_i)) | i \in I^+\}$ denotes a set of concept granules on the same level of a certain granular knowledge structure, and $\{(\phi_{1_1}, m(\phi_{1_1}) ... \phi_{n_p}, m(\phi_{n_p})) | n, p \in I^+\}$ denotes a set of concept granules one level lower than the previous set one can introduce zooming operation [7]. The purpose of the operation is to map a set of granules of a higher level to a set of granules from lower level of certain granular knowledge structure. The same can be done in the opposite direction so one can differentiate zoom-in, and zoom-out operations.

In the same manner the existing granular knowledge structure can be used to create different knowledge depending on the perspective from which it is being

observed which greatly depends on one's experience and point of interest.

IV. KNOWLEDGE CREATION FRAMEWORK

In order to be able to create knowledge having only granular knowledge structure is not sufficient. Knowledge granularity model described in this paper relies on information table which does not have any knowledge or information about relationship between objects in the table. Therefore a framework for object categorization needs to be introduced.

A satisfiability of formulas ϕ by an object x from an information table S^+, written $x \vDash \phi$ is described with a following set of rules:

$$x \vDash \neg\phi \quad \text{iff} \quad x \nvDash \phi \tag{9}$$

$$x \vDash \phi \wedge \varphi \quad \text{iff} \quad x \vDash \phi \; i \; x \vDash \varphi \tag{10}$$

$$x \vDash \phi \vee \varphi \quad \text{iff} \quad x \vDash \phi \; or \; x \vDash \varphi \tag{11}$$

$$x \vDash \phi \rightarrow \varphi \quad \text{iff} \quad x \vDash \neg\phi \vee \varphi \tag{12}$$

$$x \vDash \phi \leftrightarrow \varphi \quad \text{iff} \quad x \vDash \phi \rightarrow \varphi \; and \; x \vDash \varphi \rightarrow \phi \tag{13}$$

Furthermore, one could introduce the following regarding validity of the formula itself:

$$\vDash \phi \quad \text{iff} \quad m(\phi) = U \tag{14}$$

$$\vDash \neg\phi \quad \text{iff} \quad m(\phi) = \emptyset \tag{15}$$

$$\vDash \phi \rightarrow \varphi \quad \text{iff} \quad m(\phi) \subseteq m(\varphi) \tag{16}$$

$$\vDash \phi \equiv \varphi \quad \text{iff} \quad m(\phi) = m(\varphi) \tag{17}$$

Relations (9) to (17) represent a foundation of a framework for formal descriptions of knowledge creation based on granular knowledge approach [8].

The above presented framework can be used in two ways, either for description and interpretation of granules or for computing with granules [9].

An example of the former use can be illustrated for relation (15) which can be used to describe the fact that two concepts $m(\phi)$ and $m(\varphi)$ are disjoint if $m(\phi) \cap m(\varphi) = \emptyset$. One can also say according to relation (16) which in fact denotes that $m(\phi)$ is a subconcept of $m(\varphi)$.

An interesting aspect of computing with granules is establishing relationships among them. Relationships between granules can be expressed as rules. Rules themselves come in very handy for construction of systems dealing with knowledge organization, storing, sharing and acquisition.

A rule, or a decision rule, can be expressed in form $\phi \Rightarrow \varphi$ where ϕ and φ are formulas representing intensions of two concepts. Practical meaning of the rule could be described with a following sentence "if an object satisfies ϕ then the object satisfies φ". This introduces a mechanism for expressing cause and effect relation between concepts which further extends abilities for construction of knowledge management systems.

V. CONCLUSION

Knowledge granulation is a method for organizing, storing and acquiring knowledge. It introduces a goal of more intuitive and human-like manner of dealing with knowledge.

An infrastructure for achieving this goal consists of information tables representing formal context, concept granules and granular knowledge structures. Concept granules representing basic units of human thoughts are extracted from information tables and are characterized by their intension i.e. something we want to learn and extension i.e. a set of objects described and affected by the knowledge. Granular knowledge structures as the most complex in this infrastructure are composed from knowledge granules by putting them into relationship with use of various operations such as generalization, intersection, change of level and perspective etc.

Introduction of a formal knowledge creation framework enables one to improve the above mentioned infrastructure in a way which allows establishing cause and effect relation among concepts. The latter promotes previously mentioned infrastructure to a solid foundation for building so called knowledge management systems and makes it a cornerstone of granular computing discipline in general.

Over time telecom business has lost its former structure of tech-centric domain dominated by engineering departments and transformed slowly into service-centric domain. The accomplishments and knowledge of engineering departments are now used only to the extent and with intention of delivering services to customers. The service-centric approach requires departments of different domains to work together towards the common goal, each having their own view of the same thing. The same service is viewed differently from the technical, financial, sales and marketing departments.

The future work in this area is to allow them all to use the same sources of data for describing the same thing in a most understandable way but excluding details irrelevant to their area. The author of this article believes that the above mentioned requirements can be satisfied by establishing a model of knowledge management system. The model would be established by using the granular approach described in this paper along with furthering research in the field of perspectives aspect of knowledge granularity.

Abstract: Continuous education is highly desired in all industrial areas today, but for information and telecommunication technology professionals is almost mandatory. As much as individuals should care about theirs competencies, ICT companies should even take more care about employee's competence development. Computer aided competence management is great help in operational issues such as personal development planning and incentive programs. It is also important tool in preparing for and acquiring new business opportunities in highly competitive market, implementing strategic decisions and business shifts, as well as investing in human capital. In the core of computer aided competence management are competence data definitions, models and profiles. Based on those core elements and concepts, a number of tools and services could be developed such as competence gap analysis and team competences evaluation.

I. INTRODUCTION

Lifelong learning in rapidly changing world is priority due its importance in employment, economic success and social integration. The importance of education and training has been also institutionally recognized in the European Union by the Lisbon Strategy (2000) [1], and its successor the Europe 2020 (2010) [2]. The Lisbon Strategy is generally considered as failure, but certainly not due its learning economy concept. The learning economy is about modern economies that are considering knowledge as crucial resource and learning as the most important process. The Europe 2010 strategy, in one of its seven flagship initiatives, the Agenda for new skills and jobs, aims to equip people with the right skills for the jobs of today and tomorrow [2].

The European strategies for economic growth have brought ideas that had been already present in successful enterprises theories. It is more than two decades that enterprise human resources management shifted from measuring individual productivity toward strategic management of the human resources, focusing on competence development, and learning organizations [3]. Competence management (CM) involves the planning, implementation, and evaluation of initiatives to ensure sufficient competencies of the employees and the company to reach the objectives of the organization [4].

The use of web technologies could redistribute human resources (HR) activities, including competence management from HR department to the entire organization. More precise and descriptive name for our envisioned system will be web-aided or IT supported competence management system. Despite that computer-aided prefix sounds archaic, it is used intentionally to hail the early enthusiasm with computer applications in different fields.

The development of the computer aided competence management system was kicked of as a prototype within Ericsson Nikola Tesla company summer camp 2011. The Ericsson Nikola Tesla summer camp is traditional, five-week gathering of students mainly from the Zagreb and Split universities. The small student teams are faced with predefined project based on ideas of interest for the Ericsson. Preferred outcomes of the projects are prototypes or proof of concepts. The idea for the computer aided competence management prototype comes from the Ericsson Nikola Tesla line management. The initial aim was consolidation of already available competence related data from different sources, through web based application.

There is an ambiguous usage of competence and competency terms. Both terms are often used interchangeably, but there is some difference. Competence is a skill and the attained standard of performance, while competency is the behavior by which a competence is achieved [5]. Competence is a competency in a particular context [6]. Competence and competency are interrelated, and dependable. The possession of a certain competence is likely to make one act in a competent manner in a class of tasks (to have competency) and vice versa. Throughout the Ericsson, the term competence is used, and we believe without fine, just explained, distinction on mind. Since in the nutshell of the proposed computer aided competence management system lies management of various skills qualified with different levels, usage of term competence is justified. In concepts not directly related to the system, the term competency will be used.

This paper is organized as follows. The second section outlines main business requirements for the Ericsson enterprise competence management system. Some system's sustainability requirements such as standardizations efforts and end users requirements are introduced in the third section. The fourth section proposes innovative features and brings new ideas besides the cold, business requirements. Implementation concepts and some details of the Ericsson Nikola Tesla computer aided competence management system are presented in the fifth section. Finally, the last section presents conclusion.

II. BUSINESS REQUIREMENTS

Business requirements represent a set of requirements necessary for integration and business processes adherence, capability, deployment and user acceptance of the computer aided competence management system within enterprise. Those requirements have origins in the Ericsson competence management process and corresponding information model.

A. *Ericsson Competence Management Process*

Competence management in the Ericsson enterprise is described by the corporate competence management process, Fig. 1.

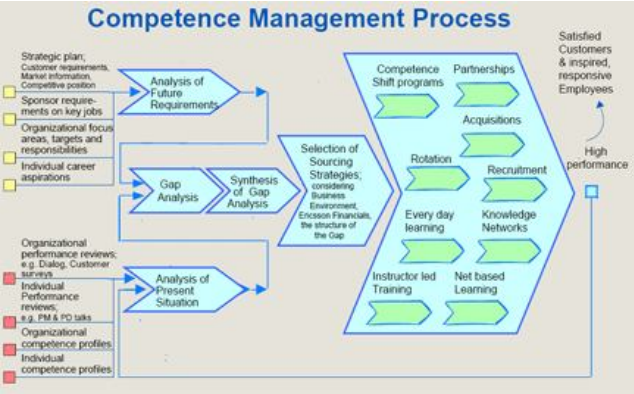

Fig. 1 Ericsson Competence Management Process

The process entry activities are two analyses, the analysis of the present situation and the analysis of future requirements. Regarding analysis of the present situation, the system, at least in the first iteration, should support individual performance reviews (personal development plans are prioritized), organizational competence profiles and individual or employee competence profiles. Those elements already exist for a long period of time within the Ericsson, but their quality and deployment vary case-by-case, and often includes a lot of administrative and repetitive work. Such way of working, inevitably leads to many inconsistencies and waste.

Customer, either internal or external, surveys are becoming extremely important in competitive enterprise and industry and certainly should be in some way included in the competence management system. One possibility is to directly create a "customer" competence gap that will be later in process combined with other system gap analyses.

Regarding analysis of future requirements we can distinguished operational (organizational focus areas, targets and responsibilities) and strategic (strategic plan, customer requirements, market information and competitive position) inputs. The system will not support analysis of operational and strategic inputs per se, but the results of the analysis could be included through operational and strategic competence profiles. Those profiles could introduce new competences and set up some time constraints and deadlines. Individual career aspirations partly take place in personal development plan. A tool for comparing personal competence profile with existed job role competence profiles could be useful in career decisions and development.

Personal developments plans, as well as, operational and strategic competence profiles introduce time component in the computer aided competence management system. Time line becomes an important requirement throughout the system, although it is not look so at the beginning of the development.

The gap analysis and the synthesis of gap analysis activities from the Ericsson competence management process should be also supported by the system, of course with the data available within the system. The system could provide useful and reliable report or view that could serve as one of inputs (decision factors) in any of activities on the right side at the Ericsson competence management process. We select the net based learning and the instructor led training as activities that could be either integrated in the system or supported by special interface.

B. *Business Information Model*

Business information model or shortly information model contains detailed, application agnostic, description of the data handled in the business processes. Due the information model serves as master reference for terms and data used in the business processes, it is also convenient for use in definition of supporting software system's or application's requirements. Therefore, managing the business information model is crucial for Ericsson.

The business information model, describing Ericsson common data that is managed in Ericsson business process and handled in the enterprise applications, is called the Ericsson Common Information Model (ECIM). ECIM provides a consistent view of Ericsson common data across the borders of processes and information systems.

The ECIM comprises a number of sub-models representing different *Subject Areas,* i.e. groups of closely related data. The primary reason for grouping data into Subject Areas is facilitating information definition ownership. Dividing enterprise data into subject areas, with clear ownership policy, should provide data stability over the time, Fig. 2.

The Ericsson competence management process is mapped to the logical business information model. The logical business information model should be further mapped to the logical system data model and physical data base model. The system data model represents computing view, while physical data base model represents data persistency view of the computing system and they are closely and mutual dependable.

From the source model, ECIM, view models can be extracted. A view model consists of a selection of model elements from the source model. Entities, attributes and relationships defined in the source model may be omitted, but not changed. The purpose of a view model can for example be to illustrate the information used in a business process or discipline or to define the scope of the data used by an information system.

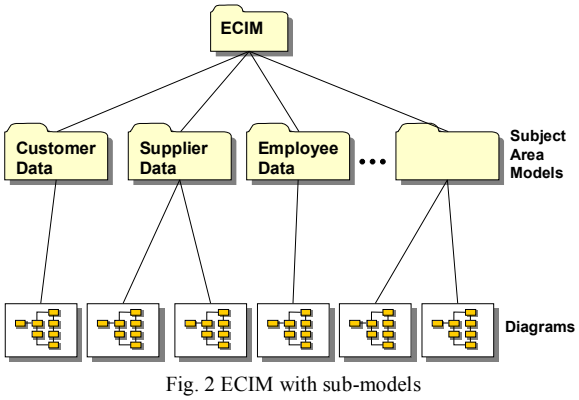

Fig. 2 ECIM with sub-models

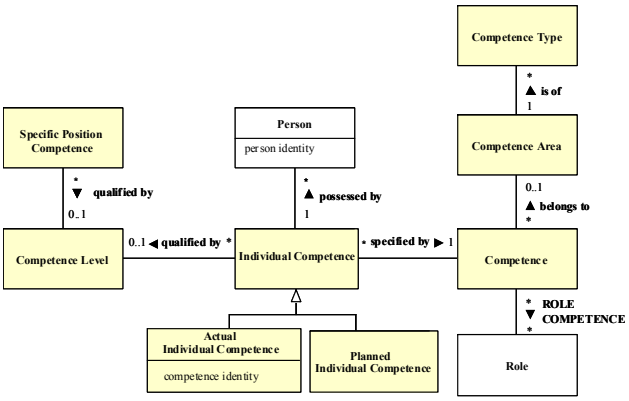

Fig. 3 Overview of the Ericsson competence information model

An overview of the Ericsson competence subject area information model is shown at Fig. 3. The important complement part to the information model is competence catalog. The purpose of the catalog is to have common competence areas for planning and developing enterprise competences. A generic list of competence areas within Ericsson is called global competence catalog. The global competence catalog supports global transparency and alignment, as well as simplifies searches for competence areas.

Competences are qualified with common five levels, from trainee to expert:

- T - Has not yet demonstrated competence required for level A.
- A - Basic knowledge and skills. Identifies and solves defined problems that require little or no analysis by using existing procedures, techniques and methods.
- B - Good knowledge and skills. Identifies and solves complicated problems that require careful analysis by adapting existing procedures, techniques and methods.
- C - Has highly developed knowledge and skills. Investigates and solves complex problems that require substantial analysis by developing existing procedures, techniques and methods.
- D - Has exceptional knowledge and skills. Investigates and solves complex problems that require in-depth analysis. Proposes solutions that require innovation in terms of procedures, techniques and methods.

III. SUSTAINABILITY REQUIREMENTS

Transactions mechanisms, data centralization, safety and security policy enforcement are coming as inherent characteristics of the new envisioned system. An important, or even crucial, requirement is computer aided competence management system sustainability. History of the last decade shows that similar tools, more or less integral, have appeared in different Ericsson organizations and sites, but have not been widely accepted from end users. Principles reasons are inadequate competence framework, tensions between global standardizations and local practices, and missing end users commitment [3]. The possible groups of sustainability requirements are standardizations efforts in the competency management field, the state of the art competency frameworks, and end users requirements.

A. Standardization efforts

The Reusable Definition of Competency or Educational Objective (RDCEO) specification provides a means to create common understandings of competencies that appear as part of a learning or career plan. The IMS (IMS Global Learning Consortium, Inc.) RDCEO information model can be used to exchange these definitions between learning systems, human resource systems, learning content, competency or skills repositories, and other relevant systems [7].

The IEEE Reusable Competency Definitions (RCD) specification is a standard (IEEE 1484.20.1) issued by the Learning Technology Standards Committee of the IEEE Computer Society. It reuses the IMS RDCEO specification to define a data model for describing, referencing and sharing competency definitions, primarily in the context of online and distributed learning [8]. IEEE RCD specifies the mandatory (RCD globally unique identifier and title) and optional (description, definition, and metadata) data elements that constitute a Competency Definition as used in a Learning Management System, or referenced in a Competency Profile, Fig. 4.

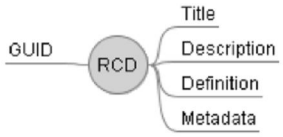

Fig. 4 IEEE Reusable Competency Definition

The IEEE Competency Profile (CP) is a proposal for standardizing description of information about relations between competencies of one person.

B. End Users Requirements

Main requirements from end users, particularly line managers as the future most frequent end users of the system, are more oriented toward visual representation of competence related data and local competence taxonomy introduction.

Regarding graphical user interface (GUI), it is interesting to highlight that end users requirements are quite influenced by Excel, the tool they regularly use. Excel-like, big tables are preferred for presentation of competence data.

The most challenging presentation view is resource/competence grid. Besides clear and visually attractive outlook of actual and planned competence levels, via the grid it should be also possible to modify competence levels or to perform level promotions. As a consequence, enforced authorization policy shall be required. Both resource and competence filtering and selection should be customizable in the resource/competence grid.

It is quite often needed to work on dedicated set of competences. They need to be bundled due various reasons like strategic streamlines, personal management or

organisational happenings. Thus, aggregation of competences should also be customizable through selection of arbitrary taxonomy. Taxonomy of choice features brings issue of mapping between different taxonomies. The taxonomy mapping could be a problem if for example the atomic competence areas do not match or if they can be interpreted and understood differently.

Import and export data from Excel datasheets is also required mandatory functionality due fact that most department managers maintain employee competence grid and employees' levels in personal Excel files. The standard Excel templates for adding or changing employee levels shall be also defined.

Local taxonomy and competence pool are important end users requirement. The computer aided competence management system will be used in daily work so it has to be aligned with local best practices as well as with corporate guidelines. There is a risk that the common global competence catalog might be too general.

The most demanding requirement is building local competence taxonomy, as a result of competence aggregation of choice. The competence taxonomy is very important since it visualizes and simplifies business decisions. Complete catalogue of all competences is a prerequisite for having competence taxonomy.

A problem appears with similar competences, i.e. basically the same competences but used and applied in different products or levels of telecommunications systems. Each application of some competence emphasized or rely on, sometimes, completely different aspects of competence. One of the possible solutions is to treat all these specializations as different competences. Such solution is the simplest one with no major implementation obstacles. On the other side there is an approach to describe common and generic aspects of each competence, and then use it in different context by extending it with different qualifiers [6].

The number of taxonomy main branches, as well as number of levels is still under consideration. One alternative is to have three main branches or categories, namely human, business and professional and additional one or two levels of subcategories, Fig. 5. Another alternative is created at global Ericsson level where the taxonomy has seventeen main categories.

From developers point of view it will be more convenient and easier to have predefined and uniform number of levels, but that is not flexible and future proof solution. It is more reasonable to allow non uniform levels of choice.

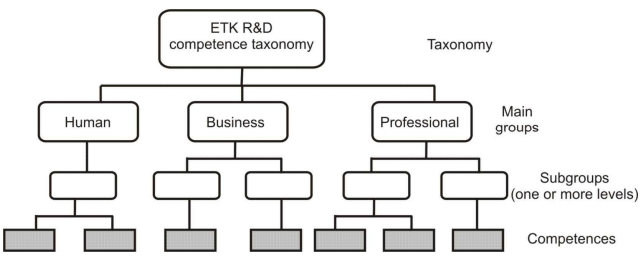

Fig. 5 Local competence taxonomy overview

IV. DISTINGUISHED FEATURES

On top of the standard business end sustainability requirements we are introducing some additional advanced and innovative features. Better integration with business processes, user friendly visualization and improved data reliability are main guidelines. Those features represent added value characteristics and distinguish our computer aided competence management system from similar systems.

A. Assesment of Competence Groups

Since the catalog of competences, even at local level, comprises approximately a couple of hundreds different competences, it would be very practical to qualify or assess the whole groups of aggregated competences with single levels in similar manner as to be done for particular, single competences using TABCD scale.

The main issue here is how to determine competence level of a group. It could be done by a specially tailored assessment, but in spirit of lean approach and tool sustainability setting of competence group level could be automated based on the levels of underlying competences. Formula used to calculate a group level from the underlying competences levels should be carefully designed and constantly challenged regarding employees' performances.

B. Promotion Wizard

Determination of competence levels becomes crucial when building central database with employee's competences. A standard procedure for level granting has to be established, otherwise the tool will be useful only at departemnt level but will misslead or fail at company level. Additional problems might appear when people change departments and units or during major reorganisational happenings. However, competency management standardization efforts aim to provide competency frameworks fully applicable in cross organizational or even cross industrial competency management.

We propose a simple promotion wizard that enforces promotion date and responsible superior manager signature at least, Fig. 6. The promotion wizard also introduces a record of competence evidences. The competence evidence record serves as assessment help. A record could comprise, besides immediate manager assessment as the only counted input at the moment, other types of competence evidences such as related trainings and courses, 360 degree assessment and self assessment.

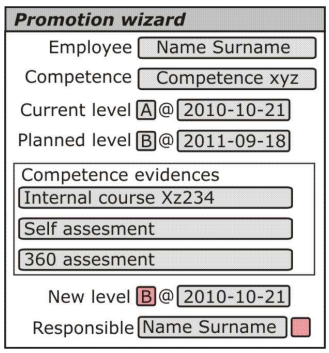

Fig. 6 Promotion wizard

Self assessment is especially interesting competence evidence. It is not completely reliable, but it is very good starting baseline, especially for new employees. Self assessment is pretty easy to implement in a form of web questionnaire. Customizable self assessment questionnaire could be also used in selection and recruitment processes.

Some additional efforts are required in creating competence evidence metadata per existing trainings, courses and certificates that will bind them with related competence or even certain level of the competence.

C. *Training Web API*

Interaction with training and course providers, both internal and external, could be realized through web API or RESTful web services. Main functionalities cover handling of course schedule, list of free seats, subscribing to a course, notifications, etc. Main challenge here is how to connect and correlate some training or course with Ericson competence and its level. The simplest procedure would be that a competence manager at Ericsson side review a course and directly interconnects the course and competence in the system database. The other approach would be to compare courses' with competence' descriptions and/or keywords resulting in the list of best possible hits, which is pretty the same as classical web search. Such approach is limited to keywords and cannot be based on concepts or semantics. The most advanced way would be usage of ontologies.

Both users of the competence management system and course providers will have benefits from training web API. Enterprise competence management system will automatically receive training information (time, costs, free seats) while training provider will get direct marketing channel. Some brave vision could even include educational system in such ecosystem in which some faculty subject and its achieved grades could be competence evidence.

D. *Agile Team Competence Profile*

In overall transition to lean and agile ways of working, scrum teams appear as new entities in an enterprise competence management system. Due expectations that the same scrum team will outlive project participated in and stay together for a couple of years, it is reasonable to assess team's competences. Similar problem as with group assessment is present with team assessment. Team self assessment is more reliable than employee self assessment as it's more like 360 degree assessment, so it will be the assessment of choice for now.

Team's competences levels could be also derived from its member levels by deploying some smart formulas or rules. An agile scrum team needs one or maximally two members at high level of proficiency in an area, to be as a team at same high level in that area.

Desired team profile could be outdrawn per some task and then searched for the closest match with existing teams' competence profiles. Wanted team competence profile could be also used to mix some teams in order to achieve desired team competence profile. Matching team competence profile is not warranty that task will be successfully accomplished, but is very good starting point. Timely taken action of evaluation of team competence status will for sure decrease if not even eliminate risk of the team failure due inadequate overall competence level. Such tool capability will definitely help the process.

V. SYSTEM IMPLEMENTATION

Development of the full beta system version and pilot usage has been organized through research organization of the Research and Development Center of the company Ericsson Nikola Tesla. It first started with two undergraduate students supported by the company small steering group in five-week period of the Ericsson Nikola Tesla Summer Camp 2011, and than continued with one and a half research engineer through additional five months period.

The software development approach used in development of the system is lightweight approach or agile software development. During the Summer Camp a simplified, student and short-time adapted, scrum methodology had been used. In the second phase, when the Ericsson Nikola Tesla research organization took over development of the system, elements of extreme programming have been used.

Through both phases the development has been iterative and incremental, but different aspects and focuses of the system prevailed in different iterations. The first phase iterations (three of them) focused on system prototype early establishment, very basic requirements definition and some exploration of latest and up-to-date views on competence management and its user front end. The second phase kicked off formal establishment of the research project and comprised basically three major iterations. The first iteration of the second phase focused on strict implementation of user front end requirements and on support of different competence taxonomies. Class model was the main development artifact of this iteration. The second iteration started with detailed redesign of data model, it than separated operational and legal organizational structures and dealt with supporting functionalities such as authentication and authorization. The third iteration integrates all functionalities, provides initial provisioning and prepares system installation for beta testing in three Ericsson Nikola Tesla Research and Development departments.

The architecture of the computer aided competence management system is the multi-tiered client server architecture. The front end is a rich and interactive web user interface built up by the Google Web Toolkit (GWT) and extensive usage of Cascading Style Sheets (CSS). The GWT specialized compiler translates Java user interface code into JavaScript code that is loaded as part of a web page and executed on the browser. JavaScript code at browser side uses GWT-RPC to make asynchronous call to a Java servlet running at server side creating interactive Asynchronous JavaScript and XML (AJAX) web application. The servlet communicates with business logic components, which then further interacts with the dedicated relational database and the Ericsson Corporate Directory service. Access to the relational database is enabled through Hibernate Object to Relational Mapping (ORM). Users are authenticated against the Ericsson Corporate Directory using already existing corporate

accounts and the Lightweight Directory Access Protocol (LDAP). Java programming language is used for all parts of the application – from the user interface, through the business logic, down to the data access code.

User front end is organized around five different views:

- Resource/competence grid with competence levels at intersections, Fig. 7,
- Competence/level grid with number of employee at intersections,

VI. CONCLUSION

Business environment is continuously exposed to dynamic changes and complex requirements. There is a need to act fast, to adapt quickly to new business strategies and to adopt new business models. Competencies are one of the organizations' key assets. They are valuable, could be rare, and difficult to build up, starting from individual, team up to the enterprise level. No doubt, every senior and successful organisation is aware of competence management importance. Despite the strategic emphasis on competence management there are few published examples of the successful implementation and use of competence system. The implementation of enterprise competence management systems is comprehensive process and there could be significant obstacles to the organizations ambitions to implement it.

The development of the system has been started as an idea for a local web tool that will cope with some competency management related issues at lower operational levels. During the development phase, thankfully to the project setup as research project, the idea has evolved in the computer aided competence management system with much broader scope than it was initially set. The system requirements are thoroughly collected and evaluated. We have tried to enlight as many as competence management system facets as we have been aware of them. Special care is dedicated to the system future perspectives, acceptance and sustainability. We hope that will have enough reasons to publish another paper about the computer aided competence management system success story after the first application.

Sažetak – Sustavi za preporuku vijesti krajnjem korisniku preporučuju potencijalno zanimljive vijesti ovisno o njegovom interesu, sklonostima te ponašanju u prošlosti. Metode preporuke mogu biti temeljene na sadržaju, gdje su preporučeni objekti slični onima koje je korisnik već kupio/pročitao/pogledao u prošlosti, ili temeljene na suradnji, gdje se objekti preporučuju prema ocjenama koje su dali drugi korisnici. Ovaj rad prikazuje web sustav za preporuku vijesti koji koristi hibridni pristup preporuke kombinirajući metode temeljene na sadržaju i metode temeljene na suradnji. On daje pregled algoritama za preporuku, arhitekture sustava te početnu ocjenu zadovoljstva korisnika korištenom uslugom.

I. UVOD

U današnjem ubrzanom i razvijenom svijetu svakog trenutka stvara se na tisuće novih informacija koje dolaze iz različitih izvora i kroz različite vrste medija. Čovjeku je, dakle, na raspolaganju velika količina informacija koje konstantno pristižu i koje on ne može obraditi. U tom svakodnevnom bombardiranju informacijama, pojedinac želi primati samo one informacije koje su u skladu s njegovim interesom.

Stoga se javlja potreba za sustavom koji će filtrirati dostupne informacije i korisniku isporučiti samo one koje bi mu potencijalno mogle biti korisne. Primjer takvog sustava je sustav za preporučivanje sadržaja.

Sustav za preporučivanje sadržaja krajnjem korisniku preporučuje potencijalno interesantne objekte procjenjujući u kojoj mjeri će se neki objekt svidjeti korisniku. Objekti koji se preporučuju mogu biti bilo koje vrste, kao npr. knjige, filmovi, novinski članci, glazba pa čak i restorani te drugi ugostiteljski objekti i usluge. Za odabir preporučenih objekata koriste se razne metode, od kojih će najpopularnije biti opisane u nastavku.

U ovom radu opisan je web sustav za preporučivanje novinskih članaka. On za preporučivanje koristi kombinaciju postojećih metoda za preporučivanje. Jezgra sustava aktivno prikuplja novinske članke s većeg broja izvora dok se profili korisnika održavaju implicitno, tj. praćenjem njihovog ponašanja.

U drugom poglavlju dan je opis sustava za preporučivanje te su navedene najvažnije metode na kojima se ti sustavi temelje. U trećem poglavlju opisana je arhitektura web sustava za preporučivanje novinskih članaka. U četvrtom poglavlju predstavljena je ocjena sustava, dok je u petom poglavlju dan pregled rješenja koja su slična sustavu opisanom u ovom radu.

II. SUSTAVI I ALGORITMI ZA PREPORUČIVANJE

Sustavi za preporučivanje nastali su na temelju istraživačkih rezultata u područjima kognitivne znanosti, teorije aproksimacija, pretraživanja informacija i teorije predviđanja, a postaju neovisno područje istraživanja sredinom devedesetih godina prošlog stoljeća. Tada se pažnja istraživanja usmjerila na preporučivanje koje se izričito oslanja na procjenjivanje vrijednosti nekog objekta za korisnika [1].

Problem preporučivanja sadržaja nekom korisniku može se pobliže opisati kao problem procjene ocjene koju bi taj korisnik pridijelio nekom objektu koji mu je nepoznat. To procjenjivanje ocjene se većinom temelji na korisnikovim ocjenama drugih objekata koji posjeduju slična svojstva, ili na ocjenama kojima su ostali korisnici ocijenili navedeni objekt. Korisniku se nakon procjenjivanja može preporučiti skup objekata koji imaju najvišu procijenjenu vrijednost. Korisnost objekta je dakle, u sustavima za preporučivanje, najčešće predstavljena ocjenom koja govori koliko se nekom korisniku svidio određeni objekt.

Korisnik može biti definiran profilom korisnika, koji može sadržavati razne značajke koje opisuju korisnika (poput dobi, spola, zanimanja, mjesta stanovanja itd.). U najjednostavnijem slučaju profil sadrži samo jedinstveni identifikacijski broj korisnika ili samo njegovo ime. Svaki element skupa objekata također može biti opisan skupom značajki. Na primjer, u slučaju preporučitelja novinskih članaka svaki novinski članak može biti predstavljen ne samo svojim identifikacijskim brojem, već i svojim nazivom, autorom, kategorijom, datumom i vremenom objave, itd.

Središnji problem sustava za preporučivanje je činjenica da korisnost nije definirana za sve parove korisnik – objekt, već samo za neke [1]. To znači da se njena vrijednost treba predvidjeti izvan intervala do tada poznatih vrijednosti. Korisnost je u sustavima za preporučivanje početno definirana samo na objektima koje su korisnici u prošlosti ocijenili. Predviđanje njene vrijednosti se obično izvodi određivanjem posebnih heurističkih funkcija koje definiraju funkciju korisnosti i empirijski provjeravaju njen učinak te procjenjivanjem funkcije korisnosti na temelju nekog kriterija. Kada su

nepoznate vrijednosti, tj. ocjene, dodijeljene, neki objekt se preporučuje korisniku birajući najveću ili najrelevantniju ocjenu između svih ocjena koje su procijenjene, a koje su do tada bile nepoznate.

Nove ocjene neocijenjenih objekata mogu se procijeniti različitim načinima, kao npr. metodama iz teorije aproksimacija, strojnim učenja ili raznim heuristikama.

Ovisno o metodama na temelju kojih se preporučivanje odvija, sustavi za preporučivanje dijele se na:

- *Preporučivanje temeljeno na sadržaju*, gdje se korisniku preporučuju objekti slični onima koji su mu u prošlosti bili zanimljivi;
- *Preporučivanje temeljeno na suradnji*, gdje se korisniku preporučuju objekti koji su bili zanimljivi ostalim korisnicima sličnih interesa;
- *Hibridni pristup*, u kojem se kombinira preporučivanje temeljeno na sadržaju i ono temeljeno na suradnji.

A. *Preporučivanje temeljeno na sadržaju*

Pristup preporučivanju temeljen na sadržaju svoje korijene vuče iz pretraživanja i filtriranja informacija. Zbog značajnog početnog uspjeha koje je napravilo filtriranje i pretraživanje mnogi sustavi temeljeni na sadržaju usredotočili su se na preporuku objekata koji sadrže tekstualne informacije (npr. različiti tekstualni dokumenti, web stranice). Poboljšanje nad tradicionalnim pristupom u pretraživanju proizlazi iz uporabe korisničkih profila koji sadrže informacije o interesima korisnika, njihovim željama i potrebama. Podaci u korisničkom profilu mogu biti dobiveni eksplicitno od korisnika putem upitnika ili implicitno, tj. praćenjem njegovog ponašanja tijekom vremena.

Kod metoda preporučivanja temeljenih na sadržaju, korisnost nekog objekta procjenjuje se na temelju korisnosti koje je korisnik dodijelio objektima koji su slični objektu kojemu se procjenjuje korisnost [1].

Profil objekta sadrži skup atributa koji opisuju neki objekt, a on se obično izrađuje izvođenjem skupa značajki iz samog objekta i koristi se za određivanje prikladnosti objekta u svrhu preporučivanja. Kako su sustavi temeljeni na sadržaju objekata uglavnom projektirani za preporučivanje tekstualnih objekata, sadržaj tih objekata obično je opisan ključnim riječima. Važnost riječi u dokumentu određena je njenom težinom koja može biti definirana na nekoliko različitih načina.

Jedna od najpoznatijih mjera za određivanje težine ključne riječi u pretraživanju sadržaja je *term frequency/inverse document frequency* (TF-IDF).

Neka je N ukupan broj dokumenata koji se mogu preporučiti korisnicima i neka se ključna riječ k_j pojavljuje u n_i dokumenata. Nadalje, $f_{i,j}$ je broj pojavljivanja ključne riječi k_i u dokumentu d_j. Tada je $TF_{i,j}$, frekvencija izraza riječi k_i u dokumentu d_j, definirana kao

$$TF_{i,j} = \frac{f_{i,j}}{max_z f_{z,j}} \quad (1)$$

gdje je maksimum računan na frekvencijama $f_{z,j}$ svih ključnih riječi k_z koje se pojavljuju u dokumentu d_j. Međutim, ključne riječi koje se pojavljuju u puno dokumenata nisu korisne za razlikovanje dokumenata koji su relevantni od onih koji nisu. Stoga se mjera inverzne frekvencije dokumenata (IDF_i) često kombinira s jednostavnom mjerom frekvencije izraza ($TF_{i,j}$). Inverzna frekvencija dokumenta za riječ k_i definirana je kao

$$IDF_i = \log \frac{N}{n_i} \quad (2)$$

Nadalje, težina TF-IDF za ključnu riječ k_i u dokumentu d_j definirana je kao

$$w_{i,j} = TF_{i,j} \times IDF_i \quad (3)$$

dok je sadržaj dokumenta d_j

$$Content(d_j) = (w_{1j}, \ldots w_{kj}). \quad (4)$$

Dakle, sustavi temeljeni na sadržaju preporučuju objekte slične onima koje je korisnik koristio u prošlosti. Razni objekti uspoređuju se s prijašnje korištenim objektima i preporučuju se oni objekti koji su najsličniji korisničkom profilu. [1]

Neka je *Profile*(*c*) profil korisnika *c* koji sadrži korisnički interes. Tada je funkcija korisnosti *u*(*c*,*s*) definirana kao

$$u(c,s) = score(Profile(c), Content(s)). \quad (5)$$

Profil korisnika *c*, *Profile*(*c*), i sadržaj dokumenta *s*, *Content*(*s*), mogu se prikazati kao TF-IDF vektori težina ključnih riječi, $\overrightarrow{w_c}$ i $\overrightarrow{w_s}$. Funkcija korisnosti *u*(*c*,*s*) obično je predstavljena nekom heurističkom funkcijom definiranom nad vektorima $\overrightarrow{w_c}$ i $\overrightarrow{w_s}$, kao što je kosinusna mjera sličnosti:

$$\begin{aligned} u(c,s) &= \cos(\overrightarrow{w_c}, \overrightarrow{w_s}) \\ &= \frac{\overrightarrow{w_c} \cdot \overrightarrow{w_s}}{\left|\left|\overrightarrow{w_c}\right|\right|_2 \times \left|\left|\overrightarrow{w_s}\right|\right|_2} \\ &= \frac{\sum_{i=1}^{K} w_{i,c} w_{i,s}}{\sqrt{\sum_{i=1}^{K} w_{i,c}^2} \sqrt{\sum_{i=1}^{K} w_{i,s}^2}}, \end{aligned} \quad (6)$$

gdje je *K* ukupan broj ključnih riječi u sustavu.

B. *Preporučivanje temeljeno na suradnji*

Za razliku od sustava preporučivanja koji su temeljeni na sadržaju, sustavi za preporučivanje temeljeni na suradnji predviđaju korisnost nekog objekta za određenog korisnika na temelju objekata kojima su drugi korisnici u prošlosti dali ocjene. Formalnije se to može opisati na sljedeći način: vrijednost funkcije korisnosti *u*(*c*, *s*) objekta *s* za korisnika *c* procjenjuje se na temelju korisnosti *u*(c_j, *s*) koje su objektu s dodijelili korisnici $c_j \in C$ koji su slični korisniku *c* [1].

Metode preporučivanja temeljene na suradnji dijele se na dvije glavne skupine: algoritme *temeljene na heuristici* i one *temeljene na modelu*.

Algoritmi temeljeni na heuristici zapravo su heurističke funkcije koje predviđanje ocjene temelje na cijeloj kolekciji objekata koje su prethodno ocijenili drugi

korisnici. To znači da se vrijednost nepoznate ocjene $r_{c,s}$ korisnika *c* za objekt *s* računa kao zbroj ocjena drugih korisnika (uglavnom *N* najsličnijih) za isti objekt *s*:

$$r_{c,s} = \underset{c' \in \hat{C}}{\text{aggr}}\ r_{c',s} \tag{7}$$

$\hat{C}$ označava skup od *N* korisnika i to onih koji su najsličniji korisniku *c* i koji su ocijenili objekt *s*.

Funkcija agregiranja može biti:

$$\text{(a)}\ r_{c,s} = \frac{1}{N}\sum_{c' \in \hat{C}} r_{c',s},$$

$$\text{(b)}\ r_{c,s} = k\sum_{c' \in \hat{C}} sim(c,c') \times (r_{c',s}), \tag{8}$$

$$\text{(c)}\ r_{c,s} = \bar{r}_c + k\sum_{c' \in \hat{C}} sim(c,c') \times (r_{c',s} - \bar{r}_{c'}),$$

gdje se množitelj *k* koristi kao uravnotežujući faktor i obično se računa kao

$$k = \frac{1}{\sum_{c' \in \hat{C}} |sim(c,c')|}. \tag{9}$$

Prosječna ocjena korisnika *c* označena je kao $\bar{r}_c$ (8c) i definirana je:

$$\bar{r}_c = \left(\frac{1}{|S_c|}\right)\sum_{s \in S_c} r_{c,s}\ ;\ \text{gdje je } S_c = \{s \in S | r_{c,s} \neq \emptyset\}. \tag{10}$$

Izraz $r_{c,s} \neq \emptyset$ označava da je korisnik *c* ocijenio objekt *s*.

Izraz (8a) prikazuje najjednostavniji slučaj gdje je funkcija zbroja obična aritmetička sredina. Unatoč tome, najčešće korištena funkcija agregiranja je težinska suma, kao npr. u (8b). Sličnost između korisnika *c* i *c'*, *sim*(*c*, *c'*), je zapravo mjera udaljenosti i koristi se kao težinska vrijednost. Što su korisnici *c* i *c'* sličniji, to će ocjena $r_{c',s}$ imati veći doprinos u izračunu nepoznate ocjene $r_{c,s}$. Razlozi zbog kojih se uvodi mjera sličnosti među korisnicima su nužnost razlikovanja razina sličnosti između pojedinih korisnika te pojednostavljivanje procjenjivanja nepoznatih ocjena.

Različiti preporučitelji mogu koristiti različite heurističke funkcije sličnosti ako se njima dobiveni izračuni uravnoteže uravnotežujućim faktorom *k*. Različiti korisnici ocjenjuju objektu po različitoj ljestvici ocjena što se kod korištenja težinske sume ne uzima u obzir, pa se tu javlja problem. On se najčešće rješava primjenom usklađene težinske sume, prikazane u (8c), koja umjesto apsolutnih vrijednosti ocjena koristi njihova odstupanja od prosječne ocjene odgovarajućeg korisnika.

Funkcija sličnosti *sim*(*c*, *c'*) između korisnika u sustavima za preporučivanje temeljenima na suradnji može se računati na više različitih načina. Većina tih načina izračun sličnosti između dva korisnika temelji na njihovim ocjenama onih objekata koji su zajednički, tj. koji su ocijenjeni od oba korisnika. Najpoznatiji su:

- *Pristup temeljen na kosinusu*, gdje se dva korisnika koja se uspoređuju zapisuju kao dva *m*-dimenzionalna vektora, gdje je *m* broj objekata koje su ocijenili oba korisnika. Sličnost između vektora računa se kao kosinus kuta između njih;
- *Pristup temeljen na korelaciji*, gdje se za određivanje sličnosti između korisnika koristi Pearsonov koeficijent korelacije.

C. Hibridni pristup

Hibridni pristup, koji kombinira preporučivanje temeljeno na sadržaju s onim temeljenim na suradnji, u nekim slučajevima može biti puno učinkovitiji jer izbjegava određena ograničena pojedinog pristupa. Postoje različiti načini na koje se metode preporučivanje temeljene na sadržaju i suradnji mogu kombinirati:

- Preporuke temeljene na sadržaju i preporuke temeljene na suradnji se računaju odvojeno te se njihovi rezultati zatim kombiniraju;
- Ugrađivanje nekih mogućnosti preporučivanja temeljenog na sadržaju u preporučivanje temeljeno na suradnji;
- Ugrađivanje nekih mogućnosti preporučivanja temeljenog na suradnji u preporučivanje temeljeno na sadržaju;
- Izgradnja modela pretraživanja koji objedinjuje oba pristupa.

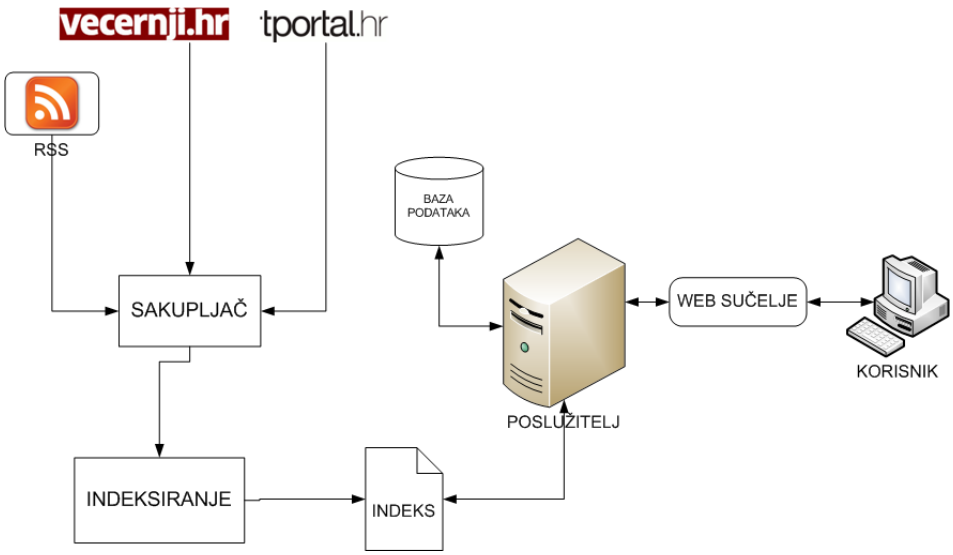
III. RECOMNEWS: ARHITEKTURA SUSTAVA

RecomNews je sustav za preporučivanje novinskih članaka koji je predstavljen u ovom radu [7]. On koristi hibridnu metodu preporučivanja. Arhitektura sustava prikazana je na slici 1.

Korištenjem kanala RSS-a (*Really Simple Syndication*) na informacijskim portalima se periodički skupljaju osnovne informacije o novinskim člancima objavljenim na tim portalima. U RecomNews sustavu trenutno je omogućeno skupljanje informacija s dva informacijska portala. Informacije koje se skupljaju direktno s kanala RSS-a su naslov članka, datum objave članka te poveznica na članak i one se dohvaćaju pomoću „sakupljača“. On za pristup kanalima RSS-a i dohvat podataka s njih koristi alat otvorenog koda Informa [2] koji je pisan u programskom jeziku Java. Svakom kanalu RSS-a pridružen je jedan sakupljač.

Ostale informacije, kao što su kategorija, autor, ključne riječi te opis članka, dobivaju se obradom HTML-a traženog članka koji se nalazi na web sjedištu informacijskog portala, a pristupa mu se preko ranije dobivene poveznice na članak.

Nakon što se prikupe potrebne informacije o novinskim člancima, one se u prilagođenom obliku indeksiraju i spremaju u Lucenov indeks [3] gdje se pripremaju za kasnije pretraživanje. Indeks je pohranjen na čvrstom disku na poslužitelju.



Slika 1. Arhitektura sustava

Korisnik aplikaciji pristupa s vlastitog računala preko web sučelja. Njegovo korisničko ime i lozinka pohranjeni su u bazi podataka pa ga tako sustav može autentificirati.

Kada korisnik od sustava zatraži preporuku pri prvoj prijavi u aplikaciju, sustav za preporučivanje vraća mu iz indeksa samo najnovije članke, jer korisnik još nije koristio sustav i nije pogledao niti jedan preporučeni članak pa sustav još nema nikakve informacije o njemu. Najnoviji članci se iz indeksa dohvaćaju tako da se nad indeksom izvodi numerički upit. Nad poljem koje predstavlja datum nastanka članka izvodi se upit koji traži sve članke od referentnog datuma pa sve do datuma uporabe sustava te ih rangira od najnovijeg prema najstarijem.

Svako izvođenje upita i pretraživanje u sustavu izvodi se pomoću Javine biblioteke Lucene [3], koja nudi široke mogućnosti za indeksiranje i pretraživanje tekstualnih kolekcija dokumenata.

Pri svakom pregledavanju preporučenog članka sustav za svakoga korisnika bilježi koji je članak korisnik pogledao na način da u tablici baze podataka korisničkom imenu pridruži poveznicu na članak i vrijeme pristupa članku. Također se, uz navedene podatke, bilježi ocjena kojom je korisnik ocijenio članak te hashcode poveznice na članak koji služi za usporedbu članaka. Ako korisnik nije ocijenio članak, u bazu se zapisuje ocjena 3.

U bazi podataka pohranjeno je i vrijeme posljednjeg zapisivanja informacija o članku u indeks. Ono služi kako bi se kod promjene kanala RSS-a, kada se na njemu objavi neki novi članak, u indeks pisale informacije samo o člancima novijim od zadnjeg vremena dohvata članaka.

Pristup koji RecomNews koristi za preporučivanje sadržaja je kombinacija preporučivanja temeljenog na sadržaju te preporučivanja temeljenog na suradnji. Obje metode preporučivanja se za svaki članak izvode odvojeno pa se rezultati preporuke zbrajaju.

Kod kasnijeg pristupa korisnika sustavu podaci iz baze koji sadrže prijašnje pregledane članke koriste se za stvaranje profila korisnika, tj. njegovog interesa. Za svaku poveznicu na članak koji je korisnik pogledao, a koja se nalazi u bazi podataka, u indeksu se traži pripadajući dokument. Iz njega se uzimaju kategorija, autor, ključne riječi i naslov, pa se pomoću njih gradi korisnički profil, tj. upit kojim će Lucene u svom indeksu pronaći članke koji su prema sadržaju najsličniji interesu korisnika. Sličnost između korisničkog profila i dokumenata u indeksu računa se kosinusnom mjerom sličnosti (6).

Nakon što se izgradi profil korisnika, koji čini zadnjih 10 pogledanih članaka, za svaki od atributa u profilu, tj. za kategoriju, autora, ključne riječi i naslov, radi se poseban upit. Svakom upitu postavlja se *boost factor*. To je decimalni broj koji označava težinu pojedinog upita u konačnom upitu kojim će se pretraživati indeks. Najveća težina dana je kategoriji, pa tako ona ima vrijednost faktora 3.0, slijedi naslov sa 2.0, dok autor i ključne riječi imaju faktor 1.5. Upiti se zajedno s numeričkim upitom, čija je uloga da se u odgovoru na upit pojavljuju samo članci noviji od zadnjeg korisnikovog pristupa aplikaciji, spajaju u konačan upit. Izvođenjem upita dobivaju se članci preporučeni metodom temeljenom na sadržaju.

Preporukom temeljenom na suradnji se prema (8c) pomoću podataka iz baze podataka dobivaju članci koji su najbolje ocijenjeni od drugih korisnika čiji su interesi slični trenutnom korisniku. Sličnost korisnika računa se prema Pearsonovom koeficijentu korelacije. Svaki članak dobiven ovom metodom preporuke traži se među člancima dobivenim metodom temeljenom na sadržaju. Ako se tamo nađe, njegova ocjena zbraja se s korisnošću dobivenom prema (5). Članci se sortiraju prema ukupno dobivenoj ocjeni te se uzima najboljih pet članaka.

Od članaka dobivenih preporukom prema sadržaju uzima se petnaest članaka koji su najrelevantniji, tj. koji imaju najveću korisnost prema (5), dok se ostali odbacuju. Za svaki od tih petnaest članaka računa se nepoznata ocjena metodom temeljenom na suradnji prema (8c). Ta se ocjena zbraja s rezultatom dobivenim u usporedbi s korisničkim profilom.

Petnaest članaka dobivenih metodom temeljenom na sadržaju se zajedno s pet članaka dobivenih metodom

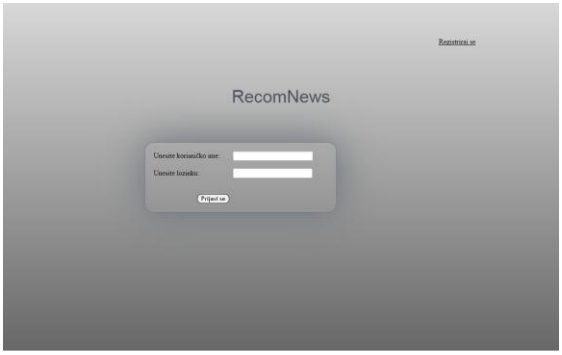
temeljenom na suradnji stavlja u listu te se ta lista sortira prema ukupnoj ocjeni. Rezultat preporuke sustava RecomNews je, dakle, dvadeset novinskih članaka.

Zapisi u tablici baze podataka koji povezuju korisnika s člankom koji je pročitao brišu se iz baze podataka ako su stariji od dva tjedna. Također, ako bilo koji korisnik u bazi ima više od deset zapisa, tj. ima informacije za više od deset pročitanih članaka, brišu se oni najstariji ali tako da u tablici i dalje ostane barem deset zapisa. Provjera ima li neki korisnik više od deset zapisa o pročitanim člancima u bazi podataka vrši se periodički svakih pet minuta.

Iz Lucenovog indeksa brišu se svi članci koji su stariji od dva tjedna. Provjera se vrši periodički i to svake noći u 02:00 sata po hrvatskom vremenu.

IV. KORISNIČKO SUČELJE

Korisnik sustavu za preporučivanje pristupa preko web sučelja prikazanog na slici 2.



Slika 4. Prijava u sustav

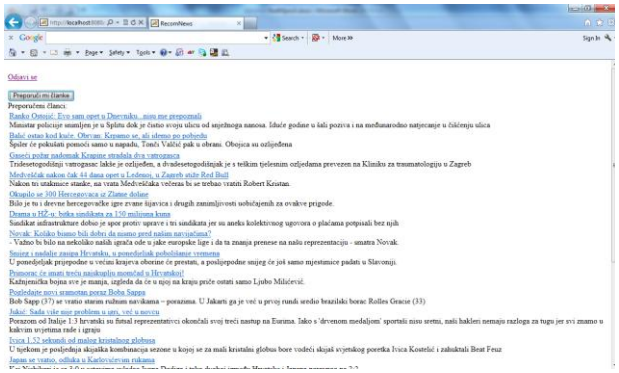
Za korištenje sustava nužna je prijava korisnika i to korisničkim imenom i pripadajućom lozinkom. Ako korisnik nije prije koristio sustav, omogućeno mu je popunjavanje obrasca za registriranje (Slika 3).

Slika 3. Registracija

Nakon uspješne registracije korisnik je ponovno preusmjeren na stranicu za prijavljivanje odakle se s podacima s kojima se registrirao može prijaviti u aplikaciju. Potom, izvršivši prijavu u sustav, korisniku je na raspolaganju glavna stranica same aplikacije (Slika 4).

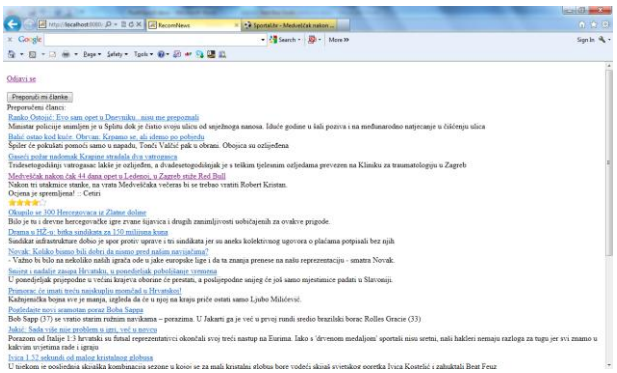
Slika 5. Glavna stranica sustava

Na glavnoj stranici aplikacije prikazana je poveznica za odjavu iz aplikacije te tipka za preporučivanje. Pritiskom na tipku za preporučivanje, na stranici se pojavljuje lista koja sadrži preporučene članke. Svaki članak u listi osim imena sadrži i kratki opis (Slika 5).



Slika 6. Prikaz preporučenih članaka

Klikom na ime članka, koje je ujedno i poveznica na sam članak, korisniku se u novoj kartici otvara odabrani novinski članak u svom originalnom obliku. Povratkom na karticu na kojoj je stranica aplikacije za preporuku korisniku se pruža mogućnost ocijeniti članak ocjenom od 1 do 5 i to klikom na pripadajuću zvjezdicu (Slika 6).



Slika 2. Prikaz mogućnosti ocjenjivanja članka

V. RELEVANTNI RADOVI

Sustavi za preporučivanje sadržaja postali su vrlo česti posljednjih nekoliko godina. Kako velika većina tih sustava za preporuku koristi metode koje su opisane u ovom radu, za svaku od metoda može se navesti barem jedan popularan primjer.

Amazon.com [5] je američki multinacionalni sustav elektroničkog trgovanja i on je jedan od najpoznatijih primjera preporuke metodom temeljenom na suradnji. Kod njega se sličnost objekata koji se preporučuju određuje na sljedeći način: objekti A i B su slični jer je relativno veliki broj korisnika koji je kupio objekt A također kupio objekt B [4].

Još jedan primjer preporuke temeljene na suradnji je popularni sustav za preporučivanje glazbe Last.fm [4]. On stvara „stanicu“ preporučenih pjesama promatrajući koje grupe i pojedinačne pjesme korisnik redovno sluša te uspoređujući te informacije sa slušalačkim navikama drugih korisnika.

Društvene mreže kao što su Facebook, MySpace te LinkedIn koriste metodu temeljenu na suradnji za preporučivanje novih prijatelja, grupa i ostalih društvenih veza.

Pandora Radio je još jedan popularni sustav za preporučivanje glazbe i on je primjer preporuke prema sadržaju [4]. On koristi neke karakteristike pjesme ili izvođača kako bi stvorio „stanicu“ koja svira sličnu glazbu. Korisnikova povratna informacija služi za poboljšanje i prilagođavanje rezultata preporuke.

Također postoji veliki broj sustava koji koriste metodu temeljenu na sadržaju a pružaju preporuku filmova, kao što su Rotten Tomatoes ili Internet Movie Database [4].

Neflix [6] je primjer hibridnog sustava preporuke jer daje preporuke usporedbom navika gledanja sličnih korisnika kao i nudeći filmove koji imaju slične karakteristike s filmovima koje je korisnik visoko ocijenio.

VI. ZAKLJUČAK

U ovom radu opisan je RecomNews, sustav weba za preporučivanje novinskih članaka uporabom hibridnog pristupa preporučivanja, koji je kombinacija preporučivanja temeljenog na sadržaju i preporučivanja temeljenog na suradnji. Preporučivanje temeljeno na sadržaju preporučuje objekte slične onima koje je korisnik koristio u prošlosti dok preporučivanje temeljeno na suradnji preporučuje objekte na temelju ocjena drugih korisnika sličnih interesa.

RecomNews aktivno prikuplja novinske članke s dva različita informacijska portala te ih u prilagođenom obliku sprema u indeks. Svi članci koje je korisnik pogledao spremaju se u bazu i oni se koriste za stvaranje korisničkog profila. Korisniku se kod svakog pogleda na članak nudi mogućnost njegova ocjenjivanja. Rezultat preporuke sustava za preporučivanje sastoji se od članaka koji su najrelevantniji u usporedbi s korisničkim profilom te od članaka koje su drugi korisnici najbolje ocijenili.

Iako opisani sustav nije testiran na većem korisničkom uzorku, može se reći da on uspješno preporučuje novinske članke kombinirajući dva pristupa preporučivanja u isporuci rezultata preporuke.

Kako bi se sustav u budućnosti unaprijedio treba provesti testiranje na većoj grupi korisnika te njihove povratne informacije iskoristiti za moguća poboljšanja, uvođenje nekih novih značajki ili eventualnu promjenu algoritama pomoću kojih se preporuka odvija.

ZAHVALA

Prikazani rezultati proizašli su dijelom iz znanstvenog projekta "Isporuka sadržaja i pokretljivost korisnika i usluga u mrežama nove generacije" provođenog uz potporu Ministarstva znanosti, obrazovanja i športa Republike Hrvatske.

Abstract - To adapt for the fading impairments and to provide a higher data rates wireless systems, a new shift in the perspectives came in the form of proposing a new evolving technology such as the multiuser diversity and the cooperative wireless networks which combines the features of the (MIMO) system without confronting the physical layer constraints by providing multiple copies of the transmitted signal from the source to the destination with the help of the relay node. In this paper, we present an analysis of a two hop cooperative multi-relay communication networks, derive a tight closed form expression of outage probability and symbol error probability (SEP) for the amplify-and-forward (AF) protocol with MUD.

Keywords: Amplify-and-forward (AF), cooperative communications, multiuser diversity (MUD), two hop cooperative multi-relay network (TCMRN).

I. INTRODUCTION

In communication systems designed to use a single signal path between transmitter and receiver have high probability to suffer from fading, such techniques are used to increase the signal to noise ratio at the receiver and reduce the SEP, the overall reliability can be improved by providing multiple copies of the transmitted signal to the receiver by using multiple relay nodes [1].

Cooperative networks diversity is available at the destination by using the intermediate relay nodes between the source and the destination which help the source in relaying it's signal. Among the most commonly used schemes is the Amplify-and-forward (AF) which simply amplifies the received signal from the source and resends it to the destination. With this in mind, this is considered easy to implement as compared to the Decode and forward (DF) relaying scheme in which the relays decode the received signal, and re-transmit an encoded version to the receiver and hence the AF is much more preferable approach in wireless networks with simple relay units such as wireless sensor networks, besides that, the (AF) relying has low complexity compared to other techniques. This is based on the fact that the user will pass or go through a different fading conditions and at any given instance of time, there would be a user whose channel gain is the best among all the other users [2].

Many researches have been done on analyzing the performance of MUD in cooperative networks. In [3]–[6], the research of MUD can be considered as the extension to multiple-input–multiple-output antenna systems (MIMO) [7], [8]. The research of MUD in cooperative networks focus on network scenarios with a single source, one single destination, and M multiple relaying nodes in between, whereas, in [2] the authors extend the analysis to multi-user two-hop cooperative networks (TCRNs) with a single relaying node, one single destination, and multiple sources.

This paper extends the work of MUD in multiuser TCRNs to multiuser two-hop cooperative wireless networks with multiple relaying nodes network (TCMRNs) with multiple relays, one single destination, and multiple users (sources) and we derive tight closed form formulas of outage probability and symbol error probability (SEP) for the amplify-and-forward (AF) scheme with MUD.

The major contributions of this paper are summarized as follows:

1. A tight closed form expression of outage probability is derived for TCMRNs, which shows that the system outage probability will be reduced by a factor of $\bar{\gamma}^{2K}$ where K being the number of the available users.
2. A closed form SEP expression is obtained; from this formula, we show that diversity order of $2K$ is achieved for AF.

This paper is further presented as follows; Section II provides the system model. Section III provides the performance analysis and derived tight closed form formulas of outage probability and SEP. Results and discussion are presented in section IV. We concluded this paper in section V.

II. SYSTEM MODEL

Consider a multiuser TCMRN system with one destination, *K*-users and M-relays as illustrated in Fig. 1. Each user can communicate with the destination directly or via the relays. In this paper, we adopt the AF scheme

[9] and that the orthogonal channel access method being used in the proposed system is the time-division multiple-access (TDMA). For MUD, at the given time instant, one "best" user among all the available *K* users is elected to transmit the signal. At the destination the channel state information (CSI) is available and can properly be obtained by the virtue of using the feedback channels between the destination and the relay nodes for MUD-based scheduling.

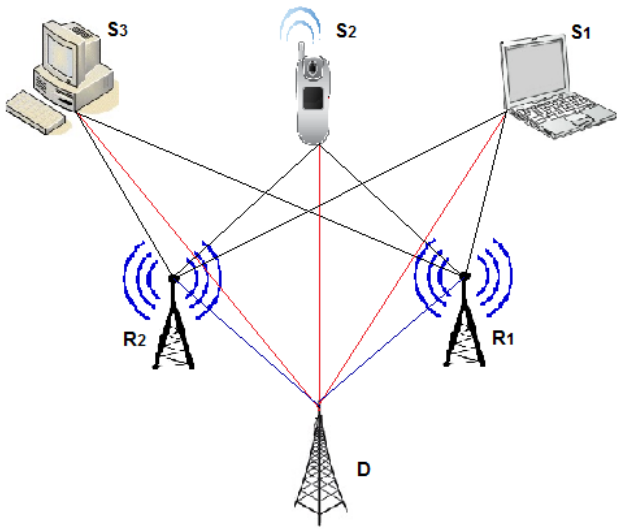

Fig. 1 MUD in multiuser TCMRNs with *K*=3, *M*=2. The lines between any two nodes represent the communication links

At the destination, the received signal from the k-th user and from the k-th user to the m-th relay node, respectively, are formulated as follows:

$$y_d^k = \sqrt{E_k} h_{k,d} x_k + n_{k,d} \quad (1)$$

$$y_m^k = \sqrt{E_k} h_{k,m} x_k + n_{k,m} \quad (2)$$

where x_k is the user-k signal, and y_d^k and y_m^k are the k-th user's transmitted signal received at destination and m-th relaying nodes, respectively. $h_{k,d}$ and $h_{k,m}$ are the channel coefficients from the k-th user to the destination and from the k-th user to the m-th relay node, respectively. $n_{k,d}$ and $n_{k,m}$ are the additive white Gaussian noise (AWGN) with the variances being $N_{k,d}$ and $N_{k,m}$, respectively.

For the AF scheme, upon receiving the k-th user's signal, the m-th relay node sends a new signal $x_m^k = \alpha_m^k \cdot y_m^k$ to the destination. The amplification factor α_m^k is given as $\alpha_m^k = 1/\sqrt{E\{|y_m^k|^2\}}$. Through the relay node–destination link, the received signal of the k-th user at the receiver of the base station is:

$$\begin{aligned} y_d^m &= \sqrt{E_m} h_{m,d}^k x_m^k + n_{m,d}^k \\ &= \sqrt{E_m} h_{m,d}^k y_m^k \alpha_m^k + n_{m,d}^k \\ &= \sqrt{\frac{E_k E_m}{E_k |h_{k,m}|^2 + N_{k,m}}} h_{k,m} h_{m,d}^k x_k + \tilde{n}_{m,d}^k \end{aligned} \quad (3)$$

where $h_{m,d}^k$ is the channel coefficient between the relaying node and the destination link when relaying the source signal, $n_{m,d}^k$ is the AWGN with variance $N_{m,d}^k$, and $\tilde{n}_{m,d}^k$ is the AWGN with variance $\tilde{N}_{m,d}^k$, which is given as $\tilde{N}_{m,d}^k = N_{m,d}^k + \left(E_m |h_{m,d}^k|^2 N_{k,m} / \left(E_m |h_{m,d}^k|^2 + N_{k,m}\right)\right)$.

The received signal-to-noise ratio (SNR) at the receiver terminal of the k-th user after maximum ratio combining (MRC) at the base station can be expressed as [3], [8]:

$$\gamma_k^{AF} = \frac{|h_{k,d}|^2 E_k}{N_{k,d}} + \sum_{m=1}^{M} \frac{\frac{|h_{k,d}|^2 E_k}{N_{k,m}} \cdot \frac{|h_{m,d}^2|^2 E_m}{N_{m,d}^k}}{\frac{|h_{k,m}|^2 E_k}{N_{k,m}} + \frac{|h_{m,d}^2|^2 E_m}{N_{m,d}^k} + 1} \quad (4)$$

where $h_{m,d}$ denote the channel coefficient from the m-th relay to destination, E is the average transmission energy. In this paper we consider the case where each user has identical fading statistics, and assume that all the noise variances are equal, i.e., $N_{k,d} = N_{k,m} = N_{m,d}^k = N_0 = 1/\bar{\gamma}$, where $\bar{\gamma}$ is proportional to all the transmitted SNRs. For more simplification, when the channel is exponentially distributed, we can express the k-th user's received SNR at the destination as:

$$\gamma_k^{AF} = \alpha_k \bar{\gamma} + \sum_m \frac{\beta_{km} C_{km} \bar{\gamma}^2}{\beta_{km} \bar{\gamma} + C_{km} \bar{\gamma} + 1} \quad (5)$$

where:

$$\alpha_k = |h_{k,d}|^2 E_k, \beta_{km} = |h_{k,m}|^2 E_k, C_{km} = |h_{m,d}^k|^2 E_m$$

are the signal powers received at the destination from the k-th user, at the m-th relaying node from the k-th user, and from the intermediate relaying node to the destination, respectively.

III. PERFORMANCE ANALYSIS

In multiuser TCMRNs with MUD, and based on the fact that the CSI is available at the destination from both the relaying nodes and the source, the destination will choose the user who can achieve the largest SNR , i.e., the largest achievable system SNR is $\gamma_s^{AF} = max_k \gamma_k^{AF}$.

Thus, the achievable channel capacity of MUD for AF is given as follows [2]:

$$I_s^{AF} = \frac{1}{2} log_2(1 + \gamma_s^{AF}) = \frac{1}{2} log_2(1 + max_k \gamma_k^{AF}) \quad (6)$$

To analyze the performance of the proposed system, i.e., the outage probability and SEP, we have to provide the cumulative density function (cdf) of γ_s^{AF}.

Based on [2], the cdf of γ_s^{AF} in multiuser TCMRNs with MUD, in large average SNR systems ($\bar{\gamma} \gg 1$), can be approximated as follows:

$$F_{\gamma_s^{AF}}(\gamma) = \frac{1}{2^{KM}} \left(\frac{\gamma}{\bar{\gamma}}\right)^{2K} \prod_{k=1}^{K} \prod_{m=1}^{M} \bar{\alpha}_k (\bar{\beta}_{km} + \bar{C}_{km}) \quad (7)$$

Proof:

For the independent identically distributed RV γ_k^{AF}, the cdf of γ_s^{AF} can be calculated as:

$$\begin{aligned} F_{\gamma_s^{AF}}(\gamma) &= Pr(\gamma_s^{AF} \le \gamma) \\ &= Pr(max_k \gamma_k^{AF} \le \gamma) \\ &= \prod_{k=1}^{K} Pr\left[\left(\alpha_k\bar{\gamma} + \sum_{m=1}^{M} \frac{\beta_{km}C_{km}\bar{\gamma}^2}{\beta_{km}\bar{\gamma} + C_{km}\bar{\gamma} + 1}\right) \le \gamma\right] \\ &= \left(\frac{\gamma}{\bar{\gamma}}\right)^{2K} \prod_{k=1}^{K} \frac{Pr\left[\left(\alpha_k + \sum_{m=1}^{M} \frac{\beta_{km}C_{km}}{\beta_{km} + C_{km} + 1/\bar{\gamma}}\right) \le \gamma/\bar{\gamma}\right]}{(\gamma/\bar{\gamma})^2} \end{aligned} \quad (8)$$

According to [9, eq. (43)], for an arbitrary user *k*, it is shown that for independent exponentially RVs α_k, β_{km}, and C_{km} with means of $\bar{\alpha}_k$, $\bar{\beta}_{km}$, and $\bar{C}_{km}$, respectively, for a large achievable SNR system, there is an approximation as follows:

$$\begin{aligned} &\lim_{\bar{\gamma}\to\infty} \frac{Pr\left[\left(\alpha_k + \sum_{m=1}^{M} \frac{\beta_{km}C_{km}}{\beta_{km} + C_{km} + 1/\bar{\gamma}}\right) \le \gamma/\bar{\gamma}\right]}{(\gamma/\bar{\gamma})^2} \\ &\quad = \prod_{m=1}^{M} \frac{\bar{\alpha}_k(\bar{\beta}_{km} + \bar{C}_{km})}{2} \end{aligned} \quad (9)$$

Thus, taking (9) into (8) and for a large average SNR $\bar{\gamma}$ system, the asymptotic cdf of γ_s^{AF} for the AF protocol is written as:

$$F_{\gamma_s^{AF}}(\gamma) = \frac{1}{2^{KM}}\left(\frac{\gamma}{\bar{\gamma}}\right)^{2K} \prod_{k=1}^{K}\prod_{m=1}^{M} \bar{\alpha}_k(\bar{\beta}_{km} + \bar{C}_{km}) \quad (10)$$

Next, we will use the cdf of γ_s^{AF} to derive the outage probability and SEP of MUD in TCMRNs.

A. Outage Probability

The outage probability of AF-based multiuser TCMRN with MUD, defined as the probability that the channel capacity falls below a specified target transmission rate *R* is calculated as:

$$\begin{aligned} P_{out}^{AF} &= Pr[I_s^{AF} < R] = Pr[\gamma_s^{AF} < 2^{2R} - 1] \\ &= F_{\gamma_s^{AF}}(2^{2R} - 1) \\ &= \frac{1}{2^{KM}}\left(\frac{2^{2R} - 1}{\bar{\gamma}}\right)^{2K} \prod_{k=1}^{K}\prod_{m=1}^{M} \bar{\alpha}_k(\bar{\beta}_{km} + \bar{C}_{km}) \end{aligned} \quad (11)$$

B. Symbol Error Probability (SEP)

Generally, the conditional SEP for a specific SNR of the most commonly used signal modulation techniques, including *M*-ary quadratic-amplitude modulation (*M*-QAM), *M*-ary phase-shift keying (*M*-PSK), and *M*-ary pulse amplitude modulation (*M*-PAM), can be written as the uniform expression [10]:

$$P_s(\gamma_s) = AQ\left(\sqrt{B\gamma_s}\right) \quad (12)$$

where *A* and *B* are the specific constellation parameters [11] and {Q} is the Gaussian Q function, for certain SNR the average SEP for Rayleigh channel can be expressed as:

$$\begin{aligned} P_s^{AF} = E_{\gamma_s^{AF}}\left\{AQ\left(\sqrt{B\gamma_s^{AF}}\right)\right\} &= AE_{\gamma_s^{AF}}\left\{\left(\sqrt{B\gamma_s^{AF}}\right) < X\right\} \\ &= AE_{\gamma_s^{AF}}\left\{\gamma_s^{AF} < \frac{X^2}{B}\right\} \\ &= AE_X\left\{F_{\gamma_s^{AF}}\left(\frac{X^2}{B}\right)\right\} \end{aligned} \quad (13)$$

where:

X is a normally distributed random variable.

$E_{\gamma_s^{AF}}\{\cdot\}$ is the expectation operator applied on the distribution of γ_s^{AF}.

Using (7), (13) can be asymptotically approximated as:

$$\begin{aligned} P_s^{AF} &\approx A\int_0^{\infty} \frac{1}{2^{KM}}\left(\frac{x^2}{B\bar{\gamma}}\right)^{2K} \prod_{k=1}^{K}\prod_{m=1}^{M} \bar{\alpha}_k(\bar{\beta}_{km} + \bar{C}_{km}) \\ &\qquad \times \frac{1}{\sqrt{2\pi}} e^{-\frac{x^2}{2}} dx \\ &= \frac{A}{\sqrt{2\pi}2^{KM}(B\bar{\gamma})^{2K}} \prod_{k=1}^{K}\prod_{m=1}^{M} \bar{\alpha}_k(\bar{\beta}_{km} + \bar{C}_{km}) \\ &\qquad \times \int_0^{\infty} x^{4K} e^{-\frac{x^2}{2}} dx \\ &= \frac{A}{(B\bar{\gamma})^{2K}} \frac{[4K-1]!}{2^{K(M+2)}[2K-1]!} \prod_{k=1}^{K}\prod_{m=1}^{M} \bar{\alpha}_k(\bar{\beta}_{km} + \bar{C}_{km}) \end{aligned} \quad (14)$$

in which we use [12]

$$\int_0^{\infty} x^{2n} e^{-px^2} dx = \frac{\sqrt{(\pi/p)}(2n-1)!}{2^{2n}(n-1)!\,p^n}$$

IV. RESULTS AND DISCUSSION

We present some results based on the analysis provided in the previous section. Fig. 2 provides the outage probability for one relay with different number of users K = 1, 2, 3 and 4 respectively, as shown in the figure, P_{out} decreases rapidly as the number of users increases. For example, given outage probability of 10^{-3} when we upgrade *K* from 2 to 3 we will get a performance

enhancement of more than 3 dB which confirms the principle of multiuser diversity in cooperative relays.

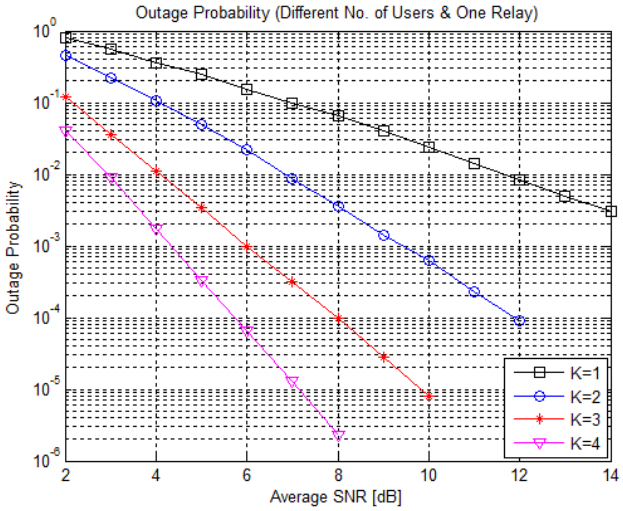

Fig. 2 Outage probability vs. SNR (1 relay)

Fig. 3 shows P_{out} in case of two relays and different number of users. From the figure we can see that the system with two relays provide better performance than the one with one relay.

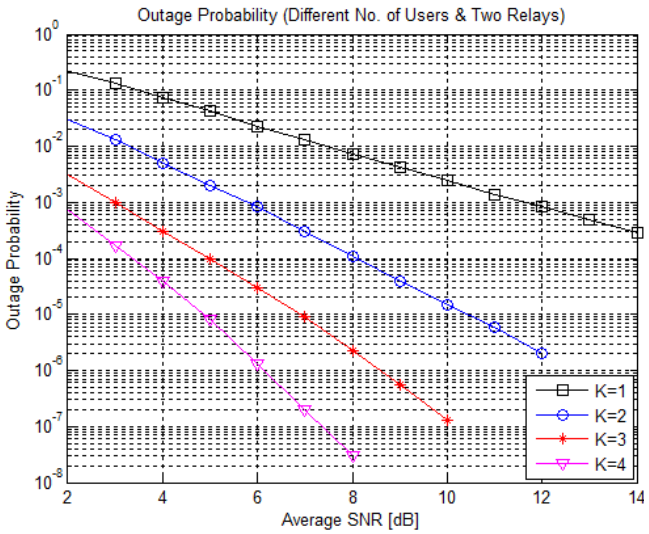

Fig. 3 Outage probability vs. SNR (2 relays)

Fig. 4 and Fig. 5 show the SEP performance of (QPSK) for different users using one relay and two relays respectively. We conclude that in multiuser TCMRNs, the number of users has more effect on the performance of SEP, for example, for one relay (Fig. 4), when the SEP is 10^{-3}, there is an enhancement in the performance of 6 dB when K is 2 over that when K is 1 and there is an enhancement in the performance of 2 dB when k is 3 over that when K is 2. Meanwhile, the performance gain will be reduced when the users increases, that is, as the number of the users increase, this cannot infinitely make a considerable reduction in the SEP.

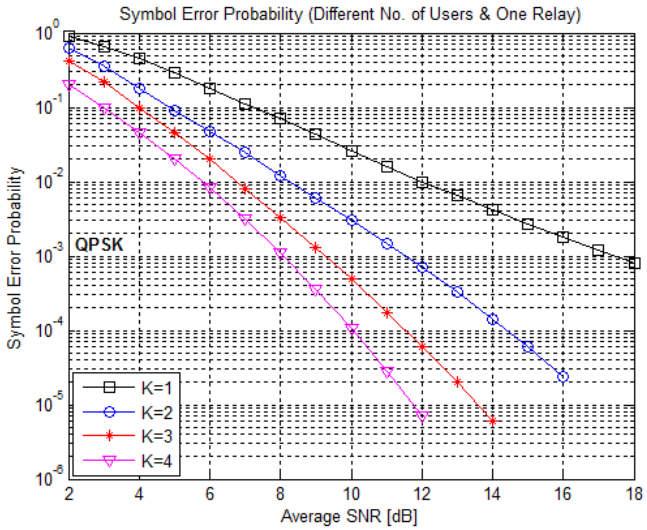

Fig. 4 SEP vs. SNR for one relay

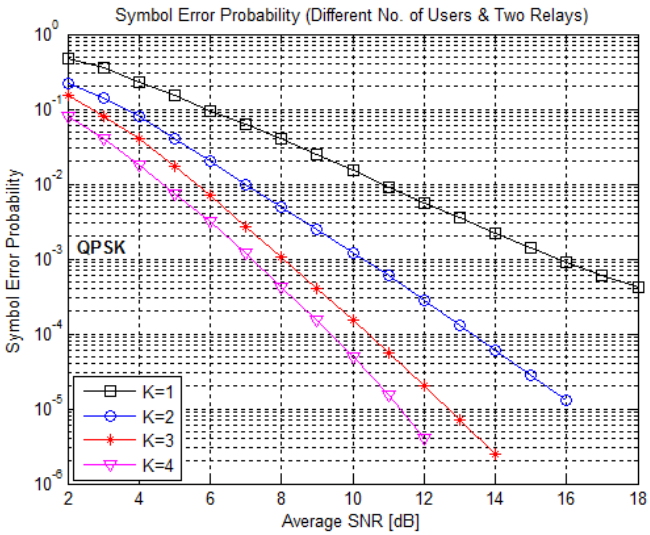

Fig. 5 SEP vs. SNR for two relays

To explain more the effect of the number of relays, Fig. 6 and Fig. 7 show the outage probability and SEP respectively, for one relay and two relays plotted on the same figures for K = 1 and 3. From the two figures we can conclude that the system with two relays provide better performance than the one with one relay. For example, for three users and for outage probability = 10^{-3} when we increase the number of relays from 1 to 2 there would be an enhancement in the performance of more than 3 dB. Also, we can conclude that in multiuser TCMRNs, the relay nodes number has a considerable effect on the performance of SEP, for example, for one user (Fig. 7), when the SEP is 10^{-3}, there would be an enhancement in the performance of more than 1.7 dB for two relays (M = 2) over that of one relay (M = 1), whereas, for three users (K = 3), there would be a performance enhancement of more than 1 dB for two relays (M = 2) over that of one relay (M = 1). Meanwhile, the relative performance gain decreases with the increase of the number of relays, that is, increasing the number of relays cannot infinitely decrease the SEP.

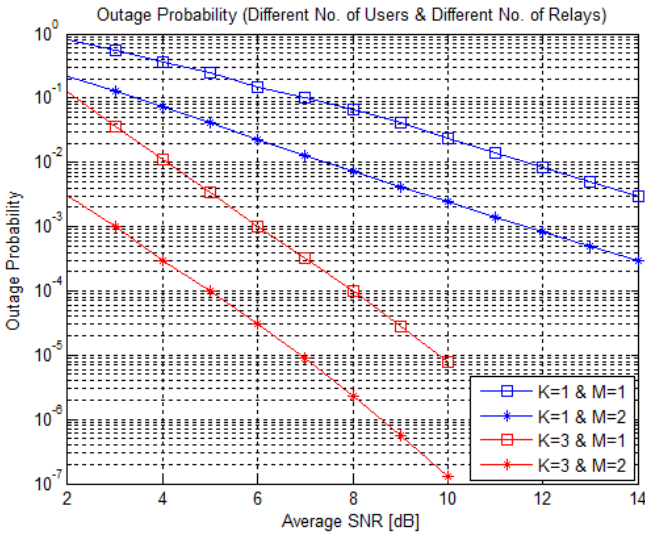

Fig. 6 Outage probability vs. SNR for different number of relays

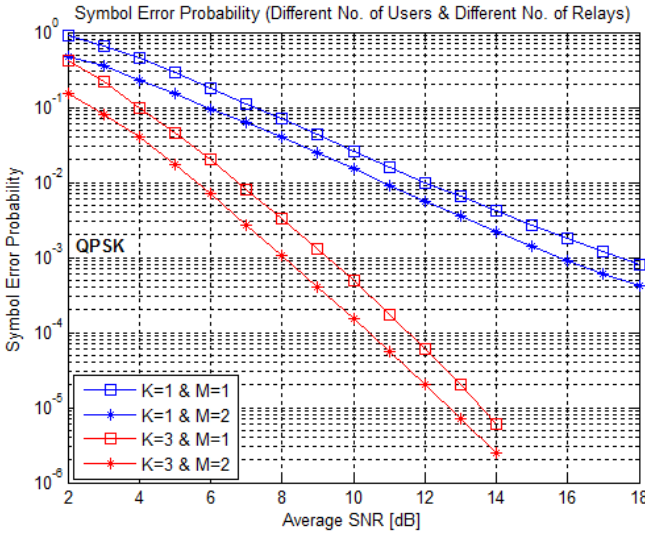

Fig. 7 SEP vs. SNR for different number of relays

V. CONCLUSION

We have derived tight close form formulas of the outage probability and the symbol error probability for MUD in multiuser cooperative multi-relay system. We have *2K* diversity order (*K* number of users) and *M+1* cooperative diversity (*M* available relays and one direct path), these assumptions and derivations are valid for Rayleigh channels and for high SNR. From the results one can see that the system with multi-relays provide better performance than the one with only one relay.

***Abstract*—Rapid development and evolution of IP based networks had major impact on all services and their migration to Next Generation Networks (NGN) infrastructure. Frequency synchronization in this environment was one of the biggest and the most significant challenges, which has to be solved. In traditional circuit-switched networks synchronization problems have been solved using standard plesiochronous digital hierarchy (PDH) and synchronous digital hierarchy (SDH) systems. This paper describes different protocols and techniques used by real-time applications in order to achieve better synchronization degree. For testing and comparing these techniques, we developed our own application in Java programming language, for generating and sending frames through our topology created in virtual environment (MikroTik router OS). This application was also used to process the emulation results, which gave us an insight on the influence of frequency synchronization on Quality of Service (QoS). This paper also discusses an algorithm for frequency synchronization. The aim of this paper is also to compare measured results between the classical synchronization algorithm and the optimized one.**

I. Introduction

Over the past few years, NGN networks have gradually replaced traditional networks architectures (like SDH and PDH) and today, are major cornerstone in transporting data across network and offering services by Telecom operators. In the near future all network architecture will be build upon NGN concepts. Because of need to transport all traffic on IP/Ethernet some of old problems arises and should be carefully look upon and dealt with.

One of these problems is synchronization of data across network and also network elements itself. Because of the nature of packet networks new measurement techniques are required for distribution of time and frequency using packet-based methods across the network. This posses new challenges who have been looked to be resolved over the past few years in parallel with NGN evolution. New methods were developed which was the base for development of special purposes protocol for clock synchronization over packet networks, such as Network Time Protocol (NTP) and Precise Time Protocol (PTP) (IEEE 1588).

As an opposite to the traditionally timing measurements, which was a single-node measurement, synchronization measurement in packet networks is a two-node measurement requiring precision time-stamping of the packets [1]. PTP is a protocol used to synchronize clock through a computer network. This protocol provides clock accuracy, making it suitable for measurement. PTP was defined in the IEEE 1588 standard, and it describe a hierarchical master-slave architecture for clock distribution. NTP like PTP describes hierarchical master-slave architecture, but contrary to PTP where masters are pushing time to clients, clients using NTP are pulling time from server.

For the clock synchronization over various network elements there are two issues that has to be addressed. First is need of mechanism for link delay measurement, and other is PDV (Packet Delay Variation) [2]. Latency and packet delay variation are two aspects of measurement that are of interest for synchronization in packet networks. Latency could be measured either one-way or round-trip. Packet delay variation in real time applications is a bigger problem than latency, and it has a bigger influence on QoS.

Chapter II describes main features of NTP and PTP protocols.

Chapter III gives a detail explanation of used algorithm for frequency synchronization.

Chapter IV explains in detail environment in which simulation will be conducted. Chapter continues with brief explanation of implementation of described algorithm. Algorithm was implemented in Java programming language. Chapter concludes with explanation of testing scenario.

Chapter V show results obtained from simulation experiment. Simple algorithm was developed which can be used to optimize frequency deviation and results obtained by this algorithm were presented.

II. Overview of NTP and PTP protocols

NTP uses a hierarchical system for synchronization of packet switched networks. Each level of this hierarchy is labeled. This indicator tells about its distance from the reference clock.

NTP clients must compute the round-trip delay (RTD) time before synchronizing clocks. This calculation uses the assumption that the incoming and outgoing routes between the client and the server have symmetrical delay.

RTD formula is given by (1):

$$RTD = (t_3 - t_0) - (t_2 - t_1) \quad (1)$$

Where t_0 is the time of the request packet transmission, t_1 is the time of the request packet reception, t_2 is the time of the response packet transmission and t_3 is the time of the response packet reception.

Distributing time works using a time reference point. Also, the distributed time is an absolute time from January first, 1900. The 64-bit timestamps provide a resolution of 233 ps [3].

Like NTP, PTP is a hierarchical master-slave architecture for time distribution. This architecture consists of a grandmaster clock, boundary clocks and an ordinary clock, that is synchronized by the grandmaster over the boundary clock. The grandmaster clock has one network connection. The ordinary clock is directly connected to the boundary clock. This scheme improves distribution accuracy by compensating delivery variability across the network.

PTP uses an epoch since Midnight, 1 January 1970. PTP clients like NTP clients have to calculate the round trip time to its master clocks. After RTT calculation the synchronization process can appear [4].

Figure 1 shows the previously decribed master-slave frequency syncronization structure.

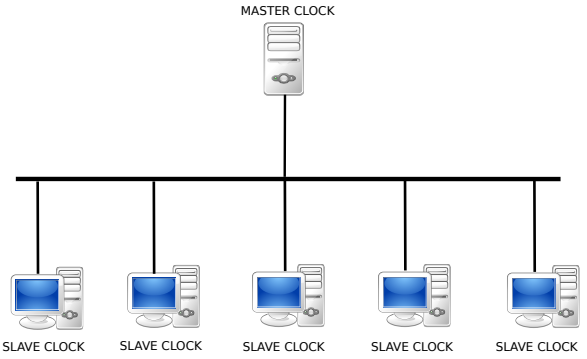

Fig. 1. Master slave frequency synchronization

III. Algorithm for frequency synchronization

There are two main problems of frequency synchronization using a master-slave clock architecture. The stability of the master clock is a hardware problem, and it is not a part of this paper. But the influence of PDV and latency can be solved using software calculations.

There are different algorithms which can be used to reduce the impact of PDV and latency [5]–[7]. Mentioned algorithms represents base for our slightly modified algorithm. These modifications are explained below. Using precision time stamping of the packets we are able to transmit the time information. First step is the client request for synchronization. After processing this request the server sends a sequence of time stamped packets at regular intervals. The client accepts this packets and calculate the mean interval between two packets. The ideal interval would be the same as on the transmit side, but as a result of the PDV influence, and the clock frequency difference between the client and the server clock, the interval would have deviations that we have to reduce.

Require: $interarrivalTime \vee definedInterarrivalTime \vee clockFrequency$
Ensure: $frequencySynchrnoization$
  $requireSynchrnoization \leftarrow TRUE$
  while $requireSynchrnoization == TRUE$ **do**
    $interarrivalTime \leftarrow interarrivalPacketTime$
    if $interarrivalTime > definedInterarrivalTime$ **then**
      $calculateMeanFrequencyDeviation$
      $clockFrequency \leftarrow reduce$
    else
      $calculateMeanFrequencyDeviation$
      $clockFrequency \leftarrow increase$
    end if
    if $interarrivalTime == definedInterarrivalTime$ **then**
      $requireSynchrnoization \leftarrow FALSE$
    end if
  end while

Fig. 2. Master - Slave frequency synchronization algorithm

Reducing this deviations begins with the client synchronization request. After a receiving very large numbers of synchronization packets from the server, which is predetermined by application preferences (here we used 10000 packets), the client will be able to calculate the frequency deviation between his clock and the grandmaster clock.

Now, the client has to harmonize its clock frequency according to the calculation. The described algorithm is presented in Figure 2.

IV. Architecture of testing system

The system architecture for synchronization measurements that is used in this paper is presented in Figure 3. The architecture consists of a server (grandmaster clock), a client (ordinary clock) and three MikroTik routers connected as shown in Figure 3.

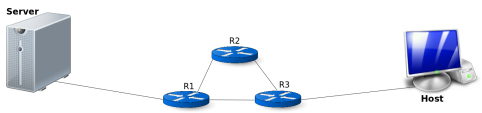

Fig. 3. Architecture of measurement system

First we had to configure the routers and provide the end to end communication. The router configuration implies interface, static route and firewall configurations as shown in Figure 4

The presented network is configured in a virtual environment. The next step was to develop a Java application, which implements the described algorithm.

```
/ip address add
address = 192.168.2.2/24
interface = ether1
```

(a) Configuration of router interface

```
/ip route add
dst-address=192.168.0.0/16
gateway=192.168.2.180
```

(b) Static route configuration

```
ip firewall nat add
chain=srcnat
action=masquerade
out-interface=ether1
```

(c) Firewall configuration

Fig. 4. Configuration of MikroTik routers

A. Implementation of described algorithm

Implementation of algorithm described in Chapter III was done in Java programming language. Application was developed with server and client module.

Therefore two classes were created, `UDPClientSide` and `UDPServerSide`. Class `UDPClientSide` is responsible for creating and sending request message for synchronization to server. Upon receiving message from client, server (`UDPServerSide` class) is starting to send periodic messages (every 100 ms) to client in order to estimate frequency deviation.

While receiving messages client side calculates frequency deviation (as described in Chapter III). For developing server and client side we used support for socket programming in Java [8]. For transport protocol we used UDP which is already implemented in Java through package `java.net`.

To send and receive messages between client and server we created simple application protocol. Because of use UDP as transport protocol we didn't have to worry about framing, because message boundaries are preserved [8]. Figure 5 shows flow of communication between client and server and exchanged messages.

B. Testing scenario

The end hosts are Linux machines, and they run the developed applications. One machine simulates a grandmaster clock, and the other one simulates an ordinary clock, which will be synchronized by the grandmaster.

Client (with a ordinary clock) sends synchronization request. Server (with a grandmaster clock) periodically sends response packets with timestamps information (every 100 ms). For each received packet client calculates frequency deviations and stores obtained values in a file. All packets travels trough MikroTik routers, which enables to impact on time needed for transmitting packets from one end to another. After collecting results simple algorithm for optimizing frequency deviation is developed and results are shown in Chapter V.

V. Simulation results

The simple network simulation was used to test previous presented algorithm. Also, we had to test two optimization algorithms to achieve a better synchronization. The first option was to optimize our system using the mean inter arrival time. And the second option was to calculate the inter arrival time variance, and use them for system optimization. For calculating values of mean inter-arrival time and variance (2) and (3).

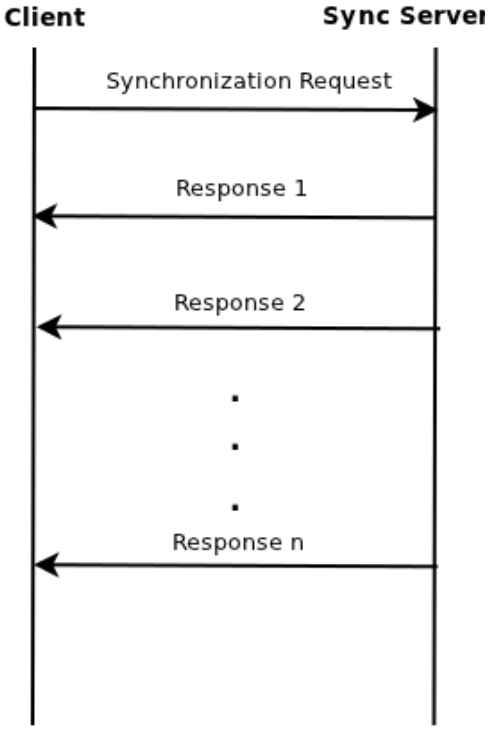

Fig. 5. MSC diagram for Server - Client communication

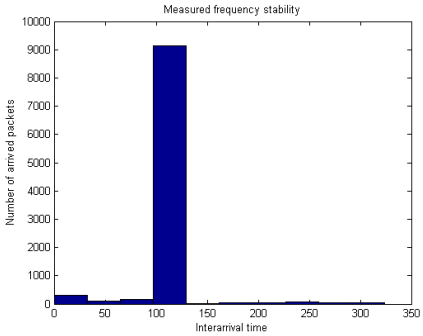
$$mean_value = \frac{\sum X}{N} \tag{2}$$

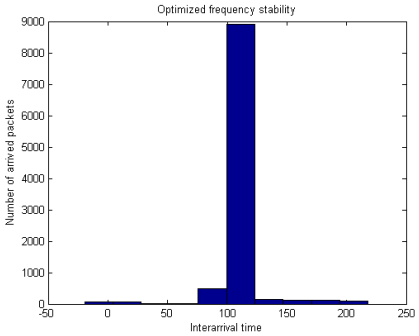
$$variance = \frac{1}{N}\sum (X-\mu)^2 \tag{3}$$

Require: $interarrivalTime \vee x \neq 0$
Ensure: $optimiseFrequencySynchrnoization$
  while $synchronizationDuration$ **do**
    if $clientPeriod > expectedPeriod$ **then**
      $variance \leftarrow estimatedSubsequenceVariance$
      $clientClock \leftarrow currentClock - sqrt(variance)$
    else
      $variance \leftarrow estimatedSubsequenceVariance$
      $clientClock \leftarrow currentClock + sqrt(variance)$
    end if
  end while

Fig. 6. Algorithm for optimization of frequency synchronization



(a) Histogram of measured raw data



(b) Histogram after using optimization algorithm

Fig. 7. Histogram for inter-arrivals times of transmitted packets

The mean inter-arrival time optimization algorithm gave as a little improvement of the mean frequency error, but the value of variance was still to large.

Where X is the current inter arrival time, N is the subsequence length, and μ is the mean inter arrival time.

The variance describes how far the frequency lies from the mean value. That is why we have to optimize the variance of the clock frequency stability.

The variance inter arrival time optimization algorithm was more successful by reducing the frequency variance. As shown in Figure 6 the optimization algorithm reduces the variance by estimating the subsequence variance, and adjust the client clock according to the estimated value. All this involves the existance of a master slave architecture.

This approach provides an improvement of the mean frequency deviation, and the frequency variance. Figure 7 shows histograms that represent the described improvement. The optimal inter-arrival time would be 100 ms. Because of the PDV, and the frequency synchronization error there are some deviations. Using our optimization algorithm we got very good results. The reduction of the variance is about 200%.

CONCLUSION

As this paper has discussed, the frequency synchronization through IP networks is a quite unexplored area. Solving this problem means also investigation the impact of frequency synchronization on QoS. QoS is specified with some parameters like latency, PDV, packet loss etc.. This parameters also affect the quality of the frequency synchronization.

Synchronization problems as a result of the packet delay variation is most critical. This paper describes an algorithm that provides the reduction of the PDV influence on the clock synchronization.

Also, if we provide a good algorithm to reduce the PDV influence, we could share a frequency through the network.

This paper has presented an algorithm to calculate and regulate the frequency stability, and we have achieved good results in this regard, but remains open to optimize the proposed algorithms in terms of optimal length of the subsequence.

Summary - 3G mobile broadband evolution offers high speed data transfer. A need to develop QoS mechanisms to ensure effective handling of radio resources occures. Bottleneck for 3G data network may be located in different parts of the network, depending on the infrastructure (eg the radio access part or core network part). Operators will decide how to deal with network congestion problem: expanding the network, increasing CAPEX or finding and using ways to control traffic.

I. INTRODUCTION

Due to mobile broadband technology evolution and increase of 3G user traffic which offers high transmission speeds there is a need to develop mechanisms that will ensure effective handling of radio resources.

With QoS mechanisms the network can differentiate users and subsequently allocate their resources in a way that all users in the system receive required QoS in terms of transmission speed and a delay in accordance with the defined QoS profile (subscription). QoS management has no effect on the service performance as long as there is no network congestion.

Historically, QoS concept started with few services with similar and narrow bandwith needs (few services, sms, voice). In such QoS concept besides *best effort* traffic class it was possible to define only one class of service. Eventually QoS concept came up with a lot of services with large and dinamic bandwith needs. Traffic profile on Internet can vary by types of users and types of transmission data. The amount of traffic per user can be arranged unequally. Depending on amount of traffic users can be categorized in two groups:

- **light users** – mostly using e-mail, Internet browsing, transferring files etc.
- **heavy users** – using eg *Peer2Peer* applications or uploading video content

Specified user variety can lead to disproportionate use of resources by a small number of users at the expense of "normal" users. To prevent this situation a mechanism for preventing cannibalization of available resources by the heavy users is developed in order to satisfy all customer requirements for QoS. QoS mechanisms for service prioritization (according to their QoS requirements) are highly important during high network load. This prioritization is also known as QoS differentiation. QoS differentiation with traffic shaping provides us with ability to:

- Manage network resources. On radio side this means managing individual flows. Flexible prioritization of users and services.
- QoS shaping depending on user needs, habits and wishes

With QoS (service and user) differentiation it is possible for operator to achieve a number of adjustments. QoS differentiation provides most efficient network resource utilization in a way that existing resources are optimally used with non or minimal additional investments. Goal is to optimally use existing resources and to gain maximum end user experience with non or minimal additional investments.

Without QoS differentiation services and users would be treated equally during the admission and retention of radio and transmission resources. Also it would be necessary to increase network capacity when QoS for one service or user cannot meet desired level. QoS differentiation and traffic shaping allows shifting priorities between services and users so all get desired quality level as long as possible.

Main purpose of QoS differentiation and user prioritization in WCDMA RAN is dynamical modification of QoS priorities in individual RABs depending on cell congestion level.

II. QOS PRIORITY MANAGEMENT

QoS priority management provides two-dimensional traffic shaping.

- **user dimension**: assign different priorities to individual users e.g. gold, silver, bronze users
- **service dimension**: eg speech prioritized over interactive data

This service provides new potential benefits for operators: eg new tariff models with possibility of guaranteed or non-guaranteed rate, grouping users depending on consumption, type of subscription, etc. Optimal resource utilization is especially required on radio network part to mitigate bottleneck issues. QoS prioritization enables:

- maximum resource utilization, postponement of network capacitive expansions,
- service and user prioritization,
- maintaining control over network resources due to increase of data traffic in mobile networks,
- introduction of *High-End* and *Low-End* subscriptions and services
  - assigns lower priority eg virtual operators,
  - the higher and highest priority is assigned to eg police, public security forces, ambulance, etc.
  - transmission speed differentiation eg business subscribers are assigned higher transmission speed.

Prerequisites for the optimum resource utilization in the RAN are:

- "soft" resource reservation, which can be dynamically modified depending on network situation
- RAB carrier that exactly matches the QoS parameters of the required service when sending requests for PDP context activation.

RAN priority management can be viewed through several components [1]:

1. **Priority handling at admission/congestion**

a. Flexible allocation/retention priority handling

b. THP/SI parameter shall be differentiation within the class of interactive services,

c. Admission/congestion based on priorities(ARP-Allocation & Retention Priority),

d. Soft reservation for interactive HSDPA traffic

2. **Priority handling in HSPA scheduling**

a) Flexible Scheduler Priority Indicator handling

b) Flexible Radio scheduling

c) Max Bit Rate QoS profiling - limits the transmission speed for HSPA, based on the MBR attribute.

3. **Priority handling in transport network**

a) Connection Admission Control (CAC),

b) QoS based transmission scheduling,

c) Configurable QoS behavior

Main QoS attributes passed from PS Core to RAN include information such as: traffic class (TC), maximum bit rate (MBR), guaranteed bit rate (GBR) and priority information, i.e. the Traffic Handling Priority (THP), allocation/retention priority (ARP), signalling indication (SI) (defines if packet is signalling or payload).

Following parameters can be controlled and modified by RAB modification request from the core network:

- Traffic Class (Conversational/Streaming/ Interactive/Background) – control at bearer setup
- modification of the ARP, THP, MBR, SI attribute - control at bearer setup, modified during session
- change between traffic class interactive and background

III. SERVICE AND USER DIFFERENTIATION USING ARP, PVI AND PCI

ARP attribute can have priority levels from 1 (highest priority) to 15 (no priority), which describes which priority service will receive when allocating radio resources and keeping the resources in case of high load or cell congestion. When radio bearer is established ARP priority has no effect on resource allocation mechanisms. ARP priority is used by all RAB types. In addition to ARP priority level two additional parameters are defined:

- Pre-emption Capability Indicator (PCI)
- Pre-emption Vulnerability Indicator (PVI)

PCI and PVI attributes can take values 0 or 1. ARP priority assigned to each RAB gives RAB control over resource allocation and retention. Pre-emption defines how strong resources are retained in the case of high load cell or cell congestion. If RAB is preemption vulnerable (PVI = 1) RAB speed will be down switched or, if necessary, RAB resources released. Preemption capable (PCI = 1) RAB has the ability to retain resources and can reduce rate to preemption vulnerable RABs (PVI=1) [2].

To decide which admission policy to evaluate and how to treat the admission request in case one or more admission policies are blocking, each admission request contains a number of attributes: request type (handover or non-handover; used in evaluation admission policies), request class (guaranteed or non-guaranteed connection parts), preemption capability (request can preempt a lower priority radio connection), the priority of the request, indication for additional resource requirement.

The Allocation/Retention Priority attribute is a subscription-attribute which is defined in the HLR as part of the QoS Profile Subscribed. ARP attributes are by default defined statically as function of RANAP

attributes, or can optionally be defined by the operator. An ARP attribute received from the packet core network is sometimes regarded as an External ARP in the WCDMA RAN. The WCDMA RAN utilizes the External ARP to define an Internal ARP within the WCDMA RAN domain. The Internal ARP is taken into consideration for Allocation and Retention Priority of resources for both Circuit Switched (CS) and Packet Switched (PS) traffic.

The default mapping of ARP attributes is based on the traffic class (conversational, streaming, interactive, background), CN indicator (CS/PS), Source Statistics Descriptor (SSD).

IV. INTERACTIVE USERS PRIORITIZATION

Traffic handling priority indicates the priority by which an PS interactive RAB should be handled in WCDMA RAN. The Traffic Handling Priority (THP) attribute (values:1-3, 1 is the highest) gives different scheduling priorities in WCDMA RAN to traffic, by the use of the Scheduling Priority Indicator (SPI). Interactive PS RAB's modification is possible using THP parameter. THP attribute is used for interactive services prioritization and it is an alternative to the absolute guarantee of Guaranteed Bit Rate (GBR) traffic classes, and thus these

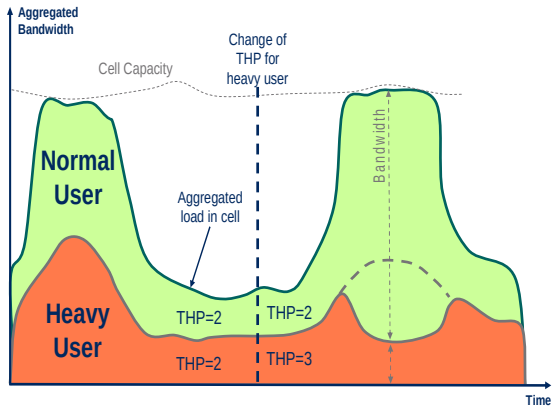

Figure 1 THP at cell congestion [3]

two attributes types cannot be used together for a single bearer. ARP parameter for interactive RABs can be configured based on the THP parameter. After RNC mapping output value is RAB's ARP priority and resources prioritization in case of high cell load or congestion. Prioritization can be done using two mechanisms[4]:

1. admission control and load/congestion control for R99 traffic.
2. by assigning different SPI priorities for HSPA traffic.

THP attribute, along with other RAB attributes sent from packet core network over IuPS interface such as ARP, traffic class, GBR, SI, can be used by RNC QoS mapping function. Based on these parameters, the RNC determines SPI priority.

THP allows preservation of scarce resources when they get limited and there is no impact on the service performance as long as there is no network congestion. In case the THP is not enabled, the Iu RAB THP attribute received by the CN is not used and THP is assumed to be 2, no THP differentiation.

In RBS scheduling process RAB bearers are mapped based on SPI priorities. SPI priority can be configured by the operator, and takes a value of 1-15 (15- the highest). Base station uses different SPI priorities with defined scheduling algorithm (Round Robin, Proportional fair, Equal rate, Max C/I Ratio) for different HSDPA flows.

The Traffic Handling Priority attribute is defined in the HLR as part of the QoS Profile Subscribed.

THP is used by the WCDMA RAN to prioritize traffic over the air interface and to allow prioritization over the transport network.

The Signaling Indication attribute (values: Yes/No) indicates the signaling nature of data units. This attribute is only defined for the Interactive Traffic Class. If signaling indication is set to Yes, the UE should set the traffic handling priority to 1. The Signaling Indication is sent by the UE in the QoS IE. The Signaling Indication attribute permits enhancement of the RAN operation accordingly.

V. MBR QOS PROFILING

Bit rate limitation allows the operator to differentiate users based on user subscription. It is possible to set maximum bit rate in downlink and uplink based on MBR attribute that RNC received from core network in the RAB Assignment message.

- DL transmission flow limited to *MBR* by means of shaping in the flow control algorithm in RNC
- UL *MBR* limitation by limiting the scheduled grant that is given to a user by the serving cell in RBS

Bit rate limitation refers to the interactive HSPA users. This functionality enables operator to differentiate subscribers on gold, silver and bronze depending on maximum allowed bit rate. QoS differentiation between gold, silver and bronze customers is efficient way for ensuring required QoS in cases when resources are limited. Depending on the configuration gold users can obtain 4-10 time higher speed comparing to bronze users in similar circumstances. The value may vary depending on the weight factor. The concept of user differentiation on gold, silver and bronze should not be mixed with the MBR parameter, which is among others used for flow control in a particular application, e.g. in high load periods, it is possible to reduce the speed of certain applications, without affecting other applications.

In downlink bit rate limitation mechanism is HSDPA flow control on IuB interface. HSDPA flow control can be configured as *on* or *off* per SPI. When HSDPA Flow

Control is off SRNC uses MBR as the upper limit for the HSDPA data frame bit rate shaping. No Capacity Allocation (CA) control frames are used when flow control is off.

In case HSDPA Flow Control is on and HSDPA MBR QoS Profiling is not defined, the CA control frames bit rate is used per HSDPA flow in SRNC to limit the HSDPA data frames bit rate shaping.

In case HSDPA Flow Control is on and HSDPA MBR QoS Profiling is defined, the HSDPA traffic is shaped to a minimum function of MBR and CA bit rate.

The MBR profiling functionality for the downlink is implemented in the RNC.

Capacity allocation received for each user from RBS is compared with the MBR value. The smaller value of these two is used to decide the data rate sent down to the RBS for a particular user. Thereby the throughput to the user is profiled without dropping packets.

In case of multi RAB speed limit applies to each RAB.

In uplink speed limit is achieved by limiting the power grant to each user during admission control. For multi RAB in uplink connection it is not possible to assign different power level to different flows. Due to this limitation MBR in uplink is limited by maximum value of interactive RABs.

VI. MAPPING ARP PRIORITY

ARP attributes are by default defined statically as function of RANAP attributes, or can optionally be defined by the operator. Operator has the possibility to configure and change, in flexible manner, the priority of different services/users compared to what was received from CN. The flexible ARP configuration is realized through an operator configurable mapping function, where the ARP attributes received from CN on RANAP/Iu are mapped into RAN internal attributes. QoS attributes mapping is optional functionality. If functionality is not implemented WCDMA RAN assigns a default value for the internal ARP, PVI and PCI as a function of Iu attributes. Assigned value is system default value.
As stated, system defined values are predefined and can be mapped on a set of tables in the RNC. When QoS mapping functionality is not included in determining internal RAN ARP priorities, non- configurable mapping is used. RANAP ARP received during RAB establishment is unchanged and mapped to an internal RANAP ARP.

Table 1. ARP mapping priorities

Packet core input values (RANAP)					Internal ARP output value		
Traffic Class	**SSD**	**SI**	**THP**	**External ARP priority**	**Internal priority**	**PVI**	**PCI**
Conversational	speech	-	-	1	3	-	-
Interactive	-	YES	1	0	5	YES	YES
Interactive	-	NO	2	0	7	YES	YES
Streaming	-	-	-	0	3	YES	YES

If RANAP ARP priority is missing or its value is 15 (which means no priority) internal ARP is generated according to pre-default mapping. Configurable mapping is used if the functionality is implemented in RNC and mapping tables are configured by the operator. Mapping functionality provides:

- canceling default and undefined ARP attributes and attributes that are missing and replacing them with configured attributes
- undoing the RANAP ARP and replacing it with a configured internal RAN priority. PVI and PCI parameters remain unchanged. Internal ARP is mostly used by C-RNC during admission and load control. RAB with positive PCI value in high load situations can take resources from the RAB with lower priority ARP and positive values of PVI.

In the ARP mapping example (Table 1) left side of the table lists the input values received from the core network, while the right side of the table lists the output values after the mapping.
Each row in the table represents a particular RAB. Important input values:

- Traffic class - conversational, interactive, streaming
- Source Statistics Descriptor - attribute (values: Speech/Unknown) specifies the characteristics of the source of submitted units of data in a UMTS bearer.
- Signaling Indication - attribute (values: Yes/No) indicates the signaling nature of the data units. This attribute is only defined for the Interactive Traffic Class. If signaling indication is set to Yes, the UE should set the THP to 1.
- THP for interactive RAB

The examples in the table show:

- Conversational class transmitting voice traffic is mapped to the ARP 3
- Interactive class due to positive signaling indicator gets the highest THP and is mapped to the ARP value 5.
- In the second example interactive traffic class does not transmit signaling and gets lower THP - 2 compared to the previous interactive class. THP is mapped to an internal ARP value of 7
- streaming class due to strict QoS requirements gets high priority ARP 3

VII. MAPPING SPI PRIORITY (HSPA)

SPI defines HSPA RAB's priorities when there are not enough EUL or HSDPA resources [5].

It is possible to prioritize individual flows for a particular connection. With individual flow control it is possible to achieve more stable connection rate, higher throughput,

better end-user experience as well as better transmission resource management.
SPI priority is characterized by:

- value range from 0 to 15 (15 is the highest)
- is defined for uplink and downlink separately
- SPI value is known to RNC and base station, is used for prioritizing High Speed Downlink Packet Access (HSDPA) flows in base station scheduler
- is used as input value for QoS attributes mapping in transport network (for assigning DSCP or QoS classes)
- is function of attributes: TC, SSD, THP, NE, GBR, TD

Table 2 SPI mapping priorities

Input value from packet core network (RANAP)						Output value
Traffic class	**SSD**	**Signaling indication**	**THP**	**GBR**	**Transfer delay /ms**	**DL SPI**
N/A	SRB	N/A	N/A	N/A	N/A	15 (HCoded)
Interactive	N/A	YES	1	N/A	N/A	14
Streaming	Unknown	N/A	N/A	129-max	0-5000	9
Streaming	Unknown	N/A	N/A	129-max	5001-max	5
Interactive	N/A	NO	1	N/A	N/A	3
Interactive	N/A	NO	3	N/A	N/A	1
Background	N/A	N/A	N/A	N/A	N/A	0

- mapping SPI priority is operator configurable, in case the mapping is not configured system defined values apply

Signaling RAB has the highest priority and is mapped to the SPI value 15. This is hardcoded so signaling RAB is not competing for resources.
SPI prioritization gives operator a possibility to assign different priorities to interactive RABs carrying signalization; also depending on the THP value differentiation of various interactive users is possible. It is possible to prioritize GBR services (conversational and streaming) depending on the GBR characteristics and users and services depending on the range of maximum allowed transfer delay.

VIII. E2E QoS SOLUTION

The QoS negotiation capabilities between SGSN, GGSN and SAPC allow optimized QoS control between the Packet Core Network and the Radio Access Network. The nodes take subscription data and session information and forward the capabilities to SAPC.

QoS E2E solution is shown in Figure 2 The function per subscriber monitors the extent to which service is used. Reporting can be done using GGSN. GGSN node with function to report service usage is connected to SAPC, which is responsible for monitoring traffic usage per subscriber.

Traffic consumption level can be observed through the traffic volume or time.

Allowed quota of traffic per subscriber is located in SAPC. Once the quota is reached, SAPC initiates E2E QoS modification towards GGSN.

Final goal of this modification is to modify the QoS attributes in the WCDMA RAN. GGSN forwards the request for QoS profile PDP context modification towards SGSN. SGSN forwards the RAB modification request to modify QoS profile to UTRAN. UTRAN performs QoS changes ordered from SAPC. QoS changes can include any of the following:

- Reducing the QoS level of transport network. For the transport network based on IP, traffic is mapped to different DSCP code and receives a lower priority through a transport network which means lower throughput during high load or congestion.
- Reduction of THP. In the case of cell congestion, RAB gets a lower priority on the radio interface. This means lower transfer rate in the case of high load or congestion.
- Reduction of the MBR. Maximum bit rate reduction in downlink and uplink.

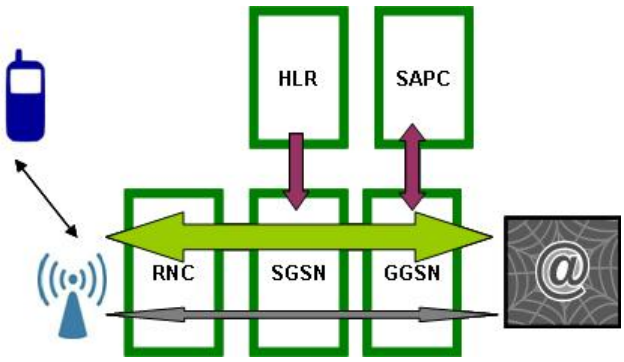

Figure 2 E2E QoS solution

IX. THP MODIFICATION TEST

Test objective is to change user's QoS to a lower THP value when user reaches a predefined traffic limit. Test is supported by the GGSN as an integrated solution. Two active users are in the same cell. The cell is high loaded.

Prerequisites:
QoS profiles with two different THP values are defined in SAPC Table 3

Table 3 THP values defined in QoS profile in SAPC

SAPC		
QoS profie	**THP**	
QoS _1	1	When User_1 reaches 30MB -> QoS_2
QoS _2	3	

This test uses interactive class. For User_1 in SAPC the rule is defined when volume of user traffic reaches 30MB, QoS profile changes, ie THP value changes. User_1 changes initial QoS profile from QoS_1 to QoS_2. QoSProfileID definition is shown in Table 4. QoSProfileId configuration corresponds to the maximum speed of certain services (MBR) configuration in GGSN. Test defines QoSProfileId_1 with the FTP and HTTP application speed values. Two users who share the same cell resources initiate the PDP context. Users have the same THP = 1 (QoS_1). The cell will be pushed to congestion.
For the initial establishment of the PDP context for each user SAPC will apply QoSProfile "QoS_1" and QoSProfileId 1 according to GGSN.
When User_1 reaches the limit, GGSN reports used traffic volume to SAPC. SAPC will apply new QoS profile QoS_2 with THP value 3.

Table 4 QoS parameters in GGSN

GGSN		
QoSProfileId	**Traffic**	**MBR**
1	FTP	4 Mbps
	HTTP	256 Kbps

Both users in the cell start downloading with the same THP (THP=1). When usage limit (30MB) is reached THP is changed to lower value (THP=3) and User_1 throughput is decreased as shown in Figure 3.

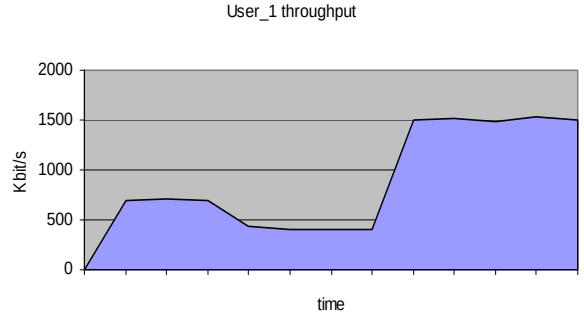

Figure 3 User_1 throughput depends on THP

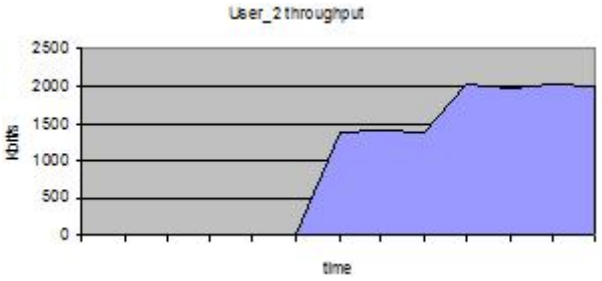

Figure 4 User_2 throughput depends on THP

When User_2 has finished downloading, User_1 gets more cell resources with same THP value (THP=3) and gets higher throughput (Figure 3).

User _2 starts downloading with the same THP as User_1 (THP=1). THP is changed for User_1 so User_2 gets more throughput. User_2 has finished downloading and frees cell resources (Figure 4).

X. CONCLUSION

Due to radio resources limitation using QoS mechanisms network has the ability of user differentiation and the subsequent resource allocation in a way that all users in the system receive the required QoS in terms of transmission speed and delay in accordance with the allowed QoS profiles and capacitive network capabilities.

This work investigates the role and importance of some key aspects of QoS planning, QoS management, QoS differentiation and priority management for UMTS and HSPA network.

bojan.puskarevic@ericsson.com

Sažetak - IP Multimedia Subsystem (IMS) je standardizirani okvir koji treba da u budućnosti postane dio jezgrenih (core) mreža. IMS rješenja postoje za sve pristupne mreže. Primarni fokus ovog rada je kvalitet VoIP (Voice over IP) usluge kao primarnog IMS servisa u različitim komercijalnim pristupnim mrežama. Cilj ovog rada je izvršiti analizu kvalitete VoIP servisa u različitim pristupnim mrežama, korištenjem različitih tipova terminalne opreme i različitih IMS klijenata. Analiza kvalitete VoIP servisa vrši se na osnovu izmjerenih Quality of Service (QoS) parametara. Posmatrani su sljedeći parametri: propusnost (throughput), kašnjenje, varijacija kašnjenja (jitter) i gubitak paketa.

I. UVOD

U ovom radu izvršena je analiza kvalitete IMS VoIP poziva u jednoj komercijalnoj operatorskoj mreži. IP Multimedia Subsystem (IMS) je standardiziran okvir koji treba da u budućnosti postane dio jezgrenih (*core*) mreža.

Jedna od najvažnijih karakteristika IMS sistema je potpuna nezavisnost od pristupne mreže. U slučaju da se radi o fiksnom (*wireline*) pristupu, kvaliteta govornog poziva ne bi trebala biti upitna, s obzirom da su skoro sve fiksne pristupne mreže sada širokopojasne, bilo da se radi o xDSL-u, kablovskim ili optičkim mrežama.

Primarni fokus ovog rada će biti kvalitet VoIP usluge preko 3G mreže. Universal Mobile Telecommunication System (UMTS) je tehnologija koja je prihvaćena kao treća generacija mobilne telefonije u svijetu. UMTS omogućava paketski prenos pri brzinama većim od 7.2 Mbps, s tim da se prenos govora kao i u prethodnoj generaciji (2G) ostvaruje komutacijom krugova. U ovom radu će biti istražene mogućnosti ostvarivanja kvalitetnog VoIP poziva korištenjem UMTS pristupne mreže.

U drugom poglavlju ovog rada dat je kratak opis IMS tehnologije.

Mjerenja su izvršena u različitim pristupnim mrežama. To su:

- *Asymetric Digital Subscriber Line* (ADSL) mreža
- Kablovska mreža
- UMTS mreža

U testiranjima je korišteno nekoliko različitih tipova terminalne opreme.

U testiranjima su također korištena i dva različita IMS klijenta: jedan besplatni i jedan komercijalni.

Poređenja kvalitete VoIP poziva u različitim uslovima koji su gore definisani izvršeno je na osnovu *Quality of Service* (QoS) parametara. U ovoj analizi su posmatrani sljedeći parametri:

- Propusnost (*throughput*)
- Kašnjenje
- Varijacija kašnjenja (*jitter*)
- Gubitak paketa

Cilj ovog rada je izvršiti poređenje kvalitete VoIP poziva u različitim pristupnim mrežama, korištenjem razičitih tipova terminalne opreme i različitih IMS klijenata. Poređenja su izvršena na osnovu objektivnih QoS parametara.

II. IP MULTIMEDIA SUBSYSTEM

U ovom poglavlju je dat kratak opis samog IMS sistema.

Ovaj rad se fokusira na mjerenje i analizu kvalitete prenosa govora kao primarnog telekomunikacijskog servisa. Naravno, IMS ne podrazumjeva samo pružanje VoIP usluge. Komunikacija između ljudi već neko vrijeme ne podrazumjeva isključivo govor. Ulazimo u novu eru telekomunikacija u kojoj se aplikacije kao što su videokonferencije, *presence* (prisutnost) i razmjena poruka dio svakodnevnog života. *IP Multimedia Subsystem* je okvir koji omogućiti sve te usluge.

IMS je međunarodno priznati standard koji specificira interoperabilnost, *roaming*, kontrolu nosioca, naplatu i sigurnost.

IMS je nezavistan od pristupne tehnologije i IMS rješenja postoje za sve mreže (GSM, WCDMA, WLAN, širokopojasne fiksne mreže). Ovaj sistem je standardiziran od strane 3GPP-a (*3rd Generation Partnership Project*) i obezbjeđuje efikasan način za telekomunikacijsku industriju da nudi multimedijalne usluge bazirane na IP-u. IMS predstavlja operatorsku verziju budućnosti telekomunikacijskih usluga, jer standardni modeli omogućuju operatoru da evolvira prema tehnologijama nove generacije pri čemu su i dalje podržani poslovni modeli koji trenutno donose dobit.

Tradicionalna telekomunikaciona mreža se može predstaviti vertikalnom arhitekturom, pri čemu su usluge koje se nude i infrastruktura mreže jedinstveni za svaku od tradicionalnih mreža. Nova arhitektura se sastoji od odvojenih horizontalnih nivoa. Jedinstvene pristupne mreže su spojene zajedničkom konekcijskom mrežom i iznad njih

je aplikaciona mreža. Kada se to predstavi sa tri nivoa, dobije se arhitektura data na slici 1 (slika preuzeta sa [8]).

- Aplikacioni nivo (*application layer*) sadrži aplikacije i servere koji pružaju usluge korisnicima.
- Kontrolni nivo (*control layer*) sadrži kontrolne servere, koji kontrolišu uspostavljanje, modifikaciju i raskidanje sesija i poziva. Ovi serveri kontrolišu mobilnost, sigurnost, naplatu i komunikaciju prema eksternim mrežama.
- Konekcioni nivo (*connection layer*) se sastoji od *router*-a, *switchev*-a i ostalih elemenata korisničke ravni.

U mrežnom okruženju se nalaze i funkcionalnosti za podršku (*supporting functions*) koje omogućavaju mrežni menadžment, naplatu i provizioniranje.

Inter-working čvorovi su potrebni radi komunikacije između IMS mreža i tradicionalnih mreža kao što je PSTN.

IP Multimedia Subsystem se može implementirati na različite načine, u zavisnosti od postojeće operatorske mreža, ali u svakoj izvedbi se sastoji od nekoliko cjelina kao što je predstavljeno na slici 2 (slika preuzeta sa [8]).

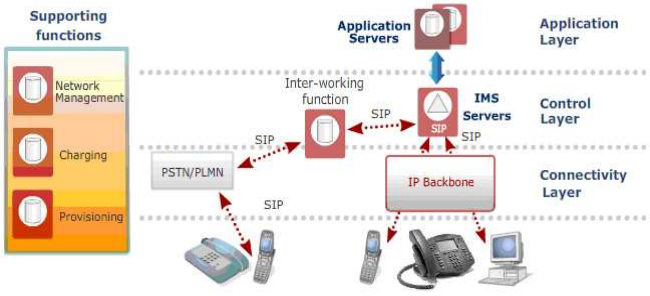
Bez udubljivanja u ostatak sistema, jer sam IMS nije tema ovog rada, u nastavku će detaljnije biti opisana dva ključna čvora u sistemu - CSCF i HSS.

A. Call Session Control Function

Call Session Control Function (CSCF) kontroliše sve multimedijalne sesije, koristeći SIP (Session Initiation Protocol) kao signalizacijski protokol. Podešen je da obavlja tri različite uloge, odnosno sastoji se od tri logička čvora:

Proxy-CSCF predstavlja prvu točku kontakta korisničke opreme i IMS sustava. Svi dolazni SIP zahtjevi, od strane klijenta, se obrađuju te prosljeđuju prema drugim SIP poslužiteljima u mreži (npr. S-CSCF, I-CSCF). Isto tako, P-CSCF prima sve SIP zahtjeve upućene prema pretplatnicima u njegovoj domeni te ih nakon obrade šalje prema korisnicima.

Interogation-CSCF ja prva dodirna točka za sve zahtjeve upućene iz neke druge mreže prema korisnicima u pripadnoj mreži. Skriva unutrašnju topologiju mreže te pronalazi S-CSCF, koji poslužuje određenog korisnika, kroz interakciju s HSS-om.



Slika 1: Arhitektura IMS sistema [8]

Serving-CSCF je glavni kontrolni čvor koji vrši uslugu kontrole sesije za korisnike, što obuhvaća usmjeravanje odlaznih i dolaznih poziva. Poslužitelj filtrira sve dolazne SIP zahtjeve te odlučuje da li ih je potrebno proslijediti aplikacijskom poslužitelju kako bi se osigurala njihova pravilna obrada. Takva odluka se donosi u skladu s podacima dobivenih od HSS-sa u procesu registracije. Identifikatori aplikacijskih poslužitelja se također nalaze u podacima. S-CSCF podržava uspostavu, modifikaciju, raskidanje IP multimedijske sesije koristeći SIP te indirektno pokretanje usluge kroz korištenje sučelja prema aplikacijskom sloju.

B. Home Subscriber Server

Home Subscriber Server (HSS) je glavna baza podataka koja čuva sve korisničke i pretplatničke podatke te nakon registracije vodi računa o dodijeljenim CSCF čvorovima pojedinim korisnicima. Na HSS-u se nalaze korisnički podaci koji se tijekom registracije pohranjuju i na CSCF.

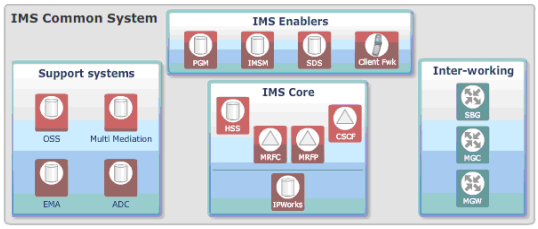
HSS nudi sljedeće mogućnosti:

- Identifikacija – održava odnose između privatnih korisničkih identifikatora (IMPI) te pripadajućih javnih korisničkih identiteta (IMPU) u obliku SIP URI-a (Uniform Resource Identifier). Isto tako čuva i MSISDN za potrebe naplate i SSO (*Single Sign On*) registracije.
- Autentikacija – sigurnosna usluga koja verificira korisnički identitet. Podržava HTTP i SSO mehanizme.
- Pristupna autorizacija – donosi odluku o dopuštanju korisniku da se registrira na IMS sustav ili ne.
- Informacije o usluzi – pohranjuje profil usluge sa pripadajućim IFC-ima (*Initial Filter Criteria*) te identifikatorima aplikacijskih servera.
- Pristup netransparentnim podacima – pruža mogućnost aplikacijama za čitanje netransparentnih podataka, kao što su: javni korisnički identiteti, alocirani CSCF čvor, status registracije i IFC filtri.
- Pristup transparentnim podacima – pruža mogućnost aplikacijama za dohvat i pohranu transparentnih podataka na HSS-u, a to su: podaci specifični za pojedinu uslugu i korisnika pojedine usluge. Aplikacija se može pretplatiti na obavijesti o promjeni transparentnih podataka na HSS-u.

C. IMS kodeci

IP Mutimedia Subsystem (IMS) koristi kodeke G.711 i G.729. Radi se o standardnim govornim kodecima koji se koriste u današnjoj telefoniji.

G.711 je najčešće korišten kodek u telefoniji. G.711 kodek je najbrži sa stanovišta vremena za procesiranje signala u odnosu na druge korištene kodeke. Također je i najjednostavniji za implementaciju. Koristi frekvenciju



Slika 1.2: Komponente IMS sistema [8]

uzorkovanja od 8 kHz i s obzirom da se svaki uzorak kodira sa 8 bita, bitska brzina signala iznosi 64 kb/s.

G.729 je jedan od kodeka koji se koristi za digitalizaciju govora koji je najefikasniji sa stanovišta korištenja frekventnog opsega. Bitska brzina signala iznosi 8 kbps. U odnosu na G.711, kompleksniji je za implementaciju i koristi više vremena za procesiranje signala.

III. QUALITY OF SERVICE PARAMETRI

U ovom poglavlju su definisani neki *Quality of Service* (QoS) parametri. Potrebno je napomenuti da u ovom radu mjereni parametre koji su karakteristični za paketske mreže.

Posmatrani su sljedeći *Quality of Service* (QoS) parametri:

- kašnjenje
- varijacija kašnjenje (*jitter*)
- propusnost (*throughput*)
- gubitak paketa (*packet loss*)

Kašnjenje (*delay*) u paketskim mrežama se definiše kao vrijeme koje je potrebno paketu da pređe put između dva čvora[9]. Obično se mjeri *end-to-end* kašnjenje, koje se odnosi na kašnjenje paketa između korisnika servisa i poslužitelja. U ovom slučaju radi se o kašnjenju između terminalne opreme i IMS sistema. Ovako definisano kašnjenje se može razlikovati u zavisnosti o tome da li se radi o slanju paketa prema poslužitelju (*upload*) ili primanju paketa (*download*).

Izmjeriti kašnjenje u *upload*-u ili *download*-u je obično poprilično kompliciranо jer je potrebno da obje mjerne tačke budu sinhronizirano dovoljno točno, što obično nije slučaj. Zbog toga se češće mjeri dvostruko kašnjenje, odnosno vrijeme koje je potrebno paketu da stigne do odredišta i da se vrati. Mjeri se na vrlo jednostavan način, korištenjem ping aplikacije, odnosno slanjem ICMP paketa.

Mjerenje dvostrukog kašnjenja konkretnih VoIP poziva nije bilo moguće na ovaj način jer IMS čvorove nije moguće poslati ICMP pakete od strane terminalne opreme. Kao parametar koji je dobar pokazatelj kašnjenja u sustavu je delta. Delta se odnosti na vrijeme između primanja dva paketa na odredišnoj strani.

Varijacija kašnjenja (*jitter*) je mjera brzine promjene kašnjenja paketa. U [10] se definiše *interarrival* jitter i-tog paketa sljedećim formulom:

$$J(i) = J(i-1) + (|D(i-1,i)| - J(i-1))/16 \quad (1)$$

pri čemu je:

$$D(i,j) = (Rj - Ri) - (Sj - Si) \quad (2)$$

U (2) su i,j uzastopni paketi, a Ri,Rj vremena dolaska, a Si,Sj vremena slanja istih. Vrijednost Sj – Si je gore definisani parametar delta.

Propusnost (*throughput*) jedne mreže se odnosi na ukupni broj prenesenih bita u jedinici vremena u posmatranom trenutku. Obično se mjeri prosječna propusnost mreže u nekom periodu. Maksimalna propusnost se definira kao maksimalni broj prenesenih bita u jedinici vremena. Kao i kašnjenje, može se razlikovati u *upload*-u i *download*-u i u praksi se gotovo uvijek i razlikuje. Jedinica je b/s (bit u sekundi).

Količina prenesenih bita u jedinici vremena pojedinačnog govornog signala definiran je kao *bandwidth* govornog signala. Potreban uslov da jedan ili više digitalnih govornih signala bude bez gubitaka prenesen kroz neku mrežu je da ukupna količina bita u jedinici vremena bude manja od propusnosti te mreže.

Gubitak paketa (*packet loss*) se odnosi na količnik između broja izgubljenih paketa (razlike između poslanih i primljenih paketa) i ukupnog broja poslanih paketa. Izražava se u procentima.

Granične vrijednosti za navedene parametre za VoIP mreže su predloženi od strane *International Telecommunication Union* (ITU) organizacije. Vrijednosti su date u tabeli I. Ove vrijednosti su uzete kao referentne u nastavku rada.

IV. MJERENJA KVALITETE IMS VOIP POZIVA

U ovom radu su izvršena mjerenja QoS parametara u dole navedenim scenarijima.

Korištena su dva IMS klijenta: jedan besplatni (*freeware*) (x-lite) i jedan komercijalni (eyebeam).

Korišteni su sljedeći tipovi terminalne opreme:

- PC sa 3G modemom
- Klasični mobilni aparat (u nastavku rada T1)
- Napredni mobilni aparat (*smartphone*) sa Symbain OS (u nastavku rada T2)

TABELA I. GRANIČNE VRIJEDNOSTI ZA QOS PARAMETRE ZA VOIP MREŽE

QoS parametri	
End-to-end kašnjenje	150 ms
Varijacija kašnjenja	30 ms
Gubitak paketa	1 %

TABELA II. MJERENJA KARAKTERISTIKA PRISTUPNIH MREŽA

	Propusnost (DL)	*Propusnost(UL)*	*kašnjenje*	*Varijacija kašnjenja*
Kablovska	3.89 Mbps	0.24 Mbps	31 ms	2 ms
ADSL	68.7 Mbps	36.60 Mbps	13 ms	1 ms
3G – modem	1.29 Mbps	1.11 Mbps	85 ms	9 ms
3G – T1	1.7 Mbps	0.06 Mbps	217 ms	10 ms
3G – T2	1.44 Mbps	0.64 Mbps	210 ms	10 ms

Mjerenja su izvršena u različitim pristupnim mrežama:

- 3G (UMTS)
- Kablovska mreža koja koristi *Data Over Cable Service Interface Specification* (DOCSIS)
- ADSL

Izvršena su mjerenja karakteristika pristupnih mreža. Navedena mjerenja su izvršena korištenjem *web-based* alata speedtest. Rezultati dobiveni ovim mjerenjama moraju se posmatrati sa rezervom jer se ne radi o profesionalnom alatu, ali su ipak dati u ovom radu kao dobra aproksimacija karakteristika pristupne mreže. Ti rezultati su dati u tabeli II.

Kašnjenje koje je dato u tabeli se odnosi na dvostuko kašnjenje za posmatrane pristupne mreže.

Izmjerena propusnost se odnosi na maksimalnu propusnost posmatranih pristupnih mreža u oba smijera (*download* i *upload*).

Uzimanje *trace*-ova i analiza VoIP poziva je izvršeno Wireshark alatom [7].

Svi podaci koji su dati u tabeli III su dobijeni iz Wireshark *trace*-ova. Mjerne tačke su terminalna oprema i *Session Borser Gateway* (SBG) koji je pristupna tačka za čitav IMS sistem. Time je praktično pokrivena trasa između klijenta i poslužitelja ako pretpostavimo da u internoj IMS mreži nema gubitaka te da su kašnjenja zanemariva, što je realna pretpostavka.

U svim scenarijima koristi se G.711 govorni kodek.

V. ANALIZA I INTREPRETACIJA REZULTATA MJERENJA

U ovom poglavlju je izvršeno poređenje pristupnih mreža, IMS klijenata i terminalne opreme na osnovu izmjerenih QoS parametara.

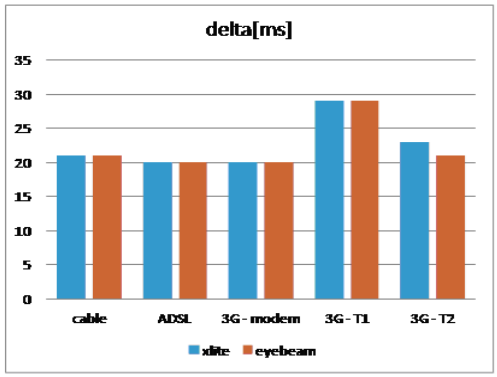
Prvi parametar koji se posmatra je broj prenesenih bita u jedinici vremena za pojedinačni VoIP govorni signal (*stream*), odnosno *bandwidth* tog signala. Kao što je

TABELA III. MJERENJA KARAKTERISTIKA PRISTUPNIH MREŽA

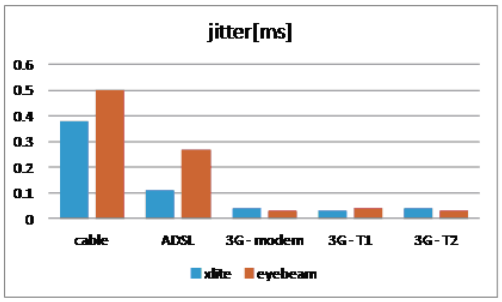
Mreža/client		**bandwith**		**delta**		**varijacija kašnjenja**		**gubitak paketa**	
		D	**U**	**D**	**U**	**D**	**U**	**D**	**U**
Kablovska	***xlite***	80 kbps	80 kbps	20 ms	21 ms	0.38 ms	3.76 ms	0%	0%
	eyebeam	80 kbps	80 kbps	20 ms	21 ms	0.5 ms	3.2 ms	0%	0%
ADSL	***xlite***	80 kbps	80 kbps	20 ms	20 ms	0.11 ms	0.16 ms	0%	0%
	eyebeam	80 kbps	80 kbps	20 ms	20 ms	0.27 ms	0.29 ms	0%	0%
3G – modem	***xlite***	80 kbps	80 kbps	20 ms	20 ms	0.04 ms	6.2 ms	0%	0%
	eyebeam	80 kbps	80 kbps	20 ms	20 ms	0.03 ms	7.5 ms	0%	0%
3G – T1	***xlite***	80 kbps	60 kbps	20 ms	29 ms	0.03 ms	9.78 ms	0%	10.93 %
	eyebeam	80 kbps	60 kbps	20 ms	29 ms	0.04 ms	9.89 ms	0%	15.25%
3G – T2	***xlite***	80 kbps	82 kbps	20 ms	23 ms	0.04 ms	6.52 ms	0%	0.25 %
	eyebeam	80 kbps	82 kbps	20 ms	21 ms	0.03 ms	17.17 ms	0%	0 %

navedeno u prethodnom poglavlju, u svim scenarijima je korišten G.711 kodek koji kodira govorni analogni signal na 64 kbps. Kada se tome dodaju *overhead* biti, dobije se *bandwidth* od približno 80 kbps što je i potvrđeno mjerenjima.

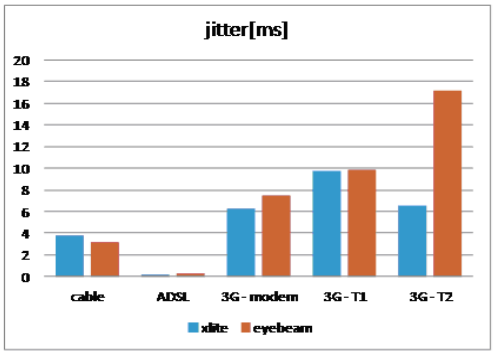
Kada se rezultati mjerenja dati u tabeli III usporede sa propusnošću (*throughput*) pojedinih mreža (Tabela II)



Slika 3:Delta – upload



Slika 4:Jitter – download



Slika 5:Jitter – upload

pokazuje se da je u većini slučajeva propusnost mreže daleko veća od *bandwidtha* pojedinih signala, osim u slučaju T1 mobilnog terminala.

Izmjerena propusnost u *upload*-u 3G mreže na navedenom terminalu iznosi 60 kbps, što nije dovoljno za prenošenje govornog signala bez gubitaka. Zbog toga je u ovom slučaju izmjeren *bandwidth* na *upload*-u od 60 kbps. Naravno, izmjeren je i značajan gubitak paketa, što će biti detaljnije analizirano u nastavku. Rezultati mjerenja *bandwidtha* također pokazuju da taj parametar ne zavisi od IMS klijenta, odnosno da se oba klijenta ponašaju vrlo slično.

U četvrtom poglavlju je navedeno da u mjerenjima pojedinačnih VoIP poziva nije izvršeno mjerenje kašnjenja već je kao mjera kašnjenja dat parametar delta. Delta, odnosno razlika između dolaznih paketa, je izmjerena za različite scenarije. Izmjerene vrijednosti za ovaj parametar su identične za *download*. Rezultati mjerenja za parametar delta u *upload*-u je dat na slici 3.

Razlika između vremena slanja paketa se može izračunati iz RTP paketa na osnovu *timestampa* pojedinih paketa. Pokazuje se da je ta razlika konstantna u svim scenarijima, jer se koristi isti kodek, i da iznosi 20 ms. Identična razlika na prijemu (delta) pokazuje da se radi o mreži sa malim kašnjenjem, što vrijedi za sve slučaje u *download*-u, te za kablovsku, ADSL i 3G mrežu (modem). To potvrđuju i rezultati mjerenja u tabeli II.

Što se tiče mobilnih terminala, izmjerene su veće vrijednosti delta parametra od 20 (Slika 6), te znatno veće vrijednosti dvostrukog kašnjenja od 217 ms (T1) i 210 ms (T2). Čak i kad se uzme u obzir da se ne radi o simetričnom kanalu što se tiče kašnjenja, može se pretpostaviti da je kašnjenje u jednom smijeru u oba slučaja manje od 150 ms, što je granična vrijednost za ovaj parametar. Znači, može se zaključiti da je kašnjenje unutar dozvoljene granice predložene od strane ITU-a (tabela I).

Kao i za *bandwidth*, i na osnovu mjerenja delta parametra se može zaključiti da nema značajne razlike između dva IMS klijenta.

Varijacija kašnjenja je data za sve scenarije na slikama 4 i 5.

Vrlo zanimljivo je da je izmjereni *jitter* u *download*-u manji za 3G mrežu nego za *wireline* mreže, ali treba navesti da se radi o veoma malim vrijednostima, ispod 0.5 ms. Vrijednosti *jittera* u *upload*-u su znatno veće i, kao što je i logično, veći *jitter* je izmjeren za 3G mrežu.

U svim scenarijima, izmjerena varijacija kašnjenja je ispod 30 ms, što je preporučena granica za VoIP mreže.

Kada se radi o ovom parametru, primjećuju se razlike između dva IMS klijenta pri čemu bolje rezultate pokazuje freeware klijent.

Kada se radi o gubitku paketa, mjerenja pokazuju da u *download*-u u svim slučajevima nema gubitka paketa.

Gubitaka nije bilo u kablovskoj, ADSL i 3G mreži (modem). Kada se radi o T2 terminalu, izmjeren je gubitak paketa od 0.25 %, što je znatno manje od predložene granice (1 %).

Gubitak paketa je znatan kada se radi o T1 mobilnom terminalu (između 10 i 15 %) i može se zaključiti da je osnovni razlog već navedeno ograničenje propusnosti u ovom scenariju.

Subjektivni doživljaj kvalitete govornog signala je odličan za sve scenarije osim za test sa T1 mobilnim telefonom. U tom slučaju je konverzacija skoro nemoguća jer, iako mobilni terminal prima govorni signal bez problema, sagovornik na drugoj strani dobiva signal sa velikim akumuliranim kašnjenjem, što je očito rezultat pokušaja dekodera da rekonstruiše signal koji dolazi sa velikim gubicima.

VI. ZAKLJUČAK

IP Multimedia Subsystem predstavlja osnovu za operatorske mreže budućnosti koje će biti bazirane na IP-u. Zbog toga je potreno osigurati odgovarajući nivo kvalitete kada se radi o svim IMS servisima, a posebno osnovnom servisu – govoru.

IMS je nezavistan od pristupne tehnologije i kao takav može biti dio i fiksne i mobilne mreže. S obzirom da je *broadband* fiksni Internet pristup široko dostupan rezidencijalnim i poslovnim korisnicima, ne postoje prepreke za uvođenje IMS servisa tim korisnicima. Sa rastom kapaciteta 3G mreže i uvođenjem sljedeće generacije

pristupnih mobilnih mreža (4G) moguće je ponuditi IMS servise i mobilnim korisnicima.

Cilj ovog rada je bio da pokaže da IMS može u kombinaciji sa različitim pristupnim mrežama (ADSL, kablovska, 3G) korisnicima ponuditi zadovoljavajući nivo kvalitate VoIP usluge. Preduslov za to je korištenje PC-ja ili naprednih mobilnih terminala (*smartphone*-a). Mjerenja su pokazala da je kod starijeg modela telefona očigledno ograničena propusnost na *upload*-u na samom terminalu. Razlog za to može biti što su mobilni terminali obično korišteni za servise koji uključuju *download* podataka, a u veoma maloj mjeri *upload*, dok je govor prenošen komutacijom krugova. Noviji modeli uređaja nemaju to ograničenje. Daljnja istraživanja koja bi uključila veći broj uređaja su potrebna da bi se donijeli definitivni zaključci po tom pitanju.

Jedan od faktora koji za sada spriječava masovno korištenje VoIP usluge u 3G paketskoj mreži je cijena. U operatorskoj mreži u kojoj su izvršena mjerenja 3G saobraćaja je znatno jeftinije korištenje klasičnog govornog nego *upload*-ani paketski saobraćaj u istom vremenskom intervalu. Toj cijeni treba dodati i naknadu za korištenje same IMS usluge. Slična situacija je i kod većine svjetskih operatera i smanjenje cijene paketskog saobraćaja će sigurno dovesti do povećanja korištenja VoIP servisa u mobilnim operatorskim mrežama, bilo da se radi o IMS-u ili nekom drugom VoIP poslužitelju. Naravno, sljedeća generacija mobilnih mreža (4G) je *all-IP* rješenje i mobilni VoIP će postati jedino rješenje za korisnike 4G mreža s obzirom da komutacija krugova u tim mrežama više nije podržana.

Zaključak ovog rada je da se sa stanovišta kvalitete servisa mobilnim i fiksnim korisnicima može ponuditi IMS VoIP usluga . Na taj način operatori mogu ostati konkurentni u ICT tržištu koje se okreće *all-IP* rješenjima i na taj način se pripremiti i za 4G mreže.

Iskustvena kvaliteta video sadržaja za usluge u pokretnoj mreži treće generacije

Dunja Vučić*, Iva Medvid **
* Belmet97, Zagreb, Hrvatska
** Ericsson Nikola Tesla/Networks, Zagreb, Hrvatska
dunja.vucic@belmet97.hr, iva.medvid@ericsson.com

Sažetak - Iskustvena kvaliteta (*Quality of Experience*) korisnika video usluge je višedimenzionalni problem kome se pristupa i subjektivno i objektivno. Subjektivni pristup analizira ocjenjivanje gledatelja, a objektivni istražuje rezultate mjerenja, koja se mogu podijeliti u dvije glavne grupe parametara koji najviše utječu na percepciju korisnika. Jedni opisuju kvalitetu usluge, a drugi opisuju kvalitetu video zapisa. U radu će biti promatrana ovisnost subjektivne ocjene o metričkim parametrima, tražit će se relacija između kodiranih - ulaznih i transmisijom oštećenih - izlaznih sekvenci. U tu svrhu mjereni su QoS parametri (gubitak paketa, kašnjenje) i parametri objektivne metrike kvalitete video sadržaja (zrnatost, zamućenje). Usporedbom izmjerenih rezultata ulaznih i izlaznih video sekvenci pokazane su mogućnosti i ograničenja glede predviđanja subjektivne ocjene video kvalitete u stvarnoj komercijalnoj mreži uz stvarne uvjete.

I. UVOD

Pojam iskustvene kvalitete podrazumijeva potpun dizajnerski koncept koji uključuje razne aspekte korisničkog iskustva s proizvodom, a prema tradicionalnoj spoznaji, dijelom je orijentiran na korisnost, estetiku, zabavnost i zadovoljstvo [1]. Puno je istraživanja dizajnerski orijentirano, brojni modeli nastoje opisati iskustvenu kvalitetu dovoljno jednostavno, radi olakšanja razvoja proizvoda.

U današnjim multimedijskim proizvodima kao i u budućim, zbog tehničkih ograničenja (od kapaciteta i brzina procesora do prijenosa podataka) nužno je optimiranje multimedijskih podataka. Zato su potrebni kompromisi u tehničkim parametrima sustava, a koji su temeljeni na kvantifikaciji subjektivnih eksperimenta s doživljajem multimedijske kvalitete.

Metode za mjerenje multimedijske subjektivne kvalitete su različite, ali sve koriste kvantitativni pristup. U kvantitativnom pristupu od ispitanika se traži da pridruži neku oznaku rangiranja za određenu osobinu predmeta vrednovanja. Često se koristi veći broj predmeta vrednovanja uz postupno mijenjanje kvalitete, a od ispitanika se traži subjektivno vrednovanje razlike u kvaliteti između pojedinih predmeta [2].

Primjenjuju se ITU (*International Telecommunication Union*) preporuke u pojedinim vrstama mjerenja kvalitete, kako od malih uređaja tako do aplikacija za virtualnu stvarnost [3][4]. Kao dodatak ITU metodama, postoje i korisnički orijentirane metode, koje su više usredotočene na ovisnost kvalitete o korisničkim grupama, sadržaju i kontekstu. Sve te metode povlače slične probleme kritične kvalitete (faktori oštećenja) spram poželjne i prihvatljive kvalitete. Stoga, proučavanje multimedijske kvalitete treba pojasniti dinamičke procese audiovizualne percepcije, gdje relativna važnost jednog modaliteta spram drugog može varirati s različitim sadržajem, kontekstom ili zadaćama [5].

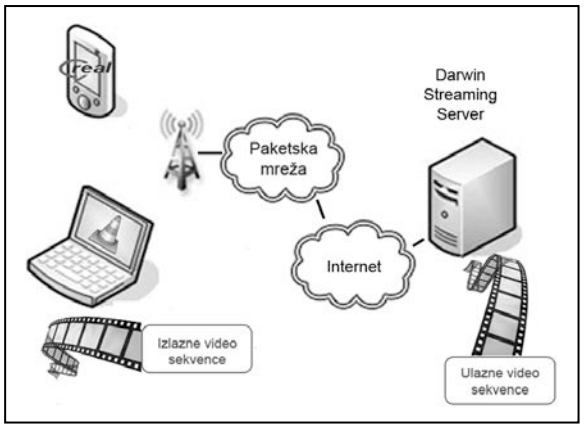
II. ISPITNA OKOLINA I POSTUPAK MJERENJA

Pristup iskustvenoj kvaliteti može biti subjektivni ili objektivni. Subjektivni pristup sadrži parametre ocjenjivanja gledatelja, a objektivni, parametre određene mjernim postupcima. Parametre objektivnog pristupa moguće je podijeliti na dvije glavne, spram utjecaja na percepciju korisnika. Jedni opisuju kvalitetu usluge, a drugi opisuju kvalitetu video zapisa [6][7].

Cilj mjerenja je pokazati zavisnost subjektivne ocjene o metričkim parametrima, između kodiranih-ulaznih i transmisijom oštećenih-izlaznih sekvenci. Ispitivanja su provedena u komercijalnoj mreži sa stvarnim pokretnim uređajem. S računalnim alatima izmjerene su vrijednosti subjektivne i objektivne ocjene. Izmjerene su dvije grupe parametara objektivne metrike: parametri mrežne metrike kao što su gubitak paketa, kašnjenje i kolebanje kašnjenja, te parametri kvalitete videa, zrnatost i zamućenje.

Odabrane su četiri standardne video sekvence, Foreman, News, Hall i Mobile, s različitim stupnjem prostorne i vremenske složenosti. Sekvence pokrivaju širok raspon tipičnih karakteristika sadržaja aplikacija za pokretne uređaje, kao što su: ravne plohe, složene teksture, krupni planovi, pokretna kamera i/ili objekti. Izvorne sekvence traju 10 sekundi, prostorne su rezolucije 320x240 piksela, formata YUV 4:2:0, bez zvuka, brzine prijenosa 9000 kbps, brzine okvira 10 i 15 fps. Izvorne sekvence se kodiraju MPEG-4 standardom u ulazne sekvence, pogodne za strujanje uz tipične brzine prijenosa, 64 i 96 kbps, u pokretnoj mreži.

Za mjerenje kvalitete postavljena je ispitna okolina: video poslužitelj – Internet – pokretna mreža – pokretni uređaj (sl. 1). Za strujanje podataka koristi se video poslužitelj Darwin Streaming Server (DSS), tehnologija koja omogućava strujanje podataka korisnicima putem Interneta, korištenjem protokola RTP (*Real-time Transport Protocol*) i RTSP (Real *Time Streaming Protocol*). Za prijenos podataka do pokretnog uređaja koristi se bežični WCDMA kanal pokretne mreže.



Slika 1. Ispitna okolina

Mjerenja su izvedena na Symbian operacijskom sustavu pametnog telefona Nokia E-72 s RealPlayer klijentom strujanja. Mjerenje svakog ispitnog slučaja ponavlja se pet puta. Mjerenje započinje pokretanjem SymPA aplikacije na pokretnom uređaju, kojom se otvara konekcija prema poslužitelju za video strujanje, putem IP adrese DSSa i porta 554 [8]. Nakon SymPA-e pokreće se RTP klijent na pokretnom uređaju, kroz izbornik aplikacije RealMedia player, također putem IP adrese i 554 porta, ostvaruje konekciju i započinje video strujanje, odnosno prikaz video materijala na zaslonu pokretnog uređaja. Nakon završetka strujanja, u SymPA aplikaciji se vrši pohrana snimljenog prometa u sirovom formatu, koji se konvertira u format softvera *Wireshark* pogodnog za analizu RTP toka podataka i E2E parametara karakterističnih za kvalitetu video usluge: gubitak paketa, kašnjenje i kolebanje kašnjenja. Za određivanje objektivne video kvalitete potrebno je snimiti izlazne, strujane sekvence. Stoga u isto vrijeme, na računalu radi VLC player aplikacija, koja izvodi strujanje i simultano snimanje izlaznih video sekvenci. Izlazne video sekvence, s oštećenjem zbog prolaska kroz pokretnu mrežu, snimljene su u AVI formatu koji nema gubitaka. Parametri objektivne video kvalitete, zrnatost i zamućenje, mjere se alatom MSU (*Video Quality Measurement Tool*).

Opsežna testiranja subjektivne video kvalitete često su skupa i dugotrajna, stoga su razvijeni alati koji u zadovoljavajućoj mjeri mogu ponuditi rezultate vrlo bliske ocjeni gledatelja. U tu svrhu, u radu se koristi alat VQA (*Video Quality Analyzer v 1.0.*). Prema autorima VQA alata, ugrađena tehnologija mjerenja video kvalitete pokazuje veliku točnost u predviđanju DMOS-a (*Difference Mean Opinion Score*) spram rezultata polučenih tijekom subjektivne procjene kvalitete gledatelja uz uvjete prema preporuci ITU.T BT.500-12. DMOS ukazuje na razinu doživljenog gubitka vizualne kvalitete mjerenog videa spram njegovog izvornog videa i poprima vrijednosti od 0 (odlično) do 100 (loše).

III. SUBJEKTIVNA OCJENA I OBJEKTIVNA VIDEO METRIKA

Iako video strujanje pripada kategoriji jednosmjerne usluge, usluga je osjetljiva na kašnjenje i kolebanje kašnjenja. Velike varijacije kašnjenja treba kontrolirati, radi konstantnosti toka podataka i izbjegavanje prekida

TABLICA I. STATISTIČKE VRIJEDNOSTI MREŽNIH PARAMETARA

	Brzina okvira	**10 fps**		**15 fps**

zbog praznog međuspremnika. Inače se kod gledatelja značajno može pogoršati percepcija kvalitete. Gubitak paketa je parametar koji bitno može utjecati na kvalitetu usluge. U pokretnim mrežama do gubitka paketa dolazi zbog popunjenosti međuspremnika ili pogrešaka na kanalu. U svim provedenim mjerenjima su mala kolebanja vrijednosti, unutar ispitne skupine od pet mjerenja. Vrijednosti kašnjenja svih ispitnih slučajeva su se kretale između 39 i 78 ms, što su za video uslugu prihvatljive vrijednosti.

Tijekom mjerenja, sve sekvence, osim Mobile, kodirane brzinom okvira 10 fps, imale su gubitak između 0% i 1.11%, dok su 15fps sekvence imale gubitak od 0% do 3.43%. Sekvence Mobile su imale prosječni gubitak od 19.12%, a broj izgubljenih RTP paketa kretao se od 36 do 64. Uočljiv je rast gubitka paketa s povećanjem brzine kodiranja. U tablici I. prikazane su statističke vrijednosti parametara mrežne metrike za pet mjerenja svih ispitnih skupina.

A. *Sekvence Foreman*

Ocjena subjektivne kvalitete za sve ispitne sekvence bila je vrlo dobra, osim u slučaju 15fps i 96k kada je DMOS dostigao vrijednost 100, što je loša ocjena, tablica II. Prosječni gubitak od 3.27% imao je vrlo veliki utjecaj na percipiranu kvalitetu. Nakon početnog kratkotrajnog oštećenja video materijala, poslije nije bilo vidljive

TABLICA II. SREDNJE VRIJEDNOSTI SUBJEKTIVNE OCJENE I OBJEKTIVNIH PARAMETARA VIDEO KVALITETE

Foreman 320x240			**DMOS**	**Zrnatost**	**Zamućenje**
10 fps	64 Kbps	Ulaz	26.45	35.02	16.24
		Izlaz	28.65	32.38	15.82

		Izlaz	21.39	28.09	18.88
	96 Kbps	Ulaz	12.28	23.91	19.74
		Izlaz	32.89	23.12	19.12

degradacije. Gubitak paketa na početku transmisije i kratak vremenski period trajanja sekvenci od 10 sekundi nisu ostavili mogućnost poboljšanja ukupnog DMOS-a. Ovaj primjer potvrđuje da gledatelji brzo primjećuju i sporo zaboravljaju. Objektivna kvaliteta je ostala slična kao kod ulaznih sekvenci. Najlošija varijanta 15fps i 64k ima prosječnu vrijednost zrnatosti 40.92, dok zamućenje iznosi 15.55. Najbolja varijanta 10fps 96k ima zrnatost 23.91, a zamućenje 16.53. Međutim, prosječne vrijednosti parametara zrnatosti i zamućenja zapravo su vrlo bliske ulaznim vrijednostima, time su oštećenja prouzročena transmisijom u ovom slučaju zanemariva. Od svih ispitnih sekvenci, Foreman postiže najviše vrijednosti zrnatosti, što rezultira i velikom zrnatošću u prikazu slike.

B. Sekvence Hall

U slučaju Hall najveći gubitak paketa je doživjela sekvenca s 15fps i 96K, iznos od 0.58% ne utječe bitno na subjektivnu procjenu, jer srednja vrijednost DMOS-a iznosi 28.13, što predstavlja ocjenu vrlo dobro. Za sve ostale kombinacije sekvenci, subjektivna ocjena je također bila vrlo dobra. Vrijednosti objektivnih parametara svih Hall varijanti postigle su najbolje rezultate za zrnatost. Vrijednosti su se kretale između 19.36 i 26.61. Obzirom da su Hall sekvence relativno statične, bez puno detalja, to je bilo i za očekivati. Iako su vrijednosti zamućenja slike relativno niske 17.92,

Slika 2. Najlošiji okvir sekvence Foreman, Hall, News, Mobile, varijante 15fps 96kbps parametra zrnatost

obzirom na sadržaj materijala, zamućenje nije toliko došlo do izražaja.

C. Sekvence Mobile

Mobile je za sve varijacije kodiranja postigao DMOS 100, odnosno ocjenu loše. Tijekom strujanja neugodna oštećenja su bila prisutna većinu vremena. Gubitak od 15.83% do 21.15% u ovom slučaju je imao vrlo veliki utjecaj na subjektivnu ocjenu.

Za razliku od loše DMOS ocjene, zrnatost i zamućenje imaju vrlo dobre vrijednosti. Srednja vrijednost parametra zrnatost ne odskače puno od ostalih ispitnih sekvenci, međutim vrijednosti zamućenja postižu najbolje rezultate od svih slučajeva.

D. Sekvence News

Prosječni gubitak od 2.17% nije ostavio značajniji trag na doživljenu iskustvenu kvalitetu, obzirom da prosječna vrijednost DMOS-a iznosi 32.89, što predstavlja vrlo dobru subjektivnu ocjenu. Treba primijeti, Foreman sekvenca od 15fps i 96K, s bliskim prosječnim gubitkom paketa od 3,27%, ima 100 za DMOS vrijednost. Dakle, malo odstupanje postotka gubitka paketa rezultiralo je s kardinalno različitom ocjenom kvalitete.

News materijal ima najmanje zamućenje u svim varijantama u usporedbi s ostalim ispitnim sekvencama, izuzevši Mobile, prosječne vrijednosti su 19.06. Vrijednosti indeksa zrnatosti kretale su se od 19.87 za slučaj 10fps 96k do 28.09 za slučaj 15fps 64k.

IV. POVEZIVANJE REZULTATA

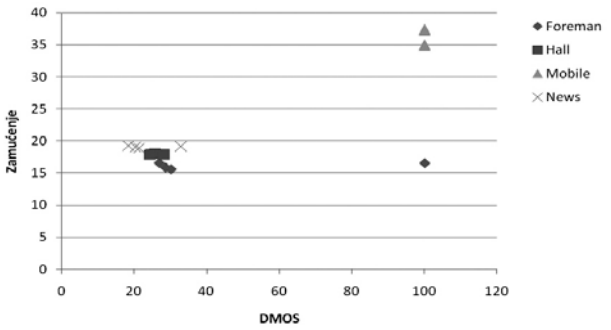
Uz pomoć QoS podataka može se procjenjivati iskustvena kvaliteta. Izmjereni QoS parametri nisu uvijek dovoljni za subjektivnu procjenu, što se vidjelo u slučaju Foreman i Mobile za DMOS vrijednosti 100, odnosno najlošiju ocjenu. Naime, video je osjetljiviji, od drugih multimedijskih usluga, na učinke manjih ali strateški postavljenih mrežnih oštećenja. U stvaranju prikaza jasne i glatke slike, zbog načina kodiranja, neki su okviri važniji od drugih. Stoga gubitak paketa, koji ne sadrži ključni okvir, neće utjecati na subjektivnu ocjenu gledatelja, jer gledatelj neće niti primijetiti efekt kojeg je izazvao taj gubitak. S druge strane, ako gubitak paketa utječe na jedan od I-okvira, učinak je vidljiv. Obzirom da u video svijetu svi paketi nemaju jednaku relativnu važnost, broj ili omjer izgubljenih paketa ne daje dovoljnu informaciju za procjenu gubitka percipirane kvalitete. Stoga je nužno uključiti i ostala objektivna mjerenja u proces ocjenjivanja iskustvene kvalitete.

Objektivna metrika kvalitete slike koristi matematičke modele u izračunu razlika između izvornog i obrađenog videa. Pri tome su zrnatost, zamućenje te omjer signala i šuma najčešći široko korišteni parametri u objektivnim metrikama [9]. Zrnatost se javlja pri pogreškama u kodiranju prostornih komponenti i pri gubitku informacija u stvarnom vremenu preuzimanja i prikaza video materijala [10]. Pozicija i broj oštećenih blokova određuju percepciju i razinu degradacije kvalitete. U ispitnim slučajevima najizraženija zrnatost i zamućenje su kod sekvence Foreman. Zrnatost je vidljivija u glatkim dijelovima slike u područjima koja se brzo kreću. Vrijednosti zrnatosti provedenih mjerenja su relativno bliske, efekt zrnatosti lakše je zamijetiti kod sekvenci s puno gibanja, kao kod sekvenci Hall i News. Sekvenca Hall ima manju zrnatost od sekvence News, zbog kretnji u pozadini koje nisu prisutne i u slučaju Hall.

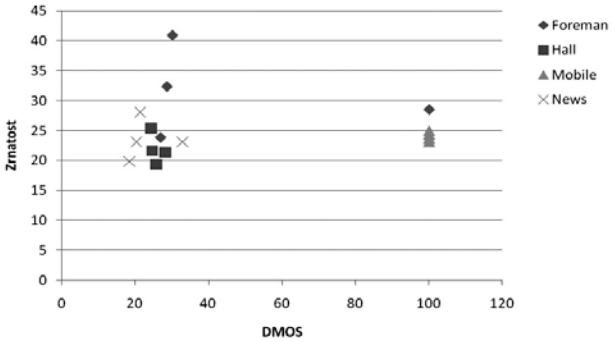
Zamućenje je gubitak oštrine rubova i prostornih detalja. Kompresija je čest uzrok zamućenja, jer se nastoji smanjiti broj bitova pri kodiranju kretanja u slici. Za očekivati je da sekvenca s najviše detalja i kretanja, Mobile, bude najzamućenija, a ne najbistrija. Međutim, na prosječno visok indeks zamućenja utjecale su vrlo visoke vrijednosti pojedinih okvira. Ipak, visoka ukupna jasnoća slike nije bitno utjecala na subjektivnu ocjenu, jer sve su varijante ulazne sekvence Mobile na granici DMOS skale dobro-slabo, dok je za sve izlazne sekvence ocjena glasila loše. Prema rezultatima mjerenja, sekvenca Foreman postigla je najlošije prosječne rezultate, odnosno najveću zamućenost. Iz bliskih izmjerenih vrijednosti ulaznih i izlaznih sekvenci, tablica II, proizlazi da kompresija ima glavnu ulogu u stvaranju efekta zamućenja, a ne oštećenja prouzročena transmisijom.

Koristeći rezultate izlaznih mjerenja provedeno je povezivanje izmjerene izlazne DMOS vrijednosti i vrijednosti izmjerenih izlaznih metričkih parametara (sl. 3,4,5,6). Grafički prikazi rezultata pokazuju kako niti jedan parametar ne može biti direktna mjera DMOS ocjene. Za većinu vrijednosti parametra zamućenja vidljiva je bliskost s opisom kvalitete koju percipiraju korisnici. Međutim, rezultati sekvence Mobile imaju najmanju zamućenost, a najlošiju subjektivnu ocjenu, što potvrđuje kako pojedinačni parametar ne može biti izravni odraz iskustvene kvalitete. Iz rasipanja izmjerenih vrijednosti proizlazi da je ljudski vizualni sustav osjetljiviji na gubitke kvalitete zbog povećane zrnatosti nego na učinke zamućenja.

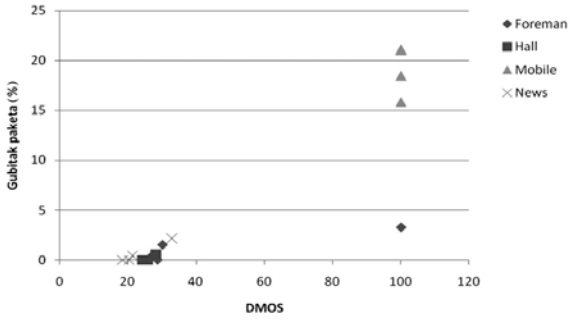
Isto tako nije moguće uspostaviti direktnu povezanost DMOS vrijednosti i izmjerenih vrijednosti mrežnih parametara. Prosječni gubitak paketa u slučaju Foreman, varijante 15 fps i 96 kbps, od 3.27% postigao je najlošiju DMOS ocjenu, dok je DMOS sekvenca News, u istoj varijanti, s prosječnim gubitkom od 2.18% postigla vrlo dobru DMOS ocjenu.



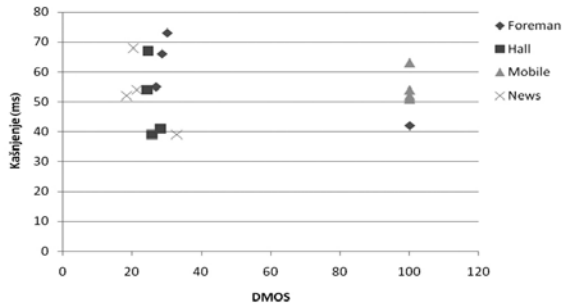
Slika 3. Odnos između DMOS ocjene i parametra zamućenje



Slika 4. Odnos između DMOS ocjene i parametra zrnatost



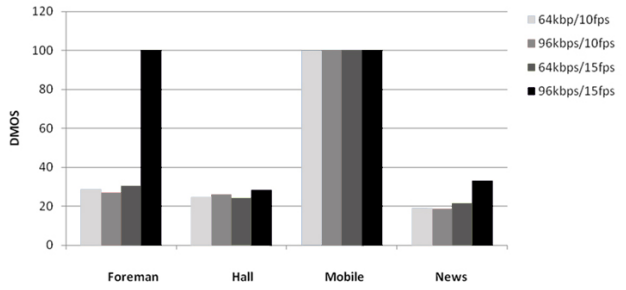
Slika 5. Odnos između DMOS ocjene i parametra gubitak paketa



Slika 6. Odnos između DMOS ocjene i parametra kašnjenje

Slika 7. pokazuje da vrijednosti subjektivne ocjene za sekvence Mobile uopće ne variraju. Za sve kombinacije brzine prijenosa i okvira postignuta je najlošija ocjena. Obzirom da su DMOS vrijednosti ulazne sekvence Mobile, prije prolaska kroz pokretnu mrežu, bile slabe, za očekivati je da će nakon prolaska kroz pokretnu mrežu vrijednosti biti slične. U ovom slučaju prosječni gubitak paketa od 19.13% uzrok je dodjeljivanja najlošije DMOS ocjene. Vrijednosti ispitne sekvence Hall ne variraju puno i sličnih su vrijednosti kao i sekvence News. Sekvenca News je malo dinamičnijeg sadržaja od sadržaja sekvence Hall, što je rezultiralo većom varijacijom subjektivne ocjene i malo većim prosječnim gubitkom paketa. DMOS vrijednosti za sve kombinacije sekvence Foreman su također bile stabilne i vrlo dobre, osim za slučaj 96kbps/15fps, gdje je postignuta vrijednost 100. Interesantno je da je u ovom ispitnom postupku VQA alat pri donošenju subjektivne ocjene preferirao niže brzine okvira i više brzine prijenosa, odnosno da je kombinacija 10 fps i 96 kbps svih ispitnih sekvenci postigla najbolje rezultate.

Ukupno gledano, mjerenje objektivne kvalitete svih ulaznih i izlaznih varijanti jedne sekvence, iste ispitne skupine, daje slične mjerne rezultate. U ovom eksperimentu kompresija je glavni uzrok u stvaranju nepoželjnih efekata koji degradiraju video kvalitetu, a ne pokretna mreža kako to često doživljava korisnik. Najbolje rezultate ostvarile su sekvence Hall i News, koje su relativno statičnog scenarija, a najlošiji rezultat postigla je jedna varijanta sekvence Foreman (15fps 96K) i sve varijante dinamične sekvence Mobile. Ova varijanta sekvence Foreman postigla je loše DMOS rezultate uz relativno malen gubitak paketa, ali očito je taj gubitak bio na ključnim mjestima, što je značajno utjecalo na loš ukupni dojam proživljenog iskustva.



Slika 7. DMOS vrijednosti različitih brzina prijenosa i okvira izlaznih sekvenci

V. ZAKLJUČAK

U eksperimentu su korištene četiri standardne video sekvence: Foreman, Hall, Mobile, News u četiri varijante, putem dvije brzine prijenosa (64 i 96 kbps) i dvije brzine okvira (10 i 15 fps). Izabrane sekvence pokrivaju različita obilježja video materijala (različite teksture, količina detalja, kretanja u slici). Tijekom mjerenja pokretna mreža je bila stabilna. Naime, izmjerene su male vrijednosti za gubitak paketa, kašnjenje i kolebanje kašnjenja, osim za sekvencu Mobile. Izmjerene male razlike DMOS vrijednosti ulaznih i izlaznih sekvenci, pokazuju da mreža praktički nije imala utjecaja na izmjerene subjektivne vrijednosti. Sve varijante sekvence Mobile ocijenjene su najlošijom DMOS ocjenom. Iako je izgubljeno dosta paketa prolaskom kroz pokretnu mrežu, u prosjeku 19.12%, mreža nije jedina utjecala na lošu subjektivnu ocjenu sekvence Mobile. Naime DMOS ocjena ovih ulaznih sekvenci već je bila na granici slabog. Ako je kvaliteta sadržaja na ulazu slaba nije za očekivati da će se prolaskom kroz mrežu poboljšati. Stoga je za uspješni prikaz i transmisiju s malo gubitaka potrebno razvrstati video prema sadržaju. Rezultati također pokazuju kako objektivne parametre kvalitete videa (zrnatost i zamućenje) kao i mrežne parametre (gubitak paketa i kašnjenje) nije moguće izravno povezati sa subjektivnim ocjenama, čak i kad se uzmu u obzir dinamička obilježja video sadržaja (brzina prijenosa i brzina okvira). Pojedini parametri, kao i pozicioniranje njihovih vrijednosti, imaju različite učinke na subjektivnu ocjenu kvalitete videa. Njihov zajednički utjecaj je složen i nelinearan te zahtijeva daljnja istraživanja.

A Multi-Dimensional View of QoE: the ARCU Model

Lea Skorin-Kapov*, Martín Varela†

lea.skorin-kapov@fer.hr, martin.varela@vtt.fi

***Abstract*—Understanding and modeling the wide range of influence factors that impact end user Quality of Experience (QoE) and go beyond traditional Quality of Service (QoS) parameters has become an important issue for service and network providers, in particular for new and emerging services. In this paper we present a generic ARCU (Application-Resource-Context-User) Model which categorizes influence factors into four multi-dimensional spaces. The model further maps points from these spaces to a multi-dimensional QoE space, representing both qualitative and quantitative QoE metrics. We discuss examples of applying the ARCU Model in practice, and identify key challenges.**

I. Introduction

Quality of Experience (QoE) has, as of late, become a fashionable research topic. So much so, that a significant portion of work related to *Quality of Service* (QoS) in the literature also carries the "QoE" moniker. QoE, however, is a markedly different concept from that of QoS, and it goes beyond the scope of much of the current QoE literature. For the most part, the current usage of QoE refers to the perceptual quality of multimedia applications. Granted, for multimedia applications, perceptual quality is a very important component of QoE. However, QoE is a multi-dimensional concept, and it is not limited to the technical factors which we can measure, be it at the network level or the application level.

Increasingly, service and network providers are looking to identify and model the complex relationships between factors impacting QoE and the actual QoE as subjectively perceived by end users [1] [2] [3]. In addition to well understood QoS and application-level parameters, additional factors affecting QoE include the usage context and intent of usage of the service [4], service content [5], and the users' cultural, socio-economic and psychological state [6]. These, however, are seldom considered together and in depth in most available QoE literature.

In order to understand QoE for any given service and how to instrumentally estimate it, we need to take into account the different factors that affect QoE for the service in question, and map them to the QoE. There are several difficulties associated with this, namely:

- The list of potential factors that affect QoE is very long, and the most relevant factors need to be identified for each service.
- Some of the factors, in particular those related to the context of usage and the user, are difficult, and in some cases impossible, to measure instrumentally.
- QoE is a multi-dimensional concept, and thus the mapping of the quality affecting factors to the QoE is a rather complex proposition.

In this paper, we propose a novel way to model the quality-affecting factors and their relationship to QoE, for different types of services. The proposed model splits factors into different multi-dimensional spaces, according to their type, and establishes a mapping between those factors and points in an also multi-dimensional QoE space.

The rest of the paper is organized as follows. In Section II we discuss related work on this topic. Section III describes the proposed model in detail. In Section IV we discuss the practical issues associated with applying the proposed model to actual services, and provide examples of how the model can be applied. Finally, we conclude the article and provide future research directions in this domain in Section V.

II. Related Work

While the ITU-T defines QoE as the "overall acceptability of an application or service, as perceived subjectively by the end user" which "may be influenced by user expectations and context" [7], a common definition cited by the research community defines QoE as "the degree of delight of the user of a service, influenced by content, network, device, application, user expectations, and goals, and context of use" [8].

Existing studies have proposed classifications of factors impacting QoE, often termed *QoE influence factors*, for various types of multimedia services [9], [1], [2], [5], [10]. While a factor is a characteristic which influences QoE, it is not a part of the perceived QoE itself. Extensive work on factor classification has been performed by S. Jumisko-Pyykkö [11] in the form of a User-Centered Quality of Experience (UC-QoE) model where characteristics of the user, system/service, and context of use are identified as contributing to different experiential dimensions of QoE.

In addition to understanding what impacts QoE, there is a need to understand and model what constitutes QoE, in terms of different subjective and objective quality metrics that can be identified and perceived by end users [12]. Determining the correlation between influence factors and quality dimensions has proven to be a challenging task.

A large number of studies have modeled the correlation between QoS and QoE [13], [2], [14], [15], [16], however often focusing only on overall user perceived quality (often in terms of a Mean Opinion Score, MOS [17]). Wu et al. [6] have gone on to study the correlation of different dimensions of QoS and QoE, in particular for distributed interactive multimedia environments, identifying the degree to which different QoS factors impact different QoE dimensions.

The notion of considering QoE as a multi-dimensional value has been addressed in a number of approaches. In the context of multimodal human computer interaction, S. Möller et al. [18] relate influence factors and performance metrics with QoE aspects (quality dimensions), including e.g., interaction quality, efficiency, usability, aesthetics, utility, and acceptability. Wälterman et al. [19] study quality dimensions related to speech transmission, and further model integral listening quality in terms of the identified dimensions.

The idea of mapping points in multi-dimensional spaces from one space to another has been used in the past in the context of utility-based multimedia adaptation [20], where points in an adaptation space (representing multimedia adaptation operations) are mapped to resource and utility spaces. Such mappings are also used in the scope of the MPEG-21 digital item adaptation (DIA) [21] standard to be used for making multimedia content adaptation decisions.

III. The ARCU Model

In this section, we build on prior knowledge by proposing a generic QoE model independent of a particular service type. We model QoE influence factors as falling into one of the four following multi-dimensional spaces:

1) *Application space* (A): composed of dimensions representing application/service[1] configuration factors. Examples of such factors include encoding, resolution, sample rate, frame rate, buffer size, SNR, etc. Content type is also a key factor to be considered (e.g., in the case of video, action movie with fast scene changes vs. more static news report).
2) *Resource space* R: composed of dimensions representing the characteristics and performance of the technical system and network resources used to deliver the service. Examples of such factors include network performance in terms of delay, jitter, loss, and throughput. Furthermore, system resources such as server processing capabilities and end user device capabilities (e.g., CPU power, memory, screen resolution, user interface) are included.
3) *Context space* C: composed of dimensions indicating the situation in which a service or application is being used. A wide variety of dimensions may be considered in this category, include ambient conditions (e.g., lighting conditions, noise), user location, time of day, and social context. Furthermore, the task (or purpose) related to using a given application is considered. Dimensions representing economic context may also be considered, such as service costs.
4) *User space* U: composed of dimensions related to the specific user of a given service or application. Example factors include demographic data, user preferences, requirements, expectations, prior knowledge, mood, motivation, specific task/behaviour, etc.

As compared to previous classifications, we believe that it is beneficial to distinguish between factors related to the actual application and media configuration parameters, from the network/system resources, as these sets of parameters my be considered and varied independently and by different actors.

The proposed model is illustrated in Fig. 1. Dimensions in each of the spaces may correspond to different types of scales, such as e.g., ordinal, interval, and ratio scales. We denote $\mathsf{ARCU} = \mathsf{A} \oplus \mathsf{R} \oplus \mathsf{C} \oplus \mathsf{U}$, and refer to the ARCU space when considering all QoE-affecting factors. Points from the ARCU space are further mapped to points in a *QoE space*. The QoE space is composed of dimensions representing different quantitative and qualitative quality metrics which can be perceived by an end user (e.g., perceptual quality / MOS, ease-of-use, efficiency, comfort, etc.).

A slight conceptual hurdle needs to be dealt with when considering the quality-affecting factors as dimensions in the ARCU space and the A, R, C and U spaces themselves. While conceptually, all the quality affecting factors can be seen as independent of each other, in practice, there often exists a correlation between different subsets of parameters, both within a space (e.g. loss rates and delays in networks tend to be correlated), and across spaces (for example, using a mobile service is an instance in which the context of usage might create bounds for network resources). This would imply that the spaces themselves are not actually spaces, as they don't have orthogonal bases. We model this by introducing a function $\mathcal{V}$ that defines a set of valid regions in the ARCU space by taking into account these correlations, and conforming to reality.

$$\mathcal{V} : \mathsf{ARCU} \rightarrow \{1, 0\}$$

$$\mathcal{V}(a, r, c, u) = \begin{cases} 1 \text{ if } (a, r, c, u) \text{ is valid} \\ 0 \text{ otherwise} \end{cases}$$

for all $\{(a, r, c, u) | (a, r, c, u) \in \mathsf{ARCU}\}$

The *Mapping Function* (MF) can be considered as a function $\mathrm{MF} : \mathsf{ARCU}_{\mathcal{V}} \rightarrow \mathsf{QoE}$, where $\mathsf{ARCU}_{\mathcal{V}}$ denotes the valid regions of ARCU under the constraints of $\mathcal{V}$, invoking different QoE assessment methods depending on the type of application. In the case of objective quality assessment, it can feed relevant input parameters to standardized (provided they exist) models to determine values for a

[1]We will use the terms application and service interchangeably throughout the paper, unless otherwise noted.

given QoE dimension (metric). In the case of subjective assessment, it will correlate input parameters with user specified QoE.

Following the mapping to a QoE space, we can consider how to then go from a point in a multidimensional space to a measure of integral QoE. The term "integral quality" may be used when the quality due to the totality of quality dimensions (or features) is considered [22]. The overall evaluation of subjective user perceived quality should be based on a weighted, possibly non-linear, combination of quality evaluation metrics (dimensions). If we are using a set of evaluation metrics to evaluate QoE, the issue to determine is how much and in which way each metric contributes to integral QoE.

If we assume that the QoE space is composed of dimensions $q_1, ..., q_n$ with corresponding weight factors assigned as $w_1, ..., w_n$, then we can express $QoE_{Integral}$ as the following

$$QoE_{Integral} = f(w_1 q_1, ..., w_n q_n)$$

Different metrics may be of different relative importance (depending on application purpose / type of application, user task, user preferences, etc.), and hence be assigned different weight factors. For example, an evaluation of the QoE metric "content reliability" is very important for an eHealth application and contributes in large to overall QoE, while evaluation of the same metric contributes to a smaller degree to the overall QoE of a gaming application.

IV. Service Examples

The aim of the proposed model is to provide a systematic and generic view of modeling QoE. A number of challenges need to be addressed related to applying the proposed model in practice, including the following:

- Identification of relevant influence factor dimensions and relevant QoE dimensions for different types of services and applications (e.g., VoIP, streaming multimedia, multi-user networked environments, Web applications, Cloud-based applications, etc.). A challenge related to identifying QoE dimensions will be to cover as many dimensions of user perceived quality as necessary to further enable a reliable estimation of integral QoE.
- Specification of the mapping functions calculating QoE dimensions based on influence factors. In many cases, regression techniques or other machine learning tools such as neural networks (as in [16]) can be used, but the amount of training data required might prove too large for practical application in some instances.
- Specification of integral QoE as a weighted combination of QoE dimensions, taking into account the possibility of different dimensions being represented with different scales. In addition, calculation of integral QoE in the case of a service comprised of multiple modalities, e.g., audio and video (in such cases integral QoE would be considered as a function of the QoE of individual modalities, as studied previously by Prangl et al. [23]).

While more detailed investigation into each of these challenges is out of scope for this paper, we provide an illustrative example set of model dimensions for different service types, as shown in Table IV.

The first example we consider is that of a one-way streaming video service. Relevant dimensions of each of the ARCU sub-spaces are shown in the table. Content type may refer to video sequences differing in Spatial Information and Temporal Information indexes [24]. The characteristics of the device on which the content is displayed are also critical for the user's perception of quality, and are thus also considered. The user's motivation when watching video (e.g. entertainment vs. distance learning) can also play a significant role in how quality is assessed. Example QoE dimensions are listed as being color quality, blurriness, jerkiness, and blockiness. Integral QoE may then be considered as being a function of such dimensions, whose coefficients will be related to the weighted impact of each of the dimensions on integral QoE. For example, a given study may indicate that increased video jerkiness will have a greater impact on integral quality then blockiness.

In the second example, we list input dimensions and QoE dimensions related to a two-way conversational VoIP service. Detailed analysis of factors influencing VoIP quality and the correlation with a set of proposed QoE dimensions can be found in the work done by Wälterman et al. [19], while a mapping of several network- and application-level parameters into conversational quality was done by Couto da Silva et al. in [15]. Wältermann's study shows concrete coefficients (weight factors) assigned to multiple dimensions for narrowband and wideband VoIP, and further used for calculation of integral QoE. For example, of three identified QoE dimensions for narrowband speech transmission, the authors conclude that "discontinuity" is of greatest importance for integral quality, followed by "noisiness" and "coloration".

In the third example, we consider a multiplayer gaming scenario. Application related parameters which are listed are factors specific to networked gaming and / or networked interactive environments. Game mechanics refer to the game design and functional mechanisms. Different levels of cheating protection may be implemented, on one hand securing fair play, while on the other hand in certain case slowing down game play. With regards to system and network resources, input device capabilities play a critical role. Context parameters encompass the situation in which the game is being used. Extensive research on categorizing different user tasks (e.g., trading, peer-to-peer combat, raiding, etc.) in Massively Multiplayer Online Role Playing Games (MMORPGs) and their relationship with network requirements has been reported in [25]. With

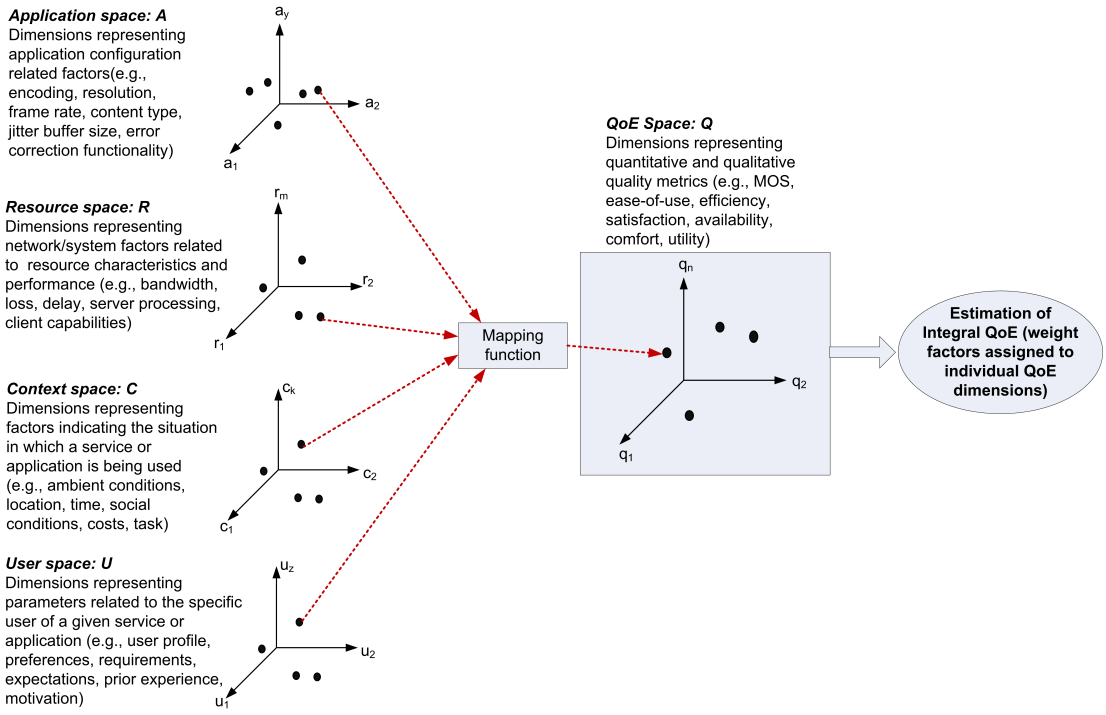

Fig. 1. The ARCU Model

regards to end user parameters, game experience and player motivation are key QoE influence factors. The QoE dimensions listed are in part taken from a categorization of user perceived quality metrics related to networked virtual reality services in general [26] (interactivity, immersion, and plausibility - user acceptance of events as reasonable and valid). A weighting of the individual dimensions would in large part depend on the gaming scenario, for example with user perceived quality of highly interactive combat games relying most heavily on perception of real-time interactivity, whereas a strategy game may rely more on plausibility or immersion.

V. Conclusions and Future Work

The proposed model is intended to provide a basis for the systematic identification of QoE influence factors and understanding of their relationship with different dimensions constituting parts of the overall QoE. Ongoing work is targeted at studying identification and specification of QoE dimensions and integral QoE functions for different types of services, additionally taking into account the temporal nature of QoE. We are further looking to address the issue of modeling QoE in the case of multimedia services composed of multiple media components.

An IP Based Security Threat in Mobile Networks

M. Nagy* and M. Kotočová *

Abstract - Mobile networks based on GSM/GPRS/UMTS and lately LTE standards are slowly becoming a regular part of our lives. We use our brand new smartphones daily, don't even bothering, whether these devices and applications are properly secured. In this paper we briefly explain a security issue that was found in one commercial mobile network. This security issue is most visible on Android OS platform. However, many other mobile networks and mobile platforms may be impacted in certain circumstances. IP addresses of connected end user devices can be determined by an attacker and subsequent application attack could lead to device failure. We examine this problem and propose simple solution on mobile network side and smartphone side.

I. INTRODUCTION

Mobile networks based on GSM (Global System for Mobile communications) standard and its evolutions are probably the most widely used communication networks. According to statistics from Global Mobile Suppliers Association [1], GSM and its evolution had more than 5.2 billion subscriptions worldwide in Q3 2011. Despite this fact, not much extensive security research was done in these networks (except mobile malware and cipher analysis). In this paper we focus on configuration and implementation mistakes made by network operators and network equipment vendors, we examine them and describe their consequences. Finally we propose solutions on network operator side and user side.

II. MOBILE NETWORK ARCHITECTURE

First generation of mobile networks was analog. They offered mainly voice oriented services. As an example we can mention NMT (Nordic Mobile Telephone) in Europe and AMPS (Advanced Mobile Phone System) in America [2].

Second generation (GSM) brought many improvements such as digital communication and global usability of the same handset. Networks of second generation offered voice oriented services as well as circuit oriented data services – Circuit Switched Data / High Speed Circuit Switched Data (CSD/HSCSD) and short messages. Later, packet switched data support was added – General Packet Radio Service (GPRS). Next, some improvements were made to radio interface allowing higher data rates – Enhanced Data Rates for GSM Evolution (EDGE) [2].

Third generation – Universal Mobile Telecommunications System (UMTS) brought new radio access network based on Code Division Multiple Access (CDMA). Some minor changes had to be done in core network as well. Improvements on radio interface were done in third generation mobile networks like in second generation of mobile networks to enable higher data rates – High Speed Packet Access/ Evolved High Speed Packet Access (HSPA/HSPA+) [2].

Nowadays, first Long Term Evolution (LTE) networks are being deployed. They come with new air interface and new packet based only core network called Evolved Packet Core (EPC). These networks cannot be labeled as the fourth generation of mobile networks, because they do not fulfill the required data rates specified in ITU recommendation [3]. This standard should be fulfilled with LTE Advanced evolution step. These networks are omitted from this paper.

Generally a mobile network can be divided to 4 main parts (Fig. 1):

- Mobile Station (MS)
- Radio Access Network (RAN)
- Core Network (CN)
- Operations and Maintenance Center (OMC)

Mobile station is the mobile phone or a data card, which we use daily. It is connected to radio access network, which consists of base stations and logic that controls the base stations. Main logic of the networks is located in core network. Operations and maintenance center is used to configure and monitor the whole mobile network.

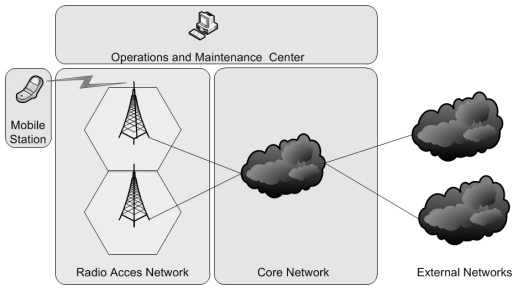

Figure 1. Main parts of the mobile network

In this paper we focus on GPRS/EDGE/UMTS networks. A simplified structure of this network is depicted in Fig. 2, circuit switched part of the network is omitted from this schema because this paper aims at the packet switched part.

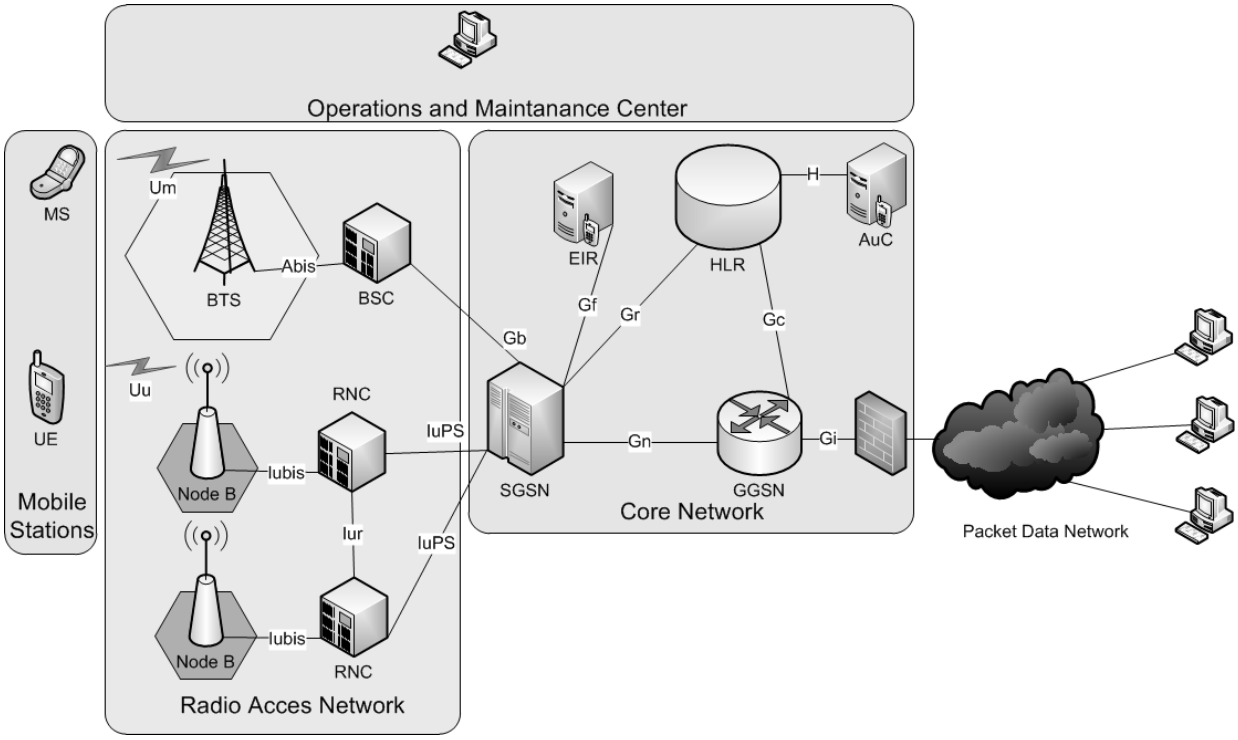

Figure 2. GPRS/UMTS network

Mobile stations connect to the network via Base Transceiver Station (BTS) in GSM network or node B in UMTS network. Radio access network is controlled by Base Station Controller (BSC) in GSM network or Radio Network Controller (RNC) in UMTS network. User data then pass a common core network. First, data go through serving GPRS support node (SGSN), which is responsible for mobility and session management and then they pass gateway GPRS support node (GGSN), which is basically a router. This special router supports TCP/IP protocol stack from the Packet Data Networks (PDN) side and Signaling System #7 stack (SS#7) from the internal network side. Home Location Register (HLR) and Authentication Center (AuC) are used during subscriber authentication. Equipment Information Register (EIR) is used for example to block stolen mobile phones [4].

If a mobile station wants to communicate with other packet data networks, first it has to attach to the network. At this point, mobile network tracks the mobile station, but there is no user data exchange between the network and mobile station. Second step is to activate Packet Data Protocol (PDP) context. A virtual tunnel from GGSN to BSC/RNC is created with this procedure and an IP address is assigned to the mobile phone [4].

IP addresses are usually assigned randomly via Dynamic Host Configuration Protocol (DHCP), although there is an option to have a static address. Static IP address is used when a mobile station needs to be available even with deactivated PDP context. So when data for this mobile station reaches GGSN, GGSN knows to which mobile station is this packet addressed, even it has no IP address assigned yet [4]. GGSN therefore activates its PDP context and transmits this packet.

III. SECURITY THREADS IN MOBILE NETWORKS

We have to mention, that in past two or three years, a lot has been done by the open source community to support experiments with GSM/GPRS based networks. Projects like OpenBTS[5], OpenBSC [6] or Osmocom-BB [7] will help people to understand mobile protocol stack better. However, our paper aims on security issues that can be exploited without special radio hardware (software defined radio, hacked mobile phone or commercial BTS).

We executed a series of experiments on live commercial mobile networks. A common mobile phone connected to Windows and Linux computer as modem was used. From this point of view, the whole mobile network was just another IP network, with its pros and cons. We discovered, that one of the networks, on which security experiments were performed was not properly configured. We explain these security issues in next chapters.

First discovered security issue was the lack of subscriber isolation. It is common practice for most of the Internet service providers to isolate each user, so they have no access to computers of other users, even they are on same subnet. It is not desirable, that these subscribers can communicate directly via local network. Customers can communicate only with gateway. This prevents for example malware spreading across the internal network.

However, such malware spreading was reported in one of Austria's mobile networks [8]. In our examined network this communication was possible as well (Fig. 3). This lack of subscriber isolation has impact to security of users, but it also poses a security risk to network operator. Anybody from the inside of the network can generate

traffic to private address space and this will have following consequences:

- Drain of victim's mobile station battery
- Depletion of victim's prepaid data limit
- Depletion of access network resources
- Depletion of core network resources

It has to be noted, that this kind of attack can be executed only against terminals that actually have an IP address assigned (activated PDP context), else the packets are dropped on GGSN.

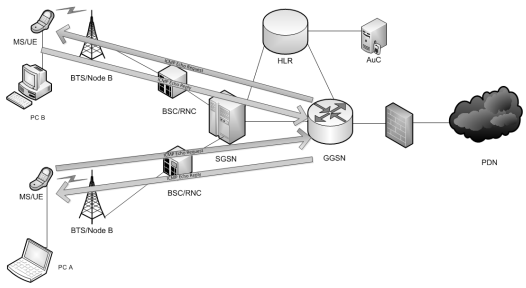

Figure 3. User to user communication without user isolation

Battery depletion means that attacker or malware that generates traffic to victim's IP address is opening a radio channel to the victim by sending the data, therefore spending battery power to receive and process incoming malicious traffic. If victim of this attack has a prepaid data plan from the network operator, the data limit is also consumed by this malicious communication.

From the network operator perspective, this attack is consuming resources on radio access network, mainly radio channels. It also increases load to intermediary devices that are in the path of the malicious packets.

It is a kind of denial of service attacks that no personal firewall can mitigate. Only operator can set up the network to not allow this kind of communication.

According to [9], Google Android based mobile devices activate their PDP contexts right after powered on. It means that mobile phone has an IP address right from the start (if connection to data network is subscribed and properly configured). Android phones are therefore very vulnerable in mobile networks that do not isolate subscribers. Moreover, we discovered, that mobile phones with assigned IP addresses are replying to ICMP echo request messages. Tested mobile phones:

- Sony Ericsson J102 Elm (firmware version: 1231-1917 R7CA061 100619)
- Sony Ericsson K310i (firmware version: prgCXC1250466 R4EA031)
- Sony Ericsson K510i (firmware version: prgCXC1250231 R4EA031)
- HTC WildFire S (Android 2.3.3)
- Nokia E66 (Symbian Series 60)
- iPhone 4S (iOS 5)

This means, that mobile stations with assigned IP address can be easily discovered by simple ICMP echo sweep. ICMP echo capability is a common feature, mainly used to debug network settings. But in this case, we do not see any sense of mobile stations replying ICMP echo request messages. Other mobile platforms do not activate PDP context at their start [9]. On these platforms, the activation of PDP context is triggered mostly by application request, however, with more and more always-online applications, the number of always connected phones will rise. Experiments were performed in GPRS/EDGE and UMTS mode and results were same.

Android phones with assigned IP address are very easy to find in the network, because they are always on-line. After finding a suitable victim by ICMP echo sweep, an attacker can launch an application attack.

After discovering, that phones are accessible in mobile network, we tried a well known network tool nMap [10]. Our aim was to identify the platform of the phone in order to focus the application attack better. nMap was able to guess the platform, however the identification was sometimes not exact. This can be improved in the future by the community, so the attacks against mobile devices would become more precise.

When we were tracing the route from one mobile phone to another (from one PC with mobile phone to another), we tried to open telnet and SSH sessions to IP addresses that appeared in the traceroute log. We found out, that some of these addresses responded to our session initiation with login dialog (Fig. 4). A real attacker would probably continue with brute-force password guessing. However this would be highly illegal and we did not try this approach. It has to be noted, that these devices could have been honneypots used precisely to this purpose.

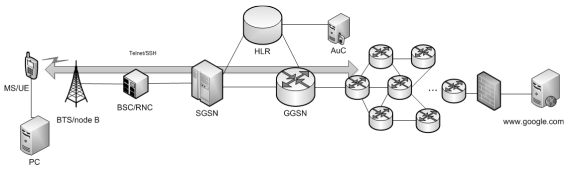

Figure 4. SSH/telnet communication with intermediary devices in the mobile network

We discussed this issue with the network operator and surprisingly some of the devices changed their behavior after some time. Devices, which responded to SSH suddenly don't respond anymore with the login dialog and they close session. Because of these facts, we could assume, that devices, we discovered were not honneypots, but they were real core network devices.

IV. CONCLUSION

All of mentioned security issues were discussed with the network operator. Subscriber isolation is not used due to lack of this functionality on GGSN. Moreover, this kind of communication cannot be denied in the core network behind GGSN, because of other services. Identity of devices, which were responding to SSH and telnet was never revealed.

The user isolation problem should be solved by the operator. But on the other hand, GGSN is an expensive

device and we do not expect the operator to change it in a short time. Therefore user has to secure its device. We propose to install and configure firewall on computers connected to the Internet via mobile network. We suggest using firewalls on mobile devices as well. Installing a firewall should not be a problem on smartphones, but for example Android based phones need root privileges to execute a free firewall application. User can also install iptables binary, but it also requires root privileges. For Symbian, there are commercial applications available, however, Symbian is at the end of life and will be replaced with Windows phone. We are not aware of any free or commercial firewall software or firewall feature on Windows phone.

Moreover, low-end phones can be vulnerable also to old network attacks such as ”Ping of Death” or malformed packed reception (no such phone was found yet). These vulnerabilities can eventually lead to phone failure.

To sum up, firewall applications protect only security of the data stored in mobile phone and the mobile phone itself. The mobile networks remain unprotected against DOS attacks and billing attacks if not properly configured.

Last thing, there is no practical use of ICMP echo functionality in mobile stations. It just exposes mobile phone to the attacker. This ICMP echo legacy may be result of copying traditional TCP/IP stack to mobile devices by equipment vendors. All in all, the mobile TCP/IP stack should be modified to fit the needs of a mobile network and its security threads.

Mobile network protection system against fraudulent and unwanted messaging traffic

T. Gojević, K. Matas, M. Skomeršić and M. Žuvanić
Infobip Ltd / Products and Solutions dpt., Zagreb, Croatia

In this paper, mobile network protection system against fraudulent and unwanted messaging traffic is discussed. Application to Person (A2P) messaging traffic is raising every year and with that raise fraudulent and unwanted traffic is gaining momentum as well. Home Location Register (HLR) lookup, Short Message Service (SMS) and Unstructured Supplementary Service Data (USSD) is exchanged between mobile network operators and along with regular traffic, there are also cases of traffic affecting network performance, link utilization and subscriber satisfaction. This paper will, discuss technical, commercial and security challenges of the aforementioned messaging traffic and how mobile network protection system can help to solve them.

Keywords: mobile networks, SMS, HLR, USSD, A2P

I. INTRODUCTION

Total SMS traffic in the world is expected to reach 9.089,3 billion in 2012 from 8.015,5 billion in 2011[1]. Along with the increase in regular Person to Person (P2P) and Application to Person (A2P) SMS traffic, there is also a huge increase in unwanted and fraudulent SMS traffic, and vast numbers of HLR lookups and USSD traffic that is either not regulated or it is used for some other purposes than the one it was created for.

All of the aforementioned trends significantly influence mobile network performance; link utilization and subscriber (dis)satisfaction, which leads to subscriber churn and potential loss of revenue for a mobile network operator (MNO).

To minimize these issues, mobile network operators were looking for a platform, similar to a firewall, to protect their network against various cases of spam, signalling overload, faking inside SS7 signalling parts of the message, theft of identity and unbalanced messaging traffic.

The only way to analyse and essentially stop fraudulent messaging traffic in real time is to integrate an SS7 analysing system directly on the signalling links. This way an MNO is able to detect all unwanted messaging traffic without any delay, which leaves no time for the fraudsters to adapt and change the patterns of behaviour.

II. TECHNICAL BACKGROUND

Standard SMS signalling flow, composed of HLR lookup and followed by SMS delivery, is displayed on Figure 1.

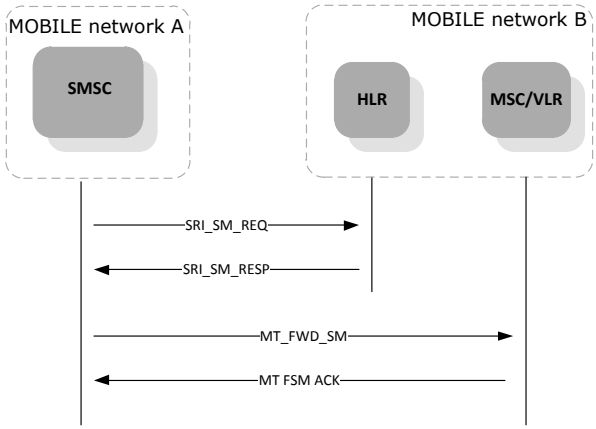

Figure 1.
Standard SMS signalling flow

Standard network initiated USSD signalling flow is depicted below on Figure 2.

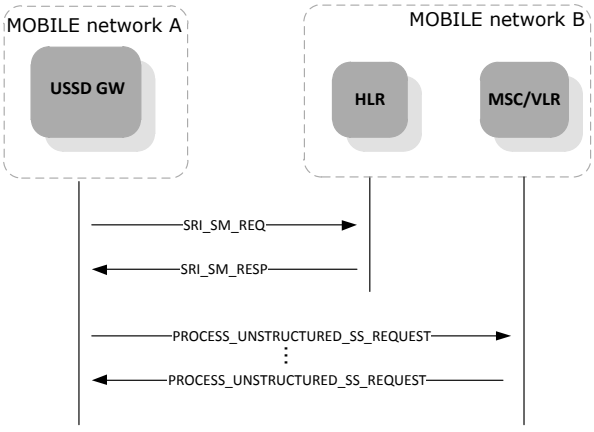

Figure 2.
Standard USSD signalling flow

When sending signalling messages to other networks, mobile network nodes use, among other distinctive marks, addresses – Global Titles (GT) to represent themselves to other network nodes. GT is written in two different layers of an SS7 signalling message, Signalling Connection Control Part (SCCP) [2] and Mobile Application Protocol (MAP) [3]. From its beginning, SS7 was a relatively closed network community; with none or very little access to external parties e.g. service providers. But in the recent years mobile network operators have started to open their networks and provide access to the SS7 signalling network, to external parties. That resulted in usage of HLR, SMS and USSD signalling messages for other purposes that originally intended. Mobile network operators have some very basic and crude ways of stopping unwanted messaging traffic, but there is no bulletproof way of stopping various manipulations on the SCCP and MAP level i.e. changing of Global Titles to bypass basic blocking rules inside network nodes.

Below are various techniques on how to avoid basic blocking rules and cases that are troubling the mobile network operators:

- SMS Fake – occurs when an incoming message (MT_FWD_SM) comes from a foreign SMSC, and terminates at one of the receiving operator's VLR/MSCs. The message bears a manipulated originating address, destination address, or other items.[4]
- SMS spoofing – SMS-MO (coming into operators network from a foreign VLR/MSC, and terminating at operators network SMSC) which bears a wrong originating address, a wrong destination address, or other manipulated items.[4]
- SMS Spam – occurs when the receiving network clients receive unsolicited SMS
- Unbalanced HLR, SMS and/or USSD traffic – occurs when an operator receives more messaging traffic from a certain partner operator than it sends back. This results in a signalling misbalance and higher costs for the receiving operator
- Unsolicited USSD – occurs when an operator clients start to receive unsolicited USSD sessions to their mobile phone screens. USSD is not regulated and there are virtually no benefits for the receiving network

To be able to handle these cases, mobile network operators should use a robust system that is placed directly on the signalling links.

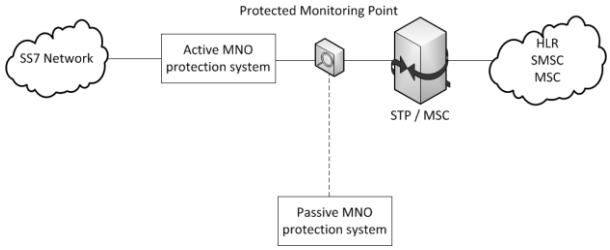

Figure 3.
MNO protection system

As shown on Figure 3, MNO protection system can be deployed in two different ways; *passive*, where the system doesn't interfere with the signalling flow but rather receives a carbon copy of the signal attenuated by -20 or -30 dB (so it doesn't interfere with the original signal) through a Protected Monitoring Point (PMP) [5] and analyses it; *active*, where the system is directly on the signalling link and it can interfere with the signalling flow e.g. stop a signalling unit, or generate a "dummy" response as if was coming from a real network node.

MNO protection system receives the Message Signal Unit (MSU) on the monitored E1 link(s) and analyses SCCP and MAP parts of an MSU is displayed in Figure 4.

```

Figure 4.
MNO protection system

Parts that are in bold and italic should be the same, but by manipulation on the MAP layer, third party that has access to the MNO signalling network is able to bypass basic blocking rules by implementing a so called trusted GT inside MAP layer.

MNO protection system is able to detect any kind of manipulation on either SCCP or MAP layer, along with tracking of**:**

- Incoming and outgoing traffic balances – shows that there are some mobile networks that are sending a lot of A2P and spam traffic. Counting of incoming and outgoing SMS
- Signalling link (over)load – shows Denial of Service (DoS) attempts. Counting of signalling MSU messages in a pre-defined time window
- Excessive HLR lookup requests – shows an misuse of HLR lookups which should be used only for routing purposes. Counting of incoming HLR lookups compared to incoming SMS coming from the same network, measured ratio greater than 2.5 should be considered as fraudulent activity.
- SMS spam – unwanted SMS traffic, not requested by the user. Counting of all incoming SMS that have in their SMS text words or phrases that are on the spam definition list
- Unsolicited USSD traffic – unwanted USSD traffic, not requested by the user. Counting of incoming USSD related signalling MSU messages

III. IMPACT ON MOBILE OPERATORS

Mobile network operators, like mentioned before, are facing issues with misuse of their signalling network and subscriber churn, but there is also one impact most measurable just by a glance at the traffic volume figures. Mobile network operators exchange, on a daily basis, hundreds of thousands or even millions of HLR, SMS and USSD messages. If these figures, when comparing incoming and outgoing traffic, are roughly the same it means that the network is pretty well protected, but if these figures are greatly misbalanced, it means that the MNO is poorly protected.

There is an example of incoming and outgoing messaging traffic for one day in figure 4 and figure 5, where it is very clear that there is a huge misbalance of incoming and outgoing traffic (approx. 350 000 messages during peak time).

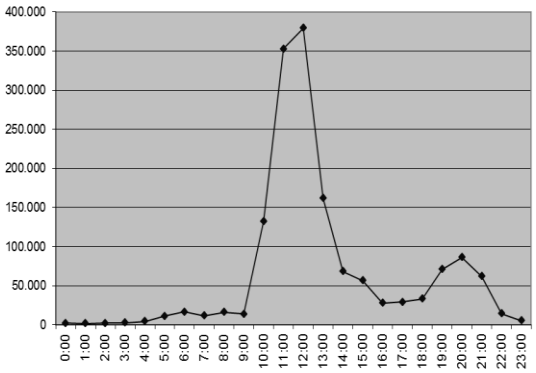

Figure 4.
Incoming messaging traffic

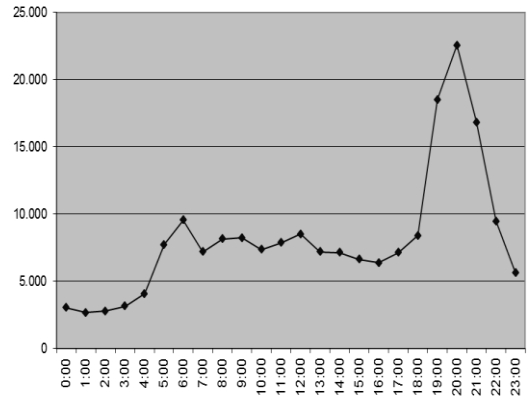

Figure 5.
Outgoing messaging traffic

Mobile operator doesn't have the means to capture and detect these kinds of anomalies in the messaging traffic in real time, but rather this was detected after analysing the Call Data Records (CDR), with at least 24 hour delay.

With a network protection system the following information were at hand immediately:

- Country from where the traffic originated
- Network from which the traffic originated
- Global Title (GT) from which the traffic originated
- Type Of Number (TON) of the senders
- Sender identification

Extracts from the reports that are provided in real time to the mobile network operators, which contain the aforementioned data is shown in Figure 6 and Figure 7.

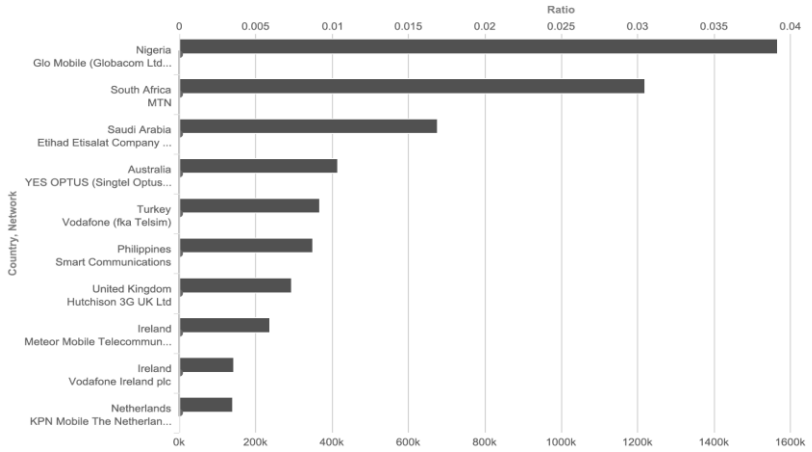

Figure 6.
SMS traffic misbalance report

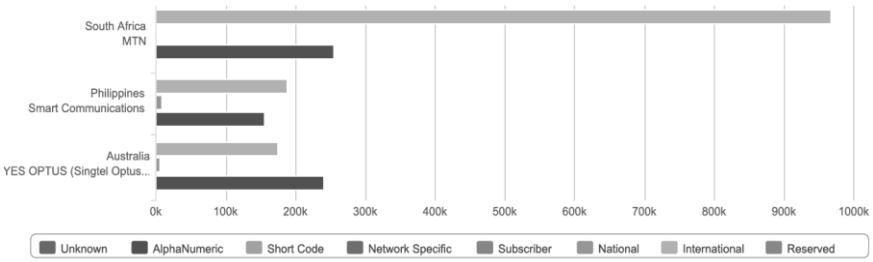

Figure 7.
Sender identification and TON report

Figure 6 shows the SMS traffic misbalance i.e. it shows the ratio of incoming to outgoing SMS traffic, the graph shows that the incoming traffic is much bigger in volume compared to the outgoing traffic. This means that the MNO is receiving a lot of A2P SMS traffic, which is entering the network without his knowledge, and ultimately without financial benefit for the MNO.

Figure 7 shows top networks from where the SMS traffic is coming from. Looking at this graph, the MNO can immediately know what kind of SMS traffic is entering the network e.g. alphanumeric senders (e.g. BARCLAYS BANK), international senders (e.g. 447781234567). By gaining knowledge on what kind of traffic is entering the network, MNO can better adjust the protection system to block certain type of traffic.

By implementing the mobile network protection system, the MNO can eliminate the entire traffic with alphanumeric senders, international senders that repeat themselves, Global Titles which are used for A2P traffic exclusively, SMS fraudulent traffic and SMS spam. SMS spam and unwanted A2P traffic are toughest to detect and the mobile network protection system needs to be updated regularly to maintain a high rate of detection of 80 up to 87% of the aforementioned cases

IV. CONCLUSION

This paper addresses potential threats and risks that are rising along with the raise of global messaging traffic, especially A2P, and gives an example of how those threats and risks could be mitigated with a network protection system. Not only that the network protection system would help mobile network operators to gain real time insight on what is happening on their signalling links, but it could also help them protect their end customers, influence the regulators to improve the deficiency of relative laws and regulations [6] and ultimately operators could protect their revenue too.

Abstract – The mobile ad-hoc networks (MANET) having features like self organizing, working as router and dynamic topology. In MANET, nodes are limited resources like bandwidth, battery power and storage space. Denial of service (DoS) attacks is common place in mobile ad hoc networks. As compared to wire line DoS attacks there is lack of research for DoS attack in the MANETs. DoS attack is an event that eliminates a network's capacity to perform its expected function. MANET is vulnerable of different types of DoS attack in which packets are not transfer to the next node. In this paper we examine DoS attacks in MANETs.

Keyword: DoS attacks, Mobile Ad-hoc Networks, Security, Routing Protocols

I. INTRODUCTION

Mobile ad hoc networks are multi-hop wireless network. It is dynamically formed amongst groups of mobile users having wireless network. It has different characteristics such as lack of centralized administration, distributed cooperation, changing topology and requires no existing infrastructure. Without router or access point wireless clients connect directly together. Nodes with ad hoc networks are mobile and they communicate with each other within the radio range through wireless links. There are different researches in MANET such as routing, power management, bandwidth management, radio interface and security issues. There are different applications of mobile ad hoc networks such as tactical networks, emergency services, commercial and civilian environments, home and enterprise networking, education, entertainment etc.

Security services for MANET are authentication, availability, confidentiality and integrity to the mobile users. The security solution should provide complete protection to the entire protocol. Security in MANET is in different layers such as application layer, transport layer, network layer, link layer and physical layer. MANET is suitable for applications such as military battlefield, emergency rescue etc. The paper is organized like this in section II routing protocols, section III security attacks in routing protocols, section IV classification of DoS attack detection scheme and finally section V concludes the paper.

II. ROUTING PROTOCOLS

Routing is an activity or a function that connects a call from source to destination in the network [1][2]. Routing concepts involves two activities: determining optimal routing paths and transferring the packets through on internetwork. Three general categories of routing protocols are proactive, reactive and hybrid routing protocols.

1. Proactive (table-driven) Routing Protocol:

The proactive routing is also called table-driven routing protocol. Mobile nodes periodically broadcast their routing information to the next node. Each node needs to maintain the records of the adjacent and reachable nodes with a number of hops. Nodes have to evaluate their neighborhood as per the network topology change. Proactive routing protocols are Destination Sequenced Distance Vector (DSDV) routing protocol and Optimized Link State Routing (OLSR) protocol.

2. Reactive (On-demand) Routing Protocol:

These protocols are called reactive routing protocol because they are not maintaining routing information if there is no communication. If a node wants to send packet to another node then the protocol searches for the route in on demand and establish the connection in order to transmit and receive the packet. The reactive routing is simply started when nodes desire to transmit data packets. On-demand routing protocols are ad hoc on-demand distance vector (AODV) and dynamic source routing (DSR) protocol.

3. Hybrid Routing Protocol:

The hybrid routing protocol combines the advantages of proactive routing and reactive routing to overcome the defects of the both. Hybrid routing protocols are designed as a hierarchical or layered network framework. Proactive routing is employed to completely gather the unfamiliar routing information and using the reactive routing to maintain the routing information when network topology changes. Hybrid routing protocols are designed as a hierarchical or layered network framework. Proactive routing is gathering unfamiliar routing information and using the reactive routing to maintain the routing information when network topology changes. Hybrid routing protocols are Zone Routing Protocols (ZRP) and Temporally-Ordered Routing Algorithm (TORA).

III. SECURITY ATTACKS ON ROUTING PROTOCOLS

General attack types are threats against physical, MAC and network layers that function for the routing mechanism of the mobile ad hoc networks [3][4][5].

There are two basic types of attacks in mobile ad hoc networks: passive and active attacks.

1. Passive attacks:

This type of attack does not disrupt the normal operation of the network. Detection of passive attacks is difficult to identify because the network operation is normal. The mechanism for solving the passive attack is to use encryption of the data being transmitted. It is difficult for the attacker to get information from the data. Passive attacks are eavesdropping, traffic analysis and monitoring.

2. Active attacks:

In this type of operation, an attacker actively participates and disrupts the normal operation of the network services. A malicious node can create an active attack by altering information in the mobile ad hoc networks. It degrades the network performance. Forms of active attacks are jamming, spoofing, modification, replaying and Denial of Service (DoS). Active attacks are classified into as internal and external attacks.
Internal attack nodes are the legitimate part of the networks. External attacks nodes are not legitimate part of the networks.

Denial of Service Attacks:

The goal of Denial of Service (DoS) attacks is to prevent availability of networks services from their legitimate users [6][7]. The prevention of authorized access to the resources or of time delaying is basic aim. DoS attack has different scenarios. First attack scenario targets the memory, storage space, or CPU of the service provider. Second attack scenario targets energy resources like the battery power of the service provider. The third scenario targets bandwidth. In the first scenario a node continuously sends an executable flooding packet to its neighborhoods to overload the storage space and deplete the memory of the node. In such a situation neighborhood monitoring can prevent such events and exclude such malicious nodes. In the second scenario a malicious node continuously send a bogus packet to a node with the intension to consume the battery energy and prevent the other nodes from communicating with the node. Local monitoring scheme can detect these malicious nodes and prevent the consequences. In the third scenario attacker is located between multiple communicating nodes and wastes the network bandwidths and disturb the connectivity. The malicious node continuously sends the packets to the node with the intention of overloading the network and degradations the performance.

Black hole attack:

It is kind of DoS attack where malicious node can attract all packets by pretending shortest route to the destination [8][9]. It drops all traffic destined for that node when traffic is received by it. The effect of this attack completely degrades the performance of the network because the destination node never receives any information from the source. The access to the information is denied.

Cooperative Black hole attack:

It is a type of black hole attack when multiple black hole nodes are acting in a coordinated manner with each other: e.g.black hole node B1 cooperates with another black hole node B2 in the next hop.

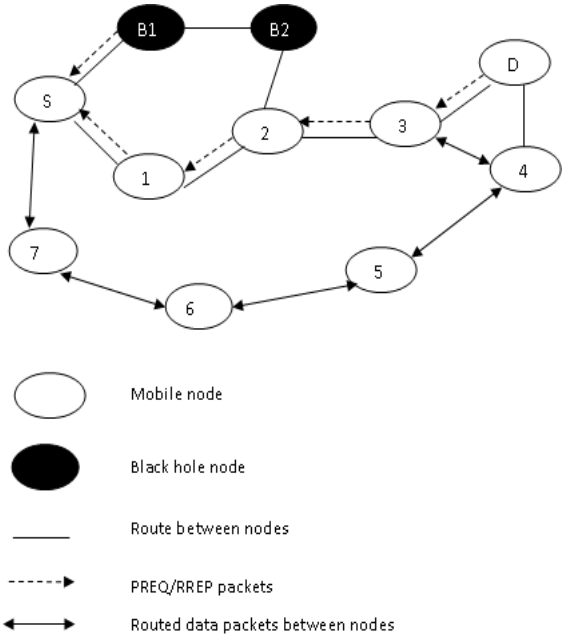

Figure 1. Cooperative black hole attack

Figure 1 shows the source node S, destination node D, the black hole nodes B1 and B2 are cooperating to each other and working as a malicious node. Route Reply (RREP) path is D-3-2-1-S.The attacker node drops the intercepted packets without forwarding them. Route S-B1-B2 is not a secure route.

Gray hole attack:

Gray hole attack is a variation of black hole attack, where some nodes switch their states from black hole to honest intermittently and vice versa. Detection of gray hole attack is harder because nodes can drop packets partially not only due to its malicious nature but also due to congestion.

Flooding Attack:

In the flooding attack, attacker selects many IP addresses which are from outside of the networks [10]. Attacker sends Route Request (RREQ) message with such IP address. Nodes cannot give response RREP packets for RREQ. So reverse path is in the route table of the node will used for longer time. Attacker can select any IP address. Attackers are continuously sending RREQ packets without waiting for RREP, thus flooding the network. The complete communication bandwidth is utilized and the resource of nodes is exhausted at the same time. With the increase the flooding frequency and the number of attack nodes, the network performance drops. Figure 2. shows the route request flooding attack, attacker node A sending route request message to all nodes.

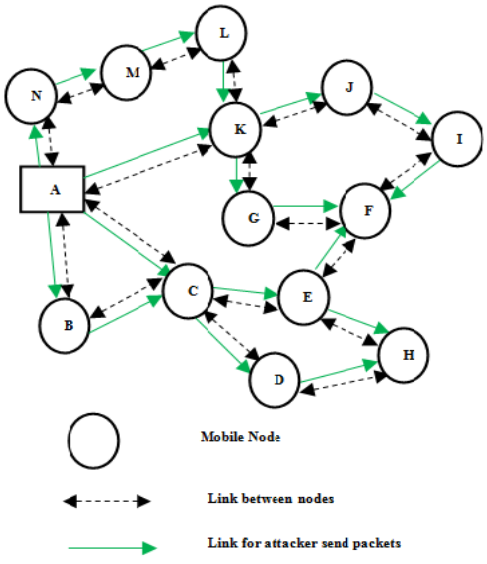

Figure 2. Route Request Flooding Attack

Worm hole Attack:

This is attack in MANET routing. Attacker is connected by high speed off-channel link [11]. This is called worm hole link which is wired or wireless transmission link. Endpoint of wormhole link is equipped with radio transceivers compatible with ad hoc networks to be attacked. Worm hole link attack records the wireless data, forward this data and replays the packet through worm hole link. In the wormhole attack, nodes will not show the true picture of the network and there is effect on the decisions i.e. may be wrong. So wormhole link is unreliable. Figure 3 shows the wormhole link between two networks. X and Y are malicious nodes which make wormhole link between two networks.

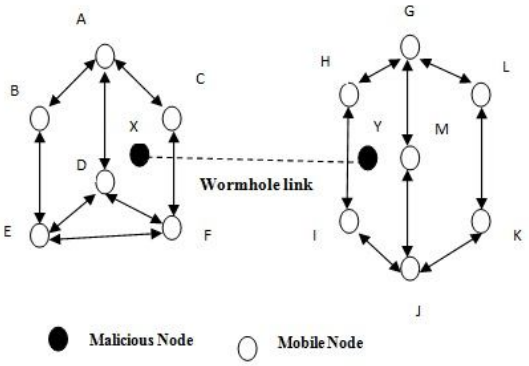

Figure 3. Wormhole attack

Jamming attack:

One of the simplest DoS attack is the jamming of mobile ad hoc networks, sharing a wireless medium [12][13]. In this attack, adversary interface with the set of frequency bands used for communication by transmitting continuous jamming signals. The objective of jammer is to interfere with legitimate wireless communication and to degrade the overall network performance. Due to jamming attacks packets are dropped. Frequency hopping spread spectrum (FHSS) and direct sequence spread spectrum (DSSP) are two commonly used techniques that overcome jamming attacks. Some possible strategies in the jamming attacks are constant jammer, deceptive jammer, random jammer and reactive jammer. Constant jammer continuously emits radio signals. Deceptive jammer transmits semi-valid packets. Here packet header is valid but payload is not use. Random jammer is in two modes, in first mode the jammer jams random period of time and in second mode jammer stop transmission of signal for another random period of time. Reactive jammer wastes resources by jamming as well as target the receiver by trying to input more noise in the packet.

DDoS attack:

Distributed DoS attack is a coordinated attempt made by malicious users to flood the victim network with large amount of data [14]. Resources of the victim network are exhausted and resulting the degradation of network performance. DDoS attack consists of two phases i.e. deployment phase and attack phase. In deployment phase, an attacker installs a tool in the vulnerable nodes. In attack phase, an attacker coordinates a attack against a victim by flooding the unwanted data to capture the bandwidth and resources.

Rushing attack:

Rushing attacker exploits the duplicate suppression mechanism by fast sending route discovery packets [15]. Attacker immediately can forward the route discovery packets by skipping routing steps. This type of attack will be on routing protocol. Malicious node passes packets via multiple paths and quickly reaches to the destination to

reduce routing overhead. A source node is unable to find legitimate route. A set of generic mechanisms [16] that work together defend against the rushing attack. Secure neighbor detection, secure route delegation and randomized ROUTE REQUEST forwarding are set of mechanisms.

JellyFish attack:

This is a denial of service type of attack, which is targeted against closed-loop flows such as TCP [17]. JellyFish attack is following the routing and forwarding protocol specification. This is passive type of attack which is difficult to detect. It is responsive to the network conditions like delay and packet drop rate. It is targeting end-to-end congestion control.

Behavior of JellyFish attacks are

1. **JellyFish Recorder Attack:**

   In this attack JellyFish nodes are behaving like malicious nodes and reorder packets. Such type of re-ordering of packets having zero goodput, but all packets is transmitted.

2. **JellyFish Periodic Dropping Attack:**

   In this attack, attacking nodes drop all packets for short duration. This kind of periodic dropping is possible at relay nodes. JellyFish chooses the duration is long to result maximum losses. In the long duration packet dropping attack is maximum. Throughput may be reduced zero even for small duration.

3. **JellyFish Delay Variance Attack:**

   This attack is high delay variation reduce the TCP throughput. Attacking node randomly delays packets without varying the reorder of packets.

IV. CLASSIFICATION OF DOS ATTACK DETECTION SCHEME

Sr. No.	Name of attack	Solution / Security Mechanism
1.	Black hole attack	1. Satoshi Kurosawa [18] proposed scheme using dynamic training method in which training data is updated at regular time intervals. This method is effective for detecting black hole attack. 2. Time-based Threshold Detection Scheme [19], 3. Random Two hop ACK and Bayesian Detection Scheme [20]. 4. Resource-Efficient Accountability (REAct) [21] scheme is reactive misbehavior detection. 5. Detection, Prevention and Reactive AODV (DPRAODV) [22] is using dynamic threshold value. 6. Next hop information scheme [23] is having a parts detection and reaction 7.Nital Mistry's solution for security against black hole attack [24] 8. CBDS-Cooperative Bait Detection Scheme [25] is a mechanism to detect malicious nodes black, gray and cooperative black hole attacks.
2.	Cooperative black hole attack	1.Zho Min [26] Proposed mechanisms, Message Authentication Code (MAC) and Pseudo Random Function (PRF) is hash based for identifying multiple black hole attack and discover safe route. 2. Data Routing Information (DRI) and cross checking [27] is a solution to detect the cooperative black holes. It modified the AODV protocol to get the methodology. 3. Data Routing Information (DRI) table and cross checking using Further Request (FREQ) and Further Reply (FREP) [28] to identify the multiple black hole nodes. Simulation shows better performance than other solutions. 4. Distributed Cooperation Mechanism (DCM) [29] to solve the Collaborative black hole attack. 5. Hash based scheme [30] is defending method to generate node behavioral proofs. It involves the data traffic information within traffic. 6. Backbone Nodes (BBN) and Restricted IP (RIP) [31] is a mechanism to detect and

		remove black and gray hole attack. 7. Bait DSR (BDSR)[32] is a solution to prevent the collaborative black hole attack. 8.CBDS-Cooperative Bait Detection Scheme [25]
3.	Gray hole attack	1.CBDS-Cooperative Bait Detection Scheme [25] 2. Backbone Nodes (BBN) and Restricted IP (RIP) [31] 3. Propose [33] to use aggregate signature algorithms to produce evidence on forwarded packets. It is tracing malicious nodes by using evidence.
4.	Flooding attack	Flooding Attack Prevention (FAP) [10] is resisting the flooding attack. It is composed of two techniques which are neighbor suppression and path cutoff.
5.	Worm hole attack	Defence against Wormhole (DaW) [11] security model for detection and defense mechanism against wormhole attack.
6.	Jamming attack	1. Propose [12] a new method of detection of jamming attack by the measurement of error distribution. 2. Loukas Lazas [13] examined jamming games in random access-based MAC model and evaluated the effects of stochastically varying packet traffic on jamming attacks.
7.	Distributed DoS attack	Proposed [34] statistical filtering for Distributed DoS (DDoS) attacks in MANETs without any filtering mechanism. It explores and understands the effects of DDoS attacks on the performance of the network.
8.	Rushing attack	Rushing Attack Prevention (RAP)[16] applied on existing on-demand routing protocols to prevent rushing attack.
9.	JellyFish attack	Design and study JellyFish attack [17] is targeted against closed loop flows such as TCP.

V. CONCLUSION

In this paper, we studied DoS attacks in mobile ad hoc networks. This attack periodically drop packets that they are expected to forward. We studied black hole attack, cooperative black hole attack, gray hole attack, flooding attack, worm hole attack, jamming attack, DDoS attack etc. We studied the defense mechanism for different types of attacks. This type of attack may lead to degrade the performance of the network. There is need to develop efficient security mechanism and secure routing protocols for avoiding different types of attacks.

ACKNOWLEDGEMENTS

We would like to thanks Erausmus Mundus 'Mobility for Life' under the Erausmus Mundus External Cooperation Window Lot 11 for supporting the research work. We would also thanks to Prof. Ramaji Prasad coordinator of Erausmus Mundus 'Mobility for Life' program. Abstract – In this article we explain approach in using Access Performance Manager System (APM) for analyses of ADSL lines in production of broadband (BB) Operator. Results of monitoring and optimization are shown. In our case optimization is done by DAO subsystem. We compare results of two Operators with the same goal to maximize service availability with minimum decrease of service characteristics, specially speed in downstream. APM has purpose for monitoring of all performances of BB system as well as interdependency of lines. APM monitoring and optimization of line parameters is based on changing of End User Profiles and using line testing mechanism integrated in DSLAM devices. APM is designed around a selection of configurable batch jobs that store vital Line Test (SELT and Loop Diagnostic) and DSL-link parameters in the APM database. By selecting the appropriate view, it is possible to follow and understand faulty behaviour in detail. APM is also equipped with a real-time view that is essential when troubleshooting on a per-line basis or when re-configuring a DSL link online.
Support for equipment/DSLAM of other vendors than Ericsson is also implemented in APM.
APM offers several tools that are designed to solve different problems in a DSL-based network.

I. INTRODUCTION

Broadband Access Networks - General
Through xDSL and FTTx technologies the Broadband Access solutions offer operators Ethernet based access for voice, video and data services, for example VoIP, High Speed Internet Access, IPTV, etc.
Figure 1 below presents the overview of the BBA network architecture.

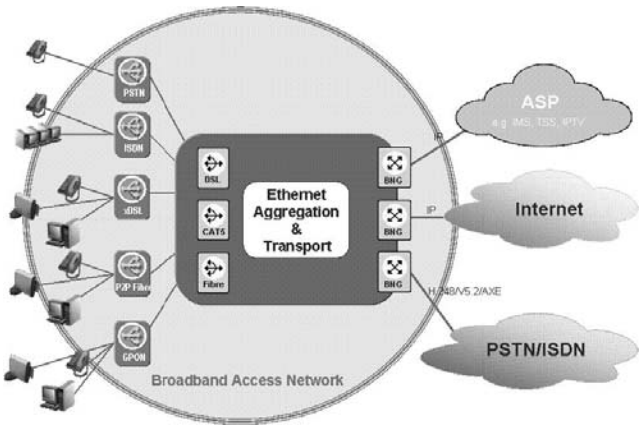

Figure 1 Broadband Access Network Solution Overview

Main purpose of this article is to describe APM product and results of monitoring and optimisation of broadband lines in two Pilot Projects and compare results.
Generally Pilot Projects where organized in two phases: implementation of the system and monitoring, and than optimisation according defined constrains.
APM is a product aimed at detecting errors on the line and improving DSL line quality. APM 1.1 was selected for this pilot projects.
The purposes of the Pilot Project are:

- Demonstrate the utility of the tools comprised within the APM system
- Test the system in a real-life network
- Test the DAO functionality on lines with subscriber traffic

Operator1
The pool of lines under test at Operator 1 (O1) was made up of 2 ECN330 running as EDN288 DSLAMs, which gives a total of about 600 lines, all running EDA 4.1 software. All the embedded nodes under the ECN's are EDN312x running ADSL, ADSL2 or ADSL2+.

The 2 nodes include 600 active lines:

- 270 lines that run IP-TV service
- 330 lines that run Internet service

The test period was structured as follows:

- Monitor the lines and use results from the last 5 days to extract the list of faulty lines
- Automatically apply DAO on the faulty lines
- Monitor the lines after DAO has optimized them

In the paper are presented results obtained for the 100 lines that were under optimization process:

- APM found a new better profile for 41 lines
- APM detected the current profile as being best for 40 lines
- APM could not find a good enough profile for 19 lines

The current document focuses on the 41 lines where APM has found a better profile and outlines the customer benefits with respect to that.

Operator 2
The pool of lines under test at Operator 2 (O2) was made up of 2 ECN330 running as EDN288 DSLAMs, which gives a total of about 450 lines, all running EDA 4.1 software. All the embedded nodes under the ECN's are EDN312x running ADSL, ADSL2 or ADSL2+.

The 2 nodes include 450 active lines:
- 130 lines that run IP-TV service
- 320 lines that run Internet service

The test period was structured as follows:
- Monitor the lines and use results from the last 5 days to extract the list of faulty lines
- Automatically apply DAO on the faulty lines
- Monitor the lines after DAO has optimized them

In the paper are presented results obtained for the 97 lines that were under optimization process:
- APM found a new better profile for 40 lines
- APM detected the current profile as being best for 37 lines
- APM could not find a good enough profile for 20 lines

We proposed that, for each main profile, there should be alternative profiles with optimal SNR, INP and delay values. Alternative profiles created according to the TR-176 recommendation.
Original profiles are not optimal for all lines because:
- Fixed data rate has been used.
- Some profiles can not correct errors because INP and delay are not used or they have incorrect values.
- Maximum SNR margin is equal to the target SNR margin and that can increase number of errors.

II. SYSTEM DESCRIPTION

The Access Performance Manager (APM) is a collection of tools for monitoring and analyzing DSL and POTS lines behaviour ranging from individual twisted pair lines to entire copper plants on site level. APM logs and stores any operation initiated from APM application on a per process basis allowing keeping track of changed behaviour in the local loop. New bandwidth demanding triple play services, such as high-speed Internet, high-definition IPTV and IP telephony, place high requirements on the access network. When providing these services over DSL it is of great importance to minimize service interruptions, that is, keeping the adequate Quality of Service. As these services put pressure on the DSL layer in terms of capacity as well as BER and delay, a reliable and "healthy" link can only be guaranteed if the tools that are used give room for proactive measures. The primary purpose of APM is to test lines on Access Nodes from the IP Access Network and store the results into the database. The results are submitted to the Web clients either as tables or as graphs. APM has built-in functions to analyze problems arisen on the DSL and POTS lines and present possible diagnostic information.
The inventory of third party product network can be imported through an XML file.
FLT is a tool in APM to locate the faulty and low performance lines in the plant. The purpose of the Fault Localization Tool is to provide the operator with means to inspect and test the network as well as make post analysis of data collected.
It uses the following six test methods:
• Line Monitoring
• Single Ended Line Test (SELT)
• Loop Diagnostics Test
• Noise Test
• Narrowband Test
• Line Driver Integrity Test

1) Technical characteristics of the system
Configuration of the APM system is shown on Figure 2. APM is based on modular concept shown on Figure 3.
Modularity is ensured by using following components:
FLT (Fault Localization Tool)
- Normal network operations
- Installation support
  - SELT (NB, BB)
- Module Domain (Real-time operations)
  - Non-interrupting (Primitive Monitor)
  - Interrupting
    - SELT (NB, BB)
    - DELT
    - Line driver test

- DAO (DSL Automatic Optimizer)
  - DSL stability optimisation
  - Service optimisation
- OVT (Network Overview Tool)
  - Network overview
    - Topology
    - Capacity, Performances
  - Statistical analyses
    - Aggregation Statistic
    - Co relational analyses

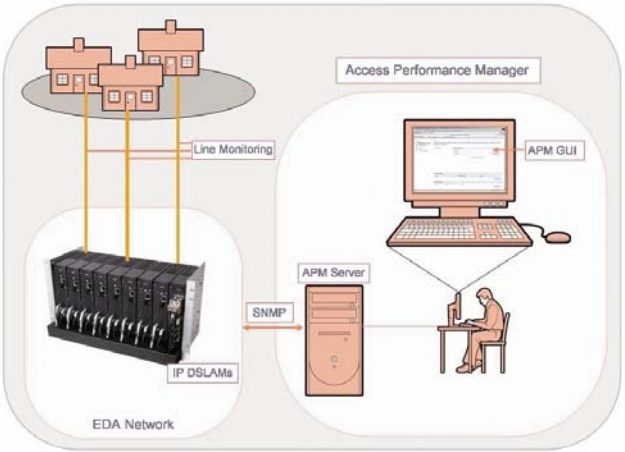

FIGURE 2
APM SYSTEM

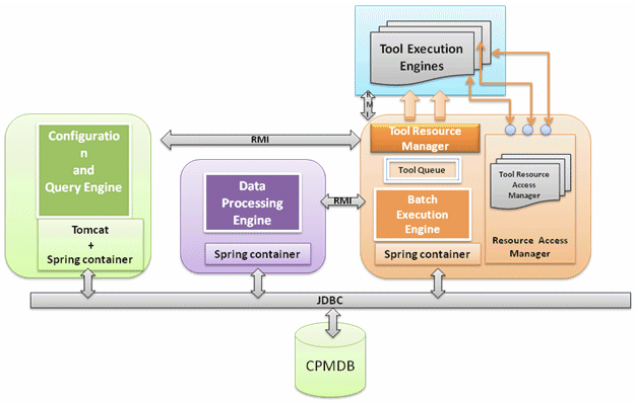

FIGURE 3
APM installed with Distributed Architecture

Methodology

2) Initial Monitoring

The monitoring period was of 5 days, at 1 hour intervals. This gave 120 monitoring samples for each line under test. This monitoring was used to build up a list of faulty lines that were handed over to the DAO.

3) Thresholds

The report has been made using two sets of thresholds, as shown in Table 1. The two sets of thresholds will be referred to as S1 and S2

Threshold set #1 (S1)	**Threshold set #2 (S2)**
DELTA_UAS_DS ≥ 5 counts/hr	DELTA_UAS_DS ≥ 1 counts/hr
DELTA_ES_DS ≥ 40 counts/hr	DELTA_ES_DS ≥ 5 counts/hr
DELTA_SES_DS ≥ 5 counts/hr	DELTA_SES_DS ≥ 1 counts/hr
DELTA_INITS_L_DS ≥ 1 count/hr	DELTA_INITS_L_DS ≥ 1 count/hr
SNR_MRGN_DS 3 ≥ counts/hr	SNR_MRGN_DS ≥ 1 counts/hr

TABLE 1
Threshold sets for comparative report

4) Comparative report

The comparative report will show the difference between the final monitoring and the initial monitoring periods for the group of lines optimized by the DAO.

The comparative report is taking into account the following parameters:

- SES downstream
- Init restarts
- ES downstream
- UAS downstream
- SNR margin
- Mean data rate

The comparative report will focus on these 100 lines that were optimized and describe the change in behaviour before optimization and after optimization monitoring periods.

5) Final monitoring period

The monitoring period was of 5 days, at 1 hour intervals. This gave 120 monitoring samples for each line under test. This monitoring was used to illustrate the effect of DAO with respect to line performance.

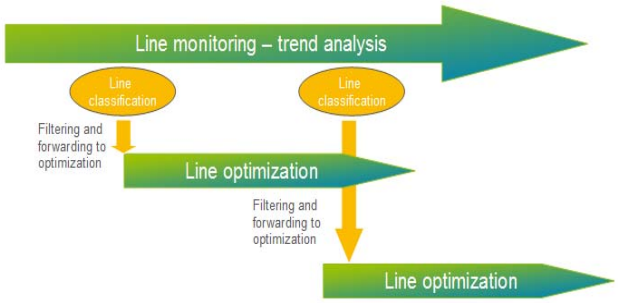

FIGURE 4

On Figure 4 is shown that line monitoring is continuous process. Line classification is prerequisite for line optimisation.

At Figure 5 is shown an example of IP Access Network that uses APM for testing, diagnosing, monitoring and optimisation. It is important to notice that Ericsson systems EDA 1200, EDA 2530 and EDA 1500 (GPON) are supported as well as access nodes of other vendors.

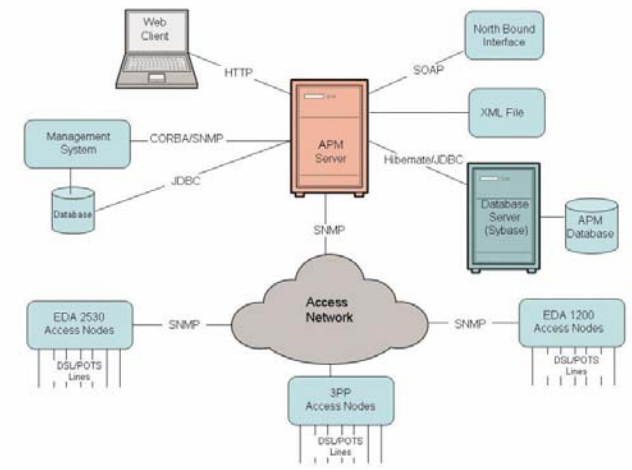

FIGURE 5
Example of IP Access Network that Uses APM for Testing and Diagnosing

III. PROCESS DESCRIPTION

1) Procedure

Due to configuration settings on the test system, APM has selected 100 of the 109 lines detected as faulty for further optimization.

Line monitoring is a pre-requisite for the DAO and results from line monitoring are used for line classification. In our case FLT is collecting parameter samples every 1 hour Parameters to be collected during line monitoring are:

- Initialization attempts
- Severely error seconds downstream
- Error seconds downstream
- Unavailable seconds
- SNR margin downstream
- Data rate downstream

Line classification is an offline process based on the data fetched from the APM database

Line classification procedure:

For each of the parameters above (UAS and Data rate excluded) a threshold value and a threshold percent is needed. For counters the threshold value is of x counts/hour (ES, SES) or counts/day (Init restarts) or dB (SNR); samples with values higher than the threshold are marked as faulty. If more than y% of samples within the last 1 week are crossing the above mentioned threshold then the line is marked as faulty.

DELTA_ES_DS Difference between 2 consecutive samples	counterThresholdPercentage	10%
	thresholdValue	40 counts/hr
DELTA_INITS_L_DS Difference between 2 consecutive samples	counterThresholdPercentage	17%
	thresholdValue	1 count/hr
SNR_MRGN_DS	counterThresholdPercentage	20%
	thresholdValue	3 counts/hr
DELTA_SES_DS Difference between 2 consecutive samples	counterThresholdPercentage	10%
	thresholdValue	5 counts/hr

Table 1a)

The criteria shown in Table 1a) were used to classify the lines

Figure 6 shows details related with classification and optimisation flow.

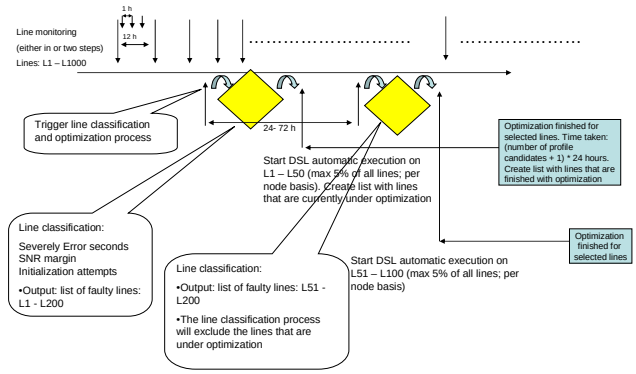

FIGURE 6
Figure shows details related to the classification and optimization flow.

Service Classification

Service Classification is derived from Line Monitoring results.

In service classification three entities are displayed.

• Line Quality (LQ)

It depend on the parameter LQE

LQE >=0.75 ->> Good

LQE >= 0.5 && LQE < 0.75 ->>> Should be improved

LQE < 0.5 Performing badly

• Line Stability (LS)

It depend on the LSE value.

LSE =1 ->> Stable

LSE =0 ->> Unstable

• Service Qualifier (SQ)

It depends on the SLI parameter.

SLI = 1 HDTV Supported

SLI = 0.75 SDTV Supported

SLI = 0.5 IPTV Not Supported

SLI = 0 Line needs optimization

Line optimization is the process of changing the line profile in a controlled way with a view to find the best profile for the given line. Line optimization process requires the following as pre-requisites:

-End-user profiles (regular and fault repair) must be defined into the Management system and then imported to APM.

-Logic for optimization process regarding changing of End-user profiles must be defined into the APM.

-Service Qualifiers specifying the quality norms (thresholds) for the lines should be defined into the APM system.

Optimization flow goes as follows:

1. Line has been forwarded for optimization
2. APM reads the current profile on the line
3. APM selects the flow where the start profile is the current profile on the line
4. APM tries all profiles pertaining to the flow above and finds the best candidate

Each profile candidate is assessed during a period of 24 hours (called time window) that is made up of typically 24 monitoring periods of 1 hour coupled with some decision points over entire time window the mean value of the quality of service parameters should be below and the mean value of data rate and delay should be above the specified threshold in order to make the candidate qualify for the best candidate selection.

IV. PRESENTATION OF RESULTS

Operator 1

Impact of changes on all 576 lines for Operator1 is as follows:

Mean Init restarts per day 22,14%, Mean SES per hour 75,17%, Mean UAS per hour -0,89%, Mean ES per hour 60,08%, Mean data rate 0,78%.

Table 2 shows the overall improvement for the lines optimized during the Project for both operators. As the table shows, the QOS on the access level showed quite a good evolution, the overall ratio between new and old values ranging between 20% (UAS) to 90% (SES) at the expense of loosing only 0.7% in data rate. This small data rate decrease is the penalty of using protection on the lines and is a stabilization cost.

Operator 2

For Operator 2 we have following achievement:

Achieved good optimization of the quality of service parameters at the expense of data rate reduction by only 8%
Decrease of the mean Severely error seconds count per hour for 94%
-> Lowered impact on service interruption
Decreased the initialization restarts for 78%
-> lowered the line instability due to spontaneous line restarts

	Before	**After**	**Overall Changes/ improvement**
Operator 1 (O1)			
Mean Init restarts per day (for all optimized lines)	26.28	5.45	79.26%
Mean SES per hour (for all optimized lines)	14.47	1.56	89.22%
Mean ES per hour (for all optimized lines)	277.55	31.89	88.51%
Mean data rate (Mbps)	4.46	4.43	0.7%
Operator 2 (O2)			
Mean Init restarts per day (for all optimized lines)	36,30	7,89	78,27
Mean SES per hour (for all optimized lines)	11,81	0,71	93,98
Mean ES per hour (for all optimized lines)	242,94	51,92	78,63
Mean data rate (Mbps)	3,85	3,55	7,87

TABLE 2

At Figure 7 graph with data before and after optimisation shows considerable improvement of previously explained parameters. It is also obvious that same setup has similar results in two networks in two different countries.

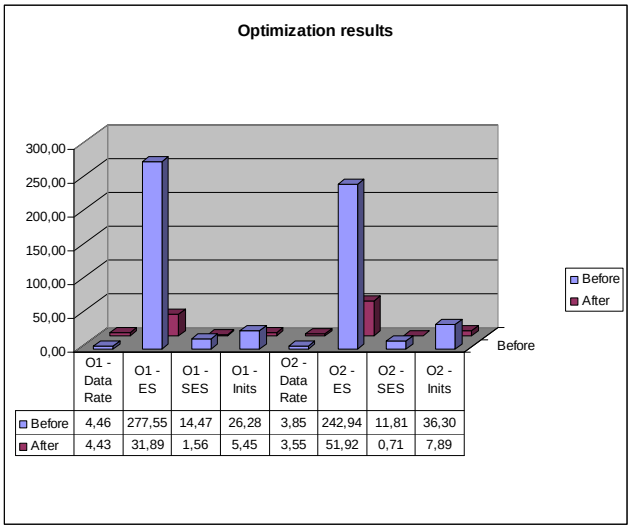

FIGURE 7
Figure shows graph of data before and after optimisation for Operator 1 (O1) and Operator 2 (O2)

V. CONCLUSION

In this article, a technique for optimization of line characteristics by using APM system was presented. APM system was tested on more than 500 lines in the live network using monitoring and line optimization at Operator 1 and about 500 lines at Operator 2. Presented results show us that it is possible to achieve better line characteristics by monitoring, automatic selection of lines according to thresholds and automatic changing of End-user profiles. EUP has been changed with existing NMS System. The changes on the lines where fault repair End-user profiles were applied, were significant and showed representative improvements. As well, improvements were shown on the whole pilot location. This is an indicator that improving some lines on one location (node) has positive feedback on the whole location. Having this in mind it can be concluded that if APM would be applied on the whole network, not all lines would be optimized, but the improvement would be shown in the whole network. Pilot projects in operator's network fulfilled our expectations. It is also confirmed by repeating similar setup at another country at another Operator. Operators are very satisfied with results and plans to deploy APM or similar system in broadband network. With APM system generally operator has collected huge amount of data that enables further analysis.

SOFTWARE ENGINEERING

Archetypes Based Development from the Perspective of Domain Engineering Research Topics

Abstract **- Archetypes Based Development (ABD) utilizes software engineering triptych together with archetypes and archetype patterns. In ABD, the domain is analysed and the domain model is developed by using the product (what), business process (how), organization structure (where), person (who), order and inventory (when), and rule (why) archetype patterns. In the current paper, ABD is evaluated from the perspective of domain engineering research topics proposed by Bjørner in 2007. The evaluation shows that ABD is in accordance with an approved and important domain facets based domain analysis methodology and provides additional insight into the research questions related to its main processes. We also explain use of ABD and domain models designed in compliance with ABD in real life software development. These outcomes indicate that our domain analysis and modelling approach complements Bjørner's domain modelling and together with Test Driven Modeling results in more flexible, customizable, reliable and interoperable software.**

Keywords - Software engineering methodology evaluation, archetypes, archetype patterns, domain analysis, domain modelling.

I. INTRODUCTION

According to the software engineering triptych [1], in order to develop software we have to (a) informally and/or formally describe a domain ($\mathcal{D}$); (b) derive requirements ($\mathcal{R}$) from these domain descriptions; and (c) from these requirements we have to determine software design specifications and implement the software ($\mathcal{S}$), so that $\mathcal{D}, \mathcal{S} \vDash \mathcal{R}$ (meaning the software is correct) holds [2]. Partly based on the ideas of software engineering triptych, we have proposed Archetypes Based Development (ABD) - a business archetypes and archetype patterns based methodology for modelling of business domains, requirements and software ([3], [4], [5]). The main objective of this methodology is to understand and model business domains ("what to do") as they are, without any reference to the software requirements or to the design of any software system.

ABD utilizes software engineering triptych [1] together with archetypes and archetype patterns [6]. In ABD, the domain is analysed and the domain model is developed by using the product (what), business process (how), organization structure (where), person (who), order and inventory (when), and rule (why) archetype patterns. Later this domain model is used in engineering and specification of user requirements and in developing (in the future, hopefully generating) of software.

An important part of a methodology development is its evaluation – systematic determination of quality and significance of the methodology using specified evaluation criteria. The main objective of this paper is to evaluate the ABD in a broader context of the software engineering triptych. We also show how we use domain models designed in compliance with ABD in real life software development to get more flexible, customizable, reliable and interoperable software.

The organisation of the paper is as follows. In Section 2 we present our approach to ABD evaluation. Section 3 is devoted to description of ABD. In Section 4 we describe the usefulness of ABD by describing real life LIMS (Laboratory Information Management Systems) software developments in CBPG (Clinical and Biomedical Proteomics Group) at University of Leeds. In Section 5 we evaluate ABD methodology according to Bjørner's domain engineering research topics. We finalize with conclusions (Section 6).

II. THE APPROACH TO ABD EVALUATION

There exist many evaluation methods, starting from systematic and rigorous application of scientific methods (for example, proving absence of contradictions or redundancies in the methodology), proceeding with comparisons with other recognized frameworks, and finishing with case studies. In the earlier studies, we have evaluated ABD from MDA (Model Driven Architecture), XP (Extreme Programming) and CMMI (Capability Maturity Model Integration) for Development perspectives ([3], [5]). We have also used the case study method applying ABD in development of LIMS software.

In the current paper, ABD is evaluated by comparing it with Bjørner's domain facets [7] based domain analysis methodology according to the domain theory research topics [2] proposed by Bjørner in 2007. Bjørner has numbered the research topics from R1 to R17. From these, we have selected research topics R5...R13, as they are associated with domain modeling – a process which leads to informal, narrative, and formal domain descriptions and which is one of the basic ABD processes. The selected research topics relate to the following steps (facets) of domain modeling: (a) intrinsic; (b) support technology; (c) management and organization; (d) rules and regulations; and (e) human behaviour ([2]). The criteria for this evaluation are that to be really of value, the methodology should be in

accordance with similar approved methodologies, as well as provide additional insight into the research questions related to its main processes. In Section 5, a short analysis is provided for each research question to explore to which extent these criteria are satisfied.

As ABD is a quite extensive methodology, presentation of evaluation in Section 5 is based on references to the overview of ABD and ABD based development in Sections 3 and 4. Another option for the presentation would have been to organise it around the evaluation topics – for example, to present relevant features of ABD directly with each research question. Due to the broad scope of ABD and the volume restrictions of the paper this would have resulted in a presentation that is difficult to understand, does not give a picture of ABD, and is therefore also difficult to follow with respect to evaluation.

III. OVERVIEW OF ABD

ABD is a software engineering triptych [1] based software development process with archetypes and archetype patterns. Business archetype patterns are originally proposed by Arlow and Neustadt [6].

Business archetype patterns by Arlow and Neustadt (product, party, order, inventory, quantity and rule), composed by business archetypes (person's name, address, phone number, etc.), describe the universe of discourse of businesses as it is, neither referring to the software requirements nor to the software design. We analysed Arlow and Neustadt's business archetype patterns according to the Zachman Framework [8] and Bjørner's domain analysis methodology [7]. We also compared these archetype patterns with analysis and data model patterns by Hay [9; 10], Fowler [11], and Silverston [12; 13]. As a result we proposed the refined and enhanced version of business archetypes and archetype patterns [3].

Table 1: ZF Columns with Archetype Patterns.

<table>
<tr><th colspan="6">Business requirements</th></tr>
<tr><th>What</th><th>How</th><th>Where</th><th>Who</th><th colspan="2">When</th><th>Why</th></tr>
<tr><th>Things</th><th>Processes</th><th>Locations</th><th>Persons</th><th colspan="2">Events</th><th>Strategies</th></tr>
<tr><td>Products and services</td><td>Reporting (feedback)</td><td>Organization and organization structure</td><td>Persons</td><td colspan="2">Business events</td><td>Business rules</td></tr>
<tr><td colspan="3">Party AP</td><td colspan="3"></td></tr>
<tr><td>Product AP</td><td colspan="3">Party relationship AP</td><td>Order AP</td><td>Inventory AP</td></tr>
<tr><td colspan="6">Rule AP</td></tr>
<tr><td colspan="6">Quantity and money AP</td></tr>
<tr><td colspan="6">Common infrastructure</td></tr>
</table>

In ABD (Table 1), the independent phenomena, described by (Zachman Framework) ZF columns, are analysed and developed by using product (what), business process (how), organization structure (where), person (who), order and inventory (when), as well as rule (why) archetype patterns. Therefore the ZF columns with archetypes describe "what to develop".

In ABD, we utilize Test Driven Modelling (TDM) [14]. TDM is tied with ZF rows (Table 2) and describes "how to develop". In TDM, we first delimit the scope of phenomena to get a contextual model (according to ZF Row 1). We next specify requirements with unit tests. These unit tests form semantic models (ZF Row 2) of phenomena. By incremental specification and implementation of requirements we get step by step closer to logical (ZF Row 3) and physical (ZF Row 4) models. Logical models are models of phenomena in terms of interfaces (or class designs) and their relationships. Physical models are models of phenomena in some general purpose programming language. Physical models have to satisfy semantic models (ZF, Row 2) specified by unit tests. A detailed model (ZF Row 5) is a model in ready to run byte-code (e.g. CIL in .NET) and a product (ZF Row 6) is a DLL (read model or framework in any executable code) used as embedded DSL for prescribing software requirements or an application used by a customer.

Table 2: ZF Columns with Archetype Patterns.

<table>
<tr><th colspan="2">ZF</th><th rowspan="2">MDA</th><th colspan="5">Abstraction Concretization</th></tr>
<tr><th></th><th>Model</th><th colspan="5">A&AP Domain Requirements</th></tr>
<tr><td>1</td><td>Contextual Scope</td><td></td><td rowspan="6">domain engineering</td><td rowspan="6">domain analysis</td><td>Terms</td><td>Terms</td><td>Terms</td><td rowspan="6">triptych software engineering</td></tr>
<tr><td></td><td></td><td colspan="3">Glossary specified as unit tests</td></tr>
<tr><td>2</td><td>Conceptual Business Semantic</td><td>CIM</td><td>Specs</td><td>Specs</td><td>Specs</td></tr>

<tr><td>5</td><td>Detailed</td><td>Code</td><td colspan="3">Byte-code (CIL) ready to run</td></tr>
<tr><td>6</td><td>Product</td><td></td><td colspan="2">DLL used as DSL in concretization</td><td>Application</td></tr>
</table>

There are (at least) three separated development processes in the ABD (Table 2): (a) Development of A&APs (archetypes and archetype patterns); (b) Development of domain models; and (c) Development of applications.

TDM is utilized in all of these developments. A general purpose programming language is used in the development of A&APs. The target of the development of A&APs is to get the embedded (into general purpose programming language) DSL for development of domains. In development of domains, the A&APs based embedded DSL (API/framework in executable binary code) is used for specifying domain descriptions (contextual and semantic models of domains). The target of the development of domain models is to get the embedded DSL (API/framework in executable binary code) for developing applications. In application development (customizing and hopefully automated generating in future), the domain model based embedded DSL is used for specifying customer requirements.

Following the software engineering triptych [1], we have a domain ($\mathcal{D}$) model specified by using A&APs based embedded DSL. This domain model is then used for specifying customer requirements ($\mathcal{R}$). According to specified requirements, the software (meaning application) ($\mathcal{S}$) is developed (customized and hopefully can be generate in future). With TDM we ensure the correctness of application ($\mathcal{D}, \mathcal{S} \vDash \mathcal{R}$) as much as possible.

IV. REAL LIFE DEVELOPMENT WITH ABD

We use the ABD described in Section 3 in real life LIMS software development in CBPG (Clinical and Biomedical Proteomics Group) at University of Leeds (GP) under the project called MyLIS. LIMS represent the class of computer systems designed to manage laboratory information [15].

In research laboratories, like CBPG, business processes are continuously changing and different research groups within the same research laboratory, sometimes even different investigators in one and the same research group, require different business processes and different or differently organized data. While standardized in some ways, such system for scientists has to be flexible and adaptable so, that there are customizable possibilities to describe data, knowledge and also research methods.

This is why we decided not to develop only LIMS, but decided to develop a software factory for LIMS. By Greenfield, *et al.* [16], the software factory is the domain specific RAD (Rapid Application Development) with frameworks, languages, patterns and tools. When general-purpose RAD uses *„logical information about the software captured by general-purpose development artefacts*“, then the software factory uses *„conceptual information captured by domain specific models*“ [16 p. 564]. Figure 1 illustrates our research and developments towards LIMS Software Factory (SF).

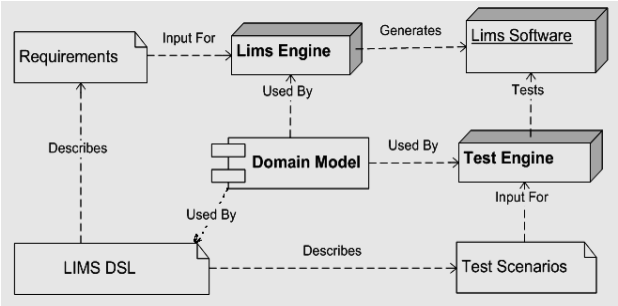

Figure 1. The Architecture of the LIMS Software Factory

Based on the archetypes and archetype patterns based domain model of laboratory, the LIMS SF architecture consists of the LIMS DSL (domain specific language), the LIMS Engine and the Tests Engine. Requirements for the particular LIMS software will be described with the LIMS DSL. The LIMS Engine has to generate the LIMS software according to these requirements. The Tests Engine has to validate these requirements with respect to the domain model of laboratory and has to verify the generated LIMS software. Figure 1 is based on the software engineering triptych (from domain model via requirements to software) [1]. The key point is that all models we are talking about are not only documentation artefacts, but also source artefacts, as common in software factories [16].

Layering is a common technique for complicated software systems [17 p. 17]. Both .Net and Java framework have tools for developing 4-tier software systems [18]. Nowadays 4-tier software architecture is a modification of common 3-tier architecture [17 pp. 19-22]. 3-tier architecture has got a data source layer (accessing data), a domain model layer (defining logic) and a presentation layer (using logic). 4-tier architecture has an additional communication layer (containing and connecting logic).

We are looking for ways to minimize (better to completely avoid) changes in the domain logic and in the data source layers as these changes are risky and time consuming. We are trying to find possibilities to fulfil user requirements only by making changes in the presentation or in the communication layers. It is desirable that these changes could be made by end users even at run-time.

In our understanding, to minimize or avoid changes in the domain logic and in the data source layers, we need a universal domain model that is implemented in the domain logic layer together with supporting database layout and data access layer. This domain model has to be mature, ought not to be changed all the time and it has to be possible to use this domain model to fulfil various user specific requirements for a particular class of software systems.

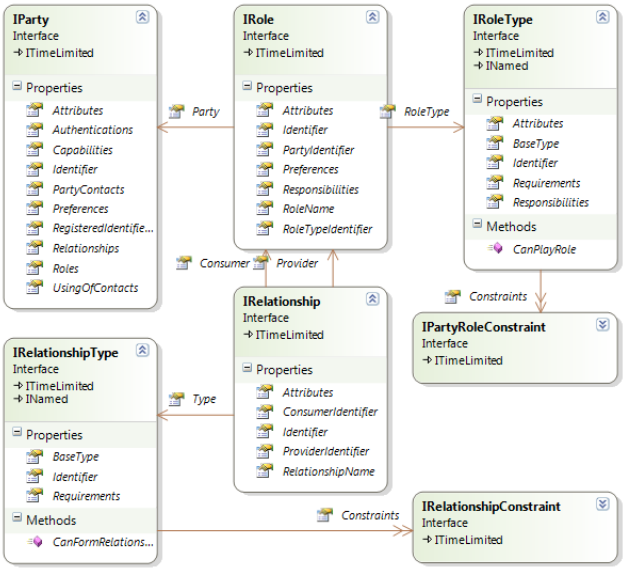

Figure 2. Logical Model of Party Relationship Archetype Pattern

If such domain model (e.g. for clinical laboratory) is available, then in order to make changes in the presentation layer or in the communication layer we need some tools. By using these tools, the user (preferably the end user) has to be able to define and change (preferably at run-time) the formats of user interfaces (web, windows, mobile, etc.) and other electronic documents (printouts, communication protocols, input documents, etc.) according to business requirements. These tools should preferably be supported by DSL that is based on the domain model mentioned above.

In CBPG LIMS developments, the database layout is based only on archetypes and on archetype patterns (Table 1). For example, the medical laboratory has terms patient, physician and MTA (medical technical assistant). However, in the database layout we do not see tables for

patients, physicians and MTAs. Database layout (for patients, physicians and MTSs) is designed using only archetypal concepts of the party archetype pattern (Figure 2).

We use the *single table inheritance* pattern proposed by Fowler [17]. In this pattern, the inheritance hierarchy of classes is represented as a single table which has fields for all properties of various classes. The domain model classes, as well as classes designed according to user requirements (if any), are designed so that they are only concretizations of A&AP classes. We do not have to know all the derived classes before we design database layouts.

As the target is to change requirements and domain models even at runtime, the presentation (rich client, web client) as well as communication (XML document based communication interface between server and client) layer artefacts in CBPG LIMS developments are implemented using reflection [19] (.NET reflection for example). For this the presentation layer uses access modifiers (private, protected, internal and public) for selecting properties of objects to show in user interface. Browsing forms show public read-only and read-write properties but editing forms show only public read-write properties.

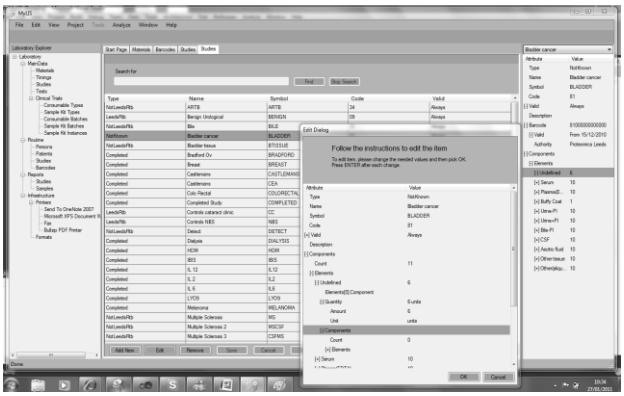

Figure 3. Screenshot of MyLIS user interfacse

For this the UI generator analyses the structure (type and properties) of an object and generates UI according to this information at runtime. We also have a small "language" to describe which properties and in which order to show in UI. Figure 3 illustrates an UI generated in this way.

V. EVALUATION OF ABD

Bjørner's domain analysis methodology [7] is based on domain stakeholders as well as on pragmatically chosen domain facets. Domain facets, proposed by Bjørner in [2], are: (a) *intrinsic*; (b) *support technology*; (c) *management and organization*; (d) *rules and regulations*; and (e) *human behaviour*. Bjørner has numbered the research topics as R1 to R17 [2]. In this evaluation we have selected only related to domain facets research topics R5...R13, as explained in Section 2 above.

A. Research Topic R5 - Intrinsic

Bjørner uses *domain intrinsic* for these phenomena and concepts of a domain which are fundamental to any of the other domain facet (business processes, supporting technologies, management and organization, rules and regulations and human behaviour). For instance, in clinical laboratory the intrinsic can be a *sample*, an *analyser*, a *rack* and a *determination*. These are all products (goods or services) and can be abstracted by product archetype pattern (Figure 4). In archetypes based domain analysis, instead of the term *intrinsic*, we use the term *product* for all of these concepts of domain, which are things and of which we can ask a question "what".

B. Research Topics R6 and R7 – Support Technologies

Support technology is a domain facet carrying out business processes [7]. For example, there is support technology radar, which "observes" flight traffic [2]. The radar technology is not perfect. Its positioning of flights follows some probabilistic or statistical pattern [2]. In archetypes based domain analysis, all business processes and support technologies (also process) are modelled by using business process archetype pattern which metaphor is report or feedback. By using feedback, it is possible to collect information about processes. Similar to movies that emulate dynamics of reality by showing sequences of static pictures, the feedback (progress report) emulates business process dynamics by static "pictures" concerning the business process. Based on *party relationship archetype pattern* (Figure 2), each *progress report* (possibly *from* address *to* address) is a party relationship where a *subordinate* reports to a *supervisor*. With this approach, we have a set of reports which is not perfect, but with some probabilistic pattern describes the whole business process.

The quality control (QC) process in a laboratory is a support technology supporting the main business process (sample determination) of laboratory. QC is similar to the laboratory's main business process. When in the laboratory the main business process is sample testing (some sample parameters are measured) in order to get some information about samples (e.g. reports from analyser to work-area manager), then in laboratory QC procedure QC samples (artificial samples with known parameters) are tested in order to get information about the testing procedure (reports from analyser to QC manager). The QC technology is not perfect, but with some probabilistic or statistical pattern we still can say something about the quality of measurement in a laboratory.

C. Research Topics R8 and R9 – Management and Organization

In archetypes based domain analysis, we strongly separate parties (persons, organizations, artificial agents) from roles (patient, physician, hospital, etc.) these parties are involved with within business domains. We use the *party relationship archetype pattern* for modelling of *management and organization*. With party relationship archetype pattern (Figure 2) it is possible to model quite complicated organization and management structures. When the management structure is a set of binary relationships between roles (posts like manager, MTA, etc.) in which persons are involved, the organization structure is set of binary relationships between roles (e.g.

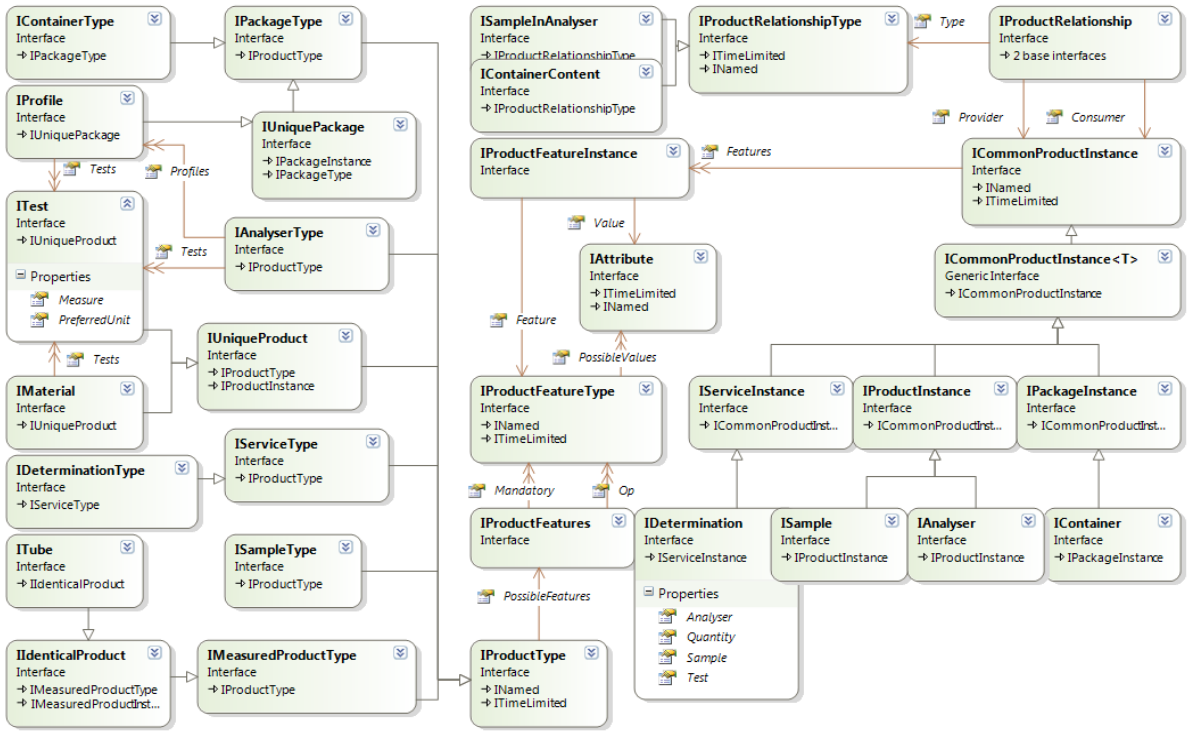

Figure 4. Logical Model of Products in Laboratory based on Product Archetype Pattern

laboratory, hospital, workstation, etc.) in which organizations and organization units are involved. Each role, according to the role archetype (Figure 2), has *requirements for role*, *assigned responsibilities* and *conditions of satisfaction*. These requirements, responsibilities and conditions can be matched with capabilities (Party, Figure 2) – collections of facts about what a *party* is capable of doing.

D. Research Topic R10 – Rules and Regulations

Rules and regulations are prescriptions that have to be followed in order to do business [2]. Rules and regulations are either followed or not. In this sense we can look at rules and regulations as logical statements. In archetypes based domain models, all *rules and regulations* are modelled by using the *rule archetype pattern* [3]. A *rule* in the rule archetype pattern is a constraint on the operation which semantic is defined by sequence of *rule elements* [6]. Rule elements can be *operators* and *variables*. Some variables (Boolean) are *propositions*. Operator is either a Boolean operator (e.g. and, or, xor, not), a quantifier operator ($=, !=, <, >, <=, >=$) or an arithmetic operator. When a *rule* represents some kind of a mask or a pattern, then a *rule context* contains an informational context for the evaluation of the rule. When evaluating a rule, we will get the Boolean value of either true or false.

E. Research Topics R11 and R12 – Human Behaviour

Human behaviour is a quality spectrum (careful, diligent, accurate, sloppy, delinquent, criminal, etc.) of carrying out assigned responsibilities [2]. There are properties for modelling of *responsibilities*, *capabilities* and *conditions of satisfactions* in party and party relationship archetype patterns (Figure 2).

- Capability (*party*, e.g. "Can operate analysers X, T and Z", "Can validate tests")
- Responsibility (*role type*, e.g. "motivating the team", "operating analysers")
- Condition of satisfaction (rule set, *responsibility*, e.g. "average score for staff motivation >= 7 out of 10 on staff feedback")
- Assigned responsibility (*role*, responsibility assigned to the specific party role in specific relationship)

In archetypes based domain modelling, we use party and process archetype patterns for modelling of human behaviour. This means that capabilities, responsibilities and conditions are modelled by party archetype pattern but the monitoring and control of human behaviour, as a management process where supervisor gives periodical feedback to subordinates, we will model by process archetype pattern. This feedback is based on stated capabilities, responsibilities and on stated conditions of satisfaction.

F. Research Topic R13 – Sufficiency of Domain Facets

Instead of domain facets based methodology, we use ZF (Zachman Framework) with archetypes and archetype patterns based methodology [20]. We found that the Bjørner's domain facets based domain analysis method is a special case of the domain analysis methodology based on ZF with archetype patterns (Table 3). For example, the set of intrinsic concepts (basic concepts to any other domain facet) is the subset of all products and services businesses use, buy or sell and can be analysed and modelled using product archetype pattern (column 1);

main business process and related processes using process (progress report) archetype pattern (column 2); organization structure and management using party relationship archetype pattern (column 3); stakeholders and human behaviour using party archetype pattern (column 4); and rules, regulations and scripts using rule archetype pattern (column 6).

Table 3: Archetypes versus Facets based Domain Analysis.

	Column 1	Column 2	Column 3	Column 4	Column 5	Column 6
ZF	What (Things)	How (Processes)	Where (Location)	Who (Persons)	When (Events)	Why (Strategies)
ABD	Product AP	Progress Report AP	Party and Party Relationship AP		Order and Inventory AP	Rule AP
Bjørner	Intrinsic	Main Business Process; Related Processes	Management and Organization	Stakeholders; Human Behaviour		Rules, Regulations and Scripts

In addition to the Bjørner's facets, the ZF with archetypes and archetype patterns has order and inventory archetype patterns for analysing and modelling business events (column 5). Such an order based modelling of events is also used by the REA system [21]. Behind such modelling is the fact that generally all events in businesses are triggered by some kind of orders being either written or verbal and all these events somehow affect the business inventory list.

VI. Conclusions and Future Work

We have evaluated ABD in a broader context of software engineering triptych by comparing it with Bjørner's domain facets [7] based domain analysis methodology according to the domain theory research topics [2] (Sections 2 and 5). The evaluation demonstrates that ABD is in accordance with an approved and important methodology and provides additional insight into the research questions related to its main processes. We have also demonstrated use of ABD and domain models designed according ABD in real life software development (Sections 3 and 4). In our understanding, these two results together demonstrate that our domain analysis and modelling approach complements Bjørner's domain modelling and together with Test Driven Modelling results in more flexible, customizable, reliable and interoperable software.

The wider research goal is to develop archetypes and archetype patterns based information systems that software end users, in collaboration with software developers, are able to change safely and easily according to changes in business processes. A possible direction of future work involves specification and validation of user requirements and software according to the $\mathcal{D}, \mathcal{S} \vDash \mathcal{R}$ formula described in introduction.

Acknowledgment

This work is supported by Estonian Ministry of Education and research (SF0140013s10); by Tallinn University of Technology (Estonia); by University of Leeds (United Kingdom); by Cancer Research UK. We would also like to thank the reviewers for useful comments and suggestions.

Agile Experiences in Software Development

D. Duka
Ericsson Nikola Tesla, Split, Croatia
e-mail: denis.duka@ericsson.com

Abstract - **From the traditional *waterfall* model to streamlined ways of software development and to Agile, is a long journey for each organization. In that journey, transition into Agile way of working means a significant change. For any change to happen there is a significant involvement expected from the people, more so in case of Agile, as it involves individuals, interactions and collaborations over different processes. This paper deals with different Agile experiences. It proposes when to use Agile and what are the advantages of such approach. It also describes agility criteria helping to determine if the Agile is followed indeed. The special highlight is put on people and teams investigating their size and impact of geographical distribution on project success. Some reflections after using Agile in our own organization are also presented.**

I. INTRODUCTION

Agile software development is an evolutionary, highly collaborative, disciplined, quality-focused approach to software development and delivery, whereby potentially shippable working software is produced at regular intervals for review and course correction [1].

Agile software development techniques have taken the industry by storm, with 76% of organizations reporting in 2009 that they had adopted Agile techniques, and that on average 44% of the project teams within those organizations had adopted one or more techniques [2]. Agile development is becoming widespread because it works well – organizations are finding that Agile and iterative project teams, when compared to traditional project teams, enjoy higher success rates, deliver higher quality, have greater levels of stakeholder satisfaction, provide better return on investment (ROI), and deliver systems to market sooner [3]. By following quality techniques such as refactoring and developer regression testing throughout the lifecycle, *agilists* are able to progress safely and surely, increasing their productivity. By working closely with stakeholders in an iterative manner they have a better understanding of what stakeholders actually need and are more likely to deliver solutions that people actually want to use for their business purposes. By working in priority order, Agile teams are able to provide the greatest return on investment as defined by their stakeholders. In short, Agile teams work smarter, not harder, and thereby achieve better results.

Agile was once considered viable only for small, co-located teams. More recently, improvements in product quality, team efficiency and on-time delivery, all attributable to Agile practices, have caused larger teams to take a closer look at adopting Agile principles in their environments. A recent study conducted by the *Agile Journal* [4] determined that 88 % of companies, many with over 10,000 employees, are using or evaluating Agile practices on their projects. Agile is truly poised to become the dominant software development paradigm. This trend is also echoed in other industry studies, including one conducted by *Dr. Dobb's Journal* [5] which found a 76 % adoption rate of Agile techniques, and within those organizations doing Agile, 44 % of the project teams on average are apply in Agile techniques in some way.

Unfortunately, we need to take adoption rate survey results with a grain of salt: A subsequent another survey found that only 53 % of people claiming to be on "Agile teams" actually were [6]. It is clear that Agile methods have been overly hyped by various media over the years, leading to abuse and misuse; in fact, the received message regarding Agile appears to have justified using little or no process at all. For too many project teams this resulted in anarchy and chaos, leading to project failures and a backlash from the IT community that prefers more traditional approaches. Properly executed, Agile is not an excuse to be undisciplined. It is clear that the execution of mainstream Agile methods have always demanded a disciplined approach, certainly more than traditional approaches such as *waterfall*.

It should not be surprising that working together closely in co-located teams and collaborating in a unified manner towards a goal of producing working software produces results superior to those based on working in specialized silos concerned with individual rather than team performance. It should also come as no surprise that reducing documentation and administrative bureaucracy saves money and speeds up delivery.

However, why wouldn't we always use Agile methods? Well, maybe they are not always the best approach for the circumstances! So how do we decide? It is tempting to thinking that all projects should be handled in an Agile way.

Indeed, projects would benefit from the improved collaboration and communications encouraged on Agile projects. However, collaboration and communications are just two attributes of Agile projects and we must consider wider parameters that influence project success or failure.

The *Slider* (presented in Figure 1) is a simple model that illustrates that the Agile/Traditional choice is not necessarily binary [7].

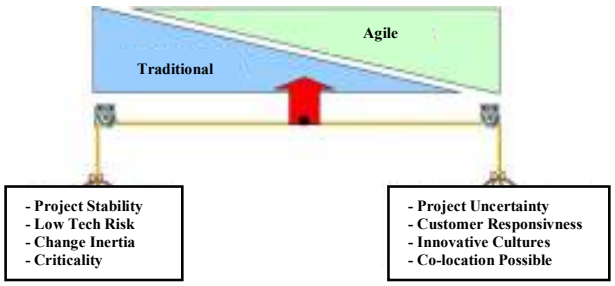

Figure 1. The Slider model

The model is fashioned after an old fashioned car heater control mixer, allowing for "No", a "Mixture", or a "fully Agile" approach as indicated by the position of the arrow. Characteristics that would pull the pointer one way or another are depicted as weights. Some project characteristics are a good fit Agile and would pull the pointer towards the Agile scale. Other characteristics make Agile introduction more problematic and might instead favor a more traditional approach. Traditional and Agile approaches can also be successfully combined to effectively address hybrid or hard to classify projects.

This paper deals with implementing the Agile approach in software development. It starts with exploring the reasons behind moving to Agile approach which is given in the following chapter. The paper continues with determining the team agility criteria trying to underline the difference between *doing* Agile and *being* Agile. Size of teams, their distribution and impact of geographical distribution on project success in Agile are presented in the fourth chapter. The final chapter deals with real experiences following the Agile implementation in R&D section in Ericsson highlighting some changes noticed during this new way of working.

II. WHY AGILE SW DEVELOPMENT

One of several reasons why Agile techniques are so effective is that they reduce the feedback cycle between the generation of an idea (perhaps a requirement or a design strategy) and the realization of that idea. This not only minimizes the risk of misunderstanding, it also reduces the cost of addressing any mistakes.

Figure 2 depicts the traditional cost of change curve, which shows that the longer it takes you to find a defect then on average the more expensive it is to address. The average cost rises exponentially the longer that you wait because you continue to build upon a shaky foundation. To be fair, some defects become less expensive the longer it takes to find them, perhaps the defect is found in functionality that is no longer needed or perhaps the defect is now addressable by a reusable component that is inexpensive to deploy [8].

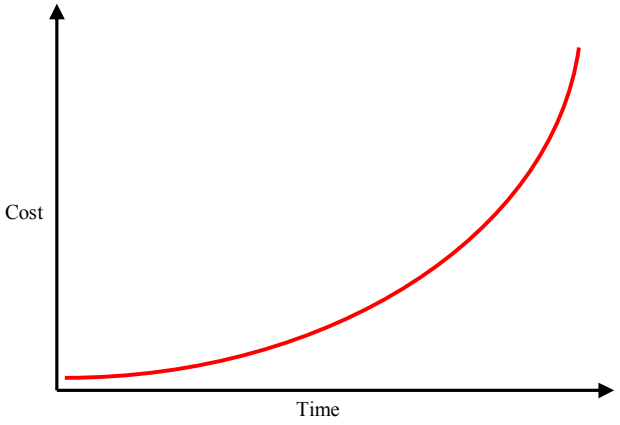

Figure 2. The traditional cost of change curve

In the past the X-axis of this curve was depicted in terms of the traditional project phases (requirements, analysis, architecture, design, ...) but the real issue really is one of the length of the feedback cycle. Although the cost of change curve has been questioned since it was first proposed by Barry Boehm in *Software Engineering Economics* (Prentice Hall, 1981), Boehm had looked at overly bureaucratic environments (mostly US Government and contractors to them), the real issue seems to be around how steep the curve is. As an aside, modern development processes have abandoned the idea of phases in favor of an evolutionary (iterative and incremental) if not Agile (evolutionary and highly collaborative) approach.

Figure 3 maps the feedback cycle of common development techniques to the cost curve. Agile approaches, such as Test Driven Design (TDD), Model Storming (MS), Agile Model Driven Development (AMDD) etc., all have very short feedback cycles, often on the order of minutes or hours. Traditional approaches, such as reviews, inspections, and Big Requirements Up Front (BRUF) have feedback cycles on the order of weeks or months, making them riskier and expensive [8].

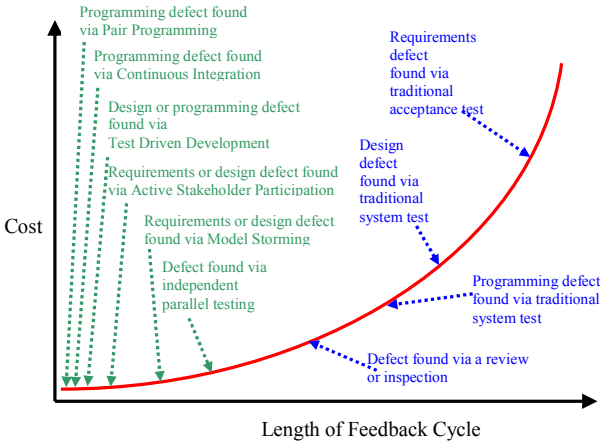

Figure 3. Mapping common techniques to the cost of change curve

Figure 4 presents a cost of change curve that can be expected for Agile software development projects.

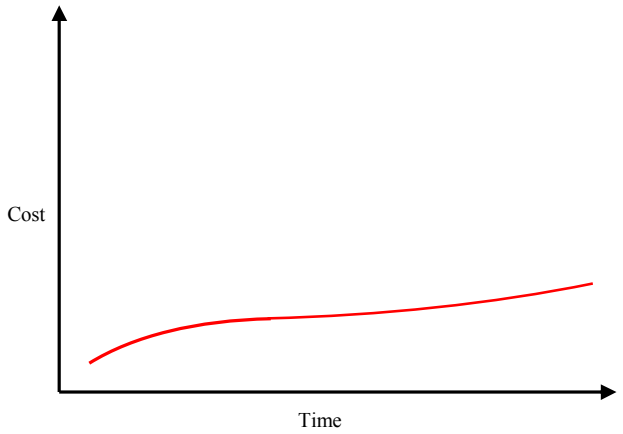

Figure 4. A realistic cost of change curve for Agile software development

As can be seen, the curve doesn't completely flatten but in fact rises gently over time. There are several reasons for this:

- Minimally business code and test code bases will grow over time, increasing the chance that any change that does occur will touch more things later in the project.
- Not only code base increase over time. There will be documents such as user manuals, operations manuals and system overview documents that you will need to update. There are models, perhaps a requirements or architectural models, that will also be updated over time. Taking an AMDD approach will help to reduce the cost of this but will not fully eliminate it.
- When it becomes expensive to release software, perhaps you choose to distribute using some media instead of releasing software electronically to shared servers. Consequently, your cost of change increases because you begin to follow more conservative and more expensive procedures.
- Many Agile software development teams find themselves in very non-Agile environments and as a result are forced to follow procedures, such as additional paperwork or technical reviews, that increase their overall costs. These procedures not only increase the feedback loop but they are also very often not conducive to supporting change.
- *Agilists* create high-value documentation, or in other words, far less documentation than traditionalists do, and don't tolerate unnecessary bureaucracy. As a result they can act on changes quicker because they have less work to do. In other words, they maximize the amount of work not done.

III. CRITERIA TO DETERMINE IF A TEAM IS AGILE

A common problem in many organizations is that undisciplined *ad-hoc* teams often claim to be Agile, because they've read an article or two about Agile development and interpret agility to mean any cool, liberated form of undocumented software creativity. These *ad-hoc* teams often run into trouble, and give actual Agile teams a bad name. The following five criteria determine if a team is truly Agile [1]:

- Working software - Agile teams produce working software on a regular basis, typically in the context of short, stable, time-boxed iterations.
- Active stakeholder participation - Agile teams work closely with their stakeholders, ideally on a daily basis.
- Regression testing - Agile teams do, at a minimum, continuous developer regression testing. Some Agile teams take a TDD approach.
- Organization - Agile teams are self-organizing and disciplined teams working within an appropriate governance framework at a sustainable pace. Agile teams are also cross-functional "whole teams," with enough people with the appropriate skills to address the goals of the team.
- Improvement - Agile teams are disciplined and also measure, how they work together and then act to improve on their findings in a timely manner. Continuous improvement is a key aspect for success in all organizations using Agile.

An important aspect of these criteria is that they are flexible. If we analyze the terms used in the description of the criteria – *regular basis, closely, continuous, appropriately, regularly, timely*; they are all situational in nature. For example, for some teams *regular basis* might be once every week, for other teams in more complex situations once every six weeks. Because every team finds itself in a unique situation, they must be flexible in the way that they assess their agility. The real goal is to be as effective as possible given the situation.

In fact, it is quite easy to *do* Agile. We pick the non-threatening pieces and parts and simply do those. Unfortunately, in doesn't mean we are doing Agile very well.

Being Agile is completely different. Being Agile means we understand the principles which lead to true Agile success. It also means the team and organization are both constantly improving. When we are being Agile, daily standup meetings and retrospectives are both very important meetings which help the team to be successful. Finally, being Agile means being unafraid of failure. Doing Agile has none of these qualities because it is all about doing the Agile practices, not living the Agile principles!

What is the right way from doing Agile to being Agile? One possible approach is understanding the difference. Once we understand the difference we can start to rely on the process to self-correct you toward being Agile.

For example, retrospective meetings might be a right place for new proposals based on different questions e.g. do we need a new way of communication flow, why do we not meet the commitment made during iteration planning, is the team willing to be Agile and work toward continuous improvement rather than continuous mediocrity, etc.

Once the questions are asked the team should strive to find some action items which will help them get better in those areas. If the team is truly dedicated to *being* Agile rather than *doing* Agile they will find action items which they can commit to in order to improve. This is the key first step to being Agile. Once we have a breakthrough in this area it is very easy to continue being more Agile [9].

IV. AGILE AND TEAM STRUCTURE

An interesting survey was performed in July 2009. The goals was to investigate how size of the teams and their geographical distribution influence the project success.

Figure 5 summarizes results from the *Agile Practices Survey* [10] which asked about Agile team size. Although the majority of Agile teams are 20 people or less, some organizations do in fact have fairly large Agile teams. Team size increases communication and organizational risks on Agile delivery teams and is often an indication of both technical and organizational complexity (the more complex the situation, often the larger the team required to address that situation).

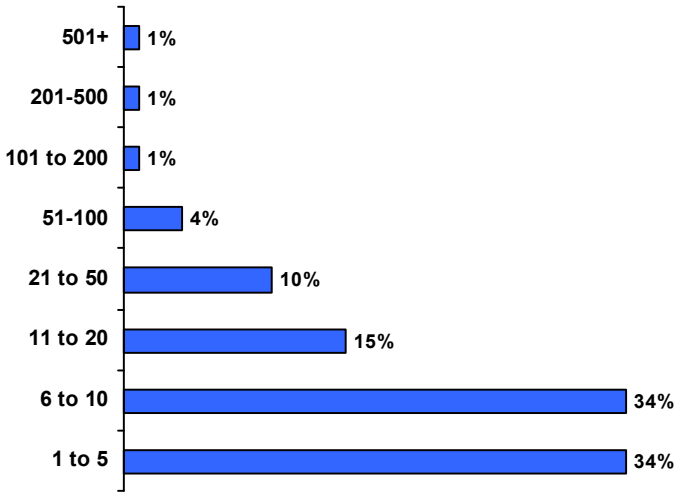

Figure 5. Average size of Agile teams

Figure 6 summarizes results of a question from the same survey asking about Agile and geographical distribution. Apparently, only a minority of Agile teams are co-located, with the rest exhibiting some form of geographical distribution.

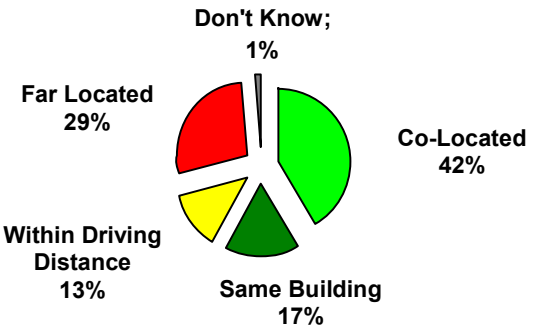

Figure 6. Agile software development and geographical distribution

More importantly, Figure 7 summarizes the results of several questions from the how the project success rate decreases as your team becomes more geographically distributed (*Near Located* in Figure 7 is the combination of *Same Building* and *Within Driving Distance* in Figure 6). It is interesting to note that some organizations are in fact succeeding even when their Agile teams are very distributed.

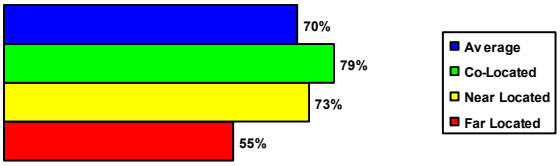

Figure 7. Success rates and distribution level

In order to have full understanding of figure above it is critical to understand how people actually define process success.

- Functionality: 83% believe that meeting actual needs of stakeholders is more important than building the system to specification.
- Quality: 82% believe that delivering high quality is more important than delivering on time and on budget.
- Money: 70% believe that providing the best ROI is more important than delivering under budget.
- Schedule: 58% believe that delivering when the system is ready to be shipped is more important than delivering on schedule.

Nevertheless, as a conclusion, geographical distribution increases the communication risks faced by Agile delivery team, which in turn decreases your success rate, requiring you to adopt your process accordingly to hopefully address those risks.

V. AGILE EXPERIENCES

Agile approach was implemented in one R&D section at Ericsson. The section was chosen since it was targeted to take responsibility for approaching international project matching following criteria: new development including pre-study/feasibility activities, combining both design and test activities, active quality and tool support. Experiences after using Agile as well as some changes are highlighted below.

When using Agile approach in software development, everything begins with a *Product Backlog*. This product backlog, just like any other product backlog, has high-level requirements and the expected timelines. Every item in the product backlog had a clear *Definition-of-Done* (DoD), prioritization and was sized and estimated [11].

The coach role is very important. The coaches, who are none other than the engineers from the development community, spread the message of good Agile practices into the teams, and making the teams see the benefits through their own eyes. Coaching happened in various forms: motivational, consultative and educational. Initially, the teams were in an educational mode, trying to understand what Agile is, what the practices are. The basic Agile workshops were given, for the various Agile roles and for team members.

Once the basic understanding was there, there were more queries on *how* and *why*. The coach's role here was more consultative in nature. The teams actively took help from them to understand how to practice Agile in a proper form. For example, the teams started estimating, doing planning and other key aspects well. The coaches had a high level view of how the teams were practicing Agile and helped them share good practices across teams. There were many motivational aspects that needed to be supported as well.

Sprint planning is crucial. The *User Stories* from the prioritized backlog were picked up by the teams across the three sites. It was always "Think Global and Act Local". So all common strategies were laid down at a global level and the implementation of them was taken care at the local level, with a common vision.

The heartbeat of the team was in stand-up meetings. There was also a monthly sync-up across all three sites. In this sync-up we updated each other on what was done, what are good practices, what are the impediments that teams faced, etc.

A. Self-organizing Teams

One of the critical ingredients for success of Agile are self-organizing Agile Teams. Traditionally, the teams had been working on detailed requirements being provided by the parent organization. They were used to being told what to do and even how to do. Self-organizing requires the teams to be willing to go the extra mile in identifying what needs to be done, how and when it needs to be done. So the team needs to demonstrate a lot more ownership on their tasks, taking them to a closure by themselves.

Ownership is a lot to do with self-belief; with each individual seeing their own potential and trusting themselves to do better. While the Line Managers stood by their people, any failures were seen as a step towards success, encouraging them to keep trying, and doing better than the previous attempts.

Periodic retrospectives (outside of the retrospectives at the end of iterations) helped to focus initially not on the tasks of the completed iteration, but on the Agile practices, the ownership behaviors that were demonstrated besides other softer aspects. These retrospectives helped the team to do a lot of introspection and realize their own potential and set the bar higher each time. When the team members saw that their managers are not watching them to find fault, but to hold them from falling down, they grew in confidence. The culmination of this effort was, when the teams took on the ownership for these retrospectives and the managers started to step back. The team reported their retrospective findings, and the actions that they, as a team were committing themselves to. The creation of the self-organizing teams had begun and in no time was gathering a lot of momentum.

The Line Managers gave up a lot of control and took a step back, when dealing with self-organizing teams. Once the self-organized teams were in place, the decision-making process underwent considerable changes with the teams feeling the need to be involved. Consequently, a more shared ownership has evolved in decision making since teams were actively involved in giving their views and recommendations to the Line Managers.

In some of the teams, the team members resorted to pair-programming without being asked to try it out, improving quality and reducing the time on inspections and handovers. This became a point for learning for the other teams.

Change happened: from high management commitment to high worker commitment, from management controlled to self controlled.

B. Cross-functional Teams

Every activity has different tasks attached to it, requiring different skills. Agile teams were created in a manner that it was balanced with regard to the skills required. Testing was also included in every team. When dealing with teams that are about 5-6 members having dedicated testers was not a preferred option compared to having a domain or technology expert. In order to change this situation, testers' role were played in rotation; which ever specific skills were not going to be much used in a particular iteration, the related engineers took on the role of the tester for that iteration. This ability to switch between development and testing proved to be very useful in optimizing the size and the skills available in a team.

Change happened: from isolated specialists to multi skilled workforce.

C. Stable Teams

Most significant aspect of Agile is prioritizing people and interactions over documentations and processes. When we talk about people and interactions, a lot is to be gained through the relationship and rapport that is built amongst team members. To enable this relationship to be built resulting in intra-team trust, it is essential to keep the members of the teams stable. A team structure was put up and consciously kept in place for long periods. Any changes that had to be done, for example on account of attrition of a member of a team, would result in replacement being fitted into that same vacancy in that team, there by not disturbing any other team.

To keep stable teams, would mean that every team should be capable enough to handle any of the requirements of the project. Otherwise, there would be situations where one team is loaded with a lot of things to do, while another does not have enough on its plate. The creation of the teams to be cross-functional came in handy here. As a result, stability of the Agile teams over long periods of time could be achieved.

Stability in team also brought in another benefit – a predictable pace of work, helping in better and more predictable schedules and commitments from a project release perspective. Also over a period of time, the team picks up a lot of self discipline aspects which are key to success.

Change happened: from a management driven team to self-organized team.

VI. Conclusion

Agile approach begins with an Agile belief with all individuals in the organization. It has to be the entire team knowing how to play and move towards a common goal. Similarly, every team member needs to understand the value of Agile and how it has to be played/practiced and be Agile while developing the software. Successfully implementing organizational wide change requires extra time and high energy level from the whole organization.

Our motivation behind the change was not only the current product under development but also to increase the level of Ericsson R&D center ability. First-hand experience of Agile framework is the real source of learning. Preliminary evidence we've collected from a team survey, rework, velocity, point growth, acceptance test defect trends, and other sources all tell us that Agile software development is making a positive difference in our organization. In addition, interest and respect for Agile practices is growing. Other software teams are adopting Agile practices and requests for our guidance and support are increasing. Other parts of the company are interested in what we're doing and how we're making it work. It's required our resolve, our persistence and some measurable success, but Agile practices are taking hold in our culture.

To summarize, by using this approach in software design we are able to first recognize and then eliminate activities which don't add value e.g. partially done work without any guarantee if customer will take it in use, unnecessary task swapping, waiting, handoffs, faults, etc. This way of working also implies improved responsiveness through rapid deliveries allowing customers to delay decisions. This is especially enabled by short feedback loops and continuous integration. From organization perspective Agile approach creates many added values since it enforce creating self- organizing and cross-functional teams capable to develop the whole software, from systemization via coding to functional testing. Finally, Agile requires everyone to be involved creating the big cultural change.

Multivariate Logistic Regression Prediction of Fault-Proneness in Software Modules

Goran Mauša*, Tihana Galinac Grbac* and Bojana Dalbelo Bašić**
* Faculty of Engineering, University of Rijeka, Rijeka, Croatia
** Faculty of Electrical Engineering and Computing, University of Zagreb, Zagreb, Croatia
goran.mausa@riteh.hr, tihana.galinac@riteh.hr, bojana.dalbelo@fer.hr

Abstract - This paper explores additional features, provided by stepwise logistic regression, which could further improve performance of fault predicting model. Three different models have been used to predict fault-proneness in NASA PROMISE data set and have been compared in terms of accuracy, sensitivity and false alarm rate: one with forward stepwise logistic regression, one with backward stepwise logistic regression and one without stepwise selection in logistic regression. Despite an obvious trade-off between sensitivity and false alarm rate, we can conclude that backward stepwise regression gave the best model.

I. INTRODUCTION

Considering the complexity of modern software products and the numerous constraints which follow its production, it is not unusual for the delivered software to have faults. Software quality models have the task to automatically predict fault prone modules and enable verification experts to concentrate on solving problem areas of the system under development. That is why applying software quality models in the early stages of software life cycle is essential. It provides an efficient defect removal procedure and results in delivering more reliable software products [1, 2].

Fault prediction modeling is an important area of research in software engineering. With overall testing costs estimated at 50% of entire development costs, testing consumes a lot of resources. Ideally, testing should be exhaustive in order to be confident that most faults are detected. In practice, however, due to many constrains, that is not possible and every additional save of resource is more than welcome. Fault prediction can be of assistance there, allowing software engineers to focus development activities on fault-prone code, improving software quality and making better use of resource.

Various techniques have been proposed for model building with logistic regression being among better ones. Among various statistical methods, machine learning methods, parametric models, and mixed algorithms, this paper explores the capabilities of logistic regression. The logistic regression has been recognized as one of the best methods used for fault-proneness prediction [1-5]. That is why the multivariate logistic regression is performed to build fault-proneness prediction model.

In this paper we are investigating following research questions:

1) Can we choose a smaller subset of independent variables in the fault prediction model using logistic regression to obtain better results?
2) Which static code attributes used as independent variables influence the model prediction performance?

Using too many independent variables can have negative effects on model's fault-proneness prediction, making the model more dependent on the data set currently in use and therefore less general [6]. Selecting the appropriate measures to be used in the model requires a strategy of minimizing the number of independent variables in the model. This paper investigates the usage of static code attributes as independent variables and forward and backward stepwise selection principles in choosing variables. The model performances are evaluated using widely used performance measures such as accuracy, sensitivity and false alarm rate [1, 2]. A defect prediction model should identify as many fault prone modules as possible while avoiding false alarms [7].

A public domain NASA data set is used for building and testing the fault-proneness predicting model. The capabilities of logistic regression are tested on data set CM1, which contains certain parameters describing a program code written in C. The paper consists of following sections: the first section contains the description of whole case study process; the second section examines the potential threats to validity and the third section gives a conclusion based on conducted research.

II. CASE STUDY

A. Data set

CM1 is a public data set acquired from PROMISE (**PR**edict**O**r **M**odels **I**n **S**oftware **E**ngineering) repository at http://promise.site.uottawa.ca/SERepository. The goal of PROMISE repository is to encourage repeatable, verifiable, refutable, and/or improvable predictive models in software engineering [8]. The CM1 data set's creator is the NASA Metrics Data Program and the donor was Tim Menzies on December 2, 2004. The CM1 data is obtained from a spacecraft instrument, written in C, containing approximately 506 modules, structured as a matrix of 498 lines and 22 columns, where lines represent different software modules and columns represent different static code attributes. All but the last column describe the complexity of the software code and the last one gives the information weather there was a defect detected or not.

Table 1 DESCRIPTIVE STATISTIC CHARACTERISTICS OF EACH FEATURE IN CM1 DATA SET

Method Level Features				
Name	***Mean.***	***Std. Dev.***	***Min.***	***Max.***
McCabes line count of code - loc	29,64	42,8	1	423
McCabe "cyclomatic complexity" - v(g)	5,38	8,3	1	96
McCabe "essential complexity" - ev(g)	2,49	3,7	1	30
McCabe "design complexity"- iv(g)	3,53	5,5	1	63
Halstead total operators+operands - n	143,96	221,0	1	2075
Halstead "volume"-v	900,18	1690,8	0	17124
Halstead "program length" - l	0,15	0,2	0	1
Halstead "difficulty" – d	15,83	15,3	0	126
Halstead "intelligence" - i	38,46	37,0	0	294
Halstead "effort" - e	34884,93	134164,7	0	2153691
Halstead - b	0,30	0,6	0	6
Halsteads time estimator - t	1938,06	7453,6	0	119650
Halsteads line count - LOCode	3,79	8,5	0	80
Halsteads count of lines of comments	12,28	25,8	0	339
Halsteads count of blank lines	11,53	20,0	0	164
LOCode And Comment	0,01	0,1	0	2
unique operators	15,20	9,6	1	72
unique operands	25,45	33,9	0	314
total operators	88,39	134,9	1	1261
total operands	55,57	87,0	0	814
branchCount of the flow graph	9,35	15,1	1	162
defects: TRUE or FALSE'	0,10	0,3	0	1

These data are used to evaluate the performance of the defect detecting models based on the Logistic regression. The 22 different code attributes from CM1 data set, along with its mean, standard deviation, minimum and maximum of each parameter calculated using Statistica are given in Table 1.

Halstead metrics mostly measure program size and time and effort put in to the process of programming. McCabe metrics, on the other hand, define complexity of the program code. Both metrics, along with total number and number of unique operators and operands and branch count help in identifying vulnerable code [5]. The last parameter is the one that tells us whether there was a defect in the software code. There are 449 software modules without defect and 49 modules with one or more defects.

As it is always recommended to plot the data, box and whisker plot was done as well. Box and whisker plot is able to graphically represent three different features. In large data sets, there is often the risk of misinterpreting descriptive statistic features such as range or mean due to the presence of outliers. That is why median is calculated instead of mean, and non-outlier range and interquartile range are calculated instead of range. As it can easily be noticed in table 1, the Halstead e parameter has much larger values comparing to other parameters and it stands in the way of appropriately examining all the parameters. Parameters Halstead t, Halstead v and Halstead n, though smaller in values than Halstead e, pose the same problem and that is why in the figure 1 all 4 parameters were omitted. On each box, the central mark is the median, the edges of the box are the interquartile range and the whiskers are the non-outlier range.

B. Logistic Regression

Logistic regression, in statistics, is a modeling method used for prediction of the probability of occurrence of an event. The independent variables are fitted to a logistic function and therefore the output can take on values between zero and one. Due to these reasons, it is suitable for building software classification models, especially for defect proneness prediction, because there are only two possible outcomes: either the software module is fault-prone or it is non-fault-prone. Logistic regression is related to some other statistical analysis techniques but it offers more flexibility and robustness [9, 10]. Logistic regression does not assume linear relationship between the

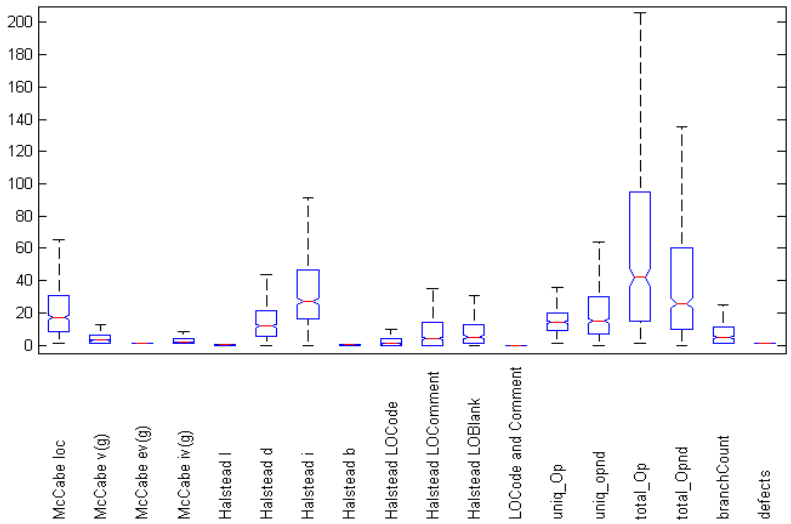

Fig. 1 BOX AND WHISKER PLOT OF EACH FEATURE IN CM1 DATA SET

input and output variables, nor normal distribution and equal variance within input variables. The purpose of logistic regression is usually to model the probabilities of two different classes via linear functions in *x*, a posteriori. Moreover, it ensures the sum of probabilities equals 1 and all of them remain within usual range between zero and one, inclusive [11]. The model has the form:

$$\ln\left(\frac{\hat{Y}_i}{1-\hat{Y}_i}\right) = u \tag{1}$$

where $\hat{Y}_i$ is the estimated probability within range [0, 1] that the *i*-th case is in one of the categories and u is the usual linear regression equation of x:

$$u = A + Bx \tag{2}$$

with constant A, coefficient B and predictor x. With a simple calculation, this logit or log of the ods equation (1) gives the probability equation:

$$\hat{Y}_i = \frac{e^u}{1+e^u} \tag{3}$$

The output of equation (3) is the probability of occurrence of an event and a cut-off percentage needs to be set in order to perform prediction based on given probability.

C. Multivariate Logistic Regression

In order to include more than just one predictor, a multivariate logistic regression model has to be used. Its functionality is based on equation (3) and performs according to equation:

$$\pi(X_1, X_2, \ldots X_n) = \frac{e^{C_0+C_1X_1+\cdots+C_nX_n}}{1+e^{C_0+C_1X_1+\cdots+C_nX_n}} \tag{4}$$

where X_i are the numerous independent variables included in predicting model, C_i are the regression coefficients of each independent variable X_i, and π is the output probability. In our case, the independent variables are 21 features of software module and the output is probability weather the module is fault-prone.

Maximum likelihood is the procedure for estimating coefficients. The goal is to find the best linear combination of predictors to maximize the likelihood of obtaining the observed outcome values. Maximum likelihood estimation is an iterative procedure that starts with arbitrary values of coefficients for a set of predictors and determines the direction and size of change in the coefficients that will maximize the likelihood of obtaining the observed values. The residuals for the predictive model based on those coefficients are then tested and another determination of direction and size of change in coefficients is made. This procedure repeats until each coefficient converges to a steady value. In effect, maximum likelihood estimates are those parameter estimates that maximize the probability of finding the correct output data [5]. A great number of predictors that multivariate logistic regression tolerates does not always offer the best predicting performance. Including the predictors not related to the outcome may degrade that performance. One way to appropriately select predictors is to use stepwise selection procedure.

D. Stepwise Logistic Regression

Forward selection and backward elimination are the two main principles used in stepwise selection procedure. The general forward selection procedure initially has a model with the intercept coefficient only. Based on a certain statistical criteria, variables are selected one at a time for inclusion in the model, until a stopping criteria is fulfilled. The general backward elimination procedure, on the other hand, starts with a model that includes all the independent variables and, one at a time is to be removed from the model, until a stopping criteria is fulfilled. However, the two described principles are rarely used alone. Both forward stepwise and backward stepwise regression combine the principles of selecting and eliminating variables. The difference is that forward stepwise regression starts with only intercept included in the model and backward stepwise regression starts with all variables included in the model. Entry of a variable into the model is based on the p1-value, while removal of a previously entered variable is based on the p2-value.

The p-value is level of statistical significance. To assess the statistical significance of each independent variable in the model, a likelihood ratio chi-square test is used. Let l be the log-likelihood of the model given in equation (4), and l_i be the log-likelihood of the model without variable X_i. Assuming the null hypothesis that the true coefficient of X_i is zero, the statistic $G = -2\ (l - l_i)$ follows a chi-square distribution and $p = P(\chi^2(I) > G)$ is tested. If p overcomes the usual level of significance of 0.05, the observed change caused by X_i is not considered significant. However, if p is lower than mentioned level of significance, X_i is considered to be significant and it becomes included in the logistic regression model [6]. In practice the p1-value is often set to 0.05 and the p2-value to 0.1.

E. Performance Evaluation Metrics

The most appropriate measure of overall fitness of an observed model is usually within interval from zero to one. Confusion matrix provides four scores that serve as basis for such an evaluation. A true positive (TP) score and a true negative (TN) score are counted for every correctly classified fault-prone module and non-fault-prone module, respectively. A false positive (FP) score and false negative (FN) score are counted for every misclassified non-fault-prone module and fault-prone module, respectively. Evaluation metrics used in this paper are:

- Accuracy, also known as precision as:

$$ACC = \frac{TP+TN}{TP+FP+TN+FN} \tag{5}$$

- True positive rate (TPR), also known as sensitivity, rate of detection, hit rate or recall as:

$$TPR = \frac{TP}{TP+FN} \tag{6}$$

- False positive rate (FPR), also known as false alarm rate or fallout as:

$$FPR = \frac{FP}{FP+TN} \tag{7}$$

Accuracy gives the percentage of accurately predicted modules in whole set of tested modules, evaluating the general appropriateness of the model. Sensitivity tells us the percentage of correctly classified fault-prone modules in whole set of faulty modules, indicating how many fault-prone modules we missed. False alarm rate shows the percentage of non-fault-prone modules that were misclassified as faulty in whole set of non-fault-prone, telling us the chance of focusing at dealing with fault that does not exist, which could prove to be a rather expensive mistake.

F. Research Method

Matlab 7.11.0. is used in research procedure. The procedure includes several steps:

1) Acquire the CM1 data set
2) Use descriptive statistics to examine the data set
3) Divide data randomly to learning and testing set
4) Apply forward and backward stepwise logistic regression to identify input variables
5) Build fault predicting models conducting the logistic regression upon the preselected parameters
    a) Build models on learning sample
    b) Test models on testing sample
6) Evaluate the results
7) Repeat from step 3) for *iter* times

We acquired the CM1 data set from (http://promise.site.uottawa.ca/SERepository/) and transferred it to Matlab where basic statistical features of each parameter in the data set were analyzed.

In order to automate the model building process we created a script in Matlab. The script is designed to choose independent variables according to forward and backward stepwise regression procedure, split the data set into a matrix of independent variables X and a vector matrix of dependent variable Y, to randomly split 67% of the data set as a learning test and to define the remaining 33% as a testing set, to include only the chosen parameters into the fault predicting model and finally to evaluate its performance.

Forward and backward stepwise regression were done using the *stepwisefit* function which by default performs forward stepwise procedure and needs the initial model that includes all of the parameters in order to perform backward stepwise procedure. When using both forward and backward stepwise model building p1-value is left at default value of 0.05 and the p2-value is left at 0.1. Maximum number of steps is left at default infinite value. The *mnrfit* function is used to calculate the coefficients of the multinomial logistic regression model. The matrix of independent variables from learning set is used as the first input variable and the vector matrix of dependent variable from learning set is used as the second input variable into the *mnrfit* function. It is important to notice that instead of using value of 0 for non-fault prone modules and 1 for fault-prone modules we had to increment their values to 1 and 2, respectively. That had been done in order to satisfy the *mnrfit* function demands (for example, if value of 3 had been used, the logistic regression model would try to fit the output data into 3 different categories). Coefficients are the output of the function and there is one coefficient more than the number of included variables. This is because mnrfit automatically includes a constant term in all models so it is not necessary to enter a column of 1s directly into X. Testing the acquired models is done in Matlab as well. The coefficients from the *mnrfit* function and the matrix of independent variables from testing set are the first and second input variables, respectively, of the *mnrval* function. The *mnrval* function computes predicted probabilities for the multinomial logistic regression model with chosen predictors and intercept and coefficient estimates returned by the *mnrfit* function. A cut-off percentage which determines if the program code is fault prone is set to the middle value, at 0.5. Evaluation metrics of accuracy, true positive rate and false positive rate are calculated separately for forward stepwise model, for backward stepwise model and for overall model (that includes all of the input variables). The whole process from randomly dividing sets to computing evaluation measures was repeated for 50 iterations.

G. Results

Before any stepwise logistic regression model bulding commenced, a simple modification had to be done. The Halstead e parameter that was problematic even for box and whisker plot due to its large range when comparing to other variables, proved to be problematic for stepwise regression as well. That is why it had been divided by a factor of 1000. That way the information this parameter holds is preserved and the problematic range is reduced.

While performing the forward stepwise and backward stepwise regression variable selecting process in Matlab, we counted how frequently each of the variables appears in chosen subset. Frequencies were counted in forward and backward stepwise regression procedure separately and along with their sum, they are given in table 2. With entrance p1-value set to 0.05 and exit p2-value set to 0.1, table 2 indicates some of the parameters that should be included in the logistic regression model and some that should be avoided as well. We can see that Halstead total operators + operands, Halstead "program length", Halstead "difficulty" and Halsteads count of blank lines have been included in the model for less than 10 out of 100 times. Since both forward and backward regression procedures often reject them, we can conclude these parameters, along with total operands, hold almost no information for fault prediction. On the other hand, Halsteads count of lines of comments has been included almost every time, unique operators has been included in over 80% of the times, Halstead "intelligence", Halstead "effort" and LOCode And Comment are selected approximately 50% of the times, indicating these variables are significant in fault predicting models.

Table 2 FREQUENCY OF CHOOSING EACH OF THE INDEPENDENT VARIABLES WITH STEPWISE LOGISTIC REGRESSION

Method Level Features			
Name	***Forward***	***Backward***	***Sum***
McCabes line count of code	11	18	29
McCabe "cyclomatic complexity"	6	37	43
McCabe "essential complexity"	14	8	22
McCabe "design complexity"	8	34	42
Halstead total operators+operands	0	6	6
Halstead "volume"	2	16	18
Halstead "program length"	0	1	1
Halstead "difficulty"	0	4	4
Halstead "intelligence"	18	36	54
Halstead "effort"	18	34	52
Halstead	4	23	27
Halsteads time estimator	11	24	35
Halsteads line count	9	11	20
Halsteads count of lines of comments	48	48	96
Halsteads count of blank lines	1	7	8
LOCode And Comment	18	29	47
unique operators	33	48	81
unique operands	2	28	30
total operators	0	26	26
total operands	1	10	11
branchCount of the flow graph	19	17	36

Table 3 EVALUATION AVERAGE RESULTS

Model	***Accuracy (ACC)***	***Sensitivity (TPR)***	***False alarm rate (FPR)***
Overall (no selection)	0,852	0,927	0,834
Forward selection	0,883	0,971	0,929
Backward selection	0,880	0,963	0,875

After parameters selection had been done, the learning and testing procedure was performed. The script repeated from the 3rd step of the research procedure, described in previous subsection, 50 times over. Each time a different randomly chosen learning and testing data sets were extracted. In the end, the mean value of each evaluating metric was calculated. Performing such logistic regression model building, testing and evaluating process in Matlab, we obtained results given in figure 2.

Table 3 presents the average values of accuracy, sensitivity and false alarm rate of 50 iterations for model that includes all parameters, model that includes the parameters suggested by forward stepwise procedure and model that includes the parameters suggested by backward stepwise procedure.

Examining figure 2 and table 3, we notice that all three models have high score of accuracy and false alarm rate and even higher score of sensitivity. In term of accuracy the forward stepwise and backward stepwise selecting model have the best results, but the difference between the three models is insignificant. When it comes to observing sensitivity vs. false alarm rate, the trade-off between the two is obvious. Having higher sensitivity score comes with higher false alarm score and vice versa. False alarm rate offers more diversities and therefore easier comparison. Forward stepwise selecting model has worst results, while the other two models have similar results, with backward stepwise selecting model having chance of achieving lowest false alarm rate.

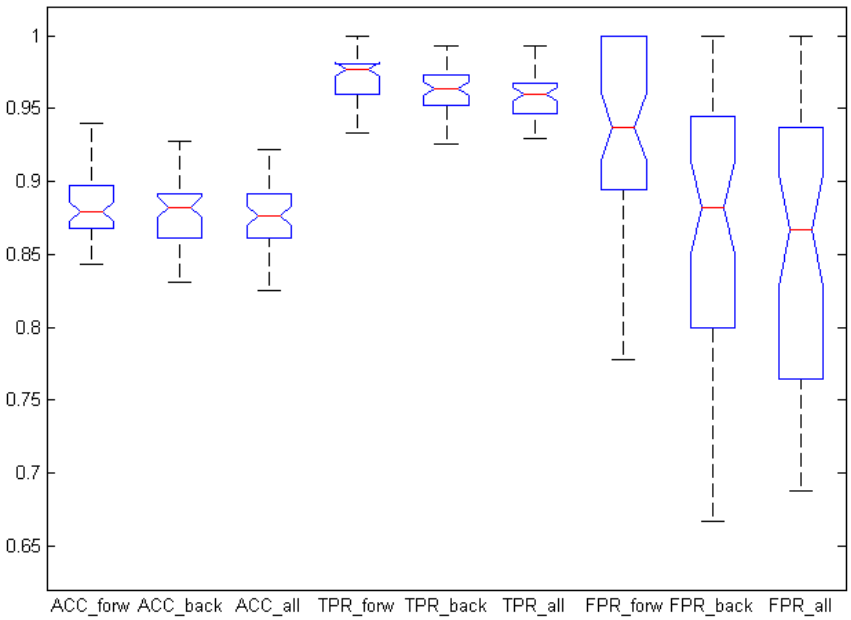

Fig. 2 BOX AND WHISKER PLOT OF EVALUATION RESULTS FOR 50 ITERATIONS

III. THREATS TO VALIDITY

Every case study should be aware of potential threats to validity. Each stage of a case study research is prone to such threats and they should be pointed out [12]. In this research bias can be detected in choice of data set, choice of method for fault-proneness prediction model building method and choice of evaluation metrics.

We were aware that selection of data set can lead to bias of results and conclusions. That was one of the reasons for choosing the verified and trustworthy NASA PROMISE repository. Lack of data quality, a problem often present in data sets of unchecked origin was overcome. Another advantage of PROMISE repository is its public accessibility, which makes our results open to verification by the whole research community. However, limiting ourselves to only one company as source of data offers another threat to validity and we plan to include a greater number of data sets in our future work. The fact that only a small number of only 49 software modules with defects is present in the CM1 data set, has to be taken into consideration of threats to validity as well. Our decision to randomly split the data set into learning and testing set also leaves room for bias. In order to minimize that threat to validity, we conducted research process with 50 iterations. The mere choice of stepwise logistic regression method as means for finding which software modules' features could be indicated as best suitable for defect proneness prediction is another threat to validity. Including other prediction and variable selection methods is planned for our future research. The evaluation metrics in this problem area are numerous and the once we used are one of the most commonly found in similar researches. They are also rather self-explanatory and offer a valuable insight into models' performance. Inclusion of AUC as even more general evaluation metric is expected in future.

IV. CONCLUSION

In this paper, we investigated the capabilities of logistic regression based fault prediction model. An empirical comparison of two different approaches to selecting independent metrics for fault-proneness prediction model has been reported. Logistic regression was the tool and a public domain development data set CM1 from NASA PROMISE repository was the object of research. Three different models have been compared in terms of accuracy, sensitivity and false alarm rate: the one that includes all the independent variables, the one that includes only the independent variables suggested by forward stepwise logistic regression and the one that includes only the independent variables suggested by backward stepwise logistic regression.

The level of accuracy in all the models confirmed their general appropriateness in defect predicting task. The sensitivity is even higher in all the models, which is also advisable. The level of false alarm rate, on the other hand, is too high in all the models while it should be otherwise. It is difficult to say which model has best results because the differences are subtle. Forward model, however, could be indicated as one that achieves best results in sensitivity, but with too great a cost in high false alarm rate. Backward stepwise selecting model has equally good results in accuracy as forward stepwise selecting model, better results in sensitivity than the overall model and, though in rare cases, it even achieves the lowest false alarm rates. These conclusions that we draw from the results have to be taken in respect to the threats to validity described in previous section.

Despite the limitations the chosen data set presents, we conclude that the backward stepwise regression proved to have great potential in choosing a smaller subset of independent variables for better results of logistic regression fault prediction model. We also found which static code attributes used as independent variables influence the model prediction performance. There are 2 features that must not be excluded from the model: Halsteads count of lines of comments and unique operators and there are several features that can easily be omitted: Halstead total operators + operands, Halstead "program length", Halstead "difficulty", Halsteads count of blank lines and total operands.

***Abstract* – Triple Play service is now one of the most important services for Telecom operators. This service contains: IPTV, VoIP, VoD, Internet and in some cases even fixed telephony and mobile telephony. The aim of Telecom operators is to improve this service by introducing some new subservices to get better business results. One example of these subservices is a Hosting service. This paper describes the process of introducing of Hosting system in one Telecom operator in Bosnia and Herzegovina and compares business results of Telecom operators without a Hosting service and with a Hosting service which is integrated into Triple Play. This paper has a scientific value because it describes steps of introducing Hosting service into Triple Play and describes the importance of Hosting service for Telecom operators.**

Keywords- ***Hosting; IPTV; VoIP; VoD; business benefit.***

I. INTRODUCTION

Triple Play is today one of the most important services for Telecom operators. Triple Play is basically package which contains these services: IPTV, VoIP, Video on Demand and even in some cases fixed telephony and mobile telephony [2], [3]. The challenge for Telecom operators is to introduce some new service to the Triple Play. Triple Play, which is a convergence of telecommunication networks, Internet and the broadcasting media, in the developed countries has been achieved to a greater extent as compared to the developing nations [4], [5]. It has played an important role for the economic surge and the social progress. Triple play is a multi-level synthesis of technical, business and marketing agencies. Telecom operators can improve Triple Play even if they perform it by just 1% or 2%. The best way to improve it is to do a convergence between IPTV and fixed telephony or mobile telephony, or to introduce one new service such as Hosting service.

Web hosting is a type of Internet Hosting service that allows individuals and organizations to make their own accessible via WWW. The most basic is web page and small-scale file hosting, where files can be uploaded via FTP or a web interface [5]. The files are usually delivered to the Web with a little processing. The availability of a website is measured by the percentage of a year in which the website is publically accessible and reachable via the internet [6]. This is different than measuring the uptime of a system. The convergence of Hosting service into Triple Play requires these steps: design and implementation of Hosting system, design and implementation of provisioning system for Hosting service, design of packages for Hosting service and a measurement of business benefits which are got after the convergence of Hosting service into Triple Play [10].

Section II of the paper describes the existing Triple Play service in the Telecom operator in Bosnia and Herzegovina. Section III of the paper describes the design and implementation of Hosting service and its convergence into Triple Play. Section IV describes business benefits for Telecom operator after the implementation and convergence of Hosting service into Triple Play. In the conclusion of the paper is presented how much is better a new Triple Play with an integrated Hosting service and what are benefits of this implemented system for Telecom operators.

Previous researches from this field include: the design of peer to peer network for web hosting [7] which can effectively address some problems and open a new era for the next generation of web technology and [8] in which is described application Hosting service for multiple grid environments middleware. Researches in which is described the importance of Triple Play services for Telecom operators are [1], [2] and [3]. These researches show the importance of Triple Play and describe IPTV and VoIP as the main services for Triple Play. The research which is covered in this paper is a continuous of these researches and introduces one new service and importance of it for Telecom operators [9].

II. DESCRIPTION OF EXISTING TRIPLE PLAY SYSTEM IN TELECOM OPERATOR

Existing Triple Play system consists these subsystems: Middleware system, VoIP system, Infocast system, DHCP system, Real Time Encription system, Verimatrix system, Real Application Clusters system, Video on Demand system, Radius system and Monitoring system [9]. All of these systems have some role for IPTV service, VoIP service or Internet service. Figure 1. shows network infrastructure for all these systems.

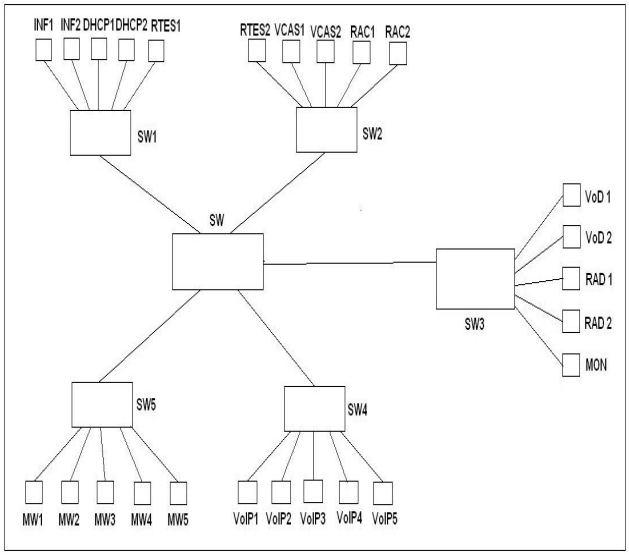

Figure 1. Network infrastructure for Triple Play system

Table I describes every specific Triple Play system. The importance of every Triple Play system is signed in table I [1], [3].

TABLE I: DESCRIPTION OF TRIPLE PLAY SYSTEMS

The name of one specific Triple Play system	**The description of one specific Triple Play system**
Middleware system (MW)	Middleware system is responsible for the normal working of all IPTV applications like: liveTV channels, radio channels, Electronic Programme Guide, TV Mosaic, instant recording options, programme recording options, Video on Demand, TV Internet, games and VoIP options on TV.
Voice over Internet Protocol system (VoIP)	VoIP system is responsible for the redirecting a telephone call from one user to another user and for the administration of VoIP users, numbers and adapters.
Infocast system (INF)	Infocast system is responsible for assigning an image for each Set Top Box in IPTV network. This system keeps STB images from many different STB vendors like: Motorola, Albis or ZyXEL.
Dynamic Host Configuration Protocol system (DHCP)	DHCP system is responsible for the assigning of IP addresses to all modems, Set Top Boxes and VoIP adapters in the network of Telecom operator.
Real Time Encription System (RTES)	The Real Time Encryption system is responsible for encoding and decoding live TV channels. Encoding TV channels enables safety for the user to watch just those channels which he rented in a certain package.
Verimatrix system (VCAS)	Verimatrix system is responsible for encoding and decoding of video contents. This is important because with the encoding of video contents the purchase of video contents is enabled.
Real Application Clusters system (RAC)	RAC system keeps data for IPTV users, Set Top Boxes, IPTV packages, video contents, TV channels, radio channels, EPGs, games, TV channels with recording mode, information about purchased VoD contents, VoIP users, VoIP packages, VoIP numbers, VoIP adapters, Internet users and Internet packages.
Video on Demand system (VoD)	Video on Demand system is responsible for emitting video content which is inserted into this system and also for emitting the recorded content whose recording is done over the Middleware system.
Radius system (RAD)	Radius system is responsible for the keeping all data for Internet users and Internet packages. This system measures the consumption of Internet traffic and provides application security for all Internet users.
Monitoring system (MON)	The role of the Monitoring system is to control IPTV/VoIP system through few modules: module for monitoring the quality of TV picture in certain regions, module for monitoring the telecommunication parameters for every fixed STB, VoIP adapter or modem as for example, jitter, uptime, packet loos and bandwidth and module for monitoring the activity of all servers.

III. DESIGN AND IMPLEMENTATION OF HOSTING SERVICE

Hosting system consists these components: Hosting Control Panel which is responsible for the administration of all actions with users and packages, Oracle database which stores all data for users and packages, Web servers which connect users to the Internet and MySQL database which stores all data for subscribers and their hosting pages [4]. Administration of users and packages means: adding new subscribers, adding basic hosting packages for subscribers, adding additional hosting packages for subscribers, adding new basic and additional hosting packages, deleting existing subscribers, deleting basic hosting packages for subscribers, deleting additional hosting packages for subscribers and deleting basic and additional hosting packages [8].

Figure 2. shows new designed Hosting service with all components [4], [8].

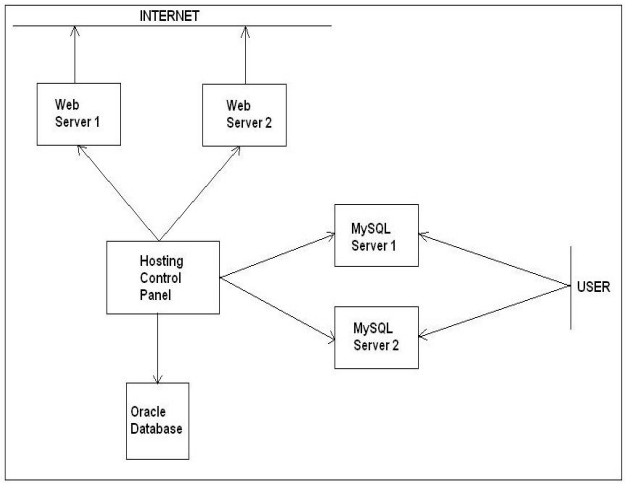

Figure 2. Hosting service with all components

Figure 3. presents Entity Relationship Diagram for a Hosting service which includes all tables for: Category, Subscriber, Consumption, Consumption Addition, Package, Web service, Statistics, Database and Internet. Tables II, III, IV, V, VI, VII, VIII, IX and X describe all parameters for all these tables [7], [10].

TABLE II: TABLE SUBSCRIBER

The name of field	The meaning of field	Type of the variable
ID_SUBSCRIBER	The unique number for each subscriber	INTEGER
SUBSCRIBER_NAME	The name of subscriber	VARCHAR(30)
SUBSCRIBER_SURNAME	The surname of subscriber	VARCHAR(40)
SUBSCRIBER_ADDRESS	The address of subscriber	VARCHAR(50)
SUBSCRIBER_PLACE	The place of subscriber	VARCHAR(50)
USERNAME	The unique Hosting username for each subscriber	VARCHAR(20)
DOMAIN	The unique domain address for each subscriber	VARCHAR(60)

TABLE III: TABLE CATEGORY

The name of field	The meaning of field	Type of the variable
ID_CATEGORY	The unique number for each category of subscriber	INTEGER
CATEGORY_NAME	The name for each category of subscriber	VARCHAR(20)

TABLE IV: TABLE CONSUMPTION

The name of field	The meaning of field	Type of the variable
ID_CONSUMPTION	The unique number for each consumption of subscriber	INTEGER
CONSUMPTION_VALUE	The value for each consumption of subscriber	REAL

TABLE V: TABLE CONSUMPTION ADDITIONAL

The name of field	The meaning of field	Type of the variable
ID_CONSUMPTION	The unique number for each consumption of subscriber	INTEGER
CONSUMPTION_VALUE	The value for each consumption of subscriber	REAL

TABLE VI: TABLE PACKAGE

The name of field	The meaning of field	Type of the variable
ID_PACKAGE	The unique number for each Hosting package	INTEGER
PACKAGE_NAME	The name of Hosting package	VARCHAR2(20)
PACKAGE_TYPE	Description of each Hosting package	VARCHAR2(20)

TABLE VII: TABLE STATISTICS

The name of field	The meaning of field	Type of the variable
ID_STATISTICS	The unique number for each user's statistics	INTEGER
TRANSFER_LOG	The information about moving one page from one location to another location	VARCHAR(50)
REFERRER_LOG	The information that contains statistics about user's using of some previous pages	VARCHAR(50)
AGENT_LOG	The information about total number of visits on one specific page	VARCHAR(50)
ERROR_LOG	The information about possible errors during the normal working of one page	VARCHAR(50)
WEBALIZER_RESOURCE	The information that contains statistics about user's using of one specific page	VARCHAR(50)
MODLOGAN_RESOURCE	The information that contains statistics about user's successful login to some pages	VARCHAR(50)
AWSTATS	The information that contains statistics about user's using of all his pages	VARCHAR(50)

TABLE VIII: TABLE DATABASE

The name of field	The meaning of field	Type of the variable
ID_DATABASE	The unique number of	INTEGER

	each database	
MYSQL	The information does user have or does not have MYSQL database	BOOLEAN
POSTGRESQL	The information does user have or does not have POSTGRESQL database	BOOLEAN
MS SQL 2000	The information does user have or does not have MS SQL 2000 database	BOOLEAN

TABLE IX: TABLE INTERNET

The name of field	The meaning of field	Type of the variable
ID_INTERNET	The unique number of each Hosting page	INTEGER
FTP_ACCOUNT	The information about user's FTP account	VARCHAR(20)
DNS_CONFIGURATION	The information about user's DNS configuration	VARCHAR(30)
CRONTAB	The information about time when some of hosting scripts are running	VARCHAR(20)
SITE_STUDIO	The information about URL page	VARCHAR(20)

TABLE X: TABLE WEB SERVICE

The name of field	The meaning of field	Type of the variable
ID_WEBSERVICE	The unique number of web server for specific hosting page	INTEGER
PHP	The information about PHP version which is used for the development of pages	VARCHAR(20)
CGI	The information about Common Gateway Interface web server	VARCHAR(20)
FRONT_PAGE	The information about Home URL	VARCHAR(20)
SERVER_SIDE_INCLUDE	The information about IP address of central Web server	VARCHAR(20)
REDIRECT_URL	The information about replacement URL if the home url is not working	VARCHAR(20)

Provisioning functions are responsible for the connection between central information system and Hosting service, as the one part of Triple Play service. Table XI describes all Provisioning functions which are in basic web services. These are functions which are connected to the adding and deleting subscribers, hosting packages, subscribers to specific basic and additional hosting packages [4].

TABLE XI: FUNCTIONS OF THE PROVISIONING SYSTEM

Provisioning system function name	Meaning of the Provisioning function
addHostingSubscriber	This function adds new hosting users into central information system.
deleteSubscriber	This function deletes one subscriber from Hosting service.
setSubscriber	This function is responsible for changing some parameters for hosting subscribers like: name, surname, address, place and username.
addSubscriberHostingPackage	This function is responsible for the assigning one specific hosting package to one user.
addSubscriberHostingAdditionalPackage	This function adds some additional functionalities to one specific hosting package to one user which are defined in tables: Statistics, Database, Internet and Web Service.
deleteSubscriberHostingPackage	This function deletes one specific hosting package from one user.
deleteSubscriberHostingAdditionalPackage	This function deletes some additional functionalities from one specific hosting package from one user which are defined in tables: Statistics, Database, Internet and Web Service.
addHostingPackage	This function adds one new hosting package.
deleteHostingPackage	This function deletes one hosting package from Hosting system.
readConsumptionForSubscriber	This function is responsible for reading a basic consumption for each subscriber.
readAdditionalConsumptionForSubscriber	This function is responsible for reading an additional consumption for each subscriber.

IV. BENEFITS OF THE IMPLEMENTED HOSTING SERVICE INTO TRIPLE PLAY SERVICE

Table XII shows hosting packages, description of these packages and the price for each Hosting package [4], [6]. As we can see from table XII, there are 3 basic packages: linOS, winos and G Hosting respectively with these prices: 3.00 E, 4.00 E and 5.00 E.

TABLE XII: HOSTING PACKAGES

Hosting package	Description of Hosting package	Price for each Hosting package
linOS	RedHat Enterprise Linux operating system 10 GB of traffic HTTP+FTP 400 MB of disc space 1 hosted domain 1 subdomain	5.00 E

	1 alias for domain 1 MySQL database 10 e-mail addresses	
winOS	MS Windows operating system 10 GB of traffic HTTP+FTP 400 MB of disc space 1 hosted domain 1 subdomain 1 alias for domain 1 MySQL database 10 e-mail addresses	4.00 E
G Hosting	5 GB of traffic HTTP+FTP 200 MB of disc space 1 subdomain 1 MySQL database 5 e-mail addresses	3.00 E

We did measurements on consumption of Triple Play service in 2011, which is the first year after releasing into production of a new Hosting service [5], [8]. Figure 4. shows the number of users in 2011 which number is from 12.100 in January to 39.110 in December. Figure 5. shows the consumption of Triple Play users without a Hosting service which is respectively from 315.810 E in January 2011 to 1.034.460 E in December 2011. Figure 6. shows the consumption of Triple Play users with a Hosting service which is respectively from 319.962 E in January 2011 to 1.102.990 Euros in December 2011. It is evident that are results of user's consumption better for Telecom operators when the Hosting service is inserted into business model for a Triple Play [5].

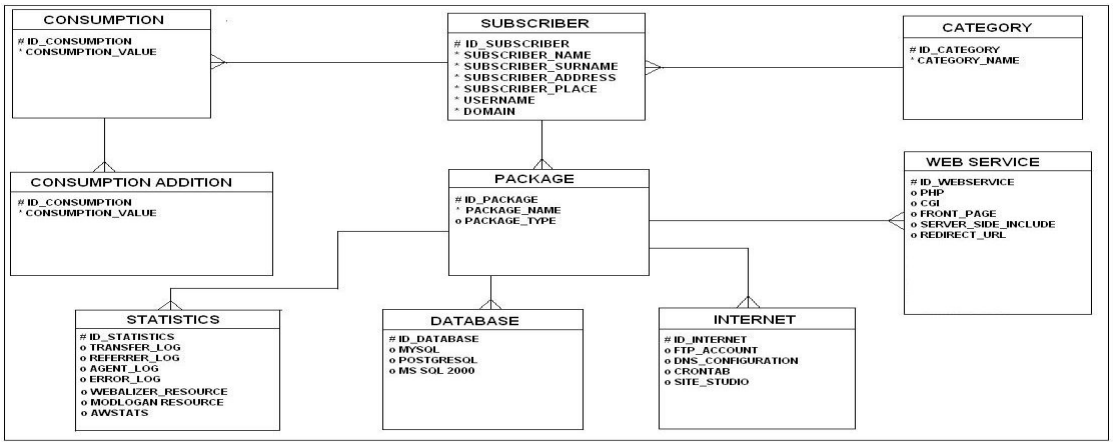

Figure 3. Entity Relationship Diagram for a Hosting service

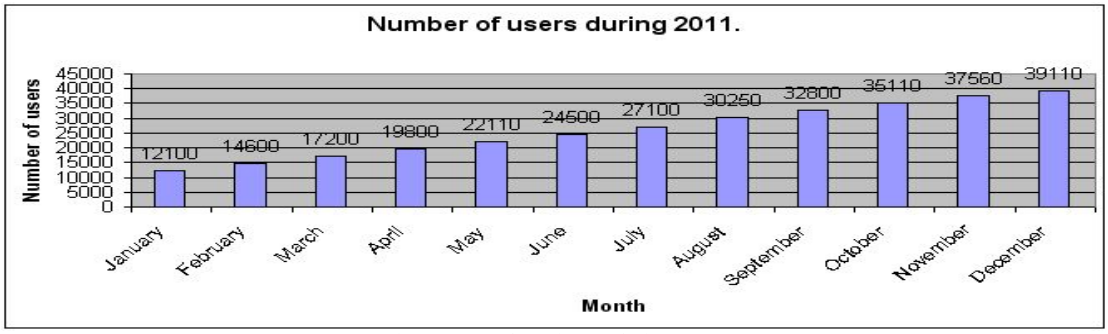

Figure 4. Number of users during 2011.

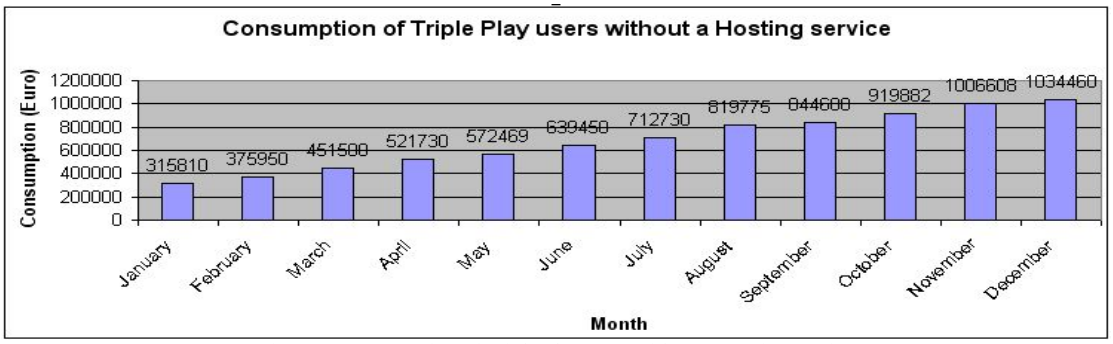

Figure 5. Consumption of Triple Play users without a Hosting service

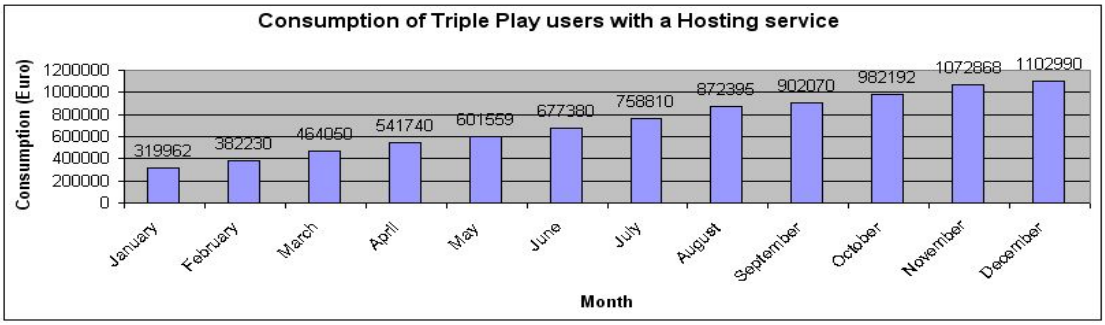

Figure 6. Consumption of Triple Play users with a Hosting service

V. CONCLUSION

Results show that the total consumption of Triple Play users without a Hosting service is 8.214.964 Euros, and with a Hosting service result is 8.678.246 Euros. The ratio of total earning is 51.38% against 48.62% for a business model for Triple Play in which is inserted a Hosting service. It means that a business model with inserted Hosting service is better for 2.76% than the old model without inserted Hosting service. This increases service profit margin by 2.67%. Figure 7. shows the ratio between a total consumption of Triple Play service without a Hosting service and a total consumption of Triple Play service with a Hosting service. This is the proof that Telecom operators have to do on the improvement of their services because this is the only way how they can improve their benefits [2], [3].

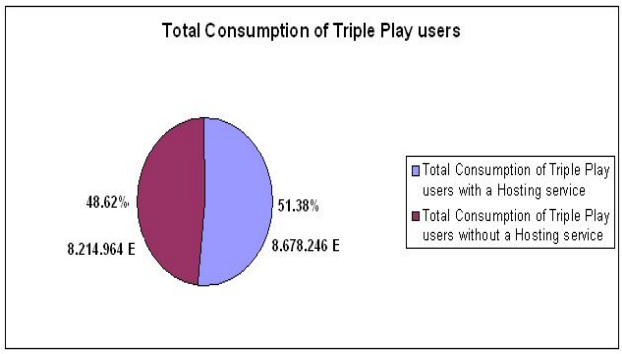

Figure 7. The ratio between a total consumption of Triple Play service without a Hosting service and a total consumption of Triple Play service with a Hosting service

Future work of authors in this area is also connected to the improvement of Triple Play service quality. The aim is to integrate E-mail service also to Triple Play service and try to achieve better business results [9].

ACKNOWLEDGMENT

The authors of this paper would like to thank the experienced professionals from Telecom operators on their suggestions while writting this document.

Telecom Services Self-care Portal for Business Customers

Katarina Rebernak, Maja Botinčan, Davor Šarić
Services Development Planning and Deployment Department
Croatian Telekom Inc.
Ozaljska 91, 10000 Zagreb, Croatia
{katarina.rebernak, maja.botincan, davor.saric} @t.ht.hr

Summary – Telecom service providers are constantly challenged to increase their top line revenues and reduce operational costs. Experiences with self-care and web shop portals for residential customers together with some limited functions for business customers were gathered in Croatian Telecom through last 7+ years and were well accepted. Having all this in mind, orientation towards fulfilling business customer needs for quality service support, as well as enabling easy purchasing of new services or prolongation of existing contracts through reliable web portal, gives us one of the possible solutions. In this paper we will present abstract model development of organizational structure for companies in Croatia and respective functional blocks that are required in order to ensure proper self-care role definitions for different employees within the company. Additionally we will describe our solution to challenges in customer and service data integration from different backend IT systems inherited from different organizations (T-Mobile Croatia – mobile services; T-Com Croatia – fixed line, Internet and IPTV services) in new data model for integrated company/service view. At the end we will present existing and planned services on T-HT's "My T Business" portal that was launched in summer 2011.

I. INTRODUCTION

EBITDA pressure, daily topic in every telecom operator board meeting is usually handled from two sides – top line revenues and cost containment or bottom line efficiency. Operators today are launching more products than ever before, while competing for the market share in usually saturated markets. In such market environment, agility, cost efficiency and flexibility in meeting customer expectations is determining competitive advantage for the operators. Clear communication of product benefits is essential for successful sales, regardless the sales channel. Existing customers prefers fast and easy support in service exploitation and support (changing of password, configuring and activating services, viewing invoice etc.). Therefore, operators who are able to provide this will keep close connection to its customers and have an obvious advantage in customer retention and building opportunities for up-sale and cross-sale of its services.

Business customer's segment is traditionally high-value segment, with slower churn dynamic than residential segment; but with greater churn influence on operator's financial figures. There are (at present) around 176.000 companies in Croatia, of which about 2080 proprietary companies and 132 holding companies. T-HT is clear leader in providing telecommunication service for business customers in Croatia [1], but its position is constantly challenged by growing competition. Therefore, it was foreseen as an important step forward in customer service to provide self-care portal specialized in serving business customers needs. In this article we will present challenges on a way to successfully building such a portal service.

In section two of this paper we will describe reference Croatian model for company structure and its variations due to the size. Section three will deal with challenges in internal data model, due to the merger of mobile and fixed operator with its separately developed IT systems. Also we will discuss mapping of different data models to the unique one – ensuring "one view" to the client company data. In section four we will present different roles developed in order to ensure efficient business portal usage for different business purposes in the company. All current functionalities of My T Business portal (MTB) will be described in section five, as well as brief overview of individual business customer self-care possibilities on My Telekom portal. Conclusions, some learning's from the project and next steps will be presented in section six.

II. DATA INTEGRATION CHALLENGES

From the beginning of Mobile Services development and integration, due to specific functionalities and billing needs, whole Customer-Service structure was built in different way than for the Fixed Services.

Also, for many years Fixed and Mobile part of HT Company were two separated legal entities with completely different Customer databases.

When an idea about common portal for business customers was born, main challenge was to build an architecture that will support so called "one-customer-view" knowing in mind that there are different Data structures below the surface within our company.

Since, this portal was meant for Business customers, first goal was finding right (and unique) identifier for one

Company. Naturally, we recognized "Personal Identification Number" (OIB); unique 11-digit number that is assigned to every citizen and company in Croatia since 2009; as Company identifier and that was a starting point for Data model structure for the portal.

Luckily, this OIB data was set already in majority of Customer objects. For missing OIB's we initiate internal process of obtaining this data from various external sources.

The Customer-Service hierarchy that we developed is shown on Fig. 1.

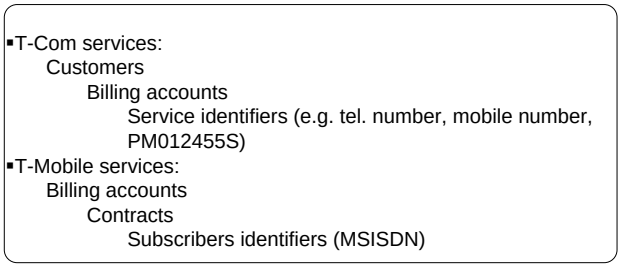

Fig. 1. Customer-Services hierarchical relationship

Under one Entity (legal or residential) there could be more than one customer relationship with its different Billing accounts and Services.

Beside this, there was a possibility of another "layer" in the hierarchy – Holding Company. Holding company is organizational structure that comprises more than one Subsidiary company and in our model it stays on top of the group of companies.

In that case the hierarchy can be graphically presented as in Fig. 2.

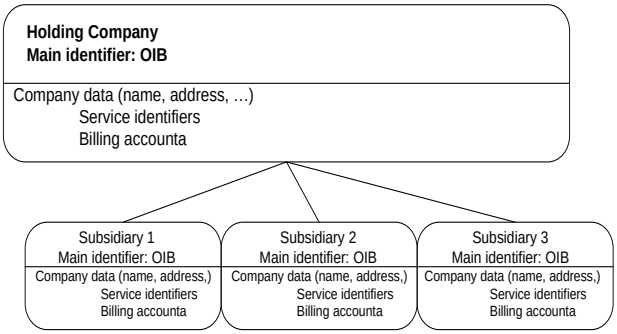

Fig. 2. Hierarchical view on Holding structure

The main challenge in data integration for one business customer was an ongoing process of mapping the parameters of two big CRM platforms: fixed and mobile, that were developed separately and should continue to work "as is" in parallel, due to their purpose of supporting all customer-related business processes. Due to the complexity of building one convergent CRM (extremely complex project that was out of scope) we decided to develop a middleware that communicates with two different CRM backend systems.

This layer consists of internal business logic and series of web services ([2], [3]) towards separate CRM's and it enables transparent view on business portal customer information as if they were in single database (Fig. 3.).

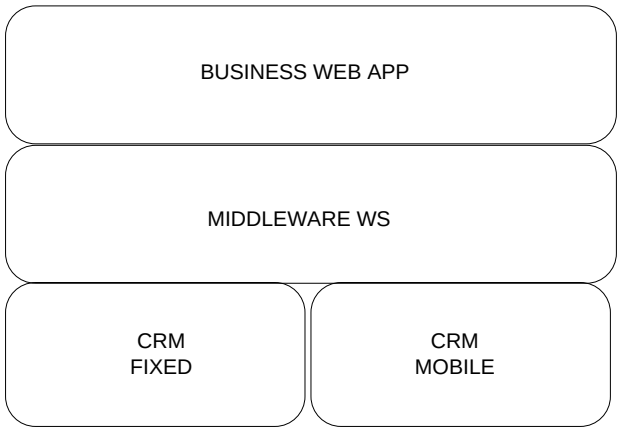

Fig. 3. Integration of Fixed and Mobile CRM

The issue of "business customer" definition completeness also arises since customers had the possibility to have their private and business services mapped together under the same OIB identifier. That is the case with so called "craftsmen" businesses which have a specific legal stand in Croatia.

So, extracting only "the business part" was another task for business portal that caused important relation that had to be considered: between OIB and Customer_ID as it was defined in CRM systems (with its own identifier).

III. LOGICAL ARCHITECTURE AND DESIGN

Business portal platform consists of a two main parts: Customer self-care portal and Admin portal.

Customer self-care portal (also called "end user portal") is a portal application which is available for Business customers and their users.

Admin portal is a module which is used by HT administrators for Business self-care portal customer provisioning (creating, updating or deleting).

As explained in Section II, the relevant information from backend systems are fetched by Middleware Web services layer and presented to the users on front-end presentation layer.

Besides viewing, users can change or interact with the backend systems through the same MW WS layer.

When business user requires access to some specific portals on which features of a specific services are implemented (like some value-added service – SLA monitoring etc.), Customer provisioning is done by Business self-care portal, but the features and functionalities are presented on a different web portal which has to implement the same SSO (Single Sign-On - common authentication platform) configuration as My T Business self-care portal (Fig. 4.).

IV. ROLES AND ADMINISTRATION

Figure 5 depicts relations among the predefined roles and their permissions towards different modules.

Administration module of the portal consists of Administration module for Croatian Telecom employee and Administration module for My T Business administrators.

Administration module for Croatian Telecom employee consists of two parts: User module and Content module.

End user application is a web application for business customers intended to be used for viewing inventory, bills, orders and faults.

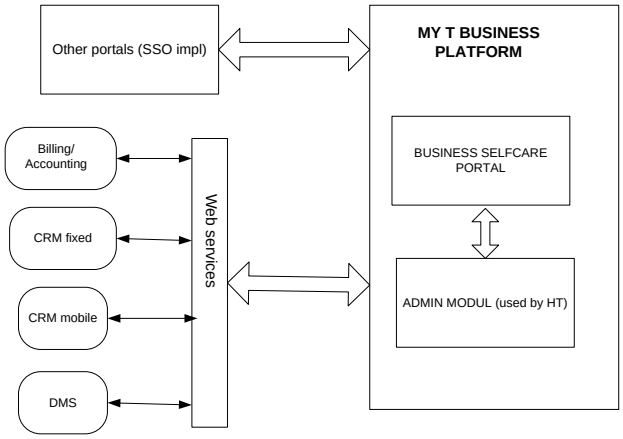

Fig. 4. Key Integration points – SSO & backend web services

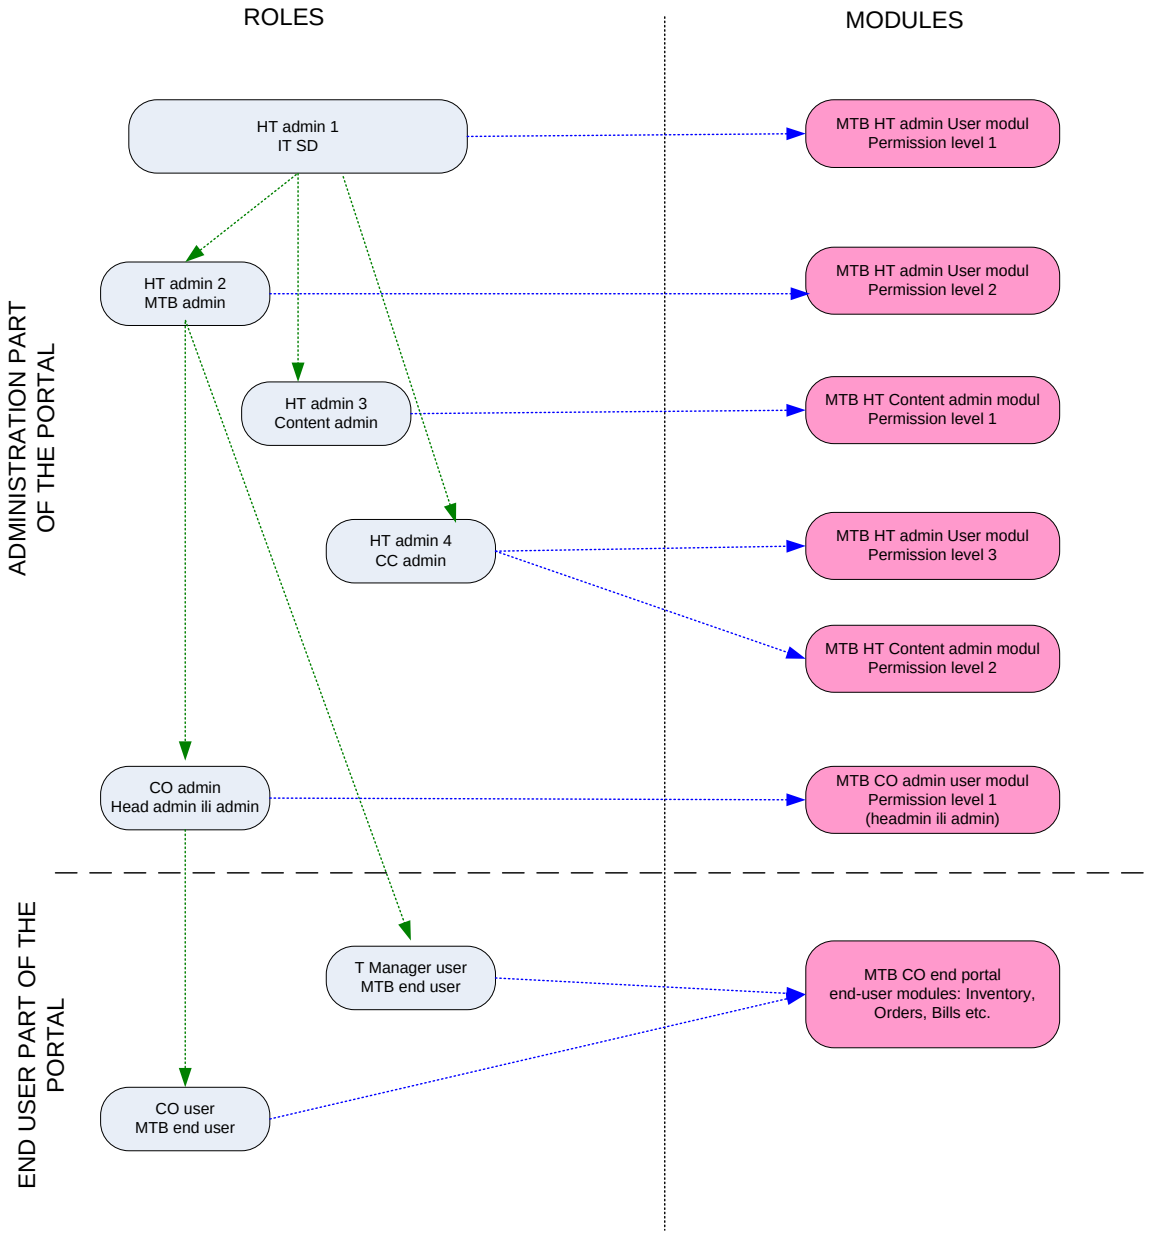

Fig. 5. Permission relationship between portal roles and modules

A. *Roles and administrators*

The following list describes administrator roles and their default permissions:

- main company administrator (headAdmin or Admin)
  - can't be deleted by any user, only T-Com can delete this administrator
  - permissions can be dynamically setup, by default this administrator can access every section and every data on the portal for the whole Holding and every subsidiary, customer_id
  - can create, change, delete administrator accounts
  - can create, change, delete end user accounts
  - can create, change, delete roles

- administrator
  - permissions can be dynamically setup
  - by default this role is allowed to access every portal module for the specific company, OIB or customer_id
  - can create, change, delete administrator accounts
  - can create, change, delete end user accounts
  - can create, change, delete roles

The following list describes end user roles that are predefined on the portal along with their permissions.

End user roles and default permissions:

- Secretary
  - Allowed access to Inventory and Orders modules, for his company – one OIB or customer_id
- Accountant
  - Allowed access to Inventory, Orders and Bills modules and all BAs, for his company – one OIB or customer_id
- IT manager
  - Allowed access to Inventory, Orders and Faults modules, for his company – one OIB or customer_id
- Employee
  - Access to My T Business portal isn't allowed
  - Allowed access only to end user (residential) My T portal
  - If user with this role tries to access My T Business portal, he will be redirected to My Telekom residential portal

Permissions for each role can be altered by any administrator; also administrators can delete roles or create new roles with new permissions. This approach enables companies in flexible role definition – in accordance to their business/organisational needs.

B. *Registration Process*

The registration process for the main Holding administrator is described below:

1. Croatian Telecom Administrator (HT admin 1) enters the OIB number
2. Administration application is checking whether the entered OIB exists in the imported table (the table contains all the business customer records)
3. The obtained data from the table are stored during the session
4. Each validated OIB number that exists in the table, is an input data for receiving the Holding information and services from the backend systems
5. The results are stored during the session for further data manipulation
6. Checking in backend systems if there is at least one active service
7. The user page is displayed for creating My T Business Administrator (main administrator). The main administrator has permissions to all modules/OIB numbers/customer IDs
8. SSO procedure
9. When the My T Business administrator is created, all the data are sent to HT CRM system
10. My T Business profile is created with the following data: user roles, username, password, contact e-mail etc.

A main administrator can be created for the company within the Holding company as well as for the "plain" company which is not Holding.

Creating an administrator (user) is possible only in cases where the main administrator is created (OIB level).

V. MY T BUSINESS PORTAL FUNCTIONALITIES

Four priority modules were recognized during MTB portal initial scope definition process: Faults, Bills, Orders and Services (Fig. 6.). Decision was taken that this is minimal set for launch

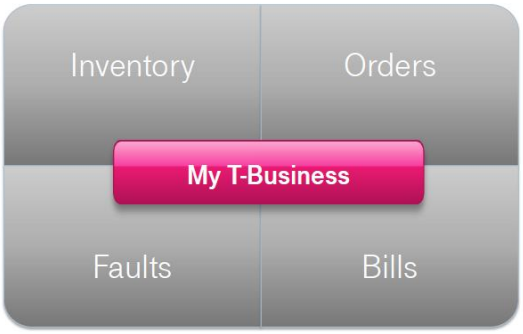

Fig. 6. My T Business portal initial modules

"Faults" module presents to the MTB user (with appropriate role) lists of registered faults on its T-Com and T-Mobile services and their mobile devices currently on repair. Information on current fault repair and device repair status is presented as well as history data on

previous faults and device repairs. It is also possible to file a new fault on any company's T-Com or T-Mobile services online.

"Bills" module entry page consists of two lists for quick view on company's T-Com and T-Mobile bills. Those lists enables different view on bills history according to bill attributes (bill delivery address, payment status, bill No. etc.). Selecting the particular bill from the list will open the complete bill statement and present its details.

Module "Orders" entry page consists of quick view lists for T-Com services order status and T-Mobile order history. Due to the character of service ordering and contracting, it is possible to order some T-Com services online and therefore have an online view to its completion status. Current rule for ordering/contracting new T-Mobile service accounts (SIM's) via sales representative personnel and online mobile service provisioning for existing SIM users (which means instant change) does not require status view on "open" orders but history view on fulfilled orders instead. Separate page with ordering forms (in PDF) for T-Com and T-Mobile services is prepared within this module with aim to further simplify service ordering process for end customer.

List of all services business customer is currently subscribed for is given in module "Services". From the service list it is possible to review service details, mark particular service for its list/presentment on MTB first page (after login), or even to file a new complaint on each service. It is possible to navigate to separate T-Com and T-Mobile service presentment and to list services according to service attributes.

One of the roles for My T Business administrator in the company is also to issue username/password to end user (Employee role) for self-administering his/hers single service (e.g. corporate mobile phone service). In order to achieve this, such end-user (employee) will have to logon to recently developed *My Telekom portal* (https://moj.hrvatskitelekom.hr/public) which is integrated via the same SSO mechanism.

On My Telekom portal, MTB user is offered limited set of self-care administration services. Those services includes bill review and statistics, paid option status, synchronization of contacts, free SMS's, prepaid recharging etc.

VI. CONCLUSION

In this paper we presented challenges on our path to develop efficient telecom services self-care portal for business customers. Due to the goal to include ALL services provided by T-HT and necessity to build robust and reliable solution; this project (with detailed specification, development, integration, internal testing as well as pilot phase testing with friendly users) lasted more than a year prior to portal's commercial launch (https://business.t.ht.hr). Its success, measured in more 2800 companies subscribed to the portal in 6 month after its launch confirms that our decisions on initial scope and accent on robustness and reliability was the right one.

Currently ongoing further developments are heading in two main directions:

- Closer integration with new web shop functionalities that should enable further improvement and automation of sales process and online contracting
- Integration of other service modules or existing separate web solutions for their self-administering (mostly for ISP - "online services").

Udaljena pohrana podataka korištenjem slobodnog softvera

Branko Radojević, Matija Nalis, Valentin Vidić, Saša Čavara
Hrvatska akademska i istraživačka mreža – CARNet, Zagreb, Hrvatska
{Branko.Radojevic,Matija.Nalis,Valentin.Vidic,Sasa.Cavara}@CARNet.hr

***Sažetak* - CARNet već preko 20 godina uz povezivanje ustanova iz sustava znanosti i obrazovanja u jedinstvenu komunikacijsku mrežu pruža i usluge izgradnje i održavanja pojedinih internetskih servisa. Tako je jedan od prvih zadataka CARNet-a bio ustrojiti osnovne internetske servise i na samim ustanovama članicama, a sigurno pohranjivanje korisničkih i sistemskih podataka (backup) na siguran i pouzdan način je uvijek predstavljao izazov za sistem inženjera na samim ustanovama. Od 2011. godine nudi uslugu udaljene pohrane podataka za sve svoje članice koristeći postojeću mrežnu infrastrukturu i slobodni softver. Na taj način je praktički minimalnim ulaganjima uspostavljena usluga koja se može koristiti i u daleko kritičnijim informacijskim servisima od onih koje koriste CARNet-ove ustanove članice.**

I. UVOD

Još u prvoj polovici devedesetih godina prošlog stoljeća, zahvaljujući petorici mladih inženjera elektrotehnike, ujedno entuzijasta u području računalnih komunikacija uspostavljena je prva CARNet mreža [1]. Nakon uspješno završenog posla povezivanja pojedinih fakulteta iz svih krajeva Republike Hrvatske, te priključivana na Internet, postalo je jasno da treba napraviti i slijedeći korak – uvesti internetske servise.

No, to su bila vremena kada je Internet još uvijek bio u povojima, web praktički nije još ni postojao, a većina ljudi na fakultetima je još uvijek izražavala sumnje u uspjeh cijelog poduhvata. U takvoj klimi je bilo teško očekivati da će pojedine ustanove samostalno uložiti financijska sredstva u relativno skupe UNIX poslužitelje kako bi na njima podigli servise za koje je samo šačica ljudi vjerovala da su upotrebljivi. Iz tog razloga su ljudi iz Sveučilišnog računskog centra – SRCE, Sveučilišta u Zagrebu odlučili napraviti korak dalje te uložiti u računalnu infrastrukturu na ustanovama kako bi se mreža CARNet obogatila i dodatnim internetskim servisima.

U tadašnje vrijeme na samim poslužiteljima bili su smješteni gotovo nebitni podaci: osnovne informacije o ustanovi na *gopher* servisu, poneka datoteka na *ftp* poslužitelju i elektronička pošta lokalnih entuzijasta s fakulteta. Vrijednost podataka je bila vrlo mala, pa i nije bilo potrebe za ulaganjem u uređaje za sigurnu pohranu podataka (eng. *backup*).

No popularnost Interneta i pripadajućih servisa je pojavom weba počela eksponencijalno rasti, a samim tim je i vrijednost pohranjenih podataka na poslužiteljima značajno porasla. Tada je postalo jasno da se poslužitelji moraju proširiti tračnim uređajima za snimanje sigurnosnih kopija podataka.

U narednim nabavkama poslužitelja vodilo se računa o tome da uz njih dolazi i uređaj za sigurnosnu pohranu podataka, što je značajno povisilo cijenu pojedinog poslužitelja. No, nabava uređaja nije riješila problem sama po sebi, već je bilo potrebno uložiti dodatni trud na samoj ustanovi da se pohrana podataka redovito i provodi.

Na žalost, iz evidencije Službe za pomoć sistem-inženjerima ustanova članica za slučajeve u kojima je došlo do gubitka podataka, vidi se da je pravilna pohrana podataka na ustanovi bila više rijetkost nego pravilo. Razlozi za to su mnogobrojni i nisu vezani isključivo za sistem-inženjere, već je problem bio i u nezainteresiranosti ustanova da propišu sigurnosne politike i nabave trake za snimanje podataka.

Analizirajući višegodišnju praksu u ustanovama članicama, uzimajući u obzir da u današnjim poslužiteljima uređaj za pohranjivanje na trake čini gotovo 50% cijene kompletnog poslužitelja i poštujući želju da se u potpunosti pojednostavi i automatizira ovaj proces, CARNet je 2011. godine samostalno razvio sustav za udaljenu pohranu podataka, koristeći postojeću mrežnu infrastrukturu i uređaj za pohranu podataka (eng. *tape library*). Za softver je odabrano slobodno rješenje otvorenog koda Bacula [4] koji se izdaje pod AGPLv3 [5] licencom. Postoji i komercijalna verzija navedenog softvera, koja predviđa i naprednije funkcionalnosti kao i određeni nivo podrške, ali naravno - nije besplatan.

Iako postoje i mnoga druga komercijalna rješenja, koja nude i neke bitno naprednije funkcionalnosti (npr. deduplikaciju) a i komercijalnu podršku proizvođača, ta se rješenja ipak nisu detaljnije razmatrala uglavnom zbog financijskih ograničenja.

U nastavku su opisane pretpostavke i ograničenja na temelju kojih je sustav izgrađen, te izvedba sustava na stani korisnika (ustanove članice) i pružatelja usluge (CARNet-a). U zaključku su navedena dosadašnja iskustva u korištenju usluge.

II. OSNOVNE PRETPOSTAVKE ZA USPJEŠAN DIZAJN SUSTAVA

Kada je početkom 2011. godine odlučeno krenuti u izgradnju ovakvog sustava trebalo je preispitati prihvatljivost preduvjeta da bi sustav uopće mogao biti uspješno izgrađen. Prije svega je trebalo razmisliti o tome gdje postaviti fizički sustav za pohranu podatka, provjeriti i po potrebi poboljšati mrežnu povezanost do odabrane fizičke lokacije te prilagoditi klijentski i poslužiteljski softver potrebama ove usluge.

Odlučeno je da će u početku biti moguće pohranjivati podatke samo s poslužitelja koji opslužuju osnovne Internet servise na ustanovama, a radi se o poslužiteljima koji kao operacijski sustav imaju posebnu inačicu Debian GNU/Linux distribucije s prilagođenim programskim paketima za potrebe CARNet-ovih ustanova članica.

Zatim je izvršena procjena prostora na sustavu za pohranu podataka koji se može dodijeliti ustanovama članicama, sa zaključkom da je očekivanih 50 ustanova u prvoj fazi proširenja, moguće spremati 200 gigabajta podataka sa poslužitelja ustanova, s tim da se podaci pohranjuju svakodnevno i čuvaju sljedeća 2 mjeseca.

Za fizičku lokaciju je odabrano CARNet-ovo čvorište u Osijeku, gdje je nedavno uređena sistem sala, te je na osnovi dobivenih geofizičkih karata ustanovljeno da je ta lokacija na području gdje se potresi veće magnitude do sada nisu nikada pojavili, a i manji potresi su rijetkost. Također je riješen i eventualni problem poplava, jer sistem sala nije u razini zemlje.

Što se tiče mrežne povezanosti, napravljen je radni sastanak s CARNet-ovim odjelom mrežne infrastrukture, gdje je ustanovljeno da je u tom trenutku čvorište u Osijeku povezano s gigabitnim linkom na kojemu u noćnim satima (kada se radi pohrana podataka) iskorištenje u prosjeku ne prelazi 15%, što ostavlja više nego dovoljno prostora za promet od ustanova do sustava za pohranu podataka. Također je predviđeno povećanje linka na 10 gigabita tijekom 2011. godine, što je u međuvremenu i realizirano.

Zadnji korak je prilagođavanje softvera, što CARNet-u ne predstavlja veći problem jer zapošljava tim ljudi koji razvijaju programske pakete za Debian Linux distribuciju, tako da je i taj posao odrađen vlastitim snagama.

III. KLIJENTSKA STRANA

U želji da se korisnicima na ustanovi (sistem-inženjeri ustanove članice) maksimalno pojednostavne poslovi oko izrade sigurnosnih kopija podataka, odlučeno je da se uključenje u sustav napravi što je jednostavnije moguće. Ispitivanjem niza mogućnosti, došlo se do zaključka da se svi poslovi, osim inicijalne prijave, mogu napraviti automatski.

Dovoljno je da sistem-inženjer na svom poslužitelju instalira samo jedan programski paket, koji tijekom instalacije automatski odradi niz potrebnih radnji. Ustanove paket dohvaćaju iz CARNet-ovog repozitorija paketa. Paket je u repozitoriju digitalno potpisan CARNet-ovim javnim ključem što omogućava detekciju neovlaštenih izmjena u instalacijskoj skripti.

Naime, skripte koje dolaze s programskim paketom prije svega naprave instalaciju samog klijentskog softvera, zatim naprave katalog podataka koje treba pohranjivati, te izrade kripto ključeve kojim će se podaci kriptirati prije slanja na CARNet-ov sustav za pohranu. Za jedinstvenu identifikaciju novog klijenta potrebno je generirati i na siguran način razmijeniti dijeljenu tajnu (eng. *shared secret*). Dijeljena tajna stvara se na klijentu kao slučajni niz znakova i šalje zajedno s ostalim podacima o klijentu kao poruka elektroničke pošte u CARNet-ov sustav zahtjeva (eng. *ticketing system*). Navedena poruka ujedno predstavlja službeni zahtjev ustanove za pokretanjem usluge. Sama poruka kriptirana je javnim ključem CARNet-ovog sustava zahtjeva tako da dijeljena tajna i ostali podaci sadržani u zahtjevu nisu vidljivi trećim stranama.

Dakle rezultat instalacije klijentskog softvera na ustanovi je elektronička poruka u CARNet-ovom sustavu zahtjeva putem koje je zatraženo pokretanje servisa. Zahtjev u privitku sadrži i katalog podataka koje korisnik želi pohranjivati iz kojeg je vidljivo je li količina podataka unutar trenutnog ograničenja od 200 gigabajta po poslužitelju.

Time je instalacija na strani klijenta završena. Na poslužitelju ustanove se sada nalazi instaliran klijentski program, a CARNet ima sve potrebe podatke za uključivanje ustanove u sustav. Ako ustanova zadovoljava sve zahtjeve za pokretanje usluge, CARNet administratori dodaju novog klijenta u konfiguraciju Bacula poslužitelja i već slijedeću noć pokreće se pohrana cijelog poslužitelja (enf. *full backup*) [6][7]. Klijentski program na poslužitelju ustanove ne spaja se sam na centralni sustav, već čeka zahtjev od središnjeg Bacula poslužitelja za pokretanje pohrane podataka. Na taj način CARNet može upravljati vremenom kad se tijekom noći radi pohrana podataka, bez uplitanja korisnika. Za sigurnu komunikaciju između klijenta i poslužitelja koristi se SSL protokol.

Ponekad je potrebno prilagoditi i postavke lokalnog vatrozida na samoj ustanovi, o čemu je sistem-inženjer i unaprijed obaviješten. No, prilikom inicijalne pohrane podataka zna se dogoditi da nije moguće pristupiti poslužitelju na ustanovi što obično ukazuje na potrebe za daljnjim podešavanjem vatrozida na ustanovi ili samom poslužitelju na kojem je instaliran Bacula klijent.

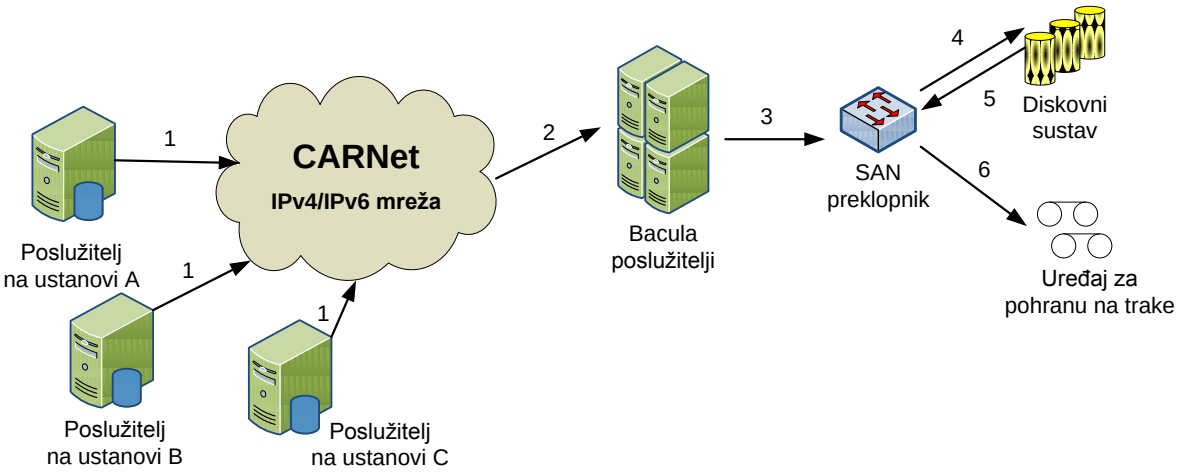
Korisnik također može izabrati da mu se o svakom uspješno provedenom snimanju podataka pošalje iz centralnog sustava elektronička pošta s potvrdom.

Kada je potrebno raditi povrat podataka iz sustava, za sada je to moguće isključivo koristeći komandno-linijski program koji je dio Bacula klijentskog softvera. Naravno, za tu operaciju je potrebno imati i odgovarajuće ključeve.

Još jedna od zanimljivih mogućnosti je i oporavak kompletnog poslužitelja na novom hardveru (uobičajeni naziv na engleskom jeziku je *bare metal recovery*) gdje je moguće na potpuno novom hardveru (bez obzira da li se radi o novom poslužitelju ili samo o zamjeni npr. pokvarenog sistemskog diska) u potpunosti vratiti sve podatke i upogoniti poslužitelj u vrlo malom vremenskom roku.

IV. CENTRALNI POSLUŽITELJI I SUSTAVI ZA POHRANU PODATAKA

Na lokaciji CARNet-ovog čvorišta u Osijeku nalaze se tri uređaja koji čine središnji dio ovog sustava: poslužitelji na kojima je pokrenuta Bacula, zatim uređaja za brzu pohranu podataka (eng. *disk storage system*) i uređaj za pohranjivanje podataka na trake (eng. *tape library*). Arhitektura sustava se može vidjeti na slici 1.



Slika 1. Arhitektura sustava s numeriranim fazama prijenosa i pohrane podataka

Poslužitelji su putem optičkog (*Fiber-Channel*) spoja priključeni na oba uređaja za pohranu podataka. Kada se pokrene pohrana podataka s ustanove, podaci se radi brzine prvo pohranjuju na diskovni sustav, a zatim se tijekom dana pohranjuju na trake.

Na diskovnom sustavu je uvijek snimljena zadnja kopija podataka, pa je pristup do posljednje sigurnosne kopije podataka brz. Prethodne kopije se čuvaju na trakama, te je pristup tim podacima ponekad nešto sporiji, što najviše ovisi o trenutnoj raspoloživosti pojedinih uređaja za čitanje traka.

Bacula klijent na poslužitelju ustanove kriptira sve podatke prije slanja na centralni poslužitelj CARNet-a. Za kriptiranje se koriste kripto ključevi stvoreni tijekom instalacije klijenta koji su dostupni samo administratoru na ustanovi (ne šalju se CARNet-u u inicijalnom zahtjevu za uslugom). Podaci su zbog kriptiranja sigurni dok putuju kroz CARNet mrežu, te je onemogućena zloupotreba od strane CARNet-a ili vanjskog napadača u slučaju provale na centralnu lokaciju u Osijeku. Kripto ključevi potrebni su za dekripciju kod vraćanja podataka, te ih administrator ustanove osim na poslužitelju treba spremiti na sigurnu lokaciju. To je dovoljno učiniti jednom nakon instalacije usluge jer se kripto ključevi kasnije ne mijenjaju. U slučaju da se dođe do katastrofalnog gubitka svih podataka na poslužitelju ustanove, a administrator ustanove nema sigurnosnu kopiju ključeva podaci se nakon vraćanja neće moći dekriptirati u izvorni oblik jer je gubitkom poslužitelja ustanove nestala i posljednja kopija ključeva. Prema tome odgovornost za siguran povrat podataka i dalje ostaje na administratoru ustanove, ali je problem značajno jednostavniji. Umjesto svakodnevnog prenošenja velike količine podataka na sigurnu lokaciju, potrebno je samo jednom spremiti manju količinu podataka (npr. snimiti ključeve na CD i spremiti ga u sef). Administratoru ustanove također se savjetuje periodički testirati ispravnost sustava: korištenjem sigurne kopije ključeva pokušati vratiti najvažnije podatke poslužitelja.

Nedostatak sigurnog kriptiranja podataka na klijentu je to što onemogućava deduplikaciju podataka na strani poslužitelja. Identična datoteka kriptirana na dva klijenta dati će dva različita niza podataka. Poslužitelj ih oba mora nezavisno pohraniti jer ni po čemu ne može zaključiti da se zapravo radi o istoj polazišnoj datoteci. Deduplikacijom bi se najviše moglo uštedjeti na prostoru koji zauzimaju datoteke operacijskog sustava koje su na svim klijentima identične.

V. ZAKLJUČAK

Uvođenjem u rad ovog sustava CARNet je zadovoljio većinu zahtjeva u sigurnosne pohrane podataka [3]:

AUTOMATIZACIJA PROCESA: sustav je u potpunosti automatiziran i ne ovisi o sistem inženjeru na ustanovi niti o CARNet-ovim administratorima. Prije uvođenja ovog sustava bilo je potrebno dnevno ručno mijenjati trake na ustanovi što je predstavljalo nepotreban fizički posao (dolazak na lokaciju poslužitelja, zamjena traka, prijenos snimljenih traka na udaljenu lokaciju, i sl.).

GEOGRAFSKA REDUNDANCIJA: sustav sprema podatke na geografski udaljenoj lokaciji i to u dva koraka tako da postoji totalna geografska redundancija podataka. Kada su ustanove same radile svoje sigurnosne kopije, rijetko je postojala geografska redundancija, jer su se trake obično čuvale na istom mjestu gdje je i poslužitelj s kojeg se podaci kopiraju. U slučaju nekog katastrofalnog događaja (potres, požar, poplava i sl.) svi podaci bi mogli biti trajno izgubljeni.

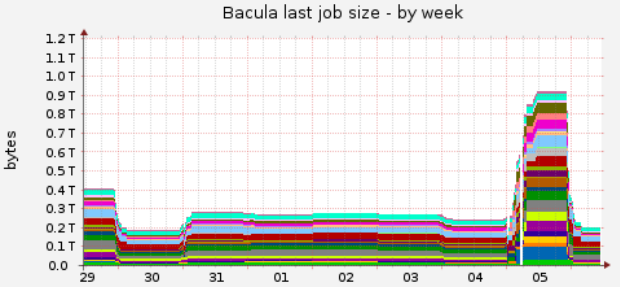
NEPOVREDIVOST PODATAKA: sustav već na samom klijentu kriptira podatke, tako da je nemoguće ni na mrežnom nivou ni na samom sustavu za pohranu podataka doći do samih podataka, osim ako nemate potrebne kripto ključeve. Na taj način su korisnici sigurni da je nemoguće neovlašteno doći do podataka. Prije je bilo moguće doći do podataka ako bi se fizički došlo do snimljenih traka, jer nije bilo uobičajeno kriptirati podatke na samim trakama.

Uz navedeno treba naglasiti da je CARNet uvođenjem ovog sustava dodatno uštedio prilikom nabavke poslužitelja za ustanove, jer više nije potrebno nabavljati pojedinačne tračne uređaje, koji su kod posljednjih nabavki poslužitelja sačinjavali oko 50% cijene poslužitelja.

Također, treba naglasiti da troškovi uspostave ovog sustava u CARNet-u minimalni, jer je za uspostavu sustava bilo potrebno samo nabaviti određeni broj diskova za proširenje postojećeg diskovnog sustava u Osijeku, kao i odgovarajuću količinu traka za pohranjivanje podataka.

Ovaj sustav je u CARNet-u poznat pod imenom sys.backup, a koncept sustava je prikazan i na TERENA sastanku TF-STORAGE radne skupine [2], gdje su druge akademske mreže iz Europe iskazale interes za uspostavu sličnog sustava.

Danas u sustavu sudjeluje oko 40 ustanova članica iz cijele Hrvatske, a pohrana podataka se vrši isključivo u noćnim satima. Nedjeljom je po unaprijed definiranom rasporedu pohrane predviđena izrada pune kopije podataka, a ostalim danima samo razlikovne kopije. Slika 1. prikazuje karakterističan raspored prenesene količine podataka kroz jedan tjedan na prijelazu iz siječnja u veljaču 2012. godine. Oznakom 05 je označen datum 5.2.2012. koji je bio nedjelja kada je u rasporedu prijenos pune kopije podataka.



Slika 2. Tjedni graf prijenosa podataka u terabajtima

Kao moguća nadogradnja sustava, predviđena za 2012. godinu, je proširenje prostora od 200 gigabajta koje je danas ograničavajuće za neke ustanove koje imaju potrebu za većom količinom prostora, te priprema klijentskih programa i za druge operacijske sustave (poglavito na bazi Microsoft Windowsa). Također, razmišlja se i o mogućnosti web pristupa pojedinim pohranjenim datotekama umjesto današnjeg klijenta koji se koristi iz komandne linije. Moguća je i nadogradnja središnjih poslužitelja kako bi se njihova mrežna povezanost povećala sa sadašnjeg 1 gigabita na 10 gigabita, jer je u statistikama uočeno da postoje razdoblja tijekom noći kada bi se moglo prenositi i više od 1 gigabita podataka po poslužitelju.

Dosadašnja iskustva su izvrsna, a većina sistem inženjera je istakla da im ovaj način sigurnosne pohrane podataka umnogome olakšava taj segment posla.

ULOGA PRISTUPNE TOČKE JAVNE SIGURNOSTI U TELEKOMUNIKACIJSKOJ USLUZI EPOZIV

Pavao Britvić, Hrvoje Strepački

Državna uprava za zaštitu i spašavanje, Nehajska 5, 10000 Zagreb, Hrvatska
Ericsson Nikola Tesla d. d., Krapinska 45, 10000 Zagreb, Hrvatska
e-mail: pavao.britvic@duzs.hr, hrvoje.strepacki@ericsson.com

Sažetak: Usluga ePoziva nova je telekomunikacijska usluga automatske dojave prometne nesreće pristupnoj točki javne sigurnosti (u Republici Hrvatskoj: Državnoj upravi za zaštitu i spašavanje). Predložena i podržana od strane Europske komisije, usluga ePoziva trebala bi biti uspostavljena od 2015. godine na nacionalnoj razini zemalja članica Europske unije koje su potpisale Sporazum o razumijevanju za pitanje uvođenja ePoziva, uključujući i Republiku Hrvatsku, koja je Sporazum potpisala 2010. godine.
U ovom radu predstavljena je uloga pristupne točke javne sigurnosti (Public Safety Answering Point – PSAP) u pružanju usluge ePoziva na nacionalnoj razini. U radu su razmotreni tehnološki i operativni aspekti pristupne točke javne sigurnosti unutar arhitekture u podršci usluge ePoziva, te razmotrene funkcionalnosti ePoziva podržane od strane pristupne točke javne sigurnosti. Budući da se usluga ePoziva ostvaruje na temelju ranije implementiranog nacionalnog 112 sustava, u radu se razmatra potrebna nadogradnja 112 sustava potrebna za uspostavu usluge ePoziva. Rad završava analizom poboljšanja kvalitete javne sigurnost, koja se postižu implementacijom usluge ePoziva, te doprinosa pristupne točke javne sigurnosti poboljšanju iste.

I. UVOD

Uspostava jedinstvenog europskog broja za hitne službe 112 definirana je Zakonom o elektroničkim komunikacijama [1] koji je usklađen s direktivom Europske unije [2]. Prema Zakonu o elektroničkim komunikacijama, 112 je jedinstveni troznamenkasti broj koji mora biti rezerviran za hitne službe, a operatori moraju omogućiti svim korisnicima usluga besplatne pozive na 112.

Pristupna točka javne sigurnosti (jedinstveni operativno-komunikacijski centar - Centar 112) zaprima sve pozive vezane uz hitne situacije, nesreće i prijetnje od nastanka katastrofe te putem sredstava veze, na temelju standardnih operativnih postupaka, žurno izvješćuje sve nadležne službe i koordinira djelovanje po pozivu [3, 4, 5, 6].

Nova telekomunikacijska usluga ePoziva [7] temelji se na postojećem sustavu 112. Njena uspostava traži određene modifikacije postojećeg sustava 112, posebno sa strane pristupne točke javne sigurnosti.

U ovom se radu najprije predstavlja arhitektura sustava u podršci uspostave usluge ePoziva. Zatim se razmatraju tehnološki i operativni aspekti pristupne točke javne sigurnosti u usluzi ePoziva, uključivo funkcionalnosti Centra 112, kao i potrebne preinake i nadogradnje Centra 112 u podršci usluge ePoziva. Uvođenje usluge ePoziva na temelju modificiranog sustava 112 argumentira se poboljšanjem kvalitete javne sigurnosti, koja se postiže implementacijom usluge ePoziva, i doprinosom pristupne točke javne sigurnosti tom cilju.

II. EPOZIV

Telekomunikacijska usluga ePoziva (engl. eCall) [7] nova je javna telekomunikacijska usluga namijenjena automatskom obavještavanju Centra 112 (pristupne točke javne sigurnosti) o nastanku prometne nesreće, te automatskom ostvarenju prioritetnog govornog komunikacijskog kanala između Centra 112 i vozila u nesreći, uz korištenje javne pokretne mreže [10, 9, 8]. Europska komisija podržava razvojne i regulatorne aktivnosti vezane za uspostavu usluge ePoziva na nacionalnoj i razini Europske Unije, uz očekivanu implementaciju na području EU od 2015. godine [7].

U slučaju prometne nesreće, očitanja odgovarajućih osjetila unutar vozila (osjetilo zračnog jastuka, MEMS akcelerometri i dr.) obrađuju se prikladnim algoritmom za identifikaciju nastanka prometne nesreće. U slučaju pozitivne identifikacije, automatski se pokreće postupak unutar IVS-a, kojim se najprije otvara prioritetni komunikacijski kanal iz vozila prema Centru 112, a zatim se istim (govornim) kanalom šalje poruka s tzv. minimalnim skupom podataka (engl. Minimum Set of Data, MSD). MSD sadrži na objektivan način prikupljene podatke, poput: jedinstvenog identifikacijskog broja vozila (engl. Vehicle Identification Number, VIN), položaja vozila u nesreći (procijenjeno ugrađenim GPS prijamnikom [9, 10]), orijentacije vozila, vrste i marke vozila, te broja osoba u vozilu (određeno npr. broj korištenih sigurnosnih pojaseva). Prioritetni status usluge ePoziva ostvaruje se postavljanjem posebne, tzv. eCall zastavice.

Arhitektura sustava u potpori usluge ePoziva (slika 1) sastoji se od tri temeljna elementa:

- opreme za ePoziv ugrađene u vozilo (engl. In-Vehicle System, IVS)
- javne pokretne mreže (engl. Mobile Network, MN) i
- pristupne točke javne sigurnosti (u Republici Hrvatskoj: Centar 112)

Usluga ePoziva treba biti dostupna kako za lokalno stanovništvo (vozila registrirana u RH), tako i za vozila iz drugih zemalja koje su nacionalnoj razini uspostavile uslugu ePoziva (većina zemalja EU, Rusija i dr.) [7].

III. TEHNOLOŠKI I OPERATIVNI ASPEKTI PRISTUPNE TOČKE JAVNE SIGURNOSTI U USLUZI EPOZIV

Pristupna točka javne sigurnosti (Centar 112) središnji je komunikacijski čvor za prihvat svih vrsta hitnih poziva. Ovisno o naravi poziva 112 i traženoj pomoći, operator Centra 112 prihvatit će informacije o događaju i proslijediti ih odgovarajućim hitnim službama (policija, hitna medicinska pomoć, vatrogasci). U obradu poziva za pomoć mogu biti uključene i neke druge službe.

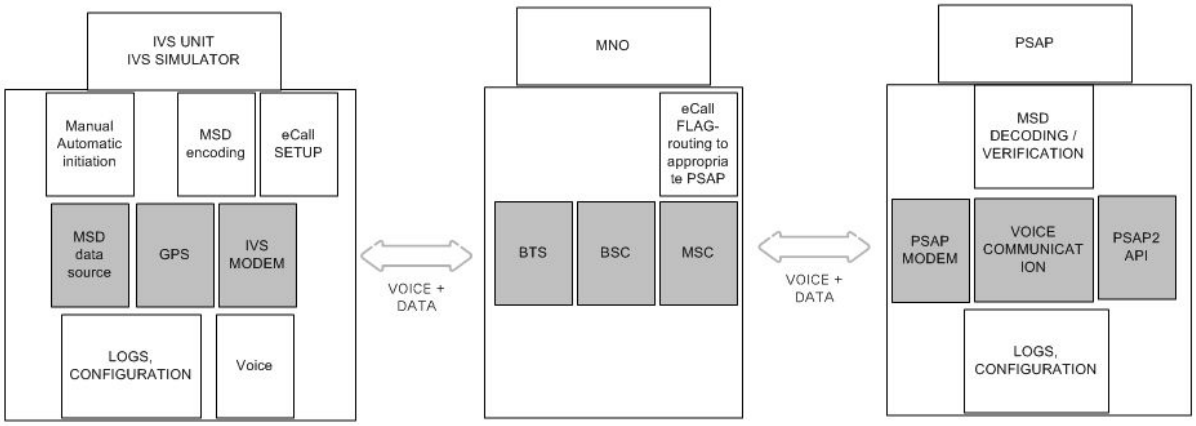
Centar 112 u sebi objedinjuje sklopovsku (hardware) i programsku (software) podršku koja podržava cjelovit proces:

- primanja,
- provjere,
- obrade
- prosljeđivanja žurnih poziva te
- komunikacijske koordinacije - koordinira djelovanje svih sudionika zaštite i spašavanja.

Operater Centra 112 zaprima hitni poziv provjera vjerodostojnost poziva i lokacije pozivatelja (ukoliko je to moguće), unosi sve relevantne podatke o samom događaju odnosno o vrsti, tipu i težini hitne situacije te slijedi prijenos poziva i/ili informacija određenoj hitnoj službi (policija, hitna medicinska pomoć, vatrogasci i dr.) u svrhu raspoređivanja, izdavanja naloga, angažiranja snaga i sl. U slučaju da poziv na Centar 112 zahtjeva angažiranje više službi tada slijedi komunikacijska koordinacija među službama. Centar 112 opremljen je snažnim Geografskim Informacijskim Sustavom (GIS) koji omogućuje kvalitetno upravljanje informacijama o položaju, što uvelike olakšava i optimizira organizaciju pružanja pomoći.

Sklopovska i programska oprema Centra 112 moraju biti modificirana kako bi podržale rad usluge ePoziva. Modifikacije se odnose na razlikovanje običnog 112 poziva od ePoziva. Posebna programska podrška ugrađuje se u Centar 112 kako bi se omogućilo dekodiranje i verifikacija MSD poruke. Dekodirani MSD podaci na prikladan se način nakon toga pojavljuju na operatorskom zaslonu. Ujedno, navedeni se podaci pohranjuju u elektronički dnevnik događaja Centra 112.

Aktivnosti nakon zaprimanja ePoziva opisane su u posebnoj Standardnoj Operativnoj Proceduri (SOP) Centra 112. Osim zaprimanja i obrade poziva, hitni se poziv može preusmjeriti na odgovarajuće hitne službe sukladno procjeni stanja, što obuhvaća prosljeđivanje MSD ili u cijelosti ili djelomično. Budući da usluga ePoziva isključivo pokriva nesreće u prometu, preusmjeravanje poziva i obavijesti o nesreći mogu biti vezani i za druge hitne službe, poput: pružatelja usluga informacija o stanju u prometu (Hrvatski autoklub, HAK), operatora cesta i auto-cesta, službe pomoći na cestama i dr. Navedeni postupci zahtijevaju razvoj i instalaciju potrebne informacijsko-komunikacijske podrške u opremi Centra 112 na način pokriven europskim standardima usluga poziva 112 i ePoziva.



Slika 1. Detaljna arhitektura sustava u potpori usluge ePoziva

Standardizirana verzija koncepta usluge ePoziva, kako je predstavljena u ovom poglavlju, upravo se ispituje i verificira u okviru pan-europskog projekta HeERO (engl. Harmonised eCall European Pilot) [12], čije su članice: Češka, Finska, Grčka, Hrvatska, Italija, Nizozemska, Njemačka, Rumunjska i Švedska. Hrvatski nacionalni pilot projekt ePoziva predvodi Državna uprava za zaštitu i spašavanje, s glavnim partnerima Hrvatskim autoklubom (HAK) i kompanijom Ericsson Nikola Tesla d. d.

IV. DISKUSIJA

Podaci vezani za operativni rad Sustava 112 tijekom 2011. godine koji je nadležan za zaprimanje svih pozive vezanih uz hitne i izvanredne situacije i prijetnje od njihovog nastanka, komunikacijski je koordinirao sve nadležne službe i operativne snage zaštite i spašavanja pokazuju da je broj zaprimljenih poziva u 2011. bio 3.000.396 s prosječnim vremenom odziva Centra 112 od 8 sec. Navedeni pozivi zaprimljeni u Sustavu 112 rezultirali su 498.604 komunikacijski obrađenih događaja među kojima je 18.294 događaja vezanih za prometne nesreće. U Zagrebačkoj županiji i Gradu Zagrebu Županijski centar 112 je komunikacijski obradio 4705 nesreća (slika 2). i 345 nesreća na autocesti.

Usluga ePoziva uspostavlja se upravo s ciljem dobivanja osvježene i kvalitetne slike stanja, što rezultira znatno brzim odzivom hitnih službi, dakle i kvalitetnim upravljanjem operacijama javne sigurnosti vezanim za prometnu nesreću.

Slijedom navedenog, uz razumijevanje hrvatskog godišnjeg prosjeka poginulih (601) u periodu od 2001. do 2010. [11], izravnim dobivanje informacije o nesreći i mjestu gdje se dogodila smatramo da će se smanjiti vrijeme reagiranja na nastanak prometne nesreće, što će rezultirati učinkovitijem spašavanju ljudskih života, sprečavanjem gomilanja novih prometnih nesreća, skraćenjem vremena oporavka osoba ozlijeđenih u prometnim nesrećama, kao i smanjenjem troškova zdravstvene zaštite i rehabilitacije ozlijeđenih.

V. ZAKLJUČAK

Usluga ePoziva primjer je uspješne implementacije informacijsko-komunikacijskih tehnologija u sustavu javne sigurnosti. Jednostavan tro-komponentni lanac

Slika 2. Prometne nesreće na cestama u Zagrebačkoj županiji i Gradu Zagrebu tijekom 2011.

arhitekture ePoziva osigurava uključenje svih vozila u sustav, čime se ostvaruje cilj pružanja jedinstvene razine javne sigurnosti u prometu na nacionalnoj razini. Uspostava usluge ePoziva omogućava smanjenje vremena reagiranja na nastanak prometne nesreće, što će rezultirati učinkovitijem spašavanju ljudskih života, sprečavanjem gomilanja novih prometnih nesreća, skraćenjem vremena oporavka osoba ozlijeđenih u prometnim nesrećama, kao i smanjenjem troškova zdravstvene zaštite i rehabilitacije ozlijeđenih.

Jedinstvena uloga Centra 112 u upravljanju procesima vezanim za obradu prometnih nesreća dobiva kvalitetniju dimenziju uvođenjem usluge ePoziva. Podrška uspostavi usluge ePoziva traži stanovite modifikacije opreme Centra 112. Nakon implementacije navedenih modifikacija i testiranja i validacije funkcionalnosti usluge ePoziva i sustava 112 u okviru pan-europskog projekta HeERO, Republika Hrvatska bit će spremna za obveznu implementaciju usluge ePoziva [7] na području Republike Hrvatske s početkom 2015. godine.

NEW TELECOMM APPLICATIONS

Evaluating a Medical Grade Network through Network Calculus

N.R. Kakanakov*

* Technical University of Sofia, Plovdiv branch / Computer Systems and Technologies, Plovdiv, Bulgaria
kakanak@tu-plovdiv.bg

Abstract - The paper aims to present an analytic evaluation of a Medical Grade Network for the purpose of the Clinic for Pediatric Surgery in Plovdiv. It presents the design of the network based on the security and throughput needs of the organization and the requirements of Medical grade Networks. It also presents a method to analytically obtain the maximum delays for the critical services, based on the mathematical apparatus of deterministic Network Calculus and its ability to foreseen the delay boundaries in a network knowing the traffic envelopes and the services provided by the network elements. Using the presented method and defining the traffic classes in the network and their characteristics, the delay boundaries for the designed network are obtained. Results can be used as a basis for further configuration tuning of the network devices and for defining parameters of QoS policy, suitable for the network.

I. Introduction

The growing adoption of networking and communication technologies in all parts of human life makes it impossible to provide public services (e.g. health and medicine) without having access to/from Internet and without intelligent information management and exchange. The health service is no more hospital or physician centered, it is patient centered. The information about every patient should be synchronized between different service providers, patient organizations, and public control bodies. This new model of the health-care requires computer-aided information management and seamless network infrastructure. More and more of the hospitals are relying on Hospital Information Systems (HIS) that should collect, organize, maintain and provide access to patient, or disease information. The HIS should cover all technical, economic, and other requirements for the health-care services. For investigation of specific diseases and patient some custom information should be stored and maintained that is not necessary to be part of the HIS. In such cases Clinical Information Systems (CIS) are employed that should work as part of HIS, but providing the custom information and more important the custom view on the data for specific investigations. Both HIS and CIS are relying on network and communication services for information exchange. Some of these services are sensitive to network delays and throughput.

The rest of paper is organized as follows: Section II presents a local area network design of a Clinic for Pediatric Surgery in University Hospital Plovdiv (PedSurgCIS); Section III presents a mathematical model for evaluation deterministic boundaries for network delays and Section IV presents mathematical model for evaluation of the particular network. Section V provides numerical results based on the model.

II. Design of the Medical Grade Network

A. Background

Medical Grade Networks (MGN) concept was introduced by Cisco Systems to describe a specific type of corporate networks that are very sensitive to information loss, data consistency, response time and improved security [1]. MGN must apply all requirements of the cooperative networks: scalability, security, reliability. But they also should provide interactivity and should be dynamically reconfigurable. Unlike traditional business networks, clinical and hospital networking growth could hardly be foreseen because it integrate the hospital network, clinical networks, general practitioners, mobile physicians, patients, public and private health bodies, laboratories, research centers, etc. To fulfill these requirements the MGN should be easy to expand/shrink and should provide smart, dynamic security mechanisms to cover all temporal, long-term and permanent users [2]. The MGN should then be built in typical hierarchical manner, using Core, Distribution and Access layers.

Clinical networks can be viewed as an isle in the MGN, built for specific purposes and should rely on the hospital Core and Distribution layers. But as long as the clinic needs to provide services and remote access to specific users, it should have some seamless external access and managed security policies. It should also have access to external health services and to the internal hospital services from other clinics, laboratories, physicians and provide some services to them. According to some sources [1, 3], every clinical network should have Firewall and Intrusion Prevention System, a management switch to connect with hospital distribution layer, and access switches to connect end devices. This switch is the core of the clinical network and should provide traffic management in the local network and to the output traffic trough CoS/QoS [4]. Evaluating the delays of the traffic classes traversing the access switches, the management switch and the security appliance can provide valuable parameters to help choosing the best QoS policy and could put some restrictions to the network devices.

B. Design of the Network for PedSurgCIS

Having in mind the guidelines presented in section II-A, all that is needed for the design of PedSurgCIS network is to define network services and user needs. The clinic has one Application and Database server for the Clinical Information System, thirty user computers with IP phones, and some medical electronic equipment (ECGs, EEGs, Monitors, etc.) The local devices should have access to the image diagnostic department, laboratory, VoIP gateway, and mail server in the hospital network. The VoIP, mail and camera traffic is not important for the work of the physicians, so can be marked as bulk.

The access layer is realized by three layer 2 switches, two for the computers and IP phones and one for the medical equipment. These switches are with 100 Mbps interfaces and 1Gbps uplink (i.e. HP-2620-24). They are connected to Layer 3 management Gigabit switch (i.e. HP 5120-24g EI), together with the Application and Database server. The connection of this core switch to the hospital network is trough firewall appliance (i.e. SmoothWall UTM100). In these design the majority of the traffic will be serviced by one L2 switch and the L3 switch (PC-to-PC, local file transfer, mail exchange with server, information system, medical equipment). The outbound traffic to/from HIS servers or Internet services access will traverse the firewall appliance. This appliance will provide perimeter security as long as content-based application level intrusion detection and prevention. The UTM100 will also act as a VPN server for remote secure access. The topology of the designed network along with the device connections and types is shown on Fig. 1.

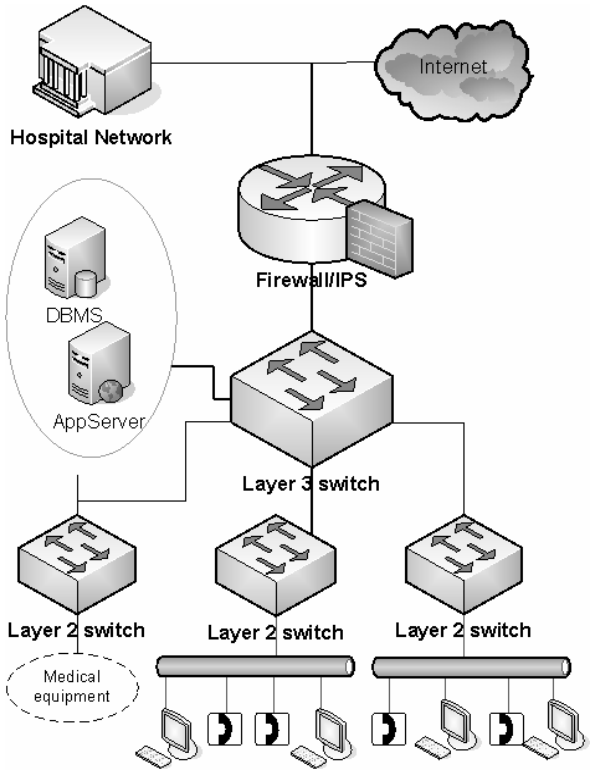

Figure 1. Network design for PedSurgCIS

III. Network Calculus Background

Network Calculus is a collection of results based on Min-Plus algebra, which applies to deterministic queuing systems found in communication networks. It is similar to system theory but using different algebra. It is based on the research works by Cruz [5], [6] on the calculus for network delay and traffic envelopes and on the works by Parekh and Gallagher [7], [8] on the service curve definition of Generalized Processor Sharing (GPS) schedulers. Main input parameters of the Network Calculus theory are: per-flow arrival curves, service curves of network elements, and the route selecting mechanism. Most of the network flows can be described using arrival curves, represented with leaky bucket traffic envelopes and most of the network elements provide service to flows, described with its rate and slack term [5, 7, 9]. The service curves for network nodes that provide QoS is called rate-latency or R-SPEC (1), defined with the forwarding rate – R and the internal latency without queuing (slack term) – S. The notation exp^+ means that the expression is true when it is positive and is zero otherwise.

$$S(t) = R.[t - S]^+ . \tag{1}$$

The envelopes used with QoS in the Internet are modified token bucket called T-SPEC (2). It is defined by the peak rate – p, maximum packet size – M, long term average rate – r, and the burst size – b.

$$A(t) = \min[p.t + M, r.t + b] . \tag{2}$$

Both T-SPEC and R-SPEC are used in QoS RSVP protocol. In some cases, when constant bit rate (or periodic) flow is investigated, the arrival curve is defined by its packet size – L and period – T. These produces a stair function and for ease of calculations and formula that looks like token bucket is used (3):

$$A(t) = L + L\left\lfloor \frac{t}{T} \right\rfloor . \tag{3}$$

The actual formula for representing the service curve depends on the queue management policy: First-In-First-Out (FIFO), Strict Priority (SP), or Weighted Round Robin (WRR). In FIFO-based multiplexer each node is served as it comes with the maximum rate. In that case the rate offered to each flow depends on the average rate of other flows and the slack term depends on the burst size of other flows:

$$S_i(t) = \left(R - \sum\nolimits_{j \neq i} r_j\right).\left[t - \left(S + \frac{\sum\nolimits_{j \neq i} b_j}{R}\right)\right]^+ , \tag{4}$$

where S is the latency of switch without multiplexing.

In Strict Priority (SP) queuing, the packets form the flow with the highest priority are forwarded immediately but that forwarding cannot interrupt the forwarding of a packet that already is started. So, the high priority packet can wait for low priority packet in some cases. The packet with medium priority must wait for all packets with higher priority and sometimes for packet with lower priority if their forwarding was started. Low priority packets must wait for all other flows if they are presented. According to this reasoning the service curve for Strict Priority (assuming that flow with smaller index has bigger priority) is a rate-latency curve with rate (5) and slack term (6) [10]:

$$R_i = R - \sum_{j>i} r_j \,, \tag{5}$$

$$S_i = S + \frac{\sum_{j>i} b_j}{R - \sum_{j>i} r_j} + \frac{\max(M_j; j < i)}{R} \,, \tag{6}$$

where r_i, M_i, and b_i are the T-SPEC parameters of the i-th flow.

In Weighted-Round-Robin (WRR) queue management every flow receives a quota for forwarding according to the weights associated with it. In the worst case scenario, when the receiving packet has just missed its flow turn it must wait for all other flows quota and even the packet form the same flow that is entered the forwarder. According to this case the service curve for WRR assuming that packets that enter the forwarder cannot be interrupted is with rate (7) and latency (8) [10]:

$$R_i = R.\frac{w_i - M_i}{\sum_j w_j - M_i} \,, \tag{7}$$

$$S_i = S + \frac{\sum_{j \neq i} w_j}{R} \,, \tag{8}$$

where with w_i and M_i are marked the weight and maximum packet size of the i-th flow.

As FIFO, SP, and WRR policies have service curves that are well known, for the combined queuing policy it is not an easy task to define the service curve. As in many Ethernet switches the combined policy SP+WRR is used, it is a challenge to obtain the service curves for them. If one flow is served with SP and other with other policy, the leftover service curve offered to non-SP flows is [12]:

$$S^*(t) = [S(t) - E(t)]^+ \,, \tag{9}$$

where $S^*(t)$ is the service offered to other flows, $S(t)$ is the normal service curve of the node, and $E(t)$ is the envelope of the high-priority traffic.

The Network Calculus model provides the mathematical connection between arrival and service curves as input parameters and the bounds for virtual delay and the backlog in network elements (for precise definition of these terms see [9]). If the arrival and service curves are plotted on a same plane (bits vs. time), then the virtual delay is bound by the maximum horizontal distance and backlog by the maximum vertical distance between two functions. Moreover, as in systems theory, the particular strength of the min-plus convolution is the ability to concatenate tandem systems along a network path. This facilitates the notion of network service curve that can characterize whole networks by a single transfer function and provides a way to obtain the end-to-end delay [9]. Latest research revealed the main problem with the concatenation of service curves – pay-burst-only-once theorem holds for FIFO based and not for all SP and GPS schedulers [11].

The basic network calculus uses a fluid flow model where data are infinitely divisible. This model does not capture irregularities that are due to constant or variable sized packets, such as store-and-forward delays. To cope with this problem the system that operates on packets could be decomposed into a tandem of a fluid system and a packetizer which subsequently delays data until entire packets are completed to restore the packet sequence [9]. The result service curve for a node with service $S(t)$ and maximum packet size of a flow – M is $[S(t) - M]^+$.

If the network topology has no cycles (i.e. is feed-forward), the concept of leftover service curves can be applied. In this concept, on each node the traffic is determined as cross-traffic and trough-traffic. The trough-traffic is the one for which the end-to-end delay is investigated and the cross-traffic is the bulk one. If we know the cross traffic envelope on each node, it is straight-forward to calculate the service offered to the trough traffic [12].

IV. Evaluation of the Delay in MGN

To develop a model for evaluation of the delays of a particular network, first the traffic classes in the evaluated network must be identified. Then the traffic of interest must be defined and its route must be found. This route will determine which network nodes will be crossed by the traffic of interest. For each of these network nodes the service curve should be chosen. These service curves can be used separately or a network path service curve could be calculated. The next step is to define parameters and traffic envelopes for all traffic classes in the network. The final step is to calculate the delay and backlog for the traffic of interest.

In Ethernet networks the communication latency is separated in two parts: the transmission time and the delay in the network node (multiplexing and queuing). As the transmission delay is straightforward to calculate (depending on the bit-times and signal speed), the current paper deals with the delay in the network nodes due to multiplexing and queuing. As long as the investigated network is difficult to present as feed-forward, the concept of the leftover service curves is not fully applicable. It is difficult to distinguish cross and trough traffic and in most

of the cases they go through the same sequence of nodes. In presented model instead of end-to-end delay, separate analyses of the delay bounds in the network nodes are made. The heterogeneity of nodes and queuing strategies does not allow us to apply pay-burst-only-once theorem.

For the presented network, we define three different classes of traffic. The first is the bulk traffic that includes web, mail, VoIP and other Internet applications not important for the Clinical Information System (CIS) – WT1. The second class (WT2) is the traffic from/to the medical equipment, which should be served with high priority. The third class (WT3) is the traffic of the information system – the one of interest for the current evaluation. As WT1 includes standard Internet applications traffic, it can be assumed TSPEC (*p, M, r, b*) – it is described with (2). WT2 traffic depends of the type of the equipment – periodic with small packets (real-time medical devices, sensors), or non-periodic with larger size packets (image diagnostics, scanners). It can be modeled as a combination of periodic traffic (3) and token bucket:

$$A(t) = \left(r + \frac{L}{T} \right).t + \max(M, L), \qquad (10)$$

where L is the packet size and T – period for the periodic, and r is the average rate, M – maximum packet size of non-periodic. The traffic of the CIS (WT3) is modeled as token bucket (*r, b*). With this assumption the delay bound can be calculated a little bigger but token bucket parameters can be directly used in device QoS configuration for delay guarantee.

There are two data routes for the traffic of interest (WT4): from computers (users) to the CIS server, and from CIS server to the hospital network (updates, laboratory results, image diagnostics, etc.). In the first route, the traffic will traverse the access switch (L2SW) and core switch (L3SW) and in the second route – through the core switch and the firewall appliance (FW). As it can be seen (Fig.1), there are three network nodes that will be crossed (L2SW, L3SW, FW). The service curves offered by these nodes depend on the type of multiplexing and queue management policy in the node. To select the most appropriate queuing policies for every node, we use the real devices proposed in section II-B (firewall: SmoothWall UTM100; access switch: HP-2620-24; core switch: HP 5120-24g EI). The firewall appliance offers no traffic shaping and thus uses FIFO multiplexing – (4). The access switch supports IEEE 802.1p classifying and offers no priority (FIFO) or priority queuing with three classes (high, normal, low). In the presented setup it works with SP queuing. The core switch supports eight queues that can be serviced by strict priority, weighted round robin, or combined policy. In most cases the high priority traffic is scheduled in expedite queue (SP) and all other traffic classes are scheduled in the Weighted Round Robin queues with appropriate weights. In the presented setup it works with 1 expedite queue and three WRR queues. As it is seen from (5) and (6), the high priority class is served almost with the line speed, except it cannot preempt low priority packet already entered the queue. For other flows, served with WRR policy, the rate and latency from (7) and (8) can be used, but modified as it is leftover curve from high priority traffic – (9). The result service curve, if $A_{HP}(t)$ is the arrival envelope of high-priority traffic, is:

$$S(t) = \left[R.\frac{w_i - M_i}{\sum_j w_j - M_i}.\left(t - S - \frac{\sum_{j \neq i} w_j}{R} \right)^+ - A_{HP}(t) \right]^+ \qquad (11)$$

Knowing the traffic envelopes of all traffic classes and service curves of the nodes and providing the mapping of the traffic classes to the corresponding queue of the nodes, Network Calculus can be used to obtain the delay bounds for all traffics, on every node of the network. For the L2SW we assume that the WT1 is classified to low priority queue, WT3 to the medium priority queue, and WT2 to high priority queue. For L3SW we assume that WT2 is served in expedite queue, and WT1 and WT3 are served in WRR queues. For the FW, there is no mapping as all traffics are served in one queue. In this case the delay for each flow depends on the aggressiveness of others (rate and burst/packet size).

Substituting (10) in (11), we can calculate the leftover service curve offered to WT1 and WT3 in L3SW – rate (12) and latency (13):

$$R_i = R.\frac{w_i - M_i}{\sum_j w_j - M_i} - r_2 - \frac{L_2}{T_2}, \qquad (12)$$

$$S_i = \frac{\frac{w_i - M_i}{\sum_j w_j - M_i}.\left(R.S + \sum_{j \neq i} w_j \right) + \max(M_2, L_2)}{R.\frac{w_i - M_i}{\sum_j w_j - M_i} - r_2 - \frac{L_2}{T_2}}. \qquad (13)$$

As the delay is the horizontal distance between arrival and service curves, it is easy to obtain formula for the delay with TSPEC envelopes (or token bucket) and rate-latency service curves (d_{max} – Fig.2).

For TSPEC flow the delay is:

$$D_i = S_i + \frac{M_i}{R_i} + \left(\frac{b_i - M_i}{p_i - r_i} \right).\frac{(p_i - R_i)^+}{R_i}. \qquad (14)$$

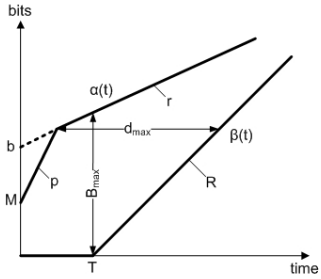

Figure 2. Graphical representation of delay and backlog bounds

The last member of the equation represents the packets stored in the queue if the arrival rate is bigger than the service rate for a particular flow (this means that the traffic alone overloads the node). For periodic or token bucket shaped flows the delay this member is omitted:

$$D_i = S_i + \frac{b_i}{R_i}, \tag{15}$$

As it can be seen from (15), the delay depends on the service curve offered to it (rate and latency) and its own burst size.

The delay bounds for WT3 (traffic of interest – CIS) can be calculated using (15) and substituting rate and slack term for L2SW – (5) and (6), L3SW – (12) and (13), and for FW – (4). The obtained formulas are respectively: (16), (17), and (18).

$$D_3^{L2SW} = S + \frac{M_1}{R} + \frac{b_3 + \max(M_2, L_2)}{R - r_2 - \frac{L_2}{T_2}} \tag{16}$$

$$D_3^{L3SW} = \frac{\frac{w_3 - b_3}{w_1 + w_3 - b_3}\left(R.S + w_3\right) + b_3 + \max(M_2, L_2)}{R.\frac{w_3 - b_3}{w_1 + w_3 - b_3} - r_2 - \frac{L_2}{T_2}} \tag{17}$$

$$D_3^{FW} = S + \frac{b_1 + \max(M_2, L_2)}{R} + \frac{b_3}{R - r_1 - r_2 - \frac{L_2}{T_2}} \tag{18}$$

The parameters w_1 and w_3 are the respective weights of WT1 and WT3 in WRR queuing. The formulas for the delay bounds of other flows (WT1 and WT2) are also obtained but are not presented in the paper due to limited space.

The delays of the traffic of interest for traversing the switches mostly depend of the rate and packet sizes of the high priority medical traffic. For the firewall appliance the delay depends on the parameters of all other traffics.

V. Numerical Results and Discussion

For the calculation of the real values for the delay bounds using (16), (17) and (18), the parameters of the traffic envelopes and service curves should be substituted with real values.

The parameters for the three network nodes are taken from the specifications of the devices: (HP-2620-24, HP 5120-24g EI, SmoothWall UTM100). The latency is built up by internal multiplexing latency and switch port latency. For the rate the wire forwarding speed is used as the flows compete for the same egress interface. For L2SW the rate is 100 Mbps and the latency is 10 μs. For L3SW the rate is 1000 Mbps and the latency is 5 μs. For FW the rate is 800 Mbps and the latency is 25 μs.

The parameters of the three traffic flows are difficult to be exactly foreseen, as they are subject to change dynamically during the network exploitation. The parameters chosen for current evaluation are based on statistical analysis of traffic patterns in real hospital and clinical networks or medical device specifications [13].

For WT1, as it is combined traffic, the burst size is considered five maximum sized packets, for peak rate is assumed that it can use all available bandwidth, the maximum size packet is the MTU of the network (Ethernet). In numbers this means: $r_1 = 1$ *Mbps;* $p_1 = 100$ *Mbps;* $M_1 = 1520$ *bytes;* $b_1 = 7600$ *bytes.*

For WT2 the non-periodic part has maximum packet size equal to the MTU of the network (Ethernet) and relatively low average rate, and the periodic part has non-intensive traffic with small packets: $r_2 = 300$ Kbps, $M_2 = 1520$ bytes, $L_2 = 100$ bytes, $T_2 = 2$ seconds.

The WT3 is similar to the typical information/database traffic but token bucket shaped. It has relatively small average rate as most of the time only small queries are made but with medium burst indicating bigger inquiries: $r_3 = 150$ Kbps, $b_3 = 2500$ bytes.

The associated weights for the WRR queues in L3SW for WT1 and WT3 are respectively 40% and 60% of the bandwidth. It is chosen to give the WT3 traffic some priority without strongly influencing the aggressive bulk traffic. For the calculation the weights are expected to be in number of bits per round. The actual weights used are $w_1 = 20000$ bits and $w_3 = 30000$ bits.

The calculated results for the delay bounds are presented in Table I. As it can be directly seen on the switches with applied strict priority the high priority traffic has the lowest delay. The difference between the two delays is due to the big difference in the forwarding rate. On the firewall appliance with FIFO multiplexing the delays of the WT3 is the lowest one and the delays for other two are almost the same. It is due to the lack of prioritization and the delay depends on the aggressiveness of other traffics. As the WT1 and WT2 are not aggressive the delay of WT3 is low.

The traffic of interest (WT3/CIS traffic) has relatively small queuing delays for traversing the network nodes (L2SW – 434, L3SW – 104, FW – 136). The actual delay of the network will be higher due to packet transmission and propagation times. One interesting observation is that

TABLE I. Delay in the network nodes for all flows*

	L2SW	L3SW	FW
WT1	900	360	78
WT2	317	36	135
WT3	434	104	136

* Results are in microseconds (μs)

the lack of prioritization in FIFO multiplexing (FW) leads to the delay inversion – the most aggressive traffic has the lowest delay. If the CIS traffic needs low-latency access to external resource (Internet of hospital network) the bulk traffic must be shaped before reaching the firewall, as it is the main resource of delay with its aggressiveness.

VI. Conclusions and Future Work

The paper provides model for delay calculation and network evaluation in clinical network, based on Network Calculus. It proposes the application of mathematical modeling on a real network topology with real devices. The presented model can be used for maximum delay calculation based on the traffic parameters, or if the delay bounds for a specific traffic are given (e.g. VoIP, video streaming) the best token bucket parameters for traffic shaping can be calculated for meeting these bounds.

The numerical results based on statistical parameters of typical traffic in hospital networks provide result for evaluation the design network for PedSurgCIS. The results show that queuing delay can be kept low if the high priority traffic is not very aggressive. If the CIS traffic needs lower delays it must be serviced with high priority and bulk traffic must be shaped.

The future work includes generalization of the model for typical MGN topologies and running test-bed experiments on the real devices to check the results.

gunnar.piho@computer

***Abstract* - In Clinical and Biomedical Proteomics Group (CBPG), Cancer Research UK Clinical Centre at University of Leeds we develop Laboratory Information Management System (LIMS) software for clinical research laboratories under the codename MyLIS. According to ASTM (American Society for Testing and Materials) LIMS Standard Guide, LIMS represents a class of computer systems designed to manage laboratory information. In this paper we briefly describe the functionality, challenges and goals; archetypes based development methodology; architecture, design and implementation; also current stage and future developments of MyLIS project. Our experiences give us a basis to believe that our archetypes based methodology allows interoperability of semantically heterogeneous software systems and therefore, for example, gives cancer researchers possibilities to share and distribute their data and knowledge with other researchers from the whole world automatically and conveniently.**

Keywords - software engineering, LIMS (laboratory information management systems).

I INTRODUCTION

The 2020 Science Group (Venice, July 2005) [1], group of internationally distinguished scientists highlighted, that "*...end-to-end scientific data management, from data acquisition and data integration, to data treatment, provenance and persistence*", is one of the immediate and important science challenges for the year 2020. They also indicated that "*a first step in that direction is peer-to-peer and service-oriented architectures*" and "*the development of an infrastructure for scientific data management is therefore essential*". It would be good if, for example, cancer researchers were able to share and distribute their data and knowledge with other researchers from the whole world automatically and conveniently. It would be also good if cancer researchers were able to use the normal clinical data from patients' medical record from the whole world in their research.

Such a world-wide, peer-to-peer and service oriented infrastructure for scientific data management requires that data and knowledge are semantically understandable for machines. It is also important, that patients' clinical data and patient sensitive personal data are strongly separated. While standardized in some terms, such system for scientists has to be flexible and adaptable to describe data, knowledge and research methods. This system has to be tied with and be flexible for data processing features and mathematical methods. It also needs advanced authorizing and security features.

Based on our research and on working prototype we developed and use in Clinical and Medical Proteomics Group, we can say that our archetypes and archetype patterns (A&AP) based techniques for domains, requirements and software can be the promising idea on which to build such an infrastructure for cancer research scientists. Laboratory system and laboratory researchers will use their own structure and semantics of data, knowledge and research methods, but communication between different laboratory systems will be organized by using unified archetypes and archetype patterns.

We explain the system of archetypes and archetype patterns we developed and use (Sections 2); describe the domain model of laboratory built based on archetypes and archetype patterns (Section 3); exemplify the idea of LIMS in Global Context (Section 4); and present conclusions (Section 5).

II ENHANCED AND COMPLEMENTED FRAMEWORK OF BUSINESS ARCHETYPE PATTERNS

Business archetype patterns are originally proposed by Arlow and Neustadt [2]. Business archetype patterns by Arlow and Neustadt (product, party, order, inventory, quantity and rule), composed by business archetypes (person's name, address, phone number, etc.), describe the universe of discourse of businesses as it is, neither referring to the software requirements nor to the software design.

We analysed Arlow and Neustadt's business archetype patterns according to the Zachman Framework [3] and Bjørner's domain analysis methodology [4]. We also compared these archetype patterns with analysis and data model patterns by Hay [5; 6], Fowler [7], and Silverston [8; 9]. As a result we proposed the refined and enhanced version of business archetypes and archetype patterns [10]. We only give the brief definitions of Party, Party Relationship, Product, Inventory, Order, Quantity, Money and Rule archetype patterns. We then describe a bit more precisely the *Process Archetype Pattern* we use for modelling business processes. For complete descriptions, of all archetype patterns from enhanced and complemented business archetype patterns framework, please refer to [10].

Person and *organization* are types of **party**. A party *identifier* uniquely identifies a party. A *registered identifier* (e.g. passport number) has been assigned to a party by a recognized statutory body (e.g. Home Office) and is valid for some period of time. A party *authentication* is an agreed and trusted way to confirm that parties are who they say they are. A party *address* (e-mail, webpage, phone number, address) represents information that is used to contact a party. Party can have

different *attributes* (e.g. capability, preferences, ethnicity, body metric, and etc.). For example, the informal notation "person is 176 cm tall, measured by Dr Smith at 3rd of May 2000" represents an instance of an attribute with category denoting "body metrics", name denoting "is tall", value denoting "176 cm", confirmed by denoting "Dr Smith", and valid from denoting "3rd of May 2000". Similarly to party archetype, most other archetypes have attributes property to store user specific data.

A **party relationship** captures the fact that there is a semantic relationship between two parties in which each party plays a specific role. There are only binary relationships (flexible, conceptually cleaner and easier to understand) between exactly two parties. This means that every n-ary relationship is reduced to two or more binary relationships. The *party role* archetype captures semantic of a party role (e.g. mother, customer, patient, etc.) played by a *party* in a particular *party relationship*. Not separating parties from roles they are involved with is a quite common design mistake in information systems. For flexibility reasons there is a *role type* archetype to store all the common information for a set of party role instances and a *party relationship type* to store all the common information for a set of party relationship instances. Role and relationship types also describe constraints (rules) for valid party types that are allowed to play a role or a valid role pairs that is allowed to perform a relationship.

The **product** archetype pattern represents a generalized model for products (goods or services) parties (persons or organizations) produce, use, sell or buy. There are special product types like unique products (e.g. Mona Lisa by Leonardo da Vinci), identical products (e.g. loaves of bread), identifiable products (e.g. cars with unique serial numbers), measured products (e.g. flour measured in tons) and services.

The *product type* archetype describes common properties of a set of goods or services. The *product instance* archetype represents a specific instance of a product type. The *product feature type* archetype and the *product feature instance* archetypes are used for product specifications. The *product catalogue* archetype represents a persistent store of product information. The *catalogue entry* archetype represents information about a specific type of product held in a product catalogue. A selection of different products grouped together as a unit is often called a package. The package is also a product and therefore we have a *package type* and a *package instance* archetypes inherited accordingly from the product type and the product instance archetypes.

Our **product relationship** pattern is similar to the party relationship pattern. This means, that in addition to the *product relationship* archetype, we have the *product relationship type* archetype. The product relationship archetype stores all common information for a set of product relationships and describes constraints for valid "provider" and "consumer" product types in product relationship.

The **inventory** archetype pattern represents a model for managing a stock (or store) of products (goods or services). The *inventory* archetype represents a collection of *inventory entries* held in a stock by a business. An *inventory entry* records a product type and a collection of available instances of that product type. There are two inventory entry types: inventory entry for products and inventory entry for services.

One of the key functions of an inventory is to decide whether product or service instances are available for sale. The *reservation* archetype represents an assignment of one or more product instances to one or more receivers. The *reservation request* archetype represents a request from a requester for a reservation to be made. Each reservation has a unique identifier which uniquely identifies a reservation. This reservation identifier is used for product reservation. The *availability policy* and *cancellation policy* are rule sets describing either availability or cancellation rules. And naturally, all archetypes have the attributes property to store user specific data.

The **order** archetype represents a record of a request from a buyer to a seller to supply some goods or services. There are two order types: a *purchase order* and a *sales order*. The main archetypes of the order archetype pattern are the *order manager*, the *order* and the *order line*. In comparison to the order archetype pattern by Arlow and Neustadt our model has a different order status management system and is designed as a static document which maintains information about company events (e.g. order is created, payment is made, payment is accepted, delivery is sent, and etc.). The dynamic part of Arlow and Neustadt's order archetype pattern (designed by activity diagrams) we removed from the order archetype pattern as these are processes and therefore can be modelled using the process archetype pattern (see next page).

A **quantity** (e.g. 10 kg) is an amount of something measured according to some standard of measurements. **Money** (e.g. £10, special case of quantity) archetype represents an amount of a specific currency. The **rule** (e.g. Alcohol may be sold only from ten o'clock in the morning and only for adults) archetype represents a business constraint and is defined by a sequence of rule elements. Those (quantity, money and rule) patterns are utilized by several other archetype patterns.

Arlow and Neustadt have no archetype pattern for recording processes. This is the reason why we have designed the process archetype pattern (Figure 5, except the leftmost column of classes). The metaphor of our process model is a subordinate's report (or feedback, Figure 1) to a supervisor. Therefore processes in our model are described by communications between two parties (persons, organizations, or even artificial agents) "playing" some roles. In our understanding this metaphor is quite powerful for modelling of different kinds of business processes. Similarly to movies, that emulate dynamic reality by sequences of static pictures, the process archetype pattern emulates dynamics of business processes by sequences of reports (feedbacks).

More reports from trusted and different parties means better and more implicit picture about the whole process as a dynamic phenomenon. In our understanding,

the business process archetype pattern can also be used for planning of business processes. When an actual report is a feedback about what has already happened, then a plan is a "feedback" about business processes we hope will occur in future. By comparing plans, modelled as expected future reports, and actual reports we can monitor the compliance of plans and reality and correct the plans if needed.

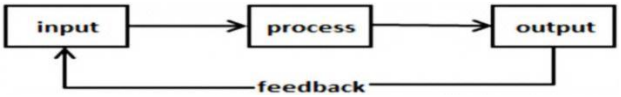

Figure 1. Process and Feedback

In the **process archetype pattern** (Figure 5) we utilize party relationship archetype pattern. Each *task* (*ITask* in Figure 5) is a party *relationship* which binds together consumer and provider roles. The *process manager* archetype (not shown in figure 5) records all possible *processes* of allowed *process types* described by the *process manager type*. An example of a process manager type is *sales manager*. Examples of *process types* are different sales types (debited, invoiced, credited, prepaid, etc.). Each business process consists of one or more *business threads*. A business thread is described by a *thread type*. Allowed thread types are listed in a *business process type*. Examples of *thread types* in a *sales business process* are sales initialization, receiving of payments, despatch of deliveries, change of sales conditions and cancellation of sales. Each business process has a *manager* (property of *IProcess* archetype, hidden in Figure 5), which is a *party role*. One and the same thread (e.g. receiving of payments) can include more than one task (e.g. receiving a payment). This is why we need threads (e.g. all payments) and tasks (e.g. particular payment) in our model. Similarly to threads that consist of one or more tasks, tasks consist of one or more *actions*. Each *action* has an *action type* and one or more *outcome* properties. Each outcome has an *outcome type*.

As business processes vary and can be changed often, we have designed the business process archetype pattern to be managed by rules. This means, that each process element type (*IProcessType*, *IThreadType*, *ITaskType*, *IActionType* and *IOutcomeType* - inherited from *IProcessElementType*) has *RuleSet* property, and each process element (*IProcess*, *IThread*, *ITask*, *IAction* and *IOutcome* - inherited from *IProcessElement*) has *RuleContext* property. For example, to establish that the buyer has rights to withdraw within 14 days from purchases transaction, the *receive purchase cancellation task type* must have the following simple rule

$$R = \{CancellationDate, InitDate, DIFF_IN_DAYS, AllowedDays, LESS\}$$

Depending on *cancellation* and *initiation* dates, a seller either accepts or declines the sales cancellation. For example, when a seller receives the cancellation request which gives context $C = \{28.12.2010, 20.12.2010, 14\}$, the buyer has rights to withdraw.

III Domain Modelling with Archetypes and Archetype Patterns

In the following we exemplify the domain modelling with archetypes and archetype patterns. The domain is a clinical laboratory. This domain model of clinical laboratory domain is based on the ASTM standard guidelines [11; 12] and utilizes the archetypes and archetype patterns framework presented in [10] and explained in Section 2. In analysis and modelling we follow independent phenomena described by the columns of Zachman Framework (ZF) [3]. This means that by asking common questions ([13], Section 3, Table 1) *what* (products), *how* (processes), *where* (locations), *who* (persons), *when* (events) and *why* (motivations), we analyse and model different independent phenomena of clinical laboratory domain. We found, that there are no laboratory specific aspects for events (*when*), modelled using the *inventory* and the *order* archetype patterns. The same is also true regard to motivations (*why*), modelled using the rule archetype pattern. Therefore, in current section we describe only laboratory phenomena related to stakeholders (*who* and *where*), products (*what*) and processes (*how*).

A. Stakeholders in Laboratory

A domain stakeholder [4] is a person or an organization united somehow in interest or dependency on the domain.

Each stakeholder has some roles, rights, duties as well as specifically identified perspective or view on a domain. Lindqvist and Christensen [14] have generalized stakeholders to a global administrator, a local administrator, a person, and a third party. We use the same classification along with the assumption, that a stakeholder is a role that persons and/or organizations are playing. Figure 2 illustrates roles in laboratory and Figure 3 illustrates the logical model of roles and relationships in laboratory.

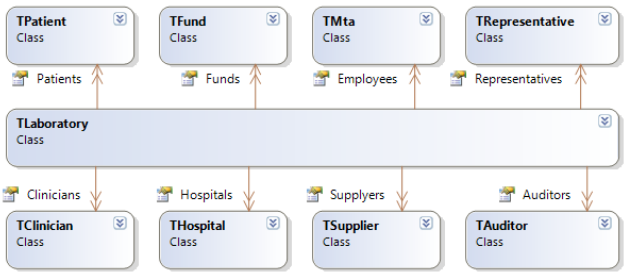

Figure 2. Abstraction of Clinical Laboratory Related Party Roles

A *person* is an individual (employee) capable of sample analysis in a laboratory. A role that persons are involved laboratory is the role of a MTA (Medical Technical Assistant). Some MTA's are laboratory *local administrators* (laboratory managers). A *global administrator* (the institution, e.g. Business Register) tracks and uniquely identifies organizations and individuals. A *third party*, in a laboratory, is a person or an organization, which causes MTA to analyse samples or is somehow affected by sample analysis process in the laboratory.

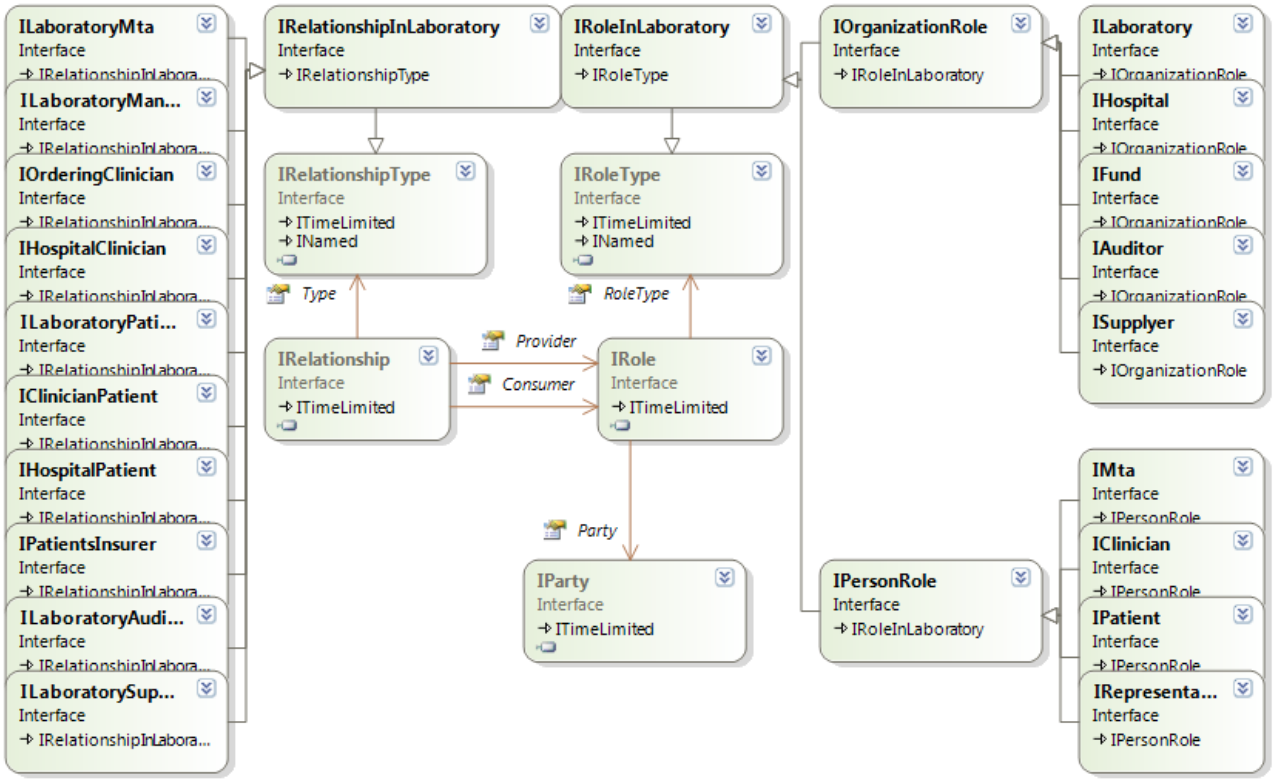

Figure 3. Logical Model of Laboratory Role and Relationship Types

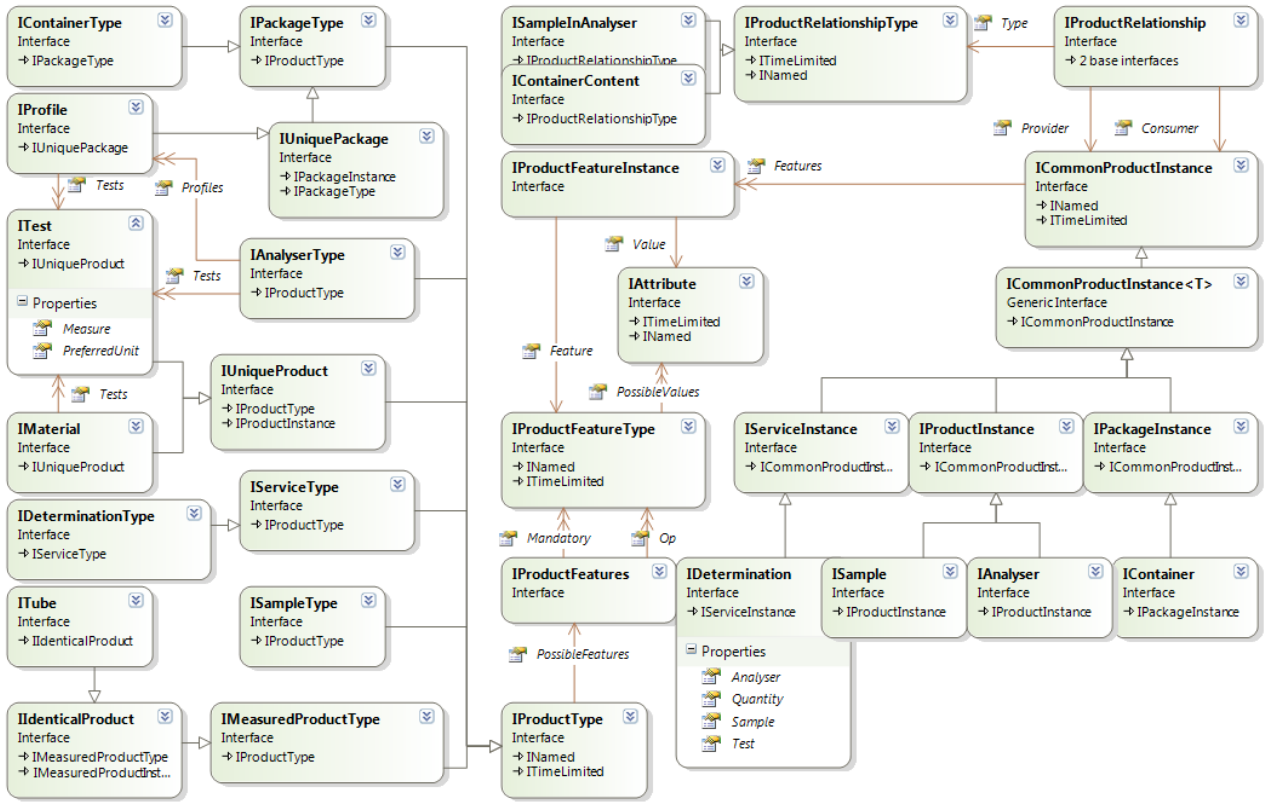

Figure 4. Logical Model of Laboratory Products and Product Relationships

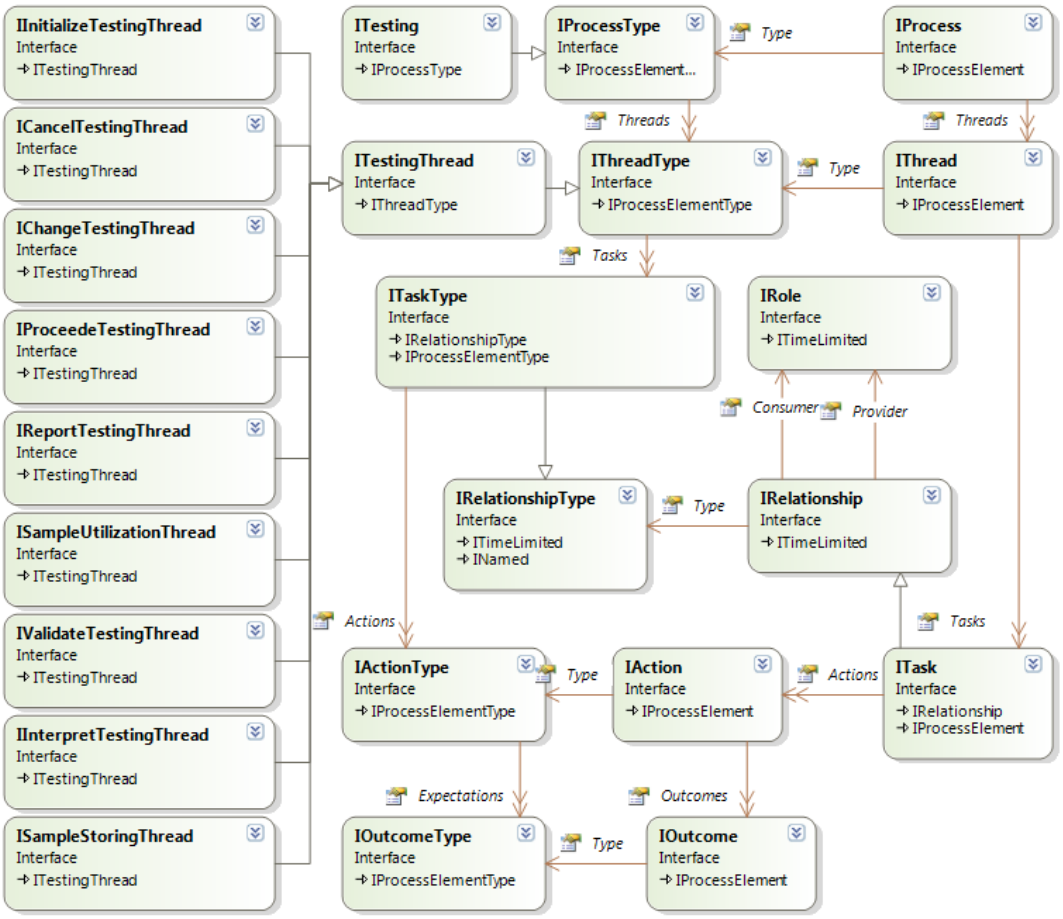

Figure 5. Logical Model of Process Archetype Pattern (right site) and Sample Determination (left site) based on this Pattern

Third parties in a laboratory are: (a) *laboratory* – a sample analysing company. A MTA works for a laboratory; (b) *patient* – a person whose sample (blade, serum, urine, etc.) is being analysed; (c) *clinician* – a person who treats patients (a clinician requests/initiates a sample analysis in a clinical laboratory and clinicians receive analysis reports from a laboratory MTA); (d) *hospital* – a company where clinicians are working and patients can be hospitalized (a laboratory can be a department of a hospital); (e) *auditor* – a company (institution) which for example audits QC in a clinical laboratory (a laboratory has to send periodical reports about laboratory QC to auditors); (f) *fund* – a company or a fund offering health insurance for patients; (g) *supplie***r** – a company which maintains laboratory equipment and sells reagents and spare parts to laboratories; (h) *representative* – a person who represents a company (hospital, auditor, etc.) or a person (patient, clinician).

The domain model of laboratory stakeholders in terms of party and party relationship archetype patterns is shown in Figure 3. According to laboratory stakeholders' skeletons (Figure 2) all we need in laboratory domain model additionally to the party role and party relationship archetypes (Section 1) is to define the laboratory specific types for roles and relationships as follows: (a) Specific role types (*patient, MTA, clinician, and representative*) that persons can play; (b) Specific role types (*laboratory, hospital, auditor, supplier and fund*) that organizations can play; (c) Specific relationship types (*laboratory MTA, laboratory manager, hospital clinician, hospital patient, laboratory patient, clinician patient, etc.*).

Similarly to party and party relationship types (Figure 3), also the product (Figure 4) and processes (Figure 5) have been analysed and modelled in clinical laboratory.

IV Towards LIMS Software in Global Context

Based on our research and on working prototype we developed and use in Clinical and Medical Proteomics Group, we can say that our archetypes and archetype patterns based techniques for domains, requirements and software can be the promising idea on which to build world-wide, peer-to-peer and service oriented infrastructure for scientific data management for cancer research scientists. The kernel of techniques in question is business archetypes and archetype patterns (framework of models abstracting products, business processes, persons and organizations, relationships between persons and organizations, inventory, orders and rules) used for describing domain models (e.g. clinical laboratory) and requirements. Database layouts, communication protocols and graphical user interfaces are implemented on top of these archetypes and archetype patterns and not on top of particular laboratory requirements nor on laboratory domain. Therefore it is possible to modify descriptions of data, knowledge and research methods even at runtime

and distribute and compare them with data, knowledge and methods which are described differently. This is a first step towards a wider research goal to develop information systems based on A&AP that evolve in an evolutionary way together with the business processes, using collaborative system development by their users and developers.

Our experiences give us a basis to believe that this archetypes based methodology allows interoperability of semantically heterogeneous software systems. Laboratory system and laboratory researchers will use their own structure and semantics of data, knowledge and research methods, but communication between different laboratory systems will be organized by using unified archetypes and archetype patterns.

V CONCLUSION AND FUTURE WORK

We have explained the main idea of A&AP of domains, used it in development of real life LIMS Software Factory project, and presented arguments towards applying LIMS software in global context.

The main future work is related to test driven modeling (TDM). Currently we use TDM both for domain analysis and for development. Domain models engineered in this way are used as DSL for specifying software requirements from customer. The main difference of proposed TDM, comparing for example with other test driven modelling initiatives [15; 16; 17] is that no additional tool is needed and that unit tests are designed according to domain descriptions in the domain analysis process. Domain models engineered with TDM can be used to partially validate software requirements according to domain model and verify generated software. To raise the degree of formality of TDM, a project of analyzing the possibilities of TDM and comparing its features with these of specification languages such as RAISE is under development.

ACKNOWLEDGMENT

This work is supported by Estonian Ministry of Education and research (SF0140013s10); by Tallinn University of Technology (Estonia); by University of Leeds (United Kingdom); by Cancer Research UK. We would also like to thank the reviewers for useful comments and suggestions.

Abstract – In this article, a proof of concept is made for the wireless sensor based on the of the shelf radio frequency identification (RFID) chip. The component used is the NXP Semiconductors G2iL+. This novel chip supports bidirectional digital data transfer not only to the standard RFID reader, but also to the microcontroller or similar digital hardware connected directly to it's terminals.

If the RFID tag is to be used as the part of the active wireless sensor in the field, the tag should be able to operate locally until requested to transmit data by the RFID reader (RFID interrogator). Some limited amount of measured data could be stored in the active RFID chip itself, but for prolonged periods of operation without contact with the reader, data should be stored in some local non volatile memory. In ideal case the RFID chip supports two connections: bidirectional wired digital link to the on-board microcontroller, and wireless link when found itself in the RF field produced by the standard RFID reader.

In the example demonstrated in this article, the G2iL+ is connected to the ARM Cortex M3 based board. Programmable RFID interrogator is then used to transmit commands and receive sensor data simulated by the microcontroller.

I. INTRODUCTION

RFID is widely adopted and mature technology used in manufacturing, supply chains, warehouse and inventory handling, document tracking and management systems, access control, electronic toll collection, waste management, cashless payments, animal tracking, ticketing, and so on. [1] [2]

In its simplest form the RFID tag could be used for product identification by just reading the product identification code. In such scenario RFID system would serve the similar role as well known bar code labeling system. However, there are several important advantages of RFID tags over bar code labeling systems:

- RFID tag already on the product could be rewritten, reused (recomissioned), or killed dead, depending on product status and user application. It is not possible to change the bar code label without producing and applying new one on each product.
- RFID tag can hold more information which could also be site specific or event specific (i.e. error log written during production test procedure).
- RFID tag can be read when out of sight, or within a product. RFID tag could also be used within a sterile or hostile environment.
- RFID tags do not wear out, they are not susceptible to dirt, and it is not possible to scan (and later forge) product codes without proper equipment.

Despite all this, it is not likely that RFID technology would completely replace optical bar code systems (EAN systems).

Simple EAN labels will always be less expensive, which will be of most importance for many high volume, low cost products. It is not just because of the lower tag price, RFID readers are also more expensive to produce, setup, and maintain than bar code scanners.

EAN label optical scanning is often also more reliable. RFID tag might be difficult to read reliably from metallic containers, bottles containing liquids, and in some other cases, depending on specific environment. It is usually good idea to consult the RFID expert before the installation. User will probably have to do some fine tuning of the RFID system including the reader antenna setup and positioning after the installation to make sure the system would perform as expected.

Obviously, it is very important to understand the RF technology used behind the scene to be able to select proper RFID solution. Potential user should understand differences and limitations which could result from improper choice of tags, their frequency range, improper antenna placement or some other misunderstood aspects of the RFID technology.

Considering all this, it is no wonder that RFID technology was slowly gaining momentum. It took a lot of time and effort to come to the point where mass production could lower the price of a technology making it usable for more applications. As it was often the case in electronic industry history, collaboration of government (military applications), universities and some key industry companies resulted in solid standardization, pawing the way for commercial success.

II. RFID HISTORY AND STANDARDS

Several RFID standards have emerged over the decades, and short overview of RFID history can be found in [3].

Although systems have been installed for many applications, UHF RFID applications did not gain a momentum until Auto-ID Center at the Massachusetts Institute of Technology was established with funding from several large organizations and companies with global impact. It was in 1999. Result was a new idea: RFID technology would be used to create unique ID for every object, but instead of tag holding all the information itself, tag ID would be used to link objects to their data base entries over the Internet. This approach would open many new application possibilities, but standards were needed not only for communication between the tag and the reader, but also for the complete infrastructure connecting tags with database servers. Standards should be open, so that everyone could build devices upon them. Such set of standards has been created by new organization taking over responsibility from Auto-ID Center and later Auto-ID Labs, the EPCGlobal. [4]

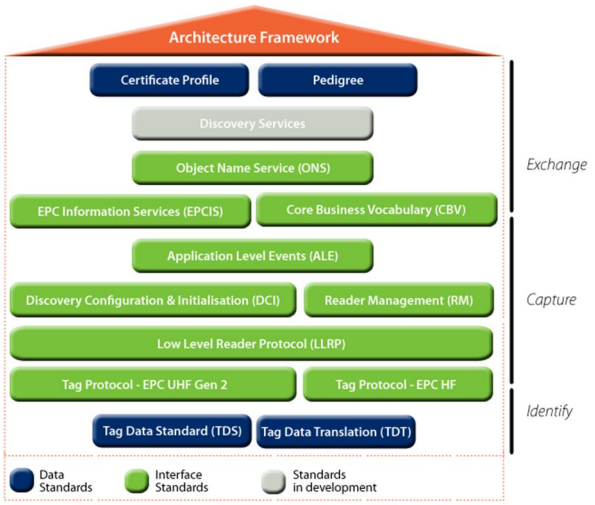

Figure 1: EPCGlobal system architecture and standards

Complete system architecture covered by EPCGlobal standards is shown in the Figure 1. It is not purpose of this article to cover those standards any further, but it should be noted that without those standards the RFID applications would not be able to offer all services needed by the industry. The phrase 'The Internet of Things' which is becoming very popular today was first used at the Massachusetts Institute of Technology to describe communication between 'Things' without human intervention. The RFID technology is today at heart of this development, and the fact that standards are open and global can only help its development and deployment.

Since this article is describing possible usage of specific RFID tag as a sensor, only communication between the tag and the standard tag reader (interrogator) was necessary. In such case relevant standards should be those describing the physical layer of communication between the tag and the reader. This layer is known as Layer 1, or the PHY Layer in the OSI networking model. Primary function of this layer is to ensure controlled access to the media, handle collisions if necessary, and deliver stream of bits between two nodes. For dense population RFID applications it is also responsibility of this layer to ensure proper operation when multiple readers simultaneously access the same tag. Of course, multiple tag environment is almost standard use case for RFID, but multiple reader (dense) environment would not be typical scenario for sensor applications.

In our case this all has been already handled by the tag and the reader. However, in order to understand respective manufacturer documentation, and what commands are available, relevant standards should be studied. Those standards are the ISO 18000-6C [5], and the EPCGlobal Class 1 Gen 2 UHF Air Interface Standard v. 1.2.0 [6]. Depending on the tag frequency range, other standards like the ISO 14443 might need to be studied in depth.

III. NXP UCODE G2iL+ RFID CHIP

In a April 2010 the NXP Semiconductors has introduced new generation RFID chips referenced as the UCODE G2iL and G2iL+. Chips have six pins, and the package is sized only 1mm x 1.45mm x 0.5mm. Figure 2 shows the block diagram of both chips, it can be seen as digitally controlled state machine with EEPROM memory, and RF front end. [7]

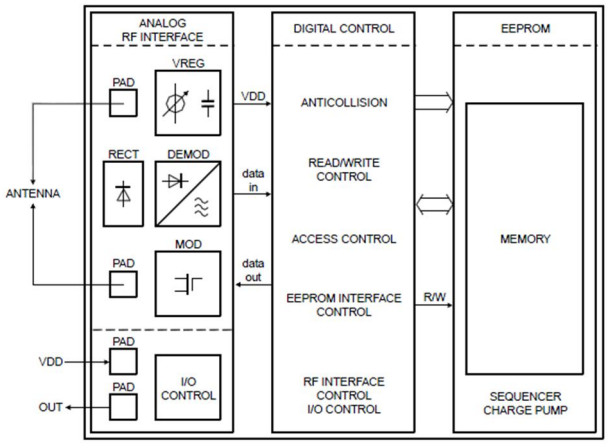

Figure 2: NXP UCODE G2iL/G2iL+ block diagram

Pin VDD had dual purpose, as power supply and digital input. Antenna terminals are tolerant to DC short circuit, so that loop antenna design could also be used. OUT pin is digitally controlled output terminal.

Both chips are compliant with EPCGlobal v1.2.0, but in addition to all mandatory commands they also support some interesting custom commands. This is allowed by the standard in order to enable manufacturers to implement some specific functionality not provided, or foreseen by the standard.

Of the two mentioned components, the G2iL+ is more interesting since it provides commands of special interest if we wanted to send or receive some digital data:

- Read digital input to check status of some device connected to the RFID chip input pin
- Set digital output to control some device connected to the RFID digital output pin
- Pass through RF data envelope as demodulated data stream to the RFID output pin

NXP engineers have decided to include those commands in EPC memory block (bank 01) so that standard RFID readers could be used to issue command and interpret results. In other words, there is a 16-bit Configuration Word accessible to standard readers at the address 200h (counting in bits from the start of EPC memory block). Those 16 bits are divided in three groups:

- Indicator bits which reflect state of some input, and cannot be changed by command
- Temporary bits which are reset at power up (or when passive RFID chip is out of the field)
- Permanent bits which are stored into EEPROM after changed by user command

The Figure 3 shows the layout of the configuration word with short description of each bit.

Address 200h - 20Fh							
Indicator bits				Temporary bits			
Tamper indicator	External Supply Indicator	0 RFU	0 RFU	Invert Output	Transparent Mode on/off	Transparent Mode data/rw	0 RFU
0	1	2	3	4	5	6	7
Permanent bits							
0 RFU	Max Backscatter Strength	Digital Output	Privacy mode	0 RFU	Protect EPC	Protect SNR	PSF Alarm
8	9	10	11	12	13	14	15

Figure 3: G2iL+ configuration word bits

It is important to study manufacturers documentation, and read all fine printed notes regarding various modes of operation. For example, writing to the Digital Output bit is 'toggle' operation: it is necessary to write '1' to change it's state, and writing zero does not have any effect. This fact is mentioned in the documentation, but not exactly in bold print, so it is something easy to overlook. [7]

For sensor applications bits of interest are those at addresses 201h (External Supply Indicator), and 20Ah (Digital Output). Tamper indicator bit could not be used simultaneously with local battery, and this bit is also somewhat cumbersome to use since the G2iL+ reads it in only at specific chip state (chip entering the ready state). In other words, the only remaining resource useful for getting sensor data into the tag is the Battery Supply Indicator.

The purpose of our experiment was to check how useful will this bit prove to be, and to make sure it was possible to unconditionally read some sensor data into standard RFID reader by stimulating the input provided for battery power supply on the G2iL+ chip side.

The sensor prototype platform used for the test simply served some digital data with microcontroller GPIO (General Purpose I/O) set as output. However, it was necessary to adapt the voltage levels between the microcontroller I/O pins, and the RFID chip.

Considering dimensions of G2iL+ packages (SOT886), any prototyping with those components could be best described as 'mission impossible' unless the person building the prototype was a high skilled professional with many years of experience using fine pitch SMT components, and having access to necessary tools. For the rest of us, some sort of ready made evaluation or development board is the way to go. NXP Semiconductors has designed such a board [8], and it's block diagram is shown in the Figure 4.

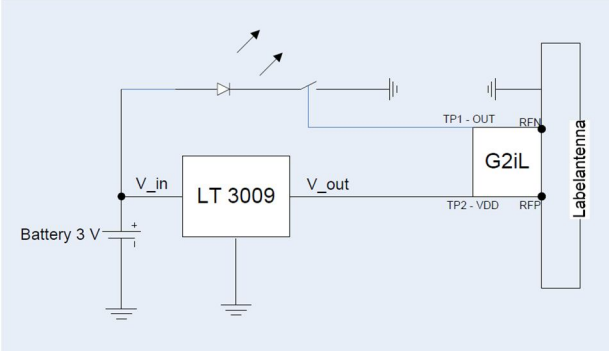

Figure 4: G2iL+ NXP demonstration board - block diagram

The RFID chip can work in passive mode, and the battery is needed only to boost the reading range. A LED is added to the board for demonstration of Digital Output command. Of course, some switch to control the LED based on the Digital Output bit state need to exist as the G2iL' cannot drive the LED directly. LT 3009 is low dropout linear regulator with adjustable output. Since G2iL+ power supply should never go above 1.95 V in normal operation (2.5 V is the absolute maximum rating) this regulator limits the power supply coming from the optional external battery. The switch from the block diagram is BSS83 MOS transistor (Q1), and some RF filtering was added by NXP engineers to prevent Q1 gate capacitance to act as a short circuit for RF signal.

Complete schematic diagram is shown in the Figure 5.

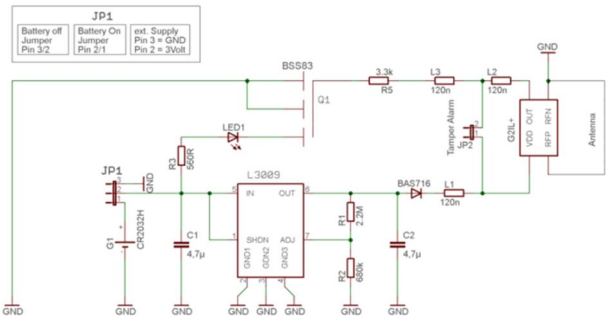

Figure 5: G2iL+ NXP demonstration board - schematic diagram

Original function of two jumpers (JP1 and JP2 in the Figure 5) was demonstration of the Tamper Indicator operation (JP2), and option to disconnect the battery provided on the board (JP1).

Those jumpers will come handy when connecting microcontroller sensor board prototype to the G2iL+ demonstration board.

IV. RFID SENSOR HARDWARE PROTOTYPE

Any microcontroller could be used for this prototype, and the choice is often only matter of preference, and available tools and components. One interesting option for rapid prototype development is the NXP mbed module.

ARM Cortex M3, and specifically ARM Cortex M0 microcontroller family members ended up in many battery operated and portable electronic devices, while still offering high flexibility, and wide range of development

tools. The mbed module used in this experiment has the powerful NXP LPC1769 Cortex M3 microcontroller, but similar module with the same pin out is available containing less power hungry LPC11U24 MCU with Cortex M0 core.

Both modules are supported with the on-line development environment at http://mbed.org free of charge, so it is very easy to start both hardware, and firmware prototyping. Programming is done natively in C++, and there are libraries of classes, methods, and code examples developed by NXP engineers and community available for just about every application.

For the purpose described in this article, few lines of code calling some C++ methods from provided classes was enough to read analog information from potentiometer, toggle I/O pins with required timing, and display some information on local LCD provided for convenience. Normally sensor in the field would not have local display. Without such library support, a simple prototype like this would require much more coding, which was not the intention in this proof of concept application.

Connections between the microcontroller board (in this case the mbed board) and RFID tag (in this case the G2iL+ NXP demonstration board) have to provide three simple functions:

- send digital output from microcontroller output pin to the RFID tag side input pin
- receive digital output from RFID tag output pin at the microcontroller side input pin
- provide the common reference level (ground)

Care should be taken regarding the necessary voltage levels. The G2iL+ can accept power supply of up to 1.95 V, so obviously it's 'high' level output would not qualify as 'high' level from the microcontroller point of view.

As for many modern CMOS microcontrollers, the LPC1769 I/O is referenced to 3.3V power supply, and the usual convention about CMOS logic levels apply here: 70% of the power supply and more is high logic level. Since the signal path is unidirectional for each line, and speed is not critical here, the voltage conversion is easiest to deal with by using some NMOS transistor as a switch. For the prototype, the BS170 in TO92 case was available, and with some luck it's voltage threshold would be low enough for G2iL+ high output to turn it on. Pull up resistor was connected to 3.3 V at the microcontroller side, and 100k resistor was connected from the G2iL+ output and NMOS transistor gate to the ground at the RFID tag side.

According to the specification, the G2iL+ output high level at it's OUT pin is minimum 1.5 V, while the maximum Ugs threshold voltage for the BS170 was 1.45 V. This is the worst case scenario for both sides, but operation of specific BS170 transistor to be used was checked by applying the square signal with 1.45 V amplitude to it's gate, and recording the signal at the drain pin. For production design, it would be safer to use for example the same BSS83 transistor as chosen by NXP engineers, or find another available with low Ugs threshold voltage.

In the opposite direction, microcontroller would supply up to 3.3 V at the output pin, which would destroy the G2iL+ if this was not taken into consideration. Here the simple voltage divider from microcontroller output pin to the ground has provided safe value of 1.95 V when microcontroller output was high. Resistors values are 3k3 in the upper side, and 4k7 in the lower side. Downside of this solution might be the battery life time in real sensors in the field. Using higher resistor values would be fine, unless the RFID tag current consumption start to change output voltage significantly.

Obviously, the best solution would be to use the same power supply level for both RFID tag chip, and the microcontroller. This is not a problem with for example NXP LPC11U24 microcontroller which can be powered with as little as 1.8 V (both the core and the I/O) if USB operation was not needed. So, for this prototype voltage divider and transistor switch were fine, for the 'real' custom made sensor they are to be avoided by using the same 1.95 power supply for both the tag, and the on-board microcontroller. Just for comparison, the NXP LPC1769 Cortex M3 microcontroller used in this prototype was designed for more demanding applications, and as a result it's power supply would not go below 2.4 V. This is fine example why designer should have range of options available, and of course be aware of those options in the first place. Just to give another option, the Texas Instruments MSP430 family of 16-bit microcontrollers is well known for their minimum power consumption, both in the active, and stand by mode of operation.

Finally, the microcontroller board was assembled on the breadboard together with all mentioned voltage translation components, LC Display was added, and before mentioned jumpers on the G2iL+ demonstration board have been used to connect boards together. LCD proved to be useful for debugging in situations when it was not clear what signal was 'seen' by the microcontroller, and mbed module does not support the JTAG debugger. The whole setup during the operation is shown in the Figure 6.

Figure 6: mbed connected to the G2iL+ demonstration board

Schematic diagram with details of connection between boards is shown in the Figure 7. Pin 3 of JP1 was used for ground connection with mbed board. JP1 pins 1 and 2 are left open so that on-board battery is not used. If needed, those pins can be closed making the battery power available to the G2iL+ without any damage to the mbed board, but then the state of External Supply Indicator bit would be high all the time, disabling the communication from microcontroller towards RFID chip.

It is logical, and also well stated in the G2iL+ documentation that existence of external battery supply, the External Supply Indicator operation, and the Tamper Indicator operation were mutually exclusive and cannot be

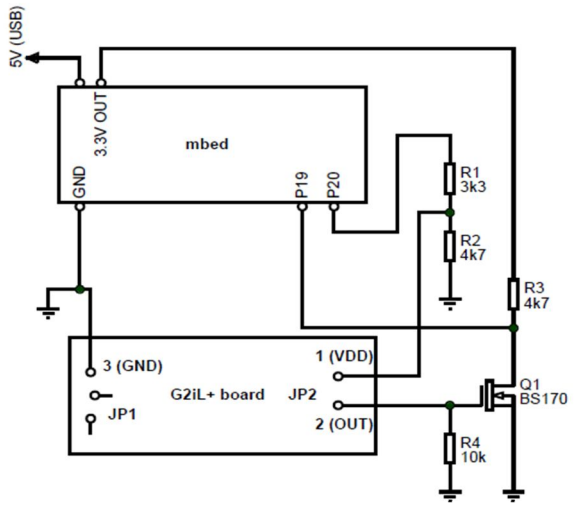

Figure 7: Connection between RFID and mbed board

used simultaneously. If battery operation was needed during operation, microcontroller could use some switch (not provided here) to be able to switch on the battery as necessary. This could be for example to boost the operation range while listening, and not sending any data.

Pin 1 of JP2 was used for communication from microcontroller towards the RFID chip. Instead of the battery, now the mbed microcontroller is able to supply the 'power', which is actually the digital data which than can be read by the RFID reader as the state of the External Supply Indicator bit. Mbed can supply about 40 mA per digital output pin, so this could be considered the 'real' power supply. Each time the RFID reader checked the state of the bit at EPC memory address 201h, it would depend on what the mbed microcontroller has done with it's pin P20 driving the before mentioned resistor divider.

Pin 2 of JP2 is used for the opposite direction of communication, from the RFID chip towards the mbed microcontroller pin P19 set as digital input. As explained earlier, the BS170 NMOS transistor with the pull-up resistor in it's drain connected to power supply is doing the level conversion necessary. It is also doing the logic inversion of the signal, so that mbed will get logic low signal level when RFID reader set (toggle) the Digital Output bit at address 20Ah to logic high state.

V. USAGE OF THE RFID READER

The Sirit INfinity 510 UHF reader is the EPC certified reader that provides flexibility in supporting multiple tag protocols, multi-regional regulatory compliance, and programmability for a multitude of EPC applications environments. It supports human and machine communication across either the serial or Ethernet ports.

The human interface is used to establish a direct connection to the readers' CLI (*Command Line Interface*) and allowing the user to manually submit commands to the reader, and observe responses.

The machine interface is a direct connection to the reader's two communication channels:

- Command and response channel.
- Event channel

Both of those channels use the Ethernet port.

Command and response channel is a bidirectional interface which connects to the TCP/IP port 50007. This channel is used for submitting commands to the reader and reading responses accordingly.

Event channel is a unidirectional interface from the source (reader) to the listener (host machine) which connects to the TCP/IP port 50008. It is used to register for reader events and it receives notifications when event of interest occurs: reader status change, tag arrival event, tag read event, tag depart event, etc.

To connect to the reader interface, a Socket Connection for reading and writing data should be established. The INfinity 510 also supports embedded user applications by using scripting languages such as Python, or by running Java applications onboard. Option to run embedded reader applications directly on the reader hardware allows faster read and write commands in a succession, compared to submitting a batch process through the terminal.

The reader's Python version is 2.4.2. and the JVM is compatible with the J2SE 1.4 specification. Applications may use the reader's RAM (up to 16 MB) and Flash memory (up to 5.4 MB), and the memory contents is preserved during reboot. These applications can communicate with external applications over Ethernet on ports 50010 through 50015 exclusively (both TCP and UDP ports). Other ports are blocked by the internal firewall.

All reader functions are performed by sending a specific CLI command to the reader's command channel. These commands are grouped within namespaces for easier navigation. For accessing the low level modem control, the modem namespace functions have to be used.

The following sequence of commands is needed to perform the write to the tag:

1) Tag singulation and initialization for the subsequent commands to the tag. The commands sent between the start and the end command will not cause resingulation of the tag, but with this command the handle to the specific tag will be obtained.

   `modem.protocol.isoc.cmd_seq_start`

2) Tag data read from a specified EPC memory bank. The read function accept parameters to specify start address, and number of 16-bit words to read.

   `modem.protocol.isoc.read`

3) Tag data write to a specified tag memory bank. The write function supports the parameters that specify starting address, and data to be written in the HEX format. A read before write is required for the successful write command.

   `modem.protocol.isoc.write`

4) End of command sequence that releases the handle.

   `modem.protocol.isoc.cmd_seq_end`

The following example shows the commands with parameter values and reader responses received while

performing the write sequence to the tag. Normally the command is written on a single line, and here there is hyphenation due to the lack of space. Commands are entered using the appropriate terminal program (i.e. putty).

modem.protocol.isoc.cmd_seq_start (tag_id = 0xE2006805000000000000011)

-->>ok

modm.protocol.isoc.read (tag_id=0xE2006805000000000000011, mem_bank=1, word_ptr=32, word_count=1)

-->>ok data = 0x4040

```
modem.protocol.isoc.write
(tag_id=0xE2006805000000000000011,
mem_bank=1, word_ptr=32, data=0x0860)

-->>ok

modem.protocol.isoc.cmd_seq_end(1)

-->>ok
```

The following example shows the reader responses to consecutive tag read commands while the tag was written to by an external device. Notice the change in the first HEX value of the response (data). The read commands are entered consecutively using a script tool provided by the manufacturer. Value returned is 16 bits from the register shown in the Figure 3. It can be seen from data responses below that second bit from the left (next to the MSB) was changed as a result of toggling of mbed (microcontroller) output bit. No option is provided to determine the wait time between two commands here, and it was assumed here that microntroller was ready with new data whenever needed.

```
modem.protocol.isoc.cmd_seq_start (tag_id =
0xE2006805000000000000011)

-->>ok

modem.protocol.isoc.read
(tag_id=0xE2006805000000000000011,
mem_bank=1, word_ptr=32, word_count=1)

-->>ok data = 0x4040

modem.protocol.isoc.read
(tag_id=0xE2006805000000000000011,
mem_bank=1, word_ptr=32, word_count=1)

-->>ok data = 0x0040

modem.protocol.isoc.cmd_seq_end(1)-->>ok
```

VI. CONCLUSION

The NXP UCODE G2iL+ component is suitable for building some interesting devices due to several proprietary commands built in. The purpose of this experiment was to test the concept of building the wireless sensor based on those commands.

The test has proven that G2iL+ is useful for sensor applications where some data from the environment is to be acquired, and transferred at request using the RFID standard. This does not mean the RFID is proposed to be used as the primary choice for wireless sensor applications. Other standards, like the ZigBee, have their own characteristics that need to be evaluated, and compared for specific application. The advantage of the RFID is high level of standardization on the reader side.

However, the sensor (microcontroller) communication to the tag is not covered by any standard, even commands used in this example were custom commands implemented by specific manufacturer. If the complete RFID tag was built from the scratch, for example using the FPGA technology, sensor data could be directly written into the EPC memory, and sensor to tag communication would not be such an issue. Since off the shelf RFID tag was used here, a different approach was needed and everything depends on two specific G2iL+ indicator bits.

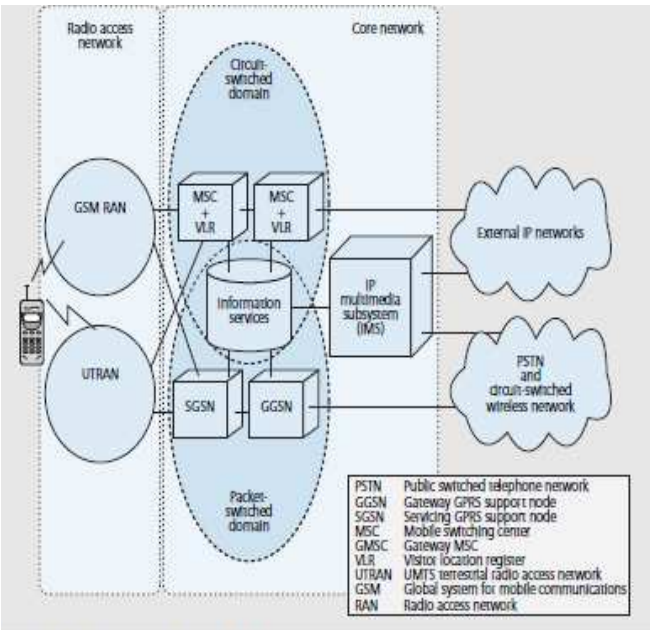
IP Multimedia Subsystem (IMS) sigurnost: Pregled standardizacije IMS sigurnosti i potencijalnih prijetnji na sistem

Bojan Puškarević* i Adnan Hota **
Ericsson/Sarajevo, BiH
* Bojan.Puskarevic@ericsson.com
** Adnan_Hota@yahoo.com

Sažetak - IP Multimedia Subsystem (IMS) predstavlja mrežnu funkcionalnu arhitekturu koja operatorima nudi mogućnost pružanja kvalitetnih multimedijalnih paketski baziranih usluga kao što su instant poruke, presence (prisutnost), VoIP (Voice Over IP), video konferencije i chat. Kako se radi o Internet uslugama i njihovoj otvorenosti, veoma je važan sigurnosni aspekt IMS sistema. Ovaj rad će pokušati dati pregled standardizacije IMS sigurnosti i potencijalnih prijetnji na IMS sistem kao i pratećih protokola kako bi pružio osnovne smjernice kod uvođenja novog ili održavanja postojećeg IMS sistema.

I. UVOD

IP Multimedia Subsystem (IMS) nudi mogućnost pružanja multimedijalnih paketski baziranih usluga kao što su instant poruke, *presence*, VoIP (*Voice Over IP*), video konferencije i *chat*. Kako se radi o Internet uslugama i njihovoj otvorenosti, sigurnost predstavlja nove izazove za operatore. Cilj ovog rada je da pokuša dati pregled standardizacije IMS sigurnosti i potencijalnih prijetnji na IMS sistem kao i pratećih protokola kako bi pružio osnovne smjernice kod uvođenja novog ili održavanja postojećeg IMS sistema. Takodjer, rad će pružiti kratku uvid u moguće napade kao i alate za pornalaženje sigurnosnih rupa IMS sistema, osobito u interakciji IMS sistema sa korisnicima putem IP mreže i Interneta.



Slika 1. 3GPP konceptualna mrežna arhitektura

II. PREGLED IMS MREŽE

A. Pregled IMS Standardizacije

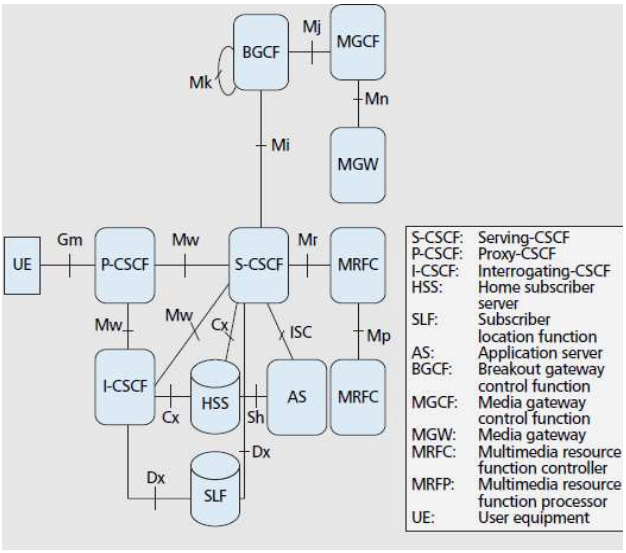
Kako se Internet veoma počeo širiti zadnjih godina, povećala se potražnja za IP baziranim multimedijalnim uslugama. Istovremeno, mobilne mreže se razvijaju od mreža komutacionih krugova orijentisanih prema glasovnim uslugama prema bežičnim mrežama treće generacije (3G) koje podržavaju prenos IP podataka velikim brzinama, kao i glasovne multimedijske usluge.

Međutim, veliki je izazov integrisati IP bazirane usluge s mobilnim mrežama. Prvo, korisnici mogu odlaziti iz jedne mobilne mreže u drugu. Dakle, uspostava, prekid, i održavanje sesija u više mobilnih mreža je složeniji i teži zadatak nego što je to slučaj u fiksnim mrežama. Drugo, tuneliranje se koristi unutar 3G jezgrenih mreža umjesto standardnih IP usmjeravanje. Dakle, usmjeravanje IP paketa preko Interneta i 3G mreža je složeniji proces. Kao treće, *bandwith* (količina saobračaja koji se može prenjeti u jedinici vremena) u 3G bežičnim mrežama je još uvijek ograničen u odnosu na Internet. Podrška kvaliteti usluge (Quality of Service - QoS) s kraja na kraj preko Interneta i 3G mreže predstavlja veliki izazov. I pod četiri, 3G mreže i dalje zahtijevaju izvediv i fleksibilan način kako bi se omogućilo mobilnim korisnicima pristup bogatim IP-baziranim aplikacijama i uslugama.

3G bežične mreže definirane od strane *Third Generation Partnership Project* (3GPP) standardiyacijskog tijela, temelje se na globalnom sistemu za mobilne komunikacije (GSM) i generalnim paketskim

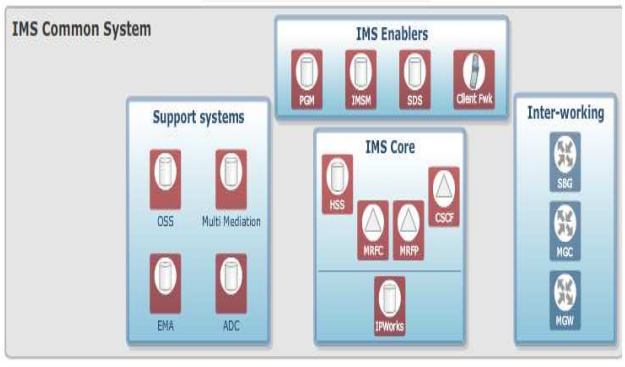
radio servisima (GPRS). 3GPP dijeli osnovne mreže u domenu komutacije krugova (CS) i domenu komutacije paketa (PS). PS domena omogućuje mobilnim korisnicima pristup Internetu koristeći IP protokol. Brzina prijenosa podataka može dosegnuti 144 kb / s za korisnike koji se kreću automobilom, 384 kb / s za korisnike koji se kreću s pješačkim brzinama, i 2Mb / s za stacionarne korisnike. Za integraciju Interneta i 3G bežične mreže za multimedijske usluge, 3GPP je definisao *IP Multimedia Subsystem* (IMS). Kao što je prikazano na slici. 1, IMS je krovni podsistem preko 3GPP PS domene za podršku IP multimedijskim uslugama, uključujući glasovne, video, audio i tekstualne prenose.

Third-Generation Partnership Project 2 (3GPP2) predstavlja drugo vodeće 3G standardizacijsko tijelo. Definiše 3G mrežnu arhitekturu na temelju IS-41 standarda jezgrene mreže i *code division multiple access* (CDMA) -2000 pristupne radio tehnologije. Jezgrene mreže se također sastoje od dvije domene: CS domene za podršku uobičajenim CS uslugama i PS domene za podršku IP baziranim PS uslugama.



Slika 2. 3GPP IMS funkcionalna arhitektura

3GPP2 također razvija IP multimedijske domene (MMD) koje se temelje na 3GPP IMS specifikacijama. IMS koristi protokole definisane od strane *Internet Engineering Task Force* (IETF) standardizacijskog tijela, u svrhu usklađivanja s internetskim uslugama. Konkretno, 3GPP IMS propisuje korištenje IPv6 protokola, dok 3GPP2 IMS podržava i IPv4 i IPv6 protokole. IMS koristi



Slika 3. IMS sistem

Session Initiation Protocol (SIP, IETF RFC 2543) za signalizaciju i upravljanjem sesija. Također se koristi *Diametar* (IETF RFC 3588) protokol i *Common Open Policy Service* (COPS, IETF RFC 2748) za operacije i upravljanje.

B. Struktura IMS mreže

Postoje različite implementacije IMS-a u zavisnosti od postojeće operatorske mreže. Svaka izvedba sadrži cjeline kao što je propisano standardom (slika 3).

Opšta struktura IMS-a obuhvata sljedeće podsisteme:

- IMS *enabler*-i: PGM server, IMS *Messaging* server, SDS i drugi razvojni paketi i *Client Framework* (softverski paket za IMS korisničke uređaje).
- Pomoćni sistemi: OSS, multi medijacija, *Ericsson Multi Activation* (sistem za provizioniranje), ADC (automatsko podešavanje uređaja).
- IMS jezgro: HSS, CSCF, MRFC, MRFP i IPWorks (DNS server) čvorovi.
- Inter-working: SBG, MGC, MGW čvorovi.
- Aplikacioni serveri.

C. Pregled protokola koji se koriste u IMS-u

Većina protokola koji se koriste u IMS-u su standardizirani od strane IETF standardizacijskog tijela. Ukratko su objašnjeni u nastavku teksta.

1) Protokol za signalizaciju i opis toka medije

Glavni signalizacijski protokol koji se koristi u IMS-u je Session Initiation Protocol (SIP). Primarno je definisan u RFC 2543 (koji je u međuvremenu napušten) i kasnije u RFC 3261 dokumentu. SIP posuđuje neke od *Hyper Text Transfer Protocol* (HTTP) i *Simple Mail Transfer Protocol* (SMTP) principa koja su dva najuspješnija Internet protokola. SIP protokol je odabran za IMS jer se smatralo da je fleksibilan i siguran. U principu, IMS SIP je proširena verzija SIP protokola uključujući i razne dodatke kako je opisano u 3GPP TS.24.229 standardu . Glavni cilj SIP protokola je uspostavljanje, modifikacija i prekidanje multimedijskih sesija između dva terminala.

Tijelo SIP poruke je opisano koristeći *Session Description Protokol* (SDP). SDP predstavlja sintaksu za opis medijskih tokova (adresa, port, tip medije, enkodiranje, itd.) standardiziranih u dokumentu RFC 2327 (koji je u međuvremenu napušten) i kasnije u RFC 3264.

SIP najvjerovatnije predstavlja ključni protokol u IMS-u.

2) Protokol za isporuku multimedijskih podataka u realnom vremenu

U IMS-u se koristi *Real-time Transport Protokol* (RTP) kao protokol za isporuku multimedijskih podataka u realnom vremenu. Protokol je definisan u RFC 3550 dokumentu. Ovaj protokol također sadrži i isporuku servisa za prenos podataka u realnom vremenu:

- Identifikacija tipa sadržaja (payload type) koji se prenosi (kodek),

- Numerisanje sekvence paketa,
- Označavanje vremena paketa,
- Praćenje isporuke.

RTP protokol ne omogućava mehanizme za osiguranje kvaliteta servisa (QoS) ali omogućava monitoriranje QoS parametara kroz sestrinski protokol - *RTP Control Protocol* (RTCP). RTCP razmjenjuje informacije o kvaliteti servisa između učesnika u razmjeni multimedijskih podataka RTP protokolom.

3) XCAP protocol

Kod mnogih servisa danas, isporučioci usluga trebaju imati pristup informacijama koje su postavljene od strane korisnika. Primjer ovakvih servisa je dostupnost (*presence*), razmjena poruka (*messaging*) i konferencije.

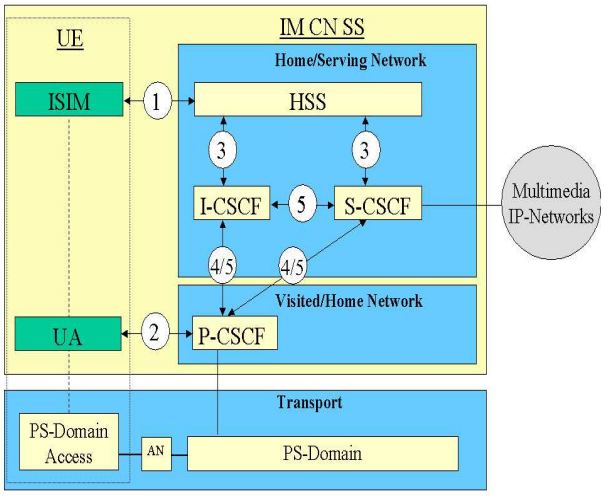
Kod XCAP protokola, korisnik može postaviti informacije na XCAP server koji poslužuje ove informacije aplikativnim serverima koji ove informacije koriste da zadovolje zahtjeve postavljene od strane korisnika. XCAP protokol omogućava korisnicima da manipulišu svojim podacima, dodaju nove ili brišu postojeće podatke. Primjer je da korisnik može da postavi svoju listu resursa za dostupnost (*presence*).

XCAP koristi HTTP protokol za prenos podataka.

Podaci se smiještaju u tijelo HTTP poruke u XML (*Extensible Markup Language*) formatu.

4) The Message Session Relay Protocol (MSRP)

MSRP je TCP bazirani protokol koji služi za prijenos podataka. SIP protokol se koristi za signalizaciju i uspostavu MSRP konekcije između dva korisnika. Koristi se u slučajevima prenosa serije poruka s kraja na kraj koje su veće nego što bi mogle stati u dio predviđen za *payload* (korisni dio paketa) u samim SIP porukama. MSRP protokol se može primjeniti u aplikacijama za *chat* i prenos fajlova.



Slika 4. IMS sigurnosna arhitektura [14]

5) Generalno korištenje Web servisa

IMS takodjer nudi mogućnosti različitih primjena web servisa u svrhu provizioniranja, naprednog AAA modela i nudjenja različitih servisa krajnjim korisnicima i razvojnim inženjerima softvera.

III. IMS SIGURNOST

A. Uvod u IMS sigurnost

IMS sigurnosna arhitektura je opisana u referenci [12].

Arhitektura identificira pet različitih sigurnosnih asocijacija unutar IMS-a, kao što je prikazano na slici 4.

Pregled IMS sigurnosti:

1. Međusobna autentifikacija između korisničke opreme (*User Equipment - UE*) i IMS-a. HSS delegira ovu aktivnost S-CSCF čvoru ali HSS je odgovoran za stvaranje ključeva i izazova (*chalange*).

2. Sigurna veza i sigurna asocijacija između korisničke opreme i P-CSCF-a za provjeru porijekla podataka.

3. Osiguranje unutarnje sigurnosti za vezu između CSCF i HSS-a. Ovo je poznato kao Cx interfejs. Ova asocijacija ima važnu ulogu u osiguranju ključeva i izazova tokom procesa registracije UE-a.

4. Pruža sigurnosti između P-CSCF-a i ostalih temeljnih SIP usluga kada je UE u roamingu u mreži u posjeti (*Visited Network - VN*).

5. Pruža sigurnosti između P-CSCF-a i ostalih temeljnih SIP usluga kada se UE nalazi u domaćoj mreži (*Home Network - HN*).

IMS sigurnosti je podijeljena u dva dijela: sigurnosti pristupa (specificirano u 3GPP TS 33,203 [12]) i sigurnost mreže (specificirano u 3GPP TS 33,210 [13]). Sigurnosti pristupa uključuje autentifikaciju korisnika i mreže i zaštitu saobraćaja između IMS terminala i mreže. Mrežna sigurnost se bavi zaštitom saobraćaja između mrežnih čvorova, koji mogu pripadati istom ili različitim operaterima.

IMS koristi IPsec za pristupnu i mrežnu sigurnost. Međutim, osnovni SIP protokol pruža samo podršku za izvorni TLS, koji je najčešće *hop-by-hop* sigurnosni mehanizam za SIP na javnom internetu.

B. Sigurnost pristupa

Sigurnosti pristupa obuhvaća sigurnost između NG i IMS mreže, pokrivajući SIP, XCAP i Web korisničke interfejse.

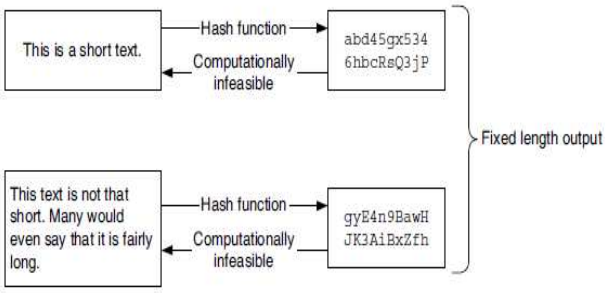
Svrha autentifikacije korisnika je kako bi se osiguralo da je korisniku pristup mreži autoriziran, a time sprječavajući lažne korisnike da iskorištavaju mrežu i njene usluge. Mrežna autentifikacija, sa druge strane, omogućava UE-ovima osiguranje da je mreža kojoj pristupaju namjenska, legitimna i da se ne radi o lažnoj mreži. Autentifikacija se može obavljati kako na IMS razini tako i na osnovnoj mreži koji pruža IP konektivnost.

1) SIP interfejs - SIP Digest Authentication

Prvi problem sa kojima se suočava SIP server je autentifikacija korisnika koji potražuje usluge.

SIP je naslijedio autentifikacijski mehanizam iz HTTP protokola koji se naziva *digest* pristupna autentifikacija (specificirana u RFC 2617 dokumentu). U kontekstu SIP servera, autentifikacija korisnika (npr., pozivatelja) može biti *proxy* server za preusmjeravanje, ili korisnički agent (korisnički agent pozivanog). Koriste se WWW autentifikacijska i autorizacijska polja u zaglavlju.

Prilikom korištenja digest autentifikacijskog pristupa, klijent i server imaju zajedničku tajnu (npr. lozinku), koja se razmjenjuje putem *out-of-band* mehanizma. Kad server na određenoj domeni primi zahtjev od klijenta, server traži od klijenta da mu dostavi važeća uvjerenja (*credentials*) za tu domenu.U tom trenutku klijent dostavi serveru



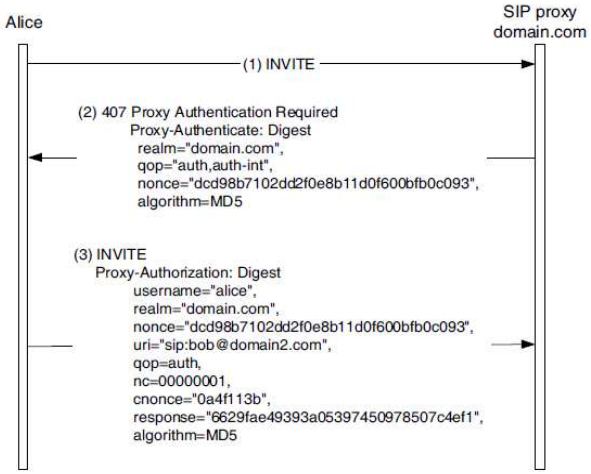
Slika 5. Hash funkcija

korisničko ime i dokazuje da klijent zna zajedničku tajnu. Očigledan način za klijenta da dokaže da zna zajedničku tajnu bi bio da je pošalje na server u jasnom tekstu (tj. bez šifriranja). U stvari, to je ono što HTTP osnovna pristupna autentifikacija i radi (također specificirano u RFC 2617 dokumentu). Ipak, sigurnosni rizici slanjem lozinke u jasnom tekstu su očiti. Bilo koji napadač koji uspije da dobije pristup poruci koja nosi dijeljenu tajnu, također dobije pristup i samoj tajni. Prethodna SIP specifikacije je dopuštala korištenje osnovne autentifikacije, ali se već neko vrijeme ne koristi.

Korištenje digest pristupne autentifikacije je trenutno preporučena metoda. Klijenti koji koriste *digest* pristupnu autentifikaciju mogu dokazati da oni znaju zajedničku tajnu bez slanja te tajne preko mreže. *Digest* koristi *hashe* i *nonce* u tu svrhu. Algoritam predstavlja jednosmjerna funkcija koja uzima argument proizvoljne duljine i proizvodi rezultat fiksne duljine, kao što je prikazano na slici 5. Činjenica da su *hash* algoritmi jednosmjerna funkcija znači da je računarski neizvodivo dobiti izvorni argument iz rezultata. Dva popularna *hash* algoritma su MD5 (specificiran u RFC 1321 dokumentu) i SHA1 (specificiran u RFC 3174 dokumentu). *Nonce* predstavlja slučajnu vrijednost koja se koristi samo jednom.

Slika 6 prikazuje kako *digest* upotrebljava *hashe* i *nonce*. Alice šalje INVITE (1) zahtjev upućen Bobu kroz njezin izlazni *proxy* (na domain.com). *Proxy* server odgovara na INVITE sa 407 (Proxy Authentication Required) - odgovor (2).

Proxy dodaje Proxy-Authenticate polje u zaglavlju sa skupom parametara. *Realm* parametar označava domenu *proxy* servera, tako da klijent zna koju lozinku treba



Slika 6. Digest operacija

koristiti. QOP (*Quality Of Protection* - kvaliteta zaštite) parametar pokazuje da server podržava zaštitu integriteta za liniju zahtjeva pojedinačno (auth) ili za liniju zahtjeva i tijelo poruke zajedno (auth-int). Server opslužuje klijenta sa slučajnom *nonce* vrijednosti u *nonce* parametru. Parametar algoritama dentificira i *hash* funkciju (MD5, u ovom primjeru).

Kada klijent dobije odgovor, šalje novu INVITE poruku (3) koja sadrži Proxy-Authorization polje u zaglavlju. Proxy-Authorization polje sadrži skup određenih parametara. Parametar *response* je posebno zanimljiv. Sadrži *hash comprising*, između ostalog, korisničko ime, lozinku, *nonce* servera, nonce klijenta (cnonce parametar), i liniju zahtjeva. Kada je izabrana opcija auth-int qop, tijelo poruke je također uneseno u *hash* algoritam za generisanje *response* parametra.

Kad server primi polje u zaglavlju Authorization, računa drugu *hash* vrijednost koristeći iste ulazne podatke kao klijent, ali koristeći zajedničku tajnu koju server također posjeduje. Ako se rezultat podudara sa vrijednosti u response parametaru iz INVITE poruke, server smatra da je autentifikacija uspješna i nastavlja procesirati INVITE poruku od klijenta. U suprotnom, server će ponovo zahtjevati response na ovaj INVITE.

Uključivanjem slučajnih *nonce* vrijednosti odabranih od strane servera u *hash*-u sprječava ponavljane napade. Čak i ako prisluškivač uspije dobiti ispravnu *hash* vrijednost za određeni *nonce*, neće biti u mogućnosti pristupiti serveru, jer će server zahtjevati odgovor sa drugom slučajnom vrijednosti *nonce* parametra.

2) IMS AKA autentikacija

IMS AKA (*Authentication and Key Agreement*) postupak se koristi za međusobnu autentifikaciju između korisnika i matične mreže, kao i postavljanje IPsec Security Association (SA) metode između UE i P-CSCF čvorova. Sljedeći postupci se koriste u tu svrhu:

Autentifikacija i dogovaranje ključeva koristeći AKA mehanizam, baziran na generalnom okviru SIP autentifikacijskog mehanizma specificiranog u RFC 3310

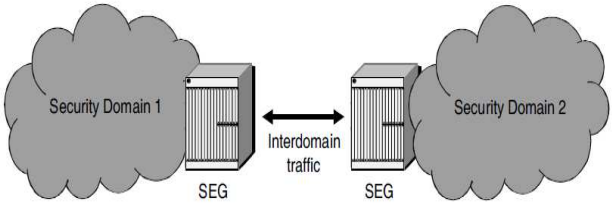
i RFC 2617 dokumentima. Uključene logičke funkcije su UE, P-CSCF, S-CSCF, i HSS.

Usaglašavanje sigurnosnog mehanizma koji se koristi između UE i P-CSCF čvora u svrhu pregovaranja o Ipsec parametrima i portovima koji će se koristiti.

Identifikacija zaštite prema S-CSCF-u. P-CSCF naznačava S-CSCF čvoru kada se zaštita koristi ubacivanjem parametra u autorizacijsko zaglavlje.

Kada je IMS AKA postupak izvršen, sve kasnije SIP poruke između UE i P-CSCF-a će biti zaštićene koristeći Ipsec mehanizam. P-CSCF će identificirati / autentificirati sve dolazne SIP poruke od UE na temelju sigurnosne asocijacije. Ova šema provjere se primjenjuje i na mobilne i fiksne UE-ove.

3) XCAP interfejs



Slika 7. Među domenski saobraćaj između dva sigurnosna gateway-a

XML Configuration Access Protocol (XCAP) se koristi preko HTTP protokola u svrhu dohvaćanja i manipulacije konfiguracijskim podacima koji se odnose na servise i koji su pohranjeni u XML dokumente.

Dvije odvojene autentifikacijske šeme su omogućene od strane mreže, HTTP *Digest* autentifikacija, i implicitna autentifikacija (*Single Sign On*).

HTTP Digest autentifikacija je slična SIP *Digest* autentifikaciji, sa glavnom razlikom da se autentifikacija izvršava od strane HSS čvora; implicitna autentifikacija je slična GPRS-IMS-bundled autentifikaciji (GIBA) (opisana u 3GPP TS 24.229 and TS 33.203 standardima).

IMS mreža podržava XCAP / HTTP zaštitu između UE-a i AP-a koristeći *Transport Layer Security* (TLS), koji osigurava integritet, povjerljivost, i zaštitu od ponavljanja za HTTP signalizaciju po IETF RFC 2818 standardu. TLS također pruža mogućnosti UE-u za provjeru autentičnosti matične mreže putem server certifikata koji dostavlja *Aggregation Proxy* (AP) tokom TLS razmjene poruka.

C. Sigurnost mrežne domene

Mrežna sigurnost se bavi osiguravanje saobraćaja između različitih sigurnosnih domena, gdje sigurnosna domena predstavlja mrežu kojom upravlja jedno administracijsko tijelo.

Na primjer, sesije gdje se P-CSCF i S-CSCF čvorovi nalaze u različitim mrežama uključuju razmjenu saobraćaja između različitih sigurnosnih domena.

Sav saobraćaj koji dolazi ili odlazi iz sigurnosne domene prolazi SEG (*Security Gateway* – sigurnosni prolaz). Dakle, saobraćaj poslan iz jedne domene u drugu domenu prolazi dva SEG čvora, kao što je prikazano na slici 7.

Saobraćaj između SEG čvorova je zaštićen koristeći IPsec ESP (*Encapsulated Security Payload*, specificiran u RFC 2406 dokumentu). Sigurnosna asocijacija između SEG čvorova se ostvaruje i odrava koristeći IKE (*Internet KeyExchange*, specificiran u RFC 2409 dokumentu).

Unitar sigurnosne domene, mrežni entiteti razmjenjuju saobraćaj sa domenskim SEG čvorovima koristeći IPsec.

Mrežni entiteti unutar domene također koriste IPsec za razmjenu saobraćaja. Na ovaj način, sa sigurnosnog aspekta, SEG čvorovi se tretiraju kao bilo koji drugi mrežni entitet unutar domene (pogledajte sliku 8).

Interfejs između regularnih mrežnih entiteta i između SEG čvorova je isti: Zb interfejs. Interfejs između SEG čvorova u različitim mrežama se naziva Za interfejs.

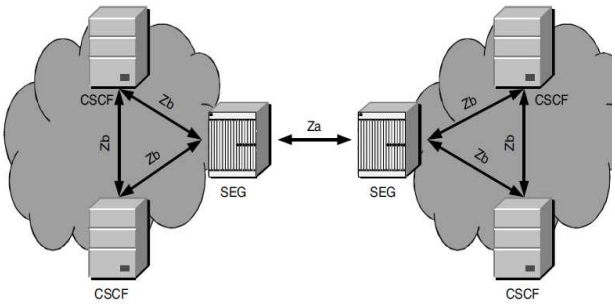
Autentifikacija, zaštita integriteta, i enkripcija su obavezni u Za interfejsu. To nudi među-domenskom IMS saobraćaju maksimalan nivo protekcije.

Zb interfejs je dizajniran za zaštitu IMS signalizacijske ravni. Kako interfejs služi samo za prenos internog saobraćaja, na operatoru je da odluči da li da postavi taj interfjes i, ako ga postavi, koje sigurnosne funkcije da uključi (zaštita integriteta je obavezna ako je implementiran Zb interfejs, ali korištenje enkripcije je opcionalno).

IV. SIGURNOSNE PRIJETNJE

A. Novčane prevare

Na temelju SIP protokola, IMS predviđa odvajanje logičkih puteva za signalizaciju i prenos medije. Iako ovaj dizajn pruža nekoliko prednosti, koči sposobnost



Slika 8. Za i Zb interfejsi

operatora da revidira ili potvrdi da li mehanizam za izvještavanje od *User Agent*-a (UA) funkcionira ispravno. Ova manjkavost kod operatora povećava mogućnost da korisnici mogu koristiti usluge neovlašteno, što je rezultiralo pojavu namjerne i nenamjerne novčane prevare. Većina UA-ova su razvijeni i proizvedeni od strane trećih osoba, a ne operatora samih. Iz tog razloga, kao i zbog povećanja raznolikost UA-ova, nepraktično je za operatora da provjerava ispravnost sigurnosti svakog UA prije nego mu omogući pristup svojoj mreži.

Također je rizično za operatora pretpostaviti da će UA na mreži funkcionisati ispravno. Kad se mobilni uređaji oslanjaju na resurse za povezivanje koje dobiju od operatora, operatori mogu imati sposobnost da prikupe i revidiraju protok podataka kako bi provjerili da li terminal ispravno funkcioniše. Međutim, uz uvođenje telefona sa dvojnim načinom rada, mnogo saobraćaja može stići do IMS-a preko čvorova koje ne kontroliše operator. Ako su UA-ovi direktno spojeni na javni internet, vrlo je moguće za korisnike da komuniciraju direktno koristeći *peer-to-peer* konekciju, što bi moglo biti u sukobu sa načinom naplate usluga od strane operatora. U IMS mreži, HSS pruža uslugu mapiranja između UA IP adrese i javnog identiteta dodjeljenog tokom SIP REGISTER procesa. Međutim, otkrivanje povezanih IP adresa nije težak zadatak. Tokom faze uspostavljanja poziva, IP adresa pozivanog se dostavlja pozivaocu za uspostavljanje zasebnog kanala za prenos podataka. Nakon što UA dobije IP adresu od pozivanog UA, jednostavno može poslati CANCEL zahtjev jezgrenoj mreži i uspostaviti vlastitu vezu prema pozivanom direktno, koristeći iste podatke i glasovnu komunikaciju kao kod usluge koja se plaća.

SIP *proxy* serveri se također mogu koristiti za ostvaranje zlonamjerne novčane prevare. Iako se *proxy* serveri najčešće koriste legitimno u komercijalnom okruženju, ista tehnologija se može iskoristiti unutar personalnog okruženja u svrhu dijeljenja istog računa među zajednicom korisnika. Ta eksplatacije se može lako provesti zbog nedostatka fizičkih lokacijskih ograničenja telefona koji su u prošlosti bili na tradicionalnim PBX centralama. *Proxy* serveri koriste već standardizirana SIP odgovor za usmjeravanje saobraćaja na pravilan UA, što ovaj način čini legitiman za implementirati od strane bilo koga. Kreiranjem UA *proxy* servera ili izgradnju posvećenog *proxy* servera koji se registrira na IMS mrežu, grupa korisnika bi potencijalno mogla dijeliti identitet koji se naplaćuje i koji je povezan s datim računom. To otvara složena pitanja politike IMS operatorima i mogu zahtijevati implementaciju sigurnosti koja je komplicirana za izvesti.

Napadi sa ciljem novčane prevare modu utjecati na fiskne i mobilne usluge na različite načine. U slučaju fiksnih IMS usluga, mnoge od struktura definisanih cijena obično se temelje na neograničenom korištenju unutar zemljopisne granice. Ova metoda napada može preći te granice bez odgovarajućih dodatnih troškova. Na primjer, UA s neograničenim planom u cijeloj državi, sada će biti u mogućnosti za upućivanje međunarodnih poziva prema IP biranju nakon što je otkrio IP adresu pozivanog. U slučaju mobilnih usluga, većina cijenovnih struktura se temelji na korištenju, obično po minuti i po kilobajtu. Napad može krivotvoriti korištene minuta ili trajanja poziva, te će također biti u mogućnosti da uspostavi bilo koji tip prenosa podataka između UA-ova s malo ili nikakve šanse za otkrivanje od strane jezgrene mreže.

B. Autentifikacija

Fiksni VoIP telefoni i druge *soft* telefoni nisu opremljeni za pohranu tajnog ključa. Korisničko ime i lozinka se koristi za autentifikaciju za uređaje koji trenutno nemaju dijeljeni tajni ključ (kao što je slucaj kod SIM-a). Međutim, trenutna autentifikacija koja koristi korisničko ime / lozinku implementirana u IMS-u je sklona *brute force* napadima i napadima ponavljanjem.

Na primjer, Home Subscriber Server (HSS) je dizajniran da prihvati IP adresu posljednjeg REGISTER zahtjeva kao IP adresu klijenta. Budući da je autentifikacija ranjiva na napade ponavljanjima do sljedećeg REGISTAR zahtjeva, napadač je u stanju ponovno se registrirati koristeći isti odgovor s različitom IP adresom kako bi preusmjerio sve servise na bilo koju drugu željenu destinaciju. To djelotvorno stvara DoS i utvrđuje rizik krađe legitimnom korisniku. Također, s nedostatkom dvosmjerne autentifikacije, napadač može oteti sesiju koristeći čovjek-u-sredini (*man-in-the-middle*) napad.

C. Napadi na gateway

IMS *gateway*-i su nedvojbeno najranjiviji *host*-ovi u mreži zbog njihove izloženosti prema vani i utjecaj koji oni mogu imati kada su ugroženi. Konkretnije, Signalizacijski *Gateway* (SGW), *Media Gateway Control* funkcija (MGCF) i *Media Gateway* (MGW) zahtijevaju neki nivo pretvaranja formi sadržaja, što zahtijeva legitimnu manipulaciju sadržaja. Kad god se podaci konvertuju u različite medije, integritet provjere bi trebao biti implementiran kako bi se provjerilo da je pretvoren sadržaj isti sadržaj kao i prije i da se rezultirajući podaci još uvijek mogu smatrati benignim. Moguće je da napadač izvrši obrnutu konverziju zlonamjerne skripte u nešto što može naškoditi mreži nakon konverzije.

D. DoS napad

IMS se suočava s prijetnjom *denial of service* (DoS) napada od više izvora, a ima i mnogo širu izloženost DoS napadima od bilo koje prethodne telekomunikacijske infrastrukture. Očigledna prijetnja je veza s Internetom. Iako postoje tehnologije koje mogu ublažiti DoS napade s Interneta, ostaje činjenica da napadač koji posjeduje dovoljno sredstava može prouzrokovati, barem privremeno, prekid bilo kojeg Internet *host*-a, a time i sa pomno planiranom napadu na IMS implementaciju može prouzrokovati ozbiljnu degradaciju servisa. Druga opasnost dolazi od moćnih i konfigurabilnih UA-ova koji su osjetljivi na ispravnost sadržaja. Scenarij u kojem su mnogi takvi korisnici pregledali zlonamjerni sadržaj može dovesti do preplavljivanja IMS-a sa zahtjevima i na taj način uskratiti servis ostalim kupcima sa manje osjetljivim UA-ovima.

Dok se DoS napad obično smatra prijetnjom mrežnom operateru, IMS prezentuje novi niz uslova, od kojih neki mogu biti da bi i pojedini korisnik mogao postati žrtvom takvog napada. Jedna od temeljnih garancija koje pruža IMS je garancija kvalitete usluge za sadržaj koji prima UA. Dok se IMS ne može adresirati za probleme na prvom mrežnom sloju, kao što su nagli gubitci signala ili RF smetnje, odgovornost IMS-a je da osigura da je dodijeljeni *bandwith* dostupan korisnicima. Zlonamjerni osoba može pokušati da dio ili sav *bandwidth* učini nedostupnim legitimnom UA-u, što bi također predstavljalo DoS napad. Čak i ako napadač ne pokušava ukrasti *bandwith* za vlastitu upotrebu, IMS se i dalje mora braniti od bilo koje situacije u kojoj bi napadač mogao konzumirati *bandwidth* legitimnog korisnika.

E. Alati za testiranje sigurnosti

Postoje razliciti alati na tržištu koji pomažu testiranju SIP sigurnosti. Jedan ot takvih alata je Open Source SIP Proxy aplikacija. SIP Proxy omogućava prisluškivanje i manipulaciju SIP saobraćaja. Nadalje, predefinirani sigurnosni test slučajevi se mogu izvršiti kako bi se pronašle slabe tačke u IMS uređajima. Sigurnosni analitičari mogu dodavati i izvršavati posebne slučajeve ispitivanja.

Kako se sigurnost u IMS-u bazira u dobroj mjeri na Internet sigurnosti, postoji dosta besplatnih alata koji mogu simulirati npr. DOS napade, napad na autentifikaciju, preslušavanje mreže, itd.. Preporuka je da mrežni administratori i administratori IMS sistema zajednički testiraju slabe tačke IMS sistema, osobito vezane uz direktni pristup korisnika putem javnih adresa.

V. ZAKLJUČAK

Kako IMS sve više predstavlja osnovnu jezgrenu mrežu za osnovne i napredne telekomunikacijske servise kod fiksnih i mobilnih operatora, tako je sigurnost tih servisa kao i korisnika koje ih koriste veoma važan aspekt kojem bi svaki operater ozbiljno trebao pristupati.

I pored od strane 3GPP standardiziranih dokumenata sa smjernicama za sigurnost pristupa (3GPP TS 33,203) i sigurnost mreže (3GPP TS 33,210), veoma je važno skrenuti pažnju i na otvorenost i sličnost IMS servisa sa Internet servisima te bi se u svakom slučaju znanja iz oblasti Internet i VOIP-a sigurnosti mogla upotrijebiti i u ovoj oblasti.

Također, kako se radi o sličnoj problematici sigurnosti kao na Internetu, a kako je Internet veoma rasprostranjena tehnologija, dosta stručnjaka, materijala i alata za testiranje je dostupno i u svakom slučaju bi se svaki operater opsežno trebao služiti njima.

GREEN ICT

Fundamental Optimization Criteria For Green Wireless Communications

Abstract – Traditional wireless networks mainly focus on providing ubiquitous access and large capacity. One of the main challenges for future information and communication systems and technologies, including wireless networks, is reduction of the power consumption. Recent analysis by manufacturers and network operators have shown that current wireless networks are not very energy efficient, particularly the base stations that are used as access points from network to services. This paper presents an overview of the most important topics in research and practice for energy efficient mobile radio networks. Green radio researches propose four fundamental tradeoffs: deployment efficiency–energy efficiency, spectrum efficiency–energy efficiency, bandwidth–power, and delay–power, which are presented in this paper.

I. INTRODUCTION

In the last decade energy-efficient communications have been paid increasing attention under the background of limited energy resource and environmental-friendly transmission behaviors. Worldwide climate change debates address one goal - to reduce energy consumption and CO_2 emissions. That is why every emerging technology, including rapidly growing ICT (Information and Communication Technologies) is scrupulously evaluated on its carbon footprint. As ICT becomes more and more wide-spread and pervasive in our daily life, it is important to get a realistic overview of the worldwide impact on the environment in general and on energy needs in particular. It is estimated that the complete life cycle (production, use and end-of-life) of ICT is responsible for about 2-4% of the worldwide carbon emissions. The power consumption during the use phase of the equipment is roughly about 40–60% of the carbon emissions. By 2020 these emissions are expected to double if no initiatives are taken to reduce this footprint. A significant part of these emissions, about one sixth, is attributed to telecommunication networks [1]. It is important to note that the mobile communications industry, as a part of ICT, is considered to have very small percentage of overall energy consumption (about 0.12%) and emissions of carbon dioxide (about 0.14%), despite their rapid growth. Studies have indicated that the energy consumption and CO_2 emission for manufacturing the handset devices is much larger than the base stations (BS). In a mobile network, BS consumes much more energy than mobile terminal, implying that big saving potential in network lies in the operation [2]. The main reason for this difference is the limited lifetime of mobile phones, the effort for distribution of the devices, and the small recycling fraction of mobile phones compared to radio network equipment.

As it is noted, along with number of environmental debates, some green initiatives in ICT appeared. But those isolated efforts devoted to energy saving in wireless networks could not form a global vision of what can be done in energy saving, and thus could not achieve some significant results towards energy efficient networks. First global initiative for reducing power consumption in wireless networks was the Green Radio (GR) project [3]. The main goal of such project was to investigate strategies of deployment and resource-management for energy-efficient wireless broadband access. The research activities are spread to overall system architecture in order to find the relation between power consumption and bandwidth efficiency. In that manner, significant reduction in power consumption over current designs for wireless communication networks should be achieved, without significant influence on quality of service (QoS) experienced by the network's users. In order to measure the achieved success of energy reduction, appropriate measures of energy consumption must be applied. The Green Radio project defines two different perspectives – to examine alternatives to the existing cellular network structures to reduce energy consumption, and to study novel techniques that can be used in base stations or handsets to reduce energy consumption in the network, [4].

This paper is organized as follows: after the introduction, the Section II gives an overview of the problems faced by standardization bodies in defining the framework for energy efficiency. Then, Section III presents the ways to increase energy efficiency. Section IV gives an overview of fundamental trade-offs for the construction of Green Radio frame. Finally, concluding remarks are given in Section V of the paper.

II. EVALUATION OF ENERGY EFFICIENCY IN WIRELESS NETWORKS

The deployment of cellular networks is typically optimized for providing ubiquitous access and service to mobile users. Thus, significant number of base stations are primarily used to provide coverage, meaning that they usually do not operate at full load, even at peak traffic hours. During off-peak hours all base stations operate at lower load, or might not even serve any user at all. That leads to conclusion that the energy efficiency of base stations is particularly poor in this condition, which can be attributed to several components, such as the efficiency of

the power amplifier (PA) that is degraded at lower output power. The other component is system information, synchronization, and reference signals (pilots) that are transmitted continuously (base stations are required to be always on). Another important element is the usual combination of large macro-cells (used for coverage) with additional micro- or pico-cells (for capacity demand) that does not adapt to low load situations, [1].

Having in mind the energy consumption issue in rapidly growing ICT (and wireless networks, in particular), standardization of an energy efficiency evaluation framework has already started in a number of bodies. However, three major shortcomings of wireless networks are:

- System performance is optimized for capacity and evaluated at full load, which implies that the system is poorly configured at low loads
- The output power at the antennas is taken as performance measure, but in order to evaluate the energy consumption, the total input power should be considered
- Performance metrics that measure the energy efficiency.

III. Reducing Energy Consumption In Wireless Networks

Research in this area clearly show that reducing power consumption of the base station or access point has to be an important element of Green Radio project. When it is about the power consumption of a mobile handset per subscriber, it is much lower than the base station. However, manufacturing energy is a much larger component in the mobile handset than in the base station. It is mainly due to the fact that lifetime of a base station is much longer (typically 10–15 years) compared to a handset (approximately 2 years). In addition, the energy costs of a base station are shared between many mobile subscribers, leading to a large imbalance in the contribution of embodied energy. Some of the opportunities for energy saving in wireless networks are presented further in this paper.

Certain energy saving potential lays in network traffic characteristics. Namely, strong variations in traffic patterns are observed at base stations. In addition, the traffic demand varies strongly by location and requires different cell site planning. In these deployments, the system capacity can be designed to serve the local traffic demand without overprovisioning the surrounding area with macrocells. Such design should allow energy efficient network operation during high local load, but these additional small cells and relays in a hierarchical deployment each consume additional power in the network. However, due to the daily variations of traffic significant potential savings can be expected from completely switching off capacity-cells or sectors of cells during low load times, when the macrocells can take over the remaining local traffic, or even from switching off sectors in the macro layer, [5]. It is worth to mention that some large manufacturers already implemented some Power Savings features which reduce energy consumption by disabling transmitters during low traffic hours.

Another potential for improving the energy efficiency of a wireless cellular networks are different base station components, since they are the main contributors to the total energy consumption. Ways to improve energy efficiency at the component level are: finding the right metric, improving the power amplifier efficiency, interference management and mitigation, deactivation of components, reducing load, optimizing power consumption of the remaining components, [1].

Additional energy consumption reduction can be achieved in redesigning the radio interface, with no significant influence on possibility to provide high data rates, optimal spectral efficiency, appropriate coverage, and low latencies. Reduction the overhead of reference symbol and control signals, baseband signal processing, discontinuous transmission and base station (micro or deep) sleep modes, energy efficient routing and multihop transmission offer potential to increase the energy efficiency [6].

On network level, the potential for reducing energy consumption is in the layout of networks and in their management. The energy consumption for maintaining network operation has to be evaluated as a function of cell size and deployment scenario, for given traffic distributions and environments ranging from dense urban to rural areas [7]. Energy efficient adaptation to the daily and spatial variation of the traffic demand requires specific network management functionalities. The state-of-the-art solution is to simply reduce the number of active network elements when the traffic demand decreases [8]. However, once different energy efficient deployment scenarios are available for different traffic situations, new horizons open for network management.

IV. Fundamental Trade-Offs On Green Wireless Networks

GR research is a large and comprehensive area that covers all layers in the protocol stack of wireless access networks as well as the architectures and techniques. Four fundamental tradeoffs in green wireless network design are identified in order to improve energy efficiency while guaranteeing satisfactory quality-of-service/cost, [4]:

- Deployment efficiency (DE)–energy efficiency (EE) trade-off: to balance the deployment cost, throughput and energy consumption in a network as a whole
- Spectrum efficiency (SE)–EE trade-off: given bandwidth available, to balance the achievable rate and energy consumption of the system
- Bandwidth (BW)–power (PW) trade-off: given a target transmission rate, to balance the bandwidth utilized and the power needed for transmission
- Delay (DL)–PW trade-off: to balance the average end-to-end service delay and average power consumed in transmission

A. DE–EE Trade-Off

DE presents a measure of system throughput per unit of deployment cost. EE is defined as system throughput for unit of energy consumption, and it is mostly considered during network operation.

In order to minimize the deployment costs (including the equipment and site rental) larger cell size is advised. But due to signal attenuation, higher transmitted power is needed. In order to minimize energy radiation, smaller cells are deployed. Smaller cell size inevitable leads to larger number of cells, i.e. higher deployment cost. That is why a trade-off between DE and EE is necessary. Since the equipment and implementation costs usually do not scale proportionally with the target cell size and transmitted energy, simple trade-off relation can not be derived. That is why planning a cell site means the following: for any target network throughput and given deployment budget, the corresponding deployment efficiency should be calculated. Then the decision on the maximum achievable energy efficiency should be made, that should lead to the corresponding optimal cell size. For LTE-Advanced or beyond networks, heterogeneous networks (HetNet) have been approved as a work item. In these networks, using the macro and micro/pico/femto cells, coverage and capacity provision can now be decoupled into different tiers of the network. The other candidate for future architectures is cooperative networks (CoopNet), where new air interface techniques, such as relay and distributed antenna systems (DAS), are employed. Dynamic switch off/on of coverage overlaid cells in low traffic is an example in HetNet, while dynamic relay selection or CoMP pattern selection is the counterpart in CoopNet. As it introduces no extra cost but saves redundant energy consumption, it can improve DE and EE simultaneously, [9].

B. SE-EE Trade-Off

SE is defined as the system throughput per unit of bandwidth, and is a widely accepted criterion for wireless network optimization. On the contrary, EE was previously ignored by most research efforts and was not considered by 3GPP as an important performance indicator until very recently, but now it becomes an important and indispensable factor in wireless networks. The main issue is how to balance these two metrics in future systems, because they are usually not consistent and sometimes conflict with each other. A detailed study of such trade-off is needed, in order to determine how much spectrum efficiency should be sacrificed for energy efficiency to obtain optimal system. SE and EE can be expressed as, [4]:

$$\eta_{SE} = \log_2\left(1+\frac{P}{WN_0}\right), \tag{1}$$

and:

$$\eta_{EE} = W\log_2\left(1+\frac{P}{WN_0}\right)/P, \tag{2}$$

where N_0 present power spectral density of AWGN, P is transmit power and W is system bandwidth. Their relation can be expressed as:

$$\eta_{EE} = \frac{\eta_{SE}}{\left(2^{\eta_{SE}}-1\right)N_0}. \tag{3}$$

It can be seen that μ_{EE} decreases monotonically with μ_{SE}. However, in practical systems the SE-EE relation is not as simple as given in (3). In fact, electronic circuit energy consumption changes the fundamental tradeoff between EE and SE. That is mainly due to the fact that EE presents information bits per unit energy (not only transmit energy), so that an additional circuit power factor needs to be added in the denominator of (3). Accordingly, the μ_{EE}- μ_{SE} curve becomes bell shape that decrease with the circuit power.

Interesting research topics may include the following aspects: characterizing the SE-EE trade-off under practical hardware constraints, investigating the network SE-EE trade-off in multi-user/multicell environments, joint design of physical layer transmission schemes and resource management strategies that will improve the network SE-EE trade-off, [10].

C. BW-PW Trade-Off

Bandwidth and power are the most important but limited resources in wireless communications. Their relationship can be expressed as:

$$P = WN_0\left(2^{R/W-1}\right). \tag{4}$$

This expression shows that PW is monotonically decreasing function of BW, and this BW-PW relation is crucial to radio resource management. In practical systems the circuit power consumption actually scales with the system BW, which entangles the BW and PW relation. Some of interesting research topics are advanced techniques for BW-PW trade-off with practical concerns and novel network architectures and algorithms to improve BW-PW trade-off. The future deployment of LTE or LTE-Advanced systems provides more flexibility on the spectrum usage so that the transmission BW can be tuned for different applications, unlike 2G and 3G wireless communication systems that use fixed BW transmission, leaving no space for dynamic BW adjustment. Technologies such as spectrum refarming, CA (Carrier Aggregation), and software defined radio (SDR)-based CR (Cognitive Radio) techniques are maturing to support the flexible use of BW. Hence, the BW-PW trade-off with advanced resource management algorithms under new network architectures deserves future research, [11].

D. DL-PW Trade-Off

DL, also known as service latency, is a measure of QoS and user experience, and is closely related to the upper layer traffic types and statistics. In GSM communication system the DL between the transmitter and the receiver mainly consists of signal processing time and propagation delay, because the traffic generated in voice service is continuous and constant, so fixed rate coding and modulation schemes are good enough. Future networks must deal with various applications and heterogeneous DL requirements. That raises an issue how to get balance between QoS (e.g. delay) and power consumption. Shannon's formula gives us the insight how

many bits of information are transmitted in the unit of time:

$$R = W \log_2\left(1+\frac{P}{WN_0}\right). \quad (5)$$

This means that it takes $t_b=1/R$ to transmit a bit. The average power per bit can be expressed as:

$$P_b = WN_0 t_b\left(2^{\frac{1}{t_b W}}-1\right). \quad (6)$$

From the above given relation, (2), it can be seen that PW is monotonically decreasing function of DL.

In the case with traffic dynamics the service DL should include both the waiting time in the traffic queue and the time for transmission. More open issues need to be addressed, including: DL-PW tradeoff for heterogeneous DL requirements in multi-user/multi-cell scenarios; joint design of physical layer transmission schemes and resource management to improve DL-PW tradeoff with consideration of practical concerns; simplified and insightful but approximate mathematical models for DL-PW relation. In general, there is no closed form expression available to show the direct relation between DL and PW.

It is clear that any of the above described target efficiencies could be obtained at the cost of some other benefit in overall network performance. Finding the optimal resource allocation and maintaining high level of QoS is very difficult task, especially due to the fact that most of the results that give some insight in optimal trade-off is of rather theoretical than practical interest. That is because such relations are very complex, why certain assumptions are made. Under practical conditions, such assumptions are not valid, thus leading to less optimal solution. Such differences are illustrated in Fig. 1, [4].

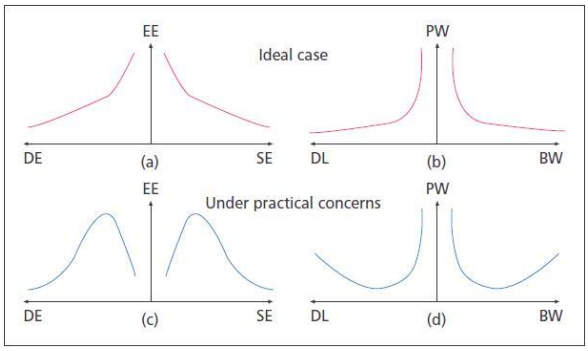

Figure 1. Trade-off relations in theoretical and practical case

V. CONCLUSION

Green communication is a very important research topic in recent years due to increasing growth of overall ICT sector. It started as several isolated projects, but during last few years research on this subject has received a lot of attention and grew into worldwide initiative.

Starting from the Green Radio program, which is the first global research project with the goal to increase energy efficiency and reduce emissions of carbon dioxide, more and more workshops and conferences are dedicated to this subject. Many ideas and solutions are proposed in each network level, but still, it is a question how operators are ready to invest in a green network. However, it is almost certain that future wireless networks will be based on more environmental friendly concept. Therefore, such research will be a great need and the inevitable trend for operators and equipment manufacturers.

Thereby, this paper deals with one very important issue which is a concern of industry, operators, regulatory bodies and whole society, and that is energy efficiency of mobile cellular networks. Initially, it presents an overview of most important issues and trends. It also identifies wireless network elements that could be redesigned in order to be more energy efficient.

Abstract - In cognitive radio networks, the first cognitive task preceding any form of dynamic spectrum management is the spectrum sensing and identification of spectrum holes in wireless environment. In cognitive radio, spectrum sensing is fundamental crucial task. Energy detection method is a basic method, which requires knowledge of noise power but suffers from noise uncertainty problem. Covariance based detection exploits space-time signal correlation that does not require the knowledge of noise and signal power. The covariances of signal and noise are generally different which can be used in detection of licensed user. However, there are not many studies that show the feasibility of the detectors and analyze their performance under fading channels. In this paper, we analyzed the detector performance exploiting TV White Space under Rayleigh and Rician fading channel by setting probabilities of false alarm and measuring probability of detection. We further analyze the effect of smoothing factor and overall correlation coefficient on the performance of covariance based detector. Covariance based detector outperformed the energy detector with noise uncertainty even under the time-varying fading channels.

I. INTRODUCTION

In our day to day life, devices such as TV remote controls, cellular phones, personal digital assistants (PDA), satellite TV receivers or mobile computers are based on wireless communications technology and still many new technologies are emerging, which demand more spectrum and bandwidth for faster growth. The fixed spectrum allocation policies lead to underutilization of spectrum allocated to primary user (PU) [1], thus demanding dynamic allocation of spectrum instead of static [2], [3]. Recently, there have been growing interests in cognitive radio, where secondary opportunistic radio exploits opportunistically spectrum left-overs, or so-called "White Spaces", by means of knowledge of the environment and cognition capability, and adapts their radio parameters accordingly [2], [3], [4], [5]. The upcoming IEEE 802.11af standard (known as "super-Wi-Fi" or "Power over Ethernet") is based on cognitive radio (CR)[6], utilizing the bandwidth within TV broadcast stations [7], [8], [9], [10]. CR makes opportunistic use of the spectrum by allowing unlicensed or secondary user (SU) to reuse the spectrum whenever the licensed or primary user (PU) is inactive. The SUs are required to perform the frequent spectrum sensing for detecting the presence of PUs with a high probability of detection and vacant the channel or reduce transmit power. For IEEE 802.11af standard, time to vacate band after PUs detection is 2s with 90% of probability of detection and 10% of probability of false alarm at SNR level as low as -20dB along with geo-location accuracy of +/-50m [6], [9], [10]. Sensing a spectrum is a crucial task in CR.

There have been several sensing methods, including the Likelihood ratio test (LRT)[11], Energy detection (ED) method [11],[12],[13],Matched filtering (MF)-based method [11],and Cyclostationary detection method [11], each of the mentioned methods has different requirements together with advantages or disadvantages. Although LRT is proven to be optimal, it is very difficult to use, because it requires exact channel information and distributions of the source signal and noise. To use LRT for detection, we need to obtain the channels and signal and noise distributions first, which are practically intractable. The MF-based method requires perfect knowledge of the channel responses from the primary user to the receiver and accurate synchronization (otherwise, its performance will dramatically be reduced). Energy detection method is a semi-blind detection which requires knowledge of noise power only for signal detection. In [12], sets of receiver operating characteristic (ROC) curves are drawn for several time-bandwidth product for spectrum sensing using energy detection. In [11], Blindly combined energy detection method which uses the spatial correlation of received signals based on energy detection, is analysed for independent and identically distributed source signal which is FM modulated wireless signal operated in vacant TV channels with a bandwidth less than 200 kHz , the flat-fading and the multipath fading channel. The experimental study for spectrum sensing in 2.4 GHz ISM band over 85 MHz of bandwidth using energy detection for sine wave carrier and QPSK sensing is evaluated in [14]. In the same reference minimum detectable signal levels set by the receiver noise uncertainties are measured. The cyclostationary detection method needs to know the cyclic frequencies of the primary users, which may not be realistic for many spectrum reuse applications. Furthermore, this method demands excessive analog-to-digital (A/D) converter requirements and signal processing capabilities [11]. In the references: [11],[15],[16], a new spectrum sensing algorithm based on covariance of the received signal called as Covariance Absolute Value (CAV) is proposed. CAV is a blind

detection method, uses space-time signal correlation for signal detection which does not require any knowledge of noise and signal power. The covariances of signal and noise are generally different, which can be used in detection of PU.

In [15],[16], the performance of ED and CAV is evaluated for Advanced Television Systems Committee (ATSC) (used in USA and South Korea)of 6MHz bandwidth for the narrow-band signal of a wireless microphone, by analysis of multiple antennas. In [15], ROC curve is analyzed for wireless microphone signal for outdoor environment with Rician channel, further probability of detection (P_d) versus the smoothing factor is studied for a wireless microphone signal. Also in [15] P_d versus different values of SNRs are studied for ATSC signal with single and multiple antennas which is concluded by the effect of time variant channel on the detection of ATSC signal. But in [15]–[16] the ROC curve and the effect of time-variant Rayleigh channel using ED and CAV spectrum sensing algorithms on detection of ATSC signal has not been studied. Further CAV method for DVB-T standard for 8 MHz bandwidth has not been evaluated.

Since cognitive radio is an emerging technology, the performance of the spectrum sensing algorithm needs to be analyzed under conditions of different fading channels.

The goal of this paper is to present an analysis of energy detection with noise uncertainty and covariance based detection for DVB-T standard for 8MHz bandwidth in 2k mode used for mobile reception of standard television. This paper focuses on analyzing two algorithms under conditions of AWGN channel, Rayleigh and Rician fast and slow time variant fading channels using time-variant Jakes' model based on probability of detection under varying SNR conditions, P_d versus P_{fa} for different SNRs, P_d versus smoothing factor, P_d versus overall correlation coefficient and receiver operating characteristic (ROC) curve for DVB-T signal .

The organization of the paper is as follows. The overview of ED and CAV is made in section II. Simulation is performed in section III for terrestrial digital video broadcasting based on the two methods under different channel conditions, followed by conclusions in section IV.

II. ANALYSIS OF ED AND CAV METHODS

The Neyman-Pearson criteria say that the spectrum detection is a binary hypothesis sensing problem [11], [12], [13].

$$H_0: y(n) = \eta(n) \qquad n = 1,2,3, \ldots\ldots \qquad (1)$$
$$H_1: y(n) = s(n) + \eta(n) \quad n = 1,2,3, \ldots\ldots$$

where $s(n)$ indicates the PU and $\eta(n)$ is the additive white Gaussian noise which is assumed to be independent and identically distributed random variable with zero mean and variance σ_η^2. Here, the hypothesis H_0 means the absence of signal and H_1 its presence. Performance of spectrum sensing algorithm is indicated by two metrics: by a probability of detection, P_d, which is the probability of the algorithm correctly detecting the presence of the PU and by a probability of false alarm, P_{fa}, which defines probability of the algorithm mistakenly declaring the presence of PU leading to underutilization of available spectrum opportunities.

A. Energy Detection Method

Energy detection method compares the energy of the received waveform over a specified time with a threshold obtained for a given P_{fa} limit to decide whether primary signal exists or not. Note that for a given signal bandwidth B, a pre-filter matched to the bandwidth of the signal needs to be applied as shown in Fig.1.

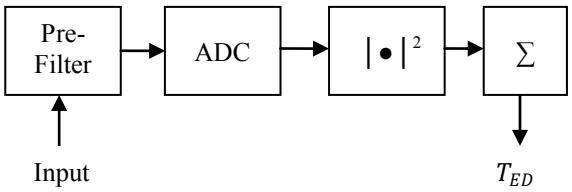

Figure 1. Implementation of energy detection

The decision statistic for energy detector is [12], [13]:

$$T_{ED} = \frac{1}{N} \sum_{n=0}^{N-1} (|y(n)|)^2 \qquad (2)$$

where N is the total number of taken signal samples. This decision statistic is compared with a threshold β_{ED} in order to decide whether the signal is present or not. If $T_{ED} > \beta_{ED}$, the signal is assumed to be present; otherwise it is assumed to be absent. In case of large N, according to Central Limit Theorem (CLT), the probability distribution function of T_{ED} can be approximated by Gaussian distribution. The expressions for probability of detection and false alarm can be obtained as:

$$P_d = Q\left(\frac{\sqrt{N}\,(\beta_{ED} - (\sigma_s^2 + \sigma_\eta^2))}{\sigma_s^2 + \sigma_\eta^2}\right) \qquad (3)$$

$$P_{fa} = Q\left(\frac{\sqrt{N}\,(\beta_{ED} - \sigma_\eta^2)}{\sigma_\eta^2}\right) \qquad (4)$$

where σ_s^2 is primary user signal variance, σ_η^2 is noise variance and Q(t) is Q function given by:

$$Q(t) = \frac{1}{\sqrt{2\pi}} \int_t^{+\infty} e^{-\frac{u^2}{2}}\, du \qquad (5)$$

In energy detection accurate knowledge of noise power is a must for signal detection. But unfortunately in practice, the uncertainty always exists due to uncertainty of the measurements and of the time-variation of noise power. Due to the noise uncertainty [14], [17], [18] the estimated noise power may be different from the actual noise power by a factor γ, called as noise uncertainty factor: $\hat{\sigma}_\eta^2 = \gamma\sigma_\eta^2$. The noise uncertainty bound (in dB) is given as:

$$A = \sup\{10log_{10}\gamma\} \qquad (6)$$

The noise uncertainty bound is usually 1 to 2 dB [17].This creates Signal -to-Noise Ratio wall (SNR wall) under which it is not possible to detect the signal [18].

B. Covariance Absolute Value Method

CAV is a blind detection method which does not require any knowledge of noise and signal power, uses space-time signal correlation for signal detection. The covariances of signal and noise are generally different. This difference is used in CAV method to differentiate the signal component (PU) from background noise [15],[16].

Let

$$s(l) = [s(N-1-l), \dots\dots\dots, s(-l)] \quad (7)$$
$$\eta(l) = [\eta(N-1-l), \dots\dots\dots, \eta(-l)]$$
$$y(l) = [y(N-1-l), \dots\dots\dots, y(-l)]$$

where N is the total number of signal samples, the range of l is from 0 to L-1, the parameter L is called smoothing factor as explained in [15], [16]. $s(l)$ represents signal samples, $\eta(l)$ represents noise samples and $y(l)$ the received signal samples.

$$y(l) = s(l) + \eta(l) \quad (8)$$

The auto-correlations of the received signal is

$$c(l) = \frac{1}{N}\sum_{n=0}^{N-1} y(n) * y(n-l) \;\; l = 0,1,.,L-1 \quad (9)$$

The covariance matrix of $y(l)$ under H_0 and H_1 is given by

$$R_y(l) = E[y(l)y(l)^H] = \sigma_\eta^2 I_L \quad : H_0 \quad (10)$$
$$= R_s(l) + \sigma_\eta^2 I_L \;\; : H_1$$

where $R_s(l)$ is the covariance matrix of $s(l)$, I_L is the identity matrix of dimension L and

$$\sigma_\eta = E[\eta(l) * \eta(l)^*]$$

If there is correlation between the signal samples due to oversampling, the $R_s(l)$ will be different from identity matrix. In the matrix form, the covariance matrix of the received signal is

$$R_y(N) = \begin{bmatrix} c(0) & c(1) & .. & c(L-1) \\ c^*(1) & c(0) & .. & c(L-2) \\ c^*(L-1) & c^*(L-2) & .. & c(0) \end{bmatrix} \quad (11)$$

This matrix is Toeplitz and Hermitian. Based on this covariance matrix, two metrics T_1 and T_2 are defined as follows:

$$T_1 = c(0) + \frac{2}{L}\sum_{l=1}^{L-1}(L-l)\,|c(l)| \quad (12)$$

$$T_2 = c(0) \quad (13)$$

The ratio $\frac{T_1}{T_2}$ can be used to detect the presence of the signal. When there is no signal, $\frac{T_1}{T_2} = 1$ and if the signal is present, $\frac{T_1}{T_2} > 1$. The following decision metric for CAV is derived as:

$$T_{CAV} = \frac{T_1}{T_2} \quad (14)$$

According to this decision metric, probability of false alarm and the probability of detection have the following form:

$$P_{fa} = 1 - Q\left(\frac{\frac{1}{\beta_{CAV}}\left(1+(L-1)\sqrt{\frac{2}{N\pi}}\right)-1)}{\sqrt{2/N}}\right) \quad (15)$$

$$P_d = 1 - Q\left(\frac{\frac{1}{\beta_{CAV}} + \frac{\beta_L\, SNR}{\beta_{CAV}\;(SNR\;+1)} - 1}{\sqrt{2/N}}\right) \quad (16)$$

where signal-to-noise ratio:$SNR = \frac{\sigma_s^2}{\sigma_\eta^2}$, β_{CAV} is the decision threshold and β_L is a very important parameter for CAV called overall correlation coefficient. It is defined as:

$$\beta_L = \frac{2}{L}\sum_{l=1}^{L-1}(L-l)\,|e(l)| \quad (17)$$

where $e(l) = \frac{E[s(n)s(n-l)]}{\sigma_s^2}$ (18)

This is normalized correlation strength between the signal samples (range is between 0 to 1).

C. Comparison between ED and CAV based detection

The comparison between ED and CAV based detection method is done based on following parameters:

- Number of samples required to achieve P_d and P_{fa} >0:

$$N_{ED} = \frac{2\left(Q^{-1}(P_{fa}) - Q^{-1}(P_d)\right)^2}{SNR^2} \quad (19)$$

$$N_{CAV} = \frac{2\left(Q^{-1}(P_{fa}) - Q^{-1}(P_d) + \frac{L-1}{\sqrt{\pi}}\right)^2}{(\beta_L\; SNR)^2} \quad (20)$$

Equation (20) indicates that for a fixed P_d and P_{fa}, N_{CAV} is only dependent on smooting factor and overall correlation strength.

Comparing "(19)" and "(20)", if we want $N_{CAV} < N_{ED}$, we need

$$\beta_L > 1 + \frac{L-1}{\sqrt{\pi}(Q^{-1}(P_{fa}) - Q^{-1}(P_d))} \quad (21)$$

This holds true iff signal samples are highly correlated [15], [16].

➢ Computational Complexity :

ED requires N multiplications and additions and CAV requires L times that of ED computations.

III. SIMULATION RESULTS

In the following, we will show the simulation results of energy detection without noise uncertainty, energy detection with noise uncertainty and covariance based detection for the primary signal which is Digital Video Broadcast–Terrestrial (DVB–T) signal generated using MATLAB according to European Telecommunications Standards Institute (ETSI) specifications given in [19] intended for mobile reception of standard definition TV in 2K mode with 8 MHz bandwidth. The received signal is sampled at the rate 36 times sampling rate at the transmitter. Signal-to-Noise Ratio (SNR) of the received signal is unknown. In order to use the signals for simulating the algorithms at very low SNR, we need to add white noise to obtain various SNR levels [20]. The DVB-T signal and the added white noise are passed through a raised cosine filter with bandwidth 8MHz, and rolling factor 0.5 with 217 taps. The number of used samples is 30000. For covariance based detection the smoothing factor is chosen as L=6.The threshold for detection for both the methods is calculated based on P_{fa}.

Fig.2 shows the performance of ED and CAV for probabilities of false alarm P_{fa} = 0.1 in AWGN channel. With "ED-x dB" means energy detection with x-dB noise uncertainties. ED and CAV show probability of detection for SNR = -20 dB as 0.35 and 0.28 respectively.

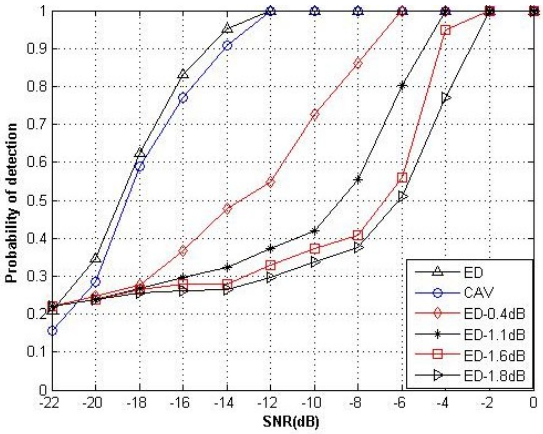

Figure 2: Probability of detection versus SNR for P_{fa} =0.1 with N=30000 in AWGN channel.

For noise uncertainty like ED-0.4dB, ED-1.1 dB, ED-1.6dB and ED-1.8dB probability of detection is 0.247, 0.239, 0.238 and 0.237 respectively. Comparison of the curves in Fig.2 for all values of SNR clearly indicates that even if the noise uncertainty is only 0.4dB, the probability of detection of energy detection is much worse than CAV. On the other hand, Fig.2 also shows that ED with the exact knowledge of noise power performs better compared to CAV method.

To check the performance of the methods for time-varying channels, the time- varying channel is generated based on the simplified Jakes' model with Doppler frequency DF1=100Hz and DF2=1000Hz for Rayleigh channel with P_{fa}=0.1and N=30000. As shown in Fig.3, in case of Rayleigh slow time-varying channel at SNR of -14dB, ED, CAV, ED - 0.4dB and ED - 1.1 dB show probability of detection as 0.8, 0.58, 0.21, 0.18. For Rayleigh fast fading channel at SNR of -14 dB, ED, CAV, ED - 0.4dB and ED - 1.1 dB show probability of detection 0.6,0.52,0.15,0.14, respectively.If the curves as shown in Fig.3 are compared for slow and fast time-varying channels for all values of SNR, CAV shows good probability of detection compared to ED with noise uncertainty. But the probability of detection for CAV degrades in fast time-varying channel compared to slow time-varying channel. Same is true for ED.

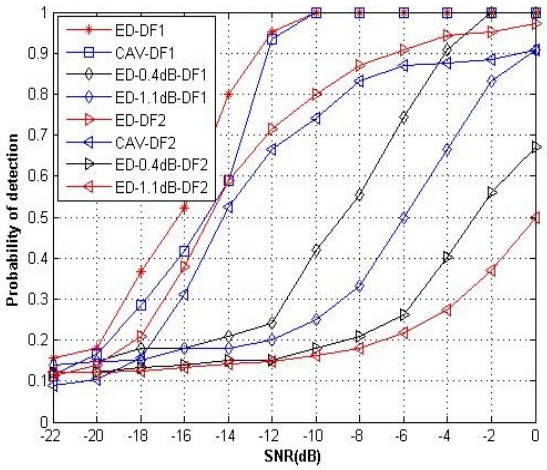

Figure 3: Probability of detection versus SNR for P_{fa}=0.1, N=30000 under Rayleigh time- varying channel.

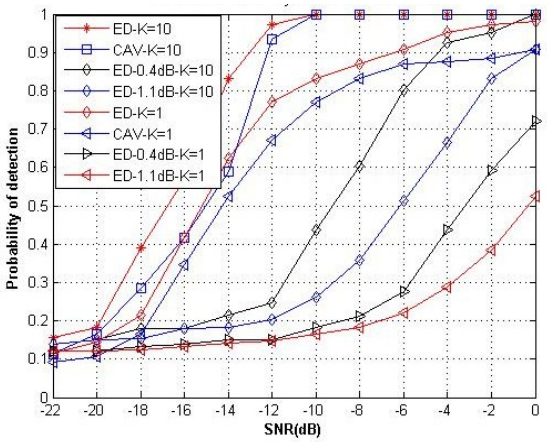

Figure 4: Probability of detection versus SNR for P_{fa} =0.1 and N=30000 under Rician time-varying channel with K=10 and K=1.

For Rician channel, Doppler frequency of 100Hz with P_{fa}=0.1and N=30000 is considered, Fig. 4 reflects its effect on the probability of detection for ED and CAV for K=1and K=10. At K=10 and SNR = -14dB; ED, CAV,

ED-0.4dB, ED-1.1dB show probability of detection as 0.83, 0.6, 0.21, 0.18 respectively. For K=1 and SNR= -14dB; ED, CAV, ED-0.4dB, ED-1.1dB show probability of detection as 0.62, 0.52, 0.15, 0.14 respectively. By comparing the curves for all values of SNR with K=1 and K=10, it reveals that CAV performs well compared to ED with noise uncertainty. The probability of detection for Rician time-varying channel with K=10 is good, compared to K=1.

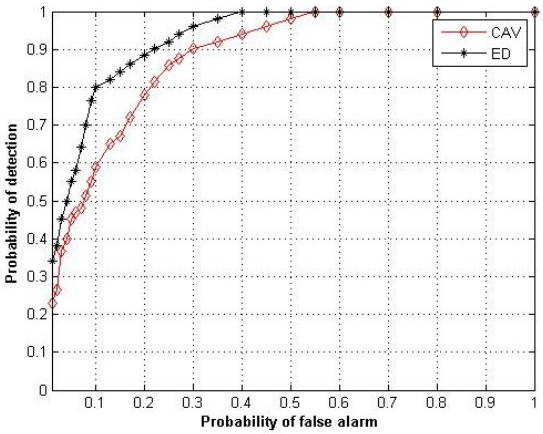

Figure 5: Receiver operating characteristics (ROC) curve for ED and CAV with P_{fa}=0.1, SNR= -14dB and N=30000 under Rayleigh time-varying channel

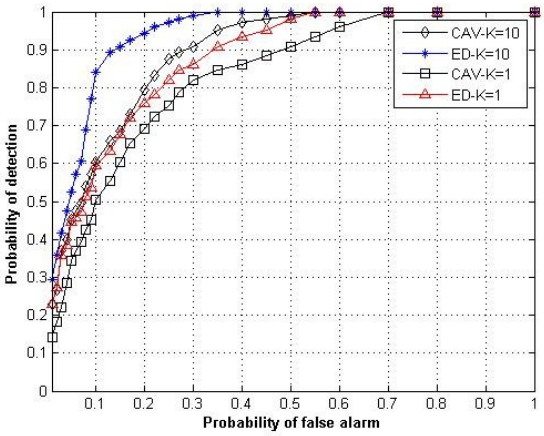

Figure 6: Receiver operating characteristics (ROC) curve for ED and CAV with P_{fa} =0.1, SNR= -14dB and N=30000 under Rician time-varying channel for K=1 and K=10.

The effect of time-varying channels at Doppler frequency of 100Hz on the receiver operating characteristic (ROC) curve is analyzed for both the methods by plotting Fig.5 and Fig.6 with values SNR= -14dB, N=30000 and P_{fa} =0.1.Fig. 5 reflects ROC curve under Rayleigh channel, there is performance deterioration both for ED and CAV but ED provides probability of detection better than CAV. Fig. 6 reflects ROC curve under Rician Channel with K=1, there is performance deterioration both for ED and CAV at SNR of -14dB compared to K=10.But if we compare the curves with K=1 and K=10, the performance of detection schemes are better for K=10.
Fig. 5 and 6 reveals that ROC curve will be poor at low SNR values than -14dB.

To test the impact of smoothing factor, we fix P_{fa}=0.1and SNR= -20dB and N=30000 and vary smoothing factor L from 5 to 10. Fig.7 shows the results for probability of detection. Since ED is not dependent on L, there is a line parallel to x-axis. For CAV, as L increase from 5 to 9, the probability of detection increases from 0.22 to 0.75 .We see that for probability of detection is not very sensitive for smoothing factor greater than 9. We note that smaller the value of L means lower complexity in practice; thus, we can select a relatively small L. However, it is difficult to choose the best smoothing factor so that computational complexity reduces as it is related to the signal property which is unknown.

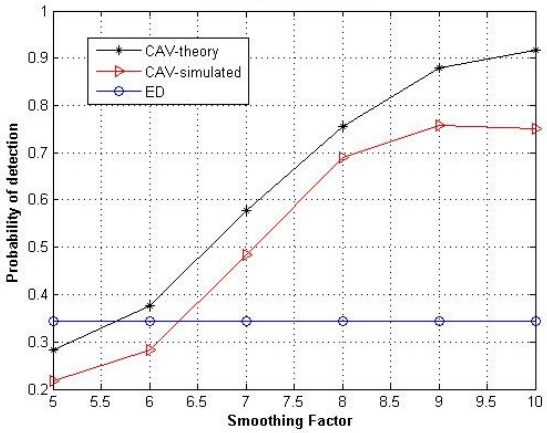

Figure 7: Probability of detection versus smoothing factor for P_{fa} =0.1, SNR= -20dB and N=30000.

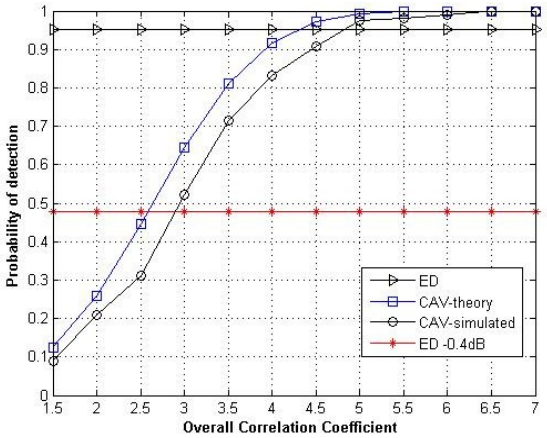

Figure 8: Probability of detection versus overall correlation coefficient for P_{fa} =0.1, SNR= -14dB and N=30000.

For testing the impact of overall correlation coefficient on probability of detection for CAV, we fix P_{fa}=0.1and SNR= -14dB and N=30000. As the overall correlation coefficient increases, the probability of detection also increases. Fig.8 reveals this fact. The theoretical probability of detection for CAV is also plotted. Further the probability of detection for ED and ED-0.4 dB are plotted. It clearly reveals that ED and ED-0.4dB are not dependent on correlation coefficient so there is line parallel to x-axis. ED with 0.4dB noise uncertainty shows poor probability of detection.

IV. CONCLUSIONS

In this paper, sensing algorithms based on energy detection without noise uncertainty, energy detection with noise uncertainty and covariance based detection are analyzed. The simulation based on DVB-T signals have been carried out to evaluate performance of the both methods. The simulation results show that energy detection with accurate noise power can be applied for signal detection and outperformed the covariance method. It is shown that covariance based detection outperformed energy detection with noise uncertainty present in case of fast and slow time-varying channels. The performance of covariance based detection degrades in fast time-varying compared to slow time-varying fading channels. The probability of detection for covariance based detection improves as smoothing factor and overall correlation coefficient increase. Hence this analysis provides a new insight in spectrum sensing for dynamic spectrum access in cognitive radio network and can be applied to IEEE 802.11af standard for spectrum sensing exploiting the TV white space.

Abstract - Energy efficiency is one of the most important design requirements in wireless sensor networks (WSN). In this paper, three performed benchmarks compared code size and execution speed of ARM Cortex-M series processors with processors which are commonly used in WSN. In addition, power consumption is taken into account in order to determine energy efficiency of tested processors. Results show that recently introduced ARM Cortex-M series processors are best choice for energy efficient WSN nodes according to all design criteria: power consumption, execution speed and code size.

I. INTRODUCTION

Wireless sensor networks are used in many areas, such as home and industrial automation, military applications, habitat monitoring and medical applications. These applications are limited by the operating lifetime of battery - powered nodes. Requirements for low power consumption and long life can be achieved through compromises between computing performance and power consumption [1]. In the earlier work on the processors, performance and silicon area were represented as a main target of design while power consumption was considered as additional task. With wider introduction of low power applications, power consumption became important in the same way as computational performance. Appropriate design of low power consumption system results in improvements such as longer battery life, better reliability of the system, lower cost of the system and reduction of environmental issues [2].

Reduction of power consumption in processors are difficult due to the fact that processors are required to have increasing computation power, flexibility and very low power. These features that affect design are contradictory among themselves. Therefore, designers have to make a compromise between these requirements to obtain an appropriate solution [3]. Designing system with reduce power consumption without affecting its performance has become an important design criterion.

High computing performances enables microcontroller to perform required task faster, thus sufficient time can be spent in low power mode, which leads to improved power efficiency. In addition, improvements in architecture enabled faster transitions for low power to active mode and vice versa which reduced power consumption and response latency. Higher code density requires less memory, which is one of the most dominant power consumers in microcontroller chip.

Paper [4] analyzes just computational performance of some of the most widely used low power embedded processors, without any details of power consumption of tested processors. Also, benchmarks from paper [4] were performed several years ago, when ARM Cortex-M processors haven't been introduced to the market. Similarly, computational performances of some microcontrollers were analyzed in diploma thesis [5] without analysis of power consumption. Paper [6] presents WiSeNBench, set of benchmark tests which are typical for wireless sensor networks which are executed on ARM microprocessor.

This paper presents detail analysis of computational performance and power consumption of actual low power processors, including recently introduced ARM Cortex-M series processors. Benchmark tests were conducted according to benchmarks performed in paper [4].

II. BENCHMARKING PROCESSOR PERFORMANCE

Benchmark represents test application developed to allow comparison of computational performances from processors with different architectures. Benchmarks are used to measure one or more features of a system like processor or memory performance or compiler performance. Benchmarks can be divided into mathematic, application ("real world") based and synthetic benchmarks. Mathematic benchmarks judge about system performance based on execution of some mathematical algorithms. Application benchmarks judge about system performance based on execution of some real world application. A synthetic benchmark is created in such way to simulate execution of general real world applications.

Benchmark programs are always written in high-level languages in order to be executable on various platforms. Compilers are responsible for translation of high-level language code to machine code of specific target

Work presented in this paper was funded by grant TR32043 for the period 2011-2014, by the Ministry of Education and Science of the Republic of Serbia.

processor. As a result of compilation, performances of executed application can drastically change using different levels of compiler optimization. Compiler optimization is the process of tuning the output of a compiler to minimize code size or maximize execution time of an executable application. Compiler optimization is very important in systems with restrained resources, such as embedded systems and WSN, where it can drastically increase overall system performance. Usual means of compiler optimization are:

- Common subexpression elimination
- Loop unrolling
- Function inlining
- Code motion
- Type-based alias analysis
- Static clustering
- Instruction scheduling

Besides optimizing usage of system resources, compiler optimization can be used to artificially increase benchmark performances of analyzed processors, by optimizing benchmark code to certain processor architecture. Good benchmarking algorithm should be compiler independent in order to fairly judge performances of analyzed processor and not performances of both processor and compiler. In order to extract just processor performances, result of benchmarks should be presented under various levels of compiler optimizations.

In this paper processor's computational performance was tested using three benchmark tests. First test is based on application benchmark of FIR (Finite Impulse Response) filter [7], while the other two tests are synthetic benchmarks, known as Dhrystone [8] and Whetstone [9].

III. BENCHMARKING RESULTS

Two most commonly used processors in wireless sensor devices are Texas Instruments MSP430 and Atmel ATmega128 [10], whereas the ARM7 processor is rarely used in these kinds of applications, because it is targeted to higher performance applications. Recently introduced ARM Cortex-M series processors have been used in only few WSN applications [10].

Three different benchmark applications have been executed on above-mentioned processors with use of appropriate C/C++ compilers from IAR Systems [11]. Benchmarks were conducted under various optimization levels in order to determine code size and execution speed limits.

Filtering is commonly used in sensing applications in order to extract data form noise. Filtering is usually done using digital filters, which are implemented in software. This benchmark tested real finite impulse response (FIR) filter application, which filtered signal, which consisted of 51 16-bit values. FIR filter is characterized with its order N = 17, or number of taps which are used for calculation of output signal according to appropriate order weights b_i as in (1)

$$y(n) = \sum_{i=0}^{N} b_i \cdot x(n-i) \qquad (1)$$

In this paper, processors were tested using FIR filter application for code size and execution time under various optimization levels.

Results in Fig. 1 show that ARM Cortex-M0 processor produced the densest code for FIR filter application, closely followed by ARM Cortex-M3 with about 10% larger code size and MSP430 with about 22% larger code size. ATmega128 produced about 58% larger code size while the ARM7 processors produced largest code, 68% larger than ARM Cortex-M0 processor (Table I).

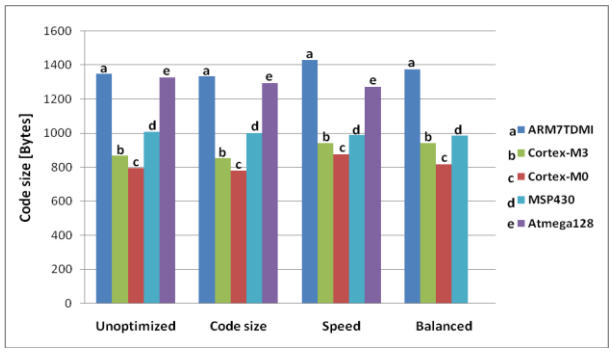

Figure. 1. FIR code size

TABLE I. FIR FILTER CODE SIZE IN BYTES

MCU	Unoptim.	Optim. size	Optim. speed	Optim. balance
ARM7TDMI	1352	1336	1432	1376
Cortex-M0	796	780	876	820
Cortex-M3	868	856	944	944
ATmega128	1329	1295	1275	----
MSP430	1010	1002	992	988

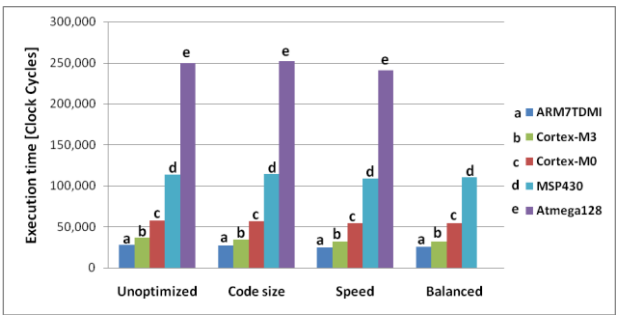

Figure. 2. FIR execution time

TABLE II. FIR FILTER EXECUTION TIME IN CLOCK CYCLES

MCU	Unoptim.	Optim. size	Optim. speed	Optim. balance
ARM7TDMI	28370	27585	24897	25257
Cortex-M0	57610	56918	54214	54574
Cortex-M3	36676	34763	32292	32292
ATmega128	249368	252061	240696	----
MSP430	113919	114383	109138	110434

Results from Fig. 2 show that ARM7 processor has fastest execution time for FIR filter application, closely followed by ARM Cortex-M3 with about 28 % slower execution time. ARM Cortex-M0 processor was 2.1 times slower while MSP430 was 4.2 times slower than ARM7. ATmega128 has highest execution time which was 9.3 times slower then ARM7 processor (Table II).

Dhrystone benchmark is used to measure the integer performance of the processor in handling pointers, structures, and strings. Dhrystone benchmark is widely used for benchmarking, because it's free, light, and easy to run and performances can be expressed using just one parameter. Performances of Dhrystone benchmark are compared to performances of reference VAX 11/780 1 MIPS processor which is capable to perform 1757 Dhrystone loops per second. Referent parameter, addressed as DMIPS (Dhrystone MIPS) tells how many times tested processor is faster than referenced VAX processor. In this paper, processors where tested using Dhrystone benchmark with 100 iterations for code size and execution time under various optimization levels.

Results from Fig. 3 show that MSP430 processor produced the densest code for the Dhrystone benchmark, closely followed by ARM Cortex-M3 and Cortex-M0 with about 22% and 25% larger code size. ATmega128 produced about 74% larger code while the ARM7 produced largest code, 83% larger then MSP430 processor (Table III).

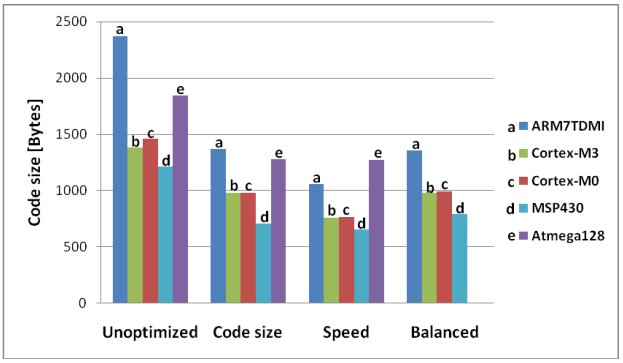

Figure. 3. Dhrystone code size

TABLE III. DHRYSTONE CODE SIZE IN BYTES

MCU	Unoptim.	Optim. size	Optim. speed	Optim. balance
ARM7TDMI	2368	1368	1060	1360
Cortex-M0	1464	980	768	996
Cortex-M3	1384	980	760	980
ATmega128	1843	1277	1271	----
MSP430	1214	706	656	794

Results from Fig. 4 show that ARM7 processor has the fastest execution time for the Dhrystone benchmark. It is closely followed by ARM Cortex-M3 with about 36% slower execution time and ARM Cortex-M0 processor with 57% slower execution time. MSP430 was 3.4 times slower execution time than ARM7. ATmega128 has highest execution time which was 5.4 times slower then ARM7 processor (Table IV). Dhrystone results for tested processors are expressed in DMIPS units (Table V).

TABLE IV. DHRYSTONE EXECUTION TIME IN CLOCK CYCLES

TABLE V. DHRYSTONE RESULTS IN DMIPS/MHZ

MCU	Unoptim.	Optim. size	Optim. speed	Optim. balance
ARM7TDMI	0.91	1.65	3.29	1.74
Cortex M0	0.59	1.30	3.36	1.35
Cortex M3	0.60	0.99	2.24	1.05
ATmega128	0.24	0.29	0.35	----
MSP430	0.34	0.48	0.55	0.50

Whetstone benchmark focuses on floating-point processor performance, which is measured for execution of mathematic functions, such as sine, cosine, exponents, and logarithm. The Whetstone benchmark measures computing power in MWIPS (Millions of Whetstone Instructions per Second). In this paper, processors where tested by Whetstone benchmark for code size and execution time under various optimization levels.

Results from Fig. 5 shown that ATmega128 processor produced the densest code for the Whetstone benchmark, closely followed by MSP430 with about 31% larger code size. ARM Cortex- M0 and Cortex-M3 produced about 49% and 65% larger code then ATmega128, respectively. ARM7 processor produced largest code, two times larger than ATmega128 processor (see Table VI).

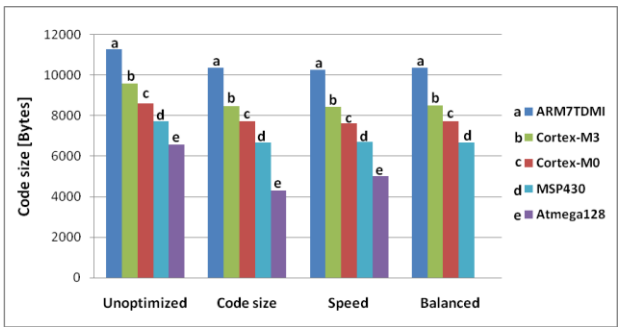

Figure. 5. Whetstone code size

TABLE VI. WHETSTONE CODE SIZE IN BYTES

MCU	Unoptim.	Optim. size	Optim. speed	Optim. balance
ARM7TDMI	11300	10368	10264	10380

Cortex-M3	58758	57578	56692	57314
ATmega128	175892	177010	174316	----
MSP430	115406	115586	112151	115177

Processor power consumption is usually defined for various operating modes, among which active mode and sleep mode are most commonly used by processor. Active mode represents fully operational mode, where power consumption is dependant of operating voltage and current consumption. Current consumption is dependant of operating frequency, but because of static and dynamic consumption, it is not linear function of operating frequency. Sleep mode power consumption is mostly dependant of leakage currents. Current consumption of tested processors is presented in Fig. 7, both for active and sleep mode (Table VIII).

Measured results for average execution speed and current consumption were combined in order to extract the most accurate information about processors energy efficiency. Energy consumption was calculated using time of the average execution and processors power consumption under 3.3 V supply voltage.

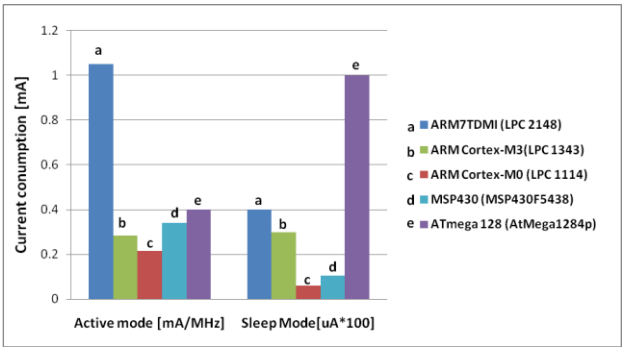

Figure. 7. Current consumption of microcontrollers

$$E = P \cdot t = V_{dd} \cdot I \cdot t = V_{dd} \cdot I \cdot \frac{cycles}{f} \quad (2)$$

TABLE VIII. CURRENT CONSUMPTION OF MICROCONTROLLERS

MCU	Active mode (mA/MHz)	Sleep (µA)
ARM7TDMI (LPC 2148)	0.60- 1.5	40
Cortex-M0 (LPC 1114)	0.18-0.25	6
Cortex-M3(LPC 1343)	0.24-0.33	30
ATmega128 (AT 1284p)	0.4	100
MSP430 (MSP430F5438)	0.31-0.37	10.5

Results obtained from (2) for tested processors are shown on Fig. 8 (Table IX).

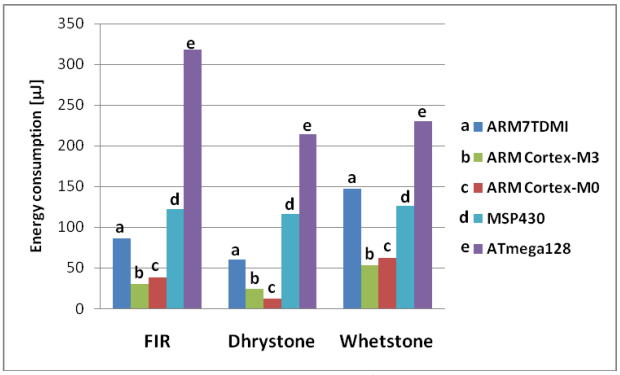

Figure. 8. Energy consumption of tested benchmarks

Results shown that processors of ARM Cortex-M series are among most efficient from tested processors. ARM7 processor, which has twice-lower energy efficiency, then these two processors follows them. They are also about 3.4 times more energy efficient then MSP430 processors and about 7 times more energy efficient then ATmega128 processors.

TABLE IX. ENERGY CONSUMPTION OF TESTED BENCHMARKS IN MICRO JOULES

MCU	FIR	Dhrystone	Whetstone
ARM7TDMI	86.27	59.86	146.57
Cortex-M0	38.46	12.03	61.84
Cortex-M3	30.37	23.94	53.32
ATmega128	317.72	214.34	230.10
MSP430	122.45	115.69	125.83

IV. CONLUSION

According to conducted benchmarks, ARM Cortex-M series processors proved to be the best choice for WSN applications because they produce smallest and fastest code. In addition, they have smallest power consumption both in active and sleep mode then competitive processors. Energy consumption tests show that ARM Cortex-M series processors are most energy efficient processors among tested. Performed benchmarks show that it's advisable to use high level of compiler optimization, especially optimization for speed of execution.

Abstract – The need to reduce power consumption makes a great impact in the world of roadway lighting. The adaptive lighting is now used to define the concept of varying the levels of lighting in order to significantly reduce the consumed power. In this paper a novel approach in vehicle detection and tracking using WSN (Wireless Sensor Networks) radio irregularity is proposed for use in adaptive roadway lighting. Radio irregularity is a common phenomenon which arises from multiple factors and is considered a shortcoming of wireless communication. However, this phenomenon can be exploited for detecting obstacles in the propagation path, such as vehicles on roadways. The idea is based on monitoring RSSI (Received Signal Strength Indicator) between WSN nodes, where the propagation path intersects the roadway. The method is analyzed experimentally using *XBee Series 2* modules in different scenarios and the comparison is given. The advantage over the existing detection methods is the reduction in cost by avoiding the need to additionally install multiple sensors for vehicle detection.

I. INTRODUCTION

An important aspect of energy saving is reducing power consumptions in roadway lighting. By correct investments and utilizing new technology it is possible to reduce current energy consumption for street and road lighting by as much as approximately 60%. For Europe as a whole, this stands for about 36TWh a year. In addition, it is possible to achieve a significant saving on maintenance costs. As much as 50-70% of the original energy consumption can be saved by investing in new technologies for roadway illumination [1].

One of these technologies includes adaptive lighting technology. The term "Adaptive Lighting" is now being used to define the concept of varying lighting levels to suit activity levels. By varying the levels of lighting on roadways, substantial power can be saved [2]. By implementing the intelligence into luminaries it is possible to achieve accurate feedback on the lamps condition and thereby reduce the need for manual control [1]. Also, the management of the installed lamps is done remotely, enabling the supervision of the entire lighting system and dynamically changing the required illumination levels.

The induced intelligence to the luminaries brings a set of advantages to the proposed system. Primary, the supervision of all luminaries from a control center is possible, alongside with remote diagnostic and failure reporting. Further on, the control of the luminaries is possible by dimming the lamps or an array of lamps, to suit the current activity levels. In order to interconnect the luminaries, the most common approach in the use of WSN (Wireless Sensor Network) [3, 4].

Primary task of the adaptive roadway lighting is adjusting lighting levels depending on the amount of traffic, time of day and weather condition, in purpose of reducing power consumption [1]. According to [5], dimming of the roadway lighting does not influence the visibility of drivers, allowing the implementation of an adaptive lighting system.

In order to utilize the benefits of adaptive roadway lighting, a cost effective way of detecting vehicles and amount of traffic must be proposed. The existing methods include setting up inductive loops or other proprietary sensors, presenting a costly solution for a large number of units. Since the adaptive lighting system already uses WSN for data exchange, this paper proposes the use of WSN wireless links for vehicle and traffic detection, by the means of radio irregularity.

The paper presents a novel method of vehicle detection by monitoring RSSI (Received Signal Strength Indicator) values from *ZigBee* or IEEE802.15.4 nodes where the propagation path is intersected by the roadway. Once a vehicle intersects the propagation path, the drop in RSSI value is evident. This drop correlates with the size and speed of the vehicle, so a model is proposed to determine the required setup for the detection.

The measurement of the proposed method is shown in various different scenarios. In order to detect vehicles traveled at higher velocities, the adaptation of the proposed detection method is shown. The testing was carried out using *ZigBee* WSN nodes, specifically *Digi's XBee Series 2* modules. The calculation of the maximum detection speed and the RSSI attenuation is done from a theoretical aspect, following by the comparison of the measured values.

In the following section, the basic concept of adaptive roadway lighting is presented. Also, the proposed vehicle detection is placed into the frame of adaptive roadway illumination (statistically measuring amount of traffic and dynamically anticipating movement). Section III proposes the theoretical and practical implementation of vehicle detection using radio irregularity, while Section IV shows the results of the measurement in a rural area. Section V gives the conclusion alongside with the future work suggestions.

This work was sponsored by the Ministry of Science, Education and Sports of the Republic of Croatia under project 165-0362027-1479.

II. THE CONCEPT OF ADAPTIVE ROADWAY LIGHTING

In order to understand the concept of adaptive roadway lighting one must understand how road light levels are typically determined. Light levels for roadways and pedestrian traffic are established through engineering design by applying minimum criteria based on the type of roadway and level of pedestrian activity [2]. According to [6] and supported by [7], the ANSI/IES RP-8 document proposes minimum luminance levels for different types of roads and different pedestrian activities (Figure 1).

Road and Pedestrian Conflict Area		Pavement Classification (Minimum Maintained Average Values)			Uniformity Ratio	Veiling Luminance Ratio
Road	Pedestrian Conflict Area	R1 lux/fc	R2 & R3 lux/fc	R4 lux/fc	E_{avg}/E_{min}	L_{max}/L_{avg}
Freeway Class A		6.0/0.6	9.0/0.9	8.0/0.8	3.0	0.3
Freeway Class B		4.0/0.4	6.0/0.6	5.0/0.5	3.0	0.3
Expressway	High	10.0/1.0	14.0/1.4	13.0/1.3	3.0	0.3
	Medium	8.0/0.8	12.0/1.2	10.0/1.0	3.0	0.3
	Low	6.0/0.6	9.0/0.9	8.0/0.8	3.0	0.3
Major	High	12.0/1.2	17.0/1.7	15.0/1.5	3.0	0.3
	Medium	9.0/0.9	13.0/1.3	11.0/1.1	3.0	0.3
	Low	6.0/0.6	9.0/0.9	8.0/0.8	3.0	0.3
Collector	High	8.0/0.8	12.0/1.2	10.0/1.0	4.0	0.4
	Medium	6.0/0.6	9.0/0.9	8.0/0.8	4.0	0.4
	Low	4.0/0.4	6.0/0.6	5.0/0.5	4.0	0.4
Local	High	6.0/0.6	9.0/0.9	8.0/0.8	6.0	0.4
	Medium	5.0/0.5	7.0/0.7	6.0/0.6	6.0	0.4
	Low	3.0/0.3	4.0/0.4	4.0/0.4	6.0	0.4

Figure 1. ANSI/IES RP-8 illumination levels

Pedestrian activity (conflict) levels do not necessary remain constant throughout the hours of darkness, taking into consideration that in late evening and early morning hours the businesses are closed, thus reducing the number of pedestrians [2]. Another important fact to examine is the presence and frequency of traffic on a designated road. This primarily encompasses the rural areas where the traffic frequency tends to drop rapidly in late evening hours. Due to this fact, and the fact that the pedestrian activity tends to drop as well, the implementation of adaptive roadway lighting in these areas could significantly reduce power consumptions. Also, according to [5], dimming of the roadway lighting does not influence the visibility of drivers. With this, the road safety is preserved, allowing for the implementation. This is supported by the work done in [25], where the comparison of various adaptive illumination projects is given. By implementing adaptive roadway lighting, the safety of road condition is generally improved [25].

The implementation of adaptive lighting in rural areas with the advancement of cost effective vehicle (traffic) detection could be performed in two different approaches. This paper proposes the following approaches:

The first approach is the statistical approach: The system measures statistical amount of traffic throughout the day and compensated by weather condition parameters predicts the necessary illumination levels for the next time period (several hours or an entire day). The main advantage of this method is constant traffic monitoring providing statistics that change by the hour. Further on, the detection system doesn't have to be very reliable regarding vehicle detection (a drop in vehicle detection is tolerated to a certain degree), however the system must be able to tell apart vehicles from pedestrians and other objects. On the other side, the proposed system uses only statistic parameters, meaning that real-time reactions are not supported.

The second approach utilizes real-time monitoring of traffic and pedestrian activates, and adaptively corrects the lighting levels. If no vehicles are present in the range of the luminary's network segment, the lighting levels are mitigated due to the reduced pedestrian risk (lack of vehicles). When the system detects a vehicle in range of the luminary network segment, it predicts the movement of a vehicle and accordingly raises the luminance levels along the vehicle propagation way, discreetly following the vehicle along the rural settlement (Figure 2).

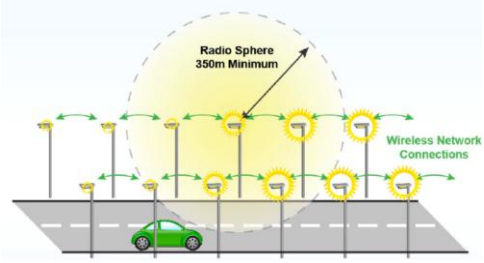

Figure 2. Adaptive illumination network with a vehicle following feature [3]

The advantage of this system is the real-time operation and the ability to reduce power when no vehicles are present in the area. The system can be designed to detect pedestrian presence, thus additionally reducing the risk to the pedestrians. However, this type of system proposes additional load on the system due to the fact that the system needs to operate in real-time and the detection of vehicles in the network must be very reliable (the system must detect every passing vehicle).

Each approach presents its own advantages and drawbacks and the choice of approaches and systems must be presented according to the studies developed for this specific approach. On the other hand, vehicle detection can also dictate the choice of presented approaches, depending on the reliability of vehicle and pedestrian detection. The proposed method of vehicle detection is a novel approach that needs to be analyzed and a conclusion of the practical use of the proposed method should be assessed.

A. Wireless Sensor Networks in Adaptive Roadway Lighting

Wireless Sensor Network (WSN) is a wireless network consisting of sensing, computing and communication elements that gives the ability to instrument, observe and react to events and phenomena in specified environment. Typical applications include data collection, monitoring, surveillance, medical telemetry and others [9], such as adaptive lighting.

Upon discussing communication protocol used in WSN, *ZigBee* is one of the most frequently used protocols. It is designed for use in personal networks of low bandwidth, low power consumption, low cost and high level of security [9]. Forming a *ZigBee* WSN has many advantages, foremost the ability to route data packets along the mesh network to the desired end node (multi hop routing [10]. This presents a major advantage in the adaptive roadway lighting, since the network topology is as such that multi hop routing is essential (seen in Fig. 2).

On the other hand, the problem with using a *ZigBee* based WSN is the need for centralized network control. In *ZigBee* network, the Coordinator establishes an entire network, and all nodes must answer to the coordinator. This presents a problem in Adaptive Roadway Lighting, since all nodes needs to answer to the coordinator. This could be avoided by using protocols such as IEEE 802.15.4 and *DigiMesh* [12]. These protocols support P2P (peer-to-peer) routing, giving the option to exchange messages between the nearby sensors. The example of the topology used is shown in Fig.3.

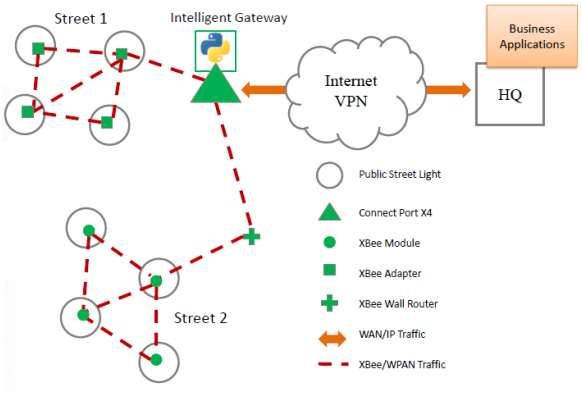

Figure 3. Dynamic Street Illumination network topology [12]

In order to connect the network to the Internet, an intelligent gateway is used. The *DigiMesh* intelligent gateway provides a connection to the Central control room by means of Internet or Cloud based communication. The access technology can vary, such as 3G, Wi-Fi or Satellite communication [12]. The solution proposed by [12] is the interconnection of WSN to the Cloud infrastructure by the means of *ConnectPort X4* or *ConnectPort X5* devices. These devices contain the hardware to connect the WSN to the Internet (via 3G, Wi-Fi etc) and relay the data to the *iDigi Cloud* service. From the application point of view, the cloud presents an aggregation point for all data. The data is easily accessed from the cloud, where the need for device addressing or establishing communication is avoided.

Since the WSN is the backbone for establishing communication in adaptive roadway lighting, this paper proposes the novel method using WSN for vehicle detection by means of radio irregularity.

III. USING RADIO IRREGULARITY FOR VEHICLE DETECTION

Radio irregularity is a common phenomenon in wireless networks. It can arise from multiple factors, such as the different signal radiated powers caused by hardware imperfection and the different path losses in different directions of transmitted signal [13]. According to [14], radio irregularity is mainly caused by device properties and the propagation medium. Device properties include SNR (Signal-to-Noise Ratio), the antenna gain, antenna type, the receiver's sensitivity and threshold and the transmitter's radiated power. Medium properties include the background noise and the environmental factors such as obstacles within the propagation medium.

The variations in the signal path loss can also cause the radio irregularity. When the signal travels through a medium, it may be diffracted, scattered or reflected. Diffraction occurs when the signal encounters an irregular surface. Scattering occurs when the signal propagates through a medium which contains a large number of objects smaller than the signal's wavelength whereas reflection occurs when the signal during its propagation through a medium encounters an object which is larger than the signal's wavelength [13, 14].

The variations in RSSI (received signal strength indicator) caused by radio irregularity are especially expressed by the presence of a large conductive object in the propagation path between two WSN nodes, which vehicles are. Since vehicles consist mostly of conductive material (sheet metal, iron, steel, aluminum) and exhibits the dimensions much larger than the wavelength of WSN communication (4.5m for a vehicle vs. 0.125m for wavelength), the main cause of radio irregularity are reflection and scattering.

According to various sources [13, 15, 16 and 17] the detection of human presence by the means of radio irregularity is well documented, and it is confirmed that the detection of human presence in-between propagation path using radio irregularity is possible. However, a similar approach in vehicle detection using radio irregularity was not perused by any researchers. Related work consists of detecting the attenuation and packet loss in VANET (Vehicular Ad-Hoc Network) networks [18]. Mostly the work was focused on using the WSN as a data relay network and using specific sensors for vehicle detection (magnetic, acoustic etc) [19, 20]. Supported by the work for human presence detection, this paper proposes the use of radio irregularity in *ZigBee* or IEEE802.15.4 based WSN for purpose of vehicle detection.

A. *Theoretical aspects of vehicle detection using radio irregularity*

The main claim for supporting the detection of vehicles using radio irregularity is the reflection and scattering effect that a vehicle has on a propagation signal. This results in the drop of RSSI value during a pass of a vehicle. The depth of the signal mitigation is dependent on the type of vehicle and distance between nodes but the duration of the drop is in correlation with the speed of a vehicle. Due to the fact that every vehicle is different in geometry, analytically representing the depth of the RSSI drop presents a problem. On the other hand, the duration of the RSSI drop is in direct correlation with the vehicle speed, the proposed propagation path and the width of the 1st Fresnel zone.

Due to the fact that the *ZigBee* and *DigiMesh* WSN is digital based network, all communications are sent in packet form in timed intervals. The fact that for the RSSI value to be obtained, the communication must be established to a nearby node imposes a delay that defines maximum sampling rate of RSSI value. This presents a problem for moving obstacle detection, due to the fact that for faster moving object the detection can skip the vehicle do to the low sampling rate. Do to this fact this paper proposes the adaptation of the detection model based on maximum possible velocity an object can achieve. The adaptation is based on widening the width of the 1st Fresnel zone, extending the effective length of a vehicle. The

effective length is the result of the propagation link and 1st Fresnel zone in conjunction with the length of a vehicle. If the detection is performed in a form of a laser beam sampled at a rate f_s, and the vehicle passing through the beam has the length of l, then the maximum vehicle speed this system can detect is:

$$v_{max} = l \cdot f_s \tag{1}$$

However, if a detection system is not composed of thin beam (as a laser beam is thin compared to a car) but a wide spatial beam (the width of the 1st Fresnel zone), then the length l is not only the length of a car but the sum of the car length l_{CAR} and the width of the 1st Fresnel zone l_{1FR}. This length can be named effective car length. Accordingly, maximum detectable speed of a system, sampled at a rate f_s, is:

$$v_{max} = (l_{CAR} + l_{1FR}) \cdot f_s \tag{2}$$

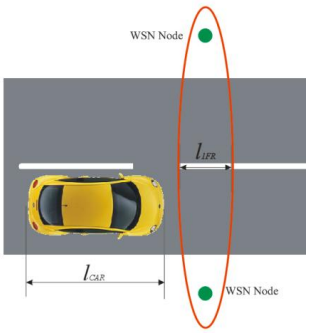

Figure 4. Vehicle detection model

Figure 4 shows a basic model for vehicle detection using radio irregularity. The length of a car and the length of the 1st Fresnel alongside with the sampling rate of *ZigBee* WSN define the maximum possible velocity for a car to be detected. According to the testing of the used *ZigBee XBee Series 2* modules, the maximum sampling rate is equal to 3.6Hz. If the distance between the nodes is 8m, the average length of a car is 4.2m and the 1st Fresnel zone is 1m, the maximum speed detectable by the system is 18.7m/s (67.4km/h). If the proposed system is installed on an open road, where the speed limitation is set to 90km/s, the vehicle detection of this system will fail. In order to enhance the ability to detect vehicles traveling at higher velocities, it is required to widen the 1st Fresnel zone. The method presented in this paper is placing the propagation path in a lower angle to the roadway, seeking to be parallel (Fig. 5.).

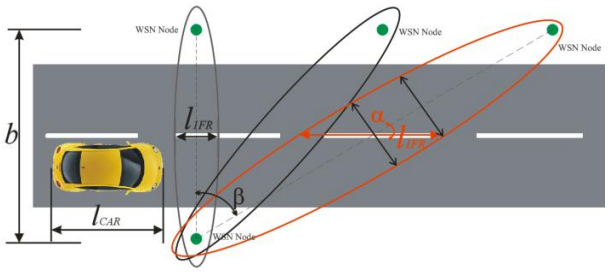

Figure 5. Enhanced model for vehicle detection

The Fig. 5 shows the enhanced model where the detection zone area is expanded throughout the roadway. By placing the propagation path to an angle from the initial position, the detection length of the propagation path is expanded from the original 1st Fresnel zone. The detection length depends on the node distance in y plane, b, and angle α.

$$l_{1FR} = \frac{2}{\sqrt{\frac{4b}{\lambda}\sin\alpha - 4\,(\cos(\alpha))^2}} \cdot \frac{b}{\sin\alpha} \tag{3}$$

Where the λ represents the wavelength and b represents the distance from the nodes longitudinal to the road. If the length is graphed versus the angle β (which represents the angle between the initial position and current position), the data is shown on Figure 6. The expression was obtained from trigonometric functions and 1st Fresnel zone calculation formula [22].

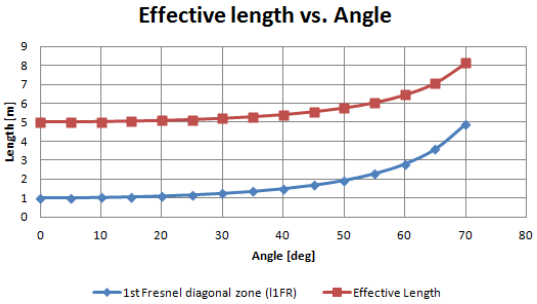

Figure 6. Effective length vs. Angle

If the maximum detectable velocity is expressed from (1), the graphic representation of maximum detectable velocity vs. angle is shown in Fig. 7. According to Fig.7, the minimum angle β required to enable the detection of vehicles traveling at velocities up to 90km/h is 60°.

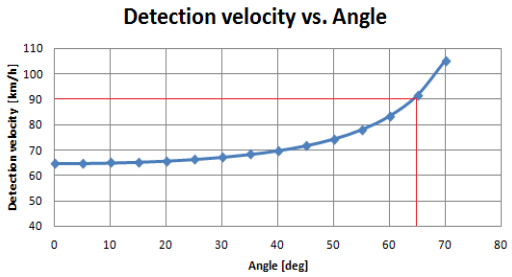

Figure 7. Detection velocity vs. Angle

Another theoretical aspect that has to be taken into consideration is the free space loss and the expected received power in *dBm* versus the distance of the nodes (angle β respectively). According to [22], the amount of loss between receiving and transmitting node is equivalent to free space losses (if no obstacles are present in 60% of 1st Fresnel zone) subtracted by antenna gain. If the maximum transmit power is 2mW (3dBm) and receiver sensitivity is equal to -96dBm [23] then the maximum angle β is defined by the induced losses. The projected received power against angle β is shown in Fig. 8.

From Fig. 8 (mathematically derived from [22]) it is clearly seen that for all possible angles in interval 0–80 the received signal strength is higher than the lowest recommended level of -96dBm, defined by [23]. Having this in mind, the arbitrary chosen angle β can be freely set

according to desired vehicle detection velocity. By increasing the angle β, the width of the Fresnel zone is incising as well, so the mitigation caused by the pass of the vehicle is reduced. This can present a positive aspect in terms of packet loss; however it can reduce the chances to detect a passing vehicle by means of radio irregularity.

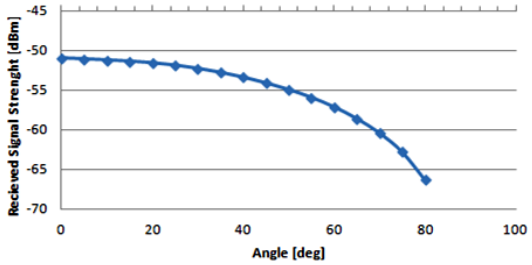

Figure 8. Received Signal Strength (RSSI) vs. Angle

IV. TESTING OF THE PROPOSED VEHICLE DETECTION METHOD

In order to test the theoretical aspects stated in Section III, the measurement of the vehicle influence on RSSI value was conducted in three scenarios. The first scenario was set up according to Fig. 4 whereas the two remaining scenarios were set according to Fig.5 with angles β 56.3° and 68.2° respectively. The equipment was set up in a rural environment (near the town Požega, Croatia).

To set up the WSN and detect the RSSI values, *ZigBee Digi XBee Series 2* modules were used. In order to acquire the RSSI values, a *LabVIEW* application was developed to periodically poll the remote *ZigBee* node. After every poll, the received signal strength was displayed on a graph. The first test included testing the ability to detect a vehicle traveling at low velocity, and the results alongside with the *LabVIEW* application are shown in Fig.9.

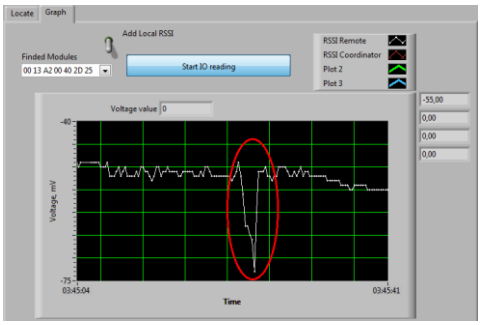

Figure 9. *LabVIEW* application displaying a drop in RSSI value

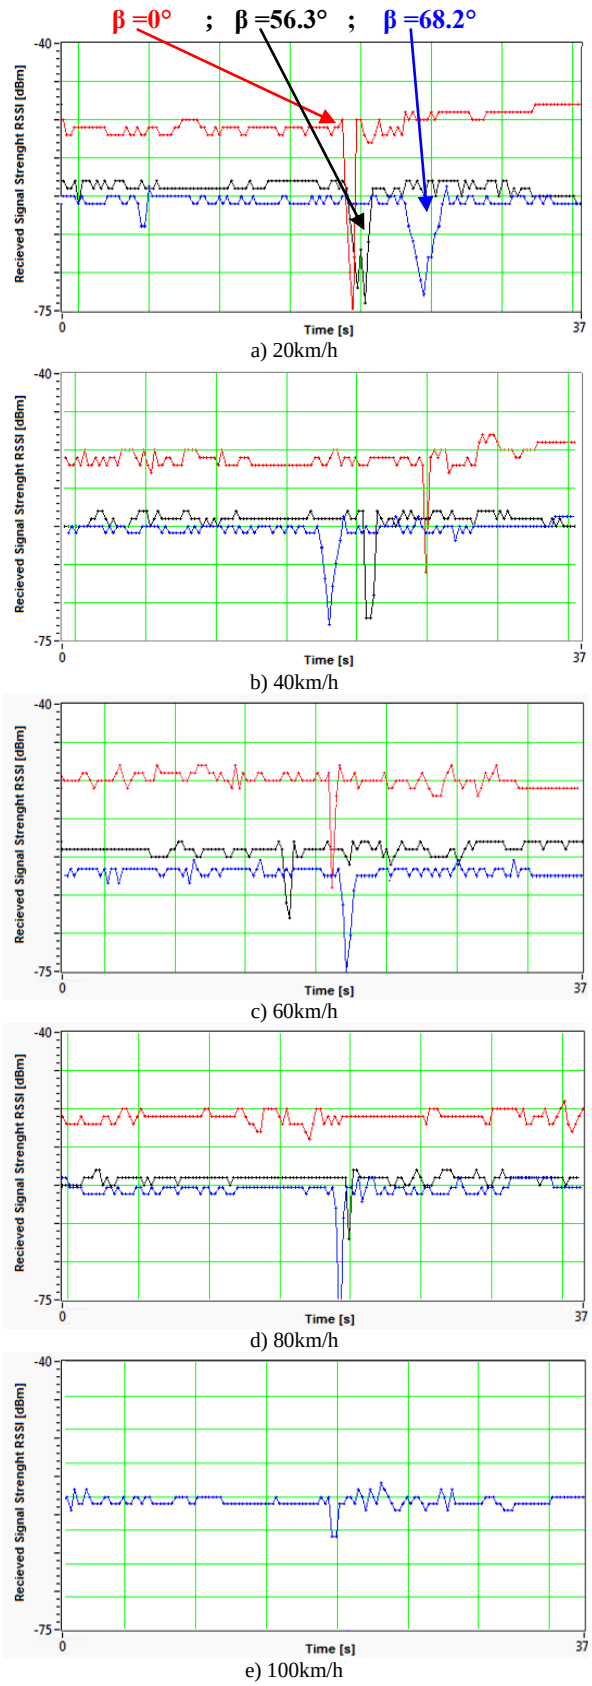
Figure 9 shows a drop in RSSI value upon a vehicle pass (circled in red) by approximately 22dB. This proves the theoretical background presented in Section III and demonstrates the ability to detect a passing vehicle using radio irregularity phenomenon. Also, it is visible that the static RSSI value is located around -51dBm which corresponds with the calculated RSSI value for angle of 0°, according to Figure 8. Furthermore, the end of a graph displays a drop in RSSI value by 5dB, however due to the low gradient value it can be concluded that the drop was not caused by a passing vehicle, but by an unknown fading phenomenon. The gradient parameter can be effectively used in vehicle detection, as the following figures display the RSSI values in time for different vehicle velocities.



a) 20km/h

b) 40km/h

c) 60km/h

d) 80km/h

e) 100km/h

Figure 10. RSSI Values for different velocities:
a) 20km/h, b) 40km/h, c) 60km/h, d) 80km/h, e) 100km/h

As seen from Figure 10, the velocity of the vehicle is in direct correlation with the duration of the RSSI value drop and the angle β. The higher the angle β is the wider the RSSI drop is, thus allowing the detection of higher velocities. For the angle β = 0, after a certain speed the traveling vehicle avoids detection, Fig 10 d). If the angle is raised the detection is possible for even higher velocities (Fig. 10 d) and e)).If the comparison is made between the measured delays translated into effective length, then it is visible that the measured length follows the calculated lengths shown in Fig. 11.

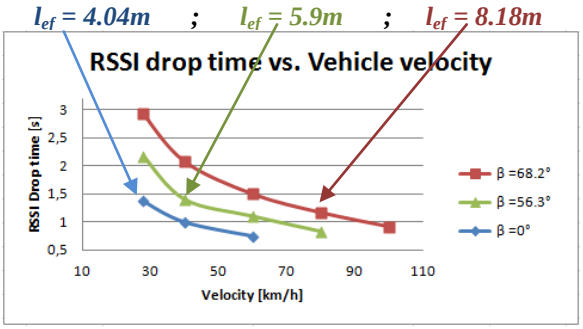


Figure 11. RSSI Drop time against vehicle velocity

V. CONCLUSION AND FUTURE WORK

This paper presents a novel method for vehicle detection in adaptive roadway lighting by the means of radio irregularity. After proposing two basic approaches for adaptive roadway lighting, the idea of vehicle detection using radio irregularity is proposed form a theoretical point of view. From the measurements conducted it can be concluded that the theoretical background proposed for vehicle detection using radio irregularity is valid, giving the proposed method for vehicle detection a practical aspect for implementation. From the measured results it is clearly seen that the pass of a vehicle is evident in drop of RSSI value under a certain gradient. The gradient depends mostly on the vehicle velocity, the angle β and in smaller amount on the physical dimensions of a vehicle. In order to detect vehicles traveling at higher velocities, the angle β must be set to allow the detection restricted by the sampling rate of WSN nodes. By using WSN nodes with the possibility of higher sample rates, the detection can be enabled for even higher velocities (e.g. highway)

Future work involves implementing a detection system inside a programmable *ZigBee* or a *DigiMesh* node (e.g. *Digi XBee Pro S2B* modules) in order to enable the detection of vehicles by analyzing RSSI value drop through time. The proposed detection could be based on the gradient analysis or an AI agent to learn and adapt to the RSSI drops, thus enhancing the precision of vehicle detection. Finally, the implementation and testing of the proposed method is recommended alongside with the analysis of vehicle detection accuracy.

***Abstract*— Wireless communication technologies enable communication among different devices that are within a certain radius. Although, this radius is definite, communication when using wireless communication technologies is more flexible than when using wireline approach. This paper presents results from a measurement study where we measured energy consumption of three wireless communication technologies: Bluetooth, WiFi and 3G. We proposed an energy consumption model that is based on these measurements. Using proposed model one can calculate energy consumption for each communication technology. We show how our energy consumption model can be used on an example of the service called *Collaborative Downloading*. The primary goal of *Collaborative Downloading* service is to lower the overall energy consumption of mobile users while downloading data combining together 3G and Bluetooth or 3G and WiFi communication technologies.**

Keywords: Bluetooth, WiFi, 3G, energy consumption model, energy savings

I. Introduction

When talking about Machine-to-Machine (M2M) systems, it is well known Ericsson's 50 B prediction saying that by 2020 there will be up to 50 billion interconnected devices [1]. However, it is less known that by 2016 282 million of them will be cellular M2M subscribers [2]. Not only does this predict the sizable and long-term growth opportunities for mobile operators, but also shows that the potential size of the cellular M2M market is enormous. Cellular M2M subscribers can use different kinds of M2M devices (e.g. smartphones) and different kinds of communication technologies (e.g. WiFi, 3G). Common characteristic of those M2M devices is that they have limited energy resources (i.e. batteries). Namely, when using devices with limited energy resources, it is very important to know how much energy is consumed during communication.

Therefore, in this paper we present a measurement study of energy consumption and throughput when using Bluetooth, WiFi and 3G communication technologies in Android phones. We investigate relationships between energy consumption and the elapsed time, as well as between energy consumption and the amount of transferred data when using aforementioned communication technologies. Based on those measurements, we developed an energy consumption model for Android phones. All measurements were performed on HTC Desire HD phone running Android operating system version 2.3.

The rest of this paper is organized as follows. Section II presents related work, while Section III describes our methodology used for the measurement study. This section also proposes an energy consumption model for Android phones. Section IV shows a simple case study example explaining the usage of our model. Finally, Section V gives conclusions and the guidance for future work.

II. Related work

Many papers have recently investigated how characteristics of wireless communication technologies affected energy consumption. For instance, in [3] and [4] authors proposed different algorithms for predicting the availability of the smart WiFi networks together with the energy consumption reduction. Furthermore, in [5] Xiao et al. compared 3G with WiFi, while Balasubramanian et al. compared GSM, 3G and WiFi [6]. However, none of these papers compared energy consumption of Bluetooth, WiFi and 3G communication technologies in smartphones (i.e. Android).

In [3] Gupta and Mohapatra made a measurement study of energy consumption when using VoIP applications with WiFi connection in smartphones. They showed that the usage of *power save mode* in WiFi together with intelligent scanning techniques for networks can reduce energy consumption. Rahmati and Zhong modeled wireless interfaces selection as a statistical decision problem [4]. Xiao et al. measured energy consumption when using mobile applications for a video streaming [5]. They compared 3G and WiFi communication technologies and concluded that WiFi is more energy efficient than 3G communication technology.

Furthermore, Balasubramanian et al. present a measurement study of energy consumption when using GSM, 3G and WiFi [6]. They showed that 3G and WiFi have high tail energy overhead at the end of data transfer and therefore proposed the *TailEnder* protocol to reduce energy consumption after data transfer is completed. Feeney and Nilsson made the series of experiments in which they obtained detailed measurements of energy consumption of an IEEE 802.11 wireless network interface operating in ad hoc networking environments [7]. Their work provided linear equations collection for calculating energy consumption for sending, receiving and discarding broadcast and point-to-point data packets of various sizes.

In 2011 Friedman et al. made a measurement study where they measured power and throughput performance of Bluetooth and WiFi usage in smartphones [8]. They concluded that power consumption for WiFi is generally linear with the obtained throughput, while power consumption while sending and receiving using Bluetooth is lower than WiFi, but only by about a half. Their work was performed using different platforms (i.e. Samsung Omnia i900 running Windows Mobile 6.1, HTC Diamond 2 running Windows Mobile 6.5, Samsung Galaxy running Android 1.5 and Samsung Spica running Android 2.1). Their conclusion was that none of the phones can be claimed to be better than the others taking into an account all the measured parameters.

In [9] authors presented the *CoolSpots* system in which a switch between WiFi and Bluetooth interfaces is performed in order to increase battery lifetime. Similar to the *CoolSpots* system, Agarwal et al. presented the *Cell2Notify* system in which they use GSM interface to wake up WiFi interface when VoIP call comes to achieve a better service and reduce energy consumption [10]. Finally, Rahmati and Zhong presented a study in which they proved that intelligent switching between WiFi and GSM reduces energy consumption [11]. They have also presented an algorithm that predicts WiFi availability in specific area to reduce high energy consumption while searching for WiFi networks.

III. Energy consumption model

In order to design an energy consumption model of Bluetooth, WiFi and 3G communication technologies, we conducted measurements in which we used each of aforementioned communication technologies at full load. Our measurement methodology can be divided into three phases, while in the fourth phase we analyzed our results. In the first phase we collected relevant data for each communication technology (i.e. percentage of available battery, amount of transferred data and elapsed time). In the second phase we compared the collected data and showed them in relation to one another. Based on measurements performed in the previous phase, in the third phase we presented a simple energy consumption model of all three communication technologies. Finally, in the fourth phase we compared our results with the results of previous studies. Moreover, we compared our results with the data specified in technical specifications for the given communication technology.

A. The first phase

In order to collect the required data, we developed a simple Android application that sends or receives data continuously and monitors a battery status (i.e. percentage of available battery). The application also records the elapsed time and the amount of transferred data. Measurements of data transfer when using these three communication technologies are performed for continuous data download from the server as well as for continuous data upload to the server.

B. The second phase

Figure 1 shows energy consumption compared to the elapsed time when using Bluetooth, WiFi and 3G communication technologies for data download and data upload. As shown in Figure 1, data transfer when using Bluetooth consumes significantly less energy than data transfer when using WiFi or 3G. The battery lasted approximately 4 hours longer when using Bluetooth communication technology continuously than when using WiFi or 3G. If we compare WiFi and 3G communication technologies, we can conclude that the battery lasted approximately equal, but WiFi communication technology transferred twice more data than 3G communication technology.

Figure 2 shows energy consumption compared to the amount of transferred data when using Bluetooth, WiFi and 3G communication technologies for data download and data upload. As shown in Figure 2, the smallest amount of data is transferred when using 3G (3.04 GB data in download and 1.42 GB in upload). WiFi and Bluetooth transferred several times more data than 3G. WiFi transferred 5.91 GB in download and 5.66 GB in upload, while Bluetooth transferred 4.04 GB in download and 5.54 GB in upload. The amount of transferred data when using WiFi and Bluetooth is similar, but it is important to note that data transfer when using Bluetooth lasted twice longer than when using WiFi.

Combining results from Figure 1 and Figure 2, we can calculate measured download and upload throughputs of Bluetooth, WiFi and 3G communication technologies. Bluetooth measurements were performed using Bluetooth v2.0 that allows a maximum application throughput of 2 Mbit/s [12], while our results showed that throughput in real world environments is around 1 Mbit/s (0.9 Mbit/s in download and 1.1 Mbit/s in upload). WiFi measurements were performed using 802.11g network with a maximum throughput of 20 Mbit/s in download and upload, while the measured throughput was 2.5 Mbit/s in download and 2.7 Mbit/s in upload. Finally, 3G measurements were performed using HSDPA mobile network that provides a broadband Internet access with throughput of 7.2 Mbit/s in download and 1.4 Mbit/s in upload. Results of our measurements showed throughput of 1.4 Mbit/s in download and 0.5 Mbit/s in upload. Table I shows measured throughput ratios for 3G/Bluetooth, WiFi/Bluetooth and WiFi/3G.

TABLE I
THROUGHPUT RATIOS FOR 3G VS. BLUETOOTH, WIFI VS. BLUETOOTH AND WIFI VS. 3G

	Download	Upload
3G/Bluetooth	1.56	0.45
WiFi/Bluetooth	2.78	2.45
WiFi/3G	1.79	5.40

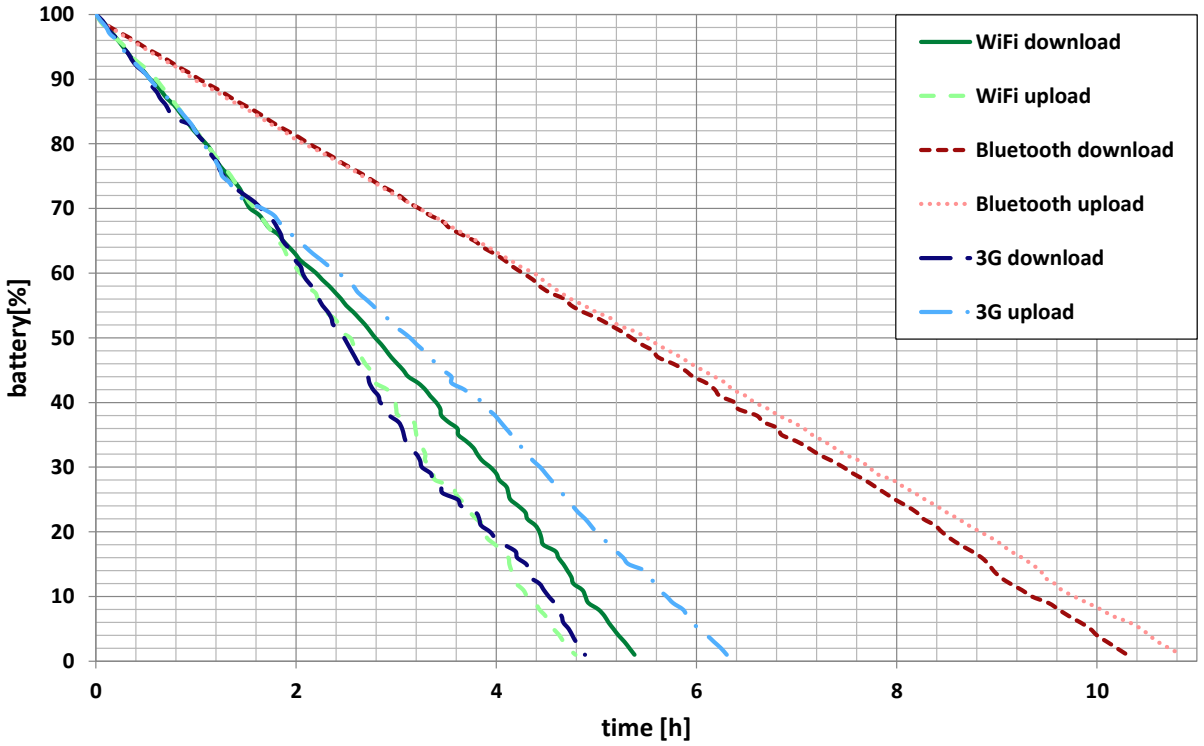

Figure 1. Energy consumption compared to the elapsed time

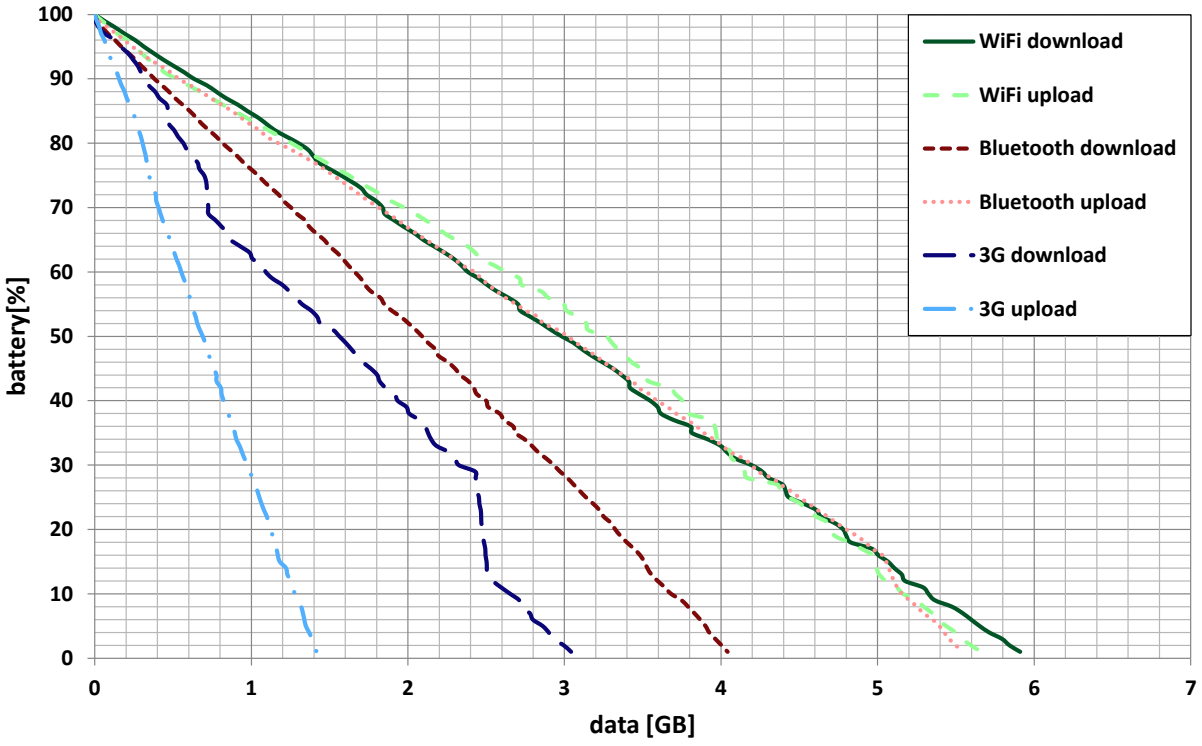

Figure 2. Energy consumption compared to the amount of transferred data

C. The third phase

Based on the collected and processed data, we propose a simple linear energy consumption model. Table II shows energy consumption functions in respect to the elapsed time when using Bluetooth, WiFi and 3G communication technologies for data download and data download. These functions can be used to calculate the percentage of battery (i.e. y) that is consumed when using a particular communication technology for a period of x hours. Additionally, Table III shows energy consumption functions in respect to the amount of transferred data when using Bluetooth, WiFi and 3G communication technologies for data download and data upload. These functions can be used to calculate the percentage of battery (i.e. y) that is consumed when using a particular communication technology for the x amount of transferred data expressed in GB.

In order to verify our energy consumption model, we made additional measurements and compared obtained results with the results calculated with energy consumption functions from Table II and Table III. For instance, if we download files for 0.18 hours using WiFI, according to Table II and the following function $y = 18.09x + 0.17$, for $x = 0.18$, we need 3.43% of the battery. Moreover, since the measured download throughput of WiFi is around 2.5 Mbit/s, it means that during that time 0.21 GB of data is downloaded. Measurements in a real world environment showed that this downloading process consumed around 4% of the battery and that during that time 0.25 GB of data was downloaded on the Android phone. Real world energy consumption is slightly higher than energy consumption calculated using energy consumption functions from Table II due to slightly higher network throughput at the time of measurement.

TABLE II
ENERGY CONSUMPTION FUNCTIONS IN RESPECT TO THE ELAPSED TIME

	Download	Upload
Bluetooth	$y = 9.53x - 0.39$	$y = 9.01x + 0.84$
WiFi	$y = 18.09x + 0.17$	$y = 21.24x - 2.68$
3G	$y = 20.59x - 1.09$	$y = 15.31x + 2.67$

Additionally, if we want to calculate how much energy is consumed when receiving 0.25 GB of data using Bluetooth, we use the following function $y = 24.58x + 0.18$ from Table III. When we include $x = 0.25$ in the aforementioned function, we calculate that for data transfer of 0.25 GB, we need 6.33% of the battery. Measurements in a real world environment showed that this receiving process at throughput of 1.14 Mbit/s consumed slightly more than 5% of the battery and took 0.48 hours, which corresponds to the calculated value obtained from our energy consumption model.

TABLE III
ENERGY CONSUMPTION FUNCTIONS IN RESPECT TO THE AMOUNT OF TRANSFERRED DATA

	Download	Upload
Bluetooth	$y = 24.58x + 0.18$	$y = 17.09x - 0.53$
WiFi	$y = 17.01x - 0.93$	$y = 17.31x - 2.28$
3G	$y = 31.74x + 2.15$	$y = 71.27x - 0.03$

D. The fourth phase

In this section we compare our results with the results from related work. Based on the measured data, we can calculate energy consumption ratios for all three communication technologies (see Table IV). Energy consumption ratios shown in Table IV were calculated using the data obtained by measuring energy consumption and the amount of transferred data in download and upload. Our results confirmed the results obtained by previous studies. 3G communication technology is the largest consumer of energy, followed by WiFi and Bluetooth communication technologies. This implies that energetically the most economical way to transfer data is when using Bluetooth communication technology.

In [6] Balasubramanian et al. showed that data transfer of 50 KB when using 3G needs 12.5 J, while when using WiFi the same data transfer consumes 7.6 J of energy indicating that WiFi communication technology is 39.2% more energy efficient than 3G communication technology. Our measurements showed that for data transfer of 0.5 GB when using WiFi 8% of the battery was used, while 3G for the same amount of data needs 18% of the battery. This implies that WiFi communication technology is up to 55.56% more energy efficient than 3G communication technology. In [8] Friedman et al. calculated energy consumption ratios for WiFi and Bluetooth and showed that it is equal to 3.03. In our model we measured the same ratio and calculated that it is 1.32 when downloading files and 2.22 when uploading files.

TABLE IV
ENERGY CONSUMPTION RATIOS FOR 3G VS. BLUETOOTH, WIFI VS. BLUETOOTH AND WIFI VS. 3G

	Download	Upload
3G/Bluetooth	2.81	8.89
WiFi/Bluetooth	1.32	2.22
WiFi/3G	0.47	0.24

IV. CASE STUDY

Different communication technologies (e.g. WiFi, 3G) have different data transfer throughputs and consume different amounts of energy. By combining these communication technologies together, energy consumption can be reduced. In our previous work, we proposed a collaborative service called *Collaborative Downloading* [13], [14], [15], [16]. Its purpose is to increase energy efficiency of the mobile telecom service provisioning process. This is important for mobile users since limited energy resources are the main obstacles for frequent usage of advanced mobile telecom services and for mobile telecom operators since it enables service provisioning compliant with the green communication concept.

The *Collaborative Downloading* presents a distributed model of service provisioning process for mobile users who share a common interest in a service content offered by mobile telecom operators. The model is based on an idea that such users could individually acquire disjunctive parts of service content from a remote server using 3G communication technology, and then subsequently exchange those parts among themselves in a Bluetooth or WiFi ad hoc network in a peer-to-peer fashion. The system model for the *Collaborative Downloading* service is illustrated in Figure 3. $I = i_1, ..., i_N$ denotes the set of N mobile users who are subscribers of a mobile telecom operator, while $J = j_1, ..., j_M$ denotes the subset of mobile users who form the ad hoc network. Finally, $K = k_1, ..., k_P$ denotes the set of content parts on the server.

In our previous work [16] we made an analytical model for energy consumption of mobile users for the *Collaborative Downloading* service. In this paper we modified our analytical model according to our energy consumption model proposed in the previous section. The *individual approach* refers to the standard approach of the mobile telecom service provisioning, while the *collaborative approach* refers to the approach proposed in the *Collaborative Downloading* service. Energy consumption E_{ind} of a single file download when mobile telecom operators use the *individual approach* for mobile telecom service provisioning can be calculated as follows:

$$E_{ind} = N E_{\%(3G)} S_{file} \tag{1}$$

where N is the number of mobile users in the system, $E_{\%(3G)}$ denotes energy consumption in percentage per GB needed for downloading data via 3G and S_{file} denotes size of the downloaded file in GB. Energy consumption E_{col} of a single file download when mobile telecom operators use the *collaborative approach* can be calculated as follows:

$$E_{col(3G+Bluetooth)} \approx E_{ind}(\frac{1-2\alpha}{N} + 2\alpha), \tag{2}$$

$$E_{col(3G+WiFi)} \approx E_{ind}(\frac{1-2\beta}{N} + 2\beta), \tag{3}$$

where

$$\alpha = \frac{E_{\%(Bluetooth)}}{E_{\%(3G)}}, \quad \beta = \frac{E_{\%(WiFi)}}{E_{\%(3G)}}. \tag{4}$$

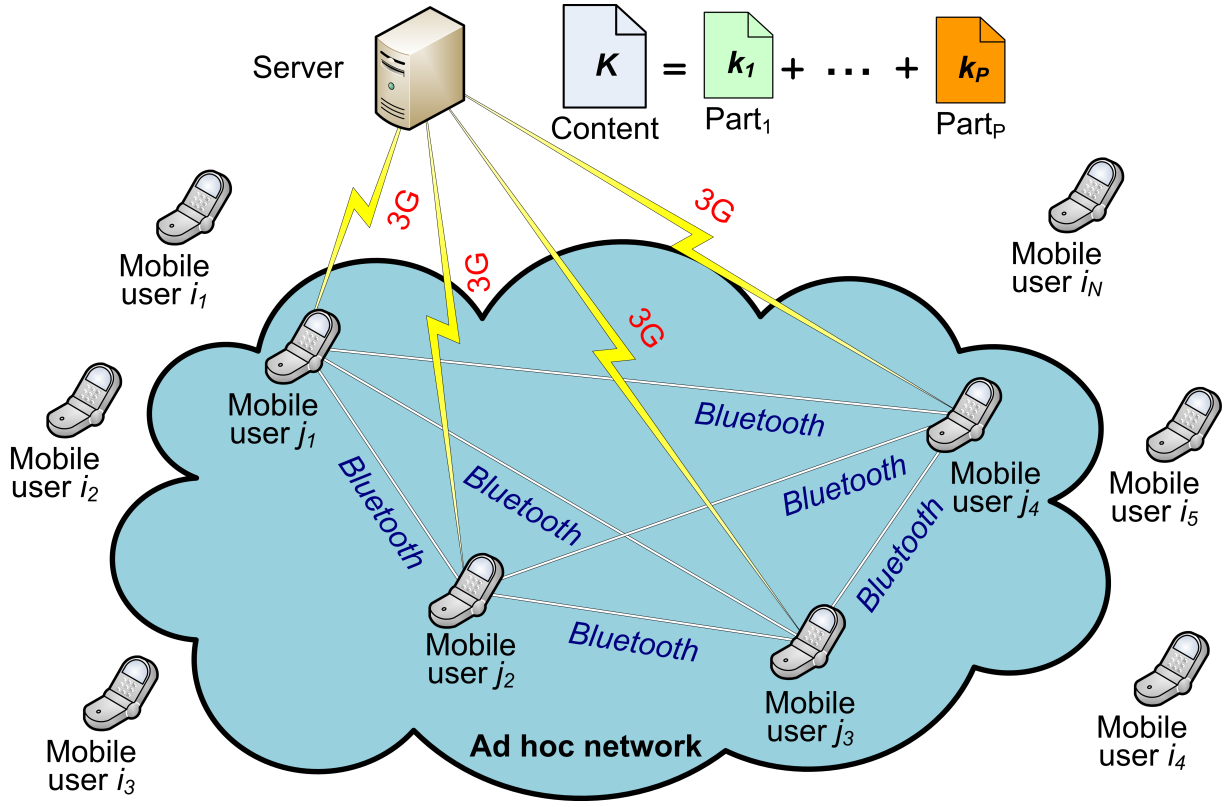

Figure 3. The system model for the *Collaborative Downloading* service

Using data from Table IV (for download), we can calculate that $\alpha = 1/2.81 = 0.36$ and that $\beta = 0.47$. If we have 5 mobile users, then we can calculate $E_{col(3G+Bluetooth)}$ and $E_{col(3G+WiFi)}$. $E_{col(3G+Bluetooth)} \approx 0.78\ E_{ind}$ and $E_{col(3G+WiFi)} \approx 0.95\ E_{ind}$. In our previous work [16] we compared GPRS and Bluetooth communication technologies and calculate that $E_{col(GPRS+Bluetooth)} \approx 0.27\ E_{ind}$. Moreover, we compared UMTS and WiFi communication technologies and got the following result $E_{col(UMTS+WiFi)} \approx 0.82\ E_{ind}$. Results are different due to different versions of communication technologies.

V. Conclusions and future work

In this paper we presented a measurement study of energy consumption for data transfer when using Bluetooth, WiFi and 3G communication technologies. This is important since devices are becoming more powerful and tasks that they can perform are becoming more complex. That results with the increased demands for energy. Therefore, if device can use several of different communication technologies for data transfer, it is important to know energy consumption characteristics of each of them.

The measured data were collected and analyzed. On that basis a simple energy consumption model for Android phones was design. Using our model, we showed how to calculate energy consumption for the *Collaborative Downloading* service. The main idea behind the service is to combine different communication technologies when downloading files in parts, and reduce the amount of energy required to transfer the entire file to a group of mobile users.

Measurements were made using a simple Android application in which we were downloading or uploading data continuously. In future work we will upgrade our application in order to adjust the size of the file being transferred, as well as the time between transmissions. Moreover, apart from monitoring the battery status in percentage, we will directly measure phone's energy consumption using a measuring device.

Power line Communication System Modeling Based on Coded OFDM

Mario Bogdanović

Siemens d.d., Osijek, Croatia

Email: mario.bogdanovic@siemens.com

Abstract - Over the last years there is more intensive research on realization of PLC (Powerline Communication) as access network. Since the power line channel shows hostile properties for communication signal transmission (noise, multhipath, strong channel selectivity), the major issue is to choose an adequate modulation technique for the evolution and realization of such a system. This paper introduces a power line communication system model based on the coded OFDM (Orthogonal Frequency Division Multiplexing) modulation technique. Coded OFDM presents a good performance in difficult signal transmission environments and stands as a good candidate for the realization of a PLC system.

Keywords: power line communication, coded OFDM, PLC channel model

I. INTRODUCTION

Due to the increasing importance of networking in homes, offices and business buildings, PLC (Power Line Communication) systems become more significant. The main advantages of PLC technology are accessibility and the existing of wiring infrastructure; each wall outlet can be access point for high speed data transmission.

On the other hand, the power line medium was not designed for data transmission. The negative properties of the PLC transmission channel are frequency-dependent attenuation, changing impedance, fading and time variable noise conditions. Also, to provide a high data rate, PLC networks frequently work in a frequency spectrum of up to 30 MHz and in this condition the PLC network produces electromagnetic radiation and acts as an antenna [1].

PLC systems can be divided into two fields according to frequency band: narrowband PLC and broadband PLC. The narrowband technology works with a frequency range up to 150 kHz and the theoretical bit rate is up to 2 Mbit/s. This technology is developed for the purpose of remote metering systems: AMR (Automated Meter Reading) and AMM (Automated Meter Management). Nowadays it is used for metering and controlling, so called Smart Metering.

The broadband technology works with a frequency range from 150 kHz up to 34 MHz and the theoretical bit rate is up to 200 Mbit/s. Given the properties of BPLC (Broadband Power line Communication) offers the possibility of broadband communication services (fast Internet access or implementation of LAN networks) [1][4]. It is important to select adequately the modulation technique to achieve these properties in BPLC. Most research in the literature recommends OFDM as a relevant solution because of its excellent bandwidth efficiency. It is based on a form of multicarrier systems and subdivides transmission bandwidth into parallel subchannels with orthogonal carriers, which is a proper solution in the case of intersymbol interference (ISI), signal fading, channel noise, etc.

BPLC networks become a possible pay out market solution for advanced information technology such as real-time video, HDTV, voice connections and high speed data transfer. Therefore, there is a need to understand and to develop BPLC systems in order to enhance performances. One of the methods is to develop a mathematical computer model of BPLC system. This paper focuses on the development of a BPLC model based on coded OFDM. The model was realized in MATLAB and Simulink [3].

The rest of the paper is organized as follows. In Section II, proposed power line channel models are presented. The proposed model based on coded OFDM is presented in Section III. The paper finishes with discussion and the conclusion in Section IV.

II. POWER LINE CHANNELS MODELS

One of the most important elements in the BPLC system model is power line channel model. There are several possible methods for modeling the power line channel and the two presented are today wide spread and rather developed. The first one is based on methods for radio channel modeling and the power line channel is representing as a multipath propagation environment [2]. The second one is based on methods used to model long electricity distribution networks. This method models transfer function of power line channel using chain matrix theory (ABCD matrix theory) [4][5][6].

A. Multipath Signal Propagation Model

The power line medium is an unstable transmission channel. Because it is time varying, the power line can be defined as a multipath channel caused by reflections

generated at the cable branches through the impedance mismatch. Multipath signal propagation can be analyzed and described by the model depicted in Figure 1. where parameters are: r – reflection factor, t – transmission factor, l – branch length, Z_L – branch caracteristic impedance, $g=r\cdot t$ – weighting factor of branch, $\tau_i = d_i / v_p$ – delay. Attenuation $A(f,d)$ and the losses of cables increases depending on length and frequency [2].

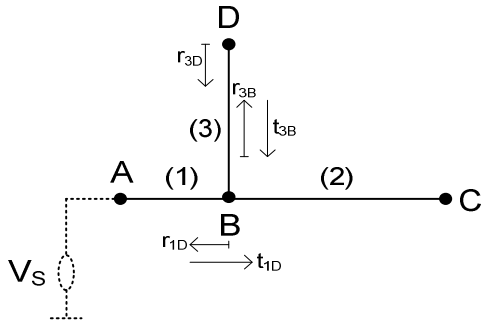

Figure 1. Channel amplitude response

The frequency response $H(f)$ from A to C can be defined as

$$\underline{H}(f) = \sum_{i=1}^{N} g_i \cdot A(f, d_i) \cdot e^{-j2\pi f \tau_i}. \qquad (1)$$

Considering the attenuation and frequency response the channel model can be mathematically defined as

$$\underline{H}(f) = \sum_{i=1}^{N} \underbrace{|g_i(f)| e^{\varphi_{g_i}(f)}}_{\text{weighting factor}} \cdot \underbrace{e^{-(a_0 + a_1 f^k) d_i}}_{\text{attenuation portion}} \cdot \underbrace{e^{-j2\pi f \tau_i}}_{\text{delay portion}}. \qquad (2)$$

Equation (2) describes signal propagation with the low-pass characteristic and the delay portion. Also each path is characterized by a weighting factor g_i which is the product of transmission and reflection factors with path length d_i. The attenuation factor is modeled by the parameters a_0, a_1 and k obtained from measurements.

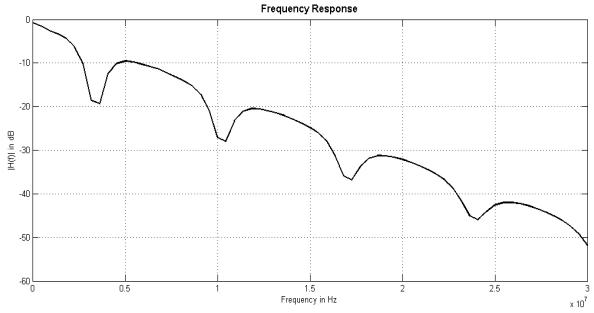

Figure 2. Amplitude response of reference model with 4 paths

Figure 2. depicted a frequency response of channel defined with the parameters in TABLE I.

TABLE I. ATTENUATION PARAMETERS

Attenuation parameters: $a_0=0$ $a_1 = 8{,}8\cdot10^{-10}$s/m $k=1$				
i	*1*	*2*	*3*	*4*
$\mathbf{g_i}$	0,64	0,38	-0,15	0,05
$\mathbf{d_i}$ **(m)**	200	222,4	244,8	267,5

B. Chain Matrix Theory Model

Second the most wide spread channel model is based on a two-port network model of a two-conductor transmission line. Figure 3. illustrates the transmission line model obtained by applying the distributed parameter line theory on the basic transmission line configuration with parameters. In the distributed parameter model, the unit line constants are:

- R – resistance per unit length (Ω/m)
- G – conductance per unit length (S/m)
- L – inductance per unit length (H/m)
- C – capacitance per unit length (C/m).

These constants are uniformly distributed along the line and therefore we can define $z=R+j\omega L$ and $y=g+j\omega C$ as series impedance per unit length and the shunt admittance per phase, respectively.

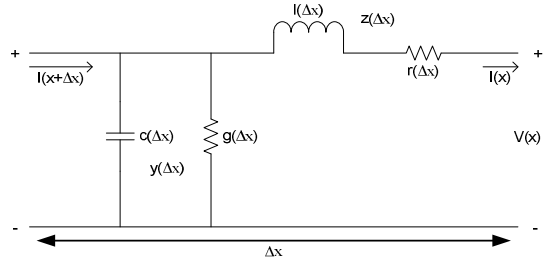

Figure 3. Distributed Parameter Transmission Line

Applying Kirchoff's current and voltage laws on model in Figure 3. [5] we get

$$\begin{aligned} V(x) &= V_R \cdot \cosh(\gamma \cdot x) + Z_C \cdot I_R \cdot \sinh(\gamma \cdot x) = V_S \\ I(x) &= \frac{V_R}{Z_C} \cdot \sinh(\gamma \cdot x) + I_R \cdot \cosh(\gamma \cdot x) = I_S \\ &for\ x = 0; V(x) = V_R; I(x) = I_R \end{aligned} \qquad (3)$$

Introducing substitution:

$$\begin{aligned} A = D &= \cosh(\gamma \cdot x) \qquad B = Z_C \cdot \sinh(\gamma \cdot x) \\ C &= \frac{1}{Z_C} \cdot \sinh(\gamma \cdot x) \end{aligned} \qquad (4)$$

Where γ and Z_C are then defined as the propagation constant and the characteristic impedance, respectively.

$$\begin{aligned} Z_C &= \sqrt{\frac{R + j \cdot \omega \cdot L}{G + j \cdot \omega \cdot C}} \\ \gamma &= \sqrt{(R + j \cdot \omega \cdot L)(G + j \cdot \omega \cdot C)}. \end{aligned} \qquad (5)$$

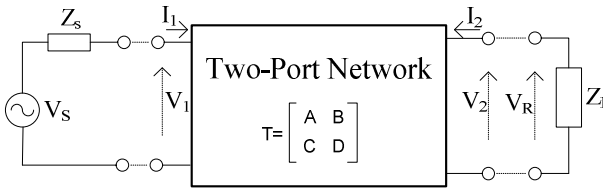

Figure 4. Two-port network model

The relationship between the sending and receiving end of the two-port network, shown in Figure 4. , can be written as:

$$\begin{vmatrix} V_1 \\ I_1 \end{vmatrix} = \begin{vmatrix} A & B \\ C & D \end{vmatrix} \begin{vmatrix} V_2 \\ I_2 \end{vmatrix} \tag{6}$$

Also, we can define the transfer function, *H(f)*, of the cable channel with length *l* as a relationship between the output and input signals $V_R=V_2=I_2 \cdot Z_L$ and $V_S = V_1+I_1 \cdot Z_S$ (model is depicted in Figure 4.), as:

$$H(f) = \frac{V_R}{V_S} = \frac{Z_L}{A \cdot Z_L + B + C \cdot Z_S \cdot Z_L + D \cdot Z_S} \tag{7}$$

Where Z_L and Z_S are the receiver and transmitter impedance, respectively.

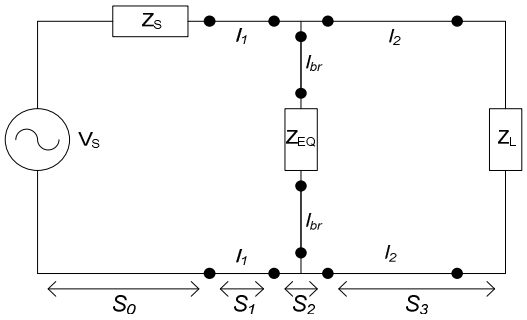

Figure 5. One bridge tap network model

If we add a bridge tap with load impedance *Z* as in Figure 5. , equivalent impedance Z_{EQ} is defined as:

$$Z_{EQ} = Z_{Cbr} \cdot \frac{Z + Z_{Cbr} \cdot \tanh(\gamma_{br} \cdot 1_{br})}{Z_{Cbr} + Z \cdot \tanh(\gamma_{br} \cdot 1_{br})} \tag{8}$$

And this network can be specified as a network of four serial segments network, denoted by S_0, S_1, S_2, S_3. Each segment is defined by own ABCD matrix and the ABCD matrix for total system can be calculated as:

$$\begin{bmatrix} A & B \\ C & D \end{bmatrix} = \prod_{i=0}^{3} S_i = S_0 S_1 S_2 S_3 \tag{9}$$

Now the substitution is given as:

$$C_1 = \cosh(\gamma_1 \cdot 1_1) \quad C_2 = \cosh(\gamma_2 \cdot 1_2)$$
$$S_1 = \sinh(\gamma_1 \cdot 1_1) \quad S_2 = \sinh(\gamma_2 \cdot 1_2) \tag{10}$$

And it follows:

$$\begin{bmatrix} A & B \\ C & D \end{bmatrix} = \begin{bmatrix} 1 & Z_S \\ 0 & 1 \end{bmatrix} \begin{bmatrix} C_1 & Z_{C1}S_1 \\ \frac{S_1}{Z_{C1}} & C_1 \end{bmatrix} \begin{bmatrix} 1 & 0 \\ Z_{EQ} & 1 \end{bmatrix} \begin{bmatrix} C_2 & Z_{C2}S_2 \\ \frac{S_2}{Z_{C2}} & C_2 \end{bmatrix} \tag{11}$$

$$A = C_2 \cdot \left(C_1 + \frac{Z_{C1}S_1}{Z_{C1}} \right) + \left(Z_{C1}S_1 + C_1 Z_S \right) \cdot \left(\frac{C_2}{Z_{EQ}} + \frac{S_2}{Z_{C2}} \right) \tag{12}$$

$$B = Z_{C2}S_2 \cdot \left(C_1 + \frac{Z_{C1}S_1}{Z_{C1}} \right) + \left(Z_{C1}S_1 + C_1 Z_S \right) \cdot \left(C_2 + \frac{Z_{C2}S_2}{Z_{EQ}} \right) \tag{13}$$

$$C = \frac{S_1 C_2}{Z_{C1}} + C_1 \cdot \left(\frac{C_2}{Z_{EQ}} + \frac{S_2}{Z_{C2}} \right) \tag{14}$$

$$D = \frac{Z_{C1}Z_{C2}S_1}{Z_{C1}} + C_1 \cdot \left(\frac{Z_{C2}S_2}{Z_{EQ}} + C_2 \right) \tag{15}$$

The frequency response of a channel model shown in Figure 5. was coded and simulated in MATLAB with the following cable parameters: R=1.9884 Ω/m, G = 0.01686 nS/m, C= 0.13394 nF/m, L = 362.81 nH/m. The total cable length is 4m with a bridge tap of length 2m and a branch impedance 50Ω, Z_S = 50Ω and Z_L = 50Ω [6].

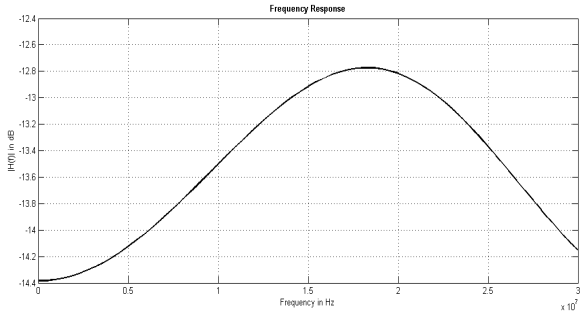

Figure 6. Frequency response of one bridge tap network

III. CODED OFDM MODULATION IN PLC TECHNOLOGY

The PLC transmission medium behavior strongly depends on its own characteristic (frequency selectivity, multipath, nonlinearity) and on the environment (impulse noise). It is very important to select an appropriate modulation technique to reduce errors in data transmission. OFDM has shown a good performance in wireless communications and DTV (Digital Television) systems and it was presented as a good candidate for a modulation technique in PLC systems. Moreover, OFDM is outlined because of its excellent bandwidth efficiency. The main principle of the OFDM is data transmission over a number of parallel bit streams. Each stream has its own carrier distributed in a frequency spectrum, called also subcarrier, which are orthogonal to each other. The spread of the spectrum provides also the spread of the effect of impulse noise over subcarriers.

OFDM computer simulation models can greatly speed up the analysis and improvement of PLC systems. By building quality models based on facts, the construction of prototypes can be avoided. Models simulate the system

behavior by introducing parameters harvested from real networks, changing them and observing system behavior.

A. Coded OFDM Simulation Model

The PLC OFDM model is composed of three basic elements: transmitter part, the PLC channel and receiver part. The input data source is a Bernoulli Binary Generator generating random binary numbers using a Bernoulli distribution. The Bernoulli distribution with parameter *p* produces zeros with probability *p* and ones with probability *1-p* [3]. The channel coding is the next procedure. It is used to ensure that correctly received data can correct possibly erroneous data received at the receiver end. In this case the particular block code, Reed-Solomon code (*RS(15:11)*), is used as an effective code in combating burst errors caused by a noisy environment.

After coding, a serial symbol data stream should be conveyed in the *l-th* OFDM time slot and over *k-th* OFDM subcarrier and needs to be mapped to the adequate modulation symbol $S_{l,k}$. Differential encoding is applied with Grey encoded Rectangular QAM Modulator before mapping. Select Row block is used to make sub-band separation of a useful signal. In the case of a coherent detection system, channel estimation is necessary and the known symbols and pilots are inserted (PN Sequence Generator block). The middle carrier frequency is inserted by help of the DSP Constant block. In the Matrix Concatenation block all inputs (signal, carrier frequencies) are concatenated in a contiguous output signal. Further the signal needs to be adjusted for IFFT, where Zero Pad and Selector block are used for size and reorder adjustment, respectively. Now, the data needs to be converted from the frequency to the time domain and that is realized by the help of the IFFT block. At the end on the transmitter side, a protective cyclic prefix is added in order to eliminate ISI in a linear dispersive channel. At the Receiver side, the blocks are connected inversely.

Transmitter and receiver side are connected with the transmission channel. In this phase of developing coded OFDM PLC system, the AWGN (Additive White Gaussian Noise) channel is used to add white noise to the transmitted signal. The AWGN channel is used in order to validate OFDM system.

1) Encoding with Reed-Solomon Codes

A Reed-Solomon code is a linear cyclic systematic non-binary block code and it has very high coding rate and low complexity. It can be represent as *RS(n,k,t)* where *n* is the length of the codeword symbols (block length), *k* is the number of information symbols, *t* is the error-correction capability and each symbol contains *m*-bits. The error correction capability (maximum number of correctable errors) is defined as $t=(n-k)/2$. Also, the code rate can be introduced as $R_c=k/n$, the rate between the number of information symbols and the entire block length. The binary input *RS(15,11)* and *RS(15,9)* are used in simulating the model, size of the codeword (block length) is 15 bits, the number of data symbols is 11 or 9 bits and the maximum number of symbol (bit) errors that the decoder can correct is equal to (15-11)/2=2 or (15-11)/2=3 bits. Code rates are 0.733 and 0.6, respectively.

Validation of the coded OFDM model is obtained in a way that we simulate the model with and without the

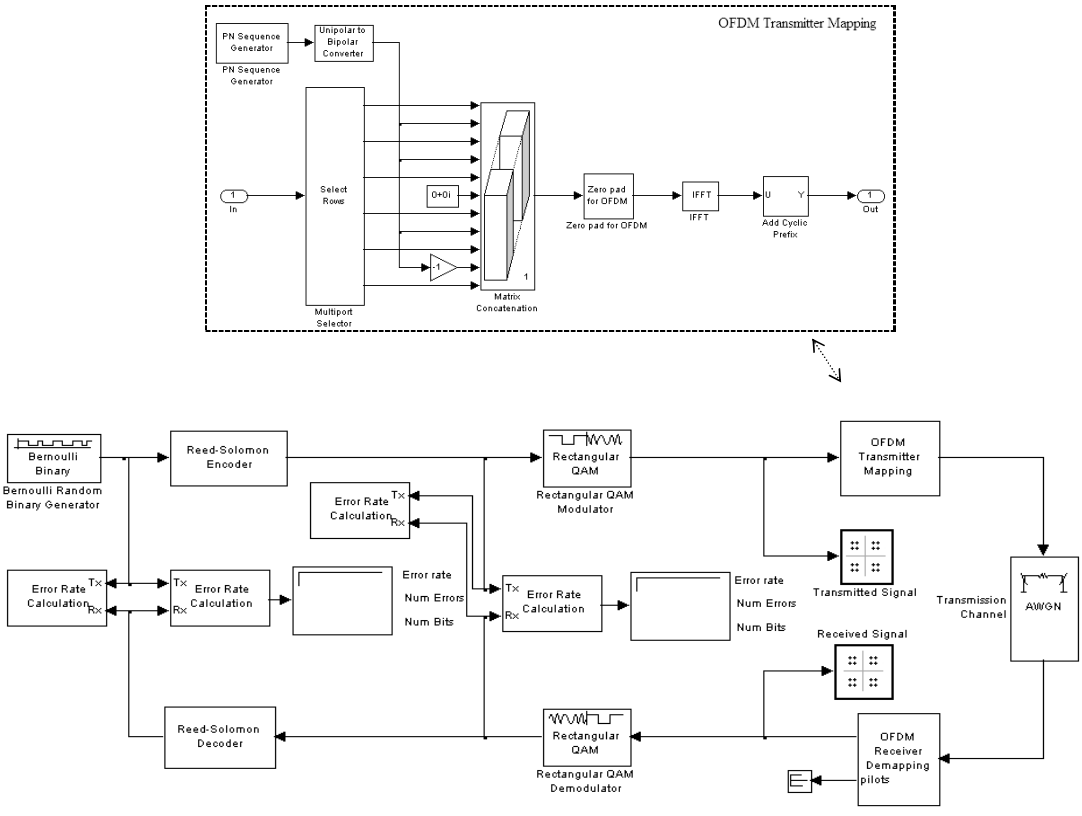

Figure 8. PLC Coded OFDM Model (modeled by Simulink)

Reed-Solomon coder and with two different QAM modulation techniques (4-QAM and 8-QAM). Functional dependence of BER (Bit Error Ratio) towards S/N (Signal to Noise Ratio) is used for performance estimation of coded systems. The simulation results are depicted in Figure 7. and benefits of using a RS coder can be noticed in a decrease of the BER on dependence of signal/noise ratio in both models: 4-QAM with RS(15,11) and 8-QAM with RS(63,47). Besides, it is observed from the depicted curves, as the symbol redundancy increases (therefore the code rate is lower) the BER performance is improved, revealing that properly chosen RS coding scheme can significantly improve the BER performance.

An important factor in the PLC model is environmental noise. As the power line channel does not represent an AWGN environment, the following categories of noises should be considered in PLC channel model:

1. coloured background noise
2. narrow band noise
3. periodic impulsive noise (synchronous and asynchronous)
4. aperiodic impulsive noise.

Impulse noise in the environment is the main reason for use of a block code, in this particular case the Reed-Solomon class, because their efficiency in combating burst errors.

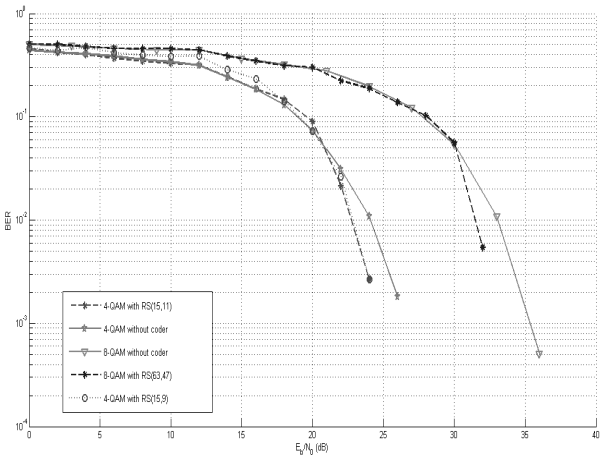

Figure 7. BER of coded and uncoded OFDM simulation model

Future interest lies in developing the transmission channel according to multipath models introduced in section II including noise models and to investigate the efficiency of coded OFDM systems with a modeled PLC transmission channel.

IV. CONCLUSION

In this paper we present a power line communication channel model and propose a simulation model based on the coded OFDM system. The channel characteristics were obtained in earlier research and the computer simulations are performed in order to create the frequency response of the proposed channel models. These results will be the basis for future models of transmission PLC channels.

Further, as the PLC transmission channel is a very hostile environment for data transmission (burst errors), it was important to choose appropriate coders/decoders for the OFDM system. The simulation model of a coded OFDM system is introduced and the comparison between uncoded and coded (Reed-Solomon code) OFDM system is carried out. Multiple scenarios were considered: 4-QAM and 8-QAM without coder; 4-QAM with RS(15,11) and RS(15,9) coder; 8-QAM with RS(63,47) . From the results of simulation it follows that the coding improves system performance, which can be seen in BER performance. Therefore, from the simulation results, the Reed-Solomon coder seems to be good candidate for performance improvement.

The constructed OFDM model is the first phase of creating a power line communication model in order to simulate real PLC systems that will be used for performance research of different coding schemas and modulation techniques.

Abstract-Since the spectrum is the scarce resource, spectrum sensing is an important part of Green Engineering. The cognitive radio has been proposed as the future technology to meet the ever increasing demand of the radio spectrum by allocating the spectrum dynamically to allow unlicensed access on non-interfering basis. In cognitive radio, spectrum sensing is the fundamental problem. Energy detection method is the simplest method but suffers from noise uncertainty problem. Covariance based detection exploits space-time signal correlation, but its performance is very sensitive to the signal correlation. Hybrid detection method exploits the advantages of these two methods by utilizing energy detection in low correlation and covariance based detection in high correlation. We analyze the performance of hybrid detection method exploiting TV White Space under Rayleigh and Rician fading channel for different Signal-to-Noise Ratio values by setting probabilities of false alarm and measuring probability of detection. Simulation shows that the hybrid detection method outperformed energy detection and covariance based detection method and is more insensitive to the type of input data. The hybrid detection method shows the better performance compared to energy detection and covariance method under time-varying fading conditions.

I. INTRODUCTION

Although spectrum is seen as a scarce natural resource, measurements show that often there are moments in time and space where the spectrum is not being fully utilized by the services that have allocated it and therefore it is being used inefficiently[1]. ITU predicted that 1720 MHz spectrum will be required by year 2020 for new wireless technology. Many new wireless services/applications cannot be rolled out due to non-availability of spectrum [2], which demands dynamic allocation of spectrum instead of static [3], [4]. Recently, there have been growing interests in cognitive radio (CR), where secondary opportunistic radio exploits opportunistically spectrum "White Spaces", by means of knowledge of the environment and cognition capability, and adapts their radio parameters accordingly [3], [4].The upcoming IEEE 802.11af standard (so-called "super-Wi-Fi") is based on CR utilizing the bandwidth within TV broadcast stations [5], [6], [7], [8]. In CR, unlicensed or secondary user (SU) is required to perform the frequent spectrum sensing for detecting the presence of licensed or primary users (PUs) for reusing the spectrum with a high probability of detection and vacant the channel or reduce transmit power. As described in [5], [7], [8] for IEEE 802.11af standard, time to vacate band after PUs detection is 2s with 90% of probability of detection and 10% of probability of false alarm at SNR level as low as -20dB along with geo-location accuracy of +/-50m.

But in cognitive radio sensing a spectrum is a crucial task and it is an important part of Green Engineering.There have been several sensing methods, including the Likelihood ratio test (LRT) [9], Energy detection (ED) method [9],[10],[11], Matched filtering (MF)-based method [12],Cyclostationary detection method [13] and Wavelet transform based estimation [14], each of the mentioned methods has different requirements ,together with advantages or disadvantages. Although LRT is proven to be optimal, it is very difficult to use, because it requires exact channel information and distributions of the source signal and noise which are difficult to obtain practically.The MF-based method requires perfect knowledge of the channel responses from the primary user to the receiver and accurate synchronization. This is possible only if the primary users cooperate with the secondary users else leads to degradation in the performance of MF-based method [12].

The cyclostationary detection method requires the exact knowledge of the cyclic frequencies of the primary users, which is not possible practically for many spectrum reuse applications. Also this method demands excessive analog-to-digital (A/D) converter requirements and signal processing capabilities [13].

Multitaper spectrum estimation [10] has shown to be an approximation to maximum likelihood Power Spectrum Density (PSD) estimator, and it is nearly optimal for wide band signals. Although the complexity of this method is smaller than the maximum likelihood estimator, it is still computationally demanding. Wavelets [14] are used for detecting edges in the PSD of a wideband channel. Once the edges, which correspond to transitions from an occupied band to an unoccupied /vacant / empty band or vice versa, are detected, the powers within bands between two edges are estimated. Using this information and edge positions, the frequency spectrum can be identified as vacant or occupied.

Energy detection method is a semi-blind detection which requires knowledge of noise power only for signal detection. In [10], sets of receiver operating characteristic (ROC) curves are drawn for several time-bandwidth product for spectrum sensing using energy detection. In

[9], blindly combined energy detection method which uses the spatial correlation of received signals based on energy detection, is analysed for independent and identically distributed source signal which is FM modulated wireless signal operated in vacant TV channels with a bandwidth less than 200 kHz , the flat-fading and the multipath fading channel. The experimental study for spectrum sensing in 2.4 GHz ISM band over 85 MHz of bandwidth using energy detection for sine wave carrier and QPSK sensing is evaluated in [15]. In the same reference minimum detectable signal levels set by the receiver noise uncertainties are measured.

In the references: [9],[16],[17], a new spectrum sensing algorithm based on covariance of the received signal called as Covariance Absolute Value (CAV) is proposed. CAV is a blind detection method, uses space-time signal correlation for signal detection which does not require any knowledge of noise and signal power. The covariances of signal and noise are generally different, which can be used in detection of PU. The performance of ED and CAV is evaluated for Advanced Television Systems Committee (ATSC) (used in USA and South Korea) having 6MHz bandwidth.

But CAV method is very sensitive to the signal correlation. Its performance degrades in low correlation signal strength [11]. In [11], the new method called as 'Hybrid detection' is proposed which exploits the advantages of ED and CAV method. This method utilizes ED in low correlation and CAV in high correlation for signal detection.

Since cognitive radio is an emerging technology, the performance of the spectrum sensing algorithm needs to be analysed under different fading channels. The goal of this paper is to present an analysis of hybrid detection for terrestrial digital video broadcasting for (DVB-T) standard for 8MHz bandwidth in 2k mode used for mobile reception of standard television.The analysis is performed under conditions of AWGN channel, Rayleigh and Rician fast and slow time variant fading channels using time-variant Jakes' model based on probability of detection (P_d) versus overall correlation coefficient for different values of Signal-to-Noise ratio (SNR) , P_d versus SNR for different values of probability of false alarm(P_{fa}) . We will show that how hybrid detection method is more insensitive to the type of input data.

The organization of the paper is as follows. The E-animal husbandry application is discussed in section I. The analysis of ED, CAV and hybrid detection method is done in section II. Simulation is performed in section III for terrestrial digital video broadcasting based on these methods, followed by conclusions in section IV.

I. E-ANIMAL HUSBANDRY

One of the promising application of TVWS as stated in [7] [8] is e-Animal husbandry; a practical solution to bring farmers out of the poverty trap and its importance needs to be recognized in ICT programmes. An online disease reporting system known as National Animal Disease Reporting (NADR) System can be implemented using CR networks utilising TVWS based on IEEE 802.11 af standard. With this system farmers will have benefit by providing wireless connectivity among various units like Taluka unit ,district unit, state unit, centre unit, Veterinary(Vet) dispensary, Taluka level NGO etc. The Central Unit at DAH&D would be responsible for analysis and maintenance of data. All the disease related information would be available online ensuring transparency and benefit of all concerned.

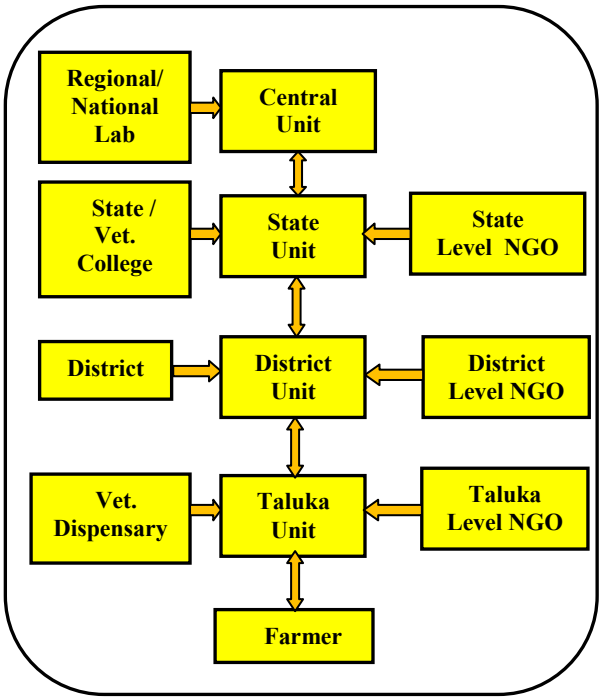

Figure 1: NADR System

II. ANALYSIS OF ED, CAV AND HYBRID DETECTION METHODS

The Neyman-Pearson criteria say that the spectrum detection is a binary hypothesis sensing problem [9], [10].

$$H_0: y(n) = \eta(n) \qquad n = 1,2,3, \ldots\ldots \qquad (1)$$
$$H_1: y(n) = s(n) + \eta(n) \quad n = 1,2,3, \ldots\ldots$$

where $s(n)$ indicates the PU and $\eta(n)$ is the additive white Gaussian noise which is assumed to be independent and identically distributed random variable with zero mean and variance σ_η^2. Here, the hypothesis H_0 means the absence of signal and H_1 its presence. Performance of spectrum sensing algorithm is indicated by two metrics: by a probability of detection, P_d, which is the probability of the algorithm correctly detecting the presence of the

PU and by a probability of false alarm, P_{fa}, which defines probability of the algorithm mistakenly declaring the presence of PU leading to underutilization of available spectrum opportunities.

A. Energy Detection Method

Energy detection method compares the energy of the received waveform over a specified time with a threshold obtained for a given P_{fa} limit to decide whether primary signal exists or not. Note that for a given signal bandwidth *B*, a pre-filter matched to the bandwidth of the signal needs to be applied as shown in Fig.1.

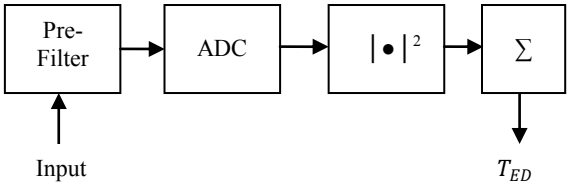

Figure 2. Implementation of energy detection

The decision statistic for energy detector is [10][11]:

$$T_{ED} = \frac{1}{N} \sum_{n=0}^{N-1} (|y(n)|)^2 \quad (2)$$

where *N* is the total number of taken signal samples. This decision statistic is compared with a threshold β_{ED} in order to decide whether the signal is present or not. If $T_{ED} > \beta_{ED}$, the signal is assumed to be present; otherwise it is assumed to be absent. In case of large *N*, according to Central Limit Theorem (CLT), the probability distribution function of T_{ED} can be approximated by Gaussian distribution. The expressions for probability of detection and false alarm can be obtained as:

$$P_d = Q\left(\frac{\sqrt{N}\,(\beta_{ED} - (\sigma_s^2 + \sigma_\eta^2))}{\sigma_s^2 + \sigma_\eta^2}\right) \quad (3)$$

$$P_{fa} = Q\left(\frac{\sqrt{N}\,(\beta_{ED} - \sigma_\eta^2)}{\sigma_\eta^2}\right) \quad (4)$$

where σ_s^2 is primary user signal variance, σ_η^2 is noise variance and Q(t) is Q function given by:

$$Q(t) = \frac{1}{\sqrt{2\pi}} \int_t^{+\infty} e^{-\frac{u^2}{2}}\, du \quad (5)$$

B. Covariance Absolute Value Method

Covariance absolute value (CAV) is a blind detection method, uses space-time signal correlation for signal detection which does not require any knowledge of noise and signal power. The covariances of signal and noise are generally different, which can be used in detection of PU. CAV method uses sample auto-correlation for the signal detection [16] [17]. The auto-correlations of signal and noise are generally different. Let

$$y(l) = s(l) + \eta(l) \quad (6)$$

where $s(l)$ represents signal samples, $\eta(l)$ represents noise samples and $y(l)$ the received signal samples.
The auto-correlations of received signal is

$$c(l) = \frac{1}{N}\sum_{n=0}^{N-1} y(n) * y(n-l) \;\; l = 0,1,.,L-1 \quad (7)$$

where N is the total number of signal samples, the range of l is from 0 to L-1, the parameter L is called smoothing factor as explained in [11], [16], [17].

The covariance matrix of $y(l)$ under H_0 and H_1 is given by

$$R_y(l) = E[y(l)y(l)^H] = \sigma_\eta^2 I_L \quad : H_0 \quad (8)$$
$$= R_s(l) + \sigma_\eta^2 I_L \;\; : H_1$$

where $R_s(l)$ is the covariance matrix of $s(l)$, I_L is the identity matrix of dimension L and

$$\sigma_\eta = E[\eta(l) * \eta(l)^*]$$

If there is correlation between the signal samples due to oversampling, the $R_s(l)$ will be different from identity matrix. Based on this covariance matrix, two metrics T_1 and T_2 are defined as follows:

$$T_1 = c(0) + \frac{2}{L}\sum_{l=1}^{L-1}(L-l)\,|c(l)| \quad (9)$$

$$T_2 = c(0) \quad (10)$$

The ratio $\frac{T_1}{T_2}$ can be used to detect the presence of the signal. When there is no signal, $\frac{T_1}{T_2} = 1$ and if the signal is present, $\frac{T_1}{T_2} > 1$. The following decision metric for CAV is derived as:

$$T_{CAV} = \frac{T_1}{T_2} \quad (11)$$

According to this decision metric, probability of false alarm and the probability of detection have the following form:

$$P_{fa} = 1 - Q\left(\frac{\frac{1}{\beta_{CAV}}\left(1+(L-1)\sqrt{\frac{2}{N\pi}}\right)-1)}{\sqrt{2/N}}\right) \quad (12)$$

$$P_d = 1 - Q\left(\frac{\frac{1}{\beta_{CAV}} + \frac{\beta_L\, SNR}{\beta_{CAV}\,(SNR\,+1)} - 1}{\sqrt{2/N}}\right) \quad (13)$$

where Signal-to-Noise Ratio: $SNR = \frac{\sigma_s^2}{\sigma_\eta^2}$, β_{CAV} is the decision threshold and β_L is a very important parameter for CAV called overall correlation coefficient. It is defined as:

$$\beta_L = \frac{2}{L}\sum_{l=1}^{L-1}(L-l)\,|e(l)| \quad (14)$$

where $e(l) = \frac{E[s(n)s(n-l)]}{\sigma_s^2}$ (15)

This is normalized correlation strength between the signal samples (range is between 0 to 1).

C. Hybrid detection method

For energy detection, in the case of noise uncertainty as shown in [18] and [19], there exists a minimum SNR level below which no detection is possible called SNR_{wall}. As already mentioned in [11] and from the simulation results shown in [11], CAV underperforms in low correlation. In [11] new method called as 'Hybrid detection (HD)' method is proposed which takes the advantage of both the methods based on the signal correlation. For spectrum sensing, the hybrid detection uses ED in low correlation and CAV in high correlation. Threshold (β_{HD}) for hybrid detection method is given as:

$P_d\ (\mathrm{ED}) = P_d\ (\mathrm{CAV})|_{\beta_{HD}}$

$$\beta_{HD} = \frac{\beta_{CAV}\ (SNR+1)}{SNR}$$

$$\left(Q^{-1}(1-(P_d\ (ED))\sqrt{\frac{2}{N}} + 1 - \frac{1}{\beta_{CAV}}\right) \qquad (16)$$

For spectrum sensing, the hybrid detection method calculates the estimate of β_L from the signal samples and compares this estimate with the threshold β_{HD}. It chooses ED if $\beta_L \leq \beta_{HD}$ and CAV if $\beta_L \geq \beta_{HD}$

D. Computational Complexity for Hybrid detection Method

If $\beta_L \leq \beta_{HD}$ ED is selected else CAV method, hence the computational complexity for hybrid detection method will be N multiplications and additions if $\beta_L \leq \beta_{HD}$ else L times N multiplications and additions.

E. Design steps for Hybrid Detection Method

1: Calculate the estimate of β_L from the signal samples.
2: Compare the estimate with the threshold.
3: Choose ED or CAV dependent on the result of 2.

III. SIMULATION RESULTS

In the following, we will show the simulation results of hybrid detection method, energy detection and covariance based detection for the primary signal which is Digital Video Broadcast–Terrestrial (DVB–T) signal generated using MATLAB according to the European Telecommunications Standards Institute (ETSI) specifications given in [20] intended for mobile reception of standard definition TV in 2K mode with 8 MHz bandwidth. The received signal is sampled at the rate 36 times sampling rate at the transmitter. The Signal-to-Noise ratio (SNR) of the received signal is unknown. In order to use the signals for simulating the algorithms at very low SNR, we need to add white noise to obtain various SNR levels [21]. The DVB-T signal and the added white noise are passed through a raised cosine filter with bandwidth 8MHz, rolling factor 0.5 with 217 taps. The number of samples used is 40000. The threshold for detection in case of ED and CAV is calculated based on P_{fa} and for HD as specified in section II. C.

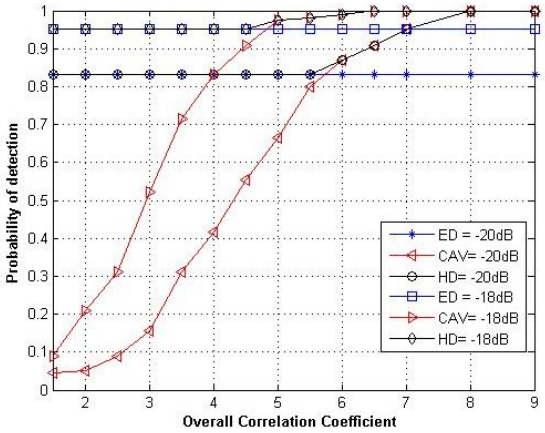

Figure 3: Probability of detection for ED, CAV and HD versus overall correlation coefficient for different values of SNRs with P_{fa} =0.1, L=9 and N=40000 in AWGN channel.

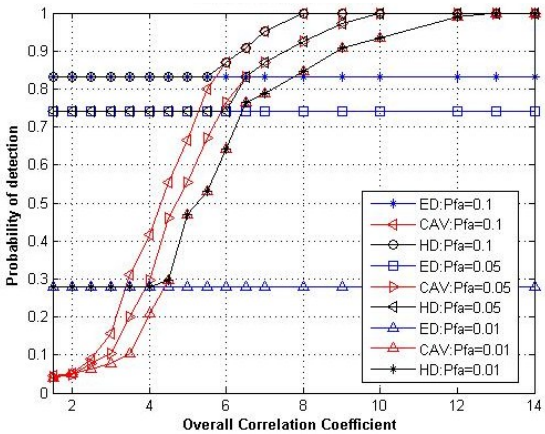

Figure 4: Probability of detection for ED, CAV and HD versus overall correlation coefficient for different values of P_{fa} with SNR= -20dB, L=9 and N=40000 in AWGN channel.

Fig.3 shows the performance of ED, CAV and HD in AWGN channel under different values of SNRs. Since ED does not depend on the overall correlation coefficient, there is a line parallel to x-axis. At SNR= -18dB and -20dB, ED gives probability of detection as 0.95 and 0.83, respectively, which is better than CAV at low value of correlation coefficient. For CAV depending on overall correlation coefficient, the probability of detection varies, which approaches to 1 at β_L =6.5 and 8 for SNR= -18dB and SNR= -20dB, respectively. It is noted that hybrid detection method is performing better in low correlation compared to CAV and ED in case of high correlation. The behavior near β_{HD} can be clarified as follows: depending on incoming signal correlation sometimes ED

is chosen and sometimes CAV is chosen based on $\beta_L \leq \beta_{HD}$ and $\beta_L \geq \beta_{HD}$, respectively. The same is true for SNR = -20dB.

Fig. 4 indicates probability of detection for ED, CAV and HD as a function of overall correlation coefficient for different values of P_{fa} with SNR= -20dB, L=9 and N= 40000 in AWGN channel. ED gives probability of detection for P_{fa} =0.1, 0.05 and 0.01 as 0.83, 0.74 and 0.28 respectively. For CAV depending on overall correlation coefficient, the probability of detection varies; which approaches to 1 at β_L = 8, 10 and 13 for P_{fa} =0.1, 0.05 and 0.01 respectively. It is noted that hybrid detection method is performing better in low correlation compared to CAV and ED in case of high correlation.

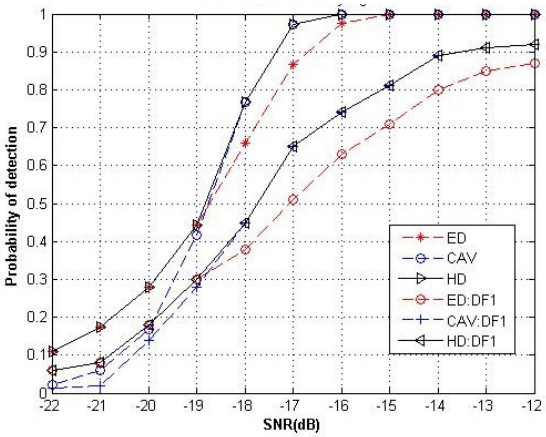

Figure 5: Probability of detection for ED, CAV and HD versus SNR with P_{fa}=0.01, L=6, β_L=2.5 and N=40000 under Rayleigh time-varying channel with DF1.The label ED,CAV and HD are of AWGN channel response value.

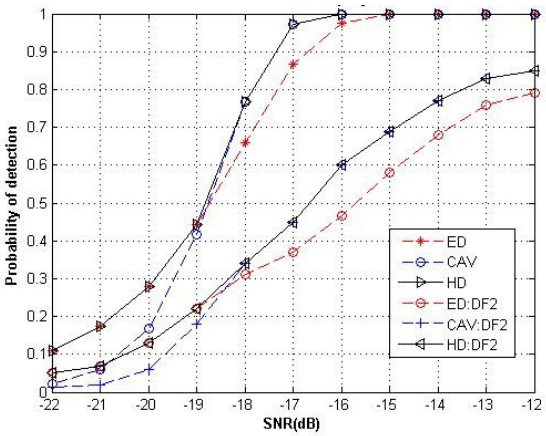

Figure 6: Probability of detection for ED, CAV and HD versus SNR with P_{fa}=0.01, L=6, β_L=2.5 and N=40000 under Rayleigh time-varying channel with DF2. The label ED, CAV and HD are of AWGN channel response value.

To check the performance of the methods for time-varying channels, the time-varying channel is generated based on the simplified Jakes' model with Doppler frequency DF1=100Hz and DF2=1000Hz for Rayleigh channel with P_{fa}=0.01, L=6, β_L = 2.5 and N=40000. Fig.5 and Fig.6 reflect the fact that the performance of ED and CAV degrades in fast time-varying compared to slow time-varying fading channels. The hybrid detection method takes the benefit of both the methods and performs better even in fast time-varying Rayleigh channel compared to ED and CAV methods.

For Rician channel, Doppler frequency of 100Hz with P_{fa}=0.01, L=6, β_L = 2.5 and N=40000 is considered.

Fig. 7 reflects its effect on the probability of detection for ED and CAV for K=1and K=10.Under time-varying Rician channel the performance of both the methods degrades compared to their performance in AWGN channel. The hybrid detection method exploits the advantage of both the methods and outperforms the two original methods. The probability of detection for ED, CAV and HD methods in case of Rician time-varying channel with K=10 is good compared to K=1.

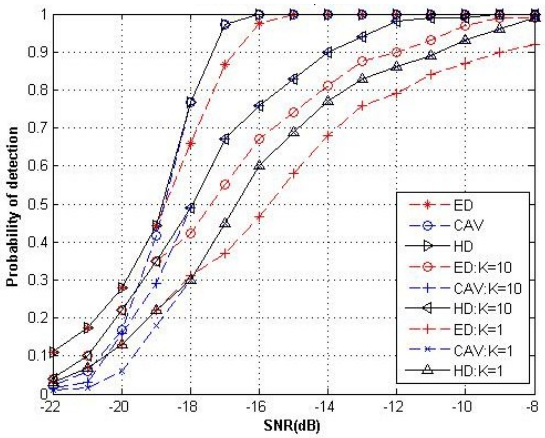

Figure 7: Probability of detection for ED, CAV and HD versus SNR with P_{fa}=0.01, L=6, β_L=2.5 and N=40000 under Rician time-varying channel with K=10 and K=1. The label ED, CAV and HD are of AWGN channel response value.

IV. CONCLUSIONS

The simulation based on ETSI -DVB-T signals have been carried out to evaluate performance of energy detection, covariance based detection and hybrid detection methods. Covariance based detection outperforms in high correlation environment. But in case of poor correlation even though SNR conditions are high, it performance is poor. The performance of energy detection and covariance based detection degrades in fast time-varying fading channels. The hybrid detection method becomes less sensitive to the signal correlation by taking the advantage of the both methods; by choosing energy detection in low correlation and covariance based detection in high correlation. Furthermore, in time-varying fading channels like Rayleigh and Rician, hybrid detection method outperforms the both original methods: energy detection and covariance based detection. The simulation results clearly indicate that hybrid detection method can be applied to upcoming IEEE 802.11af standard based on CR networks exploiting TV white space.

A Solution for BER Performance and Energy Efficiency Improvements of OFDM-CDMA System with Pilot Tone

U. Urosevic *, Z. Veljovic * and M. Pejanovic-Djurisic *
* University of Montenegro/Faculty of Electrical Engineering, Podgorica, Montenegro
ugljesa@ac.me

Abstract - In this paper, incorporation of MIMO concept is proposed as a solution for improving BER performance and energy efficiency of OFDM-CDMA downlink system with pilot tone and threshold detection combining (optimum TDC). The new presented system with MIMO included uses space-time block coding applied to two, three and four transmit antennas and it has an arbitrary number of receive antennas. BER (Bit Error Rate) performance in the case of Ricean frequency selective fading is evaluated for the original system as well as for the one with MIMO included. For that reason an adequate simulation model is developed. The results show that the proposed system significantly outperforms the OFDM-CDMA downlink system with pilot tone and optimum TDC. The proposed system provides greater energy efficiency and lower BER in comparison with the original system.

I. INTRODUCTION

Future mobile-radio systems should be able to cope with continuously increasing user demands for high bandwidth services and applications. Multi-carrier (MC) techniques represent an attractive solution for achieving high speed data transmissions. Additionally, increased downlink capacities can be accomplished by the combination of MC and code division multiple access (CDMA), [1]-[2]. If orthogonal subcarriers are used, this MC-CDMA scheme is known as orthogonal frequency division multiplexing (OFDM-CDMA), [3]-[4].

In the case of frequency-selective fading channel, received signals suffer from frequency distortion and thus orthogonality destruction occurs, thereby producing large multi-user interference (MUI). Frequency-domain equalization is necessary at the receiver to restore orthogonality among different users. In [1], OFDM-CDMA downlink scheme with pilot tone and threshold detection combining (optimum TDC) as a combining technique at the receiver is presented. It has been shown that optimum TDC outperforms orthogonal restoring combining (ORC) and controlled equalization combining (CEC). However, implementation of optimum TDC requires computation of optimum weighting coefficients for each SNR, and it is more complex than ORC and CEC.

The results presented in this paper are part of the "Performance analysis of OFDM based relay systems" bilateral research project, funded by Montenegrin Ministry of Science and Croatian Ministry of Science, Education and Sports .

Furthermore, in the scheme from [1], in order to improve BER performance transmitted power should be increased or the number of subcarriers used for transmitting single data symbol should be greater, i.e. wider frequency bandwidth is necessary.

Since energy efficiency improvement is one of the most actual problem and research activities on a global level, increasing transmitted power with the goal to decrease BER isn't acceptable solution. Also, radio spectrum available for mobile communications is a scarce resource thus one of the main targets in the design of radio access technologies is to optimize their spectrum efficiency.

In order to achieve better BER performance while providing greater energy efficiency and frequency resources utilization the OFDM-CDMA system from [1] should be improved. Multiple-Input Multiple-Output (MIMO) approach is very attractive for that purpose. MIMO technologies are nowadays fully integrated into existing systems, being always foreseen as a promising technology for future communication systems, due to their ability to provide increased data rates, greater energy efficiency, better reliability, improved spectrum efficiency, etc.

In this paper, MIMO with space-time block coding (STBC) is proposed as a solution for improving BER performance and energy efficiency of the OFDM-CDMA scheme from [1]. It is shown that, with the same transmitted power and spectrum efficiency, the proposed system achieves significantly lower BER than the original scheme. Moreover, the proposed scheme enables better BER performance even with the reduced frequency bandwidth, while retaining the same transmitted power. Also for the same values of BER the proposed system provides representative SNR gains. Besides better energy efficiency, reliability and spectrum efficiency, the presented solution has another advantage since the implementation of a very complex optimum TDC equalization technique is avoided.

This paper is composed in the following order. In Sect. 2 the proposed MIMO OFDM-CDMA system with STBC is described. Simulation model and results are presented in Sect. 3. Conclusions are drawn in Sect. 4.

II. SYSTEM MODEL

The transmitter of the proposed MIMO OFDM-CDMA downlink transmission system is shown in Figure 1. A single cell system with N users is assumed, with binary transmitted data mapped at the base station according to a chosen modulation scheme. The space–time block coder is implemented in order to collect a block of K successive symbols which are mapped into a sequence of L consecutive vectors $\mathbf{a}[l]=[a_1[l]\ldots a_{Mt}[l]]^T$, $0\leq l<L$. The code rate is $R_c=K/L$ and it is assumed that the mobile radio channel remains constant during one code block, [6]. In that way, M_t symbols for each l are assigned to M_t parallel branches, corresponding to transmit antennas. A sequence of pilot tones is implemented at each branch and it is multiplexed with coded data symbols. Further on, at each parallel branch the same signal processing is performed in a way that after spreading in frequency domain using F-length orthogonal spreading sequence $C^k_n(k)=\{-1, 1\}$, $k=0,\ldots, F-1$, $F\geq N$, signals originated from different users are summed.

Then, they are multiplied by a long pseudo noise (PN) sequence $c_{PN}(k)=\{-1, 1\}$, $i=1, 2,..., R$, $R>>F$, used to randomize the multi-user interference produced by partial orthogonality destruction due to imperfect frequency equalization. The sum of F modulated subcarriers forms the OFDM-CDMA waveform of length T_S. This process can be performed using the inverse fast Fourier transform (IFFT). Finally, a guard interval (GI) of length T_{guard}, is added to the OFDM-CDMA symbol, to form a resultant OFDM-CDMA symbol of length $T=T_S+T_{guard}$. The orthogonality of F subcarriers is achieved by assuring their frequency separation of $1/T_S$.

OFDM-CDMA symbols formed in the previously described way are then transmitted by M_t antennas. A receiver is equipped with M_r antennas. Thus, a MIMO channel is established and for the k-th subcarrier it can be described with the next channel coefficient matrix:

$$\mathbf{H}=\begin{bmatrix} h_{1,1}(k) & h_{1,2}(k) & \cdots & h_{1,M_t}(k) \\ h_{2,1}(k) & h_{2,2}(k) & \cdots & h_{2,M_t}(k) \\ \vdots & \vdots & \ddots & \vdots \\ h_{M_r,1}(k) & h_{M_r,2}(k) & \cdots & h_{M_r,M_t}(k) \end{bmatrix} \quad (1)$$

where $h_{i,j}(k)$ represents the channel coefficient between the transmit antenna j ($j=1, \ldots, M_t$) and the receive antenna i ($i=1, \ldots, M_r$).

Output signals $r_i(k)$ from receive antennas are given with:

$$\begin{bmatrix} r_1(k) \\ r_2(k) \\ \vdots \\ r_{M_r}(k) \end{bmatrix} = \mathbf{H} \begin{bmatrix} u_1(k) \\ u_2(k) \\ \vdots \\ u_{M_t}(k) \end{bmatrix} + \begin{bmatrix} n_1(k) \\ n_2(k) \\ \vdots \\ n_{M_r}(k) \end{bmatrix} \quad (2)$$

In relation (2) $u_j(k)$ represents a symbol transmitted from antenna j, while $n_i(k)$ is an additive white Gaussian noise (AWGN).

The receiver of the MIMO OFDM-CDMA downlink transmission system for the n-th user is shown in Fig. 2. After each receive antenna, received signal is converted into F parallel streams. Subcarriers demodulation is performed using the fast Fourier transform (FFT). Calculation of the channel coefficients is performed after the extraction of pilot sequence. This is necessary for space-time block decoding and frequency-domain equalization for the purpose of subcarriers' orthogonality restoration. That is followed by long PN sequence decoding, orthogonal spreading sequence decoding and symbol demodulation.

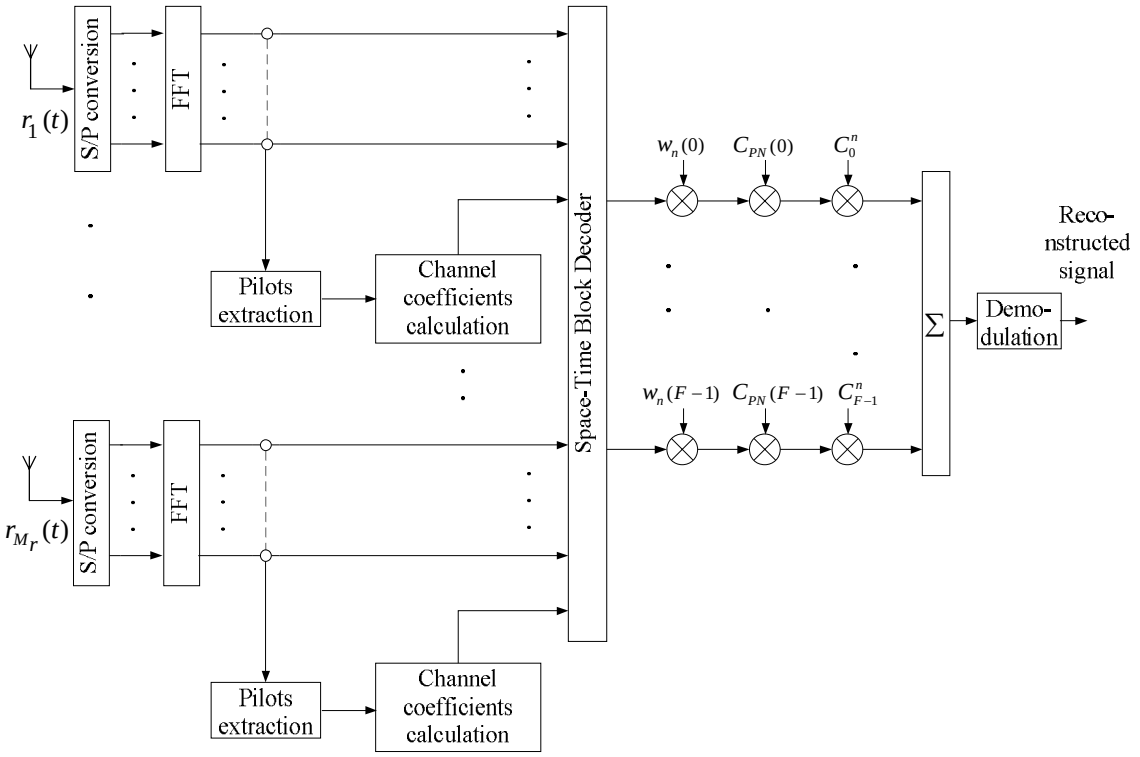

Figure 2. Receiver of the MIMO OFDM-CDMA downlink transmission system for the *n*-th user

III. Simulation Model and Performance Analysis

In order to analyze performance of the proposed MIMO OFDM-CDMA system, we have developed an original simulation model. It is based on the assumption that channels between the *j*-th transmit antenna and the *i*-th receive antenna are uncorrelated. In that case MIMO channel is modeled with M_tM_r Single-Input Single-Output (SISO) wireless channels. Propagation conditions are defined with Ricean fading statistics. For the given Ricean channel parameter (K_{dB}), the maximum delay spread (T_{max}), and the rms delay spread (T_{rms}), the simulation model generates one direct and many reflected waves for each channel.

Subcarriers from Fig. 1 are realized using the IFFT. In the simulation we have used QPSK modulation, Walsh Hadamard matrix whose rows represent orthogonal spreading sequences for every user, T_{max}=150 ns, T_{rms}=150/7 ns.

As it was said in Sect. 2, space-time block coding is implemented in the proposed system. For the purpose of simulation we have used STBC that can be applied to two, three and four transmit antennas and to an arbitrary number of receive antennas.

The space-time codewords arranged in space and time can be described using vector notations, [7]:

$$\mathbf{X}_2 = \begin{bmatrix} a_1 & -a_2^* \\ a_2 & a_1^* \end{bmatrix} \tag{3}$$

$$\mathbf{X}_3 = \begin{bmatrix} a_1 & -a_2 & -a_3 & -a_4 & a_1^* & -a_2^* & -a_3^* & -a_4^* \\ a_2 & a_1 & a_4 & -a_3 & a_2^* & a_1^* & a_4^* & -a_3^* \\ a_3 & -a_4 & a_1 & a_2 & a_3^* & -a_4^* & a_1^* & a_2^* \end{bmatrix} \tag{4}$$

$$\mathbf{X}_4 = \begin{bmatrix} a_1 & -a_2 & -a_3 & -a_4 & a_1^* & -a_2^* & -a_3^* & -a_4^* \\ a_2 & a_1 & a_4 & -a_3 & a_2^* & a_1^* & a_4^* & -a_3^* \\ a_3 & -a_4 & a_1 & a_2 & a_3^* & -a_4^* & a_1^* & a_2^* \\ a_4 & a_3 & -a_2 & a_1 & a_4^* & a_3^* & -a_2^* & a_1^* \end{bmatrix} \tag{5}$$

$\mathbf{X}_2$, $\mathbf{X}_3$ and $\mathbf{X}_4$ are codewords for systems with two, three and four transmit antennas, respectively. The columns comprise symbols transmitted at a certain time instant, while the rows represent symbols transmitted over a certain antenna.

In analyzing the proposed system, the instantaneous channel estimation for the *n*-th user at the *k*-th subcarrier frequency position, between the transmit antenna *j* and the receive antenna *i*, is taken to be $h^n_{i,j}(k)$. Thus, after space-time block decoding, frequency equalization weight factor at the *k*-th subcarrier frequency position, for the *n*-th user becomes:

$$w_n(k) = \frac{1}{\sum_{i=1}^{M_r}\sum_{j=1}^{M_t}\left|h^n_{i,j}(k)\right|^2} \tag{6}$$

Other simulation parameters are given in Table 1.

TABLE I. SIMULATION PARAMETERS

Modulation	QPSK
System capacity	50 Mb/s
Number of users	64
Subcarrier separation	$1/T_S$
Rice channel parameter (K_{dB})	4 dB

BER performance of the proposed MIMO OFDM-CDMA system is analyzed and compared with OFDM-CDMA system from [1] in different conditions, described with three simulation scenarios. In the first scenario, for both systems we assume the same number of subcarriers that are used for transmitting single data symbol, so the systems have identical spectrum efficiencies. In that manner it is possible to verify if the proposed scheme has better BER performance and energy efficiency while using the same frequency resources. In the second scenario, the spectrum efficiency of the proposed system is examined, so less subcarriers are used in the proposed scheme, i.e. smaller frequency bandwidth is occupied. The aim of this scenario is to investigate if the proposed system can achieve better spectrum efficiency while retaining the lower BER and greater energy efficiency. Finally, in the last scenario BER performance of both systems (with the same number of subcarriers) are compared taking into account Doppler spreading.

We have assumed that 128 subcarriers are used in both systems compared in the first scenario. BER performances over the average received SNR are depicted in Fig. 3 for the proposed system (M_t=2, 3 and 4 transmit antennas, M_r=1, 2, 3 and 4 receive antennas) and for the original scheme from [1].

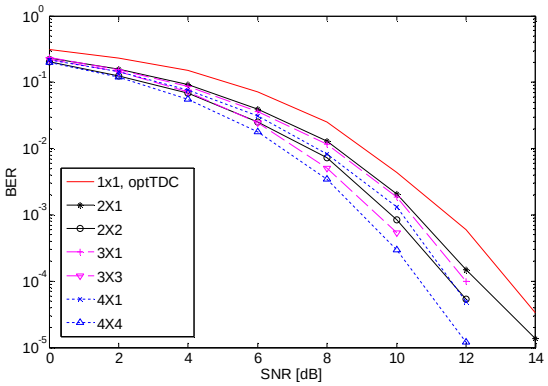

Figure 3. BER performance of the proposed system (M_t = 2, 3 and 4; M_r =1 , 2, 3 and 4) and of the original scheme

It can be seen from Fig. 3 that the proposed system achieves better performance especially in the region of medium and high SNRs. It is obvious that it even provides significantly lower BER when just two antennas at the transmitter side and one antenna at the receiver side are applied. For example, for the BER value of 10^{-4} the proposed system with M_t=2 transmit antennas and M_r=1 receive antenna, attains the SNR gain of around 1dB in comparison with the original scheme, while for the analyzed system with M_t=2 transmit antennas and M_r=2 receive antennas, this SNR gain is about 1,5 dB. In the case of M_t=4 transmit antennas and M_r=4 receive antennas the proposed system enables SNR gain of about 2 dB.

In the second scenario we have assumed that the proposed scheme uses less subcarriers than the original system. Fig. 4 shows BER performances of the proposed system (M_t=2 and 4 transmit antennas, M_r=1, 2 and 4 receive antennas) and of the original scheme from [1]. It has been assumed that 64 subcarriers are used in the scheme including MIMO, while the number of subcarriers for the original scheme is 128. From Fig. 4, it is clear that, despite using a smaller number of subcarriers, the analyzed system with M_t=2 transmit antennas and M_r=2 and 4 receive antennas, has better BER performance. Only the scheme with M_t=2 transmit antennas and M_r=1 receive antenna has slightly worse BER performance when compared with the original scheme. For M_t=4 transmit antennas the considered scheme provides lower BER in every case. The proposed system even with two times less number of subcarriers is more energy efficient than the original. For example, for the BER value of 10^{-3} the proposed system with M_t=4 transmit antennas and M_r=1 receive antenna, attains the SNR gain of around 0,5 dB in comparison with the original scheme, while for the analyzed system with M_t=4 transmit antennas and M_r=4 receive antennas, this SNR gain is about 1,5 dB.

Frequency shifts due to Doppler spreading were taken into account in the third scenario. For the various values of the normalized maximum Doppler frequency f_dT, BER performances of the proposed and the original scheme from [1], both with 128 subcarriers, are shown in Fig. 5. It can be seen that for the small frequency shifts the proposed scheme retains evidently better BER performance and energy efficiency. For example, for the BER value of 10^{-3} and f_dT=0.0002, the proposed system with M_t=2 transmit antennas and M_r=2 receive antennas, reduces the required SNR for around 1,5 dB in comparison with the original scheme, while for the BER value of 10^{-3} and f_dT=0.001 and the proposed system with M_t=2 transmit antennas and M_r=2 receive antennas, this SNR reduction equals around 1 dB.

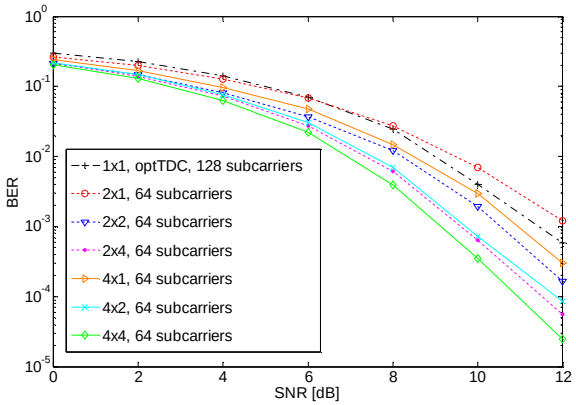

Figure 4. BER performance of the proposed system (M_t = 2 and 4, M_r = 1, 2 and 4) with 64 subcarriers and of the original scheme with 128 subcarriers

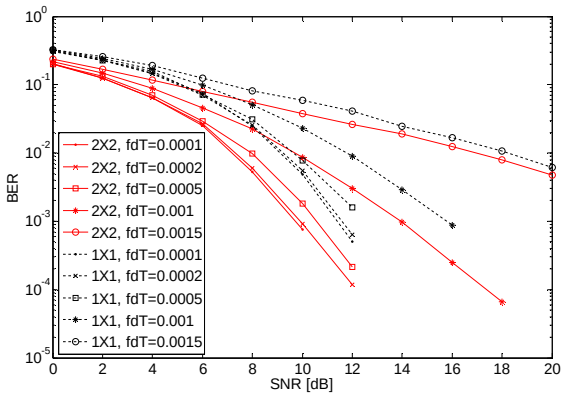

Figure 5. BER performance of the proposed system ($M_t = 2, M_r = 2$) and of the original scheme, in the case of Doppler spreading

Meanwhile, in the case of high frequency shifts, e.g. f_dT=0.0015, both systems have very poor BER performance with no real difference between them. Therefore, maintaining acceptable BER performance in these severe propagation conditions will be a subject of our further research activities.

IV. CONLUSION

In this paper, the MIMO OFDM-CDMA scheme was proposed as a solution for improving BER performance and energy efficiency of the OFDM-CDMA system with pilot tone and optimum TDC combining. Evaluations and comparisons between the proposed and the original systems were performed using the originally developed simulation model. Three different scenarios were analyzed.

In the first scenario, an equal number of subcarriers is assumed for both systems, with the goal to verify if the proposed scheme can provide better BER performance and energy efficiency while using the same frequency resources. It was shown that the proposed scheme significantly outperforms the original system, even when only two transmit antennas and one receive antenna are applied.

In the second scenario, besides BER performance and energy efficiency, the proposed scheme is analyzed from the point of its spectrum efficiency. Thus, it was shown that with a smaller number of subcarriers, i.e. with higher spectrum efficiency, the proposed system still provides noticeably better BER performance and energy efficiency.

In the last scenario, two schemes were compared taking into account the level of Doppler spreading. It was shown that for small frequency shifts the proposed system retains evidently better BER performance and energy efficiency.

Thus, it is evident that the proposed system can be considered as a good solution for BER performance and energy efficiency improvements of the OFDM-CDMA system with pilot tone. As it was shown, significantly lower BER, increased energy efficiency and frequency resources utilization can be achieved. Besides these improvements, another advantage of the proposed system is in avoiding implementation of the very complex optimum TDC equalization technique.

Abstract - The paper discusses the process of outdoor software prediction of radio wave propagation, practical realization of the simulation and measurement procedure and a comparative analysis of obtained results. In this regard, the Wireless InSite has been used to perform precise estimation of value and spatial distribution of total power and RMS of electric field strength. Handling by the Wireless InSite software and calculation of specified parameters, in frequency bands of 900 MHz and 1800 MHz, is briefly described. Practical realization of measuring of the same parameters, at the same locations and under the same circumstances as the simulation had, are also described. This has enabled detailed and relevant comparison of simulation and measurement results and ultimately verification of the Wireless InSite software using comprehensive analyses of quality and accuracy. The obtained results are also compared with the limits prescribed by the Rule 37/2008 on limiting the emission of electromagnetic radiation of the Council of the Communications Regulatory Agency of Bosnia and Herzegovina.

I. INTRODUCTION

In recent years, there has been an unprecedented increase in the use of devices emitting electromagnetic field (EMF). This influences on every aspect of day-to-day living. Due to significant public and media concern which continues to be expressed about increases in electromagnetic field exposure of people and potential-related adverse effects on health, it has been tried to perform the most precise prediction of the spatial distribution of EMF caused by 134 transmitters of 47 mobile telephony base stations at wide downtown area of Banja Luka, Bosnia and Herzegovina. In this purpose, Wireless InSite software package from U.S. Company Remcom has been used. Measuring procedure has been performed in two areas of downtown Banja Luka using Rohde&Schwarz spectrum analyzer FSH3. Simulation results are compared to measurements in order to check and verify the software. Results are also compared to the Rule 37/2008, which has been used to limit the electromagnetic emissions and determine the methods for RF emission measuring.

II. SIMULATION PROCEDURE AND RESULTS

A. About Wireless InSite Software

The program Wireless InSite [Ref.1] is a powerful electromagnetic modeling tool which applies physics-based propagation models to site-specific predictions in rural, urban and indoor environments. It also allows viewing and analyzing the predictions including the effects of buildings and terrain on the propagation of electromagnetic waves. This program predicts how the locations of the transmitters and receivers within an urban area affect signal strength, also models the physical characteristics of the rough terrain and urban building features, performs the electromagnetic calculations, and then evaluates the signal propagation characteristics. With only a few steps it is possible to import data for buildings, foliage, floor plans and terrain, define the antennas, specify the transmitter and receiver locations, select the desired output, and run the calculations.

The computations are ray based with reflections from ground (triangular pixels) as well as from building walls and roofs. Diffractions from corners and edges are calculated also. The software uses advanced high frequency electromagnetic methods to provide accurate results over a frequency range from approximately 50 MHz to 40 GHz.

Wireless InSite (WI) presents results in a number of ways. It provides visual representation of some results, such as transmitter coverage areas and power distributions, placing these visually within the modeled environment. The software is also capable of playing movies of time-domain E-field evolution. For other types of data, WI provides an advanced plotting system. Overlays of data allow quick comparison to imported measurements, or even previous calculations. The program allows many Output and Analysis files. Also WI offers possibility of real time (RT) overview. With the RT module, WI users have a choice between two options: high fidelity results very quickly, or extremely high fidelity results with a physics-based model [Ref.2].

B. Implementation of software simulation

This section describes prediction of the radio waves propagation and spatial distribution of EMF. For this purpose, a digital map of Banja Luka town (GISDATA production in GK6 and UTM34 map projections with different height systems) is used. GK6 is a projection that is officially used in B&H, while UTM projection is used at the global level and differs from our official projection. Digital orthophoto of treated area is a satellite image with resolution of 1m x 1m in .tiff format. Buildings and terrain data are provided in ESRI shape format, with the available terrain model resolution 20m x 20m and 10m height accuracy. As these formats could not be imported in WI, they have had to be converted into appropriate formats like DXF, Shape file, DTED, and USGS.

WI has modeled the physical characteristics of the building urban area, carried electromagnetic calculations, and estimated propagation characteristics of the signal defined. Data and parameters that should be imported and configured to perform the simulation refer to the following:

- City and terrain features
- Study area(s)
- Transmitters
- Receivers
- Materials
- Antennas
- Waveforms
- Requested output
- Output [Ref.1].

Structures of Banja Luka city have been imported in DXF file format. Total number of covered structures is 8243. Building material is concrete with the following dielectric half-space properties: permittivity 15, conductivity 0.015 and thickness 0.3 m. Terrain model has been created manually through the software option for creating a new terrain. Bearing in mind that urban environment has been analyzed; the material that is assigned to the ground surface is asphalt with the dielectric half-space properties: permittivity 5.72, conductivity 0.0005, thickness 0.2 m and roughness 0.

The size and location of a study area have been specified automatically in order to include the entire region defined by the terrain and building features. Transmitters, receivers and object falling outside the study area boundary have not been considered. The selected propagation model is Full 3D, which is the most complex from the viewpoint of computation time. This model places no restriction on object shape and includes transmission through surfaces. The selected ray tracing method is SBR (Shot-and-Bounce Ray). Ray paths are traced without regard for the location of specific field points. Rays are first traced from the source points. Some of them that hit building walls would be reflected and would continue to be traced up to the maximum number of reflections. For the particular application, rays are stopped when they hit the study area boundary.

In order to retain the phase of the electric field of each ray path when combining the fields to predict the received power and path loss, Sum-Complex Electric Field option under advanced Study area properties has been set to correlated. Therefore, Wireless InSite combines the ray paths, which follow nearly the same path through environment, with the phase. It then adds the powers of all the correlated groups.

Base stations (BS) have been created by combining a total of 134 transmitter (Tx) points, where each Tx point has been set independently. 47 base stations have been created on the observed area from the data submitted by the three operators: M:tel, HT Eronet and BH Telecom. Most of the base stations have three sectors, which have been created as three different Tx points, with the difference in orientation of about 120 degrees. Antenna radiation pattern has been assigned specifically for each transmitter. Transmitters have been located in virtual space using latitude and longitude. Most of them are mounted on poles on the roofs, fewer on poles located on ground. Input power has been set to the value determined by taking into account the antenna and Equivalent Isotropic Radiated Power, EIRP, of each sector.

Receivers have been created in the form of grid, which allows a large area to be easily covered. It is important to determine spacing between receiver (Rx) points. This value affects the "grid resolution" and quality of results. In particular case, it is impossible to work with a dense grid due to hardware limitations, large number of transmitters and complex city model. First step is to make a rough prediction in order to locate the points with the highest levels of electric field strength (EFS) and after that prediction should be performed with higher resolution in the region with the highest levels. The advanced Receiver Properties window contains a Noise figure value that has been set to 3dB. This value represents the contribution of the receiver itself to thermal noise at its output. It is the ratio of the thermal noise power at the output to that at the input.

The geometrically defined directional antenna beam is used by transmitters. The antenna pattern is specified by the: Vertical half-power beamwidth (°), Vertical first null beamwidth (°), Horizontal half-power beamwidth (°) and Horizontal first null beamwidth (°). These data have been inserted from antennas datasheet. In this case vertical half-power beamwidth takes values from 6.5° to 10°. Horizontal half-power beamwidth has been set to be 65°. Vertical and Horizontal first null beamwidth have been set to 180°. Maximum antenna gain, as an offset from the origin of the antenna indicating where the points is located within the array, takes values from 15.5 to 18, depending on the specific antenna. VSWR and temperature (K) have been set to 1 (which represents a perfect impedance match between antenna and transmission line resulting in no addition loss) and 293, respectively. Receiver threshold has been set to -100 dBm which determines which individual ray paths will be ignored when evaluating the power at an Rx point. Ray paths are ignored when their power falls beneath the set value.

Waveform in Wireless InSite allows adjustment of parameters that describe the signal radiated from the transmitting antenna. Selected waveform is Gaussian. Carrier frequencies are 900 and 1800 MHz.

C. *Prediction results*

Due to lack of space in this paper, Fig. 1 and Fig. 2 show only partial 2D and 3D orthographic views of spatial distribution of EFS, in the frequency bands 900MHz and 1800 MHz, respectively. Nevertheless, the treated area of downtown Banja Luka is actually 10 times larger than area shown in Fig. 1 and Fig. 2 (about 1 km²).

Receivers have been created in the form of 5m x 5m grid, in order to obtain the values of the EFS in the 115000 Rx points. In this paper only 80 Rx points located in areas marked in Fig.1 are considered.

Predicted EFS values are shown in the range of the spectrum of the rainbow colors according to the legend in the bottom of the image. Also, in the Table I and Table II below, together with measurements results, EFS values at Area 1 and Area 2 are shown, with corresponding Rx points on the left side. On this basis, it is evident that in the frequency band of 900 MHz , at Area 1 and Area 2, predicted EFS values are ranging from 0.1029 V/m to 1.7893 V/m and from 0.3448 V/m to 1.7203 V/m, respectively. Also, in the frequency band of 1800 MHz, these ranges are from 0.183 V/m to 2.82 V/m and from 0.42 V/m to 2.573 V/m, respectively.

III. MEASUREMENTS PROCEDURE AND RESULTS

A. *About Handheld Spectrum Analyzer R&S FSH3*

Measurements in Banja Luka town were performed using Rohde&Schwarz FSH spectrum analyzer with TS-EMF antenna system and RFEX software package [Ref.3, 4]. Spectrum analyzer R&S FSH3 provides measurement in the range from 100kHz to 3GHz, depending on the connected sensor antenna. When used in conjunction with

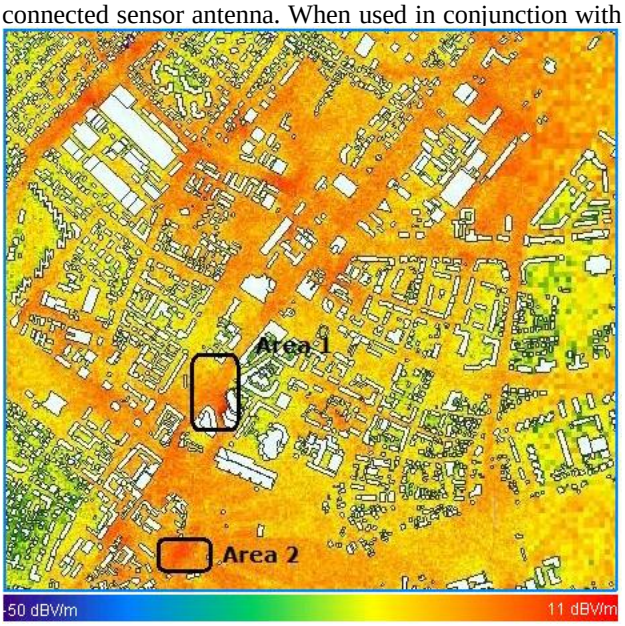

Fig. 1. 2D view of EFS at frequency 900 MHz, 5m x 5m

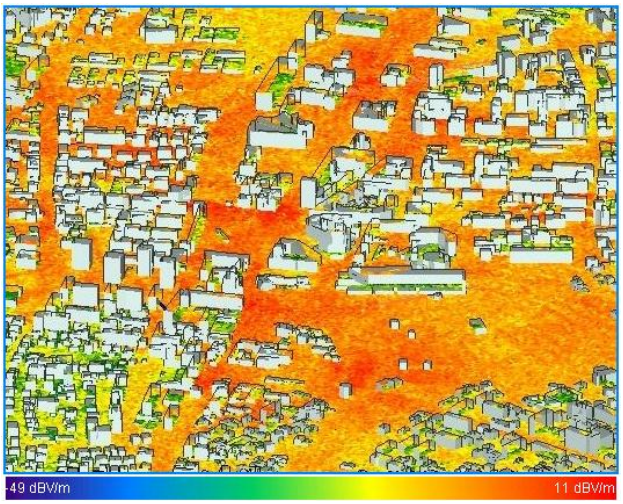

Fig. 2. 3D view of EFS at frequency 1800 MHz, 5mx5m

R&S TS-EMF isotropic antenna, the R&S FSH3 can determine the resultant field strength in the frequency range from 30MHz to 3GHz. The antenna has three orthogonal elements for measuring the resultant field strength. Measurement is performed in each axis individually and the overall field strength is calculated using the formula:

$$Er = \sqrt{E_x{}^2 + E_y{}^2 + E_z{}^2}\ . \qquad (1)$$

Transducer factors of each antenna element and antenna cable losses are compensated in the measurement. Transducer factors are specificity of antenna that comes together with TS-EMF antenna and they are entered into the R&S FSH3 with R&S FSH View Control Software.

Isotropic antenna is linked to the device by connecting RF cable with N connector to the input. Control switching cable between X, Y and Z axes with a 9-pin D-Sub connector is linked to the R&S FSH3 using connector probes. When antenna is linked with the device, is it necessary to activate each of the three transducer factors for X, Y and Z axes respectively before measurement performing. System R&S TS-EMF is operational with the software R&S RFEX. This software runs on PC or laptop. Interface cable supplied with the R&S FSH3 is used to connect the spectrum analyzer with a PC via COM port. For better accuracy, the system TS-EMF is supplied with individual calibration. Antenna factors for each axis are given in a table format and set in RFEX software. All measurements are fully automated using RFEX. In order to simplify the measurement process, measurement packages are predefined. Measurement packages define the parameters of signal being measured. For GSM and UMTS frequency list contains only channel frequencies on which base station broadcasts the signal. The user is able to define its frequency list to measure the signal characteristics and use created list in RFEX. To avoid damage, threshold calibration should be repeated after each measurement

package change, measurement settings change or cable replacement. Single measurement is the most common way of displaying the current value of measured size. The selected packages are measured once and the result is displayed on the screen. At the top of the report the sum value of each package and the total sum are shown. It also describes in detail the results for each frequency individually. The measured results are obtained in Excel of ASCII file, depending on RFEX setting.

B. Measurement results

Single measurements of EFS were performed at the same Rx points for which EFS values are predicted already, at a height of 1.5 m, in two areas indicated in Fig. 1. All results are, together with the prediction results, shown in Table I and Table II.

Measured EFS values, in the frequency band of 900 MHz, at Area 1 and Area 2, are ranging from 0.1503 V/m to 0.7876 V/m and from 0.2554 V/m to 1.8525 V/m, respectively. Also, in the frequency band of 1800 MHz, these ranges are from 0.4571 V/m to 3.8327 V/m and from 0.4947 V/m to 3.2811 V/m, respectively.

IV. COMPARISON RESULTS

Comparisons of the electric field strenght values, based on the prediction and measurements results, were made at points that are located within areas indicated in Fig. 1. For this purpose, results in the Table I and Table II, generated by Wireless InSite and R&S RFEX software, are used. Measured values were compared with the corresponding values obtained by WI prediction at the frequency bands of 900 MHz and 1800 MHz. Deviation diagrams are shown in Fig. 3.

Satisfactory similarity between results is observed by analyzing these results. It is obvious that the deviation is within a range ± 1 V/ m, except in the Rx points 40 and 44 , where the deviation is slightly larger. It is assumed that this is a result of inactivity of some of the base stations at the time of measurement. It is probably a BS "Micro Palace" located nearby, which contributes the most to the level of the electric field strenght at these points. Total EFS $E_{T,}$ caused by 2G BS radiation, using the values related to aforementioned frequency bands in Tables I and II, are calculated by using the formula

$$E_T = \sqrt{E_{900}{}^2 + E_{1800}{}^2}\ . \qquad (2)$$

Eventually, it must be stated that maximum measured value of electric field strength E_{max} = 3.85 V/m does not exceed the limit values E_{900} = 16.5 V/m and E_{1800} = 23.3 V/m for general population, prescribed by the Rule [Ref.5].

V. CONCLUSION

Satisfactory similarity between prediction and measurements results are, in a way, verification of the Wireless InSite software. It can be stated that Wireless InSite is accurate and very reliable urban wave propagation calculation tool for planning and designing mobile wireless networks.

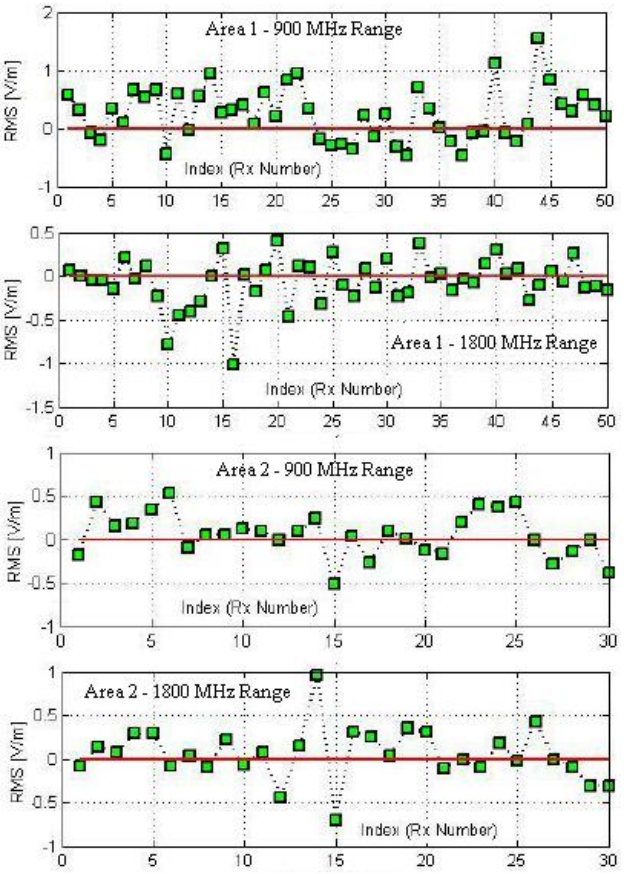

Fig. 3. Deviation diagrams: Predicted Values – Measurements Values

Such accurate and reliable prediction of the spatial distribution of EM fields on the entire territory of Banja Luka, will enable us in the future to locate places for the potential installation of sensitive measuring sensors, as the basic components of the future system for automated remote monitoring and storage of nonionizing EM field radiation.

Obviously, according to simulation and measurements results, it can also be stated that there is no danger to the health of the general population.

Abstract – It has been shown that cooperative communication schemes can solve many of the issues faced by future broadband WWAN and WLAN networks. It is about communication concept based on resource sharing and coordination among terminals in wireless network that provides significant performance improvements in terms of increased coverage, data rates, capacity, reliability, spectral and energy efficiency. This paper gives detailed overview of cooperative communication concept based on replacement of direct communication link between source and destination with several shorter links using network terminals called relays. Several, so called fixed relaying techniques, are described: amplify-and-forward fixed gain (AF FG), amplify-and-forward variable gain (AF VG) and decode-and-forward (DF). Appropriate analytical models for bit error rate and system capacity values are presented. Further on, assuming Rayleigh fading channels, comparison of the presented relaying techniques are performed, enabling identification of optimal signal transmission scenarios for cooperative communication systems.

I. INTRODUCTION

With the increasing demand for new smart services and applications, a significant focus is on the further development of wireless communication networks, so that the required high throughputs and energy efficiency will be provided. However, it is well known that wireless signal transmission imposes serious challenges in fulfilling those demands, due to the complex nature of wireless radio channel. Thus, in defining the adequate technical solutions for future broadband wireless networks, all relevant characteristics of this specific transmission medium have to be taken into account. That is why research efforts have been directed towards new solutions and techniques that would support high data rates and higher capacities of future wireless systems, with the better coverage and energy efficiency at the same time.

Cooperative communication concept based on resource sharing and coordination among units of wireless network, where one or more intermediate nodes (relays) intervene in the communication between a transmitter and a receiver can solve many of the issues faced by future broadband WWAN and WLAN networks. The idea of exploiting benefits of diversity systems by mutual cooperation among terminals originates from 1970s, [1]. It is about a concept that attains broader coverage by splitting the communication link from the source to the destination into several shorter links/hops. Since future wireless communications are likely to take place at higher and less congested frequency bands, where path loss is larger, and higher transmission powers are needed to keep the same coverage area, such concept is likely to be adopted in next generation systems. One of the main advantages of this communication technique is that it distributes the use of power throughout the hops, reducing the need to use a large power at the transmitter, which results in extended battery life and lower level of interference introduced to the rest of the network. Moreover, different energy aware schemes can be used to further save energy in transmitting data from the relays to the destination, such as different cooperative algorithms, power allocation, relay selection, sharing or distributing tasks among cooperating entities, etc.

This paper gives detailed explanations of relay aided communication concept. In its simplest form, a relay based system has just one relay station and the entire communication process between a source (S) and a destination (D) is performed over R, [2]. This represents *dual-hop* relay system with three communication terminals (Fig. 1), where R receives a signal from the source, performs adequate processing and after that transmits it towards the destination. In order to achieve full advantages of the relay implementation, it is necessary to obtain that the communication channel between S and R is orthogonal with the communication channel between R and D. The required orthogonality can be realized in the frequency domain, in the time domain, or using signals which are orthogonal in space-time constellation.

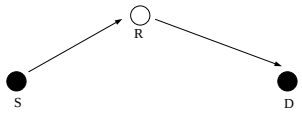

Figure 1. Dual-hop relay system

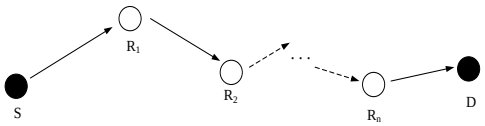

Figure 2. Multi-hop relay system

A relay system with three communication terminals represents the simplest example of relay aided communication network and it could be considered as a particular case of a multi-hop relay system. It is clear that an extended wireless link, covering greater distances between S and D, cannot always be successfully realized including just one R. If *n* denotes the number of relay stations participating in communication between S and D,

then the multi-hop relay system is characterized with the S-D communication link being divided into n+1 links (hops). There, each relay station communicates with the two neighboring terminals, as it is illustrated in Fig. 2.

The above mentioned dual-hop and multi-hop cooperative relay systems are basically introduced in order to better cope with the effects of severe propagation losses present in wireless communications over longer distances. At the same time, their implementation contributes towards overall capacity improvements of wireless systems, enabling extension of their coverage range by maintaining the message transmission in the areas where it would not be possible without relay stations. However, relaying concept could also be implemented in a form of diversity system, transmitting multiple signal replicas towards destination terminal. In a simple three terminals scenario, diversity is actually formed if additional direct communication link between S and D exist (Fig. 3).

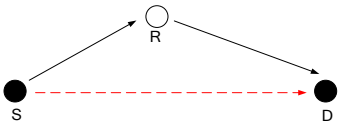

Figure 3. *Dual-hop relay system with diversity*

When this scenario with three communication terminals is considered, assuming that the orthogonality between S-R and R-D links is achieved in the time domain, i.e. that R operates in half-duplex mode, it is possible to identify different models for the realization of diversity transmission. Actually, as the communication process between S and D is divided in two time intervals, or two phases depending on terminals which participate in a particular phase, several models of this cooperative diversity could be recognized. Dual-hop relay system with diversity

Following growing interest for MIMO (Multiple Input Multiple Output) systems in wireless communications, additional focus has been directed towards relaying after presenting the idea of creating virtual MIMO system using single antenna relay terminals, [3]. MIMO systems, already incorporated in different wireless network standards, offer significant performance improvements of wireless systems characterized with the communication channel exposed to fading and other known impairments. However, a practical implementation of this concept might be a problem in certain conditions due to limitations related with placing multiple antennas on a single terminal. That is why virtual, or distributed, MIMO system has emerged as an interesting solution for obtaining benefits of MIMO concept in a scenario with single antenna terminals (Fig. 4).

Another option for incorporating relay systems in wireless environments can be created with wireless mesh networks, [4], which include mesh clients, mesh nodes and gateways (Fig. 5). In this configuration mesh nodes actually represent relay stations that can communicate with all neighboring terminals (nodes). Thus, the existence of such redundant communication links makes mesh networks highly reliable.

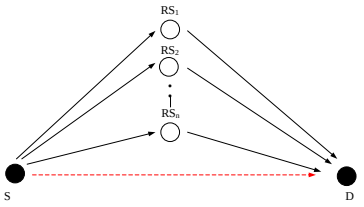

Figure 4. Virtual (distributed) MIMO

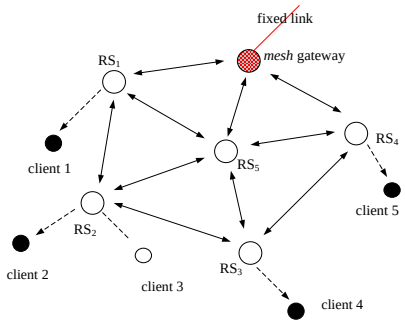

Figure 5. Mesh network

II. RELAYING TECHNIQUES

Performances of relaying systems highly depend on signal-to-noise ratio (SNR) of particular communication links, as well as the implemented signal processing method at the relay. With regard to algorithms of signal processing and forwarding applied at relay stations, relaying techniques can be classified as, [5]:

- Transparent relaying techniques that perform simple power scaling and/or phase rotation, i.e. linear transformation of a signal received at RS,
- Regenerative relaying techniques that include modifications of a signal waveform.

Transparent relaying techniques are Amplify-and-Forward (AF), Linear-Process-and-Forward, Nonlinear-Process-and-Forward. AF attracts most of the attention in relay systems considerations, where R receives a signal from a source, amplifies it and then forwards it towards a destination. In contrast with this approach, Decode-and-Forward (DF) is typical example of regenerative relaying technique. Thus, a relay station with DF first fully decodes a received signal, re-encodes it and then retransmits it towards a destination. Performances of the mentioned AF and DF relaying techniques highly depend on signal-to-noise ratio (SNR) of particular communication links, what can be considered as a limitation factor for identification of a generally optimal relaying technique. That is why a choice of an optimal relaying technique could be done only for a well defined specific communication scenario. When comparing the two relaying techniques AF and DF, considered as the most used ones, it can be noticed that AF is characterized with the simpler realization and less delay introduced at relay stations. On the other side, it has a significant disadvantage in the fact that amplifying a signal it amplifies a present noise as well. DF relaying has specific advantage as it allows completely separated optimizations of S-R and R-D links, due to the fact that the process of re-encoding at R could be done with a code

which is the most adequate for R-D link no matter what was a code used for signal transmission over S-R link.

Taking into account the importance of AF and DF relaying techniques that can be considered as bases for all the other signal processing and forwarding techniques used in relay aided communications, it is necessary to describe their behavior and performances in detail.

III. AMPLIFY AND FORWARD RELAY TECHNIQUE

As it has already been mentioned, Amplify-and-Forward (AF) relay technique represents one of the two basic methods used for processing a signal received at the relay station. Depending on the way the signal is amplified, the following types of AF systems can be recognized:

- AF with fixed gain (FG),
- AF with variable gain (VG).

In AF FG relaying, R amplifies the received signal always with the same level, no matter the actual conditions on the S-R link. On the other hand, in the AF VG system the relay station permanently estimates the S-R link and, depending on the channel state information, determines the level of signal scaling applied.

For the elementary configuration of a dual-hop relay system with three communication terminals, shown in Fig. 1, the signal received at R is given as:

$$y_R(t) = x(t)h_1(t) + n_1(t), \tag{1}$$

with $x(t)$ being a data symbol emitted by the source at the time instant t, $h_1(t)$ is the fading amplitude of the S-R channel and $n_1(t)$ is an additive white Gaussian noise, with variance N_{01}. The signal received at D depends on the way the signal is amplified.

A. AF With Fixed Gain

In AF relay systems with fixed gain G, the signal received at the destination can be represented with:

$$\begin{aligned} y_D(t) &= Gy_R(t)h_2(t) + n_2(t) \\ &= Gx(t)h_1(t)h_2(t) + Gn_1(t)h_2(t) + n_2(t), \end{aligned} \tag{2}$$

where $h_2(t)$ is the fading amplitude of the R-D channel at the given instant of time and $n_2(t)$ is an additive white Gaussian noise with variance N_{02}. The above relation (2) illustrates the following two important characteristics of AF FG systems: 1) if fixed gain G is neglected, the total fading amplitude at the time instant t introduced over the S-R-D channel can be obtained by multiplication of fading amplitudes on S-R and R-D links at the same instant of time, i.e. $h(t)=h_1(t)\cdot h_2(t)$, and 2) these systems are characterized with the cumulative propagation of noise from S to the destination. Usually, in the systems with the fixed gain, G is taken to be:

$$G = \sqrt{\frac{\dot{\sigma}_R}{\mathbf{E}\left[\left|y_R(t)\right|^2\right]}} = \sqrt{\frac{\dot{\sigma}_R}{\dot{\sigma}_S \mathbf{E}\left[\left|h_1(t)\right|^2\right] + N_{01}}}. \tag{3}$$

In (3), σ_R and σ_S denote energy of the symbols emitted by R and S, respectively, and E(·) is expectation operator. AF relay system which implementing this type of gain at relay station is usually called semi-blind AF relay system, or AF relay system with the average power limitation. There, it is assumed that R has information on the S-R channel statistics, i.e. on the average fading power, which is assumed to have relatively slow variations. Therefore, there is no need for continual estimation of the S-R channel. Using (2) for the analyzed AF relay system with fixed gain, the following expression for the instantaneous signal-to-noise ratio at D can be written, [6]:

$$\gamma_{end} = \frac{\gamma_{SR}\gamma_{RD}}{\frac{\dot{\sigma}_R}{G^2 N_{01}} + \gamma_{RD}}, \tag{4}$$

where:

$$\gamma_{SR} = \frac{\dot{\sigma}_S \left|h_1(t)\right|^2}{N_{01}} \text{ and } \gamma_{RD} = \frac{\dot{\sigma}_R \left|h_2(t)\right|^2}{N_{02}} \tag{5}$$

denote the instantaneous signal-to-noise ratios of the S-R and R-D links, respectively. Instantaneous SNR at the system receiving end is given with:

$$\gamma_{end} = \frac{\gamma_{SR}\gamma_{RD}}{1 + \overline{\gamma}_{SR} + \gamma_{RD}}. \tag{6}$$

$\overline{\gamma}_{SR}$ represents the average SNR of the S-R link.

Despite the fact that AF relay systems with fixed gain have come into research focus long after AF systems with variable gain, their performance have been analyzed in different communication scenarios, as well as for various types of communication channels, [6]-[8]. For dual-hop AF relay system, when S-R and R-D channels have Rayleigh narrowband fading statistics, the probability density function (PDF) and the moment generating function (MGF) of the end-to-end SNR is given in, [6]. PDF of SNR is:

$$\begin{aligned} f_{\gamma,end}(\gamma) = \frac{2e^{-(\gamma/\overline{\gamma}_{SR})}}{\overline{\gamma}_{SR}} \Bigg[\sqrt{\frac{\rho\gamma}{\overline{\gamma}_{SR}\overline{\gamma}_{RD}}} K_1\left(2\sqrt{\frac{\rho\gamma}{\overline{\gamma}_{SR}\overline{\gamma}_{RD}}}\right) + \\ \frac{\rho}{\overline{\gamma}_{RD}} K_0\left(2\sqrt{\frac{\rho\gamma}{\overline{\gamma}_{SR}\overline{\gamma}_{RD}}}\right)\Bigg], \end{aligned} \tag{7}$$

where $K_0(\cdot)$ and $K_1(\cdot)$ represent the zero order and the first order, respectively, modified Bessel functions of the second kind, and coefficient ρ is equal to:

$$\rho = G^2 \dot{\sigma}_R / N_{01}. \tag{8}$$

Knowing the PDF, MGF of the end-to-end SNR for dual-hop AF relay system with fixed gain is given as:

$$M_{\gamma,end}(s) = \frac{1}{(\overline{\gamma}_{SR}s+1)} + \frac{\rho\overline{\gamma}_{SR}s e^{\frac{\rho}{\overline{\gamma}_{RD}(\overline{\gamma}_{SR}s+1)}}}{\overline{\gamma}_{RD}(\overline{\gamma}_{SR}s+1)^2} E_1\left(\frac{\rho}{\overline{\gamma}_{RD}(\overline{\gamma}_{SR}s+1)}\right) \tag{9}$$

In the above relation $E_1(\cdot)$ denotes exponential integral function.

Knowing PDF and MGF of the received SNR, BER performance and capacity of AF FG relay systems can be analyzed. Upper bound of the average ergodic capacity for AF relay system with FG, and Rayleigh fading channel on both hops, can be defined as, [8]:

$$C = \frac{1}{2}\mathbf{E}\left(\log_2(1+\gamma_{end})\right) \le \frac{1}{2}\log_2\left(1+\mathbf{E}(\gamma_{end})\right), \quad (10)$$

where multiplication with 1/2 is introduced as a consequence of the fact that communication process is realized in two time intervals. Such definition of the average ergodic capacity represents the system capacity normalized over the unit bandwidth, for the channel which is considered as ergodic. Expectation of SNR at the system receiving end is:

$$\mathbf{E}(\gamma_{end}) = \overline{\gamma}_{SR} e^{\frac{\theta_R}{2\overline{\gamma}_{RD}}}\left[2W_{-2,\frac{1}{2}}\left(\frac{\theta_R}{\overline{\gamma}_{RD}}\right) + \sqrt{\frac{\theta_R}{\overline{\gamma}_{RD}}}W_{-\frac{3}{2},0}\left(\frac{\theta_R}{\overline{\gamma}_{RD}}\right)\right], \quad (11)$$

where $W_{k,\mu}(z)$ denotes Whittaker function, and coefficient θ_R is equal to:

$$\theta_R = \frac{\dot{\alpha}_R}{G^2 N_{01}}, \quad (12)$$

B. AF With Variable Gain

Using the relation (1) which describes the signal received at R, the signal at D of the AF relay system with variable gain can be represented with:

$$\begin{aligned} y_D(t) &= G(t)\,y_R(t)\,h_2(t) + n_2(t) \\ &= G(t)\,x(t)\,h_1(t)\,h_2(t) + G(t)\,n_1(t)\,h_2(t) + n_2(t). \end{aligned} \quad (13)$$

As it can be noticed, the applied gain is a function of time, having variations which follow changes of the S-R channel in accordance with:

$$G(t) = \sqrt{\frac{\dot{\alpha}_R}{\dot{\alpha}_S\left|h_1(t)\right|^2 + N_{01}}} \quad (14)$$

With Rs with variable gain, it becomes possible to compensate deleterious effects related with the signal propagation over S-R link, so that a relay station R always transmits the signal with the same power. That is the reason why AF relay system with this type of gain is also known as AF system with the instantaneous power limitation. It is clear that the AF VG system is more complex than the AF FG, as it requires permanent estimation of the S-R channel. Introducing the gain factor G(t) into (13), the fading amplitude of the whole S-R-D channel at the given time t is obtained as:

$$h(t) = \frac{\sqrt{\dot{\alpha}_R}\,h_1(t)\,h_2(t)}{\sqrt{\dot{\alpha}_S\left|h_1(t)\right|^2 + N_{01}}}. \quad (15)$$

The above given relation shows that end-to-end characteristics of uplink and downlink channels are not identical. Following the expression for the signal received at the destination (13), SNR at the receiving end of the system with variable gain can be defined with:

$$\gamma_{end} = \frac{\gamma_{SR}\gamma_{RD}}{1+\gamma_{SR}+\gamma_{RD}} \quad (16)$$

Analyses of the AF VG relay system, focused on its capacity as well as on its bit error rate, have been performed for different communication scenarios including dual-hop, multi-hop or cooperative diversity configurations, [9]-[11]. It has been shown that, even for the elementary dual-hop configuration, derivation of the closed form relation for the PDF of the received SNR, in AF VG relay system with Rayleigh narrowband fading statistics, might be very complex without certain approximations. That is why performance analyses of these systems usually assume that a relay station introduces variable gain $G(t)$ given as, [9]:

$$G(t) = \sqrt{\dot{\alpha}_R \Big/ \left(\dot{\alpha}_S\left|h_1(t)\right|^2\right)}. \quad (17)$$

The above given expression gives a relation for the received SNR which is much more suitable for further mathematical manipulations:

$$\gamma_{end} = \frac{\gamma_{SR}\gamma_{RD}}{\gamma_{SR}+\gamma_{RD}} \quad (18)$$

PDF of the above defined γ_{end}, in the assumed dual-hop scenario with Rayleigh fading statistics on each particular channel (hop), can be determined as, [9]:

$$\begin{aligned} f_{\gamma,end}(\gamma) &= \frac{2\gamma e^{-\left(\gamma/\overline{\gamma}_{SR}+\gamma/\overline{\gamma}_{RD}\right)}}{\overline{\gamma}_{SR}\overline{\gamma}_{RD}} \times \\ &\times\left[\frac{\left(\overline{\gamma}_{SR}+\overline{\gamma}_{RD}\right)}{\sqrt{\overline{\gamma}_{SR}\overline{\gamma}_{RD}}}K_1\left(\frac{2\gamma}{\sqrt{\overline{\gamma}_{SR}\overline{\gamma}_{RD}}}\right) + 2K_0\left(\frac{2\gamma}{\sqrt{\overline{\gamma}_{SR}\overline{\gamma}_{RD}}}\right)\right]. \end{aligned} \quad (19)$$

When the MGF of the received SNR is considered, for the assumed communication scenario and the case when $\overline{\gamma}_{SR} = \overline{\gamma}_{RD} = \overline{\gamma}$, it is given with, [9]:

$$M_{\gamma,end}(s) = \frac{\sqrt{\frac{\overline{\gamma}}{4}s\left(\frac{\overline{\gamma}}{4}s+1\right)} + \operatorname{arcsinh}\left(\sqrt{\frac{\overline{\gamma}}{4}s}\right)}{2\sqrt{\frac{\overline{\gamma}}{4}s\left(\frac{\overline{\gamma}}{4}s+1\right)^{3/2}}}. \quad (20)$$

Using the PDF of the received SNR given with (19) and (10), an upper bound of the average ergodic capacity of AF VG relay system, for Rayleigh fading statistics on both hops, is defined as, [8]:

$$\begin{aligned} \mathbf{E}(\gamma_{end}) = \frac{4\sqrt{\pi}\beta_R^2}{3,3233\left(\varepsilon_R+\beta_R\right)^3}\Bigg[&{}_2F_1\left(3,\frac{1}{2};\frac{7}{2};\frac{\varepsilon_R-\beta_R}{\varepsilon_R+\beta_R}\right) + \\ &+\frac{3\varepsilon_R}{\varepsilon_R+\beta_R}\,{}_2F_1\left(4,\frac{1}{2};\frac{7}{2};\frac{\varepsilon_R-\beta_R}{\varepsilon_R+\beta_R}\right)\Bigg]. \end{aligned} \quad (21)$$

In the above relation, coefficients ε_R and β_R are equal to:

$$\varepsilon_R = \frac{1}{\overline{\gamma}_{SR}} + \frac{1}{\overline{\gamma}_{RD}} \text{ and } \beta_R = \frac{2}{\sqrt{\overline{\gamma}_{SR}\overline{\gamma}_{RD}}} \quad (22)$$

while ${}_2F_1(\cdot,\cdot;\cdot;\cdot)$ is Gaussian hypergeometric function.

IV. DECODE AND FORWARD RELAY TECHNIQUE

Decode and forward (DF) technique in dual-hop relay communication system is performed over two completely separated subchannels, since R first decodes the signal received from S and then the signal is re-encoded at R and transmitted to the destination. If the signal received at RS is represented as in (1), then the signal received at the destination becomes:

$$y_D(t) = \hat{x}(t)h_2(t) + n_2(t), \quad (23)$$

where $\hat{x}(t)$ denotes an estimation of the signal $x(t)$, obtained at R. Decoding process which is applied at R introduces evident system performance improvements since the total noise at the destination is decreased when compared with AF relay systems. At the same time, it becomes possible to implement modulation schemes at S-R and R-D links which are not necessarily identical, so that optimal modulations can be applied in accordance with SNR levels at particular links. Thus, communication process is divided in two asymmetric time intervals, where the longer time interval is always dedicated to the communication process over the link with smaller SNR. This presents another advantage of the system with DF relaying, when compared with AF systems, and it is clear that it leads towards better BER performance. On the other side, DF signal processing at R can be at the origin of certain drawbacks in the case of channels with severe fading. When BER is concerned, degradation appears if there is an error in the decoding process engaged at the relay station, since erroneously decoded symbols are then further transmitted to D. There is no doubt that characteristics of R-D link can also contribute to overall BER performance degradation of DF relay system, as additional errors might be introduced in the signal recuperation at terminal D. In order to reduce those negative implications of the error propagation and to improve BER performance, different encoding schemes for error detection and correction can be applied in the process of signal regeneration at DF relay stations, [12].

When achievable capacity of DF dual-hop relay system is concerned, it is of the uttermost importance to notice that it is limited with the characteristics of the worse of the two links engaged in the communication process. Namely, ergodic capacity of DF dual-hop relay system can not be higher than the ergodic capacity of the link (S-R or R-D) which has the lower instantaneous signal-to-noise ratio, i.e.:

$$C = \frac{1}{2}\min\left\{\log_2(1+\gamma_{SR}),\ \log_2(1+\gamma_{RD})\right\} \quad (24)$$

Knowing ordered statistics of random variables, and Rayleigh fading channel on both hops, capacity of dual-hop DF relay systems can be analyzed. Assuming equal average SNR at both hops, $\overline{\gamma}$, ergodic capacity for DF can be defined as:

$$C = \frac{1}{2\log(2)}\exp\left(\frac{2}{\overline{\gamma}}\right)E_i\left(\frac{2}{\overline{\gamma}}\right) \quad (25)$$

V. PERFORMANCE ANALYSIS OF RELAY SYSTEMS

BER of the wireless communication system can be determined using the known MGF of SNR at the system receiving end, [13]. Thus, for example if DPSK (Differential Phase Shift Keying) modulation is applied, bit error rate is defined with:

$$P_b = 0,5M_{\gamma,end}(1), \quad (26)$$

Introducing (9), or (20) into (26), BER expressions for dual hop AF FG and AF VG relay system are obtained, in that both channels are characterized with Rayleigh fading statistics.

In DF relay systems a signal is transmitted over two cascade links and its decoding is done twice. If the transmission implies a binary signal with two possible symbol states (DPSK or BPSK), an error will appear at the final destination terminal only if an error in the signal detection is performed once (either on the first or on the second link):

$$P_b = 1-\left[(1-P_{b1})(1-P_{b2})+P_{b1}P_{b2}\right] = P_{b1}+P_{b2}-2P_{b1}P_{b2}, \quad (27)$$

where P_{b1} and P_{b2} are bit error rates at the first and the second link (hop), respectively. When DPSK is assumed, probability of error for each of the links is given with (26) and, for Rayleigh fading statistic on both links, the overall BER is obtained in the form:

$$P_b = \frac{1+\overline{\gamma}_{SR}+\overline{\gamma}_{RD}}{2(1+\overline{\gamma}_{SR})(1+\overline{\gamma}_{RD})}. \quad (28)$$

Fig. 6 illustrates BER graphs for DPSK modulated DF, AF FG and AF VG dual-hop relay systems operating in the assumed scenario with Rayleigh narrowband fading statistics on S-R and R-D links. It is assumed that the average SNR of the S-R link is equal to the average SNR of the R-D link, i.e. $\overline{\gamma}_{SR} = \overline{\gamma}_{RD}$.

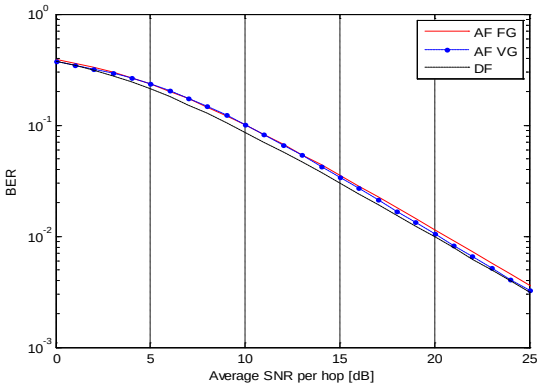

Figure 6. BER performance comparison for AF and DF dual-hop relay systems

Graphs presented in Fig. 6 give interesting and in a certain manner surprising results, since differences among BERs for the three systems considered are unexpectedly small, having in mind considerable differences related with the complexity of the systems and their implementations. Still, it can be seen that DF relay technique has the best BER performance. However, even when compared with AF FG system which has the worst

BER performance, SNR gain does not overpass 0.5dB for the whole range of BER values analyzed. At the same time, for higher SNRs per hop (over 24dB), BER results for AF VG relay system are identical with the ones obtained for DF relay technique.

In order to gain a complete insight into benefits and trade-offs related with the choice of a particular signal processing/forwarding technique applied at relay stations, it is necessary to take into account achievable capacity as well. Fig. 7 shows appropriate graphs for ergodic capacity of AF FG, AF VG and DF relay systems. Presented results are obtained by simulation under assumption that S-R and R-D links are characterized with Rayleigh narrowband fading statistic with the average SNR at the first hop being equal to the average SNR at the second hop.

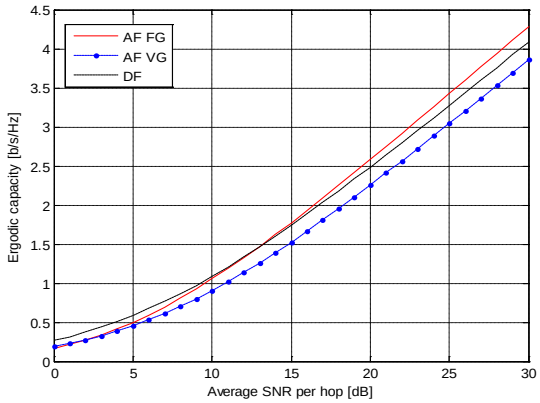

Figure 7. Comparison of ergodic capacity of dual-hop relay systems

It can be clearly noticed that AF VG relay system achieves the lowest ergodic capacity for the whole range of SNRs per hop, excluding very small SNRs (up to 2.5dB) where its capacity performance is slightly better when compared with AF system with fixed gain. DF relay system has the highest ergodic capacity for SNRs per hop bellow 12.5dB, while for higher SNRs it is AF FG system which has the best values of ergodic capacity. Thus, for example, the presented graphs show that for ergodic capacity being equal to 3b/s/Hz, AF FG relay system has SNR gain of almost 1dB in comparison with DF relay system, while its SNR gain in comparison with AF VG relay system is a bit less than 2.5dB.

In addition, authors in [14] considered the case when the links are highly unbalanced in terms of their average fading power. In that case, optimal power allocation enhances the system performance, in terms of BER and outage probability. Interestingly, they also show that nonregenerative systems with optimum power allocation can outperform regenerative systems with no power optimization, i.e. same performance can be obtained with less power.

VI. CONCLUSIONS

This paper gives detailed explanations of relay aided communication concept, with the description of techniques applied for the message processing and/or forwarding at the relay nodes. Assuming a wireless channel with Rayleigh fading, comparisons of the presented relaying techniques are performed, enabling identification of optimal signal transmission scenarios for cooperative communication systems.

Following the description of individual relaying techniques, as well as the comparison of theirs BER and capacity performances presented in this paper, it is quite clear that it is not possible to identify a technique which would be absolutely superior in terms of performances for the whole range of SNR values. However, depending on characteristics of S-R and R-D links and on a performance being of interest for a specific communication process, there is always a possibility to assume which of the three analyzed systems will provide the best transmission quality and reliability.

In addition, it has been stated that one of the main advantages of such system is that it distributes the use of power throughout the hops. This implies more energy efficient system that will provide longer battery life and lower interference introduced to the rest of the network. Furthermore, it enables power allocation strategy that can further enhance the system performance and energy efficiency.

Abstract - Paper deals with NN compensated odd symmetric nonlinear actuators. Most actuators are nonlinear sporting odd symmetric nonlinearities such as deadzone and saturation. One of ways of dealing with such actuators is to try to compensate for nonlinearities by static neural networks. Compensated actuators can improve behavior of the system, but then arises the problem of stability analysis because compensated nonlinearity is now complex nonlinearity not described in common literature. One way of dealing with such problem is to perform stability analysis via describing function method. Paper describes the method for compensating nonlinearities, recording describing function and performing stability analysis.

I. INTRODUCTION

In all control systems there are present actuators. Virtually all of them have nonlinearities. Depending on the control system these nonlinearities can be neglected or one has to deal with them in some way. Nonlinear control theory is reach with different methods of compensation or stability analysis of systems with nonlinear actuators ([9],[11],[12]).

Many actuators have odd nonlinearity followed by linear filter type element. Examples are many electrical motors, hydraulic cylinders and solenoid actuators. There are different methods for dealing with such systems (introduction of ditter signal, different anti wind-up schemes etc,), This paper deals with such nonlinearities compensated with simple neural network. More precisely, paper deals NN compensated nonlinearities of type dead zone, saturation and deadzone with saturation.

II. ACTUATOR WITH ODD NONLINEARITY

Many actuators with odd nonlinearity can be represented by structure shown in Figure 1.

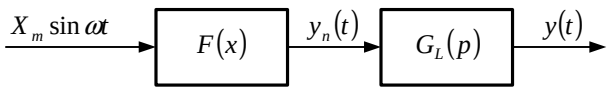

Figure 1. Actuator represented with decoupled nonlinear F(x) and linear parts $G_L(p)$, p=d/dt

Nonlinearity F(x) can be any odd type nonlinearity and we will deal with saturation and dead zone as shown in Figure 2 and Figure 3.

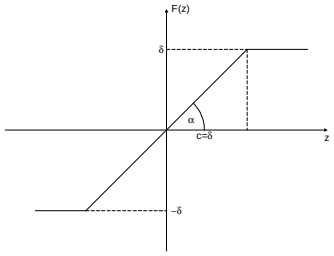

Figure 2. Saturation

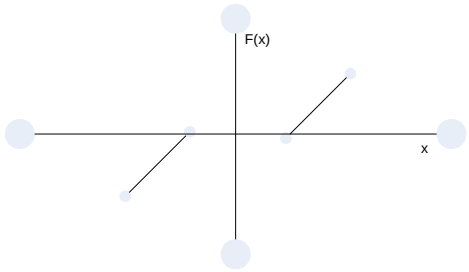

Figure 3. Dead zone

Linear part of the system $G_L(p)$ can be any linear system as long as it is of low-pass filter type, i.e. it will damp higher frequencies.

III. DESCRIBING FUNCTION

Describing function is an equivalent gain of nonlinear element, defined by the harmonic linearization method of nonlinear static characteristic ([2], [9], [10], [11], [12] and many others). It is a known method of analysis and synthesis when nonlinear system can be decoupled into linear and nonlinear parts. If the linear part of the system has the characteristics of low-pass filter and if we apply periodical signal to the system, output signal will have the same base frequency as input signal with damped higher frequencies.

If the amplitudes of higher harmonics are relatively small when compared to the amplitude of the first harmonic, i.e. if filter hypothesis holds, output signal can be approximated by it's first harmonic. Mathematically, first harmonic of the output signal, for the sinusoidal input signal $X_m \sin \omega t$, can be expressed by Fourier expressions:

$$\begin{aligned} y_N(t) &\approx Y_{P1} \sin \omega t + Y_{Q1} \cos \omega t \\ y_N(t) &\approx \mathrm{Im}\left\{\left(Y_{P1} + jY_{Q1}\right) e^{j\omega t}\right\} \end{aligned} \tag{1}$$

$$Y_{P1} = \frac{1}{\pi} \int_0^{2\pi} F(X_m \sin \omega t) \sin \omega t \, d(\omega t) \tag{2}$$

$$Y_{Q1} = \frac{1}{\pi} \int_0^{2\pi} F(X_m \sin \omega t) \cos \omega t \, d(\omega t) \tag{3}$$

where Y_{P1} and Y_{Q1} are first Fourier coefficients. Describing function is the ratio between first harmonic of the output signal and input signal in complex form:

$$G_N(X_m) = P(X_m) + jQ(X_m) = \frac{Y_{P1}}{X_m} + j\frac{Y_{Q1}}{X_m} \tag{4}$$

where $P(X_m)$ and $Q(X_m)$ are coefficients of the harmonic linearization ([2], [9], [10], [11], [12] and many others).

IV. Determination of Describing Function

Determination of describing function boils down to the determination of integral expressions for the known static characteristic of the nonlinear part of the system.

There are many conventional nonlinearities for which static characteristics and describing functions are theoretically derived and given in analytical form.

The problem arises when the static characteristic of nonlinear system cannot be analytically expressed or integral expressions cannot be solved. In that case describing function can be determined by experiment or simulation ([3][4][5][6][7][8]) or some method of numerical integration ([10]).

In this work we will use numerical integration in Simulink as given in [10]. The approach is very simple, yet effective. In essence, equations (2) and (3) are directly applied in Simulink on nonlinear element outputs. A simulation scheme adapted from Schwartz is given in Figure 4. In this case dead zone nonlinearity is analyzed. Instead of dead zone, any other nonlinearity can be included in model.

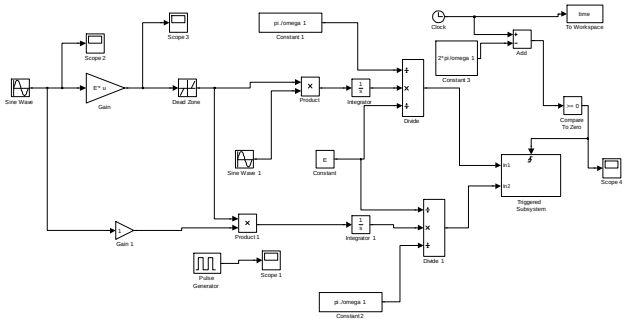

Figure 4. Simulink model 'csm' for generating describing function (Schwartz)

Model is called from Matlab script (adapted from [10] as well) as shown in Figure 5. Simulation parameters are passed to Simulink schematic from Matlab script, as given in Figure 6.

Figure 5. Matlab script for describing function generation

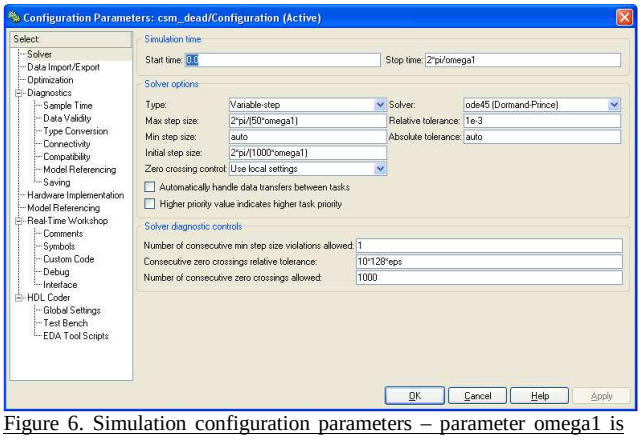

Figure 6. Simulation configuration parameters – parameter omega1 is taken form Matlab script

Triggered subsystem is shown in Figure 7. The whole file is built to stop simulation after one full period for a given frequency. This scheme can work for any nonlinearity and will yield 3 dimensional graphical representation of Y_{P1} and Y_{Q1}. Procedure will be later illustrated and the example of system with neural network. This approach can be used Matlab real time software and hardware for physical measurements. Of course Matlab script needs be adapted in similar way as it will be shown

later for NN, i.e. Simulink model will not take vector inputs E and omega at once.

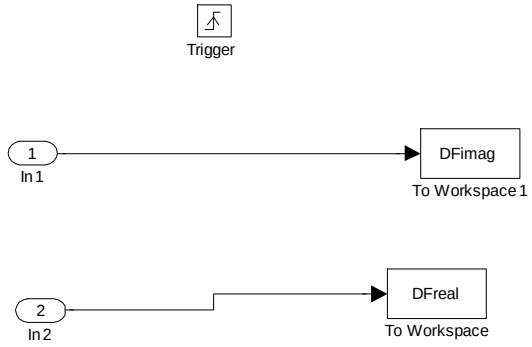

Figure 7. Triggered subsystem

V. NN Compensated Odd Symmetric Nonlinear Actuator

In this section we describe simple compensation of nonlinearities via neural network. We deal with actuator with architecture shown in Figure 1. It is important that in practice $y_n(t)$ is measurable. This is often the case because many motor drives and hydraulic drives have nonlinearity in part of their electronic driver and this value can be measured. We then connect an in input with changeable amplitude and measure and save inputs and outputs. Once this is done we will use recorded data to train simple neural network in such way that we try to achieve neural network that will have opposite action to nonlinearity.

Let us illustrate the procedure on dead zone nonlinearity.

We used Simulink model as given in Figure 8 to generate data needed for neural network training.

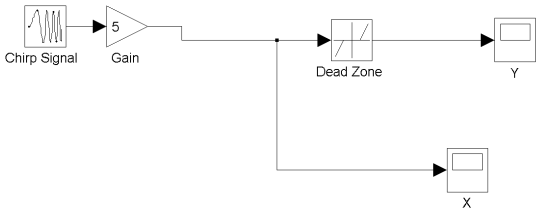

Figure 8. Data generation

Datasets X and Y were generated using chirp signal generator with starting frequency 0.1 Hz, final frequency 20 Hz and simulation end time 1000s with fixed step size 0.001. Dead zone is static nonlinearity so frequency really does not have effect on it but we used chirp signal in order to generate a number of different data points.

Now, we used dataset Y as network input and dataset X as network output for training. There are many tools available for neural network training. Here, Matlab neural networks toolbox was used. Feed forward network had two layers, first layer with seven nodes and sigmoid tangent activation function and one node in output layer with linear gain activation. Network was trained for seven hundred epochs with gradient descent with adaptive learning rule backpropagation.

Comparison between neural network and data set is given in Figure 9, where dataset is in blue and network output in red. It can be seen that NN putput has higher values than deadzone output, i.e. deadzone effect is somewhat compensated with neural network.

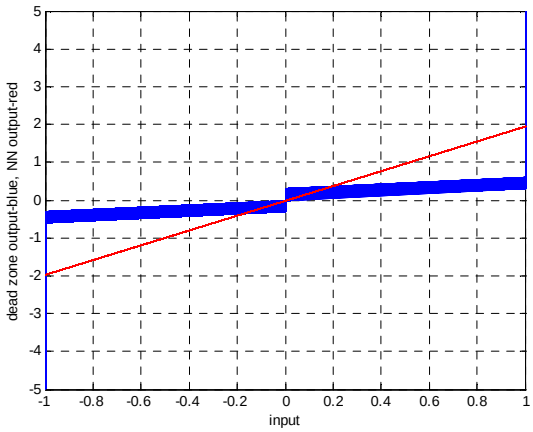

Figure 9. Comparison between data set and NN output

With trained neural network we can compensate for dead zone as shown in Figure 10

Figure 10. NN nonlinearity compensation

where NN stands for neural network and F(p) is nonlinearity. The idea is that neural network compensates for some effects of nonlinearity since neural network is trained to act as inversion of nonlinear function.

However, realizing neural network sometimes can be complicated. One possibility is to replace the neural network with its describing function. We will use numerical integration as given in [10]. Simulation script has to be changed a bit since with neural network we cannot use vector inputs. Redone script is done in Figure 11.

Figure 11. Matlab script for neural network describing function generation

This script will result with graphic presentation of describing function in 3D. Since nonlinear element is odd and time independent so it is neural network. Thus, we need only 2D representation of describing function. Furthermore, we can represent this graphic describing function by polynomial. In this case we used third order polynomial and represented the neural network describing function with polynomial $G_{NN}(x)$:

$$G_{NN}(x) = a_3 x^3 + a_2 x^2 + a_1 x + a_0 \qquad (5)$$

Describing function of neural network and its polynomial representation for dead zone with start and end of dead zone equal to 1 are shown in Figure 12.

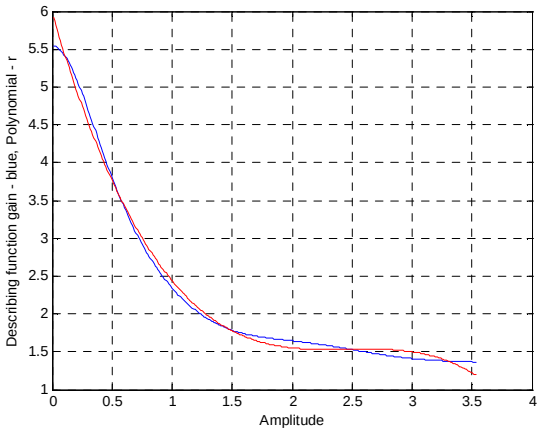

Figure 12. Neural network describing function and its polynomial approximation for dead zone

Polynomial approximation is easier to realize than neural network, i.e. we can use simpler hardware to do so.

We will now see how this system performs for simple closed loop circuit. Simulink simulation circuit is shown in Figure 13.

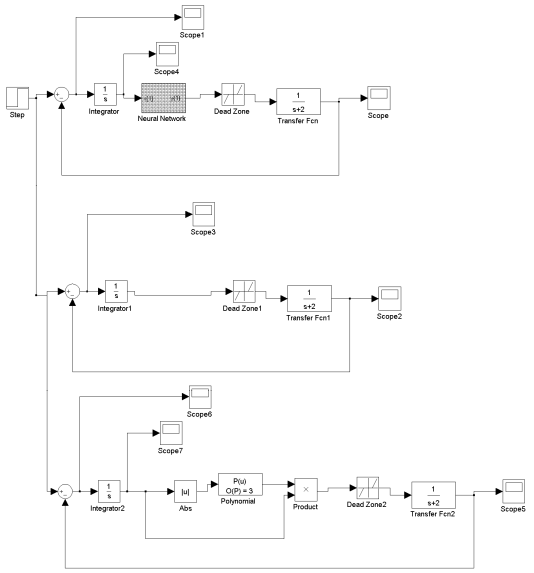

Figure 13. Simulink simulation file

Simulation results for step input 1.7 are shown in Figure 14.

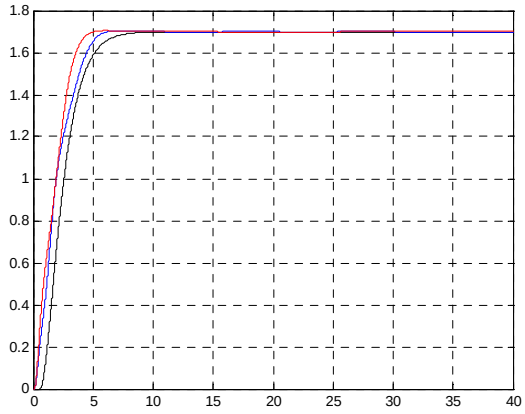

Figure 14. Simulation responses for step input 1.7

Output of non-compensated system is shown in black, response of system compensated with neural network is shown in blue and response of system compensated with polynomial approximation of neural network in red. It can be seen that compensated system has better response and reaches the reference value faster.

The same procedure can be performed for compensating any odd symmetric nonlinearity. For example, neural network describing function and its 3rd order polynomial approximation for saturation with upper and lower limit equal 0.5 are shown in Figure 15.

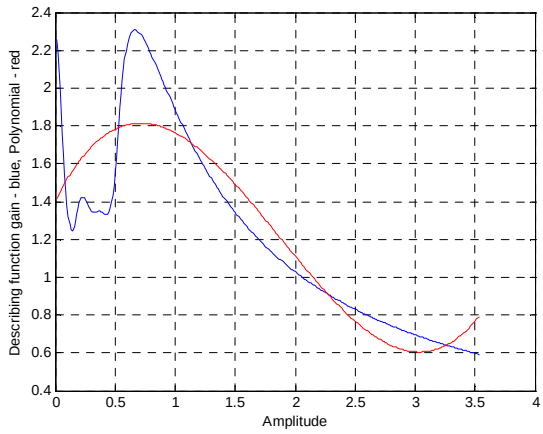

Figure 15. Neural network describing function and its polynomial approximation for saturation

Simulation results for step input 0.5 are shown in Figure 16.

Output of non-compensated system is shown in black, response of system compensated with neural network is shown in blue and response of system compensated with polynomial approximation of neural network in red. It can be seen that compensated system has slightly better response and reaches the reference value a bit faster.

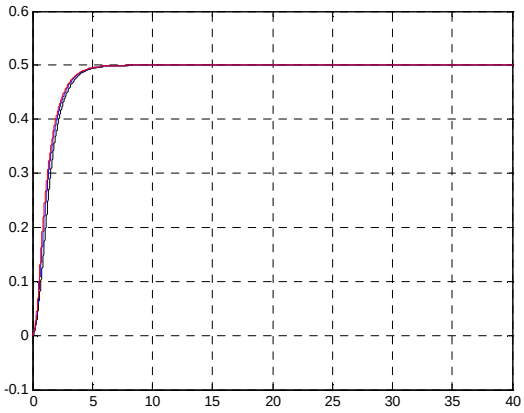

Figure 16. Neural network describing function and its polynomial approximation for saturation

VI. Stability Analysis of NN Compensated Odd Symmetric Nonlinear Actuator

It is clear that when we make compensation of nonlinearity with neural network or neural network polynomial approximation in essence we have a new nonlinearity as shown in Figure 17.

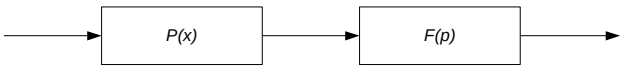

Figure 17. Compensated nonlinearity

With compensated nonlinearity we can record describing function using method given in Section IV. In this example we recorded describing function of deadzone compensated with polynomial for parameters already given in this paper. Describing function is shown in Figure 18.

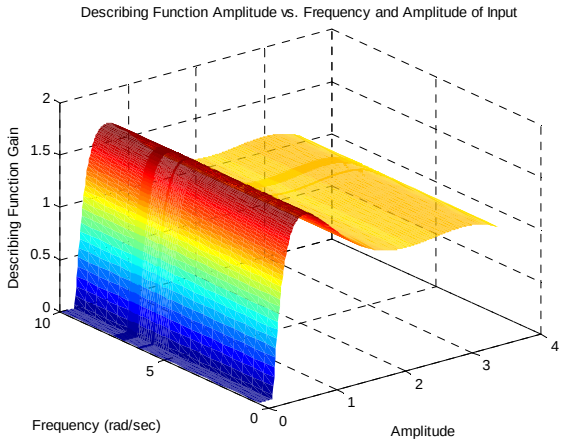

Figure 18. Describing function – compensated dead zone

Characteristic equation of closed loop system with compensated nonlinearity as shown in Figure 13 can be written as

$$s^2 + Ks + G = 0 \tag{6}$$

where G is describing function of compensated nonlinearity and K is linear parameter system of actuator transfer function represented by

$$\frac{1}{s+K} \tag{7}$$

Once we have describing function we can use any stability criterion we use for linear systems. By Hurwitz criterion the system will be stable if

$$KG > 0 \tag{8}$$

Since K is always positive, system will be stable if G>0. In case of our system with dead zone that is always the case, thus the system is stable. The same analysis can be conducted with other types of nonlinearity.

VII. Conclusion

Paper gives the procedure for training neural network to act as compensator for odd symmetric nonlinearities. It is shown how to record the describing function of such neural network. In cases that available hardware cannot deal with neural network we can use neural network describing function polynomial approximation to control the systems with odd symmetrical nonlinearities.

Finally, a simple procedure for analyzing stability of such systems is given.

Hydroelectric Power Unit Simulator for Turbine Governor Testing

V. Bakarić, I. Mišković, K. Horvat

Abstract - Computer-based simulator of water turbine and its environment has been developed for the purpose of turbine governor analysis, design and testing. During the final governor testing in the factory, the finished governor cubicle is linked with the hardware-in-the-loop turbine simulator using the signals which will later link it with the real hydroelectric power unit and other systems at the plant. During the earlier development phases, the governor is implemented as a part of the simulator. Besides helping in the governor design and subsequent improvements, the simulator significantly quickens commissioning of the governor system and thus both improves its quality and reduces costs.

I. INTRODUCTION

The research effort reported in this paper was initiated with the goal to develop a computer-based simulator for the purpose of development and testing of turbine governors for hydroelectric power plants. Initially, the main objective was to perform hardware-in-the-loop (HIL) testing of completed turbine governors as the central part of Factory Acceptance Testing (FAT) for the governors. In such tests the new hardware unit which has to be tested is connected with the simulator of the plant in order to check its behavior over the wide range of operating conditions before it will be installed in the real plant. Therefore, a HIL simulator has to run in real time and be pretty versatile. However, the most important part of the simulator is appropriate plant model.

Modeling of water turbines is very complex task. The turbine itself is highly nonlinear and the model also has to encompass influences of both water intake and electric power unit [1]. The most accurate turbine models are non-analytical, described by several three-dimensional hill diagrams. Various simplified analytical non-linear models have been also developed [2], [3], [4]; these models can be further linearized and used for both governor design and simulation analysis. All these models in most cases describe only nominal operating conditions of the turbine, while HIL simulation requires seamless circling through all important operating modes, including start-up, stop and reaction to large disturbances. This problem has to be dealt with in a satisfactory way, as well as the other big modeling challenge, determination of the model parameters, since they are often not known precisely.

After short introductions into HIL simulations and modeling of water turbines, this paper presents the HIL simulator which has been used in turbine governor FAT testing for several hydro power plants [5]. Several important observations on lessons learned during the simulator development are highlighted in the paper.

II. HARDWARE-IN-THE-LOOP SIMULATORS

During a HIL simulation the controller which is being tested is not a part of the simulator – instead, it is implemented using the same hardware and software as in the real world and connected with the simulator of the plant and its environment. The signal interface between the controller and the simulated plant is set as it will be with the real plant. The simulation runs in real time.

Depending on the intended testing program and the system to be tested, complexity of a HIL simulator can vary widely, as well as its fidelity to the real plant. The simplest form of a HIL simulator is the simulation board with arrays of lights and manually operated switches and knobs, quite enough for check of input and output signal logic, reaction to alarm states and even some simple control loops. The modern HIL simulator is, nevertheless, much more powerful and flexible because it has in its core a real-time digital processor running mathematical model of the plant. The required complexity and fidelity of a HIL simulator has been rising steadily because of ever more complex control systems and algorithms, as well as ever higher demands on the desired control performance. HIL simulators of the most critical applications (e.g. aircraft engines) are very complex and highly specialized emulators of the real plant. They are extraordinary expensive, but, nevertheless, much less so than the plant prototype. However, if not such stringent fidelity is required, a pretty good HIL simulator can be accomplished with quite affordable costs, based on a commercially available general-purpose real-time hardware platform and its associated software. The most demanding task during the development of such simulator is development and subsequent tuning of the simulation model. In any case, when the HIL simulator customized for one controller exists, it can be rather easily modified to perform tests of a different controller intended for the same control task at similar plant.

HIL simulations excel with very complex, sensitive and expensive plants and their equally complex and sensitive controllers. They have been traditionally associated with aircraft and ships and their subsystems as well as with various military systems, but today they are commercially most widespread in the automotive industry.

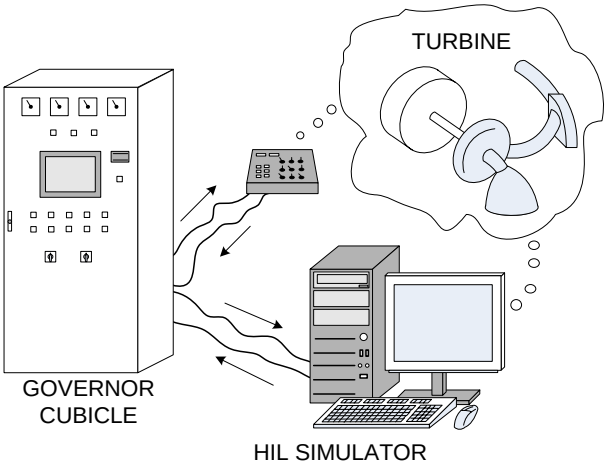

Figure 1. Hardware-in-the-loop simulation for turbine governor testing

They are also widely used in other areas, including robotics and power systems.

As an example, HIL simulation setup for turbine governor testing is shown in Fig. 1. The governor is implemented on the PLC (Programmable Logic Controller) platform built into the governor cubicle, which contains also the local operator station and various elements for equipment protection, power supply, signal distribution and conversion. The simulator emulates the governed turbine and its environment, as well as other plant subsystems and some parts of the turbine governing system not available for HIL testing. The real-time application runs on the PC workstation with either dedicated real-time controller board or specialized real-time operating system. It makes the main part of the simulator. Additional simulation board with buttons, switches and knobs is a convenient method to emulate numerous signals used by the turbine governor but not needed by the real-time water turbine model at the workstation; it can be made either as a hardware unit (as in Fig. 1) or as an independent software application.
